- hearing loss, deafness by age 4 (30%)
- bilateral leukokoria + microphthalmia
- cataract, blindness ← absence of retinal ganglion cells

√ microphthalmia
√ dense vitreus with blood-fluid level
√ cone-shaped central retinal detachment
√ calcifications

OCULAR TRAUMA

Frequency: 3% of all visits to Emergency Department in USA
Cause: blunt trauma (97%)
Mechanism: motor vehicle accident, sport-related accident, industrial accident, fall, violent trauma
Associated with: facial fractures (up to 11%), head injury (84%)

- clinical evaluation: testing of visual acuity, slit-lamp evaluation of cornea + anterior segment, intraocular pressure measurement, funduscopy

US (used if ocular media opaque due to vitreous hemorrhage / hyphema / traumatic cataract):

◊ Dynamic imaging improves visualization of the entire eye and depicts movement of vitreous echoes / lines.

√ may depict hyphema, lens dislocations, globe rupture, intraocular foreign body, vitreous + retinal hemorrhage

Contraindications for ocular US:
suspected traumatic globe rupture / recent surgery to prevent extrusion of ocular contents

CT (modality of choice):
√ especially useful for foreign body

MR:
√ CONTRAINDICATED with metallic foreign bodies
√ usually reserved for subtle open-globe injury / organic foreign body

Anterior Chamber Injury

1. Corneal laceration
   Cause: usually penetrating trauma
   √ decreased anterior-posterior dimension of anterior chamber compared to a normal globe on CT
   Cave: anterior subluxation of lens may mimick a decreased anterior chamber volume
   Cx: globe rupture with complete penetration of cornea
2. **Traumatic hyphema**
   Cause: disruption of blood vessels in iris / ciliary body
   - blood-fluid level in anterior chamber

   √ increased attenuation in anterior chamber on CT
   Cave: US NOT RECOMMENDED → excessive pressure

Lens Dislocation

Cause:
(1) Blunt trauma to eye (> 50% of all lens dislocations)
(2) Spontaneous (and often bilateral)
associated with connective tissue: Marfan syndrome, Ehlers-Danlos syndrome, homocystinuria

Pathomechanism: deformation of globe in anteroposterior direction → compensatory expansion equatorially → stretching + tearing of zonular attachments → dislocation of lens

Location of lens: posterior (common) / anterior (unusual)

Types:
(a) partial luxation = one margin of lens maintains its normal position behind iris
√ posteriorly angled position of lens
(b) complete luxation
√ lens in dependent portion of vitreous humor

In trauma associated with: echogenic lens (= traumatic cataract) + vitreous hemorrhage

Traumatic Cataract

Pathophysiology: disruption of lens capsule → edema within lens → cataract

√ hypoattenuating lens compared with nonaffected lens (in acute phase)

√ hyperattenuating / calcified lens (= mature cataract)

Open-Globe Injury = Ruptured Globe

= disruption of scleral integrity by blunt trauma / penetrating injury

Site: behind insertion of intraocular muscles (= thinnest portion of sclera)

• enlarged anterior chamber

US: CONTRAINDICATED in suspected globe rupture

CT (56–75% sensitive):
√ direct signs of globe injury:
√ change in globe contour (DDx: coloboma, staphyloma, posttraumatic orbital hematoma)
√ "flat tire" sign = loss of volume
√ scleral discontinuity with prolapse of vitreus
√ indirect signs of globe injury:
√ deep anterior chamber = mild posterior movement of lens (in spite of intact zonular fibers)
Mechanism: rupture in posterior segment → decrease in pressure + volume → allows lens to sink posteriorly
√ decreased anterior chamber depth = decreased volume in anterior segment ← severe corneal laceration

One indirect imaging finding of open-globe injuries is alteration of the anterior chamber depth.

√ intraocular air (DDx: injected perfluoropropane gas for treatment of retinal detachment)
√ intraocular foreign body (DDx: metal buckle of scleral band for treatment of retinal detachment)

◊ Consider MRI when a clinically suspected open-globe injury is not identified at CT!

Cx: blindness

Nontraumatic mimics:
coloboma, staphyloma, congenital glaucoma, elongated globe from myopia, phthisis bulbi
Altered globe contour:
mass effect from orbital mass / hematoma

Ocular Detachments / Posterior Segment Injury

1. **Traumatic retinal detachment**
   = separation of retina from choroid
   Mechanism: traumatic retinal tear → accumulation of vitreous fluid + blood between retina and choroid → detachment of retina
   (a) **Total retinal detachment**
   √ characteristic V-shaped appearance with apex at optic disc
   √ retina remains bound down at ora serrata
   (b) **Focal retinal detachment**
   √ elevated immobile line close to sclera at periphery of globe

Retinal detachments may have a characteristic V-shaped appearance with the **apex at the optic disc** !

2. **Vitreous detachment**
   = separation of vitreous from retina
   √ thin undulated mobile line moving away from posterior aspect of globe during eye motion
3. **Traumatic choroidal detachment**
   = separation of choroid from sclera by fluid accumulation in potential suprachoroidal space
   Mechanism: traumatic injury → decreased pressure in posterior segment + suprachoroidal space → accumulation of fluid / blood → detachment of choroidal layer
   Site: from vortex vein to ora serrata
   √ biconvex / lentiform fluid accumulation
   √ lentiform / biconvex shape with sparing of posterior portion of globe
   DDx: high-attenuation silicone oil injected between vitreus and retina for treatment of retinal detachment

Choroidal detachments have a lentiform / biconvex shape and **spare the posterior portion of the globe** !

Intraocular Hemorrhage

1. **Vitreous hemorrhage** (53%)
   Mechanism: disruption of retinal blood vessels → hemorrhage into vitreous humor of posterior segment
   • "black rain" / decreased visual acuity (frequent)
   US:
   √ normal / slightly increased vitreous echogenicity (= mild acute bleeding)

√ poorly defined low-level echoes / hypoechoic clots within vitreous (= abundant hemorrhage)
√ echogenic material moving freely within vitreous chamber during eye movement
CAVE: Severe vitreous hemorrhage may obscure other ocular findings!

CT:
√ hyperattenuating fluid in posterior segment

Cx: retinal detachment ← vitreous traction ← fibrovascular ingrowth following hemorrhage

Prognosis: resolution may occur within 2–8 weeks

Rx: vitrectomy

2. **Retrohyaloid hemorrhage** (2%)
√ echogenic material remaining behind detached vitreous capsule during eye movement
3. Hematoma in retroocular space

Intraocular Foreign Body

Incidence: penetrating eye injury in 3.1÷100,000 per year
◊ Intraorbital foreign bodies are present in 10–17% of all ocular injuries + in 41% of open-globe injuries!

Cause: violent trauma, motor vehicle accident, recreational accident, work-related industrial accident

Location: anywhere (commonly in posterior segment)

Type: (a) inorganic: metal, glass, plastic
(b) organic: wood → may cause a severe infection

Radiography (40–90% sensitive, depending on type of material)

US (95% sensitive for intraocular + 50% for intraorbital foreign body):
√ echogenic spot

DDx: intraocular air may mimic a foreign body

CT (up to 100% sensitive):
√ metallic fragments < 1 mm can be demonstrated
√ glass foreign body: (detection depends on location, size + type of glass)
√ 96% of > 1.5-mm glass foreign bodies
√ 48% of 0.5-mm glass foreign bodies
√ wood splinter:
√ Wood is initially of low attenuation similar to air
√ geometric margins
√ increase in density after 1–5 days

MR:

N.B.: Failure to detect a metallic foreign body before performing MR may result in blindness!

√ more sensitive than CT in depicting organic material

Cx: siderosis (if metallic), endophthalmitis, retinal toxicity, vision loss

DDx: optic drusen; scleral plaques (calcifications along insertions of medial + lateral rectus mm. in elderly); calcified cataract; material for treatment of retinal detachment (scleral bands, silicon oil, gas)

OPTIC DRUSEN

[*druse*, German = geode]
= accretions of hyaline material on / near surface of optic disc; often familial
Age: patient with macular degeneration; also in young patient
• usually asymptomatic
• headache, visual field defects
• pseudopapilledema
Location: at junction of retina + optic nerve; bilateral in 75%
US:
√ hyperechoic lesions at papilla + acoustic shadowing
CT:
√ hyperattenuating small flat / round calcification
Cx: atrophy of optic nerve

OPTIC PATHWAY GLIOMA

= JUVENILE PILOCYTIC ASTROCYTOMA = OPTIC NERVE GLIOMA
= isolated to single prechiasmatic optic nerve anywhere along optic tract ± extension to other optic nerve, chiasm, optic tract
◊ Most common › cause of optic nerve enlargement
› primary tumor of optic nerve
› intraconal tumor of childhood
› CNS neoplasm in NF1
Frequency: 1% of all intracranial tumors; 4% of orbital masses; 80% of primary tumors of optic nerve
Path: optic nerve is embryologically part of hypothalamus and develops gliomas instead of schwannomas
(a) perineural spread = fusiform enlargement of optic nerve: boundary between tumor and nerve often indistinguishable, overlying dura stretched but intact
(b) subarachnoid spread = tumor predominantly involves subarachnoid space surrounding a relatively spared nerve: infiltration through pia mater but contained by dura
Histo: proliferation of well-differentiated astrocytes
= low-grade glial neoplasm with cystic components
(a) <u>in children</u> (most common): juvenile pilocytic astrocytoma = grade 1 WHO with spindle-shaped astrocytes having hairlike (pilocytic) processes ± eosinophilic degenerative cell processes (Rosenthal fibers)
(b) <u>in adults</u>: glioblastoma
Mean age: 4–5 years; 1st decade (75%); rare in adults without NF1 (GBM); M÷F = 1÷2 to 2÷3
Associated with: neurofibromatosis type 1 (NF1) in 10–33–50% (± bilateral optic gliomas)
◊ 15–21% of children with NF1 have (often bilateral) optic nerve gliomas
◊ 10% of all optic nerve gliomas are associated with neurofibromatosis
• decreased visual acuity / visual-field deficit
• optic disc edema, pallor, atrophy (axonal damage)
• abnormal pupillary reflex; relative afferent pupillary defect

- axial proptosis with larger masses (less common)
- vision loss, strabismus
- spasmus nutans (= high-frequency nystagmus of low amplitude associated with head nodding movement)
- precocious puberty with accelerated growth (in 39% of only NF1 patients) ← involvement of optic chiasm + hypothalamus

Location: any part of optic pathway (intraorbital optic nerve in 25–48%); unilateral (most common); bilateral / multifocal (PATHOGNOMONIC for NF1); involvement of chiasma (more common in sporadic cases without NF1)

Extension to: intracanalicular + retrocanalicular optic nerve; lateral geniculate body and optic radiation (rare)

√ tubular / fusiform / excrescentic well-circumscribed homogeneous enlargement of optic nerve-sheath complex:
  √ CHARACTERISTIC kinking / buckling of nerve

√ posterior extension to involve chiasm + hypothalamus in 25–60% (indicates nonresectability)

√ ipsilateral optic canal enlargement (90%) > 3 mm / 1 mm difference compared with contralateral side

CT:
  √ iso- to slightly hypodense compared to normal optic nerve
  √ variable contrast enhancement (less intense than meningioma)
  √ calcifications (rare)

US:
  √ well-defined homogeneous mass of medium echogenicity inseparable from optic nerve

MR: more sensitive than CT in detecting intracanalicular + intracranial extent
  √ fusiform enlargement of nerve (without NF1):
    √ effacement of surrounding subarachnoid space
  √ tortuous / kinked / buckled diffusely enlarged optic nerve (NF1 patient):
    √ tumor in subarachnoid space surrounds normal-sized optic nerve
  √ lesion isointense to muscle on T1WI
  √ lesion heterogeneously hyperintense on T2WI
  √ rim of T2-hyperintensity at tumor periphery (mimicking expanded subarachnoid space) = arachnoidal gliomatosis ← leptomeningeal infiltration + proliferation
  √ ± cystic spaces
  √ calcifications (rare)
  √ nerve indistinguishable from tumor (DDx to meningioma)
  √ variable enhancement (in 50%):
  √ additional intracranial findings:
    √ other gliomas
    √ macrocephaly
    √ hydrocephalus ← aqueductal stenosis (almost exclusive to patients without NF1)
    √ neurofibromatosis spots (= foci of T2 prolongation due to myelin vacuolization)

Cx: precocious puberty ← hypothalamic impingement

Prognosis: slow growth / stability over time; 87–97% 5-year survival

Rx: conservative management; chemotherapy (for young patients), radiation therapy (for patients > 5 years of age)

DDx: optic nerve sheath meningioma (middle age, hyperattenuating mass, plaquelike calcifications, hypointense on T2WI, intense enhancement, no intracranial extension along optic pathway)

Malignant Optic Glioma of Adulthood

Prevalence: extremely rare; 30 cases in this century
Mean age: 6th decade; M÷F = 1.3÷1.0
Histo: anaplastic astrocytoma / glioblastoma multiforme
• rapidly progressive monocular visual loss culminating in monocular blindness within a few weeks
• with retrograde tumor extension: contralateral temporal hemianopia, polyuria, polydipsia
√ focal / diffuse enlargement of optic nerve
√ hypo- to isointense on T1WI + hyperintense on T2WI
√ obliteration of subarachnoid space around affected portion of nerve
√ diffuse intense enhancement of optic nerve
√ thickening + abnormal enhancement of optic nerve sheath
Tumor extension: optic chiasm, hypothalamus, basal ganglia, brain stem, medial temporal lobes, leptomeninges, ependyma
Prognosis: < 1-year survival despite aggressive therapy
DDx: (1) Optic neuritis (demyelinating plaques elsewhere)
(2) Perioptic meningioma (hypointense on T2WI, stippled calcifications, hyperostosis)
(3) Sarcoidosis, lymphoma, orbital pseudotumor (moderately / markedly hypointense on T2WI)

OPTIC NERVE SHEATH MENINGIOMA

= PERIOPTIC MENINGIOMA
Frequency: 2% of space-occupying orbital masses; < 2% of intracranial meningiomas
◊ 2nd most common optic nerve tumor!
Mean age: 49 years; M÷F = 1÷4; slightly more aggressive in children
Occasionally associated with:
neurofibromatosis type 2 (usually in teenagers)
Origin: meningothelial cells in arachnoid sheath of optic nerve in orbit / middle cranial fossa
Histo: syncytial growth pattern composed of meningioma cells with indistinct cytoplasmic margins ± multiple ringlike psammoma bodies (= round calcifications)
• classic clinical triad of retinal examination:
(1) Painless slowly progressive loss of visual acuity over months
(2) Optic nerve atrophy → progressive loss of vision
(3) Optociliary shunt vessels = dilated connections between ciliary circulation + central retinal vessels ← long-term compression of central retinal vein
• proptosis
Location:
(a) orbit = <u>intraoptic</u> nerve sheath meningioma
(b) in optic canal = <u>intracanalicular</u> meningioma
(c) <u>intracranial</u> opening of optic canal = foraminal meningioma

(d) middle cranial fossa

√ tubular (most common) / fusiform / eccentric (excrescentic) thickening of optic nerve

√ calcifications in 20–50% (HIGHLY SUGGESTIVE)

√ sphenoid bone hyperostosis

US:

√ hypoechoic tumor with irregular border

CECT: enhancement is the rule

√ tumor enhancement around nonenhancing optic n.:

√ "tram-track" configuration on axial CECT = enhancing tumor on either side of spared optic nerve

√ ringlike / doughnut configuration on coronal CECT

√ linear high-attenuation area parallel to optic nerve (= tumor spread along subarachnoid space)

√ bone remodeling ± enlargement of optic canal

√ minimal extension into optic canal (not uncommon)

MR (most valuable in determining extent of disease):

√ hypointense to fat on T1WI

√ iso- to slightly hyperintense relative to optic nerve on T2WI

√ "tram-track" sign = intensely enhancing extrinsic soft-tissue mass surrounding optic nerve on fat-suppressed T1WI

Rx: surgical intervention to prevent disease dissemination to contralateral eye if disease spreads to optic chiasm

OPTIC NEURITIS

= nerve involvement by inflammation, degeneration, demyelination

Etiology:

(1) Multiple sclerosis (involves optic nerve in ⅓)

(2) Inflammation ← ocular infection

(3) Degeneration: toxic, metabolic, nutritional

(4) Ischemia

(5) Meningitis / encephalitis (= viral infection)

(6) Systemic lupus erythematosus

(7) Radiation therapy

◊ 45–80% of patients develop multiple sclerosis within 15 years of their first episode of optic neuritis!

• ipsilateral ocular pain on eye movement

• sudden onset of unilateral loss of vision over several hours to several days

CT:

√ normal / mildly enlarged optic nerve + chiasm

√ may show enhancement

MR:

√ mild enlargement + enhancement of optic nerve best demonstrated on axial T1WI

√ hyperintense optic nerve on T2WI

Prognosis: spontaneous improvement of visual acuity within 1–2 weeks

Perioptic Neuritis

Etiology: demyelination from
(1) Multiple sclerosis
(2) Infection: measles, mumps, syphilis
(3) Sarcoidosis

√ leptomeningeal enhancement obscures lucent optic nerve

ORBITAL SCHWANNOMA

= slowly progressive benign tumor

Location: branches of trigeminal (CN V) nerve (most common) > oculomotor > trochlear > abducens > para-sympathetic > sympathetic fibers > ciliary ganglia

Site: extraconal superior orbit often abutting orbital apertures ← origin from supratrochlear and supraorbital nn. of frontal branch of ophthalmic n.

√ cone-shaped tumor ← involvement of orbital apex

√ dumbbell shape ← involvement of superior orbital fissure

MR:
√ well-circumscribed mass:
√ uniformly T1-isointense ± variations
√ T2-hyperintense heterogeneous pattern ← mixture of solid and cystic components
√ typically heterogeneous uptake of contrast medium

DDx: cavernous malformation (homogeneous pattern, progressive enhancement)

PERSISTENT FETAL VASCULATURE

= PERSISTENT HYPERPLASTIC PRIMARY VITREUS

= rare congenital nonhereditary condition with persistence + hyperplasia of fibrovascular system derived from embryonic primary vitreus + its hyaloid arterial supply ← arrest of normal regression

Embryology:

› **Hyaloid artery**
= important source of intraocular nutrition until 8th month of gestation; arises from dorsal ophthalmic artery at 3rd week of gestation; grows anteriorly with branches supplying vitreus + posterior aspect of lens

› **Primary vitreous humor**
[*vitreus*, Latin = glass; *humor*, Latin = body fluid]
= fibrillar ectodermal meshwork + mesodermal tissue consisting of embryonic hyaloid vascular system; appears during 1st month of life in posterior ocular chamber between lens + retina; involutes by 6th month of gestation

› **Secondary / adult vitreous humor**
begins to form during 3rd gestational month; watery mass of loose collagen fibers + hyaluronic acid gradually replaces primary vitreus, which is reduced to a small S-shaped remnant (hyaloid canal = Cloquet canal) and serves as lymph channel

Pathogenesis: breakdown in posterior capsule → invasion of lens → absorption of lens → cataract formation + glaucoma; hemorrhage from fibrovascular tissue (common) → folding of retina with detachment (30–56%)

May be associated with: any severe ocular malformation / optic dysplasia / trisomy 13
Age: noticed at birth / within first few weeks of life
• unilateral leukokoria (2nd most common cause)
  ◊ 19–28% of leukokoria cases
• seizures, mental deficiency, hearing loss
• ± cataract, strabismus, painful glaucoma, hyphema, uveitis
• ophthalmoscopy: S-shaped tubular mass extending between posterior surface of lens + region of optic nerve head; lens opacity may preclude diagnosis
Location: unilateral
  ◊ Bilaterality is a feature of a congenital syndrome (Norrie disease, Warburg disease)!
√ microphthalmia = small hypoplastic globe (61–92%):
  √ normal-sized globe (13%)
  √ buphthalmos (in up to 26%)
√ retinal detachment ← vitreoretinal traction in 30%
US:
  √ hyperechoic band extending from posterior pole of globe to posterior surface of lens (= embryonic rest of primary vitreus)
  √ central anechoic line (= persistent hyaloid artery) with positive Doppler signals
  √ hyperechoic band extending from papilla to ora serrata (= retinal detachment)
  √ heterogeneous increased echogenicity of vitreus ← hemorrhage
CT:
  √ enhancing cone-shaped central retrolental density extending from lens through vitreous body to back of orbit, just lateral to optic nerve (= primary vitreus)
  √ linear band / septum extending to posterior pole
  √ small optic nerve
  √ abnormally small lucent rounded lens ← absorption / swelling
  √ hyperdense vitreus (from previous hemorrhage)
  √ fluid-fluid levels from breakdown of recurrent hemorrhage in subhyaloid (between vitreus + retina) / subretinal space (between sensory + pigment epithelium)
    ◊ Blood does NOT layer in extremely viscous vitreous humor
  √ enhancement of vascular retrolental mass
  √ NO calcifications
MR:
  √ hyperintense vitreous body on T1WI + T2WI from chronic blood degradation products (methemoglobin) / proteinaceous fluid
  √ hypo- to isointense thin triangular band with base near optic disc and apex at posterior surface of lens
  √ marked enhancement of fibrovascular mass within vitreus
  √ lens abnormalities
  √ elongated ciliary process
  √ anterior tenting retina
Cx: (1) Glaucoma, cataract from recurrent spontaneous intravitreal hemorrhage (due to friable vessels)
(2) Proliferation of embryonic tissue

(3) Retinal detachment from organizing hemorrhage / traction
(4) Hydrops / atrophy of globe + resorption of lens
(5) Phthisis bulbi (scarred shrunken eye)

Rx: preservation of globe for cosmetic reasons; enucleation for retinal hemorrhage + glaucoma only

PHTHISIS BULBI

[*phthinein*, Greek = to waste away]
= "wood eye" = shrunken nonfunctioning + usually calcified eye
Cause: trauma, angiomatosis, intrauterine environmental conditions, infection, genetic disorders, retrolental fibroplasia (retinopathy of prematurity)
US:
√ shrunken eye
√ usually calcified wall
√ ± hyperechoic fibrous tracts within vitreous + resultant retinal detachment

PLEOMORPHIC ADENOMA OF ORBIT

= BENIGN MIXED TUMOR
Frequency: 57% of epithelial lesions in lacrimal gland
◊ Most common benign neoplasm of lacrimal gland
Age: 4th to 5th decade of life
• proptosis (= commonly downward displacement of globe)
• rarely painful slow-growing tumor
Histo: fibrous pseudocapsule with epithelial cells that may form nests / tubules resembling ducts; myxoid / mucinous background stroma with spindle-shaped cells ± cartilage or bone
Location: superotemporal orbit
√ well-circumscribed usually homogeneously enhancing mass
√ larger lesion heterogeneous ← cystic degeneration, hemorrhage, serous / mucous collections, necrosis
√ smooth concavity of lacrimal fossa ← bone remodeling
√ T1-hypointense + T2-hyperintense mass
DDx: lacrimal gland malignancy (infiltrative borders, nodularity, bone erosion)

PRIMARY ORBITAL MELANOMA

= UVEAL MELANOMA = Choroidal Melanoma
Most common primary intraocular neoplasm in adult Caucasian
Prevalence: 5–7÷1,000,000
Mean age: 56 (range, 50–70) years; in 65% > 50 years of age; Whites÷African Americans = 8÷1 to 15÷1
Predisposed: exposure to sunlight, fair skin complexion, light eye color, preexisting melanocytic nevi
At risk: Caucasian, light-colored iris, ocular melanocytosis
Path: mushroom-shaped tumor with broad choroidal base / flat mass / crescentic mass; range

from amelanotic to heavily pigmented lesion

Histo: (a) spindle containing varying amounts of spindle-B cells
(b) epithelioid cells with abundant cytoplasm, clear cellular borders, enlarged ovoid nuclei

Metastases to: globe, optic nerve; liver (90%), lung (24%), bone (16%), kidney, brain, subcutis

- asymptomatic (most frequently) detected on routine eye exam
- pain (uncommon), floaters, astigmatism
- visual loss ← vitreous hemorrhage
- visual field (campimetric) defect
- photopsia (perceived flashes of light) ← retinal detachment
- glaucoma (with iris location)
- accommodation impairment (with ciliary body location)

Location: choroid (85–93%) > ciliary body (4–9%) > iris (3–6%); almost always unilateral

√ initially flat growth profile, later becoming elevated, erupting through Bruch membrane (= innermost layer of choroid) into a CHARACTERISTIC mushroom shape
√ episcleral spread after infiltration of underlying sclera
√ moderate to strong contrast enhancement

US (95% diagnostic accuracy):
√ low-to-medium internal reflectivity spikes on tumor surface + vascular oscillations (A-mode US)
√ domed lobulated mushroom-shaped mass / round hyperechoic solid mass / small flat lesion
√ well-defined solid mass with smooth surface (unless hemorrhagic / necrotic)
√ NO calcification
√ choroidal excavation beneath a small posterior wall mass with retinal bowing ← local invasion (TYPICAL)

CT:
√ nonspecific ill-defined hyperdense thickening of wall of globe with inward bulge
√ diffuse moderate enhancement
√ calcifications may appear after therapy
√ diffuse moderate enhancement ← abnormal / absent blood-ocular barrier
√ restricted diffusion + low apparent diffusion coefficient

MR (superior to CT, mainly used for extraocular extension):
(a) melanotic melanoma (75%) = T1 + T2 shortening effect of paramagnetic stable free radicals with unpaired electrons in melanin pigment
√ paramagnetic effect of melanin → intrinsic T1 + T2 shortening: ⇑ T1 signal intensity + ⇓ T2 signal intensity
(b) amelanotic / slightly melanotic melanoma (25%)
√ iso- to hypointense on T1WI
√ hyperintense lesion on T2WI

Dx: indirect ophthalmoscopy, clinical history, transillumination, sequential US evaluation
Cx: retinal detachment and extrascleral spread
Rx: plaque brachytherapy, external beam radiation, transpupillary thermotherapy, surgical enucleation

N.B.: small nonprogressive melanoma < 3 mm thick can be followed every 3–6 months by US

Prognosis: 5-year survival rate for (a) small < 3 mm thick choroidal melanoma 85%, (b) medium 3–10 mm thick choroidal melanoma 68%, (c) large > 10 mm thick choroidal melanoma 47%; mean survival of 2–7 months for metastatic disease

DDx: (1) Choroidal metastasis (frequently bilateral + multiple, usually broad-based flat lesion, iso- to hyperintense on T1WI, hyperintense on T2WI, heterogeneous enhancement)

(2) Choroidal hemangioma (typically hypointense on T1WI + extremely hyperintense on T2WI, appreciable enhancement, high internal reflectivity at A-mode US)

(3) Vitreous hemorrhage / clot (typically hyperintense on T1WI + extremely hypointense on T2WI greater than for melanoma ← intracellular methemoglobin, no enhancement)

(4) Retinal detachment (similar to vitreous hemorrhage, pathognomonic V shape)

(5) Melanocytic nevus (common small flat lesion, difficult to detect at MRI, no flow at Doppler, pigmented tumor at direct examination)

(6) Orbital melanocytoma= subtype of nevus (enhancing hyperintense lesion on T1WI + extremely hypointense on T2WI, indistinguishable from uveal melanoma at MRI)

(7) Retinoblastoma (younger patient, calcifications at CT, high internal reflectivity at A-mode US, heterogeneously enhancing T1 hypointense + T2 hyperintense lesion)

(8) Retinal hamartoma = hemangioblastoma (in tuberous sclerosis, heterogeneously enhancing T1 hypointense + T2 hyperintense lesion)

(9) Osteoma (same SI characteristics as uveal melanoma, bone attenuation at CT)

PSEUDOTUMOR OF ORBIT

= INFLAMMATORY MYOFIBROBLASTIC TUMOR = IDIOPATHIC ORBITAL INFLAMMATORY SYNDROME

= idiopathic nongranulomatous inflammatory process affecting all intraorbital soft tissues

Etiology:

(a) cause not apparent at time of study: bacterial, viral, foreign body

(b) systemic disease presently not apparent: part of in IgG4-related disease, sarcoidosis, collagen, endocrine

(c) idiopathic: probably abnormal immune response

Frequency: 6% of all orbital lesions

◊ 2nd most common cause of exophthalmos (25% of all unilateral exophthalmos)

◊ 3rd most common primary tumor of the orbit

Age: young to middle-aged; M = F

Histo: myofibroblastic spindle cells with an inflammatory infiltrate of plasma cells + lymphocytes + eosinophils

May be associated with:

Wegener granulomatosis, sarcoidosis, fibrosing mediastinitis, retroperitoneal fibrosis, thyroiditis, cholangitis, vasculitis, lymphoma

- sudden acute onset of unilateral eye pain
- ophthalmoplegia (= impaired ocular movement) + diplopia
- decreased visual acuity, proptosis; eyelid swelling, chemosis

Location: retrobulbar fat (76%), commonly superior + medial extraocular muscle (57%), optic

nerve (38%), uveal-scleral area (33%), lacrimal gland (5%), thyroid gland, skull base; usually unilateral

Subcategories: often coexistence

(1) Myositic type (most common) affects extraocular muscles
- √ enlargement of one / more extraocular muscles with ill-defined margins close to insertion on globe
- √ typically at muscles + tendon insertions (DDx to Graves disease with muscle involvement only)

(2) Dacryoadenitis-related form affects lacrimal glands
(3) Neuritis-associated form affects optic nerve sheath
(4) Apical form affects orbital apex
(5) Episcleral form affects anterior orbit with sclera and preseptal soft tissues
(6) Diffuse form affects entire orbit

√ inflammatory stranding of retrobulbar fat (may involve anterior compartment)
√ SPECIFIC uveoscleral thickening (⅓) with enhancement (sclera near Tenon capsule)
√ orbital muscle thickening ← myositis
√ enhancement of optic nerve sheath
√ enlarged inflamed lacrimal gland
√ proptosis
√ bone destruction and intracranial extension (rare)

MR:
- √ lesion isointense to fat on T2WI

Prognosis:
(1) Remitting / chronic + progressive course (= intermediate malignant potential)
(2) Rapid dramatic + lasting response to steroid therapy

Cx: Tolosa-Hunt syndrome (= involvement of cavernous sinus by pseudotumor)

DDx: (1) Lymphoma (may be confused with lymphoma clinically, radiographically, pathologically)
(2) Thyroid ophthalmopathy (tapering of distal muscles, painless proptosis)
(3) Radiation therapy

RETINAL ASTROCYTOMA

= RETINAL ASTROCYTIC HAMARTOMA
= low-grade benign neoplasm / hamartoma arising from the nerve fiber layer of retina / optic nerve

Etiology: tuberous sclerosis (53%); neurofibromatosis type 1 (14%); sporadic (33%)
- ◊ 50% of patients with tuberous sclerosis develop astrocytic hamartomas (bilateral in ¼)!

Path: usually multiple + bilateral in tuberous sclerosis;
(1) small flat noncalcified semitranslucent lesion in posterior / peripheral retina
(2) "mulberry" lesion = raised white tumor in posterior retina with fine nodularity containing calcifications + cystic fluid accumulations

Histo: spindle-shaped fibrous astrocytes with small oval nuclei

Age: congenital

• leukokoria (3% of all childhood cases of leukokoria)
• asymptomatic, progressive loss of vision

Location: retina near optic disc; bilateral in 25%

√ retinal mass ± enhancement ± calcifications

√ typically unilateral (DDx to drusen)

Cx: (1) Central retinal vein occlusion + secondary hemorrhage
(2) Neovascular glaucoma
(3) Extensive tumor necrosis

Rx: not necessary

DDx: retinoblastoma

RETINAL DETACHMENT

= separation of the sensory retina from retinal pigment epithelium (RPE) = deep retinal layer adjacent to choroid

◊ MEDICAL EMERGENCY!

Cause: inflammation, neoplasm, trauma

Pathophysiology: formed vitreous gel liquefies with age, eventually separates from retina

Mechanism:

(a) rhegmatogenous / retinal tearing (most common) = tear in retina → accumulation of liquefied vitreus in subretinal space → separation of retina from underlying RPE [*rhegma*, Greek = discontinuity, break]

Predisposed: diabetic retinopathy, trauma, high myopia, congenital cataract, surgery, congenital glaucoma, sickle cell disease, leukemia, systemic lupus erythematosus, metastases

(b) tractional: pulling / tugging by vitreous membranes /fibrovascular tissue (scar)

(c) exudative: = blood / fluid / tumor within subretinal space

√ CHARACTERISTIC V-shape (= total detachment)

√ in one quadrant only (= partial detachment)

√ thick folded retina with loss of mobility (long-standing detachment)

√ subretinal space normal / occupied by blood / inflammation / tumor (depending on cause)

MR:

√ differentiation of serous vs. proteinaceous vs. hemorrhagic fluid

US:

√ curvilinear line of high echogenicity fixed at optic disc (= papilla) + extending to ora serrata forming an acute angle of V shape with apex at optic disc

√ floating echogenic line fixed at papilla extending to ora serrata (if acute)

√ thick folded fixed echogenic line (if chronic)

√ ± anechoic retinal cysts

√ fluid = anechoic; blood = anechoic / hypoechoic with low-level echoes; neoplasm = solid heterogeneous hypoechogenicity

Cx: vision loss (if macula involved)

Rx: scleral buckle, pneumatic retinopexy, laser therapy, cryotherapy, vitrectomy

DDx: proliferative vitreous membranes (lines / irregularities), choroidal detachment (point of fixation not at papilla)

DDx of partial detachment: diabetes, macular lesion, retinal ischemia

N.B.: Examine subretinal space and vitreous for blood / exudative fluid / tumor since determination of cause is usually not possible at ophthalmoscopy.

RETINOBLASTOMA

= NEUROEPITHELIOMA OF RETINA
= rare aggressive malignant congenital intraocular tumor

Prevalence: 1÷18,000 children < 5 years old in USA; 1÷17,000 – 1÷24,000 live births
◊ Most common intraocular childhood malignancy

Frequency: 1% of all pediatric malignancies; 11% of all cancers in 1st year of life; in 80% diagnosed < 3 years of age; in 95% < 5 years of age

Origin: primitive photoreceptor cells of immature retina (included in primitive neuroectodermal tumor group)

Cause: biallelic mutation (= loss of function of both alleles) in primitive neuroepithelial cells located on long arm of chromosome 13 (13q14) → inactivation of retinoblastoma tumor suppressor gene Rb1

Men age: at presentation 18 (range for bilateral tumors 7–16, range for unilateral tumors 24–29) months; M÷F = 1÷1; no race predilection

Location: bilateral in 20–34%

Classification:

(A) SPORADIC NONHERITABLE FORM (60%)

Clinical DDx to nonheritable form:
◊ Tumor typically solitary
◊ Age of onset usually > 2 years

(1) Sporadic postzygotic somatic mutation (subsequent generations unaffected)
Mean age at presentation: 23 months

(2) Chromosomal anomaly
= monosomy 13 / deletions of 13q
Associated with: microcephaly, ear changes, facial dysmorphism, mental retardation, finger + toe abnormalities, malformation of genitalia

(B) HERITABLE FORM (40%)

= autosomal dominant transmission to offspring with 90–95% penetrance
Genetics: mutation of tumor suppressor gene RB1 located on long arm of chromosome 13 (13q14)

Clinical DDx to nonheritable form:
◊ Tumors bilateral in ⅔ and multifocal
◊ Age at presentation usually < 2 years
√ multiple tumors in 60–75%

(1) Heritable sporadic form (20–25%)
= sporadic germline mutation (50% chance to occur in subsequent generations)
Mean age at presentation: 12 months
√ bilateral retinoblastomas in 66%

(2) Familial retinoblastoma (10–30%)

= autosomal dominant with 95% penetrance
Mean age at presentation: 8 months
√ usually 3–5 ocular tumors per eye
Risk of secondary nonocular malignancy (8%):
osteo-, chondro-, fibrosarcoma, malignant fibrous histiocytoma, melanoma, carcinoma (20% risk within 10 years, > 90% by 30 years of age); high risk within field of external-beam radiation (30%)
Location: head, skin, bone, brain

Trilateral retinoblastoma

Quadrilateral retinoblastoma
= trilateral retinoblastoma + 4th focus in suprasellar cistern
√ enhancing midline suprasellar mass

Path: (1) Endophytic form = centripetal tumor invasion → floating islands of tumor within semiliquid vitreus ± anterior chamber
(2) Exophytic form = growth toward sclera into subretinal space → retinal detachment + invasion of vascular choroid → hematogenous spread
(3) Mixture of endo- and exophytic growth (common)
(4) Diffuse infiltrating form = thin en-plaque lesion extending along retina (in 1–2%) → cells discharged into vitreus → seeding of anterior chamber mimicking an inflammatory process (= pseudohypopyon)
(5) Necrotic retinoblastoma with orbital cellulitis
(6) Complete spontaneous regression (rare) → phthisis bulbi (= shrunken nonfunctioning globe)

Histo:
√ primitive neuroepithelial neoplastic cells tend to outgrow blood supply → necrosis → foci of calcifications
(a) Flexner-Wintersteiner rosettes (in 50%)
= neuronal cells line up around an empty central zone filled with polysaccharides (= photoreceptor differentiation)
◊ Very specific for retinoblastomas!
(b) Homer-Wright rosettes
= neuronal cells line up around a central area containing a cobweb of filaments (also found in other primitive neuroectodermal tumors) = neuronal differentiation
(c) "fleurettes"
= flowerlike groupings of tumor cells that form photoreceptor elements (specific for retinal differentiation)

- "cat's eye" = leukokoria (white pupillary reflex) in 56–72%

◊ About 50% of all childhood leukokoria cases are caused by retinoblastoma!

- strabismus = crossed eyes = lack of binocular vision (22–24%)
- proptosis (less common)
- decreased visual acuity, heterochromia iridis, anisokoria
- spontaneous hyphema, periocular inflammation
- iris neovascularization

• ocular pain ← secondary angle-closure glaucoma

Location: posterolateral wall of globe (most commonly); 60% unilateral; 40% bilateral + frequently synchronous (90% bilateral in inherited forms)

√ normal ocular size

√ presence of calcifications

◊ Lack of calcifications OFTEN INDICATIVE of another disease!

US:

√ irregular heterogeneous hyperechoic solid intraocular mass

√ cystic areas of tumor necrosis

√ secondary retinal detachment (common)

Staging of Retinoblastoma
International Classification for Intraocular Retinoblastoma (2006)

Group	*Description*	*Features*
A	small	< 3 mm in diameter, > 3 mm from fovea, > 1.5 mm from optic disc; confined to retina (no vitreous seeding)
B	large	macular / juxtapapillary location without dissemination; subretinal fluid extends < 3 mm from tumor
C	local dissemination	vitreous / subretinal seeding < 3 mm from tumor
D	diffuse	massive tumor + diffuse / greasy vitreous seeding / fine subretinal seeds; avascular plaques / exophytic disease
E	unsalvageable / extensive	nonvascular glaucoma / intraocular or corneal hemorrhage / tumor contacting lens or in anterior segment / diffuse infiltrating tumor
F	extrascleral	extrascleral spread to optic nerve / orbit / brain; distant metastases

√ focal fine calcifications with acoustic shadowing (in 75%)

√ echogenic foci of vitreous hemorrhage (frequent)

CT (primary modality in leukokoria):

√ solid smoothly marginated lobulated retrolental hyperdense mass of endophytic type (DDx to exophytic type: retinal detachment)

√ partial punctate / nodular calcification (50–75–95%)

◊ Retinoblastoma is the most common cause of orbital calcifications!

√ dense vitreus (common)

√ extraocular extension (in 25%): optic nerve enlargement, abnormal soft tissue in orbit, intracranial extension

√ contrast enhancement (27%)

√ ± macrophthalmia

Risk: cataract formation

MR:

Advantage: assessment of extension into optic pathway + subarachnoid space + vitreous

seeding; follow-up without radiation exposure

√ mass with SI similar to gray matter:

√ mildly hyperintense on T1WI relative to vitreus
√ distinctly T2 hypointense (similar to uveal melanoma)
√ hyperintense on DWI (= reduced diffusion) with high tumor cellularity

√ heterogeneous intensity in the presence of calcifications

√ calcifications of low / high signal intensity with various pulse sequences ← dependent on proton content (susceptibility imaging for DDx to hemorrhage!)

◊ Even large calcifications may be missed on MR!

√ subretinal exudate usually hyperintense on T1WI + T2WI (proteinaceous fluid) = retinal detachment

√ assessment for 1–2 mm small vitreous seeds on high resolution T2WI 3-dimensional fast spin echo sequences

√ vitreous hemorrhage (= high SI on T1WI + low SI on T2WI) may obscure tumor

√ discontinuity within dark band of sclera = trans-scleral spread

√ tumor within orbital fat on enhanced fat-suppressed T1WI = extrascleral spread

CEMR:

√ moderate to marked enhancement

√ thinning with focal ↓ in enhancement OR thickening with focal ↑ in choroidal enhancement (= choroidal invasion)

√ thickening of enhancing choroidoretinal complex = prelaminar invasion

√ focal enhancement ± focal thickening of optic nerve (DDx: reactive gliosis)

√ leptomeningeal enhancement = dissemination into CSF

Cx: (1) Metastases to: meninges (via subarachnoid space), bone marrow, lung, liver, lymph nodes

◊ Optic nerve involvement through optic disc = port for dissemination into subarachnoid space!

◊ No risk of metastases without penetration of lamina cribrosa!

(2) Radiation-induced sarcomas develop in 15–20%

Prognosis: spontaneous regression in 1%

√ calcifications = favorable prognostic sign

√ contrast enhancement = poor prognostic sign

Mortality:

(a) choroidal invasion: 65% significant, 24% slight

(b) optic nerve invasion through optic disc:

< 10% not invaded
15% through lamina cribrosa
44% significantly posterior to lamina cribrosa

(c) margin of resection not free of tumor: > 65%

Rx: cryoablation, laser photocoagulation, chemothermotherapy, brachytherapy, plaque radiation therapy; chemoreduction and surgery; enucleation

Survival: 90–95% due to earlier detection

DDx: Pseudoretinoblastomas (in order of decreasing frequency)

(1) Persistent fetal vasculature (no calcifications, microphthalmia, vertical septum

between optic disc + posterior lens)

(2) Coats disease (subretinal exudation, no calcification, slightly older age group, no enhancement of subretinal space)

(3) Toxocara endophthalmitis (no calcification, usually > 5 years of age, contact with dogs, serology)

(4) Retrolental fibroplasia (microphthalmia, bilateral, low birth weight, periventricular leukomalacia)

(5) Giant drusen = nodular type of retinal astrocytic hamartoma (confined to sensory retina / optic disc, often lack hemorrhage / necrosis, may be associated with tuberous sclerosis / NF1)

(6) Norrie disease (retinal dysplasia)

(7) Coloboma of choroid / optic disc coloboma

(8) Retinoma = retinocytoma (benign variant)

RETROLENTAL FIBROPLASIA

= RETINOPATHY OF PREMATURITY

= bilateral often asymmetric postnatal fibrovascular organization of vitreous humor, which usually leads to retinal detachment

Pathophysiology:

retinal vascularization occurs in 4th–9th months of fetal life progressing from papilla to periphery; vascularization is incomplete in premature neonates, especially in temporal sectors

Predisposed: premature infants with respiratory distress syndrome requiring prolonged oxygen therapy

Severity directly related to:

(1) Degree of prematurity

(2) Birth weight

(3) Amount of oxygen used in therapy

- leukokoria in severe cases (traction retinal detachment, usually bilateral + temporal) [3–5% of all childhood leukokoria cases]
- Ophthalmoscopic stages:

1st stage	=	arteriolar narrowing of most immature vessels at the border of the vascular-avascular retina ← spasm as a reaction to hyperoxygenation
2nd stage	=	dilatation + elongation + tortuosity of retinal vessels (after oxygen withdrawal)
3rd stage	=	retinal neovascularization with growth into vitreus → vitreous hemorrhage
4th stage	=	fibrosis → retraction of fibrovascular tissue → retinal detachment

√ bilateral microphthalmia ± retinal detachment

US:

√ hyperechoic tracts extending from temporal side of periphery of retina to vitreus behind lens

CT:

√ dense vitreus bilaterally (neovascular ingrowth)

√ ± dystrophic calcifications in choroid + lens (late stage)

MR:

√ hyperintense vitreus on T1WI + T2WI ← chronic subretinal hemorrhage

√ hypointense retrolental mass ← apposition of detached leaves of retina displaced from retinal pigment layer

Prognosis:

(1) spontaneous regression of vitreous neovascularization (85–95%) ± retinal detachment

(2) progression to cicatricial stage characterized by formation of dense membrane of gray-white vascularized tissue in retrolental vitreus + retinal detachment + microphthalmia

DDx: Retinoblastoma (calcifications in eye of normal size)

STAPHYLOMA

= sacculation of posterior pole of globe (or berrylike protrusion of cornea)

Prevalence: increasing with size of globe

Cause: axial myopia (temporal side of optic disc / anteriorly / along equator), trauma, scleritis, necrotizing infection

√ increase of anteroposterior ocular axis > 25 mm

√ focal bulge + thinning of sclera of posterior pole

Cx: advanced chorioretinal degeneration (77%), choroid retraction from optic disc, posterior vitreous detachment, choroidal hemorrhage, retinal detachment, cataract, glaucoma

SUPERIOR OPHTHALMIC VEIN THROMBOSIS

Cause: paranasal sinusitis

• orbital pain, headache, visual disturbance, cranial nerve palsy

• periorbital edema, chemosis, proptosis

√ filling defect in superior ophthalmic vein

√ enlargement of both superior ophthalmic veins + cavernous sinus

√ periorbital edema

√ engorgement of extraocular muscles

√ exophthalmos

Cx: vision loss, thrombosis of cavernous sinus, sepsis

Rx: anticoagulation + antibiotics

TOLOSA-HUNT SYNDROME

[Eduardo Tolosa (1900–1981), Spanish neurosurgeon]

[William Edward Hunt (1921–1999), neurosurgeon at Ohio State University]

= rare disorder characterized by painful ophthalmoplegia ← cavernous sinus inflammation responsive to steroid therapy

Cause: inflammation of cavernous sinus and orbital apex

Path: lymphofibroblastic lesion (similar to orbital pseudotumor)

Age: 5th decade

• acute onset of severe retro- / periorbital pain

• ophthalmoplegia ± exophthalmos

• diplopia, ptosis, pupillary + variable extraocular muscle dysfunction

• visual loss with optic nerve involvement
• fever, chronic fatigue, vertigo, arthralgia

Location: unilateral, bilateral (5%)

CT:
- √ inflammatory soft-tissue density around orbital apex
- √ asymmetric enlargement of cavernous sinus
- √ abnormal nodular enhancement in prepontine cistern

MR (thin-section contrast-enhanced MRI + fat suppression):
- √ loss of SI of orbital fat
- √ enlargement of the cavernous sinus with convex outer margin
- √ abnormal soft tissue in cavernous sinus:
  - √ isointense to gray matter on T1WI
  - √ hypo- to isointense to gray matter on T2WI ← fibrous tissue
  - √ homogeneous enhancement
- √ extension of lesion into orbital apex through superior orbital fissure with involvement of extraocular muscles
- √ narrowing of cavernous segment of ICA (in 50%)
- √ enhancement of dura, trigeminal n., facial n. (uncommon)

Angio:
- √ narrowing of carotid siphon
- √ occlusion of superior ophthalmic vein
- √ nonvisualization of cavernous sinus

Rx: corticosteroids, immunosuppressive agents (methotrexate, azathioprine)

Dx: findings reversible with steroid use

DDx: perineural tumor spread, fungal infection, schwannoma, meningioma (no resolution with steroids), lymphoma (systemic symptoms), sarcoidosis (systemic symptoms)

VARIX OF ORBIT

◊ Most common cause of spontaneous orbital hemorrhage!

Etiology:
(a) congenital: weakness in postcapillary venous wall
(b) acquired: intraorbital / intracranial AVM
◊ Orbital veins are valveless!

Frequency: uncommon

Age: 2nd–3rd decade; M÷F = 1÷1

May be associated with: contiguous / noncontiguous intracranial venous anomalies

• stress proptosis = dramatic protrusion of eye with straining (coughing, forward bending, breath holding, Valsalva)
• frequent blindness

√ involvement of superior / inferior orbital vein; phleboliths rare
√ may produce bony erosion without sclerotic reaction
√ well-defined markedly enhancing mass
√ enlargement of mass during Valsalva maneuver / jugular vein compression

CT:

√ normal / only mild enlargement of veins in supine position (repeat scan during Valsalva maneuver / in prone position / with neck tourniquet)
√ smoothly contoured clublike / triangular tangled mass of vessels
√ intense contrast enhancement

US:
√ anechoic tubular / oval structure ± thrombus
√ venous flow increasing / reversing with Valsalva

MR:
√ flow void (rapid flow) / flow-related enhancement (slow flow)

Cx:
1. Hemorrhage
2. Spontaneous thrombosis (with rapid painful proptosis)

WARBURG DISEASE

= autosomal recessive syndrome characterized by
(1) Bilateral persistent hyperplastic primary vitreous
(2) Hydrocephalus, lissencephaly
(3) Mental retardation

• bilateral leukokoria + microphthalmia

EAR, NOSE AND THROAT

DIFFERENTIAL DIAGNOSIS OF EAR, NOSE, AND THROAT DISORDERS

FACE

Facial Swelling in Childhood

A. ACUTE SWELLING with inflammation (most common)
   1. Lymphadenitis of neck and face
      Cause: upper-airway viral (common) / bacterial infection (S. aureus, group A streptococci)
      • erythema in upper neck, submandibular, parotid region
      Cx: abscess (CECT!)
   2. Sinusitis
      • swelling around malar / brow region
      Cx: preorbital / preseptal cellulitis
   3. Odontogenic infection
      • jaw swelling, trismus ← masticator space phlegmon

B. NONPROGRESSIVE SWELLING
   (a) congenital midfacial mass
      • broad nasal bridge, glabellar swelling, hypertelorism
      1. Frontoethmoidal cephalocele
      2. Nasal glioma
      3. Nasal dermoid / epidermoid cyst
   (b) developmental
      1. Dacryocystocele
      2. Orbital dermoid
      3. First branchial cleft cyst

C. SLOWLY PROGRESSIVE SWELLING
   (a) underlying mass
      1. Neurofibroma
      2. Lymphangioma
      3. Hemangioma
      4. Plunging ranula
   (a) osseous disease
      1. Craniofacial fibrous dysplasia

D. RAPIDLY PROGRESSIVE SWELLING
   1. Rhabdomyosarcoma
   2. Langerhans cell histiocytosis
   3. Ewing sarcoma of mandible

4. Osteogenic sarcoma
5. Metastatic neuroblastoma

Facial Nerve Paralysis

A. INTRACRANIAL SEGMENT
   (a) intraaxial brainstem glioma, metastasis, multiple sclerosis, cerebrovascular accident, hemorrhage
      • cranial nerve VI also involved
   (b) extraaxial CPA tumor (acoustic neuroma, meningioma, epidermoid), CPA inflammation (sarcoidosis, basilar meningitis), vertebrobasilar dolichoectasia, AVM, aneurysm
      • cranial nerve VIII also involved
B. INTRATEMPORAL SEGMENT
   fracture, cholesteatoma, paraganglioma, hemangioma, facial nerve schwannoma, metastasis, Bell palsy, otitis media
   • loss of lacrimation, hyperacusis, loss of taste
C. EXTRACRANIAL PAROTID SEGMENT
   forceps delivery, penetrating facial trauma, parotid surgery, parotid malignancy, malignant otitis externa
   • preservation of lacrimation, stapedius reflex, taste

Bell Palsy

= facial nerve paralysis without identifiable cause
Cause: ? viral inflammation (herpes simplex virus)
• rapid onset of facial nerve paralysis progressing over a few hours to up to 3 weeks
√ enhancement of canalicular, labyrinthine, geniculate portion of facial n.
Prognosis: spontaneous improvement (in 80%); persistent Bell palsy (in 5% caused by neurinoma)
N.B.: if symptoms persist for > 3 weeks → MRI

EAR

Hearing deficit

A. CONDUCTIVE HEARING LOSS
   • decrease in air conduction via EAC, tympanic membrane, ossicular chain, oval window (sound via headphones)
   • normal bone conduction (sound via bone oscillator)
   (a) congenital (uncommon):
      1. EAC atresia / stenosis
      2. Malformed ossicles
      3. Absence of oval window
   (b) trauma: incudostapedial / malleoincudal subluxation; incus dislocation; stapes dislocation; stapes / malleus fracture
   (c) destruction of ossicular chain:
      1. Otitis media

(d) restriction of ossicular chain: fenestral otosclerosis
◊ CT is the modality of choice!

B. SENSORINEURAL HEARING LOSS (most common)
• elevated conduction thresholds for bone + air
(a) sensory / **cochlear SNHL** = damage to cochlea / organ of Corti (less common)
› bony labyrinth
» demineralization:
1. Otosclerosis (otospongiosis)
2. osteogenesis imperfecta
3. Paget disease, syphilis
» congenital deformity:
1. Cochlear dys- / aplasia
2. Michel anomaly
3. Mondini dysplasia
4. Enlarged vestibular aqueduct syndrome
5. X-linked sensorineural hearing loss
» traumatic lesion:
1. Transverse fracture
2. Perilymphatic fistula, cochlear concussion
» destructive lesion: inflammation, neoplasm
◊ High-resolution CT is the modality of choice!
› membranous labyrinth
» enhancement: labyrinthitis, Cogan syndrome (early phase of autoimmune interstitial keratitis), intralabyrinthine schwannoma, site of postinflammatory perilymphatic fistula
» obliteration: labyrinthitis ossificans, Cogan syndrome (late phase)
» hemorrhage: trauma, labyrinthitis, coagulopathy, tumor fistulization
» Ménière disease (vertigo + fluctuating sensory sensorineural hearing loss)
◊ Thin-section MR is the modality of choice!
(b) neural / **retrocochlear SNHL** (more common)
= abnormalities of neurons of spiral ganglion + central auditory pathways
› IAC / cerebellopontine angle
(1) Neoplastic lesion: vestibular / trigeminal schwannoma (acoustic neuroma in 1%), meningioma, arachnoid cyst, epidermoid cyst, leptomeningeal carcinomatosis, lymphoma, lipoma, hemangioma
(2) Nonneoplastic lesion: sarcoidosis, meningitis, vascular loop, siderosis
› intraaxial auditory pathway
(brainstem, thalamus, temporal lobe)
(1) Ischemic lesion
(2) Neoplastic lesion
(3) Traumatic lesion
(4) Demyelinating lesion
◊ MR is the modality of choice!

Pulsatile tinnitus ± Vascular Tympanic Membrane

= perception of a rhythmic cardiac synchronous sound of ringing / buzzing / roaring

A. NO ABNORMALITY (20%)

B. CONGENITAL VASCULAR VARIANTS (21%)
   1. Aberrant ICA
   2. Dehiscent jugular bulb
   3. High-riding nondehiscent jugular bulb (= jugular megabulb)
      √ high jugular bulb with diverticulum projecting cephalad into petrous temporal bone

C. ACQUIRED VASCULAR LESIONS (25%)
   1. Dural AVM
   2. Extracranial arteriovenous fistula
   3. High-grade stenotic vascular lesion:
      carotid artery atherosclerosis, fibromuscular dysplasia, carotid artery dissection
   4. Aneurysm involving horizontal segment of petrous ICA

D. TEMPORAL BONE TUMORS (31%)
   1. Paraganglioma (27%):
      glomus tympanicum, glomus jugulare
   2. Meningioma
   3. Hemangioma

E. MISCELLANEOUS
   1. Cholesterol granuloma

External Ear Masses

A. CONGENITAL
   1. Atresia

B. INFLAMMATORY
   1. Malignant external otitis
   2. Keratosis obturans
   3. Cholesteatoma

C. BENIGN TUMOR
   1. **Exostosis** = surfer's ear
      Cause: irritation by cold water
      √ bony mass projecting into EAC; often multiple + bilateral
   2. **Osteoma**
      √ may invade adjacent bone
      √ single in EAC / mastoid
   3. **Ceruminoma**
      from apocrine + sebaceous glands; bone erosion mimics malignancy

D. MALIGNANT TUMOR
   1. Squamous cell carcinoma
      • often long history of chronic suppurative otitis media = "malignant otitis"
   2. Basal cell carcinoma
   3. Melanoma, adenocarcinoma, adenoid cystic carcinoma
   4. Metastases
      (a) hematogenous: breast, prostate, lung, kidney, thyroid
      (b) direct spread: skin, parotid, nasopharynx, brain, meninges

(c) systemic: leukemia, lymphoma, myeloma

5. Histiocytosis X: in 15% of patients

Middle Ear Masses

A. CONGENITAL
   1. Aberrant internal carotid artery
   2. Dehiscent jugular bulb

B. INFLAMMATORY
   1. Cholesteatoma
   2. Cholesterol granuloma
   3. Granulation tissue
      √ linear strands partially opacifying middle ear cavity without bony erosion

C. BENIGN TUMOR
   1. Adenomatous tumor (mixed pattern type)
      √ intense enhancement
      √ no osseous destruction
   2. Glomus tumor (multiple in 10%; 8% malignant)
      (a) glomus tympanicum: at cochlear promontory
         √ seldom erodes bone
      (b) glomus jugulare: at jugular foramen
         √ invasion of middle ear from below
         √ destruction of bony roof of jugular fossa + bony spur separating vein from carotid artery
   3. Facial nerve schwannoma
   4. Ossifying hemangioma
   5. Choristoma = ectopic mature salivary tissue
   6. Endolymphatic sac tumor
   7. Meningioma

D. MALIGNANT TUMOR
   1. Squamous cell carcinoma
   2. Metastasis
   3. Rhabdomyosarcoma
      Location: orbit > nasopharynx > ear
   4. Adenocarcinoma (rare), adenoid cystic carcinoma

Mass on Promontory

[promontory = bone over basal turn of cochlea]

1. Glomus tympanicum
2. Congenital cholesteatoma
3. Aberrant carotid artery
4. Persistent stapedial artery

Inner Ear Masses

A. CONGENITAL
   1. Congenital / primary cholesteatoma

= epidermoid tumor (3rd most common CPA tumor)

B. INFLAMMATION
   1. Cholesterol granuloma
   2. Petrous apex mucocele

C. TUMOR
   1. Glomus jugulare tumor
   2. Hemangioma, fibro-osseous lesion
   3. Metastasis
   4. Facial nerve neurinoma
   5. Large CPA tumors: acoustic neuroma, meningioma (2nd most common CPA tumor)

TEMPORAL BONE

Congenital Malformation of Temporal Bone

- congenital hearing deficit

Developmental malformations affecting the EAC + middle ear may cause conductive hearing loss.

Those affecting the membranous + bony labyrinth may result in sensorineural hearing loss (SN HL).

Cause: (a) nongenetic
(b) genetic
› isolated
› associated with:
(1) **CHARGE syndrome** (= **C**oloboma, **H**eart defect, **A**tresia of nasal choanae, **R**etardation of growth ± development, **G**enital ± urinary abnormalities, **E**ar abnormalities and deafness)
(2) Klippel-Feil syndrome
(3) Trisomy 21
(4) Goldenhar syndrome
(5) Crouzon syndrome

Location: external ear, middle ear, inner ear

1. Congenital atresia of EAC
2. Otic capsule dysplasia
3. Large vestibular aqueduct syndrome

Vascular Abnormalities of Temporal Bone

1. Aberrant internal carotid artery (rare)
2. High-riding jugular bulb
3. Persistence of stapedial artery

Inflammatory Temporal Bone Lesion

The most common inflammatory condition affecting the temporal bone is acute otitis media.

@ External auditory canal
   1. EAC cholesteatoma

2. Keratosis obturans
3. Malignant otitis externa

@ Middle ear
1. Acute otitis media
2. Chronic otitis media
3. Cholesterol granuloma
4. Cholesteatoma

@ Inner ear
1. Labyrinthitis

Tumor of Temporal Bone

A. CEREBELLOPONTINE ANGLE + IAC
1. Vestibular schwannoma (most common)

B. MIDDLE EAR
◊ First exclude a vascular structure!
(a) Vascular structure
1. Persistent stapedial artery
2. Lateral / aberrant carotid artery
3. Dehiscent jugular bulb

(b) benign neoplasm

Paraganglioma (glomus tumor / chemodectoma) is the 2nd most common tumor to involve the temporal bone and most common tumor of the middle ear.

1. Paraganglioma
2. Facial nerve schwannoma
3. Geniculate hemangioma
4. Salivary choristoma
5. Meningioma
6. Middle ear adenoma

(c) malignant neoplasm (rare)
1. Carcinoma
2. Metastasis
3. Perineural spread along facial n.

C. EAC AND MASTOID
(a) malignant neoplasm (common)
1. Squamous cell carcinoma
2. Others: basal cell carcinoma, melanoma, lymphoma, myeloma, metastasis, chondro-, osteosarcoma

(b) benign process
1. Langerhans cell histiocytosis
2. Tuberculosis
3. Wegener granulomatosis
4. Malignant otitis media
5. Radiation necrosis

D. PETROUS APEX

(a) primary neoplasm
1. Chondrosarcoma: most common primary malignancy
2. Endolymphatic sac tumor

Petrous Apex Lesions	
Type	*Imaging Characteristics*
Developmental	
Cholesterol granuloma (most common)	√ hyperintense on T1 + T2WI • long Hx of otitis media
Cholesteatoma (4–9%)	√ restricted diffusion at DWI
Cephalocele (rare)	√ CSF signal intensity
Mucocele (uncommon)	
Inflammatory	
Petrous apicitis, osteomyelitis, inflammatory pseudotumor, Wegener granulomatosis	
Benign tumor	
Meningioma, schwannoma, paraganglioma	
Chondroma, chondroblastoma	√ chondroid matrix calcification
Myxoma, osteoblastoma, giant cell tumor	
Malignant tumor	
Chondrosarcoma	√ chondroid matrix calcification
Chordoma	√ honeycomb enhancement
Endolymphatic sac tumor	√ hemorrhage, bone destruction
Metastasis, plasmacytoma, lymphoma, nasopharyngeal ca., rhabdomyosarcoma, LCH	
Vascular	
Petrous carotid aneurysm	
Intraosseous dural AV fistula	√ multiple intraosseous flow voids
Osseous dysplasia	
Fibrous dysplasia	√ ground-glass matrix calcification
Paget disease	
Pseudolesion	
asymmetric marrow	√ fat signal with all sequences
pseudofracture	√ through superior semicircular canal
effusion	

(b) secondary involvement by regional tumor:
trigeminal schwannoma, jugular paraganglioma, nasopharyngeal carcinoma

Dumbbell Mass Spanning Petrous Apex

1. Large trigeminal schwannoma
2. Meningioma
3. Epidermoid cyst

Enhancing Lesion in Internal Auditory Canal

A. NEOPLASTIC
   1. Acoustic schwannoma
   2. Ossifying hemangioma
   3. Lymphoma
   4. Metastasis

B. NONNEOPLASTIC
   1. Sarcoidosis
   2. Meningitis
   3. Postmeningitic / postcraniotomy fibrosis
   4. Vascular loop of anterior inferior cerebellar artery
   5. Syphilis

Demineralization of Temporal Bone

1. Otosclerosis = otospongiosis
2. **Paget disease** = osteoporosis circumscripta
   • sensorineural / mixed hearing loss (cochlear involvement / stapes fixation in oval window)
   √ usually lytic changes beginning in petrous pyramid + progressing laterally; otic capsule last to be affected
   √ calvarial changes ± basilar impression
3. **Fibrous dysplasia** monostotic with temporal bone involvement
   Cause: inability to form mature lamellar bone owing to disordered osteoblastic activity
   • painless mastoid swelling
   • conductive hearing loss ← narrowing of EAC / middle ear
   √ homogeneously dense thickened structurally weak bone (fibro-osseous tissue less dense than calvarial bone)
   √ bone expansion with preserved cortex → osseous narrowing of vascular channels + neuroforamina
   √ lytic lesions (less frequent)
   √ sparing of membranous labyrinth, facial nerve canal, IAC is the rule
4. Osteogenesis imperfecta
   √ changes similar to otosclerosis
   van der Hoeve-de Kleyn syndrome
   = osteogenesis imperfecta + hearing loss + blue sclerae in patients in late 2nd / early 3rd decade
5. Otosyphilis: labyrinthitis + gummatous lesion of internal auditory canal + inflammatory

resorptive osteitis
√ moth-eaten permeative osteolysis of temporal bone

6. Metastasis

Mastoid Abnormality in Child

1. Acute otitis media
2. Langerhans cell histiocytosis
3. Rhabdomyosarcoma
4. Metastatic disease: most commonly neuroblastoma

SINUSES

Opacification of Maxillary Sinus

A. WITHOUT BONE DESTRUCTION
   1. **Sinus aplasia / hypoplasia**
      Age: NOT routinely visualized at birth, by age 6 antral floor at level of middle turbinate, by age 15 of adult size
      Location: uni- / bilateral
      √ depression of orbital floor with enlargement of orbit
      √ lateral displacement of lateral wall of nasal fossa with large turbinate
   2. Maxillary dentigerous cyst
      usually containing a tooth / crown; without tooth = primordial dentigerous cyst
   3. Ameloblastoma
   4. Acute sinusitis
      √ air-fluid level

B. WITH BONE DESTRUCTION
   1. Maxillary sinus tumor
   2. Infection: aspergillosis, mucormycosis, TB, syphilis
   3. Wegener granulomatosis; lethal midline granuloma
   4. Blowout fracture

Paranasal Sinus Masses

1. Mucocele
   Cause: obstruction of a paranasal sinus
   √ ± bone remodeling / sinus expansion
2. Mucus retention cyst
   Cause: obstruction of small seromucinous gland
   Location: commonly in floor of maxilla
   √ smoothly marginated soft-tissue mass
3. Sinonasal polyp
4. Antrochoanal polyp
5. Inverting papilloma
6. Sinusitis
7. Carcinoma
8. Rhabdomyosarcoma (of adulthood)

Site: ethmoid sinuses
Prognosis: poor (due to frequent intracranial extension)

Sinonasal Granulomatous Disease

√ sinus mucosal thickening
√ osseous + cartilaginous erosion (through cribriform plate)
√ nasal septal perforation
√ intraorbital extension

A. Chronic irritants
   1. Beryllium
   2. Chromate salts
B. Infection
   1. Tuberculosis
   2. Actinomycosis
   3. Rhinoscleroma
   4. Yaws
   5. Blastomycosis
   6. Leprosy
   7. Rhinosporidiosis
   8. Syphilis
   9. Leishmaniasis
   10. Glanders
C. Autoimmune disease
   1. Wegener granulomatosis
   2. Churg-Strauss syndrome
D. Lymphoma-like lesions
   1. Midline granuloma
E. Unclassified
   1. Sarcoidosis

Hyperdense Sinus Secretions

1. Inspissated secretions
2. Mycotic (fungal) sinusitis
3. Hemorrhage into sinus
4. Chronic sinusitis infected with bacteria (in particular in very long-standing disease / cystic fibrosis)

Opacified Sinus & Expansion / Destruction

mnemonic: PLUMP FACIES
Plasmacytoma
Lymphoma
Unknown etiology: Wegener granulomatosis
Mucocele
Polyp
Fibrous dysplasia, **F**ibroma (ossifying)

Aneurysmal bone cyst, **A**ngiofibroma
Cancer
Inverting papilloma
Esthesioneuroblastoma
Sarcoma: ie, rhabdomyosarcoma

Frontal Soft-tissue Swelling

1. Pott puffy tumor
2. Dermoid and epidermoid cyst
3. Cephalocele
4. Cephalhematoma
5. Mucocele
6. Destructive lesion: Langerhans cell histiocytosis, metastasis

NOSE

Nasal Vault Masses

A. BENIGN
   1. Sinonasal polyp
   2. Inverted papilloma
   3. Hemangioma
      • history of epistaxis
   4. Pyogenic granuloma
      √ pedunculated lobular mass
   5. Granuloma gravidarum
      = nasal hemangioma of pregnancy
   6. Hemangiopericytoma
   7. Juvenile nasopharyngeal angiofibroma
      √ arises in superior nasopharynx with extension into nose via posterior choana

B. MALIGNANT
   1. Squamous cell carcinoma (most common primary)
      Predisposed: nickel workers
   2. Adenocarcinoma, mucoepidermoid carcinoma, adenoid cystic carcinoma
   3. Rhabdomyosarcoma: head and neck most frequent site
   4. Lymphoma, chloroma
   5. Melanoma
   6. Metastasis

Mass in Nasopharynx

mnemonic: NASAL PIPE
Nasopharyngeal carcinoma
Angiofibroma (juvenile)
Spine / skull fracture
Adenoids
Lymphoma

Polyp
Infection
Plasmacytoma
Extension of neoplasm (sphenoid / ethmoid sinus ca.)

Congenital Midline Nasal Mass

= result of faulty regression of embryologic dural diverticulum through foramen cecum + fonticulus frontalis (= nasofrontal fontanel) from the prenasal space

Frequency: 1÷20,000 to 1÷40,000 births

1. Teratoma, dermoid, epidermoid
2. Nasal glioma = nasal cerebral heterotopia
3. Sincipital encephalocele
4. Hemangioma / lymphangioma
5. Dacryocystocele
6. Dacryocystitis

Nasal Septal Perforation / Destruction

> Nasal septal perforation due to granulomatous pressure erosions and cartilage destruction is most commonly seen in granulomatosis with polyangiitis (formerly Wegener granulomatosis), sarcoidosis and relapsing polychondritis.

A. AUTOIMMUNE DISEASE
   1. Wegener granulomatosis
   2. Relapsing polychondritis
B. IDIOPATHIC
   1. Sarcoidosis
   2. Reparative giant cell granuloma
C. INFECTION
   1. Syphilis
   2. Leprosy
D. TOXIC EXPOSURE
   1. Cocaine abuse
E. TRAUMA
   1. Rhinotillexomania (= chronic nose picking)
   2. Surgery
F. MALIGNANCY
   1. Lymphoma

ORAL CAVITY

Infections of Oral Cavity

1. Periodontal disease
2. Ludwig angina
3. Descending necrotizing mediastinitis

Cystic Lesion in Floor of Mouth

A. CYSTIC LESION
   1. Ranula
   2. Dermoid / epidermoid
B. INFLAMMATION / INFECTION
   1. Ludwig angina
   2. Dental infection: premolar / 1st molar
   3. Penetrating trauma
   4. Obstructing submandibular calculus
   5. IV drug use
C. SUBMANDIBULAR DUCT OBSTRUCTION
D. VASCULAR MALFORMATION
   1. High-flow AVM
   2. Low-flow hemangioma / venous malformation / lymphangioma
E. NEOPLASM
   (a) benign: lipoma, pleomorphic adenoma of sublingual / minor salivary gland, neural sheath tumors
   (b) malignant: SCC, salivary gland tumor
F. PSEUDOTUMOR: compensatory hypertrophy of sublingual gland, ectopic submandibular salivary gland, ectopic thyroid tissue

Primary Lesion at Root of Tongue

A. CONGENITAL (75%)
   (a) nonvascular
      1. Thyroglossal duct cyst (70%)
      2. Dermoid / epidermoid cyst
      3. Foregut duplication cyst (7%)
      4. Lingual thyroid
      5. Lipoma (0.1–5%)
      6. Capillary hemangioma
   (b) vascular
      1. Lymphatic malformation
      2. Venous malformation
      3. Venolymphatic malformation
      4. Arteriovenous malformation
B. INFECTIOUS (rare)
      1. Abscess
C. NEOPLASTIC
   (a) benign (rare)
      1. Rhabdomyoma
      2. Leiomyoma
      3. Schwannoma
      4. Neurofibroma, plexiform neurofibroma
   (b) malignant (rare)
      ◊ More aggressive than cancers of oral tongue

1. Rhabdomyosarcoma (5% of oral rhabdomyosa.)
2. Alveolar soft part sarcoma

PHARYNX

Pharyngeal Abnormalities

A. NONMALIGNANT
   (a) congenital
      1. Branchial arch anomaly
      2. Laryngeal cleft
      3. Laryngeal cyst
      4. Tracheoesophageal fistula
   (b) acquired
      1. Foreign body ingestion
      2. Perforation
      3. Laryngocele
      4. Zenker diverticulum
      5. Killian-Jamieson diverticulum
   (c) infection / inflammation:
      1. Epiglottitis, pharyngitis
      2. Granulomatous disease: tuberculosis, sarcoidosis
      3. Amyloidosis
      4. Irradiation
B. MALIGNANT
   ◊ Squamous cell carcinoma in 90%!
   @ Oropharynx
   Location: tonsils (75–80%) > tongue base > valleculae > pharyngeal wall cancer
   @ Larynx
   Location: glottic > supraglottic > subglottic cancer
   @ Hypopharynx
   Location: piriform sinus > postcricoid > posterior pharyngeal wall cancer

Parapharyngeal Space Mass

A. BENIGN
   1. Asymmetric pterygoid venous plexus
      √ racemose, enhancing area along medial border of lateral pterygoid muscle
   2. Abscess
      Origin: pharyngitis (most common), dental infection, parotid calculus disease, penetrating trauma
   3. Atypical second branchial cleft cyst
      √ exits pharynx at level of tonsillar fossa
   4. Third branchial arch anomaly
      √ exits pharynx at piriform sinus
   5. Pleomorphic adenoma of ectopic salivary tissue / of deep lobe of parotid gland (common)

6. Schwannoma, neurofibroma
   Origin: usually from cranial nerve X
   √ carotid artery pushed anteriorly
7. Paraganglioma
   √ posterior to carotid artery
   √ extremely vascular (numerous flow voids)
8. Lipoma

B. MALIGNANT
1. Squamous cell carcinoma
   √ direct extension from pharyngeal mucosal space
   √ vertical extension to skull base / hyoid bone
2. Salivary gland malignancy

Pharyngeal Mucosal Space Mass

1. Asymmetric fossa of Rosenmüller
   = lateral pharyngeal recess = asymmetry in amount of lymphoid tissue
2. Tonsillar / peritonsillar abscess
   • sore throat, fever, painful swallowing
3. Postinflammatory retention cyst
   √ 1–2-cm well-circumscribed cystic mass
4. Postinflammatory calcification
   • remote history of severe pharyngitis
   √ multiple clumps of calcification
5. Benign mixed tumor
   • pedunculated mass arising from minor salivary glands
   √ oval / round well-circumscribed mass protruding into airway
6. Squamous cell carcinoma
   √ infiltrating mass with epicenter medial to + invading parapharyngeal space
   √ middle-ear fluid (eustachian tube malfunction)
   √ cervical adenopathy
7. Non-Hodgkin lymphoma
8. Minor salivary gland malignancy
9. Thornwaldt cyst
   ◊ Most common congenital head and neck cyst in a child!

PET in Squamous Cell Carcinoma of Head and Neck

(1) Mucosal primary not identified (in 1–5%): 25–35% sensitive
(2) Staging: detection of contralateral nodal involvement
(3) Restaging (88–100% sensitive, 75–100% specific): more sensitive and specific than CT / MR

Masticator Space Mass

A BENIGN
1. Asymmetric accessory parotid gland
   Frequency: 21% of general population

Location: usually on surface of masseter muscle
√ prominent salivary gland tissue

2. Benign masseteric hypertrophy
   Cause: bruxism (= nocturnal gnashing of teeth)
   √ homogeneous enlargement of one / both masseters
3. Odontogenic abscess / mandibular cysts
   • bad dentition + trismus
4. Lymphangioma, hemangioma

B. MALIGNANT
1. Sarcoma (chondro-, osteo-, soft-tissue sarcoma, especially rhabdomyosarcoma in children)
   √ infiltrating mass with mandibular destruction
2. Malignant schwannoma
   √ tubular mass along cranial nerve V_3
3. Non-Hodgkin lymphoma
4. Infiltrating squamous cell carcinoma
   √ extending from pharyngeal mucosa
5. Salivary gland malignancy: mucoepidermoid carcinoma, adenoid cystic carcinoma
   √ extending from parotid gland

N.B.: (1) check course of V_3 to foramen ovale for skull base extension to Meckel cave area + cavernous sinus

(2) check for extension to pterygopalatine fossa + infraorbital fissure into orbit

Carotid Space Mass

A. VASCULAR LESION
1. Ectatic common / internal carotid artery
2. Carotid artery aneurysm / pseudoaneurysm
3. Asymmetric internal jugular vein
4. Jugular vein thrombosis, Lemierre syndrome

B. BENIGN TUMOR
1. Paraganglioma: carotid body tumor + glomus jugulare + glomus vagale
2. Schwannoma
   √ displacement of carotid artery anteromedially + internal jugular vein posteriorly
   √ well-encapsulated mass
3. Neurofibroma of cranial nerves IX, X, XI
4. Branchial cleft cyst

C. MALIGNANT TUMOR
1. Nodal metastasis from squamous cell carcinoma to interior jugular chain (common)
   √ encasement of carotid artery = inoperable
2. Non-Hodgkin lymphoma

Carotid Artery Aneurysm

= aneurysm of extracranial carotid artery

1. Trauma

2. Infection (mycotic aneurysm)
3. Congenital (very rare): manifestation of connective tissue disorder (Ehlers-Danlos, Marfan, Kawasaki, Maffucci syndrome)

Retropharyngeal Space Mass

A. INFECTION
   Organism: S. aureus, Haemophilus parainfluenzae, b-hemolytic Streptococcus
   1. Reactive lymphadenopathy
      √ nodes > 10 mm in diameter
   2. Suppurative lymphadenitis (common in childhood)
      √ cystic change with peripheral enhancement
   3. Retropharyngeal cellulitis
      √ retropharyngeal edema
   4. Retropharyngeal abscess
B. BENIGN TUMOR
   1. Hemangioma
   2. Lipoma
C. MALIGNANT TUMOR
   1. Metastasis to retropharyngeal nodes
      Source: nasopharyngeal squamous cell carcinoma, melanoma, thyroid carcinoma
      N.B.: **sentinel node of Rouvière** (= lateral retro pharyngeal node) = early sign of nasopharyngeal cancer before primary mass becomes obvious
   2. Non-Hodgkin lymphoma
   3. Direct invasion by squamous cell carcinoma

Prevertebral Space Mass

A. PSEUDOTUMOR
   1. Anterior disk herniation
   2. Vertebral body osteophyte
B. INFLAMMATION
   1. Vertebral body osteomyelitis
   2. Abscess
      √ extension from retropharyngeal space / osteomyelitis / diskitis / epidural abscess
C. TUMOR
   1. Chordoma
   2. Vertebral body metastasis: lung, breast, prostate, non-Hodgkin lymphoma, myeloma
      ◊ Metastases to prevertebral space = inoperable

LARYNX

Vocal Cord Paralysis

◊ Follow anatomic course of laryngeal nerve
A. INTRACRANIAL CAUSES
   √ outward bowing of ipsilateral oropharynx
   √ atrophic thinning of pharyngeal constrictor muscle

√ uvular deviation away from side of causative lesion

1. Birth injury
2. Arnold-Chiari malformation
3. Intracranial tumor
4. Medullary infarct

B. MEDIASTINAL CAUSES

(a) neoplastic: bronchogenic ca., lymphoma, esophageal ca., thyroid ca., neurogenic tumor (paraganglioma, schwannoma), thymic malignancy, nodal metastasis (breast, lung, esophagus), retrosternal goiter

(b) inflammatory: sarcoidosis, silicosis, fibrosing mediastinitis

(c) infectious: TB, histoplasmosis, coccidioidomycosis, bacterial abscess, mycotic aortic aneurysm

(d) infiltrative: amyloidosis

(e) vascular / cardiac: vascular ring, aortic dissection / pseudoaneurysm, left atrial enlargement, CHD, pulmonary artery enlargement, pulmonary embolism

(f) traumatic / surgical procedure: median sternotomy (CABG, valve repair), ligation of PDA, mediastinoscopy, radical esophagectomy, left pneumonectomy / left upper lobectomy, carotid endarterectomy, thyroidectomy, anterior cervical spine fusion, central venous line placement, endotracheal intubation, deceleration injury

C. PARALYTIC PERIPHERAL NEUROPATHY

1. Radioactive iodine ablation treatment
2. External beam radiation effect
3. Chemotherapy (vinca alkaloids)
4. Jugular vein thrombosis

Fluoroscopy

√ fixed vocal cords

CT (true axial):

√ ipsilateral dilatation of piriform sinus

√ ipsilateral dilatation of laryngeal ventricle

√ medial rotation + thickening of aryepiglottic fold

√ anteromedial displacement of ipsilateral arytenoid cartilage + medial displacement of posterior vocal cord margin

√ "sail" sign = medialization of posterior vocal cord margin + air distention of ipsilateral laryngeal ventricle

CT (oblique axial):

√ mushroom-like appearance = "stem" between posterior vocal cords + "head" tilted toward side of paralysis

PET/CT:

√ asymmetric increased uptake in normal cord

Mimics of Vocal Cord Paralysis

1. Tilted patient positioning (oblique imaging)
   √ subglottic air seen anterior to obliquely imaged vocal cord ≠ dilated laryngeal ventricle
2. Invasion of aryepiglottic cartilage by squamous cell carcinoma of larynx / piriform sinus

√ immobilization of vocal cords
√ apparent medialization of cord by thickening from enhancing tumor
√ obliteration of normal fat planes
√ sclerosis of adjacent cartilage
√ regional lymphadenopathy

3. Arytenoid cartilage dislocation / subluxation
   √ poorly defined cricoarytenoid joint
   √ disparity in height of vocal cords (coronal CT)
4. Injection laryngoplasty
   √ "medialization" of paralyzed cord (to improve glottis closure + competence)

Epiglottic Enlargement

A. NORMAL VARIANT
   1. Prominent normal epiglottis
   2. Omega epiglottis
B. INFLAMMATION
   1. Acute / chronic epiglottitis
   2. Angioneurotic edema
   3. Stevens-Johnson syndrome
   4. Caustic ingestion
   5. Radiation therapy
C. MASSES
   1. Epiglottic cyst
   2. Aryepiglottic cyst
   3. Foreign body

Aryepiglottic Cyst

1. Retention cyst
2. Lymphangioma
3. Cystic hygroma
4. Thyroglossal cyst

• may be symptomatic at birth
√ well-defined mass in aryepiglottic fold

Laryngeal Neoplasms

A. SQUAMOUS CELL CARCINOMA (95–98%)
   Location: glottic > supraglottic >> subglottic
   • endoscopically visible due to mucosal involvement
B. NON-SQUAMOUS CELL NEOPLASMS (2–5%)
   malignant÷benign = 1÷1
   (a) vasoformative tumor 33%
      BENIGN
      1. Hemangioma
      2. Lymphangioma
      3. Angiofibroma

4. Angiomatosis
5. Granuloma pyogenicum
6. Arteriovenous fistula
7. Phlebectasia, telangiectasia

MALIGNANT

1. Angiosarcoma (Kaposi sarcoma)
   Location: epiglottis (most frequent)
   √ intensely enhancing mass
2. Hemangiopericytoma

(b) chondrogenic tumor 20%
1. Chondroma
2. Chondrosarcoma
3. Osteosarcoma

(c) hematopoietic tumor 12%
1. Hodgkin / NHL / leukemia
2. Plasmacytoma
3. Pseudolymphoma

(d) salivary gland tumor 10%
1. Pleomorphic adenoma
2. Adenoid cystic carcinoma
3. Mucoepidermoid carcinoma
4. Adenocarcinoma

(e) fatty-tissue tumor 7%
1. Lipoma
2. Liposarcoma

(f) metastasis 7%
skin (melanoma) > kidney > breast > lung > prostate > colon > stomach > ovary

(g) neurogenic tumor 5%

(h) myogenic tumor 2%

(i) fibrohistiocytic tumor 2%

AIRWAYS

Inspiratory Stridor in Children

1. Croup
2. Congenital subglottic stenosis
3. Subglottic hemangioma
4. Airway foreign body
5. Esophageal foreign body
6. Epiglottitis

Airway Obstruction in Childhood

Predisposing anatomy compared to adult:

(1) Narrower nasopharynx

(2) Shorter trachea

(3) Larynx location more anterosuperiorly at level of C3–C4
(4) Cricoid cartilage = narrowest part
(5) Conus elasticus (located 1 cm below glottis): very susceptible to edema
(6) Vocal cords more anteriorly angled
(7) Epiglottis broader and longer
(8) Tongue larger
(9) Intercostal and diaphragmatic muscles weaker

In *acute **upper** airway obstruction* obtain lateral and frontal soft-tissue radiographs of the neck in upright position. If unstable, a single upright soft-tissue lateral radiograph is usually sufficiently diagnostic.

In *acute **lower** airway obstruction* → upright frontal CXR during inspiration with depiction of > 6 anterior ribs at mid-hemidiaphragmatic level + lateral neck radiograph and also expiratory CXR with possible foreign body aspiration.

Nasopharyngeal Narrowing

(a) Congenital:	choanal atresia, choanal stenosis, encephalocele
(b) Inflammatory:	adenoidal enlargement (= pharyngeal tonsils narrow pharynx), polyps
(c) Neoplastic:	juvenile angiofibroma, rhabdomyosarcoma, teratoma, neuroblastoma, lymphoepithelioma
(d) Traumatic:	foreign body, hematoma, rhinolith

Oropharyngeal Narrowing

(a) Congenital:	glossoptosis + micrognathia (Pierre Robin, Goldenhar, Treacher Collins syndrome), macroglossia (cretinism, Beckwith-Wiedemann syndrome)
(b) Inflammatory:	abscess, tonsillar hypertrophy (if tonsils occupy > 50% of oropharynx)
(c) Neoplastic:	lingular tumor / cyst
(d) Traumatic:	hematoma, foreign body

Retropharyngeal Narrowing

= potential space (normally < ¾ of AP diameter of adjacent cervical spine in infants / < 3 mm in older children)

(a) Congenital:	branchial cleft cyst, ectopic thyroid
(b) Inflammatory:	retropharyngeal abscess
(c) Neoplastic:	cystic hygroma (originating in posterior cervical triangle with extension toward midline + into mediastinum), neuroblastoma, neurofibromatosis, hemangioma
(d) Traumatic:	hematoma, foreign body
(e) Metabolic:	hypothyroidism

DDx: "pseudothickening" ← flexed position (exacerbates respiratory distress), young age, during expiration

Vallecular Narrowing

= valleys on each side of glossoepiglottic folds between base of tongue + epiglottis

(a) Congenital: congenital cyst, ectopic thyroid, thyroglossal cyst
(b) Inflammatory: abscess
(c) Neoplastic: teratoma
(d) Traumatic: foreign body, hematoma

Supraglottic Narrowing

= area between epiglottis and true vocal cords

(a) Congenital: aryepiglottic fold cyst
(b) Inflammatory: acute bacterial epiglottitis, angioneurotic edema
(c) Neoplastic: retention cyst, cystic hygroma, neurofibroma
(d) Traumatic: foreign body, hematoma, radiation, caustic ingestion
(e) Idiopathic: laryngomalacia

Glottic Narrowing

= area of true vocal cords

(a) Congenital: laryngeal atresia, laryngeal stenosis, laryngeal web (anterior commissure)
(b) Neoplastic: laryngeal papillomatosis
(c) Neurogenic: vocal cord paralysis (most common)
(d) Traumatic: foreign body, hematoma

Subglottic Narrowing

= short segment between undersurface of true vocal cords and inferior margin of cricoid cartilage = narrowest portion of child's airway

(a) Congenital: congenital subglottic stenosis
(b) Inflammatory: croup, Wegener granulomatosis
(c) Neoplastic: hemangioma, papillomatosis
(d) Traumatic: acquired stenosis ← prolonged endotracheal intubation in 5%
(e) Idiopathic: mucocele = mucous retention cyst (rare complication of prolonged endotracheal intubation)

Most Common Tracheal / Laryngeal Mass in Childhood

(a) endoluminal
    1. Recurrent respiratory papillomatosis
    2. Laryngocele
    3. Subglottic hemangioma
(b) extraluminal (compressing airway)
    1. Bronchogenic cyst
    2. Lymphadenopathy
    3. Neuroblastoma

Epiglottic and Aryepiglottic Fold Thickening

1. Epiglottitis
2. Ingestion of caustic substance / foreign body
3. Angioedema
4. Hemorrhage
5. Epiglottic cyst
6. Postirradiation edema and fibrosis

NECK

Torticollis

= "wry neck" = congenital / acquired deformity characterized by rotational deformity of the cervical spine

Congenital Torticollis

A. MUSCULAR
   1. Congenital muscular torticollis
      (a) fibromatosis colli
      (b) muscular torticollis = muscular tightness
      (c) postural torticollis
   2. Absence of sternocleidomastoid muscle (SCM)

B. SKELETAL
   1. Occipitoatlantal fusion
   2. Klippel-Feil syndrome
   3. Achondroplasia
   4. Osteogenesis imperfecta
   5. Down syndrome

C. CUTANEOUS
   1. Pterygium colli

D. NEUROLOGIC
   1. Syringomyelia
   2. Ocular abnormalities: strabismus, nystagmus

Acquired Torticollis

A. TRAUMATIC
   1. Atlantoaxial rotary fixation
   2. Occipital condyle fracture
   3. Unilateral facet dislocation
   4. Muscle spasm
   5. Spinal hematoma

B. INFECTIOUS / INFLAMMATORY → SCM SPASM
   1. Upper respiratory infection
   2. Otitis media, mastoiditis
   3. Cervical adenitis
   4. Retropharyngeal abscess
   5. Osteomyelitis, diskitis, epidural abscess, meningitis

6. Juvenile idiopathic arthritis

C. NEOPLASTIC

› CNS tumor: posterior fossa, brainstem, spinal cord

› Bone tumor:

1. Eosinophilic granuloma
2. Osteochondroma
3. Osteoid osteoma
4. Metastasis to skull base / spine

(d) miscellaneous (eg, Langerhans cell histiocytosis)

Solid Neck Mass

Soft-tissue Tumors of Head & Neck

= group of mesenchymal tumors with widely varied biologic behaviors [benign (76%), intermediate (13%), malignant (11%)]

Location: head & neck (27%)

Age: in 1st year of life (50%),; during 1st decade (71%)

◊ 12% of soft tissue tumors in children + adolescents

(a) benign

1. Fibromatosis colli
2. Infantile myofibromatosis / myofibroma
3. Nodular fasciitis
4. Giant cell angiofibroma
5. Myositis ossificans

(b) intermediate malignant potential

1. Desmoid-type fibromatosis
2. Solitary fibrous tumor
3. Hemangiopericytoma
4. Inflammatory myofibroblastic tumor

(b) malignant

1. Extraskeletal fibrosarcoma

Features of malignancy:

Malignant soft tissue tumors usually have lower ADC values than benign tumors. ADC value correlates with tumor cellularity in soft tissue sarcomas.

(a) size

√ large volume with > 5 cm in diameter

(b) internal texture

√ intratumoral hemorrhage + necrosis

√ heterogeneous texture

√ high T2 signal intensity

(c) margin

√ poorly defined margin

√ broad interface with underlying fascia

√ extracompartmental extension

(d) vascularity
√ marked primarily peripheral enhancement
(e) interaction with surroundings
√ invasion of bone + neurovascular structures

Demographics of soft-tissue tumors of head & neck:

› Child: Infantile hemangioma, lymphangioma, lipoblastoma, fibromatosis colli, myofibroma, rhabdomyosarcoma
› Adolescent: Hibernoma, desmoid-type fibromatosis, synovial sarcoma, Ewing sarcoma
› Older adult: Liposarcoma, malignant fibrous histiocytoma

Radiation-induced sarcoma of head & neck:,

1. Fibrosarcoma 41.5%
2. Osteosarcoma 22.6%
3. Malignant fibrous histiocytoma 13.2%

A mass at a previously irradiated site and average latency period of 9 (range, 3–26) years raises concern for radiation-induced sarcoma.

Solid Neck Mass in Neonate

1. Cystic hygroma
2. Hemangioma
3. Neuroblastoma
4. Teratoma
5. Fibromatosis colli

Solid Neck Mass in Childhood

1. Lymphadenopathy
2. Fibromatosis colli
3. Aggressive fibromatosis
4. Malignancy: neuroblastoma (most common), lymphoma, embryonal rhabdomyosarcoma
5. Teratoma
6. Hemangioma
7. Cervicothoracic lipoblastomatosis
8. Lipoma
9. Thyroid mass / lingual thyroid
10. Parathyroid adenoma
11. Ectopic thymus

Soft-tissue Tumors of Neck (WHO Classification 2002)				
Histology	*Benign*	*Intermediate locally aggressive*	*Intermediate rarely metastasizing*	*Malignant*
Adipocytic	Lipoma, lipoblastoma, hibernoma, lipomatosis	Atypical lipomatous tumor, well-differentiated liposarcoma	...	Liposarcoma
Fibroblastic / myofibroblastic	Fibromatosis colli, myofibroma, giant cell angiofibroma	Desmoid-type fibromatosis	Solitary fibrous tumor, hemangiopericytoma, inflammatory myofibroblastic tumor (inflammatory pseudotumor)	Fibrosarcoma
So-called fibrohistiocytic	Benign fibrous histiocytoma, diffuse-type giant cell tumor (PVNS)	...	Giant cell tumor of soft tissues	Malignant fibrous histiocytoma (undifferentiated pleomorphic sarcoma)
Skeletal muscle	Rhabdomyoma	...	...	Rhabdomyosarcoma
Smooth muscle	Leiomyoma, angioleiomyoma	...	...	Leiomyosarcoma
Vascular	Hemangioma, lymphangioma	Kaposiform hemangioendothelioma	Kaposi sarcoma	Angiosarcoma
Perivascular	Glomus tumor, myopericytoma	...	...	Malignant glomus tumor
Chondro-osseous	Soft tissue sarcoma	...	...	Mesenchymal chondrosarcoma, extraskeletal osteosarcoma
Uncertain differentiation	Myxoma	...	Ossifying fibromyxoid tumor	Synovial sarcoma, alveolar soft part sarcoma, primitive neuroectodermal tumor, Ewing sarcoma

Pediatric Neck Lesions

@ Superficial
1. Teratoma

@ Visceral
1. Retropharyngeal cellulitis
2. GI duplication cyst
3. Thyroglossal duct cyst
4. Goiter
5. Laryngocele
6. Lymphadenopathy

@ Prevertebral space
1. Descending necrotizing mediastinitis

@ Carotid space
1. Lemierre syndrome

@ Parotid space
1. Acute parotitis
2. HIV parotitis

@ Submandibular space
1. 2nd branchial cyst
2. Thyroglossal duct cyst

@ Masticator space
1. Venous malformation

@ Parapharyngeal space

1. Rhabdomyosarcoma

@ Posterior cervical space

1. Lymphatic malformation

@ Perivertebral space

1. Cervical sporadic Burkitt lymphoma
2. Cervical neuroblastoma
3. Cervical dermal sinus

@ Sternocleidomastoid muscle space

1. Fibromatosis colli

@ Multiple spaces

1. Cervical lymphadenitis

Congenital Cystic Lesions of Neck

It is critical to identify common congenital lesions like branchial cleft + thyroglossal duct cysts, and to recognize their complications (eg, superinfection)

1. Thyroglossal duct cyst
   - vertical movement with protrusion of tongue

   Location: anterior cervical triangle close to midline between foramen cecum + thyroid isthmus
2. Lateral ectopic thyroid tissue

   √ NO thyroid tissue in normal location

   √ thin fibrous band attaching it to an orthotopic gland
3. Lymphangioma / cystic hygroma

   Location: mostly in posterior cervical triangle, occasionally in floor of mouth / tongue

   √ transspatial extent containing locules

   Age: congenital lesion detected by age 2 years
4. Branchial cleft anomalies
   - often noted during upper respiratory infection

   (a) 2nd branchial cleft cyst

   Location: near mandibular angle along anterior surface of sternocleidomastoid muscle, lateral to carotid sheath structures, posterior to submandibular gland
   - painless fluctuating mass often appearing after an upper respiratory infection

   √ round mass displacing sternocleidomastoid muscle posterolaterally

   √ PATHOGNOMONIC beak insinuating itself between ICA + ECA

   (b) branchial cleft fistula

   Location: apex of piriform sinus to thyroid
5. Cervical dermoid / epidermoid cyst

   Location: base of tongue, anterior portion of neck, floor of mouth

   √ fat content / diffusion restriction
6. **Cervical thymic cyst** = persistent thymopharyngeal duct

   Location: mostly on left side of neck
7. **Cervical bronchogenic cyst**

   Cause: anomalous foregut development

Histo: columnar ciliated pseudostratified epithelial lining
M÷F = 3÷1
• draining sinus in suprasternal notch / supraclavicular area
√ cyst up to 6 cm in diameter
√ indentation of trachea

8. **Parathyroid cyst**
   Age: 30–50 years
   • hormonally inactive
   √ noncolloidal cyst near lower pole of thyroid gland
9. Obstructed laryngocele
   Location: lateral aspect of superior paralaryngeal space connecting to larynx ← originating from saccule / appendix of laryngeal ventricle
   √ well-defined smooth mass / saccular cyst
10. Lingual abscess
    = infected lingual thyroglossal duct cyst / dermoid cyst / ranula / secondary to instrumentation or tongue piercing

Midline Neck Mass

1. Thyroglossal duct cyst
2. Epidermoid / dermoid cyst
3. Lymph node
4. Abscess

Pediatric Lesions compared to Neck Compartments	
Space	*Differential Diagnosis*
Superficial fascia	teratoma, vascular malformation, cellulitis, plexiform neurofibroma, keloid, scar, SQ fat fibrosis
Visceral space	all 3: cellulitis, abscess, extension of goiter
Retropharyngeal space	lateral and medial retropharyngeal lymphadenopathy, extension of pharyngeal tumor
Retrovisceral ~	esophageal duplication
Pretracheal ~	thyroglossal cyst, laryngocele, lymphadenopathy, spondylodiskitis
Danger space	cellulitis, abscess
Carotid space	Internal jugular / retromandibular vein thrombosis or phlebitis, lymphadenopathy, paraganglioma
Submandibular / sublingual space	thyroglossal / branchial cyst, venous / lymphatic malformation, dermoid cyst, ranula, sublingual gland disease, lymphadenopathy, facial vein disease
Masticator space	venous / lymphatic malformation, cellulitis, abscess, rhabdomyosarcoma
Parapharyngeal space	cellulitis, abscess, rhabdomyosarcoma, paraganglioma
Perivertebral space	cervical dermal sinus, meningocele, rhabdomyosarcoma, lymphoma extension
Posterior cervical ~	lymphatic malformation, lymphadenopathy

Air-containing Masses of Neck

1. Laryngocele
2. Tracheal diverticulum
   arising from anterior wall of trachea close to thyroid
3. Zenker diverticulum
4. Lateral pharyngeal diverticulum
   located in tonsillar fossa / vallecula / pyriform fossa

Fat-containing Masses of Neck

1. Dermoid cyst
2. Lipoblastoma
3. Liposarcoma
   ◊ 4% of all liposarcomas
   • extremely rare < 10 years of age
   Location: neck (28%), larynx (20%), pharynx (18%)

Lymph node enlargement of neck

◊ Most common neck mass in children!

A. NORMAL LYMPH NODES
- √ few small oval hypoechoic masses
- √ ± central linear echogenicity (= invaginating hilar fat)
- √ larger in transverse than anteroposterior dimension

B. CERVICAL ADENITIS

Location: posterior cervical triangle

1. **Cat scratch disease**

   Organism: Bartonella henselae

   Mode of transfer: cat bite / lick / scratch (bacteria present in cat saliva may be transferred to paws)

   • common cause of enlarged lymph nodes in children
2. Tuberculous lymphadenitis

C. NEOPLASTIC LYMPH NODES
- • firm, nonmobile, painless

Cause: Castleman disease, lymphoma (Hodgkin disease, NHL), leukemia, metastasis
- √ increased anteroposterior diameter
- √ prominent calcifications suggestive of medullary thyroid cancer
- √ axial diameter of > 15 in jugulodigastric region / > 11 mm elsewhere (in squamous cell carcinoma)

US:
- √ loss of hilar echogenicity
- √ peripheral / mixed hypervascularity on Doppler
- √ ± intranodal cystic change

CT:
- √ irregular peripheral (marginal) enhancement
- √ central necrosis (regardless of size)
- √ fuzzy borders as sign of extracapsular extension
- √ ill-defined borders + loss of fat plane between node and adjacent structures (muscle, vasculature, bone) ← extracapsular spread

Low-density Nodes with Peripheral Enhancement

1. Suppurative adenitis
2. Tuberculosis
3. Metastatic malignancy
4. Lymphoma
5. Inflammatory conditions

Lymph Node Metastasis by Location

@ SUPRACLAVICULAR
head & neck, lung, breast, esophagus

@ INTERNAL JUGULAR
supraglottic larynx, esophagus, thyroid

@ MIDJUGULAR
tongue, pharynx, supraglottic larynx

@ JUGULODIGASTRIC

nasopharynx, oropharynx, tonsils, parotid gland, supraglottic larynx

@ SUBMANDIBULAR
skin, submandibular gland, base of tongue

@ POSTERIOR TRIANGLE
nasopharynx, base of tongue

@ LATERAL PHARYNGEAL
nasopharynx, oropharynx

Tonsillar Enlargement

1. Tonsillitis
2. Lymphoid hyperplasia
3. Mononucleosis
4. Tonsillar neoplasm: squamous cell carcinoma, lymphoma)
5. Angioedema
6. Mucositis ← Kawasaki disease

SALIVARY GLANDS

Multiple Small Hypoechoic Areas in Salivary Gland

1. Sialadenitis: chronic / acute
2. Granulomatous disease: sarcoidosis
3. Sjögren syndrome
4. Disseminated lymphoma
5. Metastases: hematogenous (uncommon)
6. Benign lymphoepithelial lesions: HIV

Anechoic Cystic Areas in Salivary Gland at US

A. BENIGN LESION
   1. Pleomorphic adenoma
   2. Basal cell adenoma
   3. Abscess
   4. Benign lymphoepithelial lesions
   5. Warthin tumor

B. MALIGNANT LESION
   1. Mucoepidermoid carcinoma
   2. Acinic cell carcinoma
   3. Necrotic metastatic node

Inflammatory Disease of Salivary Glands

1. Acute inflammation
   Organism: viral (mumps, CMV); bacterial (S. aureus)
   √ hypoechoic enlargement of gland
   √ multiple small oval hypoechoic areas
   √ enlarged lymph nodes with increased blood flow
2. Abscess

3. Chronic sialadenitis
4. Sialolithiasis
5. Sjögren syndrome

Parotid Gland Enlargement

A. LOCALIZED INFLAMMATION / INFECTION
   1. Chronic recurrent sialadenitis
   2. Sialosis
   3. Sarcoidosis
   4. Tuberculosis
   5. Cat-scratch fever
   6. Syphilis
   7. Parotid abscess ← acute bacterial (suppurative) sialadenitis
   8. Reactive adenopathy
   9. Parotitis

B. SYSTEMIC AUTOIMMUNE RELATED DISEASE
   1. Sjögren disease
   2. Mikulicz disease

C. NEOPLASM (incidence in %)
   (a) benign parotid tumor
      1. Pleomorphic / monomorphic adenoma 59%
      2. Cystadenolymphoma (= Warthin tumor) 7%
      3. Benign lymphoepithelial lesions
      4. Lipoma
      5. Facial nerve neurofibroma
      6. Oncocytoma
      7. Parotid hemangioma
      8. Angiolipoma
   (b) primary malignant parotid tumor
      1. Mucoepidermoid carcinoma 8%
      2. Adenoid cystic carcinoma (= cylindroma) 3%
      3. Malignant mixed tumor
      4. Adenocarcinoma
      5. Acinic cell carcinoma 3.5%
      6. Rhabdomyosarcoma
   (c) metastatic parotid tumor
      ◊ Parotid gland undergoes late encapsulation, which leads to incorporation of lymph nodes!
      1. Squamous cell carcinoma 2%
      2. Melanoma of periauricular region
      3. Non-Hodgkin lymphoma
      4. Thyroid carcinoma

D. LYMPHOPROLIFERATIVE DISORDER
   1. Lymphoma / leukemia
   2. Primary non-Hodgkin lymphoma (MALToma)

E. CONGENITAL
   1. First branchial cleft cyst

Bilateral Enlargement of Salivary Glands

1. Viral infection (mumps)
2. Acute phase of Sjögren syndrome
3. Mikulicz disease
4. Sarcoidosis
5. Lymphoma

Salivary Gland Neoplasm

Frequency: 90–95% occur in parotid gland, 5% in submandibular + sublingual glands; only 1% of all pediatric tumors!

◊ Most salivary gland neoplasms are benign (70%–80%) and found in parotid glands (80–90%)!

◊ The smaller the salivary gland the higher the rate of malignancy: parotid (20–25%) < submandibular (40–50%) < sublingual + minor salivary glands in tongue / floor of mouth / retromolar region (50–81%)

◊ Spread to regional lymph nodes is infrequent!

Benign Salivary Gland Neoplasm

1. Pleomorphic adenoma (80%)
2. Warthin tumor (5%–10%)

Others: oncocytoma, basal cell adenoma, hemangioma, lipoma, neurinoma, schwannoma

Malignant Salivary Gland Neoplasm

1. Mucoepidermoid carcinoma
2. Adenoid cystic carcinoma
3. Acinic cell carcinoma
4. Carcinoma ex-pleomorphic adenoma

Others: squamous cell carcinoma, adenocarcinoma

Solitary Lesion of Parotid Gland

1. Pleomorphic adenoma (80%)
2. Warthin tumor
3. Mucoepidermoid carcinoma

Multiple Lesions of Parotid Gland

1. Warthin tumor
2. Metastases to lymph nodes: squamous cell carcinoma of skin, malignant melanoma, non-Hodgkin lymphoma
3. Benign lymphoepithelial lesions (HIV)

THYROID

Congenital Dyshormonogenesis

1. Trapping defect
   = defective cellular uptake of iodine into thyroid, salivary glands, gastric mucosa
   ◊ High doses of inorganic iodine facilitate diffusion into thyroid permitting a normal rate of thyroid hormone synthesis
   ◊ Normal ratio of iodine concentration for gastric juice÷plasma = 20÷1
   √ nearly entire dose of administered radioiodine is excreted within 24 hours
2. Organification defect
   = deficient peroxidase activity, which catalyzes the oxidation of iodide by H_2O_2 to form monoiodotyrosine (MIT) / diiodotyrosine (DIT)
   • ↑ serum TSH; ↓ serum T_4
   • diffuse symmetric thyromegaly
   √ high thyroidal uptake of radioiodine / pertechnetate
   √ rapid ^{131}I turnover
   √ positive perchlorate washout test
   Pendred syndrome = autosomal recessive trait of deficient peroxidase regeneration characterized by hypothyroidism + goiter + nerve deafness
3. Deiodinase (dehalogenase) defect
   = deficient deiodination of MIT / DIT to release iodide, which is reutilized to synthesize thyroid hormone production
   • hypothyroidism; "intrinsic" iodine deficiency goiter
   • identification of MIT + DIT in serum + urine following administration of ^{131}I
   √ high thyroidal ^{131}I uptake
   √ rapid intrathyroidal turnover of ^{131}I
4. Thyroxin-binding globulin (TBG) deficiency
   • abnormal T_4 transport
   • low bound serum T_4 concentration
   • euthyroid
5. End-organ resistance to thyroid hormone
   • high serum T_4
   • euthyroid / hypothyroid; growth retardation
   √ goiter
   √ stippled epiphyses

Thyrotoxicosis

= clinical syndrome of increased systemic metabolism
• elevated free T_4, elevated free T_3, or both

Cause:

(a) increased thyroid function
   1. Graves disease
   2. Marine-Lenhart syndrome
      = nodular Graves = Graves disease coexistent in multinodular goiter
   3. Toxic autonomous nodule
   4. Toxic multinodular goiter

(b) thyroid inflammation

1. Subacute thyroiditis
2. Painless / silent thyroiditis
3. Postpartum thyroiditis

(c) iodine-induced hyperthyroidism

(d) hyperthyroidism of extrathyroidal origin

1. Factitious hyperthyroidism
2. Ectopic thyroid hormone production: metastatic thyroid cancer, toxic struma ovarii
3. Thyrotropin-induced hyperthyroidism (pituitary adenoma)

Hyperthyroidism

= excessive thyroid hormone activity

• tachycardia, weight loss, muscle weakness, anxiety, decreased temperature tolerance

Radioiodine Therapy for Hyperthyroidism

Dose:

(a) empiric: 15–30 mCi

(b) calculation (Y): 80–160 μCi/gram

Calculation:

Dose [mCi] = (gland weight [gram] x Y [μCi/gram]) divided by 24-hour uptake

Hyperthyroidism with High Radioiodine Uptake

(a) stimulation of thyrotropin receptor by specific immunoglobulin

1. Graves disease

(b) autonomous production of thyroid hormone

2. Toxic adenoma
3. Toxic multinodular goiter

(c) thyroid stimulation by endogenous hormones

4. Trophoblastic disease
   = hydatidiform mole / choriocarcinoma / testicular trophoblastic carcinoma
   • stimulation of thyroid by hCG
5. TSH-mediated hyperthyroidism

Hyperthyroidism with Low Radioiodine Uptake

1. Iodine-induced hyperthyroidism = Jod-Basedow

Mechanism of low thyroid uptake:

large serum concentration of exogenous non-radioactive iodine dilutes radioiodine tracer

Sources of iodine:

1. Foods: seaweed, sushi, Japanese cuisine, Portuguese stew
2. Health food supplement: Kelp tablets
3. Radiographic contrast agent: renografin, Gastrografin®
4. Topical antiseptic: povidone iodine, iodoform gauze
5. Medication: amiodarone, Entero-Vioform®, COMBID®, iodine-containing expectorants
6. Iodine solutions: KI, Lugol's solution, saturated solution of potassium iodide

Wolff-Chaikoff effect = continued organification of iodine is inhibited once intrathyroidal iodide stores reach a critical level

Escape from the Wolff-Chaikoff effect = intrathyroidal level of iodide decreases despite persistent high serum iodine levels → iodide organification and thyroid hormone synthesis resume

Duration: weeks – months

Hyperthyroidism with Radioiodine Uptake < 1%

1. Subacute thyroiditis
2. Ectopic hyperthyroidism
   = extrathyroidal source of thyroid hormone
   (a) **Thyrotoxicosis factitia / medicamentosa**
   = factitious surreptitious (stealthy) self-administration of thyroid hormones (eg, hamburger thyroiditis ← bovine thyroid in hamburger meat)
   (b) **Struma ovarii**
   = monodermal ovarian teratoma containing thyroid tissue
   Frequency: up to 3% of all teratomas (malignant teratoma in 24% of cases)
   Peak age: 50 years
   • hyperthyroidism in 5%
   √ multilocular cystic ovarian mass with solid components
   MR:
   √ multiple intracystic areas with low SI on T2WI + intermediate SI on T1WI
   NUC:
   √ higher uptake than thyroid gland
   DDx: thyroid cancer metastatic to the ovary
   Prognosis: > 95% benign; malignant transformation to papillary / follicular thyroid cancer (rare)
   (c) Metastatic functional thyroid cancer (very rare, 25 cases)
   • mild T_3 toxicosis

Hypothyroidism

A. PRIMARY HYPOTHYROIDISM (most common)
   = thyroid's inability to produce sufficient thyroid hormone
   • TSH >10 mU/L + FT_4 below reference range
   1. Agenesis of thyroid
   2. Congenital dyshormonogenesis
   3. Chronic thyroiditis
   4. Previous radioiodine therapy
   5. Ectopic thyroid (1÷4,000)

B. SECONDARY HYPOTHYROIDISM
   = failure of anterior pituitary to release sufficient quantities of TSH
   • low to mildly elevated TSH + low FT_4
   1. Sheehan syndrome
   2. Head trauma
   3. Pituitary tumor (primary / secondary)

4. Aneurysm
5. Surgery

C. TERTIARY / HYPOTHALAMIC HYPOTHYROIDISM
= failure of hypothalamus to produce sufficient amounts of TRH

Prominent Pyramidal Lobe

= distal remnant of thyroid descent tract
1. Normal variant: present in 10%
2. Hyperthyroidism
3. Thyroiditis
4. S/P thyroid surgery

DDx: esophageal activity from salivary excretion (disappears after glass of water)

Thyroid Calcifications

(a) microcalcifications = psammoma bodies
√ punctate hyperechoic foci without acoustic shadowing

(b) large coarse calcifications = tissue necrosis
√ spicules / fragmented plates / granular deposit within fibrous septa with posterior acoustic shadowing
◊ Common in multinodular goiter + medullary cancer
◊ Associated with 75% malignancy rate in solitary nodule

(c) peripheral calcifications
√ alignment along periphery of lesion
◊ Common in multinodular goiter ± malignancy

Psammoma Bodies

= 10–100 μm round crystalline calcific deposits
Frequency: in 29–59% of all primary thyroid cancers
◊ Most specific feature of thyroid malignancy (86–95% specific, 59% sensitive, 84% accurate, 42–94% PPV)
1. Papillary carcinoma 61%
2. Follicular carcinoma 26%
3. Undifferentiated carcinoma 13%
4. Follicular adenoma
5. Hashimoto thyroiditis

Cystic Areas in Thyroid

◊ 15–25% of all thyroid nodules!
◊ Cystic component in 13–26% of all thyroid malignancies!

A. Anechoic fluid + smooth regular wall:
1. Colloid accumulation in goiter
= colloid-filled dilated macrofollicle
2. Simple cyst (extremely uncommon)

B. Solid particles + irregular outline:
1. Hemorrhagic colloid nodule

2. Hemorrhagic adenoma (30%)
3. Necrotic papillary cancer (15%)
4. Liquefaction necrosis in adenoma / goiter
5. Abscess
6. Cystic parathyroid tumor

- bloody fluid = benign / malignant lesion
- clear amber fluid = benign lesion

Aspiration: cystic lesions often yield insufficient number of cells

Thyroid Nodule

Frequency: (increasing with age)

(a) 4–8% by palpation (> 2 cm in 2%, 1–2 cm in 5%, < 1 cm in 1%); M÷F = 1÷4
- 16% have no corresponding nodule on US
- 15% have an additional nonpalpable nodule > 1 cm

(b) 10–41% by thyroid US if clinically normal: multiple in 38%, solitary in 12% (occult small cancers found in 4%)

(c) incidental nodule in 9% by CT and MR

(d) incidental nodule in 2%–3% by PET
BOTH benign + malignant nodules show increased uptake (= 14–40% risk for malignancy) → evaluate further with US + FNAB

(e) 50% by autopsy

A. THYROID ADENOMA (most common)
1. Adenomatous nodule (42–77%)
2. Follicular adenoma (15–40%)
3. Ectopic parathyroid adenoma

B. INFLAMMATION / HEMORRHAGE
1. Thyroiditis: chronic lymphocytic (Hashimoto)
2. Inflammatory lymph node in subacute + chronic thyroiditis
3. Hemorrhage / hematoma: frequently associated with adenomas
4. Abscess

C. MALIGNANCY (5–7% of all thyroid nodules)

◊ Higher risk of malignancy if
- › patient < 15–20 and > 45–60 years of age
- › patient is male
- › Hx of radiation therapy to neck / upper chest
- › family Hx of thyroid cancer / MEN syndrome
- › new nodule in long-standing goiter
- › nodule firm / fixed to adjacent structures
- › growth rapid
- › vocal cord paralyzed
- › regional lymph nodes enlarged

1. Thyroid carcinoma
   (a) papillary carcinoma (70%)
   (b) follicular carcinoma (15%)
   - › Hürthle cell carcinoma

› Poorly differentiated carcinoma

(c) medullary carcinoma (5–10%)

(d) anaplastic / undifferentiated carcinoma (5%)

(e) primary thyroid lymphoma (5%)

2. Nonthyroidal neoplasm
   (a) Metastasis: from breast, lung, kidney, malignant melanoma
   (b) Lymphoma (uncommon):
   (usually) NHL as secondary involvement in generalized lymphoma / primary lymphoma in Hashimoto thyroiditis
3. Hürthle cell carcinoma
   √ very thin hypoechoic halo
4. Carcinoma in situ
   √ echogenic area inside a goiter nodule

Role of Fine-needle Aspiration Biopsy (FNAB):

◊ FNAB as initial test leads to a better selection of patients for surgery than any other test!

◊ Large-needle biopsy has more complications with no increase in diagnostic yield

Diagnostic adequacy:

> 6 follicular cell groups each containing 10–15 cells derived from at least 2 aspirates of the nodule

Diagnostic accuracy (70–97%):

(a) 60–70% benign (with US guidance up to 0.6% false negative rate due to sampling error)

Dx: benign follicular nodule / thyroiditis

Recommendation: clinical follow-up

Risk of malignancy: 0–3%

(b) 10% positive specimens (3–6% false-positive rate often due to Hashimoto thyroiditis)

(c) 10–20% indeterminate (follicular neoplasm, Hürthle cell neoplasm, cellular atypia / findings suggestive but not diagnostic of malignancy)

◊ FNA cannot distinguish between benign and malignant follicular lesions!

Nondiagnostic material: in up to 20%

too few follicular cells, too much blood, cyst fluid only, excessive air drying

Nondiagnostic rate: 9–30% for palpation; 4–17% for US

Technique of Fine-Needle Aspiration Biopsy

Needles: 27-gauge, 18- / 20-gauge core biopsy

Target: solid / central vascular component of nodule

6 passes for each nodule:

› 3 passes with capillary technique without suction

› 3 passes with aspiration technique = continuous 0.5–1-mL suction applied to attached 10-mL syringe

• each pass consists of ~ 50 vigorous controlled excursions of the needle through nodule for a 20-second period

If repeat biopsy inadequate: Use FNAB + core biopsy

Indeterminate result: repeat biopsy after 3 months

Role of Imaging:

◊ Imaging cannot reliably distinguish malignant from benign nodules!

Radionuclide scanning (limited role):

◊ Useful in suppressed TSH / indeterminate cytology

◊ Hyperfunctioning nodule is almost always benign!

US:

◊ Best method to determine volume of nodule

◊ Useful during follow-up to distinguish nodular growth from intranodular hemorrhage

◊ US-guidance recommended for

› nodules that are difficult to palpate

› predominantly cystic nodule

› nondiagnostic cytology from palpation-guided FNAB

› growing nodule with prior benign cytology

◊ US-follow-up recommended to ensure stability

› initially at 12 + 24 months

› subsequently at 3–5-year intervals

Discordant Thyroid Nodule

= nodule "warm" on ^{99m}Tc-pertechnetate scan + "cold" on ^{123}I scan, which indicates ^{99m}Tc trapping but no organification

Cause:

1. Malignancy: follicular / papillary carcinoma
   ◊ < 5% of thyroid carcinomas manifest as discordant nodules
2. Benign lesion: follicular adenoma / adenomatous hyperplasia
   (autonomous nontoxic nodules have accelerated iodine turnover + discharge radioiodine as hormone within 24 hr)

Rx: thyroid fine-needle aspiration biopsy

Hot / Hyperfunctioning Thyroid Nodule

Frequency: 5–8%

1. Adenoma
   (a) Autonomous adenoma = TSH-independent
   • euthyroid (80%), thyrotoxicosis (20%)
   √ partial / total suppression of remainder of gland
   (b) Adenomatous hyperplasia = TSH-dependent ← defective thyroid hormone production
2. Thyroid carcinoma (extremely rare)
   √ discordant uptake

N.B.: (1) Any hot nodule on ^{99m}Tc scan must be imaged with ^{123}I to differentiate between autonomous and cancerous lesion

(2) A hot hyperfunctioning (= low TSH level) nodule is rarely malignant → further evaluation with US / FNAB NOT NECESSARY

Increased Thyroid Uptake of Radiotracer

mnemonic: THRILLEr
Thyroiditis (early Hashimoto)
Hyperthyroidism (diffuse / nodular)
Rebound after withdrawal of antithyroid medication
Iodine starvation
Low serum albumin
Lithium therapy
Enzyme defect

Cold / Hypofunctioning Thyroid Nodule

A. BENIGN TUMOR
   1. Nonfunctioning adenoma
   2. Cyst (11–20%)
   3. Involutional nodule
   4. Parathyroid tumor

B. INFLAMMATORY MASS
   1. Focal thyroiditis
   2. Granuloma
   3. Abscess

C. MALIGNANT TUMOR (10–23%)
   1. Carcinoma
   2. Lymphoma
   3. Metastasis

US features of cold nodule:
√ hypoechoic (71%), isoechoic (22%), hyperechoic (3%)
√ mixed echogenicity (4%)
√ cystic (rarely malignant)

mnemonic: CATCH LAMP
Colloid cyst
Adenoma (most common)
Thyroiditis
Carcinoma
Hematoma
Lymphoma, **L**ymph node
Abscess
Metastasis (kidney, breast)
Parathyroid

Probability of a cold nodule to represent thyroid cancer:
(a) 5–25% for solitary cold nodule
(b) 1–6% for multiple nodules (DDx: multinodular goiter)
(c) 4% for palpable cold nodule in Graves disease
(d) with history of neck irradiation in childhood
   › 31% for solitary nodule (found in 70% of irradiations)
   › 37% for multiple nodules (found in 25% of irradiations)
   › 20% with normal thyroid scan (found in 5%)

◊ Solitary cold nodule by scintigraphy → multinodular by US in 20–25%!

Thyroid Uptake Measurements

Agents: ^{123}I / ^{131}I (easier to use), ^{99m}Tc-pertechnetate (requires calibration)

Method:

» orally administered isotope of iodine is absorbed from upper GI tract
» tracer mixes with intravascular iodine pool
» iodine is cleared by thyroid in competition with kidneys
» uptake parallels thyroidal clearance of plasma inorganic iodide
» all measurements are taken for 3 minutes at 4 and 24 hours (measurements at both 4 and 24 hours prevent missing the occasional rapid-turnover hyperthyroid patient returning to normal by 24 hours)

Radioactive Iodine Uptake (RAIU):

RAIU = Thyroid Counts* / Capsule Counts˘

* = background corrected (thigh) + decay corrected

˘ = decay corrected

Interpretation:

(a) normal: < 25% at 4 hours, < 35% at 24 hours

(b) increased: in Graves disease

(c) decreased: in subacute thyroiditis

N.B.: Uptake values do not diagnose hyperthyroidism, which is done with laboratory values (T_4, T_3, TSH) and clinical history

Decreased / No Thyroid Uptake of Radiotracer

A. BLOCKED TRAPPING FUNCTION
   1. Iodine load (most common)= dilution of tracer within iodine flooded pool
      Source of flooding:
      ◊ Suppression usually lasts for at least 4 weeks!
      ◊ A low-iodine diet for 3–10 days may be prescribed
   2. Exogenous thyroid hormone (replacement therapy) → suppresses TSH release

B. BLOCKED ORGANIFICATION
   1. Antithyroid medication (propylthiouracil [PTU] / methimazole)
   2. Goitrogenic substances

   √ ^{99m}Tc uptake not inhibited

C. DIFFUSE PARENCHYMAL DESTRUCTION
   1. Subacute thyroiditis
   2. Postpartum thyroiditis
   3. Chronic lymphocytic thyroiditis

D. HYPOTHYROIDISM
   1. Congenital hypothyroidism
   2. Surgical / radioiodine ablation
   3. Thyroid ectopia (struma ovarii, intrathoracic goiter)

mnemonic: H MITTE

Hypothyroidism (congenital)

Medications: PTU, perchlorate, Cytomel®, Synthroid®, Lugol solution
Iodine overload (eg, after IVP)
Thyroid ablation (surgery, radioiodine)
Thyroiditis (subacute / chronic)
Ectopic thyroid hormone production

Thyroxin-binding Globulin Dysfunction

A. ELEVATION OF TBG
   1. Pregnancy
   2. Estrogen administration
   3. Genetic trait
B. REDUCTION IN TBG
   1. Androgens
   2. Anabolic steroids
   3. Glucocorticoids
   4. Nephrotic syndrome
   5. Chronic hepatic disease
C. INHIBITION OF T_4 BINDING TO TBG: salicylates

Ultrasound Characterization of Thyroid Nodules

Ultrasound Features of Malignancy

√ microcalcifications = psammoma bodies
√ extension beyond thyroid margin
√ cervical lymph node metastasis (in 19%)
√ taller-than-wide shape in transverse plane
√ marked hypoechogenicity relative to thyroid parenchyma

<u>less specific:</u>

√ irregular / microlobulated / ill-defined margin
√ solid composition
√ increased central vascularity

Ultrasound Features of Benignity

√ nodule surrounded by uniform halo
√ predominantly cystic composition
√ avascularity
√ enlarged thyroid with multiple nodules

Thyroid Nodule with Halo

= hypoechoic rim around a thyroid nodule

Cause: pseudocapsule of fibrous connective tissue + compressed thyroid parenchyma + chronic inflammatory infiltrate

Cancer Risk of Thyroid Nodule by Ultrasound		
US Finding	*Low Risk*	*Increased Risk*
Echogenicity	hyperechoic	hypoechoic
Calcification	coarse + large	microcalcifications
Vascularity	in periphery	central
Internal texture	spongiform	
Margin		irregular ± vascular invasion
Edge definition	well-defined	incomplete halo
Shape	taller than wide	wider than tall
Growth	none	enlarging

(a) complete uniform halo
highly suggestive of benignity (95% specific);
BUT in 10–24% of papillary carcinomas
(b) incomplete / absent halo
in > 50% of all benign nodules

Thyroid Nodule with Ill-defined Border

= > 50% of margin not clearly demarcated with irregular jagged edges (= absence of pseudocapsule)
◊ suggests malignancy (7–97% sensitive)
◊ Unreliable sign unless frank invasion beyond capsule

Shape of Thyroid Nodule

◊ A nodule that is taller than wide suggests malignancy (93% specific)

Vascularity of Thyroid Nodule

√ marked intrinsic hypervascularity = flow in central part of nodule greater than in surrounding parenchyma
◊ in 69–74% of all thyroid malignancies
◊ > 50% hypervascular nodules are benign
√ perinodular flow = vascularity in > 25% of circumference
◊ characteristic of benign nodules
◊ in 22% of all thyroid malignancies
√ avascularity
◊ malignancy unlikely
◊ All malignant papillary carcinomas show some vascularity

Echogenicity of Thyroid Nodule

√ hypoechoic solid nodule less than thyroid parenchyma (87% sensitive + 15–27% specific for carcinoma / lymphoma)
◊ in 55% of benign nodules
√ hypoechogenicity less than infrahyoid / strap muscles (12% sensitive + 94% specific for malignancy)

Cystic Thyroid Nodule

= hemorrhagic / cystic degeneration

Features associated with cancer:

1. > 50% solid tissue component
2. Eccentricity of cystic space
3. Microcalcifications

Growth of Thyroid Nodule

= 2 mm / 10% increase (if > 20 mm) in 2 dimensions

◊ 40% of benign nodules grow at least 15% by volume over 5 years

Size of Thyroid Nodule

Papillary carcinomas < 1 cm are usually nonaggressive

Follicular carcinomas < 2 cm are usually nonaggressive

◊ Papillary microcarcinoma (< 1 cm) are incidentally detected in 10% of surgical specimens for benign disease + in 12% at autopsies

◊ The rate of metastases + invasion is the same for lesions of 8–10 mm as for lesions of 11–15 mm

Likely Benign Thyroid Nodule

1. Entirely cystic nodule
2. Predominantly cystic nodule < 2 cm, its solid part without flow / calcifications
3. Honeycomb / spongiform nodule < 2 cm
4. Pseudonodule of autoimmune thyroiditis
5. Mixed nodule with functioning solid component

ANATOMY AND FUNCTION OF NECK ORGANS

PARANASAL SINUSES

Mucus production of 1 L/d (Liter/day); mucus blanket turns over every 20–30 minutes; irritants are propelled toward nasopharynx at a rate of 1 cm/minute

Maxillary Sinus

Size: 6–8 cm at birth

Walls: roof = floor of orbit; posterior wall abuts pterygopalatine fossa

Extension: 4–5 mm below level of nasal cavity by age 12

Ostium: maxillary ostium + infundibulum enter middle meatus within posterior aspect of hiatus semilunaris; additional ostia may be present

Plain film: present at birth; visible at 4–5 months; completely developed by 15 years of age

Variations: sinus hypoplasia in 9%; aplasia in 0.4%

Ethmoid Sinuses

Size: adult size by age 12; 3–18 air cells per side

Walls: roof = floor of anterior cranial fossa; lateral wall = lamina papyracea

Plain film: very small at birth; visible at 1 year of age; completely developed by puberty

(a) anteromedial ethmoid air cells

2–8 cells with a total area of 24 x 23 x 11 mm

Ostia: opening into anterior aspect of hiatus semilunaris of middle meatus (anterior group), opening into ethmoid bulla (middle group)

Agger nasi cell

[*agger*, Latin = mound, heap]

= anteriormost ethmoid air cell in front of the attachment of middle turbinate to cribriform plate near the lacrimal duct = intranasal portion of frontal process of maxilla

Frequency: 78–99%

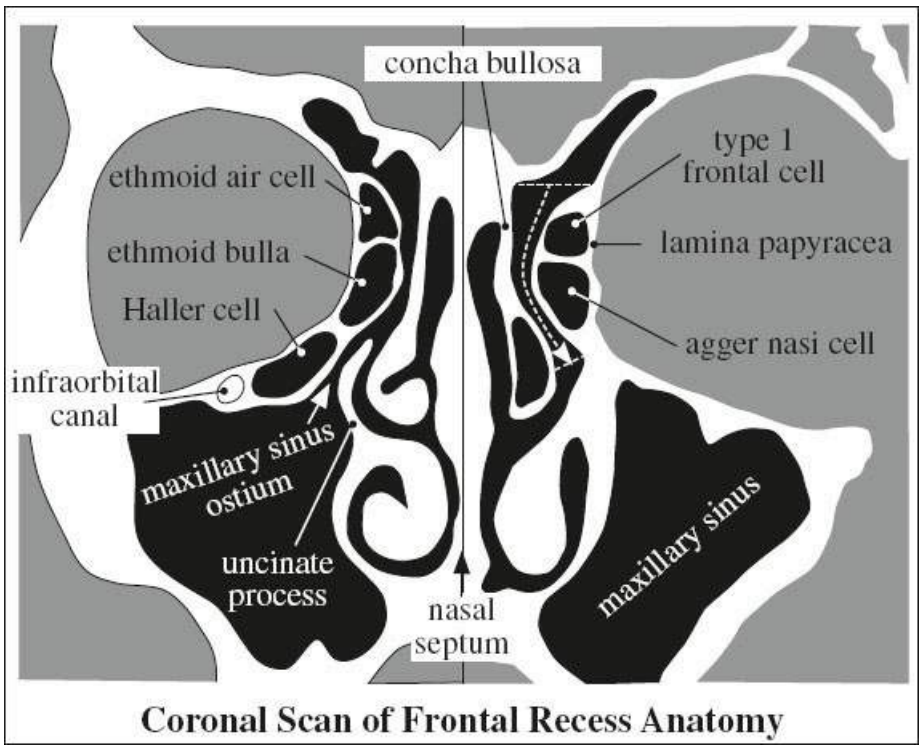
Location: anterior, lateral + inferior to frontoethmoidal recess = on lateral nasal wall at leading edge of middle turbinate

Prevalence: present in > 90%

Ethmoidal bulla

= ethmoidal air cell above + posterior to infundibulum + hiatus semilunaris, located outside the lamina papyracea at the lateral wall of the middle meatus

Haller cells



Coronal Scan of Frontal Recess Anatomy

= INFRAORBITAL ETHMOIDAL AIR CELL = MAXILLOETHMOIDAL / ORBITOMAXILLARY CELL
= anterior ethmoid air cells inferolateral to ethmoidal bulla, on lateral wall of infundibulum, along inferior margin of orbit / roof of maxillary sinus, protruding into maxillary sinus

Prevalence: 2–10–45%

Significance: may narrow ipsilateral ostiomeatal complex if large → obstruction of ipsilateral maxillary antrum

(b) posterior ethmoid air cells

1–8 cells, larger cells, total area smaller than that of anteromedial group

Location: behind the basal (= ground) lamella of the middle turbinate

Ostium: into superior meatus / supreme meatus, ultimately draining into sphenoethmoidal recess of nasal cavity

Onodi cell

= most posterior ethmoid air cell pneumatized into sphenoid bone ± surrounding the optic canal

Location: superolateral to sphenoid sinus

Frontal Sinus

Size: 28 x 24 x 20 mm in adults, rapid growth until late teens

Walls: posterior wall = anterior cranial fossa; inferior wall = anterior portion of roof of orbit

Ostium: into frontal recess of middle meatus via frontoethmoidal recess (= nasofrontal duct)

Outflow tract: frontal infundibulum + frontal ostium + frontal recess

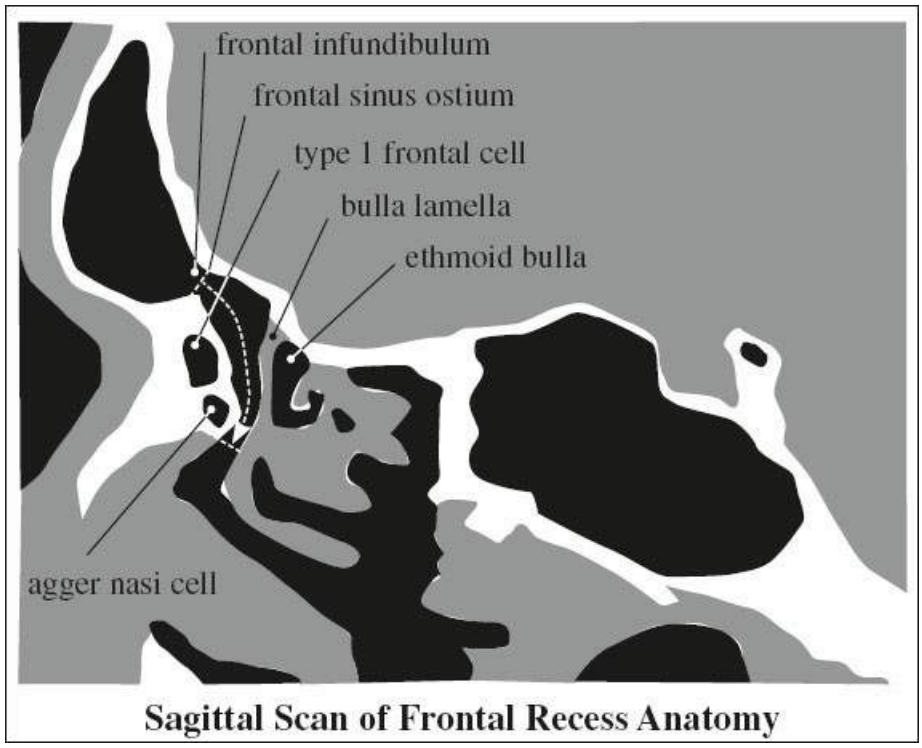
Plain film: visible at age 6 years
Variations: sinus aplasia in up to 4% (in 90% with Down syndrome)

Frontal Recess = Frontoethmoidal Recess

Walls: agger nasi cell anteriorly; lamina papyracea laterally; middle turbinate medially; ethmoid cell with bulla lamella posteriorly

Frontal Recess Cells *(20–33%)*

= pneumatization of frontal recess by various anterior ethmoid cells
Relevance: obstruction of frontal sinus outflow



Sagittal Scan of Frontal Recess Anatomy

(a) anterior group
- › Type 1 frontal cell (in up to 37%)
  = single anterior ethmoid cell within frontal recess above agger nasi cell
- › Type 2 frontal cell (in up to 19%)
  = tier of > 2 anterior ethmoid cells above agger nasi cell
- › Type 3 frontal cell (in up to 7%)
  = single massive cell above agger nasi pneumatizing into frontal sinus
- › Type 4 frontal cell (2%)
  = isolated air cell along anterior wall of frontal sinus not abutting the agger nasi cell

(b) posterior group
1. Supraorbital ethmoid cell (in up to 15%)
   = pneumatized orbital plate of frontal bone posterior to frontal recess mimicking septated frontal sinus = anterior ethmoid air cell extending from frontal recess superiorly + laterally over orbit

2. Frontal bullar cell
   = pneumatized anterior skull base atop ethmoid bulla with extension into frontal sinus as part of posterior boundary of frontal recess + sinus
3. Suprabullar cell
   = atop ethmoid bulla but below level of frontal sinus ostium without extension into frontal sinus as part of posterior boundary of frontal recess
4. Interfrontal sinus septal cell
   = pneumatized interfrontal sinus septum; may extend into crista galli

Sphenoid Sinus

Size: 20 x 23 x 17 mm in adults, small evagination of sphenoethmoidal recess at birth, invasion of sphenoid bone begins at age 5 years; aerated extensions into pterygoid plates (44%) + into clinoid processes (13%)

Walls: roof = floor of sella turcica; anterior wall shared with ethmoid sinuses; posterior wall = clivus; inferior wall = roof of nasopharynx

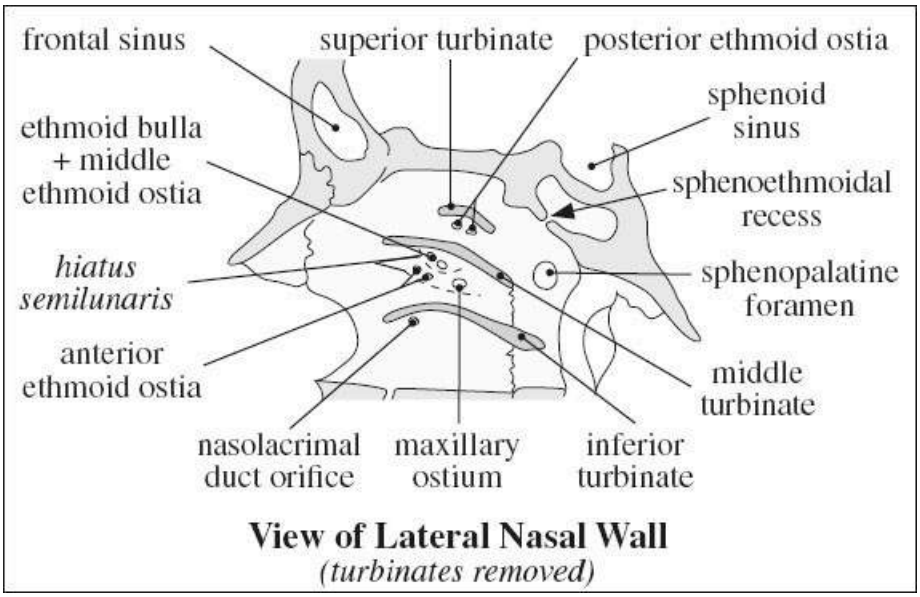
Ostium: 10 mm above sinus floor into sphenoethmoidal recess posterior to superior meatus at level of sphenopalatine foramen

Plain film: appears by 3 years of age; continues to grow posteriorly + inferiorly into the sella until adulthood

OSTIOMEATAL UNIT

= area of superomedial maxillary sinus + middle meatus as the common mucociliary drainage pathway of frontal maxillary, and anterior + middle ethmoid air cells into the nose

Coronal CT: visualized on two or three 3-mm–thick sections



View of Lateral Nasal Wall
(turbinates removed)

Components:

Infundibulum

= flattened conelike passage between inferomedial border of orbit / ethmoid bulla (laterally) + uncinate process (medially) + maxillary sinus (inferiorly) + hiatus

semilunaris (superiorly)

Uncinate process

= key bony structure in lateral nasal wall below hiatus semilunaris in middle meatus defines hiatus semilunaris together with adjacent ethmoid bulla

Attachment: skull base / middle turbinate / lamina papyracea / agger nasi

√ pneumatized in < 2.5% of patients

Ethmoid bulla

√ located in cephalad recess of middle meatus

Hiatus semilunaris

= final segment for drainage of maxillary sinus; located just inferior to ethmoid bulla in middle meatus

Ostia:

(1) Multiple ostia from anterior ethmoid air cells (at its anterior aspect)

(2) Maxillary ostium infundibulum (at its posterior aspect)

Anatomic variations predisposing to ostiomeatal narrowing:

1. **Concha bullosa** (4–15%) = aerated / pneumatized middle turbinate
2. **Intralamellar cell** = air cell within vertical portion of middle turbinate
3. Oversized ethmoid bulla
4. Haller cell
5. Uncinate process bulla
6. Bowed nasal septum
7. **Paradoxical middle turbinate** = convexity of turbinate directed toward lateral nasal wall (10–26%)
8. Deviation of uncinate process

◊ These conditions are not disease states per se!

FACIAL BUTTRESSES

= areas of relatively increased bone density that support functional units of the face (muscles, eyes, dental occlusion, airways)

› sufficient bone thickness to accommodate metal screw fixation

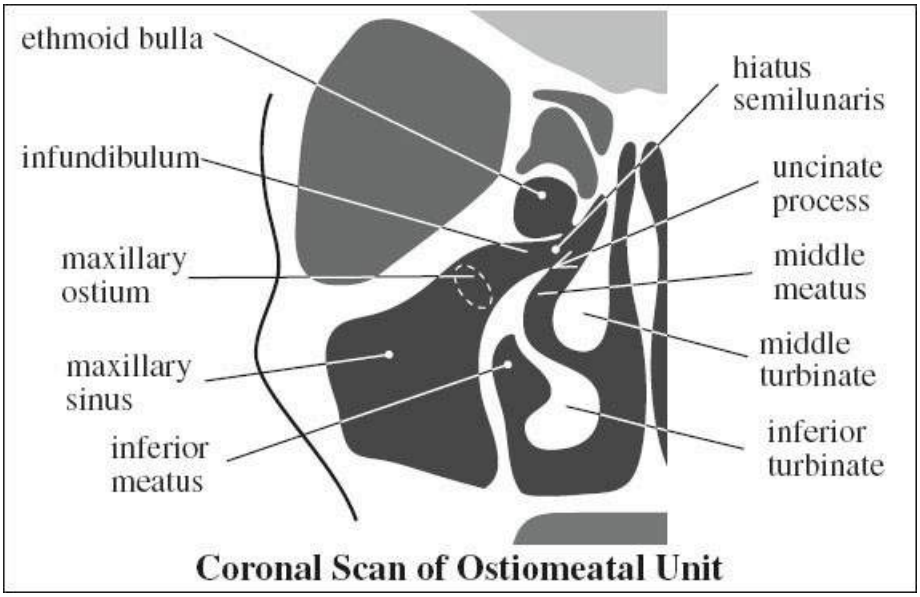
› linked directly / through another buttress to cranium / skull base

(a) horizontal buttresses

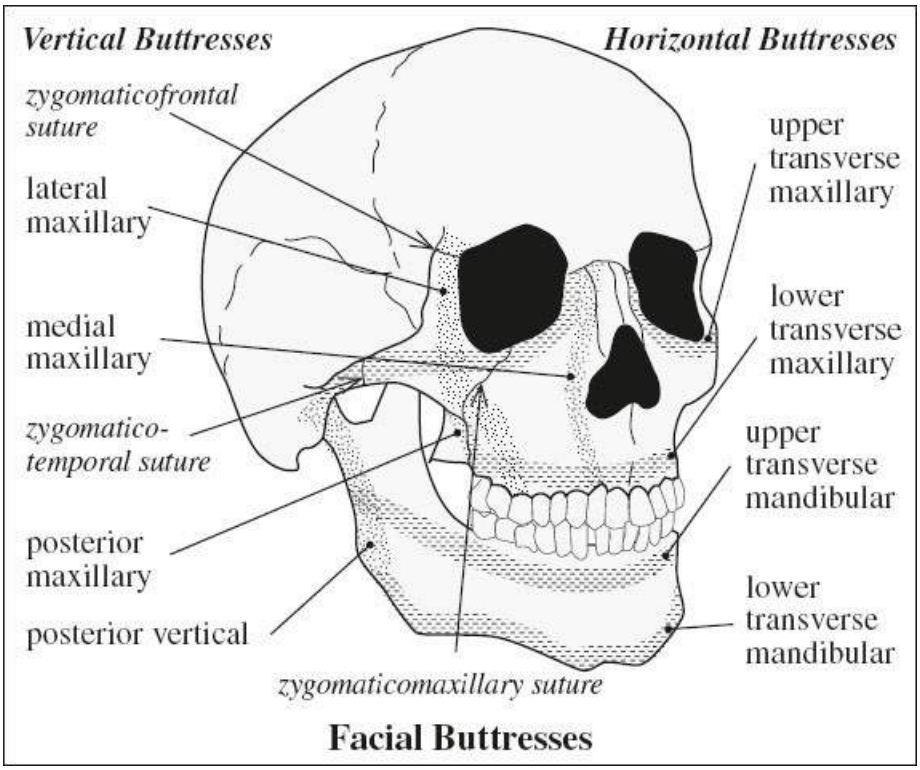
• responsible for facial height

(1) Upper transverse maxillary buttress: temporal squamosa → zygomatic arch → inferior orbital rim → nasofrontal junction

Posterior extension: orbital floor



Coronal Scan of Ostiomeatal Unit



Facial Buttresses

(2) Lower transverse maxillary buttress: maxilla above alveolar ridge
Posterior extension: hard palate
(3) Upper transverse mandibular
(4) Lower transverse mandibular

(b) vertical buttresses
- responsible for facial profile and width

(1) Medial maxillary buttress: anterior nasal spine → rim of piriform aperture → frontal process of maxilla → nasofrontal junction → frontal bone

Posterior projection: medial orbital wall
Anterior projection: lateral nasal wall

(2) Lateral maxillary buttress: above posterior maxillary molar → zygomaticomaxillary suture → body of zygoma → lateral orbital rim → zygomaticofrontal suture → frontal bone
Posterior projection: lateral orbital wall, lateral wall of maxillary sinus

(3) Posterior maxillary buttress: pterygomaxillary junction

(4) Posterior vertical buttress

BRANCHIAL CLEFT DEVELOPMENT

Branchial apparatus: branchial arches, pharyngeal pouches, branchial grooves, branchial membranes

› 6 paired branchial arches are responsible for formation of lower face + neck; recognizable by 4th week GA
› each branchial arch contains a central core of cartilage + muscle, a blood vessel, and a nerve
› 5 ectodermal "clefts" / grooves on outer aspect of neck + 5 endodermal pharyngeal pouches separate the 6 arches with a closing membrane located at the interface between pouches and clefts

Formation: during 4th–6th week of embryonic development

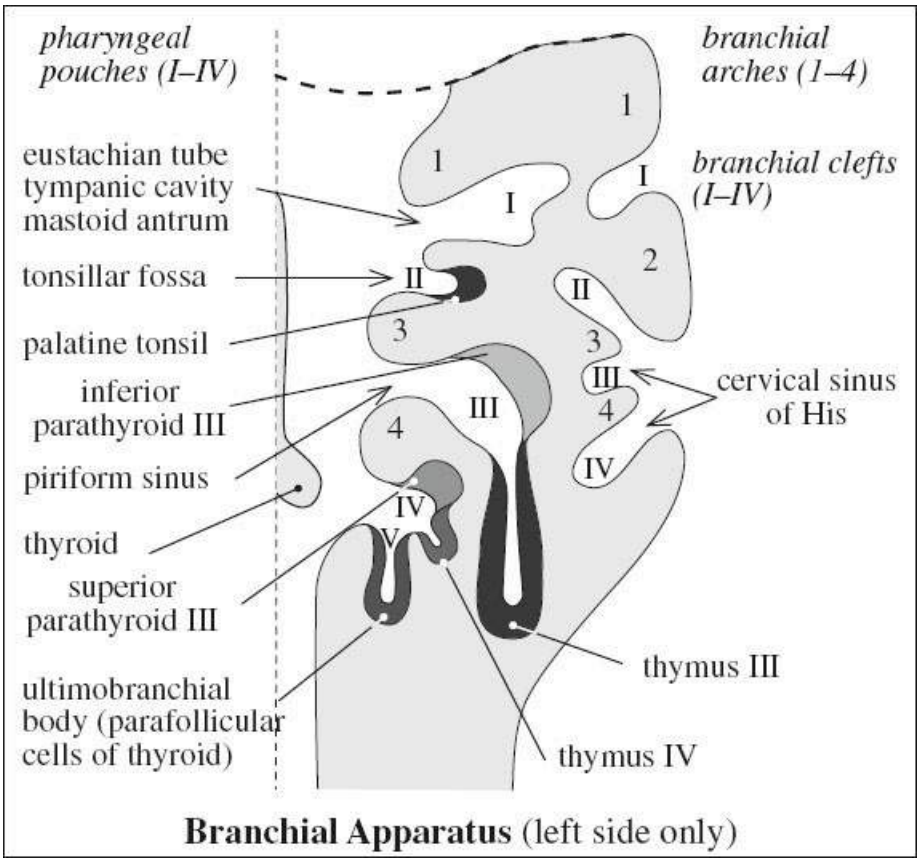
1st Branchial Arch = maxillomandibular arch

(a) large ventral / mandibular prominence
forms: mandible, incus, malleus, muscles of mastication

(b) small dorsal / maxillary prominence
forms: maxilla, zygoma, squamous portion of temporal bone, cheek, portions of external ear
nerve: mandibular division of trigeminal nerve (CN V_3)
pouch forms: mastoid air cells + eustachian tube
cleft forms: external auditory canal + tympanic cavity

2nd Branchial Arch = hyoid arch

nerve: facial nerve (CN VII)



Branchial Apparatus (left side only)

arch forms: thyroid gland, stapes, portions of external ear, muscles of facial expression
pouch forms: palatine tonsil + tonsillar fossa
→ cleft involutes completely by 9th fetal week; 2nd arch overgrows 2nd + 3rd + 4th clefts to form cervical sinus, which creates a tract that runs from the supraclavicular area just lateral to carotid sheath, turns medially at mandibular angle between external + internal carotid artery, and terminates in tonsillar fossa

3rd Branchial Arch

sinks into retrohyoid depression
nerve: glossopharyngeal nerve (CN IX)
arch forms: glossoepiglottic fold, superior constrictor m., internal carotid a., parts of hyoid bone
pouch forms:
(a) thymus gland, which descends into mediastinum by 9th fetal week
(b) inferior parathyroid glands passing down with the thymus

4th Branchial Arch

sinks into retrohyoid depression
nerve: superior laryngeal branch of vagus nerve (CN X)
arch forms: epiglottis + aryepiglottic folds, thyroid cartilage, cricothyroid m., left component of aortic arch, right component of right proximal subclavian a.
pouch superior parathyroid glands, apex of piriform fossa

forms:

cleft ultimobranchial body, which provides parafollicular ("C") cells of thyroid *forms:*

5th + 6th Branchial Arches

cannot be recognized externally

nerve: recurrent laryngeal branch of vagus nerve (CN X)

TONGUE

= complex of muscle groups + fibrous scaffolding

A. FIBROUS SCAFFOLDING

1. Hyoglossal membrane
   anchors inferior posterior edge of tongue to hyoid bone
2. Midline lingual septum
   inserts into hyoglossal membrane + extends superiorly along midline of tongue dividing tongue into halves + providing attachments for transverse intrinsic muscles

B. INTRINSIC MUSCLES (named for their orientation):

Function: wide range of motion for mobile tongue

› vertical + transverse

› inferior + superior longitudinal

C. EXTRINSIC MUSCLES

Function: raising + lowering of tongue, forward + backward motion

1. Genioglossus m.
   Origin: symphysis menti on back of mandible
   Insertion: dorsum of tongue (interdigitating with intrinsic tongue muscles); hyoid bone (few inferolateral fibers)
2. Geniohyoid m.
   Origin: symphysis menti on back of mandible
   Insertion: hyoid bone
3. Hyoglossus m.
   Origin: hyoid bone
   Insertion: lateral aspect of tongue
4. Styloglossus m.
5. Palatoglossus m.

Anatomic subdivision:

(A) Mobile tongue (part of oral cavity)
= frenulum to circumvallate papillae

› "**Root of tongue**"
= region deep to mobile tongue + anterior to base of tongue

Parts: (1) Lingual septum
(2) Genioglossus-geniohyoid complex
= both genioglossus m. + geniohyoid m.

Borders:
(a) anterior: mandible

(b) lateral: sublingual space
(c) inferior: U-shaped mylohyoid m. underneath geniohyoid m.
(c) superior: indistinct ← genioglossus m. fans out and blends with intrinsic tongue muscles

(B) **Base of tongue** (part of oropharynx)
= posterior to circumvallate papillae

ORAL CAVITY

= most ventral portion of aerodigestive tract

Borders:

(a) inferior: circumvallate papillae
(b) superior: soft palate
(c) lateral: anterior tonsillar pillars

Anatomic subdivisions:

lips; floor of mouth; oral tongue (= anterior ⅔ of tongue); buccal mucosa; upper + lower gingiva; hard palate;
retromolar trigone

Sites of squamous cell carcinoma: lower lip > oral tongue > floor of mouth (in 75%)

Floor of Mouth

= horizontally aligned U-shaped space situated in the part of the oral cavity that lies beneath the tongue between mucosal surface and mylohyoid muscle sling

Anatomic components:

1. Squamous epithelium of mucosal surface
2. Mylohyoid muscle sling (paired)
   [*mylai*, Greek = molar (mill) teeth]
   separates floor of mouth from R + L submandibular spaces and midline submental space
   Origin: inner surface of mandible from symphysis menti to last molar posteriorly
   Insertion: fibrous median raphe (medially), posterior aspect of hyoid bone (midline); free edge (posterolaterally) allowing communication between sublingual + submandibular space
   • palpable lump ← herniated sublingual salivary gland mylohyoid defect into adjacent submandibular space
   √ boutonniere = defect in mylohyoid m. (77% of CTs)
3. **Sublingual space**
   = located on both sides of tongue, superomedial to mylohyoid m. and lateral to midline geniohyoid-genioglossus muscle complex
   Content:
   › lingual artery (medial to hyoglossus m.)
   › lingual vein + main submandibular duct (lateral to hyoglossus m.) coursing between hyoglossus + mylohyoid mm.
   √ higher T1 + T2 signal ← higher fat + connective tissue content
4. Submandibular space
5. Submental space

Content: salivary glands (see below); nerves (lingual n. = branch of mandibular division of trigeminal nerve with input from chorda tympani branch of facial n.), distal portions of hypoglossal n. and glossopharyngeal n.

Salivary Glands at Floor of Mouth

1. Sublingual glands
   Excretion via:
   (a) **Rivinus ducts** = numerous small ducts that open at mucosa of floor of mouth
   (b) **Bartholin duct** = formation of a common duct from joining of several of more anterior ducts typically emptying into main submandibular duct
2. Deep portion of submandibular glands
   Excretion via: **Wharton duct** = main submandibular duct coursing anteriorly through sublingual space from deep aspect of submandibular gland
   Orifice: sublingual papilla on ipsilateral side of frenulum, anterior to sublingual gland
3. Subepithelial minor salivary glands

PHARYNX

Barium Pharyngography:

Patient maneuvers:

(a) modified Valsalva maneuver = patient puffs out cheeks as if blowing a trumpet
(b) phonation = patient phonating letter E → widening of oropharynx + deepening of valleculae with forward movement of tongue

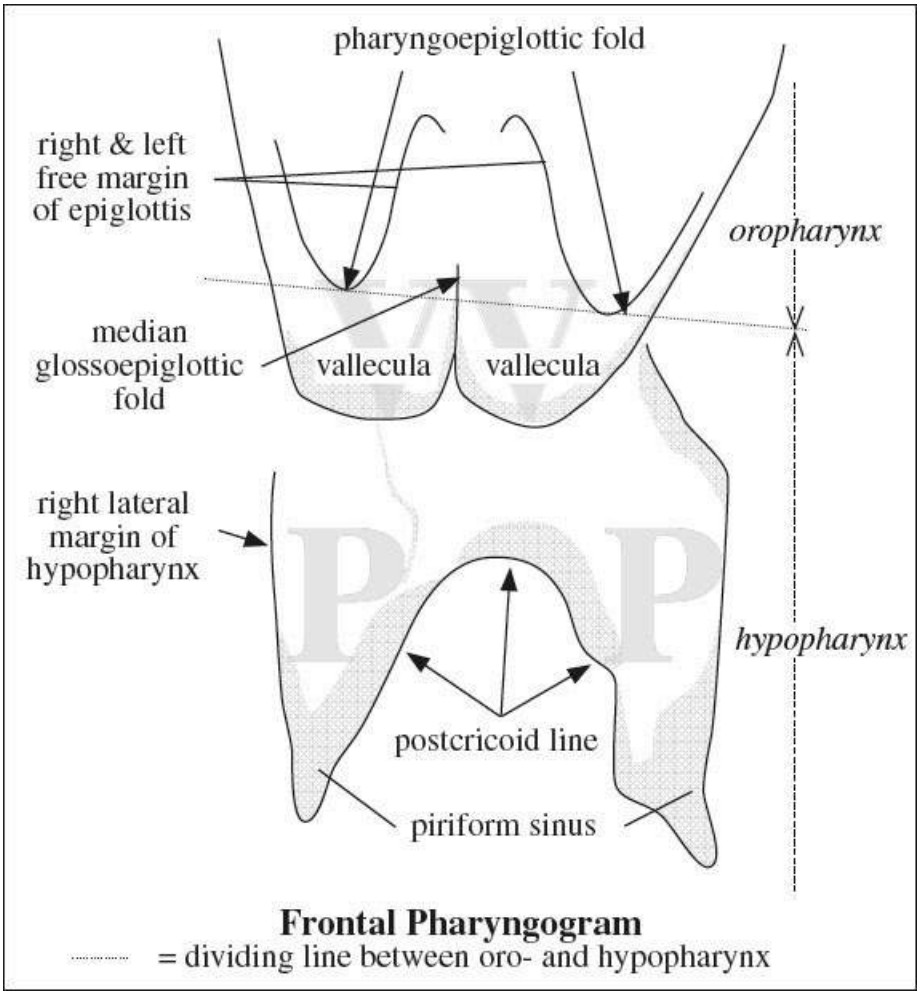
Technique: videofluoroscopic recording

› patient standing in upright position
› initial swallow with high-density barium assessing for aspiration, leak, stricture, obstruction, delayed emptying on lateral view
› second swallow to coat oro- and hypopharynx in LAT + AP projection during maneuvers
› solid-column evaluation for inferior hypopharynx

The pharynx is divided into oropharynx and hypopharynx by the pharyngoepiglottic fold, which is not seen at barium pharyngography. Instead the base of the free margin of the epiglottis / hyoid bone are used as a proxy landmark.

Normal variants:

1. Lateral protrusion of superior ⅓ of lateral hypopharyngeal wall



Cause: weakening of thyrohyoid membrane in elderly / glassblower / trumpet player

√ symmetric bilateral outward bulge of superior aspect of lateral wall of piriform sinus, more pronounced during modified Valsalva maneuver

2. Mild asymmetry of vallecular pouches due to lymphoid tissue

Structural abnormalities of the pharynx are diagnosed by a change in the normal coated surfaces / an alteration in density.

Oropharynx

consists of

(a) oropharyngeal mucosa (pharyngeal wall between nasopharynx + pharyngoepiglottic fold)
(b) soft palate
(c) palatine tonsils
(d) base of tongue (= posterior ⅓ of tongue)

Borders:

(a) superior: soft palate and **Passavant ridge** (= ridge of pharyngeal muscle that opposes the soft palate when soft palate is elevated)
[Philippas G. Passavant, German surgeon, 1815–1893]

(b) anterior: plane formed by the posterior border of soft palate, anterior tonsillar pillars, circumvallate papillae
(c) posterior: posterior pharyngeal wall
(d) inferior: valleculae
[*valles*, Latin = valley → *vallecula* = little valley]
(e) lateral: tonsillar region consisting of anterior tonsillar pillar (= palatoglossus m.) + palatine / faucial tonsil + posterior tonsillar pillar (= palatopharyngeus muscle)

Anatomic subdivisions: base of tongue; tonsils

Tonsillar complex: tonsillar fossa + tonsillar pillars

Barium Pharyngography:

√ valleculae = paired symmetric structures divided by median glossoepiglottic fold posteroinferior to tongue base
√ free margin of epiglottis projects posterior + superior to valleculae
√ cornua of hyoid project on end with change in position during swallowing
√ slightly nodular surface of base of tongue superior to valleculae
√ aryepiglottic fold covers posterior surface of arytenoid cartilage

Hypopharynx

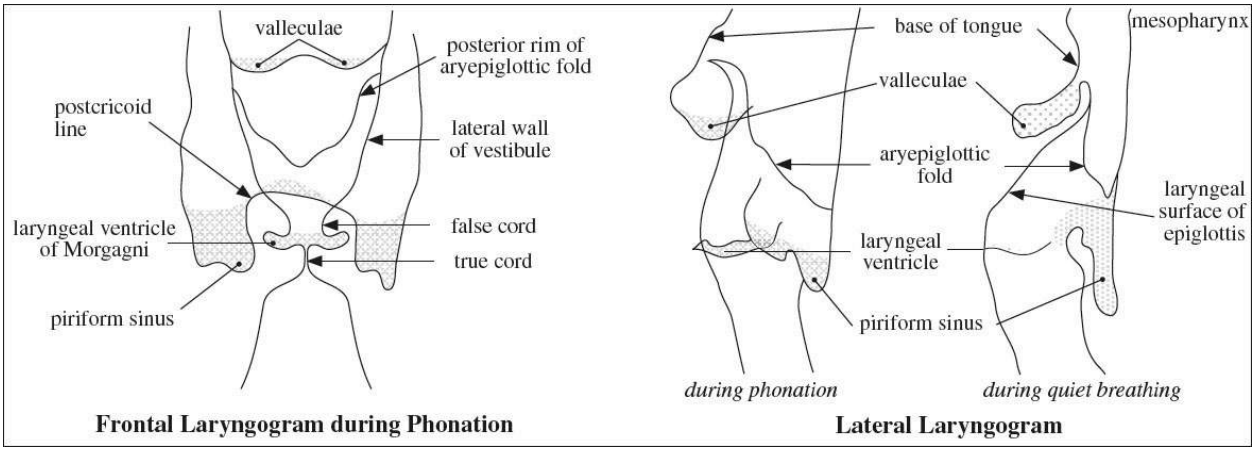
= LARYNGOPHARYNX
= compartment of aerodigestive tract posterior to supraglottic larynx bridging oropharynx above + esophagus below

Origin: derived from 4th branchial arch (= buccopharyngeal bud) → rich lymphatic drainage directed cranially to upper deep jugular chain (levels II + III)

Superior boundary: valleculae at level of hyoid bone

Inferior boundary: lower edge of cricopharyngeus m. = lower edge of cricoid cartilage

1. Piriform sinus [*pirum*, Latin = pear; *forma*, Latin = shape → pear-shaped]
= two symmetric lateral stalactites of air hanging from hypopharynx behind larynx
› inferior wall: level of cricoarytenoid joint
› anteromedial wall: lateral wall of aryepiglottic fold
› lateral wall: abuts posterior ala of thyroid cartilage
› posterior wall: most lateral aspect of posterior hypopharyngeal wall
2. Postcricoid area = pharyngoesophageal junction extends from level of arytenoid cartilages to inferior border of cricoid cartilage
› anterior wall of hypopharynx = posterior wall of lower larynx = "party wall"



3. Posterior hypopharyngeal wall extends from level of valleculae to cricoarytenoid joints

Barium Pharyngography:

√ lateral walls of piriform sinuses = lateral margins of hypopharynx

√ "postcricoid line" = coated mucosal surface ← larynx pressing on anterior wall of hypopharynx

√ barium coating of inner anterior surface of laryngeal vestibule ± laryngeal ventricle ← laryngeal penetration + aspiration

LARYNX

Vertical length: 44 mm (males), 36 mm (females), at 4th–6th cervical vertebrae (from tip of epiglottis to lower end of cricoid cartilage)

Function: (1) Protection against aspiration

(2) Phonation

Lymphatic drainage:

(a) supraglottis: rich drainage directed cranially to upper deep jugular chain (levels II + III)

(b) glottis + subglottis: sparse drainage directed inferiorly to lower deep jugular + paratracheal nodes (levels IV + VI)

Supraglottis

extends from tip of epiglottis to laryngeal ventricle

derived from 4th branchial arch (= buccopharyngeal bud)

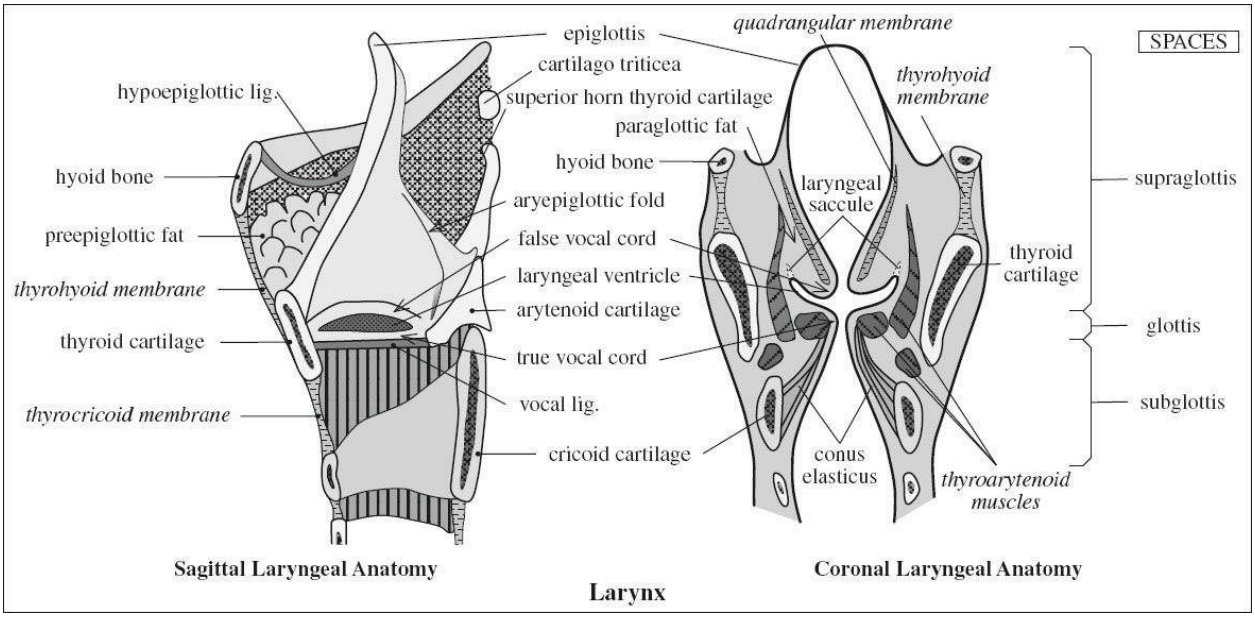
1. Vestibule = airspace within supraglottic larynx
2. **Epiglottis**
   = leaf-shaped cartilage that functions as a lid to endolarynx
   (a) petiole = stem of epiglottis
   (b) thyroepiglottic ligament = connects petiole to thyroid cartilage inferiorly
   (c) hyoepiglottic ligament = connects epiglottis to hyoid bone anteriorly, covered by a mucosal fold between the valleculae (glossoepiglottic fold)
   (d) "free margin" = superior portion of epiglottis
3. **False vocal cords**
   = ventricular folds = inferior continuation of aryepiglottic folds = mucosal surface of ventricular ligaments; forming superior border of laryngeal ventricle

4. Arytenoid cartilages
5. Aryepiglottic folds
   = mucosal reflections between cephalad portion (= arytenoid processes) of arytenoid cartilage + inferolateral margin of epiglottis
   √ soft-tissue folds forming border between lateral piriform sinuses + central laryngeal lumen
6. **Laryngeal ventricle of Morgagni**
   = slitlike fusiform cavity between true + false cords
   Boundary: crescentic edge of false cords superiorly + straight margin of true cords inferiorly
   √ generally not visible on axial scans
7. Laryngeal saccule of Hilton = laryngeal appendix
   = small conical mucosa-lined blind pouch (diverticulum) arising from anterosuperior third of laryngeal ventricle
   Boundary: superiorly between ventricular fold (= false vocal cord) and aryepiglottic fold medially + inner surface of thyroid cartilage laterally
   Function: lubrication of vocal folds
   √ relatively large in infancy
   √ usually involutes by 6th year of life
8. Preepiglottic space
   Boundary: hypoepiglottic lig. (superiorly), thyrohyoid membrane (anteriorly), thyroepiglottic lig. (inferiorly), epiglottis (posteriorly)
9. Paraglottic (paralaryngeal) space
   Boundary: quadrangular membrane + medial piriform sinus wall (superiorly), conus elasticus (inferiorly), thyroid cartilage (laterally)
   √ low-density tissue between true + false cords
   √ contiguous with preepiglottic space anterosuperiorly + aryepiglottic folds superiorly

Glottis

Boundary: from laryngeal ventricles to imaginary plane 1 cm below laryngeal ventricles
Origin: 5th branchial arch (= tracheobronchial bud)

1. **True vocal cords**
   = extend from vocal process of arytenoid cartilage to anterior commissure
   √ vocal cords adduct during phonation of "E" / breath holding



epiglottis
cartilago triticea
superior horn thyroid cartilage
paraglottic fat
hyoid bone
aryepiglottic fold
false vocal cord
laryngeal ventricle
arytenoid cartilage
true vocal cord
vocal lig.
cricoid cartilage
hypoepiglottic lig.
hyoid bone
preepiglottic fat
thyrohyoid membrane
thyroid cartilage
thyrocricoid membrane
quadrangular membrane
thyrohyoid membrane
laryngeal saccule
thyroid cartilage
conus elasticus

SPACES
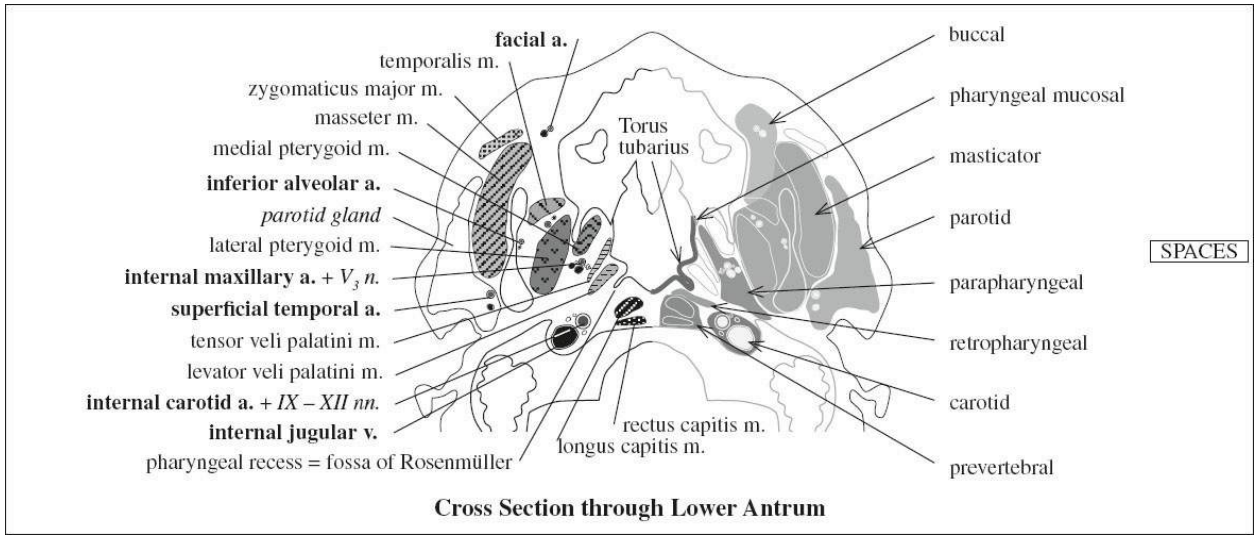
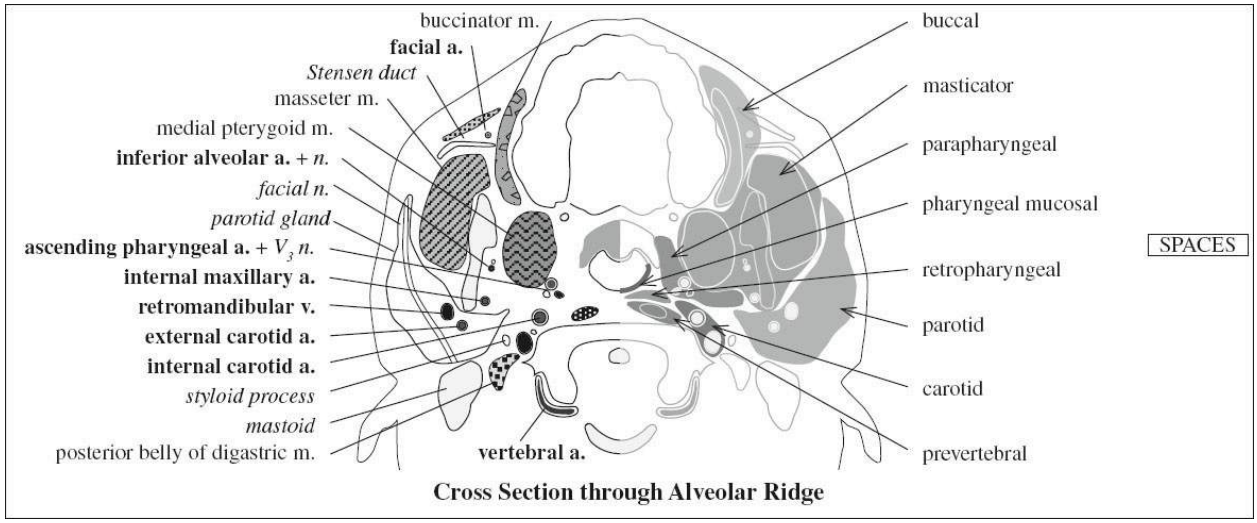
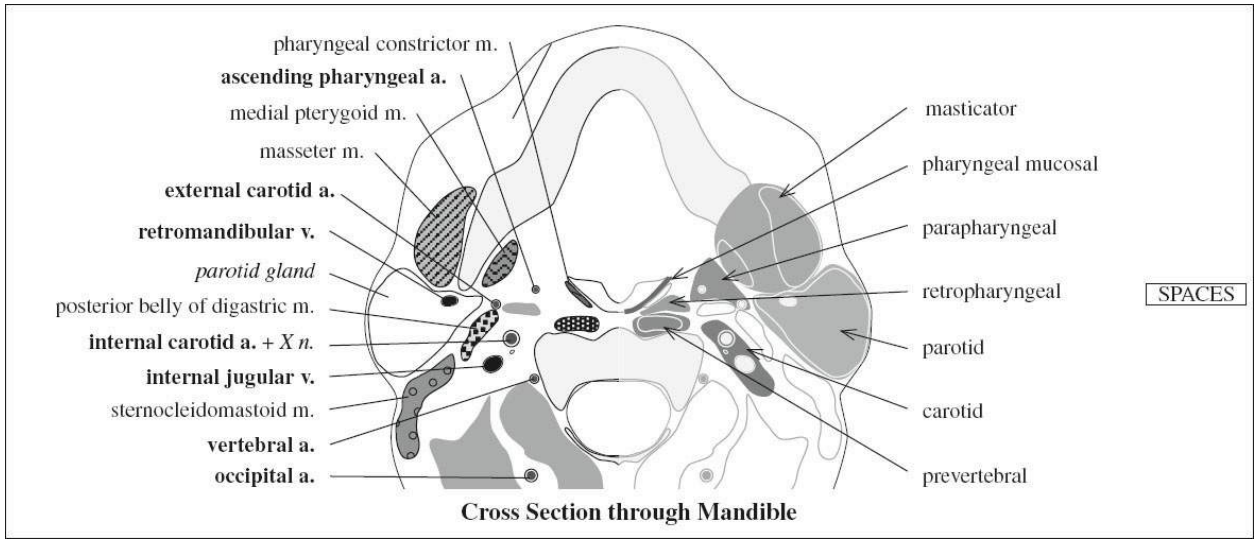
Cross Section through Upper Antrum



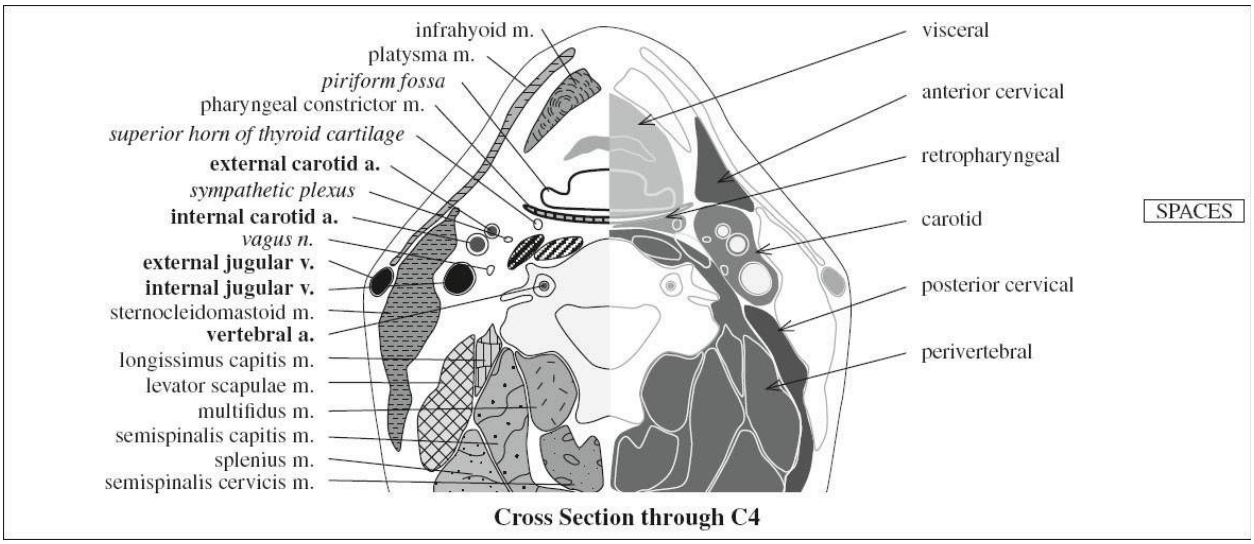
Cross Section through Lower Antrum



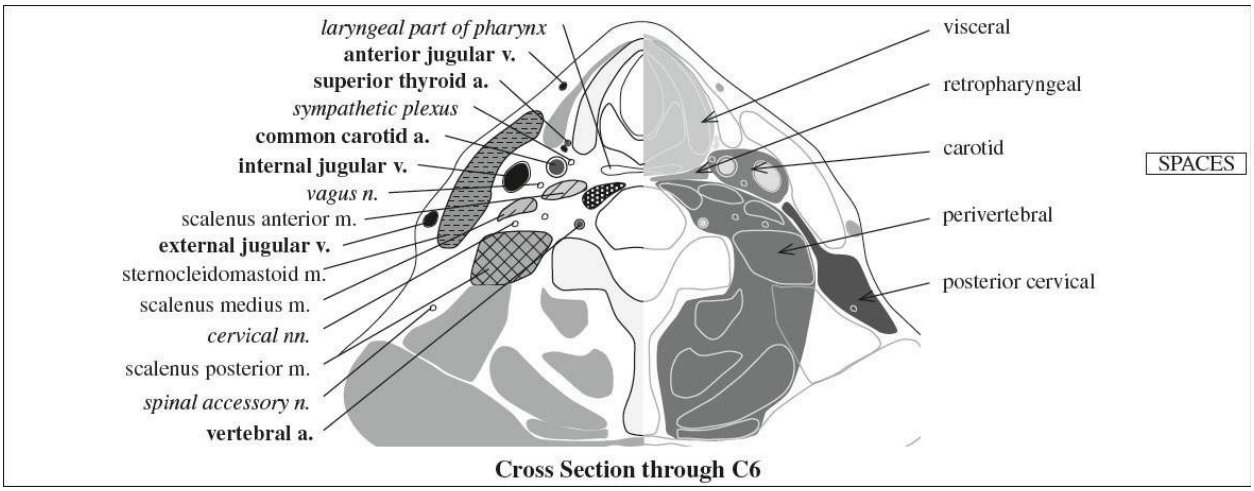
Cross Section through Alveolar Ridge



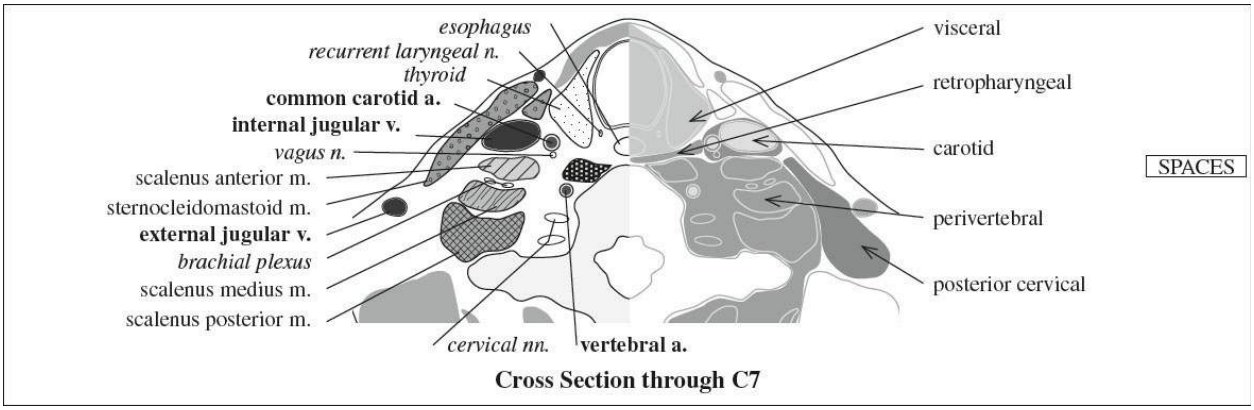
Cross Section through Mandible



Cross Section through C4



Cross Section through C6



Cross Section through C7

2. Anterior commissure
   = midline laryngeal mucosa covering anterior portions of the true vocal cords where they abut the laryngeal surface of the thyroid cartilage
   √ < 1 mm soft tissue behind thyroid cartilage (during abduction of vocal cords with quiet breathing)

3. Posterior commissure
   = midline laryngeal mucosal surface between attachment of true vocal cords and the arytenoid cartilages

Subglottis

extends from undersurface of true vocal cords to inferior edge of cricoid cartilage
derived from 6th branchial arch (= tracheobronchial bud)

1. Conus elasticus
   = fibroelastic membrane extending from cricoid cartilage to medial margin of true vocal cords; forming lateral wall of subglottis

FASCIAE OF THE NECK

= well-defined sheets of fat + fibrous tissue that circumscribe several compartments / spaces

A. Superficial cervical fascia
B. Deep cervical fascia
   (a) superficial layer
   (b) middle layer
   (c) deep layer

DEEP SPACES OF SUPRAHYOID HEAD & NECK

Masticator Space

= lateral to parapharyngeal space

Fascia: superficial layer of deep cervical fascia encloses muscles of mastication

Contents:

› muscles of mastication (medial + lateral pterygoid muscles, masseter, temporalis muscle)
› ramus + body of mandible
› cranial nerve V_3

Pharyngeal Mucosal Space

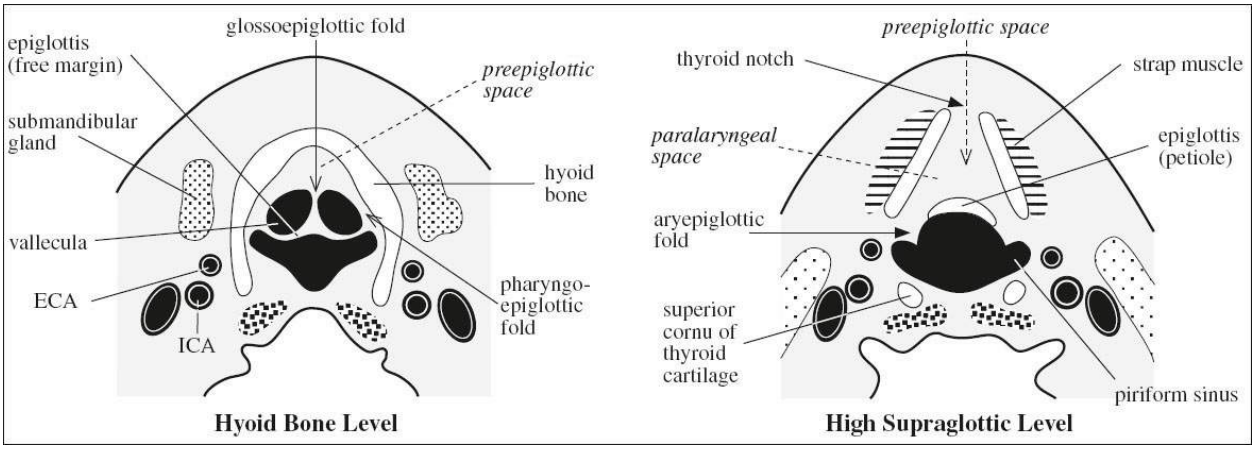
Components:

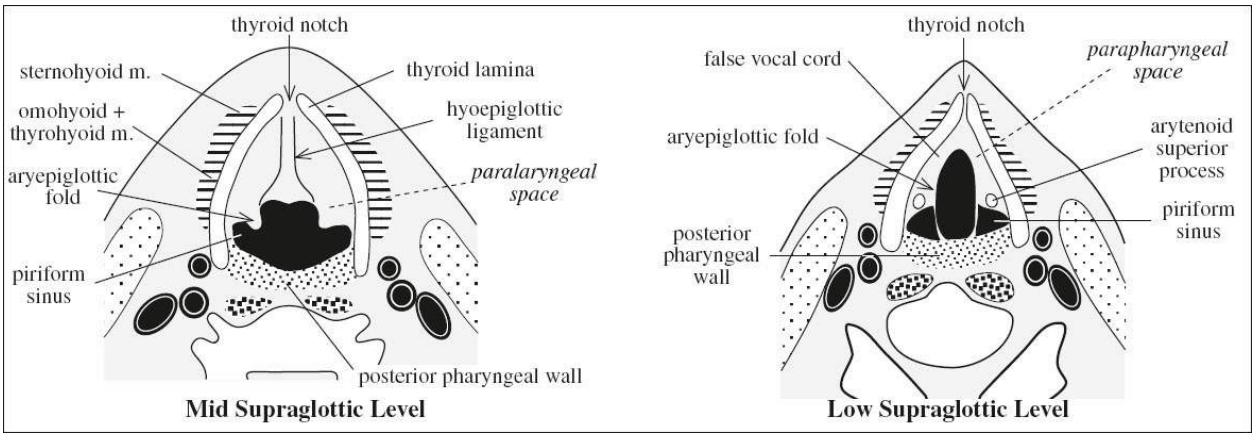
› **Waldeyer ring** = adenoids, faucial + lingual tonsils + submucosal lymphatics
  [Heinrich Wilhelm Gottfried Waldeyer-Hartz (1836–1921), professor of pathology in Breslau, Strasbourg and Berlin]
› superior + middle constrictor muscles
› salpingopharyngeal muscle
› levator palatini muscle underneath torus tubarius
› torus tubarius = prominent ridge between orifice of eustachian tube anteroinferiorly + fossa of Rosenmüller posterosuperiorly
› pharyngeal recess = **fossa of Rosenmüller**
  [Johann Christian Rosenmüller (1771–1820), professor of anatomy and surgery at University of Leipzig]

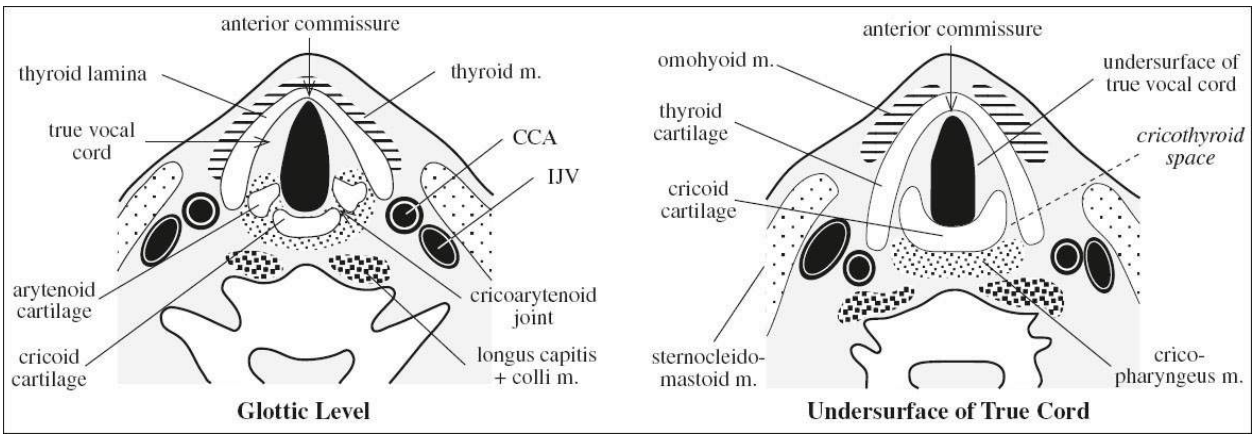
Contents: squamous mucosa, lymphoid tissue, minor salivary glands

Parapharyngeal Space

= triangular-shaped centrally located space; major vertical highway extending from skull base to hyoid







Fascial borders:

medial = middle layer of deep cervical fascia

lateral = superficial layer of deep cervical fascia

posterior = carotid sheath

Contents:
- › fat
- › internal maxillary artery
- › ascending pharyngeal artery
- › pharyngeal venous plexus
- › branches of cranial nerve V3

Vectors: if parapharyngeal fat is effaced

anteriorly = lesion in masticator space
medially = lesion in pharyngeal mucosal space
laterally = lesion in parotid space
posteriorly = lesion in carotid space

Retropharyngeal Space

= potential space posterior to pharyngeal mucosal space + anterior to prevertebral space; major vertical highway from skull base to T4

Fascial borders:

mid + deep layers of cervical fascia; alar fascia laterally

Contents:
- › fat
- › medial + lateral retropharyngeal nodes

Prevertebral Space

= major highway from skull base to T4; posterior to retropharyngeal space

Fascial borders:

(a) anterior compartment of deep cervical fascia:
from one transverse process to the other anteriorly in front of longus colli muscle

(b) posterior compartment of deep cervical fascia:
from transverse process posteriorly to spinous process

Contents:
- › prevertebral muscles (longus colli)
- › scalene muscles
- › vertebral artery + vein
- › brachial plexus
- › phrenic nerve

Carotid Space

Carotid fascia extends from skull base to aortic arch

Contents:

(a) below hyoid bone:
- › common carotid artery
- › internal jugular vein
- › cranial nerve X (= vagus nerve)
- › cervical sympathetic plexus

(b) at level of nasopharynx:

› internal carotid artery
› internal jugular vein
› cranial nerves IX–XII
› internal jugular chain of nodes

Parotid Space

Contents:

› parotid gland with Stensen duct
› intraparotid lymph nodes
› external carotid + internal maxillary arteries
› retromandibular vein
› facial nerve

Submandibular Space

Contents:

› submandibular gland with Wharton duct
› facial artery + vein
› cranial nerve XII

TEMPORAL BONE

A. SQUAMOUS PORTION
= lateral wall of middle cranial fossa + floor of temporal fossa

B. MASTOID PORTION

1. **Mastoid antrum**
[*mastos*, Greek = woman's breast; *eidos*, Greek = form / shape]; [*oeides*, Greek = like; *mastoeides*, Greek = resembling a nipple]
[*antron*, Greek / *antrum*, Latin = cave]
2. **Aditus ad antrum**
connects epitympanum (= attic) of middle ear cavity to mastoid antrum
[*ad* + *ire*, Latin = to go to; *aditus*, Latin = entrance]
[*tympanum*, Latin / *tympanon*, Greek = drum]
3. **Körner septum**
= small bony projection extending inferiorly from roof of mastoid antrum as part of petrosquamosal suture between lateral + medial mastoid air cells posteriorly from epitympanum

C. PETROUS PORTION = inner ear

1. **Tegmen tympani**
[*tegmina*, Latin (pl) = covering structure or roof]
= roof of tympanic cavity
2. **Arcuate eminence**
= prominence of bone over superior semicircular canal
3. Internal auditory canal (IAC)
4. Vestibular aqueduct
5. Cochlear aqueduct
6. Otic capsule = densest portion of temporal bone that surrounds osseous labyrinth

7. Petrous apex
   = separated from clivus by petrooccipital fissure + foramen lacerum

D. TYMPANIC PORTION
   1. External auditory canal (EAC)

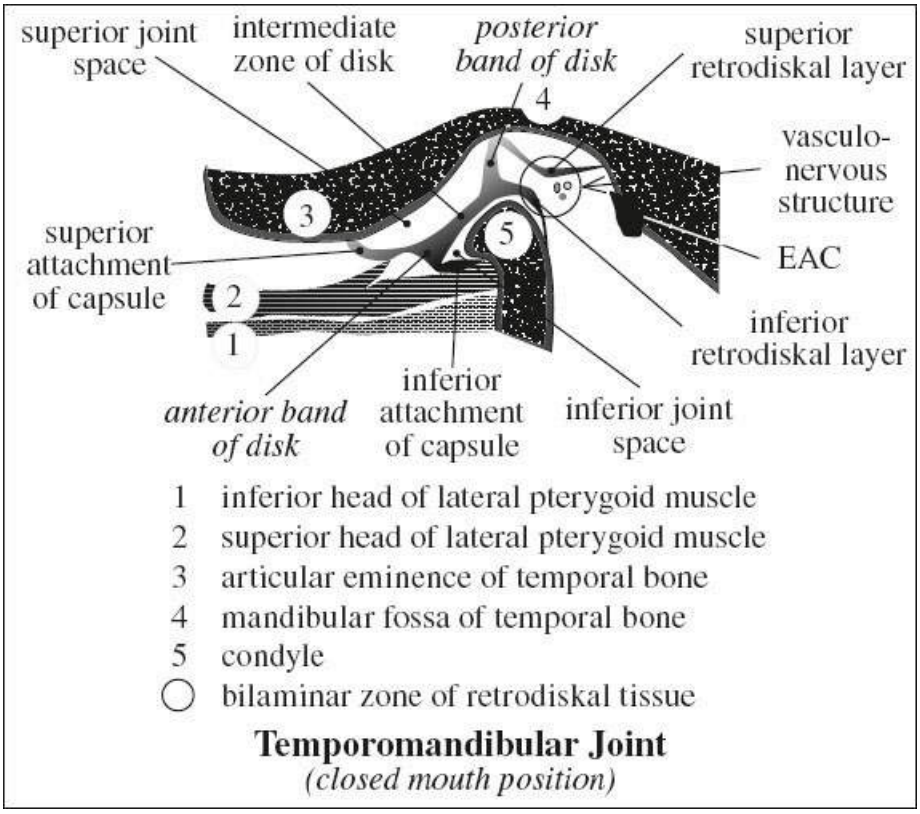
E. STYLOID PORTION

TEMPOROMANDIBULAR JOINT

Components:

1. **Meniscus** = articular disk
   = biconcave fibrocartilaginous structure that divides the synovial TMJ into superior + inferior compartments
   Location: between mandibular condyle and temporal bone component of TMJ
   Shape: round / oval
      (a) thin center (= intermediate zone)
      (b) thicker periphery (= bands of disk)
   Function: interposition of thinnest part between condyle and temporal bone prevents articular damage (in closed- or open-mouth position)
   (a) hyperintense **anterior band of disk** attached to
      › superior attachment of capsule
      › inferior attachment of capsule
      √ lies immediately in front of condyle + junction of bilaminar zone
      √ may form bulge (? normal variant)
   (b) hyperintense **intermediate zone**
      √ lies at superior part of the condyle
   (c) mildly hyperintense **posterior band of disk** formed by
      › superior retrodiskal layer
      › inferior retrodiskal layer
      √ best depicted in open-mouth position
2. **Retrodiskal tissue** = **bilaminar zone** composed of
   (a) retrodiskal layers
   (b) vasculonervous structures
   √ best depicted in open-mouth position

Muscles:



Temporomandibular Joint
(closed mouth position)

1. Lateral pterygoid m.
   (a) superior lateral pterygoid m.
   (a) inferior lateral pterygoid m.
2. Digastric muscle

Motion:

1. **Rotation** around horizontal axis through condylar heads
2. **Translation** = <u>condyle + meniscus</u> move together anteriorly to lie beneath articular eminence
   → central part of disk interposed between condyle and articular tubercle

Closed-mouth position:

√ thick posterior band of meniscus lies immediately above condyle near 12 o'clock position
√ junction of posterior band + bilaminar zone should fall within 10° of vertical

Open-mouth position:

√ best depiction of posterior band + retrodiskal tissue
√ anterior band lies immediately in front of condyle + junction of bilaminar zone
√ condyle may lie beneath anterior band of meniscus when mouth is fully opened
√ disk lies at superior part of condyle
√ anterior band may be seen as a bulge

EXTERNAL (OUTER) EAR

Origin: 1st branchial cleft and 1st + 2nd branchial arches during 6th–12th weeks of intrauterine life

A. Auricle

B. External auditory canal (EAC)

Origin: meatal plate (= solid core of epithelium) that migrates toward 1st pharyngeal pouch and hollows out during 2nd–7th months of intrauterine life

Wall of lateral ⅓: fibrocartilage

Wall of medial ⅔: tympanic portion of temporal bone

Anterior wall: posterior aspect of glenoid fossa

Posterior wall: anterior margin of mastoid

Medial border: tympanic membrane,

MIDDLE EAR / TYMPANIC CAVITY

= air-filled cavity within petrous portion of temporal bone containing ossicular chain

Borders:

› anterior wall = carotid wall

› posterior wall = mastoid wall including from lateral to medial

(a) facial nerve recess for descending facial nerve

(b) pyramidal eminence overlying stapedius muscle (inserting onto head of stapes)

(c) sinus tympani (clinically blind spot)

(d) round window niche

› superior wall = tegmen tympani (= thin bony plate separating dura of middle cranial fossa from middle ear)

› inferior wall = jugular wall

› lateral wall = tympanic membrane

› medial wall = labyrinthine wall

A. EPITYMPANUM (= **attic**)

= tympanic cavity superior to level of tympanic membrane above a line drawn between the inferior tip of drum spur (= scutum) + tympanic portion of facial nerve

[*scutum*, Latin = shield; tympanum, Latin = semicircular area enclosed by the arch above the horizontal portion of a portal]

Contents: malleus head, body + short process of incus, **Prussak space** (= superior recess between incus + lateral wall of epitympanum)

Communication: with mastoid via aditus ad antrum

B. MESOTYMPANUM (= tympanic cavity proper)

= tympanic cavity at level of tympanic membrane between inferior tip of scutum + line drawn parallel to inferior aspect of bony EAC

Contents: manubrium of malleus, long process of incus, stapes, tensor tympani muscle (innervated by V_3), stapedius muscle (innervated by VII)

C. HYPOTYMPANUM

= shallow trough in floor of middle ear inferior to tympanic membrane

Contents: opening of eustachian tube

Medial margin: ICA

D. TYMPANIC MEMBRANE (**eardrum**)

= thin cone-shaped membrane separating external from middle ear

Origin: ectoderm from 1st branchial groove; mesoderm and endoderm from 1st branchial

pouch
√ may be faintly discerned on CT
Diameter: 10 mm
Function: transmission of sound from air to malleus
Attachment: superiorly at scutum (=sharp bony projection); inferiorly at tympanic annulus
Regions:
(a) pars flaccida (= **Shrapnell membrane**)
= small triangular fragile 2-layered membrane in upper region loosely attached to petrous bone
Location: above malleolar folds; forms superior ⅛ of drum circumference
Relationship: chorda tympani crosses on inner surface
(b) pars tensa
= larger robust tightly attached region consisting of 3 layers (skin + fibrous tissue + mucosa)

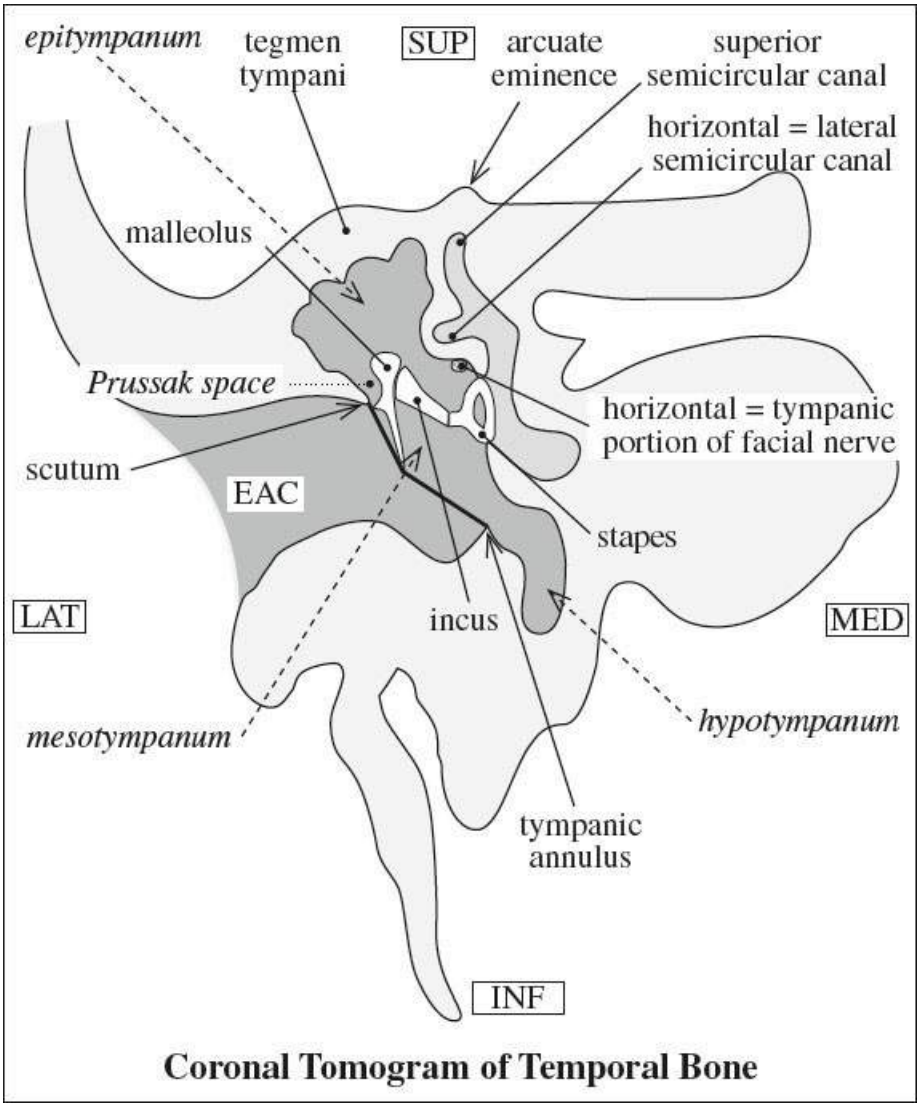
E. TYMPANIC CAVITY & EUSTACHIAN TUBE
Origin: from 1st pharyngeal pouch during 10–30 weeks EGA

Wall Ridges of Tympanic Cavity

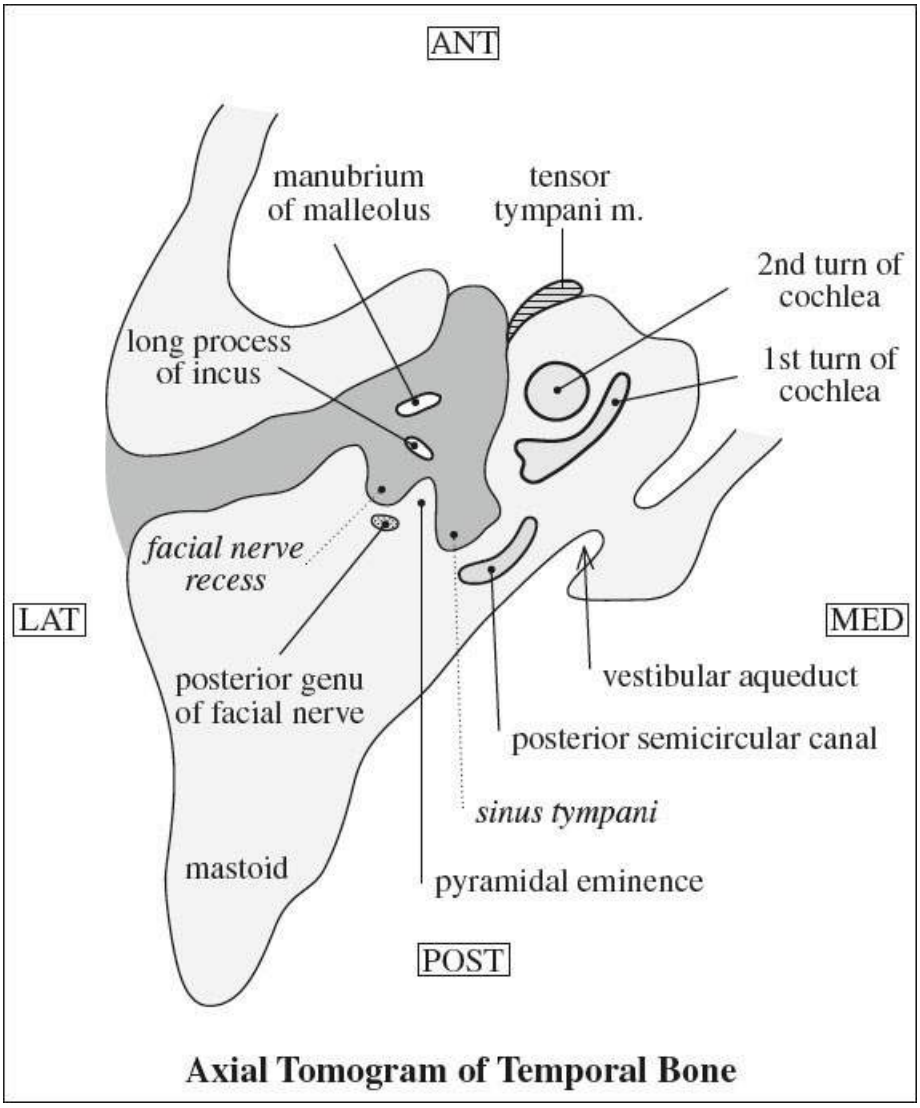
on medial & posterior wall of tympanic cavity produced by:
» MEDIAL WALL:
(1) Anterior limb of lateral semicircular canal
√ wall prominence posteriorly + superiorly
(2) Bony canal for facial nerve
√ wall prominence inferior and anterior to (1)
(3) Terminus of septum canalis musculotubarii
= landmark for geniculate ganglion
√ wall prominence anterior to (2)
(4) **Oval window**
√ inferior to (3)
(5) **Basal turn of cochlea**
√ convexity inferior + slightly anterior to (4)
= rounded promontory
» POSTERIOR WALL:
(6) **Sinus tympani**
= landmark for ampulla of posterior semicircular canal
√ recess on posterior wall
(7) **Facial nerve recess**
= important surgical landmark when tympanic cavity is entered via mastoid approach
√ recess on posterior wall lateral to (6)
(8) **Pyramidal eminence**
= protrusion that gives rise to stapedius muscle
√ situated between sinus tympani + facial nerve recess

Embryology of Stapedial Artery (complex & simplified)

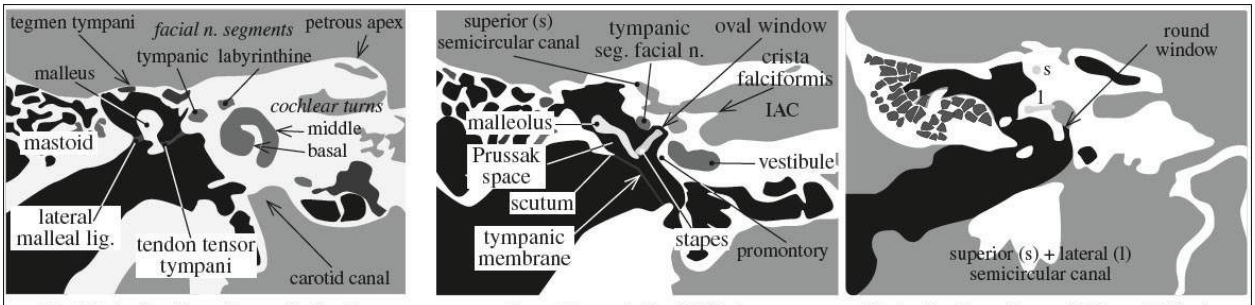
› 2nd aortic arch becomes hyoid artery and persists as caroticotympanic branch of the ICA



Coronal Tomogram of Temporal Bone



Axial Tomogram of Temporal Bone

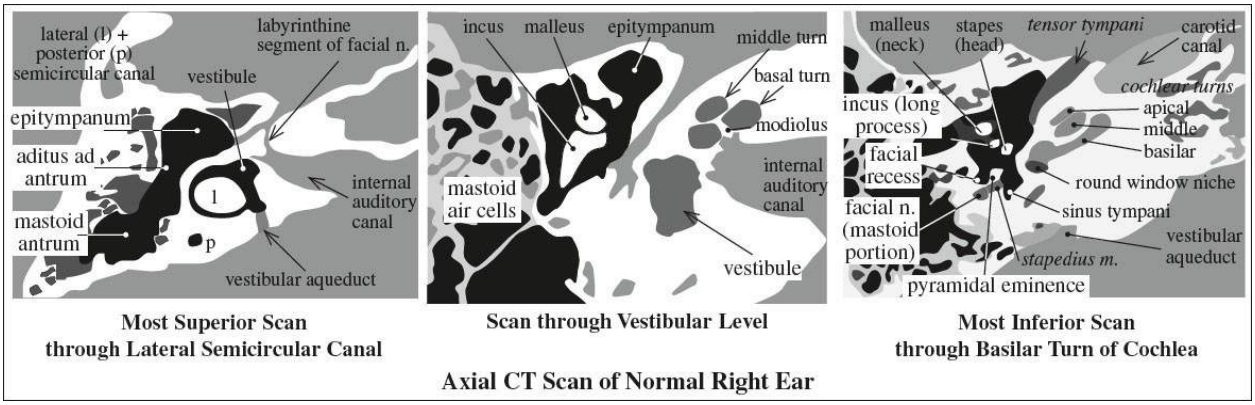


Most Anterior Scan through Cochlea
"snake eyes" = two facial n. segments

Scan through Oval Window

Posterior Scan through Round Window

Coronal CT Scan of Normal Right Ear



› **stapedial artery** arises from hyoid artery near its origin from the proximal ICA (3rd arch) at 4–5 weeks of fetal life following regression of 1st + 2nd aortic arches
  » stapedial artery extends cranially to pass through obturator foramen of stapes and branches into
    (a) upper supraorbital branch with its posterior division that becomes middle meningeal artery
    (b) lower maxillofacial branch forms an anastomosis with ventral pharyngeal artery (precursor of external carotid artery) and exits through foramen spinosum
› as ventral pharyngeal artery supplies flow to middle meningeal artery, stapedial artery regresses leaving a small caroticotympanic artery

OSSICULAR CHAIN

[*malleus*, Latin = hammer; *manubrium*, Latin = handle ← manus = hand; *incus*, Latin = anvil; *stapia*, Latin = stand; *pes*, Latin = foot; *stapes*, Latin = stirrup; *umbo*, Latin = boss at center of a circular shield]

Origin: from 1st + 2nd branchial arches

Function: transmits + amplifies vibrations incident on tympanic membrane across middle ear cavity → deflection of oval window (area of tympanic membrane is 30 x greater than that of oval window)

A. **Malleus**

Location: anterolateral to incus and stapes

Attachment: manubrium to tympanic membrane

Articulation: diarthrodial **incudomalleal joint** between facet on posterior surface of head of malleus and body of incus
√ "ice cream cone" configuration on axial CT

Components:
› head: articulating facet on posterior surface
› neck: at inferior aspect of club-shaped head; provides attachment for tensor tympani m.
› **manubrium**: long process that lies further inferiorly; tip attaches to tympanic membrane at **umbo**
› anterior + lateral processes: small bony spicules that project from upper portion of manubrium; provide attachment for anterior + lateral malleal ligaments that support malleus within middle ear cavity

√ lateral process with ligament may be visible on CT

B. **Incus**

shaped like a premolar tooth

Articulation:

(1) facet on anterior surface of body of incus → head of malleus

(2) lenticular process of incus → head of stapes

Components:

› body

› short process: directed posterolaterally

› long process: directed inferiorly parallel to manubrium; tip of long process bends medially to end in lenticular process (rounded projection) articulating with stapes

› lenticular process: for articulation with head of stapes

C. **Stapes**

most medial ossicle resembling a stirrup

Attachment: footplate to oval window of vestibule (= **incudostapedial joint**)

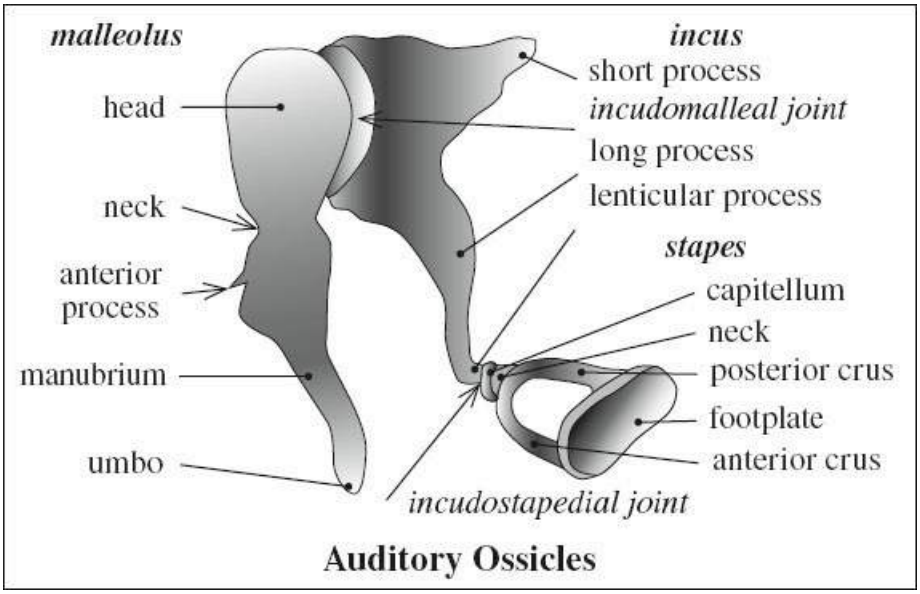
Articulation: with lenticular process of incus

Components:

› head / capitellum

› neck: provides insertion for stapedius muscle at its posterior aspect

› anterior + posterior crus



Auditory Ossicles

› footplate: attached to margins of oval window by annular ligament

D. Suspensory ligaments

1. Superior malleal
2. Lateral malleal
3. Posterior malleal
4. Posterior incudal

√ sometimes visible on CT as thin linear structures (most commonly lateral malleal lig.)

INNER EAR

A. OSSEOUS LABYRINTH

encloses membranous labyrinth = **otic capsule**

◊ Densest bone in entire body

Embryology: develops from mesenchyme around membranous labyrinth between 4–8 weeks EGA → continued growth between 8–16 weeks EGA → ossification by 24th week EGA

Location: petrous portion of temporal bone

1. **Cochlea**

[*kokhlias*, Greek; probably related to *konkhe* = conch]

[*modiolus*, diminutive of *modius*, Latin = hub of a wheel]

= spiral-shaped structure with 2½ – 2¾ turns encircling central bony axis (= **modiolus**) like conical snail shell

› basal first turn opens into round window posteriorly

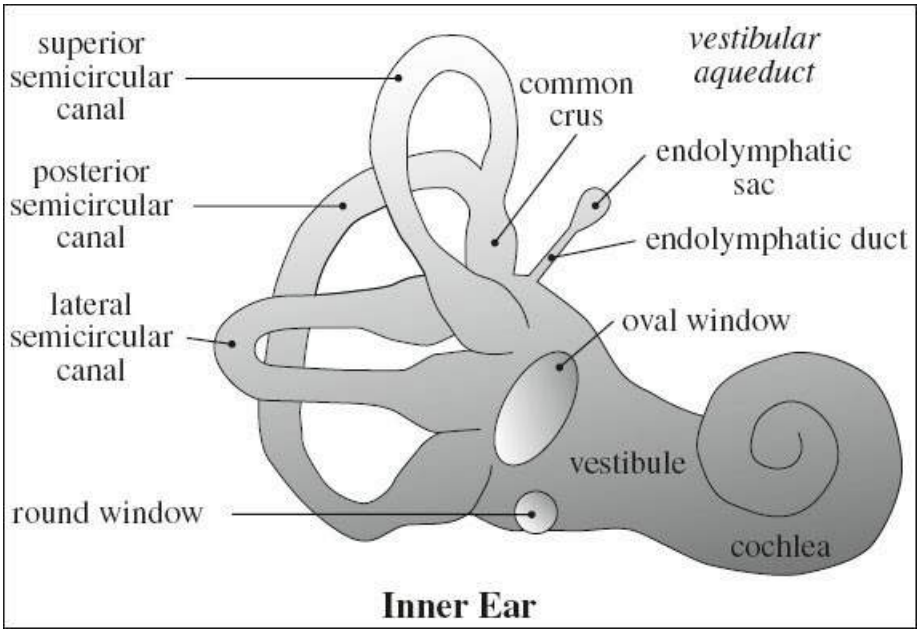
› lateral aspect of basal turn bulges into middle ear cavity forming cochlear promontory

› nerve of Jacobson = tympanic branch of glossopharyngeal n. (CN IX) courses over promontory

Division by interscalar septum:

(a) **scala vestibuli** (upper compartment)

(b) **scala tympani** (lower compartment)



Inner Ear

(c) **scala media** / cochlear duct contains organ of Corti (sensory organ of hearing)

helicotrema = open communication between scala vestibuli + tympani at cochlear apex

[*scala*, Latin = stair, slope]

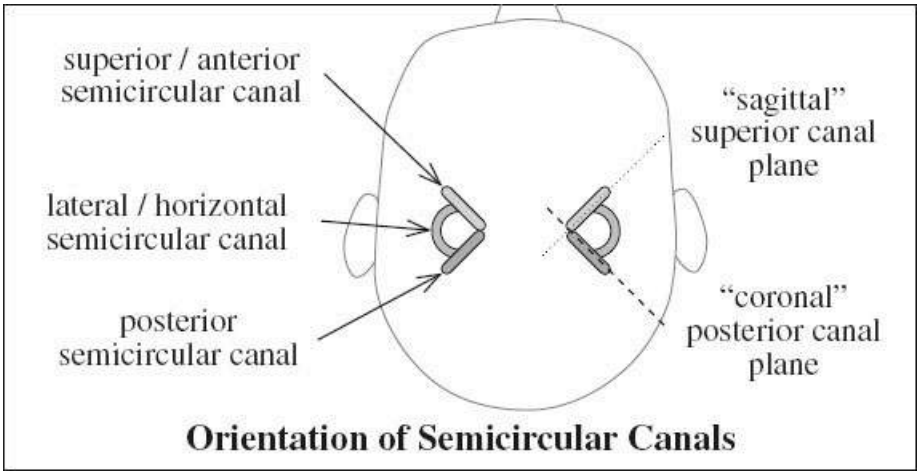
[*helix*, Greek = coil and *trema*, Greek = hole]

2. **Vestibule**

= central and most capacious ovoid part of bony labyrinth posterior to cochlea
› continuous anteriorly with cochlea
› continuous posteriorly with semicircular canals
› separated from middle ear by oval window
Subunits: (not separately visualized)
(a) utricle [*utriculus*, Latin = little bag]
Location: in elliptical recess superiorly and posteriorly on medial wall of vestibule
(b) saccule [diminutive of *saccus*, Latin = bag]
Location: in spherical recess inferiorly + anteriorly
Function: both involved with balance

3. **Semicircular canals** (SCC)
= 3 canals oriented orthogonal to each other
› each canal has a dilatation at one end (= ampulla)
› common crus ← junction of posterior end of superior SCC + upper end of posterior SCC
Function: detection of angular acceleration
(a) **lateral** / horizontal (external) SSC
• detects rotation in transverse plane around vertical axis (ie, left-right movement of head)
Location: lateral
Arch direction: horizontal backward
√ juts into epitympanum
(b) **superior** / anterior SCC
• detects rotation in sagittal plane around lateral axis (ie, nodding of head)
Location: anteromedial
Arch direction: superiorly
√ vertical orientation transverse to long axis of petrous part of temporal bone
√ forms convexity of arcuate eminence
(c) **posterior** SCC
• detects rotation in coronal plane around anterior-posterior axis (ie, head touching shoulder)
Location: posteromedial
Arch direction: superiorly
√ nearly parallel to posterior surface of petrous bone

4. **Cochlear aqueduct**
= thin osseous canal containing 8-mm–long perilymphatic duct
Size: ≤ 0.1–0.2 mm
Course: from basal turn of cochlea (anterior to round window) to lateral border of jugular foramen paralleling IAC inferiorly



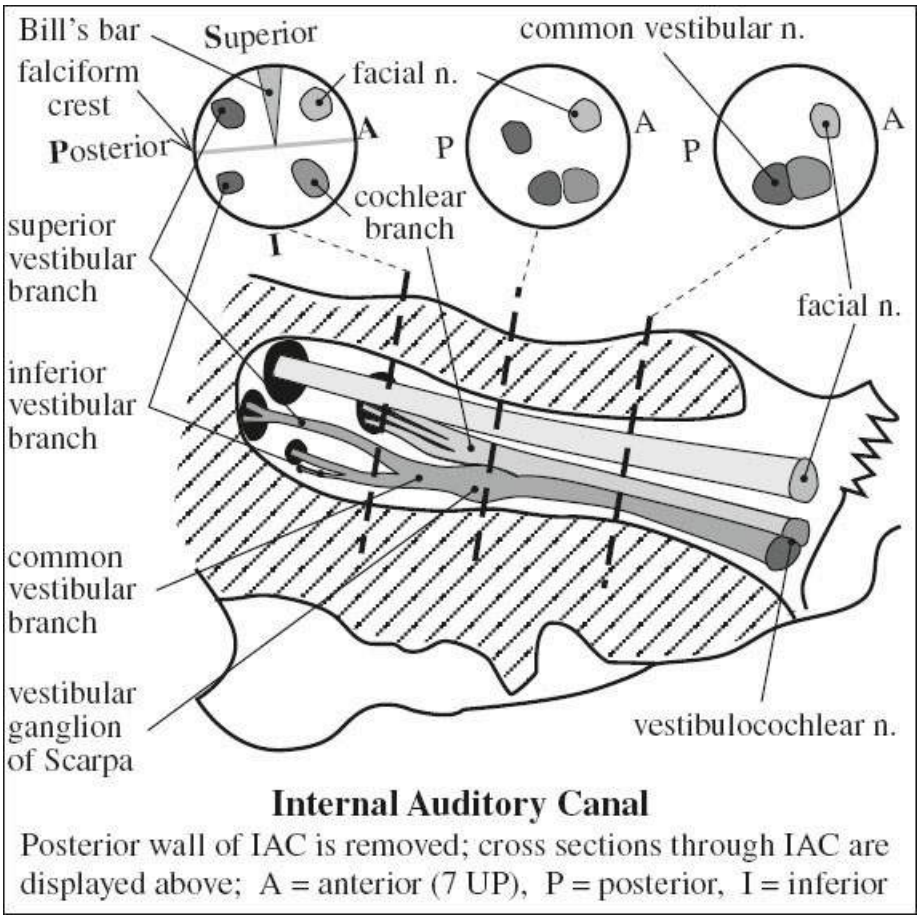
Orientation of Semicircular Canals

Function: regulates CSF + perilymphatic fluid pressure

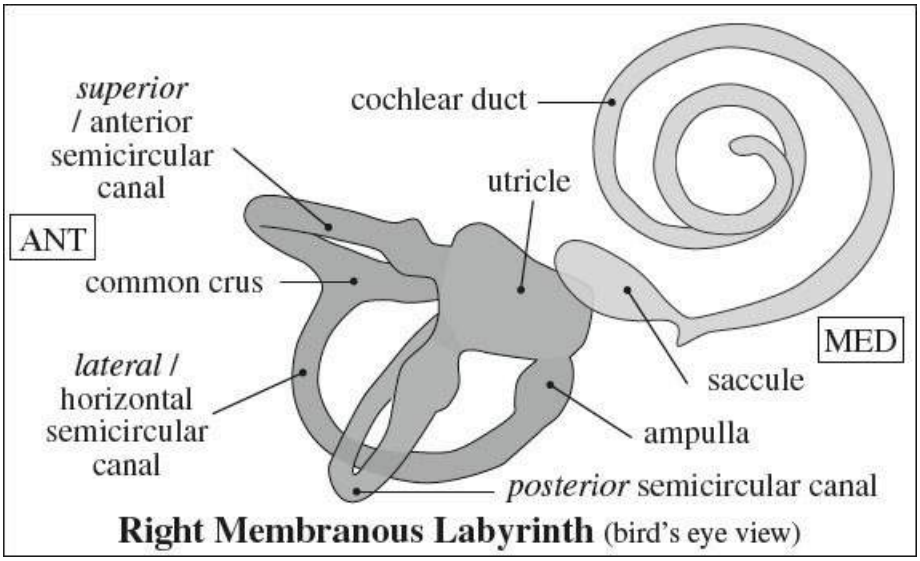
5. **Vestibular aqueduct**
   = curvilinear duct connected to utricle + saccule
   Size: ≤ 1 mm at midpoint; ≤ 2 mm at operculum
   Content: endolymphatic duct and sac
   Course: from vestibule to endolymphatic sac
   Function: equilibration of endolymphatic fluid pressure
   Location: along posteroinferior surface of petrous bone to the medial wall of vestibule in a course parallel + posterior to posterior SCC
6. **Internal auditory canal** (IAC)
   traverses petrous portion of temporal bone; extends from labyrinth to cerebellopontine angle
   Content:
   (a) 7th (facial) CN (anterosuperior quadrant)
   (b) 8th (vestibulocochlear) CN
   › superior vestibular branch (posterosuperior)
   Innervation: utricle, superior + lateral SCC
   › inferior vestibular branch (posteroinferior)
   Innervation: saccule, posterior SCC
   › cochlear branch (anteroinferior quadrant)
   Innervation: cochlea
   Borders:
   (a) medial opening = **porus acusticus** internus
   (b) lateral opening abutting labyrinth = **fundus;** separated from inner ear by **lamina cribrosa** (= perforated vertical plate of bone) allowing passage of facial + vestibulocochlear nerves
   › **crista falciformis** (= falciform crest)
   = horizontal bony septum dividing IAC into superior and inferior compartments
   » superoposteriorly: superior vestibular n.
   » inferoposteriorly: inferior vestibular n.
   › **"Bill's bar"** = vertical crest divides superior compartment into anterior + posterior areas

» anterosuperiorly: facial n. (CN VII)
» anteroinferiorly: cochlear n.
mnemonic: "Seven Up Coke Down"

B. PERILYMPH
= fluid within space between osseous + membranous labyrinth
Osseous openings:



Internal Auditory Canal
Posterior wall of IAC is removed; cross sections through IAC are displayed above; A = anterior (7 UP), P = posterior, I = inferior



(a) **oval window**: compresses perilymph in scala vestibuli via stapes excursions
(b) **round window**: pressure-relief diaphragm that bulges outward with each pressure wave in scala tympani

C. MEMBRANOUS LABYRINTH
Origin: arises from neuroectoderm in 4th week EGA
Embryology: **otic placode** (neuroectoderm) invaginates → **otic pit** → otic vesicle (**otocyst**); otocyst divides into superior (dorsal pars) + inferior (ventral pars) pouches = precursors to utricle, semicircular canals, cochlear duct, saccule
√ filled with endolymph
1. Cochlear duct
2. Utricle
3. Saccule
4. Semicircular ducts
5. Endolymphatic duct
Course: from posterior aspect of vestibule toward posterior cranial fossa
6. Endolymphatic sac
Location: posterior margin of petrous ridge

D. ENDOLYMPH
= fluid within membranous labyrinth

SALIVARY GLANDS

US:
√ homogeneous texture varying from markedly hyperechoic to slightly hyperechoic (compared to adjacent muscles)

Parotid Gland

Embryology:
glandular component arises from ingrowth of local proliferation of oral epithelium, which

creates ducts by 10th week GA; secretions begin by 18th week GA

◊ Epithelial buds branch around divisions of facial nerve thus incorporating it into parotid parenchyma

◊ The only salivary gland that becomes encapsulated after development of the lymphatic system resulting in intraglandular lymph nodes and lymph vessels

Location: mainly in upper + lower poles of parotid

Features of normal intraparotid lymph nodes:

√ short axis–to–long axis ratio > 0.5 (in 60%)

√ short axis diameter < 5–6 mm

√ hyperechoic hilum

Location: retromandibular fossa; wraps around mandibular angle (within parotid space)

Anatomic divisions:

(a) superficial lobe = main bulk of gland superficial and posterior to masseter muscle; separated by invisible facial nerve / (in its place) retromandibular vein

(b) deep lobe = small extension of gland deep to angle of mandible

(c) accessory lobe (20%) = superficial and lateral to masseter muscle + anterior to superficial lobe along course of Stenon duct draining directly into parotid duct

Drainage route: Stensen / Stenon duct

Stensen / Stenon Duct

[Stensen, Niels aka Steensen, Latin: Nicolaus Stenonius, Italian: Stenone, French *:* Stenon (1638–1686), Danish anatomist, natural scientist, theologist in Holland, France, Italy and Germany]

= main excretory duct of parotid gland

Length: 3–5 cm

Course: lies on masseter muscle about 1 cm below zygomatic arch → crosses buccal muscle

Orifice: parotid papilla above upper 2nd molar tooth

√ normal duct sonographically not visible

Submandibular Gland

Location: in posterior part of submandibular triangle (created by anterior + posterior bellies of the digastric muscle and body of the mandible)

√ may be connected to parotid / sublingual glands by glandular processes

Drainage route:

5-cm long submandibular duct (Wharton duct) forms at hilum superiorly; runs forward between mylohyoid m., hyoglossus m. and genioglossus m.; bends around margin of mylohyoid muscle; exits through orifice (= sublingual caruncle) along medial aspect of sublingual gland

[Thomas Wharton (1614–1673), English anatomist, in 1956 published "Adenographia", a description of the glands of the entire body, associated with St. Thomas's Hospital, London]

√ duct sonographically not visible

Relationship to adjacent vessels:

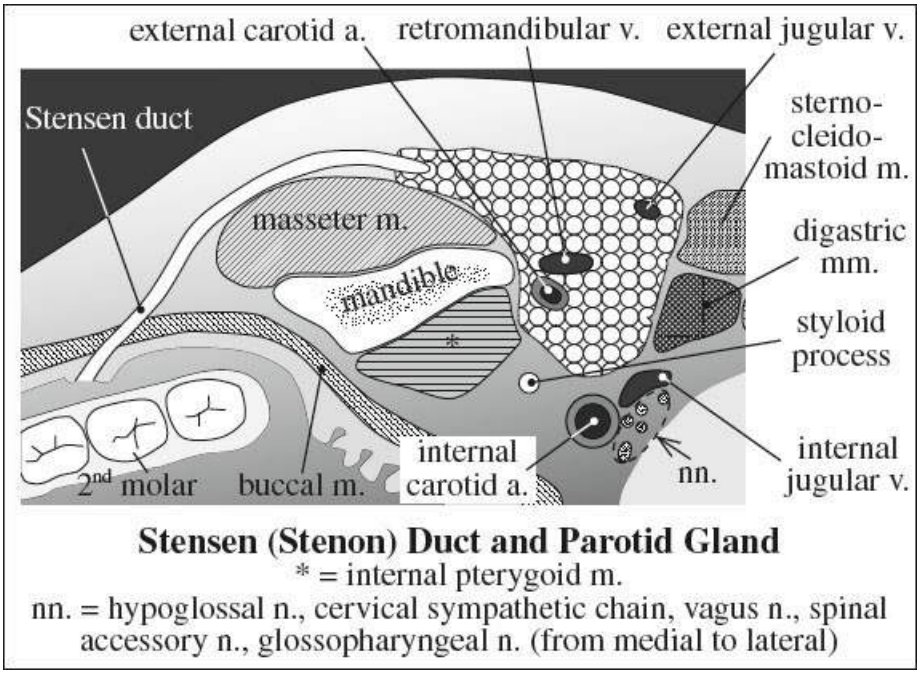
› tortuous facial artery may cross through parenchyma

› facial vein runs along anterosuperior part of gland
› ± branch vein connecting to retromandibular v. in posterior portion
› lingual artery and vein medial to gland

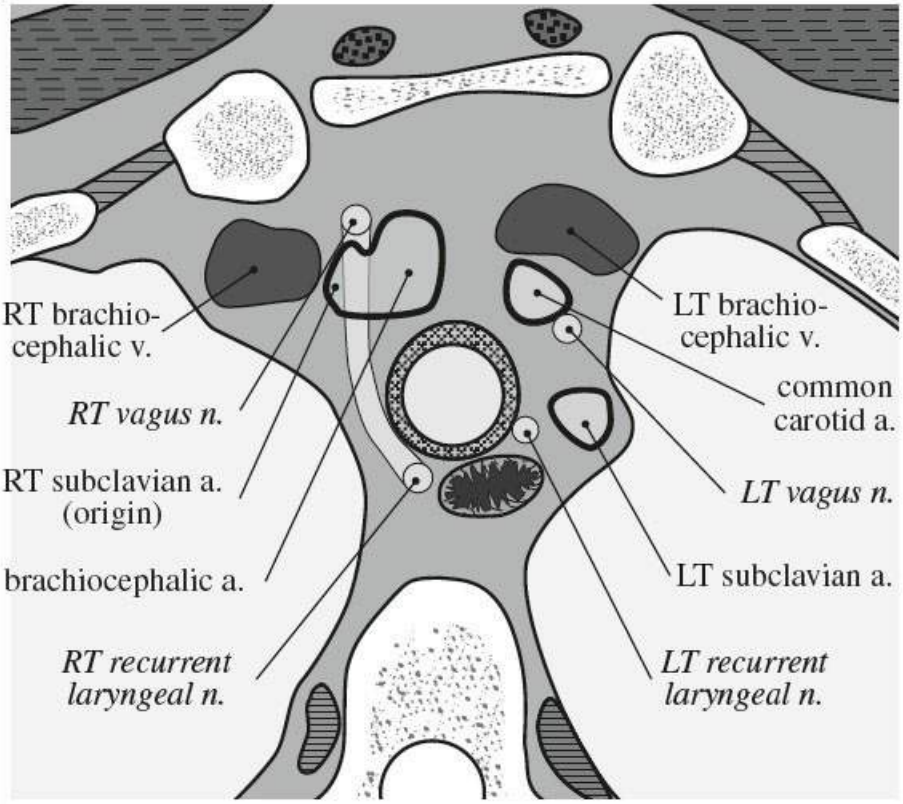
Sublingual Gland

Location: between geniohyoid m., intrinsic muscles of tongue, hyoglossal m. (medially) + mylohyoid m.; medial to mandible

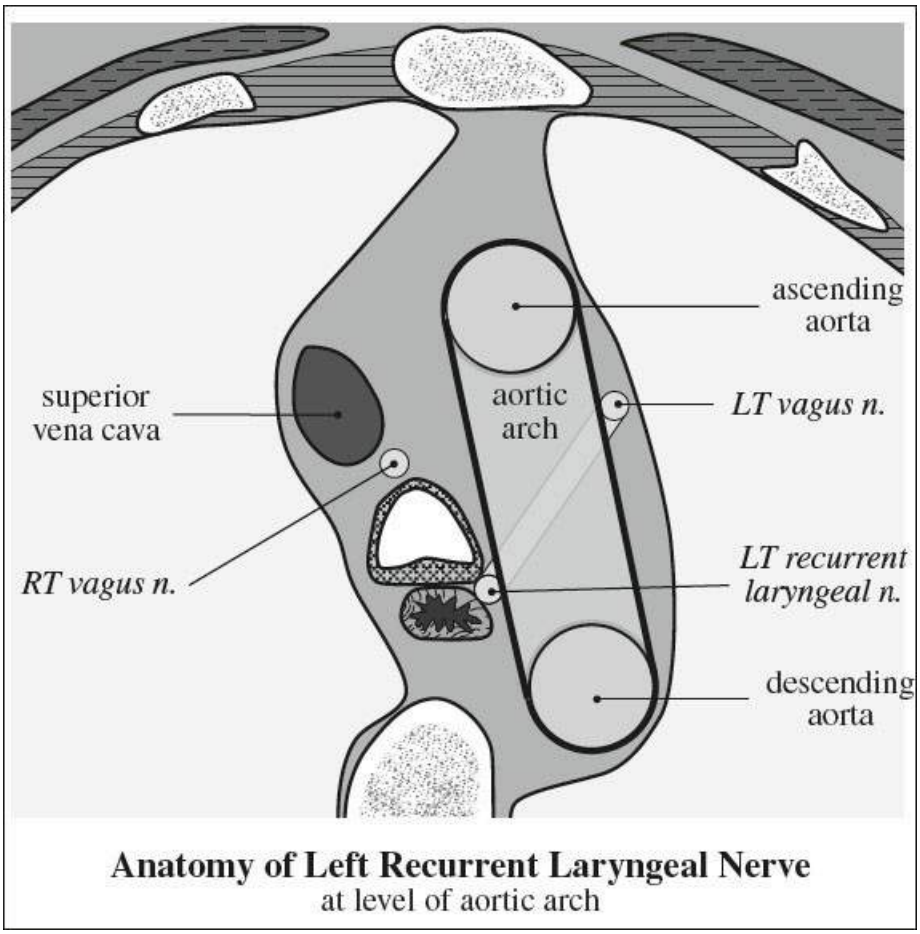
Drainage route: 8–20 excretory ducts with orifices on either side of frenulum; some form major sublingual duct of Bartholin connecting to submandibular duct



Stensen (Stenon) Duct and Parotid Gland
* = internal pterygoid m.
nn. = hypoglossal n., cervical sympathetic chain, vagus n., spinal accessory n., glossopharyngeal n. (from medial to lateral)

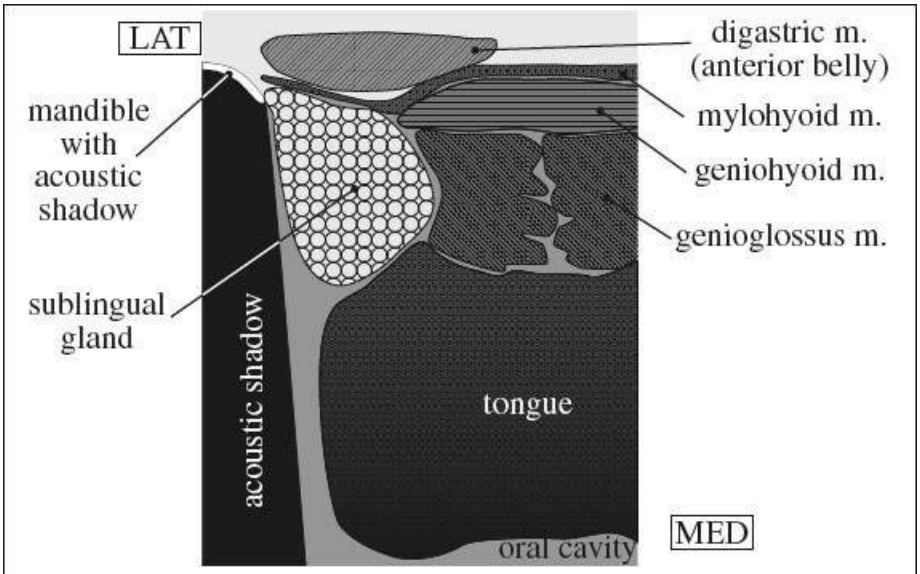


Anatomy of Right Recurrent Laryngeal Nerve
at level of origin of right subclavian artery



Anatomy of Left Recurrent Laryngeal Nerve
at level of aortic arch

Thyroid Hormones		
Thyroxin	T_4	4.5 – 12.0 µg/dL
Triiodothyronine	T_3	90 – 200 ng/dL
Thyroid stimulating hormone	TSH	0.4 – 4.5 µIU/mL
Free T_4 (0.03% of T_4)	FT_4	0.7 – 1.6 ng/dL
Free T_3 (0.4% of T_3)	FT_3	230 – 420 ng/L
Thyroxin-binding globulin	TBG	binds 70% of T_4
		binds 38% of T_3
Thyroxin-binding prealbumin	TBPA	binds 10% of T_4
		binds 27% of T_3
Albumin		binds 20% of T_4
		binds 35% of T_3
Radioiodine uptake	RAIU	8 – 35% @ 24 hr



US of Sublingual Gland
transverse image from inferiorly via floor of mouth

RECURRENT LARYNGEAL NERVE (RLN)

not directly visualized on CT

Origin: nucleus ambiguus in medulla of brainstem within vagus n.

Course:

crosses lateral in cerebellomedullary cistern → exits skull base via pars vascularis of jugular foramen (located within dural sheath shared by spinal accessory n. [CN XI]) → superior ganglion within jugular foramen → inferior ganglion immediately below jugular foramen → exit point of pharyngeal branches (containing sensory fibers of glossopharyngeal n. [CN IX]) + superior laryngeal n. → descends within carotid sheath posterolateral to internal carotid a. + posteromedial to jugular v.

(a) RT RLN:

Exit: from vagus n. anterior to subclavian a.

courses posteriorly beneath the subclavian a. at level of brachiocephalic bifurcation → right tracheoesophageal groove over surface of apical parietal pleura

Length to cricothyroid joint: 5–6 cm

(b) LT RLN:

Exit: from vagus at level of aortic arch

courses posteromedial beneath aortic arch through aorticopulmonary window + posterior to ligamentum arteriosum → ascends vertically to reach left tracheoesophageal groove

Length to cricothyroid joint: 12 cm

Innervation by superior laryngeal nerve:

motor fibers to cricothyroid + superior pharyngeal constrictor mm.

Innervation by recurrent laryngeal nerve:

intrinsic laryngeal mm. (posterior cricoarytenoid m. = main vocal cord abductor)

THYROID GLAND

Normal size: 4.0–4.8 cm (L) x 1.0–1.8 cm (W) x 0.8–1.6 (H) cm
Volume: L x W x H x π/6
Normal weight: 10–25 g
Physiology: hypothalamic TRH → anterior pituitary TSH → T_4 (= main hormone produced by thyroid); T_3 mainly produced by peripheral conversion of T_4; T_3 and T_4 are largely protein-bound in plasma to (mainly) TBG; only the unbound free portion (FT_3, FT_4) is active → increased cell metabolism by binding to nuclear receptors

√ intense homogeneous enhancement

CT:

√ homogeneous mildly hyperattenuating relative to surrounding neck musculature with an average attenuation of 80–100 (range, 70–120) HU

MR:

√ slightly hyperintense on T1WI + iso- to slightly hyperintense on T2WI relative to the neck musculature

NUC (^{99m}Tc pertechnetate / ^{123}I / ^{131}I):

√ symmetric uniform uptake in both lobes

N.B.: intravenous contrast medium impairs thyroid uptake of radioactive iodine for 4–8 weeks

Embryogenesis of Thyroid

Origin: derived from median thyroid anlage = endodermal thickening between 1st + 2nd pharyngeal arches → forming small pit at 24th day GA = **thyroid bud** → elongates into bilobate diverticulum → descends caudally while in contact with aortic primordium → reaches final location by 7 weeks GA

Cells: (a) thyroid **follicular cells** ← median thyroid anlage

(b) **parafollicular cells** (C cells) ← arise laterally from 4th pharyngeal pouch ← lateral thyroid anlagen (= ultimobranchial bodies) merge with products of median anlage after descent into infrahyoid portion of neck → dispersion of parafollicular cells throughout thyroid gland

Ectopic Thyroid Tissue

Location: (a) base of the tongue (90%);

(b) infrahyoid portion of neck (< 10%);

(c) lateral to midline = superficial to strap muscle (rare)

(d) beyond usual path of migration: mediastinum, heart, adrenal, bowel, ovary

Mean age at presentation: 40.5 years

√ absence of orthotopic thyroid tissue (in 70–80%)

NUC (^{99m}Tc-pertechnetate, ^{123}I, ^{131}I):

√ thyroid tissue identified in usual thyroid bed / at ectopic sites

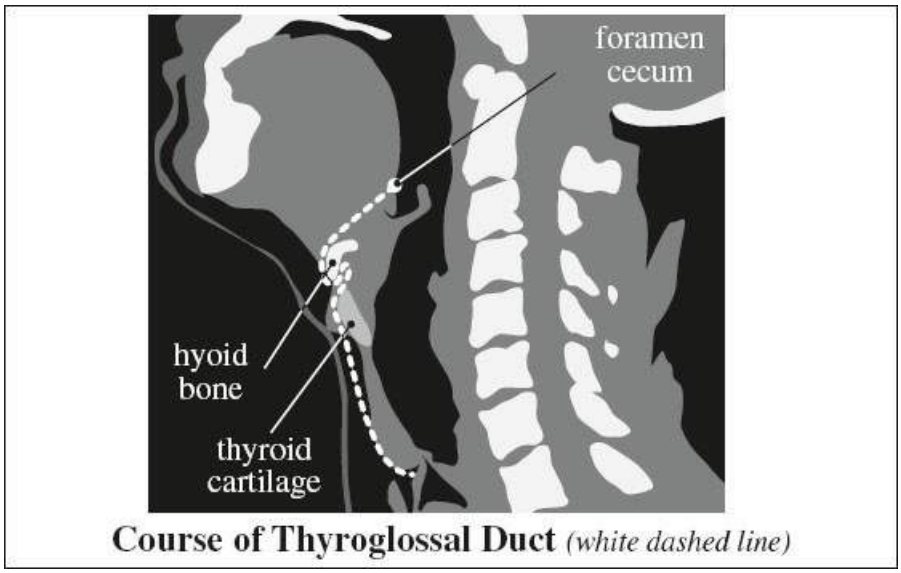
N.B.: normal thyroid gland may trap majority of radionuclide making identification of small ectopic rests difficult!

CT:

√ mildly increased attenuation of 70 HU ± 10 relative to adjacent muscle ← intrinsic iodine content

√ well-circumscribed homogeneous avidly enhancing mass
√ islands of low attenuation within ectopic thyroid tissue = clue to diagnosis of ectopic thyroid tissue

MR:
√ isointense to mildly hyperintense relative to musculature on T1WI
√ mildly hyperintense with variable enhancement on T2WI



Course of Thyroglossal Duct *(white dashed line)*

Embryogenesis of Thyroglossal Duct

= small temporary channel along which thyroid primordium descends in midline of neck to its final position → forms in 3rd week GA → usually involutes by 8th–10th week of fetal life prior to definite formation of thyroid

Origin: **foramen cecum** at base of tongue (= vertex of sulcus terminalis linguae formed by circumvallate papillae)

Course: passes from foramen cecum anterior to primordial hyoid bone → makes a recurrent loop through / posterior to precursor of hyoid bone → finally descends to infrahyoid portion of neck anterior to thyrohyoid membrane + thyroid cartilage + trachea + strap muscles

Inferior end: becomes **pyramidal lobe** of thyroid

Biosynthesis of Thyroid Hormone

(1) Uptake of iodide by thyrocytes

NIS (natrium-iodide symporter) gene:

› located on chromosome 9p12-13.2 → intrinsic thyrocyte-based plasma membrane glycoprotein NIS

Sodium iodide symporter (NIS):

driven by Na+/K+ ATPase cotransports two Na+ and one I- into follicular cell raising cytoplasmic iodine concentration to 20–40 times that of plasma (**iodide trapping**)

Biodistribution of NIS expression:

thyroid, salivary gland (ductal cell), gastric mucosa (parietal + mucus cells), lactating

mammary gland (nonlactating breast in 6%), lacrimal gland, choroid plexus, ciliary body, skin, placenta, thymus [lower levels in prostate, ovary, adrenal gland, lung, heart, colon, orbital fibroblasts, nasopharyngeal mucosa]

(2) Efflux into follicular lumen

(3) Organification onto thyroglobulin thyroid peroxidase → oxidisation of two I- to nonreactive I2 and very reactive I0 → iodinates tyrosyl residue of thyroglobulin within colloid

Thyroglobulin

produced in endoplasmic reticulum of follicular cell → secreted into colloid of thyroid follicle by exocytosis

PARATHYROID GLANDS

Embryology: parathyroid glands develop by 6 weeks GA + migrate into neck at 8 weeks

Size: 6 x 3–4 x 1–2 mm = 29.5 ± 17.8 (range, 25–65) mg

Histo: gland composed of chief cells (secretion of parathyroid hormone), oxyphil cells (packed with mitochondria of unknown function), transitional oxyphil cells mixed with adipose tissue

A. SUPERIOR PARATHYROID GLANDS

Embryology: derived from 4th pharyngeal pouches, descending together with thyroid gland in close relationship to its posterolateral lobes

Eutopic location:

posterior to superior / middle third of thyroid gland in tracheoesophageal groove on dorsal surface of thyroid / intracapsular (> 90%); posterior to inferior thyroid artery + recurrent laryngeal n.

◊ Fairly constant position due to minimal descent

Ectopic location:

› above upper pole of thyroid lobe (< 1%)

› posterior to pharynx / esophagus, on either side of neck or superior mediastinum (1%–4%)

› intrathyroidal (< 3%)

B. INFERIOR PARATHYROID GLANDS

Embryology: derived from 3rd pharyngeal (branchial) pouches migrating caudally with thymus

Eutopic location:

anterior / lateral / posterior to inferior third of thyroid (61%); anterior to inferior thyroid artery + recurrent laryngeal nerve

◊ More variable position ← descent over greater distance

Ectopic location:

› in neck, inferior to lower pole of thyroid lobe: either in thyrothymic ligament / associated with cervical portion of thymus (26%)

› on / adjacent to the posterior aspect of the middle third of the thyroid lobe (7%)

› in anterior mediastinum (4%–5%): within thymus / at posterior aspect of thymic capsule / in contact with great vessels

› along the carotid sheath (< 1%–2%)

› intrathyroidal (< 3%)

C. SUPERNUMERARY PARATHYROID GLANDS

5^{th} / 6^{th} gland may occupy an ectopic site

◊ Up to 12 parathyroids may be present!

D. ABSENCE OF 1 PARATHYROID GLAND

Surgical success rates for finding parathyroid glands:

› 95% for initial cervical exploration

› 60% for repeat surgical exploration

Cause for failure: overlooking an adenoma, multiple abnormal glands, diffuse hyperplasia

Localization technique:

US (75% sensitivity), thallium-technetium subtraction scintigraphy, MR (88% sensitivity)

LYMPH NODES OF THE NECK

Imaging of normal lymph nodes:

Shape: oval similar to a lima bean

CT:

√ iso- or hypoattenuating to muscle

MR:

√ low to intermediate signal intensity on T1WI

√ intermediate to high signal intensity on T2WI

US:

√ hypoechoic in comparison with muscle

√ ovoid shape with echogenic fatty hilum

Reactive lymph nodes:

Organism:

(a) bacterium

√ greater enlargement + inflammation of surrounding tissue

Cx: progression to suppurative adenopathy

(b) virus (CMV, infectious mononucleosis, HIV)

√ diffuse enlargement + little surrounding inflammation

(c) inflammatory cause: sarcoidosis

(d) idiopathic:

Kimura, Kawasaki, Kikuchi-Fujimoto disease

• signs of local or systemic infection

• painful mobile nodes at physical examination

√ normal to slightly enlarged in size

√ ± enhancement ← increased vascularity

A. CENTRAL COMPARTMENT

= between right and left carotid arteries

1. Delphian (prelaryngeal) / pretracheal

[The Delphic Oracle in the Greek world was consulted before all major undertakings. An enlarged Delphian node is ominously evidence of metastatic thyroid cancer.]

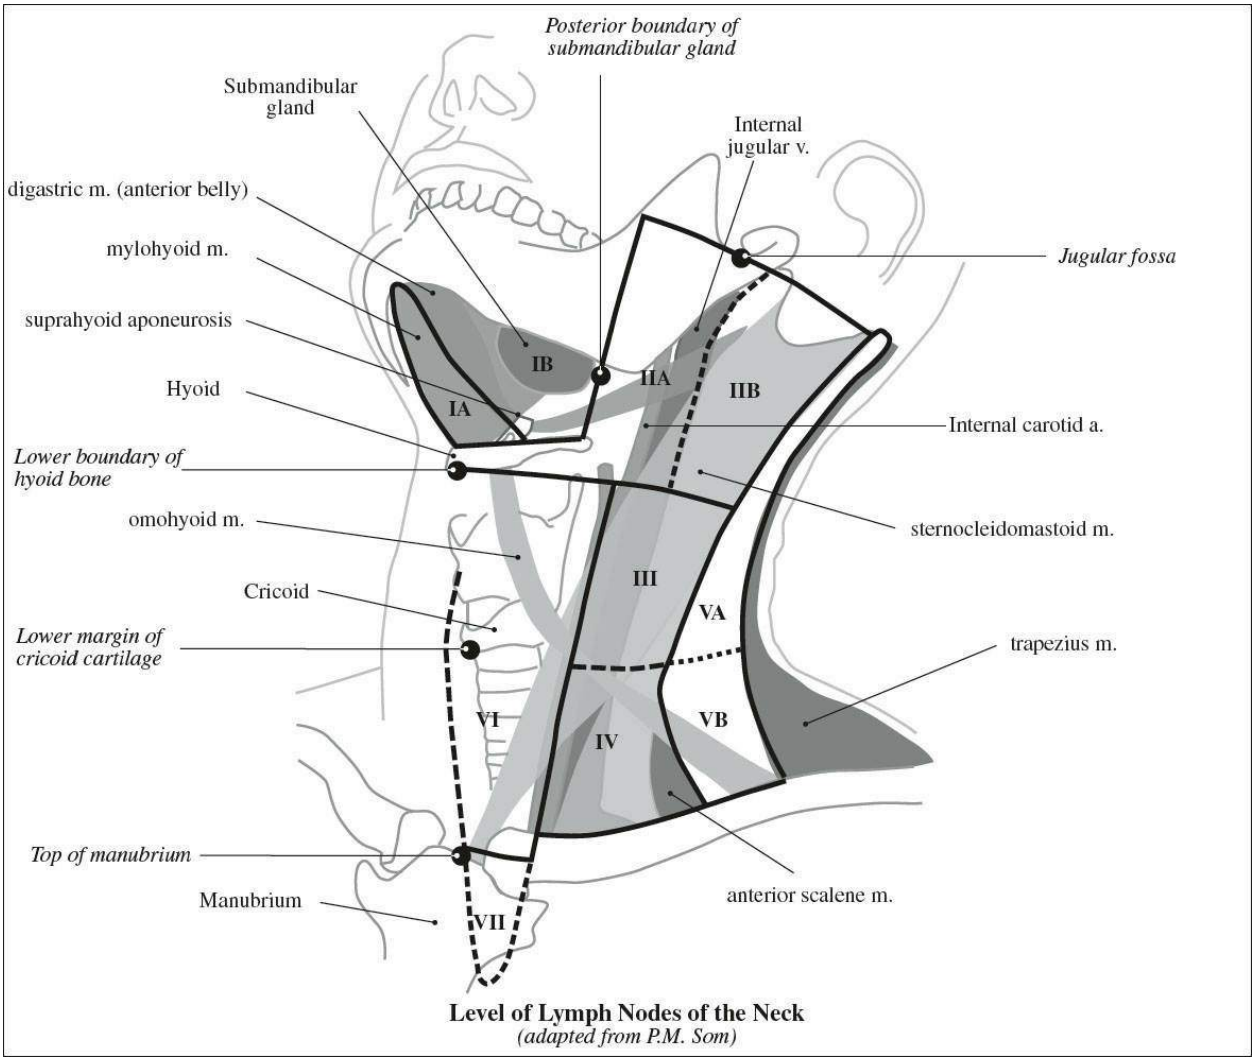
= level VI node (not routinely excised during radical neck dissection)

Involvement with: thyroid carcinoma, squamous cell carcinoma, laryngeal cancer

2. Paratracheal: alongside recurrent laryngeal nerve
3. Thymic / perithymic: within fatty tissue in the lower anterior part of neck

B. LATERAL COMPARTMENT

1. Internal jugular
   - › jugulodigastric node: < 15 mm maximal longitudinal diameter, < 10 mm axial diameter
   - › retropharyngeal: < 8 mm maximal longitudinal, < 10 mm axial diameter
   - › others: < 10 mm maximal longitudinal diameter, < 10 mm axial diameter
2. Spinal accessory: posterior triangle
3. Transverse cervical: supraclavicular



Level of Lymph Nodes of the Neck
(adapted from P.M. Som)

Essential anatomic landmarks:

jugular fossa of skull base, bottom of hyoid body, bottom of cricoid arch, top of manubrium, back edge of submandibular gland, back edge of sternocleidomastoid m., lateral posterior edge of anterior scalene m., anterior edge of trapezius m., internal + common carotid a., internal jugular v., clavicle, medial margin of anterior belly of digastric m., mylohyoid m.

I	above hyoid + below mylohyoid m. + anterior to posterior edge of submandibular gland (**submandibular nodes**); IA = between medial edge of anterior bellies of both digastric mm. (**submental nodes**)
II	skull base at jugular fossa + lower body of hyoid bone + anterior to posterior edge of sternocleidomastoid m. + posterior to posterior edge of submandibular gland; IIA = anterior to internal jugular vein (**upper internal jugular nodes**); IIB = posterior to internal jugular v. (**upper spinal accessory nodes**); **retropharyngeal node** = level II node medial to internal carotid a.; **jugulodigastric node** = where posterior belly of digastric muscle crosses internal jugular vein
III	lower body of hyoid + lower margin of cricoid arch + posterior edge of sternocleidomastoid m. (**midjugular nodes**)
IV	lower margin of cricoid + clavicle + posterior edge of sternocleidomastoid m. + posterolateral edge of anterior scalene m. + medial aspect of common carotid a. (**jugular nodes**)
V	behind posterior edge of sternocleidomastoid m.
VI	lower body of hyoid + top of manubrium + between common carotid aa. (**visceral nodes**)
VII	top of manubrium to innominate v. + between common carotid aa. (**superior mediastinal nodes**)

Supraclavicular nodes = level IV & VB nodes; **Internal jugular nodes of Rouvière** = level II or III or IV nodes

ABERRANT INTERNAL CAROTID ARTERY

= collateral pathway = anastomosis of enlarged inferior tympanic artery with enlarged caroticotympanic artery (= remnant of embryonic hyoid artery) ← involution of normal cervical portion (1st embryonic segment) of ICA

• vascular tympanic membrane, sensation of fullness in ear

• pulsatile tinnitus, hearing loss, vertigo

√ tubular soft-tissue density entering middle ear cavity posterolateral to cochlea → crossing mesotympanum along cochlear promontory → exiting anteromedial to become horizontal portion of carotid canal

√ protrusion into middle ear without bony margin

Cave: catastrophic hemorrhage from tympanotomy / biopsy

DDx: neoplastic process (eg, paraganglioma); inflammation (eg, effusive otitis media)

ADENOID CYSTIC CARCINOMA

= CYLINDROMA

Frequency: 4–15% of salivary gland cancers; 1–3% of all head & neck malignancies

Histo: (a) cribriform subtype, grade 1
(b) tubular subtype, grade 2
(c) solid / basaloid subtype, grade 3
◊ Perineural invasion is typical!

Age: 3rd–9th decade; maximum between 40 and 70 years; M=F

• slowly growing with pain ← tendency to infiltrate nerves

Location:

◊ Most often found in minor salivary glands

@ Minor salivary glands (most common; 25–31% of malignant neoplasms occur in minor salivary glands)
◊ Most common tumor of the minor salivary glands!
• nasal obstruction + swelling
Site: oral cavity > pharynx > nose > paranasal sinuses > trachea > larynx

@ Submandibular gland (15% of tumors affecting this gland)

@ Parotid gland (2–6% of tumors in this gland; arises from peripheral parotid ducts with propensity for perineural spread along facial nerve)
• hard mass + facial nerve pain / paralysis
√ infiltrating parotid mass

@ Trachea

MR:

√ hypo- to hyperintense (high signal corresponds to low cellularity with a better prognosis) on T2WI

√ adenoid cystic carcinomas have the highest relative incidence of perineural invasion (up to 56%)

Metastases to: lung, cervical lymph nodes, bone, liver, brain

Prognosis: slow growing but relentless malignant course with repeat recurrences; the greater the cellularity, the worse the prognosis (requires entire tumor); 60–69% 5-year survival rate; 40% 10-year survival rate

Rx: repeat surgical excision + radiation therapy

Laryngeal Adenoid Cystic Carcinoma

0.25–1% of all malignant laryngeal tumors

Histo: uniform small basaloid cells with large deeply staining ovoid nuclei arranged in anastomosing cords or islands

- coughing attacks, wheezing, hemoptysis
- CHARACTERISTIC paralysis of recurrent laryngeal nerve ← propensity to invade nerves
- absent history of cigarette smoking

Location: subglottis at junction with trachea (80%)

√ extensive submucosal tumor spread of entire larynx

√ invasion of cricoid cartilage, thyroid + esophagus

√ regional neck nodes hardly ever involved

ANGIOFIBROMA

Giant Cell Angiofibroma

= benign tumor with rapid growth mimicking malignancy / with slow growth over many years

Mean age: 45 years

Histo: pseudovascularized spaces within stromal matrix

Location: orbital region / eyelid (most common); buccal mucosa, submandibular region, parapharyngeal space

√ NO osseous erosion

CT:

√ circumscribed enhancing mass

MR:

√ usually hyperintense relative to muscle on T2WI

√ isointense relative to muscle on unenhanced T1WI

√ heterogeneous mass with stippled areas of low signal intensity / signal void ← multiple pseudovascular spaces

√ intense enhancement

Juvenile Angiofibroma

= most common benign nasopharyngeal tumor, can grow to enormous size and locally invade vital structures

Frequency: 0.5% of all head and neck neoplasms

Mean age: 15 years; almost exclusively in males

- recurrent + severe epistaxis (59%)
- nasal speech ← nasal obstruction (91%)
- facial deformity (less common)

Location: nasopharynx / posterior nares; center of mass within sphenopalatine foramen
Extension: posterolateral wall of nasal cavity; via pterygopalatine fossa into retroantral region / orbit / middle cranial fossa; laterally into infratemporal fossa
Vascular supply: primarily by ipsilateral internal maxillary / ascending pharyngeal / palatine artery
√ widening of pterygopalatine fossa (90%) with anterior bowing of posterior antral wall
√ osseous erosion of nasal cavity, hard palate, pterygoid plates
√ invasion of sphenoid sinus (⅔) from tumor erosion through floor of sinus
√ widening of inferior + superior orbital fissures → spread into orbit via inferior orbital fissure + into middle cranial fossa via superior orbital fissure
√ highly vascular nasopharyngeal mass
CECT:
√ avid enhancement of mass (only enhances on CT scan immediately after bolus injection)
MR (best for tumor extension into skull base / intracranially):
√ low to intermediate SI on T1WI with discrete punctate areas of hypointensity ← highly vascular stroma
√ heterogeneous intermediate SI on T2WI
√ avid enhancement with flow voids
Angio (to define vascular supply):
√ may involve branches of contralateral ICA + ECA
NOTE: Biopsy contraindicated!

ANGIOLIPOMA OF PAROTID GLAND

= benign nodular lesion similar to ordinary lipomas except for associated angiomatous proliferation
Age: rare before puberty
CT:
√ circumscribed (more common) / infiltrating mass
√ marked enhancement around fatty components
DDx: hemangioma with fatty degeneration

APICAL PETROSITIS

= PETROUS APICITIS = PETROSITIS
= infectious process caused by medial extension of acute otitis media into pneumatized petrous air cells
Frequency: chronic > acute apicitis
Etiology: spread from middle ear + mastoid infection; requires presence of air cells in petrous apices (which is normally found in 9–30% of population)
Organism: Streptococcus pneumoniae, Haemophilus influenzae, Staphylococcus aureus
• **Gradenigo syndrome** = classic triad of
  • deep facial (retroorbital) pain in distribution of cranial nerve V_1 (trigeminal pain) ← focal meningitis over petrous apex with irritation of gasserian ganglion in Meckel cavity
  • diplopia ← 6th nerve palsy
  • ipsilateral otorrhea ← otitis media

[Giuseppe Conte Gradenigo (1859–1926), Italian otolaryngologist in Wien, Torino and Napoli]

√ opacification of aerated petrous apex + air-fluid levels
√ osseous erosion
√ fluid in ipsilateral middle ear + mastoid

MR:
√ hyperintense signal on T2WI + hypointense on T1WI
√ avidly enhancing mass in pneumatized petrous apex
√ enhancing meninges ← adjacent meningeal inflammation

Cx: meningitis; epidural / brain abscess (ring enhancement, restricted DWI); venous sinus thrombosis; cranial nerve palsy (abducens, trigeminal, vagus nn.)

Mortality: up to 20% (prior to antibiotic era)

Rx: intravenous antibiotics, myringotomy, surgery

DDx: petrous apex osteomyelitis (nonpneumatized petrous apex, septal + cortical destruction, predisposing diabetes mellitus); neoplastic disease (rhabdomyosarcoma, metastasis); epidermoid tumor

BENIGN LYMPHOEPITHELIAL LESIONS

= BLL = HIV-ASSOCIATED LYMPHOEPITHELIAL CYSTS
= painless idiopathic swelling of one / both parotid glands characterized by chronic progression in the absence of retroviral therapy

Prevalence: 5% of HIV population

Cause: serves as index lesion for diagnosis of HIV infection without AIDS; NOT an AIDS defining illness

Pathogenesis: cystic dilatation of terminal salivary ducts

Age: 6th decade; M÷F = 2÷3 to 4÷5

Histo: polyclonal CD8+ lymphoid hypertrophy → obstruction + dilatation of intraglandular ducts

Location: one / both (20%) parotid glands

US:
√ cystic lesions with multiple small septations + small mural nodules (in 40%)
√ ± vascular pedicle entering the cystic region
√ moderately vascular (79%), hypervascular (14%), avascular (7%) on color Doppler

CT:
√ numerous (rarely isolated single) mixed cystic + solid lesions
√ reactive cervical lymphadenopathy
√ tonsillar hypertrophy

CECT:
√ rimlike enhancement around cystic parotid lesions
√ heterogeneous enhancement of solid parotid lesions

Cx: transformation into B-cell lymphoma (rare)

DDx: acute phase of Sjögren syndrome (lesions predominantly solid, of decreased echogenicity, smaller, more numerous), sarcoidosis, lymphoma, viral infection (mumps), Warthin tumor (frequently multicentric or bilateral, internal cystic elements, no cervical

adenopathy)

BRANCHIAL CLEFT ANOMALIES

= BRANCHIAL CLEFT CYST
= failure of involution of branchial cleft
Frequency: 2nd most common congenital lesion of head & neck after thyroglossal duct cyst!
• neck mass / cyst; respiratory compromise, dysphagia (if large)
Barium pharyngography:
√ performed for localization of a fistulous tract in 2nd + 3rd arch anomalies
Cx: high incidence of infection

First Branchial Cleft Cyst (5–8%)

= PAROTID LYMPHOEPITHELIAL CYST
Frequency: 5–8% of all branchial cleft anomalies (rare)
Age: middle-aged women
• enlarging mass near lower pole of parotid gland
• recurrent parotid abscesses near ear / angle of mandible
• otorrhea (if cyst drains into EAC) ± facial nerve palsy
Spectrum: branchial cyst (68%) / sinus (16%) / fistula (16%)
Location: from submandibular triangle (posterior / inferior to angle of mandible) near branches of facial nerve within parotid gland to preauricular region extending anterior / posterior to pinna to junction of cartilaginous + bony external auditory canal
Pathologic classification (Work):
Type 1 duplication anomaly of membranous EAC; derived from ectoderm + lined with squamous epithelium; no skin appendages
Site: postauricular region = course parallel to EAC; medial to concha of ear
Type 2 parotid cyst containing ectoderm and mesoderm involving EAC + pinna; skin appendages (hair follicles, sweat and sebaceous glands)
• otorrhea without otitis media
√ cystic mass within parotid or immediate periparotid region (superficial to / deep to parotid gland)
√ may extend into adjacent fat-containing parapharyngeal space ± connection to EAC
DDx: inflammatory parotid cyst, benign cystic parotid tumor, necrotic metastatic lymphadenopathy

Second Branchial Cleft Cyst (95%)

= incomplete obliteration of 2nd branchial cleft tract (cervical sinus of His) resulting in sinus tract / fistula / cyst (75%)
Frequency: 95% of all branchial cleft anomalies
◊ Most common branchial cleft abnormality!
Age: 10–40 years; M = F
Classification (Bailey):
Type I along anterior surface of sternocleidomastoid muscle, just deep to platysma

Type II: along anterior surface of sternocleidomastoid muscle, lateral to carotid space, posterior to submandibular gland adhering to the great vessels (most common)

Type III: extension medially between bifurcation of external and internal carotid arteries to lateral pharyngeal wall

Type IV: within pharyngeal mucosal space

Path: 1–10-cm large thin-walled cyst, lined by stratified squamous epithelium overlying lymphoid tissue, filled with turbid yellowish fluid ± cholesterol crystals

- skin openings with sinus / fistula
- painless fluctuant mass at mandibular angle
- history of multiple parotid abscesses unresponsive to drainage + antibiotics
- otorrhea (if connected to external auditory canal)

Location:
anywhere along a line from the oropharyngeal tonsillar fossa to supraclavicular region of neck; CLASSICALLY at anteromedial border of sternocleidomastoid muscle + lateral to carotid space + at posterior margin of submandibular gland; may be in parapharyngeal space (after extension through stylomandibular tunnel + middle constrictor muscle)

Internal opening: oropharyngeal tonsillar fossa

√ oval / round cyst near mandibular angle

√ displacement of sternocleidomastoid muscle posteriorly, carotid artery + jugular vein posteromedially, submandibular gland anteriorly

√ cyst may enlarge after upper respiratory tract infection / injury

US:

√ well-marginated thin-walled ovoid compressible hypoechoic mass:

√ occasionally fine internal echoes = internal debris (due to hemorrhage / infection) obscuring its cystic nature

√ lack of internal flow

CT / MR:

√ "beak" sign = curved rim of tissue pointing medially between internal + external carotid arteries (PATHOGNOMONIC)

√ slight enhancement of capsule

DDx: necrotic neural tumor, cervical abscess, submandibular gland cyst, cystic lymphangioma, necrotic metastatic / inflammatory lymphadenopathy

Atypical Second Branchial Cleft Cyst

Age: child / young adult

- protruding parotid gland
- bulging posterolateral pharyngeal wall

√ cystic mass projecting from deep margin of faucial tonsil toward skull base

Third Branchial Fistula / Cyst

= above superior laryngeal nerve

Frequency: extremely rare

Internal opening: piriform sinus anterior to fold formed by internal laryngeal nerve

Course: fistula pierces thyrohyoid membrane; passes anterior to vagus nerve + above

hypoglossal nerve + below glossopharyngeal nerve; between internal + external carotid arteries; caudolateral / posterolateral to proximal ICA + CCA

External opening: at base of neck anterior to sternocleidomastoid muscle

√ unilocular cystic mass within posterior cervical space

Fourth Branchial Fistula

= below superior laryngeal nerve

Frequency: extremely rare (R > L)

Internal opening: apex of piriform sinus

Course: between cricoid + thyroid cartilage, below cricothyroid muscle, caudal course between trachea + carotid vessels, deep to clavicle into mediastinum, looping forward below aorta (left side) / right subclavian artery (right side), ascending along ventral surface of common carotid artery, passing over hypoglossal nerve

External opening: at base of neck anterior to sternocleido-mastoid m. + anteroinferior to subclavian a.

• recurrent episodes of "suppurative thyroiditis'" / neck abscesses

Site: 90% on left side

CALCIFIC LONGUS COLLI TENDINITIS

= ACUTE CALCIFIC RETROPHARYNGEAL TENDINITIS

= calcification anterior to C1–C2 ← deposition of calcium hydroxyapatite

Location: near insertion of longus colli tendon in close proximity to anterior arch of C1

Site: superior oblique tendon fibers of the longus colli muscle

• recent history of upper respiratory infection / minor trauma to head or neck, acute to subacute onset of neck pain and stiffness

• dysphagia, odynophagia

• low-grade fever, mildly elevated WBC count

√ prevertebral / retropharyngeal soft-tissue swelling

√ amorphous calcification anterior to C1–C2 (CT most sensitive)

√ fluid originating in prevertebral space ± extension to retropharyngeal space:

√ retropharyngeal space smoothly expanded in all directions from C1 tapering inferiorly to C5-6

√ effusions may involve both lateral atlantoaxial joints

√ no rimlike enhancement

Rx: antiinflammatory medication

DDx: retropharyngeal abscess (similar clinical manifestation, enhancing wall), suppurative retropharyngeal lymphadenitis (low-attenuation centers), traumatic injury, infectious spondylitis

CAROTID ARTERY STENOSIS

High-grade ICA stenosis is associated with increased risk for TIA, stroke, carotid occlusion, embolism arising from thrombi forming at site of narrowing

Increased risk for stroke:

(a) significant ICA stenosis → compromised blood flow:

◊ Reduction of blood flow occurs at 50–60% diameter stenosis / 75% area stenosis
◊ 2% risk of stroke with nonsignificant stenosis
◊ 16% incidence of stroke with significant stenosis
◊ 2% incidence of subsequent stroke following endarterectomy

(b) intraplaque hemorrhage → embolic stroke

Histo:

Arteriosclerosis = generic term for all structural changes resulting in hardening of the arterial wall

1. **Diffuse intimal thickening**
   = growth of intima ← migration of medial smooth muscle cells into subendothelial space through fenestrations in internal elastic lamella associated with increasing amounts of collagen, elastic fibers, glycosaminoglycans
   Age: beginning at birth slowly progressing to adult life
2. **Atherosclerosis**
   = intimal pool of necrotic, proteinaceous + fatty substances within hardened arterial wall
   Location: large + medium-sized elastic and muscular arteries
   (a) <u>fatty streak</u> = superficial yellow-gray flat intimal lesion characterized by focal accumulation of subendothelial smooth muscle cells + lipid deposits
   (b) <u>fibrous plaque</u> = *whitish protruding lesion* consisting of central core of lipid + cell debris surrounded by smooth muscle cells, collagen, elastic fibers, proteoglycans; fibrous cap separates lipid core (= atheroma) from vessel lumen
   (c) <u>complicated lesion</u> = fibrous plaque with degenerative changes such as calcification, plaque hemorrhage, intimal ulceration / rupture, mural thrombosis
   Plaque hemorrhage = vascularized plaque may cause ulceration, thrombosis + embolism, and luminal narrowing
   ◊ In 93% of symptomatic patients
   ◊ In 27% of asymptomatic patients
   Plaque ulceration exposes thrombogenic subendothelial collagen + lipid-rich material
   ◊ Frequent in plaques occupying > 85% of lumen
   ◊ 12.5% stroke incidence per year
3. **Mönckeberg sclerosis** = medial calcification
4. **Hypertensive arteriosclerosis**

Temporal course of carotid artery stenosis:

1. Stable stenosis (68%)
2. Progressive stenosis to > 50% diameter reduction (25%)

Angiography:

@ Extracranial
√ smooth asymmetrical excrescence encroaching upon vessel lumen
√ crater / niche = ulceration
√ mound within base of crater = mural thrombus
√ **Holman "carotid slim" sign** = diffuse narrowing of entire contrasted ICA distal to high-grade stenosis ← decrease in perfusion pressure
√ occlusion of ICA

@ Intracranial
√ carotid siphon stenosis

- √ retrograde flow in ophthalmic artery filled via ECA
- √ small vessel occlusion
- √ focal areas of slow flow
- √ early draining vein = reactive hyperemia = "luxury perfusion" ← shunting between arterioles + venules surrounding an area of ischemia
- √ ICA-MCA slow flow = delayed arrival + washout of ICA-MCA distribution in comparison to ECA

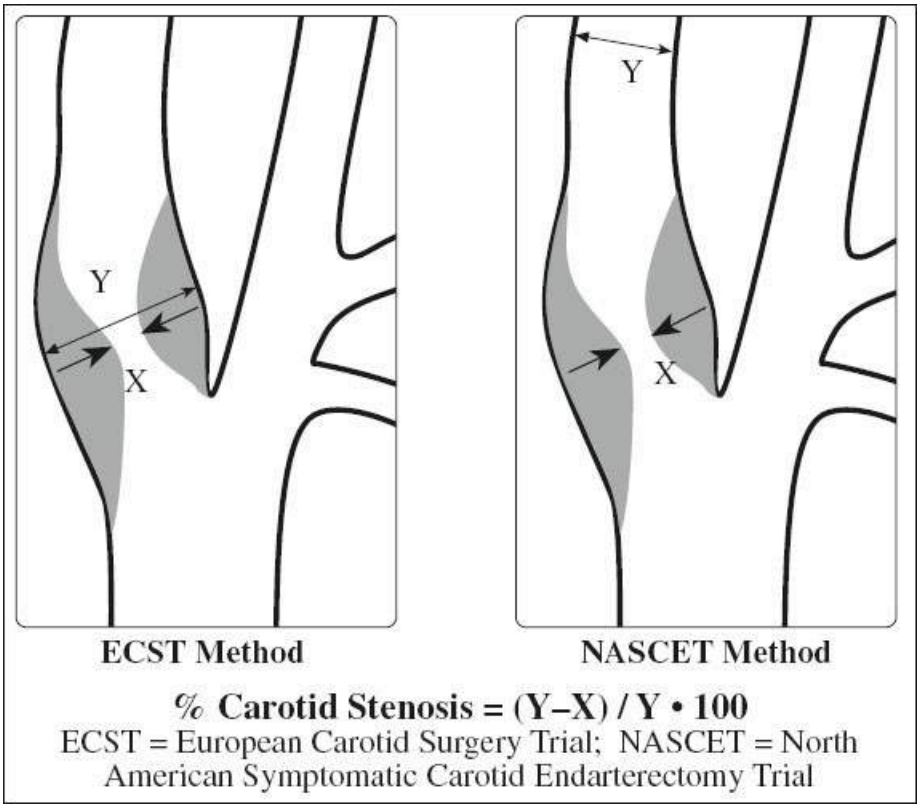
Carotid endarterectomy:

Benefit: 17% reduction of ipsilateral stroke at 2 years in patients with > 70% carotid stenosis (NASCET = North American Symptomatic Carotid Endarterectomy Trial)

Risk: 1% mortality; 2% risk of intraoperative neurologic deficit

Predilection Sites of Arterial Stenosis

	Incidence of Lesions	
	Stenosis	*Occlusion*
Right ICA origin	33.8%	8.6%
Left ICA origin	34.1%	8.7%
Right vertebral artery origin	18.4%	4.8%
Left vertebral artery origin	22.3%	2.2%
Right carotid siphon	6.7%	9.0%
Left carotid siphon	6.6%	9.2%
Basilar artery	7.7%	0.8%
Right MCA	3.5%	2.2%
Left MCA	4.1%	2.1%



Carotid Duplex Ultrasound

Indications for carotid duplex US:

(1) Screening for suspected extracranial carotid disease
  (a) high-grade flow-limiting stenosis
  (b) low-grade stenosis with hemorrhage
(2) Nonhemispheric neurologic symptomatology
(3) History of transient ischemic attack / stroke
(4) Asymptomatic carotid bruit
(5) Retinal cholesterol embolus
(6) Preoperative evaluation before major cardiovascular surgery
(7) Intraoperative monitoring of vascular patency during endarterectomy
(8) Sequential evaluation after endarterectomy
(9) Monitoring of known plaque during medical treatment

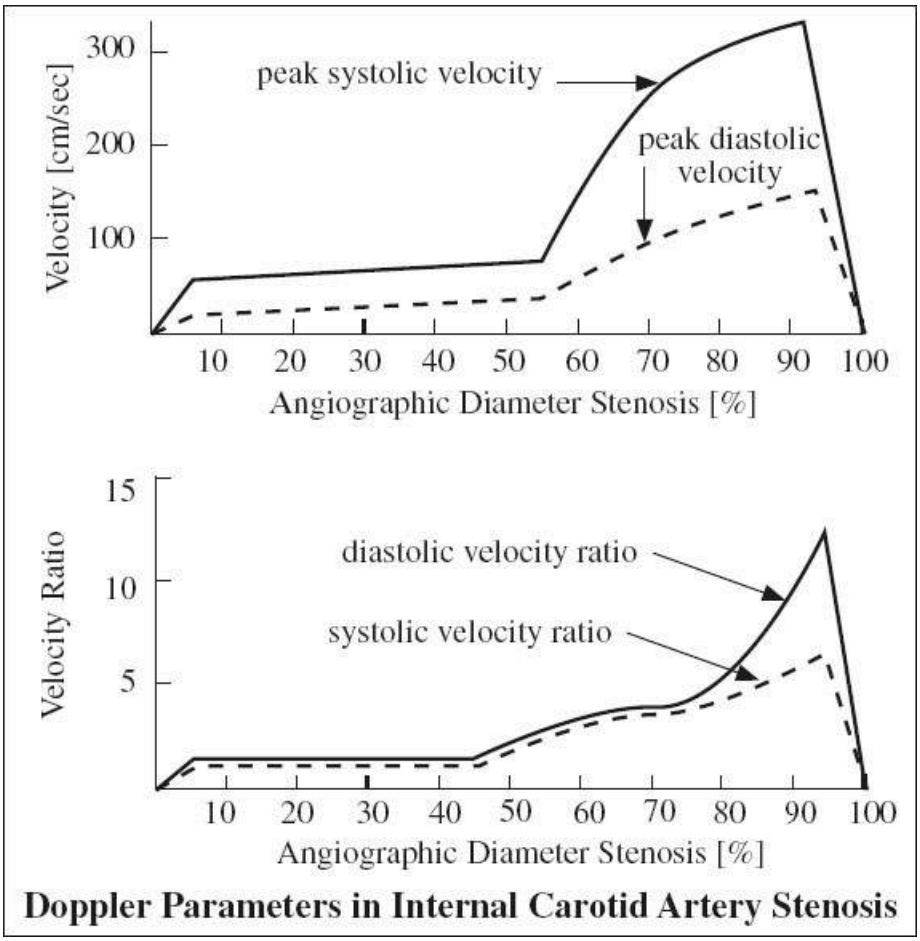
Grading of Internal Carotid Stenosis

= severity of stenosis is primarily graded as a ratio of lumen diameter narrowing NOT reduction in cross sectional area

Decrease in Luminal Diameter vs. Cross-sectional Area	
Decrease in Lumen Diameter	*Decrease in Cross-sectional Area*
20%	36%
40%	64%
60%	84%
80%	96%

Limitations of assessment by US:

1. Calcification > 1 cm in length obscures vessel lumen
   ◊ A jet associated with a stenosis of > 70% usually travels at least 1 cm downstream allowing conclusion about degree of obscured stenosis!
2. Contralateral high-grade stenosis
   = ipsilateral ICA functions as collateral → increased blood flow velocities
   ◊ Use velocity ratios to compensate for this effect!
3. Tortuosity of artery
4. Increased depth of artery
5. "High" bifurcation → possibly obscured by mandible



Doppler Parameters in Internal Carotid Artery Stenosis

Accuracy of duplex scans (compared to arteriography) for ICA lesions:

91–94% sensitivity, 85–99% specificity, 90–95% accuracy for > 50% ICA diameter stenosis

A. NORMAL (0% diameter reduction)
   √ no evidence of plaque
   √ peak systolic velocity (PSV) < 125 cm/sec
   √ no spectral broadening (= clear window under systole)
B. MINIMAL DISEASE (0–15% diameter reduction)
   √ minimal amount of plaque
   √ PSV < 125 cm/sec
   √ minimal spectral broadening in deceleration phase of systole
C. MODERATE DISEASE (16–49% diameter reduction)
   √ moderate amount of plaque
   √ peak systole < 125 cm/sec
   √ end-diastolic velocity (EDV) < 40 cm/sec
   √ poststenotic spectral broadening throughout systole
D. SEVERE DISEASE = hemodynamically SIGNIFICANT LESION
   (a) 50–69% stenosis
      √ PSV 125–230 cm/sec
      √ EDV 40–100 cm/sec
   (b) > 70% stenosis (→ benefit of endarterectomy documented in NASCET study)
      √ peak systole > 230 cm/sec
      √ end diastole > 100 cm/sec
      √ peak systolic velocity ratio of ICA÷CCA > 4.0
E. CRITICAL STENOSIS (> 95% diameter reduction)
   √ PSV + EDV return to <u>normal</u> range / flow undetectable
   √ "string" sign on color Doppler with slow-flow sensitivity setting
F. OCCLUSION
   √ NO signal in ICA on longitudinal / transverse images (color sensitivity + velocity scale must be set low enough to clearly discern flow signals within internal jugular vein)
   √ absence of diastolic flow / diastolic flow reversal in CCA (= high impedance flow)
   √ increased diastolic flow in ECA (if ECA assumes the role of primary supplier of blood to brain)
   √ increase in peak systolic velocities in contralateral ICA ← collateral flow

Common Carotid Waveform Analysis

A. DISTAL OBSTRUCTION
   √ high-pulsatility waveform
      ◊ Pulsatility changes occur only with > 80% stenosis
   √ reduced amplitude
B. PROXIMAL OBSTRUCTION
   √ low-amplitude damped waveform

Hemodynamic Variations of Carotid Stenosis

A. MORPHOLOGY OF STENOSIS

1. Degree of stenosis: velocities increase up to a luminal diameter of 1.0–1.5 mm
2. Length of stenosis: peak velocities decrease with length of stenosis

√ use the same angle + beam steering direction when following a patient for disease progression

B. PHYSIOLOGIC VARIABILITY

◊ A range of velocities may be encountered with a given degree of stenosis!
◊ ICA÷CCA ratio obviates effects of physiologic variability!
◊ Compare left with right waveforms to avoid errors!
◊ Measure volume flow (more sensitive because of contralateral compensatory flow increase)

Cause:

1. Cardiac output
2. Pulse rate
3. Flow velocity: ↑ with obstruction in collateral vessels, ↓ with proximal obstruction in same vessel
4. Normal helical nature of blood flow with many different velocity vectors + nonaxial blood flow NOT detectable by color Duplex imaging
5. Peripheral resistance
6. Arterial compliance
7. Hypertension
8. Blood viscosity

Doppler Spectrum Analysis
(Consensus Conference of Society of Radiologists in Ultrasound 2002)

Diameter Stenosis (%)	*ICA Peak Systolic Velocity (cm/sec)*	*ICA/CCA Peak Systolic Velocity Ratio*	*ICA End-Diastolic Velocity (cm/sec)*	*Plaque*
Normal	< 125	< 2.0	< 40	none
< 50	< 125	< 2.0	< 40	< 50% diameter reduction
50–69	125–230	2.0–4.0	40–100	≥ 50% diameter reduction
> 70	> 230	> 4.0	> 100	≥ 50% diameter reduction
Critical stenosis	low / undetectable	variable	variable	massive, detectable lumen
Occlusion	undetectable	not applicable	undetectable	no detectable lumen

Carotid Plaque

1. Asymptomatic patients with diffuse atherosclerotic disease:
   Prevalence of > 50% stenosis: 18–20%
2. Symptomatic patients with stroke, TIA, amaurosis fugax ← emboli from atheromas at carotid bifurcation
   Prevalence of > 50% stenosis: 14%

Formation Theory of Carotid Plaque

1. Stagnant eddy that rotates at outer vessel margin (away from and opposite to flow divider = area of flow separation + low shear stress) → net influx of fluid into subendothelial tissue with progressive deposition of lipids + smooth muscle cell proliferation
2. Increased likelihood of intraplaque hemorrhage ← vascularization of plaque with fragile vessels derived from vasa vasorum / from lumen) + fissuring at a critical size
   ◊ As the degree of stenosis increases, it is more likely that plaques become denser +

more heterogeneous demonstrating an irregular luminal surface!

Density of Carotid Plaque

1. Hypoechoic = low-echogenicity plaque
   = fibrofatty plaque / hemorrhage
   √ echogenicity less than sternocleidomastoid muscle
   √ flow void / flow disturbance on color Duplex
2. Isoechoic plaque
   = smooth muscle cell proliferation / laminar thrombus
   √ echogenicity equal to sternocleidomastoid muscle + lower than adventitia
3. Hyperechoic = moderately echogenic (fibrous) plaque
   √ echogenicity higher than sternocleidomastoid muscle + similar to adventitia
4. Calcification = strongly echogenic plaque
   √ acoustic shadow impairs visualization of intima

Texture of Carotid Plaque

1. Homogeneous (stable) plaque
   Histo: deposition of fatty streaks + fibrous tissue; rarely shows intraplaque hemorrhage / ulcerations
   √ homogeneous uniform echo pattern with smooth surface (acoustic impedance similar to blood)
2. Heterogeneous (unstable) plaque
   = mixture of high, medium, and low-level echoes with smooth / irregular surface; may fissure / tear resulting in intraplaque hemorrhage / ulceration + thrombus formation → embolus / increasing stenosis
   B-mode ultrasound has 90–94% sensitivity, 75–88% specificity, 90% accuracy for intraplaque hemorrhage!
   MRI depicts intraplaque hemorrhage (methemoglobin) on T1 fat-suppressed SPGR / FLASH sequence
   Histo: lipid-laden macrophages, monocytes, leukocytes, necrotic debris, cholesterol crystals, calcifications
   √ anechoic areas within plaque (= hemorrhage / lipid deposition / focal plaque degeneration)
   √ heterogeneous complex echo pattern

Plaque Texture vs. Prognosis

Consequences	*Homogeneous*	*Heterogeneous*
Neurologic deficit	4%	27%
Ipsilateral infarction by CT	12%	24%
Ipsilateral symptoms	22%	50%
Progressive stenosis	18%	77%

Surface Characteristics of Carotid Plaque

◊ US unreliable due to poor visualization of intima

4 Categories: › smooth

› mildly irregular
› markedly irregular
› ulcerated

1. Intimal thickening
   Histo: fatty streaks
   √ wavy / irregular line paralleling vessel wall extending > 1 mm into vessel lumen
2. Ulcerated plaque
   Accuracy: 60% sensitive, 60–70% specific
   ◊ The presence of intraplaque hemorrhage is much more common than normally appreciated (neither arteriography nor US has proved reliable)!
   √ isolated crater of > 2 mm within surface of plaque demonstrated on transverse + longitudinal images
   √ reversed flow vortices extending into plaque crater demonstrated by color Doppler
   √ proximal + distal undercutting of plaque
   √ anechoic area within plaque extending to surface

Errors In Duplex Ultrasound

1. Error in proper localization of stenosis (6%)
   Cause: ECA stenosis placed into ICA / carotid bifurcation or vice versa
2. Mistaking patent ECA branches for carotid bifurcation (4%)
   Cause: complete occlusion of ICA not recognized
   √ disparity in position of bifurcation between left and right
   √ no difference in waveform pulsatility
   √ high-resistance waveform in CCA
3. Interpreter error in estimating severity of stenosis (2.5%):
   » usually overestimation, rarely underestimation
   √ absence of one / more components for diagnosis which are
   (a) significant elevation of peak velocity
   (b) poststenotic turbulence
   (c) extension of high velocity into diastole
4. Superimposition of ECA + ICA (2%)
   Cause: strict coronal orientation of ECA + ICA
   √ superimposition can be avoided by rotation of patient's head to opposite side
5. Severe stenosis mistaken for occlusion
   √ minimal flow not detectable
   √ angiogram necessary with delayed images
6. Weak signals misinterpreted as occlusion
7. Normal / weak signals in severe stenosis
   Cause: severe stenosis causes a decrease in blood flow and peak velocity → return to normal velocity levels
   √ high resistivity in CCA
8. Point of maximum frequency shift not identified
   Cause: extremely small lumen / short segment of stenosis
   √ unexplained (poststenotic) coarse turbulence

√ collateral flow in ipsilateral ECA
√ abnormal CCA resistivity

9. Stenosis obscured by plaque / strong Doppler shift in overlying vessel
10. Inaccessible stenosis
    √ abnormal CCA resistivity
    √ abnormal oculoplethysmography
11. Unreliable velocity measurements
    (a) higher velocities: HTN, severe bradycardia, obstructive contralateral carotid disease, anemia, hyperthyroidism
    (b) lower velocities: arrhythmia, aortic valvular lesion, CHF, severe cardiomyopathy, proximal obstructive carotid lesion ("tandem lesion"), > 95% ICA stenosis
    (c) **aliasing** = high velocities are displayed in reversed direction below zero baseline due to Doppler frequency exceeding half the pulse repetition frequency
    Remedy: shift zero baseline; increase pulse repetition frequency; increase Doppler angle; decrease transducer frequency; use continuous-wave Doppler probe
    (d) misalignment of Doppler "Angle Correct" cursor
    = cursor not aligned with blood stream line introducing a wrong Doppler angle
    ◊ Doppler angle larger than actual angle means velocity measurement are higher than actual velocity!

Error in Doppler "Angle Correct Cursor" Alignment
at an Actual Velocity of 50 cm/sec

Actual Angle	*Erroneous Angle*	*Estimated Velocity*	*Percent Error*
0°	5°	50.2 cm/sec	0.4%
20°	25°	51.8 cm/sec	3.6%
40°	45°	54.2 cm/sec	8.4%
60°	65°	59.2 cm/sec	18.3%
80°	85°	99.6 cm/sec	99.0%

CHOANAL ATRESIA

◊ Most common cause of neonatal nasal obstruction!

Frequency: 1÷5,000 to 1÷8,000 neonates; M < F

Etiology: failure of perforation of buccopharyngeal + oronasal membrane, which normally perforates by 7th week EGA

Associated anomalies (in 50–75%):
acrophalyngosyndactyly, amniotic band syndrome, malrotation of bowel, Crouzon syndrome, fetal alcohol syndrome, DiGeorge syndrome, Treacher-Collins syndrome, chromosome 18 / 12 anomalies, polydactyly, coloboma, facial cleft, CHD, tracheoesophageal fistula, craniosynostosis

Location: bilateral÷unilateral atresia = 3÷2 to 2÷1

- respiratory distress in bilateral choanal atresia (relieved by crying in neonates who are obligatory nasal breathers during first 2–6 months)
- nasal stuffiness, rhinorrhea, infection in unilateral choanal atresia

Types:

A. OSSEOUS / BONY SEPTATION (85–90%)
Cause: incomplete canalization of choanae
√ fusion of hard palate + vomer + ventral clivus with nasopharyngeal atresia
B. MEMBRANOUS SEPTATION (10–15%)
Cause: incomplete resorption of epithelial plugs
C. OSSEOMEMBRANOUS

CT (preceded by vigorous suctioning + administration of topical decongestant):
√ narrowing of choanal orifice to a width of < 3.4–3.7 mm (in children < 2 years of age)
√ inward bowing of posterior maxilla
√ deviation / bowing of nasal septum
√ fusion / thickening of vomer
√ bone / soft-tissue septum extending across posterior choanae
Dx: nasal catheter cannot be advanced to beyond 32 mm
Cx: bilateral choanal atresia is LIFE-THREATENING
Rx: endoscopic perforation, choanal reconstruction

CHOLESTEATOMA

= KERATOMA = EPIDERMOID
= epithelium-lined sac characterized by accumulation of desquamated keratin epithelium → bone destruction by pressure + increase in osteoclastic activity
Location: middle ear cavity, other pneumatized portions of temporal bone
Histo: (a) acellular keratin debris = content of sac
(b) matrix = biologically active sac lining consisting of
› inner layer of keratinizing squamous epithelium
› outer layer of subepithelial connective tissue (= perimatrix) producing proteolytic enzymes → bone resorption
√ NO enhancement
• pearly white lesion diagnosed otoscopically in 95%
Cx: (1) Infection → malodorous discharge
(2) Erosion of ossicular chain, scutum, mastoid bone, Körner septum

DDx of soft-tissue attenuation:
(1) Fluid attenuation of chronic otitis media
(2) Inflammation / infection (NO restricted diffusion)

Primary Cholesteatoma (2%)

= CONGENITAL CHOLESTEATOMA = EPIDERMOID CYST
= derived from aberrant embryonic ectodermal rests in temporal bone (commonly petrous apex) / epidural space / meninges
• conductive hearing loss (hypoacusis) in child with NO history of otorrhea, membrane perforation, otologic procedure
• cholesteatoma seen through intact tympanic membrane (usually difficult due to stenosis of EAC)
Associated with: dysplasia / atresia / stenosis of EAC /middle ear cavity
Location:

(a) epitympanum (commonly in anterior superior quadrant of middle ear cavity just above opening of eustachian tube)
(b) petrous pyramid: internal auditory canal first involved
(c) meninges: scooped out appearance of petrous ridge
(d) cerebellopontine angle: erosion of porus, shortening of posterior canal wall
(e) jugular fossa: erosion of posteroinferior aspect of petrous pyramid

Cx: facial palsy, mastoiditis, intracranial disease

Secondary Cholesteatoma (98%)

= INFLAMMATORY CHOLESTEATOMA = ACQUIRED EPIDERMOID

Pathophysiology:

(a) invagination theory = eustachian tube dysfunction → vacuum phenomenon in middle ear cavity → formation of posterosuperior retraction pocket in pars flaccida → repeated episodes of ear inflammation (= chronic otitis media)
(b) epithelial invasion theory = marginal perforation of eardrum → ingrowth of keratinizing stratified squamous epithelium

Location: middle ear cavity

Age: usually > 40 years

- chronic foul-smelling otorrhea
- facial paralysis ← compression of nerve VII at geniculate ganglion
- conductive hearing loss ← compromise of CN VIII in internal auditory canal / involvement of cochlea or labyrinth
- severe vertigo (labyrinthine fistula)

Type:

1. **Pars flaccida cholesteatoma** (80%)
   = PRIMARY ACQUIRED CHOLESTEATOMA
   = **Attic cholesteatoma**
   Site: centered in Prussak space (pars flaccida invaginates toward Prussak space)
   √ rounded expansile lobulated lesion
   √ increasing width of attic
   √ initially destruction of lateral wall of attic, particularly erosion of drum spur (scutum)
   √ medial displacement + erosion of auditory ossicles
   √ extension superiorly into attic + mastoid air cells through aditus ad antrum
   √ destruction of Körner septum
2. **Pars tensa cholesteatoma** (20%)
   = SECONDARY ACQUIRED CHOLESTEATOMA
   Site: centered in sinus tympani / facial recess
   √ lateral displacement of auditory ossicles
   √ erosion of ossicular chain: first affecting long process of incus

CT:

√ nondependent homogeneous mass
√ perforation of tympanic membrane posterosuperiorly (= pars flaccida)
√ poorly pneumatized mastoid (frequent association)
√ erosion of tegmen tympani (with more extensive cholesteatoma) → extradural mass ±

formation of meningoencephalocele
√ destruction of labyrinthine capsule (less common) involving the lateral semicircular canal first → labyrinthine / perilymphatic fistula
√ erosion of bony facial canal in its tympanic / mastoid pars

MR (adjunct to CT ONLY if doubt in diagnosis):
√ iso- / hypointense relative to cortex on T1WI
CAVE: occasional T1-hyperintensity similar to "white" epidermoid cyst ← high protein content
√ mildly hyperintense lesion on T2WI + FLAIR
√ restricted diffusion (highly hyperintense) on DWI ← high keratin content
FN: mural / evacuated cholesteatoma, lesion < 2–3 mm
FP: residual hemorrhage after recent surgery; silastic sheet; bone pâté; cerumen in EAC; cholesterol granuloma; artifact ← dental brace; middle ear / mastoid abscess
√ relatively hypointense ADC map (DDx: cholesterol granuloma very hyperintense)
√ NO delayed enhancement 45–60 min after Gd-DTPA (DDx: cholesterol granuloma enhances ← inflammatory / granulation / scar tissue)

Cx: (1) Intratemporal: ossicular destruction; facial nerve paralysis (1%); labyrinthine fistula; automastoidectomy; complete hearing loss
(2) Intracranial: meningitis; cerebritis; subdural / epidural empyema; temporal lobe abscess; sigmoid sinus thrombosis; CSF rhinorrhea

Rx: canal-wall-down / canal-wall-up tympanoplasty with recurrence rates of 7% and 20%, respectively

DDx: chronic otitis media; granulation tissue (= cholesterol granuloma); brain herniation through tegmen defect; neoplasm (rhabdomyosarcoma, squamous cell carcinoma)

Cholesteatoma of External Auditory Canal

Incidence: 0.1–0.5%
Cause: spontaneous (most), prior trauma, surgery, radiation
Path: local invasion of EAC by squamous epithelial lining into underlying bone → periostitis, canal wall erosion
Age: older age group
• chronic dull pain, otorrhea

CT:
√ focal soft-tissue within EAC (typically inferior wall)
√ canal wall erosion into underlying bone

DDx: carcinoma, otitis externa

CHOLESTEROL GRANULOMA

= CHOLESTEROL CYST
= acquired benign chronic inflammatory mass in petrous bone
◊ Most common lesion arising in petrous apex!

Pathophysiology:
mucosal edema → exposure of bone marrow → hemorrhage + obstruction → breakdown of

erythrocytes + tissue → release of cholesterol → foreign body giant cell reaction (= chronic granuloma) → cyst formation + bone expansion

Histo: cholesterol crystals surrounded by foreign-body giant cells; embedded in fibrous connective tissue with varying proportions of hemosiderin-laden macrophages, chronic inflammatory cells and blood vessels; brownish cyst fluid contains cholesterol crystals + blood (= **"chocolate cyst"** = **"blue-domed cyst"**)

Location: in pneumatized petrous apex; (occasionally in)mastoid segment, middle ear, orbitofrontal region

- blue (vascular) tympanic membrane without pulsatile tinnitus
- hemotympanum; conductive hearing loss, headache
- long-standing history of otitis media

√ bone gaps ← bone remodeling
√ ossicles remain intact
√ NO enhancement

CT:
√ expansile homogeneous middle ear lesion with smooth well-defined / imperceptible bone margins
√ nonenhancing mass

MR:
√ hyperintense signal on T1WI ← methemoglobin
√ heterogeneously hyperintense signal on T2WI ← cholesterol crystals + methemoglobin from repeated hemorrhage
√ remains hyperintense with fat-suppression
√ ± hypointense rim on T2WI ← hemosiderin deposition / preserved rim of bone

DDx: (1) Asymmetric petrous apex pneumatization (hyperintense fatty marrow on T1WI, hypointense with fat suppression)
(2) Petrous apex effusion (no expansion / destruction of petrous air cells)
(3) Cholesteatoma (isointense to brain on T1WI)

Rx: conservative Rx for asymptomatic lesion; surgical drainage / cyst resection for large symptomatic lesion
◊ Loss of T1-hyperintensity after successful drainage!

CHRONIC SIALADENITIS

- often painful intermittent swelling of gland

√ normal-sized / small hypoechoic heterogeneous texture
√ multiple small round / oval hypoechoic areas

Chronic Sclerosing Sialadenitis

= KÜTTNER TUMOR = IgG4-RELATED SIALADENITIS
[Hermann Küttner (1870–1932), German surgeon in Breslau]
= non-neoplastic uni / bilateral hard swelling of submandibular gland considered part of IgG4-related disease

Histo: markedly fibrous sclerotic lesion containing IgG4-positive plasma cells

√ diffuse / focal swelling of both submandibular glands

US:
√ multiple small hypoechoic foci scattered on a heterogeneous background of salivary tissue
CT:
√ homogeneous attenuation
MR:
√ low to intermediate SI on T2WI
√ intermediate SI on T1WI + homogeneous enhancement
DDx: lymphoma, acute Sjögren syndrome

Granulomatous Sialadenitis

Organism: TB, actinomycosis
√ single / multiple hypoechoic areas in enlarged / normal-sized gland of diffusely low echogenicity
√ ± increased blood flow

COGAN SYNDROME

= AUTOIMMUNE INTERSTITIAL KERATITIS
= rare autoimmune multisystem disease characterized by nonsyphilitic interstitial keratitis + audiovestibular dysfunction + vascular inflammation
Age: young white adult
• eye redness. photophobia, eye pain (from interstitial keratitis)
• audiovestibular manifestations (similar to Ménière syndrome)
• nerve deafness
@ Cardiovascular (10–15%%)
Histo: prominent lymphocytic infiltration of aortic wall, destruction of media elastica, fibrosis, aneurysm formation, neovascularization
√ aortitis → aortic insufficiency
√ necrotizing vasculitis → coronary / iliac / renal artery stenosis
@ CNS (29%)
• psychosis, headache, convulsion, stroke, coma
√ ischemic change or infarction, meningoencephalitis, cerebral venous sinus thrombosis, cranial neuropathy
MR:
√ membranous labyrinthine obliteration / narrowing
√ enhancement of membranous labyrinth

CONGENITAL ATRESIA OF EAC

= failure of EAC to fully develop
Prevalence: ~ 1÷10,000
Often associated with: abnormalities of pinna
Classification: osseous / membranous / mixed
Location: unilateral > bilateral
Imaging assessment:

(1) Size + pneumatization of middle ear
(2) Abnormalities of ossicles
(3) Location of mastoid segment of facial nerve (often displaced anteriorly)

CROUP

= ACUTE LARYNGOTRACHEOBRONCHITIS = ACUTE VIRAL SPASMODIC LARYNGITIS
= lower respiratory tract infection
◊ Most common cause of airway obstruction in young children!
Organism: parainfluenza, respiratory syncytial virus
Season: fall and winter months
Age: > 6 months of age; peak incidence 2–3 years
• prodromal symptoms of viral infection
• "brassy / barking" cough → worse at night and while crying
• inspiratory difficulty with stridor, fever, hoarse cry
√ thickening of vocal cords
√ distension of cervical trachea on expiration
AP radiograph (most helpful image):
√ "**steeple**" / subglottic "inverted V" sign = symmetrical funnel-shaped narrowing 1–1.5 cm below lower margins of pyriform sinuses (= loss of lateral convexities / normal "shouldering" of air column)
Cause: subglottic mucosal edema affecting most severely the conus elasticus + external restriction by cricoid
√ accentuated on expiration
√ paradoxical inspiratory collapse → less pronounced during expiration
LAT radiograph:
√ NORMAL epiglottis + aryepiglottic folds (→ NO epiglottitis)
√ subglottic narrowing + increased density of subglottic region
√ narrow + indistinct subglottic trachea
√ inspiratory ballooning of hypopharynx (= nonspecific sign of any acute upper airway obstruction)
DDx: normal at end of inspiratory phase in a crying child

With clinically suspected croup imaging is performed to determine if another cause of inspiratory stridor is present.
Viral croup is unlikely to occur in children > 3 years of age. With radiographic findings of croup outside this age range, consider membranous croup and foreign-body aspiration.

Prognosis: usually self-limiting
Rx: supportive

DERMOID / EPIDERMOID OF HEAD AND NECK

= benign congenital or acquired (eg, posttraumatic) inclusions of dermal elements at site of embryonic 1st + 2nd branchial arches
◊ Dermoids of the head and neck comprise 7% of all dermoids
Definition:

Teratoma = neoplasm whose tissue is foreign to the part of the body from which the tumor arises

Teratoid cyst

Origin: ectoderm + mesoderm + endoderm

Histo: inclusion cyst lined by squamous / respiratory epithelium containing derivatives of ectoderm + endoderm + mesoderm (skin appendages, nervous / GI / respiratory tissue)

Dermoid cyst

Origin: ONLY ectoderm = epidermis + dermal substructure of subcutaneous tissue + skin appendages (= annexa consisting of hair follicles, sebaceous glands, sweat glands)

Histo: inclusion cyst lined by a thick keratinizing squamous epithelium containing a variable number of skin appendages ± dystrophic calcifications; lumen filled with keratin + sebaceous material + hair (occasionally)

Path: cheesy tumor, fat content often collects in globules

√ greater signal heterogeneity ← combination of solid and cystic elements

√ intralesional fat = DISTINGUISHING feature:

√ "sack-of-marbles appearance" = globules of coalesced fat (nearly PATHOGNOMONIC)

Epidermoid cyst

Origin: ONLY epithelial elements WITHOUT skin appendages

Histo: inclusion cyst lined by thin simple squamous epithelium ± calcifications (rarely); lumen filled with debris of keratin and some cholesterol

Path: "pearly tumor" = shiny smooth waxy character

√ usually lacks observable solid components

√ ± CHARACTERISTIC restriction at DWI (= high diffusion + moderately low apparent diffusion coefficient)

Mean age: 30 years (range, 5–50 years); M÷F = 3÷1

Location:

(1) Periorbital (50%): lateral eyebrow (most common)
(2) Oral cavity (25%): floor of mouth (12%), root of tongue
(3) Nasal cavity (13%)
(4) Submental: neck

√ well-circumscribed lesions of high T2 signal

√ NO / only rim enhancement

Nasal Dermoid

= dermal inclusion in cranium through patent suture

Age: infants (most common)

Associated with: craniofacial malformation (in 41%)

Location: anywhere between *glabella* (= depressed space between eyebrows above nose) and *columella* (= fleshy external part of nasal septum); lower third of bridge of nose (most commonly)

- nasal pit (skin dimple) / fistula / fluctuant swelling
- hair protruding from cyst / sinus tract (< 50%)

√ bone defect in cranium (= dermal sinus)
MR:
√ variable nonspecific appearance of sinus ± cyst
Cx: infection with abscess in nasal septum
DDx: normal fat in crista galli / nasal septum

Cervical Dermoid / Epidermoid Cyst

Age: 2nd–3rd decades; M = F
• slowly growing soft mobile mass in the suprahyoid midline (no movement with tongue protrusion!)
Site: (a) sublingual space (superior to mylohyoid muscle) = intraoral surgical approach (more frequent)
Type: frequently epidermoid cyst
(b) submandibular (inferior to mylohyoid muscle) = external surgical approach
Type: frequently dermoid cyst
Size: few mm – up to 12 cm
√ thin-walled unilocular mass
CT:
√ homogeneous fluid material of 0–18 HU
√ heterogeneous mass ← various germinal components
√ fluid-fluid level ← supernatant lipid
√ rim enhancement frequent
MR:
√ hypointense / hyperintense (sebaceous fluid) / isointense relative to muscle on T1WI
√ hyperintense on T2WI + internally heterogeneous
Prognosis: malignant degeneration into squamous cell carcinoma in 5%
DDx: ranula

DISSECTION OF CERVICOCEPHALIC ARTERIES

= CRANIOCERVICAL ARTERIAL DISSECTION
= hematoma within media splitting off vessel wall → false lumen within media
Incidence: 5÷100,000 per year; responsible for 5–20% of strokes in young and middle-aged adult
Etiology:
A. SPONTANEOUS
(1) trivial trauma (frequent): nonrecalled minor trauma like coughing, vomiting, sports (bowling, tennis, archery)
(2) primary arteriopathy (rare): fibromuscular dysplasia (in 15%), Marfan syndrome, Ehlers-Danlos syndrome type IV, autosomal dominant polycystic kidney disease, osteogenesis imperfecta type I, cystic medial necrosis, collagen vascular disease, homocystinuria
Indirect evidence of arteriopathy:
intracranial aneurysm, widened aortic root, arterial redundancy
Associated with: hypertension (36%), smoking (47%), migraine (11%)
B. TRAUMATIC (rare)

severe blunt head and neck trauma / penetrating trauma (automobile accident, boxing, accidental hanging, diagnostic carotid compression, chiropractic cervical manipulation)

Arteriographic Injury Grading	
Grade	*Type of Lesion*
I	√ irregularity of vessel wall √ dissecting intramural hematoma with < 25% stenosis
II	√ intraluminal thrombus / raised intimal flap √ small arteriovenous fistula √ dissection / intramural hematoma ≥ 25% stenosis
III	√ pseudoaneurysm
IV	√ occlusion
V	√ transection √ hemodynamically significant AV fistula

Pathophysiology:

primary intramural hematoma / penetration of blood into arterial wall via primary intimal tear → dissection usually extends cranially (same direction as blood stream) → narrowing of vessel lumen + enlargement of external diameter → pseudoaneurysm = dissecting aneurysm (with extension of hematoma into adventitia) → nidus for distal thromboembolism

Location: cervical ICA (68%), vertebral artery (27%), both ICA + vertebral artery (5%); multiple simultaneous dissections (28%)

Site: (a) subintimal dissection = close to intima
(b) subadventitial dissection = close to adventitia

√ arterial narrowing / occlusion
√ intimal flap
√ pseudoaneurysm
√ embolic distal branch occlusion of intracranial artery

US (low sensitivity due to location, 50% accuracy):
- √ wall hematoma = thickened hypoechoic vessel wall (DDx: intraluminal thrombus)
- √ echogenic intimal flap floating in lumen (rarely depicted)
- √ echogenic thrombus

Color Doppler (71–95% sensitive):
- √ separation of 2 lumina with different Doppler signals
- √ dampened / high-resistance Doppler waveform

DDx of increased ICA flow:

ICA redundancy, fibromuscular dysplasia, vasospasm, brain AVM, carotid cavernous sinus fistula, persistent trigeminal artery, anemia, hyperthyroidism

DDx of decreased ICA flow:

ipsilateral severe stenosis / occlusion of carotid siphon or intracranial ICA or M1 segment

NECT:
- √ crescent-shaped hyperattenuating acute wall hematoma

CECT (50–100% sensitive, 67–100% specific):
- √ target picture = narrow eccentric lumen surrounded by crescent-shaped mural thickening +

peripheral thin annular enhancement (enhancing vasa vasorum)
√ increase in external diameter
√ intramural hematoma becomes isoattenuating to muscle with correct window settings (DDx: atherosclerotic plaque, thrombus)
√ intimal flap
√ dissecting aneurysm
√ arterial occlusion

MR (50–100% sensitive, 58–99% specific):
√ cross-sectional T1WI imaging ± fat saturation:
√ increase in external diameter of artery
√ narrowing of lumen
√ intramural hematoma:
√ isointense to surrounding structures during early / chronic stage
√ crescent-shaped hyperintense hematoma around eccentric flow void between 7 days and 2 months
√ iso- to hyperintense on T2WI around flow void of artery

3-D TOF MR angiography:
√ pseudoenlargement of lumen in subacute dissection = flow-simulating intramural hematoma

DDx: pseudodissection (= high SI of turbulent flow in aneurysmal dilatation)

Rx: best therapy not clear; anticoagulation (primary treatment) in absence of subarachnoid hemorrhage / dissecting aneurysm; surgery; endovascular stent placement

Carotid Artery Dissection

◊ Twice as common as vertebral artery dissection!

Frequency: 2–5–20% of strokes in persons aged 40–60 years

Age: 18–76 years (66% between 35 and 50 years)

• unremitting unilateral anterior headache (47–86%), neck pain (25%), facial pain
• TIA / stroke (49–82%), amaurosis fugax (12%):
• completed stroke usually during first 7 days after onset of symptoms, may occur up to 1 month later
• oculosympathetic paresis = Horner syndrome (52%)
• cranial nerve palsy, bruit (48%), pulsatile tinnitus

Location: cervical ICA usually at level of C1-2 (60%) within a few cm of carotid bifurcation > supraclinoid segment of ICA; bilateral carotid dissections (15%)

Length: a few centimeters

Angiography / DSA (gold standard):
√ "string" sign = long tapered usually eccentric irregular luminal stenosis beginning distal to carotid bulb + extending to base of skull (76%)
√ "string and pearl" sign = focal narrowing + distal site of dilatation
√ abrupt luminal reconstitution at level of bony carotid canal (42%)
√ fingerlike / saccular aneurysm (40%), often in upper cervical / subcranial region
√ intimal flap (29%)
√ double-barrel lumen similar to aortic dissection (rare)
√ slow ICA-MCA flow

√ tapered "flamelike" / "radish taillike" occlusion (17%) that spares the carotid bulb

Cx: (1) Thromboemboli due to stenosis
(2) Subarachnoid hemorrhage (with intracranial location)
(3) Secondary aneurysm

Prognosis: complete / excellent recovery (8%) with normalization in a few months; worsening in 10%

DDx:
(1) Fibromuscular dysplasia ("string of beads" sign, young woman, adjacent to C1-2, bilateral in 65%)
(2) Dysgenesis of ICA (hypoplastic / absent carotid canal)
(3) Atherosclerosis (carotid bifurcation + bulb)
(4) Radiation treatment (circumferential wall thickening in radiation field)
(5) Takayasu arteritis (long-segment wall thickening of aorta + side branches on both sides, young woman, common in Asia + Mexico)
(6) Giant cell (temporal) arteritis (extradural carotid siphon most severely affected, > 50 years of age)
(7) Behçet disease

Vertebral Artery Dissection

= hemorrhage into wall of vertebral artery

Prevalence: unknown; up to 15% of strokes in young adults

- headache: occipital (> 50%), frontal (20%), orbital (20%)
- neck pain (30%), ischemia of posterior circulation (57–84%)
- ischemia of cervical spinal cord, cervical root impairment

Location: in pars transversaria at level of C1/2 = V_2 (35%); atlas loop = V_3 (34%); bilateral vertebral artery dissections (5%); site of direct trauma

CT:
√ subarachnoid hemorrhage ← rupture of adventitia

MR (modality of choice):
√ decreased arterial lumen
√ diminished flow void
√ periarterial rim SI changes with time (hemoglobin)

Angio:
√ tapering of artery / intimal flap / complete occlusion

Cx: stroke (in up to 95%) after hours / weeks

Prognosis: full recovery with some residual deficit (88%); recurrence within 4–6 weeks involving multiple cervical arteries in sequence

EPIGLOTTITIS

= ACUTE BACTERIAL EPIGLOTTITIS= SUPRAGLOTTITIS

= life-threatening infection characterized by edema of supraglottic structures (= epiglottis + aryepiglottic folds)
[*glottis*, Greek = mouth of windpipe ↔ *glotta / glossa* = tongue]

Cause:

(a) infectious

Organism: Haemophilus influenzae type B, Pneumococcus, Streptococcus group A

◊ Less prevalent since introduction of vaccine against H. influenzae!

(b) noninfectious: angioedema, trauma, ingestion of caustic agent, anaphylaxis

Peak age: formerly 6 (range, 1–5) years; now more prevalent among adults + children of > 15 years

- toxic appearance, high fever, posturing with neck extension
- abrupt onset of inspiratory stridor + respiratory distress
- sore throat, drooling, severe dysphagia

Location: purely supraglottic lesion; associated subglottic edema in 25%

Lateral radiograph (preferred modality, frontal view irrelevant):

◊ Radiograph should be taken in erect position only!

√ "thumb" sign = bulbous thickening of epiglottis

√ thickening of aryepiglottic folds

√ circumferential narrowing of subglottic portion of trachea during inspiration

√ ± supraglottitis = additional swelling of supraglottic larynx

√ ballooning of hypopharynx + pyriform sinuses

√ cervical kyphosis

CT (NOT recommended in acute setting):

√ enlarged edematous epiglottis with mucosal enhancement

√ edema of entire supraglottic larynx + tongue base + tonsils

√ phlegmonous collection in adjacent soft tissues

Cx: necrotizing epiglottitis, deep neck abscess (4–25%)

Prognosis: in children mortal danger of suffocation ← hazard of complete airway closure; patient needs to be accompanied by physician experienced in endotracheal intubation

Rx: broad-spectrum antibiotics, steroids, direct laryngoscopy, emergent intubation (in children) may be required

EXTERNAL AUDITORY CANAL DYSPLASIA

Frequency: 1÷10,000 births; family history in 14%

Etiology:

(a) isolated
(b) Trisomy 13, 18, 21
(c) Turner syndrome
(d) maternal rubella
(e) craniofacial dysostosis
(f) mandibulofacial dysostosis

Spectrum:

1. Stenosis of EAC
2. Fibrous atresia of EAC
3. Bony atresia (in position of tympanic membrane)
4. Decreased pneumatization of mastoid (mastoid cells begin to form in 7th fetal month)
5. Decreased size / absence of tympanic cavity
6. Ossicular changes (rotation, fusion, absence)

7. Ectopic facial nerve = anteriorly displaced vertical (mastoid) portion of facial nerve canal
8. Decrease in number of cochlear turns / absence of cochlea
9. Dilatation of lateral semicircular canal

Location: bilateral in 29%; M÷F = 6÷4

• pinna deformity; stenotic / absent auditory canal

Cx: congenital cholesteatoma (infrequent)

EXTRACARDIAC RHABDOMYOMA

= benign tumor consisting of immature striated muscle cells

Location: 70%–90% in head & neck

1. **Adult** rhabdomyoma
   Age: 5th decade; M > F
   Location: larynx, pharynx, oral cavity
   Size: large ← slow rate of growth
2. **Fetal** rhabdomyoma
   Median age: 4 years; M > F
   Location: subcutaneous tissue with a particular predilection for postauricular region

√ signal intensity similar to muscle on T1WI and T2WI

√ usually enhancement after contrast administration

EXTRAMEDULLARY PLASMACYTOMA

= EXTRAOSSEOUS PLASMACYTOMA

Uncommon form of plasmacytoma (3–4%); questionable if precursor to multiple myeloma

Age: 40–60 years; M÷F = 2÷1

Location: air passages (50%) predominantly in upper nose and oral cavity; larynx; conjunctiva (37%); lymph nodes (3%); perirenal

• usually not associated with increased immunoglobulin titer or amyloid deposition

√ mass of one to several cm in size with well-defined lobulated border

Classification:

A. OSSEOUS
   1. Medullary plasmacytoma
   2. Multiple myeloma:
      (a) scattered involvement of bone
      (b) myelomatosis of bone

B. EXTRAOSSEOUS
   3. Extramedullary plasmacytoma

Dx: requires exclusion of multiple myeloma by:

› bone marrow biopsy with normal results
› normal plasma electrophoresis
› negative skeletal survey
› negative bone marrow imaging with MR

Prognosis: relatively benign course (dissemination may be found months / years later or not at all); better than solitary bone plasmacytoma; progression to multiple myeloma in 50%

DDx:

(1) MULTIPLE MYELOMA
= malignant course with soft-tissue involvement in 50–73%:
(a) microscopic infiltration
(b) enlargement of organs
(c) formation of tumor mass (⅓)
• usually associated with protein abnormalities
• may have amyloid deposition
Age incidence: 50–85 years
◊ Extramedullary plasmacytoma tends to occur late in the course of multiple myeloma → indicates a poor prognosis (0–6% 5-year survival)

FIBROMATOSIS COLLI

= PSEUDOTUMOR OF INFANCY = STERNOCLEIDOMASTOID TUMOR OF INFANCY = CONGENITAL MUSCULAR TORTICOLLIS
= rare form of benign self-limiting benign fibrous mass within sternocleidomastoid muscle associated with torticollis in neonates and infants
Prevalence: 0.4% of live births
Cause: in > 60–90% associated with birth trauma during difficult breech / forceps delivery; positive family history (11%)
Path: compartment syndrome with pressure necrosis + secondary fibrosis of sternocleidomastoid m.
Histo: myoblasts + fibroblasts + myofibroblasts in various stages of differentiation
Associated congenital abnormalities:
developmental hip dysplasia, rib anomalies, talipes equinovarus (clubfoot), thoracic scoliosis, metatarsus adductus, mental retardation, seizure disorder
Associated skeletal abnormalities:
ipsilateral lateral mandibular asymmetry, cervicothoracic scoliosis, facial deformity, ipsilateral mastoid process hypertrophy, ipsilateral elevation of clavicle / shoulder
Age: 2nd to 4th week of life; M > F
• unilateral firm soft-tissue mass in mid to lower ⅓ of sternocleidomastoid muscle; typically unaffected at birth; enlarging neck mass over the course of 2–6 weeks
• torticollis (14–30%) tilting toward lesion ← muscle contraction
Location: lower ⅓ of sternocleidomastoid muscle affecting sternal + clavicular heads of the muscle; usually unilateral (R > L)
Average size: 1–3 cm
√ focal / diffuse enlargement of sternocleidomastoid muscle
√ NO extramuscular extension / associated soft tissue abnormality
√ mild mass effect on surrounding structures
X-ray (NOT indicated):
√ normal in 98%
√ lytic lesion in clavicular head at insertion of sternocleidomastoid muscle
US:
√ unilateral diffuse fusiform homogeneous expansion of sternocleidomastoid muscle
√ well- / ill-defined focal mass within muscle:

√ homogeneous echotexture (51%)
√ hypo- to iso- to hyperechoic depending on duration
√ mass moves synchronously with muscle at real-time

MR:

Indication: atypical sonographic features, NO resolution within 12 months

√ isointense lesion to normal muscle on T1WI
√ hyperintense lesion relative to normal muscle on T2WI
√ subtle patchy and linear areas of decreased signal intensity
√ heterogeneous enhancement

CT:

√ focal / diffuse homogeneous enlargement isoattenuating to other muscle

Prognosis: gradual spontaneous regression over 2–3 months; spontaneous resolution during next 4–8 months in 90% with / without treatment

Rx: (1) Muscle stretching exercise
(2) Surgery in 10%

DDx: (1) Neuroblastoma (heterogeneous solid mass with calcifications)
(2) Rhabdomyosarcoma
(3) Lymphoma (well-defined round /oval masses along cervical lymph node chain)
(4) Cystic hygroma (anechoic region with septations)
(5) Branchial cleft cyst
(6) Hematoma

EXTRASKELETAL FIBROSARCOMA

= malignant tumor of fibroblasts of classic herringbone-like architecture

Prevalence: 1–3% of sarcomas in adults; 11–12% of sarcomas in infants

May be associated with: prior irradiation of head & neck

Age: 40 –70 years; M÷F = 3÷2

• painful / painless enlarging mass

Subtypes: storiform-pleomorphic (50–60%), myxoid (25%), giant cell (5–10%), inflammatory (5%)

Location: sinonasal cavity, larynx, neck

MR:

√ heterogeneous mass of predominantly low signal intensity with variable enhancement on T1WI
√ heterogeneous high signal intensity on T2WI

Prognosis: infantile extraskeletal fibrosarcoma better than adult fibrosarcoma

GENICULATE HEMANGIOMA

= venous malformation in region of facial nerve

Site: geniculate ganglion > IAC > posterior genu

CT:

√ expansile honeycomb appearance
√ intratumoral bone spicules

√ bone forming / growth among bone trabeculae (= **ossifying hemangioma**)

MRI:

√ mass of heterogeneous signal intensity

√ avid enhancement

DDx: meningioma with intraosseous involvement

GLOMUS TUMOR

◊ Distinct from head & neck paragangliomas!

= composed of cells closely resembling modified smooth muscle cells of glomus bodies of dermis

Prevalence: < 2% of all soft tissue tumors

Location: distal extremities, head & neck (15–30%)

Sinonasal Glomus Tumor (5%)

= GLOMANGIOPERICYTOMA = SINONASAL-TYPE HEMANGIOPERICYTOMA

Origin: modified perivascular glomuslike myoid cells in nasal cavity + paranasal sinuses

Path: well-delineated unencapsulated cellular tumors

Histo: closely packed cells (= high cellularity) forming short fascicles, sometimes exhibiting storiform / whorled / palisaded patterns with multiple interspersed vascular channels of staghorn configuration; NO hemorrhage, NO necrosis

Peak age: 7th decade; M = F

- nasal obstruction / congestion, epistaxis
- difficulty breathing, sinusitis, headache

Site: nasal cavity

CT:

√ soft tissue mass with strong enhancement

√ extension into orbits + intracranial compartment and destruction of adjacent bone (if large)

MR:

√ tumor isointense relative to muscle on T1WI

√ hypo- to isointense relative to muscle on T2WI

√ variable degrees of (usually marked) enhancement

Prognosis: low tendency for metastasis (5%)

GOITER

[*gutteria*, Latin = throat]

Definition: visible enlargement of thyroid gland

Volume definition: > 18 mL for women; > 25 mL for men

Clinical classification:

Class I:	palpable but not visible in normal posture of head
Class II:	palpable and easily visible
Class III:	very large + retrosternal with compression marks

Adenomatous Goiter

= MULTINODULAR GOITER

US: (89% sensitive, 84% specific, 73% positive predictive value, 94% negative predictive value)

√ increased size + asymmetry of gland

√ multiple 1–4-cm solid nodules

√ areas of hemorrhage + necrosis

√ coarse calcifications may occur within adenoma ← hemorrhage + necrosis

Cx: compression of trachea

Diffuse Goiter

US:

√ increase in glandular size, R lobe > L lobe

√ NO focal textural changes

√ calcifications not associated with nodules

Iodine-deficiency Goiter

Not a significant problem in USA because of supplemental iodine in food

Etiology: chronic TSH stimulation

• low serum T4

√ high ^{131}I uptake

Jod-Basedow Phenomenon *(2%)*

= development of thyrotoxicosis (= excessive amounts of T_4 synthesized + released) if normal dietary intake is resumed / iodinated contrast medium administered

Frequency: most common in individuals with long-standing multinodular goiter

Age: > 50 years

√ multinodular goiter with in- / decreased uptake (depending on iodine pool)

Toxic Nodular Goiter

= PLUMMER DISEASE

= autonomous function of one / more thyroid adenomas

Peak age: 4th–5th decade; M÷F = 1÷3

• elevated T_4, suppressed TSH

√ nodular thyroid with hot nodule + suppression of remainder of gland

√ stimulation scan will disclose normal uptake in remainder of gland

√ ~ 80% increased radioiodine uptake by 24 hours

Rx: (1) ^{131}I treatment with empirical dose of 25–29 mCi → hypothyroidism in 5–30%

(2) Surgery → hypothyroidism in 11%

(3) Percutaneous ethanol injection → hypothyroidism in < 1%, → transient damage of recurrent laryngeal nerve in 4%

Intrathoracic Goiter

= extension of cervical thyroid tissue / ectopic thyroid tissue (rare) into mediastinum

Frequency: 5% of resected mediastinal masses; most common cause of mediastinal masses;

2% of all goiters

- mostly asymptomatic
- symptoms of tracheal + esophageal + recurrent laryngeal nerve compression

Location:

(a) retrosternal (80%) in front of trachea

(b) posterior descending (20%) = behind trachea but in front of esophagus, caudal extent limited by arch of azygos vein, exclusively on right side of trachea

√ continuity with cervical thyroid / lack of continuity (with narrow fibrous / vascular pedicle)

√ frequent focal calcifications

CT:

√ mass of high HU + well-defined margins

√ inhomogeneous texture with low-density areas (= degenerative cystic areas)

√ marked + prolonged enhancement

GRAVES DISEASE

= DIFFUSE TOXIC GOITER

= autoimmune disorder antibodies binding to TSH receptors (LATS) with inhibitory + stimulatory effects producing hyperplasia + hypertrophy of thyroid gland

Prevalence: 5÷10,000; most common form of hyperthyroidism (60–80%)

Peak age: 3rd–4th decade; M÷F = 1÷7

- ↑ T_3 and T_4, ↓ TSH production
- elevated levels of thyroid-peroxidase antibodies (75%)
- positive thyroid stimulating immunoglobulins
- **ophthalmopathy** (50%) = periorbital edema, lid retraction, ophthalmoplegia, proptosis, malignant exophthalmos
- **dermopathy** = pretibial myxedema (5%)
- **acropachy** = bulbous swelling of hands + feet (rare)

√ diffuse thyroid enlargement

√ gland may be normal in size in early stage

√ uniformly increased uptake

√ incidental nodules superimposed on preexisting adenomatous goiter (5%)

US: (identical to diffuse goiter)

√ global enlargement of 2–3 times the normal size

√ normal / diffusely hypoechoic pattern

√ "thyroid inferno" = diffuse hyperemia on color Doppler

Rx: ^{131}I treatments (for adults):

Dose: 80–120 μCi/g of gland with 100% uptake (taking into account estimated weight of gland + measured radioactive iodine uptake for 24 hours)

Cx: 10–30% develop hypothyroidism within 1st year + 3% per year rate thereafter

HYPOPHARYNGEAL CARCINOMA

Histo: squamous cell carcinoma (95%)

Metastases: common (50–75%) due to rich lymphatic drainage

May be associated with:

Plummer-Vinson syndrome (= atrophic mucosa of tongue, achlorhydria, sideropenic anemia) affecting women in 90%

- sore throat, intolerance to hot / cold liquids (early signs)
- dysphagia, weight loss (late signs)
- cervical adenopathy (in 50% at presentation)

Stage:

T1 tumor limited to one subsite of hypopharynx ≤ 2 cm

T2 tumor involves > 1 subsite / adjacent site without fixation of hemilarynx measuring 2–4 cm

T3 same as T2 with fixation of hemilarynx > 4 cm in size

T4 invasion of thyroid / cricoid cartilage / hyoid bone / esophagus / strap muscles / SQ fat

Pyriform Sinus Carcinoma (60%)

- may escape clinical detection if located at inferior tip = often cause of "cervical adenopathy with unknown primary" (next to primaries in lingual + faucial tonsils and nasopharynx)

√ invasion of posterior ala of thyroid cartilage, cricothyroid space, soft tissue of neck in T4 lesion

Prognosis: poor ← early soft-tissue invasion

Postcricoid Carcinoma (25%)

√ difficult assessment due to varying thickness of inferior constrictor + prevertebral muscles

Prognosis: 25% 5-year survival (worst prognosis)

Posterior Pharyngeal Wall Carcinoma (15%)

√ invasion of retropharyngeal space with extension into oro- and nasopharynx

√ retropharyngeal adenopathy

Staging of Cervical Nodes in SCC of Head & Neck

N Stage	*Definition*
Nx	cannot assess regional lymph nodes
N0	no regional lymph node metastasis
N1	single ipsilateral node ≤ 3 cm
N2a	single ipsilateral node 3–6 cm
N2b	multiple ipsilateral nodes, each ≤ 6 cm
N2c	bi- / contralateral nodes, each ≤ 6 cm
N3	any nodal mass > 6 cm

IMMUNOGLOBULIN IGG4-RELATED DISEASE

= IGG4-RELATED SCLEROSING DISEASE (ISD) = HYPER-IGG4 DISEASE = MULTIFOCAL FIBROSCLEROSIS

= systemic disease with multiorgan involvement and elevated IgG4 levels

Major diagnostic criteria:

(1) Diffuse / localized swelling / masses in ≥ 1 organ

(2) Elevated serum IgG4 concentrations ≥ 135 mg/dL
(3) Marked lymphoplasmacytic infiltration + storiform fibrosis with organ infiltration by IgG4-positive plasma cells

Multiorgan involvement in IgG4-related disease make whole-body CT, MRI, and PET important diagnostic tools.

Histo: diffuse lymphoplasmacytic infiltration (by T-lymphocytes and plasma cells staining positive for IgG4) + irregular fibrosis + occasional eosinophilic infiltration + obliterative phlebitis

Head and neck are commonly involved in IgG4-related disease, most commonly salivary glands, lacrimal glands, orbits, thyroid gland, lymph nodes, sinonasal cavities, pituitary stalk.

@ Orbit: fibrotic orbital pseudotumor
@ Salivary gland
1. Mikulicz disease
2. Sclerosing sialadenitis (Küttner tumor)

@ Lacrimal gland
1. Inflammatory pseudotumor (IPT)
Location: mostly bilateral symmetric; unilateral lacrimal gland lesions may occur
CT:
√ intermediate soft-tissue attenuation
MR:
√ low T1 signal intensity (= isointense to muscle)
√ homogeneous low to intermediate SI on T2WI ← increased cellularity + fibrosis
2. Lymphoid hyperplasia

@ Thyroid
1. Hashimoto thryoiditis
2. Riedel fibrosing thyroiditis

@ Pituitary gland: hypophysitis
@ Lung: interstitial pneumonia
@ Mediastinum: mediastinal fibrosis
@ Abdomen
1. Autoimmune pancreatitis (most commonly affected organ)
2. Sclerosing cholangitis
3. Sclerosing cholecystitis
4. Sclerosing mesenteritis
5. Retroperitoneal fibrosis (RPF)
6. Prostatitis

INVERTED PAPILLOMA

= INVERTING PAPILLOMA = ENDOPHYTIC PAPILLOMA
= SQUAMOUS CELL PAPILLOMA = TRANSITIONAL CELL PAPILLOMA = CYLINDRICAL EPITHELIOMA
= SCHNEIDERIAN PAPILLOMA

Frequency: 4% of all nasal neoplasms; most common of epithelial papillomas; commonly

occurring after nasal surgery

Cause: unknown; association with human papillomavirus-11

Age: 40–60 years; M÷F = 3–5÷1

Path: vascular mass with prominent mucous cyst inclusions interspersed throughout epithelium

Histo: hyperplastic epithelium inverts into underlying stroma rather than in an exophytic direction; high intracellular glycogen content

◊ Squamous cell carcinoma coexistent in 5.5–27%!

Location: uniquely unilateral (bilateral in < 5%)

(a) most often arising from the lateral nasal wall with extension into ethmoid / maxillary sinuses, at junction of antrum + ethmoid sinuses

(b) paranasal sinus (most frequently maxillary antrum)

(c) nasal septum (5.5–18%)

• unilateral nasal obstruction, epistaxis, postnasal drip, recurrent sinusitis, sinus headache

• distinctive absence of allergic history

√ commonly involves antrum + ethmoid sinus

√ widening of infundibulum / outflow tract of antrum

√ destruction of medial antral wall / lamina papyracea of orbit, anterior cranial fossa (pressure necrosis) in up to 30%

√ septum may be bowed to opposite side (NO invasion)

√ homogeneous enhancement

MR:

√ may have intermediate to low intensity on T2WI (DDx: squamous cell carcinoma, olfactory neuroblastoma, melanoma, small cell carcinoma)

Cx: (1) Cellular atypia / squamous cell carcinoma (10%)

(2) Recurrence rate of 15–78%

Rx: complete surgical extirpation (lateral rhinotomy with en bloc excision of lateral nasal wall)

KERATOSIS OBTURANS

= expansile accumulation of keratin debris within EAC

Age: younger patient < 40 years

• severe pain, conductive hearing loss, (rarely) otorrhea

Associated with: chronic sinusitis, bronchiectasis

Location: usually bilateral process

√ diffuse widening of EAC by epidermal plug

√ ± smooth scalloping of surrounding bone

DDx: EAC cholesteatoma (periostitis, bone erosion)

LABYRINTHITIS

Acute Labyrinthitis

Cause: viral infection (mumps, measles) > bacterial infection > syphilis, autoimmune disease, toxins

• sudden hearing loss, vertigo, tinnitus

MR:
√ faint diffuse enhancement of labyrinth on T1WI (HALLMARK)

Tympanogenic Labyrinthitis
Cause: agent enters through oval / round window in middle ear infection

Meningogenic Labyrinthitis
Cause: agent propagates along IAC / cochlear aqueduct in meningitis
Location: often bilateral

Fibrous Labyrinthitis
= cochlear obstruction

Ramsay-Hunt Syndrome
= HERPES ZOSTER OTICUS
Cause: reactivation of varicella zoster virus latent in geniculate ganglion
Predisposition: immunocompromised, systemic disease, aging
• burning pain in ear, facial paralysis, hearing loss, vertigo
• mucosal vesicles of external auditory canal 1–4 days later
√ enhancement of 7th + 8th nerve, labyrinth ± pontine nucleus

Labyrinthitis Ossificans
= LABYRINTHITIS OBLITERANS = SCLEROSING LABYRINTHITIS = CALCIFIC / OSSIFYING COCHLEITIS
Cause: suppurative infection (tympanogenic, meningogenic, hematogenic) in 90%, trauma, surgery, tumor, severe otosclerosis
◊ Meningitis is the most likely etiology!
Pathophysiology: progressive fibrosis + ossification of granulation tissue within labyrinth
• bi- / unilateral profound deafness
√ loss of normal fluid signal within labyrinth on T2WI (early in course of disease)
√ inner ear structures filled with bone: most common region of cochlear ossification = scala tympani of basal turn

LARYNGEAL CARCINOMA
Frequency: 98% of all malignant laryngeal tumors; 1% of all cancers; 89,081 cases in USA (2013)
Age: 5th / 6th decade of life; M > F
Risk factors: tobacco, alcohol, airborne irritants
◊ High risk to develop 2nd primary malignancy of lung + upper aerodigestive tract (in 8%)
Histo: squamous cell carcinoma (95%)
Negative prognostic factors:
√ nodal involvement
√ invasion of cricoid / thyroid cartilage:
√ tumor within fatty medullary cavity
√ tumor on outer extralaryngeal side of thyroid cartilage

◊ Assessment made difficult by natural asymmetric ossification of thyroid cartilage!

N.B.: Reactive periostitis may lead to sclerosis of cartilage

√ invasion of pre- and paraepiglottic fat (clinically not detectable!)

√ fixation of carotid artery

√ extranodal spread

Suggestive of lymph node metastasis:

√ uptake on PET-CT (50–94% sensitive, 82–100% specific depending on lymph node size)

√ enlarged lymph node:

(a) > 15 mm in cross section for level I / II nodes

(b) > 8 mm in cross section for retropharyngeal node

(c) > 10 mm in greatest dimension for all other node levels

√ round lymph node with loss of reniform shape

√ necrotic lymph node (= central low attenuation)

√ amorphous node with spiculated / indistinct border suggests extracapsular spread

√ proximity to laryngeal mass

√ cluster of > 3 lymph nodes 6–15 mm in size

Distant metastasis (in 5–15%): lung > bone > abdomen

Prognosis: 64% 5-year survival (2013)

Rx: conservative laryngectomy (partial laryngectomy preserving speech + control of aspiration)

Supraglottic Carcinoma (20–30%)

Metastases: early to lymph nodes of deep cervical chain (levels II + III), in 25–55% at time of presentation

• symptomatic late in course of disease (often T3 / T4)

Stage:

T1 tumor confined to one supraglottic subsite

T2 involvement of adjacent supraglottic subsite / glottis without cord fixation

T3 tumor limited to larynx with cord fixation or extension to postcricoid area / medial wall of pyriform sinus / preepiglottic space

T4 extension beyond larynx with involvement of oropharynx (base of tongue) / prevertebral space / encasement of carotid a. / thyroid cartilage

A. ANTERIOR COMPARTMENT

1. **Epiglottic carcinoma**

√ circumferential relatively symmetric growth

√ extension into preepiglottic space ± base of tongue ± paraglottic space

Prognosis: better than for tumors of posterolateral compartment

B. POSTEROLATERAL COMPARTMENT

1. **Aryepiglottic fold (marginal supraglottic) carcinoma**

√ exophytic growth from medial surface of aryepiglottic fold

√ growth into fixed portion of epiglottis + paraglottic (= paralaryngeal) space

2. **False vocal cord / laryngeal ventricle carcinoma**

√ submucosal spread into paraglottic space

√ ± destruction of thyroid cartilage

√ ± involvement of true vocal cords

Prognosis: poorer than for cancer of anterior compartment

Glottic Carcinoma (50–60%)

• early detection due to hoarseness

Metastases: uncommon (< 10%) ← sparse lymphatic drainage to lower deep jugular chain (levels IV + VI)

Stage:

T1 tumor confined to vocal cord with normal mobility

T1a tumor limited to one vocal cord

T1b tumor involving both vocal cords

T2 supra- / subglottic extension + impaired mobility

T3 fixation of true vocal cord ± invasion of paraglottic space ± inner cortex of thyroid cartilage

T4 destruction of thyroid cartilage / extension outside larynx

Patterns of tumor invasion:

(1) Anterior extension into anterior commissure
- √ > 1 mm thickness of anterior commissure
- √ invasion of contralateral vocal cord via anterior commissure
- √ FDG uptake in opposite cord at PET

(2) Posterior extension to arytenoid cartilage, posterior commissure, cricoarytenoid joint

(3) Subglottic extension
- √ tumor > 5 mm inferior to level of vocal cords

(4) Deep lateral extension into paralaryngeal space

Prognosis: T1 carcinoma rarely metastasizes (0–2%) due to absence of lymphatics within true vocal cords

Subglottic Carcinoma (5%)

• late detection due to minimal symptomatology (stridor)

Stage:

T1 confined to subglottis

T2 extension to vocal cords ± impaired mobility

T3 tumor confined to larynx + cord fixation

T4 cartilage destruction / extension beyond larynx

√ any tissue seen on airway side of cricoid cartilage

Prognosis: poor due to early metastases to cervical lymph nodes (in 25% at presentation)

LARYNGEAL CHONDROSARCOMA

◊ The most common sarcoma of the larynx

Age: 50–70 years; M >> F

• lobulated submucosal mass

Location: posterior lamina of cricoid cartilage (50–70%), thyroid cartilage (20–35%)

√ coarse / stippled intratumoral calcifications

√ ± locally invasive
MR:
√ very high SI of tumor matrix on T2WI (= hyaline cartilage)
Rx: function-preserving laryngeal resection (local recurrence may be seen 10 years or more)
DDx: benign chondroma

LARYNGEAL CLEFT

= rare sagittal communication between trachea + esophagus ← lack of separation between laryngotracheal and pharyngoesophagеal systems
Cause: failure of fusion of posterior cricoid lamina
Classification: based on downward extent of cleft (ranging from submucosal interarytenoid cleft to a cleft that extends into thoracic trachea)
• swallowing difficulty, stridor, recurrent pneumonia, weak cry
• clinical suspicion of TE fistula
Associated with other congenital anomalies:
(1) CHARGE syndrome
(2) VACTERL (VATER) association; esophageal atresia; imperforate anus
√ simultaneous barium opacification of esophagus + trachea
Dx: endoscopic visualization

LARYNGEAL CYST

= rare benign pharyngeal cyst of vallecula / vocal cord / epiglottis
Age: any; most common in 6th decade
• dysphonia, airway obstruction, foreign body sensation in throat
Classification: ductal and saccular types
A. Ductal cyst (more common)
Cause: submucosal gland duct obstruction
Involvement of: valleculae, vocal cords, epiglottis
B. Saccular cyst
Cause: mucus retention within laryngeal saccule from obstruction / loss of patency of saccular orifice
√ smoothly hemispheric mass ± distortion of coated surfaces of pharyngeal / laryngeal supraglottic anatomy
DDx: laryngocele, branchial cleft cyst, oncocytic papillary cystadenoma

LARYNGEAL HEMANGIOMA

Histo: cavernous / capillary type
• dark bluish red / pale red compressible swelling on endoscopy
√ strong contrast enhancement
CT:
√ phleboliths (PATHOGNOMONIC for cavernous type)
MR:
√ very high signal intensity on T2WI
DDx: paraganglioma, hypervascular metastasis (renal adenocarcinoma)

Infantile Laryngeal Hemangioma (10%)

= SUBGLOTTIC HEMANGIOMA

◊ Most common subglottic soft-tissue mass causing upper respiratory tract obstruction in neonates

Age: < 6 months; M÷F = 1÷2

• crouplike symptoms (dyspnea, stridor) in neonatal period

• hemangiomas elsewhere (skin, mucosal membranes) in 50%

Location: subglottic region

Neck X-ray:

√ posterolateral subglottic airway narrowing (AP view)

√ eccentric thickening of subglottic portion of trachea (AP view)

√ subtle endoluminal mass arising from posterior wall below true cords (LAT view)

N.B.: CECT required to depict full extent

Rx: tracheostomy (waiting for spontaneous regression)

Adult Laryngeal Hemangioma

Location: supraglottic region (isolated); associated with extensive cervicofacial angiodysplasia

M > F

Rx: laser excision, cryotherapy, selective embolization

LARYNGEAL PAPILLOMATOSIS

= RECURRENT RESPIRATORY PAPILLOMATOSIS

◊ Squamous papilloma is the most common benign tumor of the larynx!

Etiology: human papilloma virus serotypes 6 + 11 (papova virus causing genital condyloma acuminatum)

Histo: core of vascular connective tissue covered by stratified squamous epithelium

Age of onset: 1–54 years; M÷F = 1÷1; bimodal distribution

(a) < 10 years (diffuse involvement) = juvenile laryngotracheal papillomatosis

Cause: transmission from mother to child via birth canal

(b) 21–50 years (usually single papilloma)

• signs of upper respiratory tract obstruction:

  • progressive hoarseness / aphonia, asthmalike symptoms

  • repeated episodes of respiratory distress, inspiratory stridor

• cough, hemoptysis, recurrent pneumonia

Location: (a) uvula, palate

(b) vocal cord

(c) subglottic extension (50–70%)

(d) pulmonary involvement (1–6%): lower lobe and posterior part of lung

√ thickened lumpy cords

√ bronchiectasis

Cx:

(1) **Tracheobronchial papillomatosis** (2–5%)

Cause: tracheostomy

Location: lower lobe + posterior predilection
√ solid pulmonary nodules in mid + posterior lung fields
√ 2–3 cm large thin-walled cavity with 2–4 mm thick nodular wall (foci of squamous papillomas enlarge centrifugally, undergo central necrosis, cavitate)
√ peripheral atelectasis + obstructive pneumonitis
HRCT:
√ tree-in-bud opacities

(2) **Pulmonary papillomatosis**
from aerial dissemination (bronchoscopy, laryngoscopy, tracheal intubation) 10 years after initial diagnosis
√ irregularities of tracheal / bronchial walls
√ noncalcified granulomata progressing to cavitation

(3) Malignant transformation into invasive squamous cell carcinoma

Rx: CO_2 laser resection / surgical excision

LARYNGEAL PLASMACYTOMA

Age: 50–70 years; M >> F
Histo: large sheets of uniform cells indistinguishable from normal plasma cells; marked amyloid deposition (20%)
• pedunculated / slightly prominent mass that bleeds easily
Location: epiglottis, true and false vocal cords
CT:
√ large smoothly marginated homogeneous mass
√ no significant contrast enhancement

LARYNGOCELE

= dilated appendix / saccular cyst of the laryngeal ventricle that contains air ← maintaining communication with laryngeal lumen + extending beyond superior border of thyroid cartilage
Prevalence: 1÷2,500,000
Age: middle-aged men
Pathogenesis: chronic increase in intraglottic pressure
Cause: excessive coughing, shouting, playing wind instrument, blowing glass, obstruction of appendicular ostium (= secondary laryngocele) by chronic granulomatous disease / laryngeal neoplasm (15%)

N.B.: Almost 50% of laryngoceles detected with plain radiography contain a laryngeal carcinoma!

Histo: lined by pseudostratified columnar ciliated epithelium + mixture of submucosal serous and mucous glands
Types: based on relationship to thyrohyoid membrane

(a) internal (40%) = in parapharyngeal space confined <u>within</u> thyrohyoid membrane
√ confined within larynx between false vocal cord and medial surface of thyrohyoid membrane

(b) external (26%) = protrusion through thyrohyoid membrane at the point of insertion of the neurovascular bundle (superior laryngeal nerve + vessels) presenting as lateral neck mass near hyoid bone with normal size inside the membrane

√ extension upward and laterally

(c) mixed (44%) = internal + external dilatation of saccule on both sides of thyrohyoid membrane

• visible in 10% of adults during phonation
• hoarseness / dysphagia / stridor (internal laryngocele)
• compressible anterior neck mass just below angle of mandible (external laryngocele)
• Bryce sign = gurgling / hissing sound on compression

Site: unilateral (80%), bilateral (20%)

√ sharply defined round / oval radiolucent area within paralaryngeal soft tissues:
√ increase in size during Valsalva maneuver
√ decrease in size during compression

√ cystic mass that can be followed to level of ventricle
√ may be filled with fluid / contain air-fluid level
√ DIAGNOSTIC = connection between air sac + airway

Cx: infection (laryngopyocele) in 8–10%, formation of mucocele

DDx: (1) Laryngeal cyst (lined by squamous epithelium)
(2) Lateral pharyngeal diverticulum (fills with barium)

LARYNGOMALACIA

= immaturity of cartilage;
most common cause of stridor in neonate + young infant

• only cause of stridor to get worse at rest

√ hypercollapsible larynx during inspiration (supraglottic portion only)
√ backward bent of epiglottis + anterior kink of aryepiglottic folds during inspiration

Prognosis: transient (disappears by age 1 year)

LEMIERRE SYNDROME

= SEPTIC JUGULAR VEIN THROMBOPHLEBITIS = POSTANGINAL SEPSIS = NECROBACILLOSIS

= uncommon potentially life-threatening complication of acute oropharyngeal infection (pharyngotonsillitis)

Age: adolescent, teenager, young adult > infant, child

Organism: anaerobic Fusobacterium necrophorum (81%, part of the normal oropharyngeal flora), other Fusobacterium species (11%), other gram-negative organisms (8%)

• acute pharyngitis followed by fever 3–10 days later
• pain and swelling over the sternocleidomastoid muscle
• hoarseness, dysphagia ← cranial nerve involvement
• septicemia with rigors, malaise, trismus

US / CT:
√ internal jugular venous thrombosis
√ edema of the surrounding soft tissues + wall of jugular vein

CT of chest:
√ patchy consolidation = bronchopneumonia
√ septic pulmonary emboli:

√ multiple peripheral round / wedge-shaped opacities
√ "feeding vessel" sign = vessel leading into nodule
√ peripheral enhancement with central areas of reduced attenuation = cavitation
√ pleural effusion → empyema

Cx: systemic dissemination of infection: pleuropulmonary septic emboli (97%), septic arthritis (15%), hepatic and splenic abscesses, osteomyelitis, meningitis, epidural abscess, diffuse encephalopathy

Rx: prolonged IV antibiotics with anaerobic activity, anticoagulation

LINGUAL THYROID

= solid embryonic rest of thyroid tissue, which remains ectopic along the tract of thyroglossal duct

Frequency: in 10% of autopsies (within tongue < 3 mm); M << F

- may be the only functioning thyroid tissue (in 70–80%)
  N.B.: resection of ectopic thyroid will render patient athyroid
- asymptomatic (usually), may enlarge causing dysphagia / dyspnea

Location: midline dorsum of tongue near foramen cecum (90%), thyroglossal duct, trachea; ± multifocal

CT:
√ small hyperattenuating focus relative to muscle ← iodine content + moderate contrast enhancement

MR:
√ solid avidly enhancing lesion mildly T1 hyper- / isointense relative to muscle

NUC:
√ SPECIFIC high uptake of ^{123}I and ^{99m}Tc

Cx: in 3% malignant (papillary carcinoma) / goitrous transformation

LIPOMATOSIS

= condition caused by diffuse overgrowth of mature adipocytes

Age: children < 2 years of age; may affect adults

Types:

(1) **Infiltrating congenital lipomatosis of the face**
= infiltrative nonencapsulated accumulations of mature fat cells
- lesion growth → facial asymmetry, parotid involvement, osseous hypertrophy, macroglossia

May be associated with: cutaneous capillary blush and mucosal neuromas

(2) **Encephalocraniocutaneous lipomatosis**
= infiltrative lipomatous process

Location: commonly temporofrontal area unilaterally, cerebral + leptomeningeal tissue, skull; occasionally eye and heart

May be associated with: cerebral malformations and calcifications

(3) **Madelung disease**

LUDWIG ANGINA

[Wilhelm Friedrich von Ludwig, 1790–1865, German surgeon and obstetrician in Tübingen]
[*angina* = *ankhon*, Greek = strangling]
= serious potentially life-threatening necrotizing infection of floor of mouth rapidly involving both submandibular spaces
Cause: odontogenic / gum infection (90%) surrounding a partially erupted tooth (= pericoronitis) usually of 2nd / 3rd mandibular molar; frenulum piercing
Predisposing factors: poor dental hygiene, dental extraction from lower jaw a few days prior, compromised immune status, diabetes, IV drug abuse
Spread: by direct extension of infection = tooth apices of 2nd / 3rd molar of jaw extend inferiorly to mandibular insertion of mylohyoid muscle → fascial planes of neck → mediastinitis → airway compromise
Organism: Streptococcus, Actinomyces israelii, Pseudomonas aeruginosa
Age: usually in young adults
Location: bilateral sublingual and submandibular spaces
• swelling of the submandibular (and sublingual) spaces
• brawny (firm hard) painful edema ± crepitation of submandibular tissue → elevation of tongue
• malaise, fever, laryngeal edema, stridor, difficulty breathing
• displacement of tongue → drooling, dysphagia, difficulty swallowing or speaking
Imaging: (1) Assessment of airway patency
(2) Presence of gas-forming organism
(3) Location of underlying dental infection
√ underlying dental disease
√ local skin thickening, muscle enlargement
√ increased attenuation of subcutaneous fat
√ loss of fat planes within submandibular space
√ soft tissue emphysema
√ ill-defined abscesses in submandibular / sublingual spaces
CT:
√ inflammatory change with small cystic spaces = serosanguinous accumulation in floor of mouth
√ ± extension deep into submandibular + parapharyngeal spaces + pharynx → airway narrowing / obstruction
√ well-defined fluid collection with rimlike enhancement
Cx: mandibular osteomyelitis, spread of infection into deep fascial spaces of neck, thrombophlebitis of IJV (Lemierre syndrome)
Mortality: up to 10%
Rx: IV antibiotics, aggressive drainage, surgical airway creation

LYMPHANGIOMA

= congenital lymphatic malformation
Frequency: 5.6% of all benign tumors of infancy + childhood
Age: present at birth in 50–65%, in 80–90% evident by age 2 (time of greatest lymphatic growth); M = F
Lymphatic development:

endothelial buds from veins in jugular region form confluent plexuses, which develop into rapidly enlarging bilateral juguloaxillary lymph sacs (7.5 weeks GA); these fused lymph sacs extend craniad and dorsolateral with extensive outgrowth of lymph vessels in all directions; connection with internal jugular vein at level of confluence + external jugular vein persists on left side

Pathogenesis:

(1) Early sequestration of embryonic lymphatic tissue with failure to join central lymphatic channels

(2) Congenital obstruction of lymphatic drainage ← abnormal budding of lymph vessels (= loss of connection / noncommunication of primordial jugular lymphatic sac with jugular vein)

Classification (based on size of lymphatic spaces):

(1) **Cystic lymphangioma** = cystic hygroma (see below)

(2) **Cavernous lymphangioma**
= mildly dilated cavernous lymphatic spaces with cysts of intermediate size
Location: tongue, floor of mouth, salivary glands
√ penetration of contiguous structures
√ same signal intensities as cystic lymphangioma + fibrous stromal component of low intensity on T1WI + T2WI

(3) **Capillary / simple lymphangioma** (least common)
= capillary-sized lymphatic channels
Location: epidermis + dermis of proximal limbs

(4) **Vasculolymphatic malformation**
composed of lymphatic + vascular elements, eg, lymphangiohemangioma

Histo: endothelial-lined lymphatic channels containing serous / milky fluid + separated by connective tissue stroma

- asymptomatic (in majority) soft / semifirm mass
- rapid increase in size (from infection / hemorrhage)
- ± dyspnea / dysphagia with encroachment upon trachea, pharynx, esophagus

Location: anywhere in developing lymphatic system; mostly in posterior cervical triangle, occasionally in floor of mouth / tongue

(a) posterior triangle of neck (75%), with extension into mediastinum in 3–10%
- visible at birth in 65%
- clinically apparent by end of 2nd decade in 90%

(b) anterior mediastinum (< 1%)

(c) axilla (20%), chest wall, groin

(d) retroperitoneum (1%), abdominal organs, bone

√ multilocular thin-walled cysts separated by fibrous tissue

√ well-marginated small lesions / ill-defined infiltrative large lesions with transspatial growth pattern

Cx: infection, airway compromise, chylothorax, chylopericardium

Prognosis: spontaneous regression (10–15%)

Rx: surgical excision (treatment of choice but difficult since mass does not follow tissue planes) with recurrence rate of up to 15%

Cystic Hygroma

= CYSTIC LYMPHANGIOMA

= single / multiloculated fluid-filled cavities on either side of fetal neck + head (localized form) ± trunk (generalized form) as the most common form of lymphangioma developing within loose connective tissue

Frequency: 1÷6,000 pregnancies

Path: multiple enormously dilated cystic lymphatic channels; variation in size between a few mm to > 10 cm in diameter containing chylous fluid; separated by minimal intervening stroma; may invade adjacent soft tissues / muscle and surround vessels

Histo: cystic spaces lined by endothelial cells + supporting connective tissue stroma

Associated with:

(a) chromosomal abnormalities in 60–80% (in particular when detected in 2nd trimester)
  (1) Turner syndrome (45 XO, mosaic) in 40–80%
  (2) Trisomies 13, 18, 21, 13q, 18p, 22
  (3) Noonan syndrome
  (4) Distichiasis (= second row of hair behind eyelash) -lymphedema syndrome [*stichos*, Greek = row]
  (5) Familial pterygium colli
  (6) Roberts, Cumming, Cowchock syndrome
  (7) Achondrogenesis type II
  (8) Lethal pterygium syndrome

(b) exposure to teratogens
  (1) Fetal alcohol syndrome
  (2) Aminopterin
  (3) Trimethadione

Types:

(1) Cystic hygroma with abnormal peripheral lymphatic system
  √ lymphangioma in posterior compartment of neck
  √ septations (indicate high probability for aneuploidy, development of hydrops, and perinatal death)

(2) Diffuse lymphangiectasia
  √ lymphangioma of chest + extremities
  √ peripheral lymphedema + nonimmune hydrops

(3) Isolated cystic hygroma
  (a) axillary lymph sac malformation
    √ lymphangioma restricted to axilla
  (b) jugular lymph sac malformation
    √ lymphangioma restricted to lateral neck
  (c) internal thoracic + paratracheal lymph sac malformation
    √ lymphangioma within mediastinum
  (d) combined lymph sac malformation
  (e) thoracic duct malformation
    √ thoracic duct cyst

• AF-AFP / MS-AFP may be elevated

Location: neck (frequently posterior cervical space) and lower portions of face (75–80%);

mediastinum (3–10%, in ½ extension from neck); axilla (20%); chest wall (14%); face (10%); retroperitoneum (kidneys); abdominal viscera (colon, spleen, liver); groin; scrotum; skeleton

US:
- √ thin-walled fluid-filled structure with multiple septa of variable thickness + solid cyst wall components
- √ fluid-fluid level with layering hemorrhagic component
- √ isolated nuchal cysts
- √ webbed neck (= pterygium colli) following later communication with jugular veins
- √ nonimmune hydrops (43%)
- √ progressive peripheral edema
- √ fetal ascites
- √ oligo- / polyhydramnios / normal amount of fluid
- √ bradycardia

CT:
- √ poorly circumscribed multiloculated masses
- √ homogeneous attenuation of fluid values / higher (after infection)

MR (allows the best differentiation between lymphatic malformations and surrounding soft tissues):
- √ low signal intensity on T1WI
- √ high SI lesion with low-SI septations of variable thickness on T2WI
- √ may be hyperintense on T1WI ← clotted blood / high chylous lipid content / high protein content
- √ ± fluid-fluid level (if hemorrhage present)

DDx: hemangioma (different location, feeding vessels, contrast enhancement)

Cx: (1) Compression of airways / esophagus
(2) Slow growth / sudden enlargement (hemorrhage, inflammation)

Prognosis:
(1) Intrauterine demise (33%)
(2) Mortality of 100% with hydrops
(3) Spontaneous regression (10–15%)
- ◊ Favorable prognosis for localized lesions of anterior neck and axilla
- ◊ Only 2–3% of fetuses with posterior cystic hygroma become healthy living children!

DDx: twin sac of blighted ovum; cervical meningocele; encephalocele; cystic teratoma; nuchal edema; branchial cleft cyst; vascular malformation; lipoma; abscess

Pseudocystic Hygroma
- = PSEUDOMEMBRANE
- = anechoic space bordered by specular reflection on posterior aspect of fetal neck during 1st trimester

Cause: ? developing integument
- √ NO prominent posterior bulge / internal septations

MADELUNG DISEASE

= BENIGN SYMMETRICAL LIPOMATOSIS = MULTIPLE SYMMETRIC LIPOMATOSIS

= rare benign condition characterized by symmetric proliferation of adipose tissue
Location: head, neck, shoulders (periscapular), upper chest; NO involvement of anterior mediastinal / cardiophrenic / paraspinal areas
Age: 25–60 years; white men
May be associated with:
history of alcohol abuse, dyslipidemia, diabetes mellitus, hyperthyroidism, liver disease, hypertension, hyperuricemia, renal tubular acidosis, macrocytic anemia, polyneuropathy
Cx: respiratory compromise ← tracheal compression at neck
DDx: obesity (different fat distribution)

MALIGNANT EXTERNAL OTITIS

= NECROTIZING EXTERNAL OTITIS
= severe bacterial infection of the soft tissues + bones at base of skull
Organism: almost always Pseudomonas aeruginosa
Age: elderly
Predisposed: diabetes mellitus / immunocompromised
• unrelenting severe otalgia, headache
• purulent otorrhea unresponsive to topical antibiotics
• ± malfunction of nerves VII, IX, X, XI ← skull base osteomyelitis; granulation tissue within external auditory canal
Location: at bone-cartilage junction of EAC
Spread of infection:
via fissures of Santorini (= 2–3 vertical fissures in cartilaginous portion of EAC anteroinferiorly) →
(a) inferiorly into soft tissues inferior to temporal bone, parotid space, nasopharyngeal masticator space
(b) posteriorly into mastoid
(c) anteriorly into temporomandibular joint
(d) medially into petrous apex of skull base
√ osseous erosion of external auditory canal
CT:
√ soft-tissue density in external auditory canal (100%)
√ fluid in middle ear / mastoid air cells (89%)
√ disease around eustachian tube (64%)
√ obliteration of fat planes beneath temporal bone (64%)
√ involvement of parapharyngeal space (54%)
√ masticator space disease (27%)
√ mass effect in nasopharynx (54%)
√ bone erosion of clivus (9%)
√ intracranial extension (9%)
MR (method of choice for soft-tissue complications):
√ abnormal signal intensity + obliteration of fat within stylomastoid foramen
Cx: bone destruction; skull base osteomyelitis (clivus, jugular foramen); abscess of epidural space + brain parenchyma + prevertebral space

Prognosis: 20% recurrence rate; high mortality rate

DDx: nasopharyngeal carcinoma (with obstruction of eustachian tube and secondary otomastoiditis); nonnecrotizing external otitis (no osseous erosion); cholesteatoma of EAC; squamous cell carcinoma of EAC

MIKULICZ DISEASE

= painless bilateral symmetric swelling of lacrimal and salivary glands (parotid (80%), submandibular, sublingual)

[Jan Mikulicz-Radecki (1850–1905), Polish-Austrian surgeon at universities in Kraków, Königsberg and Wrocław]

Age: 6th decade; M÷F = 2÷3 to 4÷5

Histo: "epimyoepithelial islands" = marked lymphoplasmacytic infiltration surrounding epithelial nests, excess hyaline basement membrane material, acinar atrophy and destruction

Often associated with: IgG4-related disease, Sjögren syndrome

√ homogeneous attenuation + enhancement of involved glands

CT:

√ intermediate soft-tissue attenuation

MR:

√ low signal intensity (= isointense to muscle) on T1WI

√ homogeneous low to intermediate SI on T2WI ← increased cellularity + fibrosis

DDx: viral infection (mumps), acute phase of Sjögren syndrome, sarcoidosis, lymphoma, leukemia

MUCOCELE

= end stage of a chronically obstructed sinus

Frequency: increased incidence in cystic fibrosis

◊ Most common lesion to cause expansion of paranasal sinus!

Etiology: chronic obstruction of paranasal sinus ostium

Path: expanded sinus cyst lined by mucosa + filled with accumulated secretions and desquamations

Age: usually adulthood

- history of chronic nasal polyposis + pansinusitis
- commonly present with unilateral proptosis
- ↓ visual acuity, visual field defect, intractable headaches
- palpable mass in superomedial aspect of orbit (frontal mucocele)

Location:

mnemonic: fems

frontal (60%) > **e**thmoid (30%) > **m**axillary (10%) > **s**phenoid (rare)

√ expanded airless sinus filled with homogeneous mucoid material

N.B.: Presence of air in an affected sinus effectively rules out a mucocele!

√ sinus cavity expansion (DDx: never in sinusitis)

√ bone demineralization + remodeling at late stage but NO bone destruction (impossible DDx

from neoplasm)
√ surrounding zone of bone sclerosis / calcification at edges of mucocele (from chronic infection)
√ macroscopic calcification in 5% (especially with superimposed fungal infection)
√ uniform enhancement of thin rim

US:
√ homogeneous hypoechoic mass

MR:
√ expansive well-delineated mass with homogeneously hyperintense T1 and T2 signal:
√ signal intensity varies with state of hydration, protein content, hemorrhage, air content, calcification, fibrosis
√ hypointense on T1WI + signal void on T2WI ← inspissated debris + fungus
√ NO enhancement / peripheral enhancement pattern (DDx from solid enhancement pattern of neoplasms)

Cx: (1) Protrusion into orbit displacing medial rectus muscle laterally
(2) Expansion into subarachnoid space → CSF leak
(3) Mucopyocele = superimposed infection (rare)

Rx: followed (if asymptomatic); surgical drainage (if symptomatic)

DDx: paranasal sinus carcinoma, mucus retention cyst, Aspergillus infection (enlargement of medial rectus muscle + optic nerve, focal / diffuse areas of increased attenuation), chronic infection, inverting papilloma

MUCOEPIDERMOID CARCINOMA

Path: arises from intercalated ducts of seromucinous glands

Histo: composed of a mixture of 3 cells: mucin-secreting cells + squamous cells + mucous cells; arranged in cords / sheets / cystic configuration

Age: 30–50 years

Prognosis: variable (well-encapsulated low-grade to infiltrating highly aggressive malignancy)

Rx: complete surgical removal

Parotid Mucoepidermoid Carcinoma

◊ Most common malignant lesion of parotid gland
◊ <u>In children</u>: up to 35% of all salivary gland tumors are malignant (60% are mucoepidermoid carcinomas)
• rock-hard mass; facial nerve paralysis
• pain / itching along course of facial nerve

CT:
√ may contain cystic low-attenuating areas
√ focal calcifications (rare)

(a) low-grade lesion:
√ well-circumscribed parotid mass
√ hypo- to isointense on T1WI
√ hyperintense on T2WI
Rx: wide local excision

(b) high-grade lesion:
√ infiltrating poorly marginated, more solid, relatively homogeneous lesion with few cystic areas
Rx: wide block excision + radical neck dissection

Laryngeal Mucoepidermoid Carcinoma

Prevalence: ~100 cases
M÷F = 6÷1
Location: epiglottis (most common)

MUCOUS RETENTION CYST

= obstructed submucosal mucinous gland
√ partially surrounded by air
DDx: indistinguishable from polyps, mucocele (NEVER surrounded by air)

NASAL GLIOMA

misnomer (no neoplastic features) = NASAL CEREBRAL HETEROTOPIA
= rare congenital mass composed of dysplastic sequestered neurogenic tissue (= distal part of a cephalocele in extracranial location) that has become isolated from the subarachnoid space (= disrupted central connection); analogous to nasoethmoidal encephalocele
Age: usually identified at birth
Location: (a) extranasal (60%)
Site: paramedian at bridge of nose external to nasal passage
(b) intranasal (30%)
Site: within nasal passage medial to middle turbinate
(c) combination of intra- and extranasal (10%)
Site: root of nose; unilateral right > left side
• smooth firm noncompressible mass, covered by skin
• no change in size during crying
√ no growth / very little growth / growth similar to brain
√ attached to middle turbinate bone / nasal septum
√ foramen cecum may be deeper than normal
√ ± small and bifid crista galli (intracranial extension likely)
√ soft-tissue mass of glabella
√ attached to brain by stalk of tissue (in 1–15–30%)
◊ NO communication with subarachnoid space by fluid-filled tract as in encephalocele
MR (method of choice):
√ iso- / hypointense relative to normal gray matter on T1WI
√ hyperintense on T2WI (as a result of gliosis)
√ contrast enhancement may depict tract to frontobasal region
DDx: encephalocele (communicates with subarachnoid space)

ODONTOGENIC INFECTION

Spread:

(1) dental caries → bacteria enter tooth and spread to apex (root) → apical periodontitis, granuloma, abscess, radicular cyst formation
(2) bacterial overgrowth + inflammation in space between tooth and gum → destruction of periodontal ligaments → erosion of bone

Odontogenic Abscess

- fever, tooth pain, facial swelling, dysphagia, trismus
- possibly dyspnea

CT:
√ periodontal lucency with focal cortical break / fistula
√ extraosseous fluid collection with rimlike enhancement
Cx: spread of infection into deep spaces of neck and orbit, airway compromise, internal jugular vein thrombosis, intracranial extension of infection

OLFACTORY NEUROBLASTOMA

= very malignant tumor arising from olfactory mucosa
Types:
1. Esthesioneuroepithelioma
2. Esthesioneurocytoma
3. Esthesioneuroblastoma

√ mass in superior nasal cavity with extension into ethmoid + maxillary sinuses
Cx: distant metastases in 20%

Esthesioneuroblastoma

= OLFACTORY NEUROBLASTOMA
Origin: olfactory epithelium
Age peaks: young men + 50–60 years

- hyposmia, anosmia, nasal congestion, epistaxis, facial pain
- headache, personality change (with frontal lobe involvement)
- exophthalmos, ophthalmoplegia, visual loss

Location: centered on cribriform plate
√ erosion of cribriform plate and nasal septum
MR:
√ tumor hypointense to brain on T1WI
√ tumor iso- or hyperintense to brain on T2WI
√ cysts along the superior tumor margin within anterior cranial fossa (CHARACTERISTIC)

OTIC CAPSULE DYSPLASIA

Single-cavity Cochlea

= cochlear cavity malformation
= saccular defect / cavity in otic capsule in the position normally occupied by cochlea without recognizable modiolus, osseous spiral lamina, interscalar septum

- profound hearing loss discovered in early childhood

May be associated with: recurrent bacterial meningitis, perilymphatic fistula of oval window

√ cystic cochlea (= developed basal turn, middle + apical turn occupy common nondeveloped space)

Type: (a) incomplete partition type I
= cystic cochleovestibular malformation
= complete lack of partitioning of cochlea
√ cystic structure at CT

(b) incomplete partition type II (see below)
= classic Mondini malformation

Insufficient Cochlear Turns

= normal basilar turn + varying degrees of hypoplasia of middle and apical turns

Mondini Malformation

Cause: in utero insult at 7 weeks GA

Frequency: 2nd most common imaging finding in children with sensorineural hearing loss

- some high-frequency hearing preserved; vertigo
- otorrhea, rhinorrhea, recurrent meningitis (perilymphatic fistula caused by absence / defect of stapes footplate)

√ cochlea contains 1½ turns:
√ normal basal turn
√ cystic-appearing dilated apical portion

√ absence of cochlear apex

May be associated with: deformity of vestibule + semicircular canals + vestibular aqueduct

Labyrinthine Aplasia

= **Michel aplasia** = Michel anomaly = agenesis of osseous + membranous labyrinth (rare)

Cause: arrested development at 4 weeks GA

- total sensorineural hearing loss

√ region of otic capsule normally occupied by cochlea is replaced by dense labyrinthine + pneumatized bone

√ flat medial wall of middle ear (= undeveloped horizontal semicircular canal)

√ hypoplasia of internal auditory canal

√ dysplasia of vestibule = marked enlargement into region of lateral + superior semicircular canals

DDx: labyrinthitis obliterans (no loss of lateral convexity of medial wall of middle ear)

Anomalies of Membranous Labyrinth

Scheibe dysplasia = abnormal cochlea + saccule

Alexander dysplasia = dysplasia of basal turn

√ normal CT findings

Small Internal Auditory Canal

= decrease in the diameter of IAC ← hypoplasia / aplasia of cochlear nerve (portion of

cranial nerve VIII)
• total sensorineural hearing loss
√ hypoplastic anteroinferior quadrant of IAC

Large Vestibule

Associated with: underdeveloped lateral semicircular canal
• sensorineural hearing loss (most common cause)
√ lateral semicircular canal smaller
√ vestibule extends further into lateral + superior aspects of otic capsule

Large Vestibular Aqueduct

= ENLARGED VESTIBULAR AQUEDUCT SYNDROME
Age: manifests around 3 years
Frequency: most common imaging abnormality detected in children with sensorineural hearing loss (SNHL)
May be associated with: other inner ear abnormalities
• unilateral congenital deafness (commonly missed)
◊ in 12% of children with congenital SNHL
• vertigo, tinnitus (in 50%)
Location: bilateral in 50–66%
√ vestibular aqueduct > 1.4–2 mm in diameter (measured at halfway point between posterior petrous bone + common crus at level of vestibule)
√ vestibular aqueduct larger than normal semicircular canals
√ CLASSIC funnel-shaped deformity of dilated vestibular aqueduct ← enlarged endolymphatic sac housed within dorsal vestibular aqueduct

OTITIS MEDIA

Cx: (1) Otomastoiditis
(2) Development of acquired middle ear cholesteatoma

Acute Otitis Media

◊ Most common infection of the temporal bone!
◊ Most common infection in first 5 years of life!
Cause: viral upper respiratory infection with disruption of the mucosal barrier → bacteria in nose and nasopharynx spread to middle ear
Age: infants + young children > adults
Organism: Streptococcus species, Haemophilus influenzae
• fever, otalgia, otorrhea; red bulging tympanic membrane
√ partial / total fluid-attenuation opacification of middle ear ± fluid level
√ opacification of mastoid air cells

Chronic Otitis Media

= CHRONIC OTOMASTOIDITIS
= long-term damage to middle ear
Cause: long-standing eustachian tube dysfunction, perforation of tympanic membrane

Sequelae:
√ middle ear effusion
√ granulation tissue (no displacement / destruction)
√ cholesterol granuloma
√ cholesteatoma

OTOMASTOIDITIS

= serious complication of acute otitis media in children
Anatomy: tympanic cavity communicates with mastoid air cells via the tympanic antrum (subject to viral and bacterial invasion by way of eustachian tube)
Age: young children
Organism: Streptococcus pneumoniae, Haemophilus influenzae, Staphylococcus aureus
• retroauricular swelling + erythema, protrusion of auricle
• history of recent otitis media
Temporal bone CT (87%–100% sensitive):
√ increased attenuation of the middle ear cavity (= middle ear effusion)
√ increased attenuation of the mastoid cells
√ ± fluid levels
Intratemporal Cx:
(1) **Coalescent mastoiditis** = empyema of mastoid
Pathomechanism: suppuration under pressure → local acidosis + ischemia → osseous decalcification + osteoclasis of pneumatic cell walls
√ loss of internal bone septa of the mastoid air cells ← erosion of mastoid septa / cortex with periosteal reaction
√ fluid or soft-tissue opacification of mastoid air cells
√ subperiosteal abscess located postauricular / in external auditory canal / along zygomatic bone
Rx: myringotomy, mastoidectomy
(2) Petrositis = petrous apicitis
(3) Labyrinthitis
• vertigo, nystagmus
√ abnormal labyrinthine enhancement
(4) Facial nerve paralysis
(5) Hearing loss
Cervical Cx:
(1) Carotid artery involvement: arteritis, occlusion, pseudoaneurysm, rupture
(2) **Bezold abscess** = inflammatory collection that may spread along plane of sternocleidomastoid muscle to lower neck
Location: inferior to mastoid tip + medial to insertion of posterior belly of digastric muscle
√ erosion of mastoid tip
√ adjacent involvement of posterior digastric muscle insertion
Cx: mediastinitis ← extension of infection inferiorly along fascial planes
Intracranial Cx:

(1) Meningitis
(2) Epidural abscess
› perisinus abscess = erosion of the cortical plate overlying the sigmoid sinus
(3) **Dural sinus / Sigmoid sinus thrombophlebitis**
Cause: erosion of sigmoid plate / thrombophlebitic spread via emissary veins
Location: (commonly) sigmoid + transverse sinus
• headache, otalgia, papilledema, fever
√ sinus of low attenuation on NECT and CECT
√ absence of normal flow void on spin-echo MR
√ no flow-related enhancement on gradient-echo MR
√ occlusion on MRV
DDx: aberrant arachnoid granulation
(4) **Subdural empyema**
Route: communication through intact bone and dura with vessels in subarachnoid space + brain parenchyma
Location: along posterior interhemispheric fissure; tentorium cerebelli
• meningismus, focal neurologic deficits, focal seizures
√ widening of extracerebral space
√ compression of adjacent sulci
Rx: prompt neurosurgical drainage
(5) Intraparenchymal brain abscess and empyema

OTOSCLEROSIS

= OTOSPONGIOSIS
= replacement of dense otic capsule by highly vascular spongy bone in active phase (otosclerosis = misnomer!) with restoration of density during reparative sclerotic phase
Etiology: unknown; frequently hereditary
Age: adolescent / young adult Caucasian; M÷F = 1÷2
Histo: otosclerosis limited to endochondral layer
DDx: Paget disease, osteogenesis imperfecta, syphilis

Stapedial = Fenestral Otosclerosis (80–90%)
Location: lateral wall of bony labyrinth, including oval and round windows, promontory, facial nerve canal
Site: anterior oval window margin (= fissula ante fenestrum); bilateral in 85%
• tinnitus early in course (⅔)
• progressive conductive hearing loss (stapes fixation in oval window)
√ oval window too wide (lytic phase)
√ new bone formation on anterior oval window margin ± posterior oval window margin ± round window
√ complete plugging of oval window = obliterative otosclerosis (in 2%)

Cochlear = Retrofenestral Otosclerosis (10–20%)
Location: otic capsule
Invariably associated with: fenestral otosclerosis

- progressive sensorineural hearing loss (involvement of otic capsule / cytotoxic enzyme diffusion into fluid of membranous labyrinth)
- Schwartze sign = reddish hue behind tympanic membrane when promontory involved

√ "double ring / double lucent" = lucent halo around cochlea (may appear as 3rd turn to cochlea) in early phase

√ bony proliferation in reparative sclerotic phase difficult to diagnose because of same density as cochlea

PAPILLARY ENDOLYMPHATIC SAC TUMOR

= HEFFNER TUMOR
= locally invasive papillary cystadenomatous tumor of temporal bone
Origin: epithelial lining of endolymphatic sac
Associated with: von Hippel-Lindau disease (in 7%), which may have bilateral papillary endolymphatic sac neoplasms
• hearing loss, facial nerve palsy, vestibular dysfunction
Location: along posterior petrous apex (retrolabyrinthine petrous bone) typically involving vestibular aqueduct
CT:
√ moth-eaten lytic appearance of invaded bone surrounded by thin shell of reactive bone:
√ solid + cystic components
√ intratumoral calcifications = "bone sequestra" from destruction of petrous bone
√ may be hypervascular (supplied by branches of external carotid artery)
MR:
√ speckled pattern of hyperintensity on T1WI (mimicking glomus tumor)
√ commonly contains blood products (hyperintense on T1WI + hypointense on T2WI)
√ areas of low SI may represent hemosiderin
√ heterogeneous enhancement
DDx: paraganglioma, cystic and papillary adenocarcinoma, chondroid lesions (benign chondroma, low-grade chondrosarcoma, chondromyxoid fibroma), cholesterol granuloma, metastatic disease

PARAGANGLIOMA

= NONCHROMAFFIN PARAGANGLIOMA = GLOMUS TUMOR (describes the rich arborization of blood vessels and nerves) = CHEMODECTOMA (reflective of chemoreceptor tissue of origin) = GLOMERULOCYTOMA = ENDOTHELIOMA = PERITHELIOMA = SYMPATHOBLASTOMA = FIBROANGIOMA = SYMPATHETIC NEVI
= rare neuroendocrine tumor arising from paraganglionic tissue found between base of skull and floor of pelvis; belongs to amine-precursor-uptake decarboxylation (APUD) system characterized by cytoplasmic vesicles containing catecholamines
Paraganglion = collection of tissue of the extraadrenal neuroendocrine system, frequently located near nerves and vessels with special chemoreceptor function
Origin: arises from nonchromaffin paraganglion cells of neuroectodermal origin (= neural crest cells found in adrenal medulla + parasympathetic ganglia + chemoreceptors); differs from adrenal medulla only in its nonchromaffin feature
Terminology of Neuroendocrine System:
(a) Adrenal paraganglioma arising from adrenal medulla = **pheochromocytoma**
(b) **Extraadrenal pheochromocytoma**
= pheochromocytoma arising from organs of Zuckerkandl
(c) **Paraganglioma** (10%)
= pheochromocytoma arising in other extraadrenal locations like retroperitoneum, bladder, GI tract

1. Aorticosympathetic paraganglioma associated with sympathetic chain + retroperitoneal ganglia
2. Parasympathetic paraganglioma including branchiomeric chemodectoma, vagal + visceral autonomic paraganglioma

Classification of extraadrenal paragangliomas (Glenner):

A. BRANCHIOMERIC DISTRIBUTION
   1. Associated with great vessels of chest + neck including carotid body, glomus jugulare, glomus tympanicum

B. PARASYMPATHETIC DISTRIBUTION
   2. Associated with vagal nerve
   3. Associated with aorticosympathetic chain in thoracolumbar region from aortic arch to urinary bladder, including organ of Zuckerkandl at origin of inferior mesenteric artery
   4. Associated with visceral organs

Histo: acidophil-epithelioid cells in contact with endothelial cells of a vessel; storage of catecholamines (usually nonfunctioning); histologically similar to pheochromocytoma

Peak age: 5th–6th decade (range, 6 months to 80 years); M÷F = 1÷1

- tumor may secrete catecholamine in 40% (= **functional paraganglioma**); proportion of hormonally active tumors high for pheochromocytomas, intermediate for aorticosympathetic paragangliomas, low for parasympathetic paragangliomas
- **p**aroxysmal / **p**ermanent hypertension ← secretion of vasopressor amines responsible for:
  - › **p**ain in head (headache)
  - › **p**allor
  - › **p**erspiration (excessive sweating)
  - › **p**alpitations
- elevated urinary metanephrine / vanillylmandelic acid
- pheochromocytomas secrete norepinephrine + epinephrine, extraadrenal paragangliomas secrete only norepinephrine, some paragangliomas produce dopamine
- determination of free norepinephrine most sensitive with gas chromatography / high-pressure liquid chromatography (HPLC) performed on 24-hour urine specimens

Location of functioning paragangliomas:

(a) adrenal medulla (> 80%)
(b) extraadrenal intraabdominal (8–16%)
(c) extraadrenal in head & neck (2–4%)

Four primary sites in head & neck:

1. Carotid body
2. Jugular foramen
3. Path of vagus nerve
4. Middle ear

Less common sites in head & neck:

sella turcica, pineal gland, cavernous sinus, larynx (laryngeal branches of vagus nerve), orbit (ciliary ganglion of the eye), thyroid gland, nasopharynx, mandible, soft palate, face, cheek

(d) spinal paraganglioma

(e) multiple paragangliomas, particularly in hereditary disorders (multiple endocrine neoplasia syndromes (MEN 2a and 2b) + neuroectodermal disorders of neurofibromatosis type 1, von Hippel-Lindau syndrome):
synchronous multicentricity in 3–26%:
› autosomal dominant in 25–35%
› nonhereditary in < 5%

√ highly vascular tumor with intense early blush that persists into late arterial + venous phases
√ well-circumscribed iso- to hyperintense mass on T2WI
√ flow voids ← multiple small serpentine + arborizing vessels
√ frequent hemorrhage with "cap" sign (= hypointense rim)
Cx: malignant transformation in 2–10%

Carotid Body Tumor

Embryology:
derived from mesoderm of 3rd branchial arch + neural crest ectoderm cells, which differentiate into sympathogonia (= forerunner of paraganglionic cells)
◊ Chemodectoma is misnomer (NOT derived from chemoreceptor cells)!

Histo: nests of epithelioid cells ("Zellballen") with granular eosinophilic cytoplasm separated by trabeculated vascularized connective tissue
◊ Chromaffin-positive granules (= catecholamines) may be present

Function of carotid body:
5 x 3 x 2 mm carotid body regulates pulmonary ventilation through afferent input by way of glossopharyngeal nerve to the medullary reticular formation
Chemoreceptor: detects changes in arterial partial pressures of O_2 + CO_2 + pH
Stimulus: hypoxia > hypercapnia > acidosis
Effect: increase in respiratory rate + tidal volume; increase in sympathetic tone (heart rate, blood pressure, vasoconstriction, elevated catecholamines)

• painless pulsatile firm neck mass below the angle of the jaw, laterally mobile but vertically fixed

Location: within / outside adventitial layer of CCA at level of carotid bifurcation, commonly along posteromedial wall; bilateral in 5% with sporadic occurrence, in 32% with autosomal dominant transmission
√ enhancing oval mass with splaying of ICA + ECA above CCA bifurcation
√ no narrowing of ICA / ECA caliber
Extension: inferiorly to lower cranial nerves + pharynx; superiorly to skull base + intracranial cavity
Growth rate: about 5 mm per year
Cx: malignant transformation in 6% with metastases to regional lymph nodes, brachial plexus, cerebellum, lung, bone, pancreas, thyroid, kidney, breast

Jugulotympanic Paraganglioma

= large glomus tumor with 2 components in the middle ear + jugular foramen
Age: 4th–6th decade; M÷F = 1÷4
Location: margin of jugular foramen
NUC:

√ ^{111}In-octreotide (higher sensitivity)
√ ^{123}I-metaiodobenzylguanidine (lower sensitivity)
Rx: embolization of larger tumor prior to surgery

Glomus Tympanicum Tumor

Most common tumor in middle ear
- hearing loss, pulsatile tinnitus
- reddish purple mass behind tympanic membrane

Origin: nerve of Jacobson = jugulotympanic paraganglia cells along tympanic branch of glossopharyngeal n.
Location: tympanic plexus on cochlear promontory of <u>middle ear</u>
CT (bone algorithm preferred):
√ globular soft-tissue mass abutting promontory
√ intense enhancement
√ usually small at presentation (but with early involvement of ossicles)
√ erosion + displacement of ossicles
√ inferior wall of middle ear cavity intact
Angio:
√ difficult to visualize because of small size

Glomus Jugulare Tumor

◊ Most common tumor in jugular fossa with intracranial extension
Origin: adventitia of jugular vein arising from paraganglia cells along nerves of Jacobson / Arnold
- tinnitus, hearing loss; vascular tympanic membrane

Location: at <u>dome of jugular bulb</u>
√ soft-tissue mass in jugular bulb region / hypotympanum / middle ear space
√ intense enhancement
√ destruction of posteroinferior petrous pyramid + corticojugular spine of jugular foramen
√ destruction of ossicles (usually incus), otic capsule, posteromedial surface of petrous bone
MR:
√ "salt and pepper" appearance on T1WI + T2WI ← multiple small serpentine + arborizing tumor vessels in large tumor
√ intense enhancement in small tumor
Angio: (film entire neck for concurrent glomus tumors!)
√ enlarge feeding arteries + rapidly draining veins:
√ arteriovenous shunting
√ hypervascular mass with persistent homogeneous reticular stain
√ invasion / occlusion of jugular bulb by thrombus / tumor
√ supplied by tympanic branch of ascending pharyngeal artery, meningeal branch of occipital artery, posterior auricular artery via stylomastoid branch, internal carotid artery, internal maxillary artery
Cx: malignant transformation with metastases to regional lymph nodes (in 2–4%)

Glomus Vagale Tumor

= PARAGANGLIA OF VAGUS NERVE = VAGAL BODY TUMOR

Histo: dispersed within perineurium / below nerve sheath / between nerve fiber fascicles; not organized into a compact mass

Location:

(1) within inferior ganglion (= ganglion nodosum), inferior to base of skull close to jugular foramen (most common location)

(2) within superior ganglion (= ganglion jugulare) within base of skull at level of jugular bulb

(3) elsewhere along course of vagus nerve

Inferior Nodose Paraganglion

√ spindle-shaped mass

√ compression of internal jugular vein

√ displacement of carotid vessels anteromedially

√ displacement of lateral pharyngeal wall medially

√ minimal destruction of skull base

Superior Jugular Paraganglion

√ dumbbell-shaped mass

√ may encase / displace ICA

Location in temporal bone:

(1) dome of jugular bulb = intravagal paraganglia inferior to jugular foramen

(2) mucosa of cochlear promontory related to tympanic branch of glossopharyngeal nerve (**Jacobson nerve**)

(3) auricular branch of vagus nerve (**Arnold nerve**)

Extension:

(a) superiorly into posterior cranial fossa ± compression of brainstem

(b) inferiorly into infratemporal / parapharyngeal space (⅔)

(c) medially to involve arch of atlas

(d) laterally into middle ear structures

(e) posteriorly into mastoid air cells

• slow growing + asymptomatic

√ spherical / ovoid / spindle-shaped mass with sharp interfacing margins and homogeneous enhancement

√ highly vascular mass + neovascularity + intense tumor blush

Cx: malignant transformation + metastases in 15% to regional lymph nodes + lung (for other paragangliomas in 10%)

PARANASAL SINUS CARCINOMA

Location: maxillary sinus (80%), nasal cavity (10%), ethmoid sinus (5–6%), frontal + sphenoid sinus (rare)

Maxillary Sinus Carcinoma (80%)

Histo: squamous cell carcinoma (80%)

Age: > 40 years in 95%; M÷F = 2÷1
• asymmetry of face, tumor in oral / nasal cavity
√ bone destruction (in 90%) predominates over expansion
√ nodal metastases in 10–18%

Nasopharyngeal Carcinoma (10%)

Frequency: 0.25–0.5% of all malignant tumors in whites; M > F
Predisposed: Chinese population
Histo: squamous cell carcinoma (> 85%), nonkeratinizing carcinoma, undifferentiated carcinoma
Mean age: 40 years
• asymptomatic for a long time; unilateral nasal obstruction
• history of chronic sinusitis / nasal polyps (15%)
Location: turbinates (50%) > septum > vestibule > posterior choanae > floor
Extension:
(a) lateral + superior: through sinus of Morgagni (= natural defect in superior portion of lateral nasopharyngeal wall) into cartilaginous portion of eustachian tube + levator veli palatini muscle
± masticator space and pre- and poststyloid parapharyngeal spaces
± involvement of levator + tensor veli palatini muscle, 3rd division of nerve V, petroclinoid fissure
± foramen lacerum of skull base encasing ICA
± cavernous sinus (along ICA / mandibular nerve / direct skull base invasion)
(b) anterior: posterior nasal cavity + pterygopalatine fossa
(c) inferior (⅓): submucosal spread along lateral pharyngeal wall + anterior and posterior tonsillar pillars
√ polypoid or papillary (⅔)
√ bone invasion (⅓)
MR:
√ asymmetric thickening of nasopharyngeal mucosa
√ homogeneous intermediate SI similar to that of adjacent mucosa on T2WI
√ moderate contrast enhancement less than that of normal mucosa on T1WI
√ focal homogeneous enhancing mass

Ethmoid Sinus Carcinoma (5–6%)

Histo: squamous cell carcinoma (> 90%), sarcoma, adenocarcinoma, adenoid cystic carcinoma; frequently secondarily involved from maxillary sinus carcinoma
• nasal obstruction, bloody discharge
• anosmia, broadening of nose

PARATHYROID ADENOMA

Location: posterior to thyroid gland; ectopic in 5–15%
US (82% sensitive):
◊ Often used after localization with ^{99m}Tc-MIBI scintigraphy
√ well-defined oval hypoechoic mass

√ multilobulated mass ± echogenic areas (in large adenoma)

CT:

Indication: ectopic mediastinal adenoma (detected in 50%)

MR:

√ hypointense on T1WI, hyperintense on T2WI + STIR

NUC (^{99m}Tc-MIBI):

√ increased radiotracer uptake

PAROTID HEMANGIOMA

Frequency: 90% of parotid gland tumors during 1st year of life; M < F

Histo: capillary type >> cavernous type (in older children)

- soft-tissue mass developing shortly after birth with progressive growth peaking at age 1–2 years
- gradual spontaneous regression usually complete by adolescence

US:

√ hypoechoic mass relative to parotid tissue

√ variable degree of abnormal flow

CT:

√ occasionally phleboliths

√ well-defined mass with uniform intense enhancement

MR:

√ low to intermediate signal intensity on short TR

√ bright signal intensity on long TR

√ flow voids due to prominent vasculature

Rx: surgery, sclerotherapy, laser ablation (therapy only with large size + encroachment on adjacent structures due to spontaneous regression)

PENDRED SYNDROME

[Vaughan Pendred (1869–1946), English general practitioner]

= autosomal recessive disorder of chromosome 7 characterized by dyshormonogenic goiter associated with sensory-neural deafness

Cause: deficient protein that functions as a membrane-bound chloride-iodine transporter

- slowly progressive + fluctuating / profound hearing loss
- prelingual deafness (= hearing loss prior to the age at which speech is acquired)
- vestibular symptoms
- euthyroid / variable degrees of hypothyroidism
- positive perchlorate discharge test (= 10–80% of iodine taken up by thyroid is discharged by perchlorate ← organification defect)

√ multinodular goiter

√ absence of interscalar septum of modiolus (= central bony spiral of cochlea) in 20–75%; bilateral in 80%

√ enlargement of vestibular duct in 80–100%

PERIODONTAL DISEASE

• facial swelling, pain, dysphagia, dysphonia

Location:

(a) submandibular space: roots of 2nd / 3rd molar tooth reach inferior to mylohyoid muscle

(b) sublingual space: roots of teeth anterior to 2nd / 3rd molar remain above mylohyoid muscle

CT:

√ rimlike enhancement of fluid collection (abscess), cellulitis, myositis

√ cortical dehiscence commonly on lingual aspect of mandible

√ permeative bone changes, osseous destruction, periosteal reaction

Cx: descending necrotizing mediastinitis

Rx: tooth extraction, abscess drainage, IV antibiotics

PERITONSILLAR ABSCESS

= complication of untreated / incompletely treated tonsillitis

◊ Most commonly encountered deep neck infection among adolescents + young adults!

Prevalence: ⅓ of all soft-tissue abscesses of head & neck

Organism: β-hemolytic Streptococcus, Staphylococcus aureus, pneumococcus, Haemophilus influenzae

• severe unilateral sore throat, dysphagia, otalgia, trismus

• tender cervical lymphadenopathy

• pharyngotonsillar exudate, fever

Imaging: (1) Diagnosis uncertain

(2) Limited clinical examination (severe trismus)

(3) Suspected infection of deep neck space

(4) Failed response to therapy

Location: between tonsillar capsule and pillar

CECT (75% specific, 99% sensitive):

√ tonsillar enlargement: √ "kissing tonsils" = medial apposition of enlarged tonsils

√ mass effect on oropharynx

√ linear striated enhancement of palatine tonsil + posterior pharyngeal soft tissue

√ central liquefaction + surrounding rimlike enhancement

◊ Commonly FP due to phlegmon!

Site: peritonsillar abscess typically along superior tonsillar pole (= potential space between tonsillar capsule + superior constrictor muscle)

√ true tonsillar abscess (rare)

Cx: extension of infection into parapharyngeal + masticator + submandibular space

Rx: needle aspiration, surgical drainage

DDx: tonsillitis; phlegmonous infection; necrotic retropharyngeal lymph node

PERSISTENCE OF STAPEDIAL ARTERY

= rare congenital vascular anomaly due to failure of regression of the embryonic stapedial artery that connects branches of the future external carotid artery to internal carotid artery

Prevalence: 1÷5,000

May be associated aberrant ICA

with:

Origin: petrous segment of ICA / aberrant ICA

Course: anteriorly and superiorly through middle ear to supply the middle meningeal artery

- pulsatile tinnitus
- conductive hearing loss ← ankylosis of stapes
- sensorineural hearing loss ← erosion of otic capsule (rare)

√ enlarged / separate tympanic segment of facial nerve canal
√ abnormal linear soft-tissue density crossing over cochlear promontory
√ absent / hypoplastic ipsilateral foramen spinosum
√ absence of normal origin of middle meningeal artery

PHARYNGEAL ABSCESS

Etiology: spread of infection from tonsils / pharynx
Age: children > adults

- trismus (most common presenting symptom) from involvement of pterygoid muscle, sore throat, low-grade fever

√ isodense / low-density mass with unsharp margins
√ rim enhancement
Cx: mycotic aneurysm of carotid artery (within 10 days)

PINDBORG TUMOR

[Jens Pindborg (1921–1995), Danish oral pathologist in Copenhagen]
= CALCIFYING EPITHELIAL ODONTOGENIC TUMOR
Frequency: 0.17–1.8% of all odontogenic tumors
Age: 20–60 years; M÷F = 1÷1
Histo: epithelial cells in a fibrous stroma
Associated with: crown of impacted tooth
Location: premolar / molar region of mandible (⅔), maxilla (⅓)
√ perichondral lucencies
√ radiolucent with scattered calcified components
CT:
√ diffuse highly attenuated foci = intralesional calcifications
MR:
√ predominantly low signal intensity on T1WI
√ high signal intensity on T2WI
√ heterogeneous contrast enhancement

PLEOMORPHIC ADENOMA

= BENIGN MIXED TUMOR OF PAROTIS
Frequency: 80% of all benign parotid tumors; 3rd most common tumor in pediatric parotid gland (after hemangioma + lymphangioma)
Histo: mixture of epithelial + myoepithelial cells
Age: usually > 50 (range, 30–70) years; M < F

• slow-growing asymptomatic hard painless lump in cheek
Location: usually solitary + unilateral
mnemonic: 80% in parotid gland
80% in superficial lobe
80% benign
√ lobulated round / oval sharply marginated mass
√ rarely dystrophic calcifications
√ variable, usually mild contrast enhancement
US:
√ hypo- to isoechoic well-defined lobulated mass
√ posterior acoustic enhancement
√ homogeneous well-defined tumor (if small)
√ less well-defined with low-density center if large (mucoid matrix, hemorrhage, necrosis)
√ ± hyperechogenic shadowing foci of calcifications
√ often poor / absent / occasionally abundant vascularity
MR:
√ hypointense on T1WI + hyperintense mass on T2WI
√ hyperintense areas in center (mucoid matrix)
Cx: malignant transformation after decades (= carcinoma ex pleomorphic adenoma, typically after 10–15 years); usually multifocal recurrence after inadequate surgery
Rx: facial nerve-sparing partial parotidectomy

RANULA

= mucus retention cyst / mucocele ← obstruction of sublingual / adjacent minor salivary gland
Classification:
(a) simple: confined to sublingual space; occasionally in submandibular space ← herniation through mylohyoid defect / arising from ectopic sublingual gland
(b) diving: extends to below mylohyoid muscle into submandibular space
Cause: trauma / inflammation of salivary gland
Origin: sublingual gland / minor salivary gland
• swelling in floor of mouth
US:
√ simple cystic (anechoic) lesion deep to mylohyoid muscle
√ ± fine internal echoes ← debris
MR:
√ lesion of high SI in sublingual space on T2WI
√ ± abnormally high SI on T1WI ← high protein content

Plunging / Diving Ranula

= pseudocyst (= no epithelial lining) in submandibular space
Cause: ruptured sublingual gland retention cyst
• gradually enlarging painless mass in submental / submandibular triangle
Location: posterior extension into submental / submandibular space with narrow tail to

floor of mouth

Size: < 6 cm in largest diameter

√ continuous cystic mass of comet-tail shape:

√ head of the comet = submandibular space component

√ tail of the comet = component pointing toward sublingual space

√ constriction at myohyoid muscle

RETROPHARYNGEAL ABSCESS / HEMORRHAGE

= PREVERTEBRAL ABSCESS

= spread of infection within retropharyngeal space

◊ In neck 2nd most common location after peritonsillar abscess

Etiology: tonsillitis, suppurative lymphadenitis, pharyngitis, otitis media, infection of oral cavity, dental infection, sinusitis, penetrating trauma of pharynx / esophagus, diskitis, osteomyelitis

Organism: Staphylococcus aureus, H influenzae, Streptococcus pneumoniae, Streptococcus pyogenes, Bacteroides melaninogenicus, typically mixed polymicrobial flora

Path: cellulitis > abscess

Age: usually 2–4 (range, 1–6) years (atrophy of nodes with age)

- history of upper respiratory tract infection
- fever, sore throat, neck stiffness, dysphagia, cough, sepsis

Lateral neck radiograph:

√ thickness of retropharyngeal space > ¾ of AP diameter of vertebral body:

√ may contain locules of gas / gas-fluid levels

√ reversal of cervical lordosis

√ anterior bowing / displacement of airway

N.B.: look carefully for possible ingested foreign body

DDx: "pseudothickening" (common in pediatric patients) ← neck flexion / incomplete inspiration

US:

√ hypoechoic areas + adenopathy

CECT (obligatory with concern for abscess):

√ hypoattenuating ovoid fluid collection

√ loss of normal bow-tie shape of retropharyngeal space

√ complete irregular circumferential rimlike enhancement (HALLMARK)

DDx: partial / NO enhancement = phlegmon

Cx: (1) Inferior extension through anatomic "danger space" into mediastinum

N.B.: ensure that at least part of mediastinum is imaged to exclude descending mediastinitis

(2) Direct extension to spine / epidural or carotid space

(3) Compromised airway

(4) IJV thrombosis = Lemierre syndrome

(5) Narrowing of ICA

(6) Pseudoaneurysm of ICA

Rx: aggressive treatment with IV antibiotics, airway management, surgical drainage

DDx: retropharyngeal space edema; suppurative retropharyngeal lymph node

> The differentiation of retropharyngeal abscess from retropharyngeal edema or cellulitis is critical but difficult in the absence of rimlike enhancement.

RHINOCEREBRAL MUCORMYCOSIS

= paranasal sinus / orbital infection caused by nonseptated fungi Rhizopus arrhizus and Rhizopus oryzae

Spread: fungus first involves nasal cavity, then extends into maxillary / ethmoid sinuses / orbits / intracranially along ophthalmic artery / cribriform plate (frontal sinuses are spared)

Predisposed:

(1) Poorly controlled diabetes mellitus
(2) Chronic renal failure
(3) Cirrhosis
(4) Malnutrition
(5) Cancer
(6) Prolonged antibiotic therapy
(7) Steroid therapy
(8) Cytotoxic drug therapy
(9) AIDS
(10) Extensive burns

- black crusting of nasal mucosa (in diabetics)
- small ischemic areas (invasion of arterioles + small arteries)

√ propensity for vascular invasion by fungal hyphae ← production of elastase

Cx: cerebral infarction, hemorrhage, mycotic aneurysm

√ nodular thickening involving nasal septum + turbinates
√ mucoperiosteal thickening + clouding of ethmoids
√ focal areas of bone destruction

Cx: (1) Blindness
(2) Cranial nerve palsy
(3) Hemiparesis

Prognosis: high mortality rate

SIALADENITIS

Organism: S. aureus
Location: submandibular gland, parotid gland
Site: typically unilateral

Acute Submandibular Sialadenitis

- "salivary colic" = painful swelling exacerbated by eating

US:

√ may depict ductal obstruction + calculi as small as 3 mm

CT:

√ enlargement of submandibular gland
√ ductal dilatation ← obstructive calculus / stenosis:

√ calculus in submandibular duct (80–90%) / parotid duct (10–20%) = radiographically visible in 80–90%

√ cellulitis + myositis in sublingual + submandibular space

Sialography:

√ may demonstrate cause of ductal stricture ← calculus, recurrent infection, autoimmune disease, trauma (rare)

Chronic Recurrent Sialadenitis

A. PAROTID GLAND

- painful periodic unilateral enlargement of parotid gland
- milky discharge may be expressed

Sialography:

√ Stensen duct irregularly enlarged / sausage-shaped

√ pruning of distal parotid ducts

√ ± calculi

CT:

√ diffusely enlarged dense gland

√ dilated Stensen duct ± calculi

Cx: Mucocele

B. SUBMANDIBULAR GLAND

- firm painless submandibular gland

√ unilateral atrophy + fatty infiltration

Acute Parotitis

Cause: bacterial, viral, calculus-induced

- toxic appearance, high fever, tenderness
- sudden onset of pain, swelling, tenderness

Acute Suppurative Parotitis

- purulent material expressed from Stenson duct

Organism: S. aureus (> 50%), anaerobic bacteria

At risk: elderly, debilitated, intubated + dehydrated patient

CT:

√ diffusely enlarged + enhancing parotid gland

√ ill-defined margins

√ intraparotid hypoattenuating abscess

HIV Parotitis

Histo: benign lymphoepithelial lesion consisting of an intranodal cyst lined with epithelial cells

US:

√ multiple hypoechoic / anechoic areas without posterior acoustic enhancement (70%)

√ anechoic cysts (30%)

CT / MR:

√ bilateral parotid gland enlargement with intraglandular cystic + solid masses

√ cervical lymphadenopathy + enlarged adenoids typically associated

Prognosis: parotid involvement is associated with a better prognosis in HIV-positive children!

Viral Parotitis

- self-limiting condition with prodromal symptoms

Peak age: 5–9 years
Organism: paramyxovirus (mumps) > influenzavirus, parainfluenzavirus, coxsackievirus, cytomegalovirus, adenovirus
Site: bilateral in 75%
Associated with: systemic viral illness ± involvement of submandibular and sublingual glands

Calculus-induced Parotitis

Site: typically unilateral
X-ray: √calculus radiolucent in 90%
CT: √majority of calculi visible

SIALOLITHIASIS

- recurrent swelling of salivary gland during eating
- palpable stone in floor of mouth = in distal part of submandibular (Wharton) duct

Location: submandibular gland (60–90%), parotid gland (10–20%); may be multiple
X-ray:
√ stones radiopaque (in only 20%)
Sialography (digital / MR)
US:
√ strongly hyperechoic line + distal acoustic shadowing
√ dilated excretory ducts
Cx: partial / total mechanical obstruction of salivary duct, bacterial infection, loss of glandular function

SIALOSIS

= usually bilateral nontender <u>noninflammatory</u> recurrent enlargement of parotid gland
Cause: cirrhosis, alcoholism, diabetes, malnutrition, hormonal insufficiency (ovarian / pancreatic / thyroid), drugs (sulfisoxazole, phenylbutazone), radiation therapy
Histo: serous acinar hypertrophy + fatty replacement of gland
Sialography:
√ sparse peripheral ducts
CT:
√ enlarged / normal-sized gland
√ diffusely dense gland in end stage
US:
√ enlarged hyperechoic salivary gland
√ NO focal lesion / increased blood flow

SINONASAL POLYPOSIS

= benign sinonasal mucosal lesions

Frequency: in 25% of patients with allergic rhinitis;
in 15% of patients with asthma
◊ Most frequent complication of sinusitis!

Pathogenesis: expansion of fluid in deep lamina propria of sinonasal mucosa

Cause: infectious rhinosinusitis; allergic fungal rhinitis (atopic hypersensitivity); cystic fibrosis (child); asthma; Kartagener syndrome; nickel exposure; aspirin intolerance; nonneoplastic hyperplasia of inflamed mucous membranes

Location: commonly maxillary antrum

√ multiple homogeneous soft-tissue masses with smooth convex borders within nasal cavity enlarging sinus ostium

√ remodeling / expansion of sinus with enlargement
◊ Most common expansile lesion in nasal cavity!

√ thinning of bony trabeculae ± erosive changes at anterior skull base

√ usually peripheral / occasionally solid heterogeneous enhancement

DDx: neoplasm, mucocele, mucus retention cyst

Prognosis: 75% surgical failure rate

Antrochoanal Polyp

= benign antral polyp, which widens the sinus ostium and extends into nasal cavity; 5% of all nasal polyps

Age: teenagers + young adults

√ antral clouding

√ ipsilateral nasal mass

√ smooth mass enlarging the sinus ostium

√ NO sinus expansion

Angiomatous Polyp

= derivative of choanal polyp (following ischemia of polyp with secondary neovascularity along its surface)

DDx: juvenile angiofibroma (involvement of pterygopalatine fossa)

SINONASAL PSEUDOTUMOR

Location: nasal cavity, nasopharynx, skull base, temporal bone, maxillary sinus, larynx, trachea, thyroid gland, salivary gland

√ more aggressive appearance than orbital pseudotumors:
√ osseous erosion, remodeling, sclerosis (common)

√ ± perineural spread along maxillary, mandibular, hypoglossal nn.

Cx: internal carotid occlusion

Prognosis: good after complete resection

Rx: less responsive to steroid therapy than orbital pseudotumors

SINUSITIS

Incidence:

most common paranasal sinus problem; most common chronic disease diagnosed in USA (31,000,000 persons per year); complicating common colds in 0.5% (3–4 colds per year in adults, 6–8 colds per year in children)

Pathogenesis:

viral infection → mucosal congestion → apposition of mucosal surfaces → retention of secretions → bacterial superinfection

(1) Obstruction of major ostia
  (a) middle meatus draining frontal, maxillary, anterior ethmoid sinus
  (b) sphenoethmoidal recess draining posterior ethmoid sphenoid sinus
(2) Ineffective mucociliary clearing ← contact of two mucosal surfaces

Predisposing anatomic variants:

(1) Greater degree of nasal septal deviation
(2) Horizontally oriented uncinate process NOT concha bullosa, paradoxical turbinate, Haller cells, uncinate pneumatization

Location:

(1) Infundibular pattern (26%)
  = isolated obstruction of inferior infundibulum just above the maxillary sinus ostium
  √ limited maxillary sinus disease
(2) Ostiomeatal unit pattern (25%)
  √ middle meatus opacification
(3) Sphenoethmoidal recess obstruction (6%)
  √ sphenoid / posterior ethmoid sinus inflammation
(4) Sinonasal polyposis pattern
  √ enlargement of ostia, thinning of adjacent bone
  √ air-fluid levels

Plain films (Waters, Caldwell, lateral, submental vertex views):

1. **Acute sinusitis**

   Dx: rests on clinical rather than radiologic findings!

   • "cold" symptoms (cough), fever, purulent nasal discharge
   √ mucosal thickening + enhancement
   √ air-fluid level ← retention of secretions ← ostial dysfunction ← mucosal swelling
   √ total sinus opacification
   √ hyperintense secretions on T2WI (95% water content + 5% proteinaceous macromolecules)

   DDx: mucus retention cyst

2. **Chronic sinusitis**

   √ mucosal swelling > 5 mm thick on Waters view (99% sensitive, 46% specific in maxillary sinus)
   √ bone remodeling + sclerosis ← osteitis
   √ polyposis
   √ hyperattenuating lesion on NECT ← inspissated secretions / fungal disease
   √ hypointense secretions on T1WI + T2WI ← inspissated material with chronic obstruction (DDx: air)

CT and MR lack specificity to diagnose acute sinusitis.
Either modality may be used to identify complications.

CT:
mapping bony anatomy for surgical planning

MR:
√ sinus thickening with high SI on T2WI + low SI on T1WI
√ near solid secretions with > 28% protein concentration are hypointense on both T1WI + T2WI simulating air
√ rim gadolinium enhancement (DDx to neoplasms, which enhance centrally)

Cx:
(1) Mucous retention cyst (10%)
(2) Mucocele
(3) Orbital extension through neurovascular foramina, dehiscences, or thin bones: orbital cellulitis
(4) Pott puffy tumor
(5) Septic thrombophlebitis
(6) Intracranial extension: meningitis, epidural abscess, subdural empyema, venous sinus thrombosis, cerebral abscess

Rx: functional endoscopic sinus surgery (amputation of uncinate process; enlargement of infundibulum + maxillary ostium; creation of common channel for anterior ethmoid air cells; complete / partial ethmoidectomy

Bacterial Sinusitis

Organism:
(a) acute phase: Streptococcus pneumoniae + Haemophilus influenzae (> 50%), beta-hemolytic streptococcus, Moraxella catarrhalis
(b) chronic phase: staphylococcus, streptococcus, corynebacteria, Bacteroides, fusobacteria

√ solitary antral disease (obstruction of sinus ostium)
√ uniform enhancement

Mycotic = Fungal Sinusitis

Organism: Aspergillus fumigatus, mucormycosis, bipolaris, Drechslera, Curvularia, Candida

√ polypoid lesion / fungus ball (= extramucosal infection ← saprophytic growth on retained secretions, usually caused by Aspergillus)
√ infiltrating fungal sinusitis (in immune-competent host)
√ fulminant fungal sinusitis (aggressive infection in immune-compromised individual / diabetics)

CT:
√ punctate calcifications (= calcium phosphate / calcium sulfonate deposition near mycelium)

MR:
√ dark on T2WI ← high fungal mycelial iron, magnesium, manganese content from amino acid metabolism (DDx: inspissated secretions / polypoid disease)

Dx: failure to respond to antibiotic therapy

Noninvasive Fungal Sinusitis

FUNGAL MYCETOMA / FUNGUS BALL OF SINUS

= uncommon manifestation as a tangled collection of fungal hyphae without allergic mucin

Organism: Aspergillus fumigatus, (rarely) Pseudallescheria boydii and Alternaria

Cause: deficient mucociliary clearance

Age: older individual; M < F

- asymptomatic
- minimal symptoms: chronic pressure, nasal discharge, cacosmia [*kakos*, Greek = bad, *osme* = smell]

√ nonenhancing intraluminal mass (usually limited to one sinus)

NECT:

√ hyperattenuating mass ← dense matted fungal hyphae
√ ± punctate calcifications
√ hypoattenuating mucosal lining ← inflammation
√ sclerotic thickened bony sinus walls
√ ± sinus expansion with focally thinned wall ← pressure necrosis

MR:

√ hyperintense mucosal lining on T2WI
√ hypointense intraluminal mass on T1WI + T2WI ← absence of free water
√ areas of signal void on T2WI ← calcifications and paramagnetic metals (iron, magnesium, manganese)

N.B.: NO invasion of sinus mucosa, blood vessels, bone

ALLERGIC FUNGAL SINUSITIS

◊ Most common form of fungal sinusitis characterized by presence of "allergic mucin" (= inspissated yellow-green / white-tan / gray / brown / black mucin of peanut butter consistency)

Prevalence: 5–10% of surgical patients with chronic hypertrophic sinus disease

Region: northern India, southern USA (warm humid climate)

Cause: IgE–mediated type I immediate hypersensitivity and type III delayed hypersensitivity reaction to inhaled fungal organisms (similar to allergic bronchopulmonary aspergillosis)

Organism: Bipolaris, Curvularia, Alternaria (dematiaceous pigmented fungi), Aspergillus, Fusarium (hyaline molds)

Histo: eosinophils + Charcot-Leyden crystals

Age: immunocompetent patient in 3rd decade

- chronic headaches, nasal congestion, chronic sinusitis
- history of sinus surgery

Often associated with: atopy (allergic rhinitis, asthma)

Location: multiple / all sinuses (bilateral); nose

√ near-complete opacification
√ high concentration of various metals (iron, magnesium, manganese) concentrated by

fungal organisms + high protein concentration + low free-water content:
√ hyperattenuating allergic mucin
√ mixed low / intermediate / high SI on T1WI
√ characteristic low SI / signal void on T2WI
√ inflamed mucosal lining:
√ hypointense on T1WI + hyperintense on T2WI
√ enhancement after administration of gadolinium
√ no central enhancement (DDx to neoplasm)
√ ± expansion of sinus and smooth bone erosion
√ ± intracranial and intraorbital extension

Invasive Fungal Sinusitis

Predisposed: immunocompromised
Pathophysiology: vascular invasion → rapid spread to maxillofacial soft tissues, orbit, pterygo-palatine fossa, anterior cranial fossa
MR signs of invasion:
√ obliteration of periantral fat = subtle sign of invasion
√ intraorbital invasion:
√ inflammation of orbital fat + extraocular muscle → proptosis
√ intracranial invasion:
√ leptomeningeal enhancement (initial stage)
√ adjacent cerebritis, granuloma, cerebral abscess
Cx: thrombosis of veins + cavernous sinus, meningitis, epidural + cerebral abscess, intraorbital extension, osteomyelitis, carotid artery invasion / occlusion / pseudoaneurysm → fatal cerebral infarct and intracranial hemorrhage
DDx: malignant neoplasm

ACUTE INVASIVE FUNGAL SINUSITIS

= INVASIVE FUNGAL RHINOSINUSITIS
= rapidly progressive most lethal form of sinusitis with hyphae within mucosa / submucosa / bone / blood vessels of paranasal sinuses
Predisposed: immunocompromised, poorly controlled diabetes
Organism:
(a) zygomycosis in diabetics with varied species: Rhizopus, Rhizomucor, Absidia, Mucor
(b) neutropenia (= neutropenic sinusitis) with hematologic malignancy, systemic chemotherapy, systemic steroid Rx, bone marrow transplantation, organ transplantation, AIDS : Apergillus in 80%
Associated with: nasal infection (⅔ in middle turbinate)
• painless necrotic nasal septal ulcer (eschar), sinusitis
CT:
√ aggressive bone destruction of sinus walls on CT
√ severe unilateral nasal cavity soft-tissue thickening (nonspecific)
Mortality: 50–80% among neutropenic patients
Rx: aggressive surgical débridement, systemic antifungal medication

CHRONIC INVASIVE FUNGAL SINUSITIS

= persistent + recurrent disease → invasion develops over months to years

Organism: Mucor, Rhizopus, Aspergillus, Bipolaris, Candida

• chronic rhinosinusitis: paranasal sinus pain, fever, serosanguinous nasal discharge, epistaxis, nasal polyposis

CT:

√ hyperattenuating soft-tissue collection

√ mottled lucencies / irregular bone destruction

√ sclerotic changes in osseous sinus walls (chronic)

MR:

√ decreased signal intensity on T1WI + T2WI

Odontogenic Sinusitis

Incidence: 5–38% of maxillary sinusitis

• purulent nasal discharge, facial pressure, cheek and facial pain

◊ Infection decompressed through patent ostiomeatal unit!

◊ Sinus floor mucosal inflammation may manifest with toothache!

√ sinus mucosal thickening above a carious tooth

√ focal ballooning / dehiscence above a carious tooth

√ unerupted tooth in maxillary sinus

Rx: root canal therapy, tooth extraction, antibiotics

SJÖGREN SYNDROME

= MYOEPITHELIAL SIALADENITIS

= chronic autoimmune multisystem disorder (= collagen-vascular disease) characterized by inflammation + destruction of exocrine glands (by T-lymphocytes, mainly CD4+ cells, and autoantibodies from hyperstimulated B cells) → dryness of mucous membranes affecting

(1) Salivary + lacrimal glands

(2) Mucosa + submucosa of pharynx

(3) Tracheobronchial tree

(4) Reticuloendothelial system

(5) Joints

Frequency: 0.1% of population; 3% of older adults

Cause:

A. PRIMARY SJöGREN SYNDROME

= autoimmune exocrinopathy in isolation

(a) recurrent parotitis in children

(b) **Sicca syndrome** = Mikulicz disease = xerophthalmia + xerostomia

B. SECONDARY SJöGREN SYNDROME

as a complication of other autoimmune disorders

Associated with:

(a) connective tissue diseases

1. Rheumatoid arthritis (55%)
2. Systemic lupus erythematosus (2%)
3. Progressive systemic sclerosis (0.5%)

4. Psoriatic arthritis, primary biliary cirrhosis (0.5%)
5. Polymyositis

(b) lymphoproliferative disorders

1. Lymphocytic interstitial pneumonitis (LIP)
2. Pseudolymphoma (25%)
3. Lymphoma (5%; 44 x increased risk): mostly B-cell lymphoma
4. Waldenström macroglobulinemia

Mean age: 57 (range, 35–70) years; M÷F = 1÷9

Path: benign lymphoepithelioma

Histo: lymphocytic infiltrate associated ductal dilatation, acinar atrophy, interstitial fibrosis (= parotid destruction)

- **xerostomia** (most common symptom) = atrophy of salivary + parotid glands → diminished saliva production and dryness of mouth + lips
- **xerophthalmia** = dryness of eyes = keratoconjunctivitis sicca = desiccation of cornea + conjunctiva ← decreased lacrimation
- **xerorhinia** = dryness + crusting of nasal mucosa

  Cx: epistaxis, nasal septal perforation
- decreased sweating, decreased vaginal secretions
- swelling of parotid gland:
  - › recurrent acute episodes with tenderness; usually unilateral
  - › chronic glandular enlargement with superimposed acute attacks of painless progressive swelling
- rheumatoid factor (positive in up to 95%)
- ANA (positive in up to 80%); mitochondrial antibodies (6%)

Location: lacrimal + salivary glands; mucous glands of conjunctivae, nasal cavity, pharynx, larynx, trachea, bronchi; extraglandular involvement in 5–10%

@ Lung (9–75%)

affected by airway abnormalities, interstitial pneumonias, and lymphoproliferative disorders

- chronic dry cough, recurrent bronchitis, dyspnea on exertion

Histologic pattern of interstitial lung disease:

LIP, NSIP, UIP, cryptogenic organizing pneumonia, follicular bronchiolitis, diffuse interstitial amyloidosis

√ pulmonary fibrosis (10–14%, most common finding)
√ reticulonodular pattern (3–33–52%) involving lower lobes (= lymphocytic interstitial pneumonitis)
√ patchy consolidation
√ inspissated mucus
√ atelectasis
√ recurrent pneumonia
√ bronchiectasis of both lower lobes
√ acute focal / lipoid pneumonia ← oils taken to combat dry mouth
√ ± pleural effusion (uncommon)

HRCT (usually required for detection):

√ poorly defined centrilobular nodules + branching linear opacities = tree-in-bud appearance

√ bronchiectasis + bronchiolectasis
√ bronchial wall thickening ← bronchiolar inflammation
√ groundglass opacities + air trapping
√ thickening of interlobular septa
√ cysts ← bronchiolar obstruction ← follicular bronchiolitis (= lymphocytic wall infiltration)

@ Mediastinum
√ lymph node enlargement
√ thymic lymphoid hyperplasia
√ multilocular thymic cyst
√ MALT lymphoma

@ Parotid gland
Sialogram:
√ nonobstructive sialectasia (ducts + acini destroyed by lymphocytic infiltrates / infection)
Stage I : punctate contrast collection < 1 mm
Stage II : globular contrast collection 1–2 mm
Stage III : cavitary contrast collection > 2 mm
Stage IV : destruction of gland parenchyma

US:
√ enlarged heterogeneous gland with punctate areas of increased echogenicity (= mucus-filled ducts)
√ multiple small oval usually well-defined scattered hypo- / anechoic areas bilaterally (= sialectasis ← cystic dilatation of intraparotid ducts + glands)
√ increased parenchymal vascularity on color Doppler

MR:
√ inhomogeneous "honeycomb" / "salt and pepper" appearance (= areas of low intensity between nodular parenchyma of high SI) on T2WI / Gd-enhanced T1WI

@ CNS involvement (in 25–30%)
• trigeminal neuropathy, recurrent aseptic meningoencephalitis, cerebral parenchymatous lesions

MR:
√ extensive uni- / multifocal white and gray matter lesions + infarctions + microbleeds
√ multiple arterial narrowings

Prognosis: generally good (morbidity from decreased function of exocrine organs)

Cx: **Sjögren syndrome-associated B-cell lymphoma** (occurs in salivary glands + mucosa-associated lymphatic tissue in stomach + lung in a significant number of patients + follows an aggressive course)

Dx: biopsy for fast-growing lesions > 2 cm

SUBGLOTTIC STENOSIS

A. CONGENITAL SUBGLOTTIC STENOSIS
• crouplike symptoms, often self-limiting disease
Location: 1–2 cm below vocal cords

√ circumferential symmetrical narrowing of subglottic portion of trachea during inspiration
√ NO change in degree of narrowing with expiration

B. ACQUIRED SUBGLOTTIC STENOSIS
following prolonged endotracheal intubation (in 5%)

TERATOMA OF HEAD & NECK

= GERM CELL TUMOR OF NECK

Prevalence: 1÷20,000 to 1÷40,000 live births; 5% of newborn teratomas in lateral + anterior neck

◊ 80% of mediastinal germ cell tumors are benign!

Origin: thyrocervical area / palate / nasopharynx

Spectrum:

1. Dermoid cyst (with skin appendages):
   Site: orbit, nasal region, at floor of the mouth
2. Epidermoid cyst
3. Teratoid cyst (with tissues from CNS, GI, respiratory system)

OB-US:

√ polyhydramnios in 30% ← esophageal obstruction
√ large bulky complex cystic + solid mass in cervical region
√ calcifications (in 50%)

CT:

√ hypoattenuating thin-walled unilocular mass:
  √ nodules frequent in dermoid cysts
  √ heterogeneous contents in teratomas

MR:

√ hypo- to isointense on T1WI + hyperintense on T2WI:
  √ dermoid cysts may be hyperintense on T1WI ← lipid-containing areas
  √ coronal imaging useful to depict relationship to mylohyoid muscle

Cx: airway obstruction, compromised swallowing

Rx: ex utero intrapartum treatment (EXIT) procedure

DDx: cystic hygroma (septated fluid-filled collection, posterior location), goiter, branchial cleft cyst, cervical meningo-cele, neuroblastoma of neck, hemangioma of neck

Cervical Teratoma

= usually benign; malignant transformation possible

Prevalence: 5% of teratomas in newborn

Location: anteriorly (thyroid gland) with extension to trapezius muscle (posteriorly), mastoid (superiorly), clavicle / mediastinum (inferiorly)

√ hyperextension of neck
√ solid + cystic structures within heterogeneous mass
√ calcifications (more frequent than cartilage / bone)

Cx: malpresentation, dystocia

Teratoma of Mouth

= EPIGNATHUS

Origin: hard / soft palate
√ mass filling oral cavity + extending out through mouth
DDx: frontal encephalocele, myoblastoma

TEMPOROMANDIBULAR JOINT DYSFUNCTION

= internal derangement = abnormal relationship of disk to condyle
Incidence: affects up to 28% of population
Cause: disk injury
√ intrinsic disk lesion (change in shape + signal intensity):
  √ irregular biconvex / rounded disk ← thickening of posterior band + reduction in mass of anterior band and central thin area
  √ flattening of disk
  √ reduction in normal intermediate to high SI of disk
√ disk displacement:
  √ anterior (in up to 34% of asymptomatic volunteers), anterolateral, anteromedial, lateral, medial, posterior disk displacement
  √ anterior displacement of posterior band in front of condyle with abnormal stretching of bilaminar zone
  √ anterior displacement of meniscus without reduction at maximum mouth opening
  √ "stuck disk" = fixed position of disk relative to glenoid fossa and articular eminence during closed- and open-mouth positions
  √ "locked jaw" = posterior band displaced beyond 1 o'clock position
√ joint effusion
√ osteoarthritis: flattening, osteophytes, erosions, sclerosis

THYROGLOSSAL DUCT CYST

= failure of complete involution of embryonic thyroglossal duct
Frequency: most common congenital neck mass (70% of all congenital neck anomalies); 2nd most common benign neck mass after benign lymphadenopathy; 90% of nonodontogenic congenital cysts
Histo: cyst lined by stratified squamous epithelium / ciliated pseudostratified columnar epithelium ± mucous glands; ectopic thyroid tissue in 5–62%
Age: < 10 years in 50%; 2nd peak at 20–30 years; M=F
• gradually enlarging painless midline neck mass
• cyst moves vertically / upward during protrusion of tongue / swallowing ← close relationship of cyst to hyoid bone + foramen cecum (= most SPECIFIC physical finding)
• ± history of previous incision and drainage of an "abscess" in area of cyst
Location: suprahyoid (15–25%), at level of hyoid (15–50%), infrahyoid (20–65%)
Site: midline (75%), paramedian within 2 cm of midline frequently on left (25%)
Size: 1.5–3.0 (range, 0.5–6.0) cm
√ cyst with occasional septation within 2 cm of midline
√ infrahyoid cyst embedded within / deep to strap muscle:
  √ infrahyoid strap muscles beaks over edge of cyst
  √ thin connecting stalk to midline

√ paramedian cyst with a tail that dives into hyoid bone

US:

- √ anechoic cyst (42%) in midline
- √ hypoechoic mass with fine to coarse internal echoes (= proteinaceous material) + increased through transmission

Scintigraphy:

- √ uptake in functional thyroid tissue of thyroglossal duct cyst

CT:

- √ smooth well-circumscribed midline mass with thin wall
- √ homogeneous mucoid attenuation of 0–20 HU / occasionally higher ← increased protein content
- √ thin peripheral rim of enhancement
- √ tract of thyroid tissue between cystic mass + thyroid

MR:

- √ cyst of low to intermediate SI on T1WI + high SI on T2WI
- √ NO restricted diffusion
- √ nonenhancing / enhancing very thin rim (unless inflamed)
- √ heterogeneous complex cyst with infection:
  - √ thick irregular rim of enhancement
  - √ variable SI of fluid ← infection / hemorrhage
  - √ profuse surrounding soft-tissue edema

Cx: (1) Infection → thick external wall ± internal septa
(2) Fistulous communication to the skin (15–33%)
(3) Thyroid carcinoma (1–4%): in 80% papillary ca.
(4) Squamous cell carcinoma (even rarer)

Dx: close association with hyoid bone (60–80%)

Rx: Sistrunk procedure (= resection of central portion of hyoid bone + core of tissue following the expected course of entire thyroglossal duct to foramen cecum) with 2.6% recurrence rate

DDx: (1) Ectopic thyroid (no thyroid tissue in normal location)
(2) Obstructed laryngocele (well-defined smooth mass / saccular cyst in lateral aspect of superior paralaryngeal space connecting to larynx originating from saccule / appendix of laryngeal ventricle)
(3) 2nd branchial cleft cyst (round mass near mandibular angle along anterior surface of sternocleidomastoid muscle / displacing muscle posterolaterally, lateral to carotid sheath structures (carotid artery + internal jugular vein), posterior to submandibular gland, PATHOGNOMONIC beak insinuating itself between ICA + ECA)
(4) Thymic cyst = persistent thymopharyngeal duct (mostly on left side of neck)
(5) Lymphatic malformation (mostly in posterior cervical triangle, transspatial, containing locules, congenital lesion detected by age 2 years)
(5) Lingual abscess (← infected lingual thyroglossal duct cyst / dermoid cyst / ranula / secondary to instrumentation or tongue piercing)

THYROID ADENOMA

√ round / oval mass of low attenuation with enhancement

Adenomatous Nodule (42–77%)
= COLLOID NODULE = ADENOMATOUS HYPERPLASIA
= DEGENERATIVE INVOLUTED NODULE
Cytology: abundant colloid + benign follicular cells with uniform slightly large nuclei, arranged in a honeycomb pattern (difficult DDx from follicular tumors)
√ often multiple nodules by US / scintigraphy / surgery
√ mostly hypofunctioning, rarely hyperfunctioning
√ solid form = incompletely encapsulated, poorly demarcated nodules merging with surrounding tissue
√ cystic form (= colloid cyst) = anechoic areas in nodule ← hemorrhage / colloid degeneration
√ calcific deposits

Follicular Adenoma (15–40%)
= monoclonal tumor arising from follicular epithelium
Path: single lesion with well-developed fibrous capsule
Histo subtypes:
(a) Simple colloid (macrofollicular) adenoma: most common form
(b) Microfollicular (fetal) adenoma
(c) Embryonal (trabecular) adenoma
(d) Hürthle-cell (oxyphil / oncocytic) adenoma: large single polygonal cells with abundant granular cytoplasm + uniform eccentric nuclei + no colloid
(e) Atypical adenoma
(f) Adenoma with papillae
(g) Signet-ring adenoma
◊ 5% of microfollicular adenomas, 5% of Hürthle-cell adenomas, 25% of embryonal adenomas prove to be follicular cancers in carefully performed study!
Functional status:
(1) Toxic adenoma
(2) Toxic multinodular goiter = hyperfunctioning adenoma within multinodular goiter; usually occurs in nodule > 2.5 cm in size
(3) Nonfunctioning adenoma
√ mass with increased / decreased echogenicity
√ "halo" sign = complete hypoechoic ring with regular border surrounding isoechoic solid mass
Rx: surgical hemithyroidectomy (→ 15–30% risk of malignancy if diagnosed on FNAB)

THYROID CARCINOMA

Incidence: 25,000 new cancers per year in USA (2005); clinically silent cancers in up to 35% at autopsy / surgery (usually papillary carcinomas of < 1.0 cm in size); 3.6÷100,000 (1973), 8.7÷100,000 (2002)
Age: < 30 years; M÷F = 1÷3 to 1÷2
Risk factors: age < 20 years or > 60 years; history of neck irradiation; family history of thyroid

cancer
◊ Lifetime risk of thyroid cancer < 1% in USA

Types (in order of worsening prognosis):
papillary (50–80%) > follicular (10–20%) > medullary (6–10%) > anaplastic

• history of neck irradiation, rapid growth
• stone-hard nodule:
◊ 5–7% of all thyroid nodules are malignant!

√ hypoechoic / hypoattenuating mass
√ irregular ill-defined border without / disrupted halo
√ NO hemorrhage / liquefaction necrosis
√ ancillary findings:
√ lymphadenopathy (in 19%)
Frequency: papillary carcinoma (in up to 40–90%) > medullary carcinoma (in up to 50%) > follicular carcinoma (rare)
√ increased size with round bulging shape
√ replaced fatty hilum
√ heterogeneous echotexture
√ irregular margins
√ psammomatous calcifications
√ cystic change (70% in metastatic papillary carcinoma)
√ color Doppler vascularity throughout instead of central hilar vessels only
√ destruction of adjacent structures
√ loss of fat planes
√ distant metastasis

PET:
√ well-differentiated thyroid carcinomas are not FDG-avid

Mortality: 0.5 deaths÷100,000 (unchanged over decades)

Radiation-induced Thyroid Cancer

Incidence: increases with doses of thyroidal irradiation from 6.5–1,500 rad (higher doses are associated with hypothyroidism)

Peak occurrence: 5–30 (up to 50) years post irradiation

Thyroid abnormalities in 20%:
(a) in 14% adenomatous hyperplasia, follicular adenoma, colloid nodules, thyroiditis
(b) in 6% thyroid cancer

◊ Nondetectable microscopic foci of cancer in 25% of patients operated on for benign disease!
◊ In patients with multiple cold nodules frequency of cancer is 40%

Diagnostic Whole-body ^{131}I Scintigram

Indication: to detect metastases of thyroid carcinoma after total thyroidectomy; for skeletal metastases preferred over bone scan (that only detects 40%)

◊ Metastases not detectable in presence of normal functioning thyroid tissue because uptake is much less in metastases
◊ ^{99m}Tc-pertechnetate is useless because of high background activity + lack of organification

◊ False-negative ^{131}I scan in 24% ← nonfunctioning metastases

Technique:

» low iodine diet for 7 days = avoid iodized salt; milk and diary products; eggs; seafood; bread made with iodate dough conditioners; red food dyes; restaurant food; food containing iodized salt, sea salt, iodates, iodines, algin, alginates, agar agar

» T_4 replacement therapy discontinued for 6 weeks

» short-acting T_3 is administered for 4–6 weeks

» T_3 replacement therapy discontinued 10–14 days prior to whole-body scan

» measurement of TSH level to confirm adequate elevation (TSH > 30–50 mIU/mL; administration of exogenous TSH not desirable because of uneven stimulation)

» oral administration of 1–5–10 mCi ^{131}I

» whole-body scan after 24–48–72 hours (low background activity) with high-energy collimator + 20% energy window centered at 364 keV

N.B.: posttherapy scan (1 week after therapeutic dose) identifies more lesions than diagnostic scan; CONTRAINDICATED during pregnancy!

Treatment for Follicular / Papillary Cancer

(1) Surgery: total thyroidectomy + modified radical neck dissection

(2) Postoperative radioiodine treatment with ^{131}I if diagnostic scan positive (multiple treatments are usually necessary)

◊ Radioiodine therapy only appropriate for papillary / mixed / follicular thyroid carcinomas (NOT for medullary or anaplastic carcinomas)

(a) **Ablation of thyroid tissue remnants**

Time interval: 6 weeks after surgery

• no thyroid hormone replacement for 3–4 weeks

Calculated dose:

= {(thyroid weight [g] x 80–120 μCi/g) π % uptake of ^{123}I by 24 hours} x 100

Estimated dose: 30–100 mCi ^{131}I orally

» rescan after 3–7 days

√ no change from pre-ablation: on suppression therapy

√ new foci (in up to 16%): consider therapy

√ decreased uptake: may be due to "stunning"

(b) **Treatment of metastases**

Middle-of-the-road dose:

» 100 mCi for residual neck activity

» 150 mCi for regional lymph node metastases

» 175 mCi for lung metastases

» 200 mCi for bone metastases

Tumor dose:

150 mCi of ^{131}I with an uptake of 0.5% per gram of tumor tissue and a biologic half-life of 4 days will produce 25,000 rad to tumor

◊ Rapid turnover rates may exist in some metastases (lower dose advisable)

◊ Treatment of large tumors incomplete (range of beta radiation is a few mm only)

Cx: radiation thyroiditis; radiation parotitis; GI symptoms (nausea, diarrhea); minimal

bone marrow depression; leukemia (2%); anaplastic transformation (uncommon); lung fibrosis (with extensive pulmonary metastases and dose > 200 mCi)

(3) Thyroid replacement therapy: exogenous thyroid hormone to suppress TSH stimulation of metastases

(4) External radiation therapy for anaplastic carcinoma + metastases without iodine uptake

FOLLOW-UP: thyroglobulin > 50 ng/mL indicates functioning metastases after complete ablation of thyroid tissue

Papillary Carcinoma of Thyroid (60–80%)

Peak age: 5th decade; F > M

Histo: unencapsulated well-differentiated tumor

(a) purely papillary

(b) mixed with follicular elements (more common, especially under age 40)

Metastases:

(1) Lymphogenic spread to regional lymph nodes (40%, in children almost 90%)

(2) Hematogenous spread to lung (4%), bone (rare)

• carcinoma elaborates thyroglobulin

NUC:

√ tumor usually concentrates radioiodine (even some purely papillary tumors) → ^{131}I whole-body scintigraphy to assess for recurrence after thyroidectomy / ablation

US:

√ psammoma bodies = punctate echogenic foci less than 1 mm in size WITHOUT acoustic shadowing

√ tumor of decreased echogenicity

√ purely solid / complex mass with areas of necrosis, hemorrhage, cystic degeneration

X-ray:

√ punctate / linear psammomatous calcifications at tumor periphery

Rx: total thyroidectomy (← commonly multifocal); radioactive iodine ablation

Prognosis: 90–95% 20-year survival; 60% 10-year survival for extrathyroidal cancer; worse prognosis with increasing age

Follicular Carcinoma of Thyroid (11–20%)

Peak age: 5th decade; F > M

Path: encapsulated well-differentiated tumor without papillary elements; in 25% multifocal

Histo: follicular cells with capsular / vascular invasion; cytologically impossible to distinguish between well-differentiated follicular carcinoma + follicular adenoma (vascular invasion is the only criteria)

Early hematogenous spread to:

(a) lung

(b) bone (30%): almost always osteolytic lesion (more frequent than in papillary carcinoma)

• carcinoma elaborates thyroglobulin

√ psammoma bodies + stromal calcium deposits

NUC:

√ usually concentrates pertechnetate, but fails to accumulate ^{123}I

US:
√ indistinguishable from benign follicular adenoma
Prognosis: slow growing; 75% 20-year survival; 90% 10-year survival with slight / equivocal angioinvasion; 35% 10-year survival with moderate / marked angioinvasion
Rx: total thyroidectomy (for invasive cancer); ± subsequent radioactive iodine ablation; lobectomy + isthmusectomy (for minimally invasive cancer)

Anaplastic / Undifferentiated Carcinoma of Thyroid

Prevalence: 2–15%
Age: 6–7th decade; M÷F = 1÷1
√ intrathoracic extension in up to 50%
√ ± invasion of carotid artery, internal jugular vein, larynx
NUC:
√ NO radioiodine uptake
CT:
√ mass with inhomogeneous attenuation
√ areas of necrosis (74%)
√ calcifications (58%)
√ regional lymphadenopathy (74%)
Prognosis: 5% 5-year survival; average survival time of 6–12 months

Medullary Carcinoma of Thyroid (1–5–10%)

sporadic (80%) / familial
Histo: arises from parafollicular C-cells, associated with amyloid deposition in primary + metastatic sites
Hormone activity: calcitonin, VIP, somatostatin, CEA
Mean age: 60 years for sporadic variety;
during adolescence in MEN 2
In 20% associated with:
(1) MEN 2a = pheochromocytoma + parathyroid hyperplasia (Sipple syndrome)
(2) MEN 2b = without parathyroid component
Metastases: early spread to lymph nodes (50%), lung, liver, bone
• elevated calcitonin (= primary tumor marker from tumor production) stimulated by pentagastrin + calcium infusion
• elevated carcinoembryonic antigen (CEA)
√ mass of 2–26 mm
√ granular calcifications within fibrous stroma / amyloid masses (50%)
√ local invasion (common)
√ nodal spread to neck + mediastinum (in up to 50%) at time of presentation
√ distant metastases to liver, lung, bone (15–25%)
NUC:
√ NO uptake by radioiodine / pertechnetate
√ frequently shows increased uptake of ^{201}Tl
√ concentrates ^{123}I-MIBG, pentavalent ^{99m}Tc-DMSA, ^{111}In-pentetreotide (41% sensitive)

√ FDG-PET (96% sensitive)

CT:

√ mass of low attenuation (no iodine concentration)

Prognosis: 90% 10-year survival without nodal metastases; 42% 10-year survival with nodal metastases

Rx: total thyroidectomy + modified radical neck dissection

THYROIDITIS

DeQuervain Thyroiditis

= SUBACUTE GRANULOMATOUS THYROIDITIS

= distinct clinical syndrome characterized by exquisite thyroid tenderness, goiter, and thyrotoxicosis

Etiology: probably viral / postviral process (Coxsackie, mumps) frequently occurring in seasonal clusters

Histo: infiltrate of neutrophils and lymphocytes + characteristic multinucleated giant cells

Peak age: 2nd–5th decade; M÷F = 1÷5

- upper respiratory tract infection, fever, and systemic flulike symptoms precede onset of symptoms by 2–3 weeks
- tender gland with pain radiating to jaw / ear
- firm tense mild thyroid gland enlargement
- CHARACTERISTIC elevation of ESR > 50 mm/hour
- hyperthyroidism (50%) ← severe gland destruction
- short-lived hypothyroidism (25%) ← hormone depletion

US:

√ areas of hypoechogenicity

NUC:

√ abnormally low 24-hour radioiodine uptake with clinical and laboratory evidence of hyperthyroidism

√ poor visualization of thyroid (initially)

√ single / multiple hypofunctional areas (occasionally)

√ increased uptake during phase of hypothyroidism (late event)

Cx: permanent hypothyroidism (rare)

Rx: treatment of pain with NSAID / prednisone

Prognosis: usually full recovery

Hashimoto Thyroiditis

= CHRONIC LYMPHOCYTIC THYROIDITIS = GOITROUS AUTOIMMUNE THYROIDITIS

Incidence: 0.3–1.5÷1,000 population per year

Most frequent cause of goitrous hypothyroidism in adults in the USA (iodine deficiency is the more common cause worldwide)

Etiology: autoimmune process with marked familial predisposition (antibodies are typically present); functional organification defect

Histo: diffuse lymphocytic infiltration; occasional germinal centers; small thyroid follicles

containing sparse colloid; fibrosis; Hürthle / Askanazy cells = large thyroid cells with pink cytoplasma ("oxyphil change")

Peak age: 4–5th decade; M÷F = 1÷15

- firm rubbery possibly asymmetric lobular goiter
- decreased thyroid reserve (= injection of TSH does not result in expected increase in radioiodine uptake / release of hormone from the gland)
- FT_4 most typically normal / low
- antithyroid peroxidase + antithyroglobulin antibodies

Clinical course:

- gradual painless enlargement resulting in neck tightness
- periods of mild thyrotoxicosis (4%) / subclinical to overt hypothyroidism (20%) at presentation
- progression from euthyroidism to hypothyroidism
- return to normal function over several years (in 25%)

√ moderate enlargement of both lobes (usually 2–4 x normal volume) + prominent pyramidal lobe

NUC:

√ characteristically normal / elevated tracer uptake
√ low tracer uptake with poor visualization (4%)
√ positive perchlorate washout test
√ patchy tracer distribution
√ multiple (40%) / single cold defects (28%) / normal thyroid (8%)

US:

√ enlarged thyroid (77% greater volume compared with normal size)
√ initially heterogeneous nonspecific diffusely decreased echogenicity (in 18–77%)
√ irregular surface with slight lobulation of contour
√ marked hyperemia on color Doppler
√ later densely echogenic (fibrosis) + acoustic shadowing
√ ± satellite lymph nodes (Delphian node above isthmus)

Cx: hypothyroidism

Dx: (1) Diffuse firm bosselated goiter with pyramidal lobe enlargement
(2) NO signs of thyrotoxicosis
(3) Positivity for antibodies against thyroid microsomes / peroxidase / thyroglobulin
(4) Lymphocytic infiltrates

DDx (1) Atrophic chronic autoimmune thyroiditis (small gland)
(2) Painless thyroiditis (transient disorder, painless goiter, hyperthyroidism / hypothyroidism)
(3) Graves disease (diffuse goiter, hyperthyroidism, ophthalmopathy)

Painless / Silent Thyroiditis

= SUBACUTE LYMPHOCYTIC THYROIDITIS

Frequency: up to 23% of hyperthyroid patients in USA (many cases misdiagnosed as Graves disease)

Etiology: autoimmune process frequently in postpartum period (**postpartum thyroiditis**) +

under cytokine / lithium therapy

Histo: resembles chronic lymphocytic thyroiditis (Hashimoto) with paucity of lymphocyte germinal centers and fibrosis

- clinical presentation similar to subacute thyroiditis + clinically indistinguishable from Graves disease
- anti-thyroid peroxidase antibodies (in 60%)
- small NOT painful / tender goiter (in 50–60%)
- mild thyrotoxicosis lasting for a few months

√ 24-hour radioiodine uptake < 1%

Prognosis: recovery of thyroid function (majority); persistent goiter (33%); permanent hypothyroidism (20%); recurrent episodes of subacute lymphocytic thyroiditis (10%)

Acute Infectious / Suppurative Thyroiditis

= rare entity since the introduction of antibiotics

- ill febrile usually euthyroid patient

US:

√ focal / diffuse enlargement; possibly abscess

√ decreased echogenicity

Subacute Thyroiditis

= inflammatory destruction of thyroid follicles with release of preformed hormone into the circulation

Classification:

1. Subacute granulomatous thyroiditis (de Quervain)
2. Subacute lymphocytic thyroiditis
   (a) postpartum thyroiditis:
      ◊ Enable radioiodine uptake test by suspending breast-feeding for 1 week, during which time the radioiodine-contaminated breast milk should be pumped and discarded
   (b) cytokine-associated thyroiditis (interferon-alpha for chronic hepatitis B/C, interleukin-2 as adjunctive therapy for metastatic cancer and leukemia)
   (c) lithium-associated thyroiditis
3. Subacute thyroiditis due to cellular injury
   ← amiodarone-induced thyroiditis
4. Subacute thyroiditis due to trauma
   Cause: palpation, parathyroid surgery, direct surgical trauma, thyroid biopsy, seatbelt injury
5. Subacute thyroiditis due to radiation
   Cause: radioiodine treatment, external beam radiation

Phases:

1. Hyperthyroid phase
   = initial inflammatory stage → leakage of T_4 and T_3 into the circulation → suppression of pituitary TSH production → virtually absent 24-hour uptake
   - $T_3 \div T_4$ ratio (ng/dL ÷ mg /dL) < 20

√ virtually absent radioiodine uptake (usually < 1%)
Duration: several weeks – several months
√ marked decrease in echogenicity (the lowest of all thyroid disorders)
√ normal vascularity
Rx: beta-adrenergic blocking agents; ipodate or iopanoic acid

2. Hypothyroid phase
= inflammation subsides → thyroid hormone levels decrease to euthyroid + into hypothyroid range
√ normalization of 24-hour radioiodine uptake
Duration: 4 weeks – 6 months
√ regaining of isoechogenicity during recovery phase
√ ± slightly increased vascularity
Rx: levothyroxine dose adjusted to TSH level

US:
√ discrete nodules (50%)

Riedel Thyroiditis

= IgG4-RELATED THYROIDITIS
= rare chronic inflammatory process with extensive fibrosis
• rock-hard painless mass involving thyroid parenchyma and surrounding tissues
Associated with: fibrosclerosis in other organs (in ⅓)
US:
√ heterogeneously hypoechoic thyroid mass
CT:
√ focal / diffuse low-attenuation mass of thyroid
√ minimal contrast enhancement relative to normal thyroid
PET:
√ avid uptake
Rx: steroid therapy → marked reduction of thyroid mass

TORNWALDT CYST

= midline congenital pouch / cyst lined by ectoderm within nasopharyngeal mucosal space
[Gustav Ludwig Tornwaldt (1843–1910), physician in Danzig, Germany]
Origin: persistent focal adhesion between notochord + ectoderm extending to pharyngeal tubercle of occipital bone
Frequency: 4% of autopsies
◊ Most common congenital head and neck cyst in childhood!
Peak age: 15–30 years
• asymptomatic incidental finding
• persistent nasopharyngeal drainage
• halitosis, foul taste in mouth
Location: posterior roof of nasopharynx
√ smoothly marginated cystic mass of few mm to 3 cm in size
√ low density, not enhancing
√ NO bone erosion

Cx: infection of cyst
DDx: Rathke pouch (occurs in craniopharyngeal canal located anteriorly + cephalad to Thornwaldt cyst)

TOXIC AUTONOMOUS NODULE

= PLUMMER DISEASE = TOXIC ADENOMA
= hyperthyroidism caused by one / two hyperfunctioning nodules independent of normal pituitary-thyroid control mechanism
◊ All toxic nodules are autonomous;
HOWEVER, not all autonomous nodules are toxic
Cause: gene mutation of TSH receptors of adenoma surface (not autoimmunity) result in continuous activation
Histo: adenoma
• excessive serum levels of thyroid hormone
• suppressed TSH production, clinically hyperthyroid
√ radioiodine uptake (RAIU) mildly to moderately elevated
√ concentration of radiopharmaceutical to a far greater degree than surrounding extranodular thyroid tissue
DDx: Graves disease (RAIU significantly elevated)

TOXIC MULTINODULAR GOITER

= multinodular goiter associated with hyperthyroidism
Cause: several of nodules have gradually formed areas of hyperplasia that eventually grew into autonomously functioning nodules
Age: elderly
• mildly elevated thyroid levels, suppressed TSH
√ RAIU normal / slightly elevated
√ multiple "hot" nodules in thyroid with suppressed extranodular thyroid tissue
DDx: Graves disease (younger patient, milder degree of thyrotoxicosis)

TUBERCULOSIS OF HEAD & NECK

Frequency: 15% of extrapulmonary tuberculosis; initial presentation in 1.5% of all new cases
Site: (a) lymph nodes: multiple nodal chains
(b) extranodal disease (rare): larynx > temporal bone > pharynx; sinonasal cavity, thyroid gland, skull base
√ soft-tissue thickening + infiltration of preepiglottic + paraglottic spaces
DDx of low-density node: necrotic lymph node metastasis from squamous cell carcinoma
DDx of calcified node: metastatic thyroid cancer

Tuberculous Lymphadenitis = Scrofula

Organism: Mycobacterium scrofulaceum (in children), M. tuberculosis (in adults)
Predisposed: HIV, AIDS
• bilateral chronic painless lymphadenitis growing with time
• "cold abscess" = no accompanying local color or warmth (overlying skin acquires a

violaceous color)
√ initially homogeneous nodes, later with central necrosis:
√ multichambered centrally hypoattenuating mass
√ central T1-hypointensity and T2 -hyperintensity
√ thick enhancing peripheral rim
√ peripheral nodal calcifications (in late TB)

WARTHIN TUMOR

= PAPILLARY CYSTADENOMA LYMPHOMATOSUM = ADENOLYMPHOMA = CYSTADENOLYMPHOMA

Frequency: 2nd most common benign tumor of parotid gland; 5%–10% of all benign salivary neoplasms: bilateral in 10%

Age: 5–6th decade; M > F

Origin: from heterotopic salivary gland tissue within parotid lymph nodes (direct result of incorporation of lymphatic elements + heterotopic salivary gland ductal epithelium within intraparotid + periparotid nodes during embryonic development

Histo: CHARACTERISTIC double layer of oncocytes (= epithelial cells) resting on a dense lymphoid stroma

• slow-growing painless mass

Associated with: history of smoking

Location: usually solitary + unilateral; bilateral + multifocal (±metachronous) in 10–60%
◊ Most common lesion to manifest as unilateral + multifocal masses
◊ Most common salivary neoplasm to manifest as multiple masses in one / both parotid glands

Site: often in tail of parotid gland

√ well-circumscribed single / multiple cystic / solid lesion in parotid region usually 3–4 cm in size

MR:
√ hypointense compared with fat / surrounding parotid tissue on T2WI

US:
√ oval hypoechoic well-defined tumor
√ frequently multiple anechoic areas
√ increased vascularity

NUC:
√ increased uptake with ^{99m}Tc, ^{201}Tl, FDG

Cx: sporadically malignant transformation of epithelial component

Rx: surgical resection

DDx: lymphoma, inflammatory disease

CHEST

DIFFERENTIAL DIAGNOSIS OF CHEST DISORDERS

PULMONARY HEMORRHAGE

A. WITHOUT RENAL DISEASE
   1. Bleeding diathesis: leukemia, hemophilia, disseminated intravascular coagulation (DIC)
   2. Pulmonary embolism, thromboembolism
   3. Blunt trauma: contusion
   4. Idiopathic pulmonary hemosiderosis
   5. Limited Wegener granulomatosis
   6. Drugs: amphotericin B, mitomycin, high-dose cyclophosphamide, cytarabine (ara-C), D-penicillamine, anticoagulants, lymphangiography

B. WITH RENAL DISEASE
   (a) medium-sized vessel vasculitis
      1. Polyarteritis nodosa
   (b) ANCA-associated small-vessel vasculitis:
      1. Wegener granulomatosis
      2. Churg-Strauss syndrome
   (c) immune-complex small vessel vasculitis:
      1. Goodpasture syndrome = antibasement membrane antibody disease with a linear pattern on tissue stains
      2. Henoch-Schönlein purpura
      3. Behçet disease
   (d) Collagen vascular disease:
      1. Systemic lupus erythematosus: granular pattern of immune complexes on tissue stains, noncaseating granulomas, malar rash
      2. Rheumatoid arthritis
      3. Seronegative juvenile rheumatoid arthritis
   (e) others
      1. Rapidly progressive glomerulonephritis ± immune complexes
      2. Immunoglobulin A nephropathy
      3. Idiopathic pulmonary hemorrhage
      4. Idiopathic glomerulonephritis

C. HEMORRHAGIC PNEUMONIA
   1. Bacteria: Legionnaires' disease
   2. Viruses: CMV, herpes, Rocky Mountain spotted fever, infectious mononucleosis
   3. Fungi: aspergillosis, mucormycosis

D. BLEEDING METASTASIS, eg, choriocarcinoma

• acute respiratory distress, hemoptysis (uncommon)

CXR:
√ bilateral heterogeneous + homogeneous opacities
√ multifocal patchy segmental / lobar consolidation
HRCT:
√ bilateral patchy / confluent ground-glass opacities / consolidation
√ ground-glass centrilobular nodules
√ may delineate underlying etiology (bronchiectasis, lung cancer, TB, pulmonary embolism)
NUC:
√ typically matched defect on V/Q scan in bronchial artery bleeding

Hemoptysis

= bleeding from lower respiratory tract
• frothy sputum, bright red blood, alkaline pH
• massive hemoptysis = expectoration of greater than 300–600 mL of blood in 24 hours

Risk: airway compromise

Source:
(a) bronchial artery (90–95%)
(b) pulmonary artery
(c) nonbronchial systemic aa. (brachiocephalic, intercostal, inferior phrenic, gastric, celiac, internal mammary, subclavian aa. as contributing source in 41–88%)

Pathophysiology:
(a) chronic thromboembolic disease / Takayasu arteritis → ⇓ pulmonary arterial perfusion → vasodilatation of bronchial-pulmonary arterial anastomotic connections → rupture of thin-walled anastomoses under systemic blood pressure into alveolus / bronchus
(b) chronic inflammation (eg, bronchiectasis and TB) / neoplasm → release of angiogenic growth factors → ⇑ collateral vascular supply and neovascularization → fragile + leaky new vessels prone to rupture into alveolus / bronchus

Etiology:
◊ The 2 <u>most common</u> causes (in adults) are bronchial carcinoma + bronchiectasis and (in children) cystic fibrosis + CHD!
◊ Most <u>clinically significant</u> cases of hemoptysis are due to entities that increase bronchial + systemic pulmonary blood flow: bronchiectasis, lung cancer, chronic bronchitis, cavitary infection, cavitary sarcoidosis, bronchial artery malformation

A. TUMOR
1. Carcinoma (35%)
2. Bronchial carcinoid
3. Endobronchial metastasis

B. BRONCHIAL WALL INJURY
1. Foreign body erosion
2. Bronchoscopy / biopsy

C. VASCULAR
1. COPD
2. Pulmonary embolus with infarction
√ bronchial blood flow may increase by 300% in the weeks following pulmonary artery embolization

3. Venous hypertension (most common): mitral stenosis
4. Arteriovenous malformation
5. Rupture of pulmonary artery aneurysm: TB, vasculitis, trauma, neoplasm, abscess, septic embolus, indwelling catheter

D. INFECTION (pneumonia)
1. Chronic bronchitis
Dieulafoy disease = abnormally dilated submucosal vessels of pulmonary artery prone to hemorrhage
[Paul Georges Dieulafoy (1839–1911), chief of medical services at the Hôtel-Dieu, Paris, France]
2. Bronchiectasis, mouthful (15%)
3. Tuberculosis (Rasmussen aneurysm)
4. Aspergillosis
5. Abscess
6. Cystic fibrosis

E. CRYPTOGENIC (3–10–42%)
◊ 6–10% of patients who smoke present with unresectable lung cancer within subsequent 3 years!

CT:
√ cluster of avidly enhancing "nodular" bronchial arteries in posterior mediastinum below level of aortic arch paralleling bronchial anatomy
√ abnormal bronchial arteries show tortuosity, dilatation, hypervascularity, neovascularity, aneurysms, shunts
N.B.: multidetector CT mapping prior to angiography reduces the rate of catheterization failures and the number of patients needing surgical intervention!

Angio:
√ vasodilated enlarged tortuous bronchial arteries → bronchial-to-pulmonary-artery shunting, hypervascularity, parenchymal staining

Prognosis: 50–100% mortality rate of conservatively treated massive hemoptysis; death usually from asphyxiation rather than from exsanguination

Rx: transcatheter particulate embolization of bronchial aa. using polyvinyl alcohol (PVA) + Gelfoam® pledgets (effective in 70–95%; recurrent bleeding in 20–30%)
N.B.: identify arteria radicularis (= artery of Adamkiewicz) at T5–L2 (in 75% T9–T12) to avoid postembolization transverse myelitis

DDx: hematemesis (containing food particles, dark blood, acid pH)

ASPIRATION

= intake of solid / liquid materials into the airways and lungs

Predisposing factors:
1. Alcoholism (most common in adults)
2. General anesthesia, loss of consciousness
3. Structural abnormalities of pharynx / esophagus (congenital / acquired tracheoesophageal + tracheopulmonary fistula), laryngectomy
4. Neuromuscular disorders

5. Deglutition abnormalities

Substrate:

(a) solids
- › foreign bodies
- › lentils

(b) liquids
- › gastric acid = Mendelson syndrome
- › water = near drowning
- › barium, water-soluble contrast material
- › liquid paraffin / petroleum = acute exogenous lipoid pneumonia / fire-eater pneumonia
- › mineral oil / cod liver oil = chronic exogenous lipoid pneumonia

(c) contaminated substances from oropharynx / GI tract

Acute Lower Airway Obstruction in Childhood

Location: intrathoracic trachea + bronchi

(a) infectious / inflammatory:
- • fever, cough, wheeze
- › < 2 years old:
  1. Bronchiolitis
     √ bronchial wall thickening + hyperinflation
- › > 2 years old:
  2. Lower respiratory tract inflammation
     √ bronchial wall thickening
  3. Reactive airways disease
     √ bronchial wall thickening + hyperinflation

(b) others:
1. Aspirated foreign body

PULMONARY DISEASE & CIGARETTE SMOKING

1. Bronchogenic carcinoma
2. Chronic bronchitis
3. Centrilobular emphysema
4. Panacinar emphysema with α-1 antitrypsin deficiency
5. **S**moking-related interstitial lung disease
   - › Respiratory bronchiolitis ILD (RB-ILD)
   - › Desquamative interstitial pneumonitis (DIP)
   - › Pulmonary Langerhans cell histiocytosis (PLCH)
   - › Idiopathic pulmonary fibrosis (IPF)

HYPERSENSITIVITY TO ORGANIC DUSTS

A. TRACHEOBRONCHIAL HYPERSENSITIVITY

large particles reaching the tracheobronchial mucosa (pollens, certain fungi, some animal / insect epithelial emanations)

1. Extrinsic asthma

2. Hypersensitivity aspergillosis
3. Bronchocentric granulomatosis
4. Byssinosis in cotton-wool workers

B. ALVEOLAR HYPERSENSITIVITY
= HYPERSENSITIVITY PNEUMONITIS
= EXTRINSIC ALLERGIC ALVEOLITIS
small particles of < 5 μm reaching alveoli

DRUG-INDUCED PULMONARY DAMAGE

Histopathologic manifestations:

(a) Diffuse alveolar damage:
bleomycin, busulfan, carmustine, mitomycin, cyclophosphamide, melphalan, gold salts

(b) Nonspecific interstitial pneumonia:
amiodarone, methotrexate, carmustine, chlorambucil

(c) Bronchiolitis obliterans organizing pneumonia: gold salts, bleomycin, methotrexate, amiodarone, nitrofurantoin, penicillamine, sulfasalazine, cyclophosphamide

(d) Eosinophilic pneumonia:
penicillamine, sulfasalazine, nitrofurantoin, nonsteroidal anti-inflammatory drugs, para-aminosalicylic acid

(e) Pulmonary hemorrhage:
anticoagulants, amphotericin B, cytarabine (ara-C), penicillamine, cyclophosphamide

A. CYTOTOXIC DRUGS (most important group)

1. **Cyclophosphamide**
Use: variety of malignancies, Wegener granulomatosis, glomerulonephritis
Toxicity: after 2 weeks – 13 years (mean, 3.5 years), no relationship to dose / duration of therapy
Prognosis: good after discontinuation of therapy
√ diffuse alveolar damage (most common)
√ nonspecific interstitial pneumonia
√ BOOP (least common)

2. **Busulfan** = Myleran® (for CML)
Toxicity: dose-dependent, after 3–4 years on the drug in 1–10%
√ diffuse linear pattern (occasionally reticulonodular / nodular pattern)
√ partial / complete clearing after withdrawal of drug
DDx: Pneumocystis pneumonia, interstitial leukemic infiltrate

3. **Nitrosoureas** = carmustine (BCNU), lomustine (CCNU)
Use: CNS glioma, lymphoma, myeloma
Toxicity: in 50% after doses > 1500 mg/m2; sensitivity increased after radiation Rx
√ diffuse alveolar damage (most common)
√ nonspecific interstitial pneumonia:
√ linear / finely nodular opacities (following treatment of 2–3 years)
√ high incidence of pneumothorax

4. **Bleomycin**
Use: squamous cell carcinoma of neck / cervix / vagina, Hodgkin lymphoma,

testicular carcinoma

Toxicity: at doses > 300 mg (in 3–6%); increased risk with age + radiation therapy + high oxygen concentrations

Prognosis: death from respiratory failure within 3 months of onset of symptoms

√ diffuse alveolar damage (most common)

√ nonspecific interstitial pneumonia / BOOP:

√ subpleural linear / nodular opacities (5–30 mm) in lower lung zones occurring after 1–3 months following beginning of therapy

DDx: metastases

5. **Taxoid derivatives** = paclitaxel, docetaxel, gemcitabine, topotecan, vinorelbine

Use: breast cancer, lung cancer, ovarian cancer

√ interstitial pneumonitis

B. NONCYTOTOXIC DRUGS

1. **Amiodarone**

= triiodinated benzofuran

Use: refractory ventricular tachyarrhythmia

Toxicity: in 5–10%; risk increased with daily dose > 400 mg + in elderly

Prognosis: good after discontinuation of drug

• pulmonary insufficiency after 1–12 months in 14–18% on long-term therapy

√ nonspecific interstitial pneumonia (most common) + associated BOOP:

√ alveolar + interstitial infiltrates (chronic presentation)

√ focal homogeneous peripheral consolidation (acute presentation):

√ attenuation values of iodine ← incorporation of amiodarone into type II pneumocytes

√ pleural thickening (inflammation) adjacent to consolidation

√ associated high-attenuation of liver relative to spleen

2. **Gold salts**

Use: inflammatory arthritis

Toxicity: in 1% within 2–6 months

• mucocutaneous lesions (30%)

√ diffuse alveolar damage (common)

√ nonspecific interstitial pneumonia (common)

√ BOOP (less common)

3. **Methotrexate**, procarbazine

Use: lung cancer, breast cancer, head and neck epidermoid cancer, nonmetastatic osteosarcoma, advanced stage NHL, AML, recalcitrant psoriasis, severe rheumatoid arthritis, pemphigus

Toxicity: in 5–10%; not dose-related

Prognosis: usually self-limited despite continuation of therapy

• blood eosinophilia (common)

√ nonspecific interstitial pneumonia (most common)

√ BOOP (less frequent)

√ linear / reticulonodular process (time delay of 12 days to 5 years, usually early)

√ acinar filling pattern (later)

√ transient hilar adenopathy + pleural effusion (on occasion)

DDx: Pneumocystis pneumonia

4. **Nitrofurantoin** (Macrodantin®)
   Use: urinary tract infection
   Toxicity: rare
   • positive for ANA + LE cells
   (a) acute disorder within 2 weeks of administration:
      • fever, dyspnea, cough
      • peripheral eosinophilia (more common)
      Prognosis: prompt resolution after withdrawal from drug
      √ diffuse bilateral predominantly basal heterogeneous opacities
   (b) chronic reaction with interstitial fibrosis (less common)
      • insidious onset of dyspnea + cough
      • may not be associated with peripheral eosinophilia
      √ nonspecific interstitial pneumonia (common)
         √ bilateral basilar interstitial opacities

C. OTHERS
1. **Heroin, propoxyphene, methadone**
   Toxicity: overdose followed by pulmonary edema in 30–40%
   √ bilateral widespread airspace consolidation
   √ aspiration pneumonia in 50–75%
2. **Salicylates**
   • asthma
   √ pulmonary edema (with chronic ingestion)
3. **Intravenous contrast material**
   √ pulmonary edema

LYMPHOPROLIFERATIVE MALIGNANCIES

= subgroup of hematologic malignancies comprising 4 different types:

1. Lymphoma (Non-Hodgkin Lymphoma)
   > 30 subtypes of lymphoma
2. Hodgkin disease
3. Lymphocytic leukemias (acute or chronic)
4. Plasma cell myeloma (multiple myeloma)

PULMONARY DISEASE AND OTHER ORGAN MANIFESTATIONS

Disorders with Hepatic & Pulmonary Manifestations

1. Alpha-1-antitrypsin deficiency
2. Cystic fibrosis
3. Hereditary hemorrhagic telangiectasia
4. Autoimmune disease: primary biliary cirrhosis, rheumatoid arthritis, Hashimoto thyroiditis, Sjögren syndrome, scleroderma, sarcoidosis
5. Drugs with toxic effects on lung and liver: methotrexate, phenytoin, amiodarone

Pulmonary-Renal Syndromes

1. Wegener granulomatosis = granulomatosis with polyangiitis
2. Goodpasture syndrome
3. Systemic lupus erythematosus
4. Mixed connective tissue disease
5. Microscopic polyangiitis

PULMONARY EDEMA

= abnormal accumulation of fluid in the extravascular compartments of the lung

Pathophysiology (Starling equation):

transcapillary flow dependent on

(1) Hydrostatic pressure
(2) Oncotic (= colloid osmotic) pressure
(3) Capillary permeability (the endothelial cells are relatively impermeable to protein but remain permeable to water and solutes; the tight intercellular junctions of alveolar epithelium remain nearly impermeable to water and solutes)

$$Q_{filt} = K_{filt} (HP_{iv} - HP_{ev}) - t(OP_{iv} - OP_{ev})$$

Q_{filt} = amount of fluid filtered per unit area per unit time

HP_{iv} = intravascular hydrostatic pressure

HP_{ev} = extravascular hydrostatic pressure

OP_{iv} = intravascular oncotic pressure

OP_{ev} = extravascular oncotic pressure

K_{filt} = conductance of capillary wall = water resistance of capillary endothelial cell junction

t = oncotic reflection coefficient = permeability of capillary membrane to macromolecules

Cause: disturbed equilibrium of net flow F_{net} between fluid transudation / exudation Q_{filt} and lymphatic absorption Q_{lymph}

$$F_{net} = Q_{filt} - Q_{lymph}$$

A. INCREASED HYDROSTATIC PRESSURE

(a) cardiogenic (most common)
= PULMONARY VENOUS HYPERTENSION
1. Heart disease: left ventricular failure, mitral valve disease, left atrial myxoma
2. Pulmonary venous disease: acute / chronic pulmonary embolism, primary venoocclusive disease, mediastinal fibrosis
3. Pericardial disease: pericardial effusion, constrictive pericarditis (extremely rare)
4. Drugs: antiarrhythmic drugs; drugs depressing myocardial contractility (beta-blocker)

(b) noncardiogenic
1. Renal failure
2. Massive IV fluid overload
3. Hyperosmolar fluid (eg, contrast medium)

(c) neurogenic
? sympathetic venoconstriction in cerebrovascular accident, head injury, CNS tumor,

postictal state

B. DECREASED COLLOID OSMOTIC PRESSURE
   1. Hypoproteinemia
   2. Transfusion of crystalloid fluid
   3. Rapid reexpansion of lung

C. INCREASED CAPILLARY PERMEABILITY
   Endothelial injury from
   (a) physical trauma: parenchymal contusion, radiation therapy
   (b) aspiration injury:
      1. Mendelson syndrome (gastric contents)
      2. Near drowning in sea water / fresh water
      3. Aspiration of hypertonic contrast media
   (c) inhalation injury:
      1. Nitrogen dioxide = silo-filler's disease
      2. Smoke (pulmonary edema may be delayed by 24–48 hours)
      3. Sulfur dioxide, hydrocarbons, carbon monoxide, beryllium, cadmium, silica, dinitrogen tetroxide, oxygen, chlorine, phosgene, ammonia, organophosphates
   (d) injury via bloodstream
      1. Vessel occlusion: shock (trauma, sepsis, ARDS) or emboli (air, fat, amniotic fluid, thrombus)
      2. Circulating toxins: snake venom, paraquat
      3. Drugs: heroin, morphine, methadone, aspirin, phenylbutazone, nitrofurantoin, chlorothiazide
      4. Anaphylaxis: transfusion reaction, contrast medium reaction, penicillin
      5. Hypoxia: high altitude, acute large airway obstruction

mnemonic: ABCDEFGHI - PRN
Aspiration
Burns
Chemicals
Drugs (heroin, nitrofurantoin, salicylates)
Exudative skin disorders
Fluid overload
Gram-negative shock
Heart failure
Intracranial condition
Polyarteritis nodosa
Renal disease
Near drowning

Atypical pulmonary edema = lung edema with an unusual radiologic appearance
Unusual form of pulmonary edema = lung edema from unusual causes

Increased Hydrostatic Pressure Edema

- Pulmonary capillary wedge pressure (PCWP):
  = reflects left atrial pressure and correlates well with radiologic features of CHF + pulmonary venous HTN

◊ In acute CHF radiologic features are delayed in onset and resolution

√ **flow inversion** = "cephalization of pulmonary vessels" is ONLY seen in longstanding left heart failure, NEVER in pulmonary edema of renal failure / overhydration / low oncotic pressure

HRCT:

√ smooth interlobular septal + peribronchovascular thickening

√ ground-glass opacities in a perihilar / dependent distribution, which may progress to consolidation

√ centrilobular ground-glass nodules

Radiographic Signs in Pressure Edema	
PCWP [mmHg]	*Findings*
5–12	normal
12–17	cephalization of pulmonary vessels (only in chronic conditions)
17–20	Kerley lines, subpleural effusions
> 25	alveolar flooding edema

Interstitial Pulmonary Edema

= 1st phase of pressure edema with increase in quantity of extracellular fluid

Cause: increase in mean transmural arterial pressure of 15–25 mmHg

√ mild enlargement of peribronchovascular spaces

√ appearance of Kerley lines

√ subpleural effusions

√ early loss of definition of subsegmental + segmental vessels

√ progressive blurring of vessels ← central migration of edema at lobar + hilar levels

√ small peripheral vessels difficult to identify ← decrease in lung radiolucency

◊ Often marked dissociation between clinical signs + symptoms + roentgenographic evidence

◊ Nothing differentiates it from other interstitial lesions

◊ Does not necessarily develop before alveolar pulmonary edema

◊ NOT typical for bacterial pneumonia

Alveolar Flooding Edema

= 2nd phase of pressure edema

Cause: increase in mean transmural arterial pressure of > 25 mmHg ± pressure-induced damage to alveolar epithelium

√ tiny nodular / acinar areas of increased opacity

√ frank consolidation

Bat-Wing Edema *(in < 10%)*

= central nongravitational distribution of alveolar edema

Cause: rapidly developing severe cardiac failure (acute mitral insufficiency associated with papillary muscle rupture, massive MI, valve leaflet destruction by septic endocarditis) or renal failure

√ lung cortex spared from fluid (due to pumping effect of respiration / contractile property of alveolar septa / mucopolysaccharide-filled perivascular matrix)

Asymmetric Distribution of Pressure Edema

Cause: morphologic lung changes in COPD, hemodynamics, patient position

√ lung apices spared (= lung emphysema in heavy smokers)
√ upper + middle portions of lung spared (= end-stage TB, sarcoidosis, asbestosis)
√ predominantly RUL involvement (= mitral regurgitation refluxes preferentially into right upper pulmonary vein)
√ anteroposterior gradient on CT in recumbent position
√ unilateral edema in lateral decubitus position

Pulmonary Edema with Acute Asthma

Cause: air trapping maintains a positive intraalveolar pressure and thus decreases hydrostatic pressure gradient

Pathogenesis: associated with severity of Müller maneuver

√ heterogeneous edema ← nonuniform airway obstruction
√ peribronchial cuffing
√ ill-defined vessels
√ enlarged ill-defined hila
√ patency of narrowed airways maintained ← high negative pleural pressure in forced inspiration

Postobstructive Pulmonary Edema

Cause: following relief from an upper airway obstruction (impacted foreign body, laryngospasm, epiglottitis, strangulation)

Pathogenesis:

(a) forced inspiration causes a high negative intrathoracic pressure (Müller maneuver) and increases venous return
(b) obstruction creates high positive intrathoracic pressure that impairs development of edema

√ septal lines, peribronchial cuffing
√ central alveolar edema
√ normal heart size

Prognosis: resolution within 2–3 days

Edema with Pulmonary Embolism *(< 10%)*

Cause: occlusion of pulmonary arterial bed causes redirection of blood flow and hypertension in uninvolved areas

√ areas of ground-glass attenuation
√ sharply demarcated from areas of transparency distal to occluded arteries
√ associated with dilated pulmonary arteries (70%)

Edema & Pulmonary Venoocclusive Disease

Cause: organized thrombi in small veins causes an increase in peripheral resistance and hydrostatic pressure

• rapidly progressive dyspnea, orthopnea ± hemoptysis
• normal / low pulmonary capillary wedge pressure
√ enlarged pulmonary arteries
√ diffuse interstitial edema + numerous Kerley lines
√ peribronchial cuffing
√ dilated right ventricle

Permeability Edema

Heroin-induced Pulmonary Edema

Hx: overdose of opiates (almost exclusively with heroin, rarely with cocaine / "crack")
Frequency: 15% of cases of heroin overdose
Pathophysiology: depression of medullary respiratory center leading to hypoxia + acidosis
√ widespread patchy bilateral airspace consolidations
√ ill-defined vessels + peribronchial cuffing
√ markedly asymmetric gravity-dependent distribution of edema (motionless recumbent position for hours / days)
√ resolution within 1 or 2 days in uncomplicated cases
Cx:
(1) Extensive crush injuries with associated muscle damage and ensuing renal insufficiency (from motionless recumbency)
(2) Aspiration of gastric contents
Prognosis: 10% mortality rate

Edema following Administration of Cytokines

(a) intravenous interleukin 2 (IL–2):
enhances tumoricidal activity of natural killer cells in metastatic melanoma + RCC
(b) intraarterial tumor necrosis factor:
increases production + release of IL–2
Frequency: in 75% of IL–2 therapy;
in 20% of tumor necrosis factor therapy;
in 25% of recombinant IL–2 therapy
Pathophysiology: permeability disruption of capillary endothelial cells
• 12 mmHg increase in pulmonary capillary wedge pressure (= direct toxic effect on myocardium)
√ pulmonary edema 1–5 days after start of therapy:
√ bilateral symmetric interstitial edema with thickened septal lines
√ peribronchial cuffing (75%)
√ small pleural effusions (40%)
√ NO alveolar edema (unless associated cardiac insufficiency)

High-altitude Pulmonary Edema

Predisposed: young males after rapid ascent to > 3,000 m
Cause: prolonged exposure to low partial oxygen atmospheric pressure
Pathophysiology: acute persistent hypoxia with endothelial leakage

- prodromal acute mountain sickness
- dyspnea at rest, cough with frothy pink sputum
- neurologic disturbances ← brain edema
- arterial oxygen levels as low as 38%

√ central interstitial pulmonary edema
√ peribronchial cuffing
√ ill-defined vessels
√ patchy airspace consolidation

Mixed Hydrostatic & Permeability Edema

Neurogenic Pulmonary Edema

Frequency: in up to 50% of severe brain trauma, stroke, subarachnoid hemorrhage, status epilepticus

Pathophysiology: modification in neurovegetative pathways causes sudden ↑ in pressure in pulmonary venules with reduced venous outflow

- dyspnea, tachypnea, cyanosis shortly after brain insult + rapid disappearance

√ bilateral inhomogeneous / homogeneous airspace consolidations, in 50% affecting predominantly the apices, disappearing within 1–2 days

Dx: by exclusion

DDx: fluid overload, postextubation edema

Reperfusion Pulmonary Edema

Frequency: in up to 90–100%

Cause: pulmonary thrombendarterectomy for massive pulmonary embolism / for webs and segmental stenosis

Pathophysiology: rapid increase in blood flow + pressure

- dyspnea, tachypnea, cough during the first 24–48 hours after reperfusion

√ pulmonary edema within 2 days after surgery:
  √ heterogeneous airspace consolidation, predominantly in areas distal to recanalized vessels
  √ random distribution in up to 50%

Reexpansion Pulmonary Edema

Cause: rapid reexpansion of a collapsed lung following evacuation of hydro-, hemo- or pneumothorax

Pathophysiology: prolonged local hypoxic event, abrupt restoration of blood flow, sudden marked increase in intrapleural pressure, diffuse alveolar damage

- frank respiratory insufficiency: cough, dyspnea, tachypnea, tachycardia, frothy pink sputum; may be asymptomatic

√ pulmonary edema within reexpanded entire lung within 1 hour (in 64%)
√ increase in severity within 24–48 hours with slow resolution over next 5–7 days

Prognosis: 20% mortality

Pulmonary Edema due to Air Embolism

Cause: usually iatrogenic complication (neurosurgical procedure in sitting position,

placement / manipulation of central venous line), rare in open / closed chest trauma

Pathophysiology: embolized air bubbles cause mechanical obstruction of pulmonary microvasculature

- sudden onset of chest pain, tachypnea, dyspnea
- hypotension

√ air bubbles in right-sided cardiac chambers on echocardiography
√ interstitial edema
√ bilateral peripheral alveolar areas of increased opacity, predominantly at lung bases

Postpneumonectomy Pulmonary Edema

= life-threatening complication in early postoperative period after pneumonectomy (rare in lobectomy / lung reduction surgery)

Frequency: 2.5–5%; R > L pneumonectomy

Risk factors: excessive administration of fluid during surgery, transfusion of fresh frozen plasma, arrhythmia, marked postsurgical diuresis, low serum colloidal osmotic pressure

Pathophysiology: increased capillary hydrostatic pressure, altered capillary permeability

- marked dyspnea during first 2–3 postop days

√ ARDS-like picture

Prognosis: very high mortality rate

Pulmonary Edema after Lung Transplantation

Frequency: in up to 97% during first 3 days after surgery

Pathophysiology: tissue hypoxia, disruption of pulmonary lymphatic drainage, lung denervation

√ progressive diffuse confluent areas of increased opacity, most pronounced on postop day 5
√ return to normal 2 weeks after surgery

Unilateral Pulmonary Edema

A. IPSILATERAL = on side of preexisting abnormality
   (a) filling of airways
      1. Unilateral aspiration / pulmonary lavage
      2. Drowned lung (bronchial obstruction)
      3. Pulmonary contusion
   (b) increased pulmonary venous pressure
      1. Unilateral venous obstruction
      2. Prolonged lateral decubitus position
   (c) pulmonary arterial overload
      1. Systemic artery-to-pulmonary artery shunt (Waterston, Blalock-Taussig, Pott procedure)
      2. Rapid thoracentesis (rapid reexpansion)
B. CONTRALATERAL = opposite to side of abnormality
   (a) pulmonary arterial obstruction

1. Congenital absence / hypoplasia of pulmonary a.
2. Unilateral arterial obstruction
3. Pulmonary thromboembolism

(b) loss of lung parenchyma

1. Swyer-James syndrome
2. Unilateral emphysema
3. Lobectomy
4. Pleural disease

C. RIGHT UPPER LOBE
PATHOGNOMONIC for mitral valve regurgitation

Pulmonary Edema with Cardiomegaly

1. Cardiogenic
2. Uremic (cardiomegaly ← pericardial effusion / hypertension)

Pulmonary Edema without Cardiomegaly

mnemonic: U DOPA

PNEUMONIA

"Classic" pneumonia pattern:

1. Lobar distribution: Streptococcus pneumoniae
2. Bulging fissure: Klebsiella
3. Pulmonary edema: Viral / Pneumocystis pneumonia
4. Pneumatocele: Staphylococcus
5. Alveolar nodules: Varicella, bronchogenic spread of TB

Distribution:

A. SEGMENTAL / LOBAR
   - › Normal host: S. pneumoniae, Mycoplasma, virus
   - › Compromised host: S. pneumoniae

B. BRONCHOPNEUMONIA
   - › Normal host: Mycoplasma, virus, Streptococcus, Staphylococcus, S. pneumoniae
   - › Compromised host: gram-negative, Streptococcus, Staphylococcus
   - › Nosocomial: gram-negative, Pseudomonas, Klebsiella, Staphylococcus
   - › Immunosuppressed: gram-negative, Staphylococcus, Nocardia, Legionella, Aspergillus, Phycomycetes

C. EXTENSIVE BILATERAL PNEUMONIA
   - › Normal host: virus (eg, influenza), Legionella
   - › Compromised host: candidiasis, Pneumocystis, TB

D. BILATERAL LOWER LOBE PNEUMONIA
   - › Normal host: anaerobic (aspiration)
   - › Compromised host: anaerobic (aspiration)

E. PERIPHERAL PNEUMONIA
   - › Noninfectious eosinophilic pneumonia

Transmission:

A. **Community-acquired pneumonia**
   Organism: viruses, S. pneumoniae, Mycoplasma
   Mortality: 10%

B. **Nosocomial pneumonia**
   [*nosos*, Greek = disease; *kamnein*, Greek = to suffer; *nosocomium*, Latin = hospital]
   (a) gram-negative organism (> 50%): Klebsiella pneumoniae, P. aeruginosa, E. coli, Enterobacter
   (b) gram-positive organism (10%): S. aureus, S. pneumoniae, H. influenzae

Complications:

1. Empyema
2. Pulmonary abscess
3. Cavitary necrosis
4. Pneumatocele
5. Pneumothorax
6. Pyopneumothorax
7. Bronchopleural fistula

Bacterial Pneumonia

Lobar Pneumonia

= ALVEOLAR PNEUMONIA

= pathogens reach peripheral air space, incite exudation of watery edema into alveolar space, centrifugal spread via small airways, pores of Kohn + Lambert into adjacent lobules + segments

√ nonsegmental sublobar consolidation

√ round pneumonia (= uniform involvement of contiguous alveoli)

(a) Streptococcus pneumoniae

(b) Klebsiella pneumoniae (more aggressive); in immunocompromised + alcoholics

(c) any pneumonia in children

(d) atypical measles

√ expansion of lobe with bulging of fissures

√ lung necrosis with cavitation

√ lack of volume loss

DDx: aspiration; pulmonary embolus

Lobular Pneumonia

= BRONCHOPNEUMONIA

= combination of interstitial + alveolar disease (injury starts in airways, involves bronchovascular bundle, spills into alveoli, which may contain edema fluid, blood, leukocytes, hyaline membranes, organisms)

Organism:

(a) Staphylococcus aureus, Pseudomonas pneumoniae: thrombosis of lobular artery branches with necrosis and cavitation

(b) Streptococcus (pneumococcus), Klebsiella, Legionnaires' bacillus, Bacillus proteus, E. coli, anaerobes (Bacteroides + Clostridia), Nocardia, actinomycosis

(c) Mycoplasma

√ small fluffy ill-defined acinar nodules, which enlarge with time

√ lobar + segmental densities with volume loss from airway obstruction ← bronchial narrowing + mucus plugging

Atypical Bacterial Pneumonia

= bacterial infection with radiographic appearance of viral pneumonia

Organism:

(1) Mycoplasma

(2) Pertussis

(3) Chlamydia trachomatis

Gram-negative Pneumonia

In 50% cause of nosocomial necrotizing pneumonias (including staphylococcal pneumonia)

Predisposed: elderly, debilitated, diabetes, alcoholism, COPD, malignancy, bronchitis, gram-positive pneumonia, treatment with antibiotics, respirator therapy

Organism:

1. Klebsiella
2. Pseudomonas

3. E. coli
4. Proteus
5. Haemophilus
6. Legionella

√ airspace consolidation (Klebsiella)
√ spongy appearance (Pseudomonas)
√ affecting dependent lobes (poor cough reflex without clearing of bronchial tree)
√ bilateral
√ cavitation common

Cx: (1) Exudate / empyema
(2) Bronchopleural fistula

Mycotic Lung Infection

A. IN HEALTHY SUBJECTS
1. Histoplasmosis
2. Coccidioidomycosis
3. Blastomycosis

B. OPPORTUNISTIC INFECTION
1. Aspergillosis
2. Mucormycosis (phycomycosis)
3. Candidiasis

Growth: (a) mycelial form
(b) yeast form (depending on environment)

Source of contamination:
(a) soil
(b) growth in moist areas (apart from Coccidioides)
(c) contaminated bird / bat excreta

Viral Lung Infection

= VIRAL PNEUMONIA = BRONCHIOLITIS = PERIBRONCHIAL PNEUMONIA = INTERSTITIAL PNEUMONIA = LOWER RESPIRATORY TRACT INFECTION
[terms used in an attempt to differentiate from airspace pneumonia]

= infection of bronchi + peribronchial tissues

Organism:

◊ The cause of infection cannot be reliably ascertained from its imaging appearance!

A. RNA VIRUSES
(a) Influenza A: more common during infancy, may lead to severe lower respiratory tract infection; mild URI in adults
1. Avian flu (H5N1 subtype): 1997 Hong Kong; 60% fatality rate
2. Swine influenza A (H1N1): 2009 in Mexico; pandemic; 1% fatality rate

(b) Parainfluenza 1–4: common cause of seasonal URI
(c) RSV = respiratory syncytial virus: most frequent viral cause of lower respiratory tract infection in infants
(d) Human metapneumovirus (HMPV): clinically indistinguishable from RSV
(e) Rubeola (measles): highly contagious; 1–36% mortality; febrile illness before /

with onset of rash

(f) Enterovirus, Coxsackie virus, ECHO virus: summertime URI

(g) Human T-cell lymphotropic virus type 1 (HTLV-1): retrovirus associated with leukemia / lymphoma; transmission by sexual contact + blood transfusion + breast feeding

(h) Hantavirus (hantavirus pulmonary syndrome): 1993 in southwestern USA

(i) Coronavirus (SARS = severe acute respiratory syndrome): 2002 Guangdong Province / China; 10% mortality rate

B. DNA VIRUSES

(a) Adenovirus: associated with Swyer-James-MacLeod syndrome in children

(b) Herpes simplex virus: in immunocompromised

(c) Varicella (chickenpox)-zoster virus: common in childhood; in 10% of adults; 2–5 days after rash

(d) Cytomegalic inclusion virus: features suggestive of bronchopneumonia

(e) Epstein-Barr virus

Path: necrosis of ciliated epithelial cells, goblet cells, bronchial mucous glands with frequent involvement of peribronchial tissues + interlobular septa

Clinical syndromes:

1. (**Common) cold** = mild upper respiratory tract symptoms ← tonsillopharyngitis, pharyngitis, epiglottitis, sinusitis, otitis media, conjunctivitis
   - sore throat, runny nose, congestion, sneezing, cough
   - headache, fever (milder than for influenza)

   Cause: > 200 different viruses other than influenza; Most common: rhinovirus (30–80%), coronavirus (15%), influenza virus (10–15%)
2. **Influenza**
   - abrupt fever > 100° F (38° C), chills and sweats, headache, myalgias, malaise, fatigue, weakness
   - nasal congestion, sore throat, dry persistent cough

   Cause: influenza virus types A, B, C constantly changing (= antigenic drift + shift)

Viral Pneumonia in Childhood

Pathophysiology:

tracheitis, bronchitis, bronchiolitis with peribronchial infiltrates → increased secretion of mucus + constriction of bronchi → narrowing of airways → increased resistance to air flow → air trapping → increase in residual volume; injury to alveolar cells with hyaline membranes; necrosis of alveolar walls with blood, edema, fibrin, macrophages within alveoli

Age: most common cause of pneumonia in children < 5 years of age; adults have usually acquired immunity

- retractions, tachypnea, air hunger, respiratory distress

Distribution: usually bilateral

Accuracy of CXR: 92% NPV, 30% PPV

√ hyperaeration + air trapping (best indicator!):

√ depression of diaphragm on both views:

(a) projects below anterior 6th rib

(b) projects below posterior 8th/10th rib on lordotic view
(c) loss of diaphragmatic dome on lateral view
√ increase in transverse diameter of chest
√ bowing of sternum upward + outward
√ increased anteroposterior diameter on lateral view

√ "**dirty chest**" = peribronchial cuffing + opacification:
√ symmetric parahilar peribronchial linear densities ← patchy atelectasis
√ bronchial wall thickening
√ interstitial pattern

√ segmental + subsegmental atelectasis with frequently changing distribution ← dislodgement of mucus plugs (common):
√ wedge-shaped / triangular densities

√ airspace pattern (50%) ← hemorrhagic edema
√ pleural effusion (20%)
√ hilar adenopathy (3%)
√ striking absence of pneumatoceles, lung abscess, pneumothorax
√ radiographic resolution lags 2–3 weeks behind clinical

Cx: (1) Bacterial superinfection (child becomes toxic after a week of sickness, peripheral consolidations + air bronchograms + pleural effusion)
(2) Bronchiectasis
(3) Unilateral hyperlucent lung, bronchiolitis obliterans

◊ Atypical measles pneumonia does NOT show the typical radiographic findings of viral pneumonias!

Viral Pneumonia in Adulthood

Clinical groups:
(a) atypical pneumonia in healthy host
(b) viral pneumonia in immunocompromised host

Risk factors: very young & old age, malnutrition, immunologic disorders

Histo:
(a) diffuse alveolar damage (intraalveolar edema, fibrin, variable cellular infiltrate with hyaline membrane)
(b) intraalveolar hemorrhage
(c) interstitial (intrapulmonary / airway) inflammatory cell infiltration

CXR:
√ unilateral / patchy bilateral areas of consolidation
◊ Lobar consolidation is uncommon!
√ nodular opacities
√ bronchial wall thickening
√ small pleural effusion

CT:
√ disturbances of parenchymal attenuation:
√ patchy inhomogeneities = mosaic attenuation (= bronchiolar inflammation / cicatricial scarring → bronchiolar obstruction → alveolar hypoventilation):

√ area of decreased attenuation persists during expiration ← air trapping
√ lobular ground-glass opacities (= thickening of interstitium + partial filling of airspaces)
√ pulmonary consolidation:
√ patchy + poorly defined (bronchopneumonia)
√ focal + well defined (lobar pneumonia)
√ nodules < 10 mm
√ centrilobular micronodules
√ tree-in-bud of small airway disease
= dilated centrilobular bronchioles, their lumina impacted with mucus / fluid / pus
√ widespread smooth interlobular septal thickening ± crazy paving pattern
√ bronchial ± bronchiolar wall thickening
Cx: acute pneumonia with rapid progression to ARDS

Round Pneumonia

= NUMMULAR PNEUMONIA
= fairly spherical pneumonia caused by pyogenic organisms
Pathophysiology: in young children only few intraalveolar pores of Kohn + bronchoalveolar channels of Lambert have developed to allow collateral air drift
Organism: Haemophilus influenzae, Streptococcus, Pneumococcus
Age: children >> adults
• cough, chest pain, fever of ≥ 104° F (40° C)
Location: always posterior, usually in lower lobes
√ spherical infiltrate with slightly fluffy borders + air bronchogram
√ triangular infiltrate abutting a pleural surface (usually seen on lateral view)
√ rapid change in size and shape

Cavitating Pneumonia

1. Staphylococcus aureus
2. Haemophilus influenzae
3. S. pneumoniae

other gram-negative organisms (eg, Klebsiella)

Cavitating Opportunistic Infection

◊ Repeated infections in same patient are not necessarily due to same organism!

A. FUNGAL INFECTIONS
   1. Aspergillosis
   2. Nocardiosis
   3. Mucormycosis (= phycomycosis)

B. STAPHYLOCOCCAL ABSCESS
C. TUBERCULOSIS (nummular form)
D. SEPTIC EMBOLI
   1. Anaerobic organisms

DDx: Metastatic disease in carcinoma / Hodgkin lymphoma

Recurrent Pneumonia in Childhood

A. IMMUNE PROBLEM
   1. Immune deficiency
   2. Chronic granulomatous disease of childhood (males)
   3. Alpha 1-antitrypsin deficiency

B. ASPIRATION
   1. Gastroesophageal reflux
   2. H-type tracheoesophageal fistula
   3. Disorder of swallowing mechanism
   4. Esophageal obstruction, impacted esophageal foreign body

C. UNDERLYING LUNG DISEASE
   1. Sequestration
   2. Bronchopulmonary dysplasia
   3. Cystic fibrosis
   4. Atopic asthma
   5. Bronchiolitis obliterans
   6. Sinusitis
   7. Bronchiectasis
   8. Ciliary dysmotility syndromes
   9. Pulmonary foreign body

NEONATAL LUNG DISEASE

Parenchymal Lung Disease on 1st Day of Life

◊ Radiographic findings overlap!

1. Transient tachypnea of newborn
2. Respiratory distress syndrome
3. Neonatal pneumonia
4. Meconium aspiration syndrome
5. Prematurity with accelerated lung maturity (see below)

Air Leaks in Neonatal Chest

= intrathoracic extra-alveolar gas

1. Pulmonary interstitial emphysema
2. Pneumomediastinum
3. Pneumothorax
4. Gas below visceral pleura
   √ gas at lung base / against fissure
5. Pneumopericardium
6. Gas embolus to cardiac chambers / blood vessels

Mediastinal Shift & Abnormal Aeration in Neonate

A. SHIFT TOWARD LUCENT LUNG
   1. Congenital diaphragmatic hernia
   2. Chylothorax

3. Cystic adenomatoid malformation

B. SHIFT AWAY FROM LUCENT LUNG
1. Congenital lobar emphysema
2. Persistent localized pulmonary interstitial emphysema
3. Obstruction of mainstem bronchus (by anomalous or dilated vessel / cardiac chamber)

Pulmonary Infiltrates in Neonate

mnemonic: I HEAR

Infection (pneumonia)
Hemorrhage
Edema
Aspiration
Respiratory distress syndrome

Reticulogranular Densities in Neonate

1. Respiratory distress syndrome (90%): premature infant, inadequate surfactant
2. **Prematurity with Accelerated Lung Maturity** (PALM)
   = IMMATURE LUNG SYNDROME:
   premature infant with normal surfactant ← maternal steroid therapy / intrauterine stress
   √ lung granularity (= almost clear chest)
   √ small thymus (stress / steroids)
3. Transient tachypnea of the newborn
4. Neonatal group-B streptococcal pneumonia
5. Idiopathic hypoglycemia
6. Congestive heart failure
7. Early pulmonary hemorrhage
8. Infant of diabetic mother

CONGENITAL LUNG ABNORMALITIES

= SEQUESTRATION SPECTRUM

A. BRONCHOPULMONARY (LUNG BUD) ANOMALY
1. Lung agenesis-hypoplasia complex
2. Congenital pulmonary airway malformation
3. Congenital lobar overinflation / emphysema
4. Bronchial atresia
5. Bronchogenic cyst

B. VASCULAR ANOMALY
1. Absence of main pulmonary artery
2. Pulmonary sling = Anomalous origin of left pulmonary a.
3. Anomalous pulmonary venous drainage
4. Pulmonary arterial / AV malformation

C. COMBINED LUNG & VASCULAR ANOMALY
1. Scimitar / hypogenetic lung / congenital pulmonary venolobar syndrome
2. Bronchopulmonary sequestration
3. Congenital pulmonary airway malformation = cystic adenomatoid malformation

Hypogenetic Lung Syndrome

= collective name for congenital underdevelopment of one / more lobes of a lung separated into 3 forms:

1. **Pulmonary agenesis**
   = complete absence of a lobe + its bronchus
   CT:
   √ missing bronchus + lobe(s)
2. **Pulmonary aplasia**
   = rudimentary bronchus ending in blind pouch + absence of parenchyma + vessels
   Incidence: 1÷10,000; R÷L = 1÷1
   CT:
   √ absence of ipsilateral pulmonary artery
   √ bronchus terminates in dilated blind pouch
   √ absence of ipsilateral pulmonary tissue
3. **Pulmonary hypoplasia**
   = completely formed but congenitally small bronchus with rudimentary parenchyma + small vessels
   Developmental causes:
   resulting in intrauterine compression of chest
   (a) Idiopathic (rare)
   (b) Extrathoracic compression (= Potter syndrome)
      1. Oligohydramnios (renal agenesis, bilateral cystic renal disease, obstructive uropathy, premature rupture of membranes)
      2. Fetal ascites
   (c) Thoracic cage compression
      1. Thoracic bone dysplasia: Ellis-van Creveld, Jeune, thanatophoric dystrophy, severe achondroplasia
      2. Muscular disease
   (d) Intrathoracic compression
      1. Diaphragmatic defect
      2. Excess pleural fluid
      3. Large intrathoracic cyst / tumor

ABNORMAL LUNG PATTERN

1. Mass
   = any localized density not completely bordered by fissures / pleura
2. Consolidative (alveolar) pattern
   = commonly produced by filling of air spaces with fluid (transudate / exudate) / cells / other material, ALSO by alveolar collapse, airway obstruction, confluent interstitial thickening
   ground glass = hazy area of increased attenuation not obscuring bronchovascular structures
   consolidation = marked increase in attenuation with obliteration of underlying anatomic features

3. Interstitial pattern
4. Vascular pattern
   (a) increased vessel size: CHF, pulmonary arterial hypertension, shunt vascularity, lymphangitic carcinomatosis
   (b) decreased vessel size: emphysema, thromboembolism
5. Bronchial pattern
   √ wall thickening: bronchitis, asthma, bronchiectasis
   √ density without air bronchogram (= complete airway obstruction)
   √ lucency of air trapping (= partial airway obstruction with ball-valve mechanism)

ALVEOLAR (CONSOLIDATIVE) PATTERN

Classic appearance of airspace consolidation:

mnemonic: A2BC3

- √ **A**cinar rosettes: rounded poorly defined nodules of acinus size (6–10 mm), best seen at periphery of opacity
- √ **A**ir alveologram / bronchogram
- √ **B**utterfly / bat-wing distribution: perihilar / bibasilar
- √ **C**oalescent / confluent cloudlike ill-defined opacities
- √ **C**onsolidation in diffuse, perihilar / bibasilar, segmental / lobar, multifocal / lobular distribution
- √ **C**hanges occur rapidly (labile / fleeting)

HRCT:

- √ poorly marginated densities within primary lobule (up to 1 cm in size)
- √ rapid coalescence with neighboring lesions in segmental distribution
- √ predominantly central location with sparing of subpleural zones
- √ air bronchograms

Diffuse Airspace Disease

= alveoli filled with

A. INFLAMMATORY EXUDATE = "PUS"
   1. Lobar pneumonia
   2. Bronchopneumonia: especially gram-negative organisms
   3. Unusual pneumonia
      (a) viral: extensive hemorrhagic edema especially in immunocompromised patient with hematologic malignancy + transplant
      (b) Pneumocystis
      (c) fungal: Aspergillus, Candida, Cryptococcus, Phycomycetes
      (d) tuberculosis
   4. Complication of pneumonia = lung abscess

B. HEMORRHAGE = "BLOOD"
   1. Trauma: contusion
   2. Pulmonary embolism, thromboembolism
   3. Bleeding diathesis: leukemia, hemophilia, anticoagulants, DIC, immune thrombocytopenia (ITP)
   4. Vasculitis:

Wegener granulomatosis, Goodpasture syndrome, SLE, mucormycosis, aspergillosis, Rocky Mountain spotted fever, infectious mononucleosis

5. Idiopathic pulmonary hemosiderosis
6. Bleeding metastasis: eg, choriocarcinoma

C. TRANSUDATE = "WATER" = PULMONARY EDEMA / ARDS

1. Cardiac edema
2. Neurogenic edema
3. Hypoproteinemia
4. Fluid overload
5. Renal failure
6. Radiotherapy
7. Shock
8. Toxic inhalation
9. Drug reaction
10. Drowning
11. Aspiration
12. Adult respiratory distress syndrome

D. SECRETIONS = "PROTEIN"

1. Phospholipoprotein: Pulmonary alveolar proteinosis
2. Mucus plugging

E. "CELLS"

(a) malignant: bronchioloalveolar cell carcinoma, lymphoma
(b) T4 lymphocytes: sarcoidosis
(c) Neutrophils: infection
(d) Eosinophils: eosinophilic pneumonia
(e) Plasma cells, mast cells: hypersensitivity pneumonitis

F. INTERSTITIAL DISEASE
simulating airspace disease, eg, "alveolar sarcoid"

mnemonic: AIRSPACED

Aspiration
Inhalation, Inflammatory
Renal (uremia)
Sarcoidosis
Proteinosis (alveolar)
Alveolar cell carcinoma
Congestive (CHF)
Emboli
Drug reaction, **D**rowning

Air-space Opacification in Trauma

A. ACUTE PHASE

1. Pulmonary contusion
2. Pulmonary laceration
3. Aspiration pneumonia
4. Atelectasis ← splinting / mucous plug

5. Pulmonary edema: cardiogenic / noncardiogenic

B. SUBACUTE PHASE (> 24 hours) add
   1. Fat embolism
   2. Adult respiratory distress syndrome

Localized Airspace Disease

mnemonic: 4P's & TAIL

Pneumonia
Pulmonary edema
Pulmonary contusion
Pulmonary interstitial edema
Tuberculosis
Alveolar cell carcinoma

Alveolar cell carcinoma
Lymphoma
Lipoid pneumonia
Alveolar proteinosis
Goodpasture syndrome

CT Angiogram Sign

= homogeneous low attenuation of lung consolidation, which allows vessels to be clearly seen

1. Lobar bronchioloalveolar cell carcinoma

2. Lobar pneumonia
3. Pulmonary lymphoma
4. Extrinsic lipid pneumonia
5. Pulmonary infarction
6. Pulmonary edema

Migratory / Fleeting Pulmonary Opacities

1. Simple pulmonary eosinophilia
2. Pulmonary hemorrhage
3. Pulmonary vasculitis
4. Cryptogenic organizing pneumonia
5. Recurrent aspiration / infection

INTERSTITIAL LUNG DISEASE

= thickening of lung interstices (= interlobular septa)

A. MAJOR LYMPHATIC TRUNKS
   1. Lymphangitic carcinomatosis
   2. Congenital pulmonary lymphangiectasia
   3. Pulmonary edema
   4. Alveolar proteinosis

B. PULMONARY VEINS (↑ pulmonary venous pressure)
   1. Left ventricular failure
   2. Venous obstructive disease

C. SUPPORTING CONNECTIVE TISSUE NETWORK
   1. Interstitial edema
   2. Chronic interstitial pneumonia
   3. Pneumoconioses
   4. Collagen-vascular disease
   5. Interstitial fibrosis
   6. Amyloid
   7. Tumor infiltration within connective tissue
   8. Desmoplastic reaction to tumor

Path: stereotypical inflammatory response of alveolar wall to injury
   (a) acute phase: fluid + inflammatory cells exude into alveolar space, mononuclear cells accumulate in edematous alveolar wall
   (b) organizing phase: hyperplasia of type II pneumocytes attempt to regenerate alveolar epithelium, fibroblasts deposit collagen
   (c) chronic stage: dense collagenous fibrous tissue remodels normal pulmonary architecture

Characterizing criteria:
(a) distribution:
   › vertical distribution: upper / lower lung zones
   › horizontal distribution : axial (core) / parenchymal (middle) / peripheral compartment
(b) volume loss
(c) time course

(d) interstitial lung pattern

Classification scheme:

A. Interstitial pneumonia
   1. Usual interstitial pneumonia (UIP)
   2. Nonspecific interstitial pneumonia (NSIP)
   3. Acute interstitial pneumonia (AIP)
   4. Alveolar macrophage pneumonia (AMP) = desquamative interstitial pneumonia (DIP)
   5. Bronchiolitis obliterans organizing pneumonia

B. Diffuse infiltrative disease with granulomas
   1. Sarcoidosis
   2. Hypersensitivity pneumonitis

C. Lymphocytic interstitial pneumonia (LIP)

D. Pneumoconiosis

E. Interstitial lung disease with cysts
   1. Langerhans cell histiocytosis
   2. Lymphangioleiomyomatosis

F. Interstitial lung disease with interlobular septal thickening
   1. Lymphangitic carcinomatosis
   2. Interstitial pulmonary edema
   3. Alveolar proteinosis

G. Eosinophilic syndrome

H. Pulmonary hemorrhage

I. Vasculitis

Interstitial Lung Pattern on CXR

1. LINEAR PATTERN
   (a) Kerley lines = septal lines = thickened connective septa
   Path: accumulation of fluid / tissue
   √ **Kerley A lines** = relatively long fine linear shadows in upper lungs, deep within lung parenchyma radiating from hila
   √ **Kerley B lines** = short horizontally oriented peripheral lines extending + perpendicular to pleura in costophrenic angles + retrosternal clear space
   (b) reticulations
   = innumerable interlacing linear opacities suggesting a mesh / network
   √ **Kerley C lines** = fine "spider web / lacelike" polygonal opacities distributed primarily in a peripheral / subpleural location
   Path: pulmonary fibrosis (lower lobes), hypersensitivity pneumonitis (upper lobes)
   √ thick linear opacities in a central / perihilar distribution
   Path: (a) dilated thick-walled bronchi of bronchiectasis
   (b) cysts of lymphangioleiomyomatosis / tuberous sclerosis
2. NODULAR / MILIARY PATTERN
   = small well-defined innumerable uniform 3–5-mm nodules with even distribution
   Path: diffuse metastatic disease, infectious granulomatous disease (TB, fungal), noninfectious granulomatous disease (pneumoconioses, sarcoidosis, eosinophilic

granuloma)

3. DESTRUCTIVE FORM = honeycomb lung

Signs of Acute Interstitial Disease

√ peribronchial cuffing = thickened bronchial wall + peribronchial sheath (when viewed end on)
√ thickening of interlobular fissures
√ Kerley lines
√ perihilar haze = blurring of hilar shadows
√ blurring of pulmonary vascular markings
√ increased density at lung bases
√ small pleural effusions

Signs of Chronic Interstitial Disease

◊ HRCT ~ 60% more sensitive than CXR
√ irregular visceral pleural surface
√ **reticulations**:
  √ fine reticulations
    = early potentially reversible / minimal irreversible alveolar septal abnormality
    (1) Idiopathic pulmonary fibrosis (basilar predominance)
  √ coarse reticulations
    in 75% related to environmental disease, sarcoidosis, collagen-vascular disorders, chronic interstitial pneumonia
√ **nodularity**:
  in 90% related to infectious / noninfectious granulomatous process, metastatic malignancy, pneumoconioses, amyloidosis
√ **linearity**:
  (1) Cardiogenic / noncardiogenic interstitial pulmonary edema
    √ symmetric linearity
  (2) Lymphangitic malignancy
    √ asymmetric linearity
  (3) Diffuse bronchial wall disorders: cystic fibrosis, bronchiectasis, hypersensitivity asthma
√ **honeycombing**
  = usually subpleural clustered cystic air spaces < 1 cm in diameter with thick well-defined walls set off against a background of increased lung density (end-stage lung)

Distribution of Interstitial Disease

Perihilar Interstitial Lung Disease

(a) acute rapidly changing
  1. Pulmonary edema
  2. Pneumocystis pneumonitis
  3. Early extrinsic allergic alveolitis
(b) chronic slowly progressive
  1. Lymphangitic carcinomatosis:

often unilateral, associated with adenopathy, pleural effusion

Peripheral Interstitial Lung Disease

(a) acute rapidly changing
   1. Interstitial pulmonary edema with Kerley B lines (most common)
   2. Active fibrosing alveolitis

(b) chronic slowly progressive
   1. Secondary pulmonary hemosiderosis

Upper Interstitial Lung Disease

(a) chronic slowly progressive ± volume loss
   1. Postprimary TB (common)
   2. Silicosis (common)

(b) chronic slowly progressive with volume loss
   1. Sarcoidosis (common)
   2. Ankylosing spondylitis (rare)
   3. Sulfa drugs (rare)

(c) chronic slowly progressive without volume loss
   1. Extrinsic allergic alveolitis
   2. Eosinophilic granuloma
   3. Aspiration pneumonia
   4. Postradiation pneumonitis
   5. Recurrent Pneumocystis carinii pneumonia (PCP) under aerosolized pentamidine prophylaxis

mnemonic: SHIRT CAP
Sarcoidosis
Histoplasmosis
Idiopathic
Radiation therapy
Tuberculosis (postprimary)
Chronic extrinsic alveolitis
Ankylosing spondylitis
Progressive massive fibrosis

Chronic Diffuse Infiltrative Lung Disease

= CHRONIC INTERSTITIAL LUNG DISEASE = GENERALIZED INTERSTITIAL LUNG DISEASE

Prevalence: up to 15% of pulmonary conditions

Cause: > 200 described disorders; in only 25–30% known / established etiology; 15–20 diseases comprise > 90% of cases

- dyspnea (primary complaint)
- dry basilar rales / crackles that fail to clear with coughing

CXR:

◊ Difficult to characterize due to similar findings

◊ Differentiation into alveolar + interstitial disease is unreliable as "interstitial disease"

invariably involves alveoli + vice versa
√ ± nonspecific abnormality

mnemonic: HIDE FACTS
Hamman-Rich, **H**emosiderosis
Infection, **I**rradiation, **I**diopathic
Dust, **D**rugs
Eosinophilic granuloma, **E**dema
Fungal, **F**armer's lung
Aspiration (oil), **A**rthritis (rheumatoid, ankylosing spondylitis)
Collagen vascular disease
Tumor, TB, **T**uberous sclerosis
Sarcoidosis, **S**cleroderma

Zonal Predilection of Chronic Diffuse Parenchymal Lung Disease (DPLD)

CHRONIC DPLD OF UPPER LUNG ZONE

= zone with higher oxygen tension and pH, but less efficient lymphatic drainage

(a) inhalational disease
1. Silicosis
2. Coal worker pneumoconiosis
3. Extrinsic allergic alveolitis
4. Aspiration pneumonia

(b) granulomatous disease
1. Sarcoidosis
2. Langerhans cell histiocytosis (EG)
3. Postprimary TB (common)

(c) others
1. Cystic fibrosis
2. Ankylosing spondylitis
3. Chronic interstitial pneumonia
4. Sulfa drugs (rare)
5. Radiation pneumonitis
6. Recurrent Pneumocystis carinii pneumonia (PCP) under aerosolized pentamidine prophylaxis

mnemonic: CASSET
Cystic fibrosis
Ankylosing spondylitis
Silicosis
Sarcoidosis
Eosinophilic granuloma
Tuberculosis, fungus

CHRONIC DPLD OF LOWER LUNG ZONE

lower lung zone = zone with greater ventilation, perfusion, and lymphatic drainage
1. Idiopathic pulmonary fibrosis: usual interstitial pneumonia (common)
2. Lymphangitic carcinomatosis

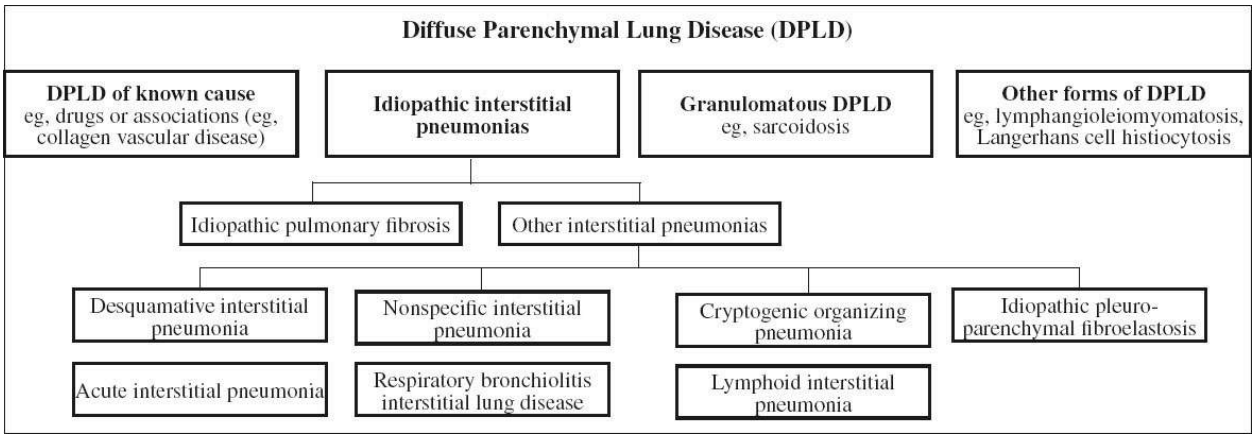
3. Collagen vascular disease: scleroderma (common)
4. Asbestosis (posterior aspect of lung base)
5. Lymphangioleiomyomatosis
6. Chronic aspiration pneumonia with fibrosis (often regional + unilateral)

mnemonic: BAD LASS RIF

Bronchiectasis
Aspiration
Dermatomyositis
Lymphangitic spread
Asbestosis
Sarcoidosis
Scleroderma
Rheumatoid arthritis
Idiopathic pulmonary fibrosis
Furadantin®

Compartmental Predilection of Chronic DPLD

A. AXIAL / CORE COMPARTMENT
= peribronchial vascular bundles + lymphatics
1. Sarcoidosis
2. Lymphangitic carcinomatosis
3. Lymphoma



B. MIDDLE / PARENCHYMAL COMPARTMENT
= formed by alveolar walls
1. Sarcoidosis
2. Lymphangitic carcinomatosis
3. Chronic medications
4. Neurofibromatosis
5. Vasculitis
6. Silicosis

C. PERIPHERAL COMPARTMENT
= pleura with subpleural connective tissue, interlobular septa, pulmonary veins,

lymphatics, walls of cortical alveoli

1. Sarcoidosis
2. Lymphangitic carcinomatosis
3. Idiopathic pulmonary fibrosis
4. Collagen vascular disease
5. Rheumatoid arthritis

Lung Volumes in Chronic DPLD

CHRONIC DPLD WITH NORMAL LUNG VOLUME

1. Sarcoidosis
2. Langerhans cell histiocytosis (in 66%)

CHRONIC DPLD WITH INCREASED LUNG VOLUME

mnemonic: ELECT

Emphysema with interstitial lung disease
Lymphangioleiomyomatosis
Eosinophilic granuloma (Langerhans) in 33%
Cystic fibrosis
Tuberous sclerosis

CHRONIC DPLD WITH REDUCED LUNG VOLUME

due to fibrotic process

1. Systemic lupus erythematosus
2. Collagen vascular disease (eg, scleroderma, dermatomyositis, polymyositis)
3. Idiopathic pulmonary fibrosis
4. Chronic interstitial pneumonias
5. Asbestosis

Pleural Disease in Chronic DPLD

CHRONIC DPLD WITH PNEUMOTHORAX

1. Lymphangioleiomyomatosis
2. Langerhans cell histiocytosis
3. End-stage lung disease

CHRONIC DPLD WITH PLEURAL EFFUSION

1. Lymphangioleiomyomatosis
2. Rheumatoid arthritis
3. Systemic lupus erythematosus
4. Mixed connective tissue disorder
5. Wegener granulomatosis
6. Lymphangitic carcinomatosis
7. Pulmonary edema

CHRONIC DPLD WITH PLEURAL THICKENING

1. Asbestosis
2. Collagen vascular disease

Lymphadenopathy in Chronic Diffuse Lung Disease

1. Silicosis
2. Sarcoidosis
3. Lymphoma
4. Lymphangitic carcinomatosis

Diffuse Fine Reticulations

Acute Diffuse Fine Reticulations

A. ACUTE INTERSTITIAL EDEMA
   1. Congestive heart failure
   2. Fluid overload
   3. Uremia
   4. Hypersensitivity

B. ACUTE INTERSTITIAL PNEUMONIA
   1. Viral pneumonia (Hantavirus, CMV)
   2. Mycoplasma pneumonia
   3. Pneumocystis carinii pneumonia

mnemonic: HELP
Hypersensitivity
Edema
Lymphoproliferative
Pneumonitis (viral)

Chronic Diffuse Fine Reticulations

A. VENOUS OBSTRUCTION
   1. Atherosclerotic heart disease
   2. Mitral stenosis
   3. Left atrial myxoma
   4. Pulmonary venoocclusive disease
   5. Sclerosing mediastinitis

B. LYMPHATIC OBSTRUCTION
   1. Lymphangiectasia (pediatric patient)
   2. Mediastinal mass (lymphoma)
   3. Lymphoma / leukemia
   4. Lymphangitic carcinomatosis:
      predominantly basilar distribution
      (a) bilateral (breast, stomach, colon, pancreas)
      (b) unilateral (lung tumor)
   5. Lymphocytic interstitial pneumonitis

C. INHALATIONAL DISEASE
   1. Silicosis: small nodules + reticulations
   2. Asbestosis: basilar distribution, pleural thickening + calcifications
   3. Hard metals
   4. Allergic alveolitis

D. GRANULOMATOUS DISEASE
from a nodular to a reticular pattern if
(a) nodules line up along bronchovascular bundles
(b) interlobular septa show fibrotic changes
1. Sarcoidosis:
√ hilar + mediastinal adenopathy (may have disappeared)
2. Eosinophilic granuloma: upper lobe distribution

E. CONNECTIVE-TISSUE DISEASE
√ reticulations in late stages
1. Rheumatoid lung
2. Scleroderma
3. Systemic lupus erythematosus

F. DRUG REACTIONS

G. IDIOPATHIC
1. Usual interstitial pneumonitis (UIP)
2. Desquamative interstitial pneumonitis (DIP)
3. Tuberous sclerosis: smooth muscle proliferation
4. Lymphangiomyomatosis
5. Idiopathic pulmonary hemosiderosis
6. Alveolar proteinosis (late complication)
7. Amyloidosis
8. Interstitial calcification (chronic renal failure)

mnemonic: LIFE lines
Lymphangitic spread
Inflammation / infection
Fibrosis
Edema

Coarse Reticulations

= architectural destruction of interstitium = end-stage scarring of lung = interstitial pulmonary fibrosis = **honeycomb lung**

√ coarse reticular interstitial densities with intervening cystic spaces
√ rounded radiolucencies < 1 cm in areas of increased lung density
√ small lung volume (decreased compliance)

Cx: (1) Intercurrent pneumothoraces
(2) Bronchogenic carcinoma = scar carcinoma

Cause:

A. INHALATIONAL DISEASE
(a) Pneumoconiosis
1. Asbestosis: basilar distribution, shaggy heart, pleural thickening + calcifications
2. Silicosis: upper lobe predominance ± pleural thickening ± hilar and mediastinal adenopathy
3. Berylliosis
(b) Chemical inhalation (late)

1. Silo-filler's disease (nitrogen dioxide)
2. Sulfur dioxide, chlorine, phosgene, cadmium

(c) Extrinsic allergic alveolitis
← hypersensitivity to organic dusts

(d) Oxygen toxicity
← sequelae of RDS therapy with oxygen

(e) Chronic aspiration
eg, mineral oil: localized process in medial basal segments / middle lobe

B. GRANULOMATOUS DISEASE
1. Sarcoidosis
2. Eosinophilic granuloma

C. COLLAGEN-VASCULAR DISEASE
1. Rheumatoid lung
2. Scleroderma
3. Ankylosing spondylitis: upper lobes
4. SLE: rarely produces honeycombing

D. IATROGENIC
1. Drug hypersensitivity
2. Radiotherapy

E. IDIOPATHIC
1. Usual interstitial pneumonitis (UIP)
√ honeycombing in 50%
√ severe volume loss in 45%
2. Desquamative interstitial pneumonitis (DIP)
√ honeycombing in 12.5%
√ severe volume loss in 23%
3. Lymphangiomyomatosis
4. Tuberous sclerosis (rare)
5. Neurofibromatosis (rare)
6. Pulmonary capillary hemangiomatosis (rare)

DDx: bronchiectasis, cavitary metastases (rare)

Reticulations & Pleural Effusion

A. ACUTE
1. Edema
2. Infection: viral, Mycoplasma (very rare)

B. CHRONIC
1. Congestive heart failure
2. Lymphangitic carcinomatosis
3. Lymphoma / leukemia
4. SLE
5. Rheumatoid disease
6. Lymphangiectasia
7. Lymphangiomyomatosis
8. Asbestosis

Reticulations & Hilar Adenopathy

1. Sarcoidosis
2. Silicosis
3. Lymphoma / leukemia
4. Lung primary: particularly oat cell carcinoma
5. Metastases: lymphatic obstruction / spread
6. Fungal disease
7. Tuberculosis
8. Viral pneumonia (rare combination)

End-stage Lung Disease

= evidence of honeycombing / cystic change / conglomerate fibrosis

A. DISTRIBUTION
   1. Usual interstitial pneumonia
      √ subpleural distribution + lower lobe predominance
   2. Asbestosis
      √ subpleural distribution + lower lobe predominance + pleural thickening
   3. Sarcoidosis
      √ subpleural honeycombing
      √ central cystic bronchiectasis
      √ conglomerate fibrosis
      √ peribronchovascular distribution
      √ upper lobe predominance
   4. Extrinsic allergic alveolitis
      √ diffuse random distribution + patchy areas of ground-glass attenuation

B. CYSTIC SPACES WITH WELL-DEFINED WALLS
   1. Langerhans cell histiocytosis
      √ upper lobe predominance
   2. Lymphangioleiomyomatosis
      √ no zonal predominance

C. CONGLOMERATE FIBROTIC MASSES
   1. Sarcoidosis
      √ peribronchovascular distribution
   2. Silicosis
      √ bronchi splayed around masses
   3. Talcosis
      √ areas of high attenuation (= talc deposits)

Honeycomb Lung

mnemonic: SHIPS BOATS

Sarcoidosis
Histiocytosis X = Langerhans cell histiocytosis
Idiopathic (UIP)
Pneumoconiosis
Scleroderma

Bleomycin, **B**usulfan
Oxygen toxicity
Arthritis (rheumatoid), **A**myloidosis, **A**llergic alveolitis
Tuberous sclerosis, **T**B
Storage disease (Gaucher)

Chronic Interstitial Disease Simulating Airspace Disease

A. REPLACEMENT OF LUNG ARCHITECTURE BY AN INTERSTITIAL PROCESS
   (a) neoplastic: Hodgkin disease, histiocytic lymphoma
   (b) benign cellular infiltrate: lymphocytic interstitial pneumonia, pseudolymphoma
   (c) granulomatous disease: alveolar sarcoidosis
   (d) fibrosis
B. EXUDATIVE PHASE OF INTERSTITIAL PNEUMONIA
   1. UIP
   2. Adult respiratory distress syndrome
   3. Radiation pneumonitis
   4. Drug reaction
   5. Reaction to noxious gases
C. CELLULAR FILLING OF AIR SPACE
   1. Desquamative interstitial pneumonia
   2. Pneumocystis carinii pneumonia

Reticulonodular Lung Disease

mnemonic: Please Don't Eat Stale Tuna Fish Sandwiches Every Morning
Pneumoconiosis
Drugs
Eosinophilic granuloma
Sarcoidosis
Tuberculosis
Fungal disease
Schistosomiasis
Exanthem (measles, chickenpox)
Metastases (thyroid)

Reticulonodular Pattern & Lower Lobe Predominance

mnemonic: CIA
Collagen vascular disease
Idiopathic
Asbestosis

Nodular Lung Disease

= round moderately well marginated opacity < 3 cm in maximum diameter

A. GRANULOMATOUS LUNG DISEASE
   (a) infection: eg, tuberculosis
   (b) fungal disease: eg, histoplasmosis

(c) silicosis
(d) vasculitis: eg, Wegener granulomatosis

B. NEOPLASM
(a) metastatic lung diseases: eg, thyroid cancer
(b) lymphoma
(c) bronchioloalveolar cell carcinoma

C. OTHER DISEASE
(a) drug-induced: methotrexate
(b) nongranulomatous vasculitis
(c) sarcoidosis

Macronodular Lung Disease

√ nodules > 5 mm in diameter

mnemonic: GAMMA WARPS

Granuloma (eosinophilic granuloma, fungus)
Abscess
Metastases
Multiple myeloma
AVM
Wegener granulomatosis
Amyloidosis
Rheumatoid lung
Parasites (Echinococcus, paragonimiasis)
Sarcoidosis

Micronodular Lung Disease

= discrete 3–5–7-mm small round focal opacity of at least soft-tissue attenuation

1. Granulomatous disease: miliary TB, histoplasmosis
2. Hypersensitivity (organic dust)
3. Pneumoconiosis (inorganic dust, thesaurosis = prolonged hair spray exposure)
4. Sarcoidosis
5. Metastases (thyroid, melanoma)
6. Langerhans cell histiocytosis
7. Chickenpox

DIFFUSE FINE NODULAR DISEASE & MILIARY NODULES

√ very small 1–4-mm sharply defined nodules of interstitial disease

(a) Inhalational disease
    1. Silicosis + coal worker's pneumoconiosis
    2. Berylliosis
    3. Siderosis
    4. Extrinsic allergic alveolitis (chronic phase)
(b) Granulomatous disease
    1. Langerhans cell histiocytosis = eosinophilic granuloma
    2. Sarcoidosis (with current / previous adenopathy)
(c) Infectious disease

1. Bacteria: salmonella, nocardiosis
2. TB
3. Fungus: histoplasmosis, coccidioidomycosis, blastomycosis, aspergillosis (rare), cryptococcosis (rare)
4. Virus: varicella (more common in adults), Mycoplasma pneumonia

(d) Metastases:
thyroid carcinoma, melanoma, adenocarcinoma of breast, stomach, colon, pancreas

(e) Alveolar microlithiasis (rare)

(f) Bronchiolitis obliterans

(g) Gaucher disease

mnemonic: TEMPEST

Tuberculosis + fungal disease
Eosinophilic granuloma
Metastases (thyroid, lymphangitic carcinomatosis)
Pneumoconiosis, Parasites
Embolism of oily contrast
Sarcoidosis
Tuberous sclerosis

Fine Nodular Disease in Afebrile Patient

1. Inhalational disease
2. Eosinophilic granuloma
3. Sarcoidosis
4. Metastases
5. Fungal infection (late stage)
6. Miliary tuberculosis (rare)

Fine Nodular Disease in Febrile Patient

1. Tuberculosis
2. Fungal infection (early stage)
3. Pneumocystis
4. Viral pneumonia

DIFFUSE LUNG DISEASE ON HRCT

Patterns of Diffuse Lung Disease on HRCT

maximum resolution = 300 μm

1. **Linear densities**
   = thickening of interlobular septa + bronchovascular interstitium
   Cause: interstitial fluid / fibrosis / cellular infiltrates
   (a) intralobular septal thickening
   = weblike network of fine lines in secondary pulmonary lobule
   (b) interlobular septal thickening
   = fine linear opacities perpendicular to pleural surface / in a polygonal pattern in a more central location

√ smooth septal thickening: pulmonary edema, lymphangitic carcinomatosis
√ beaded septa / septal nodules: lymphangitic carcinomatosis
√ irregular septa imply fibrosis
› distorted lobules: fibrosis
› no architectural distortion of lobules: edema / infiltration

2. **Reticular densities**
= clustered areas of septal thickening producing intricate network of crisscross lines in subpleural location
(a) predominantly subpleural small reticular elements of 6–10 mm in diameter with collection of small cystic airspaces with well-defined walls ("honeycombing")
Associated with: interstitial fibrosis, lymphangio- leiomyomatosis, amyloidosis
(b) fine diffusely distributed network of 2–3-mm basic elements
Associated with: miliary TB, reactions to methotrexate
Distribution:
› lower lung zones in subpleural areas: idiopathic pulmonary fibrosis, collagen vascular disease, asbestosis
› mid lung zone / all lung zones: chronic extrinsic allergic alveolitis
› mid + upper lung zones: sarcoidosis

3. **Nodules**
(a) interstitial nodules lymphangitic carcinomatosis, sarcoidosis, Langerhans cell histiocytosis, silicosis, coal worker pneumoconiosis, tuberculosis, hypersensitivity pneumonitis, metastatic tumor, amyloidosis
√ perihilar, peribronchovascular, centrilobular, interlobular septa, subpleural nodules
(b) airspace nodules lobular pneumonia, transbronchial spread of TB, bronchiolitis obliterans organizing pneumonia (BOOP), pulmonary edema
√ ill-defined nodules, a few mm to 1 cm in size
√ peribronchiolar + centrilobular
Size:
› small (< 5 mm): centrilobular location (separated by several mm from pleural surface, fissures, interlobular septa)
› large (> 5 mm): well / poorly defined occasionally surrounded by a halo of ground-glass opacity
Distribution:
› along bronchoarterial bundles + interlobular septa + subpleural: sarcoidosis
› upper zone: silicosis, coal-worker's pneumoconiosis
› centrilobular: extrinsic allergic alveolitis
DDx: vessel on cross section

4. **Ground-glass attenuation**
= hazy increase in lung opacity without obscuration of underlying vessels ← parenchymal abnormalities below spatial resolution of HRCT

◊ Often indicative of an acute, active, and potentially treatable process!

Histo:
(a) alveolar wall inflammation / thickening
(b) partial filling of air-spaces

(c) combination of both

Common cause: "water, blood, cells, no air"

A. Interstitial pulmonary edema = increased capillary blood volume
   √ perihilar + gravitational distribution
   √ cardiomegaly and pleural effusion

B. Diffuse inflammation / infection
   (a) alveolitis = minimal airspace filling as in
      1. Viral / mycoplasmal pneumonia
      2. Pneumocystis pneumonia in immunocompromised patient
      3. ARDS
   (b) early interstitial lung disease = minimal alveolar wall thickening (NSIP, DIP, RB-ILD, LIP)

C. Hypersensitivity pneumonitis
   √ centrilobular densities + air trapping
   • history of exposure to certain antigen

D. Pulmonary alveolar hemorrhage
   • hemoptysis, anemia, coagulopathy, vasculitis

E. Alveolar collapse
   1. Partial atelectasis = partial collapse of alveoli
   2. Normal during expiration

Distribution:

› peripheral in lower lung zones: DIP, UIP
› mid + upper lung zones: sarcoidosis
› "crazy paving" pattern
› mosaic perfusion

5. **Consolidation**

= homogeneous increase in pulmonary attenuation with obscuration of underlying vessels
√ ± air-bronchogram
√ sharp border at major fissure
√ advancing margin of ground-glass opacity
√ vessels visible only on enhanced CT

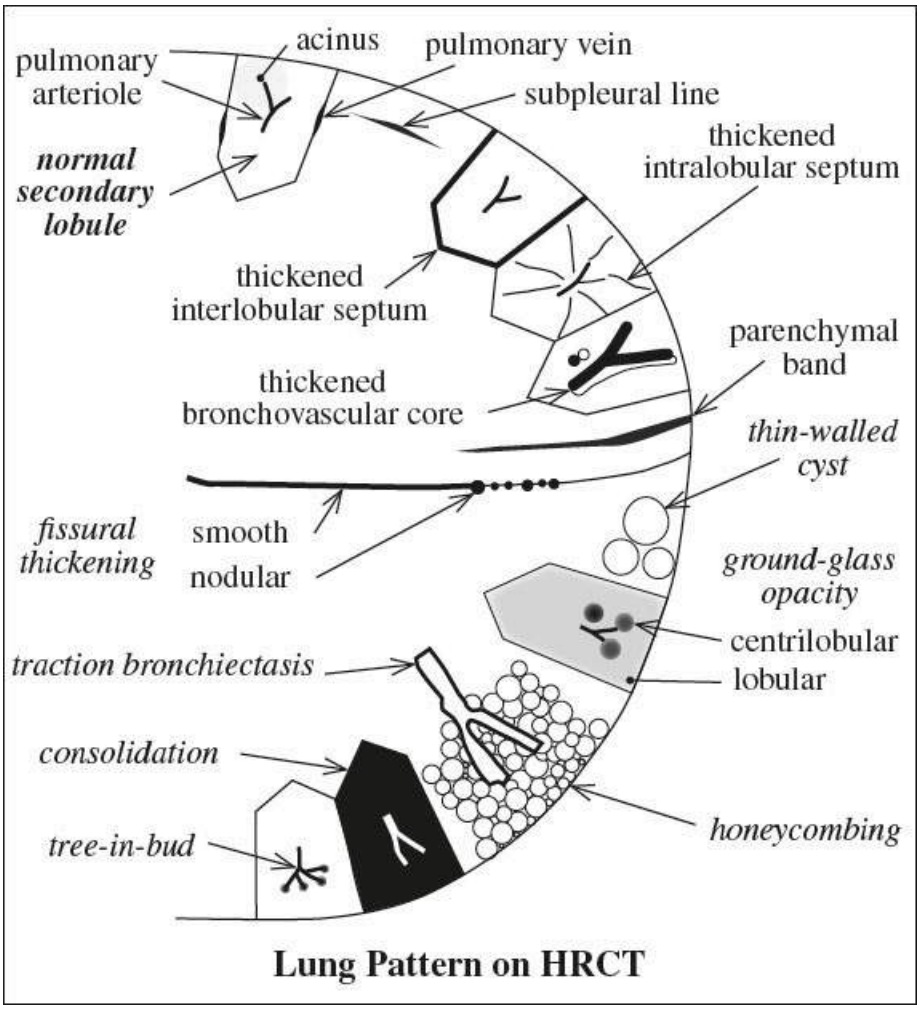
Cause:

(a) any process filling airspaces with blood, fluid, inflammatory cells, tumor cells
(b) alveolar collapse = atelectasis

› subpleural in mid + upper lung zones: chronic eosinophilic pneumonia
› subpleural + peribronchial: BOOP
› focal: bronchioloalveolar cell carcinoma, lymphoma
› random: infectious pneumonia

6. **Cystic airspaces**

= circumscribed round structure filled with air



(a) with well-defined walls:
lymphangioleiomyomatosis, pulmonary Langerhans-cell granulomatosis, DIP, LIP, honeycomb lung, cystic bronchiectasis

(b) without well-defined walls:
centrilobular, panlobular (panacinar), paraseptal emphysema

Cause:

(a) focally clustered: cystic bronchiectasis

(b) subpleural location: honeycombing, Langerhans cell histiocytosis, lymphangioleiomyomatosis

Centrilobular Nodules

A. Acute / chronic bronchiolar infection
   1. Bacterial infection
   2. Viral infection
   3. Fungal infection

B. Inflammation
   1. Hypersensitivity pneumonia
   2. Respiratory bronchiolitis-interstitial lung disease

3. Bronchiolitis obliterans organizing pneumonia
4. Bronchiolitis obliterans
5. Sarcoidosis
6. Asthma
7. Autoimmune / immunodeficiency disease

C. Pneumoconiosis

Peribronchial / Peribronchiolar Nodules

1. Metastatic calcifications
2. Endobronchial spread of infection
3. Hypersensitivity pneumonia
4. Sarcoidosis
5. Silicosis
6. Langerhans cell histiocytosis
7. Respiratory bronchiolitis

Centrilobular Nodules Without Ground-Glass Opacities

1. Endobronchial TB
2. Chronic bronchiolitis
3. Silicosis
4. Langerhans cell histiocytosis

Centrilobular Nodules with Ground-Glass Opacities

1. Hypersensitivity pneumonia
2. Bronchiolitis obliterans organizing pneumonia

Random Nodules

1. Hematogenous metastases: thyroid, kidney, breast
2. Miliary infection
3. Langerhans cell histiocytosis
4. Sarcoidosis
5. Silicosis

Thickened Bronchovascular, Interlobular Septal & Pleural Interstitium

A. Uni- / bilateral
   1. Lymphangitic tumor
   2. Lymphoma

B. Bilateral
   3. Kaposi sarcoma
   4. Edema

Parenchymal Bands & Architectural Distortion

1. Asbestos-related lung disease
2. Atelectasis
3. Tuberculosis

Classification of Bronchiolar (Small Airways) Disorders
Primary bronchiolar disorders
Constrictive bronchiolitis
Acute bronchiolitis
Diffuse panbronchiolitis
Respiratory bronchiolitis
Mineral dust airway disease
Follicular bronchiolitis
Interstitial lung disease + prominent bronchiolar involvement
Hypersensitivity pneumonitis
Respiratory bronchiolitis - interstitial lung disease
Desquamative interstitial pneumonia
Organizing pneumonia
Bronchiolar involvement in large airway disease
Chronic bronchitis
Asthma
Bronchiectasis

4. Sarcoidosis
5. Diffuse pulmonary fibrosis

Smooth Thickening of Interstitium

1. Lymphangitic tumor
2. Edema
3. Lymphoma
4. Kaposi sarcoma
5. Sarcoidosis (uncommon)

HRCT of Bronchiolitis

[CT findings are nonspecific and must be interpreted in the appropriate clinical context]

Cause:

(a) infection via endobronchial spread (acute bronchiolitis):

◊ Most common cause of tree-in-bud appearance.

› bacterial (most common)
› mycobacterial: classic TB, M. avium-intracellulare
› viral: acute infectious bronchiolitis in infants and young children due to RSV, adenovirus, mycoplasma
› parasitic
› fungal

(b) inhalation of organic / inorganic antigens: hypersensitivity pneumonitis, mineral dust airways disease

(c) immunologic deficiency or impaired host defense: cystic fibrosis, dyskinetic cilia syndrome

(d) cigarette smoking
1. Respiratory bronchiolitis
2. Respiratory bronchiolitis-interstitial lung disease

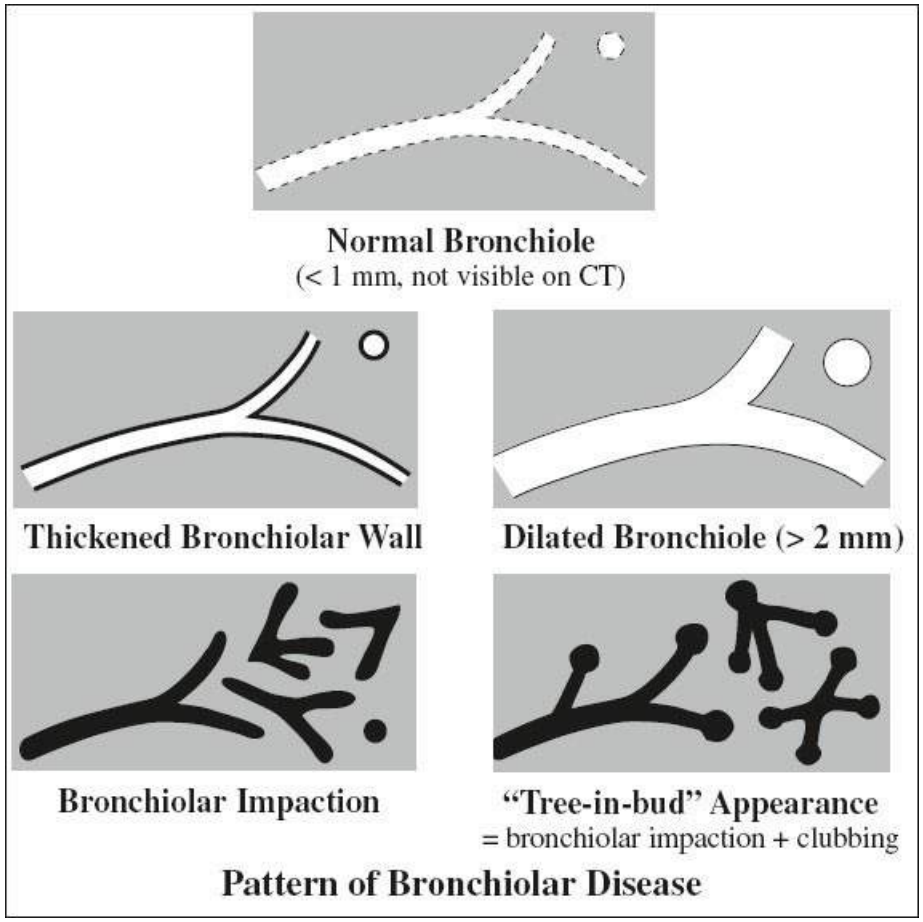
(e) idiopathic
1. Diffuse panbronchiolitis in Asians
2. Follicular bronchiolitis (← lymphoid hyperplasia): rheumatoid arthritis, Sjögren syndrome
3. Asthma
4. Bronchiolitis obliterans = constrictive bronchiolitis
5. Cryptogenic organizing pneumonia = bronchiolitis obliterans with organizing pneumonia (BOOP) = proliferative bronchiolitis

A. DIRECT SIGNS

√ ringlike tubular structures in lung periphery

Cause: wall thickening

√ dilatation of bronchioles



Cause: bronchiolectasis

√ 2- to 4-mm nodules / branching linear structures in lung periphery

Cause: bronchiolar luminal impaction with pus, mucus, granulomas, inflammatory exudate, fibrosis

B. INDIRECT SIGNS

√ subsegmental atelectasis = wedge-shaped area of ground-glass attenuation

√ air trapping = area of decreased attenuation from collateral air drift / ball-valve effect distal to occluded / stenotic airway <u>more prominent on expiration</u>:

DDx: physiologic air trapping with a few lucent secondary pulmonary lobules

√ mosaic perfusion = scattered areas of air trapping

√ centrilobular emphysema = destruction of small airways + surrounding parenchyma in the center of the pulmonary lobule

√ centrilobular airspace nodule = acinar nodule = < 1 cm ill-defined nodule of ground-glass attenuation (from inflammation within alveolar space) <u>less prominent on expiration</u>

Cause: extrinsic allergic alveolitis, sarcoidosis (perivenular nodules), pneumoconiosis (asbestosis, silicosis)

DDx: (1) Cystic lung disease (thin septum surrounds area of air attenuation, central vessel not present)

(2) Panlobular emphysema (distortion of vascular + septal architecture, bullae)

Tree-in-bud Appearance

= peripheral (within 5 mm of pleural surface) small (2–4 mm) centrilobular well-defined soft-tissue nodules connected to linear branching opacity (single stalk) with more than one contiguous branching sites

◊ Direct sign of treatable exudative bronchiolitis!

Histo: dilated centrilobular bronchioles → lumina impacted with mucus / fluid / pus + peribronchiolar inflammation (analogous to "gloved finger" appearance)

√ depiction of the normally invisible branching course of the intralobular bronchiole on HRCT

√ ± air trapping ± subsegmental consolidation

A. AIRWAY INFECTION (most common)
   1. Bacterial: Mycobacterium tuberculosis (endobronchial spread of active TB), atypical mycobacteria (M avium- intracellulare complex, M fortuitum, M chelonei), Staphylococcus aureus, Haemophilus influenzae
   2. Viral: CMV, Respiratory syncytial virus
   3. Fungal: invasive aspergillosis (A fumigatus)
   4. Parasitic

B. IMMUNOLOGIC DISORDER
   1. Allergic bronchopulmonary aspergillosis
   2. Congenital immunodeficiencies

C. CONGENITAL DISORDER
   1. Cystic fibrosis
   2. Kartagener syndrome
   3. Yellow nail syndrome

D. CONNECTIVE TISSUE DISORDER
   1. Rheumatoid lung
   2. Sjögren syndrome

E. IDIOPATHIC DISORDER
   1. Bronchiolitis obliterans
   2. Panbronchiolitis

F. NEOPLASM
   1. Primary pulmonary lymphoma
   2. Laryngotracheal papillomatosis
   3. Tumor embolism

G. TUMOR EMBOLI
   1. Gastric cancer
   2. Breast cancer
   3. Ewing sarcoma
   4. Renal cancer

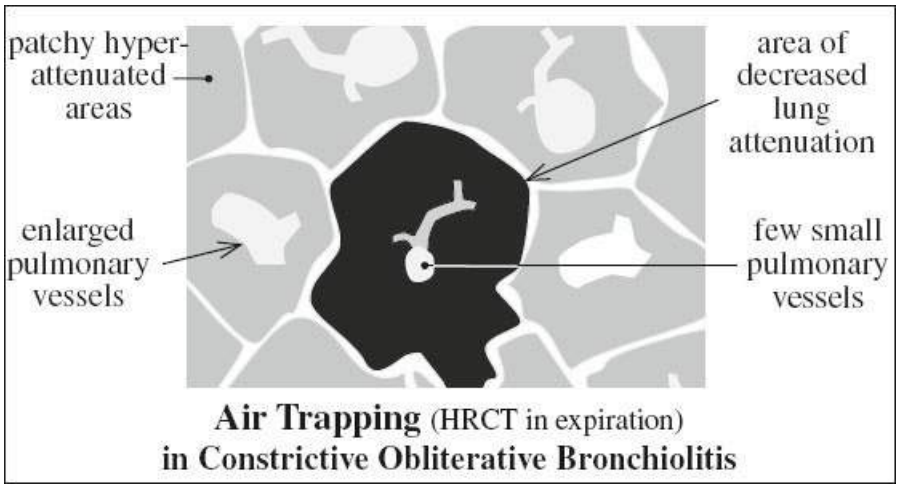
H. ASPIRATION of irritant substance
   1. Aspiration pneumonitis

I. INHALATION of toxic fumes + gases
   = alveolocapillary damage → pulmonary edema + bronchitis + bronchiolitis ± complicated by atelectasis + pneumonia

Mosaic Attenuation / Perfusion

= CT imaging pattern consisting of a heterogeneous patchwork of normal and air-attenuated segments

Mosaic Attenuation due to Ground-Glass Opacities
Acute causes
Pulmonary edema
Pulmonary hemorrhage
Infection
Pneumocystis pneumonia
Cytomegalovirus pneumonia
Herpes simplex pneumonia
Diffuse alveolar damage
Acute respiratory distress syndrome
Acute interstitial pneumonia
Acute eosinophilic pneumonia
Subacute to chronic causes
Organizing pneumonia
Hypersensitivity pneumonitis
Infection
Pneumocystis pneumonia
Diffuse alveolar damage (organizing + fibrotic changes)
Nonspecific interstitial pneumonia



Air Trapping (HRCT in expiration)
in Constrictive Obliterative Bronchiolitis

√ hypoattenuated areas with small vessels in 94% ← diminished blood flow
√ hyperattenuated areas with normal / dilated arteries and enhancement in 77% ← increased perfusion

The best method to differentiate between causes of mosaic attenuation is to perform expiratory imaging → thus allowing identification of areas trapping air.

Pathophysiology:

(a) air trapping

Cause: any obstructive lung disease

1. Chronic bronchitis / bronchiolitis obliterans
2. Bronchiectasis
3. Emphysema
4. Asthma
5. also: sarcoidosis, hypersensitivity pneumonia

√ attenuation differences are accentuated on expiratory HRCT

◊ Indirect sign of constrictive obliterative bronchiolitis without reversibility / improvement!

(b) vascular obstruction

Cause:

1. Chronic thromboembolic pulmonary hypertension (common)
2. Pulmonary venoocclusive disease
3. Idiopathic pulmonary hypertension

√ increase in lung attenuation in low- and high-attenuation areas on expiratory **HRCT**

(c) diffuse ground-glass opacities

Focal Air-trapping on HRCT

1. Asthma
2. Bronchiolitis obliterans
3. Bronchiectasis

Ground-glass Attenuation

Cause:

(a) partial airspace filling
(b) interstitial thickening with
  › inflammation
  › edema
  › fibrosis
(c) neoplastic proliferation
  › bronchioloalveolar cell carcinoma
  › lymphoma

1. Desquamative interstitial pneumonia
2. Extrinsic allergic alveolitis
3. Sarcoidosis
4. Usual interstitial pneumonia
5. Alveolar proteinosis
6. Cryptogenic organizing pneumonia

Large Symmetric Regions of Ground-glass Opacities

A. WATER
  1. Pulmonary edema
  2. Uremic lung
  3. Acute interstitial pneumonia
  4. Adult respiratory distress syndrome
B. PROTEIN
  1. Alveolar proteinosis
  2. Nonspecific interstitial pneumonia
C. RBCs
  1. Pulmonary hemorrhage
D. WBCs
  1. Hypersensitivity pneumonia
  2. Acute / chronic eosinophilic pneumonia
  3. Desquamative interstitial pneumonia
  4. Churg-Strauss syndrome
  5. Atypical pneumonia (viral, pneumocystis, mycoplasma)
E. TUMOR
  1. Bronchioloalveolar cell carcinoma

Nodular Ground-glass Opacity

A. MALIGNANCY
  1. Atypical adenomatous hyperplasia (in 2.8% of general population)
  2. Bronchioloalveolar cell carcinoma (in 5.2% of non-small cell lung cancer population)
  3. Adenocarcinoma
  4. Lymphoma
B. BENIGN CONDITION
  (a) idiopathic

1. Focal interstitial fibrosis
2. BOOP

(b) infection
1. Aspergillosis
2. Cryptococcus

(c) eosinophilic lung disease
1. Simple eosinophilic pneumonia (Löffler syndrome)
2. Idiopathic hypereosinophilic syndrome
3. Collagen vascular disease
4. Sarcoidosis
5. Parasitic infection
6. Drug reaction

(d) hemorrhagic nodule
1. Thoracic endometriosis
2. Focal traumatic lung injury
3. Wegener granulomatosis
4. Henoch-Schönlein purpura

C. TECHNICAL (false positive + false negative)
1. Excessive noise due to low tube current
2. Volume averaging

Ground-glass Opacities & Interlobular Septal Lines

A. ACUTE / SUBACUTE
1. Hypersensitivity pneumonia
2. Pulmonary edema
3. Diffuse alveolar hemorrhage
4. Viral, pneumocystis, mycoplasmal pneumonia

B. CHRONIC
1. Hypersensitivity pneumonia
2. Pulmonary alveolar proteinosis
3. Usual interstitial pneumonia
4. Bronchioloalveolar cell carcinoma

Ground-glass Opacity & Reticular Change

1. Nonspecific interstitial pneumonia
2. Desquamative interstitial pneumonia
3. Acute interstitial pneumonia
4. BOOP
5. Chronic eosinophilic pneumonia
6. Churg-Strauss syndrome

Reversed Halo / Atoll Sign

= focal area of ground-glass opacity surrounded by a complete / incomplete ring of denser consolidation initially thought to be specific for organizing pneumonia

Cause: (a) variety of infections
(b) noninfectious granulomatous disease

(c) malignancy

Airspace Nodules & Ground–glass-opacity Halo

(a) infection
1. Invasive pulmonary aspergillosis
2. Mucormycosis
3. Candidiasis

(b) noninfectious disease
1. Wegener granulomatosis
2. Bronchioloalveolar carcinoma
3. Hemorrhagic tumors (primary, metastatic)
4. Pulmonary lymphoma

Crazy-paving Pattern

= smooth thickening of interlobular septa + intralobular lines superimposed on a background of patchy ground-glass opacities in a geographic distribution
1. Pulmonary alveolar proteinosis
2. Pneumocystis carinii pneumonia
3. Mucinous bronchioloalveolar cell carcinoma
4. Sarcoidosis
5. Nonspecific interstitial pneumonia
6. Organizing pneumonia
7. Exogenous lipoid pneumonia
8. ARDS
9. Pulmonary hemorrhage syndromes
10. Bacterial pneumonia
11. Acute eosinophilic pneumonia
12. Cardiogenic edema

PULMONARY NODULE / MASS

Solitary Pulmonary Nodule (SPN) / Mass

Definition: any pulmonary / pleural sharply defined discrete nearly circular opacity

2–30 mm in diameter = nodule

> 30 mm in diameter = mass (> 90% prevalence of malignancy)

Incidence: 150,000 annually in USA on CXR

(a) roentgenographic survey of low-risk population: < 5% of nodules are cancerous

(b) on surgical resection: 40% malignant tumors (lung primaries + metastases), 40% granulomas

International Early Lung Cancer Action Project:

(1) CT detection of nodules vs chest x-ray: 23%÷7%

(2) CT detection of malignancy vs chest x-ray: 2.7%÷0.7%; stage I malignancy: 2.3%÷0.4%)

(3) Cancers: 96% resectable; 85% stage I, 83% not on CXR

Controversy:

» 80% estimated 10-year survival rate ← high proportion of stage I lung cancer (National Lung Screening Trial, 2011)

» NO mortality benefit from CT lung cancer screening (JAMA 2007)

A. INFLAMMATION / INFECTION

(a) inflammatory

1. **Granuloma** (<u>most common lung mass</u>):
   sarcoidosis (⅓), tuberculosis, berylliosis, leprosy, hypersensitivity pneumonitis, fungal disease (histoplasmosis, coccidioidomycosis, nocardiosis, cryptococcosis), gumma, atypical measles infection, Dirofilaria immitis (dog heartworm), talc, Crohn disease, primary biliary cirrhosis
2. Fluid-filled cavity: abscess, hydatid cyst, bronchiectatic cyst, bronchocele
3. Mass in preformed cavity: fungus ball, mucoid impaction
4. Rounded atelectasis
5. Inflammatory pseudotumor: fibroxanthoma, histiocytoma, plasma cell granuloma, sclerosing hemangioma
6. Paraffinoma = lipoid granuloma
7. Focal organizing pneumonia
8. Round pneumonia

(b) noninflammatory

1. Rheumatoid arthritis
2. Wegener granulomatosis

B. MALIGNANT TUMORS (< 30%)

◊ A solitary pulmonary nodule is the initial radiographic finding in 20–30% of patients with lung cancer!

(a) Malignant primaries of lung:

1. Bronchogenic carcinoma (66%, <u>2nd most common mass</u>)
2. Primary pulmonary lymphoma
3. Primary sarcoma of lung
4. Plasmacytoma (primary / secondary)
5. Clear cell carcinoma, carcinoid, giant cell carcinoma

(b) Metastases (4th most common cause)

in adults: kidney, colon, ovary, testes

in children: Wilms tumor, osteogenic sarcoma, Ewing sarcoma, rhabdomyosarcoma

C. BENIGN TUMORS

(a) lung tissue : hamartoma (6%, <u>3rd most common lung mass</u>), chondroma

(b) fat tissue : lipoma (usually pleural lesion)

(c) fibrous tissue : fibroma

(d) muscle tissue : leiomyoma

(e) neural tissue : schwannoma, neurofibroma, paraganglioma

(f) lymph tissue : intrapulmonary lymph node

(g) deposits : amyloid, splenosis, endometrioma, extramedullary hematopoiesis

D. VASCULAR

1. Arteriovenous malformation (AVM), hemangioma

2. Hematoma
3. Organizing infarct
4. Pulmonary venous varix
5. Pseudoaneurysm of pulmonary artery

E. DEVELOPMENTAL / CONGENITAL
1. Bronchogenic cyst (fluid-filled)
2. Pulmonary sequestration
3. Bronchial atresia

F. INHALATIONAL
1. Silicosis (conglomerate mass)
2. Mucoid impaction (allergic aspergillosis)

G. MIMICKING DENSITIES (20%)
(a) Pseudotumor
1. Fluid in fissure
2. Composite area of increased opacity

(b) Mediastinal mass

(c) Chest wall lesion
1. Nipple
2. Skin tumor: mole, neurofibroma, lipoma, keloid
3. Bone island, rib osteochondroma
4. Rib fracture / osteophyte
5. Pleural plaque / mass (mesothelioma)

(d) External object
1. Electrocardiographic lead attachment
2. Buttons, snaps

mnemonic: **B**ig **S**olitary **P**ulmonary **M**asses **C**ommonly **A**ppear **H**opeless **A**nd **L**onely

Bronchogenic carcinoma
Solitary metastasis, **S**equestration
Pseudotumor
Mesothelioma
Cyst (bronchogenic, neurenteric, echinococcal)
Adenoma, **A**rteriovenous malformation
Hamartoma, **H**istoplasmosis
Abscess, **A**ctinomycosis
Lymphoma

Morphologic Evaluation of Solitary Pulmonary Nodule

A. SIZE
◊ The smaller the nodule the more likely it is benign!
√ < 3 mm nodule: in 99.8% benign
√ 4–7 mm nodule: in 99.1% benign
√ 8–20 mm nodule: in 82% benign
√ > 20 mm nodule: in 50% benign
√ > 30 mm nodule: in > 93% malignant

B. MARGIN / EDGE

√ smooth well-defined margin = likely benign
◊ Mostly benign, in 21% malignant
√ corona radiata = irregular spiculated margin
◊ In 89% malignant, in 10% benign
√ pleural tag
◊ In 25% malignant, in 9% benign
√ "halo" sign (= nodule surrounded by ground-glass opacity)
◊ In neutropenic patient suggests aspergillosis
√ vessels feeding a smooth / lobulated nodule
◊ in arteriovenous malformation

C. CONTOUR
√ sharply marginated nodule: benign in 79%
√ lobulated nodule: malignant in 58%

Probability of Malignancy for Indeterminate Solitary Pulmonary Nodule	
Characteristic / Feature	*Likelihood Ratio*
spiculated margin	5.54
size > 3 cm	5.23
> 70 years of age	4.16
malignant growth rate	3.40
smoker	2.27
upper lobe location	1.22
size < 10 mm	0.52
smooth margin	0.30
30–39 years of age	0.24
never smoked	0.19
20–29 years of age	0.05
benign calcification	0.01
benign growth rate	0.01

(a) organizing mass
(b) tumor with multiple cell types growing at different rates (malignancy, hamartoma)

◊ A lobulated contour occurs in 25% of benign nodules
√ vessel leading to mass: pulmonary varix, AVM

D. SATELLITE LESION
= nodule(s) in association with larger peripheral nodule
› in 99% due to inflammatory disease (often TB)
› in 1% due to primary lung cancer

E. LOCATION
√ attached nodule = length of contact surface of nodule > 50% of nodule diameter OR major part of nonspherical nodule attached to fissure / pleura / vessel
Histo: scar, pleural plaque, post-infarction fibrosis, intrapulmonary lymph node

◊ 1-year follow-up is sufficient

√ perifissural nodule = oval / lentiform / triangular homo- generous nodule with smooth margins attached to fissure

Prevalence: 20% in lung cancer screening trial in heavy smokers

Prognosis: ± growth; almost uniformly benign

√ purely intraparenchymal = malignant

F. ENHANCEMENT PATTERN

G. INTERNAL ATTENUATION

H. CALCIFICATION

INTERNAL ATTENUATION OF SPN

√ entirely solid nodule in 15% malignant

√ nonsolid nodule of pure groundglass opacity in 34% malignant

√ partially solid nodule in 40–50% malignant

√ pseudocavitation (= small focal hypodense region) with air bronchogram suggests bronchioloalveolar cell carcinoma / lymphoma / resolving pneumonia

◊ Air bronchogram in nodules of < 2 cm: in 65% malignant, in 5% benign

√ bubblelike areas of low attenuation: bronchiolo-alveolar cell carcinoma (in 50%)

(a) CAVITATION

√ a thin (≤ 4 mm) smooth wall is benign in 94%

√ a thick (> 16 mm) irregular wall suggests malignancy

(b) Intranodular fat (–40 to –120 HU)

◊ Fat is a reliable indicator of a hamartoma!

√ fat density in up to 50% of hamartomas

CALCIFICATION IN SOLITARY PULMONARY NODULE

Sensitivities of HRCT > CT > CXR:

22–36% of nodules considered noncalcified on CXR contain calcium on thin-section CT; HRCT is 10–20 times more sensitive than CXR and detects more calcium by 24% compared to standard CT

◊ 38–63% of benign nodules are not calcified!

√ > 200 HU at CT densitometry indicates calcification within a nodule (66% sensitive, 98% specific for benign disease)

√ diffuse amorphous, eccentric, stippled = malignant pattern

√ central, completely solid, laminated: granuloma of prior infection (TB / histoplasmosis)

√ popcornlike = chondroid calcification in a hamartoma in 5–50%

√ peripheral calcification: granuloma, tumor

Calcifying malignant lung tumors:

carcinoid (up to 33%), lung cancer (up to 6%), osteosarcoma, chondrosarcoma, metastatic mucinous adenocarcinoma

ENHANCEMENT PATTERN OF SPN

(98% sensitive, 73% specific, 75–85% accurate)

√ nodule enhancement of < 15 HU suggests benign lesion

√ nodule enhancement of > 20 HU indicates malignancy

Growth Rate Assessment of Indeterminate SPN

= size comparison of nodule on current versus prior image

General recommendation for follow-up:

3-month intervals for up to 1 year and 6-month intervals for another year

Best method (quite imprecise):

early repeat HRCT (resolution in x and y planes of 0.3 mm) in 1–4 weeks for nodules > 5 mm measuring volume / area / diameter of nodule

Doubling time (= time required to double in volume):

(a) for most malignant nodules: 30–400 days = 26% increase in diameter

~ 30 days: aggressive small cell cancer

~ 90 days: squamous cell carcinoma

~ 120 days: large cell carcinoma

~ 150 days: aggressive adenocarcinoma

~ 1–80 days: average adenocarcinoma

(b) for benign nodules: < 30 and > 400 days

◊ Absence of growth over a 2-year period implies a doubling time of > 730 days

Disadvantage:

(1) only 65% positive predictive value

› very slow growth: hamartoma, bronchial carcinoid, inflammatory pseudotumor, granuloma, low-grade adenoca., metastasis from renal cell carcinoma

› very rapid growth: osteosarcoma, choriocarcinoma, testicular neoplasm, organizing infectious process, infarct (thromboembolism, Wegener granulomatosis)

(2) unreliable growth perception in nodules < 10 mm:
eg, a nodule with a doubling time of 6 months increases its diameter from 5 mm to only 6.25 mm remaining radiologically "stable"

<u>better:</u> volumetric growth assessment

(3) delay can worsen the prognosis

√ decrease in size with time: benign lesion

◊ Bronchogenic carcinoma may show temporary decrease in size due to infarction - necrosis - fibrosis - retraction sequence!

Clinical Assessment of Indeterminate SPN

- by patient age (prevalence of cancer < 30 years is low)
- history of prior malignancy
- presenting symptoms, smoking history

Management Strategies of Indeterminate SPN

A. Bayesian Analysis

◊ Analysis of patient characteristics + selected radiologic features is superior to evaluation by experienced radiologist in stratification of benign from malignant nodules!

Likelihood ratio (LR) = probability of malignancy

= LR of 1.0 means a 50% chance of malignancy

Odds of malignancy ($Odds_{ca}$) = sum of LR of radiologic features or patient characteristics

Probability of malignancy:

$pCa = Odds_{ca} / (1 + Odds_{ca})$

B. Decision Analysis

= cost-effective strategy for management decision determined by pCa

pCa < 0.05 observation

pCa > 0.05 and < 0.6 biopsy

pCa ≥ 0.60 immediate surgical resection

C. **Contrast-enhanced thin-section CT**

= degree of enhancement directly related to vascularity + likelihood of malignancy

Technique:

- 300 mg/mL iodine at 2 mL/sec (total dose 420 mg/kg)
- delay of 20 sec from onset of injection
- contiguous sections through the nodule obtained at 1, 2, 3, and 4 minute after onset of injection
- scan of chest and upper abdomen obtained between 1 and 2 minute after onset of injection

D. **^{18}F-FDG Positron Emission Tomography (PET)**

Size: 94% sensitive + 83% specific for nodules of 1–3 cm; NOT useful for nodules < 8 mm

◊ Detectable size of metabolically active lesion: (4–)7 mm

› benign nodule

√ no uptake = benign nodule (92–100% sensitive, 52–100% specific, 94% accurate)

√ SUV of 0.4 – 2.0 indicates a benign lesion

Incidental Pulmonary Nodule Follow-up by CT for Persons > 35 years
(Fleischner Society Recommendation)

*Average Nodule Size**	*Low-Risk Patient (Hx of minimal smoking; no malignancy)*	*High-Risk Patient (Hx of smoking & malignancy)*
≤ 4 mm	no f/u needed	f/u @ 12 mo
> 4–6 mm	f/u @ 12 mo	f/u @ 6–12 mo; if stable @ 18–24 mo
> 6–8 mm	f/u @ 6–12 mo; if stable @ 18–24 mo	f/u @ 3–6 mo; if stable @ 9–12 mo and @ 24 mo
> 8 mm	f/u @ 3 mo; if stable @ 9 mo and 24 mo	f/u @ 3 mo; if stable @ 9 mo and @ 24 mo

* average of length + width

Subsolid Pulmonary Nodule Follow-up by CT (*Fleischner Society Recommendation*)	
Nodule Type	*Management*
Solitary pure GGN	
≤ 5 mm	NO f/u needed
> 5 mm	f/u @ 3 mo; if persistent @ yearly intervals for 3 up to years
Solitary part-solid GGN	
solid component < 5 mm	f/u @ 3 mo; if persistent @ yearly intervals for up to 3 years
solid component ≥ 5 mm	biopsy / resection
Multiple subsolid nodules	
pure GGNs ≤ 5 mm	f/u @ 2 and 4 years
pure GGNs > 5 mm; NO dominant lesion	f/u @ 3 mo; if persistent @ yearly intervals for up to 3 years
part-solid GGNs > 5 mm; WITH dominant lesion	f/u @ 3 mo; if persistent biopsy / resection
GGN = ground-glass nodule; requires CT with contiguous 1-mm–thick sections; PET/CT for nodules only > 10 mm	

› inflammatory / infectious nodule
√ low FDG uptake = active TB, fungal infection (histoplasmosis), rheumatoid nodule, sarcoidosis, silicosis
√ gradual washout of FDG after initial increase suggests benign inflammatory lesion
› malignant nodule
√ increased FDG uptake = cancer (94–97% sensitive, 78–92% specific, 92% accurate)
√ intensity greater than mediastinum / SUV (standardized uptake value) > 2.5 indicates malignancy (95–100% sensitive, 80–89% specific, 92% accurate for nodules > 15 mm)
√ continually increasing FDG uptake over time is indicative of malignancy

FN: elevated serum glucose level > 250 mg/dL, low-grade malignancy (bronchioloalveolar carcinoma in up to 57% undetectable), carcinoid tumor, mucinous neoplasm; malignant lesion < 7 mm

FP: sarcoidosis, active TB, fungal infection (histoplasmosis, aspergillosis, coccidioidomycosis), silicoanthracosis, lipoid pneumonia, rheumatoid nodule, Wegener, radiation pneumonitis

E. **Transthoracic Needle Aspiration Biopsy**

95–100% sensitive for 10–15-mm malignancies;
50% sensitive for 5–7-mm malignancies; improved with the addition of a core
up to 91% sensitive for establishing a benign diagnosis

Cx: pneumothorax (5–30%) with chest tube placement in 1–15%; self-limiting hemorrhage

F. Bronchoscopy

10% diagnostic yield for nodules < 20 mm;

40–60% diagnostic yield for nodules 20–40 mm
Cx: lower than transthoracic needle biopsy

Decision Algorithm for Solitary Pulmonary Nodule

A. COMPARISON WITH OLD STUDY
√ growth → needle aspiration biopsy
√ no growth > 2 years → no action

B. COMPARISON NOT AVAILABLE
√ benign calcification or fat → no action
√ nodule of any size → further workup
(a) immunocompromised / fever
→ follow-up in 4–6-week intervals to resolution
→ or intervention
(b) history of malignancy
→ follow-up at 3, 6, 12 months
→ if growth consider intervention
(c) no history of malignancy ± smoking
micronodule ≤ 4 mm
→ follow-up at 12 and 24 months for age ≥ 35
→ follow-up at 12 months for age 18–35
→ if growth consider intervention
nodule of > 4–8 mm
→ follow-up at 3, 9 and 24 months for age ≥ 35
→ follow-up at 6, 12 and 24 months for age 18–35
→ if growth consider intervention
nodule of > 8 mm
→ consider PET / intervention
ground-glass nodule
→ longer follow-up for all ages
√ if no growth then no intervention

CT Halo Sign

√ central area of soft-tissue attenuation surrounded by a halo of ground-glass attenuation

A. HEMORRHAGIC PULMONARY NODULE
(a) hemorrhagic infarction (angioinvasion)
1. Early invasive aspergillosis
2. Mucormycosis
3. Hematogenous candidiasis
4. Coccidioidomycosis
(b) necrotizing vasculitis
1. Wegener granulomatosis
(c) fragility of neovascular tissue
1. Metastatic angiosarcoma
2. Metastatic choriocarcinoma
3. Metastatic osteosarcoma

4. Kaposi sarcoma

(d) trauma

1. Following lung biopsy
2. Lung transplant

B. LEPEDIC TUMOR GROWTH

1. Bronchioloalveolar carcinoma
2. Metastatic extrapulmonary adenocarcinoma
3. Lymphoma

C. OTHERS

1. Eosinophilic pneumonia
2. Bronchiolitis obliterans organizing pneumonia
3. Tuberculoma associated with hemoptysis
4. Mycobacterium avium complex
5. Herpes simplex, CMV, varicella-zoster virus

Benign Lung Tumor

A. CENTRAL LOCATION

1. Bronchial polyp
2. Bronchial papilloma
3. Granular cell myoblastoma

B. PERIPHERAL LOCATION

1. Hamartoma
2. Leiomyoma:
   benign metastasizing leiomyoma, history of hysterectomy
3. Amyloid tumor: not associated with amyloid of other organs / rheumatoid arthritis / myeloma
4. Intrapulmonary lymph node
5. Arteriovenous malformation
6. Endometrioma, fibroma, neural tumor, chemodectoma

C. CENTRAL / PERIPHERAL

1. Lipoma: (a) subpleural, (b) endobronchial

D. PSEUDOTUMOR

1. Fibroxanthoma / xanthogranuloma
2. Plasma cell granuloma
3. Sclerosing hemangioma: middle-aged woman, RML / RLL (most commonly), may be multiple
4. Pseudolymphoma
5. Round atelectasis
6. Pleural pseudotumor = accumulation of pleural fluid within interlobar fissure

Lung Tumor in Childhood

1. Metastatic (common)
2. Blastoma
3. Mucoepidermoid carcinoma
4. Bronchogenic carcinoma

5. Hemangiopericytoma
6. Rhabdomyosarcoma

Solid Intrathoracic Neonatal Mass

1. Type 3 / fluid-filled cystic adenomatoid malformation
2. Sequestration
3. Solid (high-grade) pleuropulmonary blastoma
4. Bronchial atresia

Differential Diagnosis of Airspace Opacities

Disease	*Presentation*	*Distribution*	*Adenopathy*	*Tree-in-bud*	*Cavitation*
Wegener granulomatosis	most often acute	multifocal, bilateral perihilar + peribronchovascular	rare	rare	rare
Bacterial pneumonia	acute	lobar + patchy	reactive	yes	rare
Aspiration	most often acute	dependent, associated with bronchiectasis in lower lobes	reactive	yes	sometimes
Organizing pneumonia	chronic	multifocal, peripheral, migratory, atoll sign	rare	no	no
Rheumatoid arthritis	solitary / multiple	5–7 mm	usually peripherally	rare	waxing and waning; SQ nodules
Adenocarcinoma	chronic	uni- / multifocal, ranging from ground-glass opacity to consolidation	yes	no	pseudocavitation

Differential Diagnosis for Nodules and Masses

Disease	*Number*	*Size*	*Distribution*	*Cavitation*	*Ancillary Findings*
Wegener granulomatosis	multiple	5–100 mm	usually bilateral, random (peribronchovascular, subpleural, angiocentric	in up to 50% of lesions > 2 cm	CT halo / atoll sign, radiating linear scarring, pleural tags
Metastasis	multiple	variable	bilateral, random	uncommon; if present suggestive of squamous / sarcoma / TCC primary	lymphadenopathy
Infection	variable	usually < 10 mm	peripheral (septic emboli), miliary (TB, fungus)	rare	tree-in-bud opacities, consolidation, reactive lymphadenopathy
Sarcoidosis	multiple	2 –10 mm	perilymphatic	rare	architectural distortion, symmetric adenopathy
Rheumatoid arthritis	solitary / multiple	5–7 mm	usually peripherally	rare	waxing and waning; subcutaneous nodules

5. Neuroblastoma

Large Pulmonary Mass

mnemonic: CAT PIES

Carcinoma (large cell, squamous cell, cannon ball metastasis
Abscess
Toruloma (Cryptococcus)
Pseudotumor, **P**lasmacytoma
Inflammatory
Echinococcal disease
Sarcoma, **S**equestration

Cavitating Lung Nodule

A. NEOPLASM
   (a) Lung primary:
      1. Squamous cell carcinoma (10%)
      2. Adenocarcinoma (9.5%)
      3. Bronchioloalveolar carcinoma (rare)
      4. Hodgkin disease (rare)
   (b) Metastases (4% cavitate):
      1. Squamous cell carcinoma (⅔):
         nasopharynx (males), cervix (females), esophagus
      2. Adenocarcinoma (colorectal)
      3. Sarcoma: Ewing sarcoma, osteo-, myxo-, angiosarcoma
      4. Melanoma
      5. Seminoma, teratocarcinoma
      6. Wilms tumor
B. COLLAGEN-VASCULAR DISEASE
   1. Pulmonary angiitis + granulomatosis
      › Wegener granulomatosis + Wegener variant
   2. Rheumatoid nodules + Caplan syndrome
   3. SLE
   4. Periarteritis nodosa (rare)
C. GRANULOMATOUS DISEASE
   1. Langerhans cell histiocytosis
   2. Sarcoidosis (rare)
D. VASCULAR DISEASE
   1. Pulmonary embolus with infarction
   2. Septic emboli (Staphylococcus aureus)
E. INFECTION
   1. Bacterial: pneumatoceles from staphylococcal / gram-negative pneumonia
   2. Mycobacterial: TB
   3. Fungal: nocardiosis, cryptococcosis, coccidioidomycosis (in 10%), aspergillosis
   4. Parasitic: echinococcosis (multiple in 20–30%), paragonimiasis
F. TRAUMA
   1. Traumatic lung cyst (after hemorrhage)
   2. Hydrocarbon ingestion (lower lobes)
G. BRONCHOPULMONARY DISEASE
   1. Infected bulla
   2. Cystic bronchiectasis
   3. Communicating bronchogenic cyst

mnemonic: CAVITY

Carcinoma (squamous cell), **C**ystic bronchiectasis
Autoimmune disease (Wegener granulomatosis, rheumatoid lung)
Vascular (bland / septic emboli)
Infection (abscess, fungal disease, TB, Echinococcus)
Trauma
Young = congenital (sequestration, diaphragmatic hernia, bronchogenic cyst)

mnemonic: WEIRD HOLES
Wegener's syndrome
Embolic (pulmonary, septic)
Infection (anaerobes, pneumocystis, TB)
Rheumatoid (necrobiotic nodules)
Developmental cysts (sequestration)
Histiocytosis
Oncological
Lymphangioleiomyomatosis
Environmental, occupational
Sarcoid

Pulmonary Mass with Air Bronchogram

1. Bronchioloalveolar carcinoma
2. Lymphoma
3. Pseudolymphoma
4. Kaposi sarcoma
5. Blastomycosis

Air-crescent Sign

= air in a crescentic shape separating the outer wall of a nodule / mass from an inner sequestrum

A. INFECTION
   1. Invasive pulmonary aspergillosis
   2. Noninvasive mycetoma
   3. Echinococcal lung cyst
   4. Tuberculoma
   5. Rasmussen aneurysm (most too small to be identified on CXR)
   6. Bacterial lung abscess ± pulmonary gangrene

B. CAVITATING NEOPLASM
   1. Primary / metastatic carcinoma / sarcoma
   2. Bronchial adenoma
   3. Cystic hamartoma

C. TRAUMA
   1. Pulmonary hematoma

D. THROMBOEMBOLISM

Shaggy Pulmonary Nodule

mnemonic: **S**haggy **S**ue **M**ade **L**oving **A** **R**eally **W**ild **F**antasy **T**oday
Sarcoidosis, alveolar type
Septic emboli
Metastasis
Lymphoma, **L**ung primary, **L**ymphomatoid granulomatosis
Alveolar cell carcinoma
Rheumatoid lung

Wegener granulomatosis
Fungus
Tuberculosis

Multiple Pulmonary Nodules and Masses

√ homogeneous masses with sharp borders
√ no air alveolo- / bronchogram

A. TUMORS
   (a) malignant
      1. Metastases:
         from breast, kidney, GI tract, uterus, ovary, testes, malignant melanoma, sarcoma, Wilms tumor
      2. Lymphoma (rare)
      3. Multiple primary bronchogenic carcinomas (synchronous in 1% of all lung cancers)
   (b) benign
      1. Hamartoma (rarely multiple)
      2. Benign metastasizing leiomyoma
      3. AV malformations
      4. Amyloidosis

B. VASCULAR LESIONS
   1. Thromboemboli with organizing infarcts
   2. Septic emboli with organized infarcts

C. COLLAGEN-VASCULAR DISEASE
   1. Wegener granulomatosis: vasculitis with organizing infarcts
   2. Wegener variants
   3. Rheumatoid nodules: tendency for periphery, occasionally cavitating

D. INFLAMMATORY GRANULOMAS
   1. Fungal: coccidioidomycosis, histoplasmosis, cryptococcosis
   2. Bacterial: nocardiosis, tuberculosis
   3. Viral: atypical measles
   4. Parasites: hydatid cysts, paragonimiasis
   5. Sarcoidosis: large accumulation of interstitial granulomas
   6. Inflammatory pseudotumors: fibrous histiocytoma, plasma cell granuloma, hyalinizing pulmonary nodules, pseudolymphoma

mnemonic: SLAM DA PIG
Sarcoidosis
Lymphoma
Alveolar proteinosis
Metastases
Drugs
Alveolar cell carcinoma
Pneumonias
Infarcts
Goodpasture syndrome

Progressive Massive Fibrosis Pattern

1. Sarcoidosis
2. Tuberculosis
3. Silicosis
4. Berylliosis
5. Talcosis

Multiple Cavitating Nodules / Masses

A. PULMONARY VASCULITIS
    1. Wegener granulomatosis
    2. Necrotizing sarcoid granulomatosis
    3. Bronchocentric granulomatosis
B. METASTATIC DISEASE
    particularly squamous histologic type
C. MULTIFOCAL INFECTION
    1. Pseudomonas
    2. Tuberculosis
    3. Septic abscesses
D. MULTIPLE PULMONARY INFARCTS
E. BRONCHIECTASIS
F. NEOPLASMS
    1. Lymphoma
    2. Multicentric bronchioloalveolar carcinoma
G. COLLAGEN-VASCULAR DISEASE
    1. Rheumatoid nodules
H. GRANULOMATOUS DISEASE
    1. Cystic form of sarcoidosis
    2. Langerhans cell histiocytosis

Patchy Airspace Consolidations

1. Pneumonia
2. Sarcoidosis
3. Tuberculosis
4. Bronchiolitis obliterans organizing pneumonia

Small Pulmonary Nodules

mnemonic: SMALT
Sarcoid
Metastases (esp. thyroid)
Alveolar cell carcinoma
Lymphoma, **L**eukemia
TB

Pulmonary Nodules & Pneumothorax

1. Osteosarcoma
2. Wilms tumor

3. Histiocytosis

Pleura-based Lung Nodule

√ ill-defined / sharply defined lesion mimicking a true pleural mass
√ associated linear densities in lung parenchyma

1. Granuloma (fungus, tuberculosis)
2. Inflammatory pseudotumor
3. Metastasis
4. Rheumatoid nodule
5. Pancoast tumor
6. Lymphoma
7. Infarct: Hampton hump
8. Atelectatic pseudotumor

Intrathoracic Mass of Low Attenuation

A. CYSTS
   1. Bronchogenic / neurenteric / pericardial cyst
   2. Hydatid disease
B. FATTY SUBSTRATE
   1. Hamartoma
   2. Lipoma
   3. Tuberculous lymph node
   4. Lymphadenopathy in Whipple disease
C. NECROTIC MASSES
   1. Resolving hematoma
   2. Treated lymphoma
   3. Metastasis from ovary, stomach, testes

PNEUMOCONIOSIS

= tissue reaction to the presence of an accumulation of inhaled particulates (= dust) in lungs

Path: 1. Fibrosis
(a) focal / nodular = silicosis
(b) diffuse = asbestosis
Cause: silicosis, coal worker pneumoconiosis, asbestosis, berylliosis, talcosis
2. Nonfibrotic aggregates of particle-laden macrophages in inert dusts
Cause: siderosis (iron oxide), stannosis (tin oxide), and baritosis (barium)

Types:

1. Silicosis
2. Coal worker pneumoconiosis
3. Berylliosis
4. Talcosis
5. Siderosis
6. Carbon black pneumoconiosis
7. Hard-metal pneumoconiosis
8. Asbestos-related disease

Pneumoconiosis Categories

according to ILO (International Labour Office) useful for epidemiologic purposes

A. TYPE OF OPACITIES
1. Silicosis, coal worker's pneumoconiosis
nodular (round) opacities: p = < 1.5 mm; q = 1.5–3 mm; r = 3–10 mm
2. Asbestosis
linear (irregular) opacities: s = fine; t = medium; u = coarse / blotchy

B. PROFUSION / SEVERITY
(= concentration of small opacities in affected area) 0 = normal; 1 = slight; 2 = moderate; 3 = advanced
intermediate grading: 2/2= definitely moderate profusion
2/3 = moderate possibly advanced profusion

C. ZONAL DISTRIBUTION: upper / middle / lower

D. PLEURAL THICKENING: diffuse / circumscribed

Pneumoconiosis with Mass

Anthracosilicosis with:

1. Granuloma (histoplasmosis, TB, sarcoidosis)
2. Bronchogenic carcinoma (incidence same as in general population)
3. Metastasis
4. Progressive massive fibrosis
5. Caplan syndrome (rheumatoid nodules)

PULMONARY CALCIFICATIONS

Multiple Pulmonary Calcifications

A. INFECTION
   1. Histoplasmosis
   2. Tuberculosis
   3. Chickenpox pneumonia

B. INHALATIONAL DISEASE
   1. Silicosis

C. MISCELLANEOUS
   1. Hypercalcemia
   2. Mitral stenosis
   3. Alveolar microlithiasis

Calcified Pulmonary Nodules

mnemonic: HAM TV Station

Histoplasmosis, **H**amartoma
Amyloidosis, **A**lveolar microlithiasis
Mitral stenosis, **M**etastasis (thyroid, osteosarcoma, mucinous carcinoma)
Tuberculosis
Varicella
Silicosis

◊ Central / laminated / popcorn / diffuse calcifications are characteristic of benign solitary lung nodules!

DENSE LUNG LESIONS

Opacification of Hemithorax

mnemonic: FAT CHANCE

Fibrothorax
Adenomatoid malformation
Trauma (ie, hematoma)
Collapse, **C**ardiomegaly
Hernia
Agenesis of lung
Neoplasm (ie, mesothelioma)
Consolidation
Effusion

Atelectasis

A. TUMOR
   1. Bronchogenic carcinoma (⅔ of squamous cell carcinomas occur as an endobronchial mass with persistent or recurrent atelectasis / recurrent pneumonia)
   2. Bronchial carcinoid
   3. Metastasis: primary tumor of kidney, colon, rectum, breast, melanoma
   4. Lymphoma (usually as a late presentation)
   5. Lipoma, granular cell myoblastoma, amyloid tumor, fibroepithelial polyp

B. INFLAMMATION
   1. Tuberculosis (endobronchial granuloma, broncholith, bronchial stenosis)
   2. Right middle lobe syndrome (chronic right middle lobe atelectasis)
   3. Sarcoidosis (endobronchial granuloma – rare)

C. MUCUS PLUG
   1. Severe chest / abdominal pain (postoperative patient)
   2. Respiratory depressant drug (morphine; CNS illness)
   3. Chronic bronchitis / bronchiolitis obliterans
   4. Asthma
   5. Cystic fibrosis
   6. Bronchopneumonia (peribronchial inflammation)

D. OTHER
   1. Large left atrium: mitral stenosis + LLL atelectasis
   2. Foreign body: food aspiration, endotracheal intubation
   3. Broncholithiasis
   4. Amyloidosis
   5. Wegener granulomatosis
   6. Bronchial transection

Signs:

√ local increase in lung density
√ crowding of pulmonary vessels
√ bronchial rearrangement
√ displacement of fissures
√ displacement of hilum
√ mediastinal shift
√ elevation of hemidiaphragm
√ cardiac rotation
√ approximation of ribs
√ compensatory overinflation of normal lung

Obstructive Atelectasis

RESORPTIVE ATELECTASIS

Pathophysiology:
sum of partial gas pressures in venous blood perfusing atelectatic region is less than atmospheric pressure, → gradual resorption of air trapped distal to site of obstruction; continuing secretion into small airways leads to consolidation → postobstructive pneumonitis / bacterial infection

Cause: bronchiolar obstruction by
1. Tumor
2. Stricture
3. Foreign body
4. Mucus plug
5. Bronchial rupture

• airless collapse within minutes to hours

MR:
√ high signal intensity on T2WI in atelectatic area

Nonobstructive Atelectasis

Pathophysiology:
bronchi less compliant than lung parenchyma → bronchi + pathway between bronchial system + alveoli remain patent → elimination of secretions continues with preservation of convective airflow to distal bronchioles

• collapsed lung NOT completely airless (up to 40% residual air)

MR:
√ low-signal intensity on T2WI in atelectatic area

PASSIVE ATELECTASIS

= pleural space-occupying process

1. Pneumothorax
2. Hydrothorax / hemothorax
3. Congenital diaphragmatic hernia
4. Pleural masses: metastases, mesothelioma

ADHESIVE ATELECTASIS

= decrease in surfactant production

1. Respiratory distress syndrome of the newborn (hyaline membrane disease)
2. Pulmonary embolism: edema, hemorrhage, atelectasis
3. Intravenous injection of hydrocarbon

CICATRIZING ATELECTASIS

= parenchymal fibrosis causing decreased lung volume

1. Tuberculosis / histoplasmosis (upper lobes)
2. Silicosis (upper lobes)
3. Scleroderma (lower lobes)
4. Radiation pneumonitis (nonanatomical distribution)
5. Idiopathic pulmonary fibrosis

DISCOID ATELECTASIS

mnemonic: EPIC
Embolus
Pneumonia
Inadequate inspiration
Carcinoma, obstructing

ROUNDED ATELECTASIS

Cause: any type of pleural inflammatory reaction (asbestos as leading cause)

Pathomechanism:
thickening of visceral pleura with progressive wrinkling + folding of subpleural lung

Location: posterobasal subpleural

√ round / lentiform mass incompletely surrounded by lung

√ increased attenuation in periphery of mass

√ pleural thickening in vicinity of mass
√ curving of vessels + bronchi toward mass
√ air bronchogram within mass
√ lesion may be stable / enlarge

Left Upper Lobe Collapse

PA view:

√ "**Luftsichel**" sign = sharply marginated paraaortic crescent of hyperlucency (= hyperexpanded superior segment of LLL extending toward lung apex + between aortic arch and atelectatic LUL)
√ hazy opacification of left hilum + cardiac border
√ elevation of left hilum
√ near horizontal course of left main bronchus
√ posterior + leftward rotation of heart

Lateral view:

√ retrosternal opacity
√ major fissure displaced anteriorly paralleling anterior chest wall

DDx: (1) Herniation of right lung across midline (leftward displacement of anterior junction line)
(2) Medial pneumothorax

Multifocal Ill-defined Densities

= densities 5–30 mm resulting in airspace filling

A. INFECTION
1. Bacterial bronchopneumonia
2. Fungal pneumonia:
histoplasmosis, blastomycosis, actinomycosis, coccidioidomycosis, aspergillosis, cryptococcosis, mucormycosis, sporotrichosis
3. Viral pneumonia
4. Tuberculosis (primary infection)
5. Rocky Mountain spotted fever
6. Pneumocystis carinii

B. GRANULOMATOUS DISEASE
1. Sarcoidosis (alveolar form ← peribronchial granulomas)
2. Eosinophilic granuloma

C. VASCULAR
(a) thromboembolic disease
(b) septic emboli
(c) vasculitis
1. Wegener granulomatosis
2. Wegener variants: limited Wegener, lymphomatoid granulomatosis
3. Infectious vasculitis = invasion of pulmonary arteries: mucormycosis, invasive form of aspergillosis, Rocky Mountain spotted fever
4. Goodpasture syndrome
5. Scleroderma

D. NEOPLASTIC
   1. Bronchioloalveolar cell carcinoma
      = only primary lung tumor to produce multifocal ill-defined densities with air bronchograms
   2. Alveolar type of lymphoma
      = massive accumulation of tumor cells in interstitium with compression atelectasis + obstructive pneumonia
   3. Metastases
      (a) Choriocarcinoma: hemorrhage (however rare)
      (b) Vascular tumors: malignant hemangiomas
   4. Waldenström macroglobulinemia
   5. Angioblastic lymphadenopathy
   6. Mycosis fungoides
   7. Amyloid tumor
E. IDIOPATHIC INTERSTITIAL DISEASE
   1. Lymphocytic interstitial pneumonitis (LIP)
   2. Desquamative interstitial pneumonitis (DIP)
   3. Pseudolymphoma = localized form of LIP
   4. Usual interstitial pneumonitis (UIP)
F. INHALATIONAL DISEASE
   1. Allergic alveolitis: acute stage (eg, farmer's lung)
   2. Silicosis
   3. Eosinophilic pneumonia
G. DRUG REACTIONS

Diffuse Infiltrates in Immunocompromised Patient

mnemonic: FOLD
Failure (CHF)
Opportunistic infection
Lymphangitic tumor spread
Drug reaction

Segmental & Lobar Densities

A. PNEUMONIA
   1. Lobar pneumonia
   2. Lobular pneumonia
   3. Acute interstitial pneumonia
   4. Aspiration pneumonia
   5. Primary tuberculosis
B. PULMONARY EMBOLISM
   (rarely multiple / larger than subsegmental)
C. NEOPLASM
   1. Obstructive pneumonia
   2. Bronchioloalveolar cell carcinoma
D. ATELECTASIS

Chronic Infiltrates

Chronic Infiltrates in Childhood

mnemonic: ABC'S

Asthma, **A**gammaglobulinemia, **A**spiration
Bronchiectasis
Cystic fibrosis
Sequestration, intralobar

Chronic Multifocal Ill-defined Opacities

1. Organizing pneumonia
2. Granulomatous disease
3. Allergic alveolitis
4. Bronchioloalveolar cell carcinoma
5. Lymphoma

SUBACUTE / CHRONIC CONSOLIDATION & GROUND-GLASS OPACITIES

1. BOOP
2. Chronic eosinophilic pneumonia
3. Churg-Strauss syndrome
4. Desquamative interstitial pneumonia
5. Nonspecific interstitial pneumonia
6. Chronic hypersensitivity pneumonia
7. Mycoplasma pneumonia
8. Lymphoma
9. Lipoid pneumonia

Chronic Diffuse Confluent Opacities

1. Alveolar proteinosis
2. Hemosiderosis
3. Sarcoidosis

Ill-defined Opacities with Holes

A. INFECTION
   1. Necrotizing pneumonias:
      Staphylococcus aureus, ß-hemolytic streptococcus, Klebsiella pneumoniae, E. coli, Proteus, Pseudomonas, anaerobes
   2. Aspiration pneumonia:
      mixed gram-negative organisms
   3. Septic emboli
   4. Fungus:
      histoplasmosis, blastomycosis, coccidioidomycosis, cryptococcosis
   5. Tuberculosis
B. NEOPLASM
   1. Primary lung carcinoma
   2. Lymphoma (cavitates very rarely)

C. VASCULAR + COLLAGEN-VASCULAR DISEASE
   1. Emboli with infarction
   2. Wegener granulomatosis
   3. Necrobiotic rheumatoid nodules
D. TRAUMA
   1. Contusion with pneumatoceles

Recurrent Fleeting Infiltrates

1. Löffler disease
2. Bronchopulmonary aspergillosis / bronchocentric granulomatosis
3. Asthma
4. Subacute bacterial endocarditis with pulmonary emboli

Tubular Density

A. Mucoid impaction
B. Vascular malformation
   1. Arteriovenous malformation
   2. Pulmonary varix

Mucoid Impaction

= BRONCHIAL MUCOCELE = BRONCHOCELE
= V-/Y-shaped branching tubular opacities of dilated bronchi filled with inspissated mucus surrounded by aerated lung (collateral air drift circumvents obstructed bronchi)
√ "gloved finger / **finger-in-glove**" sign
√ usually associated with bronchial dilatation
CT:
√ bronchiectasis
√ low-attenuation mucus inspissated in bronchi
√ clear connection with central airway

A. BRONCHIAL OBSTRUCTION
   (a) congenital
      1. Bronchial atresia
      2. Interlobar sequestration
      3. Intrapulmonary bronchogenic cyst
   (b) endobronchial tumor
      1. Endobronchial hamartoma
      2. Endobronchial lipoma
      3. Bronchogenic carcinoma / adenoma
      4. Carcinoid tumor
      5. Laryngeal papillomatosis
      6. Metastasis: breast, kidney, colon, rectum, uterus, skin
   (c) others
      1. Tuberculous stricture
      2. Broncholithiasis
      3. Foreign body aspiration

B. WITHOUT BRONCHIAL OBSTRUCTION
   (a) congenital
      1. Cystic fibrosis
   (b) inflammatory / infectious
      1. Allergic bronchopulmonary aspergillosis: central perihilar + upper lobe bronchiectasis
      2. Asthma (most frequent cause): esp. during acute attack or convalescent phase
      3. Chronic bronchitis
      4. Fluid-filled bronchiectasis: history of childhood pneumonia; peripheral distribution

Perihilar "Bat-wing" Infiltrates

mnemonic: **P**lease, **P**lease, **P**lease, **S**tudy **L**ight, **D**on't **G**et **A**ll **U**ptight

Pulmonary edema
Proteinosis
Periarteritis
Sarcoidosis
Lymphoma
Drugs
Goodpasture syndrome
Alveolar cell carcinoma
Uremia

Peripheral "Reverse Bat-wing" Infiltrates

mnemonic: REDS

Resolving pulmonary edema
Eosinophilic pneumonia
Desquamative interstitial pneumonia
Sarcoidosis

LUCENT LUNG LESIONS

Pulmonary Oligemia

Generalized Oligemia

= reduction in pulmonary blood volume

1. Aortic valve disease
   indicative of ⇓ stroke volume + cardiac output
   √ LV enlargement
2. Overpenetration of film = artifact
3. Deep inspiration + Valsalva maneuver
4. Positive pressure ventilation

Regional Oligemia

A. DECREASE IN BLOOD VOLUME
   1. Pulmonary arterial hypoplasia

2. Mitral valve disease
3. Pulmonary embolism
4. Flow inversion (= oligemic bases + hyperemic upper lobes in longstanding elevation of left heart pressure)

B. INCREASE IN AIR SPACES
1. Swyer-James syndrome
2. Regional emphysema
3. Valvular air trapping

Hyperlucent Lung

Bilateral Hyperlucent Lung

A. FAULTY RADIOLOGIC TECHNIQUE
1. Overpenetrated film

B. DECREASED SOFT TISSUES
1. Thin body habitus
2. Bilateral mastectomy

C. CARDIAC CAUSE of ↓ pulmonary blood flow
1. Right-to-left shunt:
Tetralogy of Fallot (small proximal pulmonary vessels), pseudotruncus, truncus type IV, Ebstein malformation, tricuspid atresia
2. Eisenmenger physiology of left-to-right shunt:
ASD, VSD, PDA (dilated proximal pulmonary vessels)

D. PULMONARY CAUSE of ↓ pulmonary blood flow
(a) decrease of vascular bed:
1. Pulmonary embolism:
bilaterality is rare; localized areas of hyperlucency (Westermark sign)

(b) increase in air space:
1. Air trapping (reversible changes):
acute asthmatic attack, acute bronchiolitis (pediatric patient)
2. Emphysema
3. Bulla
4. Bleb
5. Interstitial emphysema

Unilateral Hyperlucent Lung

A. FAULTY RADIOLOGIC TECHNIQUE
1. Rotation of patient

B. CHEST WALL DEFECT
1. Mastectomy
2. Absent pectoralis muscle (Poland syndrome)

C. INCREASED PULMONARY AIR SPACE
with decreased pulmonary blood flow
(a) large airway obstruction with air trapping
@ Bronchial compression:

1. Hilar mass (rare)
2. Cardiomegaly compressing LLL bronchus

@ Endobronchial obstruction with air trapping (collateral air drift):

1. Foreign body
2. Broncholith
3. Bronchogenic carcinoma
4. Carcinoid
5. Bronchial mucocele

(b) small airway obstruction

1. Bronchiolitis obliterans
2. Swyer-James / MacLeod syndrome
3. Emphysema (particularly bullous emphysema)
4. Emphysema + unilateral lung transplant

(c) Pneumothorax (in supine patient)

D. PULMONARY CAUSE of ↓ pulmonary blood flow

1. Pulmonary artery hypoplasia
2. Pulmonary embolism
3. Congenital lobar emphysema
4. Compensatory overaeration

UNILATERAL HYPERLUCENT LUNG IN CHILD

(a) hyperattenuating contralateral hemithorax

(b) pulmonary parenchyma

1. Idiopathic bullous emphysema
2. Bronchopulmonary dysplasia
3. Pulmonary interstitial emphysema
4. Pneumatocele

(c) airway

1. Aspiration of foreign body
2. Swyer-James syndrome
3. Congenital lobar overinflation
4. Bronchial atresia
5. Endobronchial mass (carcinoid)
6. Extrinsic bronchial compression
7. Accidental bronchial intubation

(d) pulmonary vasculature

1. (Unilateral) pulmonary agenesis
2. Pulmonary hypoplasia
3. Interruption of pulmonary artery
4. Scimitar syndrome
5. Unilateral pulmonary venous atresia
6. Unilateral congenital pulmonary lymphangiectasia
7. Unilateral massive central pulmonary embolism

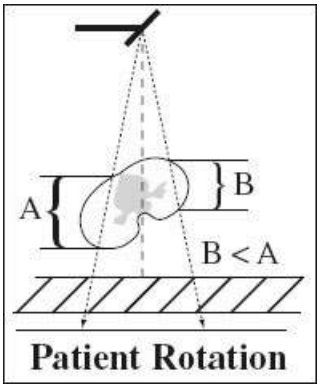
(e) pleural space

1. Anterior pneumothorax

2. Contralateral layering pleural effusion
3. Diaphragmatic hernia / rupture

(f) chest wall
1. Poland syndrome
2. Scoliosis

(g) technical
1. Patient rotation (1% of CXR)
√ hyperlucent lung on side which patient rotates toward tube / away from film ← asymmetric absorption of x-ray beam by chest wall



2. Lateral decentering = positioning of x-ray tube lateral to patient's midline

Hyperinflation in Newborn
√ level of inflation beyond 8th rib posteriorly
√ depressed configuration of hemidiaphragms best judged on LAT view
1. Fetal aspiration syndrome
2. Neonatal pneumonia
3. Pulmonary hemorrhage
4. Congenital heart disease
5. Transient tachypnea (mild)

Hyperinflation in Child
mnemonic: BUMP FAD
Bronchiectasis / **B**ronchiolitis (viral) / **B**ronchopulmonary dysplasia
Upper airway obstruction (vascular ring, laryngitis)
Mucoviscidosis (cystic fibrosis)
Pneumonia (esp. staph)
Foreign body inhalation / ingestion
Asthma (reactive airway disease)
Dehydration (diarrhea, acidosis)

Localized Lucent Lung Defect

Lung Cavity
= tissue necrosis with bronchial drainage

A. INFECTION
   (a) bacterial pneumonia
      1. Pyogenic infection = necrotizing pneumonia = abscess: Staphylococcus, Klebsiella, E. coli, Pseudomonas, anaerobes, β-hemolytic streptococcus, mixed gram-negative organisms
      2. Aspiration pneumonia = gravitational pneumonia: mixed gram-negative organisms, anaerobes
   (b) granulomatous infection
      1. TB: cavitation indicates active infectious disease with risk for hematogenous / bronchogenic dissemination
      2. Fungus: coccidioidomycosis, nocardiosis (in immunocompromised), histoplasmosis, blastomycosis, mucormycosis, sporotrichosis, aspergillosis, cryptococcosis
         √ very thin-walled cavities less likely to follow the apical distribution of TB / histoplasmosis
      3. Sarcoidosis (stage IV, upper lobe predominance)
      4. Angioinvasion → septic lung infarction followed by cavity formation: Aspergillus, Mucorales, Candida, torulosis, P. aeruginosa
   (c) parasitic infestation: hydatid disease
B. NEOPLASM
   (a) primary lung tumor: 16% of peripheral lung cancers (in particular squamous cell carcinoma (30%); also in bronchioloalveolar cell carcinoma
   (b) metastasis (usually multiple)
      1. Squamous cell carcinoma (in ⅔): nasopharynx, esophagus, cervix
      2. Adenocarcinoma: lung, breast, GI
      3. Osteosarcoma (rare)
      4. Melanoma
      5. Lymphoma (rare): with adenopathy; cavities often ← opportunistic infection with nocardiosis + cryptococcosis
C. VASCULAR OCCLUSION
   1. Infarct (thromboembolic, septic)
   2. Wegener granulomatosis
   3. Rheumatoid arthritis
D. INHALATION
   1. Silicosis with coal worker's pneumoconiosis
      › complicating tuberculosis
      › ischemic necrosis of center of conglomerate mass (rare)

MASS WITHIN CAVITY

1. Mycetoma = aspergilloma
2. Tissue fragment within carcinoma
3. Necrotic lung within abscess
4. Disintegrating hydatid cyst
5. Intracavitary blood clot

Lung Cyst

= round circumscribed space surrounded by an epithelial / fibrous wall of uniform / varied thickness containing air / liquid / semisolid / solid material

A. CONGENITAL CYST (rare)
   1. Bronchogenic cyst
   2. Intralobar sequestration: multicystic structure in lower lobes
   3. Congenital cystic adenomatoid malformation (CCAM) type I
   4. Congenital lobar emphysema
   5. Diaphragmatic hernia (congenital / traumatic)
   6. Bronchial atresia

B. ACQUIRED CYST
   (a) centrilobular / bullous emphysema
      1. **Bleb** = cystic air collection within visceral pleura; mostly apical with narrow neck
      2. **Bulla** = sharply demarcated dilated air space within lung parenchyma > 1 cm in diameter with epithelialized wall < 1 mm thick due to destruction of alveoli (= air cyst in localized / centrilobular / panlobular emphysema)
         • usually asymptomatic
         √ typically at lung apex
         √ slow progressive enlargement
         Cx:
            (1) Spontaneous pneumothorax
            (2) "Vanishing lung" = large area of localized emphysema causing atelectasis + dyspnea
         Rx: surgical resection if bulla > ⅓ of hemithorax
   (b) pneumatocele
      1. Postinfectious pneumatocele
      2. Traumatic pneumatocele: lung hematoma / hydrocarbon inhalation
   (c) cystic bronchiectasis
      1. Cystic fibrosis (more obvious in upper lobes)
      2. Agammaglobulinemia (predisposed to recurrent bacterial infections)
      3. Recurrent bacterial pneumonias
         √ multiple thin-walled lucencies with air-fluid levels in lower lobes
      4. Childhood infection: tuberculosis, pertussis
      5. Allergic bronchopulmonary aspergillosis (in asthmatic patients)
         √ involvement of proximal perihilar bronchi
      6. Kartagener syndrome (ciliary dysmotility)
   (d) infection
      1. Hydatid disease
   (e) interstitial emphysema
      1. Pseudocyst

LARGE CYSTIC NEONATAL LUNG LESION

1. Type 1 / type 4 cystic adenomatoid malformation
2. Bronchogenic cysts

3. Low-grade cystic pleuropulmonary blastoma
4. Congenital diaphragmatic hernia
5. Cavitary necrosis complicating pneumonia
6. Congenital lobar overinflation
7. Cystic lymphangioma

Small Cystic Neonatal Lung Lesion

1. Type 2 cystic adenomatoid malformation
2. Pneumonia
3. Pulmonary sequestration
4. Bronchial atresia

Multiple Lucent Lung Lesions

Multiple Lung Cavities

A. INFECTION
   1. Bacteria: cavitating pneumonia, lung abscess
   2. Granulomatous infection: TB, sarcoidosis
   3. Fungal infection: coccidioidomycosis
   4. Parasitic infection: echinococcosis
   5. Protozoan infection: pneumocystosis

B. NEOPLASM

C. VASCULAR
   1. Thromboembolic + septic infarcts
   2. Wegener granulomatosis
   3. Rheumatoid arthritis
   4. Angioinvasive organism (→ septic lung infarction followed by → cavity formation): Aspergillus, Mucorales, Candida, torulosis, P. aeruginosa

Multiple Thin-walled Cavities

mnemonic: BITCH

Bullae + pneumatoceles
Infection (TB, cocci, staph)
Tumor (squamous cell carcinoma)
Cysts (traumatic, bronchogenic)
Hydrocarbon ingestion

Multiple Lung Cysts

A. CONGENITAL
   1. Multiple bronchogenic cysts
   2. Intralobar sequestration:
      multicystic structure in lower lobes
   3. Congenital cystic adenomatoid malformation (CCAM) type I
   4. Diaphragmatic hernia (congenital / traumatic)

B. INFECTION
   1. Tuberculosis

2. Pneumocystis carinii pneumonia in AIDS

C. VASCULAR-EMBOLIC
   1. Cavitating septic emboli
      √ often seen at end of feeding vessel
   2. Angioinvasive infection: invasive pulmonary aspergillosis, candida, P. aeruginosa
   3. Pulmonary vasculitis: Wegener granulomatosis

D. DILATATION OF BRONCHI = cystic bronchiectasis
   √ bronchial wall thickening
   1. Cystic fibrosis (more obvious in upper lobes)
   2. Agammaglobulinemia (predisposed to recurrent bacterial infections)
   3. Recurrent bacterial pneumonias
   4. Tuberculosis
   5. Allergic bronchopulmonary aspergillosis (in asthmatic patients)

E. DISRUPTION OF ELASTIC FIBER NETWORK
   1. Centrilobular emphysema
      √ imperceptible walls
      √ chiefly in upper lung zones
   2. Panlobular emphysema
      √ lobular architecture preserved with bronchovascular bundle in central position, areas of lung destruction without arcuate contour
   3. Paraseptal emphysema
      √ cysts with walls arrayed in a single subpleural tier
   4. Lymphangioleiomyomatosis
      √ randomly scattered cysts surrounded by normal lung
      √ normal / increased lung volumes
   5. Tuberous sclerosis
      • skin abnormalities, mental retardation, epilepsy
   6. Air-block disease: adult respiratory distress syndrome, asthma, bronchiolitis, viral / bacterial pneumonia

F. REMODELING OF LUNG ARCHITECTURE
   = honeycombing of idiopathic pulmonary fibrosis (= fibrosing alveolitis)
   √ 3–10-mm small irregular thick-walled cystic air spaces usually of comparable diameter surrounded by abnormal + distorted lung parenchyma
   √ predominantly peripheral + basilar distribution
   √ bibasilar reticular opacities
   √ progressive reduction in lung volumes

G. MULTIFACTORIAL / UNKNOWN
   1. Langerhans cell histiocytosis
      √ cysts with walls of variable thickness + irregular shape
      √ in combination with nodules ± cavitation
      √ septal thickening
      √ predilection for upper lung zones with relative sparing of lung bases
   2. Lymphocytic interstitial pneumonia
      √ thickening of interlobular septa + bronchovascular bundles
      √ enlarged mediastinal nodes

3. Klippel-Trénaunay syndrome
4. Juvenile tracheolaryngeal papillomatosis
5. Neurofibromatosis
   √ cystic air spaces predominantly apical
6. Pneumatoceles

Cystlike Pulmonary Lesions

mnemonic: C.C., I BAN WHIPS

Coccidioidomycosis
Cystic adenomatoid malformation
Infection
Bronchogenic cyst, **B**ronchiectasis
Abscess
Neoplasm
Wegener granulomatosis
Hydatid cyst, **H**istiocytosis X
Infarction
Pneumatocele
Sequestration

PLEURA

Pneumothorax

= accumulation of air within pleural space

Pathophysiology: disruption of visceral pleura / trauma to parietal pleura

• pleuritic back / shoulder pain, dyspnea (in 80–90%)

Cause:

mnemonic: THE CHEST SET

Trauma
Honeycomb lung, **H**amman-Rich syndrome
Emphysema, **E**sophageal rupture
Chronic obstructive pulmonary disease
Hyaline membrane disease
Endometriosis
Spontaneous, **S**cleroderma
Tuberous sclerosis
Sarcoma (osteo-), **S**arcoidosis
Eosinophilic granuloma
Tuberculosis + fungus

Types:

1. Closed pneumothorax = intact thoracic cage
2. Open pneumothorax = "sucking" chest wound
3. **Tension pneumothorax** (clinical diagnosis)
   = accumulation of air within pleural space ← free ingress + limited egress of air
   Pathophysiology:

intrapleural pressure exceeds atmospheric pressure in lung during expiration (check-valve mechanism)

Frequency: in 3–5% of patients with spontaneous pneumothorax, higher in barotrauma

• compromised venous return

√ hyperexpanded ipsilateral chest

√ mediastinal shift to contralateral side

√ contralateral displacement of anterior junction line

√ "deep sulcus" sign = on frontal view larger lateral costodiaphragmatic recess than on opposite side

√ flattening / inversion of ipsilateral hemidiaphragm

√ total / subtotal collapse of ipsilateral lung

√ collapse of SVC / IVC / right heart border ← decreased systemic venous return + decreased cardiac output

√ sharp delineation of visceral pleural by dense pleural space

N.B.: Medical emergency!

4. **Tension hydropneumothorax**

√ air-fluid level in pleural space on erect CXR

Pneumothorax size:

Average Interpleural Distance (AID) = (A + B + C) ÷ 3 [in cm] converts to percentage of pneumothorax

(see nomogram in drawing)

CXR signs in upright position:

√ white margin of visceral pleura separated from parietal pleura

DDx: skin fold, air trapped between soft tissues of chest wall, hair braid, overlying tubing / dressing / line, prior chest tube track

√ absence of vascular markings beyond visceral pleural margin

CXR signs in supine position:

◊ "occult pneumothorax" = 10–30–50% of pneumothoraces go undetected on supine radiographs!

1. Anteromedial pneumothorax (earliest location)

√ outline of medial diaphragm under cardiac silhouette

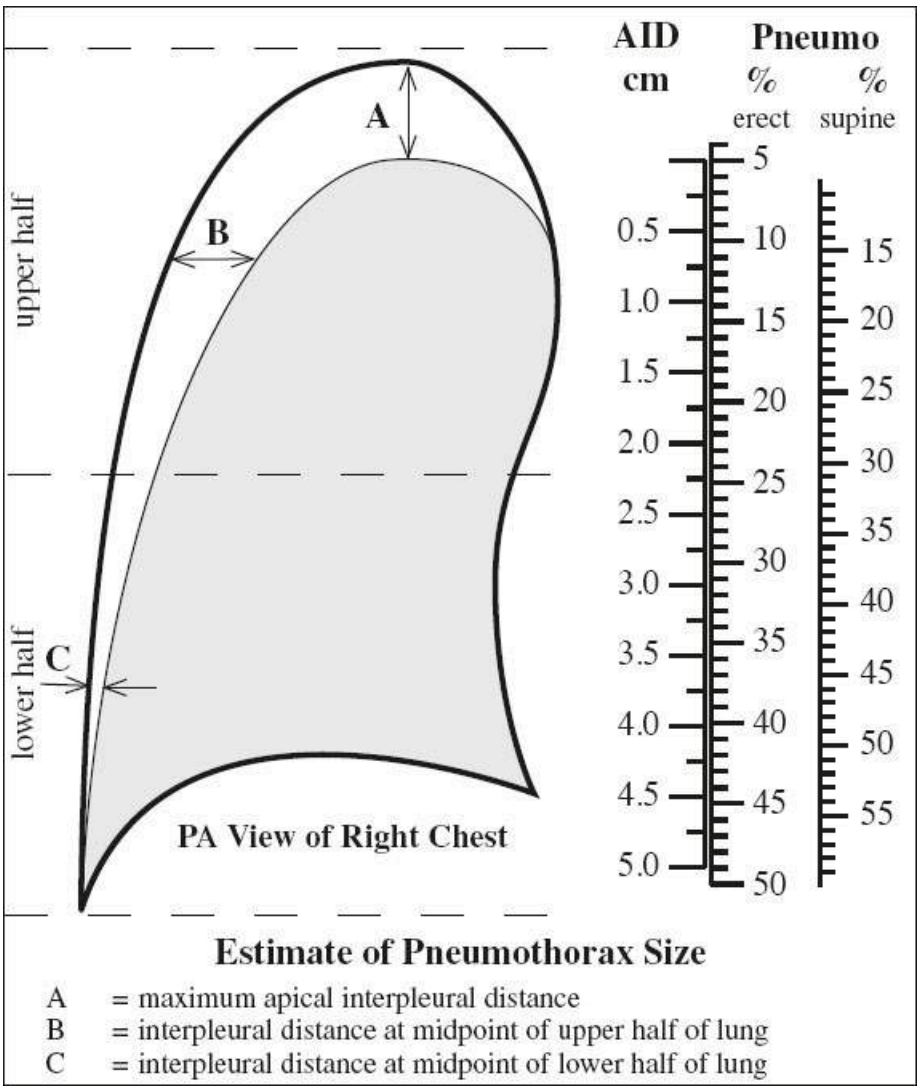
√ improved definition of mediastinal contours (SVC, azygos vein, left subclavian artery, anterior junction line, superior pulmonary vein, heart border, IVC, pericardial fat-pad)

√ relative lucency of entire lung:

√ "large hyperlucent hemithorax" sign (most common in neonates)

√ depression of ipsilateral diaphragm

√ band of air in minor fissure bounded by two visceral pleural lines



- √ outline of anterior junction line (in bilateral pneumothoraces)
- √ "figure 8" / "pseudomass" = compression of malleable lobes of thymus (in bilateral pneumothoraces)

2. Subpulmonic / anterolateral pneumothorax (2nd most common location)
   - √ "deep sulcus" sign = lucency of abnormally deep lateral costophrenic angle extending toward hypochondrium (DDx: COPD)
   - √ hyperlucent upper abdominal quadrant / hypochondrial region
   - √ increased lucency of lung base = sharply outlined diaphragm / inferior surface of lung in spite of parenchymal disease / collapsed lower lobe
   - √ "double-diaphragm" sign = air outlining anterior costophrenic sulcus + aerated lung outlining diaphragmatic dome
   - √ visible lateral edge of right middle lobe ← medial retraction
3. Apicolateral pneumothorax (least common location)
   - √ visualization of visceral pleural line
   - √ displacement of minor fissure from chest wall
4. Posteromedial pneumothorax (in presence of lower lobe collapse)

√ lucent triangle with vertex at hilum
√ V-shaped base delineating costovertebral sulcus

5. Pneumothorax → outlines pulmonary ligament

Prognosis: resorption of pneumothorax occurs at a rate of 1.25% per day (accelerated by increasing inspired oxygen concentrations)

Rx: A pneumothorax > 35% usually requires management with a chest tube!

Traumatic Pneumothorax

A. PENETRATING TRAUMA

B. BLUNT TRAUMA

Frequency: 15-40% of blunt chest trauma

Pathophysiology: ruptured alveoli (sudden increase in intrathoracic pressure), blunt crushing force, deceleration force

1. Rib fracture
2. Increased intrathoracic pressure against closed glottis: lung contusion / laceration
3. Bronchial fracture
   √ "fallen lung" sign = hilum of lung below expected level within chest cavity
   √ persistent pneumothorax with functioning chest tube
   √ mediastinal pneumothorax

C. IATROGENIC

tracheostomy, central venous catheter, PEEP ventilator (3–16%), thoracic irradiation

Rx: indication for chest tube placement dependent on symptoms + physiologic response

Spontaneous Pneumothorax

1. **Primary / idiopathic spontaneous pneumothorax** (80%)

Cause: rupture of subpleural blebs in lung apices

Age: 20–40 years; M÷F = 8÷1; esp. in patients with tall asthenic stature; mostly in smokers

• chest pain (69%), dyspnea

Prognosis: recurrence in 30% on same side, in 10% on contralateral side

Rx: simple aspiration (in > 50% success) / tube thoracostomy (in 90% effective)

2. Secondary spontaneous pneumothorax (20%):

(a) Air-trapping disease: spasmodic asthma, diffuse emphysema, Langerhans cell histiocytosis, lymph-angiomyomatosis, tuberous sclerosis, cystic fibrosis

◊ Chronic obstructive pulmonary disease is the most common predisposing disorder of secondary spontaneous pneumothorax.

(b) Pulmonary infection: lung abscess, necrotizing pneumonia, hydatid disease, pertussis, acute bacterial pneumonia, Staphylococcus aureus, Pneumocystis carinii pneumonia

(c) Granulomatous disease: tuberculosis, coccidioidomycosis, sarcoidosis, berylliosis

(d) Malignancy: primary lung cancer, lung metastases (esp. osteosarcoma, pancreas, adrenal, Wilms tumor)

(e) Connective tissue disorder: scleroderma, rheumatoid disease, Marfan syndrome, Ehlers-Danlos syndrome

(f) Pneumoconiosis: silicosis, berylliosis

(g) Vascular disease: pulmonary infarction
(h) Catamenial pneumothorax
(i) Neonatal disease: meconium aspiration, respirator therapy for hyaline membrane disease
(j) Cx of honeycomb lung: pulmonary fibrosis, cystic fibrosis, sarcoidosis, scleroderma, eosinophilic granuloma, interstitial pneumonitis, Langerhans cell histiocytosis, rheumatoid lung, idiopathic pulmonary hemosiderosis, pulmonary alveolar proteinosis, biliary cirrhosis

Pleural Effusion

A. TRANSUDATE (protein level = 1.5–2.5 g/dL)
Pathophysiology: systemic abnormality → outpouring of low-protein fluid
(a) ⇑ hydrostatic pressure
1. **Congestive heart failure** (in 65%):
bilateral (88%); right-sided (8%); left-sided (4%); least amount on left side ← stimulated lymphatic resorption ← cardiac movement
2. **Constrictive pericarditis** (in 60%)
(b) ⇓ colloid-oncotic pressure
› decreased protein production
1. **Cirrhosis with ascites** (in 6%): on right side (in 67%)
› protein loss / hypervolemia
1. **Nephrotic syndrome** (21%), overhydration, glomerulonephritis (55%), peritoneal dialysis
2. Hypothyroidism
(c) **Chylous effusion**

◊ Most frequent cause of isolated pleural effusion in newborn → 15–25% mortality rate!

• chylomicrons + lymphocytes in fluid

B. EXUDATE
Pathophysiology: increased permeability of abnormal pleural capillaries with release of high-protein fluid into pleural space
Criteria:
• pleural fluid total protein ÷ serum total protein ratio of > 0.5
• pleural fluid LDH ÷ serum LDH ratio of > 0.6

◊ Most frequent cause of isolated pleural effusion in newborn with 15–25% mortality!

• pleural fluid LDH > ⅔ of upper limit of normal for serum LDH (upper limit for LDH ~ 200 IU)
• pleural fluid specific gravity > 1.016
• protein level > 3 g/dL
√ effusion with septation / low-level echoes
√ "split pleura" sign on CECT = thickened enhancing visceral + parietal pleura separated by fluid
√ extrapleural fat thickening of > 2 mm + increased attenuation (edema / inflammation)
Cause:
(A) INFECTION

1. **Empyema necessitatis** = chronic empyema attempting to decompress through chest wall (in TB, nocardiosis, actinomycosis, aspergillosis, blastomycosis)
2. Parapneumonic effusion (in 40%)
   = any effusion associated with pneumonia / lung abscess / bronchiectasis WITHOUT criteria for an empyema
3. Tuberculosis (in 1%): high protein content (75 g/dL), lymphocytes > 70%, positive culture (only in 20–25%)
4. Fungi: Actinomyces, Nocardia
5. Parasites: amebiasis (→ liver abscess in 15–20%), Echinococcus
6. Mycoplasma, rickettsia (in 20%)

(B) MALIGNANT DISEASE (in 60%)

• positive cytologic results

Pathogenesis:

› pleural metastases → ⇑ pleural permeability
› lymphatic obstruction ← pleural vessels, mediastinal nodes, thoracic duct disruption
› bronchial obstruction → loss of volume + resorptive surface
› hypoproteinemia ← tumor cachexia

Cause: lung cancer (26–49%), breast cancer (8–24%), lymphoma (10–28% with chylothorax in ⅔), ovarian cancer (10%), malignant mesothelioma containing hyaluronic acid (5%)

Rx: sclerosing agents: doxycycline, bleomycin, talc

(C) VASCULAR

Pulmonary emboli (in 15–30% of all embolic events):

• often serosanguinous

(D) ABDOMINAL DISEASE

1. Pancreatitis / pancreatic pseudocyst / pancreaticopleural fistula (in ⅔):
   √ usually left-sided pleural effusion
   • high amylase levels
2. Boerhaave syndrome:
   left-sided esophageal perforation
3. Subphrenic abscess
   √ pleural effusion (79%)
   √ elevation + restriction of diaphragmatic motion (95%)
   √ basilar platelike atelectasis / pneumonitis (79%)
4. Abdominal tumor with ascites
5. **Meigs-Salmon syndrome**
   = primary pelvic neoplasms (ovarian fibroma, thecoma, granulosa cell tumor, Brenner tumor, cystadenoma, adenocarcinoma, fibromyoma of uterus) cause pleural effusion in 2–3%; ascites + hydrothorax resolve with tumor removal
6. Endometriosis
7. Bile fistula

(E) COLLAGEN-VASCULAR DISEASE

1. Rheumatoid arthritis (in 3%):
   unilateral; R > L (in 75%), recurrent alternating sides; pleural effusion relatively

unchanged in size for months; predominantly in men; LOW GLUCOSE content of 20–50 mg/dL (in 70–80%) without increase following IV infusion of glucose (DDx: TB, metastatic disease, parapneumonic effusion)

2. SLE (in 15–74%)
   most common collagenosis to give pleural effusion, bilateral in 50%; L > R
   √ ⇑ size of cardiovascular silhouette (in 35–50%)
3. Wegener granulomatosis (in 50%)
4. Sjögren syndrome
5. Mixed connective tissue disease
6. Periarteritis nodosa
7. Postmyocardial infarct syndrome

(F) TRAUMATIC

- hemorrhagic, chylous

Cause: esophageal rupture, thoracic / abdominal surgery, intrapleural infusion = "**infusothorax**" (0.5%), radiation pneumonitis

(G) MISCELLANEOUS

1. Sarcoidosis
2. Uremic pleuritis (in 20% of uremic patients)
3. Drug-induced effusion

CXR:

√ first 300 mL not visualized on PA view (collect in subpulmonic region first, then spill into posterior costophrenic sinus)
√ lateral decubitus views may detect as little as 25 mL
√ hemidiaphragm + costophrenic sinuses obscured
√ extension upward around posterior > lateral > anterior thoracic wall (mediastinal portion fixed by pulmonary ligament + hilum)
√ meniscus-shaped semicircular upper surface with lowest point in midaxillary line
√ associated collapse of ipsilateral lung

Massive pleural effusion:

√ enlargement of ipsilateral hemithorax
√ displacement of mediastinum to contralateral side
√ severe depression / flattening / inversion of ipsilateral hemidiaphragm
√ visible air bronchogram

Subpulmonic / subdiaphragmatic / infrapulmonary pleural effusion:

√ peak of dome of pseudodiaphragm laterally positioned
√ acutely angulated costophrenic angle
√ increased distance between stomach bubble and lung
√ blunted posterior costophrenic sulcus
√ thin triangular paramediastinal opacity (mediastinal extension of pleural effusion)
√ flattened pseudodiaphragmatic contour anterior to major fissure (on lateral CXR)

CT:

√ fluid outside diaphragm
√ fluid elevating crus of diaphragm
√ indistinct fluid-liver interface
√ fluid posteromedial to liver (= bare area of liver)

CAVE: "central oval" sign of ascites may be seen in subpulmonic effusion with inverted diaphragm

Unilateral Pleural Effusion

◊ The majority of massive unilateral pleural effusions are malignant (lymphoma, metastatic, primary lung cancer)!

1. Neoplasm
2. Infection: TB
3. Collagen vascular disease
4. Subdiaphragmatic disease
5. Pulmonary emboli
6. Trauma: fractured rib
7. Chylothorax

LEFT-SIDED PLEURAL EFFUSION

1. Spontaneous rupture of esophagus
2. Dissecting aneurysm of aorta
3. Traumatic rupture of aorta <u>distal</u> to left subclavian a.
4. Transection of distal thoracic duct
5. Pancreatitis: left-sided (68%), right-sided (10%), bilateral (22%)
6. Pancreatic + gastric neoplasm

RIGHT-SIDED PLEURAL EFFUSION

1. Congestive heart failure
2. Transection of <u>proximal</u> thoracic duct
3. Pancreatitis

Pleural Effusion & Large Cardiac Silhouette

1. Congestive heart failure (most common)
   - √ cardiomegaly
   - √ prominence of upper lobe vessels + constriction of lower lobe vessels
   - √ prominent hilar vessels
   - √ interstitial edema (fine reticular pattern, Kerley lines, perihilar haze, peribronchial thickening)
   - √ alveolar edema (perihilar confluent ill-defined densities, air bronchogram)
   - √ "**phantom tumor**" = fluid localized to interlobar pleural fissure (in 78% in right horizontal fissure)
2. Pulmonary embolus + right heart enlargement
3. Myocarditis / pericarditis with pleuritis
   (a) viral infection
   (b) tuberculosis
   (c) rheumatic fever (poststreptococcal infection)
4. Tumor: metastatic, mesothelioma
5. Collagen-vascular disease
   (a) SLE (pleural + pericardial effusion)
   (b) rheumatoid arthritis

Pleural Effusion & Hilar Enlargement

1. Pulmonary embolus
2. Tumor: bronchogenic carcinoma, lymphoma, metastasis
3. Tuberculosis
4. Fungal infection (rare)
5. Sarcoidosis (very rare)

Pleural Effusion & Subsegmental Atelectasis

1. Postoperative (thoracotomy, splenectomy, renal surgery) ← thoracic splinting + mucous plugging of small airway
2. Pulmonary embolus
3. Abdominal mass
4. Ascites
5. Rib fractures

Pleural Effusion & Lobar Densities

1. Pneumonia with empyema
2. Pulmonary embolism
3. Neoplasm: bronchogenic carcinoma > lymphoma
4. Tuberculosis

Hemothorax

= blood in pleural space

• massive hemothorax = blood exceeding 1 L + clinical signs of shock and hypoperfusion

√ rapidly enlarging pleural effusion of 35–70 HU attenuation

√ heterogeneous attenuation

√ hyperattenuating areas of debris

√ fluid-hematocrit level

A. TRAUMA
   (a) thoracic injury
      1. Closed / penetrating injury to lung, chest wall, heart, great vessels
      2. Surgery
      3. Interventional procedures: thoracentesis, pleural biopsy, catheter placement
   (b) abdominal injury with diaphragmatic rupture: trauma to liver / spleen

B. BLEEDING DIATHESIS
   1. Anticoagulant therapy
   2. Thrombocytopenia
   3. Factor deficiency

C. VASCULAR
   1. Pulmonary infarct
   2. Arteriovenous malformation
   3. Aortic dissection
   4. Leaking atherosclerotic aneurysm

D. MALIGNANCY
   1. Mesothelioma

2. Lung cancer
3. Metastasis
4. Leukemia

E. OTHER
1. Catamenial hemorrhage
2. Extramedullary hematopoiesis

Solitary Pleural Mass

CXR:
√ "incomplete border" sign (= mass density with partly invisible border)
√ obtuse angle with chest wall

CT:
√ displacement of pulmonary vessels
√ centered in pleural space
√ NO involvement of chest wall
√ ± outward displacement of extrapleural fat

DDx: (1) Chest wall mass (rib destruction reliable sign of chest wall mass)
(2) Peripheral lung mass (centered within lung tissue, acute angle with chest wall, engulfs pulmonary vessels)

Malignant Pleural Tumor

1. Metastasis (most common)
   Origin: lung, breast, GI tract
   √ tumor nodule + pleural effusion
2. Drop metastasis from thymoma / thymic carcinoma
   √ anterior mediastinal mass
3. Mesothelioma

Benign Pleural Tumor

1. Loculated pleural effusion ("vanishing tumor")
2. Organized empyema
3. Local benign mesothelioma
4. Subpleural lipoma: may erode adjacent rib
5. Mesothelial cyst
6. Neural tumor: schwannoma, neurofibroma
7. Solitary fibrous tumor of pleura (rare)
8. **Fibrin bodies**
   = 3–4 cm large tumorlike concentrations of fibrin forming in serofibrinous pleural effusions; usually near lung base
9. Hematoma

Focal Tumorlike Condition of Pleura

1. Pleural plaque
2. Thoracic splenosis
3. Catamenial pneumothorax
4. Pleural pseudotumor

= pleural fluid (frequently transudate) collected within lung fissure (most frequently minor fissure)

5. Extrapleural hematoma
   = injury to internal mammary / intercostal vessels without disruption of parietal pleura
   ◊ May expand rapidly causing respiratory / circulatory collapse
   √ "extrapleural fat" sign = inward displacement of extrapleural fat

Diffuse Tumorlike Condition of Pleura

1. Diffuse pleural thickening
   = inflammatory pleuritis fusing leaves of pleura
   Cause: empyema, hemothorax, connective tissue disorder, asbestos exposure
   • ± restrictive lung physiology
   √ ill-defined irregular thickening spanning multiple ribs
   √ costophrenic angle blunting
   √ often undergoing calcification
2. Erdheim-Chester disease
3. Diffuse pulmonary lymphangiomatosis

Multiple Pleural Densities

√ diffuse pleural thickening with lobulated borders

1. Loculated pleural effusion: infectious, hemorrhagic, neoplastic
2. Pleural plaques
3. Metastasis (most common cause)
   Origin: lung (40%), breast (20%), lymphoma (10%), ovary, melanoma, uterus, GI tract, pancreas, sarcoma
   ◊ Metastatic adenocarcinoma histologically similar to malignant mesothelioma!
4. Diffuse malignant mesothelioma:
   almost always unilateral, associated with asbestos exposure
5. Invasive thymoma (rare)
   √ contiguous spread, invasion of pleura, spreads around lung
   √ NO pleural effusion
6. Thoracic splenosis

mnemonic: **M**ary **T**yler **M**oore **L**ikes **L**emon
Metastases (especially adenocarcinoma)
Thymoma (malignant)
Malignant mesothelioma
Loculated pleural effusion
Lymphoma

Pleural Thickening

A. TRAUMA
   1. **Fibrothorax** (most common cause)
      = organizing effusion / hemothorax / pyothorax
      √ dense fibrous layer of ~ 2 cm thickness; almost always on visceral pleura
      √ frequent calcifications on inner aspect of pleural peel

B. INFECTION
   1. Chronic empyema: at bases; history of pneumonia; parenchymal scars
   2. Tuberculosis / histoplasmosis: lung apex; associated with apical cavity
   3. Aspergilloma: in preexisting cavity concomitant with pleural thickening
C. COLLAGEN-VASCULAR DISEASE
   1. Rheumatoid arthritis: pleural effusion fails to resolve
D. INHALATIONAL DISORDER
   1. Asbestos exposure: lower lateral chest wall; basilar interstitial disease (< 25%); thickening of parietal pleura + typically sparing of visceral pleura
   2. Silicosis (advanced disease)
   3. Talcosis
E. NEOPLASM
   1. Metastases: often nodular appearance; may be obscured by effusion
   2. Diffuse malignant mesothelioma
   3. Pancoast tumor
F. OTHER
   1. **Pleural hyaloserositis**
      Path: hyaline sclerotic tissue = cartilagelike whitish sugar icing appearance (Zuckerguss) with occasional calcification
   2. Mimicked by extrathoracic musculature, 1st + 2nd rib companion shadow, subpleural fat, focal scarring around old rib fractures

mnemonic: TRINI
Trauma (healed hemothorax)
Rheumatoid arthritis (collagen vascular disease)
Inhalation disease (asbestosis, talcosis)
Neoplasm
Infection

Circumferential Pleural Thickening
1. Mesothelioma
2. Adenocarcinoma
3. Lymphoma
4. Thymoma
5. Asbestos-related benign pleural disease
6. Infection

Apical Cap
1. Inflammatory process: TB, healed empyema
2. Postradiation fibrosis
3. Neoplasm
4. Vascular abnormality
5. Mediastinal hemorrhage
6. Mediastinal lipomatosis
7. Peripheral upper lobe collapse

Pleural Calcification

A. INFECTION
   1. Healed empyema
   2. Tuberculosis (and therapy for TB: pneumothorax / oleothorax), histoplasmosis
B. TRAUMA
   1. Healed hemothorax = fibrothorax:
      • history of significant chest trauma
      √ irregular plaques of calcium usually in visceral pleura
      √ healed rib fracture
   2. Radiation therapy
C. PNEUMOCONIOSIS
   1. Asbestos-related pleural disease (most common):
      √ combination of basilar reticular interstitial disease (< ⅓) + pleural thickening
      √ calcifications of parietal pleura frequently diagnostic (diaphragmatic surface of pleura, bilateral but asymmetric), visceral pleura typically spared
   2. Talcosis: similar to asbestos-related disease
   3. Bakelite
   4. Muscovite mica
D. HYPERCALCEMIA
   1. Pancreatitis
   2. Secondary hyperparathyroidism of chronic renal failure / scleroderma
E. MISCELLANEOUS
   1. Mineral oil aspiration
   2. Pulmonary infarction

√ FDG-avid pleural lesions at PET/CT with corresponding high attenuation at CT suggests pleurodesis, because < 10% of pleural malignancies develop calcifications!

mnemonic: TAFT
Tuberculosis
Asbestosis
Fluid (effusion, empyema, hematoma)
Talc

Chest Wall Tumor

A. BONE TUMOR
   (a) malignant osseous chest wall tumor
      ◊ Primary bone tumors of the chest wall represent only 5–8% of all skeletal masses!

◊ Sternal tumors are usually malignant!

      1. Metastasis
      2. Chondrosarcoma (33% of primary rib tumors)
      3. Myeloma
      4. Ewing sarcoma
   (b) benign osseous chest wall tumor
      1. Fibrous dysplasia
      2. Enchondroma

3. Osteochondroma (8% of all rib tumors)
4. Chondroblastoma
5. ABC
6. GCT
7. Langerhans cell histiocytosis

B. SOFT-TISSUE TUMOR

(a) adipocytic tumor
1. Lipoma
2. Liposarcoma

(b) vascular tumor
1. Hemangioma
2. Lymphangioma
3. Angiosarcoma

(c) fibroblastic-myofibroblastic tumor
1. Elastofibroma
2. Fibromatosis

(d) fibrohistiocytic tumor
1. Undifferentiated pleomorphic sarcoma

(e) peripheral nerve sheath tumor (PNST)
1. Schwannoma
2. Neurofibroma
3. Malignant PNST

(f) cutaneous lesion
1. Epidermal inclusion cyst
2. Pilomatricoma
3. Dermatofibrosarcoma protuberans (DFSP)

MEDIASTINUM

Conventional Radiographic Mediastinal Signs

used in the interpretation of single frontal CXR

1. "**Silhouette**" sign
   = obscured margin (ie, silhouette) of the normal air-soft tissue interface of a mediastinal structure (heart, aortic arch, hilum, azygoesophageal recess) / diaphragm
   Cause: any intrathoracic opacity of the same density as the adjacent normal structure (eg, pneumonia, atelectasis, mass, fluid)
2. "**Hilum overlay**" sign
   = normal hilar structures project through a mass → mass is not in contact with hilum but posterior / anterior to hilum
3. "**Hilum convergence**" sign
   = convergence of pulmonary arteries into the lateral border of a hilar density → enlarged pulmonary artery
   DDx: nodule / mass → vessels course through opacity
4. "**Cervicothoracic**" sign
   = uppermost border of anterior mediastinum ends at level of clavicles while middle

(higher) + posterior (highest) mediastinum project above clavicles

Use: localizing a mediastinal mass

√ posterior superior mediastinal masses are sharply outlined by apical lung

√ anterior superior mediastinal masses extending into neck have unsharp borders

Acute Mediastinal Widening

1. Rupture of aorta / brachiocephalic arteries
2. Venous hemorrhage: traumatic / iatrogenic (malpositioning of central venous line)
3. Congestive heart failure (venous dilatation)
4. Rupture of esophagus
5. Rupture of thoracic duct
6. Atelectasis abutting the mediastinum
7. Magnification + geometric distortion on supine radiograph (attempt at suspended full inspiration, no rotation, 10–15° caudal angulation of central beam)

Mediastinal Hematoma

- dyspnea, dysphagia, dysphonia, chest pain
- neck + chest wall ecchymosis, tachycardia

√ mediastinal widening

√ abnormal aortic contour

√ > 5 mm widening of right paratracheal stripe

√ deviation of nasogastric tube to right of T4 spinous process

CT:

√ soft-tissue mass > 60 HU

√ focal heterogeneous mass / ill-defined soft-tissue thickening with extension to cervical region

√ compression of trachea, main bronchi, great vessels

Mediastinal Shift

= displacement of heart, trachea, aorta, hilar vessels

◊ Expiration film, lateral decubitus film (expanded lung down), fluoroscopy helps to determine side of abnormality

A. DECREASED LUNG VOLUME

1. Atelectasis
2. Postoperative (lobectomy, pneumothorax)
3. Hypoplastic lung / lobe
   - √ small pulmonary artery + small hilum
   - √ decreased peripheral pulmonary vasculature
   - √ irregular reticular vascular pattern (bronchial origin) without converging on the hilum
4. Bronchiolitis obliterans = Swyer-James syndrome

B. INCREASED LUNG VOLUME

= **air trapping** = retention of excess gas in all / part of the lung, especially during expiration, as a result of

(a) complete / partial airway obstruction, or

(b) local abnormalities in pulmonary compliance

@ Major bronchus

1. Foreign body obstructing main-stem bronchus (common in children) with ball-valve mechanism + collateral air drift
   √ contralateral mediastinal shift → increasing with expiration

@ Emphysema

1. Bullous emphysema (localized form)
   √ large avascular areas with thin lines
2. Congenital lobar emphysema: only in infants
3. Interstitial emphysema
   Cause: Cx of positive pressure ventilation therapy
   √ pattern of diffuse coarse lines

@ Cysts / masses

1. Bronchogenic cyst: with bronchial connection + check-valve mechanism
2. Cystic adenomatoid malformation
3. Large mass (pulmonary, mediastinal)

C. PLEURAL SPACE ABNORMALITY

1. Large unilateral pleural effusion:
   √ opaque hemithorax ← empyema, congestive heart failure, metastases
2. Tension pneumothorax:
   NOT always complete collapse of lung
3. Large diaphragmatic hernia:
   usually detected in neonatal period
4. Large pleural mass

D. Partial absence of pericardium / pectus excavatum
   √ shift of heart WITHOUT shift of trachea / aorta / mediastinal border

Pneumomediastinum

= free air around mediastinal structures

Frequency: in 1% of patients with pneumothorax

Source of air:

A. INTRATHORACIC

1. Trachea, major bronchi: blunt chest trauma
2. Esophagus
3. Lung
   (a) narrowed / plugged airways (most common) = air trapping in small airways as in asthma
   (b) straining against closed glottis: vomiting, parturition, weight-lifting
   (c) blunt / penetrating chest trauma
   (d) alveolar rupture
4. Pleural space

B. EXTRATHORACIC

1. Head and neck: sinus fracture, dental extraction
2. Intra- and retroperitoneum: perforated hollow viscus

Pathophysiology:

after alveolar rupture → air tracks along bronchovascular sheath → ruptures through fascial sheath at lung root into mediastinum + facial planes of the neck → produces subcutaneous emphysema

• chest pain, breathlessness, subcutaneous emphysema

◊ NOT a life-threatening condition!

√ subcutaneous emphysema

√ streaky lucencies of air in mediastinum (look at thoracic inlet on PA + retrosternal space on LAT film)

√ "ring around artery" sign = air surrounding intramediastinal segment of right pulmonary artery (LAT view)

√ "tubular artery" sign = air adjacent to major aortic branches, eg, left subclavian + left common carotid aa.

√ "continuous diaphragm" sign = air trapped posterior to pericardium produces lucency connecting both domes of hemidiaphragms (frontal view)

√ "double bronchial wall" sign = clear depiction of bronchial wall by air next to and within a bronchus

√ "V" sign of Naclerio / "extrapleural" sign = mediastinal air extends laterally between mediastinal pleura / lower thoracic aorta + diaphragm

√ "spinnaker sail" / "thymic sail" / "angel wing" sign in children = air outlining the thymus

√ air in azygoesophageal recess

√ air in pulmonary ligament = triangular gas collection in low mid chest

DDx:

(a) other air collections:
medial / subpulmonary pneumothorax (simulating "extrapleural" sign); pneumoperitoneum (simulating "extrapleural" sign); pneumopericardium

(b) mistaken normal anatomic structures:
superior aspect of major fissure (on lordotic view); anterior junction line; Mach band effect

Spontaneous Pneumomediastinum

Age: neonates (0.05-1.00%), 2nd–3rd decade

Cause:

1. Rupture of marginally situated alveoli: sudden / prolonged rise in intraalveolar pressure → subsequent dissection of air centrally along bronchovascular bundles to hila (interstitial emphysema) → rupture into mediastinum:
   Valsalva maneuver, status asthmaticus, aspiration pneumonia, hyaline membrane disease, measles, giant cell pneumonia, coughing, vomiting, strenuous exercise, parturition, diabetic acidosis, crack cocaine inhalation = free-basing (mixing solid cocaine salt with a solvent to render it "smokeable")
2. Tumor erosion of trachea / esophagus
3. Pneumoperitoneum / retropneumoperitoneum
   = extension from peritoneal / retroperitoneal / deep fascial planes of the neck

Traumatic Pneumomediastinum *(rare)*

Cause:

1. Pulmonary interstitial emphysema
   = disruption of marginal alveoli with gas traveling toward mediastinum ← positive pressure ventilation
2. Bronchial / tracheal rupture
   √ commonly associated with pneumothorax
3. Esophageal rupture: diabetic acidosis, alcoholic, Boerhaave syndrome
4. Iatrogenic - accidental:
   neck / chest / abdominal surgery, subclavian vein catheterization, mediastinoscopy, bronchoscopy, gastroscopy, rectosigmoidocolonoscopy, electrosurgery with intestinal gas explosion, positive pressure ventilation, intubation, barium enema

Tension Pneumomediastinum

◊ MEDICAL EMERGENCY!

Pathophysiology:

increased intramediastinal pressure → compression of heart → decreased venous return + compression of tracheobronchial tree → sudden profound cardiovascular + respiratory collapse

- sudden development of severe hypoxia, hypotension, tachycardia, metabolic acidosis, high ventilation pressure

CXR:

√ thin line outlining the borders of the heart (in 50%)

CT (modality of choice):

√ substantial amount of mediastinal free air
√ flattening of anterior cardiac contour
√ uplifting of heart off the diaphragm
√ compression of right atrium
√ compression of mediastinal vessels
√ distension of IVC
√ flattening of main bronchi

Rx: percutaneous needle aspiration / CT-guided catheter placement

Tension Pneumopericardium

◊ MEDICAL EMERGENCY!

- chest pain, dyspnea, cyanosis, hypotension, tachycardia
- "mill wheel" murmur, metallic sounds of high frequency, muffled heart sounds
- ECG: elevated ST segment, low-voltage waveform

Cause:

(a) traumatic: blunt / penetrating trauma; iatrogenic (eg, occurring during or after cardiac surgery); barotrauma from positive pressure ventilation

a) nontraumatic: pericarditis with gas-forming organism; direct extension of inflammation from adjacent structures; fistulous communication with air-containing structures (eg, stomach, esophagus, airway, lung); extension of pneumomediastinum into pericardial cavity

√ intrapericardial pressure > 265 mm H_2O

CXR:

√ "halo" sign = continuous rim of air outlining left and right heart borders
√ "small heart" sign on frontal view = sudden marked decrease in size of cardiac silhouette

CT:
√ substantial amount of air in pericardial cavity
√ compression + displacement of heart:
√ collapse of heart chambers
√ flattening of anterior heart border
√ distention of inferior vena cava

Cx: cardiac tamponade → hemodynamic compromise

Rx: immediate pericardial decompression ← needle pericardiocentesis / placement of pericardial drain

Mediastinal Fat

A. MEDIASTINAL LIPOMATOSIS
B. FAT HERNIATION
= omental fat herniating into chest
1. Foramen of Morgagni
= sternocostal triangle mass, R >> L side
2. Foramen of Bochdalek
= lumbocostal triangle mass, almost always on left
3. Paraesophageal hernia
= perigastric fat through phrenicoesophageal membrane

CT:
√ fat with fine linear densities (= omental vessels)

C. LIPOMA
= un- / encapsulated fatty tissue with variable amount of fibrous septa
√ smooth + sharply defined boundaries
DDx: liposarcoma, lipoblastoma (infancy), fat-containing teratoma, thymolipoma (inhomogeneous, higher CT numbers, poor demarcation, ± invasion of surrounding structures)
D. MULTIPLE SYMMETRIC LIPOMATOSIS

Low-attenuation Mediastinal Mass

A. FLUID
1. Foregut cyst
2. Lymphocele
3. Seroma
4. Hematoma
5. Abscess
6. Hydatid disease

B. LYMPH NODE
1. Tuberculous lymph nodes
2. Metastasis from thyroid / testicular tumor
3. Lymphoma: treated / untreated

C. PRIMARY NEOPLASM
   1. Neurogenic tumor
   2. Fat-containing neoplasm

Mediastinal Cyst

= 21% of all primary mediastinal tumors

@ Anterior mediastinum
   1. Thymic cyst
   2. Dermoid cyst
   3. Parathyroid cyst (uncommon as mediastinal mass)

@ Middle mediastinum
   1. Pericardial cyst
   2. Bronchogenic cyst

@ Posterior mediastinum
   1. Esophageal duplication cyst
   2. Neurenteric cyst
   3. Thoracic duct cyst
   4. Transdiaphragmatic jejunal duplication
   5. Cystic hygroma
   6. Lateral thoracic meningocele
   7. Posttraumatic lymphocele
      = contained pleural / mediastinal lymph collection
      • history of prolonged chylous chest tube drainage
      Time of onset: several months after injury
   8. **Hydatid cyst**
      Location: paravertebral gutter
      √ erosion of ribs + vertebrae

Frequency of Developmental Mediastinal Cyst

1. Enterogenous cyst = Foregut cyst 45%
   (a) bronchogenic cyst (30%)
   (b) esophageal duplication cyst (15%)
   (c) neurenteric cyst (least common)
2. Pericardial cyst 30%
3. Thymic cyst 10%
4. Nonspecific mesothelial cyst 10%
5. Cystic hygroma 5%

Mediastinal Mass

(excluding hyperplastic thymus gland, granuloma, lymphoma, metastasis)

1. Neurogenic tumor (28%): malignant in 16%
2. Teratoid lesion (19%): malignant in 15%
3. Enterogenous cyst (16%)
4. Thymoma (13%): malignant in 46%
5. Pericardial cyst (7%)

A. BENIGN MEDIASTINAL MASS
◊ 66–75% of all mediastinal tumors are benign (in all age groups)
◊ 88% discovered incidentally on routine chest x-ray
B. MALIGNANT MEDIASTINAL MASS
◊ 57–80% of malignant tumors are symptomatic (pain, cough, shortness of breath)

Thoracic Inlet Lesion

1. Thyroid mass
   1–3% of all thyroidectomies have a mediastinal component; ⅓ of goiters are intrathoracic
   Location: anterior (80%) / posterior (20%) mediastinum
   √ displacement of trachea posteriorly and laterally ← anterior goiter
   √ displacement of trachea anteriorly and laterally + esophagus posteriorly ← posterior goiter
   √ inhomogeneous density ← cystic spaces + high-density iodine contents of > 100 HU
   √ focal calcifications (common)
   √ marked + prolonged contrast enhancement
   √ connection to thyroid gland
   √ vascular displacement + compression
   NUC (rarely helpful as thyroid tissue may be nonfunctioning):
   √ ± uptake on ^{123}I / ^{131}I scan (pertechnetate is sufficient with modern gamma cameras, SPECT imaging may be helpful)
2. Cystic hygroma
   3–10% involve mediastinum; childhood
3. Lymphoma
4. Other tumors: adenoma, carcinoma, ectopic thymoma

MASS IN RAIDER TRIANGLE

Raider triangle (= retrotracheal triangle) on LAT CXR formed by posterior wall of trachea (anteriorly) + thoracic spine (posteriorly) + aortic arch (inferiorly) + thoracic inlet superiorly)
[Louis Raider (1913–1999), professor of radiology in Mobile, AL at the University of South Alabama Medical Center]

1. Aberrant right subclavian artery
2. Aberrant left subclavian a. with right aortic arch
3. Aneurysm
4. Posterior descending goiter
5. Enlarged lymph node
6. Esophageal mass / duplication cyst

Anterior Mediastinal Mass

◊ Lymphoma is the most common anterior mediastinal mass in children + the 2nd most common in adults!

√ posterior junction line preserved
√ anterior junction line obliterated

√ "hilum overlay" sign present
√ no interface with lung above level of clavicle

mnemonic: 4 T's

Thymoma
Teratoma
Thyroid tumor / goiter
Terrible lymphoma

A. SOLID THYMIC LESIONS
   1. Thymoma (benign, malignant): most common
   2. Normal thymus (neonate)
   3. Thymic hyperplasia (child)
   4. Thymic carcinoma
   5. Thymic carcinoid
   6. Thymolipoma
   7. Lymphoma

B. SOLID TERATOID LESIONS = germ cell tumors
   1. Teratoma
   2. Embryonal cell carcinoma
   3. Choriocarcinoma
   4. Seminoma

C. THYROID / PARATHYROID
   1. Substernal thyroid / intrathoracic goiter
      (10% of all mediastinal masses)
   2. Thyroid adenoma / carcinoma
   3. **Ectopic parathyroid adenoma**:
      ectopia in 1–3% (62–81% in anterior mediastinum / thymus, 30% within thyroid tissue, 8% in posterior superior mediastinum)

D. LYMPH NODES
   1. Lymphoma (Hodgkin, NHL): may arise in thymus, more common in young adults
   2. Metastasis
   3. Benign lymph node hyperplasia
   4. Angioblastic lymphadenopathy
   5. Mediastinal lymphadenitis: sarcoidosis / granulomatous infection

E. CARDIOVASCULAR
   1. Tortuous brachiocephalic artery
   2. Aneurysm of ascending aorta
   3. Aneurysm of sinus of Valsalva
   4. Dilated SVC
   5. Cardiac tumor
   6. Epicardial fat-pad
      √ low-density mass obliterating cardiac silhouette

F. CYSTS
   1. Cystic hygroma
   2. Bronchogenic cyst
   3. Extralobar sequestration

4. Thymic cysts / dermoid cysts
5. Pericardial cyst: true cyst; pericardial diverticulum
6. Pancreatic pseudocyst

G. OTHERS
1. Neural tumor: vagus, phrenic nerve
2. Paraganglioma
3. Hemangioma / lymphangioma
4. Mesenchymal tumor: fibroma, lipoma
5. Sternal tumors
   (a) metastasis from breast, bronchus, kidney, thyroid
   (b) malignant primary: chondrosarcoma, myeloma, lymphoma
   (c) benign primary: chondroma, aneurysmal bone cyst, giant cell tumor
6. Primary lung / pleural tumor (invading mediastinum)
7. Mediastinal lipomatosis:
   (a) Cushing disease
   (b) Corticosteroid therapy
8. Morgagni hernia / localized eventration
   √ presence of bowel gas
9. Abscess

FAT-CONTAINING MEDIASTINAL MASS

1. Mature cystic teratoma
2. Mediastinal lipoma
3. Mediastinal lipomatosis
4. Thymolipoma
5. Liposarcoma

PREVASCULAR MEDIASTINAL MASS

1. Lymphadenopathy
2. Retrosternal goiter
3. Thymic lesion
4. Germ cell tumor

PRECARDIAC MASS IN CONTACT WITH DIAPHRAGM

1. Epicardial fat pad
2. Diaphragmatic hump
3. Morgagni hernia
4. Pleuropericardial cyst
5. Lymph node enlargement

Middle Mediastinal Mass

mnemonic: HABIT5

Hernia, **H**ematoma
Aneurysm
Bronchogenic cyst / duplication cyst

Inflammation: sarcoidosis, histoplasmosis, coccidioidomycosis, primary TB in children
Tumors – remember the 5 L's:
Lung, especially oat cell carcinoma
Lymphoma
Leukemia
Leiomyoma
Lymph node hyperplasia

A. LYMPH NODES

◊ 90% of middle mediastinal masses are malignant

(a) neoplastic adenopathy
1. Lymphoma: Hodgkin÷NHL = 2÷1
2. Leukemia (in 25%): lymphocytic > granulocytic
3. Metastasis: bronchus, lung, upper GI, prostate, kidney
4. Angioimmunoblastic lymphadenopathy

(b) inflammatory adenopathy
1. Tuberculosis / histoplasmosis → may lead to fibrosing mediastinitis
2. Blastomycosis (rare) / coccidioidomycosis
3. Sarcoidosis (predominant involvement of paratracheal nodes)
4. Viral pneumonia
(particularly measles + cat-scratch fever)
5. Infectious mononucleosis / pertussis pneumonia
6. Amyloidosis
7. Plague / tularemia
8. Drug reaction
9. Giant lymph node hyperplasia = Castleman dz.
10. Connective tissue disease: rheumatoid, SLE
11. Bacterial lung abscess

(c) inhalational disease adenopathy
1. Silicosis (eggshell calcification also in sarcoidosis + tuberculosis)
2. Coal worker's pneumoconiosis
3. Berylliosis

B. FOREGUT CYST
1. Bronchogenic / respiratory cyst (cartilage, respiratory epithelium)
2. Enteric cyst = esophageal duplication cyst
3. Extralobar sequestration (anomalous feeding vessel)
4. Hiatal hernia
5. Esophageal diverticula: Zenker, traction, epiphrenic

C. PRIMARY TUMORS (infrequent)
1. Carcinoma of trachea
2. Bronchogenic carcinoma
3. Esophageal tumor:
leiomyoma, carcinoma, leiomyosarcoma
4. Mesothelioma
5. Granular cell myoblastoma of trachea (rare)

D. VASCULAR LESIONS
   1. Aneurysm of transverse aorta
   2. Distended veins: SVC, azygos vein
   3. Hematoma

E. VASCULAR VARIANTS
   1. Right aortic arch (in 0.5% of general population)
      √ absence of aortic knuckle
   2. Left SVC (in 0.3% of general population)
   3. Azygos continuation of IVC

Subcarinal Space Lesion

1. Enlarged lymph nodes
2. Bronchogenic cyst
3. Pericardial effusion
4. Enlarged left atrium
5. Esophageal mass
6. Aortic aneurysm

Aorticopulmonary Window Mass

1. Adenopathy
2. Aneurysm: traumatic aortic pseudoaneurysm, pulmonary artery aneurysm, ductus Botalli aneurysm, bronchial artery aneurysm
4. Bronchogenic cyst
5. Tumor of tracheobronchial tree
6. Esophageal tumor
7. Neurogenic tumor
8. Mediastinal abscess

Widening of Paratracheal Space

Normal width: < 5 mm

1. Dilated tortuous vessels: brachiocephalic artery, SVC, azygos vein
2. Enlarged lymph node
3. Bronchogenic carcinoma
4. Mediastinal lipomatosis
5. Mediastinal hematoma
6. Bronchogenic cyst

Retrocardiac Space of Holzknecht Lesion

[Guido Holzknecht (1872–1931), pioneer in radiology and director of the X-ray laboratory at Vienna General Hospital in 1905, adjuvantly irradiated Sigmund Freud for an oral cavity squamous cell carcinoma unsuccessfully]

1. Hiatal hernia
2. Esophageal lesion
3. Left ventricular aneurysm
4. Pericardial cyst
5. Bronchogenic cyst

6. Aortic aneurysm
7. Vagal / phrenic nerve neurofibroma

Posterior Mediastinal Mass

A. NEOPLASM

› NEUROGENIC TUMOR (largest group): 30% malignant

(a) tumor of peripheral nerve origin

• more common in adulthood

√ 80% appear as a round mass with sulcus

√ lower attenuation than muscle (in 73%)

1. Schwannoma = neurilemmoma (32%)
2. Neurofibroma (10%): contains Schwann cells + nerve cells, 3rd + 4th decade
3. Malignant schwannoma

(b) tumor of sympathetic ganglia origin

• more common in childhood

√ 80% are elongated with tapered borders

1. Ganglioneuroma (23–38%): second most common tumor of posterior mediastinum after neurofibroma
2. Neuroblastoma (15%): highly malignant undifferentiated small round cell tumor originating in sympathetic ganglia, < 10 years of age
3. Ganglioneuroblastoma (14%): both features, spontaneous maturation possible

(c) tumor of paraganglia origin (rare)

1. Chemodectoma = paraganglioma (4%)
2. Pheochromocytoma

√ rib spreading, erosion, destruction

√ enlargement of neural foramina (dumbbell lesion)

√ scalloping of posterior aspect of vertebral body

√ scoliosis

CT:

√ low-density soft-tissue mass (lipid contents)

› SPINE TUMOR: metastasis (eg, bronchogenic carcinoma, multiple myeloma), ABC, chordoma, chondrosarcoma, Ewing sarcoma

› LYMPHOMA

› INVASIVE THYMOMA

› MESENCHYMAL TUMOR: fibroma, lipoma, leiomyoma

› HEMANGIOMA

› LYMPHANGIOMA

› THYROID TUMOR

B. INFLAMMATION / INFECTION

1. Infectious spondylitis: pyogenic, tuberculous, fungal

√ destruction of endplates + disk space

√ paravertebral soft-tissue mass

2. Mediastinitis

5. Pancreatic pseudocyst
3. Lymphoid hyperplasia
4. Sarcoidosis (in 2%, typically asymptomatic patient)

C. VASCULAR MASS
1. Aneurysm of descending aorta (curvilinear calcification; elderly)
2. Enlarged azygos + accessory hemiazygos vein
3. Esophageal varices
4. Congenital vascular anomalies:
aberrant subclavian artery, double aortic arch, pulmonary sling, interruption of IVC with azygos / hemiazygos continuation

D. TRAUMA
1. Aortic aneurysm / pseudoaneurysm
2. Hematoma
3. Loculated hemothorax
4. Traumatic pseudomeningocele

E. FOREGUT CYST
√ cysts may demonstrate peripheral rimlike calcifications
1. Bronchogenic cyst
2. Enteric cyst
3. Neurenteric cyst
4. Extralobar sequestration

F. FATTY MASS
1. Bochdalek hernia
2. Mediastinal lipomatosis
3. Fat-containing tumors: lipoma, liposarcoma, teratoma (rare)

G. OTHER
1. Loculated pleural effusion
2. Pancreatic pseudocyst
3. Lateral meningocele: neurofibromatosis; enlarged neural foramen
4. Extramedullary hematopoiesis:
in chronic bone marrow deficiency; paraspinal area rich in RES-elements
√ splenomegaly; widening of ribs
5. "Pseudomass" of the newborn

mnemonic: BELLMAN
Bochdalek hernia
Extramedullary hematopoiesis
Lymphadenopathy
Lymphangioma
Meningocele (lateral)
Aneurysm
Neurogenic tumor

Deviation / Disruption of Azygoesophageal Line

1. Left atrial enlargement
2. Subcarinal adenopathy

3. Esophageal disease
4. Bronchogenic cyst
5. Hiatal hernia

Cardiophrenic-angle Mass

A. LESION OF PERICARDIUM
   1. Pericardial cyst
   2. Intrapericardiac bronchogenic cyst
   3. Benign intrapericardiac neoplasm:
      teratoma, leiomyoma, hemangioma, lipoma
   4. Malignant neoplasm:
      mesothelioma, metastasis (lung, breast, lymphoma, melanoma)

B. CARDIAC LESION
   1. Aneurysm
   2. Congenital absence of pericardium = pericardial defect
      √ apparent elevation of cardiac apex
      √ prominent pulmonary artery segment
      √ lucency between aorta + main pulmonary artery caused by interposed lung

C. OTHERS
   1. Mass of lung, pleura, diaphragm, abdomen
   2. Cardiophrenic angle varices

RIGHT CARDIOPHRENIC-ANGLE MASS

A. HEART
   1. Aneurysm: cardiac ventricle, sinus of Valsalva
   2. Dilated right atrium

B. PERI- / EPICARDIUM
   1. **Epicardial fat-pad** in obesity / lipoma (most common cause)
      √ triangular opacity in cardiophrenic angle less dense than heart
      √ increase in size under corticosteroid treatment
   2. Pericardial cyst

C. DIAPHRAGM
   1. Diaphragmatic hernia of Morgagni
   2. Diaphragmatic lymph node (esp. in Hodgkin disease + breast cancer)

D. ANTERIOR MEDIASTINAL MASS: thymolipoma
E. PRIMARY LUNG MASS
F. PARACARDIAC VARICES
G. ENLARGED LYMPH NODE: lymphoma, metastasis (lung, breast, colon, ovary, melanoma)

FATTY CARDIOPHRENIC-ANGLE MASS

1. Diaphragmatic hernia (congenital > traumatic)
2. Pericardial fat necrosis
   • acute pleuritic chest pain
   √ encapsulated fatty lesion with inflammatory changes similar to epiploic appendagitis

√ local thickening of adjacent pericardium

Prognosis: benign self-limiting course with spontaneous resolution / improvement

3. Thymolipoma
4. Teratoma
5. Lipoma / liposarcoma (no diaphragmatic defect)

CYSTIC CARDIOPHRENIC-ANGLE MASS

1. Pericardial cyst
2. Thymic tumor with predominantly cystic content
3. Hydatid cyst

SOLID CARDIOPHRENIC-ANGLE MASS

1. Lymphadenopathy: lymphoma > metastasis (lung cancer, mesothelioma, several abdominal cancers)
2. Malignant / benign thymic tumor (connection with superior mediastinum maintained)

Hypervascular Mediastinal Mass

1. Paraganglioma
2. Metastasis: typically renal cell carcinoma
3. Castleman disease
4. Hemangioma
5. Sarcoma
6. Tuberculosis
7. Sarcoidosis

Popcorn-type Calcification

1. Hamartoma (lung)
2. Histoplasmosis (mediastinum)
3. Sarcoidosis (mediastinum)

Hilar Mass

A. LARGE PULMONARY ARTERIES

√ enlargement of main pulmonary artery
√ abrupt change in vessel caliber
√ enlarged pulmonary artery compared with bronchus (in same bronchovascular bundle)
√ cephalization
√ enlargement of right ventricle (RAO 45°, LAO 60°)

Cause:

1. Chronic obstructive disease: emphysema
2. Chronic restrictive interstitial lung disease: idiopathic fibrosis, cystic fibrosis, rheumatoid arthritis, sarcoidosis
3. Pulmonary embolic disease (acute massive / chronic)
4. Idiopathic pulmonary hypertension
5. Left-sided heart failure + mitral stenosis
6. Congenital heart disease with left-to-right shunt
   (a) acyanotic: ASD, VSD, PDA

(b) cyanotic (admixture lesions): transposition of great vessels, truncus arteriosus

Differential Diagnosis for Lymphadenopathy of Chest	
Disease	*Description*
Sarcoidosis / other granulomatous disease	√ symmetric hilar + mediastinal involvement
Primary lung cancer	√ usually asymmetric involvement √ following course of lymphatic drainage
Lymphoma	√ bulky anterior and middle mediastinal mass
Infection	√ hypoattenuating (TB, mycobacterium avium complex) √ calcific (TB, fungal infection)

B. DUPLICATION CYST

C. UNILATERAL HILAR ADENOPATHY

(a) neoplastic

1. Bronchogenic carcinoma (most common)
2. Metastases (lack of mediastinal involvement exceptional)
3. Lymphoma

(b) inflammatory

1. Tuberculosis (primary) in 80%
2. Fungal infection: histoplasmosis, coccidioidomycosis, blastomycosis
3. Viral infection: atypical measles
4. Infectious mononucleosis
5. Drug reaction
6. Sarcoidosis (in 1–3%)
7. Bilateral lung abscess

mnemonic: Fat Hila Suck

Fungus
Hodgkin disease
Squamous / oat cell carcinoma

D. BILATERAL HILAR ADENOPATHY

◊ Most common cause in the absence of specific symptoms / signs is sarcoidosis (in 75%)

(a) neoplastic

1. Lymphoma (in 50% Hodgkin disease)
2. Metastasis
3. Leukemia
4. Primary bronchogenic carcinoma
5. Plasmacytoma

(b) inflammatory

1. Sarcoidosis (in 70–90%)
2. Silicosis
3. Langerhans cell histiocytosis
4. Idiopathic pulmonary hemosiderosis

5. Chronic berylliosis

(c) infectious

1. Rubella, ECHO virus, varicella, mononucleosis

mnemonic: **P**lease **H**elen **L**ick **M**y **P**opsicle **S**tick

Primary TB
Histoplasmosis
Lymphoma
Metastases
Pneumoconiosis
Sarcoidosis

Bilateral Hilar Lymphnode Enlargement

in the absence of specific symptoms / signs

1. Sarcoidosis (75%)
2. Fungal / mycobacterial infection
3. Malignancy: lymphoma

Eggshell Calcification of Nodes

A. PNEUMOCONIOSIS
   1. Silicosis (5%)
   2. Coal worker's pneumoconiosis (1.3–6%) not seen in: asbestosis, berylliosis, talcosis, baritosis

B. SARCOIDOSIS (5%)

C. FUNGAL + BACTERIAL INFECTION (rare)
   1. Tuberculosis
   2. Histoplasmosis
   3. Coccidioidomycosis

D. FIBROSING MEDIASTINITIS

E. LYMPHOMA FOLLOWING RADIATION THERAPY

Enlargement of Azygos Vein

Normal azygos vein (on upright CXR): ≤ 7 mm

√ round / oval opacity at right tracheobronchial angle marks terminal portion of azygos vein

A. COLLATERAL CIRCULATION
   1. Portal hypertension
   2. SVC obstruction / compression below azygos vein
   3. IVC obstruction / compression
   4. Interrupted IVC with azygos continuation
   5. Partial anomalous venous return (rare)
   6. Pregnancy
   7. Hepatic vein occlusion

B. RIGHT ATRIAL HYPERTENSION
   1. Right-sided heart failure
   2. Tricuspid insufficiency
   3. Constrictive pericarditis

4. Large pericardial effusion

Enlargement of Bronchial Artery

= > 2 mm in diameter

N.B.: visualization of dilated bronchial arteries should initiate a search for thoracic problems

CT / MR (best with multiplanar / 3-D volumetric images):

√ undulating nodular / linear enhancing structures

√ tortuous mediastinal course

A. CONGENITAL PULMONARY ARTERY OBSTRUCTION / ANOMALIES
   1. Tetralogy of Fallot
   2. Proximal interruption of pulmonary artery
   3. Anomalous origin of LCA from pulmonary artery

B. ACQUIRED PULMONARY ARTERY OBSTRUCTION
   (a) intrinsic
      1. Chronic thromboembolic disease
      2. Takayasu arteritis
   (b) extrinsic
      1. Fibrosing mediastinitis

C. CHRONIC / ACUTE INFLAMMATION
   1. Bronchiectasis
   2. Infection: TB, nontuberculous mycobacterial infection, cystic fibrosis, chronic fungal infection
   3. Malignancy

D. PULMONARY HYPERTENSION

THYMUS

Thymic Mass

1. Thymoma
2. Thymolipoma
3. Thymic cyst
4. Thymic carcinoid

Neoplasia in Thymus

1. Epithelial thymic tumor: thymoma, thymic carcinoma
2. Thymic lymphoma: Hodgkin disease, NHL
3. Langerhans cell histiocytosis
4. Thymolipoma
5. Carcinoid tumor
6. Germ cell tumor
7. Sarcoma
8. Metastasis

Diffuse Thymic Enlargement

A. BENIGN

1. Thymic hyperplasia
2. Intrathymic hemorrhage
3. Hemangioma
4. Lymphangioma

B. MALIGNANT THYMIC INFILTRATION

• presence of adenopathy elsewhere
√ no pleural implants

1. Leukemia
2. Hodgkin disease / non-Hodgkin lymphoma
3. Langerhans cell histiocytosis

TRACHEA & BRONCHI

Malignant Central Airway Obstruction

1. Primary lung cancer
2. Lymphoma
3. Metastatic mediastinal adenopathy
4. Bronchial carcinoid
5. Endobronchial metastasis
6. Primary tracheal tumor: chondroma, adenoid cystic ca.

Tracheal Narrowing

A. ANTERIOR COMPRESSION

(a) congenital

1. Congenital goiter
2. Innominate artery syndrome

• ablation of right radial pulse by rigid endoscopic pressure
√ posterior tracheal displacement
√ focal collapse of trachea at fluoroscopy
√ pulsatile indentation of anterior tracheal wall by innominate artery on MR
Rx: surgical attachment of innominate artery to manubrium

(b) inflammatory

1. Cervical / mediastinal abscess

(c) neoplastic

1. Cervical / intrathoracic teratoma

√ amorphous calcifications + ossifications

2. Thymoma
3. Thyroid tumors
4. Lymphoma

(d) traumatic: hematoma

B. POSTERIOR TRACHEAL COMPRESSION

(a) congenital

1. Vascular ring

› complete: double aortic arch, right aortic arch
› incomplete: anomalous right subclavian a.

√ posterior indentation of esophagus + trachea

2. Pulmonary sling
   = anomalous left pulmonary artery arising from right pulmonary artery, passing between trachea + esophagus en route to left lung
3. Bronchogenic cyst most commonly between esophagus + trachea at level of carina
   (a) inflammatory: abscess
   (b) neoplastic: neurofibroma
   (c) traumatic: esophageal foreign body, esophageal stricture, hematoma

C. INTRINSIC TRACHEAL CAUSES

(a) congenital:

1. Congenital tracheal stenosis (generalized / segmental)
   = complete cartilaginous ring (instead of horseshoe shape)
2. Congenital tracheomalacia = immaturity of tracheal cartilage = chondromalacia
   • expiratory stridor
   √ tracheal collapse on expiration

(b) neoplastic: papilloma, fibroma, hemangioma

(c) traumatic: acquired stenosis (endotracheal + tracheostomy tubes), granuloma, acquired tracheomalacia (cartilage degeneration after inflammation, extrinsic pressure, bronchial neoplasia, tracheoesophageal fistula, foreign body)

Tracheal Wall Thickening

1. Wegener granulomatosis
   √ involvement of posterior membrane
2. Relapsing polychondritis
   √ thickening of cartilaginous trachea + tracheal wall
3. Tracheobronchopathia osteochondroplastica
   √ calcified / ossified nodules in cartilaginous trachea
4. Amyloidosis
   √ nodular concentric calcified / ossified wall thickening
   √ no posterior sparing

Tracheal Tumor

• asthma symptomatology, hoarseness, cough, hemoptysis
• wheeze: <u>inspiratory</u> with extrathoracic lesion, <u>expiratory</u> with intrathoracic lesion

A. PRIMARY MALIGNANT

(a) from surface epithelium

1. Squamous-cell carcinoma (commonest primary)
   ◊ 50% of all malignant tracheal lesions
2. Adenocarcinoma
3. Neuroendocrine tumor = carcinoid

(b) from salivary gland

1. Cylindroma = adenoid cystic ca.
2. Mucoepidermoid carcinoma

(c) from mesenchyme

1. Sarcoma

2. Lymphoma
3. Plasmacytoma

B. SECONDARY MALIGNANT
(a) direct invasion: thyroid, lung, larynx, esophagus
(b) hematogenous: malignant melanoma, breast cancer, renal cell carcinoma, colon cancer

C. BENIGN TUMOR
(a) from surface epithelium
1. Squamous-cell papilloma
2. Pleomorphic adenoma
3. Oncocytoma
4. Mucous gland adenoma

(b) from mesenchyme
1. Cartilaginous tumor (hamartoma)
2. Leiomyoma
3. Fibroma / lipoma
4. Hemangioma
5. Granular cell myoblastoma
6. Neurogenic tumor

D. INFLAMMATION
1. Granulomatous disease:
TB, sarcoidosis, Wegener granulomatosis
2. Inflammatory myoblastic pseudotumor
3. Amyloid tumor
4. Pseudotumor: inspissated mucus, foreign body

Tracheobronchial Tumor

Frequency: < 0.4% of all body tumors

A. PRIMARY MALIGNANT (90%)
(a) surface epithelium
1. Squamous cell carcinoma (most common)
2. Adenocarcinoma
3. Neuroendocrine tumor: carcinoid, large / small cell carcinoma

(b) salivary gland
1. Adenoid cystic carcinoma (2nd most common)
2. Mucoepidermoid carcinoma

(c) mesenchyme
1. Sarcoma
2. Lymphoma

B. SECONDARY MALIGNANT (uncommon)
(a) directly invading: thyroid cancer, laryngeal cancer, lung cancer, esophageal cancer
(b) hematogenous: melanoma, breast cancer, renal cell carcinoma, colon cancer

C. BENIGN (< 10%)
(a) surface epithelium: papilloma, papillomatosis, pleomorphic adenoma. oncocytoma
(b) mesenchyme: hamartoma, leiomyoma, lipoma, fibroma, neurogenic tumor

Endobronchial Tumor

1. Neuroendocrine tumor (typical / atypical carcinoid)
2. Mucoepidermoid carcinoma
3. Adenoid cystic carcinoma
4. Hamartoma
5. Leiomyoma
6. Myoblastoma
7. Mucous gland adenoma
8. Squamous cell carcinoma

Bronchial Obstruction

1. Foreign body: most commonly in young children
2. Granulomatous disease: granuloma formation in bronchial wall / extrinsic compression by lymphadenopathy
3. Broncholith
4. Stenosis / atresia
5. Neoplasm
   (a) Bronchogenic carcinoma
   (b) Adenoid cystic carcinoma
   (c) Mucoepidermoid tumor
   (d) Hamartoma

mnemonic: MEATFACE

Mucus plug
Endobronchial granulomatous disease
Adenoma
Tuberculosis
Foreign body
Amyloid, **A**tresia (bronchial)
Cancer (primary)
Endobronchial metastasis

Bronchial Wall Thickening

◊ Apparent thickness of bronchial wall varies with lung window chosen on CT: a mean window that is too low can make the bronchial wall appear abnormal!

Differential Diagnosis of Airway Thickening		
Disease	*CT appearance*	*Differentiating Features*
Wegener granulomatosis	√ circumferential tracheal wall thickening (mostly subglottic)	• history of sinus / renal disease √ subglottic tracheal narrowing √ involvement of posterior wall √ pulmonary cavitary nodules / pulmonary hemorrhage √ NO wall calcifications
Relapsing polychondritis	√ thickening of cartilaginous trachea + tracheal wall	• cartilaginous abnormalities of ears + nose √ sparing of posterior tracheal wall √ tracheal narrowing √ occasional wall calcifications
Trachebronchopathia osteochondroplastica	√ calcified / ossified nodules in cartilaginous trachea	√ nodular calcified / ossified tracheal wall with wall thickening √ sparing of posterior tracheal membrane + superior trachea
Amyloidosis	√ calcified / ossified nodular concentric tracheal wall thickening	√ possible involvement of larynx + upper trachea √ nodular concentric calcified / ossified tracheal wall with wall thickening √ NO sparing of posterior membrane of trachea

Windowing: level at -250 to -700 HU, width at > 1000 HU

A. PERIBRONCHOVASCULAR
   1. Sarcoidosis
   2. Lymphangitic carcinomatosis
   3. Kaposi sarcoma
   4. Lymphoma
   5. Pulmonary edema

B. BRONCHIAL WALL
   1. Airway disease
   2. Relapsing polychondritis
   3. Wegener granulomatosis
   4. Amyloidosis

C. MUCOSAL INFECTION
   1. Croup
   2. Tuberculosis
   3. Fungal disease
   4. Aspergillosis

Circumferential Tracheobronchial Wall Thickening

1. Wegener granulomatosis
2. Sarcoidosis
3. Inflammatory bowel disease
4. Post-intubation stenosis
5. Amyloidosis
6. Infection: Klebsiella rhinoscleromatis, fungal infection, TB

Signet-ring Sign

= cross section of usually thick-walled dilated ringlike bronchus + normal branch of pulmonary artery as adjacent round soft-tissue opacity

1. Bronchiectasis
2. Multifocal bronchioloalveolar carcinoma
3. Metastatic adenocarcinoma

Broncholithiasis

Broncholith = erosion of calcified peribronchial lymph node extruded into bronchial lumen → bronchial obstruction

1. Histoplasmosis
2. Tuberculosis
3. Cryptococcosis
4. Actinomycosis
5. Coccidioidomycosis

√ calcified lymph node within / adjacent to affected bronchus
√ bronchial obstruction → atelectasis, mucoid impaction, bronchiectasis, air trapping, airspace disease (obstructive pneumonia)
√ absence of associated soft-tissue mass

Distribution of Bronchiectasis

A. Bronchiectasis with upper / midlung predominance

= less effective lymphatic clearance in upper zones (← gravitational gradient of blood flow and lower respiratory excursions) may account for upper lobe predominance of certain inhalational- and perilymphatic-predominant diseases.

1. Cystic fibrosis
2. Sarcoidosis
3. Silicosis and other pneumoconioses
4. Allergic bronchopulmonary aspergillosis
5. Tuberculosis

B. Bronchiectasis with anterior predominance
1. Atypical mycobacterial infection
2. Acute respiratory distress syndrome

C. Bronchiectasis with lower lung predominance
1. Chronic aspiration
2. Pulmonary fibrosis: UIP, NIP
3. Primary ciliary dyskinesia = immotile cilia syndrome
4. Immunodeficiency
5. α1-antitrypsin deficiency

D. Bronchiectasis with central predominance
1. Tracheobronchomegaly
2. Williams-Campbell syndrome

E. Focal bronchiectasis
1. Endo- / peribronchial tumor
2. Swyer-James syndrome

F. Diffuse bronchiectasis
1. Bronchiolitis obliterans

DIAPHRAGM

Bilateral Diaphragmatic Elevation

A. Shallow inspiration (most frequent)
B. Abdominal causes:
obesity, pregnancy, ascites, large abdominal mass
C. Pulmonary causes
(1) Bilateral atelectasis
(2) Restrictive pulmonary disease: SLE
D. Neuromuscular disease
(1) Myasthenia gravis
(2) Amyotrophic lateral sclerosis

Unilateral Diaphragmatic Elevation

1. Subpulmonic pleural effusion
√ dome of pseudodiaphragm migrates toward the costophrenic angle and flattens
2. Altered pulmonary volume
(a) Atelectasis
√ associated pulmonary density
(b) Postoperative lobectomy / pneumonectomy
√ rib defects, metallic sutures
(c) Hypoplastic lung
√ small hemithorax (more often on the right), crowding of ribs, mediastinal shift, absent / small pulmonary artery, frequently associated with dextrocardia + anomalous pulmonary venous return
3. Phrenic nerve paralysis
(a) primary lung tumor
(b) malignant mediastinal tumor
(c) iatrogenic
(d) idiopathic
√ diagnosed fluoroscopically by paradoxic diaphragmatic motion (with patient asked to sniff in lateral projection)
4. Abdominal disease
(a) subphrenic abscess (history of surgery, accompanied by pleural effusion)
(b) distended stomach / colon
(c) interposition of colon
(d) liver mass: tumor, echinococcal cyst, abscess
5. Diaphragmatic hernia
6. Eventration of diaphragm
7. Traumatic rupture of diaphragm associated with rib fractures, pulmonary contusion, hemothorax
8. Diaphragmatic tumor: mesothelioma, fibroma, lipoma, lymphoma, metastases

Diaphragmatic Paralysis

A. PHRENIC NERVE INJURY
1. Birth trauma
2. Cardiac surgery
3. Resection of thoracic tumor

B. INFECTION
   1. West Nile virus
   2. Lyme disease
C. TUMOR
   1. Mediastinal tumor
   2. Neck tumor

Diaphragmatic Tumor in Children

A. MALIGNANT (80%)
   1. Rhabdomyosarcoma
   2. Undifferentiated sarcoma
   3. Germ cell tumor
   4. Ewing sarcoma
B. BENIGN (20%)
   1. Lymphangioma
   2. Hemangioma
   3. Lipoma
   4. Myofibroma
   5. Neurofibroma

Cystic Lesion of Diaphragm

1. Mesothelial cyst
   Location: between liver + posterolateral thoracic wall
2. Bronchogenic cyst
3. Cystic teratoma
4. Pleuropulmonary blastoma
5. Hydatid cyst

RETROCRURAL NEOPLASM

A. NEUROGENIC TUMOR
   › ganglion cell tumor
      1. Neuroblastoma (most common)
      2. Ganglioneuroblastoma
      3. Ganglioneuroma
   › nerve / nerve sheath tumor
      1. Neurofibroma
      2. Neurilemmoma
   › tumor of paraganglia
      1. Paraganglioma
B. MESENCHYMAL TUMOR
   › benign
      1. Lipoma, leiomyoma, lymphangioma
      3. Hemangiopericytoma, hemangioma
   › malignant
      1. Liposarcoma, leiomyosarcoma

2. Rhabdomyosarcoma, fibrosarcoma
3. Malignant fibrous histiocytoma

C. GERM CELL TUMOR
1. Teratoma
2. Seminomatous + nonseminomatous tumors

D. LYMPHOID TUMOR
√ enlarged = lymph node > 6 mm in diameter
1. Lymphoma
2. Extramedullary hematopoiesis

CHEST WALL

Chest Wall Lesions

√ "incomplete border" sign ← obtuse angle
√ smooth tapering borders (tangential views)
√ tumor pedicle suggests a benign tumor

A. EXTERNAL
1. Cutaneous lesion: moles, neurofibroma
2. Nipples
3. Artifact

B. NEOPLASTIC

C. TRAUMATIC
1. Hematoma
2. Rib fracture

D. INFECTIOUS
cellulitis, pyomyositis, abscess, necrotizing fasciitis
1. Actinomycosis (parenchymal infiltrate, pleural effusion, chest wall mass, rib destruction, cutaneous fistulas)
2. Aspergillosis, nocardiosis, blastomycosis, tuberculosis (rare)
3. Pyogenic: Staphylococcus, Klebsiella

E. CHEST WALL INVASION
1. Peripheral lung cancer (eg, Pancoast tumor)
2. Recurrent breast cancer
3. Lymphomatous nodes

Pancoast Syndrome

[Henry Khunrath Pancoast (1875–1939), the first professor of radiology in the USA at the Hospital of the University of Pennsylvania in Philadelphia in 1912]
= superior sulcus tumor invading brachial plexus + sympathetic stellate ganglion
CLINICAL TRIAD:
1. Ipsilateral arm pain
2. Muscle wasting of hand
3. Horner syndrome = enophthalmos, ptosis, miosis, anhidrosis

Cause: lung cancer (most common), breast cancer, multiple myeloma, metastases, lymphoma, mesothelioma

Lung Disease with Chest Wall Extension

A. INFECTIOUS
   1. Actinomycosis
   2. Nocardia
   3. Blastomycosis
   4. Tuberculosis

B. MALIGNANT TUMOR
   1. Bronchogenic carcinoma
   2. Lymphoma
   3. Metastasis
   4. Mesothelioma
   5. Breast carcinoma
   6. Internal mammary node

C. BENIGN TUMOR
   1. Capillary hemangioma of infancy
   2. Cavernous hemangioma
   3. Extrapleural lipoma
   4. Abscess
   5. Hematoma

Chest Wall Tumor

Location of primary tumors: ribs (95%) > sternum

A. OSSEOUS TUMOR
   (a) secondary tumor
      1. Metastasis: most common type of skeletal tumor, particularly in older patients
         √ absence of mineralization
   (b) primary malignant tumor
      Frequency: 5–8% of all skeletal masses
      1. Chondrosarcoma (33% of primary rib tumors)
         √ arc-and-ring / flocculent / stippled chondroid mineralization
      2. Myeloma
         √ absence of mineralization
      3. Osteosarcoma
         √ dense / cloudy / ivorylike osteoid mineralization greatest at center + least at periphery
      4. Parosteal osteosarcoma
      5. Ewing sarcoma
   (c) primary benign
      1. Fibrous dysplasia (in 30%)
         √ amorphous mineralization
      2. Enchondroma
         √ benign osteolytic lesion + chondroid calcification
      3. Osteochondroma
         √ continuity of medullary cavity between lesion and affected bone
      4. Chondroblastoma

5. Aneurysmal bone cyst
6. Giant cell tumor

B. SOFT TISSUE TUMOR

(a) adipocytic

1. Lipoma (common):
   Location: intrathoracic + subcutaneous
   √ deep seated growing mass between ribs
   √ mature fat tissue on CT + T1WI
2. Liposarcoma (2nd most common soft-tissue malignancy)
   √ prominent internal septa > 2 mm in thickness
   √ nodular nonadipose areas

(b) vascular

1. Hemangioma
   √ high SI on T2WI ← vascular tissue
   √ variable amounts of fat tissue on T1WI
   √ phleboliths on CT
2. Lymphangioma
   √ commonly in neck + axilla
   √ high SI greater than that of fat on T2WI
3. Angiosarcoma
   Associated with: postmastectomy lymphedema
4. Hemangioendothelioma, hemangiopericytoma
   √ usually deep seated
5. Aneurysm, false aneurysm

(c) fibroblastic-myofibroblastic

1. Elastofibroma dorsi
   √ fibrous mass located under serratus anterior / latissimus dorsi muscle
2. Fibromatosis = desmoid tumor

(d) fibrohistiocytic

1. Malignant fibrous histiocytoma = undifferentiated pleomorphic sarcoma (most common soft-tissue malignancy)

(e) peripheral nerve sheath tumor

√ "target "sign on T2WI (in 50–70% of neurofibromas, in 0–54% of schwannomas)
√ fascicular" sign on T2WI (in 63% of schwannomas and 25% of neurofibromas)

1. Schwannoma
2. Neurofibroma (may erode ribs inferiorly with sclerotic bone reaction), neuroma, neuroblastoma
3. Malignant PNST (5–10% of all soft-tissue sarcomas)
   Associated with: NF 2 (in 25–70%)

(f) cutaneous lesions

1. Epidermal cyst
   √ NO high signal intensity on T2WI
2. Pilomatricoma
   √ calcified subdermal nodule + peritumoral edema
4. Dermatofibrosarcoma protuberans

Chest Wall Tumor in Children

MALIGNANT TUMORS OF CHEST WALL IN CHILDREN

◊ More common than benign primary chest wall tumors!

1. Ewing sarcoma of rib (most common)
   (a) older child: rib involvement in 7%, predominant involvement of pelvis + lower extremity
   (b) child < 10 years: rib involvement in 30%
   DDx: osteomyelitis, unusual-appearing fracture, callus, direct spread of lung infection
2. Rhabdomyosarcoma
   relatively common in children + adolescents
   √ sclerosis / destruction / scalloping of cortex (local extension to contiguous bone)
   √ may calcify
   Metastases to: lung, occasionally lymph nodes
   Prognosis: infiltrative growth with high risk of local recurrence
3. Metastasis
   (a) Neuroblastoma
   • 10% present as chest wall mass
   √ may calcify
   (b) Leukemia
4. Askin tumor
5. Chondro- / osteosarcoma (quite rare in pediatric patients)

BENIGN TUMORS OF CHEST WALL IN CHILDREN

A. OSSEOUS
   1. Aneurysmal bone cyst
   2. Chondroblastoma
   3. Enchondroma
   4. Osteoblastoma
   5. Osteochondroma
   6. Osteoid osteoma

   Often associated with systemic syndrome: neurofibromatosis, histiocytosis, osteochondromatosis

   √ cortical rib destruction + soft-tissue mass

B. SOFT TISSUE
   1. Lipoma
   2. Hemangioma
   3. Lymphangioma
   4. Teratoma

BEDSIDE CHEST RADIOGRAPHY

Benefit:

Unexpected findings: in 37–43–65%

Change in diagnostic approach / therapy: in 27%

Indications:

A. APPARATUS POSITION + COMPLICATIONS

1. **Malposition of tracheal tube** (12%)
   √ tip of tube 4–6 cm above carina with neck in neutral position:
   √ migration by 2 cm inferiorly with flexion
   √ migration by 2 cm superiorly with extension
   √ tube diameter should be ½ to ⅔ of tracheal lumen
   √ diameter of inflated balloon should be less than diameter of trachea
   Cx:
   (a) Tracheal damage (stenosis / rupture) if ratio of cuff to tracheal lumen > 1.5
   (2) Aspiration (in 8%)
   (3) Disloding of teeth / fillings
2. **Malposition of central venous line** (9%) into internal jugular vein, azygos arch, internal mammary vein, congenital anomaly (eg, persistent left SVC), artery
   Cx: placement into branch vein / anomalous vein (eg, persistent left SVC), intraarterial placement, extravascular placement
   FDA Recommendation:
   (1) Tip of CVC within extrapericardial portion of SVC, 2 cm from cavoatrial junction = 85% of distance from sternoclavicular junction to carina = 9 mm above carina
   (2) Tip of tunneled hemodialysis catheter at junction of SVC and right atrium / in RA
   (3) Tip of nontunneled upper extremity catheter at superior cavoatrial junction = 4 cm below carina
   • fibrin sheath occlusion is suspected when a well-positioned CVC fails to function normally (confirmed at conventional catheter venography)
3. **Malposition of nasogastric tube**
   › esophageal malposition
   › bronchial intubation
   › esophageal perforation
   √ may not be on film if coiled in hypopharynx
4. **Swan-Ganz line** (= balloon-directed line)
   • 25% of catheters malpositioned on initial CXR
   √ tip should be in main / right / left pulmonary artery (NOT distal to proximal interlobar pulmonary a.)
   Cx: pulmonary infarction, pulmonary artery rupture, hemorrhage, cardiac perforation, pseudoaneurysm formation, malposition, intracardiac knot, arrhythmia
5. **Thoracostomy tube**
   √ break in radiopaque material (= most proximal side hole should be intrathoracic)
   √ intrafissural placement makes tube ineffective
6. **Tracheostomy**
   ◊ Position NOT affected by flexion / extension of neck!
   √ tube diameter should be ⅔ of tracheal lumen
   √ tip should be at level of T3

7. **Intraaortic balloon pump** (IABP)
   - tip of pump should be just distal to left subclavian artery in proximal descending aorta = 1–2 cm below top of aortic arch

   √ balloon inflates in diastole, deflates in systole
8. Retained catheter / implantable cardioverter-defibrillator lead **fragments**
9. **Calcified** fibrin sheath / calcified thrombus

B. CARDIOPULMONARY DISEASE

1. **Atelectasis**
   - most common CXR abnormality in ICU

   Incidence increased:
   after general anesthesia, thoracic / upper abdominal surgery, pre-existing lung disease, smoking, obesity, elderly

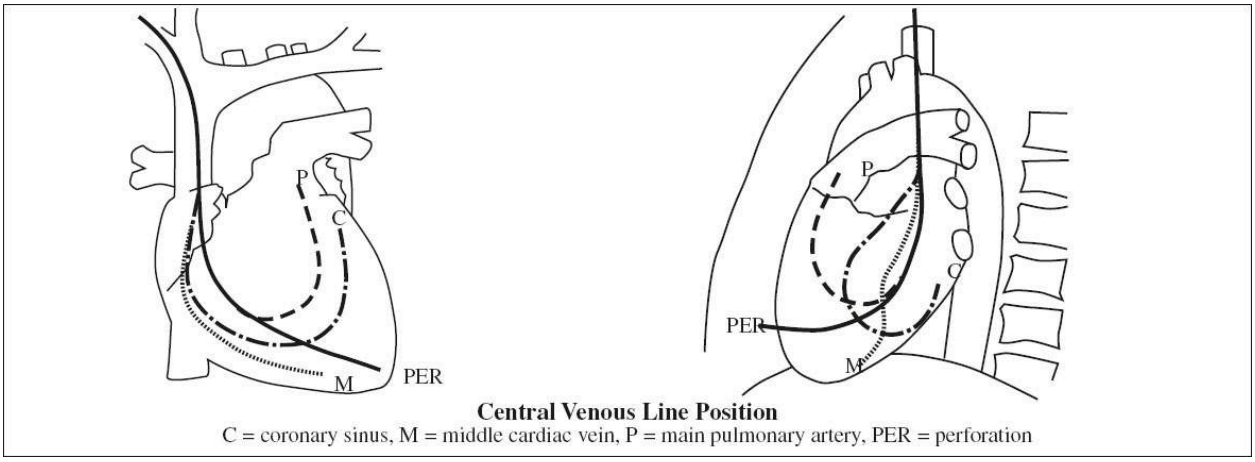
   Location: left lung base (most frequent)

   √ linear / platelike subsegmental

   √ lobar / segmental:

   √ air bronchogram present = collapse of small airways → bronchoscopy not beneficial

   √ air bronchogram absent = central mucoid impaction → bronchoscopy therapeutic



Central Venous Line Position
C = coronary sinus, M = middle cardiac vein, P = main pulmonary artery, PER = perforation

√ patchy density mimicking pneumonia

√ rapid temporal change possible

2. Pulmonary edema

(a) cardiac (hydrostatic)
including CHF, overhydration, renal failure

N.B.: cephalization of vasculature NOT helpful in supine position

√ usually cardiomegaly (cardiothoracic ratio ≥ 55%)

√ enlarged vascular pedicle (mediastinal width at SVC ≥ 70 mm)

√ Kerley lines

√ pleural effusion frequent

√ central / diffuse lung opacity

√ rapid onset + resolution

Accuracy of both CT ratio+ vascular pedicle width: 70% for pulmonary

wedge pressure > 18 mmHg

(b) noncardiac (permeability edema)
including ARDS, sepsis, drug reaction, near drowning, smoke inhalation, neurogenic edema, aspiration, fat embolism

√ cardiomegaly rare
√ Kerley lines absent
√ pleural effusions unusual + small
√ decreased lung volumes frequent
√ diffuse / peripheral lung opacity
◊ Patchy peripheral distribution in 58% of permeability edema vs. in 13% of hydrostatic edema
√ delayed onset + resolution
√ barotrauma common

3. Pleural effusion (due to CHF)
Location: bilateral / right-sided

◊ A solely left-sided effusion suggests a superimposed process / gravity!

√ homogeneous density over lower lung
√ fluid over apex / in fissures
√ intrafissural pseudotumor
√ not visible in 30%

DDx: atelectasis, empyema (loculated nonmobile effusion), postpericardiotomy syndrome (increasing effusion beyond 3rd postop. day)

4. Alveolar disease = pneumonia
• in 10% of ICU patients, in 60% with ARDS
• commonly related to aspiration
√ slowly progressing, often multifocal patchy areas of consolidation / poorly defined opacities
√ air bronchograms
√ cavitation (most specific finding)
Impossible DDx: ARDS, lobar atelectasis

5. Interstitial disease
DDx: (a) interstitial pulmonary edema changes daily
(b) pneumonia (CMV, pneumocystis)

6. Barotrauma (in 4–15% of ventilated patients)
Increased risk: underlying lung disease (ARDS, pneumonia), peak inspiratory pressure > 40 cm H_2O, use of PEEP, large tidal volume
√ pulmonary interstitial edema (initially)
√ anteromedial / subpulmonic location
√ tension pneumothorax (in 60–96%) with mediastinal shift masked by PEEP

7. Aspiration
Increased risk: general anesthesia, depressed consciousness, neuromuscular disorder, esophageal disease, presence of NG / ET tube
Location: posterior aspect of upper lobes, superior segments + posterior basilar segments of lower lobes

√ focal / multifocal consolidation in dependent location with central predominance
√ aspiration pneumonitis (may progress over first day but clearing within a few days)
√ aspiration pneumonia (lack of clearing / progression)

8. Thoracic bleeding
9. Mediastinal disease

MEDICAL DEVICES ON CXR

Cardiac Devices

Coronary Artery Bypass Grafting (CABG)

√ median sternotomy wires
√ vascular clips
√ anastomotic markers

Coronary Artery Stent

with self / balloon / thermally expandable stents

Cardiac Conduction Devices

Circulatory Assist Devices

› Intraaortic Counterpulsation Balloon Pump (IACB) inflated with CO_2 during ventricular diastole to augment perfusion of coronary arteries
› Ventricular Assist Device (VAD)

Heart Valve Replacement

(a) mechanical: Starr-Edwards, Björk-Shiley, Medtronic Hall, St. Jude Medical, Sorin Bicarbon, CarboMedics
(b) biologic: homograft (from human cadaver), xenograft from porcine aortic cusps, bovine pericardium, Carpentier-Edwards, Tissue Med, Hancock

Vascular Devices

Central Venous Pressure Catheter

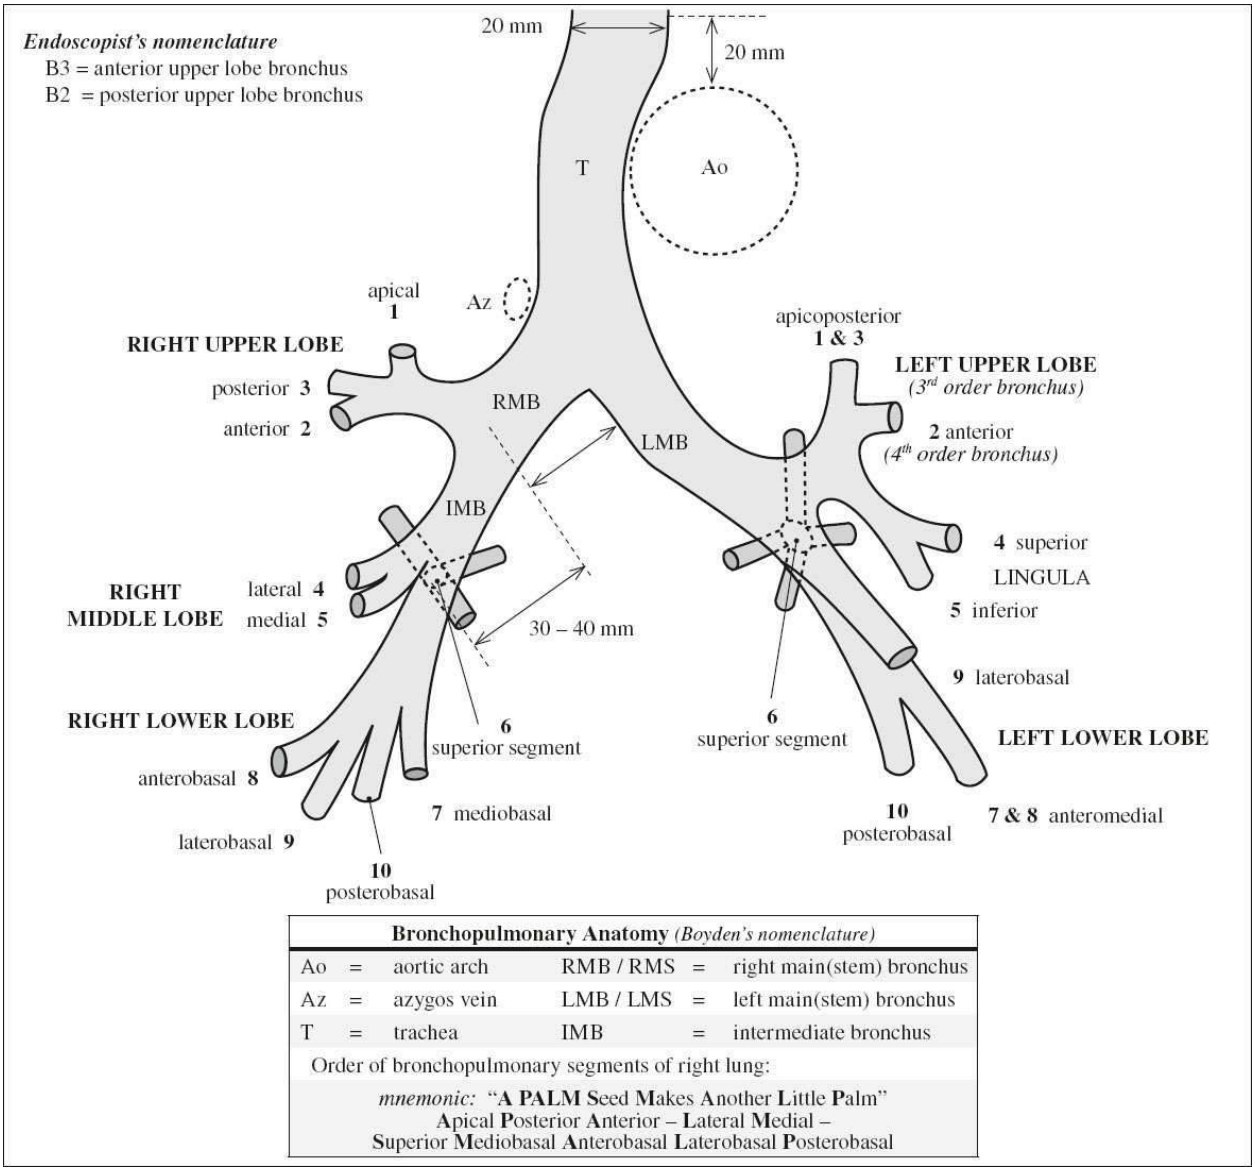
= CVP = CENTRAL CATHETER = CENTRAL LINE
Types: Hickman, Broviac, Leonard, Hohn, Cordis Sheath, Swan-Ganz (= pulmonary artery catheter), Groshong

Implantable Access Devices

= SUBCUTANEOUS PORT
Types: Port-A-Cath, SlimPort, Dialock, LifeSite

Peripheral Inserted Central Catheter (PICC)

ANATOMY AND FUNCTION OF LUNG



Bronchopulmonary Anatomy *(Boyden's nomenclature)*

Ao	=	aortic arch	RMB / RMS	=	right main(stem) bronchus
Az	=	azygos vein	LMB / LMS	=	left main(stem) bronchus
T	=	trachea	IMB	=	intermediate bronchus

Order of bronchopulmonary segments of right lung:

mnemonic: "**A PALM** Seed **M**akes **A**nother **L**ittle **P**alm"
Apical **P**osterior **A**nterior – **L**ateral **M**edial –
Superior **M**ediobasal **A**nterobasal **L**aterobasal **P**osterobasal

ORDER OF BRONCHOPULMONARY SEGMENTS OF RIGHT LUNG:

AIRWAYS

The carina is normally at the level of T4/T5.

Embryology of Airways & Maldevelopment

first 5 weeks GA	lung buds grow from ventral aspect of primitive foregut (from caudal end of laryngotracheal groove of primitive pharyngeal floor)
abnormal:	pulmonary agenesis
5th week GA	separation of trachea + esophagus
5–16 weeks	formation of tracheobronchial tree with bronchi, bronchioles, alveolar ducts, alveoli

abnormal: bronchogenic cyst ← abnormal budding;
pulmonary hypoplasia ← fewer than expected bronchi

16–24 weeks dramatic increase in number + complexity of airspaces and blood vessels

abnormal: small airways ← reduction in number and size of acini

Anomalous Bronchial Division

Branching anomalies:

(a) displaced (replaced) bronchus

√ bronchus with abnormal origin while normal bronchus ventilating corresponding parenchyma is absent

(b) supernumerary (accessory) bronchus

√ may end blindly in parenchyma of corresponding normal bronchus = congenital bronchial diverticulum

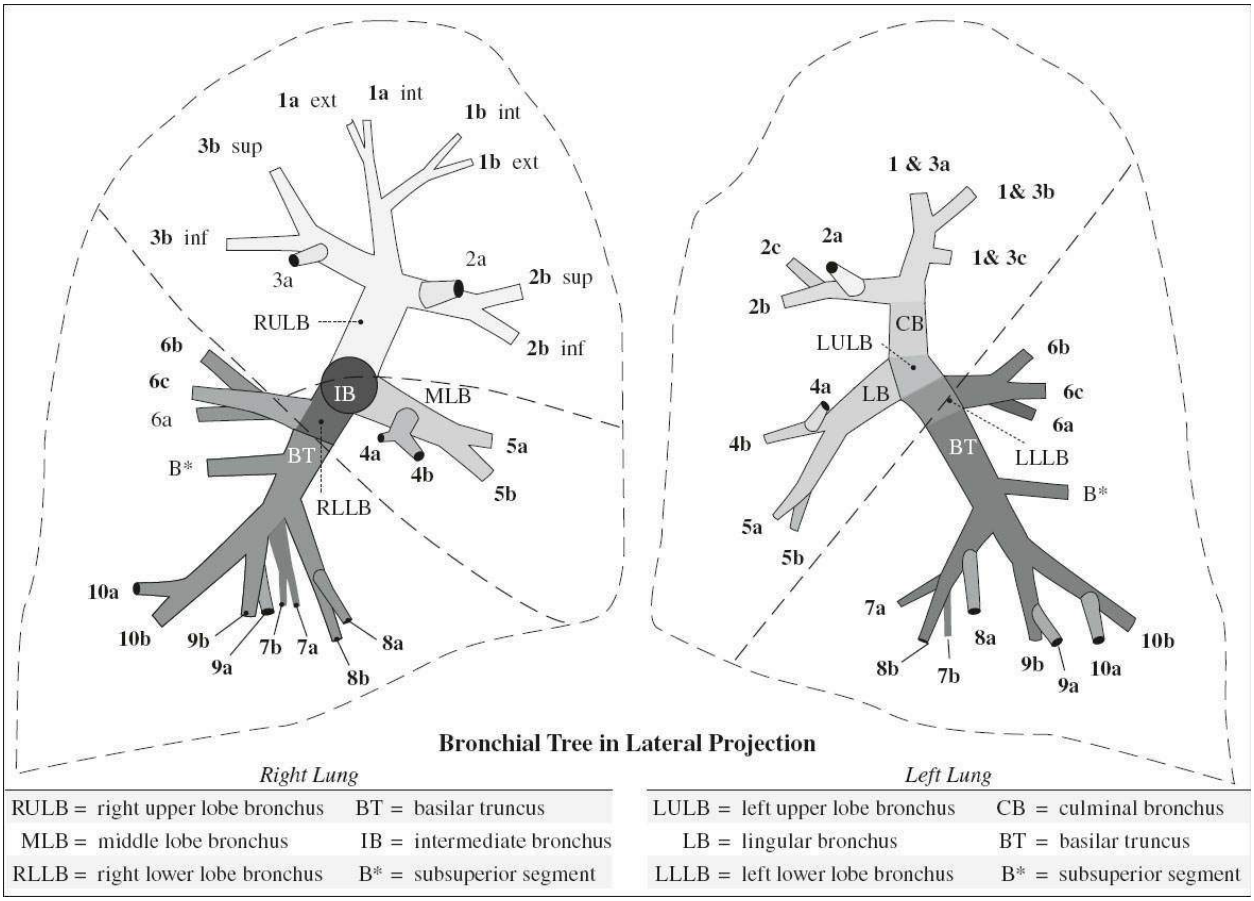
√ may ventilate additional lung parenchyma, possibly delineated by an accessory fissure

Tracheal Bronchus *(0.1–2.0%)*

= bronchus of variable length arising from lower trachea

Frequency: 0.1–1.3% in adults; 1.5–2% in childhood

In 78% associated with:



Bronchial Tree in Lateral Projection

Right Lung		*Left Lung*	
RULB = right upper lobe bronchus	BT = basilar truncus	LULB = left upper lobe bronchus	CB = culminal bronchus
MLB = middle lobe bronchus	IB = intermediate bronchus	LB = lingular bronchus	BT = basilar truncus
RLLB = right lower lobe bronchus	B* = subsuperior segment	LLLB = left lower lobe bronchus	B* = subsuperior segment

Down syndrome; malformation of thoracic cage / foregut / lung; tracheal stenosis; other

tracheobronchial branching anomalies

Type: displaced in 75%; supernumerary in 25% → ventilating intra- / extralobar tracheal lobe (NOT related to azygos lobe)

Location: almost invariably on right; bilateral (rare)

Site: distal trachea < 2 cm from carina

- recurrent pneumonia, respiratory distress in childhood
- almost invariably asymptomatic in adults

√ blind-ending pouch (= congenital right tracheal diverticulum) / aeration of a portion or all of RUL

√ early origin of apicoposterior LUL bronchus (less common)

√ "pig bronchus" = entire RULB displaced on trachea

Right Preeparterial Bronchus

= any bronchus directed toward RUL that arises abnormally from RMB above level of right eparterial ULB

Frequency: 0.9%

Type: 82% displaced

- mostly asymptomatic

DDx: accessory cardiac bronchus

Right Posteparterial Bronchus

= any bronchus directed toward RUL that arises abnormally from right bronchial tree below level of right eparterial ULB

Left Eparterial Bronchus

= any bronchus directed toward LUL that arises from posterolateral / lateral wall of LMB above level where left pulmonary artery crosses LMB

Left Prehyparterial Bronchus

= anomalous bronchus directed toward LUL that arises from LMB between level of left pulmonary artery crossing and hyparterial LULB

Accessory Cardiac Bronchus (ACB)

= true supernumerary anomalous bronchus

The only bronchus originating from medial wall of either RMB or IMB (occasionally on left side)

M÷F = 2.8÷1

√ arises from medial wall of bronchus intermedius prior to origin of apical segmental RLL bronchus

√ caudal course toward pericardium

√ blind-ending pouch / ventilation of an accessory lobe

Bridging bronchus

= aberrant bronchus that partially / totally supplies the right lung but originates from LMB

√ carina at T4–T5

√ pseudocarina in the shape of an inverted T at T6-T7

Paracardiac Bronchus

= normal bronchus arising from medial aspect of lower lobe

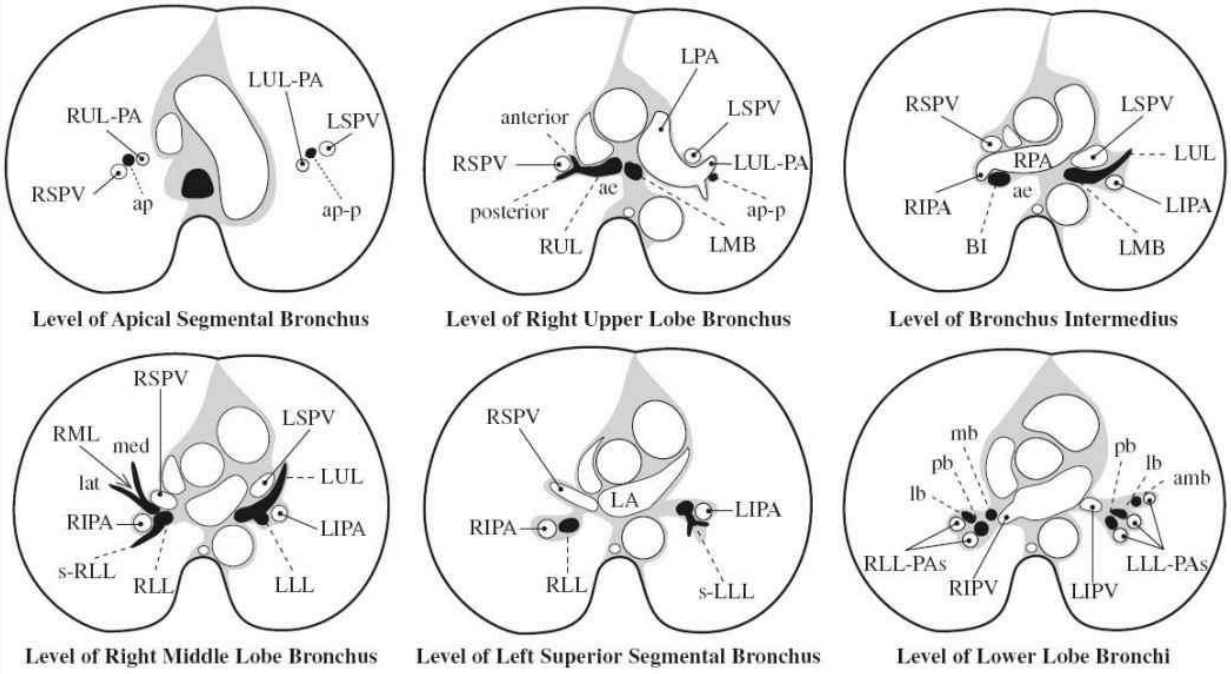
Prevalence: 5% of patients

Airway

= conducting branches for the transport of air; ~ 300,000 branching airways from trachea to bronchiole with an average of 23 airway generations

Definition:

bronchus = cartilage in wall



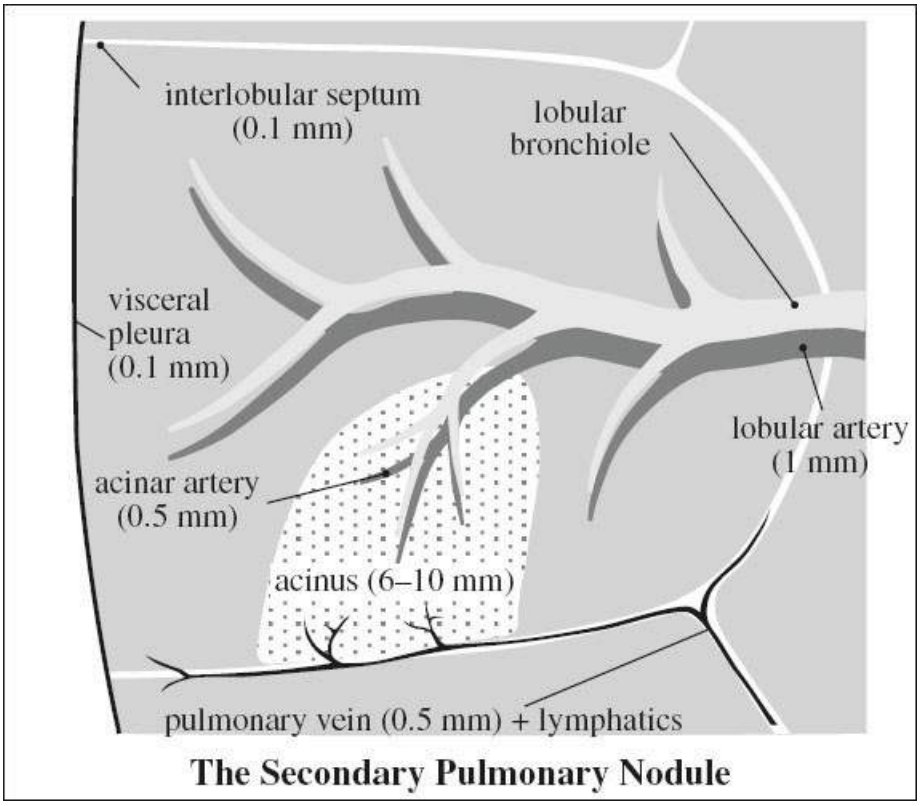
Cross-sectional Anatomy of Bronchovascular Divisions

Right Lung

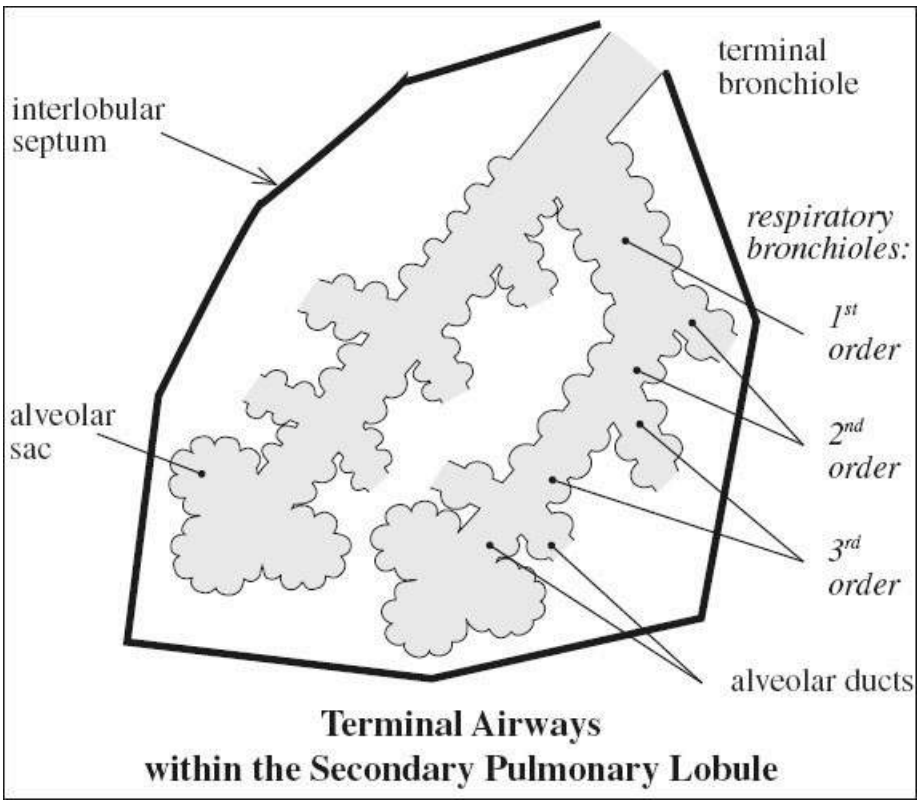
ant	=	anterior RUL	pb	=	posterobasal RLL
ap	=	apical RUL	post	=	posterior RUL
BI	=	bronchus intermedius	RLL	=	right lower lobe
lat	=	lateral RML	RML	=	right middle lobe
mb	=	mediobasal RLL	RUL	=	right upper lobe
med	=	medial RML	s-RLL	=	superior segment
RUL-PA / LUL-PA	=	R / L upper lobe pulmonary artery			
RLL-PAs / LLL-PAs	=	R / L pulmonary artery			
RIPV / LIPV	=	R / L inferior pulmonary vein			
RPA	=	R pulmonary artery			

Left Lung

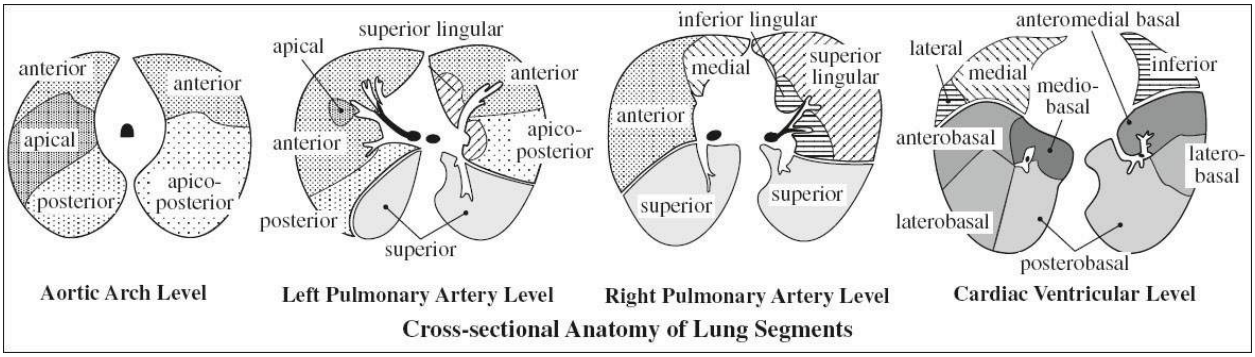
amb	=	anteromediobasal LLL	ap-p	=	apicoposterior LUL
lb	=	laterobasal LLL	LLL	=	left lower lobe
LMB	=	left main bronchus	LUL	=	left upper lobe
pb	=	posterobasal LLL	s-LLL	=	superior segment
ae	=	azygoesophageal recess			
RIPA / LIPA	=	R / L inferior pulmonary artery			
RLL-PAs / LLL-PAs	=	R / L lower lobe pulmonary arteries			
RSPV / LSPV	=	R / L superior pulmonary vein			



The Secondary Pulmonary Nodule



Terminal Airways
within the Secondary Pulmonary Lobule



Cross-sectional Anatomy of Lung Segments

bronchiole = absence of cartilage (after 6–2 divisions of segmental bronchus)
- › **membranous** bronchiole = purely air conducting
- › **respiratory** bronchiole = contains alveoli in its wall
- › **lobular** bronchiole = supplies secondary pulmonary lobule; may branch into 3 or more terminal bronchioles
- › **terminal** bronchiole = last generation of purely conducting bronchioles without alveoli; each supplying one acinus

small airways = internal diameter < 2 mm = small noncartilaginous membranous and respiratory bronchioles; account for 25% *of airway resistance*

large airways = diameter > 2 mm; account for 75% *of airway resistance*

HRCT of normal lung (window level –700 HU, window width 1,000–1,500):
- √ –875 ± 18 HU at inspiration
- √ –620 ± 43 HU at expiration
- √ 8th order bronchi visible = bronchi > 2 mm in diameter
- ◊ Normal lobular bronchioles NOT visible!

Acinus

◊ Functionally most important subunit of lung!

= all parenchymal tissue <u>distal to one terminal bronchiole</u> comprising 2–5 generations of respiratory bronchioles + alveolar ducts + alveolar sacs + alveoli

• gas exchange

√ radiologically NOT visible

Cells of Lung Parenchyma *75% of all lung cells*

1. Air-blood barrier
   - › epithelial cells (25%) = lining of air space
   - › endothelial cells (25%) = lining of vessels
   - › interstitial cells (35%), collagen fibres (15%)
2. Alveolar epithelium
   - › lining cells (type I pneumocyte) → tight junctions, no mitosis
   - › secretory cells (type II pneumocyte) → synthesis + storage + secretion of surfactant
   - › brush cells

[Primary Pulmonary Lobule]

= alveolar duct + its connected air spaces

Secondary Pulmonary Lobule

= REID LOBULE

[Lynne McArthur Reid (1923–?), experimental pathologist and dean of Cardiothoracic Institute, London University, Harvard Medical School, pathologist-in-chief emeritus at Children's Hospital in Boston]

= smallest portion of lung surrounded by connective tissue septa; supplied by 3–5 terminal bronchioles

√ basic anatomic + functional pulmonary unit appearing as an irregular polyhedron containing 3–24 acini

√ separated from each other by thin fibrous interlobular septa (100 μm)

Size: 10–25 mm in diameter

• visible on surface of lung

Contents:

› centrally = lobular core:

» branches of terminal bronchioles with a 0.1 mm wall thickness = below the resolution of HRCT

√pulmonary arterioles (1 mm)

› peripherally (within interlobular septa):

√pulmonary vein + lymph vessels

HRCT:

√ barely visible fine lines of increased attenuation in contact with pleura (= interlobular septa); best developed in subpleural areas of

› UL + ML: anterior + lateral + juxtamediastinal

› LL: anterior + diaphragmatic regions

√ dotlike / linear / branching structures (= pulmonary arterioles)

Site: near center of secondary pulmonary lobule; 3–5 mm from pleura

Interstitial Anatomy

1. **Bronchovascular** interstitium
   surrounding bronchovascular bundle
2. **Centrilobular** interstitium
   surrounds distal bronchiolovascular bundle
   √ line extending to the center of a lobule
3. **Interlobular** septal interstitium
   √ lines perpendicular to pleura surrounding a lobule
4. **Pleural** interstitium

Lung Interstitium	
Division	*Components*
Axial	bronchovascular sheaths, lymphatics
Middle (parenchymal)	alveolar wall (interalveolar septum)
Peripheral	pleura, subpleural connective tissue interlobular septa (enclosing pulmonary veins, lymphatics, walls of cortical alveoli)

Lung Development

› *embryonic phase*
respiratory diverticulum (= laryngotracheal bud) originates from ventral wall of primitive foregut
→ elongation of lung bud → lateral invagination of mesoderm → tracheoesophageal septum
→ bifurcation of laryngotracheal bud at 5–7 weeks EGA → R + L mainstem bronchi
→ mainstem bronchi branch further into lobar bronchi
→ pulmonary arteries arise from 6th aortic arch
Time: 26 days to 7 weeks EGA

› *pseudoglandular phase* development of segmental + subsegmental bronchi, respiratory bronchioles + terminal bronchioles, alveolar ducts + alveoli
Time: 7–16 weeks EGA

› *canalicular / acinar phase* development of distal acinar units + canalization of further airspaces; airspaces are approximated by network of capillaries; type II alveolar cells capable of surfactant synthesis
Time: 16–24 weeks EGA

› *saccular phase* increase in number of terminal sacs + thinning of intervening interstitium + beginning of alveolar septation
Time: 24–36 weeks EGA

› *alveolar phase* development of true fully mature alveoli with progressive formation throughout first 2 years of life
Time: 36 weeks EGA – 18th postnatal month

mnemonic: **E**very **P**remature **C**hild **T**akes **A**ir
Embryonic phase
Pseudoglandular phase
Canalicular phase
Terminal sac phase
Alveolar phase

Surfactant

= surface-active material essential for normal pulmonary function

Substrate: phospholipids (dipalmitoylphosphatidylcholine, phosphatidylglycerol), other lipids, cholesterol, lung-specific proteins

Production: type II pulmonary alveoli synthesize + transport + secrete lung surfactant; earliest production around 18th week of gestation (in amniotic fluid by 22nd week

of gestation)

Action: increases lung compliance, stabilizes alveoli, enhances alveolar fluid clearance, reverses surface tension, protects against alveolar collapse during respiration, protects epithelial cell surface, reduces opening pressure + precapillary tone

PULMONARY CIRCULATION

Primary Pulmonary Circulation

⇒ supplies 99% of blood flow to lungs pulmonary arteries travel along lobar + segmental bronchi down to subsegmental level matching caliber of airways

(a) **large elastic** pulmonary arteries (500 to > 1,000 μm) accompany lobar + segmental bronchi matching caliber of airways
- › main pulmonary artery / trunk: ≤ 28 mm
- › right / left pulmonary artery
- › lobar pulmonary artery
- › segmental pulmonary artery

(b) **muscular** arteries (50–1,000 μm) accompany subsegmental airways + terminal bronchioles
- √ provide active vasodilatation + constriction

(c) **arterioles** (15–150 μm) accompany respiratory bronchioles + alveolar ducts

(d) **capillary** network in alveolar walls

(e) venules

(f) pulmonary veins course through interlobular fibrous septa

Function: gas exchange

Bronchial Circulation

⇒ supplies 1% of blood flow to lungs = 1% of cardiac output

Pressure: systemic high-pressure system (6 x that of normal pulmonary circulation); bronchial arteries are resistant to arteriosclerosis

Origin:

(a) orthotopic bronchial artery (64%): anteriorly from proximal to mid-descending thoracic aorta at level of left main bronchus between superior endplate of T5 and inferior endplate of T6

Angio landmark: 1 cm above / below level of left main bronchus as it crosses descending thoracic aorta

(b) at least one ectopic bronchial artery (36%):
- › from undersurface of aortic arch (15%)
- › distal descending thoracic aorta, subclavian artery, thyrocervical trunk, costocervical trunk, brachiocephalic trunk, internal mammary artery, pericardiophrenic a., inferior phrenic a., coronary a.

(c) left bronchial artery: most commonly directly from aorta toward left side of esophagus

(d) right bronchial artery: most commonly originating from another artery, typically intercostal artery toward right side of esophagus

Variants of vascular anatomy (9 types):

(1) 1 right bronchial a. arising posteromedially from a common **I**nter**C**ostal **B**ronchial

Artery **T**runk (ICBAT) + 2 left bronchial a. anteriorly (41%)

(2) 1 bronchial artery on each side, the right bronchial artery originating from an ICBAT (21%)

(3) 2 bronchial aa. on each side, 1 right bronchial artery originating from an ICBAT (21%)

(4) 1 right bronchial a. + 1 right ICBAT + 2 left bronchial arteries (10%)

Course: behind trachea and main-stem bronchi; enter lung via hila; tortuous path along peribronchial sheath of mainstem airway to terminal bronchioles

Function:

⇒ nourishment for supporting structures
- › extra- and intrapulmonary airways
- › vasa vasorum of pulmonary arteries
- › nerves, pulmonary veins, lymph nodes within thorax

⇒ systemic blood supply to
- › trachea, bronchi, bronchial branches, visceral pleura
- › esophagus

The bronchial circulation + other collateral vessels (eg, intercostal, internal mammary, inferior phrenic aa.) respond to chronic pulmonary ischemia and ↓ pulmonary blood flow → vessel hypertrophy / enlargement → maintenance of blood flow to affected lung + participation in gas exchange through systemic-pulmonary arterial anastomoses beyond the pulmonary artery obstruction.

Bronchial-to-Pulmonary Artery Anastomoses

= microvascular connections (= capillary communications) at level of alveoli and respiratory bronchioles

⇒ normal L-to-R shunt accounting for 5% of cardiac output

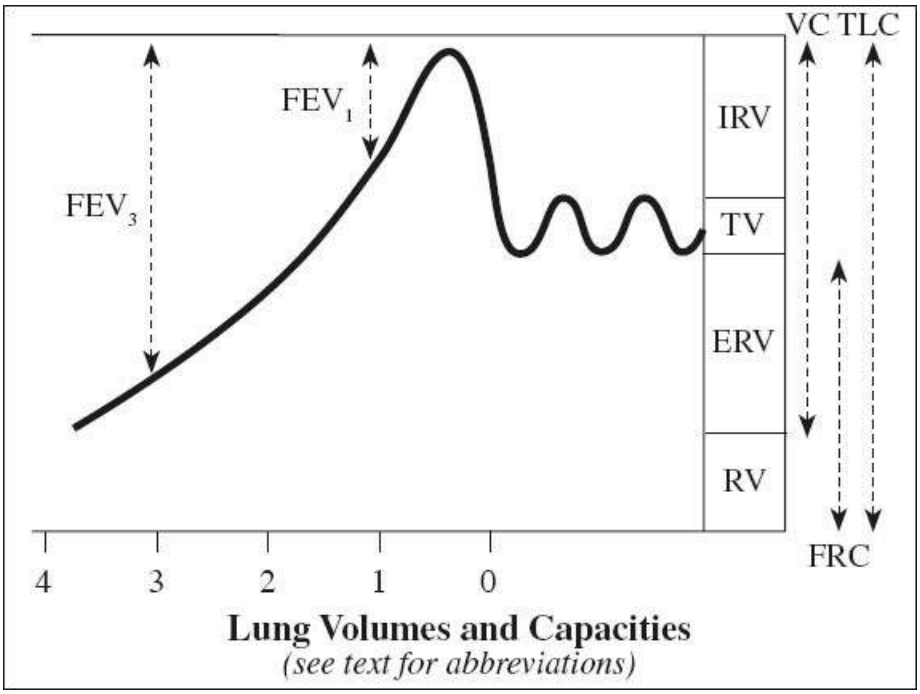
√ normal bronchial arteries NOT usually visible on thoracic angiography

LUNG FUNCTION

Lung Volumes & Capacities

1. Tidal volume (**TV**)

= amount of gas moving in + out with each respiratory cycle



2. Residual volume (**RV**)
   = amount of gas remaining in lung after maximal expiration
3. Total lung capacity (**TLC**)
   = gas contained in lung at end of maximal inspiration
4. Vital capacity (**VC**)
   = amount of gas that can be expired after a maximal inspiration without force
5. Functional residual capacity (**FRC**)
   = volume of gas remaining in lungs at end of quiet expiration

Changes In Lung Volumes

A. DECREASED VITAL CAPACITY:
   1. Reduction in functioning lung tissue due to
      (a) space-occupying process (eg, pneumonia, infarction)
      (b) surgical removal of lung tissue
   2. Process reducing overall volume of the lungs
      (eg, diffuse pulmonary fibrosis)
   3. Inability to expand lungs due to
      (a) muscular weakness (eg, poliomyelitis)
      (b) increase in abdominal volume (eg, pregnancy)
      (c) pleural effusion

B. INCREASED FRC and RV:
   = characteristic of air trapping and overinflation (eg, asthma, emphysema)
   Associated with: increased TLC
   √ normal level of inflation to 8th posterior rib

C. DECREASED FRC and RV:
   1. Process reducing overall volume of lungs

(eg, diffuse pulmonary fibrosis)

2. Process that occupies volume within alveoli
   (eg, alveolar microlithiasis)
3. Process that elevates diaphragm (eg, ascites, pregnancy), usually associated with decreased TLC

Flow Rates

A. Spirometric measurements:

1. **Forced expiratory volume** (FEV)
   = amount of air expired during a certain period (usually 1 + 3 seconds)
   Normal values: **FEV_1** = 83%; **FEV_3** = 97%
2. **Maximal midexpiratory flow rate** (MMFR)
   = amount of gas expired during middle half of forced expiratory volume curve (largely effort independent)
   Indicator of small airway resistance
3. **Flow-volume loop**
   = gas flow is plotted against the actual volume of lung at which this flow is occurring
   Useful in identifying obstruction in large airways

B. Resistance in small airways

Closing volume = lung volume at which dependent lung zones cease to ventilate because of airway closure in small airway disease or loss of lung elastic recoil

- decrease in FEV, MMFR, MBC:
  (a) expiratory airway obstruction (reversible as in spasmodic asthma / irreversible as in emphysema)
  (b) respiratory muscle weakness

Diffusing Capacity

= rate of gas transfer across alveolocapillary membrane in relation to constant pressure differences across it; measured by carbon monoxide diffusion method DLCO.

Technique:

» patient inspires maximally a gas with a known small concentration of CO
» breath-holding for 10 seconds followed by slow expiration to residual volume (RV)
» an aliquot of the end-expired (alveolar) gas is analyzed for amount of CO absorbed during breath

Measurement: in mL of CO absorbed/min/mmHg

Causes of reduction:

1. Ventilation / perfusion inequality: less CO is taken up by poorly ventilated or poorly perfused areas (eg, emphysema)
2. Reduction of total surface area (eg, emphysema, surgical resection)
3. Reduction in permeability from thickening of alveolar membrane (eg, cellular infiltration, edema, interstitial fibrosis)
4. Anemia with lack of hemoglobin

Arterial Blood Gas Abnormalities

- decreased pulmonary arterial O2:

1. Alveolar hypoventilation
2. Impaired diffusion
3. Abnormal ventilation / perfusion ratios
4. Anatomic shunting

- elevated pulmonary arterial CO_2:
  1. Alveolar hypoventilation
  2. Impaired ventilation / perfusion ratios

V/Q Inequality

A. NORMAL
   (a) blood flow decreases rapidly from base to apex
   (b) ventilation decreases less rapidly from base to apex
   ◊ V/Q is low at base and high at apex
   ◊ Pulmonary arterial O2 is substantially higher at apex
   ◊ Pulmonary arterial CO_2 is substantially higher at base

B. ABNORMAL
   chiefly resulting from non- / underventilated lung regions
   ◊ Non- / underperfused regions do NOT result in blood gas disturbances!

Compliance

= relationship of the change in intrapleural pressure to the volume of gas that moves into the lungs

A. DECREASED COMPLIANCE
   edema, fibrosis, granulomatous infiltration

B. INCREASED COMPLIANCE
   emphysema (faulty elastic architecture)

√ height of diaphragm at TLC can provide some indication of lung compliance, particularly valuable in sequential roentgenograms for comparison in:
1. Diffuse interstitial pulmonary edema
2. Diffuse interstitial pulmonary fibrosis

LUNG ZONES

Pressure Gradients in Upright Position (Erect Lung)

Gravity	20 mmHg blood pressure gradient between top and bottom for erect lung
$P_{alveolar}$	0 ± 2 cm H_20 (1.5 mmHg) at zero flow at end expiration equal to atmospheric pressure
P_{venous}	~ 5 (–5 at apex → +15 mmHg at base) mmHg
$P_{arterial}$	15 (range, 5 at apex → 25 mmHg at base) mmHg

Vertical Zonal Distribution

Zone 1: $P_{alveolar} > P_{arterial} > P_{venous}$
positive pressure ventilation / lung hemorrhage → complete vascular collapse → cessation of blood flow (= alveolar dead space)

Zone 2: $P_{arterial} > P_{alveolar} > P_{venous}$
about 3 cm above the heart → cyclical capillary blood flow (= no flow in diastole to maximum flow during systole = starlings resistor or waterfall effect)

Zone 3: $P_{arterial} > P_{venous} > P_{alveolar}$
lung in health → continuous blood flow throughout cardiac cycle determined by arteriovenous pressure difference; transmural pressure increases due to gravity → increase in vessel caliber

Zone 4: $P_{arterial} > P_{interstitial} > P_{venous} > P_{alveolar}$
lung base at low lung volumes or pulmonary edema → interstitial pressure rises with ⇓ in lung volume (← reduced radial tethering of lung) OR fluid leakage from lung vessels; pressure is highest at lung base due to weight of lung above → increase in resistance to flow → ⇓ caliber of extra-alveolar blood vessels

Effect on V/Q ratio
- highest in zone 1 of lung apex in erect person because perfusion is nearly absent
- lower in zone 3 with both high ventilation, perfusion and lymphatic drainage in erect chest

MEDIASTINUM

Terminology: coined by Spigelius "Quod per medium stat" = "what sits in the middle"

A. SUPERIOR MEDIASTINAL COMPARTMENT
= thoracic inlet

B. INFERIOR MEDIASTINAL COMPARTMENT

(1) Anterior mediastinum = retrosternal region
Anterior boundary: sternum
Posterior boundary: pericardium, aorta, brachiocephalic vessels
Superior boundary: thoracic inlet
Inferior boundary: diaphragm
Contents: thymus, lymph nodes, adipose tissue, internal mammary vessels

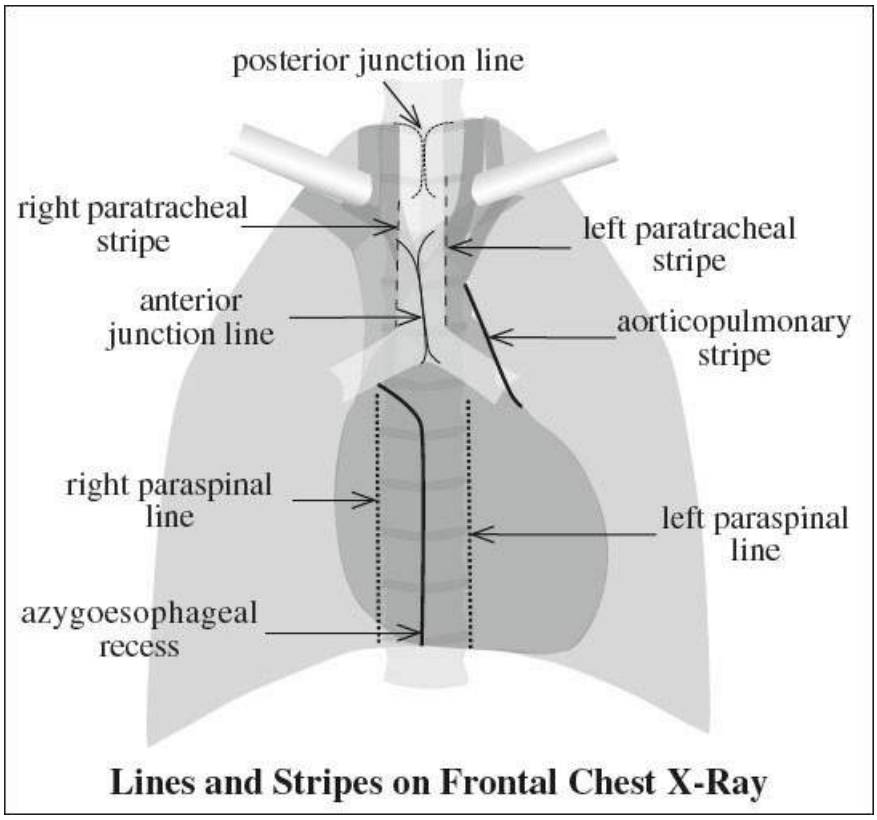
(2) Middle mediastinum = visceral region
Anterior boundary: pericardium
Posterior boundary: pericardium, posterior tracheal wall
Superior boundary: thoracic inlet
Inferior boundary: diaphragm
Contents: heart, pericardium, ascending + transverse aorta, SVC, IVC, brachiocephalic vessels, pulmonary vessels, trachea + main bronchi, lymph nodes, phrenic n., vagus n., left recurrent laryngeal n.

(3) Posterior mediastinum = contains esophagus, descending aorta, paraspinal region
Anterior boundary: posterior trachea, pericardium
Posterior boundary: line 1 cm posterior to the anterior edge of vertebral column
Superior boundary: thoracic inlet
Inferior boundary: diaphragm
Contents: esophagus, descending aorta, azygos + hemiazygos veins, thoracic duct, vagus n., splanchnic n., lymph nodes, fat

Lung-Mediastinal Interfaces on Frontal CXR

1. **Anterior junction line**
   = apposing pleural reflections
   Location: anterior to aorta behind upper ⅔ of sternum; does not extend above manubriosternal junction
   Thickness: 4 layers of pleura separated by variable amount of fat
   Course: obliquely from upper right to lower left
   Visualization in: 25–57%
   Abnormal in: thyroid mass, lymphadenopathy, neoplasm, thymic mass, lipomatosis
2. **Posterior junction line**
   = apposing 4 layers of pleural reflections
   Location: posterior to esophagus and anterior to spine (between 3rd–5th thoracic vertebrae); typically projecting through trachea
   Course: vertically from lung apices to top of aortic arch (above suprasternal notch)
   Visualization in: 32%
   Abnormal in: esophageal mass, lymphadenopathy, aortic disease, neurogenic tumor
3. **Right paratracheal stripe**
   = 1–4 mm uniformly thick line between tracheal air column and right lung
   Location: undersurface of right clavicle to azygos arch
   Course: vertical
   Visualization in: 94–97%
   Abnormal in: paratracheal lymphadenopathy, tracheal ca. + stenosis, thyroid + parathyroid neoplasm
4. **Left paratracheal stripe**
   = uniformly thick line between tracheal air column and left upper lobe
   Location: superiorly from aortic arch to left subclavian a.
   Course: vertical
   Visualization in: 21–31%
   Abnormal in: left pleural effusion, left paratracheal lymphadenopathy, neoplasm, mediastinal hematoma
5. **Azygoesophageal recess**
   = right lung abutting the azygos vein posteriorly and esophagus anteriorly
   Location: undersurface of azygos arch to aortic hiatus
   Course: vertical straight / mild leftward convexity
   Abnormal in: lymphadenopathy, hiatal hernia, bronchopulmonary foregut malformation, esophageal neoplasm, pleural abnormalities, cardiomegaly with left atrial enlargement
6. **Right paraspinal line**
   = lung abutting the lateral margins of thoracic vertebral bodies (left paraspinal line more often seen than right)
   Location: from 8th to 12th thoracic vertebra
   Course: straight vertical
   Visualization in: 23%
   Abnormal in: osteophytes, prominent mediastinal fat, neoplasm, mediastinal hematoma, extramedullary hematopoiesis

7. **Left paraspinal line**



= lung abutting the lateral margins of thoracic vertebral bodies, mediastinal fat, paraspinal muscles

Location: aortic arch to diaphragm, typically medial to lateral wall of descending thoracic aorta

Course: straight vertical

Visualization in: 41%

Abnormal in: osteophytes, prominent mediastinal fat, neoplasm, mediastinal hematoma, extramedullary hematopoiesis, tortuosity of descending thoracic aorta, esophageal varices

8. **Aorticopulmonary stripe**

= interface of anterior left lung + mediastinal fat anterolateral to left pulmonary artery + aortic arch

Course: straight / mildly convex

Abnormal in: pneumomediastinum, thyroid + thymic mass, prevascular lymphadenopathy

9. **Aortic-pulmonary (AP) window** / stripe

= space between inferior wall of aortic arch + superior wall of left pulmonary artery

Border:

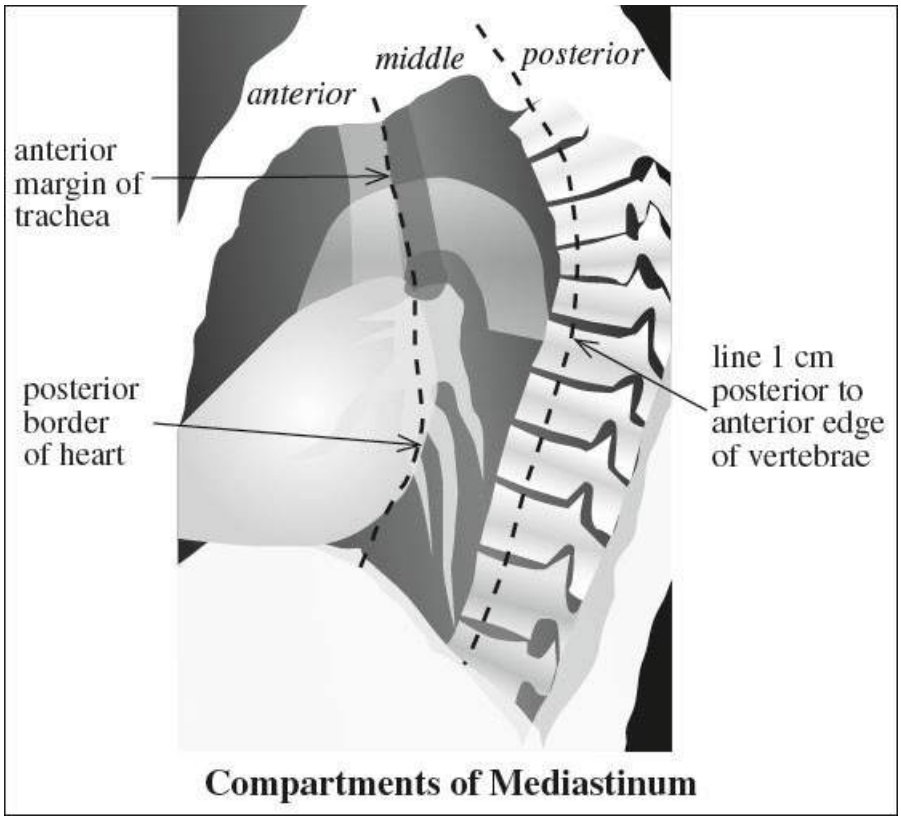
- superior: inferior wall of aortic arch
- inferior: superior wall of left pulmonary artery
- posterior: anterior wall of ascending aorta

- › anterior: posterior wall of ascending aorta
- › lateral: left lung + pleura
- › medial: trachea, lateral wall of LMB, esophagus

Location: posterior to aorticopulmonary stripe
Course: straight / concave reflection along mediastinum
Abnormal in: mediastinal fat, lymphadenopathy, aneurysm of aorta / bronchial artery, nerve sheath tumor (recurrent laryngeal nerve, left vagus nerve)

Lung-Mediastinal Interfaces on Lateral CXR

1. **Tracheoesophageal / posterior tracheal stripe**
   = formed by air within trachea and right lung
   Location: anterior border of retrotracheal space (= Raider triangle)
   Thickness: up to 2.5 mm; up to 5.5 mm (if wall of air-containing esophagus included)
   Course: vertical
   Abnormal in: congenital developmental anomalies of aortic arch, acquired vascular lesion, esophageal lesion, lymphatic malformation, mediastinitis, posttraumatic hematoma



Compartments of Mediastinum

2. **Posterior wall of bronchus intermedius**
   = formed by air in bronchus intermedius, which descends for 3–4 cm, and lung within azygoesophageal recess
   Course: thin vertical / slightly oblique stripe that projects through the radiolucent area created by left upper lobe bronchus

Thickness: 0.5–3.0 mm
Visualization in: 90–95%
Abnormal in: pulmonary edema, lung neoplasm, lymphadenopathy

THYMUS

[*thymos*, Greek = warty excrescence, soul, spirit]

Embryogenesis:

dorsal + ventral wings of 3rd (and possibly 4th) pharyngeal (branchial) pouch begin to form elongated cylindrical primordia during 7th week (= thymopharyngeal ducts); both ducts migrate caudally and medially into anterior mediastinum pulling inferior parathyroid glands along; thymic primordia fuse at their lower poles inferior to thyroid gland during 8th week; thymic tail thins + disappears by 8th week of GA

◊ Residual thymic tissue in neck in 1.8–21%

Histo: contains elements of all 3 germinal layers; until 9th week EGA purely epithelial; during 10th week EGA lymphoid cells migrate from fetal liver + bone marrow into primordia causing thymic lobulation; differentiation into cortex and medulla completed by 16th week EGA

Cortex: primarily lymphocytes = thymocytes

Medulla: more epithelial cells = nurse cells (essential for maturation of T lymphocytes); Hassall corpuscles (round keratinized formations with mature epithelial cells)

Function: development + maturation of immune system during childhood, ie, T-cells (regulating cellular immunity) and B cells (regulating humoral immunity)

Thymic weight:

increases from birth to age 11–12 years (22 ± 13 g in neonate, 34 ± 15 g at puberty); ratio of thymic weight to body weight decreases with age (largest during infancy, fatty involution after puberty, total fatty replacement after age 60)

Extent: from manubrium to 4th costal cartilage; may bulge into neck / extend down to diaphragm

√ normal thymus visible in 50% of neonates 0–2 years of age
√ "notch" sign = indentation at junction of thymus + heart
√ "sail" sign = triangular density extending from superior mediastinum
√ "wave" sign = rippled border due to indentation by ribs
√ shape changes with respiration + position

CXR:

√ prominent normal thymus visible in 50% of neonates + infants 0–3 years of age
√ **"notch" sign** = indentation at junction of thymus + heart
√ **"sail" sign** (5%) = triangular slightly right-convex density extending from superior mediastinum, usually on right side with sharply demarcated base caused by minor fissure
√ "wave" sign = rippled / undulated / scalloped / wavy lateral border due to indentation by ribs
√ shape changes with respiration + position

DDx: mediastinal mass, upper lobe pneumonia, atelectasis

CT:

√ measurement (perpendicular to axis of aortic arch):

› mean thickness of 11 (5) mm at < 20 (> 50) years
› maximal thickness of < 18 (< 13) mm at < 20 (> 20) years
√ visualization of thymus:
√ detected in 83% (17%) of subjects < 50 (> 50) years of age
√ shape of thymus:
√ quadrilateral with convex borders in child < 5 years
√ triangular like an arrowhead (62%), bilobed (32%), single lobe (6%) in older child
√ density of thymus:
√ muscular density of 30 HU (before puberty)
√ flat / concave borders with abundant fat (after puberty)

US (supra-, trans-, parasternal approach in infants):
√ homogeneous finely granular echotexture with multiple linear / branching echogenic foci
√ mildly hypoechoic (25%) / isoechoic (75%) to liver, spleen, thyroid
√ smooth well-defined margin ← fibrous capsule
√ hypo- / avascular
N.B.: pliable organ WITHOUT causing compression / displacement of adjacent structures

MR:
√ homogeneous texture hyperintense to muscle on T1WI
√ signal intensity close to fat on T2WI

PET:
√ usually barely visible
√ striking FDG avidity in rebound hyperplasia

Ectopic Thymus

√ solid mass of identical attenuation / signal as normal thymus
√ often connected to normal thymus
√ cystic mass (= endodermal-lined cavity of thymopharyngeal duct / cystic degeneration of Hassall corpuscles or glandular epithelium)

(1) Unilateral failure of thymic primordium to descend
√ neck mass of thymic tissue on one side of neck
√ ipsilateral absence of normal thymic lobe
√ parathyroid tissue within ectopic thymus

(2) Small rest of thymus left behind within thymopharyngeal tract during migration ← failure to involute
√ neck mass (32%)
√ normally positioned bilobed thymus

(3) Atypical location ← sequestration: trachea, skull base, intrathyroidal, behind thyroid (26%), adjacent to SVC / brachiocephalic vessels / aorta, posterior mediastinum, dermis
√ widened superior mediastinum

Rx: no treatment unless symptomatic

DIAPHRAGM

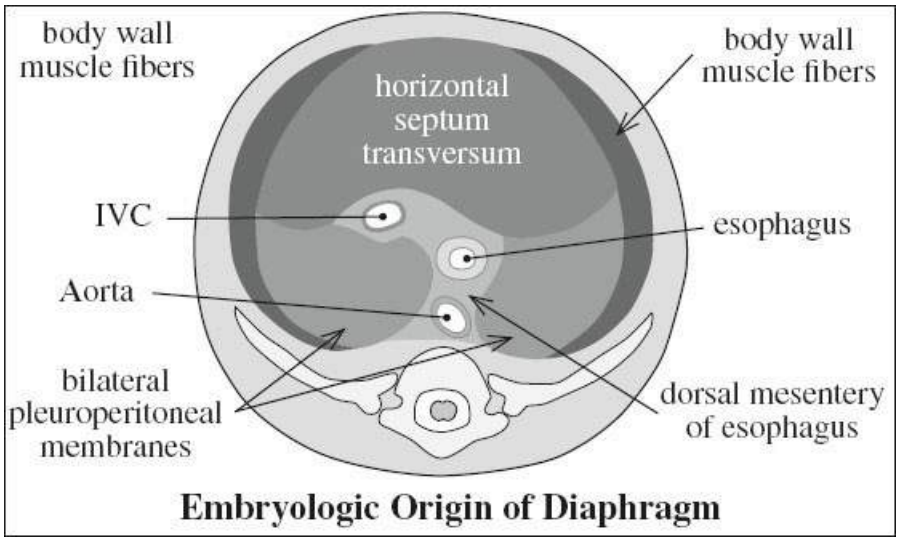
= musculofibrous septum separating abdominal + thoracic cavities

Time of formation: 4th–12th weeks of embryonic life

Embryologic precursors & final structures:

ventral septum transversum → gradually extends posteriorly around esophagus + great vessels → fuses with foregut mesentery → forms posteromedial portions by 8th week → lateral margins of diaphragm from muscles of thoracic wall → posterolaterally located pleuroperitoneal foramina close last

(1) Septum transversum ventrally during 3rd–5th week → central tendon
(2) Pleuroperitoneal membrane → muscular diaphragm
(3) Dorsal mesentery of esophagus → median portion of diaphragm and crura
(4) Body wall → peripheral muscle fibers of diaphragm attached to
    (a) sternum
    (b) costal margin of inferior ribs
    (c) lumbar portion
        › arcuate ligaments = 2 pairs of medial + lateral lumbocostal arches
            » **medial arcuate ligament**: arches over psoas major m. + attaches to anterior aspect of transverse process of L1
            » **lateral arcuate ligament**: arches over quadratus lumborum m. + attaches laterally to 12th rib + medially to anterior aspect of transverse process of L1
        › diaphragmatic crura = bilateral musculotendinous pillars attaching to anterolateral surface of lumbar vertebrae + intervertebral fibrocartilage:
            » L1-L3 for longer + broader **right crus**
            » L1-L2 for shorter **left crus**
            [*crus*, Latin = shin, leg, pillar support of a bridge]
            » medial fibers of ascending crura join to form an arch ventral to aorta just above celiac trunk = **median arcuate ligament**



Embryologic Origin of Diaphragm

Function: major respiratory muscle for quiet breathing (in concert with accessory muscles of respiration); contraction → expansion of thoracic cavity → ⇓ intrathoracic pressure → drawing of air into lungs

Openings: (1) aortic hiatus at T12 behind median arcuate lig.
(2) esophageal hiatus at T10
(3) vena cava hiatus at T8 through central tendon

(4) Medial arcuate ligament covering psoas muscle
(5) Lateral arcuate ligament covering quadratus lumborum muscle

Innervation: both phrenic nerves (C3-C5) + lower intercostal nn.

Blood supply: aorta → internal thoracic a. + inferior phrenic aa. → pericardiophrenic a. + musculophrenic artery

Pleuroperitoneal pressure gradient: negative 7–22 cm H_2O

US:

√ thick echogenic line = specular reflection from air-diaphragm interface
√ thin hypoechoic line = diaphragmatic muscle
√ both domes are visualized together (on oblique transverse subxiphoid view obtained from midline position)

CXR:

@ Infant / young child:
√ right dome of diaphragm at level of anterior 6th rib
√ left dome of diaphragm at level of anterior 7th rib (= one intercostal space lower)

@ Adult
√ right dome at 9.7 ± 0.8 (range, 7.4–11.3) thoracic vertebral levels below the top of 1st thoracic vertebra
√ left dome at 10.2 +/- 0.8 (range, 8.1–11.8) thoracic vertebral levels below the top of 1st thoracic vertebra
◊ Position of diaphragm tends to be <u>lower</u> with higher age, lower weight, smaller thoracic dimensions; <u>flatter</u> with higher age, weight, transverse thoracic dimension, pack-years smoked, and male gender

Diaphragmatic Variants

1. Diaphragmatic slip
   = fold / strip of muscle bundle protruding from inferior surface of diaphragm ± indentation of liver or spleen
   DDx: peritoneal implant, lymph node, mass
2. Hypertrophic median arcuate ligament
   = fibrous arch uniting diaphragmatic crura passing over aorta
   (a) superior to origin of celiac trunk (85%)
   (b) crossing over proximal portion of celiac trunk → vessel indentation (15%) → celiac artery compression / median arcuate ligament syndrome
3. Partial duplication of diaphragm (R > L)
   Associated with: cardiovascular malformations, ipsilateral pulmonary maldevelopment
   √ duplicated accessory diaphragm extends obliquely upward + backward to attach to 3rd–7th ribs posteriorly
   √ lower lung lobe may be partially / completely contained within accessory diaphragm + true hemidiaphragm
4. Diaphragmatic discontinuity (11%)
   Location: between crura + lateral arcuate ligaments
   DDx: diaphragmatic rupture

Retrocrural Space

= triangular region forming the most inferior portion of the posterior mediastinum

Boundaries:

› anteriorly and laterally: diaphragmatic crura decussating in front of aorta

› posteriorly: ventral aspect of vertebral bodies

Communication: posterior mediastinum + retroperitoneum

Contents:

› vessels:

» aorta and its arterial branches (= lower posterior intercostal + subcostal arteries)

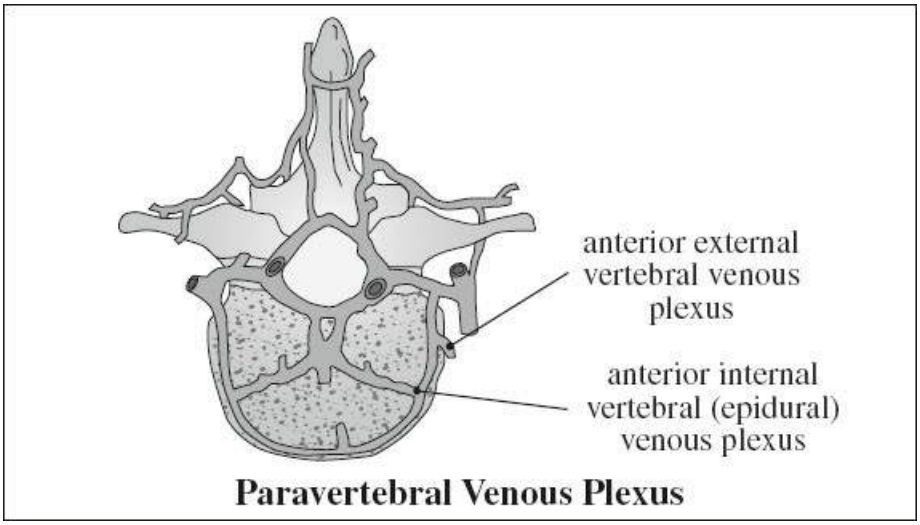
» azygos vein (R), hemiazygos vein (L)

» ascending lumbar venous plexus = valveless venous system freely communicating along entire extent of spine

› nerves: sympathetic trunks + splanchnic nerves

› lymphatics: lymph nodes (draining stations for posterior diaphragm, posterior mediastinum, lumbar spine), thoracic duct, cisterna chyli

› fat



Paravertebral Venous Plexus

Cisterna Chyli

= bulbous dilatation formed by convergence of lymphatic channels at level of upper lumbar vertebral bodies

Location: usually to right of aorta (occasionally left-sided / retroaortic)

› receives 2 afferent lumbar and intestinal lymphatic trunks

› ascends as thoracic duct

√ tubular shape (most common, in 30–43%) / rounded / oval / plexiform / fusiform:

Lymphangiography: visualized in 52%

CT: visualized in 1.7%

√ low near-water attenuation

√ delayed enhancement after oral ingestion of ethiodized oil / IV injection of contrast material

MR: visualized in 15%–96%

Thoracic Duct

Origin: arises from cisterna chyli anterior to L1-L2 (10–15 mm in diameter and 5–7 cm long)

Course: enters thorax through aortic hiatus; ascends in right prevertebral location (between azygos vein and descending aorta); swings to left at T4–6 posterior to esophagus; ascends for a short distance along right of aorta; crosses behind aortic arch; runs ventrally at T3 between left common carotid artery + left subclavian artery

Termination: 3–5 cm above clavicle at venous angle (= junction of left subclavian + internal jugular veins)

Variation: two (33%) or more (in up to 50%) main ducts each consisting of up to 8 separate channels

Azygos Vein

= major tributary of SVC

Origin: arises from junction of lumbar azygos with right ascending lumbar + subcostal vein

Course: travels along right anterior borders of thoracic vertebrae up to level of carina → traverses middle mediastinum → arches over right tracheobronchial angle → drains posteriorly into distal SVC

Azygos arch: on PA CXR at tracheobronchial angle = inferior margin of right paratracheal stripe

Transverse diameter: 6–7 mm (normal); 10 mm (upper limits); up to 15 mm (in pregnancy)

CHEST DISORDERS

AIDS

= ACQUIRED IMMUNE DEFICIENCY SYNDROME

= ultimately fatal disease characterized by HIV seropositivity, specific opportunistic infections, specific malignant neoplasms (Kaposi sarcoma, Burkitt lymphoma, primary lymphoma of brain)

= patient with CD4 cell count < 200 cells/μL (normal range, 800–1,200 cells/μL)

Prevalence: 36.9 million HIV infections worldwide with 2 million new infections (2014); 47,352 North Americans newly infected with HIV with 13,712 deaths from AIDS (2013); 13% unaware of infection; > 50% develop pulmonary disease

Organism: human immunodeficiency virus (HIV) = human T-cell lymphotropic virus type III (HTLV III) = lymphadenopathy-associated virus (LAV)

Pathomechanism:

HIV retrovirus attaches to CD4 molecule on surface of T-helper lymphocytes + macrophages + microglial cells; after cellular invasion HIV genetic information is incorporated into cell's chromosomal DNA; virus remains dormant for weeks to years; after an unknown stimulus for viral replication CD4 lymphocytes are destroyed (normal range of 800–1,000 cells/mm^3) and others become infected leading to impairment of the immune system; CD4 lymphocyte number and function decreases (at a rate of ~ 50–80 cells/year)

AIDS-defining illness related to CD4 T-lymphocyte count [cells/μL]:

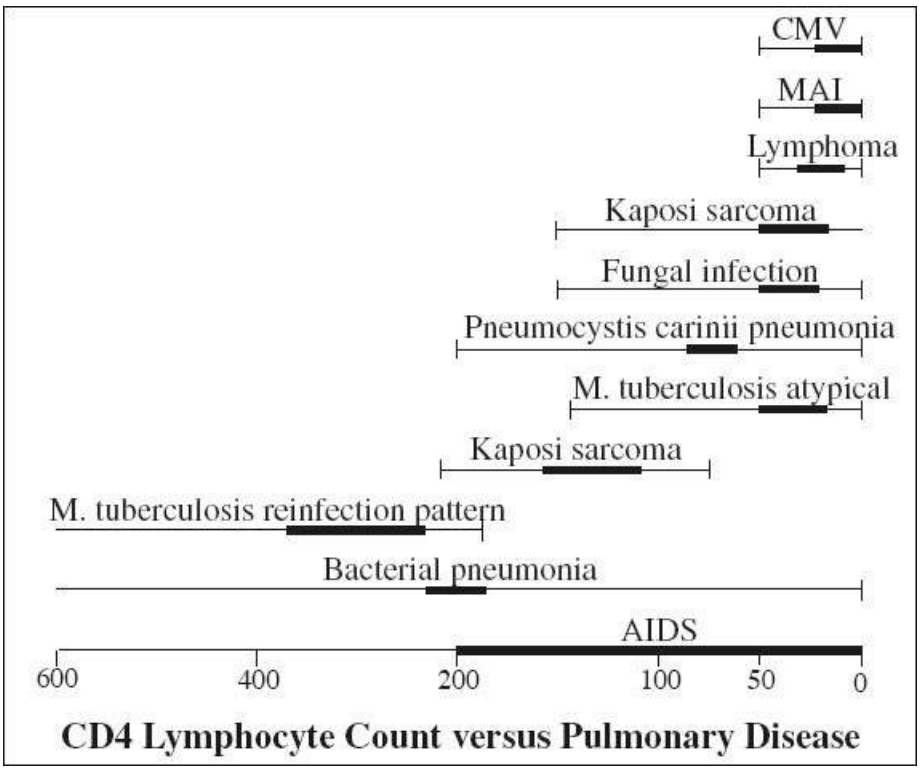
< 400	extrapulmonary Mycobacterium tuberculosis, Kaposi sarcoma
< 200	Candida albicans (thrush, hairy leukoplakia), Histoplasma capsulatum, Cryptosporidium species, Pneumocystis carinii pneumonia, non-Hodgkin lymphoma
< 150	cerebral toxoplasmosis
< 100	Cytomegalovirus, Herpes simplex virus, Mycobacterium avium complex (intestinal CMV + MAI infection)
< 50	AIDS-related lymphoma

Prognosis: median survival with a CD4 lymphocyte count of < 50 cells/mm^3 is 12 months

Transmission by: intimate sexual contact, exposure to contaminated blood / bloody body secretions

Groups at risk:

1. Homosexual males (74%)
2. IV drug abusers (16%)



CD4 Lymphocyte Count versus Pulmonary Disease

3. Recipients of contaminated blood products (3%)
4. Sexual partner of drug abuser + bisexual man
5. Infants born to a woman infected with HIV virus

◊ HIV antibodies present in > 50% of homosexuals + 90% of IV drug abusers!

◊ Rate of heterosexual transmission is increasing!

Clinical classification:

group I acute HIV infection with seroconversion

group II asymptomatic HIV infection

group III persistent generalized lymphadenopathy

group IV other HIV disease

- › subgroup A constitutional disease
- › subgroup B neurologic disease
- › subgroup C secondary infectious disease
- › subgroup D secondary cancers
- › subgroup E other conditions

AIDS-defining pulmonary conditions (CDC, 1993):

(1) Tracheal / bronchial / pulmonary candidiasis
(2) Pulmonary CMV infection
(3) Herpes simplex bronchitis / pneumonitis
(4) Kaposi sarcoma
(5) Immunoblastic / Burkitt lymphoma
(6) Pneumocystis carinii pneumonia

(7) Mycobacterium tuberculosis / avium complex / kansasii
(8) Recurrent pneumonia

A. LYMPHADENOPATHY

Cause: reactive follicular hyperplasia = HIV adenopathy (50%), AIDS-related lymphoma (20%), mycobacterial infection (17%), Kaposi sarcoma (10%), metastatic tumor, opportunistic infection with multiple organisms, drug reaction

Location: mediastinum, axilla, retrocrural

B. OPPORTUNISTIC INFECTION

accounts for majority of pulmonary disease

◊ Pulmonary infection is often the first AIDS-defining illness!

1. **Pneumocystis jirovecii pneumonia** (60–80%) (formerly Pneumocystis carinii pneumonia)

20–40% develop > 1 episode during disease

- CD4+ T helper lymphocyte cell count ≤ 200/mm³
- subacute insidious onset with malaise, minimal cough

√ bilateral ground-glass infiltrates without effusion / adenopathy
√ bilateral perihilar interstitial infiltrates
√ diffuse bilateral alveolar infiltrates
√ frequently associated with pneumatoceles
√ apical predominance (in patients on prophylactic aerosolized pentamidine)

Mortality: in 25% fatal

2. Fungal disease (< 5%)

(a) **Cryptococcus neoformans pneumonia** (2–15%) usually associated with brain / meningeal disease
√ segmental infiltrate + superimposed pulmonary nodules ± lymphadenopathy ± pleural effusion

(b) **Histoplasma capsulatum**
√ typically diffuse nodular / miliary pattern at time of diagnosis
√ normal CXR in up to 35%

(c) Coccidioides immitis
√ diffuse infiltrates + thin-walled cavities

(d) Candida albicans

(e) Aspergillus: less common + less invasive ← relative preservation of neutrophilic function
› invasive pulmonary aspergillosis
› chronic necrotizing aspergillosis
› necrotizing tracheobronchitis
› obstructing bronchopulmonary aspergillosis

3. Mycobacterial infection (10% per year)

(a) **M. tuberculosis** (increasing frequency)
◊ AIDS patients are 500 times more likely to become infected than general population!
√ postprimary TB pattern with upper-lobe cavitating infiltrate
- CD4 lymphocyte count of 200–500 cells/mm³

√ primary TB pattern with lung infiltrate / lung masses + hilar / mediastinal

lymphadenopathy + pleural effusion
• CD4 lymphocyte count of 50–200 cells/mm³)
√ atypical TB pattern with diffuse reticular / nodular infiltrates (CD4 lymphocyte count of < 50 cells/mm³)
√ adenopathy of low attenuation + rim enhancement

(b) **M. avium-intracellulare** (5%)
• in patients with low CD4 lymphocyte count only
√ diffuse bilateral reticulonodular infiltrates
√ adenopathy, miliary disease

(c) M. kansasii and others

4. Bacterial pneumonia (5–30%):

(a) Haemophilus influenzae, Streptococcus pneumoniae, Staphylococcus aureus
√ frequently multilobar distribution
• bacteremia (common)

(b) Nocardia pneumonia (< 5%)
usually occurs in cavitating pneumonia
√ segmental / lobar alveolar infiltrate ± cavitation ± ipsilateral pleural effusion

(c) Rhodococcus equi (aerobic, Gram-negative)
√ cavitary pneumonia

(d) Bartonella henselae (Gram-negative)
= bacillary angiomatosis
• cutaneous lesions
√ highly vascular small pulmonary nodules
√ dramatic enhancement of enlarged lymph nodes

5. **CMV pneumonia**
most frequent infection found at autopsy (49–81%), diagnosed before death in only 13–24%;
high prevalence combined with Kaposi sarcoma
• fever, nonproductive cough, dyspnea, hypoxia
√ bilateral hazy infiltrates, focal nodules, masses
√ scattered widespread ground-glass opacities
√ thickening of bronchovascular bundles
√ tree-in-bud pattern
√ bronchiectasis / bronchial wall thickening

6. Toxoplasmosis
√ coarse interstitial / nodular pattern
√ focal areas of consolidation ± cavities
DDx: indistinguishable from PCP

C. TUMOR

1. Kaposi sarcoma (15%)
2. **AIDS-related lymphoma** of B-cell origin (2–5%) primarily immunoblastic NHL / Burkitt lymphoma / non-Burkitt lymphoma; occasionally Hodgkin disease
Location: pulmonary involvement (8–15%), CNS, GI tract, liver, spleen, bone marrow
Site: primarily extranodal
√ pleural effusion (50%)

√ hilar / mediastinal adenopathy (25%) ± axillary / supraclavicular / cervical adenopathy
√ solitary / multiple well-defined pulmonary nodules (occasionally with doubling times of 4–6 weeks)
√ diffuse bilateral reticulonodular heterogeneous opacities
√ alveolar infiltrates
√ paraspinal masses

D. LYMPHOID INTERSTITIAL PNEUMONITIS
Age: in children < 13 years of age

E. SEPTIC EMBOLI

F. PREMATURE DEVELOPMENT OF BULLAE (40%) with disposition to spontaneous pneumothorax

AIDS-related Complex (ARC)

= GENERALIZED LYMPHADENOPATHY SYNDROME
= prodromal phase of HIV seropositivity, generalized lymphadenopathy, CNS diseases other than those associated with AIDS
Time interval: ~ 10 years between seroconversion + clinical AIDS
• weight loss, malaise, diarrhea
• fever, night sweats, lymphadenopathy
• lymphopenia with selective decrease in helper T-cells

ADULT RESPIRATORY DISTRESS SYNDROME

= SHOCK LUNG = POSTTRAUMATIC PULMONARY INSUFFICIENCY = HEMORRHAGIC LUNG SYNDROME = RESPIRATOR LUNG = STIFF LUNG SYNDROME = PUMP LUNG = CONGESTIVE ATELECTASIS = OXYGEN TOXICITY = ACUTE RESPIRATORY DISTRESS SYNDROME
= severe unexpected life-threatening acute respiratory distress characterized by abrupt onset of marked dyspnea, increased respiratory effort, severe hypoxemia associated with widespread airspace consolidation

Etiology:
◊ ARDS is the most severe form of permeability edema associated with diffuse alveolar damage

A. PRIMARY = DIRECT INJURY (← pulmonary disease)
= exposure to chemical agents, infectious pathogens, gastric fluid, toxic gas
Associated with: pulmonary consolidation

B. SYSTEMIC CONDITION (← extrapulmonary disease)
= sepsis, pancreatitis, severe trauma, blood transfusion → systemic biochemical cascade creating oxidating agents, inflammatory mediators, enzymes
Associated with: interstitial edema, alveolar collapse

Histo:
› up to 12 hr: fibrin + platelet microemboli
› 12–24 hr: interstitial edema
› 24–48 hr: capillary congestion, extensive interstitial + alveolar proteinaceous edema + hemorrhage, widespread microatelectasis, destruction of type I alveolar

epithelial cells

› 5–7 d: extensive hyaline membrane formation, hypertrophy + hyperplasia of type II alveolar lining cells

› 7–14 d: extensive fibroblastic proliferation in interstitium + within alveoli, rapidly progressing collagen deposition + fibrosis; almost invariably associated with infection

Predisposed:

hemorrhagic / septic shock, massive trauma (pulmonary / general body), acute pancreatitis, aspiration of liquid gastric contents, heroine / methadone intoxication, massive viral pneumonia, traumatic fat embolism, near-drowning, conditions leading to pulmonary edema

mnemonic: DICTIONARIES

Disseminated intravascular coagulation
Infection
Caught drowning
Trauma
Inhalants: smoke, phosgene, NO_2
O$_2$ toxicity
Narcotics + other drugs
Aspiration
Radiation
Includes pancreatitis
Emboli: amniotic fluid, fat
Shock: septic, hemorrhagic, cardiogenic, anaphylactic

- initially few / no symptoms
- rapidly progressive dyspnea, tachypnea, cyanosis
- hypoxia unresponsive to oxygen therapy ← AV shunting
- NO increase in pulmonary capillary pressure

Stages (often overlapping):

1st (early / exudative) stage

= interstitial edema with high protein content rapidly filling the alveolar spaces associated with hemorrhage → ensuing hyaline membrane formation

√ interstitial edema (with high protein content) initially
√ perihilar areas of increased opacity following rapidly
√ widespread alveolar consolidation with predominantly peripheral cortical distribution
√ air bronchogram
√ gravitational gradient (best seen on CT) ← dependent atelectasis

DDx: cardiogenic edema (cardiomegaly, apical vascular distribution, Kerley lines)

2nd (proliferative) stage

= organization of fibrinous exudate + subsequent regeneration of alveolar lining + thickening of alveolar septa

√ inhomogeneous areas of patchy / diffuse ground-glass opacities

3rd (fibrotic) stage (after days to weeks)

= varying degrees of scarring
√ dependent gradient of consolidation (often)

√ bronchial dilatation with improvement / even resolution
√ ± progression to irreversible varicoid bronchial enlargement
√ subpleural and intrapulmonary cysts
Cx: pneumothorax

CXR:
√ NO cardiomegaly / pleural effusion
› up to 12 hours:
√ characteristic 12-hour delay between clinical onset of respiratory failure and CXR abnormalities
› 12–24 hours:
√ patchy ill-defined opacities throughout both lungs
› 24–48 hours:
√ massive airspace consolidation of both lungs
› 5–7 days:
√ consolidation becomes inhomogeneous ← resolution of alveolar edema
√ local areas of consolidation ← pneumonia
› > 7 days:
√ reticular / bubbly lung pattern ← diffuse interstitial + airspace fibrosis

ALPHA-1 ANTITRYPSIN DEFICIENCY

= rare autosomal recessive disorder
Source: alpha-1 antitrypsin (glycoprotein) is to > 90% synthesized in hepatocytes + released into serum
Gene: codominant gene expression on chromosome 14 with > 100 genetic variants of the protein; most severe hepatopulmonary manifestations result from homozygous PiZZ phenotype
Action: proteolytic inhibitor of neutrophil elastase, trypsin, chymotrypsin, plasmin, thrombin, kallikrein, leukocytic + bacterial proteases; neutralizes circulating proteolytic enzymes
Mode of injury from deficiency:
PMNs + alveolar macrophages sequester into lung during recurrent bacterial infections + release neutrophil elastase, which acts unopposed + digests basement membrane
Age: early age of onset (20–30 years); M÷F = 1÷1
• rapid + progressive deterioration of lung function:
• dyspnea in 4th and 5th decade
◊ 20% of homozygotic individuals never develop clinically apparent emphysema
• chronic sputum production (50%)
√ severe panacinar emphysema with basilar predominance ← gravitational distribution of pulmonary blood flow:
√ ↓ in size + ↓ in number of pulmonary vessels in lower lobes
√ redistribution of blood flow to unaffected upper lung zones
√ bullae at both lung bases
√ marked flattening of diaphragm
√ minimal diaphragmatic excursion
√ multilobar cystic bronchiectasis (40%)

√ hepatopulmonary syndrome
Cx: hepatic cirrhosis (in homozygotic individuals)
◊ Most common metabolic liver disease in children
Prognosis: 15–20-year decrease in longevity in smokers relative to nonsmokers

ALVEOLAR MICROLITHIASIS

= very rare disease of unknown etiology characterized by myriad of calcospherites (= microliths composed of calcium + phosphorus) within alveoli
Cause: autosomal recessive inheritance of a gene mutation preventing production of a transporter protein for sodium-dependent transfer of phosphate into type II pneumocytes → phosphorus ions stay in alveolar space
Age peak: 30–50 years; begins in early life; has been identified in utero; M÷F = 1÷1; in 50% familial (in at least one sibling)
• usually asymptomatic (70%)
• progressive dyspnea on exertion, cyanosis, clubbing of fingers
• striking discrepancy between marked radiographic findings and mild clinical symptoms
• NORMAL serum calcium + phosphorus levels
• restrictive lung disease (↓ in residual volume and ↓ diffusion capacity)
Distribution: predisposition for posterior segments of lower lobes + anterior segments of upper lobes; medial lung >> lateral lung
√ very fine, sharply defined, sandstorm-like micronodular (< 1 mm) pattern
√ diffuse involvement of both lungs
√ obscuration of mediastinal + diaphragmatic reflections
√ vertical linear radiolucency between ribs + lung parenchyma ← subpleural cystic changes
√ intense uptake on bone scan
HRCT:
√ thickening + micronodulation of interlobular septa ← innumerable microliths within periphery of secondary pulmonary lobule
√ thickened micronodular appearance of bronchovascular + subpleural interstitium
√ pleural calcifications
√ ground-glass appearance (of microliths < 1 mm) ± "crazy paving" pattern
Prognosis:
(a) late development of pulmonary insufficiency ← interstitial fibrosis + cor pulmonale
(b) disease may become arrested
(c) microliths may continue to form / enlarge
Rx: NO effective treatment aside from lung transplant
Dx: open lung biopsy
DDx: (1) Pulmonary alveolar proteinosis, sarcoidosis, pneumoconiosis, pulmonary hemosiderosis, amyloidosis, miliary tuberculosis, metastatic pulmonary calcifications of renal failure
(2) "Mainline" pulmonary granulomatosis (IV abuse of talc-containing drugs such as methadone, rarely as numerous + scarring + loss of volume)

ALVEOLAR PROTEINOSIS

= PULMONARY ALVEOLAR PROTEINOSIS (PAP)
= rare disorder characterized by accumulation of lipoproteinaceous material in alveoli ← altered surfactant homeostasis

Forms:

A. CONGENITAL PAP
B. PRIMARY ACQUIRED PAP (90%)
   Age: median 39 years; M>> F
   Predisposed: smoking in 72%
C. SECONDARY PAP
   Cause: hematologic cancers, pharmacologic immunosuppression, inhalation of inorganic dust (eg, silica), toxic fumes, certain infections
   Pathophysiology: functional impairment / reduced number of alveolar macrophages

Etiology: ?; associated with dust exposure (eg, silicoproteinosis is histologically identical to PAP), immunodeficiency, hematologic + lymphatic malignancies, AIDS, chemotherapy

Pathophysiology:

(a) overproduction of surfactant by granular pneumocytes
(b) defective clearance of surfactant by alveolar macrophages

Histo: alveoli filled with proteinaceous material (the ONLY pure airspace disease), normal interstitium

Age peak: 39 years (range, 2–70 years); M÷F = 3÷1

• asymptomatic (10–20%), gradual onset of dyspnea + cough
• weight loss, weakness, hemoptysis, defect in diffusing capacity

√ bilateral air-space disease with ill-defined nodular / confluent ground-glass pattern:
  √ perihilar predominance of "bat-wing" configuration WITHOUT signs of left-sided heart failure
√ small acinar nodules + coalescence + consolidation
√ patchy peripheral / primarily unilateral infiltrates (rare)
√ reticular / reticulonodular / linear interstitial pattern with Kerley B lines (late stage)
√ slow clearing over weeks or months
√ slow progression (⅓), remaining stable (⅔)
√ NO adenopathy, NO cardiomegaly, NO pleural effusion

HRCT:

√ crazy-paving pattern = combination of patchy ground-glass opacities + smooth interlobular septal thickening often in geographic distribution
√ sharp demarcation between normal + abnormal lung
√ consolidation

Cx: susceptible to pulmonary infections ← poorly functioning macrophages + excellent culture medium for opportunistic pathogens (esp. Nocardia asteroides), other common respiratory pathogens

Prognosis:

highly variable course with clinical and radiologic episodes of exacerbation + remissions

(a) 50% improvement / recovery
(b) 30% death within several years under progression

Dx: bronchoalveolar lavage, transbronchial / open lung biopsy
Rx: bronchopulmonary lavage
DDx:
(a) during acute phase: pulmonary edema, diffuse pneumonia, ARDS
(b) in chronic stage:
1. Idiopathic pulmonary hemosiderosis (boys, symmetric involvement of mid + lower zones, progression to nodular + linear pattern)
2. Hemosiderosis (bleeding diathesis)
3. Pneumoconiosis
4. Hypersensitivity pneumonitis
5. Goodpasture syndrome (more rapid changes, renal disease)
6. Desquamative interstitial pneumonia ("ground-glass" appearance, primarily basilar + peripheral)
7. Pulmonary alveolar microlithiasis (widespread discrete intraalveolar calcifications primarily in lung bases, rare familial disease)
8. Sarcoidosis (usually with lymphadenopathy)
9. Lymphoma
10. Bronchioloalveolar cell carcinoma (more focal, slowly enlarging with time)

AMNIOTIC FLUID EMBOLISM

= most common cause of maternal peripartum death
• dyspnea, shock during / after labor + delivery
Pathogenesis: amniotic debris enters maternal circulation resulting in:
(1) Pulmonary embolization
(2) Anaphylactoid reaction
(3) DIC
√ usually fatal before radiographs obtained
√ may demonstrate pulmonary edema

AMYLOIDOSIS OF THE CHEST

= disease characterized by an extracellular deposition of insoluble fibrillar proteins aggregating into twisted ß-pleated sheets of great chemical diversity
Histo: protein (immunoglobulin) / polysaccharide complex; affinity for Congo red stain

Pulmonary Amyloidosis

Frequency: 1° amyloidosis (in up to 70%), 2° amyloidosis (rare)
A. NODULAR PARENCHYMAL TYPE (most common)
Age: 50–60 years of age; M÷F = 1÷1
• usually asymptomatic, incidental discovery on CXR
Size: 5–15 cm
Site: subpleural / peripheral
Distribution: concentrated in lower lobes
√ solitary mass = **amyloidoma** (60%)
√ multiple pulmonary nodules:

√ smooth lobulated / spiculated margins
√ cavitation (rare)
√ ± central calcification / ossification (in up to 50%)
DDx: chronic renal failure
√ mediastinal / hilar adenopathy
Dx: AL amyloid (= amyloid light chain) on biopsy
Prognosis: excellent with slow progression over years; incurable; treatment rarely required
Rx: low-dose prednisone, colchicine
DDx: metastatic disease, granulomatous disease (fungal, TB), rheumatoid lung, sarcoidosis, mucoid impaction, bronchogenic carcinoma, chondroma

Classification of Amyloidosis

Subtype	*Common Anatomic Distribution*	*Fibrillar protein*	*Common Disease Associations*	*Treatment*
Primary amyloidosis	multiple organs	amyloid light chain (AL)	plasma cell dyscrasias (eg, multiple myeloma)	chemotherapy (melphalan, steroids), stem cell transplantation
Secondary amyloidosis	single organ	serum amyloid A (AA)	chronic infection (eg, osteomyelitis), chronic systemic inflammation (eg, rheumatoid arthritis)	symptomatic (eg, diuresis in cardiac amyloidosis, surgery in tracheal amyloidosis), treatment of underlying condition

B. DIFFUSE ALVEOLAR SEPTAL TYPE (least common)
◊ Most commonly associated with systemic amyloidosis
Age: > 60 years of age
May be associated with: concurrent systemic involvement
• usually asymptomatic with normal CXR
• cough + dyspnea with abnormal CXR

CT:
√ well-defined scattered 2–4 mm micronodules
√ reticulations = widespread small irregular densities (exclusively interstitial involvement) ± calcification
√ interlobular septal thickening
√ may become confluent ± honeycombing
Distribution: basal + peripheral predominance

√ punctate lung calcifications
√ pleural thickening
√ ± pleural effusion
√ rarely associated with thin-walled cysts (most commonly in Sjögren syndrome)
Dx: AL amyloid (= amyloid light chain) on biopsy
Prognosis: median survival of 16 months ← pulmonary hypertension, respiratory failure
DDx: pneumoconiosis (especially asbestosis), idiopathic pulmonary fibrosis, rheumatoid lung, Langerhans cell histiocytosis, scleroderma, cancer with lymphangitic spread

Airway Amyloidosis (2nd most common manifestation)
= TRACHEOBRONCHIAL TYPE
= diffuse / solitary (rarely) submucosal deposition of amyloid in trachea + segmental airways
Age: 50–70 years; M > F

Rarely associated with: systemic amyloidosis
- hemoptysis (most frequent complaint)
- stridor, cough, dyspnea, hoarseness, wheezing

CXR: notoriously insensitive

CT:
√ diffuse rigid narrowing of a long tracheal segment (best depicted on COR and SAG reconstructions)

√ calcified / ossified tracheal wall also affecting posterior membrane of trachea (DDx to tracheobronchopathia osteochondroplastica / relapsing polychondritis)
√ luminal narrowing by multiple nodules protruding from wall of trachea / large bronchi
√ prominent bronchovascular markings
√ obstruction with consolidation
√ atelectasis
√ hyperinflation
√ bronchiectasis
√ destructive pneumonitis

PET/CT:
√ increased FDG uptake may allow detection of early amyloidosis + response to treatment

Cx: recurrent pneumonia
Rx: local bronchoscopic resection, laser therapy, stent placement, radiation therapy
Prognosis: 30–50% 5-year survival; worse for proximal disease
DDx: endobronchial neoplasm

Mediastinal Amyloidosis (3rd most common manifestation)
Commonly associated with: systemic amyloidosis
Location: multistation lymphadenopathy / anatomically localized isolated tumefactive amyloidoma
- asymptomatic lymphadenopathy (frequent)

√ enhancing lymphadenopathy
√ punctate / diffuse / eggshell lymph node calcifications

ASBESTOS-RELATED DISEASE

[*asbestos*, Greek = inextinguishable = several fibrous silicate minerals sharing the property of heat resistance]

Substances:

Aspect (length-to-diameter) ratio effects carcinogenicity:
eg, aspect ratio of 32 = 8 µm long x 0.25 µm wide

› commercial <u>amphiboles</u>: straight, rigid, needlelike
  - crocidolite = blue / black asbestos
  - amosite = brown asbestos

› commercial <u>serpentines</u> (= nonamphiboles):
  - chrysotile = white asbestos (the only mineral in the serpentine group accounting for > 90% of asbestos used in the USA)

› noncommercial contaminated amphiboles

- actinolite; anthophyllite; tremolite

(a) relatively benign:
  (1) Chrysotile in Canada
  (2) Anthophyllite in Finland, North America
  (3) Tremolite

(b) relatively malignant:
  (1) Crocidolite in South Africa, Australia
  (2) Amosite

◊ Very fine fibers (crocidolite) are associated with the largest number of pleural disease!

◊ Asbestos fibers up to 100 μm in length

Occupational exposure:

(a) asbestos mining, milling, processing

(b) insulation manufacturing, textile manufacturing, construction and demolition, pipe fitting, shipbuilding, gaskets, brake linings

Pathophysiology:

asbestos-activated macrophages produce a variety of growth factors that interact to induce fibroblast proliferation; oxygen-free radicals released by macrophages damage proteins + lipid membranes sustaining the inflammatory process

Asbestos-related Pleural Disease

1. **Pleural Effusion** (21%)

= earliest asbestos-related pleural abnormality, frequently followed by diffuse pleural thickening + rounded atelectasis

Prevalence: 3% (higher with increasing levels of asbestos exposure)

Latency period: 8–10 years after exposure

- **benign asbestos pleurisy**:
  - may be associated with chest pain (⅓)
  - usually small sterile serous / hemorrhagic exudate

√ recurrent bilateral effusions

√ ± plaque formation

DDx: TB, mesothelioma

2. **Focal Pleural Plaques** (65%)

= hyalinized collagen in submesothelial layer of parietal pleura

◊ Most useful marker of asbestos exposure!

Frequency: most common manifestation of exposure; 6% of general population will show plaques; 3–14% of dockyard workers; 58% of insulation workers

Latency period: in 10% (50%) after 20 (40) years

Histo: dense hypocellular undulating collagen fibers often arranged in a "basket weave" pattern ± focal / massive calcifications; may contain large numbers of asbestos fibers (almost exclusively chrysotile)

Location: bilateral + multifocal; posterolateral chest wall between 7th–10th rib following rib contours; lateral chest wall between 6th–9th rib; aponeurotic dome of diaphragm; mediastinum

◊ Apices + costophrenic angles are spared!

◊ RARE in fissures of lung (visceral pleura)

Site: parietal pleura (visceral pleura typically spared)

• asymptomatic, no functional impairment

CXR:

√ geographic / holly leaf-shaped veil-like opacity

√ localized sharply marginated pleural thickening

CT (more sensitive + specific):

√ usually focal nodular area of pleural thickening (< 1 cm thick) with edges thicker than central portions of plaque; in 48% only finding; in 41% with parenchymal changes; stable over time

√ thin layer of extrapleural fat separates plaque from underlying rib + intercostal muscle

√ "hairy plaque" = visceral pleural plaque + underlying short interstitial lines radiating from plaque (rare)

√ no hilar adenopathy

√ calcified (in 10–15% by X-ray, in 15–20% by CT)

Prognosis: NO risk of malignant degeneration; increased risk of developing mesothelioma + bronchogenic carcinoma

DDx: chest wall fat, rib fractures, rib companion shadow

3. **Pleural Calcification** (21–25–60%)

◊ HALLMARK of asbestos exposure!

◊ detected by CXR (CT) in 25% (60%)

Latency: 20% (40%) become visible in > 20 (40) years

Histo: calcification starts in parietal pleura; calcium deposits may form within center of plaques

√ dense lines paralleling the chest wall, mediastinum, pericardium, diaphragm

◊ Bilateral diaphragmatic calcifications with clear costophrenic angles are PATHOGNOMONIC!

√ advanced calcifications are leaflike with thick-rolled edges

DDx: talc exposure, hemothorax, empyema, therapeutic pneumothorax for TB (often unilateral, extensive sheetlike, on visceral pleura)

4. **Diffuse Pleural Thickening** (17%)

= smooth uninterrupted diffuse thickening of parietal pleura extending over at least ¼ of chest wall (visceral pleura involved in 90%, but difficult to demonstrate)

• may cause restriction of pulmonary function

May be associated with: rounded atelectasis

√ bilateral process with "shaggy heart" appearance (20%)

√ smooth (difficult to assess when viewed en face)

√ thickening of interlobar fissures

√ focally thickened diaphragm

√ obliterated costophrenic angles (minority of cases)

DDx: pleural thickening from parapneumonic effusion, hemothorax, connective tissue disease

Pulmonary Asbestosis

= (term "asbestosis" reserved for) chronic progressive diffuse interstitial pulmonary fibrosis

← inhalation of asbestos fibers

Frequency: in 49–52% of industrial asbestos exposure; 1,229 new cases annually in USA (2013)

Latency period: 40–45 years; dose-effect relationship

Histo: interstitial fibrosis begins around respiratory bronchioles, then progresses to involve adjacent alveoli

Diagnostic criteria:

1. Reliable history of exposure
2. Appropriate time interval between exposure + detection
3. Radiographic opacities classified as ILO s,t,u
4. Restrictive pattern of lung impairment
5. Diffusing capacity below normal range
6. Bilateral crackles at posterior lung bases, NOT cleared by cough

- dyspnea
- restrictive pulmonary function tests: progressive reduction of vital capacity + diffusing capacity
- asbestos bodies in macrophages from bronchoalveolar lavage (BAL) fluid (= single asbestos fiber surrounded by segmented protein-iron coat)

Location: lower posterior bases > apices

Site: most severe in subpleural zones (asbestos fibers concentrate beneath visceral pleura)

CXR:

√ small irregular linear opacities (NOT rounded as in coal / silica) progressing from fine to coarse reticulations:
  √ confined to lung bases, progressing superiorly
  √ septal lines (= fibrous thickening around 2ndary lobules)
  √ honeycombing (uncommon)

√ "shaggy" (obscured) heart border ← parenchymal + pleural changes

√ ill-defined outline of diaphragm

√ rarely massive fibrosis, predominantly at lung bases without migration toward hilum (DDx from silicosis / CWP)

√ ABSENCE of hilar / mediastinal adenopathy (if present consider other diagnosis)

HRCT:

◊ Obtain scan in prone position to differentiate from gravity-related physiologic phenomena

√ thickened intralobular lines as initial finding ← centrilobular peribronchiolar fibrosis:
  √ multiple subpleural curvilinear branching lines ("subpleural pulmonary arcades") = dotlike reticulonodularities connected to the most peripheral branch of pulmonary artery
  Site: most prominent posteriorly parallel to and within 1 cm of pleura

√ thickened interlobular septal lines (= interlobular fibrotic / edematous thickening):
  √ reticulations = network of linear densities, usually posteriorly at lung bases
  √ architectural distortion of lobule

√ parenchymal band formation = linear < 5 cm long + several mm wide opacity, often extending to pleura, which may be thickened + retracted at site of contact

√ subpleural curvilinear lines
√ patchy areas of ground-glass attenuation (= alveolar wall thickening due to fibrosis / edema)
√ honeycombing = multiple cystic spaces < 1 cm in diameter with thickened walls
NUC:
√ ^{67}Ga uptake gives a quantitative index of inflammatory activity
Cx: pulmonary fibrosis, pleuropulmonary malignancy (latency period of > 20 years)
DDx: idiopathic pulmonary fibrosis (NO parietal pleural thickening)

Atelectatic Asbestos Pseudotumor

= ROUND ATELECTASIS = "FOLDED LUNG"
= infolding of redundant pleura accompanied by segmental / subsegmental atelectasis
◊ Most common of benign masses caused by asbestos exposure!
Location: posteromedial / posterolateral basal region of lower lobes (most common); frequently bilateral
√ 2.5–8 cm focal subpleural mass abutting a region of thickened pleura
√ size + shape show little progression, occasionally ↓ in size
CT:
√ rounded / lentiform / wedge-shaped peripheral mass
√ pleural thickening ± calcification always present and frequently greatest near mass
√ **"crow's feet"** = linear bands radiating from mass into lung parenchyma (54%)
√ **"vacuum cleaner"** / "comet" sign
= bronchovascular markings emanating from nodular subpleural mass + coursing toward ipsilateral hilum
√ **"Swiss cheese"** air bronchogram (18%)
√ partial interposition of lung between pleura + mass
√ volume loss of affected lobe ± hyperlucency of adjacent lung

Asbestos-related Malignancy

Estimated yearly asbestos-related deaths in USA (2013):
12,000–15,000 annually

Lung Cancer

Incidence: 180,000 new cases annually in USA; 20–25% of workers heavily exposed to asbestos
Occurrence related to:
(a) cumulated dose of asbestos fibers
(b) smoking (synergistic carcinogenic effect)
◊ 100-fold increased risk in smokers versus a 7-fold increased risk in nonsmokers!
(c) preexisting interstitial disease
(d) occupational exposure to known carcinogen
Latency period: 25–35 years
Associated with: increased incidence of gastric carcinoma
Histo: bronchioloalveolar cell carcinoma (most common); bronchogenic carcinoma (adenocarcinoma + SCC)

Location: at lung base / in any location if associated with smoking

Malignant Mesothelioma

Incidence: 2,686 new cases annually in USA (2013); 7,000-fold increase in incidence
Risk: 10% over lifetime of an asbestos worker; household members of asbestos worker; residents near asbestos mines and plants
Latency period: 20–40 years

Gastrointestinal Neoplasm

= pancreatic, liver, gallbladder, colon, rectal, stomach cancer
Frequency: 3-fold increase (weak link)

ASKIN TUMOR

= EXTRASKELETAL EWING SARCOMA = PRIMITIVE NEUROECTODERMAL TUMOR (PNET)
= uncommon tumor probably arising from intercostal nerves
Mean age: 14.5 years; M÷F = 1÷3; Caucasian
Path: neuroectodermal small cell tumor containing neuron-specific enolase (may also be found in neuroblastoma)
• chest wall mass with / without pain
• constitutional symptoms: fever, anorexia, weight loss
√ large tumor involving chest wall + pleura
√ high tumor vascularity
√ rib destruction (occasionally arising from rib) in 25–63%
√ often large malignant pleural effusion
√ pulmonary parenchymal disease (25%)
√ calcifications (10%)
√ ipsilateral hilar + mediastinal lymphadenopathy
√ ± pneumothorax ← pulmonary involvement
CT:
√ large unilateral heterogeneous chest wall mass with intra- and extrathoracic components
√ ± pleural, pericardial, diaphragmatic, vertebral, spinal extension and involvement
MR:
√ predominantly intermediate SI on T1WI + high SI on T2WI
√ prominent areas of high SI on T2WI ← hemorrhage + necrosis
√ commonly invasion of chest wall musculature + mediastinum + lung
NUC:
√ ↑ activity on bone scan + 111In-pentetreotide + ^{99m}Tc-MIBI
√ NO uptake on FDG PET
Metastatic to: lung, mediastinal nodes, bone (25%), CNS, liver, adrenal
◊ At presentation pulmonary metastases (in 38%) + mediastinal lymphadenopathy (in 25%)
Prognosis: median survival of 8 months
DDx: Ewing sarcoma, lymphoma, chest wall hamartoma in infancy

ASPERGILLOSIS

Organism:

Aspergillus fumigatus = intensely antigenic ubiquitous fungus in soil, water, decaying vegetable and animal matter existing as

(a) conidiophores = reproductive form releasing thousands of spores

(b) hyphae (= matured spores) characterized by 45° dichotomous branching pattern

Occurrence:

commonly in sputum of normal persons, ability to invade arteries + veins facilitating hematogenous dissemination

M÷F = 3÷1

Transmission: spore inhalation

Predisposed:

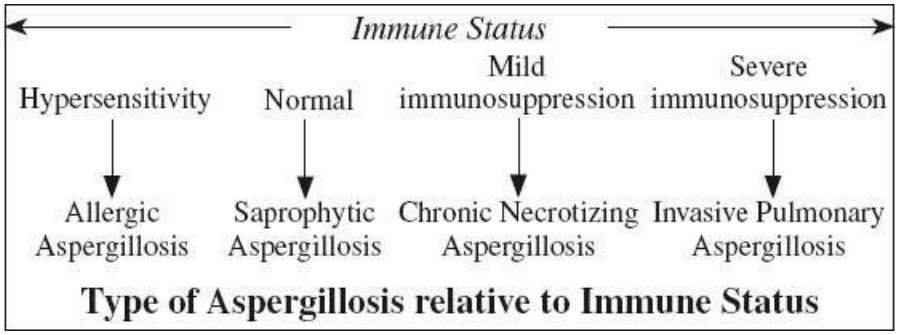
(a) preexisting lung disease (tuberculosis, bronchiectasis)

(b) impairment of immune system (alcoholism, advanced age, malnutrition, concurrent malignancy, poorly controlled diabetes, cirrhosis, sepsis)

- tracheo-bronchitis, bronchiolitis, bronchopneumonia
- fungal hyphae in lumen of airways
- positive precipitin test to Aspergillus antigen
- elevated Aspergillus-specific IgE, IgG-ELISA, polymerase chain reaction identification

Cx: dissemination to heart, brain, kidney, GI tract, liver, thyroid, spleen

◊ Sputum cultures are diagnostically unreliable because of normal (saprophytic) colonization of upper airways!



Type of Aspergillosis relative to Immune Status

Noninvasive Aspergillosis = Mycetoma Formation

= SAPROPHYTIC ASPERGILLOSIS

= noninvasive colonization of preexisting cavity / cyst in <u>immunologically normal</u> patients with cystic / cavitary lung disease like:

granulomatous disease [sarcoidosis (common), remote TB, atypical mycobacterial infection, Pneumocystis jirovecii], bronchiectasis, cystic fibrosis, abscess, bullous emphysema, carcinoma, traumatic pneumatocele, ankylosing spondylitis, Marfan syndrome, neurofibromatosis type 1

- blood-streaked sputum / severe hemoptysis (45–95%)
- elevated serum precipitins level for Aspergillus (50%)

√ solid round gravity-dependent mass within preexisting spherical / ovoid thin-walled cavity (= **Monad sign**):

[*monas*, Greek = single, alone; - *ad*, Greek suffix = group, unit]

Histo: **mycetoma** = aspergilloma = **fungus ball** = masslike collection of intertwined hyphae matted together with fibrin, mucus, cellular debris colonizing a pulmonary cavity

√ "air-crescent" sign = crescent-shaped air space separating fungus ball from nondependent cavity wall

√ fungus ball may calcify in scattered / rimlike fashion

√ pleural thickening adjacent to preexisting cyst / cavity = commonly first sign before visualizing mycetoma

Cx: life-threatening hemoptysis with mycetoma

N.B.: search for hypertrophied bronchial arteries as road map for bronchial artery embolization

Dx: transthoracic needle biopsy / bronchial washings

DDx of other organisms causing fungus ball:

Candida albicans, Pseudallescheria boydii, Coccidioides immitis, Nocardia, Actinomyces

Semiinvasive Aspergillosis

= CHRONIC NECROTIZING ASPERGILLOSIS

= chronic cavitary slowly progressive disease in patients with preexisting lung injury (COPD, radiation therapy), mild immune suppression, or debilitation (alcohol, diabetes)

• symptoms mimicking pulmonary tuberculosis

√ progressive consolidation (usually upper lobe)

√ development of air crescent and fungus ball over a period of months

Dx: pathologic examination demonstrating local tissue invasion

Invasive Pulmonary Aspergillosis

= often fatal form in severely immunocompromised patients with absolute neutrophil count of < 500

Predisposed: most commonly in lymphoma / leukemia patients with prolonged granulocytopenia; after organ transplantation

Path: endobronchial fungal proliferation followed by trans- bronchial vascular invasion eventually causes widespread hemorrhage + thrombosis of pulmonary arterioles and ischemic tissue necrosis with systemic dissemination; fungus ball = devitalized sequestrum of lung infiltrated by fungi

• history of series of bacterial infections + unremitting fever

• pleuritic chest pain (mimicking emboli)

• dyspnea, nonproductive cough

• progression of pulmonary infiltrates not responding to broad-spectrum antibiotics

(a) early signs

Frequency: 96% (19%) on day 0 (day 14)

√ single / multiple ill-defined peripheral opacities abutting the pleural surface

√ "CT halo" sign = single / multiple 1–3-cm peripheral nodules (= necrotic lung) with halo of ground-glass attenuation (= hemorrhagic edema)

√ patchy localized bronchopneumonia

(b) later signs of progression

√ enlargement of nodules into diffuse bilateral consolidation

√ development into large wedge-shaped pleural-based lesions
√ "air-crescent" sign (in up to 50%) = cavitation of existing nodule (air crescent between retracting sequestered necrotic tissue and surrounding rim of hemorrhagic lung parenchyma) 1–3 weeks after recovery from neutropenia
◊ has better prognosis than consolidation without cavitation (= feature of resolution phase)

Prognosis: mortality rate of 50–90%
Dx: biopsy showing branching hyphae at tissue examination; sputum culture positive in only 10%
Rx: amphotericin B

Allergic Bronchopulmonary Aspergillosis

= ABPA = hypersensitivity reaction to aspergillus antigens released by colonization of tracheobronchial tree by Aspergillus fumigatus in patients with long-standing asthma / cystic fibrosis
◊ Most common + clinically important form of aspergillosis!
Prevalence: in 2–32% of patients with asthma; in 2–15% of patients with cystic fibrosis
Age: mostly young patients (begins in childhood); may be undiagnosed for 10–20 years
Path: bronchocentric granulomas within bronchi and bronchioles with associated mucoid impactions
Histo: deposition of immune complexes + inflammatory cells in bronchial mucosa → necrosis + eosinophilic infiltrates
Pathogenesis: IgE-mediated type I hypersensitivity reaction + specific IgG-mediated type III hypersensitivity
Pathophysiology:
inhaled spores trapped in segmental bronchi of individuals with asthma → germinate and form hyphae → aspergillus antigen reacts with IgG antibodies → immune complexes activate complement → release of proteolytic enzymes → inflammatory infiltrates → bronchial wall damage → central bronchiectasis
Staging (Patterson):
I acute phase with all primary diagnostic criteria
II remission = clearing of pulmonary infiltrates with declining IgE levels
III exacerbation = all criteria of stage I reappear after remission
IV corticosteroid dependency

Criteria for Diagnosis of ABPA *(adapted Rosenberg-Patterson Criteria)*
Major diagnostic criteria
acronym: ARTEPICS
Asthma (present in 84–96%)
Roentgenographic fleeting / fixed pulmonary infiltrates
Test for A. fumigatus positive: immediate skin reaction (type I hypersensitivity)
Eosinophilia in blood (8–40%)
Precipitating antibodies (IgG) in serum to A. fumigatus (70%)
IgE in serum elevated > 1000 IU/mL
Central bronchiectasis (late manifestation proves diagnosis)
Serum A. fumigatus-specific IgG + IgE (> 2 x the value of pooled serum samples from asthmatics with Aspergillus hypersensitivity)
Minor diagnostic criteria
Aspergillus fumigatus mycelia in sputum
Expectoration of brown sputum plugs (54%)
Arthus reaction (= late skin reactivity with erythema and induration) to Aspergillus antigen

V irreversible lung fibrosis

A. ACUTE ABPA

Type I reaction = immediate hypersensitivity (IgE-mediated mast cell degranulation)

Histo: alveoli filled with eosinophils

- bronchoconstriction, mucus production
- bronchial wall edema ← ⇑ vascular permeability

B. CHRONIC ABPA

Type III reaction = delayed immune complex response = Arthus reaction (IgG-mediated)

Histo: bronchocentric granulomas + mucoid impaction; fungal hyphae without tissue invasion

- flulike symptoms: fever, headache, malaise, weight loss, fleeting pleuritic chest pain
- wheezing, expectoration of brown mucous plugs
- positive skin test to A. fumigatus; peripheral eosinophilia
- elevated IgE level correlates well with disease activity!

CXR:

√ initial CXR normal in up to 50%

√ NORMAL peripheral bronchi

√ hyperinflation ← bronchospasm / emphysema

(a) early stage:

√ migratory pneumonitis = ill-defined homogeneous transient recurrent **"fleeting"** alveolar patchy subsegmental / lobar opacities (in up to 90%)

Location: upper lobes (50%), lower lobes (20%), middle lobe (7%); both lungs (65%)

Duration: may persist for > 6 months

(b) later stage of bronchial wall damage:

√ central varicose / cystic bronchiectasis with thickened bronchial walls:

√ "tramline" / parallel line bronchial walls ← edema

√ 1–2-cm ring shadows (= bronchus on end)

√ "finger in glove / gloved finger / **toothpaste shadow"** = V- or Y-shaped branching and tapering tubular opacities arising centrally and extending peripherally remaining for months + growing in size

Location: perihilar + upper lobes

Path: plugging of airways by hyphal masses with mucoid impaction distally in 2nd order bronchi of 2.5–6 cm in length

√ perihilar opacities simulating hilar and/or mediastinal lymphadenopathy ←mucus-filled dilated central bronchi

√ isolated lobar / segmental atelectasis (in 14%) with collateral air drift

√ lobar consolidation (in 32%)

√ cavitation (in 14%) ± air-fluid levels ← postobstructive / eosinophilic abscess

√ UNUSUAL: aspergilloma in cavity (7%), empyema, pneumothorax

(c) chronic stage:

√ pulmonary fibrosis + retraction

√ hilar elevation ← lobar shrinkage

CT:

√ bronchiectasis of segmental + subsegmental bronchi affecting > 3 lobes

√ CHARACTERISTIC highly opaque mucus within dilated bronchi ← calcium salts / metals (iron and manganese) / desiccated mucus / calcifications (in 30%)

√ tree-in-bud appearance = centrilobular nodules connected to branching linear structures (more common in asthmatics)

√ patchy areas of mosaic attenuation ← concomitant small-airway disease + areas of air trapping

√ atelectasis, consolidation, air trapping

Prognosis: end-stage pulmonary fibrosis → respiratory and right heart failure (if untreated)

DDx: hypersensitivity pneumonitis or allergic asthma (no hyphae in sputum, normal levels of IgE + IgG to A. fumigatus), tuberculosis, lipoid pneumonia, Löffler syndrome, bronchogenic carcinoma

Cerebral Aspergillosis

Transmission:

(1) hematogenous dissemination from distant pulmonary infection

(2) angiotropic / perineural spread from paranasal sinus / orbital infection (rhinocerebral disease)

(3) direct traumatic implantation

√ ring-enhancing cerebral abscesses ← hematogenous dissemination

√ hypoattenuating intracavitary projections without associated enhancement on T2WI + ADC map ← proliferating hyphae

√ propensity for vascular invasion by fungal hyphae ← production of elastase

√ zones of low T2 signal intensity ← iron, manganese, magnesium in paranasal fungal

concretions

Cx: cerebral infarction, hemorrhage (25%), mycotic aneurysm ← invasion of vessel wall

Prognosis: in immunocompromised ~ 100% mortality

Pleural Aspergillosis

= Aspergillus empyema in patients with pulmonary tuberculosis, bacterial empyema, bronchopleural fistula

√ pleural thickening

Renal Aspergillosis

= uncommon renal infection

Renal aspergillosis occurs in immunocompromised patients with diabetes / HIV infection / on corticosteroid therapy.

Route: hematogenous dissemination (most common) / ascending infection / Aspergillus casts in renal pelvis

√ mimicks complex renal mass / cyst / abscess

CT:

√ hypoattenuating mass with thick enhancing wall

√ internal septations

√ ± features of focal pyelonephritis in surrounding renal parenchyma with delayed enhancement

Dx: urinalysis, aspiration of lesion

ASPIRATION OF SOLID FOREIGN BODY

In suspected foreign-body ingestion the initial standard imaging protocol includes frontal and lateral radiographs of the chest, neck (often included on CXR) and abdomen.

CXR (frontal + lateral view):

√ apparently normal radiograph (20–35%) ← radiolucent foreign body (in 80%)

√ overdistension of hypopharynx

√ prevertebral soft-tissue swelling

√ ipsilateral lobar / segmental overinflation despite expiration:

√ ipsilateral hyperlucency ← obstructive overinflation (68%) + reflex vasoconstriction (= decrease in perfusion of compromised segment ← air trapping)

√ air trapping → needs expiratory / bilateral decubitus views

√ chronic volume loss of affected lobe ← atelectasis

√ recurrent pneumonia / infiltrate (11%)

√ bronchiectasis

√ pleural effusion

CT (indicated to assess for residual foreign body after bronchoscopy / with suspected serious complication):

√ intrabronchial foreign body:

√ intrabronchial low-attenuation material (SUGGESTIVE)

√ radiopaque foreign body (9%)

√ thickened bronchial wall adjacent to foreign body → chronic inflammatory reaction around aspirated material
√ ipsilateral hilar adenopathy
√ hyperlucency
√ bronchiectasis
√ atelectasis (14–53%), lobar collapse
√ mucoid impaction, tree-in-bud pattern
√ ipsilateral pleural effusion

NUC (V/Q scan):
√ ventilation defect (initial breath) + retention (washout)

Cx: bronchiectasis (from long retention), hemoptysis, bronchial stricture, development of inflammatory polyps, abscess

@ Childhood
Age: peak prevalence 6 month–3 years; in 50% < 3 years; in 70% < 15 years
Delay of diagnosis: within 2–3 days (usual) / > 24 hours; weeks to months (rare)
Source:
(a) young child: in 85% vegetable origin (peanut, seed, bean, lentil, pea, barley grass); disk battery
(b) older child: nonfood items like broken fragments of tooth

Disk batteries lodged in esophagus → battery-generated current → potential leakage of caustic material → esophageal perforation within hours
N.B.: upper GI examination must follow to evaluate for esophageal stricture, erosion, tracheoesophageal / aortoesophageal fistulas

Location: R main-stem bronchus (almost exclusively in lower lobes), larynx (3%), valleculae, epiglottis, vocal folds, subglottis, trachea; R÷L = 2÷1
• varying degrees of cough mimicking asthma / bronchitis / chronic pneumonia
• respiratory difficulty, wheezing, hemoptysis, recurrent pneumonia
Technique: inspiratory + expiratory phase images (in older cooperative child) / lateral decubitus images (in young less cooperative child)

√ hyperinflation is the most common finding in children ← "ball-valve" mechanism ← increased compliance of pediatric airway

DDx: impacted esophageal foreign body may also contribute to respiratory compromise; ingestion of dishwasher / laundry detergent "pods" → severe caustic injury to esophagus and surrounding tissues

@ Adulthood (unusual)
Contributing factors: CNS disorder, alcoholism, dental procedure
Source: animal bones, nutshells, medications, metallic denture parts, needles
Delay of diagnosis: for long periods of time
• often clinically silent / recurrent pneumonia
• massive life-threatening hemoptysis
Location: RLL, intermediate bronchus, left main bronchus

Lower Airway Foreign Body in Childhood

= 75% of foreign bodies aspirated into airways below larynx

Location: trachea (13%), right lung (60%), left lung (23%); bilateral (2%)
Source: mostly organic material (ie, food)
• episode of choking followed by asymptomatic period
N.B.: consider aspirated / ingested occult foreign body with chronic cough / recurrent pneumonia
√ aspirated foreign body radiolucent (90%) / radiopaque (10%)
√ unilateral hyperinflation, atelectasis, mediastinal shift
√ affected lung will remain lucent in expiration

With partial airway occlusion, expiratory view shows an increase in diagnostic accuracy ← airway narrowing ← air trapping ← ball-valve mechanism

N.B.: lateral decubitus view is WITHOUT an increase in diagnostic accuracy
Cx: pneumomediastinum, pneumothorax
Rx: bronchoscopy = reference standard for diagnosis and management of aspirated foreign bodies

Aspiration Bronchiolitis

= chronic inflammatory reaction to repeated aspiration of foreign particles into bronchioles
Predisposed: achalasia, Zenker diverticulum, hiatal hernia, gastroesophageal reflux, esophageal carcinoma
Histo: resembling diffuse panbronchiolitis
• dysphagia, regurgitation, aspiration
√ moderate / marked dilatation of esophagus
√ lobar / segmental / disseminated small nodules
CT:
√ uni- / bilateral foci of branching areas of increased attenuation:
√ tree-in-bud appearance = centrilobular nodules + uni- / bilateral branching areas of increased attenuation
√ mottled poorly defined opacified acinar areas

ASPIRATION PNEUMONIA

Frequency: 4–8÷1000 inpatients in USA → 50,000 deaths each year from Cx of aspiration
Predisposing conditions:
(1) CNS disorders / intoxication: alcoholism, mental retardation, seizure disorders, recent anesthesia
(2) Swallowing disorders: esophageal motility disturbances, head + neck surgery

Cough may be a potential indicator of aspiration due to oropharyngeal dysphagia. However, in up to 55% aspiration can be silent producing no reflexive cough.

• low-grade fever, choking on swallowing, productive cough
Location: gravity-dependent portions of lung, posterior segments of upper lobes + lower lobes in bedridden patients; frequently bilateral; right middle + lower lobe with sparing of left lung is common
Prognosis: 20–65% mortality in patients > 65 years of age

Acute Aspiration Pneumonia

Cause: gastric acid, food particles, anaerobic bacteria from GI tract provoke edema, hemorrhage, inflammatory cellular response, foreign-body reaction

Organism: Gram-negative bacteria; Pseudomonas aeruginosa, Actinomyces israelii

√ patchy bronchopneumonic pattern

√ lobar / segmental consolidation in dependent portion

√ necrotizing pneumonia

√ abscess formation

Aspiration of high-osmolar water-soluble contrast agents can lead to severe pulmonary edema. Iso-osmolar or low-osmolar agents should be used in patients at increased risk for aspiration.

Chronic Aspiration Pneumonia

Cause: repeated aspiration of foreign material from GI tract over long time / mineral oil (eg, in laxatives)

Associated with: Zenker diverticulum, esophageal stenosis, achalasia, tracheoesophageal fistula, neuromuscular disturbances in swallowing

√ recurring segmental consolidation

√ progression to interstitial scarring (= localized honeycomb appearance)

√ bronchopneumonic infiltrates of variable location over months / years

√ residual peribronchial scarring

Upper GI:

√ abnormal swallowing / aspiration

Mendelson Syndrome

= aspiration of gastric acid with a pH < 2.5

Associated with: vomiting, gastroesophageal reflux, achalasia, hiatal hernia

Pathophysiology:

acid rapidly disseminates throughout bronchial tree + lung parenchyma → incites chemical pneumonitis within minutes; extent of injury from mild bronchiolitis to hemorrhagic pulmonary edema depends on pH + aspirated volume

Location: posterior upper lobe segments + superior lower lobe segments (with patient in recumbent position)

√ bilateral perihilar ill-defined alveolar consolidations

√ multifocal patchy infiltrates

√ segmental / lobar consolidation localized to one / both lung bases

Prognosis: 30% mortality with massive aspiration; > 50% with initial shock, apnea, secondary pneumonia, or ARDS

ASTHMA

= chronic episodic reversible bronchoconstriction (= airflow obstruction) ← hypersensitivity / hyperresponsiveness of airways to a variety of stimuli

Terminology:

Reactive airway disease = clinical diagnosis of asthma not yet established, usually in children between 2 and 6 years of age

A. INTRINSIC ASTHMA

Age: middle age

Pathogenesis:

probably autoimmune phenomenon caused by viral respiratory infection and often provoked by infection, exercise, pharmaceuticals; NO environmental antigen

B. EXTRINSIC ASTHMA = ATOPIC ASTHMA

Pathogenesis:

antigens produce an immediate hypersensitivity response (type I); reagin sensitizes mast cells → histamine release → increased vascular permeability, edema, small muscle contraction; effects primarily bronchi causing airway obstruction

Nonoccupational allergens:

pollens, dog + cat fur, tamarind seed powder, castor bean, fungal spores, grain weevil

Occupational allergens:

(a) natural substances: wood dust, flour, grain, beans
(b) pharmaceuticals: antibiotics, ASA
(c) inorganic chemicals: nickel, platinum

Path: bronchial plugging with large amounts of viscid tenacious mucus (eosinophils, Charcot-Leyden crystals), edematous bronchial walls, hypertrophy of mucous glands + smooth muscle

ACUTE SIGNS:

- during asthmatic attack low values for FEV + MMFR and abnormal V/Q ratios; normal diffusing capacity
- increased resistance to airflow due to
  (a) smooth muscle contraction in airway walls
  (b) edema of airway wall caused by inflammation
  (c) mucus hypersecretion with airway plugging

√ hyperexpansion of lungs = severe overinflation + air trapping:
  √ increased anteroposterior chest diameter
  √ flattening of diaphragmatic domes
  √ increased retrosternal air space
√ peribronchial cuffing ← inflammation of airway wall
√ bronchial dilatation
√ localized areas of hypoattenuation / atelectasis
√ peripheral oligemia

CHRONIC CHANGES:

Normal chest x-ray in 73%, findings of abnormalities depend on
(a) age of onset (< 15 years of age in 31%; > 30 years of age in none)
(b) severity of asthma

√ central ring shadows = bronchiectasis
√ scars (from recurrent infections)

Cx:

(1) Pneumonia (2 x as frequent as in nonasthmatics)
  √ peripheral pneumonic infiltrates ← blocked airways
(2) Atelectasis (5–15%) ← mucoid impaction

(3) Barotrauma in children (often overlooked on radiographs)pneumomediastinum (5%), pneumothorax, subcutaneous emphysema
(4) Emphysema
(5) Allergic bronchopulmonary aspergillosis with central bronchiectasis

ATYPICAL MEASLES PNEUMONIA

= clinical syndrome in patients who have been previously inadequately immunized with killed rubeola vaccine and are subsequently exposed to the measles virus (= type III immune complex hypersensitivity); noted in children who have received live vaccine before 13 months of age
• 2- to 3-day prodrome of headache, fever, cough, malaise
• maculopapular rash beginning on wrists + ankles (sometimes absent); history of exposure to measles
• postinfectious migratory arthralgias
√ extensive nonsegmental consolidation, usually bilateral
√ hilar adenopathy (100%)
√ pleural effusion (0–70%)
√ nodular densities of 0.5–10 cm in diameter in peripheral location, may calcify and persist up to 30 months

BARITOSIS

= inhalation of nonfibrogenic barium sulfate
• asymptomatic; normal pulmonary function (benign course)
√ bilateral nodular / patchy opacities, denser than bone ← high atomic number
√ similar to calcified nodules
√ NO cor pulmonale, NO hilar adenopathy
√ regression if patient removed from exposure

BERYLLIOSIS

= chronic granulomatous disorder caused by exposure to beryllium dust / fumes (= acid salts from extraction of beryllium oxide)
Substance: one of the lightest metals (atomic weight 9), marked heat resistance, great hardness, fatigue resistance, no corrosion
Occupational exposure: fluorescent light bulb factories, ceramics manufacture, nuclear weapon production, aerospace industry
Immunology: cell-mediated immune response (= delayed hyper-sensitivity reaction) → accumulation of CD4+ T helper cells + macrophages in lower respiratory tract
Histo: noncaseating granulomas within interstitium + along vessels + in bronchial submucosa → fibrosis
DDx: indistinguishable from other granulomatous disorders like sarcoidosis
• positive beryllium lymphocyte transformation test (= sample of blood / bronchoalveolar lavage tested for T-lymphocyte transformation + proliferation to beryllium)

Acute Berylliosis (25%)

√ pulmonary edema following an overwhelming exposure (in 54%)
Cx: pulmonary carcinoma

Chronic Berylliosis

= widespread systemic disease of liver, spleen, lymph nodes, kidney, myocardium, skin, skeletal muscle
Metabolism: removed from lungs → excreted via kidneys
Latent period: 5–15 years
Associated with: granulomatous hepatitis, hypercalcemia, kidney stones
• dyspnea, cough, fever, anorexia, weight loss, skin lesions
Location: middle + upper lung zones
CXR:
√ fine irregular reticulonodular opacities (granulomas similar to sarcoidosis) sparing apices + bases
√ progression to interstitial fibrosis, honeycombing
√ ± mass lesions ← coalescence of granulomas
√ moderate hilar + mediastinal adenopathy (may calcify)
√ emphysema in upper lobes
√ pneumothorax in 10%
HRCT:
√ diffuse small parenchymal nodules (57%) along bronchovascular bundles
√ interlobular septal lines (50%)
√ patches of ground-glass attenuation (32%)
√ hilar / mediastinal lymphadenopathy (21–39%), only in the presence of parenchymal abnormalities
√ bronchial wall thickening (46%)
√ pleural irregularities (25%)
√ honeycombing (7%), conglomerate mass (7%)
Rx: prolonged treatment with corticosteroids ± oxygen
DDx: (1) Nodular pulmonary sarcoidosis (indistinguishable)
(2) Asbestosis (no hilar adenopathy)

BLASTOMYCOSIS

= NORTH AMERICAN BLASTOMYCOSIS = GILCHRIST DISEASE = CHICAGO DISEASE
= rare systemic mixed pyogenic + granulomatous fungal infection mimicking many other diseases (TB, bacterial pneumonia, malignancy)
Organism: soil-born saprophytic dimorphic fungus Blastomyces dermatitidis; mycelial phase in soil; round thick-walled yeast form with broad-based budding in mammals
Geographic distribution:
worldwide; endemic in midwest + southeastern USA (Ohio + Mississippi river valleys), vicinity of Great Lakes, St. Lawrence River valley, Canada (northern Ontario), Africa, India, Israel, Saudi Arabia, Central + South America
Prevalence: 1–40÷100,000 persons in endemic regions
Peak age: 25–50 (range, several months to 80) years; M÷F = 10÷1

Mode of infection:
inhalation (primary portal of entry) of fungal conidia growing in warm wet soil of decayed vegetation + decomposing wood acquired through activities in woods (hunting, camping, logging); spread to extrapulmonary sites (in 17–30%) → eg, skin, bone (often direct extension from skin lesion resembling actinomycosis), joints

Pathophysiology:
conidia are usually destroyed by a granulomatous reaction mediated by neutrophils, monocytes and macrophages;
if host defenses are overwhelmed conidia transform into yeast form, which is more resistant to destruction

Predisposed: elderly, immunocompromised

Histo:
(a) exudative phase: accumulation of numerous neutrophils with infecting organism
(b) proliferative phase: proliferation of epithelioid granulomas + giant cells with central microabscesses containing neutrophils and yeast forms

- acute: fever, chills, cough similar to community-acquired pneumonia
- chronic: intermittent low-grade fevers, mild persistent productive cough, chest pain, hemoptysis, malaise, fatigue, weight loss
- mouth ulcers

@ Lung (100%)
- clinical patterns following pulmonary infection:
  (a) severe pulmonary symptoms
  (b) asymptomatic pulmonary infection with spontaneous resolution
  (c) disseminated disease to single / multiple organs indolent for several years
  (d) extrapulmonary manifestation involving male GU system, skeleton, skin

◊ Highly variable imaging features!
√ segmental / lobar patchy ill-defined airspace disease in lower lobes in acute illness (26–76%)
√ solitary / multiple irregular masses of 3–10 cm in diameter (31%) / satellite lesions in paramediastinal / perihilar location
√ air bronchogram in area of consolidation (87%)
√ solitary / multiple nodules of 0.5–3.0 cm in diameter (6%)
√ bilateral diffuse reticulonodular interstitial disease (6–9%) with tree-in-bud pattern on HRCT
√ miliary disease (11–28%) with nodules of < 3 mm in diameter in fulminant course
√ cavitary lesions (13%) mimicking TB / other granulomatous disease if located in upper lobes
√ hilar / mediastinal lymph node enlargement (< 25%)

@ Skin (20–40% in disseminated disease)
- crusted verrucous lesions on exposed body areas
- skin ulcers

√ subcutaneous areas of soft-tissue + fluid attenuation with associated skin thickening

@ Bone (25%)
Location: spine, pelvis, sacrum, skull, ribs, long bones
√ marked destruction ± surrounding sclerosis

√ periosteal reaction in long bones, but NOT in short bones
√ multiple osseous lesions (frequent)
√ destruction of vertebral bodies + intervertebral disks (similar to tuberculosis)
√ psoas abscess
√ lytic skull lesions + soft-tissue abscess
√ usually monoarticular arthritis: knee > ankle > elbow > wrist > hand
@ GU tract (20%): prostatitis, epididymoorchitis
@ CNS (5–10%): epidural / parenchymal abscess, meningitis

Dx: (1) Culture of organism
(2) Silver stain microscopy of tissues

Prognosis: spontaneous resolution of acute disease in up to 4 weeks; disease may reactivate for up to 3 years; acute respiratory distress within 1 week (in rare fulminant course)

Rx: (1) Amphotericin B IV: 8–10 weeks for noncavitary + 10–12 weeks for cavitary lesions
(2) Ketoconazole

DDx: other pneumonias (ie, bacterial, tuberculous, fungal), pseudolymphoma, malignant neoplasm (ie, alveolar cell carcinoma, lymphoma, Kaposi sarcoma)

BLUNT CHEST TRAUMA

Incidence: 100,000 hospital admissions / year (in USA)

Prevalence: 3rd most common site (after injury to head and extremities)

Cause: high-speed motor vehicle accidents (70%), fall, blow to chest

Type of injury:

1. Pneumothorax 69%
2. Lung contusion 67%
3. Rib fracture 66%
4. Hemothorax 28%
5. Flail chest 14%
6. Thoracic spine fracture 13%
7. Clavicle fracture 13%
8. Scapula fracture 8%
9. Sternal fracture 5%
10. Sternoclavicular dislocation
11. Diaphragmatic injury 5%
12. Tracheobronchial tear 2%
13. Vascular injury 2%
14. Esophageal rupture 1%

Prognosis: 10.1% fatality rate (especially due to cardiac and tracheobronchial-esophageal injury)

Fracture of Trachea / Bronchus

= TRACHEOBRONCHIAL TEAR

Prevalence: 0.2–1.5–8.0% of all blunt chest injuries

• delayed diagnosis is common

Location: (a) mainstem bronchus within 2.5 cm of carina (80%); R > L

(b) just above carina (20%)

Orientation of tear: longitudinal at junction of cartilaginous and membranous portion of trachea / parallel to cartilage rings of bronchus

Associated injuries:

√ fracture of first 3 ribs (53–91%), rare in children

√ fracture of clavicle, sternum, scapula (40%)

√ pneumothorax (70%) without improvement after chest tube placement + suction

√ increasing pneumomediastinum ± subcutaneous emphysema of neck

√ absence of pleural effusion

√ **"fallen lung"** sign = collapsed lung droops to dependent position posterolaterally away from hilum (loss of anchoring support in complete bronchial transection)

√ inadequate reexpansion of lung despite adequate placement of one / more chest tubes ← large size of air leak

√ elevation of hyoid bone above level of C3 vertebra / elevation of greater cornu to < 2 cm from angle of mandible (on LAT radiograph of spine) ← infrahyoid muscle rupture + unopposed action of suprahyoid muscles

√ atelectasis (may be late development)

CT:

√ focal peribronchial collection of air

√ discontinuity / irregularity of bronchial wall

√ abnormal position of endotracheal tube:

√ overdistension of tube cuff

√ protrusion of tube wall beyond expected margins of trachea

√ extraluminal position of tip of tube

Dx: bronchoscopy

Prognosis: 30% mortality (in 15% within 1 hour)

Long-term Cx: airway stenosis / bronchomalacia; recurrent atelectasis / pneumonia; abscess; empyema

Pulmonary Contusion

= acute traumatic injury to alveoli

Prevalence: 17-70% (most common manifestation of blunt chest trauma, esp. deceleration trauma)

Path: exudation of edema + hemorrhage into airspace + interstitium

At risk for: pneumonia, RDS

Time of onset: apparent within 6 hours after trauma

• may be clinically inapparent; hemoptysis (50%)

Location: posterior (in 60%)

Distribution: nonsegmental

Site: in lung periphery at site of impact ± contrecoup lesion

◊ Frequently not visible on CXR < 6 hours after injury

√ irregular patchy / diffuse extensive homogeneous consolidation

√ opacity may enlarge for 48–72 hours

√ rapid resolution beginning after 24–48 hours

√ complete clearing in 3-10 days
√ overlying rib fractures (frequent)
CT (more sensitive than CXR):
◊ Immediately visible!
√ nonsegmental coarse ill-defined crescentic (50%) / amorphous (45%) opacification of lung parenchyma without cavitation
√ "subpleural sparing" = 1–2-mm rim of nonopacified clear lung between contusional lesion and pleura
Cx: pneumothorax
DDx: aspiration, pneumonia, fat embolism (1–2 days after injury)

Pulmonary Laceration

= disruption / tear of lung parenchyma resulting in lung cavity ← elastic recoil of lung
Predisposed: children + young adults (greater flexibility of chest wall with higher likelihood of lung injury in blunt trauma)
Type:
1 **Compression rupture injury** (most common)
= direct compressive force
Location: deep portions of lung
2 **Compression shear injury**
= severe sudden blow to lower thorax → shift of lower lobes across spine
Location: paraspinous portion of lung
3 **Rib penetration tear**
= rib fracture + pneumothorax
Location: periphery of lung
4 **Adhesion tear**
= laceration at preexisting pleuroparenchymal adhesion
Prognosis: tear fills gradually with blood → slow regression lasting up to several months
√ single / multiple uni- / multilocular pulmonary lesions consisting of round / oval lung cavity filled with:
(a) air = **traumatic pneumatocele**
(b) blood = **traumatic hematocele** / pulmonary hematoma
(c) both = traumatic hematopneumatocele with air-fluid level
◊ On CXR laceration often obscured by surrounding contusion!

Traumatic Lung Cyst

Age: children + young adults are particularly prone
√ thin-walled air-filled cavity (50%) ± air-fluid level preceded by homogeneous well-circumscribed mass (= hematoma)
√ oval / spherical lesion of 2–14 cm in diameter
√ single / multiple lesions; uni- or multilocular
√ usually subpleural under point of maximal injury
√ persistent up to 4 months + progressive decrease in size (apparent within 6 weeks)

Traumatic Lung Herniation

= pleura-covered part of lung extruding through a traumatic defect in the chest wall
Associated with: rib fracture

BONE MARROW TRANSPLANTATION

= intravenous infusion of hematopoietic progenitor cells from patient's own marrow (autologous transplant) / HLA-matched donor (allogenic transplant) to reestablish marrow function after high-dose chemotherapy and total body irradiation for lymphoma, leukemia, anemia, multiple myeloma, congenital immunologic defects, solid tumors

Cx: pulmonary complications in 40–60%

Neutropenic-Phase Pulmonary Complications

Time: 2–3 weeks after transplantation

1. **Angioinvasive aspergillosis**
   - √ nodule surrounded by halo of ground-glass attenuation (= fungal infection spreading into lung parenchyma with surrounding area of hemorrhagic infarction)
   - √ segmental / subsegmental consolidation (= pulmonary infarction)
   - √ cavitation of nodule with "air-crescent" sign (during recovery phase with resolving neutropenia)
   - √ < 5-mm centrilobular nodules to 5-cm peribronchial consolidation (= airway invasion with surrounding zone of hemorrhage / organizing pneumonia)
2. **Diffuse alveolar hemorrhage** (20%)
   - • hemosiderin-laden macrophages on lavage
   - √ bilateral areas of ground-glass attenuation / consolidation
3. **Pulmonary edema**
   Cause: infusion of large volumes of fluid combined with cardiac + renal dysfunction
   - √ prominent pulmonary vessels, interlobar septal thickening, ground-glass attenuation, pleural effusions
4. **Drug toxicity**
   Cause: bleomycin, busulfan, bischloronitrosurea (carmustine), methotrexate
   - √ bilateral areas of ground-glass attenuation / consolidation / reticular attenuation (= fibrosis)

Early-Phase Pulmonary Complications

Time: up to 100 days after transplantation

1. CMV pneumonia (23%)
   - √ multiple small nodules + associated areas of consolidation + ground-glass attenuation (= hemorrhagic nodules)
2. Pneumocystis carinii pneumonia
   - √ diffuse / predominantly perihilar / mosaic pattern of ground-glass attenuation with sparing of some secondary pulmonary lobules
3. Idiopathic interstitial pneumonia (12%)
   - √ nonspecific findings (diagnosis of exclusion)

Late-Phase Pulmonary Complications

Time: after 100 days post transplantation

1. Bronchiolitis obliterans (in up to 10%)
2. BOOP
3. Chronic graft-versus-host disease:
   infections, chronic aspiration, bronchiolitis obliterans, lymphoid interstitial pneumonia

BRONCHIAL ADENOMA

= misnomer due to locally invasive features + tendency for recurrence + occasional metastasis to extrathoracic sites (in 10%) = low-grade malignancy

Path: arises from duct epithelium of bronchial mucous glands (predominant distribution of Kulchitsky cells at bifurcations of lobar bronchi)

Frequency: 6–10% of all primary lung tumors

Mean age: 35–45 (range, 12–60) years; 90% occur < 50 years of age; most common primary lung tumor < 16 years of age; M÷F = 1÷1; Whites÷Blacks = 25÷1

Types:

mnemonic: CAMP

Carcinoid 90%
Adenoid cystic carcinoma = cylindroma 6%
Mucoepidermoid carcinoma 3%
Pleomorphic carcinoma 1%

Location: most commonly near / at bifurcation of lobar / segmental bronchi; central÷peripheral = 4÷1

› 48% on right: RLL (20%), RML (10%), main right bronchus (8%), RUL (7%), intermediate bronchus (3%)

› 32% on left: LLL (13%), LUL (12%), main left bronchus (6%), lingular bronchus (1%)

• hemoptysis (40–50%), atypical asthma, persistent cough
• recurrent obstructive pneumonia; asymptomatic (10%)
√ complete obstruction / air trapping in partial obstruction (rare) / nonobstructive (10–15%)
√ obstructive emphysema
√ recurrent postobstructive infection: pneumonitis, bronchiectasis, abscess
√ atelectasis / consolidation of a lung / lobe / segment (78%)
√ collateral air drift may prevent atelectasis
√ solitary round / oval slightly lobulated pulmonary nodule (19%) of 1–10 cm in size
√ hilar enlargement / mediastinal widening = central endo- / exobronchial mass

CT:

√ well-marginated sharply defined mass
√ in close proximity to an adjacent bifurcation with splaying of bronchus
√ coarse peripheral calcifications in ⅓ (cartilaginous / bony transformation)
√ may exhibit marked homogeneous enhancement

Biopsy: risky ← high tumor vascularity

Prognosis: 95% 5-year survival rate; 75% 15-year survival rate after resection

Cylindroma

= ADENOID CYSTIC CARCINOMA (7%)

◊ 2nd most common primary tumor of trachea
◊ Most common carcinoma of minor salivary tissue
Path: mixed serous + mucous glands; resembles salivary gland tumor
Histo:
Grade 1: tubular + cribriform; no solid subtype
√ entirely intraluminal
Grade 2: tubular + cribriform; < 20% solid subtype
√ predominantly intraluminal
Grade 3: solid subtype > 20%
√ predominantly extraluminal
Age peak: 4th–5th (range, 3rd–9th) decade; M=F
• typical history of refractory "asthma", hoarseness
• hemoptysis, cough, stridor, wheezing, chest pain, dysphagia
√ endotracheal mass with extratracheal extension
Malignant potential: more aggressive than carcinoid with propensity for local invasion + distant metastases (lung, bone, brain, liver) in 25%
Rx: tracheal resection + adjunctive radiotherapy
Prognosis: 8.3 years mean survival

Mucoepidermoid Carcinoma

Path: squamous cells + mucus-secreting columnar cells; resembles salivary gland tumor
√ may involve trachea = locally invasive tumor
√ sessile / polypoid endobronchial lesion

Pleomorphic Adenoma

= MIXED TYPE (extremely rare)

BRONCHIAL ATRESIA

= rare anomaly resulting from focal obliteration of proximal lumen of a lobar / segmental / subsegmental bronchus
Proposed causes:
(a) local interruption of bronchial arterial perfusion > 16 weeks GA (when bronchial branching is complete)
(b) tip of primitive bronchial bud separates from bud and continues to develop
Path: normal bronchial tree distal to occlusion is patent and filled with mucus; alveoli distal to occlusion are air-filled and mildly overinflated through collateral air drift
Associated with: lobar emphysema, cystic adenomatoid malformation
Mean age: 17 years; M÷F = 2÷1
• minimal symptoms, apparent later in childhood (most by age 15) / adult life
• recurrent pulmonary infections (in 20%)
Location: apicoposterior segment of LUL (>> RUL / ML)
CXR:
√ lobular / ovoid / round / branching perihilar mass:
√ CHARACTERISTIC **"gloved finger"** sign ← accumulation of mucus in dilated central bronchus distal to atretic lumen (= mucus impaction = bronchocele / mucocele)

√ overexpanded hyperlucent lung segment (collateral air drift with expiratory air-trapping)

CT:

√ mucus-filled bronchus near hilum WITHOUT connection between mucocele + hilum

√ air trapping in surrounding area

√ decreased perfusion with focal parenchymal oligemia

OB-US (detected > 24 weeks MA):

√ large echogenic fetal lung mass ← lung fluid-filled distal to occlusion (indistinguishable from other lung masses)

√ dilated fluid-filled bronchus

Fetal MR:

√ focal lung mass of homogeneously high SI on T2WI

Rx: no treatment in asymptomatic patients; segmentectomy in symptomatic infected patients

DDx: allergic bronchopulmonary aspergillosis; cystic fibrosis; congenital lobar emphysema (no mucus plug)

DDx in fetus: congenital cystic adenomatoid malformation, bronchopulmonary sequestration

BRONCHIECTASIS

= localized mostly irreversible dilatation of bronchi often with thickening of the bronchial wall

Pathophysiology:

"vicious cycle" hypothesis = airway damage + infection play reinforcing roles in the development of bronchiectasis. Host factors that predispose to infection are impaired glandular secretion (cystic fibrosis), impaired ciliary function (ciliary dyskinesia), or systemic immune dysfunction.

Etiology:

A. Chronic or recurrent infection
   (a) congenital
      1. Structural defect of bronchi: bronchial atresia, Williams-Campbell syndrome
         Distribution: midorder bronchi
         √ cartilage deficiency
      2. Abnormal mucociliary transport: Kartagener syndrome = primary ciliary dyskinesia
         Distribution: middle lobe, lingula
         √ situs inversus, chronic sinusitis, bronchiectasis
      3. Abnormal secretions: cystic fibrosis
         Distribution: central upper lung zone
         √ extensive cystic + cylindrical bronchiectasis
      4. Mounier-Kuhn syndrome
         Distribution: central
         √ absence / atrophy of elastic fibers + muscle in trachea and main bronchial walls
   (b) congenital / acquired immune deficiency (usually IgG deficiency):
      1. Chronic granulomatous disease of childhood
      2. Alpha-1 antitrypsin deficiency
   (c) postinfectious childhood pneumonias (after necrotizing viral / bacterial bronchitis):
      1. Measles
      2. Whooping cough

3. Swyer-James syndrome
   Distribution: focal unilateral
   √ increased lucency of smaller lung ← air trapping
4. Allergic bronchopulmonary aspergillosis
   Distribution: central upper lung zone
   √ high-attenuation mucus plugging
5. Chronic granulomatous infection (TB)
   Distribution: asymmetric upper lobe involvement
   √ tree-in-bud nodules

(d) fibrosing lung disease

1. Sarcoidosis
   Distribution: central upper lung zone
   √ bihilar lymphadenopathy, perilymphatic nodules
2. Pulmonary fibrosis
   Distribution: peripheral lower lung zone
   √ varicoid bronchiectasis, architectural distortion
   √ honeycombing in UIP
3. Acute respiratory distress syndrome
   Distribution: middle lobe and lingula
   √ varicoid bronchiectasis, diffuse ground-glass opacities

B. Distal to bronchial obstruction ← accumulation of secretions: neoplasm, inflammatory nodes, foreign body

C. Aspiration / inhalation: gastric contents / inhaled fumes (late complication) / foreign object
   Distribution: periphery of lower lung zone
   √ hiatal hernia

D Bronchiolitis obliterans
   Distribution: diffuse
   √ diffuse air trapping, post transplantation

E. **"Traction bronchiectasis"** ← increased elastic recoil with bronchial dilatation + mechanical distortion of bronchi: advanced pulmonary fibrosis / radiation-induced lung injury

F. Increased inflationary pressure

The distribution and morphologic features of bronchiectasis, architectural distortion and findings of fibrosis, mosaic attenuation, presence and pattern of diffuse nodular lung disease can provide clues to the diagnosis.

Classification of anatomical abnormality: often in combination
◊ Of little value for illuminating etiology / pathogenesis!
◊ Little interobserver agreement as to bronchiectatic classes
Normal lung: 17–20 bronchial subdivisions between lung periphery + hilum

1. **Cylindrical / tubular / fusiform bronchiectasis**
   = mildly uniformly dilated bronchi (least severe type)
   ◊ reversible if associated with pulmonary collapse
   Path: bronchial subdivisions between lung periphery + hilum reduced to 16
   √ square abrupt ending with lumen of uniform diameter and same width as parent

bronchus

HRCT:

√ "tram lines" of nontapering air ways (horizontal course)

√ "signet-ring" sign (vertical course) = cross section of dilated bronchus + branch of pulmonary artery

√ Y- or V-shaped areas of attenuation = mucous plugs filling bronchiectatic segments

2. **Varicose / varicoid bronchiectasis**

= moderately dilated and beaded bronchi (rare)

Associated with: Swyer-James syndrome, interstitial fibrosis → bronchial traction

Path: bronchial subdivisions between lung periphery + hilum reduced to 4–8

√ alternating segments of bronchial dilatation + narrowing with normal pattern distally

3. **Saccular / cystic bronchiectasis**

= marked cystic dilatation = focal pouch-like areas of enlargement (most severe type)

Associated with: cystic fibrosis, severe bronchial infection

Path: bronchial subdivisions between lung periphery + hilum reduced to < 5

√ progressive ballooning dilatation toward periphery with diameter of saccules > 1 cm

√ irregular constrictions may be present

√ dilatation of bronchi on inspiration, collapse on expiration

√ contains variable amounts of pooled secretions

HRCT:

√ string of cysts = "string of pearls" (horizontal course) / cluster of cysts = "cluster of grapes"

√ air-fluid level (frequent)

Age: predominantly pediatric disease

- chronic productive cough, excess sputum production
- recurrent infection with expectoration of purulent sputum
- shortness of breath
- hemoptysis (50%) ← bronchial artery dilatation and neovascularity ← recurrent airway inflammation
  - ◊ Most common cause of massive hemoptysis!
- frequent exacerbations + resolutions ← superimposed infections
- Spirometry often reveals an obstructive physiologic condition that worsens over time

Associated with: obliterative + inflammatory bronchiolitis (in 85%)

Location: posterior basal segments of lower lobes, bilateral (50%); middle lobe / lingula (10%); central bronchiectasis in bronchopulmonary aspergillosis

CXR (37% sensitive):

√ tramlines = dilated air-filled wall-thickened bronchi:

√ parallel + ringlike opacities

√ increased background density ← parenchymal volume loss:

√ crowding of lung markings (if associated with atelectasis)

√ increase in size of lung markings (mucous plugs)

√ loss of definition of lung markings (peribronchial fibrosis)

√ cystic spaces ± air-fluid levels < 2 cm in diameter (dilated bronchi)

√ honeycomb pattern (in severe cases)

√ compensatory hyperinflation of uninvolved ipsilateral lung

HRCT (87–97% sensitive, 93–100% specific):

√ lack of bronchial tapering (in 80% = most sensitive finding)

√ bronchial wall thickening

√ "signet ring" sign = internal diameter of bronchus larger than adjacent pulmonary artery (in 60%)

√ bronchi visible within 1 cm of pleura (in 45%) implies bronchiolectasis (DDx: honeycombing)

√ mucus-filled dilated bronchi (in 6%)

√ small bronchial arterial diameter with an increase in bronchoarterial ratio ← vasoconstriction ← small-vessel / small-airways disease

√ dilatation of bronchial arteries ← pulmonary hypertension → pseudo-normalization of bronchoarterial ratio

Cx: frequent respiratory infections

Prognosis: 20% 5-year mortality rate

Rx: antibiotics for superimposed infection, bronchodilator, nasal oxygen therapy, chest physiotherapy, inhaled steroids

DDx of CT appearance:

(1) Emphysematous blebs (no definable wall thickness, subpleural location)

(2) "Reversible bronchiectasis" = temporary dilatation during pneumonia with return to normal within 4–6 months

BRONCHIOLITIS

= LOWER RESPIRATORY TRACT INFLAMMATION

Cause: inflammation of small airways ←viral antigen (usually respiratory syncytial virus / rhinovirus)

Terminology:

› **bronchiolitis:** child < 2 years of age

› **lower respiratory tract inflammation:** child > 2 years of age

√ small airways ← perihilar bronchial wall thickening ← edema

√ hyperinflation:

√ > 6 anterior rib ends depicted on frontal projection

√ downward sloping + flattening of hemidiaphragms

√ increased retrosternal airspace

√ ± lung tissue herniating through intercostal spaces

Cx: atelectasis, consolidation

Prognosis: development of asthma later in life

BRONCHIOLITIS OBLITERANS

= CONSTRICTIVE BRONCHIOLITIS = OBLITERATIVE BRONCHIOLITIS

= concentric narrowing of bronchial lumen

• decrease in forced expiratory volume in 1 second > 20%

Path: irreversible submucosal and peribronchiolar fibrosis of small airway walls (respiratory bronchiole, alveolar duct, alveoli) → narrowing / obliteration of airway lumina by

granulation tissue of immature fibroblastic plugs (Masson bodies)

Etiology:

(1) Idiopathic (most frequent) / cryptogenic: in immunocompetent patient
(2) Inhalation: 1–3 weeks after exposure to toxic fumes (nitrogen dioxide, isocyanates, phosgene, ammonia, sulfur dioxide, chlorine, diacetyl (buttery flavor of popcorn)
(3) Postinfectious: Mycoplasma (children), virus (older individual); cystic fibrosis (as a complication of repeated episodes of pulmonary infections)
(4) Drugs: bleomycin, gold salts, cyclophosphamide, carmustine, methotrexate, D-penicillamine, cocaine
(5) Collagen vascular disorder: rheumatoid arthritis (especially after treatment with penicillamine / gold salts), systemic sclerosis (= scleroderma), systemic lupus erythematosus, mixed connective tissue disease
(6) Transplantation: chronic graft-versus-host disease in bone marrow transplant, lung transplant, heart-lung transplant (30–56% after 3 years)
(7) Miscellaneous: ulcerative colitis, diffuse idiopathic pulmonary neuroendocrine cell hyperplasia (DIPNECH)Stevens-Johnson syndrome, paraneoplastic pemphigus

Peak age: 40–60 years; M÷F = 1÷1

• insidious onset of dyspnea over many months
• obstructive pulmonary function tests
• no response to antibiotics, persistent nonproductive cough, fever

√ normal CXR (in up to 40%)
√ hyperinflated lungs = limited disease with connective tissue plugs in airways
√ oligemia = decreased vascularity ← reflex vasoconstriction
√ bilateral scattered heterogeneous + homogeneous opacities: typically peripheral in distribution; equally distributed between upper + lower lobes
√ bronchiectasis

HRCT (paired expiration-inspiration images):

√ patchy <u>air trapping</u> on expiratory scan ← collateral air drift into postobstructive alveoli = failure of change in attenuation (ie, volume) between expiration + inspiration
√ "mosaic perfusion" of lobular air trapping (85–100%)
= patchy areas of decreased lung attenuation alternating with areas of normal attenuation:
√ areas of ↓ attenuation = vessels of decreased caliber ← secondary vasoconstriction of alveoli distal to bronchiolar obstruction ← alveolar hypoventilation
√ areas of ↑ attenuation = vessels of increased caliber ← compensatory increased perfusion in uninvolved areas
√ bronchial wall thickening (87%)
√ central + peripheral bronchiectasis (66–80%)
√ poorly defined nodular areas of consolidation
√ "tree-in-bud" appearance of bronchioles
= centrilobular branching structures and nodules caused by peribronchiolar thickening + bronchiolectasis with secretions (the only direct, but UNCOMMON sign)
√ centrilobular ground-glass opacities

Rx: steroids may stop progression

DDx: (1) Bacterial / fungal pneumonia (response to antibiotics, positive cultures)

(2) Chronic eosinophilic pneumonia (young female, eosinophilia in ⅔)
(3) Usual interstitial pneumonia (irregular opacities, decreased lung volume)

BRONCHIOLOALVEOLAR CARCINOMA

= BAC = ALVEOLAR CELL CARCINOMA = BRONCHIOLAR CARCINOMA
= type of adenocarcinoma showing lepedic growth pattern without surrounding stromal / vascular invasion

Frequency: 1.5–6% of all primary lung cancers (increasing incidence to ? 20–25%)
Etiology: development from type II alveolar epithelial cells
Age: 40–70 years; M÷F = 1÷1 (strikingly high in women)
Path: peripheral neoplasm arising beyond a recognizable bronchus with tendency to spread locally using lung structure as a stroma (= **lepedic** growth)
Histo: subtype of well-differentiated adenocarcinoma; cuboidal / columnar cells grow along alveolar walls + septa without disrupting the lung architecture or pulmonary interstitium (serving as "scaffolding" for tumor growth)
Subtypes:
(a) mucinous (80%): mucin-secreting tall columnar peglike bronchiolar cells; more likely multicentric; 26% 5-year survival rate
(b) nonmucinous (20%): cuboidal type II alveolar pneumocytes with production of surfactant / nonciliated bronchiolar (Clara) cells; more localized + solitary; 72% 5-year survival rate
Risk factors: localized pulmonary fibrosis (tuberculous scarring, pulmonary infarct) in 27%, diffuse fibrotic disease (scleroderma), previous exogenous lipid pneumonia

- history of heavy smoking (25–50%)
- often asymptomatic (even in disseminated disease) with insidious onset
- pleuritic chest pain (← peripheral location)
- cough (35–60%), hemoptysis (11%)
- bronchorrhea = abundant white mucoid / watery expectoration (5–27%); can produce hypovolemia + electrolyte depletion; unusual + late manifestation only with diffuse bronchioloalveolar carcinoma
- shortness of breath (15%), weight loss (13%), fever (8%)

Location: peripherally, beyond a recognizable bronchus
Spread: tracheobronchial dissemination = cells detach from primary tumor + attach to alveolar septa elsewhere in ipsi- / contralateral lung; lymphogenous and hematogenous dissemination
Metastases: involving almost any organ (in 50–60%); 33% of skeletal metastases are osteoblastic

A. LOCAL FORM (60–90%)
1. **Ground-glass attenuation**
= early stage (← lepedic growth pattern along alveolar septa with relative lack of acinar filling)
√ ground-glass haziness
√ bubblelike hyperlucencies / pseudocavitation
√ airway dilatation

√ lesion persists / progresses within 6–8 weeks

Spectrum of Adenocarcinoma of Lung (formerly Bronchioloalveolar Carcinoma *2011*)

Term	*Pathology*	*CT*
Adenocarcinoma in situ (AIS)	noninvasive ≤ 3 cm mass, purely lepedic growth	nonsolid mass ± small scattered sites of low attenuation
Minimally invasive adenoca. (MIA)	invasive ≤ 3 cm mass with lepedic growth (depth of invasion ≤ 5-mm)	nonsolid mass + 5-mm central solid component
Lepedic adenocarcinoma	invasive nonmucinous adenocarcinoma with predominantly lepedic growth	partly solid mass + bubblelike component
Acinar / papillary / micropapillary / solid adenoca.	invasive nonmucinous adenocarcinoma + small proportion of lepedic growth	usually solid mass ± small nonsolid component
Invasive mucinous adenocarcinoma	invasive mucinous adenocarcinoma + lepedic growth as predominant component	solid / mostly solid / part solid / nonsolid mass

2. **Single mass** (43%)
   √ well-circumscribed focal mass in peripheral / subpleural location arising beyond a recognizable bronchus
   √ "open bronchus" sign = air bronchogram = tumor / mucus surrounding aerated bronchus ± narrowing / stretching / spreading of bronchi
   √ "rabbit ears" / pleural tags / triangular strand / "tail" sign (55%) = linear strands extending from nodule to pleura (desmoplastic reaction / scarring granulomatous disease / pleural indrawing)
   √ spiculated margin = sunburst appearance (73%)
   √ solitary cavity ← central necrosis (7%)
   ◊ 2nd most common cell type associated with cavitation after squamous cell carcinoma
   √ pseudocavitation (= dilatation of intact air spaces from desmoplastic reaction / bronchiectasis / focal emphysema) in 50–60%
   √ heterogeneous attenuation (57%)
   √ confined to single lobe
   √ rarely evolving into diffuse form
   √ slowly progressive growth on serial radiographs
   √ NO atelectasis
   √ negative FDG PET results in 55%
   Prognosis: 70% surgical cure rate for tumor < 3 cm; 4–15-years survival time with single nodule

B. DIFFUSE FORM = Pneumonic form (10–40%)
   1. **Diffuse consolidation** (30%)
      √ acinar airspace consolidation + air bronchogram + poorly marginated borders
      √ airspace consolidation may affect both lungs (mucus secretion)

√ ± cavitation within consolidation
√ "CT angiogram" sign = low-attenuation consolidation does NOT obscure vessels (mucin-producing subtype)

2. **Lobar form**
√ ± expansion of a lobe with bulging of interlobar fissures

3. **Multinodular form** (27%)
√ multiple bilateral poorly / well-defined nodules similar to metastatic disease
√ multiple poorly defined areas of ground-glass attenuation / consolidation

• consolidation despite treatment with antibiotics
√ pleural effusion (8–10%)
Prognosis: worse with extensive consolidation / multifocal / bilateral disease; death within 3 years with diffuse disease

BRONCHOCENTRIC GRANULOMATOSIS

= rare disorder characterized by destructive necrotizing granulomatous inflammation of bronchial + bronchiolar walls and surrounding parenchyma
Peak age: 4th–7th decade
• asthma with underlying allergic bronchopulmonary aspergillosis (33–50%)
• fever, night sweats, cough, dyspnea, pleuritic chest pain
• seropositive arthritis (rare), ocular scleritis (rare)
Path: thick-walled ectatic bronchi + bronchioles containing viscous material of mucopurulent / caseous character
Histo: necrotizing granulomas surrounding small airways; pulmonary arteritis as a secondary phenomenon
(1) large masses of eosinophils in necrotic zones, associated with endobronchial mucus plugs, eosinophilic pneumonia, Charcot-Leyden crystals, fungal hyphae in granulomas (with asthma) in ⅓
(2) polymorphonuclear cell infiltrate in necrotic zones (without asthma) in ⅔
Location: unilateral (75%); upper lung zones (60%)
√ branching opacities / atelectasis ← mucoid impaction
√ solitary > multiple nodules / masses (in 60%)
Location: unilateral with upper lobe predominance
√ ill-defined parenchymal consolidation (in 27%)
√ ± cavitation
Rx: corticosteroid therapy

BRONCHOGENIC CARCINOMA

= LUNG CANCER = LUNG CARCINOMA
◊ Most frequent cause of cancer deaths in males (35% of all cancer deaths) and females (21% of all cancer deaths); most common malignancy of men in the world; 6th leading cancer in women worldwide
Prevalence: 225,000 new cases + 160,000 deaths (2012)
Age at diagnosis: 55–60 years (range 40–80 years); M÷F = 1.4÷1
• asymptomatic (10–50%) usually with peripheral tumors

- symptoms of central tumors:
  - cough (75%), wheezing, pneumonia
  - hemoptysis (50%), dysphagia (2%)

    ◊ Most common cause of massive hemoptysis at age > 40.
- symptoms of peripheral tumors:
  - pleuritic / local chest pain, dyspnea, cough, hoarseness
  - Pancoast syndrome, superior vena cava syndrome
- symptoms of metastatic disease (CNS, bone, liver, adrenal gland)
- paraneoplastic syndromes:
  - cachexia of malignancy, migratory thrombophlebitis
  - clubbing + hypertrophic osteoarthropathy
  - nonbacterial thrombotic endocarditis
  - ectopic hormone production: hypercalcemia, syndrome of inappropriate secretion of antidiuretic hormone (SIADH), Cushing syndrome, gynecomastia, acromegaly

Risk factors:

(1) Cigarette smoking (squamous cell carcinoma + SSC)
   › related to number of cigarettes smoked, depth of inhalation, age at which smoking began
   ◊ 85% of lung cancer deaths are attributable to cigarette smoking!
   ◊ Passive smoking may account for 25% of lung cancers in nonsmokers!

(2) Radon gas: may be the 2nd leading cause for lung cancer with up to 20,000 deaths annually

(3) Industrial exposure: asbestos, uranium, arsenic, chlormethyl ether

(4) Concomitant disease: chronic pulmonary scar + pulmonary fibrosis

Scar carcinoma

◊ 45% of all peripheral cancers originate in scars!

Frequency: 7% of lung tumors; 1% of autopsies

Origin: related to infarcts (> 50%), tuberculosis scar (< 25%)

Histo: adenocarcinoma (72%), squamous cell ca. (18%)

Location: upper lobes (75%)

Location:

◊ 60–80% arise in segmental bronchi

› central: small cell carcinoma, squamous cell carcinoma (sputum cytology positive in 70%); arises in central airway often at points of bronchial bifurcation, infiltrates circumferentially, extends along bronchial tree

mnemonic: **S**mall **c**ell **a**nd **S**quamous are **S**entral

› peripheral: adenocarcinoma, large cell carcinoma

› upper lobe÷lower lobe = right lung÷left lung = 3÷2

› most common site: anterior segment of RUL

› **Pancoast tumor** (3%) = superior sulcus tumor, frequently squamous cell carcinoma
- atrophy of muscles of ipsilateral upper extremity ← lower brachial plexus involved
- Horner syndrome (enophthalmos, miosis, ptosis, anhidrosis) ← sympathetic chain + stellate ganglion involved

√ apical pleural thickening / mass

√ ± soft-tissue invasion / bone destruction

√ coronal + sagittal MR images improve evaluation

› SVC obstruction (5%): often in small cell carcinoma

Presentation:

√ solitary peripheral mass with corona radiata / "pleural tail" sign / satellite lesion

√ cavitation (16%): usually thick-walled with irregular inner surface; in 80% squamous cell carcinoma, followed by bronchioloalveolar carcinoma

√ central mass (38%): common in small cell carcinoma

√ unilateral hilar enlargement ← primary tumor / enlarged lymph nodes

Histologic Classification of Lung Cancer
(WHO 2004)

Categories	*[%]*
Non-small cell lung cancer (NSCLC)	**85**
Adenocarcinoma	32–50
Adenocarcinoma (not otherwise specified)	
Bronchioloalveolar carcinoma	4–10
Squamous cell lung carcinoma	25–35
Large cell lung carcinoma	5–9
Others (carcinoid (1–2%), sarcomatoid, adenosquamous, salivary gland tumor, etc.)	
Small cell lung cancer (SCLC)	**15**
Limited disease / stage LS-SCLC (1/3) = confined to hemithorax, mediastinum, supraclavicular nodes *Rx:* curative intent chemo- + radiation therapy	5
Extensive disease / stage ES-SCLC (2/3) = hematogenous metastatic disease at presentation *Rx:* chemotherapy	10

√ calcified enlarged nodes frequently benign

√ nodes in short axis diameter:

› 0–10 mm normal (CAVE: micrometastases)

› > 10 mm (65% sensitive + specific for tumor)

› 20–40 mm (37% NOT involved by tumor)

√ PET (89% sensitive, 99% specific)

√ anterior + middle mediastinal widening (suggests small cell carcinoma)

√ segmental / lobar / lung atelectasis (37%) ← airway obstruction (particularly in squamous cell carcinoma):

√ postobstructive lung enhances to a greater extent than tumor

√ distal lung atelectasis has a higher SI on T2WI than the central mass (in 77%) ← accumulation of secretions in obstructed lung

√ **"(reverse) S"** sign of Golden on PA CXR = combination of:

√ RUL collapse (inferiorly concave margin of lateral portion of minor fissure, which moved superiorly and medially with compensatory expansion of RML)

√ bulge of central tumor (inferiorly convex margin of medial portion of minor fissure)

√ rat tail termination of bronchus

√ "bronchial cuff "sign = focal / circumferential thickening of bronchial wall imaged end-on

(early sign)
√ local hyperaeration ← check-valve type endobronchial obstruction (best on expiratory view)
√ mucoid impaction of segmental / lobar bronchus ← endobronchial obstruction
√ persistent peripheral infiltrate (30%) = postobstructive pneumonitis
√ NO air bronchogram
√ pleural effusion (8–15%): most commonly due to adenoca.
√ chest wall invasion:
• localized chest wall pain = most sensitive predictor
√ tumor interdigitation with chest wall musculature on T2WI
√ obliteration of high-intensity extrathoracic fat on T1WI
√ bone erosion of ribs / spine (9%)
√ involvement of main pulmonary artery (18%); lobar + segmental arteries (53%) may result in additional peripheral radiopacity ← lung infarct
√ calcification in 7% on CT (histologically in 14%) usually eccentric / finely stippled
(a) preexisting focus of calcium engulfed by tumor
(b) dystrophic calcium within tumor necrosis
(c) calcium deposit from secretory function of carcinoma (eg, mucinous adenocarcinoma)

PET-CT:
√ lung nodule > 1 cm (97% sensitive, 78% specific)
Spatial resolution: 4 mm diameter
Metabolic resolution: 1 mm diameter = 1,000,000 cells
False positive: infection, granulomatous disease, other inflammatory disease
False negative: partial volume effect, small tumor size < 1 cm, respiratory motion blurring, low glycolytic activity (bronchioloalveolar carcinoma, carcinoid tumor)

(1) Staging (PET-CT better than any other modality)
◊ Occult metastases detected in up to 40% of cases!
(a) intrathoracic lymph nodes
√ lymph node with short-axis diameter > 1 cm by CT + NOT FDG avid = 100% NPV
√ small lymph node by CT + intense FDG uptake = 100% PPV
√ cancerous mediastinal nodes (91% sensitive, 86% specific) better than CT alone (75% sensitive, 66% specific)
◊ 21% of normal-sized nodes harbor metastatic dz

T-Staging of Lung Cancer
7th edition of TNM in Lung Cancer by International Association for the Study of Lung Cancer (2009)

Stage	*Diameter*	*Endoscopy*	*Atelectasis / obstructive pneumonia*	*Invasion of*	*Separate nodule(s)*
T1	T1a ≤2 cm T1b >2 to ≤3 cm	no invasion proximal to lobar bronchus			
T2	T2a >3 to ≤5 cm T2b >5 to ≤7 cm	main bronchus (≥2 cm distal to carina)	to hilus but not entire lung	visceral pleura	
T3	tumor >7 cm	main bronchus (≥2 cm distal to carina)	entire lung	parietal pleura, chest wall, diaphragm, mediastinal pleura, pericardium	within same lobe
T4	any tumor size			mediastinum / trachea / heart / great vessels / esophagus / vertebral body / carina	within different lobe

Anatomic Definition of Lymph Node Stations
International Association for the Study of Lung Cancer (IASLC)

Name	*Location*	*Upper Border*	*Lower Border*
supraclavicular	low cervical, supraclavicular, sternal notch	cricoid	clavicles; manubrium
superior mediastinal	upper paratracheal	apex of right lung; manubrium	intersection of innominate v. + trachea (RT); aortic arch (LT)
	prevascular, retrotracheal	apex of chest	carina
	lower paratracheal = para- and pretracheal	intersection of innominate v. + trachea (RT); aortic arch (LT)	azygos v. (RT); Lt pulmonary artery (LT)
aortic	subaortic = aortopulmonary window	lower aortic arch	Lt pulmonary artery
	paraaortic = ascending aorta / diaphragm	upper aortic arch	lower aortic arch
inferior mediastinal	subcarinal	carina	bronchus intermedius (RT); lower lobe bronchus (LT)
	paraesophageal = below carina	bronchus intermedius (RT); lower lobe bronchus (LT)	diaphragm
	pulmonary ligament	inferior pulmonary v.	diaphragm
N1 nodes	hilar, interlobar, lobar, segmental, subsegmental		

◊ 40% of enlarged nodes are free of metastatic dz

(b) adrenal metastasis
- √ PET scan: 100% sensitive, 80–95% specific
- √ FDG can differentiate adrenal "incidentaloma" from metastasis

(c) bone metastasis
- √ bone scan: 80–94% sensitive, 67–75% specific
- √ PET scan: 92–96% sensitive, 98% specific

(2) Recurrent disease (restaging) = residual tumor versus posttreatment changes
- ◊ radiotherapy + chemotherapy alter morphology causing confusion for CXR, CT, MR
- √ increased FDG uptake at sites of residual radiographic abnormality > 8 weeks after completion of therapy

False positive: radiation pneumonitis (evaluation must be postponed for 2–4 months)

Angio:
- √ bronchogenic carcinoma supplied by bronchial arteries
- √ distortion / stenosis / occlusion of pulmonary arterial circulation

Cx:

(1) Diaphragmatic elevation (phrenic nerve paralysis)
(2) Hoarseness (laryngeal nerve involvement, left > right)
(3) SVC obstruction (5%): lung cancer is cause of all SVC obstructions in 90%

(4) Pleural effusion (10%): malignant, parapneumonic, lymphoobstructive
(5) Dysphagia: enlarged nodes, esophageal invasion
(6) Pericardial invasion: pericardial effusion, localized pericardial thickening / nodular masses
(7) massive hemoptysis ← neovascularity, parenchymal destruction, angioinvasion by tumor

Prognosis: mean survival time < 6 months; 15% overall 5-year survival; survival at 40 months: squamous cell 30% > large cell 16% > adenocarcinoma 15% > oat cell 1%

Rx:

(1) Surgical resection for non-small cell histologic types
Unresectable: involvement of heart, great vessels, trachea, esophagus, vertebral body, malignant pleural effusion
(2) Adjuvant chemotherapy + radiation therapy in extensive resectable disease
(3) Chemotherapy for small cell carcinoma + radiation therapy for bulky disease, CNS metastases, spinal cord compression, SVC obstruction
(4) Embolization of bronchial artery

MULTIPLE PRIMARY LUNG CANCERS

Frequency: 0.72–3.5%; in ⅓ synchronous, in ⅔ metachronous

◊ 10–32% of patients surviving resection of a lung cancer will develop a second primary!

Dx: biopsy mandatory for proper therapy because tumors may have / develop a different cell type

PARANEOPLASTIC MANIFESTATIONS OF LUNG CANCER

1. Carcinomatous neuromyopathy (4–15%)
2. Migratory thrombophlebitis
3. Hypertrophic pulmonary osteoarthropathy (3–5%)

NM-Staging of Lung Cancer
7th edition of TNM in Lung Cancer IASLC (2009)

Stage	*Description (node ≥1 cm in short axis)*
N1	peribronchial / ipsilateral hilar nodes
N2	ipsilateral superior + inferior mediastinal nodes
N3	contralateral hilar / mediastinal nodes; scalene / supraclavicular nodes on either side
M1a	*intrathoracic spread*: malignant pleural / pericardial effusion, separate tumor nodule(s) in contralateral lung
M1b	*disseminated (extrathoracic) disease*: liver, bone, brain, adrenal gland, etc.

4. Endocrine manifestations (15%) usually with small cell carcinoma: Cushing syndrome, inappropriate secretion of ADH, HPT, excessive gonadotropin secretion

SPREAD OF LUNG CANCER

1. Direct local extension
2. Hematogenous (small cell carcinoma)
3. Lymphatic spread (squamous cell carcinoma)
   ◊ Normal-sized lymph nodes harbor tumor in 10%
4. Transbronchial spread – least common

DISTANT METASTASES OF LUNG CANCER

Likelihood: small cell > adeno > large cell > squamous

@ Bone

(a) marrow: in 40% at time of presentation

(b) gross lesions in 10–35%:

Location: vertebrae (70%), pelvis (40%), femora (25%)

√ osteolytic metastases (¾)

√ osteoblastic metastases (¼) in small cell carcinoma / adenocarcinoma

√ occult metastases in 36% of bone scans

@ Adrenals: in 37% at time of presentation

◊ 50% of adrenal masses in lung cancer patients are benign!

@ Brain: asymptomatic metastases on brain scan in 7% (30% at autopsy), in ⅔ multiple

@ Kidney, GI tract, liver, abdominal lymph nodes

@ Lung-to-lung metastases (in up to 10%, usually in late stage)

Adenocarcinoma of Lung (32–50%)

◊ Most common histologic subtype of lung cancer (2011)!

= intermediate malignant potential → slow growth, high incidence of early metastases

Doubling time: ~ 150–180 days

Histo: formation of glands / intracellular mucin

Subtype: bronchioloalveolar carcinoma

Location: almost invariably develops in periphery; frequently found in scars (tuberculosis, infarction, scleroderma, bronchiectasis) + in close relation to preexisting bullae

√ solitary peripheral subpleural mass (52%) / alveolar infiltrate / multiple nodules

√ may invade pleura + grow circumferentially around lung mimicking malignant mesothelioma

√ upper lobe distribution (69%)

√ air bronchogram / bronchiologram on HRCT (65%)

√ calcification in periphery of mass (1%)

√ smooth margin / spiculated margin ← desmoplastic reaction with retraction of pleura

Large Cell Carcinoma of Lung (5–9%)

= most heterogeneous of primary lung cancers

Path: difficult DDx from poorly differentiated adenoca. / SCC

Subtype: large cell = LC

› LC rhabdoid carcinoma

› LC basaloid carcinoma

› LC lymphoepithelioma

› LC neuroendocrine carcinoma (LCNEC, 2–3%)

› LC undifferentiated carcinoma

Large Cell Undifferentiated Carcinoma of Lung

◊ Strongly associated with smoking

Malignant potential: intermediate → rapid growth + early distant metastases

Doubling time: ~ 120 days

Histo: tumor cells with abundant cytoplasm + large nuclei + prominent nucleoli; diagnosed per exclusion due to lack of squamous / glandular / small cell differentiation

Subtype: giant cell carcinoma with very aggressive behavior + poor prognosis

√ large bulky usually peripheral mass > 6 cm (50%)
√ large area of necrosis
√ pleural involvement
√ large bronchus involved in central lesion (50%)

Squamous Cell Carcinoma of Lung (25–35%)

= EPIDERMOID CARCINOMA

◊ Strongly associated with cigarette smoking

Histo: mimics differentiation of epidermis by producing keratin ("epidermoid carcinoma"); central necrosis is common

Histogenesis: chronic inflammation with squamous metaplasia → progression to dysplasia + carcinoma in situ

• positive sputum cytology

◊ Most common cell type that is radiologically occult!

• hypercalcemia from tumor-elaborated parathyroid hormone-like substance

◊ Slowest growth rate, lowest incidence of distant metastases

Doubling time: ~ 90 days

(a) Central location in main / lobar / segmental bronchus (⅔)
√ large central mass ± cavitation
√ distal atelectasis ± bulging fissure ← mass effect
√ postobstructive pneumonia
◊ All cases of pneumonia in adults should be followed to complete radiologic resolution!
√ airway obstruction with atelectasis (37%)

(b) Solitary peripheral nodule (⅓)
√ characteristic cavitation (in 7–10%)
√ invasion of chest wall

◊ Squamous cell carcinoma is the most common cell type to cavitate and to cause Pancoast tumor!

Small Cell Undifferentiated Lung Carcinoma (13–20%)

= OAT-CELL CARCINOMA = SMALL CELL LUNG CANCER

◊ Most common primary pulmonary neuroendocrine neoplasm!

The prevalence of SCLC in the USA has been declining over the past 30 years to 13%–15%!

Cause: associated with cigarette smoking (in 95%)

Biologic behavior:
more aggressive than non-SCLC; rapid growth (= short doubling time); high growth fraction (= ratio of proliferating cells to total cells); high metastatic potential (early metastases in 60–70% at time of diagnosis); should be regarded as systemic disease

regardless of stage; virtually never resectable

Doubling time: ~ 30 days

Path: arises from bronchial mucosa with growth in submucosa + subsequent invasion of peribronchial connective tissue

Histo: small blue cells of round / oval / fusiform shape with scant cytoplasm, ill-defined borders, finely granular nuclear chromatin, absent / inconspicuous nucleoli; high cellularity with very high mitotic rate → large areas of necrosis; positive for neurosecretory granules (chromogranin, synaptophysin); in 20% coexistent with non-small cell histologic types (most frequently squamous cell)

Immunohistochemistry:

pancytokeratin antibodies (AE1/AE3, CD56), chromogranin– synaptophysin, thyroid transcription factor 1 (TTF-1 in 80%), Ki-67 proliferation index (in 80–100%) most helpful in separating SCLC from carcinoids

Age: 60–70 years; M÷F = 2.6÷1 to 1÷1

- weight loss, fatigue, anorexia, dyspnea, persistent cough
- chest pain, hemoptysis, postobstructive pneumonia
- symptoms of SVC syndrome (10%)

◊ Most common primary lung cancer causing superior vena cava obstruction ← extrinsic compression / endoluminal thrombosis / invasion!

- dysphagia ← esophageal invasion
- hoarseness ← invasion of recurrent laryngeal nerve
- smooth-appearing bronchial mucosal surface endoscopically
- paraneoplastic syndrome (= ectopic hormone production):
  - inappropriate secretion of ADH → ↓ concentration of urine, ↓ plasma osmolarity, euvolemic hyponatremia
  - Cushing syndrome ← ectopic ACTH production
  - acromegaly ← ectopic GHRP
  - hypercalcemic hyperparathyroidism
  - Eaton-Lambert myasthenia syndrome (= autoimmune neuropathy) → muscle weakness of limbs
  - encephalomyelitis, limbic encephalitis

Signs of extrapulmonary metastases:

bone marrow suppression, bone pain, pruritus, jaundice, seizures, mental status changes, ataxia

Location: 90–95% central within lobar / mainstem bronchus (primary tumor rarely visualized)

The most common manifestation of SCLC is a large centrally located lung mass or a mediastinal mass involving a hilum!

CT:

√ typically large hilar / perihilar parenchymal mass involving at least one hilum (85%):

√ extensive necrosis + hemorrhage

√ central mass often produced by a combination of primary neoplasm + mediastinal lymphadenopathy

√ centrally obstructing lesion → atelectasis of entire lung / major lobar atelectasis (30%)

√ "bronchus cut-off" sign

√ lobulated peripheral nodule without adenopathy (5%):
  √ fine spiculations ← vascular or lymphatic invasion / irregular intraalveolar spread
  √ marginal ground-glass opacity ← focal edema / hemorrhage / intraalveolar invasion
  √ enhancement reflecting tumor angiogenesis
√ intratumoral calcification (in up to 23%)
√ large confluent mediastinal (92%) / hilar 84%) adenopathy
√ displacement / narrowing of tracheobronchial tree (68%) or major vessels (68%)
√ atelectasis of entire lung / major lobar atelectasis (30%)
√ pleural effusion (38%) / thickening ± nodules

PET:

Useful for: initial tumor staging, treatment planning, prognosis (high SUV suggests poor survival)

√ avid FDG uptake (100%)

PET modifies management in up to 27% of patients!

Staging evaluation:

CT of abdomen + head, bone scintigraphy, bilateral bone marrow biopsies

Veterans Administration Lung Study Group (VALSG) Staging:

◊ Evaluate with CECT of chest (through adrenals) + brain MRI + PET/CT ± bone marrow biopsy

Limited disease / stage (LS-SCLC):

= without extrathoracic extension

1. Encompassed within single radiation port
2. Ipsilateral mediastinal / supraclavicular lymph nodes
3. Contralateral mediastinal / supraclavicular nodes
4. Ipsilateral (benign / malignant) pleural effusion

Extensive disease / stage (ES-SCLC in 60–70%):

= hematogenous metastatic disease at presentation

1. Not confined to single radiation port
2. Metastatic disease: contralateral lung, bone (19–38%), liver (17–34%), adrenal gland (10–17%), bone marrow (17–23%), CNS (8–15%), retroperitoneum (11%), other lymph nodes

Prognosis: 2–4 months median survival without treatment; 60–70% initial response to chemotherapy with relapse and death within 2 years; 5-year survival rate of 10–15% for LS-SCLC + 1–5% for ES-SCLC (unchanged for 30 years!)

Rx: (a) chemoradiation + prophylactic cranial irradiation + surgical resection (for LS-SCLC)

(b) etoposide + cisplatin (for ES-SCLC)

BRONCHOGENIC CYST

= CONGENITAL BRONCHOGENIC CYST

= fluid-filled blind pouch of ventral primitive foregut

◊ Belongs to spectrum of foregut duplication cysts!

Cause: abnormal budding / branching of primitive foregut between 26th and 40th day of

embryogenesis forming ventral diverticulum for tracheobronchial tree (dorsal segment = esophagus)

Frequency: most common intrathoracic foregut cyst (54–63% in surgical series)

Histo: thin-walled cyst filled with mucinous material, lined by columnar respiratory epithelium, mucous glands, cartilage, elastic tissue, smooth muscle

Location: mediastinum (near carina) >> lung parenchyma > pleura > diaphragm

- mostly incidental
- wheezing, stridor, dyspnea, dysphagia (in infants)

√ sharply outlined round / oval mass

√ may contain air-fluid level ← infection / communication with airway or GI tract

CT:

√ hypoattenuating lesion with smooth imperceptible wall

√ cyst contents of water density (50%) / higher density (50%) ← proteinaceous-mucoid material / milk of calcium

OB-US:

√ single unilocular fluid-filled pulmonary cyst in middle / posterior mediastinum

◊ Most common cystic lesion in fetal chest!

√ echogenic distended lung obstructed by bronchogenic cyst

Fetal MR:

√ hyperintense signal relative to lung + CSF on T2WI

√ occasionally hyperintense signal relative to lung on T1WI (mucoid / hemorrhagic content)

√ hyperintense obstructed lobe on T2WI

DDx: esophageal duplication cyst (middle / posterior mediastinum), neurenteric cyst (posterior mediastinum, vertebral defect)

Mediastinal Bronchogenic Cyst (86%)

Associated with: spinal abnormalities

M÷F = 1÷1

- asymptomatic (usually) vs. stridor, dysphagia

Location: pericarinal (52%), paratracheal (19%), esophageal wall (14%), retrocardiac (9%); usually on right

√ rarely communicates with tracheal lumen

√ may show esophageal compression

Intrapulmonary Bronchogenic Cyst (14%)

M > F

- infection (75%), dyspnea, hemoptysis (most common)

Location: lower÷upper lobe = 2÷1; usually medial third

√ 36% will eventually contain air

DDx: solitary pulmonary nodule, cavitated neoplasm, cavitated pneumonia, lung abscess

BRONCHOPULMONARY DYSPLASIA

= RESPIRATOR LUNG = BPD

= complication of respirator therapy (PPV or nasal CPAP) treated with > 21% oxygen for > 28 days

Cause: oxygen toxicity (lung damage by oxygen radicals) + barotrauma (bronchopulmonary injury from assisted ventilation)

- chronic oxygen dependency in premature neonates:
  - mild BPD = breathing room air
  - moderate BPD = need for < 30% oxygen
  - severe BPD = need for ≥ 30% oxygen ± PPV or nasal CPAP

Pathogenesis: hypoxia + oxygen toxicity

› capillary wall damage, leakage of fluid into interstitium and pulmonary edema

Stage I (0–3 days):

Path: loss of ciliated cells + necrosis of bronchiolar mucosa

√ RDS pattern of hyaline membrane disease

Stage II (4–10 days):

Path: hyaline membranes, eosinophilic exudate, squamous metaplasia, interstitial edema

Associated with: congestive failure from PDA

√ complete opacification with air bronchogram

› fibrosis of interstitium + groups of emphysematous alveoli

Stage III (10–20 days):

Path: fewer hyaline membranes, persistent injury of alveolar epithelium, exudation of macrophages

√ small round cystic lucencies alternating with regions of irregular opacity

Stage IV (after 1 month):

Path: septal wall thickening, dilated + tortuous lymphatics

√ "spongy" / "bubbly" coarse linear densities, esp. in upper lobes

√ hyperaeration of lung

√ lower lobe emphysema

CT:

√ regional air trapping

√ thickened interlobular septa

√ subsegmental atelectasis

√ reduced bronchoarterial diameter ratios

√ bronchial wall thickening

√ bullae + pneumatoceles

Prognosis: 40% mortality if not resolved by 1 month

Cx: (1) Increased airway reactivity = increased frequency of lower respiratory tract infections

(2) Obstructive airway disease = asthmalike clinical picture

(3) Focal atelectasis

(4) Cor pulmonale

(5) Rib fractures, rickets, renal calcifications (← chronic furosemide therapy)

(6) Cholelithiasis (← hyperalimentation ± ? furosemide)

(7) Focal areas of tracheomalacia, tracheal stenosis, acquired lobar emphysema

Rx: supportive

Prognosis:

(1) Complete clearing over months / years (⅓)

(2) Retained linear densities in upper lobe emphysema (29%)

DDx:

(a) conditions present at birth:
  (1) Diffuse neonatal pneumonia
  (2) Meconium aspiration
  (3) Total anomalous pulmonary venous return
  (4) Congenital pulmonary lymphangiectasia

(b) conditions developing over time:
  (1) Recurrent pneumonias with scarring (gastroesophageal reflux, tracheoesophageal fistula, immune deficiency, etc)
  (2) Cystic fibrosis
  (3) Idiopathic pulmonary fibrosis

(c) conditions not apparent at birth:
  (1) Wilson-Mikity syndrome
  (2) Pulmonary interstitial emphysema
  (3) Patent ductus arteriosus (uncommon appearance)
  (4) Overhydration
  (5) Perinatally acquired viral infection (especially CMV)

BRONCHOPLEURAL FISTULA

= BRONCHOPULMONARY FISTULA

= communication between the bronchial system / lung parenchyma + pleural space

Cause:

A. TRAUMA
  1. Complication of resectional surgery (pneumonectomy, lobectomy, bullectomy)
  2. Blunt / penetrating trauma
  3. Barotrauma

B. LUNG NECROSIS
  1. Putrid lung abscess
  2. Necrotizing pneumonia: Klebsiella, H. influenzae, Staphylococcus, Streptococcus; tuberculosis; fungus; Pneumocystis
  3. Infarction

C. AIRWAY DISEASE
  1. Bronchiectasis (very rare)
  2. Emphysema complicated by pneumonia / pneumothorax

D. MALIGNANCY: lung carcinoma with postobstructive pneumonia / tumor necrosis following therapy

• large / persistent air leak; acute / chronic empyema

HRCT:

√ direct visualization of bronchopleural fistula (in 50%)

√ peripheral air + fluid collection (indirect sign)

Dx: (1) Introduction of methylene blue into pleural space, in 65% dye appears in sputum
(2) Sinography
(3) Bronchography

Rx: tube thoracostomy, open drainage, decortication, thoraco-plasty, muscle-pedicle closure, transbronchial occlusions

BRONCHOPULMONARY SEQUESTRATION

= congenital malformation consisting of
(1) Nonfunctioning bronchopulmonary tissue
(2) No communication with tracheobronchial tree
(3) Systemic arterial supply

Frequency: 0.15–6.4% of all congenital lung malformations; 1.1–1.8% of all pulmonary resections

◊ 2nd most common lung lesion found in utero after congenital pulmonary airway malformation!

Etiology: formation of supernumerary tracheobronchial foregut bud caudad to normal lung bud
(a) before development of pleura = intralobar
(b) after development of pleura = extralobar

◊ Pulmonary sequestration with communication to GI tract is termed **bronchopulmonary foregut malformation**!

Size: usually > 6 cm
√ round / oval, smooth, well-defined solid homogeneous mass near diaphragm with mass effect
√ occasionally fingerlike appendage posteriorly + medially (= anomalous vessel)
√ contrast enhancement of sequestration at the same time as thoracic aorta (on rapid sequential CT scans)
√ multiple / single air-fluid levels if infected
√ surrounded by recurrent pulmonary consolidation in a lower lobe that never clears completely
√ may communicate with esophagus / stomach

OB-US:
◊ The vast majority of sequestrations in fetuses are extralobar!
Age: usually in 2nd trimester
√ conical / triangular homogeneously hyperechoic mass (many interfaces from multiple microscopically dilated structures) in a paraspinal location
√ color duplex may demonstrate feeding artery from descending aorta
√ polyhydramnios (? esophageal compression, excessive fluid secretion by sequestration)
√ fetal hydrops (? venous compression):
√ edema, ascites
√ hydrothorax (obstructed lymphatics + veins in torsed sequestration)
Rx: prenatal thoracoamniotic shunt

Fetal MR:
√ solid well-defined uniform hyperintense mass on T2WI

DDx: bronchiectasis, lung abscess, empyema, bronchial atresia, congenital lobar emphysema, cystic adenomatoid malformation, intrapulmonary bronchogenic cyst, Swyer-James syndrome, pneumonia, arteriovenous fistula, primary / metastatic neoplasm, hernia of Bochdalek

Intralobar Sequestration (75–86%)

= shares pleural investment with affected normal pulmonary lobe but separated from

bronchial tree

Etiology: controversial

(1) Possibly acquired through repeated lung inflammation → hypertrophy of vessels in pulmonary ligament

(2) Early appearance of congenital accessory tracheobronchial bud → incorporation within one pleural investment

Path: chronic inflammation fibrosis: multiple irregular cordlike adhesions to mediastinum, diaphragm, parietal pleura; vascular sclerosis; multiple cysts filled with fluid / thick gelatinous / purulent material

hybrid lesion = intralobar sequestration + type II cystic adenomatoid malformation usually associated!

Age at presentation: adulthood (50% > 20 years); M÷F = 1÷1

Associated with congenital anomalies in 6–12%:

skeletal deformities (4%): scoliosis, rib + vertebral anomalies; esophagobronchial diverticula (4%); diaphragmatic hernia (3%); cardiac anomalies (including tetralogy of Fallot); failure of renal ascent + rotation; cerebral anomalies; congenital pulmonary venolobar syndrome

- about 50% have symptoms by age 20; asymptomatic in 15%
- pain, repeated infection in same location (eg, recurrent acute lower lobe pneumonias)
- high-output congestive heart failure (in neonatal period) from L-to-L shunt
- cough + sputum production, hemoptysis

Location: posterobasal segments, rarely upper lung / within fissure; L÷R = 3÷2

CXR:

√ recurrent / persistent pneumonia localized to lower lobe

√ cavitation and cysts ± fluid levels

◊ Sequestered lung is aerated via pores of Kohn / communication with tracheobronchial tree!

Bronchogram:

√ NO communication of rudimentary bronchial system of sequestration with tracheobronchial tree (rare exceptions)

Angio:

√ usually single large artery (mean diameter of 6 mm) coursing through inferior pulmonary ligament from

› distal thoracic aorta (73%)
› proximal abdominal aorta (22%)
› celiac / splenic artery
› intercostal artery (4%)
› anomalous branch of coronary artery
› subclavian artery

√ multiple arteries in 16% (with vessel diameter of < 3 mm)

√ combined systemic + pulmonary arterial supply

√ <u>venous drainage via</u>

› <u>normal pulmonary veins</u> to L atrium (in 95%)
› azygos / hemiazygos vv. / intercostal vv. / SVC into R atrium (in 5%)

CT:
- √ single / multiple thin-walled cysts containing fluid / mucus / pus / air-fluid level / air alone
- √ mucus-impacted ectatic bronchi (= fat density) in sequestered lung
- √ emphysema bordering normal lung (37%) = postobstructive hyperinflation of sequestered lung
- √ homogeneous / inhomogeneous soft-tissue mass with irregular borders
- √ irregular enhancement (rare)
- √ one / two anomalous systemic arteries arising from aorta (DDx: AVM, interrupted pulmonary artery, isolated anomaly, chronic infection / inflammation of lung or pleura, surgically created shunt)
- √ premature atherosclerosis of anomalous arteries
- ◊ Mucoid impaction of bronchus surrounded by hyperinflated lung is CHARACTERISTIC!

Cx: massive spontaneous nontraumatic pleural hemorrhage, chronic inflammation, fibrosis

DDx of mass: neurogenic tumor, lateral thoracic meningocele, extramedullary hematopoiesis, pleural tumor, CPAM type III

Bronchopulmonary Sequestrations

	Intralobar	*Extralobar*
Prevalence	75%	25%
Pleural investment	visceral pleura	own pleura
Venous drainage	pulmonary veins	systemic veins
Symptomatic	adulthood	first 6 months
Etiology	acquired	developmental
Congenital anomalies	15%	50%

DDx of cavity: lung abscess, necrotizing pneumonia, fungal / mycobacterial pneumonia, cavitating neoplasm, empyema

DDx of cysts: pulmonary abscess, empyema, bronchiectasis, emphysema, bronchogenic foregut cyst, pericardial cyst, eventration of diaphragm, congenital cystic malformation

Extralobar Sequestration (14–25%)

= accessory lobe with its own pleural sheath (= "Rokitansky lobe") preventing collateral air drift → airless round mass

[Karl Freiherr von Rokitansky (1804–1878), professor of pathological anatomy at Allgemeines Krankenhaus, Wien, Austria]

Etiology: anomalous accessory / supernumerary tracheo-bronchial foregut bud develops after formation of pleura

Path: single ovoid / rounded / pyramidal airless lesion

Histo: resembles normal lung with diffuse dilatation of bronchioles + alveolar ducts + alveoli; dilatation of subpleural + peribronchiolar lymph vessels; covered by mesothelial layer overlying fibrous connective tissue

Frequency: 0.5–6.0% of all congenital lung lesions

Age: neonatal presentation; 61% within first 6 months of life; occasionally in utero; M÷F =

4÷1

Associated with congenital anomalies in 15–65%:

@ Lung: congenital diaphragmatic hernia (20–30%), eventration / diaphragmatic paralysis (up to 60%), congenital cystic adenomatoid malformation type II (15–25%), lobar emphysema, bronchogenic cyst, pectus excavatum, congenital pulmonary venolobar syndrome
  ◊ May coexist / form part of spectrum with CAM
@ Heart: anomalous pulmonary venous return, cardiac / pericardial anomalies (8%)
@ GI tract: epiphrenic diverticula (2%), tracheoesophageal fistula (1.5%), intestinal duplication cyst, ectopic pancreas
@ Others: renal anomaly, vertebral anomaly

• respiratory distress + cyanosis + CHF in newborn ← shunting of blood
  ◊ Lower lobe pneumonia that does NOT clear with antibiotics!
• feeding difficulties
• asymptomatic (rarely becomes infected) in 10%

Location: L÷R = 4÷1; typically within pleural space in posterior costodiaphragmatic sulcus between diaphragm + lower lobe (63–77%); mediastinum; within pericardium; within / below diaphragm (5–15%)

Size: 3–6 (range, ½ – 15) cm in diameter

√ airless (NO communication with bronchial tree); presence of air → connection with GI tract is inferred
√ may contain cystic areas
√ mediastinal shift (if large)

Angio (diagnostic):
√ arterial supply from
  › aorta as single / several small branches (80%)
  › splenic, gastric, subclavian, intercostal branches (15%)
  › pulmonary artery (5%)
√ venous drainage via
  › systemic veins in 80% (IVC, azygos, hemiazygos, SVC, portal vein) to right heart
  › pulmonary vein (25%)

CXR:
√ single well-defined homogeneous triangular mass (most commonly located adjacent to posterior medial hemidiaphragm)
√ NO air bronchograms
√ small "bump" on hemidiaphragm / inferior paravertebral region
√ opaque hemithorax ± ipsilateral pleural effusion (if sequestration large)
√ ± air-fluid level

CT:
√ homogeneous well-circumscribed soft-tissue density mass (no bronchial communication)

NUC (radionuclide angiography):
√ lack of perfusion during pulmonary phase followed by rapid perfusion in systemic phase

DDx: intrathoracic kidney, scimitar syndrome (with systemic supply to affected lung), hepatic herniation through diaphragm

DDx for chest lesion:
congenital cystic adenomatoid malformation, neuroblastoma, teratoma, diaphragmatic hernia
DDx for infradiaphragmatic lesion:
neuroblastoma, teratoma, adrenal hemorrhage, mesoblastic nephroma, foregut duplication
Cx: infection (in case of communication with bronchus / GI tract)
Rx: resection (delineation of vascular supply helpful)
Prognosis: favorable (worse if pulmonary hypoplasia present); decreases in size / disappears in up to 65% before birth

Esophageal / Gastric Lung
= rare variant of pulmonary sequestration
Age: infancy (as it is symptomatic)
• cough related to feeding; recurrent pulmonary infections
√ communication of bronchial tree of sequestered lung with esophagus / stomach

CANDIDIASIS

= CANDIDOSIS
◊ Most common nosocomial fungal infection
Organism: ubiquitous human saprophyte (Candida albicans most commonly) characterized by blastospheres (yeasts) admixed with hyphae / pseudohyphae (conventional stains)
◊ Normal constituent of gut flora
Manifestation: (1) Superficial overgrowth (thrush)
(2) Invasive systemic disease
At risk: particularly common in patients receiving immuno-suppressive therapy / with indwelling catheters
Entry:
(a) aspiration
(b) hematogenous dissemination from GI tract / infected central venous catheter
• prolonged fever despite broad-spectrum antibacterial coverage
• cough, hemoptysis
√ patchy airspace consolidation in lower lobe distribution
√ interstitial pattern
√ diffuse micro- / macronodular disease
√ pleural effusion (25%)

Cerebral Candidiasis

= disseminated disease
√ scattered cerebral microabscesses of < 3 mm
√ macroabscess + meningitis (uncommon)
Cx: angioinvasion → thrombosis and hemorrhage

CARDIOPULMONARY SCHISTOSOMIASIS

= form of parasitic embolism
Organism: Schistosoma mansoni (endemic in Middle East, Africa, Atlantic coast of South

America, Caribbean; S. japonicum and S. haematobium (less commonly)

At risk: > 5 years of continuous ova secretion

Prerequisite: portal hypertension with periportal hepatic fibrosis

Cycle: eggs travel as emboli via portosystemic collateral pathways to lodge in pulmonary muscular arteries and arterioles (50–150 μm in diameter)

Pathogenesis:

eggs trapped in pulmonary arteries are antigenic → incite an obliterative endarteritis (due to delayed host hypersensitivity) → pulmonary hypertension

Path: intra- and perivascular granulomas, intimal hyperplasia, medial hypertrophy, concentric collagen deposition and fibrosis of vessel walls; localized alveolitis with eosinophilic infiltration; pulmonary infarction

Age: 25–35 (range, 1–93) years

- gradually worsening hepatosplenomegaly
- dyspnea, cough, chest pain
- severe hypoxemia, cyanosis, digital clubbing

CXR:

√ cardiomegaly
√ central pulmonary arterial enlargement
√ tiny scattered lung nodules occasionally

HRCT:

√ nodules of 2–15 mm, interstitial thickening
√ larger nodules surrounded by ground–glass-opacity halo
√ dilatation of right atrium + right ventricle + central pulmonary arteries

Cx: cor pulmonale (2–33%)

Rx: praziquantel, oxamniquine

CASTLEMAN DISEASE

= ANGIOFOLLICULAR LYMPH NODE HYPERPLASIA = BENIGN GIANT LYMPH NODE HYPERPLASIA = ANGIOMATOUS LYMPHOID HAMARTOMA = LYMPHOID HAMARTOMA

[Benjamin Castleman (1906–1982), chief of anatomic pathology at Massachusetts General Hospital, Boston]

= diverse group of rare nonclonal lymphoproliferative disorders of differing histopathologic properties + biologic behavior

Etiology: lymphoid-hamartomatous hyperplasia, autoimmune disease, immunodeficiency, chronic low-grade inflammation

Associated with: unregulated overproduction of interleukin-6

Histopathogenetic classification:

(a) **hyaline-vascular Castleman disease** (76–91%) nonclonal hyaline vascular lymph follicles; expanded mantle zones of small lymphocytes forming concentric rings ("onionskin"); prominent capillary proliferation with endothelial hyperplasia in interfollicular areas; involuted germinal centers often penetrated by single capillary vessel ("lollipop" appearance)

Age: 3rd– 4th decade

- asymptomatic

√ unicentric intensely enhancing mass (in 90%)
√ calcification + central fibrosis
Prognosis: benign course
Rx: curative surgical resection, steroids ± chemotherapy

(b) **plasma cell Castleman disease** (4–9–24%) sheets of plasma cells between normal / enlarged follicles; paucity of capillaries
Prevalence: < 10% of Castleman disease
Age: 6th decade
• systemic manifestations: fever, night sweats, malaise
• anemia, thrombocytopenia, hyperglobulinemia
√ multicentric / unicentric (9–24%) mass
√ splenomegaly
Prognosis: worse than hyaline vascular Castleman
Rx: systemic chemotherapy, antiproliferative agents

(c) **HHV-8–associated Castleman Disease**
[HHV= **H**uman **H**erpes **V**irus]
= plasmablastic variant (= microlymphoma) in immunosuppressed patients with positive HIV status
• generalized lymphadenopathy; constitutional symptoms
• hematologic ± immunologic abnormalities
Prognosis: poor with several months of survival
Rx: systemic chemotherapy, antiviral + antiproliferative regimens (rituximab)

(d) multicentric not otherwise specified

Morphologic classification: unicentric versus multicentric
Location: chest / mediastinum (46–70%), neck (15%), abdomen & pelvis (15%)
extralymphatic: lung, larynx, parotid, pancreas, meninges, muscle
Mean size: 5 cm
√ enlarged lymph node with preserved architecture

Localized / Unicentric Angiofollicular Lymph Node Hyperplasia

Cause: chronic viral antigenic stimulation with reactive lymphoid hyperplasia / developmental growth disturbance of lymphoid tissue
Age: all age groups (peaks in 4th decade); M÷F = 1÷4
Histo: mostly hyaline-vascular cell type (95%)
Location:
(a) middle mediastinum + hila
(b) cervical lymph nodes
(c) mesenteric + retroperitoneal lymph nodes
(d) extralymphatic sites: lung, larynx, parotid gland, pancreas, meninges, muscle
Morphologic types:
(a) solitary well-circumscribed mass without associated lymphadenopathy (50%)
(b) dominant mass displacing / surrounding / invading contiguous structures + lymphadenopathy (40%)
(c) multiple enlarged matted lymph nodes confined to one mediastinal compartment (10%)
• asymptomatic in 58–97%; growth retardation

- cough, dyspnea, hemoptysis, lassitude, weight loss, fever
- ↑ sedimentation rate, refractory microcytic anemia
- IgG, IgM, IgA hypergammaglobulinemia (50%)

Size: up to 16 cm in diameter

US:
- √ well-defined homogeneous hypoechoic mass
- √ increased vascularity on color Doppler with large vessels at periphery extending centrally

CT:
- √ sharply marginated smooth / lobulated homogeneous solitary mass of muscle density
- √ spotty coarse peripheral / central branching calcifications (10–31%)
- √ enhancing rim (vascular capsule)
- √ intense enhancement almost equal to aorta (in hyaline vascular type)
- √ slight enhancement (in plasma cell type)
- √ nonenhancing central areas ← fibrosis / cystic necrosis
- √ pleural effusion (uncommon)

MR:
- √ heterogeneous mass iso- / hyperintense to muscle on T1WI
- √ markedly hyperintense on T2WI
- √ T2-hypointense stellate scar = central area / linear web of hypointensity ← fibrosis / fibrous septa reminiscent of stellate scar of hepatic fibrolamellar carcinoma
  - √ scar hypointense on early phase dynamic T1WI
- √ peripheral flow voids of feeding vessels surrounding mass (in hyaline vascular type)

Angio:
- √ hypervascular mass with intense homogeneous blush (hyalin-vascular type)
- √ enlarged feeding vessels arising from bronchial / internal mammary / intercostal arteries
- √ some hypervascularity (plasma cell type)

DDx: indistinguishable from lymphoma

Prognosis: good with treatment; ~ 100% curative

Rx: (1) Complete surgical resection
(2) Radiation + steroid therapy

DDx: thymoma, lymphoma, sarcoma, hemangiopericytoma, paraganglioma, neurofibroma, schwannoma, chest wall tumor, bronchial adenoma, mesenteric fibromatosis, inflammatory myofibroblastic tumor, microcystic lymphatic malformation

Disseminated / Generalized / Multicentric Angiofollicular Lymph Node Hyperplasia

= potentially malignant lymphoproliferative disorder

Cause: disordered immunoregulation with polyclonal plasma cells from viral infection with uncontrolled B-cell proliferation + interleukin-6 dysregulation

Mean age: 40–60 years; M÷F = 2÷1

Histo: mostly plasma cell type (66%) with infiltration of nodes by sheets of mature plasma cells

Associated with:

(a) hyperplasia without neuropathy

- fatigue, anorexia, skin lesions, CNS disorders

(b) hyperplasia with POEMS syndrome

(c) osteosclerotic myeloma, HHV-8 (Kaposi sarcoma, AIDS)

√ 1–6 cm large homogeneous lymph nodes in multiple mediastinal compartments
√ variable mild contrast enhancement
√ peripheral multicentric adenopathy
√ hepatosplenomegaly
√ salivary gland enlargement
√ ascites
√ lymphocytic interstitial pneumonitis (LIP):
  √ ± ill-defined centrilobular nodules
  √ ground-glass attenuation
  √ air-space consolidation
  √ cysts ← partial airway obstruction by peribronchial + peribronchiolar LIP
  √ thickening of bronchovascular bundles

Rx: surgical resection, irradiation, systemic chemotherapy + corticosteroids

Prognosis: mean survival of 24–33 months

CATAMENIAL PNEUMOTHORAX

[*kata*, Greek = according to; *men*, Greek = month]

= recurrent spontaneous pneumothorax during menstruation associated with endometriosis of the diaphragm; R >> L

• right scapular / thoracic pain within 24–72 hours after onset of menstruation

Frequency: 24–33% of recurrent spontaneous pneumothoraces in women of reproductive age referred for surgery

◊ Coexistent abdominal endometriosis in 60–80%

Dx: brown nodules on video-assisted thoracoscopic surgery (VATS)

Rx: (1) Suppression of endometrial implants by hormonal manipulation
(2) Resection of endometrial implants with closure of diaphragmatic holes

CHEMICAL PNEUMONITIS

= inhalation of noxious chemical substances

A. ORGANIC: organophosphates, paraquat, polyvinyl chloride, polymer fumes, smoke
B. NONORGANIC: ammonia, hydrogen sulfide, nitrogen oxide, sulfur dioxide
C. METAL: cadmium, mercury, nickel, vanadium

Carbamates

= agricultural insecticides functioning as cholinesterase inhibitor (similar to organophosphates) but with poor penetration into CNS

√ pulmonary edema with respiratory failure

Paraquat

= agricultural herbicide

Exposure: often intentional ingestion

Pathophysiology: rapid accumulation in lungs with production of superoxide radicals damaging pulmonary cells

CXR (wide radiographic variability:
√ no abnormality
√ increased interstitial / granular opacities
√ pulmonary edema
√ pneumomediastinum

HRCT:
√ bilateral diffuse areas of ground-glass attenuation evolving into consolidation with bronchiectasis, irregular lines, traction bronchiectasis of interstitial fibrosis

Hydrogen Sulfide

= irritant + chemical asphyxiant gas

Industries: coal mines, tanneries, petroleum manufacturing plants, geothermal power plants, aircraft factories, sewer works, rubber works

Effect: toxic for respiratory (large quantities → inhibition of medullary respiratory center) + neurologic systems

• "knockdown" = brief loss of consciousness ← bronchial hyperresponsiveness

• determination of urine thiosulfate levels (to monitor occupational exposure); smell of rotten eggs
√ pulmonary edema

Ammonia

= highly soluble corrosive gas acts as a mucosal irritant
Industries: production of explosives, petroleum, agricultural fertilizer, plastics
√ pulmonary edema
Prognosis: complete recovery; bronchiectasis + bronchiolitis obliterans may develop

Hydrocarbon

Exposure: ingestion / aspiration (eg, accidental poisoning in children; fire-eating performers)
Path: (a) acute phase: intraalveolar, intrabronchial, peribronchial, interstitial accumulation of inflammatory cells + edema
(b) chronic phase (1–2 weeks after initial onset): proliferative bronchiolitis, parenchymal fibrosis, pneumatocele formation
√ uni- / bilateral consolidation, well-defined nodules
√ pneumatoceles (from coalescing areas of bronchiolar necrosis / partial obstruction of bronchial lumen)

Mercury

Exposure: inhalation of mercury vapor
Industries: electrolysis, manufacture of thermometers, cleaning of boilers, smelting silver from dental amalgam containing mercury
Pathophysiology: acute chemical bronchiolitis + pneumonitis followed by diffuse alveolar damage with hyaline membrane formation
• pulmonary function impairment
√ perivascular haziness + fine reticular opacities
√ pulmonary interstitial fibrosis
Prognosis: acute inhalation poisoning usually fatal

CHYLOTHORAX

= leakage of chyle (= lymph containing chylomicrons of suspended fat) from thoracic duct or its branches into pleural space ← obstruction / disruption of thoracic duct (in 2%)

Etiology:

A. Developmental defects
   1. Thoracic duct atresia
   2. Lymphangiectasia
   3. Lymphangioma
   4. Lymphangiomatosis (rare): mediastinal / thoracic cystic hygroma of neck growing into mediastinum
   5. Lymphangioleiomyomatosis ± tuberous sclerosis

B. Trauma
   1. Closed / penetrating chest trauma / birth trauma (25%): latent period of 10 days

2. Surgery (2nd most common cause):
   esophagectomy / cardiovascular surgery, esp. coarctation repair (0.5%), retroperitoneal surgery, neck surgery
3. Subclavian venous catheter

C. Neoplasm (54%)
1. Lymphoma (most common cause)
2. Metastatic cancer

D. Fibrosing conditions
1. Mediastinitis
2. Tuberculosis
3. Filariasis (rare)

E. Obstruction of central venous system / thoracic duct

F. Idiopathic / cryptogenic (15%): most common cause in neonatal period

G. Transdiaphragmatic passage of chylous ascites

Age: in full-term infants; may be present in utero; M÷F = 2÷1

Frequency: 1÷10,000 deliveries

May be associated with:
trisomy 21, tracheoesophageal fistula, extralobar lung sequestration, congenital pulmonary lymphangiectasia

- high in neutral fat + fatty acid (low in cholesterol):
  - triglyceride level > 110 mg/dL
- milky viscoid fluid (chylomicrons) after ingestion of milk / formula and clear during fasting

√ usually unilateral loculated pleural effusion
(a) right chylothorax ← duct disruption inferior to T5–6 (more common)
(b) left-sided chylothorax if duct disrupted above T5–6

√ low attenuation (fat) / high attenuation (protein content)

√ ± leakage of lymphangiographic contrast

√ polyhydramnios (? result of esophageal compression)

Cx: (1) Pulmonary hypoplasia
(2) Hydrops (congestive heart failure ← impaired venous return)

Rx: (1) Thoracentesis → loss of calories, lymphocytopenia, hypogammaglobulinemia
(2) Total parenteral nutrition
(3) Thoracic duct ligation (if drainage exceeds 1,500 mL/d for adults or 100 mL/year-age/day for children > 5 years of age; drainage > 14 days)
(4) Pleuroperitoneal shunt; tetracycline pleurodesis; mediastinal radiation; intrapleural fibrin glue; pleurectomy

COAL WORKER PNEUMOCONIOSIS

= CWP = ANTHRACOSIS = ANTHRACOSILICOSIS

Prevalence: 3%

Coal dust: inert, HOWEVER admixed silica is fibrogenic

Coal rank (= carbon content of coal):
anthracite (highest risk) > bituminous coal > lignite coal; washed coal = nearly free of silica

Pathophysiology of clearance:

inhaled coal dust deposited predominantly in respiratory bronchioles (slower air flow) + alveoli

(a) cleared by lymphatic flow (majority)
(b) cleared by mucociliary action (particle size > 5 μm)
(c) taken up by alveolar / interstitial macrophages = anthracosis (seen also in smokers + urbanites)

May be associated with: Caplan syndrome (in 1%)

DDx: silicosis, mycobacterial infection, sarcoidosis, subacute hypersensitivity pneumonitis

Simple CWP

coal macule = aggregate of centrilobular carbon-containing macrophages around bronchioles surrounded by network of collagen fibers + fibroblasts (about 1–5 mm in diameter)

◊ NO progression in absence of further exposure

Path: development of reticulin fibers associated with bronchiolar dilatation (focal emphysema) + bronchiolar artery stenosis (↓ capillary perfusion); with disease progression nodules may coalesce + become centrally necrotic ← ischemia

• poor correlation between symptoms + physiologic findings + roentgenogram

Location of coal macules:
around respiratory bronchioles in upper lobes >> lower lobes (higher pulmonary arterial gradient in lower portions of lung → higher lymphatic flow → coal dust particles clear more rapidly → particle deposition less prominent in lower lobes)

Size of nodules: < 10 mm

CXR:
√ small round 1–5-mm nodular interstitial opacities (only seen by superposition after an exposure of > 10 years):
√ granular appearance with poor definition of margins
√ nodularity correlates with amount of collagen (NOT amount of coal dust)
√ nodules calcify (in 10–20%) as central nodular dot
√ occasionally reticular / reticulonodular opacities

CT:
√ small round nodules diffusely involving both lungs in a perilymphatic distribution:
√ calcifications within nodules in 30%
√ pleural pseudoplaques (= coalescent macules in subpleural region)
√ hilar / mediastinal lymph node enlargement in 30%

Cx: (1) Chronic obstructive bronchitis
(2) Focal emphysema
(3) Cor pulmonale

Rx: reducing exposure, cessation of smoking, supplemental oxygen, bronchodilators, corticosteroids

DDx: silicosis (nodules diffusely calcified with well-defined margins, eggshell calcifications in only 1.3%)

Progressive Massive Fibrosis

= COMPLICATED PNEUMOCONIOSIS
= CONGLOMERATE ANTHRACOSILICOSIS

May develop / progress after cessation of dust exposure

Path: avascular amorphous central fibrotic mass of haphazardly arranged insoluble proteins stabilized by cross-links + ill-defined bundles of coarse hyalinized collagen at periphery; numerous pigment-laden macrophages and abundant free pigment; foci of frank necrosis, cholesterol clefts, chronic inflammatory cellular infiltrates

Location: almost exclusively restricted to posterior segment of upper lobe / superior segment of lower lobe

Size of nodules: > 10 mm

- cough (blackened sputum), dyspnea
- low FEV_1 (may not correlate with radiograph!)

√ large opacities initially at periphery of lung in middle + upper lung zones:
- √ irregular border + surrounding pericicatricial emphysema
- √ radiation toward hila starting at lung periphery; bilateral symmetry
- √ discoid contour (44%) = mass flat from front to back (thin opacity on lateral view, large opacity on PA view), medial border often ill-defined, lateral borders sharp + parallel to rib cage
- √ cavitation (occasionally) ← ischemic necrosis / superimposed TB infection

√ apparent decrease in nodularity ← incorporation of nodules from surroundings

√ bullous scar emphysema

√ pulmonary hypertension

√ ± enlargement + calcifications of mediastinal + hilar lymph nodes

MR:
- √ low SI on T1WI + T2WI compared to muscle ← fibrosis
- √ peripheral contrast enhancement

PET:
- √ hypermetabolic nodules (majority)

N.B.: Exposure reduction to coal dust does not stop progression of disease!

DDx: lung cancer (increased SI on T2WI), sarcoidosis, berylliosis, tuberculosis, talcosis

Carbon Black Pneumoconiosis

= burning of natural gas + petroleum products (filler in rubber, plastics, phonograph records, inks, carbon paper, carbon electrodes)

√ fine reticulonodular pattern with lower zone predominance

COCCIDIOIDOMYCOSIS

Organism: dimorphic soil fungus Coccidioides immitis and its close relative Coccidioides posadasii; arthrospores in desert soil spread by wind aerosolized in dry dust; highly infectious

Geographic distribution:

endemic in southwest desert of USA (San Joaquin Valley, central southern Arizona, western Texas, southern New Mexico) + northern Mexico + in parts of Central + South America; similar to histoplasmosis

Mode of infection:

arthrospores deposited in alveoli after inhalation; maturation into large thick-walled

spherules → rupture with release of hundreds of endospores (instead of budding)

Dx: (1) Culture of organism
(2) Spherules in pathologic material (demonstrated with Gomori-methenamine silver stain)
(3) Positive skin test
(4) Complement fixation titer

Primary Pulmonary Coccidioidomycosis (40%)

= ACUTE RESPIRATORY COCCIDIOIDOMYCOSIS

- 60–80% asymptomatic
- "valley fever" = influenza-like symptoms
- desert rheumatism (33%) most commonly in ankle
- rash, erythema nodosum / multiforme (5–20%)

√ segmental / lobar consolidation
√ patchy infiltrates mainly in lower lobes (46–80%) frequently subpleural + abutting fissures
√ peribronchial thickening
√ hilar adenopathy (20%)
√ pleural effusion (10%)

Chronic Respiratory Coccidioidomycosis (5–10%)

Prevalence: 5% of infected patients

- symptoms of postprimary tuberculosis, hemoptysis in 50%

√ one / several well-defined nodules (= coccidioidomycoma) of 5–30 mm in size (in 50–70%)
√ persistent / progressive consolidation
√ "grape skin" thin-walled cavities (in 10–15%), in 90% solitary, 70% in anterior segment of upper lobes (DDx: TB), 3% rupture into pleural space due to subpleural location (pneumothorax / empyema / persistent bronchopleural fistula
√ bronchiectasis
√ mediastinal adenopathy (10–20%)

Disseminated Coccidioidomycosis (1%)

= secondary phase of hematogenous spread to meninges, bones, skin, lymph nodes, subcutaneous tissue, joints (except GI tract)

- skin granulomas / abscesses

√ micronodular "miliary" lung pattern
√ pericardial effusion

Cerebral Coccidioidomycosis

= fungal meningitis (in 50%)
√ thick exudate + abnormal enhancement in basal cisterns + subarachnoid space

Cx: (1) Hydrocephalus
(2) Vasculitis (in up to 40%) involving small perforators → deep brain infarct
(3) Subarachnoid hemorrhage ← granulomatous inflammation of large vessels
(4) Cerebritis (especially in immunocompromised patients) → fungal extension

along vessel walls / in perivascular spaces

CONGENITAL HIGH AIRWAY OBSTRUCTION SYNDROME (CHAOS)

Cause: complete / near-complete obstruction of fetal airway → trapping of lung fluid + hyperplasia of pulmonary alveoli

√ tracheal dilatation

√ flattened / everted hemidiaphragm

√ massive ascites

Fetal MR:

√ enlarged hyperintense lungs on T2WI

Cx: hydrops fetalis ← cardiac compression + obstructed venous return

Prognosis: poor

CONGENITAL HYDROTHORAX

Prevalence: 1÷15,000 pregnancies

Cause: disequilibrium across pleural membranes due to

(a) primary cause: lymphatic duct abnormality → chylothorax → defective chest drainage

(b) secondary cause: generalized fluid retention related to immune / nonimmune fetal hydrops

Associated abnormalities (in 40%):

congenital cystic adenomatoid malformation, congenital diaphragmatic hernia, bronchopulmonary sequestration cardiac anomalies, Turner syndrome, Down syndrome, cystic hygroma, infection

Fetal MR:

√ lungs surrounded by fluid collection = hypointense on T1WI + hyperintense on T2WI

Rx: fetal intervention (thoracentesis / thoracoamniotic shunting) reserved for hydrothorax with marked mass effect

CONGENITAL LOBAR OVERINFLATION

= CONGENITAL LOBAR EMPHYSEMA (technically inaccurate term)

= progressive overdistension of one / multiple lobes

M÷F = 3 ÷1

Etiology:

(a) bronchomalacia: deficient / dysplastic / immature bronchial cartilage

(b) endobronchial obstruction: mucosal fold / web

(c) extrinsic bronchial compression: PDA, aberrant left pulmonary artery, pulmonary artery dilatation, bronchogenic cyst

(d) polyalveolar / macroalveolar hyperplasia

Histo: airspace enlargement without maldevelopment

Pathophysiology:

(a) collapsed airway acts as 1-way valve → air trapping with expansion of alveoli but intact alveolar wall

(b) bronchial obstruction → hyperinflated lung ← collateral air drift

Associated with: CHD in 12–15% (PDA, VSD)
• respiratory distress (90%) + progressive cyanosis within first 6 months of life; during first 2 days of life (50%)
Location: LUL (42–43%) > RML (32–35%) > RUL (20%) > either lower lobe (< 1%)
√ hazy masslike dense opacity immediately following birth ← delayed clearance of lung fluid in emphysematous lobe over 1–14 days
√ hyperlucent overinflated lobe (after clearing of fluid via lymphatic + capillary system)
√ air trapping:
  √ compression atelectasis of adjacent ipsilateral lobes
  √ contralateral mediastinal shift
  √ widening of rib spaces
  √ depression of ipsilateral hemidiaphragm
  √ widely separated but organized vascular markings
OB-US / MR:
  √ homogeneously hyperechoic mass
  √ mass of homogeneously high SI on T2WI
Mortality: 10%
Rx: ventilatory support (low-volume, low-pressure); surgical resection
DDx: pneumothorax, pulmonary cyst

CONGENITAL LYMPHANGIECTASIA

Primary Pulmonary Lymphangiectasia (⅔)

= CONGENITAL PULMONARY LYMPHANGIECTASIA
= abnormal development of lungs between 14th–20th week of GA characterized by anomalous dilatation of (pulmonary, subpleural, interlobar, perivascular, peribronchial) lymphatic vessels of chest
Path: subpleural cysts, ectatic tortuous lymph channels in pleura, interlobular septa + along bronchoarterial bundles; NO obstruction
Age: usually manifest at birth; 50% stillborn; M = F
May be associated with:
total anomalous pulmonary venous return, hypoplastic left heart, Noonan syndrome, Turner syndrome, Ehlers-Danlos syndrome, Down syndrome
• respiratory distress within few hours of birth
Site: diffuse involvement of both lungs, occasionally only in one / two lobes (with good prognosis)
√ marked prominence of coarse interstitial markings (simulating interstitial edema)
√ hyperinflation
√ scattered radiolucent areas (dilated airways)
√ patchy areas of pneumonia + atelectasis
√ pneumothorax
√ ± pleural effusion
Fetal MR:
  √ bilateral inhomogeneity of the lung parenchyma on T2WI

√ high SI in pulmonary interstitium on T2WI

Prognosis: with diffuse involvement invariably fatal at < 2 months of age

Generalized Lymphangiectasia

= DIFFUSE LYMPHANGIOMA

= proliferation of mainly lymphatic vascular spaces with relentless systemic progression

Age: children, young adults

Location: widespread visceral + skeletal involvement

√ diffuse pulmonary interstitial disease

√ chylous effusions in pleural + pericardial spaces

√ ± lytic bone lesions

√ lymphangiographic pooling of contrast material in dilated lymphatic channels / lymph nodes

Localized Lymphangioma

= rare benign usually cystic lesion

Histo: collection of dilated + proliferated lymph vessels (? hamartoma / benign neoplasm / focal sequestration of ectatic lymph tissue)

Age: first 3 years of life; M = F

• asymptomatic (33%); dyspnea ← tracheal compression

Location: neck (80%), mediastinum, axilla, extremity

√ discrete featureless mass

√ may have chylous / pleural effusion

√ may have lytic lesion in contiguous skeleton

Prognosis: propensity for local recurrence

DDx: hemangioma

Secondary Pulmonary Lymphangiectasia

Cause: surgery, infection, tumor genesis, pulmonary venous obstruction (← total anomalous pulmonary venous return, hypoplastic left heart syndrome)

CONGENITAL PULMONARY AIRWAY MALFORMATION (CPAM)

= CONGENITAL CYSTIC ADENOMATOID MALFORMATION (CCAM)

= congenital abnormality of the lung characterized by an intralobar mass of disorganized pulmonary tissue communicating with bronchial tree; normal vascular supply + drainage (pulmonary artery + vein) with delayed clearance of fetal lung fluid

Prevalence: 1÷25,000–35,000 pregnancies; 25% of congenital lung disorders; 30–40% of all congenital diseases 95% of congenital cystic lung lesions

◊ Most common fetal lung mass diagnosed in neonatal period / in utero!

Cause: arrest of normal bronchoalveolar differentiation (= branching) between 5th–7th week of gestation with overgrowth of terminal bronchioles

Path: proliferation of bronchial structures at the expense of alveolar saccular development; modified by inter-communicating cysts of various size (adenomatoid overgrowth of terminal bronchioles, proliferation of smooth muscle in cyst wall, absence of cartilage)
<u>hybrid lesion</u> = features of CPAM + bronchopulmonary sequestration with systemic arterial supply

Connections:
(a) proximal airways: abnormal communication
(b) blood supply: pulmonary artery
Exception: hybrid lesion → systemic blood supply
(c) blood drainage: pulmonary veins

Modified Stocker classification (2002):

Type 0 (< 3%, added later):
= ACINAR DYSPLASIA OF THE LUNG (previous designation)
= severe global arrest of lung development
Origin: trachea / bronchus
Histo: acinar dysgenesis / dysplasia = no cysts / very small ones (<0.5 cm)
Location: in any lobe
• incompatible with life

Type 1 = **large cyst CPAM** (60–70%):
Origin: bronchus / bronchiolus
Histo: (a) single large cyst > 20 mm
(b) 1–10 cm intercommunicating cysts surrounded by multiple smaller cysts lined by ciliated pseudo- stratified columnar epithelium, mucigenic (mucus-producing) cells in ⅓; small amount of supporting fibrous tissue + smooth muscle; NO cartilage
√ numerous variable-sized anechoic spaces of 1–10 cm in diameter intermixed with echogenic soft tissue on US
√ hyperintense uni- / multilocular lesion with discrete walls on T2WI
√ mass of variable density ± mediastinal shift on postnatal radiograph
√ round soft-tissue mass gradually filling with air on neonatal radiographs ← delayed clearance of fetal lung fluid through abnormal airway:
√ solitary well-defined air-filled cyst with thin wall
√ multiple air-filled cysts of varying sizes
√ ± air fluid levels
√ well-defined air-filled spaces on CT
√ ± abnormal systemic arterial supply
Prognosis: excellent following resection

Type 2 = **small cyst CPAM** (15–20%):
Origin: bronchiolus
Histo: multiple cysts / bronchiole-like structures < 20 mm in diameter lined by ciliated cuboidal / columnar epithelium without normal lung airspaces (similar to pulmonary hyperplasia associated with laryngeal atresia)
Strong association with: tracheoesophageal fistula, renal agenesis, intestinal atresia, diaphragmatic hernia
√ echogenic mass with multiple small 5–20 mm cysts
√ variable appearance with cystic + solid T2 components
√ heterogeneous intrapulmonary mass with small air-filled cystic areas on postnatal radiograph / CT
√ ± abnormal systemic arterial supply = hybrid lesion demonstrating features of CPAM + bronchopulmonary sequestration

Prognosis: poor secondary to associated abnormalities

Type 3 = **microcystic solid CPAM** (5–10%):

Origin: bronchiolar-alveolar duct (adenomatoid type)

Histo: solitary large bulky firm mass of bronchuslike structures lined by ciliated cuboidal epithelium with 3–5-mm small microcysts / solid type

√ large homogeneously echogenic mass compared with liver WITHOUT discernible cystic spaces

√ homogeneously hyperintense solid mass on T2WI

√ ill-defined area of increased attenuation on CT

Prognosis: poor ← pulmonary hypoplasia / hydrops

Type 4 (10–15%, added later):

Histo: type of "unlined" peripheral lung cyst

Unique association with: tension pneumothorax

√ large cyst up to 10 cm in diameter indistinguishable from a low-grade cystic pleuropulmonary blastoma / type 1 CPAM (clinically / radiologically)

In 25% associated with:

cardiac malformation, pectus excavatum, renal agenesis, prune-belly syndrome, jejunal atresia, chromosomal anomaly, bronchopulmonary sequestration

Age of detection: childhood, neonate, fetus; M÷F = 1÷1

• respiratory distress + severe cyanosis in 1st week of life (66%) / within 1st year of life (90%) ← compression of normal lung + airways

• superimposed chronic recurrent infection (10%) after 1st year

Location: equal frequency in all lobes (rare in middle lobe); more than one lobe involved in 20%; L÷R = 1÷1

◊ Mostly unilateral affecting an entire lobe!

CXR:

√ may appear normal due to prenatal regression

√ almost always unilateral expansile mass with well-defined margins (80%) ← retained fetal lung fluid / type III lesion

√ multiple air-filled cysts ← progressive expansion of cysts ← communication with tracheobronchial tree

√ effects of compression of adjacent lung:

√ contralateral shift of mediastinum (87%)

√ ipsilateral hypoplasia of uninvolved lung

√ proper position of abdominal viscera

√ spontaneous pneumothorax (late sign)

CT:

◊ Postnatally becoming obstructed and filled with air

√ solitary / multiple thin-walled cysts filled with fluid / air ± air-fluid / gas-liquid levels

√ surrounding focal emphysematous changes

OB-US (detectable at about 20 weeks GA):

√ lesion with single large / multiple large / multiple small cysts

√ echogenic (= nondiscernible microcystic) solid mass

√ rapid growth at 20–26 weeks GA followed by stabilization

√ contralateral mediastinal shift (89%)
√ polyhydramnios (25–75%) ? ← compression of esophagus / increased fluid production by abnormal lung
√ normal amniotic fluid (28%) / oligohydramnios (6%)
√ fetal ascites (62–71%)
√ fetal hydrops in 33–81% ← ⇓ venous return ← compression of heart / vena cava (= most important prognostic factor):
Predictable by: mass-thorax ratio > 0.56; CPAMvol ÷HC ratio > 1.6

Risk of recurrence: none

Cx: ipsi- / bilateral pulmonary hypoplasia

Prognosis: 50% premature, 97% survival rate (in absence of associated anomalies)
◊ Polyhydramnios, ascites, hydrops indicate a poor outcome!
◊ Postnatally lesions may regress / persist / remain stable: CPAM becomes smaller in fetuses in many cases + resolves spontaneously with < 60% of total lung volume!

Rx: (1) Thoracoamniotic shunting for single large cyst with fetal hydrops
(2) EXIT (ex utero intra partum) procedure after 32 weeks
(3) Surgical resection > 1 month of life (reason: risk of infection / small risk of malignancy)

DDx: (1) Congenital lobar emphysema
(2) Diaphragmatic hernia
(3) Bronchogenic cyst (small solitary cyst near midline)
(4) Neurenteric cyst
(5) Bronchial atresia
(6) Bronchopulmonary sequestration (less frequently associated with polyhydramnios / hydrops)
(7) Mediastinal / pericardial teratoma

CONGENITAL PULMONARY VENOLOBAR SYNDROME

= SCIMITAR SYNDROME
= unique form of congenital lung underdevelopment affecting one / more lobes in a constellation of distinctly different congenital anomalies of the thorax that often occur together; M÷F = 1÷1.4

◊ The most constant components of the syndrome are hypogenetic lung + partial anomalous pulmonary venous return

A. MAJOR COMPONENTS
1. Hypogenetic lung (69%): pulmonary lobar agenesis / aplasia / hypoplasia
√ hypoplasia / aplasia of one / more lobes of the lung with errors in lobation (= bilateral left bronchial branching pattern / horseshoe lung)
√ solid mass along posterior right hemidiaphragm (if trapped lung is unaerated)
√ large ipsilateral apical cap + blunted costophrenic angle
√ diminished radiolucency on involved side
√ small ipsilateral hemithorax + mediastinal shift
√ elevated hemidiaphragm
√ heart shifted toward involved side → cardiac dextroposition in right lung hypoplasia

2. Ipsilateral partial anomalous pulmonary venous return (PAPVR) → L-to-R shunt
   √ "**scimitar vein**" (90%) commonly connecting to infradiaphragmatic or suprahepatic portion of IVC / portal vein / hepatic vein / coronary sinus / R atrium
   √ on CXR seen only in 31%
3. Absence of pulmonary artery (14%)
   √ reticular densities (enlarged bronchial / transpleural arterial collaterals)
   √ indistinct hazy cardiomediastinal border on involved side
   √ small hilum ← absent / small pulmonary artery
   √ diminished pulmonary vascularity on involved side
4. Pulmonary sequestration (24%)
5. Systemic arterialization of lung without sequestration (10%)
   √ systemic arterial supply to abnormal segment from
   › thoracic aorta: bronchial, intercostal, transpleural
   › abdominal aorta: celiac artery, transdiaphragmatic
   √ rib notching
6. Absence / interruption of inferior vena cava (7%)
7. Duplication of diaphragm = accessory diaphragm (7%)
   = thin membrane in right hemithorax fused anteriorly with the diaphragm coursing posterosuperiorly to join with the posterior chest wall + trapping all / part of RML / RLL
   √ accessory fissurelike oblique line above right posterior costophrenic sinus (if trapped lung is aerated)
   √ broad retrosternal band of opacity (LAT view)
   CT:
   √ ovoid area of increased density in posterior right hemithorax (= dome of accessory diaphragm)

B. MINOR COMPONENTS

1. Tracheal trifurcation (extremely rare): 2 mainstem bronchi supplying the right lung
2. Eventration of diaphragm
3. Partial absence of diaphragm
4. Phrenic cyst
5. Horseshoe lung
6. Esophageal / gastric lung
7. Anomalous superior vena cava
8. Absence of left pericardium

Associated with:

(1) Vascular anomalies: hypoplastic artery, anomalous venous return, systemic arterial supply
(2) Anomalies of hemidiaphragm on affected side:
   √ retrosternal band on lateral CXR ← mediastinal rotation
   √ phrenic cyst
   √ diaphragmatic hernia
   √ accessory hemidiaphragm
(3) Hemivertebrae + scoliosis
   √ rib hypoplasia / malsegmentation
   √ anomalies of bony thorax / thoracic soft tissues

(4) CHD (25–50%): sinus venosus ASD, VSD, tetralogy of Fallot, PDA, coarctation of aorta, hypoplastic left heart, double-outlet right ventricle, double-chambered right atrium, endocardial cushion defect, persistent left SVC, pulmonary stenosis

May be associated with:
congenital tracheal stenosis, bronchogenic cyst, accessory diaphragm, diaphragmatic hernia, bronchitis, bronchiectasis

- usually asymptomatic in isolated hypogenetic lung (40%)
- may have exertional dyspnea / recurrent infections

Location: R÷L = 3÷1; RML (65%) > RUL (40%) > RLL (20%) > LUL (20%) > LLL (15%); multiple lobes (45%)

OB-US:
√ isolated cardiac dextroposition + normal abdominal situs
√ polyhydramnios
√ mild narrowing of right pulmonary artery

CXR:
√ curvilinear RLL density directed toward right hemidiaphragm

CT:
√ small bronchus + lobe
√ small hemithorax + mediastinal shift
√ abnormalities of bronchial branching
√ anomalously located pulmonary fissure
√ discontinuity of hemidiaphragm
√ pulmonary arterial hypoplasia
√ arterial supply from thoracic / abdominal aorta ← absent / hypoplastic pulmonary artery
√ hyparterial (instead of eparterial) right bronchus
√ one / more vessels increasing in diameter toward diaphragm
√ rind of subpleural fatty tissue in affected hemithorax
√ lack of normal venous confluence of right lung
√ venous drainage into IVC, hepatic vein, portal vein, right atrium, coronary sinus

DDx: meandering pulmonary vein, dextrocardia, hypoplastic lung, Swyer-James syndrome

Horseshoe Lung

= uncommon variant of hypogenetic lung syndrome in which RLL crosses midline between esophagus and heart + fuses with opposite LLL
√ oblique fissure in left lower hemithorax (if both lungs separated by pleural layers)
√ pulmonary vessels + bronchi crossing midline

COSTOCHONDRITIS

= musculoskeletal infection

Frequency: increased with IV drug abuse

Agents: Staphylococcus epidermidis, Streptococcus pneumoniae, Candida albicans, Aspergillus

CT:
√ soft-tissue swelling
√ cartilage fragmentation, bone destruction
√ low-attenuation cartilage

√ focal peripheral cartilaginous calcification

Rx: surgical excision

CRYPTOCOCCOSIS

= TORULOSIS = EUROPEAN BLASTOMYCOSIS

Organism: encapsulated unimorphic yeastlike fungus Cryptococcus neoformans; spherical single-budding yeast cell with thick capsule; stains with India ink; often in soil contaminated with pigeon excreta

Histo: granulomatous lesion with caseous necrotic center

Predisposed: opportunistic invader in diabetics + immunocompromised patients

• low-grade meningitis (affinity to CNS); M÷F = 4÷1

@ Lung

√ well-circumscribed mass (40%) of 2–10 cm in diameter, usually in peripheral location

√ lobar / segmental consolidation (35%)

√ cavitation (15%)

√ hilar / mediastinal adenopathy (12%)

√ calcifications (extremely rare)

√ interstitial pneumonia (rare, in AIDS patients)

@ Musculoskeletal

√ osteomyelitis (5–10%)

√ arthritis (rare, usually from extension of osteomyelitis)

CYSTIC FIBROSIS

= CF = MUCOVISCIDOSIS = FIBROCYSTIC DISEASE

= common autosomal recessive multisystem disease of exocrine gland dysfunction characterized by

(a) mucous plugging (= thick tenacious material obstructing conducting system)

(b) reduced mucociliary clearance

Frequency: 1÷2,500 livebirths; almost exclusively in Caucasians affecting 70,000 persons worldwide (5% carry a CF mutant gene allele); unusual in Blacks (1÷17,000), Orientals, Polynesians

Genetics: mutation of cystic fibrosis transmembrane regulator gene (CFTR) on long arm of chromosome 7 (usually necessary for absorption + secretion of salt and water); > 1000 different gene mutations (in 90% DF508)

◊ Most common lethal autosomal recessive disease in white population (highest rate is in Ireland!)

Pathophysiology:

faulty CFTR protein at cell surface → defective epithelial ion channel → abnormal transmembrane conductance / block for Cl- into bronchial lumen and excessive resorption of Na+ → decrease in osmotic forces and luminal water → mucous plugging in small + large airways → increased incidence of bacterial airway infections

Screening (for 6 most common mutations of CF gene):

85% carrier detection rate for Northern Europeans, 90% for Ashkenazi Jews, 50% for American Blacks

Mean age at diagnosis: 2.9 years (70% in 1st year of life, 80% by age 4 years, 90% by age 12 years); 50% are now adults (2012); M÷F = 1÷1

Affected organs: lung, pancreas, hepatobiliary system, kidney, GI tract

- chronic sinusitis with nasal polyposis; infertility in males
- elevated concentrations of sodium + chloride (> 40 mmol/L for infants) in sweat, decreased urinary PABA excretion
- increased susceptibility to infection by Staphylococcus aureus + Pseudomonas aeruginosa

Rx: aggressive nutrition and physiotherapy programs + antimicrobial and corticosteroid therapy, pancreatic enzyme supplementation, lung transplantation

Median survival: 41.1 years (in 2012)

@ Lung

- recurrent lung infections (reduced mucociliary clearance encourages Pseudomonas colonization), chronic cough
- progressive respiratory insufficiency ← obstructive lung disease

Location: predilection for apical + posterior segments of upper lobes

√ "gloved finger" sign = <u>mucous plugging</u> = mucoid impaction in dilated bronchi within 1st month of life

√ subsegmental / segmental / lobar <u>atelectasis</u> with right upper lobe predominance (10%)

√ progressive cylindrical / cystic <u>bronchiectasis</u> (in 100% at > 6 months of age) ± air-fluid levels ← prolonged mucous plugging preponderant in upper lobes

√ parahilar linear densities + peribronchial cuffing

√ focal peripheral / generalized hyperinflation ← collateral air drift into blocked airways with <u>air trapping</u>

√ hilar adenopathy

√ large pulmonary arteries ← pulmonary arterial hypertension

√ recurrent local <u>pneumonitis</u> (initiated by Staphylococcus aureus / Haemophilus influenza, succeeded by Pseudomonas aeruginosa)

√ allergic bronchopulmonary aspergillosis (with bronchial dilatation + mucoid impaction)

HRCT:

√ mosaic attenuation ← air trapping in early stage (on lateral decubitus HRCT in dependent lung)

√ bronchial + peribronchial thickening

√ cylindrical (varicose / cystic) bronchiectasis + bronchiolectasis

◊ in 30% of children with normal lung function!

√ bronchiectatic cyst (= bronchus directly leading into sacculation) in 56%

√ interstitial cysts in 32%

√ emphysematous bulla (= peripheral air space with long pleural attachment + NO communication to bronchus) in 12%

√ periseptal emphysema

√ mucous plugs = tubular structures ± branching pattern → centrilobular nodules + tree-in-bud pattern

√ subsegmental / segmental atelectasis / consolidations

NUC:

√ matched patchy areas of decreased ventilation + perfusion

Cx: (1) Pneumothorax (← rupture of bulla / bleb) common + recurrent
(2) Hemoptysis (parasitized bronchial arteries connect to pulmonary vessels resulting in AV fistulae)
(3) Cor pulmonale
(4) Hypertrophic pulmonary osteoarthropathy (rare)

Cause of death: massive mucous plugging (95%)

DDx: Immotile cilia syndrome (predominantly affecting middle lobe)

Rx: (1) Intratracheal instillation of aerosolized adenoviral + liposomal vector-CFTR gene preparations
(2) Lung transplant (using forced expiratory volume + body mass index as predictors of necessity)

@ GI tract (85–90%)
• chronic obstipation, failure to thrive
@ Esophagus
√ gastroesophageal reflux (21–39%) ← elevated abdominal pressures from chronic cough, hyperinflation, diaphragm depression, lower esophageal sphincter relaxation from long-term use of medication (eg, aminophylline):
√ esophagitis, reflux stricture, Barrett metaplasia
@ Small bowel
√ thickened nodular gastric + duodenal mucosal folds ± peptic ulcers ← unbuffered gastric acid, production of abnormal mucus, Brunner gland hypertrophy
√ mild generalized small bowel dilatation with diffuse distortion + thickening of mucosal folds (at times involving colon + rectum)
√ Crohn disease (increased frequency)
√ ileocecal intussusception (in 1%): often intermittent with spontaneous resolution / asymptomatic transient
Lead point: inspissated secretions, lymphoid tissue, chronically distended appendix
@ Colon
√ <u>meconium ileus</u> (10–13–16% at birth)
◊ Earliest clinical manifestation of cystic fibrosis!
√ <u>meconium plug syndrome</u> (25%, most common cause of colonic obstruction in the infant)
√ <u>distal intestinal obstruction syndrome</u>
√ proximal colonic wall thickening, pericolonic fat proliferation, mesenteric fat infiltration
√ large distended colon with mottled appearance (retained bulky dry stool) = acquired megacolon
√ "microcolon" = colon of normal length but diminished caliber
√ <u>fibrosing colonopathy</u> (in children) = stricture of right colon with longitudinal shortening ← submucosal fibrosis ← high-dose lipase supplementation
√ pneumatosis intestinalis of colon (5%) ← air block phenomenon of obstructive pulmonary disease:
√ cystic submucosal + subserosal foci of air lining up along dependent portion of bowel wall

√ "jejunization of colon" = coarse redundant hyperplastic colonic mucosa ← distended crypt goblet cells
√ rectal prolapse between 6 months and 3 years (in 18–23%) ← frequent bulky stools and diminished muscle tone in undiagnosed patient

@ Appendix
√ chronically > 6 mm distended appendix ← swollen appendix filled with inspissated secretions
√ acute appendicitis (1–4%)

Cx: gastrointestinal perforation with meconium peritonitis (in 50%), volvulus of dilated segments, bowel atresia, colon cancer (odds ratio 20÷1)

@ Liver (in up to 72% of adult patients)

Pathophysiology:
absent / dysfunctional activity of CFTR protein → impaired secretory function of biliary epithelium → accumulation + precipitation of hyperviscous biliary secretions → cholangiocyte injury → hepatic parenchymal injury

• asymptomatic / abnormal liver function tests
√ hepatic steatosis (23–67%) ← untreated malabsorption, dietary deficiencies, hepatic dysfunction, medications (= initial manifestation in infants):
√ diffuse / focal fatty infiltration
√ multilobulated pseudomasses = 1–2 cm lobulated fatty lesions with hyperechoic center surrounded by a hypoechoic ring → heterogeneity of liver echotexture + irregularity of hepatic contour
√ diffuse increase in liver echogenicity + posterior acoustic attenuation + decreased depiction of vessel walls
√ diffuse low hepatic attenuation and prominent vessels
√ hepatic T1-hyperintensity + suppression on fat saturation
√ focal biliary cirrhosis (40–78%):
√ focal portal fibrosis and cholestasis
√ > 2 mm thick hyperechoic periportal tissue
√ high signal intensity on T1WI
√ multilobular cirrhosis (5–15%) ← inspissated bile:
= multiple regenerative nodules with diffuse involvement
• signs of portal hypertension in multilobular form (clinically in 4–8%, autoptic in up to 50%)

Cx: dysplastic nodules, HCC

√ portal hypertension (in 1% of biliary cirrhosis) + hepatosplenomegaly + hypersplenism

Multilobular cirrhosis is the 3rd leading cause of death associated with CF (after cardiorespiratory + transplant complications) accounting for 2.5% of overall mortality.

@ Gallbladder

Histo: mucus-containing cysts in gallbladder wall

• symptoms of gallbladder disease (3.6%)
√ sludge (33%)
√ cholelithiasis (12–24%): mostly cholesterol stones ←
(a) interrupted enterohepatic circulation after ileal resection

(b) ileal dysfunction in distal intestinal obstruction syndrome

√ gallbladder atony

√ microgallbladder (4–45% at autopsy) ← cystic duct atresia / stenosis ← inspissated material:

√ false positive results in hepatobiliary scintigraphy

√ gallbladder atrophy

√ thickened trabeculated gallbladder wall ← cirrhosis, ascites, hypoalbuminemia, nutritional deficiencies

√ subepithelial cysts of gallbladder wall

@ Bile ducts

• cholestasis ← CBD obstruction

√ strictures + beading + dilatation of intra- and extrahepatic bile ducts similar to sclerosing cholangitis (in 50%)

√ choledocholithiasis + intrahepatic calculi

√ sclerosing cholangitis

√ hyperechoic periportal thickening ← fibrosis / focal fat

√ ductal abnormalities at MRCP in (65%)

@ Pancreas

The pancreas is the most commonly involved abdominal organ in cystic fibrosis.

Pathophysiology:

inspissated secretions in proximal pancreatic ducts → luminal obstruction with increase in fluid pressure → mild inflammatory reaction + acinar disruption → widespread loss of acinar cells → replacement with fibrous tissue + fat (= complete pancreatic atrophy / lipomatous pseudohypertrophy); increased pancreatic lobulation; recurrent acute and chronic pancreatitis → diffuse fibrosis + with microcystic transformation

Histo: progressive ductectasia = dilatation of acini + ducts

Classification of dysfunction:

(1) Exocrine insufficiency (85–90%) ← fat malabsorption ← deficient pancreatic enzyme production ← duct obstruction ← inspissated secretions ← precipitation of relatively insoluble proteins (= protein plugs)

• malnutrition, steatorrhea, fat intolerance, deficiency of fat-soluble vitamins

The degree of pancreatic fatty infiltration correlates with the severity of exocrine dysfunction. CF is the most common cause of exocrine pancreatic insufficiency in patients < 30 years of age!

(2) Endocrine gland dysfunction (30–50%) ← CF-related diabetes mellitus (unique combination of type 1 and 2) ← fibrosis and gland atrophy

• abdominal pain, bloating, flatulence, failure to thrive

• diabetes mellitus ← pancreatic fibrosis increasing with age (in 1% of children + 13% of adults):

• glucose intolerance in 30–50%

• 1–2% require insulin therapy

• acute (1.2%) by age 20 / recurrent acute (10%) pancreatitis

√ partial (in 16%) / complete (in 42%) fatty replacement of pancreas by fibrofatty tissue by age 17 years:

√ density of –90 to –120 HU on CT (in up to 93%) similar to retroperitoneal fat
√ generalized increased echogenicity (70–100%)
√ loss of fine lobular pattern of pancreas on US
√ focal hypoechoic areas + cyst formation
√ variable T1 hyper- and hypointensity depending on proportion of fatty infiltration + fibrosis
√ lipomatous pseudohypertrophy of pancreas = markedly enlarged pancreas ← complete fibrofatty replacement
√ diffuse pancreatic atrophy without fatty replacement (in 24%)
√ periductal chronic calcific pancreatitis (7%)
√ pancreatic duct strictures, beading, dilatation, obstruction
√ **pancreatic cystosis** (extremely rare) = mostly 1–3-mm small cysts completely replacing pancreas, occasionally macroscopic cysts up to 12 cm in diameter
• low levels of amylase + CEA in cyst fluid

@ Kidney
• immunoglobulin A nephropathy, amyloidosis
• symptomatic renal stones (3–6% vs. 2% in general population)
√ nephrocalcinosis, nephrolithiasis (in 90% at autopsy)

@ Skull
√ sinusitis with opacification of well-developed maxillary, ethmoid, sphenoid sinuses
√ hypoplastic frontal sinuses

OB-US:
√ hyperechogenic bowel (in up to 60–70% of fetuses affected with cystic fibrosis)

Prognosis: median survival of 41 years (2012); pulmonary Cx are the most predominant cause of morbidity and death (90%); 2.3 deaths per 100 patients from cardiorespiratory causes (78%) / hepatic disease (4%)

DIAPHRAGMATIC HERNIA

Congenital Diaphragmatic Hernia

= CDH = absence of closure of the pleuroperitoneal fold by 9th week of gestational age

Frequency: 1÷ 2,200–4,000 livebirths (0.04%); M÷F = 2÷1
◊ Most common intrathoracic fetal anomaly
◊ Delayed closure following group B streptococcal infection!

Etiology:
(1) Delayed fusion of diaphragm (spontaneous self-correction may occur) / premature return of bowel from its herniated position within the umbilical coelom
(2) Insult that inhibits / delays normal migration of the gut + closure of the diaphragm between 8th and 12th week of embryogenesis

Classification (Wiseman):
I. herniation early during bronchial branching → severe bilateral pulmonary hypoplasia; uniformly fatal
II. herniation during distal bronchial branching → unilateral pulmonary hypoplasia; survival possible
III. herniation late in pregnancy with compression of otherwise normal lung; excellent

prognosis

IV. postnatal herniation with compression of otherwise normal lung; excellent prognosis

Associated anomalies in 20% of liveborn and in 90% of stillborn fetuses:

1. CNS (28%): neural tube defects, hydrocephalus
2. Cardiovascular (9–23%): VSD, ASD, tetralogy of Fallot
3. Gastrointestinal (20%): particularly malrotation, oral cleft, omphalocele, esophageal atresia
4. Genitourinary (15%): cryptorchidism
5. Chromosomal abnormalities (4%): trisomy 21, 18, 13; tetrasomy 12p
6. Limb anomalies: polydactyly, syndactyly, reduction defects
7. Spinal defects
8. Genetic syndromes: Fryns, Lange, Marfan
9. IUGR (with concurrent major abnormality in 90%)

Location: L÷R = 85%÷13%; 2% bilateral

◊ Right-sided hernias are frequently fatal!

- respiratory distress in neonatal period = life-threatening deficiency of small airways + alveoli; scaphoid abdomen

Herniated organs:

small bowel (90%), stomach (60%), large bowel (56%), spleen (54%), pancreas (24%), kidney (12%), adrenal gland, liver (major prognostic factor), gallbladder

√ bowel loops in chest
√ contralateral shift of mediastinum + heart
√ complete (1–2%) / partial absence of diaphragm
√ absence of stomach + small bowel in abdomen
√ passage of nasogastric tube under fluoroscopic control entering intrathoracic stomach
√ incomplete rotation + anomalous mesenteric attachment of bowel

OB-US (diagnosis possible by 18 weeks GA):

√ solid / multicystic / complex chest mass
√ mediastinal shift
√ nonvisualization of fetal stomach below diaphragm
√ fetal stomach at level of fetal heart
√ peristalsis of bowel within fetal chest (inconsistent)
√ paradoxical motion of diaphragm with fetal breathing (defect in diaphragm sonographically not visible)
√ scaphoid fetal abdomen with reduced abdominal circumference
√ herniated liver frequently surrounded by ascites
√ polyhydramnios (common, due to partial esophageal obstruction or heart failure) / normal fluid volume / oligohydramnios
√ swallowed fetal intestinal contrast appears in chest (CT amniography confirms diagnosis)
√ fetal lung volume < 15–25%, decreased lung-head ratio

OB-MR:

√ calculation of relative fetal lung volume:

< 14.3% = postnatal death, > 32.8% = survival

> 44.0% = ECMO not required

Cx: (1) Bilateral pulmonary hypoplasia
(2) Persistent fetal circulation → postsurgical pulmonary hypertension
(3) PROM (47%), chorioamnionitis, premature labor

Prognosis: (1) Stillbirth (35–50%)
(2) Neonatal death (35%)

◊ Survival is determined by size of defect + time of entry + associated anomalies (34% survival rate if isolated, 7% with associated anomalies)

Indicators of poor prognosis:
large intrathoracic mass with marked mediastinal shift, IUGR, polyhydramnios, hydrops fetalis, detection < 25 weeks MA, intrathoracic liver, dilated intrathoracic stomach, other malformations

Mortality: in 10% death before surgery; 40–50% operative mortality;
(a) stomach intrathoracic vs. intraabdominal = 60% vs. 6%
(b) polyhydramnios vs. normal amniotic fluid = 89% vs. 45%

Rx: Fetal endotracheal balloon occlusion (29–34 weeks)

DDx: bronchopulmonary foregut malformation, mediastinal cyst (bronchogenic, neurenteric, thymic), sequestration, congenital adenomatoid malformation, pulmonary agenesis / hypoplasia

***Bochdalek Hernia* (85–92%)**

[Vincent Alexander Bochdalek (1801–1883), professor of anatomy in Prague]

= posterolateral hernia caused by maldevelopment of pleuroperitoneal folds / failure of fusion of folds and transverse septum with intercostal muscles
◊ 90% of congenital diaphragmatic hernias; L > R

Age: antenatal ultrasound @ 24 weeks GA; late presentation in 11%

Frequency: 1÷2,000–1÷5,000 live births

- respiratory distress
- asymptomatic with late presentation (in 11%)

Location: left (80%), right (15%), bilateral (3–5%)

Herniated organs:
(a) on left: omental fat (6%), bowel, spleen, left lobe of liver, stomach (rare), kidney, pancreas
(b) on right: part of liver, gallbladder, small bowel, kidney

mnemonic: 4 B's
Bochdalek
Back (posterior location)
Babies (age at presentation)
Big (usually large)

Morgagni Hernia (9–12% of CDH)

[Giovanni Battista Morgagni (1682–1771), professor of anatomy and theoretical medicine in Padua, Italy]

= anteromedial parasternal defect = space of Larrey / foramen of Morgagni

◊ < 10% of congenital diaphragmatic hernias

Cause: failure of fusion between septum transversum and lateral body wall where internal mammary artery crosses the diaphragm

Location: between sternum medially + 8th rib laterally; R÷L = 9÷1 (mostly unilateral)

Time of defect: between 3rd and 7th week of GA

Age: children; incidental finding in adults

Frequency: 1÷4,800 live births; M > F

Herniated organs:

(a) abdominal viscera: omentum, liver, transverse colon

(b) heart may herniate into upper abdomen

(c) fat may herniate into pericardial sac

Often associated with:

congenital heart disease (component of pentalogy of Cantrell), pericardial deficiency, bowel malrotation, chromosomal abnormality (Down syndrome, Turner syndrome), mental retardation

mnemonic: 4 M's

Morgagni

Middle (anterior + central location)

Mature (tend to present in older children)

Minuscule (usually small)

- asymptomatic (majority), epigastric discomfort
- chronic cough, choking, shortness of breath
- respiratory distress, cyanosis (in neonates)
- abdominal pain, nausea, vomiting

√ cardiophrenic angle mass

√ anteriorly located gas-filled loops of bowel on lateral chest x-ray (PATHOGNOMONIC)

Cx: bowel incarceration + strangulation

DDx on CXR: thymoma, teratoma, germ cell tumor, lymphoma, thyroid lesion, pericardial cyst, lymphangioma

DDx on CT: lipoma, liposarcoma (no omental vessels)

Septum Transversum Defect

= defect in central tendon

Hiatal Hernia (9% of CDH)

= congenitally large esophageal orifice with herniation of a portion of the stomach into mediastinum

Eventration *(5%)*

= congenital thinning of diaphragmatic muscle that causes an abnormal elevation of part (= focal bulge) / entire otherwise intact hemidiaphragm into chest cavity → upward displacement of abdominal contents

Cause: ? congenitally thinned hypoplastic / absent muscle fibers consisting only of pleura + peritoneum; focal dyskinesia; neuromuscular dysfunction; weakness from ischemia / infarct

Unilateral eventration may be associated with:
Beckwith-Wiedemann syndrome, trisomy 13, 15, 18
Bilateral eventration may be associated with:
toxoplasmosis, CMV, arthrogryposis
Location: R÷L = 5÷1; anteromedial on right; complete involvement on left (M > F)
√ small diaphragmatic excursions
√ often lobulated diaphragmatic contour
DDx for right anteromedial eventration:
Morgagni hernia, paraesophageal hernia, pericardial cyst, bronchogenic cyst, tumor
DDx for complete eventration: diaphragmatic paralysis

Traumatic Diaphragmatic Hernia

= DIAPHRAGMATIC RUPTURE = DIAPHRAGMATIC INJURY
Prevalence: 0.8–8% in blunt trauma patients; 5% of all diaphragmatic hernias, but 90% of all strangulated diaphragmatic hernias
Etiology of traumatic rupture of diaphragm:
(a) blunt trauma (5–50%) ← sudden increase in intraabdominal / intrathoracic pressure against a fixed diaphragm: motor vehicle accident (> 90%), fall from height, bout of hyperemesis; L÷R = 3÷1, bilateral rupture in < 3.6%
◊ 7–66% undiagnosed at initial presentation!
(b) penetrating trauma (50%): bullet > knife, repair of hiatus hernia
◊ 1–4 cm in length; often only detected at surgery
• may be asymptomatic for months / years following trauma, onset of symptoms may be so long delayed that traumatic event is forgotten
• virtually all become ultimately symptomatic, 80% in < 3 years
• **Bergqvist triad**:
(1) Rib fractures
(2) Fracture of spine / pelvis
(3) Traumatic rupture of diaphragm
Location: 77–90–98% on left side; right hemidiaphragm has greater strength and is relatively protected by liver; L÷R = 1.5÷1 to 7÷1
Site: posterolateral central portion medial to spleen / medial central tendon with intrapericardial hernia (3.4%) / sites of attachments of diaphragm / esophageal hiatus (rare)
Size: most tears are > 10 cm in length
Herniation of organs (32–58%) in order of frequency:
(a) right: liver, small bowel, large bowel
(b) left: stomach, colon, spleen, omentum, small bowel, kidney, pancreas
CXR:
◊ The first posttraumatic CXR is abnormal in 46–77% but nonspecific!
◊ Positive intrathoracic pressure from ventilation may delay herniation!
◊ Serial CXRs may show progressive changes!
√ nonvisualization (loss) of diaphragmatic contour
√ elevated asymmetric / irregular contour of hemidiaphragm > 4–6 cm above level of contralateral hemidiaphragm + contralateral shift of mediastinum

Cave: cephalad margin of bowel may simulate an elevated diaphragm (look for haustra)

√ herniation of air-filled viscus: stomach, colon
√ shift of mediastinum + lung to opposite side
√ lower lobe mass / consolidation (herniated solid organ / omentum / airless bowel loop)
√ inhomogeneous mass with air-fluid level in left hemithorax
√ mushroomlike mass of herniated liver in right hemithorax
√ hydrothorax / hemothorax suggests strangulation
√ "collar" sign = hourglass constriction of afferent + efferent bowel loops at orifice
√ multiple fractures of lower ribs + spine
√ abnormal U-shaped course of nasogastric tube above suspected level of hemidiaphragm

N.B.: tube first dips below diaphragm (rent spares esophageal hiatus with gastroesophageal junction remaining in its normal position)

√ location of diaphragm may be documented by

1. Gas-filled bowel constricted at site of diaphragmatic laceration
2. Barium study

CT (71% sensitive, 100% specific, 70% accurate for right side; 80–87% sensitive, 100% specific, 88% accurate for left side):

◊ Best detected on reformatted SAG + COR images!

Associated with: abdominal + pelvic injury in 90–94%

(a) direct signs:
- √ segmental diaphragmatic defect = abrupt discontinuity of hemidiaphragm (73–82%)
- √ "absent diaphragm" sign = failure to see diaphragm
- √ "dangling diaphragm" sign = free edge of injured diaphragm curls inwards + away from chest wall
- √ "curled diaphragm" sign = irregularity + thickening of diaphragmatic leaflet ← contracted torn muscle
- √ contiguous (= transdiaphragmatic) injury on either side of diaphragm in case of penetrating trauma
- √ wound trajectory crossing diaphragm

(b) indirect signs:
- √ intrathoracic herniation of omentum / bowel / abdominal organs (55%)
- √ visualization of peritoneal fat / abdominal viscera lateral to lung or diaphragm / posterior to crus of hemidiaphragm
- √ "collar" sign = waistlike constriction of viscera at level of diaphragmatic rent (27%):
  - √ "hump" sign = rounded portion of superior liver protrudes through diaphragmatic rent
  - √ "band" sign = linear area of hypoattenuation at level of torn free edge of diaphragm causing linear indentation of herniated liver edge
- √ "dependent viscera" sign = abdominal viscera (bowel loops / stomach) no longer supported posteriorly by torn diaphragm fall dependently against posterior chest wall
- √ "sinus cutoff" sign = herniated abdominal content prevents expected layering of pleural fluid

√ abdominal organ / fatty tissue peripheral to diaphragm / posterior to crura
√ elevated / cephalad displacement of abdominal organs: hemidiaphragmatic elevation by > 5 cm (RT) and > 4 cm (LT)
√ concurrent pneumothorax, pneumoperitoneum, hemothorax, hemoperitoneum

MR:
√ interruption of hypointense band of diaphragmatic muscle outlined by hyperintense abdominal + mediastinal fat

Associated injuries (in 44–81–100%):
√ head injury
√ fractures of lower ribs / pelvis (42%)
√ intraabdominal injuries (72%):
√ perforation of hollow viscus
√ rupture of spleen / kidney

Reasons for diagnostic misses:
(1) Left-sided defect covered by omentum
(2) Right-sided defect sealed by liver
(3) Positive pressure ventilation
(4) Associated injuries mask tear: atelectasis, pleural effusion, lung contusion, phrenic nerve paralysis

Cx: (1) Incarceration of herniated organs
(2) Life-threatening strangulation of bowel / stomach occurs in majority

◊ 90% of strangulated hernias are posttraumatic!

(3) Bowel perforation

Prognosis: 30% mortality in unrecognized cases

DDx: congenital hernia, acquired defect = fenestration, diaphragmatic eventration, diaphragmatic paralysis, hiatal hernia, congenital Bochdalek hernia (6–11%)

DIAPHRAGMATIC PARALYSIS

= absent orthograde diaphragmatic excursion on quiet deep breathing with paradoxical motion on sniffing

Diaphragmatic weakness = reduced / delayed orthograde excursion on deep breathing ± paradoxical motion on sniffing

Cause:
(1) Phrenic nerve injury during birth trauma / cardiac surgery / resection of thoracic tumors
(2) Infection: West Nile virus, Lyme disease
(3) Tumor of mediastinum / neck

• difficulty in weaning from mechanical ventilation, ventilatory failure (common)
• respiratory distress, tachypnea, increased oxygen requirements

› Static imaging:
√ elevation of one hemidiaphragm on CXR (not sensitive or specific)

› Functional imaging (= evaluation of diaphragmatic motion):
Fluoroscopy:
√ evaluate comparative movement of domes, excursion of individual dome, and shift of mediastinum

√ sniff test:
√ both normal hemidiaphragms move downward
√ reduced excursion of weakened hemidiaphragm
√ absent / paradoxical motion (= elevation during inspiration and vice versa) of paralyzed hemidiaphragm

M-mode US (SAG view, transducer position anteriorly, ventilator temporarily disconnected):
◊ US has replaced fluoroscopy in children!
√ diaphragm moves toward transducer during inspiration by < 4 mm
√ > 50% difference in excursion between domes

Cx: pneumonia, atelectasis, pulmonary collapse

DIFFUSE PULMONARY LYMPHANGIOMATOSIS

= rare condition consisting of proliferation + dilatation of communicating lymphatic channels in pleura + interlobular septa + mediastinum

Cause: congenital developmental abnormality of lymphatic channels

Age: teenager, young adult

Path: resembles lymphangioma

• progressive dyspnea → pulmonary failure

Location: predominantly upper lobes of lung

CT:
√ smooth symmetric thickening of interlobular septa + peribronchovascular bundles
√ diffuse increased attenuation of mediastinal fat
√ mild perihilar infiltration
√ diffuse pleural thickening
√ pleural effusion
√ pericardial effusion

Dx: biopsy; findings persist under diuretic therapy

DROWNED LUNG

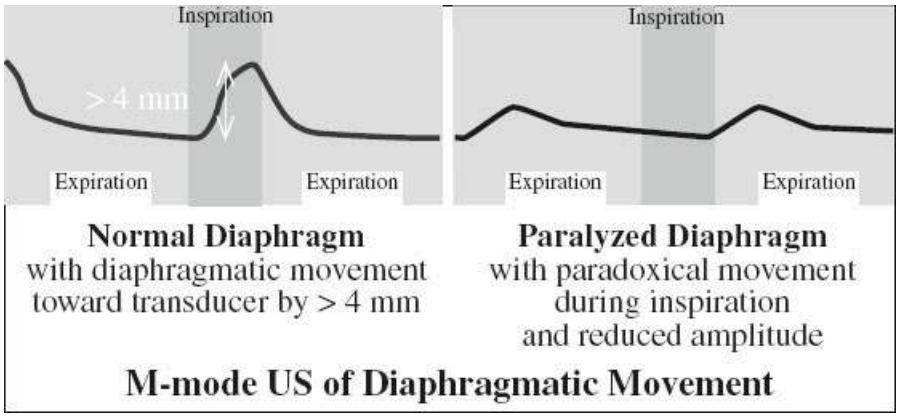
= abnormal increase in lobar / rarely whole lung volume

Pathophysiology: bronchial obstruction → acute collapse of airspaces → rapid filling of alveoli + bronchi with secretions / fluid

Cause: bronchogenic carcinoma, carcinoid, foreign body, mucus plug

• bronchial obstruction that persists beyond 3–4 weeks

√ bulging interlobar fissure
√ little / no mediastinal shift to contralateral side
√ obliteration of bronchial lumen leading to obstructed lobe



√ absence of air bronchogram
√ hilar mass + regional lymphadenopathy

CT:
√ postobstructive consolidation
√ mucus bronchogram = bronchi filled with low-attenuation material

CECT:
√ delineates enhancing tumor + lymph nodes from consolidated lung of low attenuation (= drowned lung)

MR:
√ T2WI differentiates drowned lung from obstructing tumor

PET:
√ high tumor activity centrally

Cx: necrosis, cavitation, secondary infection

DDx: resorptive atelectasis, obstructive pneumonitis, endogenous "golden" lipoid pneumonia, Gram-negative pneumonia, large pleural effusion (marked mediastinal shift to contralateral side), unilateral veno-occlusive disease, unilateral aspiration

EMPHYSEMA

= group of pulmonary diseases characterized by permanently enlarged air spaces distal to terminal bronchioles accompanied by destruction of alveolar walls + local elastic fiber network

◊ The clinical term "chronic obstructive pulmonary disease (COPD)" should not be used in image interpretation! It encompasses: asthma, chronic bronchitis, emphysema!

Prevalence: 12.7 million people in USA (2002)

Cause: imbalance in elastase-antielastase system ← increase in elastase activity in smokers / α1-antiprotease deficiency (causing proteolytic destruction of elastin resulting in alveolar wall destruction)

- irreversible expiratory airflow obstruction ← decreased elastic recoil from parenchymal destruction; dyspnea on exertion
- decreased carbon monoxide diffusing capacity

CXR (moderately sensitive, highly specific):
√ hyperinflated lung (most reliable sign):

√ low hemidiaphragm (= at / below 7th anterior rib)
√ flat hemidiaphragm (= < 1.5 cm distance between line connecting the costo- and cardiophrenic angles + top of midhemidiaphragm)
√ retrosternal air space > 2.5 cm
√ "barrel chest" = enlarged anteroposterior chest diameter
√ saber-sheath trachea
√ pulmonary vascular pruning + distortion (± pulmonary arterial hypertension)
√ right-heart enlargement
√ bullae

HRCT:
√ well-defined areas of abnormally decreased attenuation without definable wall (< –910 HU)
◊ Centrilobular + panacinar forms of emphysematous lung destruction tend to coexist!

Rx: lung volume reduction surgery

Centrilobular Emphysema

= CENTRIACINAR EMPHYSEMA = PROXIMAL ACINAR EMPHYSEMA
= emphysematous change selectively affecting the acinus at the level of 1st + 2nd generations of respiratory bronchioles (most common form)

Path: normal + emphysematous alveolar spaces adjacent to each other
Histo: enlargement of respiratory bronchioles + destruction of centrilobular alveolar septa in the center of the secondary pulmonary lobule; CHARACTERISTICALLY surrounded by normal lung; distal alveoli spared; severity of destruction varies from lobule to lobule
Predisposed: smokers (in up to 50%), coal workers
Cause: excess protease with smoking (elastase is contained in neutrophils + macrophages found in abundance in lung of smokers)

• blue bloater

Site: apical and posterior segments of upper lobe + superior segment of lower lobe (relatively greater ventilation-perfusion ratio in upper lobes favors deposition of particulate matter and release of elastase in upper lungs)

CXR (80% sensitivity for moderate / severe stages):
√ irregular scattered area of radiolucency (best appreciated if lung opacified by edema / pneumonia / hemorrhage) = area of bullae, arterial depletion + increased markings
√ hyperinflated lung

HRCT:
√ "emphysematous spaces" (= focal round area of air attenuation) > 1 cm in diameter with central dot / line = centrilobular location (representing the centrilobular artery of secondary pulmonary lobule) without definable wall and surrounded by normal lung
√ pulmonary vascular distortion + pruning with lack of juxtaposition of normal lung (advanced stage)

Panacinar Emphysema

= PANLOBULAR EMPHYSEMA = DIFFUSE EMPHYSEMA = GENERALIZED EMPHYSEMA
= emphysematous change involving the entire acinus
= uniform nonselective destruction of all air spaces throughout both lungs (rare)

Path: uniform enlargement of acini from respiratory bronchioles to terminal alveoli (from center to periphery of secondary pulmonary lobule) ← destruction of lung distal to terminal bronchiole

Cause: autosomal recessive a-1 antitrypsin deficiency in 10–15% (proteolytic enzymes carried by leukocytes in blood gradually destroy lung unless inactivated by a-1 protease inhibitor)

Age: 6th–7th decade (3rd–4th decade in smokers)

• pink puffer

Site: affects whole lung, but more severe at lung bases ← greater blood flow

CXR:

√ hyperinflated lung

√ decreased pulmonary vascular markings

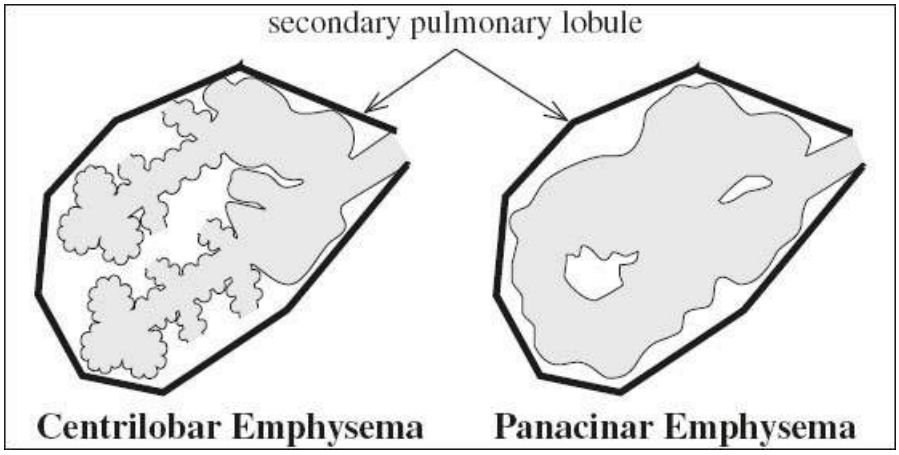
√ lung destruction extremely uniform

HRCT:

√ diffuse simplification of lung architecture with pulmonary septal and vascular distortion + pruning (difficult to detect early, ie, prior to considerable lung destruction for lack of adjacent normal lung)

√ paucity of vessels

√ bullae



Paracicatricial Emphysema

= PERIFOCAL / IRREGULAR EMPHYSEMA

= airspace enlargement + lung destruction developing adjacent to areas of pulmonary scarring

Usual cause: granulomatous inflammation, organized pneumonia, pulmonary infarction

Path: no consistent relationship to any portion of secondary lobule / acinus; frequently associated with bronchiolectasis producing honeycomb lung

• little functional significance

CXR (rarely detectable):

√ fine curvilinear reticular opacities + interposed radiolucent areas

HRCT:

√ low-attenuation areas adjacent to areas of fibrosis (diagnosable only in the absence of other forms of emphysema)

Paraseptal Emphysema

= DISTAL ACINAR / LOCALIZED / LINEAR EMPHYSEMA
= focal subpleural enlargement + destruction of air spaces in one site of otherwise normal lung
Path: predominant involvement of alveolar ducts + sacs
Site: characteristically within subpleural lung and adjacent to interlobular septa + vessels
CXR:
√ area of lucency, frequently sharply demarcated from normal lung
√ bands of radiopacity (residual vessels / interstitium) may be present
HRCT:
√ peripheral low-attenuation area with remainder of lung normal
Cx: spontaneous pneumothorax; bullae formation

EMPYEMA

= parapneumonic effusion characterized by presence of pus ± positive culture
Organism: S. aureus, Gram-negative + anaerobic bacteria
• positive Gram stain
• positive culture (anaerobic bacteria most frequent)
Stage:
I **Exudative phase** = inflammation of visceral pleura results in increased capillary permeability with weeping of proteinaceous fluid into pleural space = sterile exudate
• pH > **7.20**
• glucose > 40 mg/dL (2.2 mmol/L)
• LDH < 1,000 IU/L
II **Fibrinopurulent phase** = accumulation of inflammatory cells and neutrophils within pleural space + fibrin deposition on pleural surfaces
› early stage II empyema
• WBCs > 5 x 109/mm^3, but no gross pus
• pH between **7.0 and 7.2**
• glucose level > 40 mg/dL
• LDH < 1,000 IU/L
› late stage II empyema
• gross pus (WBC > 15,000/cm^3) = frank pus
• pH < **7.0**
• glucose level < **40 mg/dL**
• LDH > **1,000 IU/L**
Cx: multiloculation
Rx: chest tube drainage
III **Organizing phase** = recruitment of fibroblasts + capillaries results in deposition of collagen and granulation tissue on **pleural surfaces** = pleural fibrosis = **"pleural peel / pleural rind"**
Cx: limited expansion of lung
Rx: decortication (with persistent sepsis despite appropriate antibiotic Rx + drainage / persistent thick pleural rind trapping underlying lung)

CT:
- √ thickening of parietal pleura in 60% on NECT, in 86% on CECT
- √ increased thickness + density of paraspinal subcostal tissue (= inflammation of extrapleural fat)
- √ curvilinear enhancement of chest wall boundary in 96% (= inflammatory hyperemia of pleura)
- √ "split pleura" sign = pleural fluid between enhancing thickened parietal + visceral pleura
- √ gas bubbles in pleural space (gas-forming organism / bronchopleural fistula)

DDx: simple / complicated parapneumonic effusion (negative Gram + culture stain), malignant effusion after sclerotherapy, malignant invasion of chest wall, mesothelioma, pleural tuberculosis, reactive mesothelial hyperplasia, pleural effusion of rheumatoid disease

ENDOBRONCHIAL LIPOMA

Prevalence: 0.1–0.5% of lung tumors

Age: middle-aged men

• cough, hemoptysis, fever, dyspnea

Location: usually segmental bronchus

√ atelectasis, consolidation, or both

√ mass or nodule:

- √ homogeneous fatty mass without enhancement is DIAGNOSTIC (may not be large enough to characterize)
- √ high SI on T1WI + intermediate SI on T2WI

EOSINOPHILIC PNEUMONIA

= PULMONARY INFILTRATION WITH BLOOD / TISSUE EOSINOPHILIA (PIE)

Classification:

A. IDIOPATHIC EOSINOPHILIC LUNG DISEASE
   = eosinophilic lung disease of unknown cause
   1. Simple Pulmonary Eosinophilia
   2. Acute eosinophilic pneumonia
   3. Chronic eosinophilic pneumonia
   4. Idiopathic hypereosinophilic syndrome

B. EOSINOPHILIC LUNG DISEASE OF SPECIFIC ETIOLOGY
   = eosinophilic lung disease of known cause
   (a) drug induced:
   nitrofurantoin, penicillin, sulfonamides, ASA, tricyclic antidepressants, hydrochlorothiazide, cromolyn sodium, mephenesin
   1. Toxic-oil syndrome
      = oral ingestion of food-grade rapseed oil contaminated with aniline derivatives
   2. Eosinophilia-myalgia syndrome
      = ingestion of L-tryptophan
   3. Toxic epidermal necrolysis
   4. Drug rash with eosinophilia and systemic symptoms (DRESS)

   √ nonspecific peripheral airspace consolidation with ground–glass-opacity

√ reticulonodular densities
√ hilar adenopathy
√ pleural effusion

(b) parasite induced:
tropical eosinophilia (ascariasis, schistosomiasis), strongyloidiasis, ancylostomiasis (hookworm), filariasis, Toxocara canis (visceral larva migrans), Dirofilaria immitis, amebiasis (occasionally – in RLL + RML), clonorchis infestation
• peripheral blood eosinophil counts > 3000/mL
• average BAL fluid eosinophilia of 50%

(c) fungus induced:
1. Allergic bronchopulmonary aspergillosis
√ bronchiectasis ± mucoid impaction in central upper lungs
2. Bronchocentric granulomatosis
√ nonspecific focal mass / lobular consolidation with atelectasis

(d) Pulmonary eosinophilia with asthma

C. EOSINOPHILIC LUNG DISEASE ASSOCIATED WITH ANGIITIS ± GRANULOMATOSIS
= eosinophilic vasculitis
1. Allergic angiitis
2. Churg-Strauss syndrome
√ subpleural consolidation in a lobular distribution
√ centrilobular nodules
3. Wegener granulomatosis
4. Lymphomatoid granulomatosis
5. Necrotizing sarcoid granulomatosis
6. Polyarteritis nodosa
7. Rheumatoid disease
8. Scleroderma
9. Dermatomyositis
10. Sjögren syndrome
11. CREST

Maybe associated with: rheumatoid arthritis
M÷F = 1÷2
√ pulmonary opacities
• pulmonary eosinophilia (regardless of eosinophilia in peripheral blood / in bronchoalveolar lavage)

Simple Pulmonary Eosinophilia

= TRANSIENT PULMONARY EOSINOPHILIA = LöFFLER SYNDROME
[Wilhelm Löffler (1887–1972), extraordinary professor of medicine at the University of Zurich, Switzerland]
= benign disorder of unknown etiology characterized by local areas of transient parenchymal consolidation associated with blood eosinophilia
Cause: unknown (in ⅓); parasites, drug reaction, allergic bronchopulmonary aspergillosis (in some)

Path: interstitial + alveolar edema containing a large number of eosinophils
- no / mild symptoms, history of asthma + atopy (common)
- high WBC + peripheral eosinophilia

CXR:
√ peripheral patchy migratory / fleeting (= transient and shifting) noncavitary pleural-based pulmonary infiltrates changing within one to several days

√ NO associated lymphadenopathy, NO pleural effusion
Location: mainly middle and upper lobes
Distribution: uni- or bilateral, nonsegmental distribution, predominantly in lung periphery

HRCT:
√ peripheral ground-glass and/or airspace consolidation with upper and middle lobe predominance
√ solitary / multiple pulmonary nodular opacities with surrounding ground-glass halo (rare)

Prognosis: typically spontaneous resolution within 1 month
DDx: cryptogenic organizing pneumonia, pulmonary hemorrhage, multifocal pneumonia, atypical infection

Acute Eosinophilic Pneumonia

Etiology: idiopathic (no evidence of infection / exposure to potential antigens) with abrupt increase in lung cytokines; strong association with cigarette smoking
Age: 32 ± 17 years; M > F
Histo: eosinophilic infiltrates + pulmonary edema ← release of eosinophilic granules altering vascular permeability
- acute febrile illness peaking in 1–5 days, myalgia, chest pain
- acute life-threatening respiratory failure within a few hours in previously healthy individuals
- restrictive pulmonary function
- DIAGNOSTIC markedly elevated levels of eosinophils of > 25% in bronchoalveolar lavage (BAL) fluid
- no peripheral eosinophilia

√ diffuse bilateral reticular opacities mimicking pulmonary interstitial edema
√ peripheral air space opacities (rare)
HRCT:
√ bilateral patchy areas of ground-glass opacities
√ smooth interlobular septal thickening (frequent)
√ crazy-paving pattern (= ground-glass attenuation with intralobular reticular opacities)
√ small pleural effusion
uncommon:
√ poorly defined centrilobular nodules
√ airspace consolidation
√ thickening of bronchovascular bundle
√ enlarged lymph nodes

Rx: IV corticosteroids
Prognosis: prompt + complete response to steroids; no relapse after discontinuation of

steroids

DDx: hydrostatic pulmonary edema (cardiomegaly), ARDS, acute interstitial pneumonia, atypical bacterial / viral pneumonia

Chronic Eosinophilic Pneumonia

Etiology: unknown (NO underlying cause like parasites)

Histo: accumulation of numerous eosinophils, macrophages, histiocytes, lymphocytes, PMNs within lung interstitium + alveolar sacs with interstitial fibrosis

Age: middle age; M < F

- insidious onset of fever, malaise, cough, chest pain, dyspnea develops over 4–8 months (DDx to Löffler syndrome)
- common history of atopy in ~ 50% (may occur during therapeutic desensitization procedure)
- history of allergic rhinitis
- adult-onset asthma (wheezing) in 50%
- usually mild / moderate peripheral blood eosinophilia (with rare exceptions) of > 1000/µL
- increased serum IgE levels (in up to 75%)
- > 25% (usually > 40%) of eosinophils in BAL fluid
- restrictive / obstructive (asthma) pulmonary function

√ (CLASSIC) homogeneous peripheral airspace consolidation:

- √ frequently multifocal bilateral > unilateral nonsegmental with predilection for upper lung zones
- √ CHARACTERISTIC photographic negative of pulmonary edema (in 25–34%)
- √ unchanged for many days to weeks (DDx to Löffler syndrome)
- √ fast regression of infiltrates under steroids

CT:

- √ patchy consolidation / nodules with peripheral and upper lobe predominance
- √ ground-glass opacities with crazy paving
- √ subpleural reticulations (less common early, but frequent in later stages of disease)
- √ linear bandlike opacities parallel to pleural surface (> 2 months after onset of symptoms)
- √ pleural effusion (in < 10%)

Prognosis: chronic and progressive clinical features

Rx: dramatic response to steroid therapy (within 3–10 days)

DDx:
1. Churg-Strauss syndrome (lobular distribution of peripheral consolidation, centrilobular nodules within ground-glass opacities)
2. Löffler syndrome (shifting and transient pulmonary opacities in identical distribution)
3. Cryptogenic organizing pneumonia

Idiopathic Hypereosinophilic Syndrome

= rare disorder characterized by overproduction of eosinophils (= primary hypereosinophilia) that eventually leads to organ injury

Age: 3rd–4th decade; M÷F = 7÷1

Histo: striking eosinophilic infiltration of involved organs associated with necrosis

Diagnostic criteria:

(1) Persistent eosinophilia of > 500 eosinophils/mm³ for more than 6 months

(2) Absence of known causes of eosinophilia
(3) Evidence of eosinophil-mediated end organ damage (heart, CNS) with multiorgan system dysfunction

@ Heart
• restrictive cardiomyopathy
√ endocardial fibrosis
√ valvular damage (= mitral + tricuspid insufficiency)
√ formation of mural cardiac thrombus

@ Lungs (involved in 40%)
• BAL fluid eosinophilia (as high as 73%)
√ congestive heart failure with pulmonary edema
√ nonspecific focal / diffuse interstitial or alveolar nonlobar opacities
√ occasionally peripheral pulmonary opacities
√ pleural effusion (in 50%)
CT:
√ nodules ± surrounding ground-glass opacities
√ focal / diffuse areas of ground-glass opacities in a patchy + peripheral distribution
√ interlobular septal thickening

@ CNS
√ peripheral neuropathy + encephalopathy

@ Skin
• urticaria, angioedema

DDx: (1) Churg-Strauss syndrome (vasculitis)
(2) Eosinophilic leukemia (immature eosinophils)

ERDHEIM-CHESTER DISEASE

= LIPOID GRANULOMATOSIS = POLYOSTOTIC SCLEROSING HISTIOCYTOSIS

[Jakob Erdheim (1874–1937), chief of the pathological-anatomical institute of the Vienna City Hospital, Austria]

[William Chester (1903–1974), in 1930 pathology fellow under Erdheim, later American cardiologist]

= rare multisystem non–Langerhans cell histiocytosis (non-LCH) of unknown cause characterized by xanthomatous infiltration of organs by foamy lipid-laden histiocytes, commonly involving skin + long bones

Mean age: 53 (range, 7–84) years; M÷F = 3÷1

Histo: mononuclear histiocytes with clear, foamy cytoplasm (xanthoma cells) and immunohistochemical reaction positive for CD68 + negative for CD1a and S-100 immunostaining protein or Birbeck granules (DDx to LCH)

• fever, weight loss, malaise, heart failure

@ Appendicular skeleton (95% long bone involvement)
• periarticular bone pain (mostly) in lower extremity (47%)

Location: commonly distal femoral metadiaphyses

Distribution: diaphyses + metaphyses similar to progressive diaphyseal dysplasia

√ symmetric patchy long bone medullary osteosclerosis in metadiaphyseal region with

sparing of epiphyses

√ lesser involvement of flat bones + axial skeleton
√ loss of the corticomedullary junction
√ coarsened trabecular pattern
√ patchy areas of T2-signal hyperintensity
√ sparing of epiphyses + hands and feet + axial skeleton
Associated with: bone infarcts, periostitis

@ Retroperitoneum (29%)
• progressive renal failure ← fibrous perinephritis
√ perirenal rind of soft tissue with a hairy appearance encasing kidneys, ureters ± aorta
DDx: lymphoma, retroperitoneal fibrosis
√ low SI on T1WI + T2WI with minimal contrast enhancement
√ hydronephrosis
Cx: renal failure
Rx: ureteral stent placement, steroids, chemo- and immunotherapy, radiation, surgery

@ Lung (14–23%)
Age: elderly men
• dyspnea (5%) ← pulmonary fibrosis
√ circumferential pleural thickening / effusion
√ smooth interlobular septal thickening
√ centrilobular nodules ± lung cysts
√ pericardial thickening
√ mediastinal infiltration
Prognosis: significant contributor to morbidity & mortality

@ CNS (< 30%)
Types:
(a) infiltrative: widespread nodules / masses predominantly involving cerebellum + brainstem
(b) meningeal: meningioma-like nodular thickening along dura / dural xanthoma
(c) composite
Associated with: osteosclerosis of sinus walls, orbital masses

Intracranial lesions that also involve facial bones / orbits are suggestive of Erdheim-Chester disease.

• painless bilateral exophthalmos (27%); diabetes insipidus
√ retro-orbital infiltration / mass → exophthalmos
√ single / multiple dura-based extra-axial masses (particularly in sellar region) ± diffuse pachymeningeal thickening
√ iso- to slightly hypointense on T1WI
√ avid homogeneous enhancement for up to 8 days after injection
√ iso- to hypointense on T2WI

@ Heart
√ cardiac fibrosis → cardiomyopathy
√ pericardial thickening / effusion

@ Skin: xanthelasma of eyelids, xanthoma (in 15%)

Rx: corticosteroid therapy, chemotherapy, radiation, surgery

EXTRINSIC ALLERGIC ALVEOLITIS

= HYPERSENSITIVITY PNEUMONITIS

= characterized by an inappropriate host response to repeatedly inhaled organic allergens often related to patient's occupation

Cause: inhalation of organic dust (= particulate organism / protein complex) typically of 1–2 µm (always < 5 µm) particle size deposited in distal airspaces of lung acting as antigen for a type III + type IV immune reaction

Manifestation: after months / years of continuous / intermittent inhalation of inciting agent

Histo:
1. Cellular bronchiolitis = chronic inflammatory cells lining small airways
2. Diffuse chronic interstitial inflammatory infiltrate of lymphocytes, plasma cells, neutrophils, mast cells
3. Poorly circumscribed interstitial nonnecrotizing (noncaseating) granulomas < 1 mm in diameter
4. Individual giant cells in alveoli / interstitium

- asymptomatic (10–40%); recurrent episodes of fever, chills, dry cough, dyspnea following exposure after 6-hour interval
- resolution of episodic symptoms after cessation of exposure, abate spontaneously over 1–2 days
- insidious onset of gradually progressive dyspnea
- reduction in vital capacity, diffusing capacity, arterial pO2
- intracutaneous injection of antigen results in delayed hypersensitivity reaction
- presence of serum precipitins against antigen
- positive aerosol provocation inhalation test
- markedly increased cell count with often > 50% T-lymphocytes on bronchoalveolar lavage

Location: predominantly midlung zones, occasionally lower lung zones, rarely upper lung zones

Specific antigens for immune complex disease (type III = Arthus reaction):

1. **Farmer's lung** from damp moldy hay (Thermoactinomyces vulgaris or Micropolyspora faeni)
2. **Pandora's pneumonitis** from heating / humidifying / forced air conditioning systems (thermophilic actinomycetes)
3. **Bird-fancier's lung,** pigeon breeder's lung from protein in bird serum / excrements / feathers

   Average duration of exposure: 9 years
4. **Mushroom worker's lung** from mushroom compost (Thermoactinomyces vulgaris or Micropolyspora faeni)

   Average duration of exposure: 5 years
5. **Bagassosis** from moldy sugar cane in sugar mill (contamination with Thermoactinomyces sacchari /vulgaris and Micropolyspora faeni)
6. **Malt worker's lung** from malt dust (Aspergillus clavatus)
7. **Maple bark disease** from moldy maple bark in saw mill (Cryptostroma corticale)
8. **Suberosis** from moldy cork dust (Penicillium frequentans)
9. **Sequoiosis** from redwood dust (Graphium species)
10. **Mollusk shell** pneumonitis

    Average duration of exposure: 11 years

11. **Hot tub lung** from colonization of heated water by M. avium
Average duration of exposure: 2 years
Thermophilic actinomycetes:
= bacteria < 1 μm in diameter with morphologic characteristics of fungi; found in soil, grains, compost, fresh water, forced-air heating, cooling system, humidifier, air-conditioning system
Isocyanates: used for large-scale production of polyurethane polymers in the manufacture of flexible / rigid foams, elastomers, glue, adhesives, surface coating, spray paint
◊ Principal cause of occupational asthma!
Mycobacterium avium:
colonization of heated water in hot tub / lubrication of metalworking machinery
Aspergillus: in corn and malt workers
Penicillium: in production of cheese, cork, peat moss
Rx: mask, filter, industrial hygiene, alterations in forced-air ventilatory system, change in patient's habits / occupation / environment

Acute / Episodic Extrinsic Allergic Alveolitis

= renewed exposure to antigen with improvement between attacks usually within enclosed spaces with poor ventilation
Histo: filling of air spaces by polymorph neutrophils + lymphocytes
Onset of symptoms: 4–12 hours after exposure
- fever, chills, myalgia, malaise, frontal headache
- chest tightness, cough, dyspnea, scanty mucoid expectoration
- arthralgia (common)

√ No CXR abnormalities in 30–95%
√ diffuse acinar consolidative pattern (edema + exudate filling alveoli) resolving within a few days
√ lymph node enlargement (30%, more common with recurrence)
HRCT (abnormal in > 90%):
√ "headcheese" sign (= type of terrine with bits of meat scavenged from a calf or pig) = combination of patchy ground-glass opacities + normal regions + air trapping
√ usually bilateral symmetric homogeneous patchy ground-glass opacities concentrated in middle part and base of lungs
√ numerous round centrilobular ground-glass opacities usually < 5 mm in diameter with indistinct border and small central lucency (= patent bronchiole)
√ hypoattenuation + hypovascularity of scattered secondary lobules ← air trapping
√ diffuse dense airspace consolidation (= confluent collections of intraalveolar histiocytes, interstitial + intraalveolar edema)
Dx: classical presentation of a known exposure history + typical symptoms + detection of serum precipitins to suspected antigen + positive bronchoalveolar lavage (lymphocytes > 20–50%)
DDx: UIP, NSIP

Subacute Extrinsic Allergic Alveolitis

= less intense but continuous exposure to inhaled antigens, usually in domestic environment

Histo: predominantly interstitial lymphocytic infiltrate, poorly defined granulomas, cellular bronchiolitis

Onset of symptoms after exposure: weeks – months

- recurrent respiratory / systemic symptoms:
  - breathlessness upon exertion, fever + cough
  - weight loss, muscle + joint pain

√ changes may be completely reversible if present for < 1 year

√ interstitial nodular / reticulonodular pattern

HRCT:

√ widespread patchy / diffuse ground-glass attenuation in 52% (obstructive pneumonitis, filling of alveoli by large mononuclear cell infiltrates)

√ poorly defined centrilobular micronodules < 5 mm (cellular bronchiolitis + small granulomas)

√ areas of decreased attenuation + mosaic perfusion (86%)

√ irregular reticular changes, septal lines, parenchymal bands

Chronic Extrinsic Allergic Alveolitis

= prolonged insidious dust exposure

Onset of symptoms after exposure: months to years

- insidious progressive exertional dyspnea indistinguishable from idiopathic pulmonary fibrosis

Histo: proliferation of epithelial cells + predominantly peribronchiolar interstitial fibrosis

Location: usually in mid zones, relative sparing of lung apices + costophrenic sulci

√ irregular linear opacities (= fibrosis)

√ loss of lung volume ← cicatrization atelectasis

√ pleural effusion (rare)

√ lymph node enlargement may occur

CT:

√ fibrosis of middle + lower lung zones with relative sparing of lung bases:

√ intralobular interstitial thickening

√ irregular interlobular septal thickening

√ honeycombing

√ traction bronchiectasis

√ focal air trapping / diffuse emphysema

√ coexistent subacute changes ← continuing exposure

FAT EMBOLISM

= obstruction of pulmonary vessels by fat globules followed by chemical pneumonitis from unsaturated plasma fatty acids producing hemorrhage / edema

Frequency: in 67–97% of necropsy series in patients with major skeletal trauma; however, symptomatic fat embolism syndrome in < 10% (M > F)

Onset: 24–72 hours after trauma

- dyspnea (progressive pulmonary insufficiency), fever
- systemic hypoxemia; mentation changes: headaches, confusion
- petechiae (50%) from coagulopathy ← release of tissue thromboplastin

√ initial chest film usually negative (normal up to 72 hours)
√ platelike atelectasis
√ bilateral diffuse alveolar infiltrates
√ consolidation (may progress to ARDS)
NUC:
√ mottled peripheral perfusion defects (1–4 days after injury), later enlarging ← pneumonic infiltrates

FOCAL ORGANIZING PNEUMONIA

= unresolving pneumonia / pneumonia with incomplete resolution beyond 8 weeks

Pattern of organizing pneumonia: (a) unilateral / focal (10–38%)

(b) diffuse (majority)

Cause: infection (most common), collagen-vascular disease, immunologic disorders, drug reaction, aspiration, toxic inhalation, radiation, organ transplantation, idiopathic (= cryptogenic organizing pneumonia)

Prevalence: 5–10% of all pneumonias (87% of pneumonias resolve within 4 weeks, 12% within 4–8 weeks)

Predisposing factors: ? age, diabetes mellitus, chronic bronchitis, overuse of antibiotics

Path: intraalveolar exudate → transformed into connective tissue as nonspecific response to lung injury

Histo: organizing fibroblastic plugs of tissue composed of spindle-shaped cells in a pale staining matrix

Location: within airspace, alveolar septa, bronchial mucosa, bronchioles

• cough, sputum, fever, hemoptysis (in ¼)
√ ill-defined localized parenchymal abnormality with irregular margin:
√ solitary pulmonary nodule
√ focal area of consolidation / ground-glass opacity in peribronchial distribution
√ associated bronchiectasis / architectural distortion
√ "reverse halo" sign = focal area of ground-glass opacity surrounded by a complete ring of denser consolidation
√ "atoll" sign = incomplete ring of denser consolidation
√ decrease in size of mass within 3–4 weeks
HRCT:
√ flat / ovoid lesion with irregular margin in subpleural location / along bronchovascular bundle
√ ± satellite lesions (44%) + air bronchograms (22%)

DDx: acute pneumonia, pulmonary hemorrhage, lung cancer (organizing pneumonia may be adjacent to malignancy)

GIANT CELL INTERSTITIAL PNEUMONIA

◊ ALMOST PATHOGNOMONIC for hard metal pneumoconiosis
√ diffuse micronodular pattern
√ reticular pattern; in advanced disease coarse and accompanied by small cystic spaces

√ ± lymph node enlargement
HRCT:
√ bilateral areas of ground-glass attenuation
√ areas of consolidation
√ extensive reticulations
√ traction bronchiectasis

GOODPASTURE SYNDROME

[Ernest William Goodpasture (1886–1960), chair of pathology at the medical school of Vanderbilt University, developed a method for cultivating viruses and rickettsiae]
= ANTI-GLOMERULAR BASEMENT MEMBRANE ANTIBODY DISEASE
= autoimmune disease characterized by
(1) Glomerulonephritis
(2) Circulating antibodies against glomerular + alveolar basement membrane
(3) Pulmonary hemorrhage

Pathogenesis:
cytotoxic antibody-mediated disease = type II hypersensitivity; alveolar basement membrane becomes antigenic (perhaps viral etiology); IgG / IgM antibody with complement activation → cell destruction + pulmonary hemorrhage → hemosiderin deposition and pulmonary fibrosis

Age peak: 26 (range, 17–78) years; M÷F = 7÷1
• iron-deficiency anemia, systemic hypertension
√ hepatosplenomegaly
@ Lung
• preceding upper respiratory infection (in ⅔) + renal disease
• mild hemoptysis (72%) with hemosiderin-laden macrophages in sputum, commonly precedes the clinical manifestations of renal disease by several months
• cough, mild dyspnea, basilar rales
√ extensive bilateral air-space consolidation:
√ symmetric consolidation of perihilar area + lung bases with sparing of lung apices
√ air bronchogram
√ consolidation replaced by interstitial pattern within 2–3 days → organization of hemorrhage resulting in interlobular septal thickening
√ hilar lymph nodes may be enlarged during acute episode
@ Kidney
• glomerulonephritis with IgG deposits in characteristic linear pattern in glomeruli; hematuria

Prognosis: death within 3 years (average 6 months) because of renal failure
Rx: cytotoxic chemotherapy, plasmapheresis, bilateral nephrectomy
DDx: idiopathic pulmonary hemosiderosis

GRANULOMA OF LUNG

Cause:
A. SARCOIDOSIS

B. NON-SARCOID GRANULOMATOUS DISEASE

(a) infectious

› bacterial: TB, gumma
› opportunistic: cryptococcosis
› parasitic: Dirofilaria immitis (dog heartworm)
› fungal: histoplasmosis, coccidioidomycosis, nocardiosis

(b) noninfectious

› foreign body: talc, beryllium, algae, pollen, cellulose, lipids, abuse of nasally inhaled drugs, aspiration of medication
› angiocentric lymphoproliferative disease
› vasculitides
› extrinsic allergic alveolitis
› Langerhans cell histiocytosis
› pulmonary hyalinizing granuloma
› peribronchial granuloma
› chronic granulomatous disease of childhood

Histo: epithelial cells, lymphocytes, macrophages, giant cells of Langhans type
[Theodor Langhans (1839–1915), professor of pathology at the University of Bern, Switzerland, and Giessen, Germany, discoverer of multi-nucleated giant cell = Langhans giant cell]

Frequency: constitutes majority of solitary pulmonary nodules

• nonproductive cough, shortness of breath
√ spontaneous pneumothorax

CXR:

◊ CXR detection requires multiple granulomas / clusters of granulomas (individual granuloma too small)!
√ central nidus of calcification in a laminated / diffuse pattern
√ absence of growth for at least 2 years

CT (most effective in nodules ≤ 3 cm of diameter with smooth discrete margins):

√ 50–60% of pulmonary nodules demonstrate unsuspected calcification by CT

DDx: carcinoma (in 10% eccentric calcification in preexisting scar / nearby granuloma / true intrinsic stippled calcification in larger lesion)

HAMARTOMA OF CHEST WALL

= MESENCHYMOMA (incorrect as it implies neoplasm)
= focal overgrowth of normal skeletal elements with a benign self-limited course; extremely rare

Age: 1st year of life

√ moderate / large extrapleural well-circumscribed mass affecting one / more ribs
√ ribs near center of mass partially / completely destroyed
√ ribs at periphery deformed / eroded
√ significant amount of calcification / ossification (DDx: aneurysmal bone cyst)
√ mass compresses underlying lung

Rx: resection curative

HAMARTOMA OF LUNG

= most common benign tumor of the lung

Frequency: 0.25% in population (autopsy); 6–8% of all solitary pulmonary neoplasms; 77% of all benign lung tumors

Etiology:

1. Congenital malformation of a displaced bronchial anlage
2. Hyperplasia of normal structures
3. Cartilaginous neoplasm
4. Response to inflammation

Path: solitary mass composed of tissues normally found in this location in abnormal quantity, mixture, and arrangement

Histo: columnar, cuboidal, ciliated epithelium, fat (in 50%), bone, cartilage (predominates), muscle, vessels, fibrous tissue, calcifications, plasma cells originating in fibrous connective tissue beneath mucous membrane of bronchial wall

Age peak: 5th and 6th decade; M÷F = 2÷1 – 3÷1

May be associated with:

Carney triad (pulmonary chondromatous lesion, gastric leiomyosarcoma, functioning extraadrenal paraganglioma); pulmonary hamartoma syndrome

- mostly asymptomatic; fever ← postobstructive pneumonitis
- cough, hemoptysis (rare), vague chest pain

Location: ⅔ peripheral; endobronchial in 1%; multiplicity (rare)

√ round smooth lobulated mass < 4 cm (average of 2.5 cm)
√ calcification in 15–20% (ALMOST PATHOGNOMONIC if of chondroid "popcorn" type)
√ fat density in 50% (DIAGNOSTIC)
√ cavitation (extremely rare)
√ growth patterns: slow / rapid / stable with later growth
√ usually diameter increase by 1.5 mm/year doubling in size every 14 years

HRCT:

√ fat density detectable in 34% (–80 to –120 HU)
√ calcium + fat detectable in 19%

Transthoracic needle biopsy: 85% diagnostic accuracy

DDx: lipoid pneumonia (ill-defined mass / lung infiltrate); granulomatous disease, carcinoid tumor; metastatic mucinous adenocarcinoma, amyloidoma

HARD-METAL PNEUMOCONIOSIS

= alloy of tungsten, carbon and cobalt

Occupational exposure: processing of tungsten carbide + cobalt (occasionally adding titanium, tantalum, nickel, chromium)

Main cause: cobalt (= cytotoxic + allergic agent)

Histo: obliterative bronchiolitis (earliest manifestation), subacute fibrosing alveolitis (= desquamation of epithelial cells + accumulation of macrophages in alveolar space), PATHOGNOMONIC giant cell interstitial pneumonia (multinuclear giant cells), chronic interstitial lung disease = diffuse mural fibrosis with honeycombing (several years after initial exposure)

- asthma, shortness of breath, chronic cough
- dyspnea on exertion over prolonged period
- restricted / obstructive pulmonary function tests

√ diffuse small reticulonodular pattern + small cystic spaces
√ panlobular bilateral ground-glass opacities / consolidation
√ parenchymal distortion, honeycombing, traction bronchiectasis

DDx: idiopathic pulmonary fibrosis, non-specific interstitial pneumonia

HEREDITARY HEMORRHAGIC TELANGIECTASIA

= RENDU-OSLER-WEBER SYNDROME

[Henri Jules Louis Marie Rendu (1844–1902), Head of the Department of Medicine at the Hôpital Necker, Paris]
[Sir William Osler (1849–1919), first professor of medicine at Johns Hopkins University Medical School in Baltimore, USA]
[Frederick Parkes Weber (1863–1962), dermatologist, London]

= group of autosomal dominant inherited disorders that result in a variety of systemic fibrovascular dysplasias affecting mucous skin, membranes, lung, brain, GI tract:

Phenotypes of Rendu-Osler-Weber Syndrome

Type	*Gene mutation*	*Description (lesions = AVMs + AVFs)*
HHT1	ENG	most common phenotype; prevalence of pulmonary lesions
HHT2	ALK1	prevalence of hepatic lesions; frequently pulmonary hypertension
HHT3	unknown	hepatic > pulmonary lesions
HHT4	unknown	lesions in lung, brain, nose
JPHT	SMAD4	lesions in various sites + juvenile polyposis

(1) Telangiectasias
(2) Arteriovenous malformations (AV hemangiomas)
(3) Aneurysms

Etiology: gene mutation that encodes a protein binding transforming growth factor (TGF)-β controlling cell proliferation + differentiation + death → abnormal vascular remodeling into fibrovascular dysplasia

Prevalence: 1–20÷100,000; M = F

Age: manifestation usually during adulthood

Path: direct connections between arteries + veins with absence of capillaries (telangiectases are small AVMs)

(a) small telangiectasis = focal dilatation of postcapillary venules with prominent stress fibers in pericytes along luminal borders
(b) fully developed telangiectasis = markedly dilated + convoluted venules with excessive layers of smooth muscle without elastic fibers directly connecting to dilated arterioles

Histo: absence of cellular intervals in vascular endothelial cells

Diagnostic criteria: ≥ 3 of the following conditions
(1) Recurrent epistaxis
(2) Multiple vascular dilatations in face + oral cavity
(3) AVMs / AVFs in internal organs
(4) 1st-degree relative with this condition

• frequent bleeding into mucous membranes, skin, lungs, GU system, GI system ← vascular weakness

@ Nose (= telangiectasis of nasal mucosa)
• recurrent epistaxis (32–85%): more severe over time in 66%; begins by age 10, present by age 21 in most cases; up to 45 episodes per month

@ Skin
• telangiectases = small red vascular blemishes
Age: present in most cases by age 40; increase in number + size with age
Location: lips, tongue, floor of oral cavity, palate, fingers, face, conjunctiva, trunk, arms, nail beds

@ Lung (5–15%)
◊ 5–15% of patients with hereditary hemorrhagic telangiectasia have pulmonary AVMs
◊ Up to 60% of patients with pulmonary AVMs have hereditary hemorrhagic telangiectasia

@ CNS (= cerebral or spinal AVMs)
• headache; seizure; paraparesis (less common)
√ subarachnoid hemorrhage

@ GI tract (stomach, duodenum, small bowel, colon)
= dilatation of small mucosal blood vessels
May be associated with: AVMs / angiodysplasia
• recurrent GI bleeding (in 5th–6th decade)

@ Liver (8–74%)
√ hepatomegaly
√ presence of multiple AVMs (between hepatic artery branches + branches of hepatic / portal veins):
√ heterogeneous liver enhancement with mosaic perfusion
√ simultaneous enhancement of hepatic arteries + veins
√ multiple areas of transient hepatic attenuation differences on hepatic arterial phase:
(a) arterioportal shunt (65%)
(b) telangiectasia (63%)
(c) confluent vascular mass (25%)
√ dilated tortuous hepatic arteries
√ early enhancement of dilated hepatic veins
√ diffuse mottled capillary blush on angio
Cx: atypical cirrhosis, hyperdynamic portal hypertension, variceal GI hemorrhage, ascites, hepatic portosystemic encephalopathy

Cx: (1) Congestive heart failure ← AV shunting
(2) Cerebral abscess ← paradoxical emboli

HISTOPLASMOSIS

Prevalence: nearly 100% in endemic area; up to 30% in Central + South America, Puerto Rico, West Africa, Southeast Asia; annually 500,000 infected in USA; up to 30% of US population has positive skin reaction

Organism: Histoplasma capsulatum = ubiquitous dimorphic fungus; worldwide most often in temperate climates; widespread in soil enriched by bird droppings of central North America (endemic in Ohio, Mississippi, St. Lawrence River valley; exists as a spore in soil + transforms into yeast form at normal body temperature

Vector: fowl + other birds (passes through feces without infection due to high body temperature); bats

Infection: inhalation of wind-borne spores (microconidia of 2–6 μm, macroconidia of 6–14 μm), which germinate within alveoli releasing yeast forms, which are phagocytized but not killed by macrophages; invasion of pulmonary lymphatics with spread to hilar + mediastinal lymph nodes; hematogenous dissemination of parasitized macrophages throughout reticuloendothelial system (spleen!)

Path: spores incite formation of epithelioid granulomas, necrosis, calcification

Dx: (1) Culture (sputum, lung tissue, urine, bone marrow, lymph node)
(2) Identification of yeast forms stained with PAS / Gömöri methenamine silver
(3) Complement fixation test (absolute titer of 1÷64 or 4-fold rise in convalescent titer suggest active / recent infection)
(4) Serum immunodiffusion: agar gel diffusion test (H precipitin band)

Rx: ketoconazole

Pulmonary Histoplasmosis

A. ACUTE HISTOPLASMOSIS
- mostly asymptomatic and self-limiting illness (in 99.5%)
- fever, cough, malaise simulating viral upper respiratory infection 3 weeks after massive inoculum / in debilitated patients (infants, elderly)
- positive skin test for histoplasmosis; hypersensitivity develops in 1–2 weeks

√ generalized lymphadenopathy
√ bilateral nonsegmental bronchopneumonic pattern with tendency to clear in one area + appear in another
√ multiple nodules changing into hundreds of punctate calcifications (usually > 4 mm) after 9–24 months
√ "target lesion" = PATHOGNOMONIC central calcification
√ hilar / mediastinal lymph node enlargement (DDx: acute viral / bacterial pneumonia)
√ "popcorn" calcification of mediastinal lymph nodes > 10 mm (80% probability of being caused by histoplasma)
√ > 5 splenic calcifications (40%)

CT:
√ paratracheal / subcarinal mass with regions of low attenuation (necrosis) + enhancing septa

B. CHRONIC HISTOPLASMOSIS (0.03%)

Predisposed: individuals with chronic obstructive pulmonary disease + cigarette smoking

Age: middle-aged white men

Pathophysiology: hyperimmune reaction

- cough, low-grade fever, night sweats simulating postprimary tuberculosis

√ segmental wedge-shaped peripheral consolidation of moth-eaten appearance from scattered foci of emphysematous lung

√ fibrosis in apical posterior segments of upper lobes (indistinguishable from postprimary TB) adjacent to emphysematous blebs

C. DISSEMINATED HISTOPLASMOSIS

Predisposed: impaired T-cell immunity; AIDS; immunosuppression after organ transplant

Prevalence: 1÷50,000 exposed individuals

Pathophysiology: progression of exogenous infection / reactivation of latent focus

- acute rapidly fatal infection:
  - fever, weight loss, anorexia, malaise, cough (< 50%)
  - abdominal pain, nausea, vomiting, diarrhea
- chronic intermittent illness:
  - low-grade fever, weight loss, fatigue
  - adrenal insufficiency

√ normal CXR (> 50%)

√ miliary nodules of < 3 mm

√ linear irregular reticulonodular opacities

√ segmental / lobar / diffuse airspace opacities

√ hilar + mediastinal adenopathy (uncommon in immunocompromised patients)

√ hepatosplenomegaly

@ GI tract (cecum, small bowel)

√ mucosal nodularity + strictures ← ulceration

Cx: arthritis (most often knee), tenosynovitis, osteomyelitis

D. DELAYED MANIFESTATIONS

◊ Organism recovered in only 50%!

√ **histoplasmoma** (= continued growth of primary focus at 0.5–2.8 mm/year) adjacent to pleura + typically with laminated calcific rings ("lung stone")

In 20% associated with: mediastinal granulomas

√ broncholithiasis = erosion of peribronchial calcified lymph node into bronchus:

- hemoptysis, fever, chills, productive cough

√ change in position of stone on serial radiographs

√ **mediastinal granuloma** (more common)

= direct infection of mediastinal lymph nodes

Histo: involved nodes with varying degrees of central caseation ± calcification

- usually asymptomatic

Location: subcarinal / right paratracheal / hilar lymph nodes

√ widened mediastinum (enlarged nodes + veins)

√ lobulated mass of low-density lymph nodes 3–10 cm in thickness surrounded by a 2–5-mm thick fibrous capsule crisscrossed by irregularly shaped enhancing septa (CHARACTERISTIC)

√ displacement of SVC / esophagus

√ **fibrosing mediastinitis** (less common)

HODGKIN DISEASE

= HODGKIN LYMPHOMA

[Thomas Hodgkin (1798–1866), English physician and pathologist, first appointed physician at London Dispensary and curator of Pathology Museum at Guy's Hospital Medical School]

= disease of T cells

Frequency: 0.75% of all cancers diagnosed each year; 40% of all lymphomas

Age: bimodal peaks at age 25–30 years and 75–80 years; very rare in children < 5 years; M÷F = 1÷1

Histo: Hodgkin and Reed-Sternberg cells = binucleate cells with prominent centrally located nucleoli (= activated pre-B cells) scattered in infiltrate of inflammatory cells

- positive for CD30, CD15, EBV

(1) Nodular sclerosis (78%)

= lymph nodes traversed by broad bands of birefringent collagen separating nodules, which consist of normal lymphocytes, eosinophils, plasma cells, and histiocytes

- ⅓ with systemic symptoms

√ typically localized anterior mediastinal involvement

Prognosis: good

(2) Mixed cellularity (17%)

= diffuse effacement of lymph nodes with lymphocytes, eosinophils, plasma cells + relative abundance of atypical mononuclear and Reed-Sternberg cells; more commonly advanced stage at presentation and older age

√ more commonly abdominal than mediastinal

Prognosis: less favorable

(3) Lymphocyte predominance (5%)

= abundance of normal-appearing lymphocytes + relative paucity of abnormal cells

- often diagnosed in younger people < 35 years
- systemic symptoms are uncommon
- frequently in early stage + localized disease

Prognosis: most favorable natural history

(4) Lymphocyte depletion (1%)

= paucity of normal-appearing lymphocytes + abundance of abnormal mononuclear and Reed-Sternberg cells; least common subtype with worst prognosis

Age: older patients

- systemic symptoms

√ disseminated advanced stage

Prognosis: rapidly fatal

- painless lymphadenopathy: cervical > supraclavicular > inguinal > axillary
- alcohol-induced pain, generalized pruritus
- unexplained fevers, drenching night sweats, weight loss

@ CHEST

At presentation: 67% with intrathoracic disease

Sites of lymphoid aggregates:

1. Lymph nodes in mediastinum
2. Lymph nodes at bifurcation of 1st + 2nd order bronchi

3. Encapsulated lymphoid collections on thoracic surface deep to parietal pleura
4. Unencapsulated nodules at points of divisions of more distally situated bronchi, bronchioles, pulmonary vessels
5. Unencapsulated lymphoid aggregates within peribronchial connective tissue
6. Small accumulations of lymphocytes in interlobular septa + lymphatic channels

Ann Arbor Staging Classification for HD (1971)	
Stage	*Description*
I	one anatomic region / lymphoid structure (eg, spleen, thymus, Waldeyer ring) or single extralymphatic site
II	≥ 2 lymph node regions / localized contiguous involvement of extranodal site + lymph node region on same side of diaphragm (number of sites indicated by subscript, eg, II_2)
III	lymph node regions on both sides of diaphragm ± spleen (Stage III_S) / Waldeyer ring / localized contiguous involvement of one extranodal site
III_1	± splenic / hilar / celiac / portal nodes
III_2	+ paraortic / iliac / mesenteric nodes
IV	diffuse / disseminated involvement of ≥ 1 extranodal organs lymph nodes
A*	no symptoms
B*	temperature > 38°C, drenching night sweats, unexplained loss of > 10% of body weight within preceding 6 months
E*	single extranodal site contiguous to nodal site
X*	bulky disease (mediastinum widened > 1/3) OR nodal mass > 10 cm
CS*	clinical stage
PS*	pathologic stage (as determined by laparoscopy)
* these designations are applicable to any stage	

A. INTRAPULMONARY MANIFESTATIONS

Frequency: 6–11%; in 4.3% bilateral (more frequent in recurrent disease)

◊ Most commonly in nodular sclerosing type

◊ Subsequent to hilar adenopathy in ipsilateral lung

1. Bronchovascular form (most common type)
   - √ coarse reticulonodular pattern contiguous with mediastinum = direct extension from mediastinal nodes along lymphatics
   - √ nodular parenchymal lesions
   - √ miliary nodules
   - √ endobronchial involvement
   - √ lobar atelectasis ← endobronchial obstruction (rare)
   - √ cavitation ← necrosis (rare)
2. Subpleural form
   - √ circumscribed subpleural masses
   - √ pleural effusion (20–50%) ← lymphatic obstruction
3. Massive pneumonic form (68%)

√ diffuse nonsegmental infiltrate (pneumonic type)
√ massive lobar infiltrates (30%)
√ homogeneous confluent infiltrates with shaggy borders
√ air bronchogram

4. Nodular form
   √ multiple nodules < 1 cm in diameter (DDx: metastatic disease)

DDx in treated patients:
relapse, infection, radiation pneumonitis, drug-induced lung disease

B. EXTRAPULMONARY MANIFESTATIONS

1. Mediastinal + hilar lymphadenopathy
   most common manifestation, present in 90–99%, in thorax commonly multiple lymph node groups involved
   Location:
   anterior mediastinal + retrosternal nodes commonly involved (DDx: sarcoidosis); confined to anterior mediastinum in 40%; 20% with mediastinal nodes have hilar lymphadenopathy also; hilar lymph nodes involved bilaterally in 50%
   Spread from anterior mediastinum to:
   other mediastinal locations, pleura, pericardium, chest wall
   ◊ Involvement of multiple lymph node groups in 95%!
   √ CXR: on initial film adenopathy identified in 50%
   √ necrotic lymph nodes (commonly nodular sclerosing type)
   √ lymph nodes may calcify following radiation / chemotherapy
2. Pleural effusion (13%)
   ◊ NOT of prognostic significance
   Prognosis: usually resolves following treatment
3. Pleural masses + plaques
   √ sternal erosion
   √ invasion of anterior chest wall
4. Thymic involvement
   √ thymic enlargement (in 56%)

Cx:

1. Superimposed infection
   √ consolidation with bulging borders: necrotizing bacterial pneumonia
   √ multiple nodular foci: aspergillosis + nocardiosis
   √ bilateral diffuse consolidation: Pneumocystis carinii
   √ rapidly developing cavitation within consolidation: anaerobes / fungus
   Dx: by culture, sputum cytology, lung biopsy
2. Drug toxicity

Extranodal Hodgkin Disease (15–30%)

@ BONE (5–20%)
◊ During course of disease 5–32% develop bone marrow involvement
At presentation: 1–4%; indicative of widespread aggressive disease with poor prognosis
Location: dorsolumbar spine > pelvis > ribs > femora > sternum

NUC: recommended only with bone pain + elevated serum alkaline phosphatase
√ solitary (33%) / polyostotic (66%) lesions:
√ usually wide ill-defined lesion edge / sclerotic margin
√ lamellated / "sunburst" periosteal reaction
√ predominantly osteolytic with blurred borders; rarely sclerotic / mixed lytic-sclerotic
√ fractures occur rarely at presentation
√ vertebral osteolysis with collapse / patchy sclerosis / "ivory vertebra" / mixed lytic + blastic lesion
√ gouge defect of anterior vertebral body margin ← erosion by lymph nodes
√ osteolysis of sternum ← proximity to thoracic lymph ducts

@ HEAD & NECK (< 1%)
• nasopharyngeal biopsy positive in 20%
√ thyroid mass as secondary involvement (2%)

@ CNS (uncommon)
Frequency: secondary hematogenous involvement in 0.2–0.5%; usually not part of standard staging without CNS symptoms / signs
Location: supratentorial cerebral cortex + meninges in inferior aspect of brain (most frequent)
√ leptomeningeal + choroid plexus masses
√ white matter mass, typically periventricular / basal ganglionic / cerebellar
√ paraneoplastic cerebellar atrophy
√ epidural mass with spinal cord compression (in 3.0–7.6%) from extension of paraspinal nodes through intervertebral neural foramen:
√ concomitant vertebral bone involvement (in 32–42%)

@ THYMUS (30–56%)
◊ Considered a "lymph node" in staging
√ remains enlarged after treatment in 33% ← recurrent disease / rebound hyperplasia / persistence of thymic cysts

@ CHEST WALL (6.4%)
√ infiltration of parasternal soft tissues by direct extension from internal mammary nodes
√ mass beneath / between pectoralis muscles (rare)

@ HEART (7.5% at autopsy)
√ pericardial effusion (with large mediastinal mass)
√ invasion of pericardium + SVC
√ pericardial nodular mass

@ LIVER (6–20%)
◊ Primary involvement is very rare
Associated with: splenic disease (almost invariably)
√ discrete nodules (10%) = miliary lesions of < 10 mm
√ diffuse disease (87%) = patchy irregular infiltrates in portal areas

@ SPLEEN
◊ Considered a "nodal organ"
Frequency: 30–40% at staging laparotomy
√ diffuse involvement (not detectable by imaging) ± splenomegaly

√ hypoechoic hypoattenuating nodules with reduced contrast enhancement

MR:

√ hypo- / isointense nodules on T1WI + hyperintense on T2WI

√ reduced enhancement compared with normal spleen

DDx: reactive splenomegaly (in 30%)

@ PANCREAS (extremely rare)

◊ secondary to contiguous lymph node disease

@ GI TRACT (10–15%)

= rarely affecting GI tract → mostly 2ndary involvement by tumor extension from adjacent lymph nodes

◊ primary HD in < 1% of all primary gastric + small bowel lymphomas

Barium:

√ diffuse fold thickening / ulcerated mass in stomach

√ irregular luminal narrowing + nodularity in esophagus, small bowel, colon

CT:

√ concentric thickening of affected bowel wall

› Stomach (9% of all intestinal lymphomas):

√ narrow rigid obstructive lesion (DDx: scirrhous ca.)

√ wall thickening + smoothly lobulated outer border

› Small intestine:

• spruelike symptoms, steatorrhea

√ abundance of desmoplastic reaction (DDx from NHL)

√ infiltrating (60%); polypoid (26%); ulcerated (14%)

Prognosis: poorer 5-year survival rate than with other forms of this disease

› Esophagus (extremely rare):

√ esophageal nodules / irregular narrowing

Cx: focal stenosis, obstruction ← greater degree of fibrosis than lymphoma

@ GU TRACT (extremely rare)

√ perirenal / renal masses ← invasion from surrounding nodes

Cx: increased risk for other malignancies from aggressive therapy (acute leukemia, NHL, radiation-induced sarcoma)

Clinical & HRCT Features of Idiopathic Interstitial Pneumonias
American Thoracic Society and European Respiratory Society (2001)

Type	*Onset [y]*	*Gender*	*Onset*	*Smoking*	*Prognosis*	*Steroids*	*Distribution*	*HRCT*
UIP (IPF)	> 50	M > F	gradual	?	poor	poor	apicobasal, subpleural	macrocystic honeycombing, reticular opacities, traction bronchiectasis, architectural distortion, focal ground-glass opacity , spatial + temporal heterogeneity
NSIP	40–50	M = F	gradual / subacute	no	variable	good	no gradient, symmetric, subpleural	ground-glass opacities, irregular linear / reticular opacities, micronodules, consolidation, microcystic honeycombing
COP	55	M = F	subacute	+	complete recovery	excellent	basal patchy, peripheral / peribronchial	airspace consolidation, mild bronchial dilatation, ground-glass opacities, large nodules (rare)

CT Features and Differential Diagnosis of Idiopathic Interstitial Pneumonias
American Thoracic Society and European Respiratory Society (2013 revision)

Group & Diagnosis	*CT Pattern*	*CT Distribution*	*Typical CT Findings*	*DDx of CT Morphology*
Chronic fibrosing IIPs				
Idiopathic pulmonary fibrosis	Usual interstitial pneumonia (UIP)	√ peripheral √ subpleural √ basal	√ reticular opacities √ honeycombing √ traction bronchiectasis / bronchiolectasis √ architectural distortion √ focal ground-glass attenuation	(1) Collagen vascular disease (2) Hypersensitivity pneumonitis (3) Asbestosis (4) Sarcoidosis
Idiopathic NSIP	Nonspecific interstitial pneumonia (NSIP)	√ peripheral √ basal √ symmetric	√ ground-glass attenuation √ irregular lines √ traction bronchiectasis √ consolidation	(1) UIP (2) DIP (3) Cryptogenic organizing pneumonia (4) Hypersensitivity pneumonitis
Smoking-related IIPs				
Desquamative interstitial pneumonia	Desquamative interstitial pneumonia (DIP)	√ lower zone √ (mostly) peripheral predominance	√ ground-glass attenuation √ reticular lines √ cysts	(1) RB-ILD (2) NSIP (3) Hypersensitivity pneumonitis
RB-ILD	Respiratory bronchiolitis	√ (often) upper lung predominant √ centrilobular	√ bronchial wall thickening √ centrilobular nodules √ patchy ground-glass opacity	(1) DIP (2) NSIP (3) Hypersensitivity pneumonitis
Acute / subacute IIPs				
Cryptogenic organizing pneumonia	Organizing pneumonia	√ subpleural √ peribronchial	√ patchy consolidation / nodules √ perilobular pattern √ reverse halo sign	(1) Infection (2) Aspiration (3) Eosinophilic pneumonia (4) NSIP (5) Vasculitis (6) Sarcoidosis (7) Mucinous adenocarcinoma (8) Lymphoma

Group & Diagnosis	*CT Pattern*	*CT Distribution*	*Typical CT Findings*	*DDx of CT Morphology*
Acute interstitial pneumonia	Diffuse alveolar damage	√ diffuse / patchy	√ consolidation and ground-glass opacity (often with lobular sparing) √ traction bronchiectasis (late)	(1) Hydrostatic edema (2) Pneumonia (3) Pulmonary hemorrhage (4) Acute eosinophilic pneumonia
Rare IIPs				
Lymphoid interstitial pneumonia	Lymphoid interstitial pneumonia	√ lower lung predominant	√ centrilobular nodules √ ground-glass attenuation √ septal + bronchovascular thickening √ thin-walled cysts	(1) NSIP (2) Sarcoidosis (3) Langerhans cell histiocytosis (4) Other cystic lung disease
Idiopathic pleuroparenchymal fibroelastosis	Idiopathic pleuro-parenchymal fibroelastosis	√ peripheral √ upper lung predominant	√ pleural thickening √ subpleural fibrotic changes	(1) Sarcoidosis (2) Pneumoconiosis (3) Pulmonary fibrosis (4) Connective tissue disease (5) Hypersensitivity pneumonitis

Classification of Idiopathic Interstitial Pneumonias
American Thoracic Society and European Respiratory Society (2001)

#	*Entities (in order of frequency)*	*Abbrev.*
1	Idiopathic Pulmonary Fibrosis	IPF
2	Nonspecific Interstitial Pneumonia	NSIP
3	Cryptogenic Organizing Pneumonia	COP
4	Desquamative Interstitial Pneumonia*	DIP
5	Respiratory Bronchiolitis-associated Interstitial Lung Disease*	RB-ILD
6	Acute Interstitial Pneumonia	AIP
7	Lymphoid Interstitial Pneumonia	LIP

** smoking -related*

DDx: sarcoidosis, vasculitis, collagen vascular (connective tissue) disease, drug reaction, asbestosis, chronic hypersensitivity pneumonitis

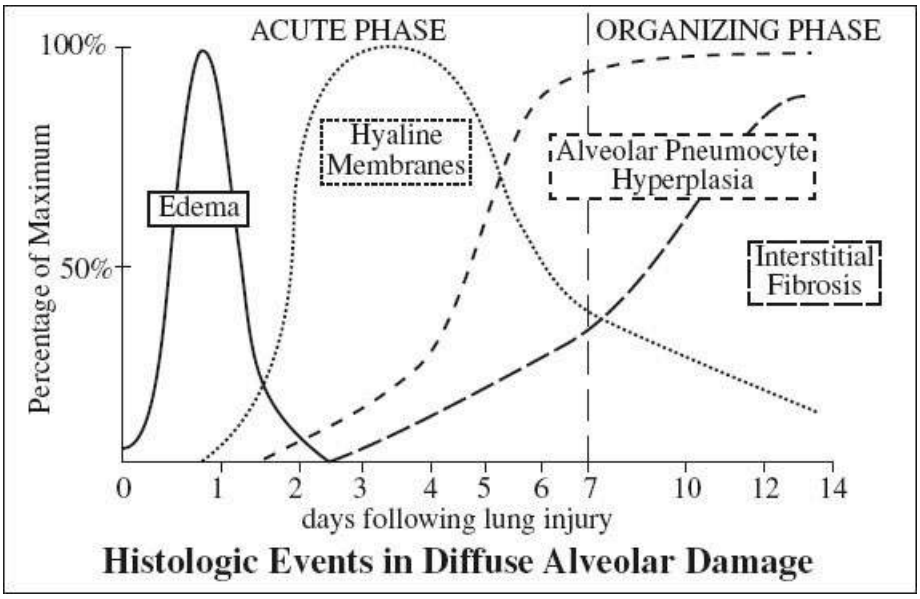
IDIOPATHIC INTERSTITIAL PNEUMONIA (IIP)

Acute Interstitial Pneumonia

= AIP = [ACCELERATED INTERSTITIAL PNEUMONIA] = DIFFUSE ALVEOLAR DAMAGE = IDIOPATHIC ARDS = ACUTE DIFFUSE INTERSTITIAL FIBROSIS = HAMMAN-RICH SYNDROME

= rapidly progressive fulminant disease of unknown etiology that usually occurs in previously healthy subjects + produces diffuse alveolar damage

Cause: diffuse alveolar damage of unknown origin from a variety of toxic insults such as infection, drugs, sepsis, shock, aspiration, toxic inhalation / ingestation, exacerbation of idiopathic pulmonary fibrosis, etc.



Histologic Events in Diffuse Alveolar Damage

Path: temporally homogeneous organizing diffuse alveolar damage; little mature collagen deposition / architectural distortion / honeycombing (as opposed to UIP); indistinguishable from ARDS caused by sepsis + shock

Histo: extensive diffuse alveolar damage

(a) acute exudative phase: alveolar + interstitial edema; hyaline membrane formation (most prominent in 1st week after lung injury); diffuse alveolar infiltrates by lymphocytes

(b) chronic organizing phase: uniform alveolar wall thickening ← marked interstitial (alveolar septal) fibroblast proliferation with stabilizing nonprogressive scarring + pneumocyte hyperplasia

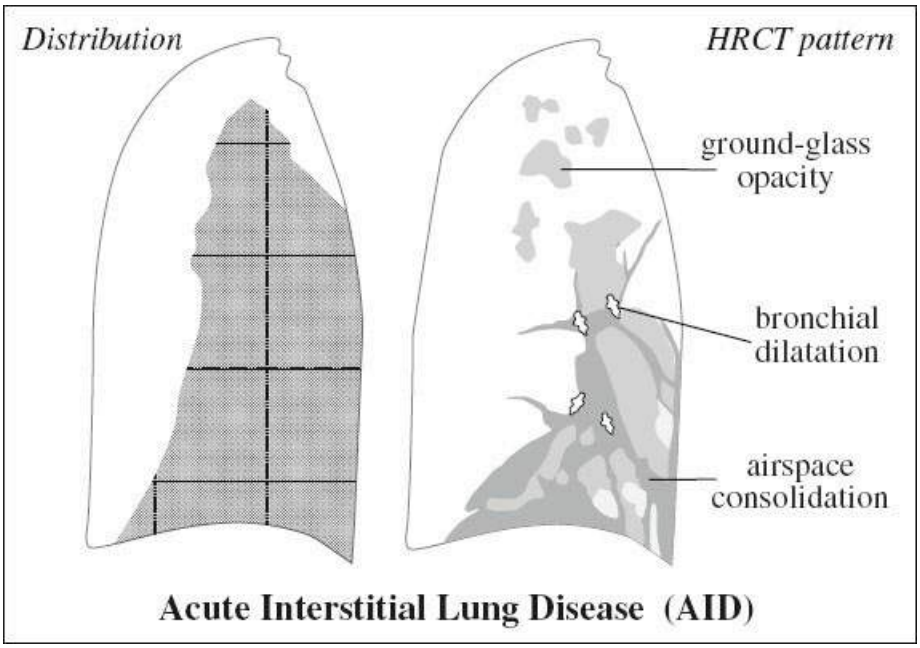
Mean age: 50 years (wide range); M = F

- prodromal viral upper respiratory infection: cough, fever
- rapidly increasing dyspnea + acute respiratory failure
- requires ventilation within days to 1–4 weeks (= "outpatient ARDS")
- decreased diffusing capacity for carbon monoxide
- pulmonary capillary wedge pressure of < 18 mmHg

AIP is the only entity of idiopathic interstitial pneumonias with acute onset of symptoms!

Location: bilateral symmetric mainly in lower lung zones

Site: predominantly central / subpleural (in 22%); anteroposterior lung attenuation gradient; costophrenic angles often spared



CXR:

√ progressive extensive bilateral hetero- / homogeneous airspace opacification: symmetric, bilateral, basilar

HRCT:

√ bilateral ground-glass opacities (in exudative phase) ← alveolar septal edema and hyaline membranes:

- √ patchy geographic (67%) / diffuse (38%)
- √ diffuse bilateral airspace consolidation (in 67%) limited to dependent area of lung (similar to ARDS) ← intraalveolar edema and hemorrhage ← alveolar closure from weight + hydrostatic pressure of more-superior lung tissue
- √ geographic focal sparing of lobules
- √ bronchial dilatation

√ architectural distortion (in organizing phase) more severe in nondependent areas of lung (atelectasis + consolidation protect from damaging effect of mechanical ventilation):

- √ airspace consolidation ← intraalveolar fibrosis
- √ distortion of bronchovascular bundles
- √ traction bronchiectasis
- √ honeycomb lung

Radiographic features of AIP are similar to ARDS with a symmetric bilateral distribution of lower lobe predominance!

Dx: NEGATIVE bacterial / viral / fungal cultures;
NO inhalational exposure to noxious agents;
NO pulmonary drug toxicity

Prognosis: death within 1–6 months (60–90%); recovery in 12%; frequently progression to fibrosis after survival in acute phase

Rx: supportive with oxygen supplementation; corticosteroids in early phase

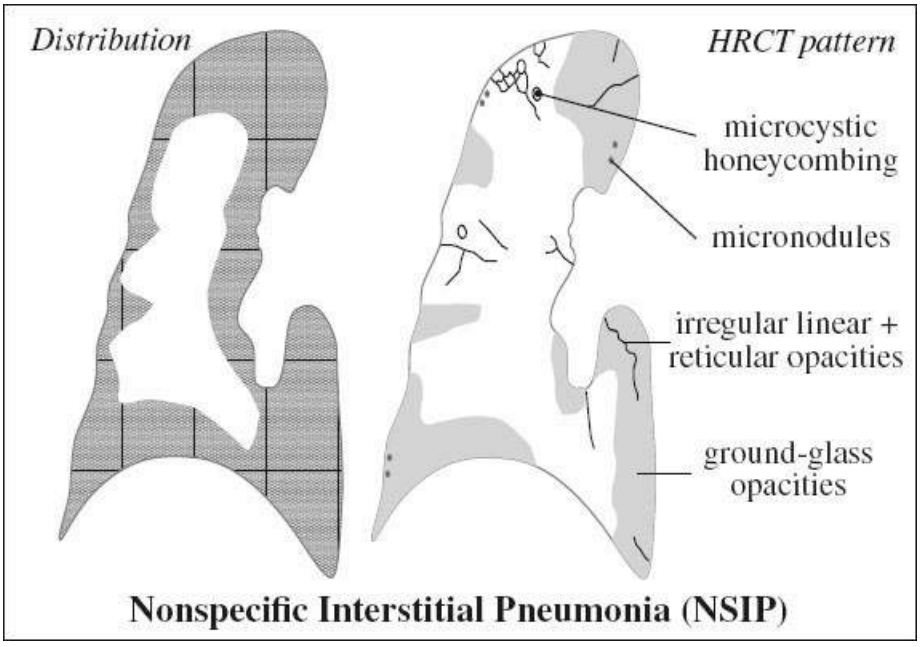
DDx: (1) ARDS (less symmetric, no lower lobe predominance)
(2) Widespread pneumonia" esp. Pneumocystis jirovecii pneumonia
(3) Hydrostatic edema (substantial interlobular septal thickening, pleural effusions)
(4) Acute eosinophilic pneumonia (substantial interlobular septal thickening, pleural effusions)
(5) Diffuse pulmonary hemorrhage
(6) Acute hypersensitivity pneumonitis (profuse centrilobular nodules / mosaic attenuation)
(7) Alveolar proteinosis

Subacute Interstitial Pneumonia

Nonspecific Interstitial Pneumonia

= NSIP = IDIOPATHIC NONSPECIFIC INTERSTITIAL PNEUMONIA = NONCLASSIFIABLE INTERSTITIAL PNEUMONIA

= provisional diagnosis for a probably heterogeneous group of interstitial pneumonia that cannot be easily classified as UIP / DIP / AIP / COP



Frequency: 14–36% (second most common IIP)

Path: spatially + temporally homogeneous alveolar wall thickening caused by inflammation and/or fibrosis

Histo: (I) cellular NSIP (48%) = mild to moderate cellular interstitial infiltrate with little / no fibrosis
(II) fibrotic NSIP (52%) = dense / loose fibrosis of uniform appearance

Clinical conditions associated with NSIP pattern:
(1) Idiopathic
(2) Collagen vascular disease (16%): scleroderma, polymyositis, dermatomyositis,

Sjögren syndrome, rheumatoid arthritis, mixed connective tissue disease, systemic lupus erythematosus

(4) Drug-induced pneumonitis

(3) Hypersensitivity pneumonitis: inhalational exposure to noxious agents (17%)

(5) Infection (8%)

(6) Immunodeficiency including HIV

Age: 40–50 years (1 decade younger than IPF); M = F

- gradually worsening dyspnea (1-week to 5-year history)
- dry cough, low-grade fever, fatigue, weight loss
- decreased diffusing capacity for carbon monoxide (less severe than idiopathic pulmonary fibrosis)

Location: lower lobe predominance (92%); symmetric involvement of both lungs

Site: peribronchovascular / subpleural distribution (21–64%)

√ normal CXR in 14%

√ bibasilar irregular linear opacities + diffuse heterogeneous airspace consolidation

√ volume loss in lower lobe (91%)

HRCT (70% sensitive, 63% specific):

√ fibrosis:

√ <u>irregular fine linear / reticular opacities</u> (87%)

√ traction bronchiectasis (82%)

√ lobar volume loss (77%)

√ relative subpleural sparing

√ bilateral symmetric areas of scattered <u>patchy ground-glass opacities</u> (44%) without zonal preference ← homogeneous interstitial inflammation

√ areas of low attenuation (34%)

√ microcystic honeycombing (inconspicuous, 30%)

√ airspace consolidation (uncommon)

√ diffuse micronodules (very infrequent)

√ mildly enlarged mediastinal lymphadenopathy (80%)

√ follow-up (stable in 35%):

√ decrease in ground-glass attenuation

√ persistence of reticular abnormalities

√ marked increase in fibrosis

Consider NSIP in homogeneous lung involvement without apicobasal gradient, a fine reticular pattern, and micronodules without progression to honeycombing!

Prognosis: substantially better than idiopathic pulmonary fibrosis; 11% overall mortality

Dx: surgical lung biopsy necessary

Rx: systemic corticosteroids combined with cytotoxic drugs (cyclophosphamide, cyclosporine) → clinical + functional + radiographic improvement in 50–86%

DDx: usual interstitial pneumonia (irregular reticular pattern + macrocystic honeycombing involving subpleural + lower lung zones); desquamative interstitial pneumonia; cryptogenic organizing pneumonia; chronic hypersensitivity pneumonitis

Respiratory Bronchiolitis-Interstitial Lung Disease

= RB-ILD = interstitial pneumonia of smokers in which respiratory bronchiolitis is associated with limited peribronchiolar interstitial inflammation; considered early and mild manifestation of DIP

Mean age: 36 (range, 30–40) years; M÷F = 2÷1

Cause: heavy cigarette smoking > 30 pack years

◊ Most common form of smoking-related lung injury

Histo: bronchiolocentric intraluminal accumulation of brown-pigmented alveolar macrophages and mild interstitial inflammation in 1st and 2nd order respiratory bronchioles + neighboring alveoli; mild peribronchial thickening with contiguous extension into alveolar septa but without significant fibrosis

- history of excessive smoking (> 30 pack year)
- usually asymptomatic / mild dyspnea + cough
- inspiratory crackles (50%)
- pulmonary function test: normal / mixed restrictive + obstructive + reduced diffusing capacity

Location: diffuse / upper lobe predominance

CXR (insensitive for detection):

√ normal CXR (21%)

√ fine bilateral reticulonodular opacities ← thickening of central + peripheral bronchial walls (71%)

√ bibasilar atelectasis (12%)

HRCT:

√ scattered patchy ground-glass opacities (66%) ← macrophage accumulation in alveolar ducts + spaces

√ inconspicuous poorly defined centrilobular micronodules (upper lobe predominance) ← peribronchial distribution of intraluminal infiltrates

√ scattered lobules of reduced attenuation ← lobular air trapping at expiration (upper lobe predominance)

√ mild interlobular septal thickening

√ bronchial wall thickening

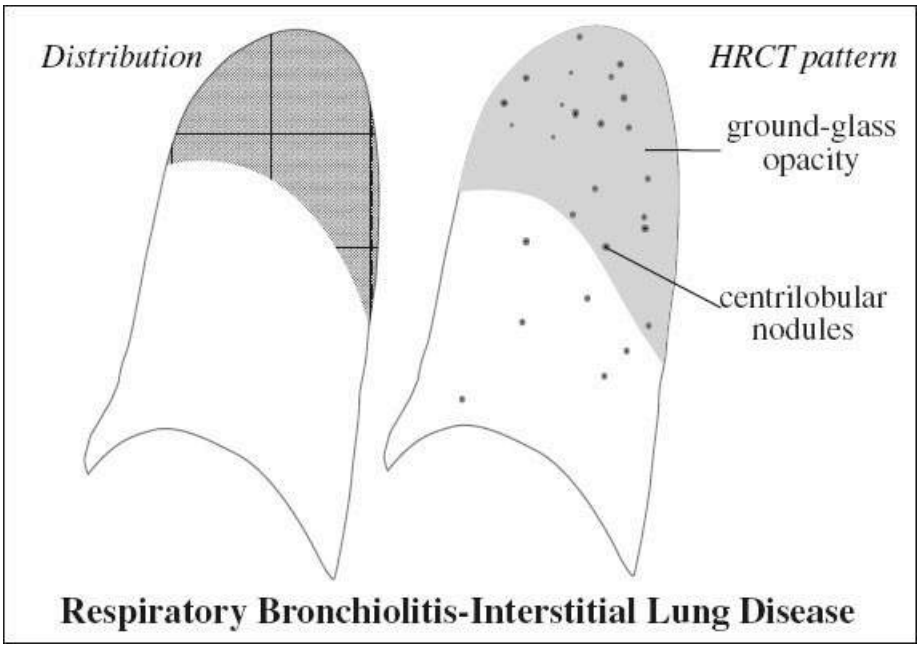
√ upper lobe centrilobular + paraseptal emphysema (rarely severe)

√ NO fibrosis

Prognosis: excellent (after cessation of smoking / corticoid therapy) without progression to end-stage lung fibrosis

Rx: smoking cessation (most important therapy!), corticosteroids

DDx: (1) Subacute hypersensitivity pneumonitis (more profuse + more diffuse poorly defined centrilobular nodules, exposure history, nonsmoker, lymphocytosis in BAL)



(2) Desquamative interstitial pneumonia (more extensive ground-glass attenuation, uncommon / sparse centrilobular nodules, lower lobe predominance)
(3) Nonspecific interstitial pneumonia (NSIP)
(4) Infectious bronchiolitis

Cryptogenic Organizing Pneumonia

= COP = BRONCHIOLITIS OBLITERANS ORGANIZING PNEUMONIA (BOOP) = IDIOPATHIC BOOP = PROLIFERATIVE BRONCHIOLITIS

Prevalence: 20–30% of all chronic infiltrative lung disease

Cause: pulmonary manifestation of collagen vascular disease, postobstructive pneumonia, organizing adult respiratory distress syndrome, pulmonary drug toxicity, extrinsic allergic alveolitis, silo filler disease, lung cancer, idiopathic (50%)

Path: temporally uniform homogeneous mild / moderate inflammation with preservation of lung architecture characterized by granulation tissue polyps filling the lumina of alveolar ducts and respiratory bronchioles (bronchiolitis obliterans) + variable degree of infiltration of interstitium and alveoli with macrophages (organizing pneumonia) [formerly known as bronchiolitis obliterans organizing pneumonia (BOOP)]

Histo: patchy distribution of intraluminal organizing fibrosis in distal airspaces = plugs of immature intraalveolar fibroblast proliferations (Masson bodies) covered with low cuboidal epithelium, which may spread through collateral air drift pathways

May be associated with: rheumatoid arthritis, polymyositis

Mean age: 55 (range, 40–70) years; M÷F = 1÷1

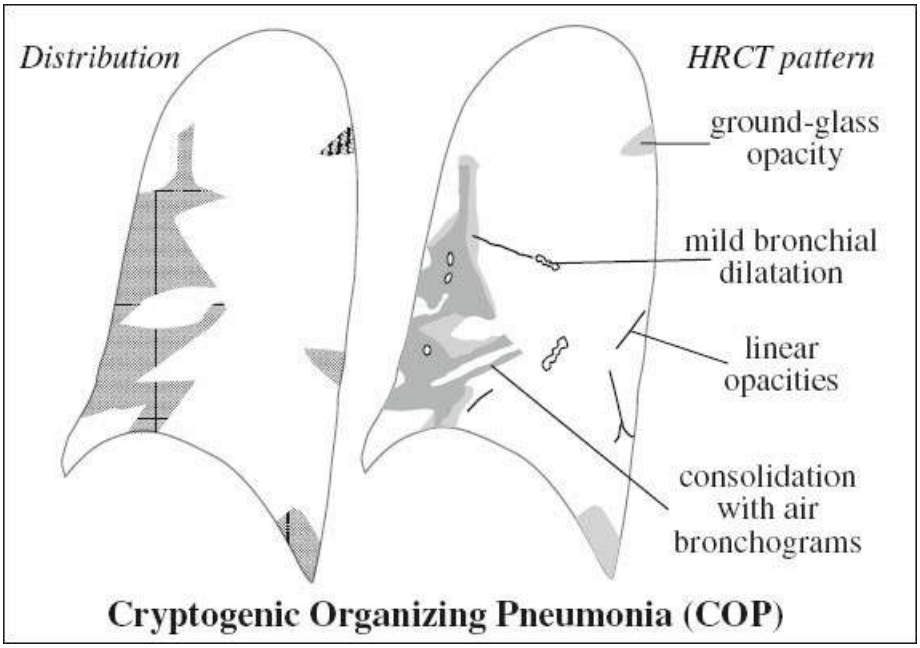
- nonproductive cough + mild dyspnea of 1–4-month duration preceded by a brief flulike illness with sore throat (40%), low-grade fever, malaise (in 33%)
- NO association with cigarette smoking

- restrictive pulmonary function tests + diminished diffusing capacity on pulmonary function tests
- consolidation often diagnosed as pneumonia with failure to respond to broad-spectrum antibiotic treatment

Location: lower lobe predominance

Site: CHARACTERISTIC peripheral (= subpleural in 50%) + peribronchial distribution (in 30–50%); tendency to expand and migrate over time

CXR: frequently a mixture of



√ preserved lung volumes
√ uni- / bilateral patchy alveolar airspace consolidation (25–73%), often subpleural, resembling pneumonic infiltrates
√ 3–5 mm nodules (up to 50%)
√ irregular linear opacities (15–42%)
√ unilateral focal / lobar consolidation (5–31%)
√ pleural thickening (13%)
√ cavitation / pleural effusion (< 5%)

HRCT: far more extensive than suggested on CXR

√ uni- / bilateral patchy airspace consolidation of triangular / polygonal shape (80–90%) a few cm in size
√ patchy ground-glass opacities ← alveolitis (60%):
  √ **"atoll"** sign = "reverse halo" sign if surrounded by 10-mm thick crescentic / ring-shaped opacities
  √ air bronchograms with mild cylindrical bronchial dilatation (in 36–70%)
√ large nodules (rare)
√ reticular opacities ← fibrosis (less common)
√ pleural effusion (28–35%)

√ adenopathy (27%)

Four distinctive HRCT patterns:

(1) Multiple bilateral symmetric patchy airspace opacities
(2) Diffuse bilateral reticular / nodular opacities
(3) Focal airspace consolidation
(4) Multiple large masses / nodules ± cavitation

Dx: tissue examination from open lung biopsy

Prognosis: radiologic improvement / resolution under steroids (in 84% of patients with idiopathic form); persistent abnormalities (30%); 10% mortality ← progressive / recurrent disease

DDx: bronchioloalveolar cell carcinoma; lymphoma; vasculitis; sarcoidosis; chronic eosinophilic pneumonia; infection; nonspecific interstitial pneumonia

Chronic Interstitial Pneumonia

= ORGANIZING INTERSTITIAL PNEUMONIA = CHRONIC DIFFUSE SCLEROSING ALVEOLITIS

Lymphoid Interstitial Pneumonia

= LIP = LYMPHOCYTIC INTERSTITIAL PNEUMONITIS

= benign lymphoproliferative disorder of lung parenchyma characterized by diffuse dense interstitial lymphoid infiltrate (probably immunologic disorder) with highly variable course

Frequency: extremely rare

Age: 50–80 years; M < F

Histo: extensive diffuse infiltration of alveolar interstitium (bronchovascular bundles, interlobular septa) and pleura by polyclonal mature small lymphocytes (predominantly T cells intermixed with some polytypic B cells) + plasma cells + histiocytes → expansion of the alveolar septa; reactive lymphoid follicles along peribronchiolar region; lymphoid hyperplasia frequent; many cases reclassified as lymphoma

Clinical conditions associated with LIP pattern:

(a) immune related
1. Immunodeficiency
2. Collagen vascular disease: Sjögren syndrome, rheumatoid arthritis, systemic lupus erythematosus
3. Immunologic disorders: autoimmune hemolytic anemia, Hashimoto thyroid disease, Castleman disease, myasthenia gravis, pernicious anemia, chronic active hepatitis, primary biliary cirrhosis, celiac sprue, Crohn disease, dysproteinemia

(b) infectious
1. HIV /AIDS
   ◊ Indicative of AIDS when present in child < 13 years of age!
2. Epstein-Barr virus (EBV) infection
3. Human herpesvirus 8
4. Chronic active hepatitis
5. Legionella pneumonia

6. Pneumocystis jirovecii
7. Tuberculosis

(c) miscellaneous

1. Drugs / toxic exposure: eg, Dilantin (phenytoin)-induced
2. Allogenic bone marrow transplant
3. Graft-versus-host disease

- slowly progressive dyspnea + cough over > 3 years
- occasionally fever, night sweats, weight loss
- cyanosis + clubbing (50%)
- enlargement of salivary glands (20%)
- NO lymphocytosis or history of atopy
- dysproteinemia (60%): hypergammaglobulinemia > hypogammaglobulinemia
- monoclonal gammopathy (usually IgM)

Distribution: bilateral; diffusely involving all lung zones / basilar predominance

LIP is suggested by thin-walled perivascular cysts in mid lung zones in combination with ground-glass opacities!

CXR (nonspecific):

√ absence of findings
√ fine reticulonodular pattern in both lower lungs
√ resembling airspace disease (in severe form)

HRCT:

√ ill-defined centrilobular nodules of varying size (100%)
√ ground-glass opacities (100%) ← diffuse interstitial inflammation
√ subpleural small nodules (in majority)
√ peribronchovascular thin-walled 1–30 mm cysts (68%) predominantly in lower lung ← air trapping ← ball-valve mechanism ← obstruction of small bronchioles ← peribronchiolar lymphocytic infiltration
√ mild patchy thickening of bronchovascular bundles + interlobular septal thickening (in majority) ← infiltration of interlobular septa with lymphocytes + plasma cells
√ mediastinal lymph node enlargement (50%)
√ pleural effusion / airspace consolidation (extremely uncommon)

N.B.: pleural effusion and > 11 mm large / growing nodules concerning for coexisting lymphoma

Prognosis:

(a) recovery / slowly improving / stable disease
(b) progression to fibrosis (in 33%)

Cx: malignant lymphoma (in 5%)

Rx: responsive to steroids

DDx: infection; primary pulmonary lymphoma; pulmonary amyloidosis; hypersensitivity pneumonitis (ground-glass attenuation, small centrilobular nodules, NOT cystic airspaces / thickening of interlobular septa or bronchovascular bundles); sarcoidosis; lymphangitic carcinomatosis; Langerhans cell histiocytosis; lymphangioleio-myomatosis; emphysema; desquamative interstitial pneumonia with cysts

Localized form = PSEUDOLYMPHOMA

Usual Interstitial Pneumonia

= UIP = MURAL TYPE OF FIBROSING ALVEOLITIS
= CRYPTOGENIC FIBROSING ALVEOLITIS

= commonest (90%) form of idiopathic interstitial pneumonia (may represent late stage of DIP)

Clinical conditions associated with UIP pattern:

(1) Idiopathic pulmonary fibrosis (IPF) / cryptogenic fibrosing alveolitis (50%)
(2) Collagen vascular disease / immunologic disorder (mostly rheumatoid arthritis) (20–30%)
(3) Drug toxicity: bleomycin, cyclophosphamide (Cytoxan®), busulfan, nitrofurantoin
(4) Chronic hypersensitivity pneumonitis
(5) Asbestosis
(6) Familial idiopathic pulmonary fibrosis (25%)

Mean age: 64 years (usually > 50 years); M> F

Path: patchy scattered fibrotic lesions of different stages (fibroblastic foci + mature fibrosis + honeycombing) mixed with areas of normal lung tissue (= temporal + spatial variegation (heterogeneity)

Dx: biopsy samples from > 1 lobe (because UIP pattern rules independent of other coexisting patterns) ← HRCT serves as a guide for appropriate biopsy sites

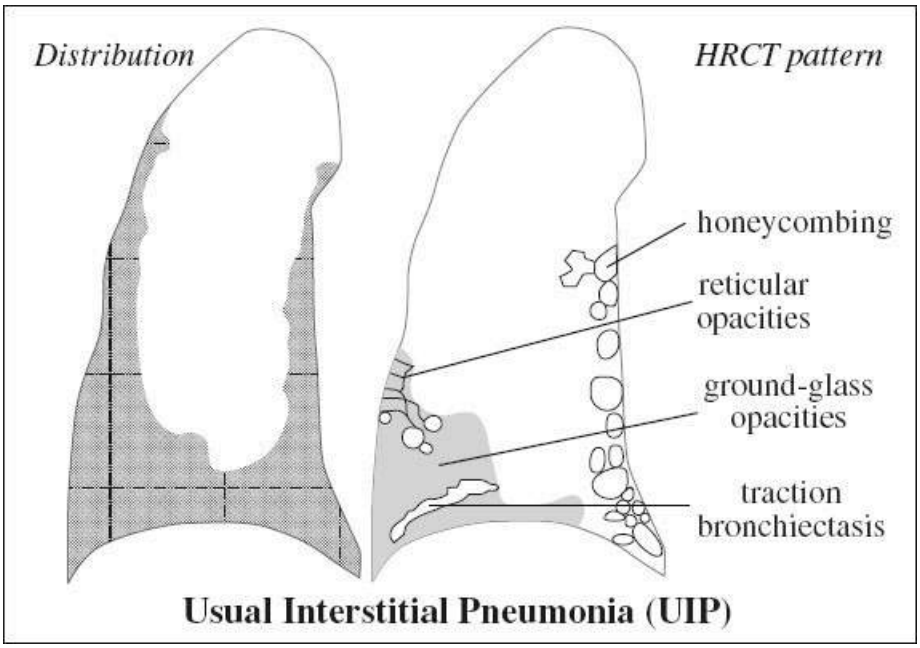
Histo: proteinaceous exudate in interstitium + hyaline membrane formation in alveoli; necrosis of alveolar lining cells followed by cellular infiltration of mono- and lymphocytes + regeneration of alveolar lining; intraalveolar histiocytes; proliferation of fibroblasts + deposition of collagen fibers + smooth muscle proliferation; progressive disorganization of pulmonary architecture

- progressive dyspnea, dry cough, fatigue (over 1–3 years)
- bibasilar fine inspiratory crackles = "Velcro" rales
- clubbing of fingers (83%)
- lymphocytosis on bronchoalveolar lavage (= marker of alveolitis)
- pulmonary function tests: restrictive defects + decreased diffusing capacity for carbon monoxide

Consider UIP with low lung volumes, subpleural reticular opacities, macrocystic honeycombing and traction bronchiectasis with apicobasal gradient!

CXR:

√ occasionally ground-glass pattern in early stage of alveolitis (= alveolar wall injury, interstitial edema, proteinaceous exudate, hyaline membranes, infiltrate of monocytes + lymphocytes) in 15–62%
√ bilateral diffuse linear / small irregular reticulations (100%); basilar (85%) + peripheral (59%)



Usual Interstitial Pneumonia (UIP)

Differentiation UIP vs. NSIP

UIP	*NSIP*
Obvious apicobasal gradient	No obvious apicobasal gradient
Heterogeneous	Homogeneous
Honeycombing	Ground-glass opacities
Traction bronchiectasis	Micronodules

√ reticulonodular pattern = superimposition of linear opacities
√ heart border "shaggy"
√ macrocystic honeycombing = numerous cystic spaces (up to 74%)
√ elevated diaphragm = progressive loss of lower-lobe lung volume (45–75%)
√ 1.5–3-mm diffusely distributed nodules (15–29%)
√ pleural effusion (4–6%), pleural thickening (6%)
√ pneumothorax in 7% (in late stages)
√ normal CXR (2–8%)

HRCT (88% sensitive, 70–100% PPV):

The primary role of CT is to separate chronic fibrosing lung diseases with a UIP pattern from those with non-UIP lesions, including those with findings associated with other idiopathic interstitial pneumonias like RB-ILD, lymphoid interstitial pneumonia, and idiopathic pleuroparenchymal fibroelastosis.

Location: apicobasal gradient affecting lung bases in 68–80%
Site: predominantly subpleural regions (79%)

√ patchy distribution with areas of normal parenchyma, active alveolitis, early + late fibrosis present at the same time (HALLMARK)
√ reticular opacities (82%)
√ small peripheral convoluted cysts (= traction bronchiectasis) in 50%
√ prominent architectural distortion of secondary pulmonary lobule (= lung fibrosis)
√ minimal focal ground-glass opacities (= diffuse inflammatory mononuclear cell infiltrates of active disease + fibroblast proliferation) in 65–76% progressing to fibrosis
√ subpleural areas of macrocystic honeycombing with cystic spaces outlined by thick fibrous walls (up to 96%) enlarging slowly over time
√ subpleural lines (= fibrosis / functional atelectasis)
√ interlobular septal thickening (10%)

NOT: micronodules, air trapping, nonhoneycomb cysts, extensive ground-glass opacification, consolidation, predominantly peribronchovascular distribution

Cx: bronchogenic carcinoma (10–15%), opportunistic infections with therapy, accelerated deterioration

Rx: usually no response to steroids (only in 10–15%)

Prognosis: median survival of 2.5–3.5 years; 43% 5-year survival rate, 15% 10-year survival rate; 87% overall mortality; no recovery

DDx: collagen vascular disease, chronic hypersensitivity pneumonitis, asbestosis

Desquamative Interstitial Pneumonia

= DIP = DESQUAMATIVE TYPE OF FIBROSING ALVEOLITIS = ALVEOLAR MACROPHAGE PNEUMONIA

= end spectrum of RB-ILD; 2nd most common (although rare) form of idiopathic interstitial pneumonia of a more benign course than UIP; may be self-limited disease or lead to UIP

Cause: cigarette smoking (history in up to 90%), lung infection, exposure to organic dust

Mean age: 42 (range, 30–40) years (~ 8 years younger than in UIP); M÷F = 2÷1

Path: spatially homogeneous thickening of alveolar septa + intraalveolar accumulation of macrophages; relative preservation of lung architecture + mild interstitial fibrosis (temporally uniform)

Histo: alveoli lined by large cuboidal cells + filled with heavy accumulation of mononuclear cells (pigmented macrophages, NOT desquamated alveolar cells); histologic uniformity from field to field

- average smoking history of 18 pack-years
- asymptomatic, weight loss
- insidious onset of dyspnea + nonproductive dry cough (for 6–12 months)
- inspiratory crackles (60%), clubbing of fingers (40%)
- markedly ⇓ diffusing capacity + restrictive defects

Distribution: lower lung lobe predominance, peripheral; more diffuse + uniform compared to RB-ILD

CXR (nonspecific):
√ normal chest x-ray (3–22%)
√ ground-glass alveolar pattern sparing costophrenic angles (25–33%), diffuse ground-glass opacities (15%)

√ linear irregular opacities (60%), bilateral + basilar (46–73%)
√ lung nodules (15%)
√ honeycombing (13%)
√ preserved lung volume

HRCT:

Location: apicobasal gradient affecting mainly middle + lower lung zones (73%); bilateral + symmetric (86%)

Site: predominantly subpleural distribution (59%); random distribution (23%)

√ bilateral peripheral patchy / diffuse ground-glass opacities (23%) ← spatially homogeneous intraalveolar accumulation of macrophages and thickening of alveolar septa:
  √ progression to reticular pattern (in 20%)
  √ round thin-walled cysts < 2 cm within ground-glass opacities
√ some irregular linear / limited reticular opacities (= fibrosis) + architectural distortion (59%) confined to subpleural lung bases
√ little peripheral honeycombing + traction bronchiolectasis (32%)
√ ± coexistent centrilobular emphysema
√ fibrosis of lower lung zones in late stage

Prognosis: better response to corticosteroid Rx than UIP (in 60–80%); improvement with smoking cessation; median survival of 12 years; 5% 5-year mortality rate (overall 16–27%); 70% 10–year survival

DDx: (1) RB-ILD (centered on respiratory bronchiole, ground-glass opacities less extensive, more patchy, more poorly defined)
(2) Acute interstitial pneumonia
(3) NSIP (fibrotic features like traction bronchiectasis + lower lobe volume loss)
(4) Acute / subacute hypersensitivity pneumonitis
(5) P. carinii pneumonia
(6) Sarcoidosis

Idiopathic Pleuroparenchymal Fibroelastosis

= rare condition consisting of a form of fibrosis rich in elastic fibers involving pleura and subpleural lung parenchyma, predominantly of upper lobes

Distribution: striking apical subpleural predominance

CT:

√ irregular pleural thickening + tags in upper zones merging with fibrotic changes in subjacent lung
√ substantial upper lobe volume loss: architectural distortion, traction bronchiectasis, hilar elevation

Prognosis: disease progression (60%), death (40%)

DDx: (1) Familial pulmonary fibrosis
(2) Connective tissue disease (esp. ankylosing spondylitis)
(3) Fibrotic sarcoidosis
(4) Chronic hypersensitivity pneumonitis

IDIOPATHIC PULMONARY FIBROSIS

= USUAL INTERSTITIAL PNEUMONIA
= specific form of chronic progressive fibrosing interstitial pneumonia of unknown cause
= clinical syndrome associated with morphologic pattern of UIP and related to cigarette smoking (in 41–83%)
◊ Most common form of idiopathic interstitial lung disease!

Histo: UIP pattern = cluster of fibroblasts + immature connective tissue within pulmonary interstitium → remodeling of lung architecture with honeycombing; temporal + spatial heterogeneity of fibrotic lesions of different stages (= fibroblastic foci, mature fibrosis, honeycombing)

Distribution: bibasilar peripheral + subpleural

Age: 50–70 years; M = F

- chronic dry cough, gradually progressing exertional dyspnea
- basilar "Velcro-type" inspiratory crackles
- digital clubbing (in ⅔)
- PFTs: restrictive defect + ⇓ diffusing capacity for CO
- decreased total lung capacity + functional residual capacity + residual volume

Distribution: lung periphery with apicobasal gradient, often patchy, asymmetric (in 25%)

CXR:

√ decreased lung volume, progressive over time
√ bibasilar subpleural reticular opacities
√ honeycombing (30%)
√ bibasilar ground-glass appearance (uncommon)
√ small nodules (< 10%), occasionally ossified

HRCT (95–100% PPV):

(a) classic:
√ lower zone macrocystic honeycombing (90%) often combined with traction bronchiectasis

(b) possible:
√ irregular reticular opacities (= intralobular interstitial thickening) in peripheral basal distribution
√ ground-glass opacities in area of fibrosis (occasionally)
√ discrete nodules (occasionally)
√ mild mediastinal lymph node enlargement (70%)

√ coexisting emphysema (common) makes Dx less reliable

Criteria for Diagnosis of IPF (without Surgical Biopsy) *American Thoracic Society and European Respiratory Society (2001)*
Major criteria
• exclusion of other causes of interstitial lung disease: toxic effects of certain drugs, environmental exposures, connective tissue disease
• abnormal PFT: reduced vital capacity, ↑ FEV_1/FVC ratio
• impaired gas exchange: $PAO_2 - PaO_2$, PaO_2 with rest / exercise, ↓ DLCO
√ lower zone macrocystic honeycombing (90%) often combined with traction bronchiectasis
√ bibasilar irregular reticular opacities
√ minimal ground-glass opacities
Minor criteria
Age: > 50 y
• insidious onset of otherwise unexplained dyspnea on exertion
• duration of illness < 3 months
• bibasilar inspiratory crackles (dry / "Velcro" type)

CT's primary role is to separate chronic fibrosing lung disease with a UIP pattern from non-UIP lesions associated with other IIPs (eg, RB-ILD, lymphoid interstitial pneumonia, and idiopathic pleuroparenchymal fibroelastosis).

Dx: (a) exclusion of other known causes of interstitial lung dz
(b) UIP pattern on CT in appropriate clinical setting = sufficient for diagnosis in > 50%
(c) on follow-up subpleural reticular opacities in upper lung zones = fibrosis creeping up along lung periphery

Rx: cyclosporine A + corticosteroids (for acute exacerbations only); lung transplantation

Prognosis: poor with invariable deterioration and a mean survival of 2.5–3.5 years (30–50% 5-year survival)
◊ Substantially poorer prognosis than NSIP, COP, RB-ILD, DIP, LIP

DDx: (1) Connective tissue disease
(2) Asbestosis (exposure history, pleural plaques, diffuse pleural thickening, subpleural dotlike / branching opacities, less-coarse reticular shadows)
(3) Chronic hypersensitivity pneumonitis (poorly defined fine micronodules, multilobular decreased attenuation / air trapping, sparing of lung bases)
(4) Sarcoidosis (large cysts, peribronchovascular nodules)
(5) Coal workers pneumoconiosis (less traction bronchiectasis, more subpleural homogeneous attenuation, more random distribution of fibrosis)

IDIOPATHIC PULMONARY HEMOSIDEROSIS

= IPH = probable autoimmune process with clinical + radiologic remissions + exacerbations characterized by eosinophilia + mastocytosis, immunoallergic reaction, pulmonary hemorrhage, iron deficiency anemia

Age: (a) chronic form: most commonly < 10 years of age
(b) acute form (rare): in adults; M÷F = 2÷1

Histo: hemosiderin-laden macrophages in bronchoalveolar lavage
- recurrent episodes of severe hemoptysis, clubbing of fingers
- hepatosplenomegaly (25%), bilirubinemia
- iron deficiency anemia

Distribution: perihilar + lower lung zone predominance
√ bilateral patchy alveolar-filling pattern (= blood in alveoli); initially for 2–3 days with return to normal in 10–12 days unless episode repeated
√ reticular pattern (= deposition of hemosiderin in interstitial space) later
√ moderate fibrosis after repeated episodes
√ hilar lymph nodes may be enlarged during acute episodes
CT:
√ diffuse homogeneous areas of ground-glass attenuation (during exacerbation)
√ nodules + patchy areas of ground-glass attenuation (subacute phase)

Prognosis: death within 2–20 years (average survival 3 years)
DDx:
1. Secondary pulmonary hemosiderosis
   Cause: mitral valve disease
   √ septal lines (NOT in idiopathic form)
   √ lung ossifications (NOT in idiopathic form)
2. Goodpasture syndrome
   - antiglomerular basement membrane antibodies

INFLAMMATORY PSEUDOTUMOR

= INFLAMMATORY MYOBLASTIC PSEUDOTUMOR = PLASMA CELL GRANULOMA = PLASMACYTOMA = (FIBROUS) HISTIOCYTOMA = XANTHOGRANULOMA = XANTHOMA = XANTHOFIBROMA = SCLEROSING HEMANGIOMA = PSEUDOLYMPHOMA
= rare mass characterized by fibroblastic / myofibroblastic spindle cell proliferation with varying degrees of inflammatory cell infiltration (lymphocytes, plasma cells, histiocytes)
Cause: ? low-grade malignancy versus primary inflammation
Associated with: minor trauma, surgery, malignancy, occult infection (Epstein-Barr virus, Mycobacterium, Actinomyces), IgG4-related sclerosing disease
Prevalence: < 1% of all tumors of lung + airways
Path: nonencapsulated circumscribed nodular mass, occasionally with infiltrative margins
Histo: mixture of inflammatory cells (plasma cells, lymphocytes, eosinophils, neutrophils) + myofibroblastic proliferation (fibroblasts, blood vessels); foamy histiocytes + multinucleated giant cells + spindle cells (70% of tumor) grouped in CHARACTERISTIC pinwheel / whorled pattern
DDx: malignancy ← highly cellular areas with mitoses
Age: young patient
- asymptomatic
- airway obstruction (symptoms often attributed to asthma / pneumonia), fever, malaise, weight loss, abdominal pain

Location: described in all major organs
@ Chest: lung > bronchus / trachea > pleura

@ Orbit
@ Abdomen: liver (2nd most common), spleen, pancreas, adrenal gland, kidney, retroperitoneum, diaphragm, mesentery GI tract, GU tract
√ well-defined smoothly marginated / infiltrating mass
US:
√ solid process with variable echogenicity ± Doppler flow
CT:
√ variable heterogeneous attenuation ± central calcification
√ no / heterogeneous / peripheral enhancement
MR:
√ hypointense lesion ← fibrotic component
√ NO restricted diffusion
Rx: surgical excision
DDx: any soft-tissue tumor

KARTAGENER SYNDROME

= IMMOTILE / DYSMOTILE CILIA SYNDROME
[Manes Kartagener (1897–1975), internist at the University department of medicine in Zurich, Switzerland]
= uncommon autosomal recessive disease characterized by congenital impairment of mucociliary transport
Frequency: 1÷40,00; high familial incidence
Etiology: abnormal mucociliary function ← generalized deficiency of dynein arms of cilia affecting respiratory epithelium, auditory epithelium, sperm
Triad: (1) Situs inversus (in 50%)
◊ Kartagener syndrome is present in 20% of patients with situs inversus!
(2) Nasal polyposis with chronic sinusitis
(3) Bronchiectasis
• chronic respiratory tract infections beginning in early childhood → chronic bronchitis + rhinosinusitis
• otitis → deafness; male infertility (abnormal sperm tails)
Location: middle lobe, lingula, lower lobes
√ ground-glass opacity / pulmonary consolidation (60%)
√ peribronchial / bronchial wall thickening (96%)
√ mucous plug (85%) + atelectatic areas
√ bronchiectasis (73%) / bronchiolectasis
√ air trapping (38%) = hyperinflation
√ ± small centrilobular opacities = tree-in-bud pattern
Associated anomalies:
transposition of great vessels, trilocular / bilocular heart, pyloric stenosis, postcricoid web, epispadia, pectus excavatum, polysplenia (8%)
DDx: cystic fibrosis (predominantly upper lobe lesions)

KLEBSIELLA PNEUMONIA

◊ Most common cause of Gram-negative pneumonias; community acquired

Frequency: responsible for 5% of adult pneumonias

Organism: Friedländer bacillus = Klebsiella pneumoniae = encapsulated, nonmotile, Gram-negative rod

[Carl Friedländer (1847– 1887), German pathologist and microbiologist at Städtische Krankenhaus Am Friedrichshain, Berlin, introduced the ampoule, also first described thromboangiitis obliterans]

Predisposed: elderly, debilitated, alcoholic, chronic lung disease, malignancy

• bacteremia in 25%

√ propensity for posterior portion of upper lobe / superior portion of lower lobe

√ dense lobar consolidation

√ bulging of fissure (large amounts of inflammatory exudate) CHARACTERISTIC but unusual

√ empyema (one of the most common causes)

√ patchy bronchopneumonia may be present

√ uni- / multilocular cavities (50%) appearing within 4 days

√ pulmonary gangrene = infarcted tissue (rare)

Cx: meningitis, pericarditis

Prognosis: 25–50% mortality rate

DDx: Acute pneumococcal pneumonia (bulging of fissures, abscess + cavity formation, pleural effusion / empyema frequent)

LEGIONELLA PNEUMONIA

= LEGIONNAIRES' DISEASE

Organism: Legionella pneumophila, 1–2 µm, aerobic, Gram-negative bacillus, weakly acid-fast, silver-impregnation stain

Predisposed: middle-aged / elderly, immunosuppressed, alcoholism, chronic obstructive lung disease, diabetes, cancer, cardiovascular disease, chronic renal failure, transplant recipients

Transmission: direct inhalation (air conditioning systems)

Prevalence: 6% of community-acquired pneumonias

Histo: leukocytoclastic fibrinopurulent pneumonia with histiocytes in intraalveolar exudate

• fever; absence of sputum / lack of purulence (22–75%)

Clue: involvement of other organs with

- diarrhea (0–25%), myalgia, toxic encephalopathy
- liver + renal disease; hyponatremia (20%)
- elevated serum transaminase / transpeptidase levels
- lack of quick response to penicillin / cephalosporin / aminoglycoside

Concomitant infection (in 5–10%):

Streptococcus pneumoniae, Chlamydia pneumoniae, Mycobacterium tuberculosis, Pneumocystis carinii

Location: unilateral / bilateral (less frequent); lobar / segmental

√ patchy bronchopneumonia (= multifocal consolidation)

√ moderate volume of pleural effusion (6–30–63%)

√ cavitation (rare)

Cx: progressive respiratory failure (most common cause of death; 6% mortality in otherwise healthy patients)

Rx: erythromycin

LIPOID PNEUMONIA

Acute Exogenous Lipoid Pneumonia

= FIRE-EATER PNEUMONIA

Material: liquid paraffin, petroleum (hydrocarbons)

Cause: accidental poisoning in children, fire-eaters

√ ill-defined nodular areas of increased radiopacity

√ pneumatoceles / thin-walled collections of air

Chronic Exogenous Lipoid Pneumonia

Etiology: aspiration / inhalation of fatlike material

Types of oils:

(a) vegetable oil: sesame oil used in medical suspensions for the treatment of constipation

(b) animal oil: cod liver oil (commonly given to children); squalene = derivative of shark liver oil (folk remedy in some Asian countries); milk

(c) mineral oil (most common): as liquid paraffin in nose drops (taken at bedtime) / oral laxatives = inert pure hydrocarbon that does not initiate cough reflex

Predisposed: elderly, debilitated, neuromuscular disease, swallowing abnormalities (eg, scleroderma)

Path: pool of oil emulsified by lung lipase + surrounded by giant cell foreign body reaction (mineral oil aspiration) / necrotizing hemorrhagic bronchopneumonia (higher content of free fatty acid in animal fat aspiration)

◊ The degree + type of tissue reaction depend on the frequency of aspiration + chemical character of oil

Histo: numerous lipid-laden macrophages distending alveolar walls + interstitium, accumulation of lipid material, inflammatory cellular infiltration, variable amount of fibrosis

- mostly asymptomatic; fever, constitutional symptoms
- lipid-laden macrophages in sputum / lavage fluid
- oil droplets in bronchial washing / needle aspirate

Location: predilection for RML + lower lobes

√ homogeneous segmental airspace consolidation (most common)

√ interstitial reticulonodular pattern (rare)

√ paraffinoma = circumscribed peripheral mass (granulomatous reaction + fibrosis often causing stellate appearance)

√ slow progression / no change

CT:

√ diffuse ground-glass opacity of centri- / panlobular distribution (= acinar pattern) + thickening of interlobular septa as earliest finding

√ airspace consolidation (filling of alveoli with exudate + inflammatory cells) at 1 week

√ return to ground-glass opacity ← expectoration + lymphatic drainage of lipid droplets + inflammatory cells at 2–4 weeks

√ volume loss + fibrosis of interlobular septa and pleura at 14–16 weeks

√ mass of low-attenuation approaching that of subcutaneous fat (–150 to 50 HU)

Dx: bronchoalveolar lavage, transbronchial biopsy

LUNG TRANSPLANT

Indications for transplantation:

emphysema / COPD (39%), idiopathic pulmonary fibrosis (17%), cystic fibrosis (16%), alpha-1 antitrypsin deficiency (9%), CHD, primary pulmonary hypertension, sarcoidosis, pneumoconiosis, malignancy (lung cancer contraindicated)

Unilateral lung transplants:

in selected cases of emphysema, pulmonary fibrosis

Contraindicated in: cystic fibrosis; bronchiectasis ← cross-contamination

Operative mortality: up to 8%

Common causes of mortality: bacterial infection, chronic graft dysfunction

Recurrence of primary disease:

sarcoidosis (in 35%); others (in 1%): lymphangioleiomyomatosis, Langerhans cell histiocytosis, talc granulomatosis, diffuse panbronchiolitis, alveolar cell proteinosis

Survival rate: 75% for 1 year, 50% for 5 years, 35% for 10 years, 25% for 15 years

Immediate Complications of Lung Transplant (< 24 hours)

A. Malpositioned monitoring tubes and lines

B. Donor-recipient mismatch

C. **Hyperacute Rejection of Lung Transplant**

= rejection in cases of an immunoglobulin G donor-specific HLA antibody positive crossmatch

Path: acute diffuse alveolar damage

√ diffuse homogeneous infiltrate of entire allograft

Early Complications of Lung Transplant (24 hours to 1 week)

Acute Pleural Complications of Lung Transplant

Frequency: 22%

Types:

1. Pneumothorax (most common)
2. Postoperative effusion (resolves by 2 weeks)
3. Air leaks ← airway ischemia, bronchial dehiscence

Reperfusion Edema

= ISCHEMIA-REPERFUSION INJURY = PULMONARY REIMPLANTATION RESPONSE

= noncardiogenic pulmonary edema = infiltrate appearing within 48 hours after transplantation unrelated to fluid overload, LV failure, infection, atelectasis, or rejection; diagnosed by exclusion

◊ Most frequent immediate postoperative complication!

Risk factors: poor organ preservation, prolonged ischemic time, unsuspected donor pathology (contusion, aspiration), interrupted lymphatic flow, cytokine-mediated injury

Pathogenesis: permeability edema ← lymphatic disruption, pulmonary denervation, organ ischemia, surgical trauma

Histo: fluid accumulation in interstitium consistent with noncardiogenic pulmonary edema

Time course: manifests after 24 hours, peaks on 4th postoperative day, generally resolves by end of 1st week (up to 6 months)

• increasing hypoxia before extubation; poor correlation between radiographic severity + physiologic parameters

Location: perihilar areas + basal regions in transplanted lung

√ perihilar haze / rapid uni- or bilateral heterogeneously dense interstitial and/or airspace disease

√ small pleural effusions

Dx: per exclusion (radiographic changes not due to LV failure, hyperacute rejection, fluid overload, infection, atelectasis)

Prognosis: usually resolves over 7–10 days

Rx: diuresis, mechanical support

Intermediate Complications (8 days – 2 months)

Acute Rejection of Lung Transplant

Cause: cell-mediated immune response

Histo: mononuclear cell infiltrate around arteries, veins, bronchioles, alveolar septa with alveolar edema (initially) + fibrinous exudate (later)

Frequency: 60–80% with 2–3 significant episodes in first 3 months

◊ Most patients will have at least 1 episode in the year following transplantation!

Time of onset: first episode 5–10 days after transplantation; occasionally by 48 hours

• drop in arterial oxygen pressure WITHOUT infection /airway obstruction / fluid overload

• pyrexia, fatigue, decreased exercise tolerance

√ heterogeneous opacities in perihilar areas

√ peribronchial cuffing

√ ground-glass attenuation on HRCT

√ new increasing pleural effusion + septal thickening (most common, 90% specific, 68% sensitive) WITHOUT concomitant signs of LV dysfunction (= increase in cardiac size / vascular pedicle width / vascular redistribution)

√ subpleural edema, peribronchial cuffing, airspace disease

Dx: (1) Transbronchial biopsy

(2) Rapid improvement of radiologic abnormalities after treatment with IV bolus of corticosteroids for 3 days

Rx: methylprednisolone, polyclonal T-cell antibody (antithymocyte globulin), monoclonal antibodies (CD3, OKT3), lymphoid irradiation

Delayed Lung Transplant Complications (> 4 months)

Chronic Rejection of Lung Transplant

= BRONCHIOLITIS OBLITERANS SYNDROME (BOS)

Prevalence: 50% at 5 years
◊ Probably develops in all transplant patients given sufficient time!
Risk factor: frequent / severe bouts of acute rejection, gastroesophageal reflux
Path: obliterative bronchiolitis (36%), interstitial pneumonitis, rejection-mediated vasculopathy
Time of onset: 3–6–75 months after transplantation

- persistent coughing and wheezing
- slowly worsening exertional dyspnea
- physiologic airflow obstruction + decline in forced expiratory volume at 1 second

CXR:
√ frequently normal
√ increased lung volumes (= hyperinflation)
√ regional volume contraction
√ diminished peripheral lung markings (= decreased peripheral vascularity)
√ thin irregular areas of increased opacity (= subsegmental atelectasis)
√ bronchiectasis
√ pleural thickening
√ nodular / reticular opacities associated with peribronchial thickening

HRCT:
√ air trapping on expiratory HRCT (HALLMARK)
√ mosaic lung attenuation (= regions of mixed hypo- and hyperattenuation)
√ central + peripheral cylindrical bronchiectasis
√ bronchial wall thickening

Complications of Lung Transplant (any time)

Anastomotic Complications of Lung Transplant

Prevalence: 15%

1. Bronchial dehiscence (2–8%)
   Time of onset: within 1 month
   √ presence of extraluminal air collections at anastomotic site (80%)
   √ bronchial wall defect / narrowing / irregularity
   DDx: telescoped anastomosis
2. Airway stricture / stenosis
   Definition: stenosis = ≥ 50% diameter reduction
   DDx: telescoped anastomosis
   Rx: laser resection, balloon bronchoplasty
3. Bronchomalacia
   √ transient airway narrowing on expiratory CT
4. Vascular stenosis
5. Diaphragmatic hernia from omentopexy
   Procedure: omental pedicle is harvested at time of transplantation through a small diaphragmatic incision + wrapped around anastomosis to prevent dehiscence

Posttransplantation Infection

Cause: immunosuppression, reduced mucociliary clearance, interruption of lymphatic drainage, direct contact of transplant with environment via airways

◊ May occur at any time during postoperative period!

Frequency: 35–86% of transplant recipients

A. INFECTION OF LUNG TRANSPLANT

Prevalence: 35–50%; major cause of morbidity + mortality in early postoperative period

Cause: absent cough reflex, impaired mucociliary transport in denervated lung, interruption of lymphatics, immunosuppressive drugs

Organism: bacteria (23%): Staphylococcus, Pseudomonas, Klebsiella > CMV > Aspergillus (6%) > Pneumocystis

(1) within 1st month: Gram-negative bacteria, fungi (candidiasis, aspergillosis)

(2) after 1st month: viruses (CMV [50%], community-acquired viruses [RSV, parainfluenza, influenza, adenovirus]); Pneumocystis carinii; bacteria; fungi

• fever, leukocytosis

√ lobar / multilobar consolidation ← bacterial > fungal pathogens

√ diffuse heterogeneous air-space / ground-glass opacities ← parainfluenza + RSV + adenovirus / disseminated fungal pathogens

√ bronchial wall thickening ← adenovirus, influenza virus, RSV

√ bronchial dilatation ← RSV

√ nodules ← fungal / unusual bacterial pathogens / CMV / septic emboli

√ septal lines

√ pleural effusion

Cx: may progress rapidly to respiratory failure + death

Dx: transbronchial / open biopsy (80% accurate)

B. EXTRAPULMONARY INFECTION

thoracotomy wound infection, bacteremia, sepsis, empyema, central venous line infection

Prognosis: primary cause of postoperative mortality in up to 50%; 2–12% mortality for CMV; 50% mortality for Aspergillus

LYMPHANGIOMYOMATOSIS

= LAM = LYMPHANGIOLEIOMYOMATOSIS

= rare disorder characterized by

(1) Gradually progressive diffuse interstitial lung disease

(2) Recurrent chylous pleural effusions

(3) Recurrent pneumothoraces

Prevalence: 1÷400,000; 1,300 women in USA (in 2001)

Etiology: unknown; hamartomatous proliferation of a particular form of HMB-45 positive smooth muscle (? forme fruste of tuberous sclerosis)

Mean age: 34 (range, 17–62) years, exclusively in women of childbearing age

Path: enlarged lungs with extensive diffuse air- / fluid-filled 5–20 mm cysts affecting both lungs + distorting pleural surfaces; ± involvement of lymph nodes

Histo: abnormal proliferation of atypically short + plump smooth muscle cells with a high nuclear-to-cytoplasmic ratio (LAM cells) in pulmonary lymphatic vessels, blood vessels, walls of airways; NO atypia / mitoses; positive staining for human melanin black-45 (HMB-45)

Pathogenesis:

proliferation of immature smooth muscle cells in a haphazard fashion causes obstruction of

(a) bronchioles → trapping of air, overinflation, formation of cysts, pneumothorax
(b) venules → venous occlusion → hemorrhage (hemoptysis), hemosiderosis
(c) lymphatics → thickening of lymphatics, chylous effusions of thorax + abdomen

Hormonal influence: menstruation, pregnancy, exogenous estrogen treatment may result in exacerbation of symptoms

Cause of thin-walled lung cysts:

(a) air trapping distal to small airways narrowed by smooth muscle proliferation
(b) destruction of collagen + elastin in the interstitium from metalloproteinases elaborated by LAM cells

In 1% associated with: tuberous sclerosis

- progressive exertional dyspnea (59%) + cough (39%)
- hemoptysis (30–40%), chyloptysis (rare)
- combination of restrictive + obstructive ventilatory defects:
  - radiologic-physiologic discrepancy = severe airflow obstruction in 100% (reduced FEV_1, reduced ratio of FEV_1 / FVC) despite relatively normal findings on CXR
  - decreased DLCO (= diffusing capacity for lung carbon monoxide) in 54%
- hypoxemia without hypercapnia on arterial blood gas
- positive immunohistochemical staining of LAM cells with HMB-45 (monoclonal antibody for melanocytic lesion)

CXR:

√ classic signs:
  √ coarse reticular / reticulonodular interstitial pattern diffusely + equal in all lung zones caused by summation of multiple cyst walls (80–90%)
  √ recurrent unilateral pneumothorax (39–53% at presentation; in up to 81% during course of disease)
  √ recurrent uni- / bilateral chylothorax (14% at presentation; in up to 39% during course of disease)
√ normal (55–78%) / increased (22–45%) lung volume

◊ The only interstitial lung disease to develop an increase in lung volume!

√ Kerley B lines = interlobular septal thickening ← dilated lymphatics (7–9%)
√ pulmonary cysts (visible if > 1 cm) + honeycombing
√ pericardial effusion / chylous pericardial effusion (rare)
√ mediastinal + retroperitoneal adenopathy ← smooth muscle proliferation

CT:

√ numerous randomly scattered thin-walled (< 2 mm) cysts of various sizes (typically 2–5 mm, up to 30 mm) surrounded by normal lung parenchyma

Parenchymal Involvement		*Cyst Size*
mild	< 25%	< 5 mm
moderate	25–80%	5–10 mm
severe	> 80%	> 10 mm

√ patchy areas of ground-glass attenuation ← hemorrhage following destruction of pulmonary microvasculature
√ dilated thoracic duct
√ pleural effusion: proteinaceous / chylous (-17 HU)
√ chylous pericardial effusion (rare)
√ hilar + mediastinal lymphadenopathy (in up to 50%)

NUC (V/Q scan):
√ "speckling" = well-defined hot spots on ventilation scan (presumably due to accumulation of coalescing droplets of DTPA aerosol trapped in peripheral cysts) in 66%

@ Abdomen (in 76% positive findings)
• bloating, increased abdominal girth, abdominal pain
• flank / pelvic pain
• perineal swelling, chylous vaginal discharge
• lower-extremity lymphedema, paresthesias
√ **lymphadenopathy** of up to 4 cm (33%):
Histo: replacement of lymph node with smooth muscle
Location: retroperitoneum (77%) > pelvis (11%) > mesentery > posterior mediastinum > axilla > neck
√ central hypoattenuating areas of –72 to +50 HU (due to chylous lymph collections / fat) ± fat-fluid level
√ **lymphangioleiomyoma** (5–21%) = well-defined lobulated complex lymphatic mass:
Path: smooth muscle proliferation in walls of lymphatics resulting in lymphatic dilatation + mural thickening
Site: retroperitoneum near aorta + renal arteries, posterior mediastinum, mesentery
√ thin- / thick-walled mass with hypoattenuating center of 3–25 HU ± fat-fluid level
√ volumes of 10–1,500 mL
√ anechoic irregularly shaped thin-walled cysts with intraluminal septa (= ectatic lymphatic vessels)
√ diurnal variations in size (↑ over course of day)
√ **chylous ascites** (10–33%): low-density ascites of -10 to +21 HU ← rupture of overdistended lymph cysts
√ dilatation of thoracic duct (10%)
√ fatty liver masses (5%): AML / lipoma
√ uterine leiomyomas
√ lymphaticoureteric, lymphaticovenous communication

@ Kidneys
• flank pain, hematuria, severe hypotension, chyluria (with > 4 cm large angiomyolipoma)
√ **angiomyolipoma** (in 20–70%):
√ occasionally lacking fat
√ multiplicity in < 20%

√ simple cysts (occasionally large enough to lead to renal insufficiency)

Dx: open / transbronchial lung biopsy; image-guided biopsy of an extrapulmonary mass

Rx: hormone therapy, oophorectomy, lung transplantation

Prognosis: survival rate of 91% at 5-year, 79% at 10 years, 71% at 15 years; death from progressive respiratory failure + cor pulmonale

DDx:

(1) Tuberous sclerosis (cortical tubers, subependymal nodules, retinal hamartomas, facial angiofibromas, periungual fibromas, mental retardation, epilepsy, multiple renal AML in 40–80%)

(2) Langerhans cell histiocytosis (irregular cysts in upper ⅔ of lung with sparing of costophrenic angles, cyst walls more variable in thickness, pulmonary nodules and cavitation, septal thickening)

(3) Centrilobular emphysema (imperceptible cyst walls, cysts chiefly distributed in upper lobes, lobular architecture preserved with bronchovascular bundle in central position, areas of lung destruction without arcuate contour)

(4) Paraseptal emphysema (evident walls, arrayed in a single subpleural tier)

(5) Idiopathic pulmonary fibrosis = fibrosing alveolitis (small irregular thick-walled cysts in a predominantly peripheral subpleural + basilar distribution, surrounded by abnormal distorted lung parenchyma)

(6) Neurofibromatosis (cystic air spaces predominantly in apical location)

LYMPHANGITIC CARCINOMATOSIS

= INTERSTITIAL CARCINOMA = LYMPHANGITIS CARCINOMATOSA

= tumor cell accumulation within connective tissue (bronchovascular bundles, interlobular septa, subpleural space, pulmonary lymphatics) from tumor embolization of blood vessels followed by lymphatic obstruction, interstitial edema, and collagen deposition (fibrosis from desmoplastic reaction when tumor cells extend into adjacent pulmonary parenchyma)

Frequency: 7% of all pulmonary metastases

Tumor origin: bronchogenic carcinoma, carcinoma of breast (56%), stomach (46%), thyroid, pancreas, larynx, cervix

mnemonic: **C**ertain **C**ancers **S**pread **B**y **P**lugging **T**he **L**ymphatics

Cervix
Colon
Stomach
Breast
Pancreas
Thyroid
Larynx

Path: (a) interstitial edema
(b) interstitial fibrotic changes
(c) lymphatic dilatation
(d) tumor cells within connective tissue planes

- dyspnea (often preceding radiographic abnormalities)
- rarely dry cough + hemoptysis

Location: bilateral; unilateral if secondary to lung primary

CXR (accuracy 23%):

√ normal chest radiograph
√ reticular / reticulonodular opacities
√ coarsened bronchovascular markings
√ Kerley A + B lines
√ small lung volume
√ hilar (20–50%) / mediastinal lymphadenopathy
√ pleural effusion

HRCT:

√ normal lung architecture without distortion
√ focal / diffuse, uni- / bilateral distribution
√ well-defined smoothly thickened polygonal reticular network of 10–25 mm in diameter (= thickened interlobular septa)
√ irregular / nodular = "beaded" thickening of interlobular septa
√ central dot within secondary pulmonary lobule = thickened centrilobular bronchovascular bundle
√ smooth / nodular thickening of fissures
√ subpleural thickening
√ pleural effusion (30–50%)
√ hilar / mediastinal lymphadenopathy (30–50%)

Prognosis: death within 1 year

DDx: (1) Fibrosing alveolitis (peripheral predominance)
(2) Extrinsic allergic alveolitis (no polygonal structures, pleural changes rare)
(3) Sarcoidosis (nodules of irregular outline more frequent in upper lobes, polygonal structures uncommon)
(4) pulmonary edema (smooth septal thickening)

LYMPHOMA

= NON-HODGKIN LYMPHOMA (NHL) = MALIGNANT LYMPHOMA

= most common primary hematopoietic malignancy

◊ 7th leading cause of death from cancer in USA

Pathogenesis: ? viral cause

Frequency: 4.3% of all newly diagnosed cancers (2015); 3rd most common cancer in childhood (behind leukemia + CNS neoplasms); 4 times more common than Hodgkin disease

Predisposed: (40–100 times greater risk) congenital immuno-deficiency syndromes, immunosuppressed organ transplant recipients, patients with HIV infection, collagen vascular disease

Age: all ages; median age of 55 years; M÷F = 1.4÷1

• chest / shoulder pain, dyspnea, dysphagia
• CHF, hypotension, SVC syndrome

Modified Rappaport Classification:

= categorization according to histologic distribution of lymphomatous cells

A. Nodular form = organized in clusters

1. Poorly differentiated lymphocytic (PDL)
2. Mixed lymphocytic / histiocytic (mixed cell)
3. Large cell (histiocytic)

B. Diffuse form = distortion of tissue architecture
1. Well-differentiated lymphocytic (WDL)
2. Intermediate-differentiated lymphocytic (IDL)
3. Poorly differentiated lymphocytic (PDL)
4. Mixed lymphocytic / histiocytic large cell (histiocytic) (DLCL); undifferentiated Burkitt lymphoma; undifferentiated non-Burkitt lymphoma (pleiomorphic); lymphoblastic (LBL); unclassified

Working Formulation Classification (Kiel / Lennert):

= categorization by grade

A. Low grade
1. Small lymphocytic (3.6%)
2. Follicular, small cleaved cell (22.5%)
3. Follicular, mixed (7.7%)

B. Intermediate grade
1. Follicular, large cell (3.8%)
2. Diffuse, small cleaved cell (6.9%)
3. Diffuse, mixed (6.7%)
4. Diffuse, large cell (19.7%)

C. High grade
1. Large cell, immunoblastic (7.9%)
2. Lymphoblastic (4.2%)
3. Small noncleaved cell (5%)

D. Miscellaneous (12%)
composite, mycosis fungoides, histiocytic, extramedullary plasmacytoma

Luke and Collins Classification:

= categorization by morphologic characteristics of cell + cell of origin (T cell, B cell, non-B, non-T cell)

Histologic types:

A. B-cell
1. **Diffuse large B-cell lymphoma**
◊ The largest subtype of NHL
Prognosis: extranodal involvement frequent at presentation, rapid spread to nodes, curable in < 50%
2. **Mantle cell lymphoma**
◊ 4–8% of all NHL
√ extranodal involvement of GI tract + bone marrow
Prognosis: poor
3. **Follicular lymphoma**
FDG PET reliable for staging + follow-up (98% sensitive, 94% specific, 95% PPV, 98% NPV)
√ potential for upstaging in a high number of patients with apparent early-stage disease

Prognosis: good response to initial therapy, pattern of repeated relapses, tendency to progress to diffuse large B-cell lymphoma

4. **Burkitt Lymphoma**

   [Denis Parsons Burkitt (1911–1993), Irish surgeon who served with the Royal Army Medical Corps in England and later in Kenya and Somaliland settling in Uganda]

   (a) endemic type (Africa)

   (b) Non-African Burkitt lymphoma sporadic type (Europe, US, Japan) and immunodeficiency type (HIV-infected patients)

   √ often in abdominal location

   √ extremely hypermetabolic

5. **Mucosa-associated lymphoid tissue (MALT)**

   ◊ Subtype related to chronic inflammation and autoimmune disease

   √ orbital MALT (low metabolism) + pulmonary MALT (metabolism similar to pneumonia) + gastric MALT (physiologic FDG accumulation) → difficult to diagnose

B. T-cell

1. **Lymphoblastic lymphoma**

   Prevalence: higher in Far East than Western nations

   Age: young adults

   √ usually manifests with a mediastinal mass

   √ < 25% leukemia cells in bone marrow (DDx to acute lymphoblastic leukemia with > 25%)

2. **Peripheral T-cell lymphoma**

   FDG PET only 40% sensitive

3. **Adult T-cell lymphoma-leukemia**

   Geography: Japan (Kyushu region), Caribbean, Central African Republic, Central & South America

   • positive human adult T-lymphotropic virus type 1 (HTLV-1)

4. **Malignancy associated with Epstein-Barr virus**

   Epstein-Barr virus (= human herpesvirus 4) may induce natural killer cell (NK) and T-cell lymphoproliferative disorders; associated with infectious mononucleosis, chronic active Epstein-Barr virus infection

Malignancy Grade vs. Type of Lymphoma at FDG PET

Malignancy Grade	*B-Cell Lymphoma*	*T-Cell Lymphoma*
Indolent	Follicular lymphoma (grade 1–3a); MALT lymphoma; chronic lymphocytic leukemia; nodal marginal zone B-cell lymphoma	Adult T-cell leukemia-lymphoma (chronic); mycosis fungoides; large granular T-cell lymphocytic leukemia
Aggressive	Follicular lymphoma (grade 3b); diffuse large B-cell lymphoma; plasma cell myeloma; intravascular large B-cell lymphoma; primary effusion lymphoma; Burkitt lymphoma; mantle cell lymphoma	Peripheral T-cell lymphoma; extranodal T-cell lymphoma; T-cell prolymphocytic leukemia; angioimmunoblastic T-cell lymphoma, aggressive natural killer-cell leukemia; enteropathy-type T-cell lymphoma;hepatosplenic T-cell lymphoma
Very aggressive	Burkitt lymphoma; lymphoblastic lymphoma	Adult T-cell leukemia-lymphoma (acute); lymphoblastic lymphoma

5. **Nasal type extranodal NK/T-cell lymphoma (angiocentric lymphoma)**

   Age: 40 years

Geography: frequent in Asia
Histo: angiocentric invasion
Prognosis: poor

PET/CT (88–100% sensitive):
◊ Most useful tool for primary diagnosis + assessment of response to treatment + prognosis

CT / MR:
√ homogeneous attenuation / signal intensity
√ vascular penetration = "sandwich" sign (CHARACTERISTIC for mesenteric lymphoma)
√ spread across existing structure ← permeative nature

Staging: same Ann Arbor system as for Hodgkin disease
Rx: involved-field radiation (stage I or II); chemotherapy (stage III and IV)
Prognosis: 64% 5-year survival; death rate of 8.9/100,000 males + 5.7/100,000 females

Extranodal Involvement in Lymphoma (NHL)

Sites other than: nodal (see below)
Frequency: NHL (in 20–40%); Hodgkin disease (4–5%)

A. FOCAL / MULTIFOCAL SOLID ORGAN DISEASE

CT:
√ discrete round well-defined homogeneous solid nodules in focal / multifocal disease
√ ± heterogeneous appearance ← central necrosis
√ mild uniform contrast enhancement

US:
√ homogeneously hypoechoic nodules resembling cysts
√ ± bull's-eye appearance
√ absence of posterior acoustic enhancement

MR:
√ nodules of low to intermediate SI on T1WI + moderately high SI on T2WI
√ moderate uniform contrast enhancement

DDx: metastases, primary cancer, infection, granulomatous disease

B. DIFFUSE SOLID ORGAN DISEASE

CT / MR:
√ NO structural abnormality → detection difficult
√ organomegaly → very low sensitivity & specificity for diagnosis of lymphoma
√ uniform infiltration of involved site
√ subtle heterogeneous areas after contrast administration, NOT visible on unenhanced images
√ uptake on PET
√ CHARACTERISTIC amorphous infiltration of tissues outside involved organ with minimal mass effect

@ Chest (40–50%):
lung (6%), pleural fluid (3.3%), pericardial fluid (0.7%), heart (0.2%)
√ hilar + mediastinal adenopathy (DDx: sarcoidosis; anterior nodes favor lymphoma)
◊ Nodes frequently not involved!
√ isolated lymph nodes may enhance (DDx: Castleman dz)
√ lung nodules + air bronchograms

√ pleural effusion

Prognosis: unfavorable

@ Spleen (41%)
@ Pancreas (30%)
@ Liver (14%)
@ GI tract: stomach (3%), small bowel (5%), large bowel (2%), peritoneal nodules + ascites (1.4%)
@ GU tract (10%): kidneys (6%), testes (1.2%), ovaries (1.8%), uterus (1.2%)
@ Skin (6.4%)
@ Bone (3.8%)
@ CNS (2.4%)
  • cranial nerve palsy / spinal cord compression
@ Head and neck (1.7%)
@ Breast (1.2%)

Nodal Involvement in Lymphoma (NHL)

Sites: lymph nodes, spleen, thymus, tonsils, pharyngeal lymphatic (Waldeyer throat) ring

@ Mesenteric lymph nodes (51%): predominantly in middle mediastinum, cardiophrenic angle
  ◊ Single lymph node involvement is often the only manifestation of intrathoracic disease!
@ Splenic hilar lymph nodes (53%)
  ◊ Lymphography 89% sensitive + 86% specific
@ Paraaortic lymph nodes (49%)

Differences between NHL and Hodgkin Disease

HD: contiguous spread → scan only abnormal area

NHL: noncontiguous spread → requires scanning of chest, abdomen, pelvis

@ Thoracic lymphadenopathy anterior mediastinal, pretracheal, hilar, subcarinal, axillary, periesophageal, paracardiac, superior diaphragmatic, internal mammary lymph nodes
  › anterior mediastinum: nodular sclerosing type of HD (75%); M < F
  › posterior mediastinum: NHL
@ Spleen

Differences between NHL and Hodgkin Disease

Organ Involvement	*NHL*	*HD*
Thoracic involvement	45%	85%
Mediastinal nodes	posterior	anterior
Lung involvement	4%	12%
Lymphadenopathy		
Periaortic adenopathy	49%	25%
Mesenteric adenopathy	51%	4%
Liver involvement	14%	8%
Hepatomegaly	57%	< 30%
Splenic involvement	41%	37%

Differences between Adult and Childhood NHL		
Characteristics	*Adult NHL*	*Childhood NHL*
Primary site	nodal	extranodal
Histology	50% follicular, 50% diffuse	diffuse
Grade	low, intermediate, high	high
Histologic subtype	many	three
Sex predilection	none	70% male

HD: most common site of abdominal involvement

NHL: 3rd most common site of abdominal involvement; may be initial manifestation in large cell NHL

@ Gastrointestinal involvement in 10% of patients with abdominal lymphoma (uncommon in HD, common in histiocytic NHL); NHL accounts for 80% of all gastric lymphomas

@ Renal involvement late manifestation, most commonly in NHL

@ Adrenal involvement more common in NHL

@ Extranodal involvement more frequent with histologically diffuse forms of NHL

Lymphoma (NHL) in Childhood

Frequency: 3rd most common childhood malignancy (after leukemia + CNS tumors); 7% of all malignancies in children < 15 years of age

Origin: B or T cell (in 90%) located outside marrow; (rarely) non-B and non-T cells located within bone marrow

Median age: 10 years; < 15 years of age (most common); unusual < 5 years of age; M÷F = 2÷1

- chest pain, back pain, cough, dyspnea, fever
- anorexia, weight loss, ± peripheral blood involvement
- bone marrow involvement:
  < 25% = lymphoma; > 25% = leukemia

Histo: Burkitt lymphoma (most common), Burkitt-like lymphoma, large B-cell lymphoma, lymphoblastic lymphoma, anaplastic large cell lymphoma, peripheral T-cell lymphoma

Prognosis: 80% cure rate with multiple-agent chemotherapy

DDx: (1) Acute lymphocytic leukemia (> 25% lymphoblasts within bone marrow)
(2) Hodgkin disease (contiguous spread, nodes are site of origin)

Undifferentiated / Small Noncleaved NHL *(39%)*

Path: non-Burkitt lymphoma; Burkitt lymphoma

- abdominal mass ± ascites
- pain similar to appendicitis / intussusception

Primary site: abdomen (distal ileum, cecum, appendix); ovaries

St. Jude Children Hospital Staging Classification for NHL	
Stage	*Description*
I	single extranodal tumor / single nodal area outside abdomen and mediastinum
II	single tumor with regional node involvement; ≥ 2 tumors / nodal areas on same side of diaphragm; primary resected GI tumor ± regional node involvement
III	tumors / nodal involvement on both sides of diaphragm; any intrathoracic / extensive intraabdominal disease; any paraspinal / epidural tumor
IV	bone marrow* / CNS^ disease regardless of other sites
* 5% malignant cells with normal peripheral blood cell count; in lymphoblastic lymphoma with > 25% malignant cells = leukemia	
^ in lymphoblastic lymphoma a WBC ≥ 5/µL with malignant cells	

Common site: mesenteric, inguinal, iliac nodes; CNS; bone marrow; kidney
Rare site: orbit, supradiaphragmatic paraspinal region, mediastinum, paranasal sinuses, bone, testes, pulmonary parenchyma
Cx: "leukemic transformation" (= extensive bone marrow involvement)

Lymphoblastic** (T-cell) **NHL (28%)

Primary site: mediastinum (66%)
Common site: neck, thymus, liver, spleen, CNS, bone marrow, gonads
Rare site: subdiaphragmatic (ileum, cecum, kidney, mesentery, retroperitoneum), orbit, paranasal sinus, thyroid, parotid

- respiratory distress, dysphagia
- SVC syndrome, pericardial tamponade

Large Cell** (histiocytic) **NHL (26%)

Origin: B cell, T cells (small percentage)
Location: nodal + extranodal
Primary site: variable (Waldeyer ring, Peyer patches)
Common site: peripheral lymph nodes, lung, bone, brain, skin
Rare site: hard palate, esophagus, trachea
PET - SUV measurement: 92% sensitive, 90% specific

LYMPHOMATOID GRANULOMATOSIS

= angioinvasive + angiodestructive oligo- / monoclonal lymphoproliferative + granulomatous disease
Cause: combination of Epstein Barr virus infection and immunosuppression
Mean age: 48 (range, 7–85) years; M÷F = 2÷1
Path: multiple sharply marginated masses adjacent to a bronchus causing obstructive pneumonitis
Histo: angiocentric infiltrate of atypical lymphoid cells (CD20-positive B-cells, some infected with Epstein-Barr virus); necrotic lung parenchyma in higher grade lesions; giant cells absent (DDx to Wegener granulomatosis)

• malaise, weight loss (35%); NO specific serum markers
◊ Less commonly found in lymph nodes, bone marrow, spleen
◊ Involvement of upper respiratory tract + sinuses is very unusual
@ Lung (100%)
• fever (60%), cough (56%), dyspnea (29%)
√ normal CXR
√ diffuse reticulonodular opacities (= granulomas)
√ large masslike opacities (= granulomas + pulmonary infarcts)
√ multiple bilateral nodules in middle + lower lobes (80%)
√ unilateral involvement (21%)
√ small pleural effusions (40%)
√ hilar lymphadenopathy (25%)
CT:
Distribution: peribronchovascular
√ peripheral subpleural 0.6–8.0 cm large nodules / masses
√ reticular / nodular airspace opacities (10–43%):
√ central cavitation (30%)
√ peripheral ground-glass halo ± air bronchogram
@ Skin (39–53%)
• nodules, ulcers, maculopapular rash (20–39%)
@ CNS (37–53%) → very poor prognosis
• neurologic complaints (21%)
@ Kidneys (32–40%)
Cx: lymphoma (12–47%)
Mortality: in 53–90% from sepsis, respiratory failure, pulmonary embolism, massive hemoptysis, CNS lesions

LYMPHOPROLIFERATIVE DISEASE AFTER TRANSPLANTATION

= POSTTRANSPLANT LYMPHOPROLIFERATIVE DISEASE (PTLD)

PTLD encompasses a group of lymphoproliferative disorders post stem cell and organ transplantation that ranges from benign polyclonal proliferation to malignant monoclonal disease. PTLD is intimately associated with EBV infection.

Cause: sequelae of chronic immunosuppression with limited ability to suppress neoplastic activity ← oral secretion transmission of virus, residual EBV DNA within bronchus-associated lymphoid tissue, lymphocytes of donated allograft, blood transfusion containing EBV-infected B cells

Pathogenesis:
90–95% of adults are Epstein-Barr virus (EBV) seropositive → T cells fight initial EBV infection by eradicating B cells that display EBV antigens → EBV-specific cytotoxic T cells may be completely lost within 6 months of transplantation

In a state of T-cell–depletion latently infected B cells can proliferate and result in PTLD. Immunosuppressive therapy in transplant recipients is responsible for a 3- to 8-fold increase in malignancies.

Pathophysiology of B-cell origin:

1. Infection of B lymphocytes (in 85%) with EBV (Epstein-Barr virus) → increased proliferation of B cells (= polyclonal B-cell expansion)

PTLD *[in %]* **with Various Organ Transplantations**

PTLD	All Tx	Pancreas Tx	Liver Tx	Heart Tx	Kidney Tx	Lung Tx
GI tract	5–15	33	12–30	14–24	11–22	20
Liver		22–40	30–45	9–23	5	5–10
Spleen	10–40		+++			
Kidney	10–30		0	0.6	10–75	1.4
Adrenal	5					
Pancreas		10–75				
Abd. nodes	15–20					
Chest			4–24	16–32	4–15	69–100
CNS	3–16	16	4	4–13	12–13	
Any PTLD			2–8	2–3	1–5	2–8

2. Loss of protective immune control by T cells allows for uncontrolled proliferation of EBV-infected B lymphocytes (= oligoclonal B-cell expansion)
3. Genetic mutation transforms some B cells into malignant cells

Frequency: PTLD in 2% of all allograft recipients (different rates likely related to differences in degree and regimen of immunosuppression)

bone marrow transplantation 0.6%
kidney transplantation 1–5%
cardiac transplantation 1.8–3.4%
lung transplantation 1.8–7.9%
liver transplantation 2.2–8.4%
heart-lung transplantation 9.4%
multivisceral transplantation 13–33%
bowel transplantation 13–33%

◊ Prevalence of NHL is 35 x greater than in general population!

The incidence + prognosis of PTLD vary according to the organ transplanted, recipient age, and intensity of immuno-suppression therapy. The risk is greatest within 1st year of transplantation, declining thereafter.

Risk factor: pretransplantation seronegative for EBV, autoimmune hepatitis, Langerhans cell histiocytosis, chronic interstitial nephritis

Time of onset: as early as 1 month after transplantation with very aggressive immunosuppressive regimen; mean of 2–5 months after bone marrow, lung, heart-lung transplantation; mean of 23–32 months after kidney, heart, liver transplantation

◊ Under cyclosporine / OKT3 within 1 month

Categories by location:

› nodal
  » mediastinal
  » retroperitoneal
› extranodal
  » GI tract
  » solid organ
    – obstructive: kidney, liver
    – hilar / solitary mass: kidney, liver, spleen, lung
    – scattered parenchymal: kidney, liver, spleen, lung
    – infiltrative: solid organ / abdominal wall
  » CNS: basal ganglia, subcortical white matter

Unique features:

(a) high propensity for extranodal involvement (80%): liver (50%), small bowel (25%), kidney (17%)

Features of Posttransplant Lymphoproliferative Disorder (PTLD)	
Clinical data:	Post stem cell and organ transplant patients Associated with EBV infection
Histopathology:	Proliferation of EBV-infected B cells Spectrum of poly- to monoclonal proliferation
Imaging findings:	*Distribution:* peribronchovascular, subpleural √ multiple pulmonary nodules / masses / airspace consolidation √ ± ground-glass halo √ air bronchograms √ septal thickening √ mediastinal + hilar lymphadenopathy √ ± pleural effusion √ invasion of adjacent structures √ avidly hypermetabolic on PET/CT
DDx:	Angioinvasive aspergillosis

(b) varied morphologic appearance
(c) strong causal association with EBV infection
(d) frequent absence of immunophenotypic / genotypic evidence of monoclonality
(e) poor response to cytolytic chemotherapy / irradiation

• unexplained fever / lymphadenopathy
• illness resembling infectious mononucleosis = pharyngitis, fever, lymphadenopathy, hepatosplenomegaly

Anatomic distribution:

◊ Frequency of location varies with type of allograft!
@ Thorax (most commonly involved in 1st year)
  √ pulmonary mass (50%)
  √ multiple / solitary discrete well-circumscribed pulmonary nodules (40–50%) (DDx: cryptococcosis, fungus, Kaposi sarcoma):

√ ± low-attenuation center ± ground-glass halo
√ patchy airspace consolidation (7–10%) (DDx: edema, infection, rejection)
√ mediastinal / hilar lymphadenopathy (in up to 50%)
√ pleural masses

@ Lymph nodes (in 2–10% of various allografts)

@ Gastrointestinal tract

Location: distal jejunum + ileum > duodenum > colon (prox > distal) > stomach > esophagus

√ bowel wall thickening + dilatation
√ eccentric mass, luminal ulceration
√ short-segment intussusception

Cx: visceral perforation (frequent)

@ Gallbladder

√ gallbladder thickening, biliary obstruction

@ Liver

Site: intrahepatic / extrahepatic (frequently extranodal)

√ discrete hypoattenuating hypovascular nodular lesion:
√ single / multiple parenchymal lesions
√ diffuse ill-defined infiltrative pattern of hepatic involvement → hepatomegaly
√ hypoechoic heterogeneous soft tissue mass encasing hilar structures
Cx: narrowing of bile duct, hepatic artery, portal vein
√ periportal adenopathy
√ portal vein constriction / focal thrombus (15%)

In posttransplant lymphoproliferative disease extrahepatic involvement is frequently extranodal and appears at US / CT as ill-defined hypoechoic / hypoattenuating periportal heterogeneous soft tissue that encases the hilar structures.

@ Spleen

√ splenomegaly

WHO Histopathologic Classification of Posttransplant Lymphoproliferative Disorder (PTLD)

Category	*Subtypes*
Hyperplastic PTLD (early)	Infectious mononucleosis-like plasmacytic hyperplasia
Polymorphic PTLD	Polymorphic diffuse B-cell hyperplasia Polymorphic diffuse B-cell lymphoma
Monomorphic (lymphomatous) PTLD	Diffuse large B-cell lymphoma Burkitt lymphoma Plasma cell myeloma Plasmacytoma-like PTLD T-cell neoplasm (up to 14%) Natural killer cell neoplasm
Hodgkin-like PTLD	Hodgkin disease, Hodgkin-like variants

√ multiple focal hypoattenuating lesions (less frequent)

@ Kidney
√ heterogeneous mass surrounding hilar vessels
√ multifocal discrete round hypovascular parenchymal masses (almost always unilateral)
√ diffuse infiltrative disease → renal enlargement
@ CNS
√ solitary hyperdense typically periventricular mass usually surrounded by vasogenic edema
@ Disseminated disease (10–14% of various allografts)
PET (modality of choice for disease staging + assessment of therapy response)
√ extremely hypermetabolic active lesions
@ Others: skin, eye, area of prior trauma / surgery, bone marrow (uncommon)

Dx: tissue sampling for DDx from invasive aspergillosis

DDx: posttransplant opportunistic infection, lymphoid hyperplasia (spontaneous resolution)

Rx: (1) Antiviral agents (controversial)
(2) Reduction / cessation of immunosuppressive agent (first-line treatment for patients with early polymorphic lesions)
(3) Rituximab = monoclonal antibody against B-cell receptor CD20 (60% response rate)
(4) Surgical resection of tumor mass (complete resolution in 63%)

MALARIA

[*mala aria*, Italian = bad air] [*anophelos*, Greek = useless]
= mosquito-borne infectious disease by Plasmodium species

Type of Malaria	*Organism*	*Fever spikes*
malignant tertian fever	P falciparum	irregular
benign tertian fever	P vivax, P ovale	every 48 h
quartan fever	P malariae	every 72 h

Prevalence: 400–500 million new cases annually worldwide

Prognosis: 2.2–2.7 million deaths annually in mostly young children

◊ Most deadly parasitic infection in the world!

Endemic to: sub-Saharan Africa, South America, southern Asia

Transmission: bite by female Anopheles mosquito (definite host)

Transmission vector: sporozoite = motile infective form

Secondary host: vertebrate (human)

Life cycle:

(a) with a mosquito's bite the motile infective form (**sporozoite**) travels through blood vessels to hepatocytes → asexual reproduction (= tissue schizogony) → thousands of merozoites
(b) **merozoites** infect new RBCs initiating a series of asexual multiplication cycles (= blood schizogony) producing 8–24 new infective merozoites → bursting of RBC (= hemolysis) at different time intervals depending on species
(c) other merozoites develop into immature **gametocytes** (= precursors of male + female gametes); during bite of an infected person by fertilized mosquito, gametocytes are taken up with blood and mature in mosquito gut
(d) male + female gametocytes fuse and form an **ookinete** (= fertilized motile zygote) → develop into new sporozoites that migrate to salivary glands of insect → transmission

during mosquito bite

• fever with chills, sweating, anemia, leukopenia, splenomegaly

@ Lung

Adult respiratory distress syndrome (ARDS)

Cause: (a) RBC sequestration + destruction → vascular injury
(b) release of parasite + erythrocyte material into circulation
(c) host response to these events

√ noncardiogenic diffuse interstitial pulmonary edema
√ pleural effusion
√ lobar consolidation

Dx: identification of trophozoites / other parasitic forms within RBCs (thin blood smear) / parasites (thick smear)

Cerebral Malaria *(2%)*

Cause: sequestration of infected erythrocytes in microcirculation

• encephalopathy, coma, retinal whitening at fundoscopy
√ diffuse cerebral edema ← microvascular occlusion
√ cortical infarcts
√ nonspecific white matter hyperintensity ← small-vessel ischemia
Location: cerebral cortex, thalamus, basal ganglia, splenium of corpus callosum
√ petechial hemorrhages, hemorrhagic infarctions

Prognosis: 15–25% mortality rate

Rx: quinine (from cinchona bark), artemisinin (from sweet wormwood)

MECONIUM ASPIRATION SYNDROME

= most common cause of neonatal respiratory distress in full term / postmature infants (hyaline membrane disease most common cause in premature infants)

Etiology: fetal circulatory accidents / placental insufficiency / postmaturity → perinatal hypoxia + fetal distress → defecation of meconium in utero

Pathogenesis: severe hypoxemia induces gasping reflex with inhalation of tenacious meconium that produces medium and small airway obstruction + chemical pneumonitis

Frequency: 10% of all deliveries have meconium-stained amniotic fluid; 1% of all deliveries have respiratory distress

• cyanosis (rare)
• **persistent fetal circulation syndrome** = neonatal pulmonary hypertension (← thick-walled pulmonary arterioles) + R-to-L shunt through PDA and foramen ovale + severe cyanosis

Rx: extracorporeal membrane oxygenation (major indication besides diaphragmatic hernia + neonatal pneumonia)

√ large infant
√ bilateral diffuse grossly patchy opacities (atelectasis + consolidation)
√ hyperinflation with areas of emphysema ← air trapping
√ spontaneous pneumothorax + pneumomediastinum (25–40%) requiring no therapy
√ small pleural effusions (10–20%)
√ NO air bronchograms

√ rapid clearing usually within 48 hours
Cx: morbidity from anoxic brain damage is high

MEDIASTINAL LIPOMATOSIS

= excess unencapsulated fat deposition
Etiology:
A. exogenous steroids (average daily dose of > 30 mg prednisone):
(1) Chronic renal disease, renal transplant (5%)
(2) Collagen vascular disease, vasculitis
(3) Hemolytic anemia
(4) Asthma
(5) Dermatitis
(6) Crohn disease
(7) Myasthenia gravis
B. endogenous steroid elevation
(1) Adrenal tumor
(2) Pituitary tumor / hyperplasia = Cushing disease
(3) Ectopic ACTH-production (carcinoma of the lung)
C. obesity
• moon facies, buffalo hump, supraclavicular + episternal fat
Location: upper mediastinum (common), cardiophrenic angles + paraspinal areas (less common)
√ upper mediastinal widening
√ paraspinal widening
√ increase in epicardial fat-pads
√ symmetric slightly lobulated extrapleural deposits extending from apex to 9th rib laterally
OTHER FEATURES:
√ osteoporosis
√ fractures
√ aseptic necrosis
√ increased rectosacral distance

MEDIASTINITIS

Acute Mediastinitis

= life-threatening condition with high mortality + morbidity
Cause: acute inflammation of connective tissues + fat surrounding mediastinal structures secondary to
(a) surgery (= postoperative)
(b) transmural esophageal perforation
(c) osteomyelitis of adjacent bone
(d) direct extension of head & neck infection
(e) hematogenous spread of any infection
• acute chest pain, high fever, chills, shortness of breath

• leukocytosis

CXR:

√ widening + loss of normal contours of mediastinum

√ diffuse / focal gas bubbles within mediastinum

CT (modality of choice):

√ increased attenuation of mediastinal fat

√ free gas bubbles in mediastinum

√ localized fluid collections

√ enlarged lymph nodes, pleural effusions, empyema

Postoperative Mediastinitis

Frequency: 0.5–5.0% after median sternotomy

Organism: Staphylococcus aureus

Risk factors: obesity, insulin-dependent diabetes, internal mammary artery graft

Frequently associated with: sternal dehiscence

CXR:

√ displacement, rotation, fracture of sternal wires

√ midsternal lucent stripe (rare)

CT:

√ midsternal lucent stripe > 3 mm = sternal dehiscence

√ pleural / pericardial effusion

N.B.: mediastinal gas bubbles + fluid collections after 14th postoperative day (almost 100% sensitive and specific)

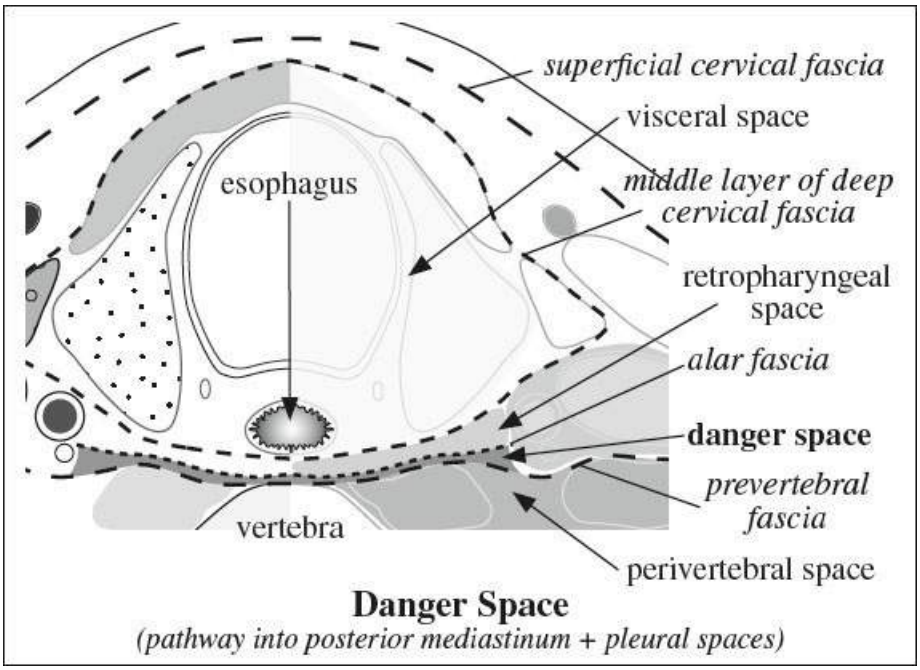
Mortality rate: 7–80%

Descending Necrotizing Mediastinitis

= DNM = rare acute emergent polymicrobial infection of mediastinum

Source: oropharyngeal / cervical / odontogenic infection

Pathways: (a) pretracheal route → anterior mediastinum



Danger Space
(pathway into posterior mediastinum + pleural spaces)

(b) lateral pharyngeal route (via carotid space) → middle mediastinum
(c) retropharyngeal-retrovisceral route → posterior mediastinum (most common)
(d) "**danger space**" = between cervical alar fascia and prevertebral fascia from skull base → posterior mediastinum and diaphragm (posterior to retropharyngeal space)

Classification of disease extent:

type 1 = localized above carina
type 2A = extends to lower anterior mediastinum
type 2B = extension to anterior + posterior mediastinum

X-Ray:

√ subcutaneous emphysema
√ prevertebral soft-tissue swelling
√ mediastinal air
√ widening of superior mediastinum

CT:

√ thickening of subcutaneous tissues of neck
√ thickening + enhancement of cervical fascia + muscles
√ increased attenuation of mediastinal fat
√ mediastinal fluid collections
√ locules of gas within mediastinum
√ pericardial / pleural effusion
√ enlarged lymph nodes

Mortality: 25–50% ← delayed diagnosis ← nonspecific subtle symptoms and findings
Rx: aggressive airway management, early mediastinal exploration, débridement, drainage

Chronic Mediastinitis

Etiology:

(1) Granulomatous infection: histoplasmosis (most frequent), tuberculosis, actinomycosis, Nocardia
(2) Mediastinal granuloma
(3) Fibrosing mediastinitis
(4) Radiation therapy

Mediastinal Granuloma

= relatively benign massive coalescent adenitis with caseating / noncaseating lesions
Cause: primary lymph node infection (commonly tuberculosis / histoplasmosis)
Histo: thin fibrous capsule surrounding granuloma
√ lymphadenopathy
DDx: fibrosing mediastinitis (infiltrative, rare)

Fibrosing Mediastinitis

= SCLEROSING MEDIASTINITIS = MEDIASTINAL COLLAGENOSIS = MEDIASTINAL FIBROSIS
= uncommon benign disorder characterized by progressive proliferation of dense fibrous tissue within mediastinum
Types:

1. Granulomatous fibrosing mediastinitis
   = focal granulomatous form
   Cause: idiosyncratic reaction to Histoplasma capsulatum antigens (organisms recovered in 50%, risk of < 1÷20,000 patients), TB, cryptococcosis, aspergillosis, sarcoidosis

The most common focal granulomatous form of fibrosing mediastinitis is caused by idiopathic proliferation of fibrous tissue in response to Histoplasma capsulatum antigen stimulation.

   √ often calcified focal mediastinal mass
   √ calcified hepatic + splenic granulomas
2. Nongranulomatous fibrosing mediastinitis
   = diffuse form
   Cause: autoimmune disorders / radiation therapy / reaction to drugs (eg, methysergide)
   Associated with:
   retroperitoneal fibrosis, orbital pseudotumor, systemic lupus erythematosus, sclerosing thyroiditis, Riedel thyroiditis, IgG4-related disease
   √ noncalcified diffuse mediastinal infiltration
   √ smooth lobulated contours

Path: ill-defined soft-tissue mass with minimal / NO apparent granulomatous foci
Histo: abundant paucicellular fibrous tissue infiltrating + obliterating adipose tissue
Age: 2nd–5th decade of life; M = F
Most common narrowed mediastinal structures:
airways, pulmonary arteries + veins, esophagus, SVC

- symptoms of central airway obstruction:

- cough (41%), dyspnea (32%)

- symptoms of pulmonary venous occlusion:
  - "pseudo-mitral stenosis syndrome" = progressive exertional dyspnea, hemoptysis (31%)
  - cor pulmonale ← pulmonary arterial hypertension ← compression of pulmonary arteries / veins
- dysphagia (2%)
- superior vena cava syndrome (6–39%)
- low left atrial pressure + widely differential elevation of pulmonary capillary wedge pressures

Location: middle mediastinum (subcarinal and paratracheal regions) + hila; right > left side of mediastinum

CXR:

√ nonspecific widening of mediastinum:
- √ distortion of normally recognizable interfaces
- √ lobulated (in 86% calcified) paratracheal / hilar mass

√ typically unilateral pulmonary artery obstruction:
- √ enlargement of main pulmonary artery + right heart
- √ diminution in size + quantity of vessels of affected lung
- √ localized regional oligemia of affected lung

√ pulmonary venous obstruction:
- √ peribronchial cuffing, septal thickening
- √ ipsilateral Kerley B lines
- √ pulmonary infarct

√ central airway narrowing:
- √ segmental / lobar atelectasis
- √ recurrent pneumonia

UGI:

√ circumferential narrowing / long-segment stricture of esophagus at junction of upper + middle ⅓

√ "downhill" esophageal varices

CT:

√ focal mediastinal mass (82%):
- √ dense / stippled calcifications (in 63%) in right paratracheal / subcarinal / hilar locations
- √ distortion and narrowing of adjacent structures
- √ calcified granulomas in lymph nodes, lung, liver, spleen

√ diffusely infiltrative mediastinal mass (18%) involving several mediastinal compartments:
- √ soft-tissue attenuation, NO calcification
- √ obliteration of normal mediastinal fat planes
- √ encasement / invasion of adjacent structures (vascular stenosis / obstruction)
- √ generally NO signs of remote granulomatous infection

√ wedge-shaped peripheral consolidation of venous / arterial infarction

√ ipsilateral bronchial artery dilatation ← critical narrowing / encasement of pulmonary artery

MR:
√ heterogeneous infiltrative mass of intermediate SI on T1WI
√ mixture of regions of increased + markedly decreased SI on T2WI

NUC:
√ unilateral decreased / absent perfusion with normal ventilation (in focal hilar fibrosis)
√ large segmental / smaller subsegmental unmatched perfusion defects
√ ventilation defects in lobar / segmental occlusion

PET:
√ variable activity → not routinely performed

Angio (with therapeutic intent):
√ unilateral / asymmetric narrowing of central pulmonary arteries / distal arterial cutoffs
√ funnel-like pulmonary vein stenosis / obstruction / focal dilatation near left atrium

Cx: (1) Compression of SVC (64%) + pulmonary veins (4%)
(2) Chronic obstructive pneumonia (narrowing of trachea / central bronchi) in 5%
(3) Esophageal stenosis (3%)
(4) Pulmonary infarcts + fibrosis ← narrowing of pulmonary artery
(5) Prominent intercostal arteries ← narrowing of pulmonary artery

Dx: tissue diagnosis is essential to diagnose malignancy

Rx: resection (laser therapy, venous graft), ketoconazole, steroid therapy (limited success); stent insertion

DDx: (1) Bronchogenic carcinoma
(2) Lymphoma
(3) Metastatic carcinoma
(4) Mediastinal sarcoma

MESOTHELIOMA OF CHEST

Benign Pleural Mesothelioma

= LOCALIZED FIBROUS MESOTHELIOMA = LOCALIZED FIBROUS TUMOR OF THE PLEURA = SOLITARY FIBROUS TUMOR OF PLEURA = BENIGN LOCALIZED MESOTHELIOMA = BENIGN PLEURAL FIBROMA = FIBROSING MESOTHELIOMA = PLEURAL FIBROMYXOMA

= slowly growing, primary pleural neoplasm unrelated to asbestos exposure

Frequency: < 5% of all pleural tumors

◊ No recognized association with asbestos exposure!

Mean age: 50–60 years (range, 3rd–8th decade); M÷F = 1÷1

Path: usually solitary mass arising from visceral pleura in 80% + parietal pleura in 20%

Histo: tumor originates from submesothelial fibroblasts, lined by layer of mesothelial cells
(a) relatively acellular fibrous tissue
(b) rounded spindle-shaped densely packed cells
(c) resembling hemangiopericytoma of lung

- asymptomatic in 50%; episodic hypoglycemia (4%)
- cough, fever, dyspnea, chest pain (larger mass)
- digital clubbing (rare) + hypertrophic pulmonary osteoarthropathy in 20–35%

Location: near lung periphery / adjacent to pleural surface / within fissure
Size: 2–30 cm in diameter
√ sharply circumscribed spherical / ovoid lobular mass:
  √ sessile with smooth tapered margin (common) / pedunculated (almost 50%)
  √ obtuse angle toward chest wall (rare, benign feature)
  √ tumor may change in shape + location upon alteration of patient's position / during respiration (if pedunculated)
  √ areas of hemorrhage / necrosis may be present (favors malignancy)
√ ipsilateral pleural effusion (rare) containing hyaluronic acid
√ mass effect on adjacent lung + mediastinum
CT:
  √ homogeneous mass of intermediate to high attenuation
  √ calcification (7%) associated with necrosis in large tumor
CECT:
  √ substantial contrast enhancement
  √ heterogeneous enhancement with central areas of low attenuation in large tumor ← myxoid changes / hemorrhage / necrosis / cystic degeneration
MR:
  √ hypointense on T1WI + hyperintense on T2WI
Cx: malignant degeneration in 37%
DDx: metastatic deposit
Rx: excision is curative (recurrence rate lower for pedunculated versus nodular tumor)

Malignant Pleural Mesothelioma

= DIFFUSE MALIGNANT MESOTHELIOMA
= uncommon fatal neoplasm of serosal lining of pleura
◊ Most common primary neoplasm of pleura!
Prevalence: 7–13÷1,000,000 persons per year; 2,000–3,000 cases per year in USA
Etiology: asbestos exposure (13–100%); zeolite (nonasbestos mineral fiber); chronic inflammation (TB, empyema); irradiation
Carcinogenic potential:
proportional to aspect ratio of asbestos fibers (= length-to-diameter) of fiber and durability in human tissue:
crocidolite > amosite > chrysotile > actinolite, anthophyllite, tremolite
◊ Occupational exposure of asbestos found in only 40–80% of all cases!
◊ 5–10% of asbestos workers will develop mesothelioma in their lifetime (risk factor of 30 compared with general population)
◊ No relation to duration / degree of exposure or smoking Hx!
Latency period: 20–35–45 years (earlier than asbestosis; later than asbestos-related lung cancer)
Peak age: 50–70 years (66%); M÷F = 2–4–6÷1
Path: multiple tumor masses involving predominantly the parietal pleura + to a lesser degree

the visceral pleura; progression to thick sheetlike / confluent masses resulting in rindlike tumoral encasement of lung

Histo: (a) epithelioid (60%), (b) sarcomatoid (15%), (c) biphasic (25%); intracellular asbestos fibers in 25%; positive stain for epithelial membrane antigen, calretinin, Wilms tumor I antigen, cytokeratin 5/6, HBME-1, mesothelin

Associated with: peritoneal mesothelioma; hypertrophic osteoarthropathy (10%)

Staging (Boutin modification of Butchart staging):

IA confined to ipsilateral parietal / diaphragmatic pleura

IB + visceral pleura, lung, pericardium

II invasion of chest wall / mediastinum (esophagus, heart, contralateral pleura) or metastases to thoracic lymph nodes

III penetration of diaphragm with peritoneal involvement or metastases to extrathoracic lymph nodes

IV distant hematogenous metastases

Stage at presentation: II in 50%, III in 28%, I in 18%, IV in 4%

- nonpleuritic (56%) / pleuritic chest pain (6%), dyspnea (53%)
- fever + chills + sweats (30%), cough (24%), weight loss (22%)
- weakness, fatigue, malaise (30%), anorexia (10%)
- expectoration of asbestos bodies (= fusiform segmented rodlike structures = iron-protein deposition on asbestos fibers [a subset of ferruginous bodies])
- elevated serum mesothelin-related protein (84%)

Spread:

(a) contiguous: chest wall, mediastinum, contralateral chest, pericardium, diaphragm, peritoneal cavity; lymphatics, blood, lung

(b) lymphatic: hilar + mediastinal (40%), celiac (8%), axillary + supraclavicular (1%), cervical nodes

(c) hematogenous: lung, liver, kidney, adrenal gland

√ extensive irregular lobulated bulky pleural-based masses typically > 5 cm / pleural thickening (60%)

√ recurrent exudative / hemorrhagic <u>unilateral</u> pleural effusion (30–60–80%) without mediastinal shift ("frozen hemithorax" = fixation by pleural rind of neoplastic tissue); bilateral effusions (in 10%) contain hyaluronic acid in 80–100%

√ distinct pleural mass without effusion (< 25%)

√ associated pleural plaques in 50% = HALLMARK of asbestos exposure

√ pleural calcifications (20%)

√ circumferential rindlike encasement of entire lung = involvement of all pleural surfaces (mediastinum, pericardium, fissures) as late manifestation

√ extension into interlobar fissures (40–86%)

√ superficial invasion of underlying lung (primarily as extension into interlobular septa)

√ rib destruction in 20% (in advanced disease)

√ ascites (peritoneum involved in 35%)

CT:

√ circumferential + nodular pleural thickening > 1 cm (92%)

√ thickening of mediastinal pleura

√ thickening of interlobar fissure (86%)
√ unilateral pleural effusion (74%) → level of fluid accumulation diminishes with advanced disease
√ contraction of affected hemithorax (42%):
√ ipsilateral mediastinal shift
√ narrowed intercostal spaces
√ elevation of ipsilateral hemidiaphragm
√ calcified pleural plaques (20%)
MR (best modality to determine resectability):
√ minimally hyperintense relative to muscle on T1WI
√ moderately hyperintense relative to muscle on T2WI
PET-CT (useful in identifying occult distant metastases)
Metastases to:
ipsilateral lung (60%), hilar + mediastinal nodes, contralateral lung + pleura (rare), extension through chest wall + diaphragm, pericardium
√ invasion of chest wall:
√ obscured fat planes in chest wall
√ invasion of intercostal muscles
√ separation / destruction of ribs by tumor
√ invasion of mediastinum:
√ obliteration of fat planes around heart, great vessels, esophagus, trachea
Prognosis: 10% of occupationally exposed individuals die of mesothelioma (in 50% pleural + in 50% peritoneal mesothelioma); 5–12 months mean survival time
DDx: pleural fibrosis from infection (TB, fungal, actinomycosis), fibrothorax, empyema, asbestos-related benign pleural disease, pleural lymphoma, metastatic adenocarcinoma (differentiation impossible)
Dx: video-assisted thoracoscopic surgery (postprocedural radiation therapy of all entry ports for tumor seeding of needle track [21%])

METASTASIS TO LUNG

Pulmonary metastases occur in 30% of all malignancies; mostly hematogenous
Age: > 50 years (in 87%)
Incidence of pulmonary metastases:
mnemonic: CHEST
Choriocarcinoma 60%
Hypernephroma / Wilms tumor 30 / 20%
Ewing sarcoma 18%
Sarcoma (rhabdomyo- / osteosarcoma) 21 / 15%
Testicular tumor 12%
Common primaries of intravascular metastases:
breast, stomach, liver, kidney, lung, prostate, choriocarcinoma
◊ Right atrial myxoma + RCC tend to embolize to large central + segmental pulmonary arteries
• progressive dyspnea, subacute pulmonary hypertension

• symptoms of acute pulmonary thromboembolism
√ multiple nodules (in 75%), 82% subpleural:
  √ often smooth + well-defined
  √ varying sizes (most typical)
  √ usually in random distribution
√ fine micronodular pattern: highly vascular tumor (renal cell, breast, thyroid, prostate carcinoma, bone sarcoma, choriocarcinoma)
√ pneumothorax (2%): especially in children with sarcoma + frequently with osteosarcoma ← bronchopleural fistula ← subpleural metastasis

Frequency of Pulmonary Metastases

Origin of pulmonary mets		*Probability of pulmonary mets*	
Breast	22%	for Kidney cancer	75%
Kidney	11%	for Osteosarcoma	75%
Head and neck	10%	for Choriocarcinoma	75%
Colorectal	9%	for Thyroid cancer	65%
Uterus	6%	for Melanoma	60%
Pancreas	5%	for Breast cancer	55%
Ovary	5%	for Prostate cancer	40%
Prostate	4%	for Head and neck CA	30%
Stomach	4%	for Esophagus CA	20%

CT:
  √ noncalcified multiple (> 10) round lesions > 2.5 cm likely to be metastatic
  √ lesions connected to pulmonary arterial branches (75%):
    √ filling defects in large pulmonary arteries (tumor thromboemboli)
    √ multifocal dilatation / beading of subsegmental arteries
    √ tree-in-bud appearance of arterioles in secondary pulmonary lobules

Solitary Metastatic Lung Nodule

◊ A solitary lung nodule represents a primary lung tumor in 62% in patients with known history of neoplasm
◊ 0.4–5.0–9.0% of all solitary nodules are metastatic; most likely origin: colon carcinoma (30–40%), melanoma, osteosarcoma, renal cell carcinoma, bladder cancer, testicular cancer, breast carcinoma

Calcifying Lung Metastases (< 1%)

mnemonic: BOTTOM
Breast
Osteo- / chondrosarcoma
Thyroid (papillary)
Testicular
Ovarian
Mucinous adenocarcinoma (colon)
+ *others:* synovial sarcoma, giant cell tumor of bone, lung metastases following radiation

/ chemotherapy

Cavitating Lung Metastases

Frequency: 4% (compared with 9% in primary bronchogenic carcinoma)
Histo: squamous cell carcinoma (10%), adenocarcinoma (9.5%)
mnemonic: Squamous Cell Metastases Tend to Cavitate
Squamous cell carcinoma, **S**arcoma
Colon
Melanoma
Transitional cell carcinoma
Cervix, during **C**hemotherapy

Hemorrhagic Lung Metastases

CT: √ill-defined nodules with fuzzy margin + "halo" sign (= surrounding ground-glass opacity)

1. Angiocarcinoma
2. Choriocarcinoma
3. Renal cell carcinoma
4. Melanoma
5. Thyroid carcinoma

Endobronchial Metastasis

Frequency: 1%
√ subsegmental / segmental atelectasis or atelectasis of entire unilateral lung
√ round endobronchial lesion on CT

1. Bronchogenic carcinoma
2. Lymphoma
3. Colorectal carcinoma
4. Breast cancer
5. Renal cell carcinoma

Lung Metastases in Childhood

mnemonic: ROWE
Rhabdomyosarcoma
Osteosarcoma
Wilms tumor
Ewing sarcoma

Metastases with Airspace Pattern

= lepedic growth along intact alveolar walls similar to bronchioloalveolar carcinoma mimicking pneumonia
√ airspace nodules
√ consolidation with air bronchogram
√ focal /extensive ground-glass opacities

1. Adenocarcinoma of GI tract (10%)

2. Adenocarcinoma of breast / ovary

Sterilized Metastasis

= persistence of metastatic nodule without significant change in size after adequate chemotherapy

Histo: necrotic nodule ± fibrosis without viable tumor cells

1. Choriocarcinoma
2. Testicular cancer
   - √ growing teratoma syndrome = conversion to a benign mature teratoma
   - √ pulmonary lacunae (= transformation into thin-walled cavity) may persist for years

Metastasis of Benign Tumor to Lung

1. Leiomyoma of uterus
2. Hydatidiform mole of uterus
3. Giant cell tumor of bone
4. Chondroblastoma
5. Pleomorphic adenoma of salivary gland
6. Meningioma

METASTASIS TO PLEURA

1. Lung (36%)
2. Breast (25%)
3. Lymphoma (10%)
4. Ovary (5%)
5. Stomach (2%)

MIXED CONNECTIVE TISSUE DISEASE

= OVERLAP SYNDROME

= disorder that shares distinctive features of ≥ 2 different connective tissue diseases in same patient (overlapping features of SLE, RA, scleroderma (PSS), poly- / dermatomyositis)

Age peak: 2nd + 3rd decade; M÷F = 1÷10

- Raynaud phenomenon, swollen hands, acrosclerosis
- arthritis / arthralgia, esophageal dysmotility + GERD, myositis
- high titer of speckled fluorescent antinuclear antibodies
- moderate to high serum level of antibodies against ribonucleoprotein (anti-U1-RNP)

@ Chest involvement (in 20–85%)

- √ interstitial lung disease (21–66%):
  Pattern: NSIP, UIP, LIP
  - √ groundglass opacities predominantly in lower lung fields
- √ pulmonary arterial hypertension (in 10–45%):
  Cause: interstitial pulmonary fibrosis / intimal proliferation of pulmonary arterioles
  - decrease in CO diffusing capacity
- √ pleural thickening / effusion (<10%)
- √ pulmonary vasculitis, thromboembolism

√ alveolar hemorrhage
√ respiratory muscle dysfunction

Cx: aspiration pneumonia ← esophageal dysmotility

MYCOPLASMA PNEUMONIA

= PRIMARY ATYPICAL PNEUMONIA (PAP)

◊ Varied radiographic + clinical picture!

◊ Commonest cause of community-acquired nonbacterial pneumonia with a mild course (only 2% require hospitalization), usually lasts 2–3 weeks; only 10% of infected subjects develop pneumonia

Frequency: 10–33% of all pneumonias; autumn peak

Organism: Eaton agent = pleuropneumonia-like organism = 350 μm long pleomorphic Mycoplasma pneumoniae with lack of cell wall

Spread: direct contact / aerosol

Age: 5–20 years (most common, esp. in closed populations)

Histo: peribronchial mononuclear cell infiltrates (similar to viral lower respiratory infection)

• incubation period: 1–2 weeks
• gradual onset beginning with pharyngitis, headache, myalgia (rhinorrhea + nasal congestion uncommon)
• mild symptoms of dry cough + low fever, malaise, otitis
• sputum with PMNs but few bacteria, mild leukocytosis (20%)
• most common respiratory cause of cold agglutinin production (60%)

◊ Severity of radiologic findings discrepant to mild clinical condition with pulmonary infiltrates having a significant lag time

√ focal reticular <u>interstitial infiltrate</u>:
  √ unilobar from hilum into lower lobe as earliest change (52%), bilobar (10%)
  √ parahilar peribronchial opacification (12%)
  √ atelectasis (29%)
√ <u>alveolar infiltrates</u>:
  √ patchy inhomogeneous unilateral (L > R) airspace consolidation in segmental lower lobe in 50%, bilateral in 10–40%
√ small pleural effusions in 20%
√ hilar adenopathy (7–22%)

Rx: erythromycin, azithromycin, tetracycline

Cx: ? as an autoimmune response
  (1) Acute disseminated encephalomyelitis
  (2) Cerebral arteriovenous occlusion
  (3) Erythema nodosum, erythema multiforme, Stevens-Johnson syndrome
  (4) pulmonary: Swyer-James syndrome, pulmonary fibrosis, bronchiolitis obliterans, ARDS

Prognosis: 20% with recurrent symptoms of pharyngitis + bronchitis ± infiltrations

DDx: viral infection of lower respiratory tract, pertussis, chlamydia (indistinguishable)

NEAR DROWNING

= asphyxiation ← water inhalation followed by survival for a minimum of 24 hour

Stage 1:

(a) acute laryngospasm after inhalation of a small amount of water
√ NO roentgenographic abnormality

(b) prolonged laryngospasm = "dry drowning" ← negative pressure edema arising from a prolonged episode of the Müller maneuver as in postobstructive pulmonary edema
√ Kerley lines, peribronchial cuffing
√ patchy perihilar alveolar airspace consolidation
Prognosis: resolution within 24–48 hours (under therapy)

Stage 2:

= laryngospasm + swallowing of water into the stomach

Stage 3:

(a) persistent laryngospasm with dry drowning (10–15%)
√ pressure edema

(b) aspiration of water after hypoxia-induced relaxation of laryngospasm (85–90%)
√ permeability edema ← hypoxia + diffuse alveolar damage
Cx: ARDS, aspiration of gastric fluid, infection by fresh-water saprophytic bacteria

1. **Sea-water drowning**
   • hemoconcentration, hypovolemia
2. **Fresh-water drowning**
   • hemodilution, hypervolemia, hemolysis
3. **Secondary drowning**
   (a) pneumonia ← toxic debris
   (b) progressive pulmonary edema
4. **Dry drowning** (20–40%)
   = laryngeal spasm prevents water from entering
   √ no roentgenographic abnormality

Similarities of all 4 types:

• hypoxemia, metabolic acidosis
√ central extensive fluffy areas of increased opacity (alveolar edema indistinguishable from other types):
√ tendency for opacities to coalesce
√ hyaline membrane formation = considerable loss of protein from blood
Cx: pneumonia ← aspirated bacteria / fungi /mycobacteria

NECROTIZING SARCOID GRANULOMATOSIS

Etiology: ? variant of sarcoidosis

Mean age: 49 years (range, 3rd–7th decade); M÷F = 1÷2.2

Path: pleural + subpleural + peribronchovascular scattered nodules / conglomerate masses ± central cavitation

Histo: confluent noncaseating granulomas, extensive necrosis, vasculitis of muscular pulmonary arteries + veins with frequently total vascular occlusion, bronchiolar obstruction, bronchiolitis obliterans, obstructive pneumonitis

• asymptomatic (15–40%)

• cough, chest pain, dyspnea, fever, weight loss, fatigue
• uveitis, hypothalamic insufficiency (13%)
◊ Almost exclusively affects lungs
√ multiple bilateral subpleural + peribronchovascular pulmonary nodules
√ numerous ill-defined parenchymal opacities
√ ± cavitation
√ hilar lymphadenopathy (8–79%)
√ pleural thickening
◊ NO upper airway disease / glomerulonephritis / systemic vasculitis
Rx: corticosteroid therapy alone
DDx: sarcoidosis (high prevalence of mediastinal + hilar lymphadenopathy, little propensity for cavitation)

NEONATAL PNEUMONIA

Pathogenesis:
(a) in utero infection: ascending from premature rupture of membranes or prolonged labor / transplacental route) = major risk factor
(b) aspiration of infected vaginal secretions during delivery
(c) infection after birth

Organism:
(1) Group B streptococcus (GBS) = most common cause: in low–birth-weight premature infants; 50% mortality
√ pulmonary opacities (87%):
√ appearance identical to RDS (in 52%)
√ appearance suggests retained lung fluid / focal infiltrates (35%)
√ normal CXR (13%)
√ cardiomegaly (common)
√ pleural effusions (in ⅔, but RARE in RDS)
Associated with: delayed onset of diaphragmatic hernia (evidenced by clinical deterioration)
Prognosis: often lethal
(2) Pneumococci: RDS-like
(3) Listeria: RDS-like
(4) Candida: progressive consolidation + cavitation
(5) Chlamydia trachomatis: bronchopneumonic pattern
(6) *others:* H. influenzae, Staphylococcus aureus, E. coli, CMV, Pneumocystis
• afebrile, lower ventilatory pressure requirements
√ bilateral focal / diffuse areas of opacities (may initially appear similar to fetal aspiration syndrome)
√ hyperaeration
√ may cause lobar atelectasis
√ may cause pneumothorax / pneumomediastinum
√ pleural effusion (exceedingly rare)

NEUROENDOCRINE TUMOR OF LUNG

= tumors arising from Kulchitsky cells (normally present in bronchial mucosa)

Incidence: 25% of all pulmonary neoplasms

Histo: neuroendocrine morphology = organoid nesting, palisading, rosettes, trabecular growth pattern

Classification of Pulmonary Neuroendocrine Neoplasms (WHO 2004)
Histologic Categories
Low-grade malignant neoplasm
Typical carcinoid
Intermediate-grade neoplasm
Atypical carcinoid
High-grade neoplasm
Large cell neuroendocrine tumor
Small cell lung cancer (SCLC)

Classification (Travis):

1. Carcinoid (25%)
2. Large cell neuroendocrine carcinoma
3. Small cell lung cancer

Carcinoid Tumor of Lung

= NEUROENDOCRINE CARCINOMA / NEOPLASM

◊ 2nd most common location after GI tract

Frequency: 1–2% of all pulmonary neoplasms; 20–30% of all carcinoid tumors; 20–25% of all invasive primary lung cancers

◊ Most common primary pulmonary neoplasm in children!

DDx of Typical Carcinoid versus Atypical Carcinoid		
Criterion	*Typical Carcinoid (80–90%)*	*Atypical Carcinoid (10–20%)*
Path	well-differentiated	intermediate grade npl.
Histo	NO necrosis; < 2 mitoses÷10 HPFs / 2 mm^2	areas of punctate necrosis; 2–10 mitoses÷10 HPFs
Association		cigarette smoking (83–94%)
Age	younger patient; M÷F = 1÷10 (?)	~ 1 decade older patient; M÷F = 2÷1 to 3÷1
Location	central: endobronchial growth	peripheral > central
Mean size	2.3 cm	3.6 cm
Spread	rare: to lymph node in 3%	adrenal gland, brain, liver, skin, bone (osteoblastic) in 30%; lymph node (25–50%)
Prognosis	5 (10)-year survival of 87–100% (82–94%)	5 (10)-year survival of 44–88% (18–64%)

Mean age: 46 (range, 4–95) years; 4% occur in children + adolescents; M÷F = 1÷1; very uncommon in Blacks

Associated with: MEN 1 in < 4% (almost all hormonally inactive)

Path:

well-defined pulmonary nodule / mass that originates from neurosecretory cells of bronchial mucosa (= Kulchitsky cells = argentaffin cells); part of APUD (amine precursor uptake and decarboxylation) system = chromaffin paraganglioma, which produces serotonin, ACTH, norepinephrine, bombesin, calcitonin, ADH, bradykinin

Histo: neuroendocrine morphology = organoid nesting, palisading, rosettes, trabecular growth pattern; uniform cells separated by prominent vascular stroma + numerous thin-walled blood vessels

Immunohisto: positive for neuron-specific enolase, CD56, Ki-67, chromogranin A, synaptophysin

- asymptomatic (20–50%) ← peripheral tumor
- recurrent unifocal pneumonitis, hemoptysis
- wheezing, persistent cough, dyspnea, chest pain
- paraneoplastic syndromes (rare):
  (a) Cushing syndrome: in 2% of bronchial carcinoids
  (b) carcinoid syndrome: in 0.7% of pulmonary carcinoids
- endobronchial exophytic mass at endoscopy

Location:

› 70–90% in main / lobar / segmental bronchi, often near bifurcation; R÷L lung = 3÷2

Site: relationship to central bronchus
(a) completely endobronchial / endoluminal
(b) partially endoluminal ("tip of iceberg" sign)
(c) abutting airway

› 10–42% peripheral in lung parenchyma

Site: no relationship to bronchus

Average size: 3 (range, 2–5) cm; atypical carcinoid is larger + more peripheral

CXR:

√ well-defined <u>central</u> hilar / perihilar mass:
√ ± consolidation ← atelectasis / postobstructive pneumonitis / recurrent pneumonia
√ ± mucus plugging = "gloved finger" appearance

√ solitary well-defined round / ovoid <u>peripheral</u> nodule / mass distal to segmental bronchus
√ ± lobulated borders < 3 cm in size

CT:

√ spherical / ovoid polypoid nodule / mass (with long axis parallel to adjacent bronchovascular bundle):
√ well-defined slightly lobulated border
√ "bronchus sign" (= bronchus leading directly to the tumor) may allow diagnosis prospectively
√ "collar button" lesion = extension through bronchial wall involving bronchial lumen + parenchyma

√ diffuse scattered eccentric punctate calcifications / dense ossification (26–33%): central carcinoid÷peripheral carcinoid = 10%÷43%
√ cavitation (rare)
√ intense > 30 HU net enhancement ← vascular tumor supplied by bronchial circulation
√ bronchiectasis, mucoid impaction, atelectasis, air trapping
√ postobstructive pneumonia
√ hilar / mediastinal lymphadenopathy (6–25%) ← metastasis / reactive hyperplasia ← recurrent pneumonia
√ metastases in liver, bone, adrenal glands

MR:
√ mass of high T2 + STIR signal intensity
√ intense enhancement during systemic circulatory phase

NUC:
Agents: 111In-octreotide / lanreotide (short-acting / long-acting somatostatin analogs), MIBG = meta-iodobenzylguanidine (norepinephrine analog)
√ typically for staging / assessing response to therapy
√ helpful in detecting occult tumor (depending on degree of somatostatin-receptor expression rather than hormonal hypersecretion)
√ MIBG less sensitive than octreotide

PET (high false-negative rate):
√ NO (most often) / increased activity (occasionally)

Prognosis: death from valvular disease
Rx: lobectomy, pneumonectomy, endobronchial resection, bronchial sleeve resection, segmentectomy
DDx: lung cancer, pulmonary hamartoma, bronchial gland tumor, metastasis

Large Cell Neuroendocrine Carcinoma

= poorly differentiated high-grade neuroendocrine tumor as a variant of large-cell carcinoma
Prevalence: 3% of all resected lung cancers; 19% of pulmonary endocrine tumors; 12% of all large cell undifferentiated carcinomas
Histo: high mitotic rate of > 10 per 10 HPFs; large cell size, polygonal shape, low nuclear-cytoplasmic ratio, finely granular eosinophilic cytoplasm, coarse nuclear chromatin, frequent nucleoli; positive neuroendocrine marker (chromogranin A, synaptophysin, neural cell adhesion molecule [NCAM/CD56], thyroid transcription factor (TTF)-1 [41–75%], Ki-67 proliferation index [50–100%])
Mean age: 65 (range, 44–82) years; M÷F = 2.5÷1
Associated with: heavy smoking (30–62 pack-years) in 60%

- asymptomatic (25%)
- chest pain, hemoptysis, cough, dyspnea, weight loss, fever

Location: peripheral (70–80%) / central (20–30%)
Mean size: 3.7 (range, 1.3–9.2) cm

CXR:
√ 3.7-cm peripheral pulmonary mass

CT:

√ nonspecific well-defined lobulated nodule / mass:
√ ± air bronchogram, cavity, bubbly lucency, necrosis
√ intratumoral calcifications (9%)
√ homo- / heterogeneous enhancement
√ attendant atelectasis / distal mucus plugging
√ pleural effusion (24%)
PET:
√ avid FDG uptake; SUV > 13.7 suggests shortened survival
Spread: mediastinal lymphadenopathy (27%); extrathoracic metastasis (36%)
Prognosis: 5-year survival rate of 15–57%; recurrence in supraclavicular / mediastinal lymph nodes within 2 years
DDx: small cell lung cancer, atypical carcinoid

NOCARDIOSIS

Organism: Gram-positive acid-fast bacterium resembling fungus
Predisposed: immunocompromised
√ multiple poorly / well-defined nodules ± cavitation
√ lobar consolidation
√ empyema without sinus tracts
√ SVC obstruction (rare)

NODULAR LYMPHOID HYPERPLASIA

= PSEUDOLYMPHOMA = LOCALIZED MASSLIKE FORM OF LIP
= reactive benign lesion = uncommon localized lymphoid hyperplasia; no progression to lymphoma
Path: usually single involvement of small area of lung
Histo: aggregates of polymorphous large + small lymphoid cells (B and T cells); multiple germinal centers; infiltration and expansion of alveolar interstitium by lymphocytes (T cells) and plasma cells, occasional giant cell; variable fibrosis; common lymphoepithelial lesions (= invasion of bronchial epithelium by lymphoid cells)
May be associated with: collagen vascular disease, Sjögren syndrome, dysgammaglobulinemia
• mostly asymptomatic / cough, dyspnea
Location: subpleural / ± peribronchial
CXR:
√ well-demarcated dense infiltrate(s) as nodule / mass / masslike consolidation
CT:
√ infiltrate typically in central location extending to visceral pleura
√ prominent central air bronchogram
√ NO invasion of adjacent bronchus / pleural space
√ NO hilar / mediastinal lymphadenopathy
√ NO pleural effusion
Prognosis: occasionally progression to non-Hodgkin lymphoma
Rx: most patients respond well to steroids initially
Dx: surgical biopsy

DDx: LIP (diffuse involvement of lung)

NONTUBERCULOUS MYCOBACTERIAL LUNG INFECTION

= ATYPICAL TUBERCULOSIS = ATYPICAL MYCOBACTERIAL INFECTION

Organism:

M. kansasii: lung infection in subjects with good immune status
M. marinum: "swimming pool granuloma"
M. ulcerans: "Buruli ulcer" in tropical areas
M. scrofulaceum: cervical lymphadenitis in infants
M. avium intracellulare: esp. in AIDS (most common)

Organism causing pulmonary disease (Runyon classification):

ubiquitous organisms as part of normal environmental flora

1. Photochromogens M. kansasii, M. simiae, M. asiaticum
   - colonies turn yellow with exposure to light
   - ◊ 70–80% of individuals from rural areas test positive on PPD-B (= antigen from M. kansasii)!
2. Scotochromogens M. scrofulaceum, M. xenopi, M. szulgai, M. gordonae
   - yellow colonies turn orange with exposure to light
3. Nonchromogens M. avium-intracellulare, M. malmoense, M. terrae
   - white / beige colonies without color change
4. Rapid growers M. fortuitum-chelonei
   - appear in culture in 3–5 days (all other groups appear in culture in 2–4 weeks)

Histo: lesions indistinguishable from M. tuberculosis

Source: soil, water, dairy products, bird droppings

Infection: inhalation of aerosolized water droplets (M. avium-intracellulare complex), food aspiration in patients with achalasia (M. fortuitum-chelonei), GI tract (in AIDS)

- cough (60–100%), hemoptysis (15–20%), asthma, dyspnea
- fever distinctly uncommon (10–13%)
- weakness + weight loss (up to 50%)
- weekly positive tuberculin skin test

A. CLASSIC FORM

Age: 6th–7th decade; in Whites (80–90%); M > F

Predisposing factors:

COPD (25–72%), previous TB (20–24%), interstitial lung disease (6%), smoking > 30 pack-years (46%), alcohol abuse (40%), cardiovascular disease (36%), chronic liver disease (32%), previous gastrectomy (18%)

Location: apical + anterior segments of upper lobes

√ chronic fibronodular / fibroproductive apical opacities (indistinguishable from reactivation TB)
√ cavitation in 80–95%
√ apical pleural thickening in 37–56%
√ additional patchy nodular alveolar opacities in ipsi- / contralateral lung in 40–70% ← bronchogenic spread
√ adenopathy (0–4%)

√ pleural effusion (5–20%)
√ typically NO hilar elevation

B. NONCLASSIC FORM (20–30%)

Age: 7th–8th decade; 86% in Whites; M÷F = 1÷4

- chronic cough, hemoptysis, malaise, weight loss, fatigue
- older woman with thin body habitus = "Lady Windermere syndrome":
  [Oscar Wilde's Victorian-era play Lady Windermere's Fan exemplifies the fastidious behavior believed to cause the syndrome by suppressing cough and never displaying any signs of illness]
  - pectus excavatum chest wall deformity, thoracic scoliosis
  - mitral valve prolapse
- older men with chronic obstructive pulmonary disease

Predisposing factors: NONE

Location: predominantly in middle lobe + lingula

√ multiple bilateral centrilobular nodules throughout both lungs in random distribution
√ irregular curvilinear interstitial opacities
√ mild to moderate cylindrical bronchiectasis
√ atelectasis / scarring

HRCT:

√ bronchiectasis, bronchial wall thickening
√ mucoid bronchial impaction
√ scattered tree-in-bud nodules
√ areas of segmental + subsegmental atelectasis + scarring

C. ASYMPTOMATIC GRANULOMAS

√ cluster of similar-sized nodules

D. ACHALASIA-RELATED INFECTION

with M. fortuitum-chelonei

E. DISSEMINATED DISEASE

in immunocompromised patients: AIDS, transplant patients, lymphoproliferative disorders (esp. hairy cell leukemia), steroid + immunosuppressive therapy

CT:

√ multifocal bronchiectasis (79–94%), esp. middle lobe + lingula
√ centrilobular nodules of varying sizes, usually < 1 cm (= micronodules) in 76–97%
√ bronchial wall thickening (97%)
√ airspace disease (76%)
√ cavitation (21%), esp. in upper lobes
√ interlobular septal thickening (12%)

◊ Unfavorable response to antituberculous therapy is suspicious for atypical TB!

Rx: multidrug regimen typically prescribed for at least 1 year

DDx: M. tuberculosis (bronchiectasis less common + less extensive), bronchiolitis obliterans, sarcoidosis, fungal disease

PANBRONCHIOLITIS

= DIFFUSE PANBRONCHIOLITIS

= progressive inflammatory lung disease characterized by chronic inflammation of paranasal sinuses + respiratory bronchioles, prevalent in Asians but rare in Europeans + North Americans

Pathogenesis: unknown

Histo: thickening of respiratory bronchiole wall + transmural infiltration of lymphocytes + plasma cells + histiocytes

Location: predominantly in lung bases

HRCT:

√ tree-in-bud pattern = small centrilobular nodules of < 5 mm connected to centrilobular branching structures (= segments of bronchiolectasis filled with secretions)

√ bronchial wall thickening

√ mosaic perfusion

√ bronchiectasis

√ cystic lesions + air trapping (in later stage)

DDx: bronchiolitis obliterans

PARAGONIMIASIS OF LUNG

= PLEUROPULMONARY PARAGONIMIASIS

= parasitic disease caused by trematode Paragonimus (usually P. westermani = lung fluke / P. kellicotti)

Prevalence: 20.7 million infected

Endemic to: certain areas of East + Southeast Asia (China, Korea, Japan, Thailand, Laos, Philippines, India); Latin America (primarily Peru); Africa (primarily Nigeria); in US among Indo-Chinese and Latin American immigrants

Infection: ingestion of raw / incompletely cooked freshwater crustaceans (crab / crayfish) infected with metacercariae; larva exists in small intestine → penetrates intestinal wall → enters peritoneal cavity; → penetrates diaphragm + pleura → enters lung (target organ)

Cycle:

from final host (tiger, cat, dog, fox, weasel, opossum, wild boar, human) eggs of worm pass to the outside with blood-streaked sputum; in fresh water ciliated embryos (miracidia) develop → become tailed larvae (cercariae) after invading a fresh-water snail; when infected snail is eaten by a crustacean, their tails detach and they become 300 µm encysted larvae (metacercariae)

- parasitic eggs in sputum / BAL fluid / pleural fluid / feces
- intradermal and serologic tests

@ Chest

- fever, chest pain, chronic cough, hemoptysis

Location: pulmonary lesions in 83%, pulmonary + pleural lesions in 44%, pleural lesions in 17%)

Early findings (lesions occur 3–8 weeks after ingestion when organisms migrate to pleural space)

√ uni- / bilateral pneumo- / hydropneumothorax (17%)

√ uni- / bilateral pleural effusion (3–54%) / empyema ± pleural thickening

√ focal patchy migrating airspace consolidation (= worm migration causes focal exudative / hemorrhagic pneumonia) in 45%:
√ ± cavitation
√ lobar / segmental collapse ← airway obstruction from egg granuloma / intrusion of worm
√ 2–4-mm thick and 2–7-cm long linear opacities / hyperattenuation abutting the pleura (41%) ← peripheral atelectasis / worm migration track (visible in up to 50%)

CT:
√ hypoattenuating fluid-filled cysts surrounded by hyperattenuating consolidation in adjacent lung
√ mediastinal lymphadenopathy

Late findings when organisms reside and reproduce in lung parenchyma:
√ lung cyst ← cyst formation ← infarction ← arteriolar / venous obstruction by worm or egg / expansion of small airway by intraluminal parasite:
√ thick-walled cyst ← fibrosis
√ "eclipse effect" = eccentric thickening of cyst wall ← one / two intracystic worms
√ < 3 mm thin-walled cyst ← cyst connected to airway
√ 10–15-mm poorly marginated subpleural / subfissural worm cyst (= nodules + masslike consolidation in 24%):
√ cyst initially masked by pericystic airspace consolidation
√ ± cyst filled with chocolate-colored necrotic fluid of low opacity
√ adjacent bronchiectasis (35%)
√ cavity formation
√ high radiotracer uptake on PET

@ CNS
• meningoencephalitis (in 25%)
√ shell-like / soap–bubble-like calcifications of varying size (~ 50%)

Dx: eggs of parasite in sputum or in pleural / BAL fluid

DDx: tuberculosis (nodular slowly changing lesion, residual fibrosis after treatment, no subpleural linear opacities), cryptococcosis, bacterial infection with abscess formation, vasculitis

PNEUMATOCELE

= discrete thin-walled cystic air collection within lung parenchyma ← obstructive overinflation
= regional obstructive emphysema
◊ Does not indicate destruction of lung parenchyma
◊ Occurs during healing phase
◊ Appears to enlarge while patient improves
◊ Frequently multiple

Developmental theories:
(1) small bronchioles undergo severe distension ← check-valve endobronchial / peribronchial obstruction
(2) focus of necrotic lung → evacuates through a bronchus narrowed by edema / inflammation → subsequent airspace enlargement due to check-valve mechanism from enlarging

pneumatocele / inflammatory exudate

(3) air from ruptured alveoli / bronchioles dissects along interstitial interlobular tissue and accumulates between visceral pleura and lung parenchyma = subpleural emphysematous bulla = subpleural air cyst

√ well-defined thin-walled pulmonary parenchymal cyst
√ may be entirely filled with gas / air-fluid level
√ ± contralateral mediastinal shift + compressive atelectasis
Cx: rupture → tension pneumothorax

Pneumatocele Associated with Infection

Organism: Staphylococcus (in childhood), Pneumococcus, Escherichia coli, Klebsiella pneumoniae, Haemophilus influenzae
Age: infant + young child; < 3 years of age in up to 70%
√ appears within 1st week, disappears within 6 weeks
√ thin-walled + completely air-filled cavity
√ ± air-fluid level + wall thickening (during infection)
√ pneumothorax
√ spontaneous resolution over several weeks to months

Traumatic Pneumatocele = Pneumatocyst

Cause: blunt chest trauma

(a) air trapped within area of pulmonary laceration is initially obscured by surrounding contusion (hematoma):
√ pneumatocyst appears within hours after trauma
√ cyst spontaneously resolves within 3 weeks

(b) intensive inflammatory response from hydrocarbon (furniture polish, kerosene) inhalation / ingestion

√ single / multiple pneumatoceles with sparing of apices

"Pulverized Lung"

Cause: severe chest trauma
√ multiple 5–10-mm air cysts in an area of airspace opacification

PNEUMOCOCCAL PNEUMONIA

Most common Gram-positive pneumonia (90% community-acquired, 10% nosocomial)
Frequency: 15% of all adulthood pneumonias, uncommon in childhood; peaks in winter + early spring; increased during influenza epidemics
Organism: Streptococcus pneumoniae (formerly Diplococcus pneumoniae, Gram-positive, in pairs / chains, encapsulated, capsular polysaccharide responsible for virulence + serotyping)
Susceptible: elderly, debilitated, alcoholics, CHF, COPD, multiple myeloma, hypogammaglobulinemia, functional / surgical asplenia

- rusty blood-streaked sputum, left-shift leukocytosis
- impaired pulmonary function

Location: usually involves one lobe only; bias for lower lobes + posterior segments of upper

lobes ← bacteria flow under gravitational influence to most dependent portions as in aspiration

√ extensive airspace consolidation abutting against visceral pleura (lobar / beyond confines of one lobe through pores of Kohn) CHARACTERISTIC
√ slight expansion of involved lobes
√ prominent air bronchograms (20%)
√ patchy bronchopneumonic pattern (in some)
√ pleural effusion (parapneumonic transudate) uncommon with antibiotic therapy
√ cavitation (rare, with type III)

Variations (pneumonia modified by bronchopulmonary disease, eg, chronic bronchitis, emphysema):

√ bronchopneumonia-like pattern
√ effusion may be only presentation (esp. in COPD)
√ empyema (with persistent fever)
› in children:
√ round pneumonia = sharply defined round lesion

Prognosis: prompt response to antibiotics (if without complications); 5% mortality rate

Dx: blood culture (positive in 30%)

Cx: meningitis, endocarditis, septic arthritis, empyema (now rarely seen)

PNEUMOCYSTOSIS

= PNEUMOCYSTIS CARINII PNEUMONIA

◊ Most common cause of interstitial pneumonia in immuno-compromised patients, which quickly leads to airspace disease

Organism:

ubiquitous obligate extracellular protozoan / fungus Pneumocystis carinii

(a) trophozoite develops into a cyst
(b) cyst produces up to eight daughter sporozoites, which are released at maturity + develop into trophozoites

Pathomechanism:

trophozoite attaches to cell membrane of type I alveolar pneumocytes → cell death + leakage of proteinaceous fluid into alveolar space

Predisposed:

(a) debilitated premature infants, children with hypogammaglobulinemia (12%)
(b) AIDS (60–80%)
(c) other immunocompromised patients: congenital immuno-deficiency syndrome, lymphoproliferative disorders, organ transplant recipients (renal transplant patients in 10%), patients on long-term corticosteroid therapy (nephrotic syndrome, collagen vascular disease), patients on cytotoxic drugs [under therapy for leukemia (40%), lymphoma (16%)]
◊ Often associated with simultaneous infection by CMV, Mycobacterium avium-intracellulare, herpes simplex

• severe dyspnea + cyanosis over 3–5 days
• subacute insidious onset of malaise + minimal cough (frequent in AIDS patients), respiratory failure (5–30%)

- WBC slightly elevated (PMNs)
- lymphopenia (50%) heralds poor prognosis

√ normal CXR in 10–39%
√ bilateral diffuse symmetric finely granular / reticular interstitial / airspace infiltrates (in 80%) with perihilar + basilar distribution (CHARACTERISTIC central location)
√ response to therapy within 5–7 days
√ rapid progression to diffuse alveolar homogeneous consolidation (DDx: pulmonary edema)
√ air bronchogram
√ fine / coarse linear / reticular pattern = thickened coarse interstitial lung markings (in healing phase)
√ pleural effusion + hilar lymphadenopathy (uncommon)
√ <u>atypical pattern</u> (in 5%):
  √ isolated lobar disease / focal parenchymal opacities
  √ lung nodules ± cavitation
  √ hilar / mediastinal lymphadenopathy
  √ thin- / thick-walled regular / irregular cysts / cavities with predilection for upper lobes + subpleural regions
√ <u>effect of prophylactic use of aerosolized pentamidine</u>:
  √ redistribution of infection to upper lobes
  √ cystic lung disease
  √ spontaneous pneumothorax, frequently bilateral (6–7%)
  √ disseminated extrapulmonary disease (1%)
  √ punctate / rimlike calcifications in enlarged lymph nodes + abdominal viscera

CT:
  √ patchwork pattern (56%)
    = bilateral asymmetric patchy mosaic appearance with sparing of segments / subsegments of pulmonary lobe
  √ ground-glass pattern (26%)
    = bilateral diffuse / perihilar airspace disease (fluid + inflammatory cells in alveolar space) in symmetric distribution
  √ interstitial pattern (18%)
    = bilateral symmetric / asymmetric, linear / reticular markings (thickening of interlobular septa)
  √ air-filled spaces (38%):
    (a) pneumatoceles = thin-walled spaces without lobar predilection resolving within 6 months
    (b) subpleural bullae (due to premature emphysema)
    (c) thin-walled cysts (? check-valve obstruction of small airways from aerosolized pentamidine)
    (d) necrosis of PCP granuloma
  √ pneumothorax (13%)
  √ lymphadenopathy (18%)
  √ pleural effusion (18%)
  √ pulmonary nodules usually due to malignancy (leukemia, lymphoma, Kaposi sarcoma,

metastasis) / septic emboli
√ pulmonary cavities / cyst formation (chronic) usually due to superimposed fungal / mycobacterial infection

NUC:
√ bilateral and diffuse 67Ga uptake without mediastinal involvement prior to roentgenographic changes
DDx: TB / MAI infection (with mediastinal involvement)

Dx: (1) Sputum collection
(2) Bronchoscopy with lavage
(3) Transbronchial / transthoracic / open lung Bx

Prognosis: rapid fulminant disease; death within 2 weeks

Rx: co-trimoxazole IV, nebulized pentamidine

PNEUMONECTOMY CHEST

Early signs (within 24 hours):
√ partial filling of thorax
√ ipsilateral mediastinal shift + diaphragmatic elevation

Late signs (after 2 months):
√ complete obliteration of space

N.B.: Depression of diaphragm / shift of mediastinum to contralateral side indicates a bronchopleural fistula / empyema / hemorrhage!

POLAND SYNDROME

= congenital chest wall anomalies

May be associated with: hypo- / aplasia of mamilla / breast

Autosomal recessive

√ unilateral partial / complete absence of muscles:
› pectoralis major (absence of sternocostal head) + minor
› latissimus dorsi
› serratus anterior
› intercostal muscles

√ ipsilateral syndactyly + brachydactyly

√ hypoplasia / absence of ribs

√ ± scoliosis

POSTOBSTRUCTIVE PNEUMONIA

= chronic inflammatory disease distal to bronchial obstruction; despite the name coexistent infection is uncommon

Cause:
1. Bronchogenic carcinoma (most commonly)
2. Bronchial adenoma
3. Granular cell myoblastoma (almost always tracheal lesion)
4. Bronchostenosis

Histo: "golden pneumonia" = cholesterol pneumonia = endogenous lipid pneumonia ←

mixture of edema, atelectasis, round cell infiltration, bronchiectasis, liberation of lipid material from alveolar pneumocytes ← inflammatory reaction

√ frequently associated with some degree of atelectasis
√ persists unchanged for weeks
√ recurrent pneumonia in same region after antibiotic Rx

PRIMARY PULMONARY LYMPHOMA

= monoclonal lymphoid proliferation within lung parenchyma

Frequency of primary lung lymphomas:

› MALT lymphoma (most common)
› diffuse large B-cell NHL (2nd most common)
› Hodgkin disease (least common)

Pulmonary MALT Lymphoma

= low-grade marginal zone B-cell lymphoma of mucosa-associated lymphoid tissue

◊ Most common type of lymphoma involving the pulmonary parenchyma (in up to 90%)

Prevalence: 3–4% of extranodal lymphomas; 1% of lung malignancies

Cause: chronic inflammation of bronchus-associated lymphoid tissue (BALT)

Age: 6th decade

Associated with:
autoimmune disease (eg, Sjögren syndrome, rheumatoid arthritis, immunodeficiency); chronic inflammation from smoking; infections (eg, HIV, hepatitis C)

Histo: sheets of monoclonal lymphocytes + occasional interspersed plasma cells (containing intranuclear inclusions of immunoglobulins = Dutcher bodies); often additional cells causing confusion, like giant cells, granulomas, reactive germinal centers

• cough, dyspnea, hemoptysis, weight loss
• asymptomatic (50%)

Location: bi- / unilateral

√ multiple nodules / masses / consolidations
√ areas of ground-glass attenuation / consolidation in bronchovascular distribution
√ air bronchograms (frequent) ± dilatation
√ patchy large areas of ground-glass attenuation throughout lungs (rare)
√ mosaic attenuation ← infiltration along airways
√ hilar / mediastinal lymphadenopathy (in up to 30%)
√ pleural effusions (uncommon)
√ hypermetabolic at PET/CT (50%)

Prognosis: 84–88% 5–10-year survival rate

DDx: granulomatosis with polyangiitis (= Wegener granulomatosis), sarcoidosis, perilymphatic spread of metastatic disease, infection

PSEUDOMONAS PNEUMONIA

= most dreaded nosocomial infection because of resistance to antibiotics in patients with debilitating diseases on multiple antibiotics + corticosteroids; rare in community

Organism: Pseudomonas aeruginosa, Gram-negative
- bradycardia, temperature with morning peaks

√ widespread patchy bronchopneumonia ← bacteremia (unlike other Gram-negative pneumonias)
√ predilection for lower lobes
√ extensive bilateral consolidation
√ "spongelike pattern" with multiple nodules > 2 cm (= extensive necrosis with formation of multiple abscesses)
√ small pleural effusions

PULMONARY ARTERIAL MALFORMATION

= PULMONARY ARTERIOVENOUS ANEURYSM = PAVM
= PULMONARY ARTERIOVENOUS FISTULA = PULMONARY ARTERIOVENOUS MALFORMATION = PULMONARY ANGIOMA = PULMONARY TELANGIECTASIA

= abnormal vascular communication between pulmonary artery and vein (95%) or systemic artery and pulmonary vein (5%)

Etiology:
(a) congenital defect of capillary structure (common)
(b) acquired in cirrhosis (hepatogenic pulmonary angiodysplasia), cancer, trauma, surgery (Glenn and Fontan procedure), schistosomiasis, actinomycosis, TB (Rasmussen aneurysm)

Path: hemangioma of cavernous type

Pathophysiology:
low-resistance extracardiac R-to-L shunt (which may result in paradoxical embolism); quantification with ^{99m}Tc–labeled albumin microspheres by measuring fraction of dose reaching kidneys

Age: 3rd–4th decade; manifest in adult life, 10% in childhood

Occurrence:
(a) isolated single abnormality (in ⅔)
(b) multiple (in ⅓)
Associated with: Rendu-Osler-Weber syndrome (in 30–60–88%) = hereditary hemorrhagic telangiectasia
◊ 15–50% of Rendu-Osler-Weber patients have pulmonary AVMs!

Types:
1. Simple type (79%)
   = single feeding artery empties into a bulbous nonseptated aneurysmal segment with a single draining vein
2. Complex type (21%)
   = more than one feeding artery empties into a septated aneurysmal segment with more than one draining vein

- asymptomatic in 56% (until 3rd–4th decade) if AVM single and < 2 cm
- orthodeoxia = with lesion in lower lobes increase in arterial hypoxemia (= PaO_2 < 85 mmHg) in erect position ← L-to-R shunting larger in sitting or standing position ← gravitational shift of pulmonary blood flow to base of lung
- cyanosis with normal-sized heart (R-to-L shunt) in 25–50%, clubbing

- audible bruit over lesion (increased during inspiration)
- dyspnea on exertion (60–71%), tachypnea, palpitation, chest pain, hemoptysis (10–15%); No CHF

Location: lower lobes (60–70%) > middle lobe > upper lobes; bilateral (8–20%); medial third of lung

√ "coin lesion" = sharply defined, lobulated oval / round mass (90%) of 1 to several cm in size
√ cordlike bands from mass to hilum (= feeding artery + draining veins)
√ enlargement with advancing age
√ change in lesion size:
  √ decrease: expiration, Valsalva maneuver, recumbent position
  √ increase: inspiration, Müller maneuver (= forced inspiration against a closed glottis after full expiration), erect position
√ phleboliths (occasionally)
√ increased pulsations of hilar vessels

CT (98% detection rate):
  √ homogeneous circumscribed noncalcified nodule / serpiginous mass up to several cm in diameter
  √ vascular connection of mass with enlarged feeding artery + draining vein
  √ sequential enhancement of feeding artery + aneurysmal part + efferent vein on dynamic CT

MR (if contraindication to contrast material / if flow slow due to partial thrombosis / for follow-up):
  √ irregular T2-hypointense lesion, usually adjacent to hilum
  √ signal void on standard spin echo / high SI on GRASS images

Angio (mostly obviated by MR / CT unless surgery or embolization contemplated):
  ◊ 100% sensitive for detection of vessels > 2 mm

Cx: CNS symptoms are commonly the initial manifestation
  (1) Cerebrovascular accident: stroke (18%), transient ischemic attack (37%) ← paradoxical bland emboli
  (2) Brain abscess (5–9%) ← loss of pulmonary filter function for septic emboli
  (3) Hemoptysis (13%) ← rupture of PAVM into bronchus, most common presenting symptom
  (4) Hemothorax (9%) ← rupture of subpleural PAVM
  (5) Polycythemia

Prognosis: 26% morbidity, 11% mortality

Recommendation: screening of first-degree relatives

DDx: solitary / multiple pulmonary nodules

Rx: embolization with coils / detachable balloons

PULMONARY CAPILLARY HEMANGIOMATOSIS

= bilateral pulmonary disease behaving like a low-grade nonmetastatic vascular neoplasm with slowly progressive pulmonary hypertension

Histo: sheets of thin-walled capillary blood vessels infiltrating pulmonary interstitium + invading pulmonary vessels, bronchioles, and pleura

Pathomechanism of pulmonary hypertension (pHTN):

(a) venoocclusive phenomenon ← invasion of small pulmonary veins
(b) progressive vascular obliteration ← in situ thrombosis + infarction
(c) pulmonary scar formation ← recurrent pulmonary hemorrhage

Age: 20–40 years

- cor pulmonale: jugular venous distension, pedal edema, ECG signs of RV failure (DDx: pulmonary venoocclusive disease)
- elevated PA pressures + normal pulmonary wedge pressure
- dyspnea on exertion; hemoptysis + pleuritic chest pain in ⅓ (DDx: pulmonary thromboembolic disease)

CXR:
√ diffuse reticulonodular pattern
√ focal areas of interstitial fibrosis (recurrent episodes of pulmonary hemorrhage + thrombotic infarction)

CT:
√ thickening + nodularity of interlobular septa + walls of pulmonary veins
√ poorly defined centrilobular ground-glass nodules
√ pleural effusions
√ lymphadenopathy

Angio:
√ combination of increased flow (to hemangiomatous areas) + decreased flow (to regions of thrombosis, infarction, and scarring)

Prognosis: death after 2–12-year interval from onset of symptoms

Rx: bilateral lung transplantation

Pulmonary capillary hemangiomatosis may develop fatal pulmonary edema if treated with vasodilators!

Dx: open lung biopsy → extremely hazardous with pHTN

DDx: (1) Pulmonary venoocclusive disease
(2) Idiopathic interstitial fibrosis
(3) Primary pulmonary hypertension (no increase in lung markings)
(4) Pulmonary hemangiomatosis (only in children, cavernous hemangiomas involving several organs)

PULMONARY INFARCTION

= ischemic coagulative necrosis of lung parenchyma

Frequency: rare due to protective effect of collateral blood flow from bronchial circulation

Path: dark necrotic material (with faint ghostlike structures of lung tissue remaining evident on histology) surrounded by a narrow rim of hyperemia + inflammation

Cause: pulmonary artery occlusion (medium- to small-sized vessel)

Pathogenesis:
ischemic capillary endothelial injury → increased vascular permeability + reperfusion via bronchial circulation causes intraalveolar extravasation of blood cells in a confined area with possible progression to infarction

Co-condition to progress to infarction:
CHF, high embolic burden, underlying malignancy, diminished bronchial flow (due to shock, hypotension, chronically impaired circulation), vasodilator use, elevated pulmonary venous

pressure, interstitial edema

Prognosis: replacement by vascular fibrous tissue folding into a collagenous platelike mass → pleural retraction

PULMONARY INTERSTITIAL EMPHYSEMA

= PIE = complication of respirator therapy with PEEP

Pathogenesis:

gas escapes from overdistended alveolus → dissects into perivascular sheath surrounding arteries, veins, and lymphatics → tracks into mediastinum forming clusters of blebs

• sudden deterioration in patient's condition during respiratory Rx

√ meandering tubular + cystic lucencies following distribution of bronchovascular tree

√ bilateral symmetrical distribution

√ pseudocysts (localized form of PIE) = multiple circular well-defined air collections with uniformly thin walls

Location: right parahilar region

√ lobar overdistension (occasionally)

Cx: (1) pneumothorax (77%) ← rupture of cyst
(2) pneumomediastinum (37%)
(3) subcutaneous emphysema, pneumopericardium, intracardiac air, pneumoperitoneum, pneumatosis intestinalis
(4) **air-block phenomenon** = buildup of pressure in mediastinum / pericardial tamponade impeding blood flow in low-pressure pulmonary veins → diminished blood return to heart (obstruction esp. during expiration); esp. common in neonatal period
√ microcardia

Rx: (1) High-frequency jet / oscillatory ventilation
(2) Placing affected side of infant down for 24–48 hours
(3) Selective bronchial intubation

DDx: air bronchograms (branching / tapering)

PULMONARY LANGERHANS CELL HISTIOCYTOSIS

= PLCH = LCH

= rare pulmonary disorder that typically affects the young adult in isolation and is associated with cigarette smoking

Associated with: extrapulmonary manifestation (in 5–15%):
bone lesions, diabetes insipidus (10–25%), skin lesions

Prevalence: in 3.4% of chronic diffuse infiltrative lung disease

Incidence: 0.05–0.50÷100,000 per year

Age: most frequently in 3rd–5th decade (range, 3 months to 69 years); M÷F = 1÷1; Caucasians >> Blacks
◊ All children with PLCH show multisystem involvement
◊ In 30% of adolescents with PLCH lung affected alone

Pathogenesis:

heavy cigarette smoking in young men → accumulation + activation of Langerhans cells (in

90–100% current / former smokers) as a result of excess neuroendocrine cell hyperplasia + secretion of bombazine-like peptides

◊ 90–100% of patient with PLCH smoke

◊ 3–5% of smokers get PLCH

Path:

multifocal granulomatous infiltration centered on walls of bronchioles (= bronchiolitis) often extending into surrounding alveolar interstitium (< 1 cm) → bronchiolar destruction → thick-walled cysts presumably caused by check-valve bronchial obstruction + pneumothorax (NO necrosis); in end-stage disease foci of PLCH are replaced by fibroblasts forming CHARACTERISTIC stellate "starfish" scars with central remnants of persisting inflammatory cells

- asymptomatic (in up to 25%); occasionally crackles + wheezes
- nonproductive cough (75%), dyspnea (40%)
- normal or mild obstructive / restrictive / mixed abnormalities on pulmonary function tests
- ↓ CO diffusing capacity (in up to 90%)
- constitutional symptoms (in up to ⅓): fatigue, fever, night sweats, weight loss, anorexia
- chest pain (15–25%) ← spontaneous pneumothorax / eosinophilic granuloma in rib
- lymphocytosis with predominance of T-suppressor cells on bronchoalveolar lavage (DDx: excess of T-helper cells in sarcoidosis)

Location: usually bilaterally symmetric, upper + mid lung predominance, sparing of bases + costophrenic angles

Evolutionary sequence on radiography:

nodule → cavitated nodule → thick-walled cyst → thin-walled cyst (secondary to progressive enlargement + air trapping of original cavitary nodule)

◊ CXR abnormalities more severe than clinical symptoms + pulmonary function tests!

√ diffuse fine reticular / reticulonodular pattern ← cellular infiltrate with predilection for apices:

√ nodules 1–10 mm (granuloma stage):

√ ill-defined / stellate with irregular borders

√ cavitation of large nodules (in up to 10%)

√ may develop into "honeycomb lung" = multiple 1–5-cm cysts + subpleural blebs (fibrotic stage)

√ lung volume increased in ⅓ or normal (DDx: most other interstitial lung diseases have decreased lung volumes!)

√ pleural effusion (8%), hilar adenopathy (unusual)

√ thymic enlargement ← infiltration

CT (CLASSIC manifestation):

√ < 10-mm small cysts with varying wall thickness → often coalescing to form irregular larger cysts / bullae

√ multiple small scattered bilateral peribronchiolar nodules with early signs of cavitation

HRCT:

The combination of nodules + cysts in correlation with demographic + clinical factors are considered DIAGNOSTIC for PLCH and obviate a lung biopsy.

√ complex / branching perivascular thin-walled (< 1 mm) cysts individually < 5 mm in size:

√ confluent contiguous cysts 2–3 cm in size
√ equally distributed in central + peripheral zones of upper + mid lung while sparing the bases
◊ As cysts become more numerous in later stages nodules occur less frequently!
√ thick-walled cysts
√ 1–5-mm centrilobular ± cavitary nodules with irregular borders in peribronchiolar distribution associated with cysts
√ fine reticular opacities (50%)
√ ground-glass opacities
√ perivascular honeycombing
√ thickening of bronchovascular bundles + interlobular septa
√ intervening lung appears normal

DDx for nodules:
sarcoidosis, hypersensitivity pneumonitis, berylliosis, TB, atypical TB, metastases, silicosis, coal worker's pneumoconiosis

DDx for cysts:
emphysema (no definable wall), bronchiectasis (communicating branching pattern), idiopathic pulmonary fibrosis, lymphangio-myomatosis (almost exclusively in women, diffuse involvement of entire lung)

DDx: sarcoidosis (equal sex distribution, always multisystem disease, not related to smoking, erythema nodosum, bilateral hilar lymphadenopathy, lung cavitation + pneumothorax rare, epithelioid cells)

Cx:
1. Recurrent pneumothoraces in 25% (from rupture of subpleural cysts) CHARACTERISTIC
2. Pulmonary hypertension ← severe diffuse pulmonary vasculopathy involving pulmonary muscular arteries and interlobar veins
3. Superimposed Aspergillus fumigatus infection

Prognosis: poor with multisystem disease + organ dysfunction (especially with skin lesions)
(a) complete / partial regression (50%)
(b) stable symptoms of variable severity (30–40%)
(c) rapid progression (10–20%) to air-flow obstruction + impaired diffusing capacity + respiratory failure + cor pulmonale
◊ May recur in transplanted lung if smoking is continued or resumed!

Mortality: 2–25%

Rx: smoking cessation; chemotherapy (vincristine sulfate, prednisone, methotrexate, 6-mercaptopurine); lung transplant

PULMONARY MAINLINE GRANULOMATOSIS

= PULMONARY TALCOSIS

= pulmonary microembolism in drug addicts ← chronic IV injection of suspensions prepared from crushed tablet compounds (talc is a common insoluble additive)

Drugs: amphetamines, methylphenidate hydrochloride ("West coast"), tripelen amine ("blue velvet"), methadone hydrochloride, Dilaudid®, meperidine, pentazocine, propylhexedrine, hydromorphone hydrochloride

Pathogenesis: talc (= magnesium silicate) particles incite a pronounced granulomatous foreign-body reaction + subsequent fibrosis in perivascular distribution

Path: multiple scattered whitish nodules of 0.3–3 mm converging into gritty fibrotic masses in central + upper lungs measuring several cm in diameter

Histo: widespread granulomas packed with doubly refractile talc particles expanding the walls of muscular pulmonary arteries and arterioles + perivascular connective tissue + alveolar septa

- talc retinopathy (80%) = small glistening crystals
- angiothrombotic pulmonary hypertension + cor pulmonale

Early changes:

√ widespread micronodularity of "pinpoint" size (1–2–3 mm) with perihilar / basilar predominance

√ well-defined nodules predominantly in middle zones

Late changes:

√ loss of lung volume of upper lobes + hilar elevation + hyperlucency at lung bases

√ indistinctly marginated coalescent opacities similar to progressive massive fibrosis (DDx: in silicosis slightly further away from pulmonary hila + distinct margin)

Cx: mycotic pulmonary artery aneurysm; right-sided endocarditis with septic emboli; chronic respiratory failure; emphysema; systemic talc breakthrough to liver + spleen + kidneys + retina

DDx of late changes:

(1) Progressive massive fibrosis of silicosis / coal worker's pneumoconiosis
(2) Chronic sarcoidosis

Dx: lung biopsy

PULMONARY THROMBOEMBOLIC DISEASE

= PULMONARY EMBOLISM (PE)

Incidence: 600,000 Americans / year (0.23%) with missed / delayed diagnosis in 400,000, causing death in 100,000; diagnosed in 1% of all hospitalized patients; in 12–64% at autopsy; in 9–56% of patients with deep venous thrombosis

Age: 60% > 60 years of age

Cause: deep vein thrombosis (DVT) of extremities / pelvis (> 90%), right atrial neoplasia / thrombus, thrombogenic intravenous catheters, endocarditis of tricuspid / pulmonic valves

Time of onset: PE usually occurs within first 5–7 days of thrombus formation

Predisposing factors:

primary thrombophlebitis (39%), immobilization (32%), recent surgery (31%), venous insufficiency (25%), recent fracture (15%), myocardial infarction (12%), malignancy (3–8%) with higher frequency in gynecologic malignancies + melanoma (hypercoagulability ← direct thrombogenic effects of malignancy / chemotherapy), CHF (5%), no predisposition (6%)

Pathophysiology: A clot from the deep veins of the leg breaks off → fragments in right side of heart → showers lung with emboli of varying size

◊ On average > 6–8 vessels are embolized!

◊ Clinical presentation is protean + nonspecific!

◊ False-positive clinical diagnosis in 62%

- Classic triad (< 33%):
  (1) Hemoptysis (25–34%)
  (2) Pleural friction rub
  (3) Thrombophlebitis
  - symptoms (nonfatal PE versus fatal PE):
    - pleuritic chest pain (88% versus 10%)
    - acute dyspnea (84% versus 59%)
    - apprehension (59% versus 17%)
    - cough (53% versus. 3%); hemoptysis (30% versus. 3%)
    - sweats (27% versus. 9%); syncope (13% versus 27%)
  - signs (nonfatal PE versus fatal PE):
    - respiratory rate > 16 (92% versus. 66%)
    - rales due to loss of surfactant (58% versus 42%)
    - tachycardia > 100 bpm (44% versus 54%)
    - temperature > 37.8°C (43% versus 30%)
    - diaphoresis (36% versus 10%)
    - heart gallop (34% versus 10%); phlebitis (32% versus 7%)
    - heart murmur (23%); cyanosis (19% versus 12%)
  - ECG changes (83%), mostly nonspecific: P-pulmonale, right-axis deviation, right bundle branch block, classic S1Q3T3 pattern
  - elevated levels of fibrinopeptide-A = small peptide split off of fibrinogen during fibrin generation
  - positive D-dimer assay (generated during clot lysis)

Location of PE: bilateral emboli (in 45%), R lung only (36%), L lung only (18%); multiple emboli (3–6 on average) in 65%

Distribution: RUL (16%), RML (9%), RLL (25%), LUL (14%), LLL (26%)

Site: central = segmental / larger (in 58%);
peripheral = subsegmental / smaller (in 42%);
in subsegmental branches <u>exclusively</u> (in 30%)

◊ Emboli are occlusive in 40%!

A. EMBOLISM WITHOUT INFARCTION (90%)
Histo: hemorrhage + edema

B. EMBOLISM WITH INFARCTION (10–60%)
= any opacity developing as a result of thromboembolic disease; more likely to develop in presence of cardiopulmonary disease with obstruction of pulmonary venous outflow (diagnosed in retrospect)

Clinical Probability of PE: Wells Score	
Variable	*Points*
clinically suspected DVT	3.0
alternative diagnosis is less likely than PE	3.0
tachycardia	1.5
immobilization / surgery in previous four weeks	1.5
history of DVT or PE	1.5
hemoptysis	1.0
malignancy (treatment for within 6 months, palliative)	1.0
Interpretation	
Score > 6.0	High (59% probability)
Score 2.0 to 6.0	Moderate (29% probability)
Score < 2.0	Low (15% probability)

Histo: (1) incomplete infarction = reversible transient hemorrhagic congestion / edema usually resolving over several days to weeks
(2) complete infarction = hemorrhagic infarction with necrosis of lung parenchyma remaining permanently

Prognosis: majority of pulmonary thromboemboli resolve with appropriate therapy

Acute Pulmonary Thromboembolism

◊ Hypertension disappears as emboli lyse

Mortality:

3÷1,000 surgical procedures; 200,000 deaths in 1975; 7–10% of all autopsies (death within first hour of PE in most patients); 26–30% if untreated; 3–10% if treated; 50–58% / 8–15% with hemodynamic instability / stability

◊ Healthy patients may survive obstruction of 50–60% of vascular bed, fatal if > 60% of pulmonary bed obstructed

- sudden onset of chest pain, acute dyspnea
- hemoptysis occasionally
- enzyme-linked immunosorbent D-dimer assay test (detects one of the products of fibrin breakdown) > 500 µg/L

Assessment of severity of PE:

ECG:

√ straightening / leftward bowing of IVS
√ paradoxical motion of interventricular septum
√ "empty LV" appearance = ↓ LV volume
√ loss of inspiratory collapse of IVC
√ tricuspid regurgitation + dilatation of PA
√ McConnell sign = regional RV wall motion abnormality with sparing of apex

CT:

√ RV÷LV diameter ratio > 1 on 4-chamber view
√ leftward septal bowing (with RV wall < 6 mm thick)
√ ↑ size of azygos v. + SVC ← ↑ R heart pressure

√ contrast reflux into IVC ← tricuspid valve insufficiency

CXR (33% sensitive, 59% specific):

◊ Abnormal nonspecific CXR in 84%; a normal CXR has a negative predictive value of only 74%!

√ general findings (patients with PE versus no PE):

√ atelectasis / infiltrate (68% versus 48%)
√ pleural effusion (48% versus 31%)
√ pleural opacity (35% versus 21%)
√ elevated diaphragm (24% versus 19%)
√ decreased vascularity (21% versus 12%)
√ prominent pulmonary artery (17% versus 28%)
√ cardiomegaly (12% versus 11%)
√ pulmonary edema (4% versus. 13%)

√ local findings:

√ Westermark sign = area of oligemia in 2–7% ← vasoconstriction distal to embolus
√ Fleischner sign = local widening of artery by impaction of embolus ← distension by clot / developing pulmonary hypertension ← peripheral embolization
√ "knuckle" sign = abrupt tapering of an occluded vessel distally
√ Fleischner lines = long-line shadows (fibrotic scar) from invagination of pleura at the base of the collapse resulting in pseudofissure
√ Hampton hump = segmentally distributed pleura-based shallow wedge-shaped consolidation with base against pleural surface + convex medial border:
√ NO air-bronchogram ← hemorrhage into alveoli
√ ± cavitation
√ "melting" sign = within few days to weeks regression from periphery toward center
√ subsequent nodular / linear scar

√ thoracentesis: bloody (65%), predominantly PMNs (61%), exudate (65%)

NECT (purpose):

√ depiction of acute changes of PE:

√ atelectasis / linear bands (100%)
√ pleural effusion (87%)
√ consolidation (57%)
√ ground-glass opacification (57%)
√ Hampton's hump (50%)
√ intraluminal area of high attenuation (= hyperdense artery) measuring 33 ± 15 HU
√ dilated central / segmental pulmonary artery

√ depiction of chronic changes of PE
√ chest findings leading to alternative diagnosis
√ localization of volume-of-interest for CECT

CT angio (method of choice):

N.B.: CT (2.2–6.0 mSv) has a 1.6–4.3 times higher radiation dose than a V/Q scan (1.4 mSv)!

◊ Helical CT equal to angio in detection of emboli within proximal arteries of ≤ 5th / 6th generation
◊ Subsegmental intraluminal filling defects (in 2–30%) usually not detectable!

◊ Detection poor in middle lobe + lingular branches (in 18%)!

N.B.: evaluate the vessel adjacent to a bronchus

√ complete filling defect of low attenuation occupying entire arterial section creating convex interface with the contrasted lumen

√ ± enlargement of thrombosed artery

√ "railway track" sign = partial filling defect = embolus floating freely within lumen surrounded by areas of intravascular contrast enhancement

√ eccentric mural filling defect forming acute angles with arterial wall

√ RV dysfunction (ratio RV÷LV ≥ 1÷1)

Pseudo-filling defects:

(1) Breathing artifact in tachypneic patient
(2) Too short / long scanning delay
(3) Unilateral increase in vascular resistance
(4) R-to-L shunt
(5) Window setting
(6) Partial voluming

Anatomic pathologic mimics:

(1) Peribronchial lymph node
(2) Unopacified veins
(3) Mucus-filled bronchi
(4) Perivascular edema

Technical failure rate: 3–4% due to severe dyspnea

CT of lung parenchyma:

√ peripheral wedge-shaped area of infarct / hemorrhage in arteries of < 3 mm in diameter

√ linear parenchymal band

MR:

√ filling defect in pulmonary artery on coronal contrast-enhanced 3-D maximum intensity projection

Angio (> 95% sensitive & specific):

Indication for pulmonary angiography:

(1) Indeterminate V/Q scan with high clinical suspicion + risky anticoagulation therapy (angio within 24 hours)
(2) Mismatch between interpretation + clinical findings
(3) Significant risk for anticoagulation + high probability for PE
(4) Specific diagnosis necessary for proper management (vasculitis, drug induced, lung cancer with predominant vascular involvement)
(5) Prior to intervention: pulmonary embolectomy, caval ligation, caval filter placement
(6) Patients too ill to undergo V/Q scan

Technique: AP & ipsilateral posterior oblique projection

√ intraluminal defect (94%)

√ abrupt termination of pulmonary arterial branch

√ pruning + attenuation of branches

√ wedge-shaped parenchymal hypovascularity

√ absence of draining vein in affected segment

√ tortuous arterial collaterals

Risks of pulmonary angiography:

(1) left bundle branch block: requires temporary pacing wire prior to right heart catheterization

(2) marginal cardiac function: therapy must be available to treat frank pulmonary edema

(3) Right ventricular end diastolic pressure > 20 mmHg: selective catheterization with occlusion balloon

Cx of pulmonary angiography (1–2%):

arrhythmia, endocardial injury, cardiac perforation, cardiac arrest, contrast reaction

Mortality rate of pulmonary angiography: 0.2–0.5%

Clinical Classification of Pulmonary Thromboembolic Disease according to Severity

Signs & Symptoms	*Class 1*	*Class 2*	*Class 3*	*Class 4*
Occlusion of pulmonary arteries	< 20%	20–30%%	30–50%	> 50%
Symptoms	asymptomatic	anxiety, hyperventilation	dyspnea, collapse	shock, dyspnea
Arterial pO_2	normal	< 80 torr	< 65 torr	< 50 torr
Arterial pCO_2	normal	< 35 torr	< 30 torr	< 30 torr
Central venous pressure	normal	normal	elevated	elevated
Mean PA pressure	normal	–	–	> 20 mmHg
Systolic blood pressure	normal	–	–	< 100 mmHg

False-negative rate:

1–4–9% due to difficulty in visualizing subsegmental emboli (with only 30% interobserver agreement about presence of subsegmental emboli)

NUC (V/Q scan = guide for angiographic evaluation) interpreted in reference to Biello or PIOPED criteria:

Indication:

(1) Allergy to iodinated contrast media

(2) Renal insufficiency

(3) Weight limit of CT table exceeded

√ low- / intermediate-probability scans in 50–70%:

◊ results in recommending additional studies; although only 12–14% will undergo angiography

◊ 25–30% disagreement between expert readers in interpreting intermediate- and low-probability V/Q scans

√ high-probability scan: in 12% normal angiogram

N.B.: V/Q abnormalities vary over time ← autoregulation (hypoxic vasoconstriction, hypercapneic bronchoconstriction) and resolution

Prognosis:

◊ Resolution less favorable with increasing age + cardiac disease

◊ Resolution improved with urokinase > heparin

(a) total resolution (90%) within 30 days after treatment ← mechanical fragmentation + endogenous fibrinolysis

(b) no resolution in 10%: organization of thromboembolus leading to retraction with total / partial obstruction, recanalization, stenosis, fibrous webs / cords and vessel atrophy

Cx: pulmonary arterial hypertension (in 4%)

Rx:

1. Heparin IV: 10,000–15,000 units as initial dose; 8,000–10,000 units/hour during diagnostic evaluation; continued for 10–14 days
2. Streptokinase: better results with massive PE
3. Urokinase: slightly better than streptokinase
4. Coumadin: maintained for at least 3 months (15% complication rate)

Acute Pulmonary Embolism in Pregnancy

Risk: increased x 4 during pregnancy

- D-dimer frequently elevated

◊ Lung scintigraphy + CTA have comparable diagnostic performances

Indeterminate results in 19%:

similar for V/Q scan and CTA (mostly poor arterial opacification ← increase in maternal blood volume)

Advantage of CT over Lung Scintigraphy:

(1) Better interobserver agreement

(2) Unsuspected alternative diagnosis in 12 % (eg, bronchopneumonia, pericardial effusion)

Dose comparison CT versus V/Q:

(a) radiation exposure of mother

› mean dose from CTA (7.3 mSv) is higher than for lung scintigraphy (0.9 mSv)

› CTA (10–70 mGy) has a higher dose to breast than low-dose perfusion scan (0.11–0.30 mGy)

(b) radiation exposure of fetus

V/Q scan (640–800 mSv) has a 5–267 times higher radiation dose than a CT scan (3–131 mSv) during all trimesters!

Iodine exposure: contrast during pregnancy

Chronic Pulmonary Thromboembolism

= CHRONIC THROMBOEMBOLIC DISEASE

Frequency: 1–5% of patients with acute pulmonary thromboembolism, especially in patients with large emboli / recurrent episodes

At risk: underlying malignancy, cardiovascular disease, pulmonary disease, splenectomy, ventriculoatrial shunt for hydrocephalus, permanent central venous line, chronic inflammatory bowel disease, myeloproliferative syndromes; M < F

Path: fibrous webs and bands (= organized thromboemboli), often with overlying recent thrombosis; embolic material is incorporated into vessel wall + covered over by a thin layer of endothelial cells

Pathogenesis:

patent pulmonary arteries develop medial hypertrophy + intimal thickening + atherosclerotic plaques in response to pressure elevation; bronchial arteries may dilate + form extensive collateral pathways to minimize areas of lung infarction

- may be clinically silent / asymptomatic for years ("honeymoon period")

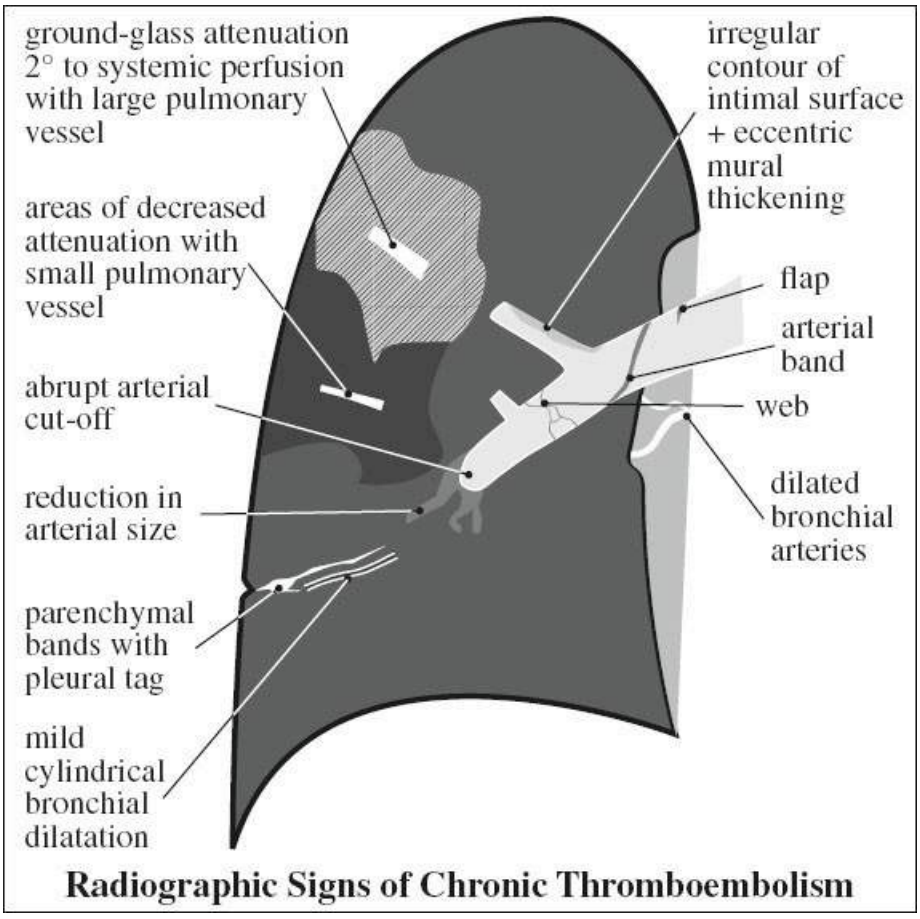
◊ To become symptomatic at least 60% of the arterial bed must be obstructed!

- history of previous embolic episodes; 63% lack a history of acute thromboembolism
- recurrent acute / gradual progressive exertional dyspnea (DDx: interstitial lung disease)

- chronic nonproductive cough, atypical chest pain
- tachycardia, syncope
- loss of RV functional capacity: elevated pulmonary arterial pressure (36–78 mmHg), normal pulmonary capillary wedge pressure; high right atrial pressures, reduced cardiac output
- lupus anticoagulant = anticardiolipin (11–24%)
- elevated plasma levels of thrombophilic factors (factor VIII + antiphospholipid antibodies)

CXR:

√ prominence of right side of heart
√ asymmetric enlargement of central pulmonary arteries
√ oligemic vascularity in patchy distribution
√ triangular / rounded opacity + adjacent pleural thickening ← pulmonary infarction
√ patchy bilateral perihilar alveolar opacities of "reperfusion edema" after thrombendarterectomy



Radiographic Signs of Chronic Thromboembolism

CT angio (77% sensitive):

◊ CT angio rivals conventional angiography!
@ Heart
√ enlargement + hypertrophy of RA + RV:
√ RV myocardial thickness > 4 mm
√ cardiomegaly ← chamber dilatation

- √ transverse diameter of RA > 35 mm
- √ transverse diameter of RV > 45 mm

√ RV÷LV > 1÷1 with leftward bowing of interventricular septum into LV

√ ± opacification of IVC + suprahepatic veins ← tricuspid valve regurgitation ← dilatation of tricuspid valve annulus

√ mild pericardial thickening

√ small pericardial effusion

@ Pulmonary vessels

√ <u>pulmonary hypertension</u> (secondary signs):

- √ pulmonary trunk diameter > 29 mm measured in scan plane of its bifurcation at right angle to long axis lateral to ascending aorta
- √ diameter ratio of main pulmonary artery to aorta > 1÷1
- √ right + left pulmonary arteries > 18 mm in diameter measured in their intrapericardial portion 1 cm beyond origin: often asymmetric in size

√ <u>visualization of chronic thrombus</u> (most specific):

- √ flattened eccentric incomplete filling defect of organized thrombus forming obtuse angles with arterial wall
- √ irregular contour of intimal surface
- √ completely obstructing thrombus:
  - √ abrupt termination / narrowing / obliteration of a pulmonary artery
  - √ convex margin of contrast column (= "pouch defect") best appreciated on reformatted images
  - √ occlusion of main pulmonary artery (3%)
- √ thrombus of increased density (87 ± 30 HU) ←
  - (a) enhancement of organizing thrombus
  - (b) thrombus retraction with concentration of hemoglobin + iron
- √ clot may become calcified = atherosclerotic pulmonary artery plaque (rare)
- √ postobstructive signs:
  - √ absence of contrast in distal vessel segment
  - √ abrupt persistent decrease in caliber of artery distal to occlusion compared to accompanying bronchus ← retraction of thrombus
  - √ poststenotic dilatation / aneurysm / tortuosity

√ <u>recanalized thrombus</u>:

- √ thickened walls of arteries with irregular contour of intimal surface in vessel parallel to scan plane / peripheral crescent-shaped intraluminal filling defect in vessel transverse to scan plane
- √ arterial band (= 1–3-mm linear structure attached at both ends to vessel wall) / flap (= attached at one end to vessel wall) / web (= network of multiple branching bands)

√ <u>collateral systemic supply</u> of occluded pulmonary arterial bed ← participation in gas exchange:

- √ bronchial artery dilatation ≥ 1.5 mm + tortuosity (47–77%) within mediastinum supplied by inferior phrenic, intercostal + internal mammary arteries

@ <u>Parenchymal abnormalities</u>:

√ mosaic perfusion on HRCT (77–100%) in segmental / subsegmental distribution:

√ scattered geometric areas of low attenuation with vessels of small cross-sectional diameter ← oligemic hypoperfusion / small-vessel arteriopathy
√ regional sharply demarcated enhancing areas of high attenuation with enlarged vessels ← compensatory hyperperfusion of lung + collateral blood flow
√ NO air trapping on expiratory scan
DDx: primary pulmonary hypertension (more diffuse pattern of mosaic perfusion)
√ isolated focal areas of ground-glass attenuation in perihilar region ← systemic perfusion
√ infarcted tissue replaced by scar (72–87%):
Location: lower lung (70%), often multiple
√ wedge-shaped pleura-based opacities with tip pointing to hilum
√ linear opacities (= parenchymal bands)
√ peripheral nodule / cavity
√ often accompanied by pleural thickening
√ cylindrical bronchial dilatation of segmental and subsegmental bronchi (64%) adjacent to severely stenosed / completely occluded + retracted pulmonary arteries ← hypoxic bronchodilatation

MR:
√ discrete fixed areas of low-to-medium SI on T1WI
Disadvantage: slow flow in central vessels may obscure fixed signal of emboli

NUC:
• A history of prior PE decreases the probability of acute embolism because small V/Q mismatches never resolve!
√ V/Q scan characteristically of high probability with multiple unmatched segmental perfusion defects

Angio (reference standard with highest specificity):
√ webs, bands
√ stenotic / absent arterial segments
√ pouchlike filling defects = convex margin of contrast material bolus
√ abrupt cutoffs often confined to one / two lung segments
√ unilateral occlusion / hypoperfusion
√ selective bronchial arteriography shows dilated bronchial artery collaterals (up to 30% of systemic blood flow) filling pulmonary arteries downstream from sites of occlusion

◊ Bronchial artery dilatation suggests chronic rather than acute thromboembolic disease!

• measurement of pulmonary artery pressure → quantification of disease severity + postoperative prognosis

Disadvantage: sensitivity for central emboli lower than for CT angio

Prognosis: partial or complete obstruction of the pulmonary vascular bed → pulmonary hypertension → cor pulmonale; 30% 5-year survival with a mean PA pressure of > 30 mmHg

Rx:
(1) Thrombendarterectomy for main / lobar / proximal segmental arteries (4–14% operative mortality) in patients with hemodynamic / ventilatory impairment
(2) Lifelong supplemental warfarin anticoagulation therapy (to avoid recurrent / growth of

thromboembolism) ± vasodilators

DDx:

(1) Idiopathic pulmonary hypertension (arteries rarely enlarged)
(2) Acute thromboembolism (diameter of pulmonary artery may be increased, nonobstructive filling defect in central location, eccentric filling defect forms acute angles with vessel wall, no dilatation of bronchial arteries, lower attenuation of thrombus, no hypertrophy of RV)
(3) Interruption of pulmonary artery (associated with congenital cardiovascular anomaly, smooth abrupt tapering of pulmonary artery blindly ending at hilum, NO endoluminal changes)
(4) Takayasu arteritis (concentric inflammatory mural thickening, mainly segmental + subsegmental arteries affected in 50–80% of late stage disease, involvement of aorta + its branches, delayed mural contrast enhancement, increased FDG uptake)
(5) Primary sarcoma of pulmonary artery (unilateral filling defect spans entire luminal diameter ± expansion of main / proximal pulmonary artery / RV, extension into lung parenchyma / mediastinum)

Ventilation-Perfusion (V/Q) Scan

Indication:

(1) Allergy to iodinated contrast media
(2) Renal insufficiency
(3) Weight limit of CT table exceeded

Rationale for Perfusion Scan:

perfusion images will detect

› 90% of surface perfusion defects > 2 x 2 cm
› 90% of emboli completely occluding a vessel > 1 mm in diameter
› 26% of emboli partially occluding a vessel

◊ A pulmonary embolus (PE) presents as segmentally hypo-perfused but normally ventilated lung (= V/Q mismatch)
◊ A normal perfusion scan excludes PE for practical purposes

Rationale for Adding Ventilation Scan & Chest X-ray

◊ A perfusion defect requires further evaluation with a ventilation scan + CXR to determine the most likely etiology
◊ If ventilation scan + CXR are normal an embolus must be suspected
◊ A ventilation scan detects obstructive lung disease because a CXR is insensitive for this entity.

Terminology:

Nonsegmental	=	does not conform to a lung segment (eg, enlarged hilar structures / aorta, small pleural effusion, elevated hemidiaphragm, cardiomegaly)
Subsegmental	=	involves 26–75% of a known bronchopulmonary segment
Segmental	=	involves > 75% of a known bronchopulmonary segment
V/Q match	=	area of abnormal ventilation identical to perfusion defect in size, shape, a location
Triple match	=	matched ventilation-perfusion defect with an associated matching area of increased opacity on CXR

V/Q mismatch = normal ventilation / normal CXR in region of perfusion defect or perfusio defect larger than ventilation defect / CXR abnormality

Reverse mismatch = area with better perfusion than ventilation suggestive of non-thromboemb cause

Interpretation: refer to Biello or PIOPED (Prospective Investigation of Pulmonary Embolism Diagnosis) criteria

Interpretive algorithm:

√ no perfusion defect

Diagnosis: normal

Interpretation: no PE

√ perfusion defect WITHOUT lung disease (= normal ventilation + normal CXR = V/Q mismatch)

Diagnosis: PE

Interpretation: high probability for PE; > 1 perfusion defect is necessary to increase certainty

√ perfusion defect WITH lung disease:

(a) ventilation abnormality + clear CXR:

Diagnosis: COPD

Interpretation: low probability for PE

◊ COPD does not diminish usefulness of V/Q scan, but increases likelihood of an indeterminate result!

(b) absent ventilation + consolidation on CXR:

Diagnosis: pneumonia, pulmonary embolism with infarction, segmental atelectasis

√ perfusion defect larger than CXR opacity

Interpretation: high probability for PE

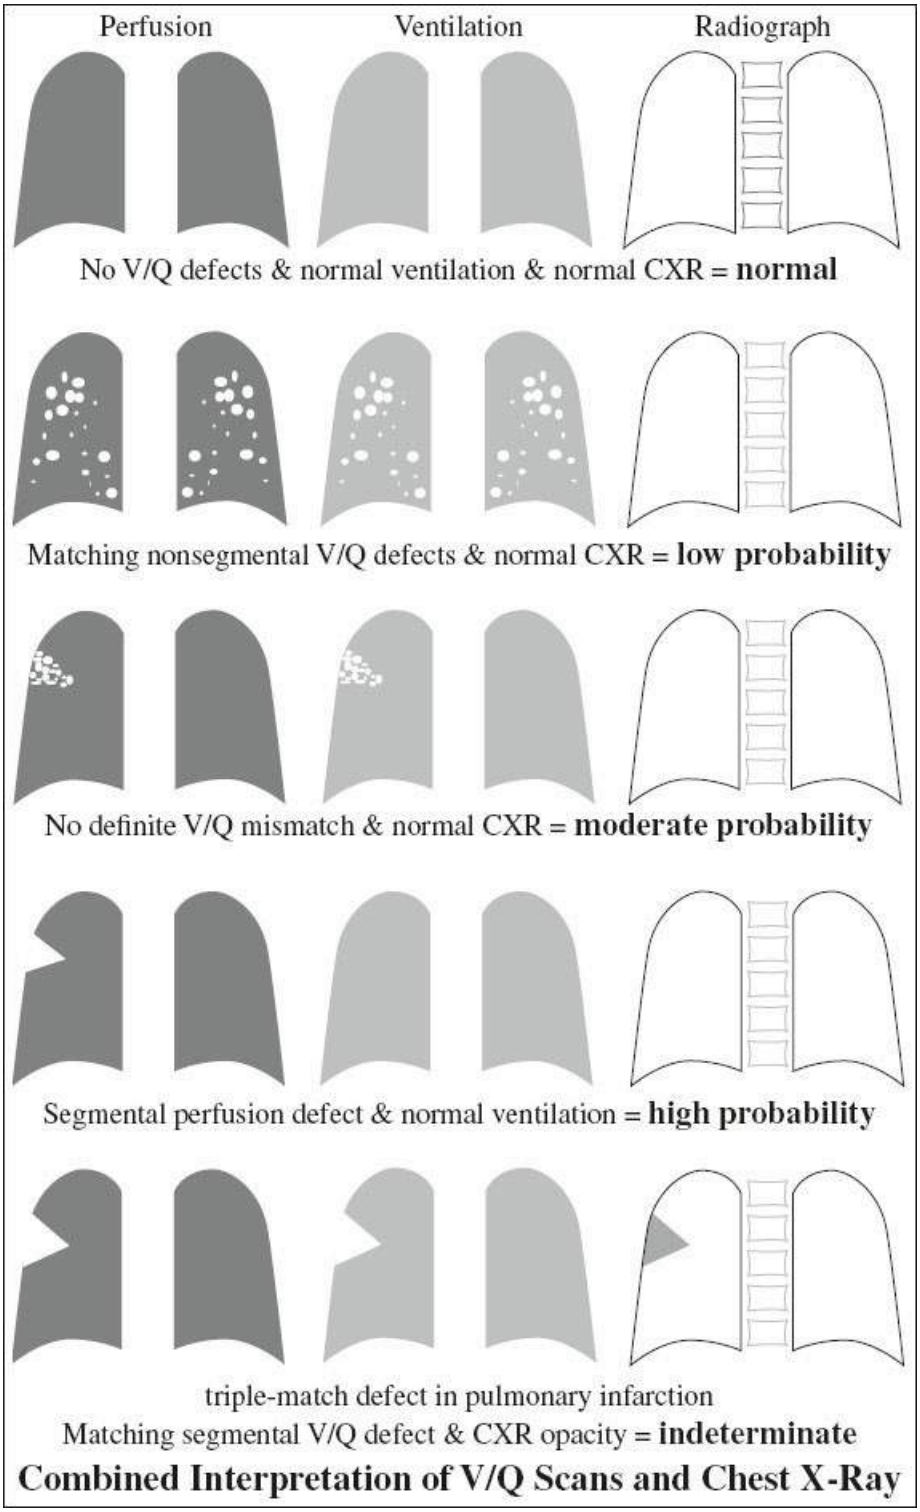
√ perfusion defect substantially smaller than opacity

Interpretation: low probability for PE

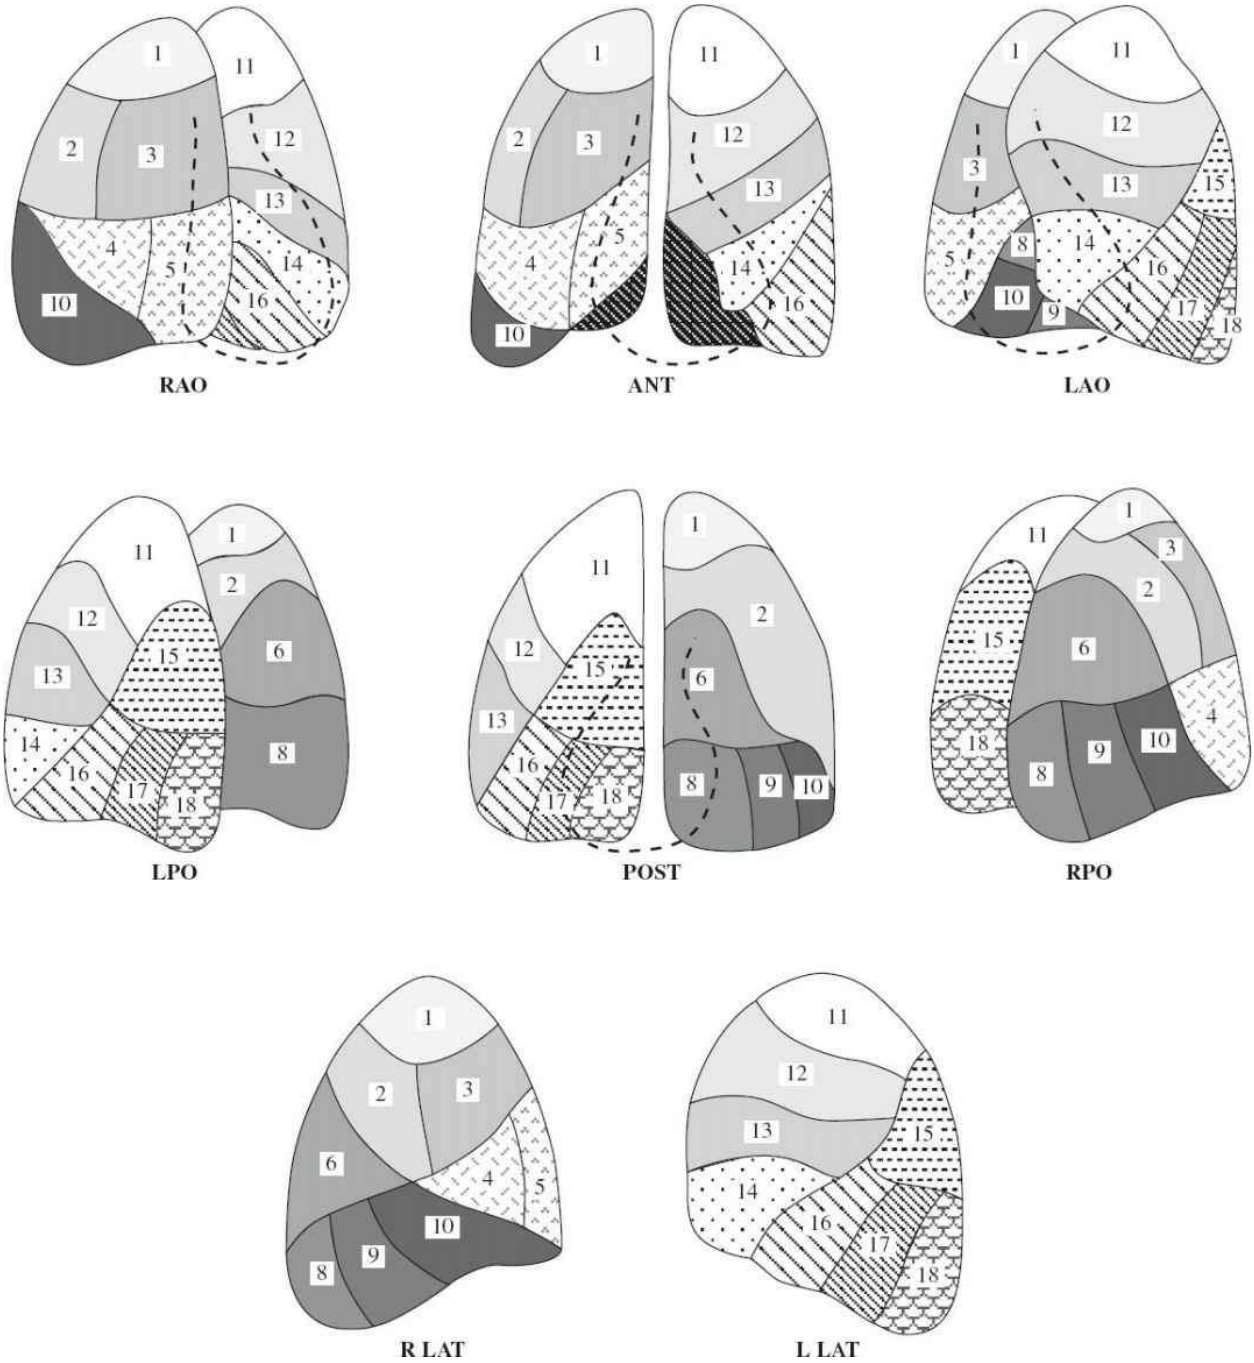
√ perfusion defect of comparable size

Interpretation: intermediate probability

√ "stripe" sign = rim of preserved peripheral activity around a perfusion defect usually indicates



Perfusion
Ventilation
Radiograph
No V/Q defects & normal ventilation & normal CXR = normal
Matching nonsegmental V/Q defects & normal CXR = low probability
No definite V/Q mismatch & normal CXR = moderate probability
Segmental perfusion defect & normal ventilation = high probability
triple-match defect in pulmonary infarction
Matching segmental V/Q defect & CXR opacity = indeterminate
Combined Interpretation of V/Q Scans and Chest X-Ray



RUL		RML		RLL		LUL		LLL	
1	apical	4	lateral	6	superior	11	apicoposterior	15	superior
2	posterior	5	medial	7	mediobasal	12	anterior	16	anteromedial basal
3	anterior			8	posterobasal	13	superior lingual	17	laterobasal
				9	laterobasal	14	inferior lingual	18	posterobasal
				10	anterobasal				

Correlation between V/Q Scan and Chest X-Ray (CXR should be taken within 6–12 hours of scan)	
CXR Category	*Nondiagnostic V/Q Scan*
No acute abnormality	12%
Linear atelectasis	12%
Pulmonary edema	12%
Pleural effusion	36%
Parenchymal consolidation	82%

Criteria for Very Low Probability Interpretation of V/Q Lung Scans (< 10% PPV for thromboembolism)	
Criterion	*PPV*
√ nonsegmental perfusion abnormality	8%
√ perfusion defect smaller than corresponding radiographic defect	8%
√ stripe sign	7%
√ triple matched defect in upper / middle lung zone	4%
√ matched ventilation-perfusion defects in 2 / 3 zones of a single lung + normal CXR	3%
√ 1 to 3 small segmental perfusion defects	1%

Study Results of Prospective Investigation of Pulmonary Embolism Diagnosis (PIOPED)		
Probability of PE	*in*	*Angiogram Positive in*
High	13%	88%
Intermediate	39%	33%
Low	34%	16%
Normal	14%	9%

Probability Estimate for Pulmonary Thromboembolism	
indeterminate	lungs cannot be adequately evaluated due to underlying consolidation / obstructive disease; impossible to give a probability estimate
high	> 85% (more than one segmental mismatch) → 12% normal angiogram!
intermediate	~ 30% = perfusion abnormality falling short of diagnostic confidence for PE (eg, single segmental mismatch)
low	< 15%
normal	< 1%
N.B.:	low- / intermediate-probability scans are diagnosed in 50–70% of all V/Q scans with disagreement between expert readers in 25–30% → recommendation of additional studies (but only 12–14% will undergo angiography)

Effect of Clinical Probability for PE on Presence of PE		
V/Q scan	*Clinical Probability*	*PE Present*
High-probability	> 80%	96%
Low-probability	< 20%	4%
Indeterminate	DVT present	93%

Indeterminate V/Q Lung Scans	
Criterion	*PPV*
√ Q defect << CXR consolidation	14%
√ Q defect equal to CXR	26%
√ Q defect >> CXR consolidation	89%

Interpretation Criteria for V/Q Lung Scans		
Probability of PE	*Modified Biello Criteria*	*Modified PIOPED Criteria*
Normal	√ normal perfusion	√ normal perfusion
Low (0–19%)	√ small (< 25% segment) V/Q mismatches	√ small perfusion defects regardless of number / ventilation scan finding / CXR finding
	√ focal V/Q matches without corresponding CXR consolidation	√ perfusion defect substantially smaller than CXR abnormality; ventilation findings irrelevant
	√ perfusion defects substantially smaller than CXR abnormality	√ V/Q match in ≤ 50% of one lung / ≤ 75% of upper / mid / lower lung zone; CXR normal / nearly normal
		√ single moderate perfusion defect with normal CXR; ventilation findings irrelevant
		√ nonsegmental perfusion defects
Indeterminate Intermediate (25 – 50%)	√ severe COPD with perfusion defects	√ 1 large (segmental) ± 1 moderate (subsegmental) V/Q mismatch
	√ perfusion defect with corresponding CXR consolidation	√ 1–3 moderate (subsegmental) V/Q mismatches
	√ single moderate / large V/Q mismatch without corresponding CXR abnormality	√ 1 matched V/Q with normal CXR
High (> 85%)	√ perfusion defects substantially larger than CXR abnormalities	√ ≥ 2 large (segmental) perfusion defects without match
	√ ≥ 2 moderate (25–90% segment) / ≥ 2 large (> 90% segment) V/Q mismatches; no corresponding CXR abnormality	√ > 2 large (segmental) perfusion defects substantially larger than matching ventilation / CXR abnormality
		√ ≥ 2 moderate (subsegmental) + 1 large (segmental) perfusion defect without match
		√ ≥ 4 moderate (subsegmental) perfusion defects; ventilation + CXR findings normal

(a) nonembolic cause
(b) old / resolving pulmonary embolism

√ focal lung opacity:
√ not ventilated + not perfused = "indeterminate scan"
√ not changed > 1 week + not ventilated + not perfused = low probability for PE

N.B.: With a lung opacity, evaluate well-aerated areas for perfusion defects!

◊ 75% of patients with pulmonary edema + without pulmonary embolism have a normal perfusion scan!

Effect of a priori suspicion for pulmonary embolus:

› increased in patients with risk factors (immobilization, recent surgery, known hypercoagulable state, malignancy, previous pulmonary embolus, DVT, estrogen therapy)

› incidence of PE for a low probability scan increases from 15% to 40% in patients with a high clinical risk!

Therapeutic implications:

(a) high probability scan : treat for PE
(b) indeterminate scan : pulmonary angiogram
(c) low probability scan : consider other diagnosis, unless clinical suspicion very high

Overall accuracy:

68% for perfusion scan only
84% for ventilation-perfusion scan

◊ 100% sensitivity in detection of PE ← occurrence of multiple emboli (usually > 6–8), at least one of which causes a perfusion defect!
◊ A normal perfusion scan virtually excludes PE!
◊ In an individual < 45 years of age a subsegmental perfusion defect + pleuritic chest pain in the same region is indicative of pulmonary embolism in 77%! (DDx: idiopathic / viral pleurisy)
◊ 73–82% of patients have equivocal perfusion scans (ie, low and intermediate probability)!
◊ Interobserver variability for intermediate- and low-probability scans is 30%!

False-positive scans: nonthrombotic emboli, IV drug abuse, vasculitis, redistribution of flow, acute asthma (due to mucus plugging)

False-negative scans: saddle embolus

Temporal Resolution of V/Q Scan

N.B.: V/Q abnormalities vary over time ← autoregulation (hypoxic vasoconstriction, hypercapneic bronchoconstriction) and resolution

(1) Abnormality resolves within weeks / months (in most)
(2) Abnormality may last permanently

◊ Baseline study necessary to detect new emboli!

Characteristic V/Q Pattern of Nonthromboembolic Disease

1. Reverse mismatch
   Cause: mucus plugging, atelectasis
   Associated with: functional venous-to-systemic shunt contributing to hypoxemia
2. Matched perfusion-ventilation defect
   Cause: chronic obstructive pulmonary disease, asthma exacerbation
3. Peripheral perfusion defects of microembolic disease
   Cause: fat / amniotic fluid / tumor cell emboli

Cause of Unilateral Lung Perfusion

Frequency: 2%

A. PULMONARY EMBOLISM (23%)
B. AIRWAY DISEASE
   (a) Unilateral pleural / parenchymal disease (23%)
   (b) Bronchial obstruction

1. Bronchogenic carcinoma (23%)
2. Bronchial adenoma
3. Aspirated endobronchial foreign body

C. CONGENITAL HEART DISEASE (15%)

D. ARTERIAL DISEASE
1. Swyer-James syndrome (8%)
2. Congenital pulmonary artery hypoplasia / stenosis
3. Shunt procedure to pulmonary artery (eg, Blalock-Taussig)

E. ABSENCE OF LUNG
1. Pneumonectomy (8%)
2. Unilateral pulmonary agenesis

mnemonic: SAFE POEM
Swyer-James syndrome
Agenesis (pulmonary)
Fibrosis (mediastinal)
Effusion (pleural)
Pneumonectomy, **P**neumothorax
Obstruction by tumor
Embolus (pulmonary)
Mucous plug

Cause of Perfusion Defect

A. VASCULAR DISEASE
(a) Acute / previous pulmonary embolus
1. Pulmonary thromboembolic disease
2. Fat embolism
√ nonsegmental perfusion defect
3. Air embolism
√ characteristic decortication appearance in uppermost portion on perfusion scintigraphy
4. Embolus of tumor / cotton wool / balloon for occlusion of AVM / obstruction by Swan-Ganz catheter, other foreign body
5. Dirofilaria immitis (dog heartworm): clumps of heartworms break off cardiac wall + embolize pulmonary arterial tree
6. Sickle cell disease

(b) Vasculitis
1. Collagen vascular disease: sarcoidosis
2. IV drug abuse
3. Previous radiation therapy:
√ defect localized to radiation port
4. Tuberculosis

(c) Vascular compression
1. Bronchogenic carcinoma:
√ perfusion defect depending on tumor size + location
2. Lymphoma / lymph node enlargement

3. Pulmonary artery sarcoma
4. Fibrosing mediastinitis ← histoplasmosis
5. Idiopathic pulmonary fibrosis:
   √ small subsegmental defects in both lungs
6. Aortic aneurysm (large saccular / dissecting)
7. Intrathoracic stomach

(d) Altered pulmonary circulation

1. Absence / hypoplasia of pulmonary artery
2. Peripheral pulmonary artery stenosis
3. Bronchopulmonary sequestration
4. Primary pulmonary hypertension
   √ upward redistribution + large hilar defects
   √ multiple small peripheral perfusion defects
5. Pulmonary venoocclusive disease
6. Mitral valve disease
   √ predilection for right middle lobe + superior segments of lower lobes
7. Congestive heart failure
   √ diffuse nonsegmental V/Q mismatch
   √ enlargement of cardiac silhouette + perihilar regions
   √ reversed distribution: more activity anteriorly than posteriorly
   √ accentuation of fissures
   √ flattening of posterior margins of lung (lateral view)
   √ pleural effusion

B. AIRWAY DISEASE

◊ Nearly all pulmonary disease produces decreased pulmonary blood flow to affected lung zones = autoregulatory reflexive vasoconstriction!

1. Asthma, chronic bronchitis, bronchospasm, mucus plugging
2. Bronchiectasis (bronchiolar destruction)
3. Emphysema (bulla / cyst)
4. Pneumonia / lung abscess
5. Lymphangitic carcinomatosis

√ perfusion defects in area of hypoxia
√ abnormal ventilation to a similar / more severe degree
√ mostly multiple nonanatomic defects (in 20%)

Tumor Embolism

◊ Diagnosis frequently missed until postmortem exam!

Frequency: 2–26% of patients with known malignancy

Primary: gastric carcinoma (most common), breast, liver, kidney, prostate, lung, ovarian, osteosarcoma, lymphoma, choriocarcinoma

◊ Right atrial myxoma + RCC tend to embolize to large central + segmental pulmonary arteries!

Pathogenesis: tumor cells form emboli in vena cava subsequently occlude small muscular pulmonary arteries + arterioles

Histo: intravascular malignant cells, acute and organizing platelet-fibrin thrombi, small

artery intimal fibrosis, adjacent intralymphatic tumor

- progressive dyspnea, cough, pleuritic chest pain
- hemoptysis, syncope; hypoxemia < 50 mmHg

CXR:

√ enlarged central pulmonary arteries
√ cardiomegaly
√ ill-defined nodular / confluent peripheral parenchymal opacities (with multiple pulmonary infarcts)
√ focal / diffuse heterogeneous opacities = lymphangitic carcinomatosis

CT:

√ subpleural linear + wedge-shaped opacities (at sites of pulmonary infarctions)
√ companion manifestations: lymphadenopathy, pulmonary venous hypertension, lymphangitic carcinomatosis:
  √ multifocal dilatation / beading of vessels
  √ thickening of interlobular septa
√ tree-in-bud pattern ← filling of centrilobular arteries with tumor cells / carcinomatous endarteritis ← fibrocellular intimal hyperplasia initiated by tumor microemboli

CECT:

√ filling defects in main pulmonary artery branches
√ multifocal beading + dilatation of subsegmental pulmonary arteries

NUC (V/Q scan):

√ multiple small subsegmental unmatched perfusion defects

Angio:

√ delayed arterial phase
√ filling defects / occlusions of subsegmental arterial branches
√ arterial wall irregularities
√ peripheral pruning of smaller arteries

Cx: subacute cor pulmonale (heralds death within 4–12 weeks)

Mercury Embolism

Cause: accidental / suicidal IV injection

Pathomechanism: intravascular mercury becomes encased in thrombus or migrates into pulmonary interstitium / alveolar spaces resulting in significant granulomatous response

√ high-density fine-caliber branching structures in symmetric distribution
√ mercury collection within apex of right ventricle

PULMONARY VENO-OCCLUSIVE DISEASE

= fibrous narrowing / occlusion of pulmonary venules + small veins; the postcapillary counterpart of primary pulmonary arterial hypertension

Pulmonary veno-occlusive disease may develop fatal pulmonary edema if treated with vasodilators!

Prevalence: 01.–0.2 per 1,000,000 persons

Age: < 20 years in 30–50% (range, 9 days to 70 years); M÷F = 1÷1

Cause: idiopathic (rare condition); venous thrombosis initiated by infection / toxic exposure /

immune complex deposition

May be associated with:

pregnancy, transplantation, drug toxicity (carmustine, bleomycin, mitomycin)

Hemodynamics:

- ↑ pressure in right atrium + pulmonary artery (PAH)
- normal / low / variably elevated pulmonary capillary wedge pressure (PCWP); decreased cardiac output
- normal pressure in left atrium + left ventricle (excludes cardiac disease as the cause for venous hypertension)

Histo:

(a) specific changes: webs, recanalized thrombus (in up to 95%), intimal fibrosis with narrowing / occlusion of pulmonary veins of all sizes; "capillary hemangiomatosis" = sheets and nodular collections of thin-walled capillaries invading pulmonary arteries + veins + bronchioles + pleura

(b) nonspecific changes of venous hypertension: venous medial hypertrophy, edematous interlobular septa with dilated lymphatic spaces, paraseptal venous infarction, interstitial + pleural lymphatic dilatation, intraalveolar hemosiderin-laden macrophages; muscularized arterioles + medial hypertrophy of muscular pulmonary arteries

- progressive dyspnea and fatigue, hemoptysis, digital clubbing
- antecedent flulike symptoms; dry / productive chronic cough
- chest pain, syncope; episodes of acute pulmonary edema

CXR:

√ enlargement of main pulmonary artery (PAH)
√ prominent Kerley B lines
√ pulmonary veins of normal caliber
√ normal contours of LA + LV
√ ± pleural effusions
√ diffuse interstitial ± alveolar pulmonary edema:
  √ central and gravity-dependent parenchymal ground-glass attenuation
√ multifocal airspace consolidation ← parenchymal hemorrhage, pulmonary edema, pulmonary infarction
√ mediastinal lymphadenopathy ← vascular transformation of lymph node sinus with various degrees of sclerosis

CT:

√ markedly small central pulmonary veins
√ dilated central pulmonary arteries
√ smoothly thickened interlobular septa
√ peribronchovascular thickening
√ diffuse / geographic / mosaic / perihilar / patchy / centrilobular ground-glass opacity
√ right heart enlargement + normal-sized left atrium
√ pleural effusions

◊ The combination of signs of pulmonary arterial hypertension + interstitial / alveolar pulmonary edema is virtually DIAGNOSTIC of pulmonary venoocclusive disease!

NUC:

√ patchy distribution of ^{99m}Tc-MAA (of "upstream" pulmonary arterial hypertension)

Angio:

√ enlarged right ventricle + central pulmonary arteries

√ prolonged parenchymal phase enhancement

√ delayed filling of normal pulmonary veins

√ normal to small left atrium

Cx: potentially fatal pulmonary edema following administration of vasodilators for misdiagnosed presumed precapillary pulmonary hypertension

Dx: often missed initially (clinical presentation + radiographic findings mimic interstitial lung disease)

Prognosis: death within 3 years ← NO effective therapy

Rx: lung / heart-lung transplant (only curative option); supportive diuretics, anticholinesterase (ACE) inhibitors, cardiac glycosides (digoxin), oxygen supplementation, pulmonary vasodilators (calcium channel blockers, prostacyclin), immunosuppressive agents

PULMONARY VEIN VARIX

= abnormal tortuosity + focal dilatation of pulmonary vein just before entrance into left atrium

Etiology: congenital / associated with chronic pulmonary venous hypertension or mitral valve disease

• usually asymptomatic

• hemoptysis ← rupture / thromboembolic disease

Location: medial ⅓ of either lung below hila close to left atrium

√ well-defined lobulated round / oval mass without Ca2+

√ change in size during Valsalva / Müller maneuver

√ opacification at same time as LA (on CECT)

Risk: (1) Death upon rupture during worsening heart failure

(2) Source of cerebral emboli

DDx: pulmonary arteriovenous malformation, pulmonary nodule, hilar lymphadenopathy

RADIATION PNEUMONITIS

= damage to lungs after radiation therapy depends on:

(a) irradiated lung volume (most important):

• asymptomatic in < 25% of lung volume

(b) radiation dose (almost always exceeds critical value for tumoricidal doses):

› pneumonitis unusual if < 20 Gy given in 2–3 weeks

› pneumonitis common if > 60 Gy given in 5–6 weeks

› significantly increased risk for pneumonitis if daily dose fraction > 2.67 Gy

(c) fractionation of dose

(d) concurrent / later chemotherapy

Pathologic phases:

(1) Exudative phase = edema fluid + hyaline membranes

(2) Organizing / proliferative phase

(3) Fibrotic phase = interstitial fibrosis

Time of onset: usually 4–6 months after treatment

Location: confined to radiation portals

Acute Radiation Pneumonitis

Onset: within 4–8 (range, 1–12) weeks after radiation Rx
Path: depletion of surfactant (1 week to 1 month later), plasma exudation, desquamation of alveolar + bronchial cells
• asymptomatic (majority), acute respiratory failure (rare)
• nonproductive cough, shortness of breath, weakness, fever (insidious onset)
√ changes usually within portal entry fields
√ patchy / confluent consolidation, may persist up to 1 month (exudative reaction)
√ atelectasis + air bronchogram
√ spontaneous pneumothorax (rare)
CT:
√ mild hazy homogeneous increase in attenuation obscuring vessel outlines (2–4 months after Rx)
√ coalescing patchy consolidations (1–12 months after therapy) not conforming to shape of portals
√ nonuniform discrete consolidation (most common; 3 months to 10 years after therapy) forming sharp edges and conforming to treatment portals
Prognosis: recovery / progression to death / fibrosis
Rx: steroids

Chronic Radiation Pneumonitis

Onset: 9–12 (range, 6–24) months after radiation therapy; stabilized by 1–2 years after therapy
Histo: permanent damage of endothelial + type I alveolar cells
May be associated with:
(1) Thymic cyst
(2) Calcified lymph nodes (in Hodgkin disease)
(3) Pericarditis + effusion (within 3 years)
√ severe loss of volume
√ dense fibrous strands from hilum to periphery
√ thickening of pleura
√ pericardial effusion
CT:
√ solid consolidation with parenchymal distortion ← radiation fibrosis + atelectasis
√ traction bronchiectasis
√ mediastinal shift
√ pleural thickening

RESPIRATORY DISTRESS SYNDROME OF NEWBORN

= RDS = SURFACTANT DEFICIENCY DISORDER = HYALINE MEMBRANE DISEASE
= acute pulmonary disorder characterized by generalized atelectasis, intrapulmonary shunting, ventilation-perfusion abnormalities, reduced lung compliance
Frequency: 6÷1,000 neonates (in 2002); M÷F = 1.8÷1

Cause: relative lack of mature type II pneumocytes → deficiency of endogenous surfactant (production usually begins at 18–20 weeks of gestational age) → increased alveolar surface tension + decreased alveolar distensibility → acinar atelectasis (persistent collapse of alveoli) + dilatation of terminal airways

Histo: uniformly collapsed alveoli + variable distension of alveolar ducts + terminal bronchioles; lined by fibrin ("hyaline membranes") ← protein seepage from damaged hypoxic capillaries

Predisposed: perinatal asphyxia; maternal / fetal hemorrhage, term infants of diabetic mothers, multiple gestations, premature infants (< 1,000 g in 66%; 1,000 g in 50%; 1,500 g in 16%; 2,000 g in 5%; 2,500 g in 1%)

Onset: < 2–5 hours after birth, increasing in severity from 24–48 hours, gradual improvement after 48–72 hours

- nonspecific tachypnea, nasal flaring
- expiratory grunting (expiratory breathing against a partially closed glottis to augment alveolar distension)
- circumoral cyanosis (carbon dioxide retention)
- substernal + intercostal retraction of chest wall

√ decreased lung expansion (counteracted by respirator therapy)

√ symmetric generalized consolidation of variable severity:

- √ complete "white out" of lung
- √ diffuse reticulogranular texture (coincides with onset of clinical signs, maximum severity at 12–24 hours of life) = summation of collapsed alveoli, transudation of fluid into interstitium, air distension of terminal bronchioles + alveolar ducts
- √ evolving hazy opacities to clearing over several days

√ effacement of normal pulmonary vessels

√ prominent air bronchograms (distension of compliant airways)

Prognosis: spontaneous clearing within 7–10 days (mild course in untreated survivors); death in 18%

Rx:
(1) Antenatal maternal corticosteroid therapy
(2) Surfactant replacement therapy (liquid bolus of exogenous surfactant delivered into tracheobronchial tree
(3) Nasal continuous positive airway pressure (CPAP)
(4) High-frequency oscillatory ventilation (HFOV)
(5) Extracorporeal membrane oxygenation (ECMO)

DDx:
(1) Diffuse pneumonia accompanying sepsis
(2) Retained fetal lung fluid (first few hours)
(3) Pulmonary hemorrhage
(4) Pulmonary venous congestion (eg, TAPVR, pulmonary vein atresia, hypoplastic left heart)
(5) Premature with accelerated lung maturity (PALM baby)

Causes of Asymmetric Clearing after Surfactant

(a) maldistribution of surfactant into right mainstem bronchus
(b) insufficient surfactant requiring additional application
(c) regional differences in aeration before surfactant treatment

DDx: neonatal pneumonia, meconium aspiration, unilateral tension pneumothorax, hemorrhagic pulmonary edema

Acute & Subacute Complications of RDS

(a) persistent patency of ductus arteriosus (PDA) with oxygen stimulus missing to close duct; gradual ↓ in pulmonary resistance (by end of 1st week) → significant L-to-R shunt
(b) barotrauma with air-block phenomena
(c) hemorrhage
    1. Pulmonary hemorrhage
    2. Cerebral hemorrhage
(d) focal atelectasis (usually from mucus plug)
(e) persisting fetal circulation
(f) myocardial ischemia
(g) diffuse opacity
    1. Worsening RDS (first 1–2 days only)
    2. Congestive heart failure (PDA, fluid overload)
    3. Pulmonary hemorrhage
    4. Superimposed pneumonitis
    5. Massive aspiration
    6. Stage II bronchopulmonary dysplasia
    7. "Weaning effect" from removal of endotracheal tube / diminished ventilator pressure
    8. Extracorporeal membrane oxygenation
(h) disseminated intravascular coagulopathy
(i) necrotizing enterocolitis
(j) acute renal failure
(k) metabolic disturbance (eg, hyperbilirubinemia, hypocalcemia)

Chronic Complications of RDS

1. Bronchopulmonary dysplasia (10–20%)
2. Subglottic stenosis (intubation)
3. Localized interstitial emphysema
4. Hyperinflation
5. Retrolental fibroplasia
6. Malnutrition, rickets
7. Lobar emphysema
8. Delayed onset of diaphragmatic hernia
9. Recurrent inspiratory tract infections

Complication of Continuous Positive Pressure Ventilation

Cause: airway overdistension (**volutrauma**) rather than high airway pressure (**barotrauma**)
Path:
(a) rupture of alveoli along margins of interlobular septa + vascular structures (= parenchymal pseudocyst)
(b) air dissecting along interlobular septa + perivascular spaces = pulmonary interstitial emphysema (PIE)

√ "pseudoclearing" of RDS

(c) interstitial air migrating centripetally into pleural space (= pneumothorax) / mediastinum (= pneumomediastinum) / pericardial cavity (= pneumopericardium)

(d) interstitial air rupturing into peritoneal space (= pneumoperitoneum) / retroperitoneal space (= pneumoretroperitoneum)

(e) air dissecting into skin (= subcutaneous emphysema)

(f) air rupturing into vessel (= gas embolism)

√ streaky / mottled lucencies radiating from hila without branching / tapering often outlining bronchovascular bundles (DDx: air bronchogram)

√ large subpleural cysts without definable wall usually at diaphragmatic + mediastinal surface compressing adjacent lung

√ pneumothorax (in up to 25%)

Rx: mechanical ventilatory assistance with positive end-expiratory pressure (to increase oxygen diffusion)

RETAINED FETAL LUNG FLUID

= NEONATAL WET LUNG DISEASE = TRANSIENT RESPIRATORY DISTRESS OF THE NEWBORN = TRANSIENT TACHYPNEA OF THE NEWBORN

Frequency: 6%; most common cause of respiratory distress in newborn

Cause: cesarean section, precipitous delivery, breech delivery, prematurity, maternal diabetes

Pathophysiology:

delayed resorption of fetal lung fluid (normal clearance occurs through capillaries (40%), lymphatics (30%), thoracic compression during vaginal delivery (30%); stiff lungs cause labored ventilation until fluid is cleared

Onset: within 6 hours of life; peaks at 1st day of life

- increasing respiratory rates during first 2–6 hours of life
- intercostal + sternal retraction
- normal blood gases during hyperoxygenation

√ linear opacities + perivascular haze + thickened fissures + interlobular septal thickening (interstitial edema):

√ symmetric perihilar radiating congestion

√ mild hyperaeration

√ mild cardiomegaly

√ small amount of pleural fluid

Prognosis: resolving within 1–2–4 days (retrospective Dx)

DDx: (1) Normal (during first several hours of life)

(2) Diffuse pneumonitis / sepsis

(3) Mild meconium aspiration syndrome

(4) Alveolar phase of RDS

(5) "Drowned newborn syndrome" = clear amniotic fluid aspiration

(6) Pulmonary venous congestion (eg, left heart failure, overhydration, placental transfusion)

(7) Pulmonary hemorrhage

(8) Hyperviscosity syndrome = thick blood

(9) Immature lung syndrome = premature with accelerated lung maturity (PALM baby)

RHEUMATOID LUNG

= autoimmune disease of unknown pathogenesis

Frequency: 2–54% of patients with rheumatoid arthritis; M÷F = 5÷1 (although incidence of rheumatoid arthritis: M÷F = 1÷3)

◊ Lung disease is 2nd most common cause of death after infection!

• rheumatoid arthritis

Stage 1: multifocal ill-defined alveolar infiltrates

Stage 2: fine interstitial reticulations (histio- and lymphocytes)

Stage 3: honeycombing

A. PLEURAL DISEASE (38–73%)

◊ Most frequent thoracic manifestation!

◊ NOT related to pulmonary disease!

• history of pleurisy (21%)

Associated with: pericarditis, subcutaneous nodules

◊ Usually late in the disease, but may antedate rheumatoid arthritis

• exudate (with protein content > 4 g/dL)

• low in sugar content (< 30 mg/dL) without rise during glucose infusion (75%); low WBC high in lymphocytes

• positive for rheumatoid factor, LDH, RA cells

√ pleural thickening, usually bilateral

√ pleural effusion (3–5%) with little change for months:

√ unilateral (92%), usually small, may be loculated

√ tendency to resolve spontaneously

√ usually not associated with parenchymal disease

B. BRONCHIAL ABNORMALITIES

√ cystic bronchiectasis on HRCT (30%)

√ bronchiolitis obliterans (may be transient regardless of penicillamine / gold therapy):

√ mosaic pattern (= areas of decreased attenuation + vascularity ← air trapping in small airways) on end-expiratory HRCT

√ bronchiolitis obliterans organizing pneumonia (BOOP):

√ bilateral air-space consolidation in peripheral / peribronchial distribution

√ follicular bronchiolitis (in 66%):

Histo: hyperplasia of peribronchial + peribronchiolar lymphatic follicles

√ multiple small centrilobular nodules with patchy areas of ground-glass attenuation

C. DIFFUSE INTERSTITIAL FIBROSIS

Prevalence: 2–5–9% of patients with rheumatoid arthritis

• restrictive ventilatory defect

Location: lower lobe predominance

Histo: deposition of IgM in alveolar septa (DDx to IPF)

Patterns: UIP > NSIP, cryptogenic organizing pneumonia, follicular bronchiolitis, bronchiolitis obliterans

√ punctate / nodular densities (mononuclear cell infiltrates in early stage)

√ reticulonodular densities
√ medium to coarse reticular opacities (mature fibrous tissue in later stage):
  √ irregular interlobular septal thickening on HRCT, predominantly in periphery of lower lung zones
  √ traction bronchiectasis
√ honeycomb lung (uncommon in late stage)
√ architectural distortion + progressive lower-lobe volume loss (advanced disease)
√ ± groundglass opacities (less extensive / impressive)

D. NECROBIOTIC (RHEUMATOID) NODULES (rare)
= well-circumscribed nodular mass in lung, pleura, pericardium identical to subcutaneous nodules associated with advanced rheumatoid arthritis
Path: central zone of eosinophilic fibrinoid necrosis surrounded by palisading fibroblasts; nodule often centered on necrotic inflamed blood vessel (? vasculitis as initial lesion)
M > F
• subcutaneous nodules (same histology)
• frequently seen in smokers with subcutaneous nodules + high rheumatoid factor titers
• may arise before manifestation of rheumatoid arthritis
Associated with: interstitial lung disease
Distribution: commonly in lung periphery of upper and middle lung regions
Size: 3–70 mm
√ usually multiple well-circumscribed nodules
√ may increase in size / resolve spontaneously
√ new ones may arise while older ones resolve
√ ± cavitation with thick symmetric walls + smooth inner lining (in 50%)
√ ± central calcification (very rare)
Cx: rupture into pleural space: pneumothorax, pleural effusion, empyema

E. CAPLAN SYNDROME
= RHEUMATOID PNEUMOCONIOSIS SYNDROME
= hyperimmune reactivity to irritating silica inhalation (of coal workers with rheumatoid arthritis)
Frequency: 2–6% of all men affected by pneumoconioses (exclusively in Wales)
Path: disintegrating macrophages deposit a pigmented ring of dust surrounding the central necrotic core + zone of fibroblasts palisading the zone of necrosis
◊ NOT necessarily evidence of long-standing pneumoconiosis
• concomitant with joint manifestation (most frequent) / may precede arthritis by several years
• concomitant with systemic rheumatoid nodules
√ rapidly developing well-defined nodules of 5–50 mm in size with a tendency to appear in crops predominantly in upper lobes + in periphery of lung
√ nodules may remain unchanged / increase in number / calcify / result in thick-walled cavities
√ background of pneumoconiosis
√ pleural effusion (may occur)

F. PULMONARY ARTERITIS
= fibroelastoid intimal proliferation of pulmonary arteries
• pulmonary arterial hypertension + cor pulmonale

G. CARDIAC ENLARGEMENT
(pericarditis + carditis / congestive heart failure)

H. BONE ABNORMALITIES ON CXR
√ erosive arthritis of acromioclavicular joint, sternoclavicular joint, shoulder joint:
√ resorption of distal end of clavicles
√ ankylosis of vertebral facet joints
√ vertebral body collapse ← steroid use
√ cricoarytenoid arthritis (frequently overlooked!)
• foreign body sensation, soreness / fullness in throat, hoarseness, dyspnea, pain radiating into ears, stridor, dysphagia, odynophagia, pain with speech

I. DRUG-INDUCED LUNG DISEASE
Gold, penicillamine: diffuse alveolar damage, obliterative bronchiolitis
Methotrexate: pneumonitis

SARCOIDOSIS

= BOECK SARCOID [*sarkos*, Greek = flesh; *sarcoid* = sarcoma-like]
[Caesar Peter Möller Boeck (1845–1917), Norwegian dermatologist describes skin lesions in 1899]

= immunologically mediated multisystem granulomatous disease of unknown etiology with variable presentation, progression and prognosis characterized by noncaseating nonnecrotic epitheloid cell granulomas

Bilateral hilar lymphadenopathy is the most common radiologic finding. Adenopathy in the right paratracheal nodes, left aortic-pulmonary window, and subcarinal nodes can also be seen, often with associated pulmonary infiltrates.

Prevalence: 10–48÷100,000 in USA in 2010 (highest in African-Americans, Swedes, Danes); Blacks÷Whites in USA = 3÷1 to 10÷1 (rare in African / South American Blacks); more common in blood group A

Age peak: 20–40 years; M÷F = 1÷3

Epidemiology: found with varying frequency in every country in the world; prevalence higher in temperate climates than tropical regions (< 10÷100,000)

Immunology:
unknown environmental antigen(s) activate <u>alveolar macrophages</u> in a genetically susceptibel host releasing
› interleukin-1 (T-cell activator)
› fibronectin (fibroblast chemotactic factor)
› alveolar macrophage-derived growth factor (stimulates fibrosis)
and activate <u>T-lymphocytes</u> releasing
› interleukin-2 (stimulates growth of T-helper / cytolytic cells)
› immune interferon (polyclonal B-cell activator)
› monocyte chemotactic factor (attracts circulating monocytes and stimulates granuloma formation)

Path: (a) acute phase: lymphocytes + scattered macrophage giant cells + small granulomas
(b) intermediate phase: well=formed granulomas + minimal scarring
(c) late phase: predominant fibrosis + few granulomas + chronic inflammation

Histo: noncaseous granulomas composed of central core (histiocytes, epitheloid cells, multinucleated giant cells) surrounded by lymphocytes, scattered plasma cells, fibroblasts and collagen; occasional minimal central coagulative necrosis

DDx: indistinguishable from granulomas of berylliosis, treated TB, leprosy, fungal disease, hypersensitivity pneumonitis, Crohn disease, primary biliary cirrhosis

Laboratory:

- **angiotensin-converting enzyme** (ACE) elevated in 70% (ACE is a product of macrophages and an indicator for the granuloma burden of the body)
  DDx: tuberculosis, leprosy, histoplasmosis, berylliosis, cirrhosis, hyperthyroidism, diabetes
- CD4÷CD8 ratio in blood serum commonly decreased
- hypercalcemia + hypercalciuria in 2–15% ← increased intestinal resorption of calcium ← hydroxylation of 1,25-dihydroxy vitamin D in macrophages
- Kveim-Siltzbach test (positive in 70%) = intracutaneous injection of 0.1–0.2 mL of a previously validated saline suspension of human sarcoid spleen / lymph nodes; no longer considered specific → rarely used
- functional pulmonary impairment (even with NO radiographic abnormality):
  (a) restrictive ventilatory defect
  › reduced VC + FRC + TLC ← generalized reduction in lung volume
  › low lung compliance ← diffuse interstitial disease
  (b) obstructive ventilatory defect (6%) ← endobronchial lesions / peribronchial fibrosis
- NO identification of infectious / inflammatory agent

Dx: based on a combination of clinical + radiological + histologic features after exclusion of other infectious / inflammatory entities

Diagnostic criteria:

(1) Compatible clinical + radiologic picture
(2) **Noncaseous epithelioid granulomas** on bronchial / transbronchial US-guided biopsy (diagnostic results in 60–95% and 80–95% respectively) or from extrapulmonary sites like cervical lymph nodes and liver
(3) Negative results of special stains / cultures for other entities

Assessment of activity:

(1) ACE titer (= angiotensin I converting enzyme)
(2) Bronchoalveolar lavage (BAL): 20–50% lymphocytes with T-suppressor lymphocytes 4–20 times above normal
(3) Gallium scan
√ uptake in lymph nodes + lung parenchyma + salivary glands (correlates with alveolitis + disease activity); monitor of therapeutic response (indicator of macrophage activity)
(4) PET
√ degree of FDG uptake correlates well with disease activity for monitoring response to therapy

Clinical Forms:

A. ACUTE FORM
- fever + malaise + arthralgia of large joints
- erythema nodosum; (occasionally) uveitis + parotitis

Löfgren Syndrome (17%)
= (1) erythema nodosum (2) periarticular ankle inflammation (3) mediastinal lymphadenopathy
Prognosis: self-limiting course with spontaneous resolution

B. CHRONIC FORM
= insidious onset (especially with involvement of lung or multiple extrapulmonary lesions) that may be followed by progressive fibrosis of lung and other organs
- asymptomatic (30–50%); fever, malaise, weight loss
- dry cough + shortness of breath (25%)
- hemoptysis in 4% (from endobronchial lesion / vascular erosion / cavitation)

Extrathoracic involvement (most commonly of skin and eyes) can be an initial manifestation in ½ of symptomatic patients.

Rx: inhaled / oral corticosteroids; immunosuppressive drugs (methotrexate, cyclophosphamide) with aggressive disease / frequent recurrence

Abdominal Sarcoidosis (30%)
- strikingly elevated ACE levels in 91%

Scattered hypoattenuating nodules involving liver and spleen suggest a diagnosis of sarcoidosis or lymphoma.

@ Liver (24–59%):
Prevalence: autoptic (50–80%), bioptic (24–59%)
√ mild homogeneous hepatomegaly (18–29%)
√ cirrhotic appearance (rare) ← diffuse granulomatous involvement along periportal tracts followed by fibrosis

CT:
√ scattered 2–5-mm hypoattenuating nodular lesions in liver (in 5–15%) ← coalescent granulomata occurring within 5 years of diagnosis
√ hypoenhancing lesions relative to background on early phase + minimal enhancement on delayed phase

MR:
√ heterogeneous nodular hepatic texture hypointense on all pulse sequences
√ lesions most conspicuous on fat-saturated T2WI

@ Spleen (pathologic involvement in 24–59%)
√ splenomegaly (20–33%)
√ scattered hypoattenuating nodular lesions (18%): more common + larger than in liver

@ Abdominal lymphadenopathy (10–31%)
- frequently associated with thoracic adenopathy

Location: mesenteric (periportal, perisplenic), retroperitoneal
Mean size: 2.6 cm
DDx: tumor-related sarcoid-like reaction = development of noncaseating granulomas in

treated malignancy

@ Pancreas

√ mass + pain mimicking pancreatic carcinoma

Cardiac Sarcoidosis (5%)

Frequency: 5% clinically, 20–50% at autopsy

1. Global / regional hypokinesis with systolic dysfunction → ↓ LV ejection fraction + ↑ end-diastolic LV diameter
2. Ventricular arrhythmia
3. Cardiomyopathy, congestive failure, angina

- may be asymptomatic throughout life
- CHF (25%) ← diffuse myocardial involvement
- cor pulmonale ← pulmonary hypertension
- conduction disturbances (in 23–30%): isolated bundle branch block to complete heart block
  - heart block (= CLASSIC clinical presentation)
- supraventricular + ventricular arrhythmias
- sudden cardiac death (in 12–65%) ← dysrhythmia

Distribution: basal portion of septum, LV wall

N.B.: rare in papillary muscle / RV

Echo (nonspecific):

√ wall motion abnormalities

√ thinning of basal septum

√ LV dilatation (30%)

CT:

√ cardiomegaly (25%)

√ pericardial effusion

√ ventricular aneurysm (10%)

MR (75–100% sensitive, 77–79% specific):

CAVE: often contraindicated ← cardiac pacemakers (unless device is MR compatible)

√ myocardial thickening

√ nodular / patchy areas of high SI on T2WI / SSFP (bright-blood steady-state free precession) ← edema

√ late gadolinium-induced enhancement (LGE) of myocardium ← expansion of extracellular space

Location:

(a) transmural

(b) nontransmural: subepi- / midmyocardial along basal or midventricular septum (in 67%)

DDx: ischemic heart disease (subendocardial distribution in vascular territory)

√ focal wall thinning + regional wall motion abnormalities ← myocardial fibrosis + scarring:

√ subepicardial > midmyocardial > subendocardial scars in random distribution

√ LV thinning with transmural involvement

NUC (^{99m}Tc, ^{201}Th SPECT, ^{82}Rb PET):

√ resting perfusion defects ← inflammation-induced tissue damage

PET (89% sensitive,78% specific):

N.B.: useful in patients with cardiac pacemakers!

√ increased FDG-uptake (SUV range, 2.5–15.8) in nonperivascular distribution ← active necrotizing granulomatous disease

also involvement of:

√ mediastinal + hilar lymph nodes (39%)

√ lung parenchymal nodules (15%) in peribronchovascular distribution

√ spleen, liver, muscle, salivary glands, subcutaneous tissue, bone (less frequent)

Cx: ventricular aneurysm, pericardial effusion

Dx: treatment-responsive cardiomyopathy, conduction defects at ECG, abnormal imaging findings, endomyocardial biopsy (on right side of heart)

Endomyocardial biopsy is rarely performed because of its diagnostic yield of only 20–50% and lack of information about cardiac distribution.

Rx: based on symptoms, ECG, imaging findings and disease course, rather than histologic confirmation

DDx: (1) Dilated cardiomyopathy (dilated LV with global dysfunction, linear stripe of LGE in ventricular septum)

(2) Hypertrophic cardiomyopathy (LV hypertrophy > 15 mm, scattered patchy midmyocardial involvement)

(3) Arrhythmogenic right ventricular cardiomyopathy (RV dilatation + dysfunction, fibrofatty infiltration of RV, dyskinetic free wall of RV + RV aneurysm)

(4) Myocarditis (patchy epicardial LGE in often inferolateral distribution, hyperemia)

(5) Amyloidosis (biventricular hypertrophy, global + diffuse LGE, LA enhancement, diffuse myocardial nulling abnormality)

Gastrointestinal Sarcoidosis (< 1%)

Location: anywhere from esophagus to rectum

@ Stomach (most common)

√ polypoid / nodular mass frequently in antrum

√ ± ulcer (simulating peptic ulcer disease)

√ diffuse fold thickening (mimicking Ménétrier disease)

√ circumferential narrowing + loss of antral compliance (resembling scirrhous carcinoma)

@ Colon (2nd most common)

√ plaque-like lesions / ulcers

√ fold thickening, focal nodularity

√ annular segmental narrowing with obstruction

@ Esophagus

√ plaquelike lesions, narrowing, aperistalsis

@ Small bowel

√ circumferential thickening of terminal ileum (rare)

Genitourinary Sarcoidosis (0.2–5%)

@ Kidney

• interstitial nephritis, glomerulonephritis (rare)
√ renal calculi
CT:
√ striated nephrograms in case of interstitial nephritis
√ multiple low-attenuation tumorlike nodules (rare)

@ Scrotum (0.5%) = Testicular sarcoid
√ diffuse enlargement of epididymis
√ hypoechoic lesions in epididymis (bilateral in ⅓)
√ multiple hypoechoic lesions in testis (typically bilateral)
MR:
√ T2-hypointense nodules with enhancement on T1WI
Ethnicity: African-American÷white males = 20÷1

◊ Strongly consider sarcoidosis in cases of multiple masses simultaneously affecting epididymis and testis.

Musculoskeletal Sarcoidosis (6–20%)

◊ Portends a more chronic + adverse prognosis!
◊ Usually accompanied by cutaneous manifestations!

@ Joint (up to 40%)
• unimpaired joint function
Location: knee, ankle, elbow, wrist
√ inflammatory arthralgia

@ Muscle
√ increased T2 signal intensity of involved muscle
√ sarcoid nodules with centrally low signal intensity on all sequences (= area of fibrosis)
√ granulomas peripherally hyperintense on T2WI with contrast-enhancement on T1WI

@ Bone (5–10%)
Histo: medullary granulomas infiltrate cortical bone → bone destruction / reactive sclerosis
Location: hands + feet (metaphyseal ends of distal + middle phalanges, metacarpals, metatarsals); vertebrae; skull
• pain and swelling
√ sharply marginated cystlike lesions of varying size:
√ reticulated "lacelike" trabecular pattern
√ neuropathy-like destruction of terminal phalanges (DDx: scleroderma)
√ extensive bone erosion with pathologic fractures
√ phalangeal endosteal sclerosis + periosteal new bone (infrequent)
√ densely sclerotic lesions in spine, pelvis, ribs:
√ vertebral involvement unusual: destructive lesions with sclerotic margin
√ diffuse sclerosis of multiple vertebral bodies
√ paravertebral soft-tissue mass (DDx: indistinguishable from tuberculosis)
√ preservation of disk spaces
√ osteolytic changes in skull
NUC (bone scan):

√ positive before radiographic manifestation

Neurosarcoidosis (9%)

= SARCOIDOSIS OF CNS

= dural / leptomeningeal noncaseating granulomas

Incidence: CNS involvement clinically in 1–5–10% (in up to 25% of autopsies)

Age: bimodal distribution: initial peak around 20–29 years + 2nd peak > 50 years more common in women + people of West African descent; black÷white = 3÷1 to 10÷1

Suspected neurosarcoidosis is difficult to confirm without evidence of systemic disease; chest imaging may be helpful to evaluate for pulmonary involvement.

- cranial neuropathy (facial > acoustic > optic > trigeminal nerves) ← granulomatous infiltration + leptomeningeal fibrosis (50–75%) of rapid onset with spontaneous resolution
- peripheral neuropathy + myopathy
- aseptic meningitis (20%)
- diffuse encephalopathy, dementia
- pituitary + hypothalamic dysfunction (eg, diabetes insipidus in 5–10%)
- generalized / focal seizures (herald poorer prognosis)
- multiple sclerosislike symptoms (from multifocal parenchymal involvement)
- prompt improvement following therapy with steroids
    - spinal fluid: normal (in up to 30%) or nonspecific (↑ protein, ↑ leukocyte count, ↔ / ↓ glucose)

Location: leptomeninges, dura mater, subarachnoid space, peripheral nerves, brain parenchyma, ventricular system

◊ Affects meninges + cranial nerves more often than brain!

Neurosarcoidosis has a strong predilection for the base of the brain.

@ Meningeal / ependymal invasion

√ diffuse meningeal thickening + enhancement (most common) / meningeal nodules (less common)

Site: particularly in basal cisterns (suprasellar, sellar, subfrontal regions) with extension to optic chiasm, hypothalamus, pituitary gland, cranial nerves at points of exit from brainstem

Cx: communicating / obstructive hydrocephalus (most common finding) ← arachnoiditis / adhesions

DDx: carcinomatous / fungal / tuberculous meningitis

√ dense enhancement of falx + tentorium (granulomatous invasion of dura)

√ solitary / multiple dura-based small enhancing nodules / masses on brain surface + in perivascular spaces

DDx: granulomatous meningitis, TB, carcinomatous meningitis

√ ependymal enhancement

√ meningeal lesions usually imperceptible on unenhanced MR: T1-isointense + T2-hypointense relative to gray matter

√ intense diffuse meningeal enhancement

@ Parenchymal disease ← extension from meningeal / ventricular surfaces

√ single / multiple ringlike nodules / masses (= invasion of brain parenchyma via perivascular spaces of Virchow-Robin):
√ T2-hyperintense
√ iso- to hyperdense
√ homogeneously enhancing (if biologically active)
Site: periphery of parenchyma, periventricular, deep white matter, intraspinal
Cx: stenosis / occlusion of blood vessels
DDx: glioblastoma, metastases
√ small vessel ischemic change
√ lacunar infarction (especially brain stem + basal ganglia)
√ focal / widespread infarcts of peripheral gray matter / at gray-white matter junction ← periarteritis
√ reactive subcortical vasogenic edema
√ usual hyperintensity of posterior pituitary lobe no longer identifiable on unenhanced T1WI ← depletion of intracellular neurosecretory granules

@ Spinal cord
√ hyperintense enlargement of spinal cord (common) on T2WI ← edema
√ intramedullary lesion of decreased T2-signal
√ enhancing focus of sarcoid granuloma on T1WI

Skin / Cutaneous Sarcoidosis (25%)

(1) **Erythema nodosum** = nongranulomatous panniculitis:
= multiple bilateral tender erythematous nodules mostly on anterior surface of lower extremities
• often associated with fever + arthralgia (= painful swollen adjacent joints)
Onset: typically associated with benign self-limiting acute sarcoidosis (eg, Löfgren syndrome)
Prognosis: remission in 6–8 weeks

(2) **Lupus pernio** = indurated red-brown to violaceous (= bluish purple) papules + plaques
Location: nasal alae, cheeks, ear lobes, fingers, toes
Associated with: pulmonary fibrosis, lytic lesions of phalanges

(3) Asymptomatic pink-yellow / red-brown papules + plaques
Onset: typically associated with chronic sarcoidosis
Location: face, posterior neck, previous trauma site
• characteristic "apple jelly" color on diascopy (= pressure applied with glass slide)

• skin plaques / scars

Thoracic Sarcoidosis (90%)

◊ Extrathoracic manifestations without intrathoracic involvement in < 10%!

Silzbach CXR stage versus percentage at presentation:
0 normal chest radiograph 5–10%
1 hilar + mediastinal lymphadenopathy only 50%
2 lymphadenopathy + parenchymal disease 25–30%
3 diffuse parenchymal disease only 10–12%
4 pulmonary fibrosis 5%

◊ Progression to pulmonary fibrosis in 25%!

Spontaneous remissions versus Siltzbach stage:

60–90% for stage 1 disease
40–70% for stage 2 disease
10–20% for stage 3 disease
0% for stage 4 disease

- mild symptoms in spite of extensive radiographic changes (DIAGNOSTICALLY SIGNIFICANT):
  - dry cough, dyspnea, hyperreactivity
  - fatigue, night sweats, weight loss, erythema nodosum
  - pulmonary arterial hypertension (50%)

Associated with: tuberculosis in up to 13%

@ intrathoracic lymphadenopathy (85% by CT):

Typical patterns of lymphadenopathy:

√ symmetric enlargement of bilateral hilar nodes + right paratracheal and aortopulmonary window nodes (75–95%) = "1-2-3" sign = **Garland triad**

Clinical Diagnostic Criteria of Cardiac Sarcoidosis *established by Japanese Ministry of Health and Welfare (2007)*
Major criteria
• advanced atrioventricular block
√ basal thinning of interventricular septum
√ positive cardiac gallium uptake
√ LV ejection fraction depressed by < 50%
Minor criteria
• abnormal ECG: ventricular arrhythmias, complete right bundle branch block axis deviation, abnormal Q wave
√ abnormal echo: abnormality of regional wall motion / morphology (ventricular aneurysm, wall thickening)
√ perfusion defect on ^{201}Th / ^{99m}Tc myocardial scintigraphy
√ late / delayed Gd-enhancement of myocardium
• endomyocardial Bx: interstitial fibrosis / monocyte infiltration

√ enlargement of middle mediastinal nodes = left paratracheal, subcarinal, aortopulmonary (50%)

Atypical patterns of lymphadenopathy:

√ asymmetric lymph node enlargement
√ isolated unilateral hilar nodal enlargement (< 5%)
√ lymphadenopathy in unusual locations: internal mammary, paravertebral, retrocrural
√ mediastinal lymphadenopathy without hilar nodes
√ calcification of lymph nodes (in 3% after 5 years, in 20% after 10 years): amorphous, punctate, popcornlike, eggshell-like

Prognosis: adenopathy commonly ↓ as parenchymal disease ↑; subsequent parenchymal disease in 32%; adenopathy does NOT develop subsequent to parenchymal disease

@ parenchymal disease (in 60% by CT):

Location: usually bilateral + symmetric; predominantly in upper lung + mid-zone

◊ NOT associated with lymphadenopathy in 16–20%
◊ Parenchymal granulomas are invariably present on open lung biopsy!
Typical parenchymal manifestations:
√ multiple bilateral symmetric micronodules (75–90%)
Cause: noncaseous epitheloid cell granulomas deposited along course of lymphatics
Distribution: subpleural peribronchovascular > interlobular septal sites
Size: 2–4 mm
√ macronodules ≥ 5 mm
Cause: coalescence of micronodules
√ bilateral perihilar consolidations radiating from hilum toward periphery ± air bronchogram
√ progressive patchy fibrosis in 20%:
√ linear reticular opacities
√ traction bronchiectasis
√ architectural distortion
√ volume loss

Pattern of distribution + upper lung predominance with coexistent mediastinal lymphadenopathy strongly favor sarcoidosis differentiating it from other nodular lesions (EG, miliary TB, metastasis).

Atypical parenchymal manifestations:
√ airspace consolidation (15–25%):
√ multiple bilateral 1–4 cm pulmonary nodules and masses:
√ ± air bronchograms
√ cavitation (0.6%)
Cause: coalescent interstitial granulomas
Distribution: in perihilar and peripheral regions
√ conglomerate masses
√ nonspecific **"galaxy" sign** = small satellite nodules at periphery of masses
Cause: coalescent parenchymal lesions
DDx: progressive massive fibrosis
√ **"sarcoid cluster"** = cluster of multiple micronodules distributed along lymph vessels
√ solitary lung nodule / mass (rare)
√ **"alveolar sarcoidosis"** = bilateral symmetric patchy airspace consolidation ± air bronchograms fading into a nodular pattern peripherally (10–20%)
Cause: confluence of acinar + interstitial micro-nodules compressing surrounding alveoli
DDx: pneumonia, tuberculosis, BOOP
√ patchy ground-glass opacities (40%)
Cause: confluence of micronodular granulomatous + fibrotic interstitial lesions → airway compression without airspace filling
DDx: bronchoalveolar cell carcinoma, lymphoma, pneumoconiosis, pneumonia, BOOP
√ reticulolinear opacities (50%)

Cause: interlobular + intralobular septal thickening
DDx: lymphangitic carcinomatosis
√ fibrocystic changes = cyst, bulla, bleb, paracicatricial emphysema
Cause: advanced stage of chronic fibrosis
√ honeycomb-like cysts
√ cavitation / pseudocavitation of parenchymal lesion (10% of end-stage sarcoidosis / primary cavitary sarcoidosis in < 1%)
√ mycetoma formation of stage 4 cystic sarcoidosis (1–3%)
√ miliary opacities (<1%)
DDx: tuberculosis, pneumoconiosis, metastases, histoplasmosis, chickenpox, Langerhans cell histiocytosis

@ <u>airway disease</u> by CT:
√ mosaic attenuation = inhomogeneous attenuation at inspiratory CT
Cause: patchy interstitial disease, obstructed small airways, vascular disease
√ air trapping = focal areas of ↓ attenuation on expiratory CT (95%)
√ tracheobronchial stenosis (2%):
√ atelectasis ← compression by large lymph nodes / endobronchial granulomas
√ bronchiectasis ← scarring / fibrosis

@ <u>pleural disease</u> (1–4%) by CT:
√ usually small pleural effusion (transudative / exudative, hemorrhagic, chylous) clearing within 2–3 months
√ pneumothorax
Cause: rupture of emphysematous bleb, necrosis of subpleural sarcoid granuloma
√ pleural plaquelike opacities
Cause: multiple subpleural coalescent micronodules

HRCT:
(a) reversible ← granulomatous inflammation resolving with time (in 80%):
√ micronodules, macronodules
√ airspace consolidation / confluent alveolar opacities
√ ground-glass opacities
√ interlobular septal thickening
√ intralobular linear opacities
(b) irreversible ← chronic interstitial fibrosis (in 20%):
√ honeycomb-like opacities, cysts, bullae, emphysema
√ architectural distortion
√ traction bronchiectasis / bronchiolectasis
√ volume loss in upper lobes with retraction of hila
√ mycetoma (in 10% of preexisting cavity)

NUC:
√ FDG uptake in lung parenchyma + mediastinal nodes ← regional inflammation + sarcoid lesions

Atypical manifestations (25%):
√ bronchostenosis (2%) with lobar / segmental atelectasis

Cx: (1) pneumothorax ← chronic lung fibrosis (rare)
(2) cardiomegaly ← cor pulmonale (rare)

(3) aspergilloma formation in apical bulla

Prognosis:

80% spontaneous remission of stage 1 + 2 disease

75% complete resolution of hilar adenopathy

33% complete resolution of parenchymal disease

30% significant improvement

20% irreversible pulmonary fibrosis (may persist unchanged for > 15 years)

5% mortality: cor pulmonale (← lung fibrosis), CNS, liver cirrhosis, pulmonary hemorrhage (← mycetoma); in Japan death from cardiac involvement in 80%

25% relapse (in 50% detected by CXR)

5% recurrence after remission lasting > 1 year

Factors effecting poor prognosis: stage 2 / 3 at time of initial diagnosis, disease onset > 40 years of age, black race, hypercalcemia, splenomegaly, osseous involvement, chronic uveitis, lupus pernio

Factors effecting good prognosis: fever, polyarthritis, erythema nodosum, bilateral hilar lymphadenopathy (Löfgren syndrome)

DDx: mycobacterial / fungal infection, malignancy, pneumoconiosis (silicosis, berylliosis)

◊ "The great mimic" = initially broad imaging DDx

Sarcoidosis of Head & Neck

√ granulomas may enhance

@ Cervical lymph nodes (rare)

• palpable peripheral lymphadenopathy (⅓): discrete, nontender and movable

@ Ophthalmic sarcoidosis (25–80%)

• typically bilateral uveitis, photophobia, blurred vision, glaucoma (rare)

√ commonly bilateral enlarged enhancing lacrimal glands ← chronic dacryoadenitis

√ masslike appearance of optic nerve / nerve sheath

√ enlargement of optic canal ← optic neuritis

√ avidly enhancing orbital soft-tissue masses with involvement of extraocular muscles + lacrimal glands

@ Larynx (5%)

√ thickening of larynx with enhancement of granulomas

@ Nose

√ multiple small granulomas of septum + turbinates

@ Parotid gland (6%), other salivary glands (30%)

CT:

√ multiple diffusely dense noncavitating nodules within parotid gland

√ enlargement of intraparotid lymph nodes

NUC:

√ **"panda" sign** = 67Ga uptake in both parotid glands + both lacrimal glands + nose

Heerfordt Syndrome

(1) Parotid enlargement (6%)

◊ May be the initial and only manifestation of sarcoid

- diffuse bilateral painless enlargement (10–30%)
- xerostomia

(2) Uveitis
(3) Facial nerve paralysis

Uveoparotid Fever

(1) Parotitis
(2) Uveitis
(3) Fever

Sarcoidosis of Other Organs

@ Peripheral lymph node enlargement (30%)
@ Muscle (25%): myopathy

SEPTIC PULMONARY EMBOLI

= lodgement of an infected thrombus in a pulmonary artery
Organism: S. aureus, Streptococcus
Predisposed: IV drug abusers, alcoholism, immunodeficiency, CHD, dermal infection (cellulitis, carbuncles)
Source:
(a) infected venous catheter / pacemaker wires, arteriovenous shunts for hemodialysis, drug abuse producing septic thrombophlebitis (eg, heroin addicts), pelvic thrombophlebitis, peritonsillar abscess, osteomyelitis
(b) tricuspid valve endocarditis (most common cause in IV drug abusers)
Age: majority < 40 years
• sepsis, cough, dyspnea, chest pain
• shaking chills, high fever, severe sinus tachycardia
Location: predilection for lung bases
√ multiple nondescript pulmonary infiltrates (initially)
√ migratory infiltrates (old ones heal, new ones appear)
√ cavitation (frequent), usually thin-walled
√ pleural effusion (rare)
CT (more sensitive than CXR):
√ multiple peripheral parenchymal nodules ± cavitation / air bronchogram (83%)
√ wedge-shaped subpleural lesion with apex of lesion directed toward pulmonary hilum (50%)
√ **"feeding vessel" sign** = pulmonary artery leading to nodule (67%)
√ cavitation (50%), esp. in staphylococcal emboli
√ air bronchogram within pulmonary nodule (28%)
Cx: empyema (39%)

SIDEROSIS

= ARC WELDER PNEUMOCONIOSIS
= inhalation of inert iron oxide / metallic iron deposits
Occupational exposure:

electric arc welding, oxyacetylene torch workers (iron oxide in fumes), mining + processing of iron ores, cutting / burning of iron + steel, foundry workers, grinders, fettlers, silver polishers (jewelry industry)

Path: iron phagocytized by macrophages in alveoli / respiratory bronchioles, elimination from lung by lymphatic circulation; NOT associated with fibrosis unless admixed with silica

Location: middle ⅓ of lung, perihilar region

• asymptomatic (for pure siderosis)

√ small nodules / diffuse fine reticulonodular opacities ← radiopaque accumulation of iron particles in macrophages aggregated in lymphatics along bronchovascular bundles:

√ may disappear after exposure is discontinued

√ small round opacities (indistinguishable from silica / coal)

√ NO secondary fibrosis + NO hilar adenopathy (unless mixed dust inhalation as in **siderosilicosis** / **silicosiderosis** = mixed-dust pneumoconiosis)

HRCT:

√ widespread poorly defined centrilobular micronodules (71%)

√ ± branching linear structures ← deposition of minute iron oxide particles along perivascular + peribronchial lymphatic vessels

√ extensive ground-glass attenuation + reticulation without zonal predominance

√ emphysematous changes (33%) likely due to smoking

√ honeycombing resembling usual interstitial pneumonia

√ pleural irregularity (suggestive of exposure to asbestos)

√ conglomerate masses with areas of high attenuation (= organizing pneumonia with siderosis)

DDx: silicosis (nodular opacities more dense + profuse)

SILICOSIS

= inhalation of crystalline silicon dioxide (= silica, one of the most widespread elements on earth); most prevalent silicosis of progressive nature after termination of exposure; similar to CWP (because of silica component in CWP)

Substance: crystalline silica (quartz); tridymite / cristbalite (less fibrogenic)

Occupational exposure:

tunneling, mining, quarrying, stone cutting, polishing, glass manufacturing, foundry work, sandblasting, pottery, brick lining, boiler scaling, vitreous enameling, ceramic industry

Dust deposition: dependent on

(a) airflow: deposition of 1–5-µm particles predominantly around respiratory bronchioles in a centrilobular location within secondary pulmonary lobule

(b) lymphatic clearance: related to pulmonary arterial pressure (gravity-related vertical gradient) + blood flow (higher blood flow through LUL) + passive milking of lymphatics by respiratory motion (lateral > anterior > posterior chest wall)

Path: small particles engulfed by macrophages; liberation of silica results in cell death; 2–3-mm nodules with layers of laminated connective tissue around smaller vessels

Clinical classification:

1. Acute silicosis = alveolar silicoproteinosis
2. Classic silicosis = chronic interstitial reticulonodular

Radiographic classification:
(a) simple = small + round / irregular opacities
(b) complicated = progressive massive fibrosis

Cx: predisposes to tuberculosis + carcinoma

DDx: coal worker pneumoconiosis (identical radiographs)

Acute Silicosis

= ALVEOLAR SILICOPROTEINOSIS

= heavy exposure to respirable free silica in enclosed space with minimal / no protection of airways (sandblasters!)

Histo: alveolar filling with PAS-positive staining substance; proliferation of type II pneumatocytes + profuse surfactant production

Exposure time: as short as 6–8 months

Associated with: increased risk to develop autoimmune disease

Distribution: lung periphery; predominantly lower lung zones; bilateral

√ diffuse bilateral perihilar airspace / ground-glass disease

√ air bronchograms

HRCT:

√ numerous bilateral patchy centrilobular nodular ground-glass opacities

√ multifocal patchy ground-glass opacities + consolidation

√ "crazy paving" = airspace filling + fine interlobular septal thickening ← edematous + fibrous tissue

Cx: infection with TB + atypical mycobacteria

Prognosis: often rapidly progressive with death from respiratory failure + cor pulmonale

DDx: alveolar proteinosis

Classic Silicosis

= chronic interstitial reticulonodular disease

Path: silicotic nodules = mature collagen centrally + peripheral zone of particle laden macrophages

Histo: birefringent silicate crystals of 1–3 μm in length

Chronic Simple Silicosis

Lag time: at least 10–20 years of dust exposure before appearance of roentgenographic abnormality

Location: posterior portion of upper lobes bilaterally

CXR:

√ multiple small 2–5 (range, 1–10)-mm round well-defined opacities:

√ typically central calcifications in 10–20%

√ hilar + mediastinal lymphadenopathy, may calcify in 5% **("eggshell pattern")**

√ ± reticulonodular pattern

HRCT:

√ multiple small calcified nodules of 2–5 mm in size:

Distribution: perilymphatic (= centrilobular, paraseptal, subpleural)

√ "pleural pseudoplaques" = aggregate of subpleural nodules in round / triangular

configuration
√ thickened intra- and interlobular lines
√ subpleural curvilinear lines ← peribronchiolar fibrosis
√ ground-glass pattern = mild thickening of alveolar wall + interlobular septa ← fibrosis / edema
√ parenchymal fibrous bands
√ traction bronchiectasis
√ honeycombing

Complicated Silicosis

= PROGRESSIVE MASSIVE FIBROSIS
= appearance of large opacities > 1 cm in diameter ← expansion + confluence of individual silicotic nodules
Location: mid lung zone / peripheral ⅓ of upper lung migrating toward hilum
Distribution: often bilateral symmetric + nonsegmental
√ focal conglomerate sausage-shaped masses with ill-defined / irregular margins (in advanced stages):
√ lateral interface typically parallels lateral chest wall
√ surrounding compensatory emphysema in unaffected portion between mass + pleura
√ slow change over years
√ may calcify + cavitate ← ischemic necrosis

Silicotuberculosis

= synergistic relationship between silicosis + primary tuberculosis (in 25%)
• intermittently positive sputa
√ asymmetric nodules / consolidation
√ cavitation (strongest indicator of associated TB)
√ rapid disease progression

Caplan Syndrome

More common in coal worker's pneumoconiosis

SOLITARY FIBROUS TUMOR

= rare benign ubiquitous spindle cell neoplasm; frequently misdiagnosed as hemangiopericytoma
Origin: neoplasm of submesothelial origin (primitive mesenchymal cell)
Path: well-defined pseudoencapsulated lobulated neoplasm of whorled fibrous tissue WITHOUT necrosis / cyst formation / hemorrhage
◊ Most solitary fibrous tumors are benign!
Histo: (a) fibrous type: hypercellular areas composed of spindle cells resembling fibroblasts + variable amount of hypocellular fibrous areas (= hyalinized collagen)
(b) cellular type: monotonous moderate to high cellularity + little intervening fibrous tissue
CHARACTERISTIC strong CD34 immunoreactivity + EMA negativity
Mean age: 54 years; M > F

Location:
(a) visceral pleura (most common)
(b) extrapleural location: lung, mediastinum, pericardium, extraperitoneal spaces, nose, paranasal sinuses, orbit, kidney, liver, skin

Extrapleural solitary fibrous tumor: mesentery, peritoneum

• hypertrophic osteoarthropathy (35%), hypoglycemia (4%)
√ solitary well-circumscribed unencapsulated lobulated mass
√ mobile mass if pedunculated
√ heterogeneous texture if large
√ ± dystrophic calcifications and enhancing internal vessels
√ intense arterial enhancement ← hypervascularity

MR:
√ intermediate SI on T1WI
√ heterogeneous SI + multiple flow voids representing prominent vascular channels on T2WI (common)

CEMR:
√ SUGGESTIVE avidly enhancing areas of low T2 signal ← fibrosis with abundant collagen
√ persistent delayed enhancement ← fibrous tumor component

Prognosis: 10–15% of extrapleural solitary fibrous tumors show malignant behavior (← recurrence after resection / metastatic disease)

DDx: (1) Hypervascular neoplasm: angiosarcoma, hemangioendothelioma, angiomyxoma
(2) Fibrous neoplasm: malignant fibrous histiocytoma, fibrosarcoma, leiomyoma, desmoid tumor

Solitary Fibrous Tumor of CNS

Mean age: 57 years; (?) F >> M
• headache
Location: dura (falx, occipital + spinal dura, tentorium, cerebellopontine angle), ventricle
√ hyperattenuating mass ± dural tail
√ diffuse / heterogeneous enhancement
√ smooth erosion of adjacent skull
√ lipid + lactate peaks + elevated myo-inositol (3.5 ppm)
DDx: meningioma (hyperostosis)

Solitary Fibrous Tumor of Pelvis

Age: 5th decade (range, 20–70 years); M = F
Location: pelvic peritoneum / retroperitoneum
• mostly asymptomatic, pressure, hypoglycemia (< 5%)
Rx: complete surgical resection ± preoperative embolization; surgical cytoreduction + intraoperative chemotherapy + radiation therapy

√ well-defined mass with intense heterogeneous enhancement that persists into delayed phase
√ areas of central low attenuation ← necrosis / hemorrhage / cystic change

Staphylococcal pneumonia

◊ Most common cause of bronchopneumonia!
(a) common nosocomial infection (patients on antibiotic drugs most susceptible)
(b) accounts for 5% of community-acquired pneumonias (esp. in infants + elderly)
◊ Secondary invader to influenza (commonest cause of death during influenza epidemics)
Organism: Staphylococcus aureus = Gram-positive, appears in coagulase-producing clusters
√ rapid spread through lungs
√ empyema (esp. in children)
√ pneumothorax, pyopneumothorax
√ abscess formation
√ bronchopleural fistula
A. in CHILDREN:
√ rapidly developing lobar / multilobar consolidation
√ pleural effusion (90%)
√ pneumatocele (40–60%)
B. in ADULTS:
√ patchy often confluent bronchopneumonia of segmental distribution, bilateral in > 60%
√ segmental collapse (air bronchograms absent)
√ late development of thick-walled lung abscess (25–75%)
√ pleural effusion / empyema (50%) (DDx from other pneumonias)
Cx: meningitis, metastatic abscess to brain / kidneys, acute endocarditis

STREPTOCOCCAL PNEUMONIA

Frequency: 1–5% of bacterial pneumonias (rarely seen); most common in winter months
Organism: Group A ß-hemolytic streptococcus
= Streptococcus pyogenes, Gram-positive cocci appearing in chains
Predisposed: newborns, following infection with measles
Associated with: delayed onset of diaphragmatic hernia (in newborns)
• rarely follows tonsillitis + pharyngitis
√ patchy bronchopneumonia
√ lower lobe predominance (similar to staphylococcus)
√ empyema
Cx: (1) Residual pleural thickening (15%)
(2) Bronchiectasis
(3) Lung abscess
(4) Glomerulonephritis

SWYER-JAMES SYNDROME

= MACLEOD SYNDROME = UNILATERAL LOBAR EMPHYSEMA = IDIOPATHIC UNILATERAL HYPERLUCENT LUNG
= chronic complication of infectious obliterative bronchiolitis in infancy or childhood as early as 9 months after initial infectious insult
Etiology: acute viral bronchiolitis in infancy / early childhood (adenovirus, RSV, mycoplasma) preventing normal development of lung
Path: variant of postinfectious constrictive bronchiolitis with acute obliterative bronchiolitis,

bronchiectasis, distal airspace destruction (developing in 7–30 months)
- asymptomatic; history of recurrent lower respiratory tract infections during childhood
- chronic cough, wheezing, dyspnea on exertion, hemoptysis
- obstructive lung disease pattern at pulmonary function test

Location: one / both lungs (usually entire lung, occasionally lobar / subsegmental)
√ hyperlucency of one lung ← air trapping ← bronchiolar obstruction
√ diminished number + size of pulmonary vessels:
  √ small ipsilateral hilum ← diminuted hilar vessels + attenuated arteries)
√ small hemithorax with decreased volume
√ normal hyperexpanded hemithorax ← collateral air drift
√ air trapping during expiration
  DDx: no air trapping with proximal interruption of pulmonary artery (no hilum), hypogenetic lung syndrome, pulmonary embolus
√ mild cylindrical bronchiectasis with paucity of bronchial subdivisions (cutoff at 4th–5th generation = "pruned tree" bronchogram)

HRCT (most useful modality):
  √ bilateral areas of decreased attenuation:
    √ areas of normal lung attenuation within hypoattenuating lung
    √ air trapping within hypoattenuating lung
    √ ipsilateral bronchiectasis
  √ diminished size of pulmonary vessels in hyperlucent areas

Angio:
  √ "pruned tree" appearance

NUC (V/Q scan):
  √ matched defects of perfusion + ventilation (with delayed washout) in hyperlucent regions

Bronchography:
  √ incomplete filling of ipsilateral peripheral bronchioles
  √ dilated bronchi with sharply terminating segments

DDx: pulmonary artery atresia (uncommon in adults), localized bullous emphysema (deviation of vessels), bronchial obstruction

SYSTEMIC LUPUS ERYTHEMATOSUS

= SLE = most prevalent of the potentially grave connective tissue diseases characterized by involvement of vascular system, skin, serous + synovial membranes

Incidence: 1–10 ÷ 100,000 persons per year; Blacks÷Caucasians = 3÷1; increased risk in relatives

Cause: complex systemic autoimmune disease including complement system, T suppressor cells, and cytokine production with deposition of antigen-antibody complexes / autoantibodies inducing necrotizing vasculitis (type III immune complex phenomenon) of arterioles + capillaries ← dysfunctional suppressive controls on immune system

Age: 16–41 years; <u>in adults</u> M÷F = 1÷11 (in ≥ 90% in women of childbearing age); <u>in children</u> M÷F = 2÷1

Diagnostic criteria (≥ 4 criteria = 98% specific, 97% sensitive):

(1) Malar rash

(2) Discoid lesions
(3) Photosensitivity
(4) Oral ulcers
(5) Nonerosive arthritis
(6) Serositis (pleuritis or pericarditis)
(7) Positive antinuclear antibody test
(8) Renal disease
(9) Neurologic disease: seizures / psychosis
(10) Hematologic abnormalities
(11) Immunologic disorder

Disease severity: defined by number of organ systems involved

- fatigue, malaise, anorexia, fever, weight loss
- clinically heterogeneous ← different types of serum antibodies
- antinuclear DNA antibodies (87%)
- hypergammaglobulinemia (77%); Sjögren syndrome (frequent)
- LE cells (= antigen-antibody complexes engulfed by PMNs) in 78%
- chronic false-positive Wassermann test for syphilis (24%)
- anemia (78%), leukopenia (66%), thrombocytopenia (19%)

Cx: deep venous thrombosis (9–35%) + thromboembolism with antiphospholipid antibodies in serum; ↑ prevalence of lymphoreticular malignancies; frequent infections

Prognosis: 60–90% 10-year survival; death from renal failure / sepsis / CNS involvement / myocardial infarction

Rx: nonsteroidal antiinflammatory drugs / oral steroids

Antiphospholipid Antibody Syndrome

= (aPL-ab syndrome) characterized by arterial + veno-occlusive disease, thrombocytopenia, recurrent vascular thromboses + miscarriages

Path: antibodies target cell surface molecules on vascular endothelium and platelets; acquired free protein S deficiency

- recurrent strokes + pulmonary embolism, Budd-Chiari syndrome, dural venous sinus thrombosis, ischemic bowel
- lupus anticoagulant serves as marker of functional activity

Dx: ≥ 1 clinical criterion: deep venous thrombosis, arterial thrombosis, pregnancy loss, thrombocytopenia AND
≥ 1 laboratory criterion: lupus anticoagulant, immunoglobulins [IgG, IgM, IgA] against cardiolipin

Minor criteria: heart valve abnormality, livedo reticularis, migraine, pulmonary hypertension, AVN, myelopathy, chorea

Cx: pulmonary arterial hypertension (25%) ← recurrent pulmonary thromboembolism

Rx: anticoagulants (for vascular occlusion)

Cardiovascular SLE

@ Cardiac valves (18–74%)
more often seen in patients with antiphospholipid antibody (aPL-ab) syndrome
√ valve leaflet thickening

√ **Libman-Sacks endocarditis**:
= small granular vegetations on mitral / aortic valve
√ 1–4 mm single / multiple verrucous vegetations
Cx: valve destruction

@ Pericardium (17–50%)
√ exudative pericardial effusion = serositis of pericardium
√ abnormal thickening + enhancement of pericardium

@ Myocardium
• clinically silent (in up to 50%)
√ global left ventricular dysfunction (uncommon)
√ cardiomegaly = primary lupus cardiomyopathy
Histo: myositis (myocarditis) with perivascular infiltration by lymphocytes and neutrophils

@ Vasculature
√ coronary atherosclerosis
Mortality rate: 9 x that of general population
√ marked arterial wall thickening < 100 μm in diameter
Histo: vasculitis with fibrinoid necrosis and minimal infiltration by inflammatory cells
Cx: ischemia / hemorrhage into bowel wall → perforation → peritonitis
√ aortitis (uncommon) → dissection, aneurysm

Drug-induced Lupus Erythematosus (DIL)

• temporary phenomenon
Agents: procainamide, hydralazine, isoniazid, phenytoin account for 90%
√ pulmonary + pleural disease more common than in SLE

Gastrointestinal SLE (in up to 50%)

• nonspecific vague abdominal pain (10–37%)
• buccal erosions / ulcerations; GI tract bleeding

@ Esophagus
• dysphagia, gastroesophageal reflux, atypical chest pain
√ hypomotility of distal ⅓ (13–32%) similar to scleroderma
√ mucosal granularity ± ulceration ← reflux esophagitis
Cx: reflux esophagitis

@ Pancreas
√ peripancreatic mesenteric fatty infiltration, phlegmon formation ± glandular enlargement = acute focal / diffuse pancreatitis (in 8–28%)
√ calcium deposition within ductal system + organ atrophy = chronic pancreatitis

@ Liver, spleen
√ hepatomegaly, hepatitis, cirrhosis, splenomegaly
√ "painful" ascites

@ Bowel
√ features of gastritis
√ features of bowel ischemia with ← small vessel vasculitis

Cx: pneumatosis intestinalis, perforation

√ mesenteric ischemia: colitis, pseudoobstruction, ileus, thumbprinting, luminal narrowing

Musculoskeletal SLE

@ Joints

• arthralgia (95%)

Location: small joints of hand, wrist, knee, shoulder

√ CHARACTERISTIC symmetric nonerosive nondeforming polyarthritis of hands

√ Jaccoud arthropathy (10%)

√ tumoral calcinosis

@ Ligaments

√ deformities in initially reversible SLE ← ligamentous instability and laxity

@ Bone

√ osteonecrosis / AVN (5–50%) of weight-bearing joints:

Location: femoral head > humeral head > femoral condyle > tibial plateau

√ insufficiency fracture

Cause: deconditioning, accelerated bone loss ← steroid therapy

√ septic arthritis and osteomyelitis

Organism: S aureus, Gram-negative bacilli, M. tuberculosis

Renal SLE

Prevalence: kidneys involved in 100% with renal disease developing in 30–50%

Histo: focal membranoproliferative glomerulonephritis = immune complex deposition in subepithelial and subendothelial layers of glomeruli (**SLE nephritis**)

• renal failure ← fibrinoid thickening of basement membrane

√ aneurysms in interlobular + arcuate arteries (similar to but less frequent than polyarteritis nodosa)

√ normal / decreased renal size

√ hydronephrosis ← detrusor muscle spasm with vesicoureteral reflux / fibrosis of ureterovesical junction

US:

√ kidney enlarged (early) / diminutive (late stage)

√ increased parenchymal echogenicity

CT:

√ multiple linear hypoattenuating bands ← vasculitis

Cx: (1) Nephrotic syndrome (common)

(2) Renal vein thrombosis (in 33%) ← nephrotic syndrome induces hypercoagulability

Prognosis: end-stage renal disease is common cause of death

Skin SLE (81%)

• "**butterfly rash**" (= facial erythema), discoid lupus erythematosus, alopecia, photosensitivity

• Raynaud phenomenon (15%)

Thoracic SLE (30–70%)

◊ Affects respiratory system more commonly than any other connective tissue disease

- pleuritic chest pain (35%); fever, cough, dyspnea (40–57%)
- respiratory dysfunction (> 50%): single-breath diffusing capacity for carbon monoxide most sensitive indicator

@ Pleura (50%)

√ recurrent small uni- / bilateral (½) pleural effusions (in 30–50% during course of disease) ← pleuritis

√ pleural thickening / fibrosis (50–83%)

Dx: pleural fluid analysis (exudate positive for lupus erythematosus cells, immune complexes, anti-DNA antibodies)

@ Lung (> 50%)

Cause: chronic antibody damage to alveolar-capillary membrane

√ parenchymal opacification:

√ <u>pneumonia</u> (most common) ← bacteria / opportunistic organism

Risk: 3 x higher than in general population ← ⇓ phagocytic activity + ⇓ natural killer cell activity against pathogens + poor clearance of secretions + immunosuppressive therapy

√ <u>diffuse alveolar hemorrhage</u> (2–5%):

√ bilateral areas of consolidation + ground-glass opacities + septal thickening in lower lungs

Prognosis: 80% mortality ← extensive blood loss

√ pulmonary edema

√ **acute lupus pneumonitis** (10–14%):

Histo: diffuse alveolar damage + necrosis with cellular infiltrates + hyaline membranes

Rx: responsive to corticosteroids

√ uni- / bilateral poorly defined patchy areas of increased density peripherally at lung bases (alveolar pattern)

√ ground-glass opacity on CT

√ cavitating nodules (vasculitis)

√ pulmonary fibrosis (< 3%):

Pattern: nonspecific interstitial pneumonia (NSIP)

√ architectural distortion, honeycombing

√ subpleural interstitial reticulations in lower lung fields (chronic form) in 3%

√ fleeting platelike atelectasis in both bases (? infarction due to vasculitis)

√ hilar + mediastinal lymphadenopathy (extremely rare)

@ Diaphragm

Path: respiratory muscle dysfunction (25%) ← primary myopathy + phrenic neuropathy + pleural inflammation

- dyspnea out of proportion to severity of chest radiographic abnormalities
- ↓ static lung volumes + vital capacity ← restrictive process with normal diffusing capacity

√ linear atelectasis + ill-defined juxtadiaphragmatic areas of increased opacity

√ **shrinking lung syndrome** (0.6%):
√ progressive loss of lung volume
√ elevated diaphragms
√ sluggish diaphragmatic excursions

Cx: (1) Community-acquired pneumonia (14%)
(2) Pulmonary arterial hypertension (14%) ← chronic interstitial disease, vasculopathy, recurrent pulmonary embolism

Neuropsychiatric SLE / CNS Lupus

Prevalence: 30–40%; 19% of lupus-related deaths

• psychosis, stroke, epilepsy, headache, cognitive defects

√ cerebral ischemia + infarction:

Cause: (a) coagulopathy ← aPL-ab syndrome
(b) accelerated atherosclerosis ← steroids
(c) vasculitis,
(d) thromboemboli ← Libman-Sacks disease

Average age: 35 years

Distribution:
(a) clearly defined arterial territory of large-vessel disease
(b) small cortical / deep gray matter infarcts ← lupus angiitis / vasculitis

√ reduced diameter / occlusion of ICA
√ intracranial venous occlusion (in 29%)
√ intracranial hemorrhage (in up to 42%) = parenchymal / subarachnoid hemorrhage, subdural hematoma, petechial hemorrhage, hemorrhagic infarcts
√ cerebral white matter lesions in subcortical and periventricular regions at FLAIR + T2WI (in 60–86%)
√ cerebral atrophy (in about 43%)
√ myelopathy (in 1–3%)
√ optic neuritis (in 21–48%)

TALCOSIS

= prolonged inhalation of talc (= hydrated magnesium silicate)

Occupational exposure: manufacture of leather, rubber, paper, textiles, ceramic tiles

Often associated with: quartz, mica, kaolin, asbestos (amphibole fibers of tremolite and anthophyllite)

Different forms of disease depending on composition:

(1) Pure talcosis

CXR:

√ generalized haziness, nodulation, reticulation

√ large opacities resembling progressive massive fibrosis

HRCT:

√ small centrilobular + subpleural nodules

√ conglomerate masses + internal foci of high attenuation

(2) Talcosilicosis

√ small rounded + large opacities

√ fibrogenic process (NO regression after removal of patient from exposure)

(3) Talcoasbestosis

√ massive and bizarre pleural plaques

√ may encase lung with calcification

(4) Recreational IV drug use

√ diffuse small nodules, perihilar conglomerate masses, ground-glass opacities, emphysema

Location: typically sparing of apices + costophrenic sulci

TERATOID TUMOR OF MEDIASTINUM

= MEDIASTINAL GERM CELL TUMOR = [= TERATOMA]

Pathogenesis: "misplaced" multipotential primitive germ cells during migration from yolk endoderm to gonad

Frequency:

› adult: 15% of anterior mediastinal tumors

› child: 24% of anterior mediastinal tumors

› fetus: 10% of all fetal teratomas

◊ 16–28% of all mediastinal cysts!

◊ Occurs in same frequency as the usually larger thymoma!

◊ ⅓ of primary neoplasms in this area are in children

Classes: (1) Mature teratoma (solid)

(2) Cystic teratoma (dermoid cyst)

(3) Immature teratoma

(4) Malignant teratoma (teratocarcinoma)

(5) Mixed teratoma

Gonzalez-Crussi Grading System of Teratomas	
Grade	*Classification*
0	mature
1	immature / probably benign
2	immature / possibly malignant
3	frankly malignant

Location: mediastinum is 3rd most common site for teratoid lesions (after gonadal + sacrococcygeal location); 5% of all teratomas occur in mediastinum, mostly anterosuperiorly (in only 1% posteriorly)

◊ The anterior mediastinum is the most common extragonadal site of primary germ cell tumors (1–3% of all germ cell tumors)!

CXR:
- √ usually incidental large round lobulated mediastinal mass
- √ DIAGNOSTIC teeth / bone / fat / amorphous peripheral wall calcifications (in 20%)
- √ frontal CXR:
  - √ silhouetting of heart
  - √ obtuse angle to mediastinum + lung
  - √ disruption of azygoesophageal recess / anterior junction line
  - √ "hilum overlay" sign (= not of hilar origin!)

lateral CXR:
- √ obliteration of retrosternal clear space

MR:
- √ variable appearance depending on components of teratoma:
  - √ areas of high signal intensity on T1WI ← fat
  - √ areas of low SI on T1WI + high SI on T2WI ← fluid

Cx:
(1) Hemorrhage
(2) Pneumothorax ← bronchial obstruction with air trapping + alveolar rupture
(3) Respiratory distress ← rapid increase in size from fluid production with compression of trachea / SVC (SVC syndrome)
(4) Fistula formation to aorta, SVC, esophagus
(5) Rupture into bronchus → expectoration of oily substance / trichoptysis in 5–14%, lipoid pneumonia)
(6) Rupture into pericardium (pericardial effusion), pleural cavity (pleural effusion)

DDx: thymoma

Benign Teratoid Tumor (75–86%)

= MATURE (CYSTIC) TERATOMA = BENIGN TERATOMA

◊ Most common histologic type

1. Epidermoid (52%) = ectodermal derivatives
2. Dermoid (27%) = ecto- + mesodermal derivatives
3. Teratoma (21%) = ecto- + meso- + endodermal derivatives

Path: spherical lobulated well-encapsulated tumor; typically multi- / unilocular cystic cavities with clear / yellow / brown liquid

Histo:
(a) ectoderm: skin, sebaceous material, hair, cysts lined by squamous epithelium
(b) mesoderm: bone, cartilage, muscle
(c) endoderm: GI + respiratory tissue, mucus glands
◊ Tumor capsule commonly has remnants of thymic tissue!
◊ Cyst formation is typical (usually lined by mucus-secreting tall epithelial cells)!
Age: young adults / children; M = F
- asymptomatic (in up to 53%)
- cough, dyspnea, chest pain, pulmonary infection, respiratory distress ← compression by large tumor

Location:
(a) anterior superior mediastinum near thymus / within thymic parenchyma
(b) posterior mediastinum (rare, 3–8%)

CT:
√ smooth round mass bulging into right / left hemithorax
√ mass sharply demarcated by well-encapsulated wall
√ multicystic mass of internal heterogeneity with densities varying from -100 to +300 HU (that may all be present):
√ water density (85–90%), fat density (65–75%)
√ DIAGNOSTIC fat-fluid level (in 10%)
√ proteinaceous / hemorrhagic fluid component
√ homogeneous soft-tissue density (indistinguishable from lymphoma / thymoma)
√ curvilinear peripheral / central calcification (20–53%, 4 x more common in benign lesions) in tumor wall / substance, ossification in mature bone
√ PATHOGNOMONIC visualization of tooth
√ often inseparable from thymic gland
√ enhancement of rim / tissue septa

MR:
√ fat, fluid, soft-tissue signal intensities on T1WI + T2WI
√ macroscopic fat on fat-suppressed imaging
√ intracellular lipid on in- and out-of-phase imaging

Prognosis: ~ 100% 5-year survival rate
Rx: complete surgical excision

Malignant Teratoid Tumor (14–20%)

= TERATOCARCINOMA = MALIGNANT TERATOMA
Peak prevalence: 3rd decade; M > F
Histo: similar to mature teratoma but with primitive / immature tissue elements; commonly neural tissue arranged in rosettes / primitive tubules
√ features of malignancy:
√ nodular poorly defined mass with more solid components
√ areas of necrosis or hemorrhage; fat density in 40%
√ thick enhancing capsule
√ compression of adjacent structures

1. **Seminoma** = germinoma = dysgerminoma

◊ 2nd most common mediastinal germ cell tumor!
◊ Most common primary malignant germ cell tumor of mediastinum!
Frequency: 2–6% of all mediastinal tumors; 5–13% of all malignant mediastinal tumors
Age: 3rd–4th decade; M >> F; white
Histo: uniform polyhedral / round cells arranged in sheets or forming small lobules separated by fibrous septa; varying amounts of mature lymphocytes
Path: large unencapsulated well-circumscribed mass
• asymptomatic (20–30%); SVC obstruction (10%)
• chest pain / pressure, shortness of breath, weight loss, hoarseness, dysphagia, fever
• ↑ serum levels of hCG (7–18%)
• ↑ serum levels of LDH (80%) correlate with tumor burden + rate of tumor growth
Metastases: to regional lymph nodes, lung, bone, liver
√ large bulky well-marginated lobulated mass
√ usually NO calcification
√ homogeneous soft-tissue density with slight enhancement
Prognosis: 75–100% 5-year survival rate; death from distant metastases
Rx: surgery + radiation therapy (very radiosensitive) ± cisplatin

2. **Nonseminomatous malignant germ cell tumor**
(a) embryonic tissue
(1) Embryonal carcinoma
(b) extraembryonic tissue
(2) Yolk sac = endodermal sinus tumor
(3) Choriocarcinoma (least frequent)
(c) combination = mixed germ cell tumor
Path: large unencapsulated heterogeneous soft-tissue mass with tendency for invasion of adjacent structures
Age: during 2nd–4th decade: M÷F = 9÷1;
in children M = F
Associated with: Klinefelter syndrome (in 20%), hematologic malignancy
• chest pain, dyspnea, cough, weight loss, fever, SVC syndrome (90–100%)
• ↑ serum level of α-fetoprotein (80%) for endodermal sinus tumor / embryonal carcinoma
• ↑ serum level of LDH (60%)
• ↑ serum level of hCG (30%) (DDx: lung cancer; hepatocellular carcinoma; adenocarcinoma of pancreas, colon, stomach)
Metastases to: lung, liver
√ large tumor of heterogeneous texture with central hemorrhage / necrosis
√ well circumscribed / with irregular margins
√ enhancement of tumor periphery
√ lobulation suggests malignancy
√ invasion of mediastinal structures (SVC obstruction is ominous)
√ ± pleural / pericardial effusion (from local invasion)

◊ The absence of a primary testicular tumor / retroperitoneal mass proves a primary malignant germ cell tumor!

Rx: cisplatin-based chemotherapy + tumor resection

Prognosis: 50% long-term survivors

THORACIC DUCT CYST

= exceedingly rare benign mass of posterior mediastinum

Origin: congenital / degenerative weakening of thoracic duct wall

Histo: cystic space lined by hyalinized fibrous connective tissue surrounded by patchy collections of lymphocytes

Location: anywhere along thoracic duct

Size: 3–22 cm

- asymptomatic (up to 50%)
- dysphagia, chest pain / pressure, dyspnea, dysphonia

√ well-circumscribed posterior mediastinal mass

√ contiguity with cisterna chyli

√ enhancement of a smooth thin wall

CT:

√ homogeneous well-defined mass of water attenuation

MRI:

√ variable SI on T1WI; mildly hyperintense ← increased lipids + proteins

√ variously heterogeneous hyperintense mass on T2WI

Cx: rapid enlargement / spontaneous rupture after high-fat meal

Rx: resection under preservation of thoracic duct pedicles to avoid postoperative chylothorax

DDx: bronchogenic cyst (located adjacent to carina / in pulmonary parenchyma), esophageal duplication cyst (thick wall, young patient), pericardial cyst (located anteriorly at pericardiophrenic angle), hiatal hernia

THORACIC PARAGANGLIOMA

= CHEMODECTOMA

= rare neural tumor arising from paraganglionic tissue

Age: 3rd–5th decade; M÷F = 1÷1

Path: extremely vascular well-marginated / irregular mass that may adhere to / envelop / invade adjacent mediastinal structures (bronchus, spinal canal)

Histo: anastomosing cords of granule-storing chief cells arranged in a trabecular pattern; identical appearance for benign and malignant tumors

May be associated with:

syn- / metachronous adrenal / extrathoracic paragangliomas; multiple endocrine neoplasia type 2; bronchial carcinoid tumor

- asymptomatic; dyspnea, cough, chest pain, hemoptysis, neurologic deficits, SVC syndrome (if tumor large)
- signs of excessive catecholamine production: hypertension, headache, tachycardia, palpitations, tremor

Location: base of heart + great vessels (adjacent to pericardium / heart, within interatrial septum / left atrial wall); paravertebral sulci

CT:

√ sharply marginated 5–7-cm middle / posterior mediastinal mass

√ hypodense areas ← extensive cystic degeneration / hemorrhage
√ exuberant enhancement

MR:
√ heterogeneous intermediate SI with areas of signal void from flowing blood on T1WI
√ high signal intensity on T2WI

NUC (123I / 131I metaiodobenzylguanidine):
√ useful and relatively specific for localization purposes

Angio:
√ marked hypervascularity, multiple feeding vessels
√ homogeneous capillary blush

Cave: Angio may precipitate cardiovascular crisis!

Rx: surgical excision with preoperative administration of α- or β-blockers (hypertensive crisis, tachycardia, dysrhythmia during manipulation)

THORACIC SPLENOSIS

= autotransplantation of splenic tissue to pleural space following thoracoabdominal trauma; discovered 10–30 years later

Pathophysiology: splenic tissue parasitizes blood supply from pleura / chest wall / diaphragm

Frequency: 18% with injury of spleen and diaphragm by blunt trauma; more common in penetrating injury

M÷F = 3÷1 (higher rate of trauma in young men)

• usually asymptomatic / RARELY recurrent hemoptysis

√ one or several nodules in left pleura / fissures measuring several mm to 6 cm

√ splenectomy / splenules in left upper quadrant

√ positive ^{99m}Tc–labeled heat-damaged RBCs (most sensitive), ^{99m}Tc–sulfur colloid scan / 111Indium-labeled platelets

THYMIC CYST

Pathogenesis:

(1) Congenital cyst = persistent embryonic remnant of 3rd pharyngeal pouch (= tubular thymopharyngeal duct), develops during 5th–8th week of gestation)

(2) Acquired reactive multilocular cyst = progressive cystic degeneration of thymic (Hassall) corpuscles + thymic epithelial reticulum induced by an inflammatory process: eg, HIV, before + after chemotherapy for NHL / Hodgkin disease

(3) Neoplastic cyst (cystic teratoma, cystic degeneration within thymoma), thymic carcinoma, Hodgkin disease + NHL, germ cell tumor

◊ No association with myasthenia gravis / neoplasia!

Frequency: very uncommon lesion; 1–2% of mediastinal masses

Age: ⅔ in 1st decade; ⅓ in 2nd + 3rd decades; M > F

Path: unilocular thin-walled cyst with thymic tissue

Histo: squamous / cuboidal / respiratory epithelium in cyst wall; lobulated lymphoid tissue in cyst wall containing Hassall corpuscles; cholesterol crystals; small foci of thyroid / parathyroid tissue

• commonly asymptomatic slowly enlarging painless mass

• hoarseness, dysphagia, stridor, respiratory distress in newborns
• sudden symptomatic enlargement with Valsalva maneuver / hemorrhage / recent viral infection

Location:

(a) adjacent to carotid sheath from angle of mandible to thoracic inlet (along path of thymopharyngeal duct) parallel to sternocleidomastoid muscle; L > R

(b) anterior mediastinum

√ unilocular cyst with thin walls containing clear fluid / multilocular cyst with thick walls containing turbid fluid or gelatinous material

√ direct extension / fibrous cord along migratory tract of thymic tissue into mediastinum in 50%: through thyrohyoid membrane into pyriform sinus

√ may show partial wall calcification (rare)

√ low-density fluid (0–10 HU), may be higher depending on cyst contents

US:

√ typically anechoic

DDx: branchial cleft cyst (no thymic tissue), benign thymoma, teratoma, dermoid cyst, Hodgkin disease, non-Hodgkin lymphoma, pleural fibroma

THYMIC HYPERPLASIA

◊ Most common anterior mediastinal mass in pediatric age group through puberty

DDx: thymoma (focal mass, loss of normal fatty infiltration)

True Thymic Hyperplasia

= increase in size + weight of thymus with preservation of its organized microscopic features ← rebound hyperplasia after recovery from recent stress

Age: commonly in child, also in adult

Stress events: systemic infection (eg, pneumonia); surgery, burns; neoplasm; corticosteroid / radiation / chemotherapy (10–25%)

◊ Thymus atrophies under bodily stress to as little as 40% of its original volume ← endogenous steroids

Timing: rebound within 2 years of initiation of chemotherapy

√ size:

√ diffuse enlargement

√ > 50% transient overgrowth (reducible with steroids)

√ after recovery regrowth to original size within 9 months

√ shape:

√ smooth contour, normal vessels

√ normal / oval shape with loss of its distinct bilobed appearance

√ fine mixture of fat and lymphoid tissue

MR:

√ homogeneously decreased signal on out-of-phase images ← fatty infiltration of normal / hyperplastic thymus (unlike thymoma)

PET/CT:

√ may take up FDG mimicking thymoma

Thymic Lymphoid Hyperplasia

= increase in number of active lymphoid germinal centers in thymic medulla associated with lymphocytic and plasma cell infiltration

Associated with autoimmune disease:

WHO Classification of Thymic Epithelial Tumors
(poorly reproducible and without clinical implications)

Tumor Type	*Description*
A	medullary (epithelial cells: oval / fusiform shape)
AB	mixed
B	(epithelial cells: epitheloid shape)
B1	lymphocyte rich, predominantly cortical
B2	cortical
B3	epithelial = well-differentiated thymic carcinoma
C	thymic carcinoma

hyperthyroidism (most common), Graves disease, idiopathic thyromegaly, thyrotoxicosis, myasthenia gravis (65%), connective tissue disease (SLE, rheumatoid arthritis, scleroderma, vasculitis), sarcoidosis, red blood cell aplasia, acromegaly, Addison disease

√ diffuse symmetric enlargement / normal size

THYMOLIPOMA

Frequency: 2–9% of thymic tumors

Age: 3–60 years (mean age of 22 years); M÷F = 1÷1

Path: lobulated pliable encapsulated tumor capable of growing to large size (in 68% > 500 g, in 20% > 2,000 g, the largest > 16 kg)

Histo: benign adult adipose tissue interspersed with areas of normal / hyperplastic / atrophic thymus tissue (thymic tissue < 33% of tumor mass)

• usually asymptomatic; chest pain, dyspnea, cough (in 50%)

√ fatty mass with fibrous septa

√ large lesions slump inferiorly from anterior mediastinum toward diaphragm enlarging the cardiophrenic space

√ may drape around heart enlarging cardiac silhouette on frontal view

√ apparent elevation of diaphragm on lateral view

√ NO compression / invasion of adjacent structures

DDx: mediastinal lipoma (most common of intrathoracic fatty tumors), liposarcoma, teratoma (cystic changes, no connection to thymic bed)

THYMOMA

= THYMIC EPITHELIAL TUMOR

= slow growing neoplasm potentially exhibiting aggressive behavior (invasion of adjacent structures + involvement of pleura and pericardium), but rarely distant metastases

◊ Most common primary neoplasm of anterior mediastinum

Incidence: 1–5 ÷ 1,000,000 per year; 1% of all adult malignancies; 20% of all mediastinal neoplasms in adults; < 5% of mediastinal tumors in children

Age peak: 5th–6th decade (70%); almost all > 25 years of age; less frequent in young adults,

rare in children; M÷F = 1÷1

Associated with: parathymic (paraneoplastic) systemic syndromes (40%) such as

1. **Myasthenia gravis** (30–50%)
   = autoimmune disorder characterized by antibodies against nicotinic acetylcholine receptors of the postjunctional muscle membrane (M < F)
   • fatigability of skeletal muscles innervated by cranial nerves, eg, ptosis, diplopia, dysphagia, dysarthria, drooling, difficulty with chewing, progressive weakness, fatigue
   • ↑ serum level of anti-acetylcholine receptor antibodies
   ◊ 30–50% of thymoma patients have myasthenia gravis; removal of thymic tumor often results in symptomatic improvement; myasthenia gravis may develop after surgical thymoma excision
   ◊ 10–15% of myasthenia gravis patients have a thymoma (in 65% thymic hyperplasia)
   Rx: edrophonium chloride (cholinesterase inhibitor)
2. **Pure red cell aplasia** (5%)
   = aregenerative anemia
   = almost total absence of marrow erythroblasts + blood reticulocytes → severe normochromic normocytic anemia
   ◊ 5% of thymoma patients develop red cell aplasia
   ◊ 50% of patients with red cell aplasia have thymoma
3. Acquired hypogammaglobulinemia (6%)
   ◊ 6% of thymoma patients have hypogammaglobulinemia
   ◊ 10% of hypogammaglobulinemia patients have thymoma
4. Autoimmune disorders:
   Dermatomyositis; SLE; Rheumatoid arthritis; Cushing syndrome (ACTH production); Myocarditis; Syndrome of inappropriate antidiuretic hormone secretion (SIADH)
5. Nonthymic cancers: NHL, GI cancer, sarcoma, multiple myeloma

◊ Thymic carcinomas rarely cause paraneoplastic syndromes

Path: round / ovoid slow-growing primary epithelial neoplasm with smooth / lobulated surface divided into lobules by fibrous septa; areas of hemorrhage / necrosis / cystic component (⅓)

(a) encapsulated (⅔) = thick fibrous capsule ± calcifications
(b) locally invasive = microscopic foci outside capsule (⅓)
(c) metastasizing = benign cytologic appearance with pleural + pulmonary parenchymal seeding
(d) thymic carcinoma

Histo:

(a) biphasic thymoma (most common)
= epithelial + lymphoid elements in equal amounts
(b) predominantly lymphocytic thymoma
= > ⅔ of cells are lymphocytic
(c) predominantly epithelial thymoma
= > ⅔ of cells are epithelial

◊ Prognosis unrelated to cell type!

Classification: (1) Thymoma

(2) Thymic carcinoma

- asymptomatic (50% discovered incidentally)
- signs of mediastinal compression (25–30%):
  - cough, dyspnea, chest pain (in up to ⅓)
  - respiratory infection, hoarseness (recurrent laryngeal nerve), diaphragmatic paralysis, dysphagia
- signs of tumor invasion (rare): SVC syndrome
- systemic complaints ← paraneoplastic syndromes ← secretion of hormones, antibodies, cytokines by tumor

Location: any anterior mediastinal location between thoracic inlet and cardiophrenic angle; rare in neck, other mediastinal compartments, lung parenchyma, or tracheobronchial tree

Mean size: 5 (range, 1–10) cm; maximum 34 cm

CXR:

√ abnormally wide mediastinum + nodule / mass in retrosternal region
√ mass usually on one side of midline obscuring heart border
√ displacement of heart + great vessels posteriorly
√ thickening of anterior junction line
√ irregular borders with adjacent lung ← advanced disease
√ elevation of hemidiaphragm ← phrenic nerve involvement
√ pleural nodularity ← pleural metastases (stage IVa)

CT:

√ oval / round well-marginated unilateral asymmetric homogeneous mass of soft-tissue density (equal to muscle)
√ smooth / lobulated border partially / completely outlined by fat
√ soft-tissue nodules in a cystic anterior mediastinal lesion = cystic thymoma
√ ± intratumoral punctate / amorphous coarse flocculent / curvilinear capsular calcifications (5–25%)
√ homogeneous enhancement (CHARACTERISTIC)
√ areas of decreased attenuation + heterogeneous enhancement (⅓) ← necrosis / cystic change / hemorrhage

Signs of invasion:

Masaoka-Koga Staging System for Thymoma *(as a good predictor of survival)*	
Stage	*Description*
I	intact capsule
II	pericapsular growth into mediastinal fat
IIA	microscopic pericapsular growth
IIB	macroscopic growth into surrounding fat
III	invasion of neighboring organs such as lung, pericardium, SVC, aorta
IV	metastatic
IVA	within thoracic cavity (metastases to pleura + lung in 6%, pericardium)
IVB	extrathoracic metastases (liver, bone, lymph nodes, kidneys, brain)

› signs of Masaoka stage II–IV thymoma:
√ lobulated / irregular contours
√ cystic / necrotic regions within the tumor
√ multifocal calcifications
› signs of Masaoka stage III–IV thymoma:
√ primary tumor ≥ 7 cm
√ fat infiltration surrounding tumor
√ lobulated tumor contours
› signs of vascular invasion:
√ irregular contour of vessel lumen
√ vascular encasement / obliteration
√ endoluminal soft tissue ± extension into heart chambers
› pleural drop metastases:
√ smooth nodular / diffuse pleural nodules / masses, almost always ipsilateral to anterior mediastinal tumor
√ pleural effusion uncommon with pleural metastases

MR:
√ low to intermediate signal intensity = isointense to skeletal muscle on T1WI
√ high signal intensity approaching fat on T2WI
√ heterogeneous signal intensity:
√ low T1 + high T2 SI ← tumor necrosis / cystic change
√ low-signal-intensity regions ← fibrous tumor septa and nodularity / hemosiderin deposition

Rx: surgical resection for stage I; radiation therapy
◊ Completeness of resection is a major prognostic factor

DDx: ◊ Thymoma rarely manifests with lymphadenopathy /pleural effusions / extrathoracic metastases
(1) Thymic hyperplasia (young child, smooth borders, preserved normal thymic shape)
(2) Primary thymic malignancy: thymic carcinoma, thymic carcinoid
(3) Nonthymic tumor: lymphoma, germ cell tumor, small-cell lung cancer (mediastinal

lymphadenopathy, pleural effusions, pulmonary metastases)

Noninvasive [Benign] Thymoma

Terminology: "benign" not acceptable ← all thymomas are malignant tumors with potential to metastasize

Thymic Carcinoma

= INVASIVE [MALIGNANT] THYMOMA

◊ Malignancy defined according to extent of invasion into adjacent mediastinal fat + fascia!

Frequency: 20–35% of thymic epithelial tumors

Mean age: 50 years; uncommon in adults, rare in children

Path: thymic carcinomas usually lack well-defined capsule

Distant metastases at diagnosis:

› 50–65% of patients with thymic carcinomas

› 5% of patients with invasive thymomas

CT:

√ large multilobulated mass with irregular contour:

√ heterogeneous attenuation

√ invasion of mediastinal fat

√ spread by contiguity along pleural reflections, extension along aorta reaching posterior mediastinum / crus of diaphragm / retroperitoneum (transdiaphragmatic tumor extension):

√ unilateral diffuse nodular pleural thickening / pleural masses encasing lung circumferentially

√ vascular encroachment

√ pleural effusion UNCOMMON

√ distant metastases + regional lymphadenopathy

MR:

√ high signal intensity on both T1WI and T2WI

√ heterogeneous signal intensity ← hemorrhage / necrosis

DDx: malignant mesothelioma, lymphoma, thymic carcinoma / malignant germ cell tumor (older male, no diffuse pleural seeding), peripheral lung carcinoma (no dominant mediastinal mass), metastatic disease (not unilateral)

Rx: radical excision ± adjuvant radiation therapy

Prognosis: 5-year survival of 93% for stage I, 86% for stage II, 70% for stage III, 50% for stage IV; 2–12% recurrence rate for resected encapsulated thymoma

TORSION OF LUNG

= rare complication of severe chest trauma

Frequency: rare (< 30 cases)

Age: almost invariably in children

Cause: compression of lower thorax, tear on inferior pulmonary ligament, completeness of fissures

Mechanism: compression of lower thorax with lung twisted through 180°; usually in presence of a large amount of pleural air / fluid

Associated with:

surgery (lobectomy), trauma, diaphragmatic hernia, pneumonia, pneumothorax, bronchus-obstructing tumor

Histo: ± hemorrhagic infarction + excessive air trapping

√ collapsed / consolidated lobe in unusual position + configuration:

√ hilar displacement of atelectatic-appearing lobe in an inappropriate direction

√ change in position of opacified lobe on sequential radiographs

√ alteration in normal course of pulmonary vasculature:

√ main lower lobe artery sweeping upward toward apex

√ rapid opacification of an ipsilateral lobe from edema + hemorrhage into airspaces ← infarction (DDx: pleural effusion)

√ bronchial cutoff / distortion

√ lobar air trapping

√ lower lung vessels diminutive

TRACHEOBRONCHOMEGALY

= MOUNIER-KUHN SYNDROME

= primary atrophy / dysplasia of supporting structures of trachea + major bronchi with abrupt transition to normal bronchi at 4th–5th division

Frequency: 0.5–1.5%

Age: discovered in 3rd–5th decade

• cough with copious sputum, shortness of breath on exertion

• long history of recurrent pneumonias

May be associated with: Ehlers-Danlos syndrome

√ marked dilatation of trachea (> 29 mm), right (> 20 mm) + left (> 15 mm) mainstem bronchi

√ sacculated outline / diverticulosis of trachea on lateral CXR (= protrusion of mucous membrane between rings of trachea)

√ may have emphysema / bullae in perihilar region

TRACHEOBRONCHOPATHIA OSTEOCHONDROPLASTICA

= rare benign disease characterized by multiple submucosal cartilaginous / osseous nodules projecting into tracheobronchial lumen

Cause: unknown; may be due to chronic inflammation, degenerative process, irritation by oxygen / chemical, metabolic disturbance, amyloidosis, tuberculosis, syphilis, heredity (high prevalence in Finland)

Pathogenetic theories:

(1) Ecchondrosis / exostosis of cartilage rings

(2) Cartilaginous / osseous metaplasia of internal elastic fibrous membrane of trachea

Path: foci of submucosal hyaline cartilage with areas of lamellar bone

Histo: adipose tissue + calcified areas with foci of bone marrow; thinned normal overlying mucosa with inflammation + hemorrhage

Average age: 50 (range, 11–78) years; M÷F = 3÷1

• usually asymptomatic (incidentally diagnosed)

• dyspnea, productive cough, hoarseness, hemoptysis, fever, recurrent pneumonia

Location: distal ⅔ of trachea, larynx, lobar / segmental bronchi, entire length of trachea; spares

posterior membrane of trachea

CXR:

√ scalloped / linear opacities surrounding + narrowing trachea (best on lateral view)

CT:

√ deformed thickened narrowed tracheal wall

√ irregularly spaced 1–3-mm calcific submucosal nodules of trachea + bronchi (similar to plaques)

Dx: bronchoscopy

DDx: relapsing polychondritis, tracheobronchial amyloidosis (does not spare posterior membranous wall of trachea), sarcoidosis, papillomatosis, tracheobronchomalacia

TUBERCULOSIS

Prevalence: 10 million people worldwide; active TB develops in 5–10% of those exposed; 3÷100,00 in USA (2014)

Organism: Mycobacterium = acid-fast aerobic rods staining red with carbol-fuchsin: M. tuberculosis (95%), atypical types increasing: M. avium-intracellulare, M. kansasii, M. fortuitum

Susceptible: infants, pubertal adolescents, elderly, alcoholics, Blacks, diabetics, silicosis, measles, AIDS (30–40% infected with HIV), sarcoidosis (in up to 13%)

At risk: immunocompromised, minorities, poor, alcoholics, immigrants from 3rd world countries, prisoners, the aged, nursing home residents, homeless

Pathologic phases:

(a) exudative reaction (initial reaction, present for 1 month)
(b) caseous necrosis (after 2–10 weeks with onset of hypersensitivity)
(c) hyalinization = invasion of fibroblasts → granuloma formation in 1–3 weeks
(d) calcification / ossification
(e) chronic destructive form in 10% (< 1 year of age, adolescents, young adults)

Spread: regional lymph nodes, hematogenous dissemination, pleura, pericardium, CNS, head & neck, spondylitis, osteomyelitis, arthritis, peritonitis, GI & GU tract

- Positive PPD tuberculin test: 3 weeks after infection
- Negative PPD test: overwhelming tuberculous infection (miliary TB); sarcoidosis; corticosteroid therapy; pregnancy; infection with atypical Mycobacterium

Former Rx: plombage with insertion of plastic packs, Lucite™ balls, polythene spheres; oleothorax (= injection of oil / paraffin)

Mortality: 1÷100,000

Tuberculoma

= manifestation of primary / postprimary TB

√ round / oval smooth sharply defined mass

√ 0.5–4 cm in diameter remaining stable for a long time

√ lobulated mass (25%)

√ satellite lesions (80%)

√ may calcify

Cavitary Tuberculosis

= hallmark of reactivation tuberculosis
= semisolid caseous material is expelled into bronchial tree after lysis
√ moderately thick-walled cavity with smooth inner surface
Cx:
(1) Dissemination to other bronchial segments
√ multiple small acinar shadows remote from massive consolidation
(2) Colonization with Aspergillus
√ aspergilloma

Rasmussen, Fritz Valdemar (1837–1877), chair of pathology at University of Copenhagen, Denmark

(3) **Rasmussen aneurysm** = fragile aneurysm of terminal branches of pulmonary artery within wall of TB cavity ← inflammatory necrosis of the vessel wall (4% at autopsies of cavitary TB):
[Fritz Valdemar Rasmussen (1837–1877), chair of pathology at University of Copenhagen, Denmark]
• sentinel hemoptysis prior to catastrophic hemorrhage
√ central cavity near hilum:
√ enlargement of intracavitary solid protrusion
√ replacement of cavity by a nodule
√ rapidly growing mass
√ opacification of pseudoaneurysm on CT / angio

Endobronchial (Acinar) Tuberculosis
◊ Most common complication of tuberculous cavitation with active organisms spreading via airways following caseous necrosis of bronchial wall
Path: ulceration of bronchial mucosa → fibrosis →
(a) bronchial stenosis → lobar consolidation
(b) bronchiectasis
(c) acinar nodules reflecting airway spread
HRCT:
√ clustered centrilobular nodules
√ "tree-in-bud" appearance = small poorly defined centrilobular nodules + branching centrilobular areas of increased opacity (= severe bronchiolar impaction with clubbing of distal bronchioles) occurring at multiple contiguous branching sites
√ masslike areas of consolidation
√ cavitation in larger nodules / masses
√ bronchiectasis

Primary Pulmonary Tuberculosis
= self-limiting disease in patients not previously exposed
Mode of infection: inhalation of infected airborne droplets ← coughing expels and aerosolizes organism in 1–5-μm particles remaining suspended in air for several hours
Age: most common form in infants + childhood (highest prevalence in children < 5 years of age); increasingly encountered in adults (23–34%)

• asymptomatic (91%); symptomatic (5–10%)

@ Parenchymal disease

Location: middle lobe, lower lobes, anterior segment of upper lobes

√ normal radiograph (in up to 15%)

√ one / more areas of homogeneously dense well-defined airspace consolidation of 1–7 cm in diameter in 25–78%:

√ absent response to antibiotic Rx for "pneumonia"

DDx: bacterial pneumonia

√ fine discrete nodular areas of increased opacity

DDx: varicella pneumonia, histoplasmosis, metastases, sarcoidosis, pneumoconiosis, hemosiderosis

√ lobar / segmental atelectasis (in 8–18%)

Location: anterior segment of upper lobe / medial segment of middle lobe

Age: in children < 2 years of age

Cause: (a) endobronchial tuberculosis

(b) bronchial / tracheal compression by enlarged lymph nodes (68%)

@ Lymphadenopathy (up to 96% of children, 43% of adults)

◊ may be the sole radiographic manifestation

Location: typically right unilateral (hilum + paratracheal region); bilateral in ⅓

√ <u>in children</u>: massive hilar (60%) / paratracheal (40%) / subcarinal lymphadenopathy

<u>in adults</u>: mediastinal lymphadenopathy in 5–35–48%

DDx of Lnn: metastases, histoplasmosis

√ nodes > 2 cm with low-attenuation center ← necrosis = highly suggestive of active disease

√ lymph node calcification (36%) in hilum / mediastinum usually > 6 months after initial infection

@ Pleural effusion

◊ Often sole manifestation of TB

Onset: 3–7 months after initial exposure ← subpleural foci rupturing into pleural space

Frequency: 10% in childhood, 23–38% in adulthood

US:

√ usually unilateral often complex septated effusion

√ may result in pleural thickening + calcification

Cx (rare): empyema, fistulization, bone erosion

Outcome of Primary Infection:

1. Restitutio ad integrum (in ⅔)

= resolution of primary focus without sequelae

√ **Simon focus** = healed site of primary infection in lung apex; may take up to 2 years

2. Immunity prevents multiplication of organism

= containment of initial infection by delayed hyper-sensitivity response + granuloma formation in 1–3 weeks

√ calcified lung lesion (in up to 17%) / parenchymal scar < 5 mm = **Ghon focus (lesion)**

√ **Ranke complex** = Ghon lesion + calcified lymph node (22%)

DDx: histoplasmosis

3. Progressive primary TB
   = inadequate immune mechanism → local progression in 10%, most common in older children / teenagers
   √ persistent masslike opacity = tuberculoma (9%) ± cavitation
4. Miliary tuberculosis (uncontrolled massive hematogenous dissemination overwhelming host defense system)
5. Postprimary TB = reactivation TB (= reactivation of dormant organisms after asymptomatic years)

Prognosis: 3.6% mortality rate; usually self-limiting

Cx: (1) Bronchopleural fistula + empyema
(2) Fibrosing mediastinitis

DDx: postprimary tuberculosis (predilection for upper lobes, cavitation, absence of lymphadenopathy

MILIARY PULMONARY TUBERCULOSIS

= massive hematogenous dissemination of organisms within 6 months of initial exposure

Cause:
(1) severe immunodepression during postprimary state of infection
(2) impaired defenses during primary infection in elderly / infants = PROGRESSIVE PRIMARY TB

Frequency: 1–3.5–7% of all forms of TB

Onset: radiographically recognizable after 6 weeks post hematogenous dissemination

√ CXR initially normal / with signs of hyperinflation
√ chronic focus often not identifiable
√ generalized evenly distributed small interstitial granulomatous foci of pinpoint to 2–3 mm size with slight lower lobe predominance (in 85%)
√ ± coalescence into focal / diffuse consolidation
√ resolution with appropriate therapy within 2–6 months

HRCT (earlier detection than CXR):
√ diffusely scattered discrete 1–2-mm nodules in random distribution

Cx: dissemination via bloodstream affecting lymph nodes, liver, spleen, skeleton, kidneys, adrenals, prostate, seminal vesicles, epididymis, fallopian tubes, endometrium, meninges

Resolution: within 2–6 months under treatment
√ NO scarring / calcification
√ may coalesce into focal / diffuse consolidation

Postprimary Pulmonary Tuberculosis

= REACTIVATION TB = RECRUDESCENT TB
= progressive infection under the influence of acquired hypersensitivity and immunity ← longevity of bacillus + impairment of cellular immunity

Frequency: 1% per year with normal immunity, in up to 10% with deficient T-cell immunity

Age: primarily in adolescents + adults

Etiology:

(a) reinfection
(b) reactivation of focus acquired in childhood (90%)
(c) continuation of initial infection = progressive primary tuberculosis (rare)
(d) initial infection in individual vaccinated with BCG

Path: foci of caseous necrosis with surrounding edema, hemorrhage, mononuclear cell infiltration; formation of tubercles = accumulation of epithelioid cells + Langhans giant cells; bronchial perforation leads to intrabronchial dissemination (19–21%)

Site: 85% in apical + posterior segments of upper lobe, 10% in superior segment of lower lobe, 5% in mixed locations (anterior + contiguous segments of upper lobe); R > L (DDx: histoplasmosis tends to affect anterior segment)

• hemoptysis (most common cause worldwide)
Rx: bronchial artery embolization

Prognosis: progressive

The features of primary and postprimary tuberculosis may overlap. The distinguishing features of postprimary tuberculosis include cavitation, a predilection for the upper lobes, and the absence of lymphadenopathy.

Local Exudative Tuberculosis

√ patchy / confluent ill-defined areas of acinar consolidation (87–91%), commonly involving two / more segments (earliest finding)
√ thin-walled cavitation with smooth inner surface (present in more advanced disease):
  √ cavity under tension (air influx + obstructed efflux)
  √ air-fluid level = strong evidence for superimposed bacterial / fungal infection
  √ "air-crescent" sign = mobile intracavitary mycetoma
√ accentuated drainage markings toward ipsilateral hilum
√ acinar nodular pattern (20%) ← bronchogenic spread
√ pleural effusion (18%)
CT:
  √ micronodules in centrilobular location (62%) = solid caseation material in / surrounding the terminal / respiratory bronchioles
  √ interlobular septal thickening (34–54%) = increase in lymphatic flow as inflammatory response / impaired lymphatic drainage ← hilar lymphadenopathy

Local Fibroproductive Tuberculosis

@ Parenchymal disease:
  √ sharply circumscribed irregular + angular masslike fibrotic lesion (in up to 7%)
  √ cavitation (HALLMARK) ← expulsion of caseous necrosis into airways; rare in children, in up to 45–51% in adults; often multiple suggesting high likelihood of active TB:
    Site: apical / posterior segments of upper lobes
    √ cavity forms within areas of consolidation
    √ thick irregular cavity wall → smooth thin cavity wall with successful treatment
    √ ± air-fluid level (rare) may indicate superinfection
  √ reticular pulmonary scars
  √ cicatrization atelectasis = volume loss in affected lobe

- √ peripheral tree-in-bud opacities (indicative of active disease)
- √ pneumothorax (5%)

@ Airway involvement
- √ long-segment bronchial stenosis (in 10–40%) with irregular wall thickening, luminal obstruction, and extrinsic compression:
  - √ persistent segmental / lobar collapse
  - √ lobar hyperinflation
  - √ obstructive pneumonia
  - √ mucoid impaction
- √ traction bronchiectasis in apical / posterior segments of upper lobes
- √ tree-in-bud opacities in lung periphery ← endobronchial spread of active infection

@ Pleural extension:
- √ small septated pleural effusions remaining stable for years (in 18%):
  - √ air-fluid level in pleural space = bronchopleural fistula
- √ pleural thickening:
  - √ apical cap = pleural rind = thickening of layer of extrapleural fat (3–25 mm) + pleural thickening (1–3 mm)
  - √ rim-enhancing / calcified soft-tissue mass of chest wall
- √ destruction of bone / costal cartilage
- √ fistulization to skin

@ Lymphadenopathy (in 5%):
- √ tuberculous lymphadenitis = enlarged nodes with central areas of low attenuation
- √ calcified hilar / mediastinal nodes:
  - broncholithiasis = erosion into adjacent airway

Extrapulmonary Tuberculosis

In order of frequency: kidney, liver, spleen, bone, adrenal

@ Genitourinary

@ Hepatosplenic

@ Musculoskeletal system (1–3%): spine (5%)

@ Lymph nodes, peritoneum, GI tract

@ Head & neck (15%)

@ CNS (5%)

@ Heart (0.5%)
- √ > 3 mm irregular pericardial thickening (in adults)
- √ IVC distention to > 3 cm in diameter
- √ pericardial effusion / localized pericardial calcification (< 20%)
- √ miliary lesions / tuberculomas of myocardium
- √ typically bilateral pleural effusions
- √ deformities of intraventricular septum

Extrarenal Signs of TB on Abdominal Plain Film
- √ osseous / paraspinous changes of TB (= diskitis + psoas abscess)
- √ calcified granulomas in liver, spleen, lymph nodes, adrenals

UNILATERAL PULMONARY AGENESIS

= one-sided lack of primitive mesenchyme

Cause: ? abnormal blood flow in dorsal aortic arch during 4th week of gestation

Associated with:

anomalies in 60% (higher if right lung involved): PDA, anomalies of great vessels, pulmonary sling, tetralogy of Fallot (left-sided pulmonary agenesis), bronchogenic cyst, congenital diaphragmatic hernia, complete tracheal rings, bone anomalies

• may be asymptomatic versus respiratory infections

Location: R (worse prognosis) > L (better prognosis)

√ completely opaque hemithorax

√ ipsilateral absence of pulmonary vessels (arteries + veins)

√ absent ipsilateral mainstem bronchus + airways

√ symmetrical chest cage with approximation of ribs

√ marked contralateral lung hyperexpansion + hyperlucency

√ ipsilateral shift of mediastinum + diaphragm

VARICELLA-ZOSTER PNEUMONIA

Frequency: 14% overall; 50% in hospitalized adults

Age: > 19 years (90%); 3rd–5th decade (75%); contrasts with low incidence of varicella in this age group

• vesicular rash

√ patchy diffuse airspace consolidation

√ tendency for coalescence near hila + lung bases

√ widespread nodules (30%) representing scarring

√ tiny 2–3-mm calcifications widespread throughout both lungs (2%)

Cx: unilateral diaphragmatic paralysis

Prognosis: 11% mortality rate

WILLIAMS-CAMPBELL SYNDROME

= congenital bronchial cartilage deficiency in the 4th–6th bronchial generation either diffuse or restricted to focal area

HRCT:

√ cystic bronchiectasis distal to 3rd bronchial generation

√ emphysematous lung distal to bronchiectasis

√ inspiratory ballooning + expiratory collapse of dilated segments

WILSON-MIKITY SYNDROME

= PULMONARY DYSMATURITY

= similarity to bronchopulmonary dysplasia in normal preterm infants breathing room air; rarely encountered anymore due to mechanical assisted ventilation

Predisposed: premature infants < 1,500 g who are initially well

• gradual onset of respiratory distress between 10 and 14 days

√ hyperinflation

√ reticular pattern radiating from both hila

√ small bubbly lucencies throughout both lungs (identical to bronchopulmonary dysplasia)
Prognosis: resolution over 12 months
DDx: perinatally-acquired infection (especially CMV)

ZYGOMYCOSIS

= PHYCOMYCOSIS
= group of severe opportunistic sinonasal + pulmonary disease caused by a variety of Phycomycetes (soil fungi)
Organism: ubiquitous Mucor (most common), Rhizopus, Absidia with broad nonseptated hyphae of irregular branching pattern
At risk: immunoincompetent host with
(1) Lymphoproliferative malignancies and leukemia
(2) Acidotic diabetes mellitus
(3) Immunosuppression through steroids, antibiotics, immunosuppressive drugs (rare)
Entry: inhalation / aspiration from sinonasal colonization
Path: angioinvasive behavior similar to aspergillosis
A. RHINOCEREBRAL FORM
= involvement of paranasal sinuses (frontal sinus usually spared) with extension into:
(a) orbit = orbital cellulitis
(b) base of skull = meningoencephalitis + cerebritis
B. PULMONARY FORM
√ segmental homogeneous consolidation
√ cavitary consolidation + "air-crescent" sign
√ nodules (from arterial thrombi + infarction)
√ rapidly progressive (often fatal) pneumonia
Dx: culture of fungus from biopsy specimen / demonstration within pathologic material
DDx: aspergillosis

BREAST

DIFFERENTIAL DIAGNOSIS OF BREAST DISORDERS

VARIATIONS IN BREAST DEVELOPMENT

Unilateral Breast Development

may exist 2 years before other breast becomes palpable

Premature Thelarche

= breast development < 7 years of age (in African American girls) and < 8 years of age (in white girls)

Cause:

(1) isolated idiopathic = mostly subtle hyperfunction of pituitary-ovarian axis

Age: 1–3 years

- NO growth spurt / advanced bone age / menses

(2) central precocious puberty

√ enlargement of uterus + ovaries

√ advanced bone age

√ uni- / bilateral normal breast tissue

Congenital Anomalies

1. Polythelia = more than normal number of nipples
2. Polymastia = more than normal number of breasts
3. Amastia = absence of mammary glands

BREAST DENSITY

= relative amount of radiopaque epithelial + stromal elements compared with amount of radiolucent fat on mammography

The masking effect of dense breasts on cancer detection is greatly reduced by digital over film-screen mammography.

Inter- and intraobserver variability on breast density:

- low reliability of interreader density agreement ($\kappa = 0.59$)
- imperfect intrareader agreement ($\kappa = 0.72$)

Factors affecting breast density between mammograms:

body mass index, weight changes, age, HRT, dietary intake

Breast density may vary over time through variability of interpretation, physiologic changes and breast positioning.

Mammographic sensitivity vs. breast density:

Mammographic sensitivity plummets from 80–98% in women with entirely fatty breasts to 30–64% in women with extremely dense breasts.

Asymmetric Breast Density

A. BENIGN
   1. Postsurgical scarring
   2. Noniatrogenic trauma
   3. Postinflammatory fibrosis
   4. Radial scar
   5. Ectopic / accessory breast tissue (in axillary tail / close to abdomen)
   6. Asymmetric breast development / asymmetric involution
   7. Simple cyst
   8. Fibrocystic conditions: fibrosis / sclerosing adenosis
   9. Hormonal therapy: replacement, contraceptives

B. MALIGNANT
   1. Invasive ductal carcinoma: desmoplastic reaction
   2. Invasive lobular carcinoma
   3. Tubular carcinoma
   4. Primary lymphoma of breast

C. IMAGING PROBLEMS
   1. Superimposed normal fibroglandular tissue
   2. Lesion obscured by overlapping dense parenchyma
   3. Lesion outside field of view

Diffuse Increase in Breast Density

◊ Increased breast density masks breast cancer detection and is also a primary risk factor for breast cancer!

The relative risk for cancer in women with heterogeneously dense breasts compared with the average woman is ~ 1.2.

The relative risk for cancer in women with extremely dense breasts compared with the average woman is ~ 2.1.

√ generalized increased density
√ skin thickening
√ reticular pattern in subcutis

A. CANCER
   1. “Inflammatory” breast cancer
   2. Diffuse primary noninflammatory breast cancer
   3. Diffuse metastatic breast cancer
   4. Lymphoma / leukemia ← obstructive lymphedema of breast

B. INFECTIOUS mastitis
   usually in lactating breast

C. RADIATION
   (a) diffuse exudative edema within weeks after beginning of radiation therapy
   (b) indurational fibrosis months after radiation therapy

D. EDEMA
E. HEMORRHAGE
   1. Posttraumatic
   2. Anticoagulation therapy
   3. Bleeding diathesis
F. ACCIDENTAL INFUSION OF FLUID
   into subcutaneous tissue

Breast Edema

1. Lymphatic obstruction: extensive axillary / intrathoracic lymphadenopathy, mediastinal / anterior chest wall tumor, axillary surgery, SVC syndrome, filariasis, intestinal lymphangiectasia
2. Skin disorder: psoriasis, burns
3. Generalized body edema: congestive heart failure (breast edema may be unilateral if patient in lateral decubitus position), hypoalbuminemia (renal disease, liver cirrhosis), fluid overload

Abnormal Uptake of Bone Agents within Breast

1. Breast carcinoma
2. Prosthesis
3. Drug-induced

MAMMOGRAPHIC RISK ASSESSMENT

for invasive breast carcinoma

A. NO INCREASED RISK
   1. Nonproliferative lesions: adenosis, florid adenosis, apocrine metaplasia without atypia, macro- / microcysts, duct ectasia, fibrosis, mild hyperplasia (more than 2 but not more than 4 epithelial cells deep), mastitis, periductal mastitis, squamous metaplasia
   2. Fibroadenoma

B. PROLIFERATIVE LESIONS WITHOUT ATYPIA
   Relative risk increase: 1.5–2.0
   1. Columnar cell change / hyperplasia = blunt duct adenosis
   2. Moderate + florid solid / papillary hyperplasia without atypia
   3. Sclerosing adenosis
   4. Intraductal papilloma with fibrovascular core
   5. Pseudoangiomatous stromal hyperplasia (PASH)
   6. Radial sclerosing lesion

C. PROLIFERATIVE LESIONS WITH ATYPIA
   Relative risk increase: 4–5
   1. Atypical ductal hyperplasia (ADH)
   2. Lobular neoplasia: separation based on degree of distension of affected terminal ductules:
      (a) Atypical lobular hyperplasia (ALH)
      (b) Lobular carcinoma in situ (LCIS)

BREAST LESION

Mammographic Evaluation of Breast Masses

True mass or pseudomass?

A. SIZE
   - › well-defined nodules < 1.0 cm are of low risk for cancer
   - › "most likely benign" nodules approaching 1 cm should be considered for ultrasound / aspiration / biopsy

B. SHAPE
   - › increase in probability of malignancy: architectural distortion > irregular > lobulated > oval > round

C. MARGIN / CONTOUR (<u>most important factor</u>)
   - › well-circumscribed mass with sharp abrupt transition from surrounding tissue is almost always benign
   - › "halo" sign of apparent lucency = optical illusion of Mach effect + true radiolucent halo is almost always (92%) benign but NOT pathognomonic for benignity
   - › microlobulated margin worrisome for cancer
   - › obscured margin may represent infiltrative cancer
   - › irregular ill-defined margin has a high probability of malignancy
   - › spiculated margin due to
     - (a) fibrous projections extending from main cancer mass
     - (b) previous surgery
     - (c) sclerosing duct hyperplasia (radial scar)

D. LOCATION
   - › intramammary lymph node typically in upper outer quadrant (in 5% of all mammograms)
   - › large hamartoma + abscess common in retro- / periareolar location
   - › sebaceous cyst in subcutaneous tissue

E. X-RAY ATTENUATION = DENSITY
   - › fat-containing lesions are never malignant
   - › high-density mass suspicious for carcinoma (density higher than for equal volume of fibroglandular tissue ← fibrosis)

F. NUMBER
   - › multiplicity of identical lesions decreases risk

G. INTERVAL CHANGE
   - › enlarging mass needs biopsy

H. PATIENT RISK FACTORS
   - › increasing age increases risk for malignancy
   - › positive family history
   - › history of previous abnormal breast biopsy
   - › history of extramammary malignancy

Focal Asymmetry

Definition:

= asymmetry confined to less than a quadrant
  (a) lesion with definable borders only seen on 1 view

(b) lesion of similar shape on 2 orthogonal views lacking convex margins + conspicuity of a true mass

A real lesion may not be included in the field of view of the orthogonal view!

Cause:

1. Pseudolesion (in 2% of screening mammograms)
   = **summation artifact** of overlapping breast tissue
2. Breast cancer
   ◊ A focal asymmetry is a malignancy in only 1–3%
   ◊ A developing / new focal asymmetry represents a malignancy in 6–27%
   ◊ In 9–38% missed cancers were retrospectively visible as a focal asymmetry
   A 1-view lesion is of concern if associated with: outward convex margins / straight lines of architectural distortion or spiculation / microcalcifications / palpability

Dense fibroglandular tissue may obscure a real lesion on the orthogonal view!

Histo: invasive lobular carcinoma (in 33%), invasive ductal carcinoma

Well-circumscribed Breast Mass

◊ Well-defined nonpalpable lesions have a 4% risk of malignancy!

A. BENIGN
   1. Cyst (45%)
   2. Fibroadenoma
   3. Sclerosing adenoma
   4. Intraductal papilloma (intracystic / solid)
   5. Galactocele
   6. Sebaceous cyst
   7. Pseudoangiomatous stromal hyperplasia

B. MALIGNANT
   1. Medullary carcinoma
   2. Mucinous carcinoma
   3. Intracystic papillary carcinoma
   4. Invasive ductal cancer not otherwise specified (rare)
   5. Pathologic intramammary lymph node
   6. Metastases to breast: melanoma, lymphoma / leukemia, lung cancer, hypernephroma

De Novo Mass in Woman > 40 Years of Age

1. Cyst
2. Papilloma
3. Carcinoma (10–20%)
   (a) Invasive ductal carcinoma (not otherwise specified)
   (b) Mucinous carcinoma
   (c) Medullary carcinoma
   (d) Intracystic papillary carcinoma
   (e) Invasive papillary carcinoma
   (f) Metaplastic carcinoma
   (g) Malignant phyllodes tumor

(h) Adenoid cystic carcinoma

4. Sarcoma (rare)
5. Fibroadenoma (exceedingly rare)
6. Metastasis (extremely rare)

Fibrous Breast Lesion

1. Fibroadenoma
2. Phyllodes tumor
3. Sclerosing lobular hyperplasia
4. Pseudoangiomatous stromal hyperplasia
5. Diabetic mastopathy
6. Focal fibrosis
7. Fibromatosis

Fat-containing Breast Lesion

◊ Fat contained within a lesion usually proves benignity!

1. Lipoma
2. Galactocele
   = fluid with high lipid content (last phase)
   • during / shortly after lactation
3. Oil cyst= traumatic lipid cyst = fat necrosis
   • site of prior surgery / trauma
4. Focal collection of normal breast fat

Mixed Fat- and Water-density Lesion

1. Fibroadenolipoma / hamartoma
2. Intramammary lymph node
3. Galactocele
4. Hamartoma = lipofibroadenoma = fibroadenolipoma
5. Small superficial hematoma
6. Cancer engulfing fat
   √ irregular / spiculated margins]

Secretory Disease

1. Retained lactiferous secretions
   = incomplete / prolonged involution of lactiferous ducts
   √ branching pattern of fat density in dense breast (high lipid content)
2. Prolonged inspissation of secretion + intraductal debris
   = **Mammary duct ectasia**
3. Galactocele
4. Plasma cell mastitis

Breast Lesion with Halo Sign

A. HIGH-DENSITY LESION
   = vessels + parenchymal elements not visible in superimposed lesion
   1. Cyst

2. Sebaceous cyst
3. Wart

B. LOW-DENSITY LESION
= vessels + parenchyma seen superimposed on lesion
1. Fibroadenoma
2. Galactocele
3. Cystosarcoma phylloides

Stellate / Spiculated Breast Lesion

= mass / architectural distortion characterized by thin lines radiating from its margins
› The majority of invasive breast cancers are stellate (stellate÷circular = 65÷35)
› 93% of all stellate lesions are malignant
Risk of malignancy:
› 75% for nonpalpable spiculated masses
› 32% for nonpalpable irregular masses

A. PSEUDOSTELLATE STRUCTURE
= SUMMATION SHADOW / ARTIFACT
caused by fortuitous superimposition of normal fibrous + glandular structures; unveiled by rolled views, spot compression views ± microfocus magnification technique

B. "BLACK STAR"
√ groups of fine straight / curvilinear fibrous strands bunched together like a broom
√ circular / oval lucencies within center
√ change in appearance from view to view
1. Radial scar = sclerosing duct hyperplasia (86%)
2. Sclerosing adenosis
3. Posttraumatic fat necrosis (11%)

C. "WHITE STAR"
√ individual straight dense spicules
√ central solid tumor mass
√ little change in different views
(a) malignant lesions
1. Invasive ductal carcinoma (65%) = **scirrhous carcinoma**
= desmoplastic reaction + secondary retraction of surrounding structures
• clinical dimensions > mammographic size
√ distinct central tumor mass with irregular margins
√ length of spicules increase with tumor size
√ localized skin thickening / retraction when spiculae extend to skin
√ commonly associated with malignant-type calcifications
2. Invasive lobular carcinoma (21%)
• palpable mass
√ lack of central tumor mass
3. Tubular carcinoma (9%)
4. Other (5%)
(b) benign lesions
1. Postoperative scar

• correlation with history + site of biopsy
√ scar diminishes in size + density over time

2. Postoperative hematoma
   • clinical information
   √ short-term mammographic follow-up confirms complete resolution
3. Breast abscess
   • clinical information
   √ high-density lesion with flamelike contour
4. Hyalinized fibroadenoma with fibrosis
   √ changing pattern with different projections
   √ may be accompanied by typical coarse calcifications of fibroadenomas
5. Granular cell myoblastoma
6. Fibromatosis
7. Extra-abdominal desmoid

mnemonic: STARFASH

Summation shadow
Tumor (malignant)
Abscess
Radial scar
Fibroadenoma (hyalinized), **F**at necrosis
Adenosis (sclerosing)
Scar (postoperative)
Hematoma (postoperative)

Tumor-mimicking Lesions

1. "Phantom breast tumor" = simulated mass
   (a) asymmetric density
   √ scalloped concave breast contour
   √ interspersed fatty elements
   (b) summation artifact = chance overlap of normal glandular breast structures
   √ failure to visualize "tumor" on more than one view
2. Silicone injections
3. Skin lesions
   (a) Dermal nevus
   √ sharp halo / fissured appearance
   (b) Skin calcifications
   √ lucent center (= clue)
   √ superficial location (tangential views)
   (c) Sebaceous / epithelial inclusion cyst
   (d) Neurofibromatosis
   (e) Biopsy scar
4. Lymphedema
5. Lymph nodes
   Frequency: 5.4% for intramammary nodes
   Location: axilla, subcutaneous tissue of axillary tail, lateral portion of pectoralis muscle,

intramammary (typically in upper outer quadrant)

√ ovoid / bean-shaped mass(es) with fatty notch representing hilum

√ central zone of radiolucency (fatty replacement of center) surrounded by "crescent" rim of cortex

√ usually < 1.5 cm (up to 4 cm) in size

√ well-circumscribed with slightly lobulated margin

US:

√ reniform hypoechoic rim with echogenic center

√ echogenic hilum for entry and exit of vessels

6. Hemangioma

Solid Breast Lesion by Ultrasound

Morphologic Descriptors of Solid Benign Breast Mass

1.	Shape	oval (84% NPV), round, irregular (62% PPV)
2.	Orientation	parallel (78% NPV), nonparallel (69% PPV) to chest wall ("taller-than-wide" / "vertical")
3.	Margin	circumscribed (90% NPV), microlobulated, indistinct, angular, spiculated (86% PPV)
4.	Lesion boundary	abrupt, echogenic halo
5.	Internal echo pattern	anechoic, hyperechoic, complex, hypoechoic, isoechoic *(in reference to SQ fat)*
6.	Posterior acoustic feature	shadowing, enhancement

Posterior Acoustic Shadowing

1. Invasive carcinoma
2. Postoperative scar
3. Complex sclerosing lesion
4. Microcalcifications
5. Dense breast tissue

Posterior Acoustic Enhancement

1. Normal anatomic structure
2. Cyst: simple / complicated
3. Fibroadenoma
4. Nodular sclerosing adenosis
5. Papilloma
6. Complex cystic mass
7. Invasive ductal carcinoma
8. Lymphoma

Echogenic Breast Lesion

Incidence: 0.6–5.6% of breast masses

◊ Hyperechogenicity alone does not allow exclusion of malignancy!

A. Benign

1. Lipoma
2. Angiolipoma
3. Hematoma
4. Seroma
5. Fat necrosis
6. Silicone granuloma
7. Sebaceous / epidermal inclusion cyst
8. Abscess
9. PASH
10. Galactocele / lactating adenoma
11. Ductal ectasia
12. Apocrine metaplasia

An echogenic mass that correlates with a well-delineated radiolucent mass at mammo is benign!

B. Malignant

1. Invasive ductal carcinoma
2. Invasive lobular carcinoma
3. Metastasis
4. Lymphoma
5. Angiosarcoma

Breast carcinoma is RARELY purely echogenic!

Malignant Sonographic Characteristics

◊ Approximately 5 malignant features are found per cancer. The combination of 5 findings increases the sensitivity to 98.4%!

√ spiculation = straight lines radiating perpendicularly from surface of tumor:
- √ coarse spiculation (less common) = hypoechoic lines (= fingers of invasive tumor / DCIS) alternating with hyperechoic lines (= interface between tumor and surrounding tissue)
- √ fine spiculation (more common):
  - √ hyperechoic spicules in fatty tissue
  - √ hypoechoic spicules in fibrous tissue
- √ thick echogenic halo = spicules too small to resolve

√ angular margins = contour of junction between hypo- or isoechoic solid nodule and surrounding tissue at acute / obtuse / 90° angles

√ acoustic shadowing behind all / part of nodule (= desmoplastic reaction as host response to tumor)

√ taller-than-wide lesion (feature of small lesions)
= AP dimension greater than craniocaudal / transverse dimension

√ microlobulations = many small lobulations at surface of solid nodule (= duct distended with DCIS / cancerized lobule)

√ duct extension (= intraductal growth of breast cancer in single large duct extending toward nipple)
√ branch pattern (= intraductal growth of breast cancer in multiple small ducts extending away from nipple)
√ hypoechoic texture = central part of solid lesion markedly hypoechoic with respect to fat ← invasive tumor mass / fluid within tumor / acoustic shadow
√ punctate echogenic calcifications within hypoechoic duct extension / branch pattern / microlobulations (acoustic shadowing commonly not present)

Sonographic Findings of Malignancy
(according to data from A.T. Stavros)

Certainty	*US Finding*
Hard = invasive carcinoma	Spiculation, thick echogenic halo
	Angular margins
	Acoustic shadowing
Indeterminate	Hypoechoic texture
	Taller-than-wide orientation
Soft = DCIS component	Microlobulation
	Duct extension
	Branch pattern
	Calcifications

Benign Sonographic Characteristics

√ absence of any malignant characteristics
◊ A single malignant feature prohibits classification of a nodule as benign!
√ marked hyperechogenic well-circumscribed nodule compared with fat = normal stromal fibrous tissue (may represent a palpable pseudomass / fibrous ridge)
√ smooth well-circumscribed ellipsoid shape
√ 2–3 smooth well-circumscribed gentle lobulations
√ thin echogenic capsule
√ kidney-shaped lesion = intramammary lymph node
◊ If specific benign features are not found the lesion is classified as indeterminate!

Complex Cystic Breast Mass

= cyst with thick wall, thick septa, intracystic discrete solid components

Classification:

Type 1 thick outer wall ± thick internal septa
Type 2 one / more intracystic masses
Type 3 mixed cystic (> 50%) and solid components
Type 4 predominantly solid + eccentric cystic foci

(a) benign breast lesion
1. Fibrocystic changes: adenosis, sclerosing adenosis, apocrine metaplasia, cyst formation ± rupture, ductal ectasia
2. Intraductal / intracystic papilloma
3. Fibroadenoma

4. Breast varix

(b) atypical (high-risk) breast lesion
1. Atypical ductal hyperplasia
2. Atypical papilloma
3. Lobular neoplasia

(c) malignant breast lesion
1. DCIS
2. Infiltrating ductal carcinoma
3. Infiltrating lobular carcinoma

Benign Sonographic Characteristics
(according to data from A.T. Stavros)

US Characteristic	*Sens.*	*Specif.*	*NPV*	*Rel. risk*
Hyperechoic	100.0	7.4	100.0	0.00
≤ 3 lobulations	99.2	19.4	99.2	0.05
Ellipsoid shape	97.6	51.2	99.1	0.05
Thin echogenic capsule	95.2	76.0	98.8	0.07

MALE BREAST DISEASE

Benign Male Breast Disease

1. Gynecomastia
2. Lipoma
3. Pseudoangiomatous stromal hyperplasia
4. Granular cell tumor
5. Fibromatosis / desmoid tumor
6. Myofibroblastoma
7. Schwannoma
8. Hemangioma

Malignant Male Breast Disease

A. CARCINOMA
1. Invasive ductal carcinoma
   Incidence: 0.17% of all male breast cancers
   Mean age: 59 years
   √ microcalcifications in only 13–30%
2. Papillary carcinoma
3. Invasive lobular carcinoma
4. Adenoid cystic carcinoma

B. SARCOMA
1. Liposarcoma
2. Dermatofibrosarcoma
3. Pleomorphic hyalinizing angiectatic tumor

C. OTHERS
1. Basal cell carcinoma of nipple

2. Lymphoma / leukemia
   = most common hematopoietic disease of the breast
   √ axillary lymphadenopathy: unilateral in primary / bilateral in secondary breast lymphoma
3. Metastasis

BREAST CALCIFICATIONS

= deposits of calcium salts
(a) precipitated salts in accumulated fluid secreted by epithelial cells
b) in / on necrotic cells
(c) fibrous capsule of foreign object

Indicative of focally active process; often requiring biopsy
◊ 75–80% of biopsied clusters of calcifications represent a benign process
◊ 10–30% of microcalcifications in asymptomatic patients are associated with cancers

Composition: hydroxyapatite / tricalcium phosphate / calcium oxalate

Results of breast biopsies for microcalcifications:
(without any other mammographic findings)
(a) benign lesions (80%)
1. Mastopathy without proliferation 44%
2. Mastopathy with proliferation 28%
3. Fibroadenoma 4%
4. Solitary papilloma 2%
5. Miscellaneous 2%

(b) malignant lesions (20%)
1. Lobular carcinoma in situ 10% in 8% no spatial relationship to LCIS
2. Infiltrating carcinoma 6%
3. Ductal carcinoma in situ 4%

◊ A positive biopsy rate of > 35% is desirable goal!

A. LOCATION
(a) intramammary
1. **Ductal microcalcifications**
   √ 0.1–0.3 mm in size, irregular, sometimes mixed linear + punctate
   Occurrence: secretory disease, epithelial hyperplasia, atypical ductal hyperplasia, intraductal carcinoma
2. Lobular microcalcifications
   √ smooth round, similar in size + density
   Occurrence:
   cystic hyperplasia, adenosis, sclerosing adenosis, atypical lobular hyperplasia, lobular carcinoma in situ, cancerization of lobules (= retrograde migration of ductal carcinoma to involve lobules), ductal carcinoma obstructing egress of lobular contents
   N.B.: lobular and ductal microcalcifications occur frequently in fibrocystic disease + breast cancer!

(b) extramammary: arterial wall, duct wall, fibroadenoma, oil cyst, skin, etc.

B. SIZE
◊ Mammography detects calcifications > 100 µg; down to ~ 75 µg for spot magnification views
√ malignant calcifications usually < 0.5 mm; rarely > 1.0 mm

C. NUMBER
√ < 4–5 calcifications per 1 cm^2 have a low probability for malignancy

D. MORPHOLOGY
(a) benign
1. Smooth round calcifications: formed in dilated acini of lobules
2. Solid / lucent-centered spheres: usually ← fat necrosis
3. Crescent-shaped calcifications that are concave on horizontal beam lateral projection = sedimented milk of calcium at bottom of cyst
4. Lucent-centered calcifications: around accumulated debris within ducts / in skin
5. Solid rod-shaped calcifications / lucent-centered tubular calcifications: formed within / around normal / ectatic ducts
6. Rimlike / eggshell calcifications in rim of breast cyst, fibrous wall of fat necrosis ("oil cyst"), pseudocapsule of fibroadenoma
7. Calcifications with parallel track appearance = vascular calcifications

(b) malignant
= calcified cellular secretions / necrotic cancer cells within ducts
√ calcifications of vermicular form, varying in size, of linear / branching shape

E. DISTRIBUTION
1. Clustered heterogeneous calcifications: adenosis, peripheral duct papilloma, hyperplasia, cancer
2. Segmental calcifications within single duct network: suspect for multifocal cancer within lobe
3. Regional / diffusely scattered calcifications with random distribution throughout large volumes of breast: almost always benign

F. TIME COURSE
malignant calcifications can remain stable for > 5 years!

G. DENSITY

Malignant Calcifications

1. **Granular calcifications** = resembling fine grains of salt
√ amorphous, dotlike / elongated, fragmented
√ grouped very closely together
√ irregular in form, size, and density
2. **Casting calcifications** = fragmented cast of calcifications within ducts
√ variable in size + length
√ great variation in density within individual particles + among adjacent particles
√ jagged irregular contour
√ ± Y-shaped branching pattern
√ clustered (> 5 per focus within an area of 1 cm^2)

Benign Calcifications

1. **Lobular calcifications** = arise within a spherical cavity of cystic hyperplasia, sclerosing adenosis, atypical lobular hyperplasia
   √ sharply outlined homogeneous solid spherical "pearl-like"
   √ little variation in size
   √ numerous + scattered
   √ associated with considerable fibrosis
   (a) adenosis
      √ diffuse calcifications involving both breasts symmetrically
   (b) periductal fibrosis
      √ diffuse / grouped calcifications + irregular borders, simulating malignant process
2. Sedimented milk of calcium
   Frequency: 4%
   √ multiple bilateral scattered / occasionally clustered calcifications within microcysts
   √ smudge-like particles ("cotton balls") at bottom of cyst on vertical beam (CC image)
   √ crescent-shaped on horizontal projection = "teacup-like" (ML / MLO image)
3. Plasma cell mastitis = periductal mastitis
   √ sharply marginated calcifications of uniform density = intraductal form
   √ sharply marginated hollow calcifications = periductal form
4. Peripheral eggshell calcifications
   (a) with radiolucent lesion
      › liponecrosis micro- / macrocystica calcificans (= fatty acids precipitate as calcium soaps at capsular surface) as calcified fat necrosis / calcified hematoma
      ◊ May mimic malignant calcifications!
   (b) with radiopaque lesion
      › degenerated fibroadenoma
      › macrocyst
      √ high uniform density in periphery
      √ usually subcutaneous
      √ no associated fibrosis
5. Papilloma
   √ solitary raspberry configuration in size of duct
   √ central / retroareolar
6. Degenerated fibroadenoma
   √ bizarre, coarse, sharply outlined, "popcornlike" very dense calcification within dense mass (= central myxoid degeneration)
   √ eggshell type calcification (= subcapsular myxoid degeneration)
   √ heterogeneously grouped macrocalcifications with circumferential nature in postmenopausal woman
7. Arterial calcifications
   √ parallel lines of calcifications
8. Metastatic calcifications
   Cause: 2° hyperparathyroidism (in up to 68%)

Dermal Calcifications

Site: hair follicle, nevus, sebaceous cyst, lupus erythematosus, dermatomyositis, scar

Cause: inspissated material in sebaceous glands, secondary to chronic folliculitis
Location: most commonly visible in lower inner breast
Site: near periphery of skin surface (may project deep within breast even on 2 views at 90° angles)
Size: same size as skin pores
√ round lucent centered calcifications:
  √ hollow radiolucent center (hair follicle)
√ linear orientation when caught in tangent
√ polygonal shape
Proof: superficial marking technique (= skin localization work-up)

Dystrophic Calcifications

= calcium deposits on / in necrotic material, cellular debris, devitalized tissue
(a) skin: lupus erythematosus, dermatomyositis, scar, parasite, breast implant
(b) foreign body: suture, parasite, breast implant
√ larger coarser calcifications than with DCIS

Calcifications in Branching Tubular Opacity

1. Ductal carcinoma in situ
2. Atypical ductal hyperplasia
3. Secretory disease
4. Peripheral papillomatosis
5. Vascular: calcified artery; Mondor disease (= thrombophlebitis of superficial vein)
6. Fat necrosis
7. S/P Galactography

NIPPLE & AREOLA

Nipple-Areolar Complex

(a) benign process
  1. Nipple inversion
     Cause: mammary duct ectasia, postsurgical changes, fat necrosis, fibrocystic changes, Mondor disease
     √ uni- / bilateral
     DDx: malignancy (developing over a few months)
  2. Inflammation / abscess
  3. Mammary duct ectasia
  4. Calcifications
     √ spherical with central area of lucency (associated with glands + hair follicles)
     √ nonspecific in association with sutures, fat necrosis, intraductal papilloma, Paget disease, intraductal ca.
  5. Cutaneous horn
     = conical projection of keratin above skin surface that may grow rapidly
     • vulnerable to trauma
     DDx: squamous cell carcinoma, Paget disease, sebaceous adenoma, granular cell

tumor
6. Nipple adenoma

(B) MALIGNANT PROCESS
1. Paget disease
2. Subareolar carcinoma
3. Lymphoma

Benign Mass of the Nipple
1. Papilloma
2. Fibroadenoma
3. Nipple adenoma

Nipple Retraction
1. Positional
2. Relative to inflammation / edema of periareolar tissue
3. Congenital
4. Acquired (carcinoma, ductal ectasia)

Nipple Discharge
Prevalence: 7.4 % of breast surgeries
◊ 3rd most common breast complaint

Classification:

A. Provoked
postovulatory state, duct ectasia, medication, stimulation by exercise, breast self-examination, sexual manipulation

B. Spontaneous
(a) physiologic: pregnancy; lactation; galactorrhea, duct ectasia; duct stricture; communicating cysts
(b) pathologic: benign / malignant neoplasm; galactorrhea ← hyperprolactinemia from a pituitary adenoma

C. Unilateral
◊ Unilateral spontaneous discharge is significant + requires investigation!
(a) benign (50%): duct ectasia; intraductal papilloma
(b) malignant (15%): papillary carcinoma; ductal carcinoma in situ (DCIS); invasive ductal carcinoma

D. Bilateral
◊ Expressed bilateral multipore blood-negative discharge is physiologic and benign!

Type of discharge:

A. Lactating breast: galactorrhea

B. Nonlactating breast:
(a) normal:
› milky
› multicolored sticky (blue, green, gray, brown, black)
(b) abnormal:
› purulent: antibiotics, incision, drainage

(c) surgically significant (in 14.3% cancerous)
› clear / watery: cancer in 33%
› bloody / sanguineous: cancer in 28%,
› pink / serosanguinous: cancer in 13%
› yellow / serous: cancer in 6%
› cheesy: chronic duct ectasia with chronic periductal mastitis / comedo-DCIS

◊ Intraductal papilloma is the most common cause of bloody and serosanguinous discharge (in 40%)!

◊ Exfoliative cytology not helpful (TP in only 11%, FN in 18%)

Site of origin:

A. Lobules + terminal duct lobular unit:
1. Galactorrhea
2. Fibrocystic changes

B. Larger lactiferous ducts (collecting duct, segmental duct, subsegmental duct)
1. Solitary papilloma
2. Papillary carcinoma
3. Duct ectasia

High-risk nipple discharge:

= discharge likely caused by carcinoma / papilloma
(1) Spontaneous
(2) Unilateral
(3) Single duct orifice
(4) Clear / serous / serosanguinous / frankly bloody

Low-risk nipple discharge:

= discharge likely caused by hyperprolactinemia, duct ectasia, fibrocystic change
(1) Expressible only
(2) Bilateral
(3) Multiple duct orifices
(4) Greenish / milky

Galactography / Ductography

= diagnostic procedure of choice for spontaneous ± guaiac-positive unilateral nipple discharge

» injection of 0.2–0.3 mL of water-soluble contrast material (Conray 60 ®, Isovue ®) through straight blunt 27-gauge pediatric sialography cannula (0.4–0.6 mm outer diameter) / 30-gauge cannula (Ranfac Corp, Avon, MA) / Jabczenski cannula (tip bent 90°)

Timing: within 24 hours of noticing discharge (without squeezing nipple / breast)

Results of positive galactography:
papilloma (48%), benign conditions (42%), intraductal carcinoma (10%)

Contraindications to ductography:
history of severe allergy to iodinated contrast material; inability of patient to cooperate (debilitating anxiety, mental disorder); history of prior nipple surgery; abscess; diffuse mastitis

DDx of dilated ducts:

(1) Duct ectasia
(2) Blocked duct (during lactation)
(3) Inflammatory infiltrates
(4) Periductal mastitis
(5) Apocrine metaplasia

DDx of intraductal defects:

(1) Papilloma
(2) Gas bubble, clot, inspissated secretions, infection
(3) Epithelial hyperplastic lesion
(4) Duct carcinoma

Galactographic Filling Defect		
Type of Tumor	*Single*	*Multiple*
Multiple papilloma	5.60%	14.0%
Cancer	0.05%	9.7%

BREAST SKIN

Skin (Dermal) Lesions of Breast

A. DERMAL
   1. Sebaceous cyst
   2. Epidermal inclusion cyst
   3. Dermal calcifications

B. HYPODERMAL = subcutaneous fat
   (a) fat-containing lesions
      1. Lipoma
      2. Fat necrosis
   (b) vascular lesions
      1. Hemangioma
      2. Angiolipoma
      3. Thrombosed vessel
   (c) neurogenic
      1. Granular cell tumor
   (d) lymphatic

C. SUPERFICIAL MAMMARY TISSUE = anterior TDLU

   N.B.: TDLUs may be located within anterior Cooper ligament extensions into subcutaneous fat

   1. Superficial breast cancer
   2. Peripheral papilloma
   3. Fibroadenoma
   4. Adenosis

Lesions of Nipple-Areolar Complex

1. Epidermal inclusion cyst

2. Sebaceous cysts / obstructed Montgomery gland
3. Breast cancer arising from anterior TDLUs / large lactiferous ducts / central papillomas
4. Nipple adenoma
5. Paget disease of nipple

NIPPLE CHANGES

(a) benign: eczema, psoriasis, allergic contact dermatitis , irritant dermatitis, lichen simplex chronicus
(b) malignant: Paget disease, Bowen disease (squamous cell carcinoma in situ)

Skin Thickening of Breast

Normal skin thickness: 0.8–3 mm; 0.5–2 mm at MRI; may exceed 3 mm in inframammary region

◊ Epidermis is indistinguishable as a separate layer from the dermis at imaging!

A. LOCALIZED SKIN THICKENING
1. Trauma prior biopsy, burns
2. Carcinoma
3. Abscess
4. Nonsuppurative mastitis
5. Dermatologic conditions: psoriasis

B. GENERALIZED SKIN THICKENING

Skin Thickening on MR		
Mild	Moderate	Severe
< 3 mm	3–5 mm	> 5 mm

◊ Skin is thickened initially and to the greatest extent in the lower dependent portion of the breast!

√ overall increased density with coarse reticular pattern ← dilated lymph vessels + interstitial fluid triggering fibrosis

(a) axillary lymphatic obstruction
1. Primary breast cancer
› advanced breast cancer
› invasive comedocarcinoma in large area
◊ Primary breast cancer not necessarily seen due to small size / hidden location (axillary tail, behind nipple)!
2. Primary malignant lymphatic disease (eg, lymphoma)

(b) intradermal + intramammary obstruction of lymph channels
1. Lymphatic spread of breast cancer from contralateral side
2. Inflammatory breast carcinoma = diffusely invasive ductal carcinoma

(c) mediastinal lymphatic blockage
1. Sarcoidosis
2. Hodgkin disease
3. Advanced bronchial / esophageal carcinoma
4. Actinomycosis

(d) advanced gynecologic malignancies

via thoracoepigastric collaterals
1. Ovarian cancer
2. Uterine cancer

(e) inflammation
1. Acute mastitis
2. Retromamillary abscess
3. Fat necrosis
4. Radiation therapy
5. Reduction mammoplasty

(f) right heart failure
may be unilateral (R > L) / migrating with change in patient position (to avoid decubitus ulcer)

(g) nephrotic syndrome, anasarca
1. Dialysis
2. Renal transplant

(h) subcutaneous extravasation of pleural fluid following thoracentesis

LYMPHADENOPATHY

Terminology for microscopic metastatic deposits:

› "isolated tumor cells": < 0.2 mm
› "micrometastasis": 0.2 – 2.0 mm

N.B.: Metastases < 2 mm are NOT identifiable at imaging!

Imaging of Normal Lymph Nodes

• nonpalpable

Mammo:
√ well-circumscribed mass of low to moderate density:
√ round to oval / bean-shaped
√ slightly lobulated margin
√ radiolucent fatty notch / hilum (visible in 78%)
√ central zone of radiolucency (= fatty replacement of center) surrounded by "crescent" rim of cortex
√ usually < 1.5 cm (up to 4 cm) in size:
√ < 1 cm within breast tissue, < 1.5 cm within axilla
◊ Normal axillary nodes may be larger than 5 cm!

US:
√ reniform hypoechoic rim + hyperechoic center
√ echogenic hilum for entry and exit of vessels
√ bidirectional hilar blood flow

MR:
√ smooth cortex + axillary symmetry → high NPV for exclusion of metastasis
√ cortical thickness of < 3 mm (91% NPV)
› T1WI
√ lymph nodes not recognizable within parenchyma

√ recognizable in extraparenchymal location as oval well-circumscribed hypointense lesion with central hyperintense area

› enhanced T1WI:

√ no / slight enhancement of bland lymph nodes

√ strong enhancement of cortex + type III wash-out kinetic pattern

› T2WI / STIR:

√ intermediate to increased signal intensity

Intramammary Lymphadenopathy

= adenopathy > 1 cm surrounded by breast tissue

Frequency: 5.4%

Location: axilla, subcutaneous tissue of axillary tail, lateral portion of pectoralis muscle, intramammary (typically in upper outer quadrant)

N.B.: nodes located high within axillary tail (= tail of Spence) are mammographically difficult to differentiate from inferior axillary lymph nodes

[James Spence (1812–1882), chair of systematic surgery at Edinburgh University in Scotland]

Axillary Lymphadenopathy

= solid node > 1.5 cm in size without fatty hilum

N.B.: lymph nodes of up to 3 cm may be normal if largely replaced by fat

A. MALIGNANT

1. Metastasis from breast cancer in 26%

◊ Primary breast lesion may not be found in 33%!

Currently, axillary surgery is considered the only definitive test to determine the absence of axillary metastases.

The main goal of preoperative imaging of the axilla is to identify metastases with a high-enough PPV to proceed directly to axillary lymph node dissection.

2. Metastases from non-breast primary (lung, melanoma, thyroid, GI tract, ovary)
3. Lymphoproliferative disease: lymphoma / chronic lymphocytic leukemia (17%)

B. BENIGN

1. Nonspecific benign lymphadenopathy (29%)
2. Reactive nodal hyperplasia (breast infection / abscess / biopsy)
3. Collagen vascular disease: rheumatoid arthritis, SLE
4. Granulomatous disease: sarcoidosis
5. Psoriasis
6. HIV-related adenopathy
7. Silicone-related adenopathy

Bilateral Axillary Lymphadenopathy

A. NEOPLASM

1. Secondary breast lymphoma

◊ Bilateral axillary lymphadenopathy is suggestive of lymphoproliferative disease!

2. Other neoplasms
3. Metastases

B. BENIGN

1. Collagen vascular disease
2. Granulomatous disease
3. HIV
4. Silicone-related adenopathy

Lymph Node Features Suspicious For Malignancy

√ size increase of > 100% over baseline:
  √ size > 3.3 cm
    ◊ Size of node usually NOT useful criterion (although small nodes have high NPV)
√ change in shape:
  √round shape / long-to-short axis ratio of < 2
  √ focal bulge / eccentric cortical thickening
√ spiculation of margins
√ intranodal microcalcifications (without history of gold Rx)
√ loss of radiolucent fatty center / hilar notch
√ increase in density

Ultrasound of Malignant Lymph Nodes

Ultrasound is the primary nonsurgical method for evaluating axillary nodes!

Value: 62–92% sensitive, 75–91% specific
Path: metastases embed subcortically in end vasculature
√ loss of reniform shape
√ bulbous contour with cortical thickening:
  √ focal eccentric cortical thickening
  √ symmetric diffuse cortical thickening > 3–5 mm
    (a) adjacent to several normal nodes
    (b) while contralateral nodes are normal
  ◊ Cortical thickening is the target for biopsy!
√ loss of normal central fatty hilum / hilar indentation
√ severely flattened / compressed node with loss of echogenic center
√ more than 1 feeding vessel:
  √ hyperemic hilar blood flow
  √ nonhilar cortical blood vessel (= entering capsule rather than lymph node mediastinum)
√ high-impedance waveform with sharp systolic high-velocity peak
DDx: reactive node (symmetric cortical thickening, adjacent nodes with similar morphology, often bilateral, no capsular vessels, low-impedance pattern with round low-velocity systolic peak)

MR of Malignant Axillary Lymph Nodes

◊ Axilla may be obscured by pulsation artifact from heart
Advantage: more global view of axillae compared to US allowing side-to-side comparison

MRI findings highly suggestive of metastatic lymph nodes (similar to other modalities):
  √ markedly enlarged lymph node

√ morphologically grossly abnormal (= distinctly different from other visible axillary nodes)

√ perifocal edema (100% PPV)

Dynamic CEMR:

√ strong heterogeneous enhancement (DDx: reactive inflammatory node)

√rim enhancement = higher SI in node periphery than center at 11 min after contrast infusion (100% PPV)

VASCULAR BREAST DISEASE

Venous Disorders of Breast

1. Collateral flow ← venous blockage / occlusion
   - √ unilateral dilatation of breast veins ← axillary or subclavian vein blockage
   - √ bilaterally enlarged breast veins ← occlusion of SVC
2. Congestive heart failure
   - √ bilateral breast venous congestion
   - √ bilateral skin thickening
   - √ interstitial breast edema

Benign Vascular Breast Mass

1. Hemangioma
2. **Lymphangioma**

   = extremely rare mass in child / young adult

   Histo: dilated lymphatic channels filled with lymphatic fluid + lined with endothelial cells

   Location: axilla / axillary tail of breast

   √ solitary lobulated mass with single cystic space (lymphangioma circumscriptum) / multicystic mass
3. Angiolipoma

Malignant Vascular Breast Mass

1. Angiosarcoma
2. Hemangiopericytoma

Devascularized Breast Mass

= loss of normal blood supply → infarction of breast tissue most commonly associated with fat necrosis

Cause: trauma, radiation therapy, spontaneous infarction of breast mass (hamartoma)

1. Infarcted lactating adenoma
2. Infarcted giant juvenile fibroadenoma

T2-HYPERINTENSE BREAST TUMOR

(in order of descending frequency)

A. EPITHELIAL TUMOR
   1. Mucinous carcinoma
   2. Invasive ductal carcinoma

3. Metaplastic carcinoma
4. Papillary carcinoma
5. Invasive lobular carcinoma
6. Adenoid cystic carcinoma
7. Sebaceous carcinoma
8. Intraductal papilloma

B. MESENCHYMAL TUMOR
1. Fibrosarcoma
2. Myofibroblastoma
3. Cavernous hemangioma

C. FIBROEPITHELIAL TUMOR
1. Myxoid fibroadenoma
2. Phyllodes tumor: benign / borderline / malignant

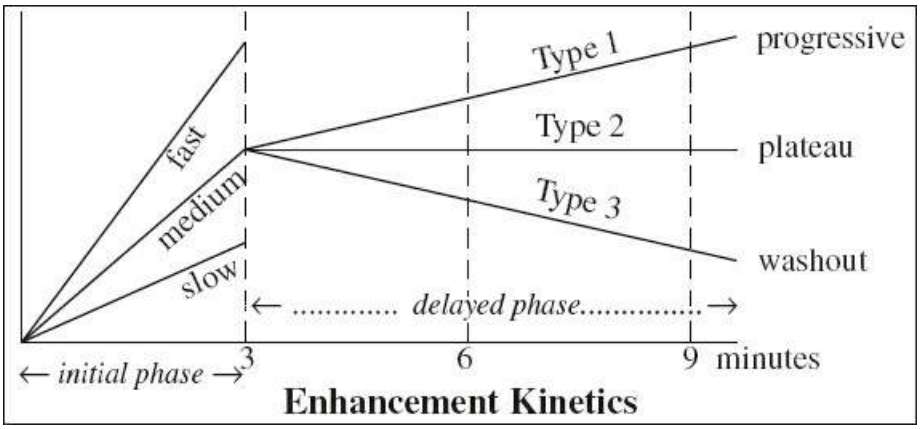
T2-hyperintensity is seen with extensive tumor necrosis, cystic + microcystic components, fatty (sebaceous) components, mucinous stroma, loose myxoid stroma, stromal edema, hemorrhagic changes!

MR ENHANCEMENT PATTERNS

Enhancement Kinetics

◊ Best performed on days 7–12 (= 2nd week of menstrual cycle) to minimize hormonal effect!

◊ Considerable overlap in enhancement characteristics between benign and malignant lesions!



◊ Nonmass-like lesion (invasive lobular carcinoma) may exhibit low-magnitude and persistent-enhancement kinetics (? due to weak angiogenic activity)

Malignant: plateau or washout pattern (63% sensitive, 65% specific)

INITIAL PHASE

= initial peak SI within first 2–3 min after contrast administration relative to SI of unenhanced image

or when shape of kinetic curve begins to change

Categories: < 50% (slow); ≥ 50% and < 100% (medium); ≥ 100% (fast)
Intensity threshold (color): 2 minutes > 50–100%
DCIS: 70% exhibit fast, initial enhancement, with variable delayed-phase enhancement patterns

DELAYED PHASE

= enhancement curve that develops after 2–3 minutes or after kinetic curve changes ($SI_{postinitial}$ = postinitial intensity during 4th, 5th, 6th minute + SI at 6 minutes by comparison with the initial peak obtained during 1st, 2nd and 3rd minute)

Type 1 = Persistent / Progressive / Continuous Pattern

= continuous increase in $SI_{postinitial}$ > **10%**

• usually benign
Distribution: 83% benign, 9% malignant
Benign lesion: 52% sensitive, 71% specific
◊ 45% PPV for malignancy

Type 2 = Plateau Pattern

= $SI_{postinitial}$ change of ±**10%**

• occasionally malignant
Malignant lesion: 43% sensitive, 75% specific

Type 3 = Washout Pattern

= progressive decrease of $SI_{postinitial}$ < **10%**

• highly suspicious
Malignant lesion: 21% sensitive, 90% specific
◊ 76% PPV for malignancy

Quantitative Kinetic Parameters

1. Initial enhancement percentage (E_1)
2. Peak enhancement percentage (E_{peak})
3. Time to peak enhancement (T_{peak})

Lack of Enhancement

• palpable lesion
• mammographically visible abnormality
NPV: 88–96%
FN: DCIS (48%), small invasive carcinoma / small invasive component (52%)
√ nonenhancing architectural distortion suggests a radial scar

Unilateral Diffuse Enhancement on MR

› Common
1. Parenchymal asymmetry
2. Fibrocystic changes
3. Adenosis
4. Unilateral implant

› Rare
5. Normal: unfavorable cycle phase, HRT
6. Mastitis
7. Inflammatory breast cancer
8. Extensive carcinoma: diffuse lobular carcinoma, lymphangiosis, extensive DCIS
9. Prior ipsilateral radiotherapy within last few months

Background Parenchymal Enhancement (BPE)

= additional tool for risk stratification in high-risk women

◊ ↑ odds of breast cancer with moderate / marked BPE

1. False-positive interpretation ← focal / regional /asymmetric BPE
2. False-negative interpretation ← moderate / marked BPE

ENHANCING LESIONS ON BREAST MR

Homogeneously Enhancing Well-Demarcated Round Lesion

◊ Homogeneous enhancement suggests benign disease!

› Common
1. Fibroadenoma: endotumoral septa
2. Adenoma
3. Papilloma
4. Carcinoma

› Rare
5. Intramammary node:
   √ lipomatous hilum
6. Fat necrosis:
   √ macrocalcifications on mammogram
7. Granuloma
8. Carcinoma: esp. medullary form
9. Phylloides tumor
10. Metastasis

Rim-Enhancing Lesion

› Common
1. Complicated cyst / postoperative seroma:
   √ narrow hyperintense ring on T2
2. Invasive carcinoma:
   √ broad hypo- / isointense ring on T2WI ← vital tumor
   √ thick irregular shaggy rim
3. Fat necrosis:
   √ centrally low signal of fat content
   √ confirmatory low-density lesion on mammogram
4. Superimposition of blood vessels: tubular structures on MIP

› Rare
5. Adenosis

6. Abscess
7. Lymphadenitis

Multiple Homogeneously Enhancing Lesions with Well-defined Borders

› Common
1. Fibrocystic changes
2. Fibroadenomas
3. Adenoma
4. Papilloma

› Rare
5. Multicentric carcinoma
6. Metastases

Dendritic Enhancement

› Common
1. Adenosis
2. Fibrocystic change
3. DCIS
4. Motion artifacts on subtraction image
5. Superposition of intramammary veins

› Rare
6. Previous galactography: history
7. Chronic mastitis

Lesion-in-Lesion Morphology

1. Giant juvenile fibroadenoma
2. Phyllodes tumor
3. Papilloma
4. Papillary carcinoma
5. Hemorrhage

Enhancing Lesion

Benign Enhancing Lesion

1. Nonproliferative lesion: mild hyperplasia, fibroadenoma
2. Proliferative lesion without atypia: sclerosing adenosis, radial and complexing sclerosing lesion, moderate hyperplasia, intraductal papilloma
3. Atypical lobular and ductal hyperplasia
4. Normal breast parenchyma in premenopausal woman

Morphologic Criteria for Benignity

√ smooth margin (95% NPV)
√ low-signal-intensity internal septa (98% NPV)
√lobulated margin + minimal / no enhancement (100% NPV)
√ enhanced portion on T1WI shows hyperintensity on T2WI

Morphologic Criteria for Malignancy

√ regional enhancement with a mass (81% PPV)
√ segmental distribution (78% PPV)
√ irregular / spiculated margin (84–91% PPV)
√ rimlike enhancement (84% PPV)
√ heterogeneous internal enhancement
√ enhancing internal septa
√ linear / branching ductal distribution (24–85% PPV)
√ regional enhancement WITHOUT a mass:
  √ homogeneous enhancement (67% PPV)
  √ clumped enhancement (60% PPV)
  √ heterogeneous enhancement (53% PPV)
  √ stippled enhancement (25% PPV)

Ancillary Features of Enhancing Lesions

√ hyperintense T2 signals in enhancing portion suggests benignity (eg, myxoid fibroadenoma of younger woman):
  √ not reliable for any irregular / spiculated mass
  Exception: medullary cancer
√ iso- / hypointense T2 signal suggests malignancy
√ focal perilesional edema highly suggestive of malignancy

MRI Differentiation of Benign from Malignant Lesion

	Benign	*Malignant*
Morphology	smooth	irregular
Kinetics	continuous rise	rapid rise
Enhancement	homogeneous	heterogeneous
T2 signal	high	variable (usually low)
T1 signal	high (protein, blood, melanin)	variable (usually low)
internal septa	nonenhancing	enhancing

√ enhancing architectural distortion highly suggestive of malignancy

POSTLUMPECTOMY BREAST MRI

Benign Postlumpectomy Changes

1. Skin thickening
2. Architectural distortion
3. Edema
   • may never resolve entirely
   √ persists in 25% at 6 years after breast conservation Rx
4. Signal voids / flare from surgical / biopsy clips
5. Fluid cavity filled with blood / seroma
6. Bleeding / hemosiderin

Probably Benign Postlumpectomy Changes

1. Small focal / thin linear non-masslike enhancement
   - √ seen for up to 18 months
   - √ slow initial + persistent delayed enhancement
2. Fat necrosis
   - √ persists up to 5 years

Suspicious Postlumpectomy Changes

- √ nodular non-masslike enhancement (NMLE) > 5 mm around a seroma cavity
- √ segmental / ductal / clumped NMLE
- √ masslike enhancement
- √ rapid initial + washout kinetics NOT consistent with fat necrosis
- √ increasing size of formerly "probably benign" lesion

Highly Suspicious Postlumpectomy Changes

- √ focal / multifocal masses with rapid initial + delayed washout kinetics
- √ irregular / spiculated margins (84–91% PPV)
- √ rim enhancement

MAMMOGRAPHIC FILM READING TECHNIQUE

1. Confirm patient identifiers are correct
2. Ensure images are of adequate quality:
   - › good contrast
   - › good compression
   - › adequate positioning (nipple in profile)
   - › lack of blur
   - › lack of artifacts
3. Compare with earlier films (preferably ≥ 2 years) whether finding is new / growing / stable
   - ◊ Beware of stability = breast cancer may grow slowly

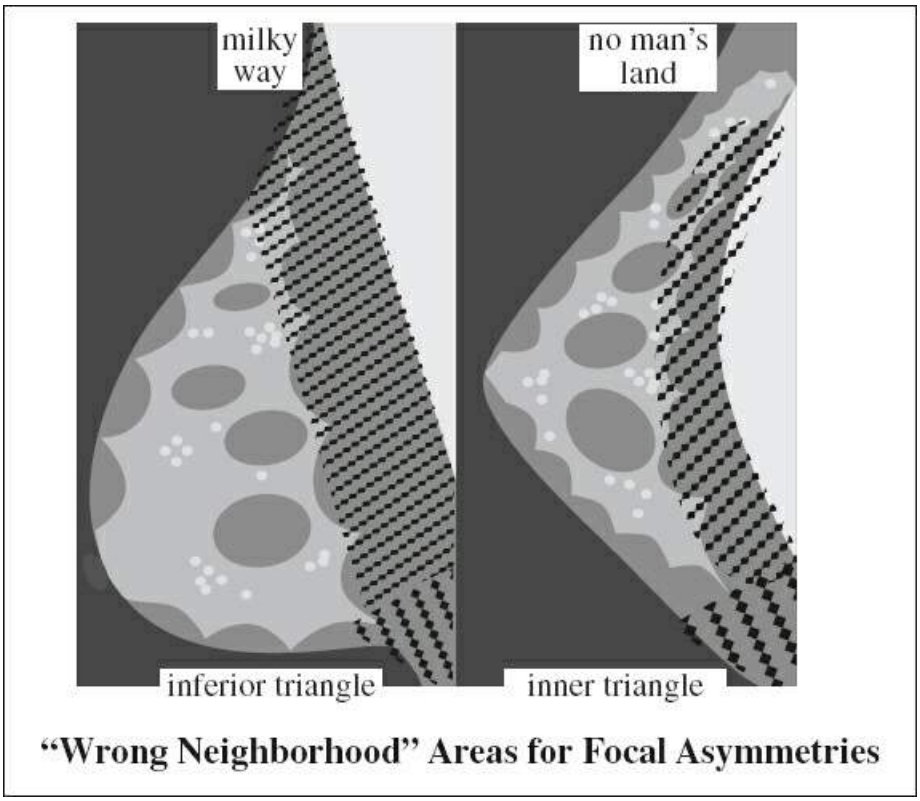
> Lesion morphology takes precedence over stability!

4. Compare left with right side
5. Scan "forbidden / living in the wrong neighborhood" areas
   - › MLO-view
     - (a) "Milky Way" = 2–3 cm wide area parallel to the edge of the pectoral muscle
     - (b) inferior triangle
   - › CC-view
     - (c) "No man's land" = retromammary fat between posterior border of parenchyma + chest wall
     - (d) Medial / inner triangle of breast

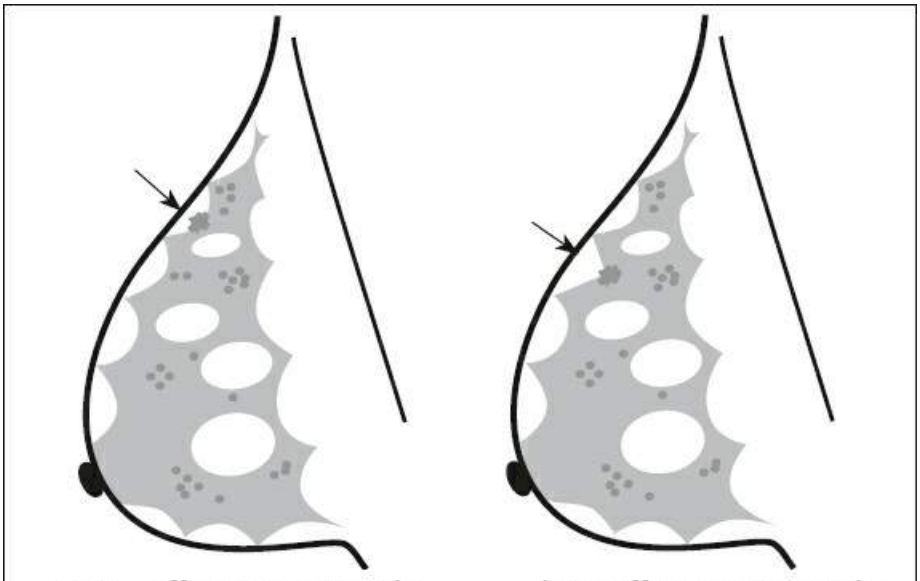
> Almost ¾ of breast cancers in women < 50 years occur in a 1-cm wide zone <u>beneath</u> the SQ fat!

6. Look for:
   - › global / focal asymmetry in breast parenchymal pattern disrespecting normal breast architecture + boundaries

› increased retroareolar density
› contour deformity at interface with fat



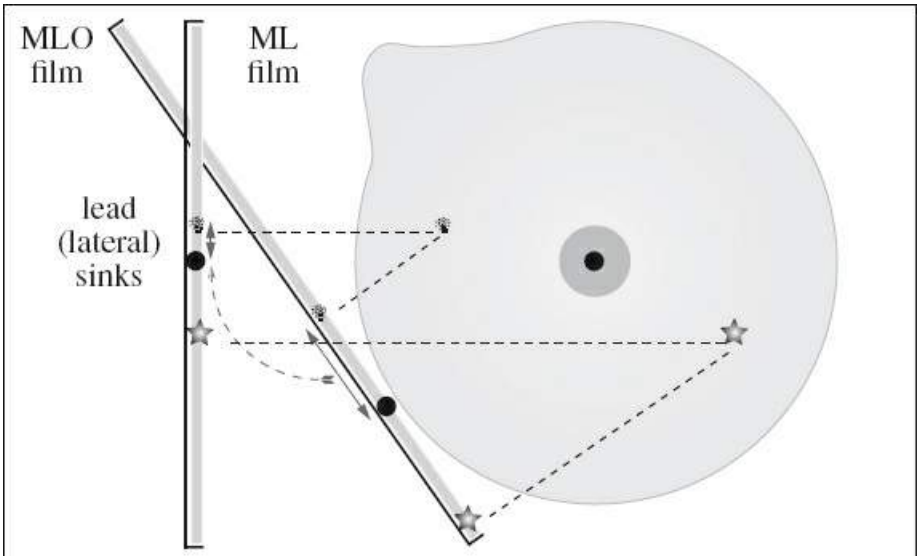
"Wrong Neighborhood" Areas for Focal Asymmetries



outwardly convex margin
"Slow down for the speed bump"

inwardly convex margin
"Look for the hook"

Breast Contour Deformity 2° to Cancer in Dense Breast



Shift in Position from MLO to ML View *(right breast)*
medial (stellate) lesion projects lower on MLO and wanders higher on ML view;
lateral lesion (calcifications) projects higher on MLO view and wanders lower on ML view
mnemonic: **"Lead (lateral) sinks, muffins (medial) rise"**;
◊ Central lesion shifts little, far lateral or medial lesions substantially!

(a) inwardly convex angulated margin
mnemonic: "Look for the hook"
(b) outwardly convex margin (= loss of scalloped margin)
mnemonic: "Slow down for the speed bump"

› straight lines superimposed on normal scalloped contour
› architectural distortion (magnification views!)
› calcifications (magnification views!)

7. DON'T STOP looking after one lesion is found

Diagnostic Evaluation of a Mass / Focal Asymmetry

Never recommend a biopsy based on screening alone!

Purpose of diagnostic workup:

1. Locate mass / focal asymmetry with additional views
   (a) mandatory additional views to characterize a lesion:
   › true LM / ML view depending on lesion location
   › spot compression in CC and MLO projections to reduce geometric unsharpness + blur
   Note: magnification (requires ↑ in exposure time → ↑ likelihood of motion-related blurring)
   ◊ Magnify microcalcifications NOT soft-tissue abnormalities

(b) optional additional views to localize a lesion:
› exaggerated CC lateral view
› cleavage view
› step-oblique views @ 15° intervals between true lateral and CC views
› medially / laterally rolled CC views
◊ Roll breast on the view that reveals the abnormality!
◊ Roll focal asymmetry toward fat!

2. Characterization of mass / focal asymmetry to develop a level of suspicion → for equivocal findings supplement with targeted US
3. Extent of disease
4. Multifocality
   Rule of multiples = the likelihood of malignancy decreases if multiple similar findings are present, especially if bilateral
   ◊ All lesions must have exclusively benign features!
5. Staging of axilla with ultrasound
   ◊ The most predictive sign of axillary metastasis is a lymph node with a cortex > 2 mm thick
6. Discuss findings with patient, answer questions
7. Arrange for biopsy

Skin Localization Work-up

» Use mammographic paddle with alphanumeric grid

(1) Compress breast with grid opening along surface Ca^{2+}
(2) Place metallic skin marker directly over calcification cluster at appropriate alphanumeric location
(3) Repeat image to confirm accurate skin marker placement
(4) Obtain magnification view in orthogonal plane with skin marker tangential to x-ray beam

Interpretation:
→ calcifications in skin project into dermis
→ superficial parenchymal calcifications project into breast tissue

Surveillance

(1) Only for lesion that satisfies benign criteria = BI-RADS ® category 3
(2) Obtain reproducible mammographic image (CC views are more consistent compared with MLO)
(3) Change
◊ Stability for several years does not guarantee benignity (eg, tubular carcinoma)
◊ Any new mass requires workup
◊ A 3-mm change represents a doubling of volume in a 1-cm lesion
If lesion acquires certain benign features change to BI-RADS ® category 2
(4) Requires a compliant patient following recommended intervals
N.B.: ~ 40% of patients are not compliant (numbers are different for US, mammography and MRI)!

False negative rate: < 2% if done appropriately

Receptor Status Correlated with Histopathology	
Receptor Status	*Histopathology*
ER–	Nonmass-like enhancement (in <20% of lesions)
ER+	Nonmass-like enhancement (in 0% of lesions)
ER+ or ER–	equal incidence of multiple masses
HER2+	multicentric masses (in 60%)
triple negative	masses
ER = estrogen receptor; HER2 = human epidermal growth factor	

MAMMOGRAPHY REPORT

based on BI-RADS® (**B**reast **I**maging **R**eporting and **D**ata **S**ystem) published by the ACR (American College of Radiology)

Report Contents

1. Indication for exam
2. Comparison to previous studies
3. Breast Composition
4. Findings
5. Overall Assessment
6. Communication of result (as IMPORTANT as the diagnosis)

A. ASYMMETRY

= planar density seen only in a <u>single projection</u> WITHOUT convex margins / suspicious calcifications / architectural distortion ± interspersed fat

1. **Global asymmetry** (= asymmetric breast tissue)
   = parenchymal volume greater in one breast compared to the other involving <u>at least one quadrant</u>
   = common and usually normal variant
   Of concern if associated with:
   architectural distortion / decrease in breast size ("shrinking breast") / skin thickening / axillary adenopathy / clinical findings
2. **Focal asymmetry**
   = asymmetry confined to less than a quadrant

B. MASS (challenge of perception)

= 3-dimensional space occupying lesion with convex margins seen in <u>two different projections</u>

size	measurements
shape	round, oval, lobulated, irregular
margins	circumscribed, lobulated, obscured, indistinct, spiculated
density	relative to an equal volume of breast tissue: high, equal, low, fat
location	based on face of clock; depth (anterior, middle, posterior); subareolar; central; axillary
posterior extent	pectoralis muscle / chest wall

C. ARCHITECTURAL DISTORTION
= straight lines in a radial arrangement

D. CALCIFICATIONS (challenge of disposition)

benign	skin, vascular, coarse popcorn-like, large rodlike (secretory), round, punctate, lucent center, eggshell / rim, milk of calcium, suture, dystrophic
indeterminate	amorphous / indistinct
probably malignant	pleomorphic (coarse heterogeneous / fine pleomorphic), fine linear / fine linear branching
number	
size	
distribution	grouped / clustered, linear, segmental, regional (within large volume of breast tissue), scattered / diffuse, multiple groups
stability	increasing, stable

E. Associated Findings

skin invasion	thickening (diffuse, focal), retraction
nipple involvement	retraction, inversion
trabeculae	thickening, architectural distortion
axilla	adenopathy

F. MULTIPLE MASSES = multicentricity / multifocality
number > 1 distance between 2 masses (outer edge to outer edge)

Breast Imaging Reporting and Data System (BI-RADS®)

◊ Additional image evaluation may be necessary: off-angle / spot compression mammographic views; ultrasound
◊ Unexplained abnormalities warrant biopsy

ASYMMETRIC BREAST TISSUE
= greater volume / density in one breast compared with corresponding area in contralateral breast

DENSITY IN ONE PROJECTION
= density seen on only one standard mammographic view

ARCHITECTURAL DISTORTION
= focal area of distorted breast tissue (spiculations with common focal point / focal retraction / tethering) without definable central mass

FOCAL ASYMMETRIC DENSITY
= focal asymmetric density seen on two mammographic views but not identified as a true mass

Lexicon Descriptors for Breast MR Reports

suspicious areas are described as (<u>underlined</u> signs suggest malignancy)

A. **Focus / foci** area < 5 mm in diameter
shape (= mini-mass: round / oval, <u>spiculated /</u>

	irregular
margin	smooth, not smooth
T2	bright, not bright
hilum	with fat, without fat
curve	persistent, washout
priors	stable, new / increasing)

B. **Mass** 3-D space-occupying lesion ≥ 5 mm with a convex margin

shape	round, oval, lobulated, irregular
margin	smooth, irregular, spiculated
internal enhancement	homogeneous, dark internal septations, heterogeneous, rimlike, enhancing internal septations, central

C. **Nonmass-like Enhancement** (NMLE)

distribution	focal area (< 25% of quadrant), linear (not ductal, sheetlike), diffuse, ductal, segmental, regional, multiregional (not ductal)
internal enhancement	homogeneous, heterogeneous, stippled / punctate, clumped, reticular / dendritic symmetry symmetrical, asymmetrical

◊ Biopsy if associated with microcalcifications / if segmentally distributed / if asymmetric / if patient > 45 years

D. **Associated findings**

edema
adenopathy
cysts
skin involvement
chest wall involvement

E. **Kinetic curve assessment** *(if morphology is probably benign)*

initial phase	slow, medium, rapid
delayed phase	persistent / plateau (→ follow up), washout (→ biopsy)

REPORT NOTICE ON BREAST DENSITY

"If your mammogram demonstrates that you have dense breast tissue, which could hide small abnormalities, you might benefit from supplementary screening tests, which can include a breast ultrasound screening or a breast MRI examination, or both, depending on your individual risk factors. A report of your mammography results, which contains information about your breast density, has been sent to your physician's office and you should contact your physician if you have any questions or concerns about this report."

BI-RADS® Categories (American College of Radiology)				
Cat.	*Mammography*	*Ultrasound*	*MR*	*Malignancy Likelihood*
0	**Need additional imaging** evaluation or prior mammogram for comparison: eg, spot compression, magnification, special views, ultrasound	**Need additional imaging**: eg, an MR for (1) palpable confirmed mass (2) recurrence versus scar after lumpectomy	**Need additional imaging** evaluation: eg, (1) technically unsatisfactory scan (2) screening MR without kinetic imaging (3) incomplete information	---
1	**Negative**: symmetric breasts, no masses, architectural distortion, suspicious calcifications	**Negative**: no mass, architectural distortion, skin thickening, microcalcifications	**Negative**: symmetric breasts; no architectural distortion, abnormal enhancement, or mass	0%
2	**Benign** findings: eg, involuting calcified fibroadenoma, multiple secretory calcifications, oil cyst, lipoma, galactocele, hamartoma, intramammary node, vascular calcifications, implants, architectural distortion related to prior surgery	**Benign** findings: eg, simple cyst, intramammary lymph node, breast implant, stable postsurgical changes, probable fibroadenoma	**Benign** findings: hyalinized nonenhancing fibroadenoma, cyst, scar, fat-containing lesion (oil cyst, lipoma, galactocele, mixed-density hamartoma), breast implant	0%
3	**Probably benign** (< 2% risk of malignancy) – initial short-interval follow-up suggested (in 6 months), not expected to change (over > 2 years) after complete diagnostic work-up: eg, noncalcified circumscribed solid mass, focal asymmetry, cluster of round punctate calcifications	**Probably benign** – short-interval follow-up suggested (< 2% risk of malignancy): eg, classic findings of a fibroadenoma, nonpalpable complicated cyst, clustered microcysts	**Probably benign** – short-interval follow-up suggested: a malignancy is highly unlikely	2% *(only 71% comply!)*
4	**Suspicious** abnormality – biopsy should be considered: not classic appearance of malignancy	**Suspicious** abnormality – biopsy should be considered: intermediate (3–94%) probability of malignancy: eg, solid mass without all criteria of a fibroadenoma	**Suspicious** abnormality – biopsy should be considered: lesion morphology not characteristic of breast cancer but of concern	3–90%
4a	Low probability	Low suspicion		3–50%
4b	Intermediate probability / suspicion	Intermediate suspicion		50–80%
4c	Moderate probability / suspicion	Moderate suspicion		80–90%
5	**Highly suggestive of malignancy** (≥ 95% probability of cancer) – appropriate action should be taken: eg, lesion could be considered for one-stage surgical treatment, however, biopsy usually required	**Highly suggestive of malignancy** (> 95% probability) – appropriate action should be taken: image-guided core needle biopsy	**Highly suggestive of malignancy** – appropriate action should be taken: almost certainly malignant	>90%
6	Known **biopsy-proven malignancy** eg, mammogram during neoadjuvant chemotherapy comparing it to pre-therapy mammogram	Known **biopsy-proven malignancy** eg, prior to chemotherapy, lumpectomy, mastectomy	Known **biopsy-proven malignancy** corresponding to the lesion imaged with MR	100%

BREAST ANATOMY AND MAMMOGRAPHIC TECHNIQUE

BREAST DEVELOPMENT

Embryology

6th week GA	"milk line" develops from ectodermal elements on ventral surface of embryo extending from axilla to medial thigh
12th week	nipple-areolar complex in 4th intercostal space develops with differentiation of mesenchymal cells into smooth muscle
16th week	special apocrine glands form Montgomery glands consisting of 8–12 mammary ducts associated with sebaceous glands near epidermis
32nd week	differentiation into breast parenchyma + pigmentation of nipple-areolar complex

Nipple-Areolar Complex

› composed of pigmented squamous epithelium
› contains sebaceous Montgomery glands
› contains many sensory nerve endings
› contains layer of circumferential smooth muscle
› contains abundant lymphatic system (= subareolar lymphatic plexus = Sappey plexus)
› hair follicles around areola may contain calcifications
› overlies area between 2nd and 6th rib at full development

[Marie Philibert Constant Sappey (1810–1896), professor of anatomy and president of Académie Nationale de Médecine, Paris, France]

MONTGOMERY GLAND

= large type of sebaceous gland of areola transitional between sweat glands + mammary gland

[William Fetherstone Montgomery (1797–1859), professor of midwifery at College of Physicians in Dublin, Ireland]

› capable of secreting milk
› openings at 1–2-mm small raised papules in periphery of areola (= Morgagni tubercles)

Variant Anatomy

Polythelia	=	supernumerary accessory nipple(s); usually unilateral; most inferior location = proximal medial thigh; may be mistaken for moles
Polymastia	=	true accessory mammary gland; most often in axilla
Hypoplasia	=	underdevelopment of breast
Amazia	=	lack of breast tissue + proper nipple; usually due to surgery / irradiation
Amastia	=	lack of breast tissue + lack of nipple; associated with aplasia of pectoral

muscle (Poland syndrome)

Tuberous breast = reduced parenchymal volume + herniation of breast parenchyma through nipple-areolar complex

Tanner Stages

= scale of physical development

Stage I (prepubertal)

Histo: epithelial-lined ducts surrounded by connective tissue stroma

- nipple elevates
- palpable subareolar nodules for first 6–12 months

√ ill-defined mildly heterogeneous hyperechoic retroareolar tissue

√ ducts often enlarged in full-term infants ← effect of maternal hormones

Stage II (formation of breast bud)

Cause F: estrogen for ductal proliferation and branching + progesterone for terminal ductal-lobular units

M: transient proliferation with spontaneous resolution ← 30-fold increase in testosterone

- palpable subareolar bud = **thelarche** begins with onset of puberty (at < 13 years of age; mean age: 9.8 years)
  - ◊ may be asymmetric / unilateral
- breast tissue + nipple arise as a single mound of tissue

√ hyperechoic retroareolar nodule

√ central star-shaped / linear hypoechoic area (= simple branched ducts)

Stage III (breast extension beyond areolar margin)

- enlargement + elevation of single mound

√ hyperechoic glandular tissue extending away from retroareolar area

√ central spider-shaped hypoechoic area

Stage IV (mounding of areola + papilla)

- secondary mound develops (very transient) with nipple + areolar complex projecting above the breast tissue

√ hyperechoic periareolar fibroglandular tissue

√ prominent central hypoechoic nodule

Stage V (mature breast)

- regression of areola forming a smooth contour with the rest of the breast tissue

√ hyperechoic glandular tissue

√ increased subcutaneous adipose tissue anteriorly

√ NO hypoechoic central nodule

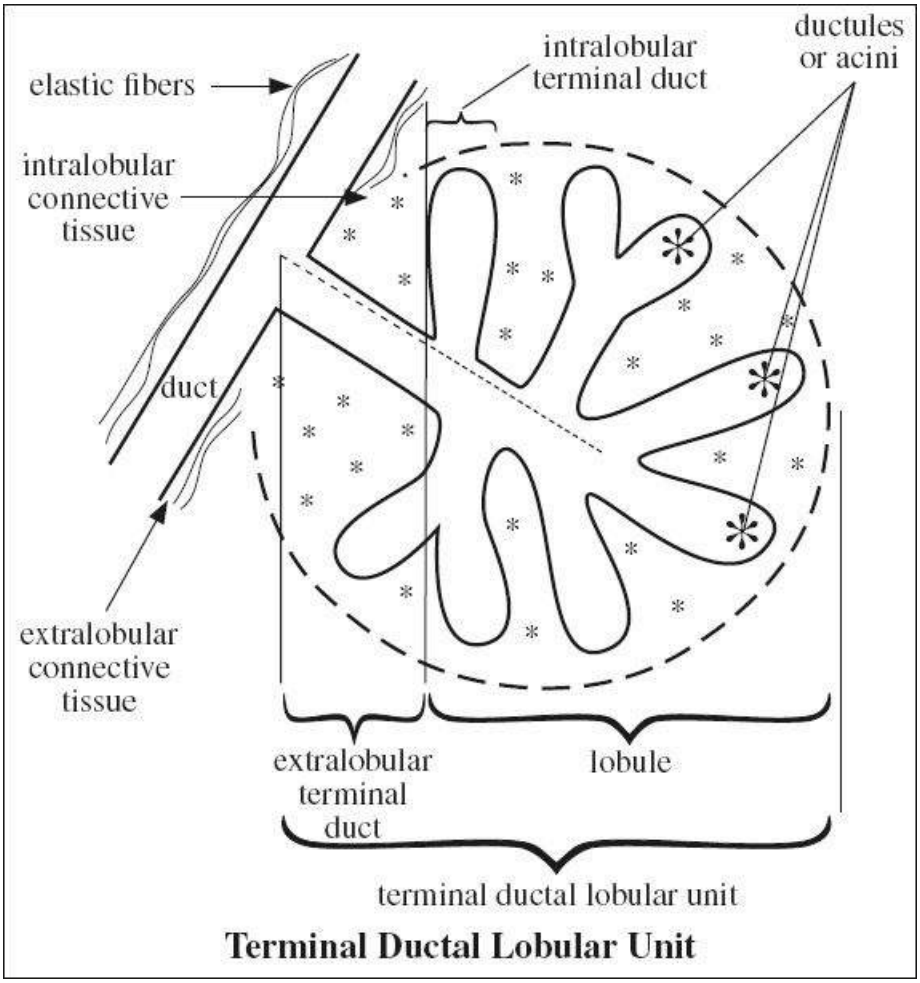
BREAST ANATOMY

Lobes

15–20 lobes disposed radially around nipple; each lobe has a main lactiferous duct of 2 mm in diameter

Nipple

(a) 5–20 duct openings on nipple surface: immediately deep to orifices are areas of dilatation (= milk sinuses) ← storage function during lactation



◊ >90% of nipples contain 5–9 ductal orifices

(b) multiple other blind-ending orifices: connected to sebaceous glands of 1–4 cm in length

√ bilateral symmetric enhancement pattern of normal nipple:

√ 1–2 mm superficial layer of intense linear enhancement

√ underlying region of nonenhancement deep to dermis

Ducts

lactiferous ducts coalesce in subareolar region into 5–8 mm wide lactiferous sinuses exiting in the central portion of nipple; organized into

(a) central ducts: extending to chest wall

(b) peripheral ducts: arranged in a radial fashion

Main lactiferous duct → branches dichotomously into segmental duct → subsegmental duct → terminal duct → blunt-ending acinus

Terminal Duct Lobular Unit (TDLU)

(1) Extralobular terminal duct
Histo: lined by columnar cells + prominent coat of elastic fibers + outer layer of myoepithelium

(2) Lobule
(a) intralobular terminal duct
Histo: lined by 2 layers of cuboidal cells + outer layer of myoepithelium (for milk propulsion)
Significance: invasive ductal, papillary, mucinous, medullary adenoid cystic cancers arise from ductal epithelium in TDLU and most commonly appear as spiculated irregular masses ± calcifications / developing asymmetries
(b) ductules / acini
(c) intralobular connective tissue

Size: 1–2 (range, 1–8) mm in diameter

Change:
(a) reproductive age: cyclic proliferation (up to time of ovulation) + cyclic involution (during menstruation)
(b) post menopause: regression with fatty replacement

Significance:
TDLU is the site of fibroadenoma, epithelial cyst, apocrine metaplasia, adenosis (= proliferation of ductules + lobules), epitheliosis (= proliferation of mammary epithelial cells within preexisting ducts + lobules), ductal + lobular carcinoma in situ, infiltrating ductal + lobular carcinoma

Components of Normal Breast Parenchyma

1. Nodular densities surrounded by fat
   (a) 1–2 mm = normal lobules
   (b) 3–9 mm = adenosis
2. Linear densities
   = ducts and their branches + surrounding elastic tissue
3. Structureless ground-glass density
   = stroma / fibrosis with concave contours

Parenchymal Breast Pattern (László Tabár)

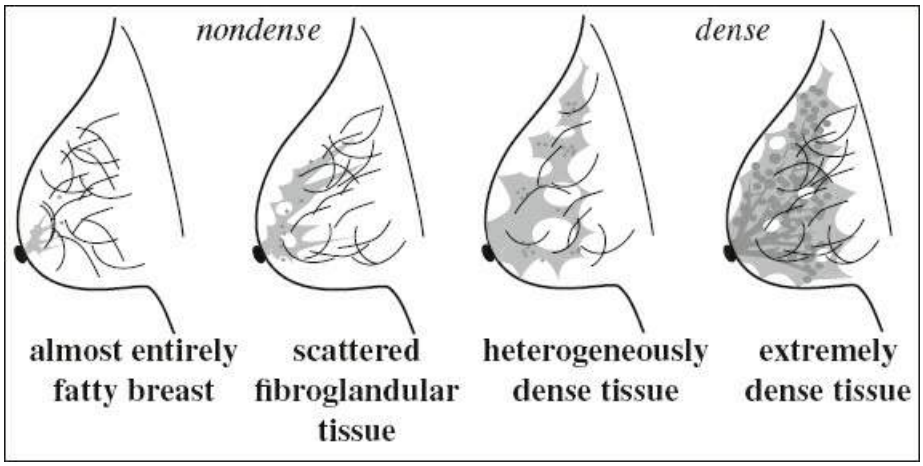
Effect of breast density on sensitivity:
women in their 40s have a 68% higher risk of a FN screening mammogram compared to older women

Recommendation: perform mammography during 1st week of menstrual cycle

Inter- and intraobserver variability on breast density:
› low reliability of interreader density agreement ($\kappa = 0.59$)
› imperfect intrareader agreement ($\kappa = 0.72$)

Factors affecting breast density between mammograms:
body mass index, weight changes, age, HRT, dietary intake

Breast Composition (*BI-RADS®*)			
Breast Density	*Population [%]*	*Descriptor*	*Glandular tissue [%]*
1	9	Almost entirely fatty breast	< 25
2	44	Scattered fibroglandular tissue that could obscure a lesion	25–50
3	38	Heterogeneously dense tissue that may lower mammographic sensitivity	51–75
4	9	Extremely dense breast tissue that lowers mammographic sensitivity	> 75



Overall odds ratio of breast cancer for > 75% tissue density:
- › compared to 10% density 4.74
- › with interval cancer developed in 1 year 17.81

Relative risk of cancer associated with breast density:
- › breast tissue density of 50–74% 2.92
- › breast tissue density of > 75% 4.64

Pattern I

named QDY = quasi dysplasia (for Wolfe classification)
- √ concave contour from Cooper's ligaments
- √ evenly scattered 1–2 mm nodular densities (= normal terminal ductal lobular units)
- √ oval-shaped / circular lucent areas (= fatty replacement)

Pattern II

similar to N1 (Wolfe)
- √ total fatty replacement
- √ NO nodular densities

Pattern III

similar to P1 (Wolfe)
- √ normal parenchyma occupying < 25% of breast volume in retroareolar location

Pattern IV = adenosis pattern

similar to P2 (Wolfe)
Cause: hypertrophy + hyperplasia of acini within lobules
Histo: small ovoid proliferating cells with rare mitoses
√ scattered 3–7 mm nodular densities (= enlarged terminal ductal lobular units) = adenosis
√ thick linear densities (= periductal elastic tissue proliferation with fibrosis) = fibroadenosis
√ no change with increasing age (genetically determined)

Pattern V
similar to DY (Wolfe)
√ uniformly dense parenchyma with smooth contour (= extensive fibrosis)

Enhancement of Normal Parenchyma on MR

= Background Parenchymal Enhancement (BPE)
◊ Breast enhancement does NOT correlate with breast density
• varies among women + within same woman over time

Proper enhancement present if:
› veins contrasted on MIP
› both internal mammary arteries depicted
› nipple enhances

Common pattern of enhancement:
√ bilateral symmetric diffuse enhancement:
√ slow minimal / early enhancement
√ persistent delayed enhancement
√ linear patchy enhancement
√ confluent enhancement on late dynamic scan

Distribution of enhancement:
√ bilateral symmetric enhancement with
(a) moderate / marked degree of BPE
(b) diffuse / regional distribution
(c) homogeneous / internally stippled
√ "picture framing" of vascular inflow = enhancement commonly begins in periphery + gradually becomes apparent in more central breast tissue
√ scattered innumerable 9–10 mm foci of enhancement
√ geographic areas of symmetric regional enhancement
√ multiple larger symmetric areas of enhancement (DDx: asymmetry suggest malignancy)

BPE Effect on Interpretation of MR Images:
1. Falsely positive ← focal / regional / asymmetric background parenchymal enhancement
2. Falsely negative ← moderate / marked BPE

Classification of Background Parenchymal Enhancement:

Minimal	< 25% of glandular tissue
Mild	25–50%
Moderate	50–75%
Marked	> 75%

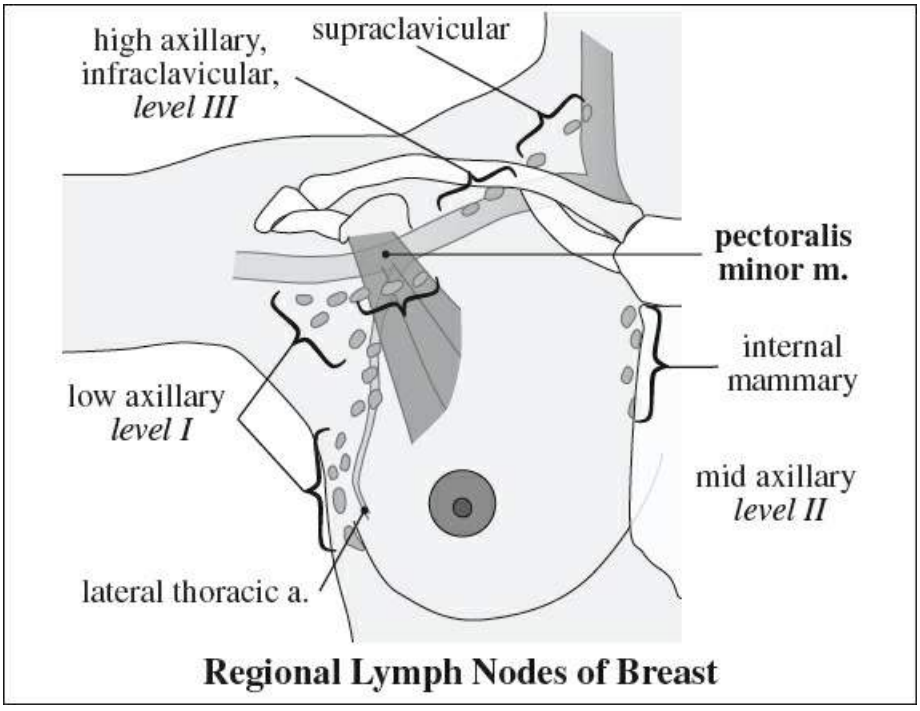
Hormonal Influence on BPE

1. Menstruation
   √ enhancement high during days 21–28 and days 1–6 after menstruation + low during days 7–20
2. Lactation
   ◊ Breast involution after lactation takes 3 months
   Note: NO impairment in cancer detection in lactating patients!
   Breast-feeding: **safe** after contrast-enhanced MRI ← minute amounts of Gd in breast milk
3. Postmenopausal period without HRT
   √ decrease in fibroglandular tissue → degree of BPE typically less than that in premenopausal women
4. Hormone replacement therapy (HRT)
   √ increase in BPE in amount + degree + distribution with great interindividual variations:
   ◊ Hormonal effect reverses after 30–60 days
5. Endocrine antihormonal therapy
   Antiestrogenic agents: selective estrogen receptor modulators, aromatase inhibitors
   √ significant decrease in amount of fibroglandular tissue + cysts + BPE
   √ effect on BPE evident early in treatment (< 90 days)
   √ tamoxifen rebound after medication discontinued:
   √ global / focal increase in BPE
6. Oophorectomy → decrease in BPE

MRI preferably performed during 2nd week of menstrual cycle!

Lymphatic Drainage

1. Axillary nodes
   = 5 groups of lymph nodes in axilla divided into 3 levels by pectoralis minor muscle



Regional Lymph Nodes of Breast

Cancerous involvement: 97%

(a) **Inferior group** = Berg I level

Location: inferior to inferolateral border of pectoralis minor muscle

Divided into:

› lateral group (deep)

Landmark: 3rd segment of axillary a. + v.; subscapular artery (arising from inferior surface of axillary artery)

› subscapular group (posterolateral)

Landmark: along course of hook-shaped thoracodorsal artery

› pectoral group (anteromedial)

Landmark: lateral thoracic artery parallel and <u>posterior</u> to lateral margin of pectoralis minor muscle arising from terminal portion of 2nd segment of axillary artery

Most sentinel nodes are inferior level I axillary nodes!

(b) **Central group** = Berg II level

Location: posterior to and between lateral and medial borders of pectoralis minor muscle + between pectoralis minor muscle and pectoralis major m. (= Rotter space nodes)

Lymphatic route: received from level I nodes

Staging: N1 = < 4 nonmatted movable nodes N2 = > 4 / matted nonmovable nodes

(c) **Apical group** = Berg III level

Location: medial to superior border of pectoralis minor muscle (+ infraclavicular nodes)

Lymphatic route: received from level II nodes → subclavian lymphatic trunk and supraclavicular nodes → (left-sided) thoracic duct + right

lymphatic duct

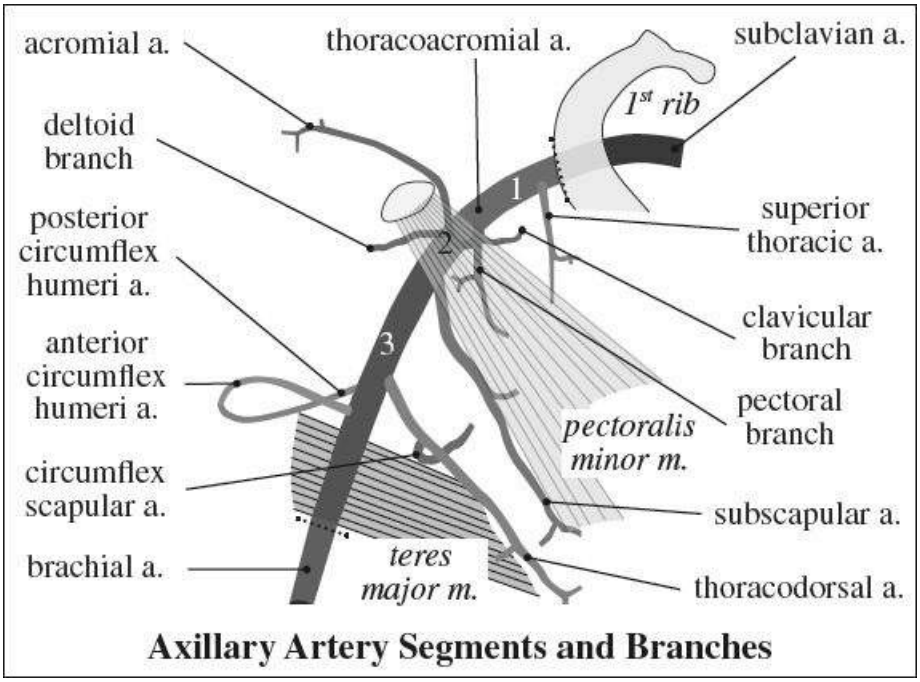
Staging: N3 = stage IIIC disease

2. Internal mammary nodes (3%)

The presence of internal mammary nodal metastasis changes stage, prognosis and radiation therapy field!

Location: follow internal mammary artery and vein between pleura / endothoracic fascia and chest wall near margin of sternum in 1st – 6th intercostal spaces

Lymphatic route: from level of diaphragm (= anterior phrenic nodes) to termination in thoracic venous system on right and thoracic duct on left



Axillary Artery Segments and Branches

Normal size: < 6 mm

Cancerous involvement: isolated in 3% originating from deep / medial lesion

Staging: (a) without axillary met = N2

(b) with axillary met = N3b / stage IIIC disease

Metastases to internal mammary nodes usually occur after a tumor has metastasized to the axilla!

Axillary Artery

Origin: lateral margin of 1st rib (out of subclavian artery)

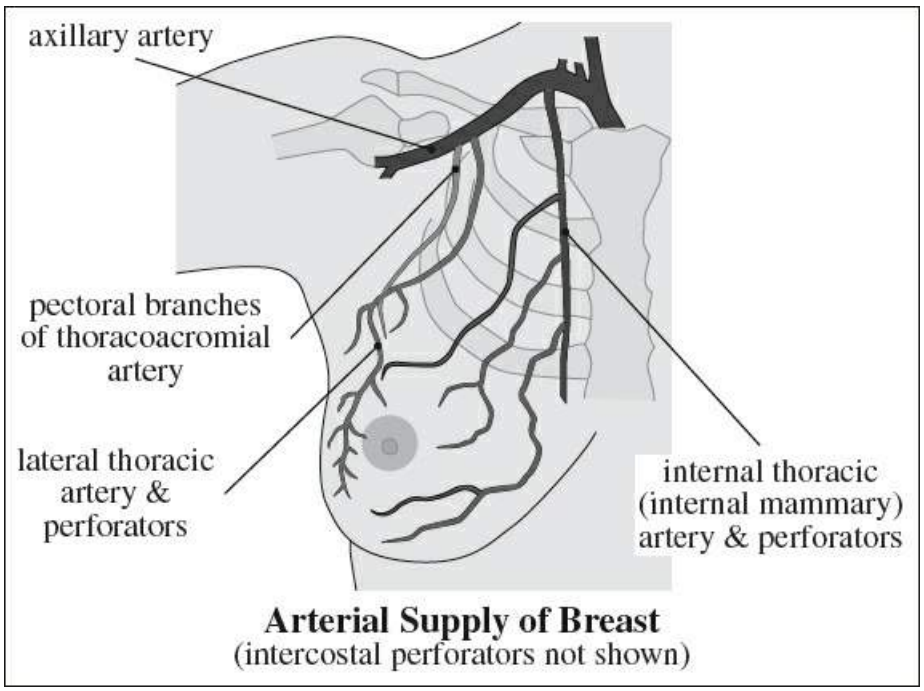
Segments & Branches:

mnemonic: "**S**crew **T**he **L**awyers **S**ave **A** **P**atient"

1. Segment: medial to pectoralis minor m.
   Superior thoracic a.
2. Segment: posterior to pectoralis minor m.
   Thoracoacromial a.
   Lateral thoracic a.

3. Segment: lateral to pectoralis minor m.
   Subscapular a.
   Anterior humeral circumflex a.
   Posterior humeral circumflex a.

Terminus: lower margin of teres major m. (into brachial a.)



Arterial Supply of Breast
(intercostal perforators not shown)

Arterial Supply of Breast

1. Branches of **internal thoracic artery** (= dominant vessel)
   Supply: medial + central breast parenchyma
2. Branches of **lateral thoracic artery**
   Supply: superolateral breast parenchyma
3. Branches of **subclavian + axillary arteries** (including thoracoacromial + subscapular + thoracodorsal arteries)
   Supply: portion of superior breast parenchyma
4. Branches of **musculophrenic artery** (= continuation of internal thoracic artery)
   Supply: variable portion of inferior breast
5. Perforating branches of anterior + posterior **intercostal arteries** perforate chest wall musculature
   Supply: deep central breast parenchyma

BREAST DURING PREGNANCY & LACTATION

Cause: increase in estrogen, progesterone, prolactin
Onset: early in 2nd month of 1st trimester
Histo:

1st trimester:

(a) marked ductular sprouting with some branching + discrete lobular growth

(b) involution of fibrofatty stroma

Breast Changes during Pregnancy & Lactation		
Period	*Histo*	*Hormone*
2nd month of 1st trimester	marked ductular sprouting → some branching + discrete lobular growth; simultaneous involution of fibrofatty stroma; increase in glandular vascularity;	estrogen
2nd + 3rd trimester	marked lobular growth with great epithelial proliferation; relative decrease of stromal components; alveolar cells of TDLU differentiate into colostrum-cell epithelium;	progesterone
	initiation of protein synthesis (lactogenesis I)	prolactin opposed by progesterone
Lactation (= secretory state)	cytoplasm of lobular cells becomes vacuolated; secretion progressively accumulates in distended lobular glands: hyperchromatic nuclei often with small nucleoli + flattening of myoepithelial cells	high prolactin level after rapid withdrawal of progesterone
	marked distention of lobular glands + accumulation of secretion of fat, lactose, and proteins (lactogenesis II) as basic nutrients of milk	in conjunction with insulin, corticosteroids, thyroid hormone, growth hormones
Milk ejection	maintenance of milk production (lactogenesis III) regulated by autocrine system (= neuroendocrine mechanism in the posterior pituitary gland)	release of oxytocin stimulated by breast-feeding
Breast involution	characterized by marked lobular atrophy that occurs over a period of about 3 months after lactation ceases	

(c) increase in glandular vascularity

<u>2nd + 3rd trimester:</u>

(a) marked lobular growth
(b) stromal decrease
(c) epithelial proliferation with cellular enlargement
(d) differentiation of alveolar cells into colostrum-cell epithelium

<u>lactation:</u>

= formation + secretion of milk (= fat + lactose + proteins)

• high levels of prolactin + rapid withdrawal of progesterone

(a) cytoplasmic vacuolation of lobular cells with hyperchromatic nuclei + small nucleoli
(b) distension of lobular glands ← accumulating secretions
(c) flattening + attenuation of myoepithelial cells

Mammography (low sensitivity):

◊ To be performed immediately after breast-feeding in case of a suspected malignancy
◊ Effective in detecting microcalcifications / subtle areas of distortion
√ diffuse, markedly dense, heterogeneously coarse, confluent nodular breast parenchyma (NOT in all patients)
√ marked decrease in adipose tissue

US (method of choice):

◊ identifies a palpable area as a true mass / normal parenchyma

(a) during pregnancy
√ slight diffuse hypoechogenicity of enlarged nonfatty fibroglandular component

(b) during lactation
√ diffuse hyperechogenicity of breast parenchyma
√ prominent ductal system + increased vascularity

MR (routine use is inappropriate + interpretation difficult):

√ diffuse high SI on T2WI ← ↑ fraction of mobile water

√ rapid enhancement + early plateau

Lactogenesis

Lactogenesis I
= formation of colostrum around 16 weeks EGA
Lactogenesis II
= secretion of copious milk around day 4 postpartum
Lactogenesis III
= maintenance of milk supply around day 10 postpartum via autocrine control
• release of oxytocin in posterior pituitary gland stimulated by breast feeding → milk ejection
Lactogenesis IV
= decreased milk production ← epithelial apoptosis
• gradual breast involution completed by 3 months

MAMMOGRAPHIC TECHNIQUE

BEAM QUALITY
Molybdenum target material with characteristic emission peaks of 17.9 + 19.5 keV (lower average energy than tungsten)
FOCAL SPOT
0.1–0.4 mm (0.1 mm for magnification views)
TUBE OUTPUT
80–100 mA
EXPOSURE
(a) without grid: 25 kV (optimum between contrast + penetration), exposure time of 1.0 sec
(b) with grid: 26–27 kV; exposure time of 2.3 sec
(c) microfocus magnification: 26–27 kV; 1.5–2.0 times magnification with 16–30 cm air gap
(d) specimen radiography: 22–24 kV
FILTER
(a) beryllium window (absorbs less radiation than glass tube)
(b) molybdenum filter (0.03 mm): allows more of lower energy radiation to reach breast
REDUCTION OF SCATTER RADIATION
(1) adequate compression (also improves contrast + decreases radiation dose)
(2) beam collimation to < 8–10 cm
(3) air gap with microfocus magnification
(greater spatial resolution, 2–3-fold increase in radiation exposure)
(4) Moving grid
grid if compressed breast > 5 cm / very dense breast (facilitates perception, 2–3-fold increase in radiation exposure)
SCREEN-FILM COMBINATION
(1) Intensifying screen phosphor
single screen systems
(2) Film-screen contact
(3) Mammography film with minimal base fog, sufficient maximum density + contrast
FILM PROCESSING

(1) Processing time of 3 min (42–45 sec in developing fluid) superior to 90-sec processor for double-emulsion film (which creates underdevelopment + compensatory higher radiation exposure)
(2) Developing temperature of 35°C (95°F)
(3) Developing fluid replenishment rate:
450–500 mL replenisher per square meter of film

QUALITY CONTROL
(1) Processor (daily)
with sensito- / densitometric measurements
(a) base fog < 0.16–0.17
(b) maximum density > 3.50
(c) contrast > 1.9–2.0
(2) X-ray unit (semiannually)
(a) beam quality
(b) phototimer

Average glandular dose:
< 0.6 mGy per breast for nonmagnification film-screen mammogram (ACR accreditation requirement)
Screen/film technique (molybdenum target; 0.03 mm molybdenum filter, 28 kVp):
mean absorbed dose: 0.05 rad for CC view 0.06 rad for LAT view

Effective dose equivalent HE:
screen-film mammography 0.11 mSv
xeroradiographic mammography 0.78 mSv
chest 0.05 mSv
skull 0.15 mSv
abdomen 1.40 mSv
lumbar spine 2.20 mSv

Advantages of magnification mammography:
1. Sharpness effect = increased resolution
2. Noise effect = noise reduced by a factor equal to the degree of magnification
3. Air-gap effect = increased contrast by reduction in scattered radiation
4. Visual effect = improved perception and analysis of small detail

Computer-Aided Detection (CAD)

Utility of Computer-Aided Detection (CAD):
(a) significant
1. Clustered microcalcifications
2. Spiculated lesion
(b) moderate
3. Poorly defined mass / asymmetry
(c) low
4. Focal asymmetry
5. Architectural distortion (1–2% detected)
(d) none
6. Developing asymmetry (no comparison with prior)

Cancers missed by Computer-Aided Detection (CAD):

(1) Microcalcifications few
(2) Nonspiculated mass 20%
(3) Architectural distortion 50%
(4) Focal asymmetry 99%
(5) Developing asymmetry 100%

Factors Affecting Mammographic Image Quality

Radiographic Sharpness

= subjective impression of distinctness / perceptibility of structure boundary / edge

1. **Radiographic contrast**

= magnitude of optical density difference between structure of interest + surroundings influenced by

(a) <u>subject contrast</u>

= ratio of x-ray intensity transmitted through one part of the breast to that transmitted through a more absorbing adjacent part; affected by

› absorption differences in the breast (thickness, density, atomic number)
› radiation quality (target material, kilovoltage, filtration)
› scattered radiation (beam limitation, grid, compression)

(b) <u>receptor contrast</u>

= component of radiographic contrast that determines how the x-ray intensity pattern will be related to the optical density pattern in the mammogram

affected by analog factors

› film type
› processing (chemicals, temperature, time, agitation)
› photographic density
› fog (storage, safelight, light leaks)

Causes of poor contrast:

underexposure, inadequate compression, high kV, target material selection (tungsten vs. molybdenum), look-up table selection (altered by engineer)

2. **Radiographic blurring**

= lateral spreading of a structural boundary (= distance over which the optical density between the structure and its surroundings changes)

(a) <u>motion</u>

reduced by compression + short exposure time

(b) <u>geometric blurring</u>

affected by

› focal spot: size, shape, intensity distribution

for analog only:

› focus-object distance (= cone length)
› object-image distance

(c) <u>receptor blurring</u>

= light diffusion (= spreading of the light emitted by the screen) affected by

› phosphor thickness + particle size

› light-absorbing dyes + pigments
› screen-film contact

Causes of image blur:
large focal spot size, damaged anode, patient motion (inadequate compression, poor patient cooperation, long exposure time)

Causes of long exposure:
inadequate compression, kV too low, low mAs output, dense breast, large breast, magnification

Radiographic Noise

= unwanted fluctuation in optical density

1. **Radiographic mottle**
   = optical density variations consist of
   (a) receptor graininess
      = optical density variation from random distribution of finite number of silver halide grains
   (b) quantum mottle (principal contributor to mottle)
      = variation in optical density from random spatial distribution of x-ray quanta absorbed in image receptor

   affected by
   › film speed + contrast
   › screen absorption + conversion efficiency
   › light diffusion
   › radiation quality

   (c) structure mottle
      = optical density fluctuation from nonuniformity in the structure of the image receptor (eg, phosphor layer of intensifying screen)
2. **Artifacts**
   = unwanted optical density variations in the form of blemishes on the mammogram
   (a) improper film handling (static, crimp marks, fingerprints, scratches)
   (b) improper exposure (fog)
   (c) improper processing (streaks, spots, scratches)
   (d) dirt + stains

   Artifacts in digital mammography:
   (a) transmission
   (b) data loss
   › processing artifact (edge artifact): raw data not affected
   › horizontal line artifact due to failure of detector element
   (c) decompression artifact
   (d) gain calibration

ABSCESS OF BREAST

= complication of mastitis

Organism:

(a) aerobes: Staphylococcus aureus, Staphylococcus epidermidis, Streptococcus pyogenes
(b) anaerobes: Peptostreptococcus, Bacteroides
(c) others: TB, other mycobacteria, fungi, parasites
(d) sterile culture (21–45%)

• palpable mass, pain (80%), redness (71%), heat, fever (5–47%):
◊ Clinical signs same as for mastitis!

US:

√ ill-defined area of altered echotexture:
√ hypoechoic often multiloculated fluid collection with acoustic enhancement + surrounding increased flow
√ adjacent hypoechoic glandular parenchyma
√ increased echogenicity of surrounding inflamed fat lobules
√ mild skin thickening ← distended lymphatics
√ mild to moderate cortical thickening of axillary lymph nodes + increased flow on Doppler

Mammo (to exclude malignancy):

Indication: in women > 30 years of age; prolonged course during breast-feeding period
N.B.: delay until after acute episode if possible

√ asymmetric density / mass / distortion
√ skin thickening

DDx: inflammatory breast carcinoma (< 1%)

Rx: percutaneous drainage + antibiotics

Rarely a malignant breast abscess can occur in inflammatory breast cancer!

Puerperal / Chronic Abscess of Breast (14–59%)

= Lactational ABSCESS = COLD ABSCESS

Frequency: 5–11% of cases of mastitis during lactation; most common in primiparous mothers (65%)

Cause: complication of mastitis (in 5–11%) developing in 1–24% of primiparous breast-feeding women

Time of onset: within 12 weeks after birth / weaning

Organism: penicillinase-producing Staphylococcus aureus

Route of infection: small skin laceration

• fever, leukocytosis, breast erythema, induration, pain
• rapid response to antibiotics

Location: most commonly in central / subareolar area

√ ill-defined / circumscribed mass of increased density with flamelike contour

√ secondary changes common: architectural distortion, nipple + areolar retraction, lymphedema, skin thickening, pathologic axillary nodes
√ liquefied center can be aspirated
US:
√ nearly anechoic / mixed / echogenic area with posterior enhancement
MR (reserved for typical situation):
› T1WI:
√ hyperintense round / ovoid lesion (high protein content)
› enhanced T1WI:
√ no contrast uptake centrally
√ strong enhancement of abscess wall
› T2WI:
√ hyperintense round / oval lesion
DDx: seroma, inflammatory breast cancer
Rx: antibiotics, repeated aspirations, percutaneous drainage > surgery; continue breast feeding to disengorge ducts; cessation of breast feeding with antibiotics (contraindicated for newborn / with surgical drainage)

Nonpuerperal Abscess (41–86%)

= abscess occurring outside breast-feeding period
Risk factors: black race, obesity, tobacco smoking, diabetes
Organism: mixed flora (Staphylococcus, Streptococcus); greater risk of anaerobes

Central / Periareolar Nonpuerperal Abscess

= complication of periductal mastitis

Most common form of abscess that develops outside of the breast-feeding period in young smoking woman!

Frequency: 34–94% of all breast abscesses
Pathophysiology:
squamous metaplasia of cuboidal epithelium → keratin plug + acute infiltrate + cellular debris → distension of obstructed lactiferous duct → secondary infection with abscess formation + cutaneous fistula
Zuska disease = recurring central nonpuerperal abscesses associated with lactiferous fistulas
Prognosis: difficult to treat; 25–40% recurrence rate
Rx: percutaneous drainage + antibiotics; cessation of smoking; diagnostic mammogram if > 35 years of age to rule out malignancy

Peripheral Nonpuerperal Abscess

Cause: underlying chronic medical condition (diabetes, rheumatoid arthritis), on steroids, recent breast intervention (postoperative / postradiation Rx)
Age: older age group
Prognosis: good response to therapy; rare recurrences

BREAST CANCER

Epidemiology of Breast Cancer

Incidence: 1.5–4.5 cases per 1,000 women per year in USA; 246,660 new cases of invasive breast cancer + 61,000 new cases of carcinoma in situ (2016) M÷F = 100÷1, whites÷blacks = 70÷1

- ◊ 2nd most common cancer among women (after lung cancer)!
- ◊ 2nd leading cause of death by cancer in women (after lung cancer)!
- ◊ 12.5% lifetime risk of breast cancer = 1 in 8 women will develop breast cancer!

Age: 0.3–2% in women < 30 years of age;
15% in women < 40 years of age;
85% in women > 30 years of age

Mortality: about 40,450 deaths in USA per year (2016)

Risk Factors (increasing risk):

Demographic Factors in Breast Cancer

- increasing age (66% of cancers in women > 50 years):

Age	*Prevalence of Breast Cancer*	
25	5÷100,000	1÷19,608
40	80÷100,000	1÷1,250
45	1075÷100,000	1÷93
50	180÷100,000	1÷555
55	3030÷100,000	1÷33
60	240÷100,000	1÷416

Relative Risk Compared with Woman of Age 60			
30 years of age	0.07	60 years of age	1.00
35 years of age	0.19	70 years of age	1.27
40 years of age	0.35	80 years of age	1.45
50 years of age	0.71		

- Ashkenazi Jewish women + nuns
- upper > lower social class
- unmarried > married women
- Whites > Blacks after age 40

Reproductive Variables in Breast Cancer

- nulliparous > parous:

Relative Risk Compared with Nulliparous:		
age at 1st pregnancy	< 19 years	0.5
age at 1st pregnancy	20–30 years	—
age at 1st pregnancy	30–34 years	1.0
age at 1st pregnancy	> 35 years	> 1.0

- first full-term pregnancy after age 35: 2 x risk
- low parity > high parity

- early age at menarche (< 12 years):
  relative risk compared with onset of regular ovulatory cycle:

	Menarche < 12	*Menarche > 12*
immediately	3.7	1.6
1–4 years	2.3	1.6

- late age at menopause:
  relative risk compared with menopause before age 44:
  natural menopause > 55 years of age 2.00
- early bilateral oophorectomy:
  relative risk compared with menopause between ages 45–49 years:
  artificial menopause at 50–54 years 1.34
  artificial menopause before age 45 0.77

MULTIPLE PRIMARY CANCERS in BREAST CANCER

- 4–5 x increase in risk for cancer in contralateral breast
- increased risk after ovarian + endometrial cancer

BRCA (breast cancer)

= mutation of tumor suppressor gene accounts for 50% of hereditary breast cancers

5–10% of all breast cancers are hereditary!

- BRCA1 on long arm of chromosome 17
- BRCA2 on chromosome 13

Carrier: group of women at high risk for breast cancer
◊ Strict surveillance mandatory!

1% of women are at very high risk for developing breast cancer due to a genetic disposition!

FAMILY HISTORY of BREAST CANCER

- breast cancer in first-degree relative:
  Relative risk compared with negative family Hx:
  (+) for mother 1.8
  (+) for sister 2.5
  (+) for mother + sister 5.6
- 25% of patients with carcinoma have a positive family history
- carcinoma tends to affect successive generations ~ 10 years earlier

BENIGN BREAST DISEASE AND BREAST CANCER

- 2–4 x increased risk with atypical hyperplasia relative risk compared with no biopsy:
  benign breast disease in all patients 1.5
  nonproliferative disease 0.9
  proliferative disease without atypia 1.6
  fibroadenoma + hyperplasia 3.5
  atypical duct hyperplasia (ADH):
  no family history of breast cancer 4.4
  family history of breast cancer 8.9

PARENCHYMAL BREAST PATTERN AND BREAST CANCER

- prominent duct pattern + extremely dense breasts according to Wolfe classification
  N1 (0.14%), P1 (0.52%), P2 (1.95%), DY (5.22%)

RADIATION EXPOSURE and BREAST CANCER

excess risk of 3.5–6 cases per 1,000,000 women per year per rad after a minimum latent period of 10 years (atomic bomb, fluoroscopy during treatment of tuberculosis, irradiation for postpartum mastitis, Hodgkin disease)

GEOGRAPHY

- Western + industrialized nations (highest incidence)
- Asia, Latin America, Africa (decreased risk)

Breast Cancer Evaluation

	MRI	*Mammo*	*US*	*Physical*	*all 4*
Sensitivity [%]	77–100	25–40	33–40	9	95
Specificity [%]	81–97	93–99	91–96		
Recall [%]	10.8	3.9–5.4			
FN [%]	0.2–0.4	0.4–1.5			

Localizing Signs of Breast Cancer

= PRIMARY SIGNS OF BREAST CANCER

1. Dominant mass seen on two views with
   (a) **Spiculation** = stellate / star-burst appearance (= fine linear strands of tumor extension + desmoplastic response); "scirrhus" caused by:
      (1) infiltrating ductal carcinoma (75% of all invasive cancers)
      (2) invasive lobular carcinoma (occasionally)
      √ mass feels larger than its mammographic / sonographic size
      DDx: prior biopsy / trauma / infection
   (b) **Smooth border**
      (1) intracystic carcinoma (rare): subareolar area; bloody aspiration
      (2) medullary carcinoma: soft tumor
      (3) mucinous / colloid carcinoma: soft tumor
      (4) papillary carcinoma
      √ "telltale" signs: lobulation, small comet tail, flattening of one side of the lesion, slight irregularity
      √ "halo" sign (= Mach band) may be present
      DDx: cyst (sonographic evaluation)
   (c) **Lobulation**
      appearance similar to fibroadenoma (only characteristic calcifications may exclude malignancy)
      ◊ The likelihood of malignancy increases with number of lobulations
      • clinical size of mass > radiographic size (1951) (**Leborgne's law**)
        [Raul Alfredo Leborgne Fossemale (1907–1986), Uruguayan radiologist created the mammograph, discovered radiological signs and developed the first method of radiologically guided mammary biopsy]

2. **Asymmetric density** = star-shaped lesion
   √ distinct central tumor mass with volumetric rather than planar appearance → additional coned compression view
   √ denser relative to other areas (= vessels + trabeculae cannot be seen within high-density lesion)
   √ fat does not traverse density
   √ corona of spicules
   √ in any quadrant → but fatty replacement occurs last in upper outer quadrant
   DDx: postsurgical fibrosis, traumatic fat necrosis, sclerosing duct hyperplasia
3. **Microcalcifications**
   associated with malignant mass by mammogram in 40%, pathologically with special stains in 60%, on specimen radiography in 86%

   ◊ 20% of clustered microcalcifications represent a malignant process!

   (a) shape: fragmented, irregular contour, polymorphic, casting rod-shaped without polarity, Y-shaped branching pattern, granular "salt and pepper" pattern, reticular pattern
   (b) density: various densities
   (c) size: 100–300 µm (usually); rarely up to 2 mm
   (d) distribution: tight cluster over an area of 1 cm^2 or less is most suggestive; coursing along ductal system seen in ductal carcinoma with comedo elements
4. **Architectural distortion**
   Cause: desmoplastic reaction
   √ ragged irregular borders
   DDx: postsurgical fibrosis
5. **Interval change**
   (a) neodensity = de novo developing density → in 6% malignant
   (b) enlarging mass → in 10–15% malignant
6. **Enlarged single duct**
   = low probability for cancer in asymptomatic woman with normal breast palpation
   √ solitary dilated duct > 3 cm long
   DDx: inspissated debris / blood / papilloma
7. **Diffuse increase in density** (late finding)
   Cause: (1) plugging of dermal lymphatics with tumor cells
   (2) less flattening of sclerotic + fibrous elements of neoplasm in comparison with more compressible fibroglandular breast tissue

Nonlocalizing Signs of Breast Cancer

= SECONDARY SIGNS OF BREAST CANCER

1. Asymmetric thickening
2. Asymmetric ducts especially if discontinuous with subareolar area
3. Skin changes
   (a) **skin retraction** = dimpling of skin
   Cause: desmoplastic reaction → shortening of Cooper ligaments / direct extension of tumor to skin

DDx: trauma, biopsy, abscess, burns

(b) **skin thickening** ← blocked lymphatic drainage / tumor in lymphatics
- peau d'orange

DDx: normal in inframammary region

4. Nipple / areolar abnormalities
   (a) **retraction / flattening of nipple**
   DDx: normal variant
   (b) **Paget disease** = eczematoid appearance of nipple + areola in ductal carcinoma
   √ associated with ductal calcifications toward nipple
   DDx: nipple eczema
   (c) **nipple discharge**
   - spontaneous persistent discharge
   - need not be bloody

   DDx: lactational discharge
5. **Axillary nodes** (sign of advanced / occult cancer)
   √ > 1.5 cm without fatty center
   DDx: reactive hyperplasia
6. Abnormal veins
   √ venous diameter ratio of > 1.4÷1 in 75% of cancers (= late sign + thus not very important)

Location of Breast Masses

benign + malignant masses are of similar distribution

@ upper outer quadrant 54%
@ upper inner quadrant 14%
@ lower outer quadrant 10%
@ lower inner quadrant 7%
@ retroareolar 15%

◊ Mediolateral oblique view is important part of screening because it includes largest portion of breast tissue + considers most common location of cancers!

Metastatic Breast Cancer

@ Axillary lymph adenopathy
Prevalence: 40–74%
Risk for positive nodes: 30% if primary > 1 cm, 15% if primary < 1 cm

@ Bone

@ Liver
Prevalence: 48–60%
US:
√ hypoechoic (83%) / hyperechoic (17%) mass

Screening of Asymptomatic Patients

Definition of screening (World Health Organization):

A screening test must
(a) be adequately sensitive and specific

(b) be reproducible in its results
(c) identify previously undiagnosed disease
(d) be affordable
(e) be acceptable to the public
(f) include follow-up services

Guidelines of American Cancer Society, American College of Radiology, American Medical Association, National Cancer Institute:

1. Breast self-examination to begin at age 20
2. Breast examination by physician every 3 years between 20–40 years, in yearly intervals after age 40
3. Baseline mammogram between age 35–40; follow-up screening based upon parenchymal pattern + family Hx
4. Initial screening at 30 years if patient has first-degree relative with breast cancer in premenopausal years; follow-up screening based upon parenchymal pattern
5. Mammography at yearly intervals after age 40
6. All women who have had prior breast cancer require annual follow-up

Additional recommendations:

7. Screening at 2-year intervals for women > 70 years
8. Baseline mammogram 10 years earlier than age of mother / sister when their cancer was diagnosed

Rate of detected abnormalities:

30 abnormalities in 1,000 screening mammograms:
20–23 benign lesions
7–10 cancers

Acceptable recall rate for screening examination:

10% for initial prevalence screening;
5% for subsequent incidence screening

Interval cancers: 10–20% of cancers surface between annual screenings

Predictive Value of Radiographic Signs of Malignancy Related to Clinical Findings		
Mammographic Sign	*Palpable*	*PPV (%)*
Classic for malignancy	+	100
Classic for malignancy	–	74
Microcalcifications*	+	25
Microcalcifications*	–	21
Indeterminate mammogram	+	11
Indeterminate mass	–	5
Benign mass	+	2
Asymmetric density (? mass)	+	4
Asymmetric density (? mass)	–	0
Dilated vein		0
Skin thickening		0
Dilated duct		0
* (>3 punctate irregular microcalcifications in area <1 cm^2)		

Role of Mammography

Overall detection rate:

58–69%; 8% if < 1 cm in size

Mammographic accuracy:

88% correctly diagnosed by radiologist

27% detected only by mammography

8% misinterpretations

4% not detected

15–30% positive predictive value (national average):
25% PPV for women in 5th decade
50% PPV for women in 8th decade

Value of Screening Mammography

Indication:

decrease in cancer mortality through earlier detection + intervention when tumor size is small + lymph nodes negative; tumor grade of no prognostic significance in tumors < 10 mm in size

1. **Health Insurance Plan** (HIP) 1963–1969
   randomized controlled study of 62,000 women aged 40–64
   - 25–30% reduction in mortality in women > 50 years (followed for 18 years)
   - 25% reduction in mortality in women 40–49 years (followed for 18 years); no significant effect at 5- and 10-year follow-up
   - 19% of cancers found by mammography alone
   - 61% of cancers found at physical examination
   - effectiveness of screening < 50 years of age is uncertain
2. **Breast Cancer Detection Demonstration Project** (BCDDP) 1973–1980

4,443 cancers found in 283,000 asymptomatic volunteers
› 41.6% of cancers found by mammography alone (77% with negative nodes)
› 8.7% of cancers found by physical examination alone
› 59% of noninfiltrating cancers found by mammography alone
› 25% of cancers were intraductal (versus 5% in previous series)
› 21% of cancers found in women aged 40–49 years (mammography alone detected 35.4%)
› 51% of cancers found with both mammography + physical examination

3. **Swedish Two-county Trial** 1977–1990
randomized controlled study of 78,000 women in study group + 56,700 in control group aged 40–74 years with screening phase lasting 7 years
(a) single MLO mammogram at 2-year intervals for women < 50 years of age
(b) single MLO mammogram at 3-year intervals for women ≥ 50 years of age
› 40% reduction in mortality at 7 years in women 50–74 years
› 0% reduction in mortality at 7 years in women 40–49 years
› At 29-year follow-up 34 years of life per 1000 women were saved screened over a 7-year period
› At 29-year follow-up 1 breast cancer was prevented for each 519 women screened for 7 years
4. **Meta-analysis** of combined results of 5 Swedish trials for women aged 39–49
• 29% reduction in breast cancer mortality with screening mammograms offered at intervals from 18 to 28 months

OCCULT VERSUS PALPABLE BREAST CANCER

◊ 27% are occult cancers (NO age difference)
Positive axillary nodes:
occult cancers (19%); palpable cancers (44%)
10-year survival:
occult cancers (65%); palpable cancers (25%)

Mammographically Missed Cancers

False-negative screening mammogram:
= pathologic diagnosis of breast cancer within 1 year after negative mammogram with the following types of misses:
(a) lesion could not be seen in retrospect (25–33%) = "acute cancer" = cancer surfacing in screening interval
(b) cancer undetected by first reader but correctly identified by second reader (14%)
(c) cancer visible in retrospect on prior mammogram (61%)
Prevalence: ~ 4–15–34% of all cancers; ~ 3 cancers ÷ 2,000 mammograms; 5–15–22% of palpable breast cancers

◊ A second reader will detect an additional 5–15% of cancers!

Cause:
1. Logistical error
(a) prior films not made available
(a) prior films not back far enough

◊ For comparison use a mammographic interval of 3 years to detect slowly developing asymmetries (tumor doubling time ~150 days)

2. Interpretation error (52%):
   (a) benign appearance (18%): medullary carcinoma, colloid carcinoma, intracystic papillary carcinoma, some infiltrating ductal carcinomas
   (b) present on previous mammogram (17%)
   (c) seen on one view only (9%)
   (d) site of previous biopsy (8%)
   (e) calcifications assumed to be benign
3. Observer error (30–43%):
   (a) overlooked: one lesion / group of calcifications doesn't fit the rule of multiplicity
   (b) intrinsic distraction = presence of an obvious finding leads to overlooking of a more subtle lesion = "satisfied search" phenomenon
   (c) no knowledge of clinical finding
   (d) rushed interpretation
   (e) heavy caseload
   (f) extraneous distraction
   (g) eye fatigue
   (h) inexperience
4. Wrong assumption
   (a) misleading long history of a lump results in screening rather than diagnostic mammogram
   (b) acceptance of irreconcilable size discrepancy / lesion location between sonogram and mammogram
   (c) suspicious findings remain suspicious!
4. Technical error (5%):
   (a) inadequate radiographic technique: improper positioning, inadequate compression, under- / overexposed image, poor screen-film contact, geometric motion blurring
   (b) misapplied workup = failure to image region of interest: spot compression magnification view may displace lesion out of field of view
   (c) suboptimal viewing conditions: inadequate luminance of view boxes, extraneous view box light, high ambient room light
5. Tumor biology:
   (a) small tumor size
   (b) failure to incite desmoplastic reaction (eg, invasive lobular carcinoma)
   (c) limitations of screen-film mammography in physically dense breasts
   (d) no associated microcalcifications (~ 50% of cancers)
   (e) developing soft-tissue density
      ◊ A developing density that cannot be reconciled with a history of trauma, inflammation or hormones and does not represent a cyst or lymph node requires a biopsy!
   (f) stability of mammographic findings
      ◊ Malignant calcifications may be stable for up to 63 months

◊ A mass may not change for up to 4.5 years

6. Difficult location:
   (a) axillary tail
   (b) inframammary fold
   (c) busy subareolar region

   Location of missed cancers:
   retroglandular area (33%), lateral parenchyma (31%), central (18%), medial (13%), subareolar (4%)

DISCLOSING UNANTICIPATED OUTCOMES

(a) Content to be disclosed to patient:
   1. Provide facts about events = presence of error / system failure if known
   2. Express regret = apology

(b) Institutional requirements:
   1. Integrate disclosure, patient safety and risk management
   2. Establish disclosure support system
   3. Use performance improvement tools to track and enhance disclosure

Radiation-induced Breast Carcinoma

◊ Lifetime risk with cumulative carcinogenic effect related to age!

(a) women age < 35: 7.5 additional cancers per 1 million irradiated women per year per rad

(b) women age > 35: 3.5 additional cancers per 1 million irradiated women per year per rad

Role of Breast Ultrasound in Breast Cancer

Indications:

◊ Ultrasound is no screening tool!

A. TARGETED EXAM
   (1) Initial study of palpable lump in patient < 30 years of age / pregnant / lactating
      ◊ Ultrasound will not add useful information in an area that contains only fatty tissue on a mammogram!
   (2) Characterization of mammographic / palpable mass as fluid-filled / solid
      ◊ Ultrasound will add useful information if there is water-density tissue in the area of palpable abnormality!
      ◊ Differentiation of cystic from solid lesion is the principal role of ultrasound!
   (3) Additional evaluation of nonpalpable abnormality with uncertain mammographic diagnosis
   (4) Search for focal lesion as cause for mammographic asymmetric density
   (5) Confirmation of lesion seen in one mammographic projection only

B. WHOLE-BREAST EXAM
   (1) Breast secretions
   (2) Suspected leaks from silicone implant
   (3) Follow-up of multiple known mammographic / sonographic lesions
   (4) Radiographically dense breast with strong family history of breast cancer

(5) Metastases thought to be of breast origin, but with negative clinical + mammographic exam
(6) Mammography not possible: "radiophobic" patient, bedridden patient, after mastectomy

C. INTERVENTIONAL PROCEDURE
(1) Ultrasound-guided cyst aspiration
(2) Ultrasound-guided core biopsy
(3) Ultrasound-guided ductography, if
(a) secretions cannot be expressed
(b) duct cannot be cannulated

Accuracy: 98% accuracy for cysts; 99% accuracy for solid masses; small carcinomas have the least characteristic features

Role of Breast MR in Breast Cancer

◊ Impact of routine breast MRI on survival still unknown → use of MRI for preoperative staging controversial!

Pathophysiology of tumor detection:
growth of tumor vessels (= neoangiogenesis) with abnormal leaky capillaries (= increased permeability) → rapid uptake (= early enhancement) and rapid washout of intravenous contrast material in cancerous lesions

Indications:
(1) Improve detection + characterization of primary
• palpable mass + negative mammogram + sonogram
• status post lumpectomy with positive resection margins
◊ Helps to reduce the rate of re-excision (4–43%)
• repeated indeterminate mammogram
• staging:
› tumor size: MR more accurate in estimate of tumor size than mammography / ultrasound
› detection of extensive intraductal component: MR superior to mammography
› multifocality (16–50%): in 70% detected by MR only
› multicentricity(15–30%): in 50% detected by MR only
◊ Reduces rate of "recurrence" / preoperatively undetected foci of cancer from 6.8% to 1.2%
◊ May change accelerated partial breast irradiation to whole-breast irradiation
› before + after 2nd cycle of neoadjuvant chemotherapy to separate responders from nonresponders
› chest wall invasion

(2) "Clearing" (= screening) of contralateral breast:
bilaterality (3–5%) in 75% detected by MR only
◊ Increases detection of contralateral breast cancer from 4% to 17% (of which 35% are DCIS)

(3) Screening of high-risk groups
• young patient with positive BRCA1 gene
• dense breast + high-risk lesion of LCIS

- status post mastectomy + breast reconstruction with implant (yearly screening)

(4) Improve detection of recurrent breast cancer
- planning for biopsy to determine scar versus recurrent tumor after breast-conserving therapy

(5) Evaluate response to neoadjuvant chemotherapy

(6) Examine breasts in patient with metastatic breast cancer but unknown origin of primary (2–7%)
- axillary node malignancy + negative mammogram

(7) Implant imaging

Sensitivity: 72–**90**–100% (for DCIS 40–**73**–100%, for invasive cancer 91%)

Specificity: 37–**70**–100%

◊ A normal MR mammogram
› correctly rules out malignancy in > 96%
› means no invasive cancer > 3 mm
› means no further exam for 2 years (for 1 year if BRCA positive)
› FN: DCIS, LCIS, lobular cancer, tubular cancer

Optimal timing of MR: 7–20 days after beginning of cycle; 6 months after open biopsy; 12 months after radiation therapy

MR:

Malignant morphology always trumps kinetics!

√ reduced signal on T2WI
√ irregular morphology
√ lymphangitic bridges / streaks
√ contrast enhancement:
√ rapid ⇑ in SI after contrast injection = rapid wash-in
◊ **90/90 rule** = cancers show an SI increase of > 90% in the first 90 sec!
√ markedly ⇑ amplitude than normal parenchymal tissue

Indication for Screening Breast MR
(if score > 2.0)

History	*Score*
BRCA 1 or 2	2.0
Personal history of breast / ovarian cancer	2.0
Breast cancer in mother < 60 years	1.0
Breast cancer in sibling < 60 years	0.5
Menstruation > 35 years	0.5
Nulliparous	0.5
First pregnancy > 30 years	0.5
Breast cancer in first-degree relative (nonsibling)	0.5
Ashkenazi Jew	0.5
Dense breast	0.5

BI-RADS® Score & Interpretation of Breast MR	
Descriptor	*Score*
Major feature	
Peak enhancement in 90 sec	2.0
Centripetal wash-in	2.0
Spiculated lesion	2.0
Rapid wash-out	2.0
T2 isointense mass	1.0
Initial contrast uptake >100%	1.0
Minor feature	
Perilesional edema (T2 / STIR)	1.0
Branching lesion	1.0
Dendritic configuration adjacent to primary	1.0
Heterogeneous lesion on T2	1.0
Size of lesion >10 mm	0.5
Lobulated margins of lesion	0.5
Interpretation	
Compatible with malignancy	> 7
Probably malignant	> 5
Indeterminate	3–5
Probably benign	< 3
Compatible with benignity	< 1

√ plateau / fast wash-out in postinitial phase
√ "arterial feeder" sign
√ intense early rim / peripheral enhancement (± central necrosis)
√ centripetal progression of enhancement
√ malignant mass margination

Slowly / Nonenhancing Breast Cancer on MR

1. Lobular carcinoma
2. Tubular carcinoma
3. Mucinous carcinoma
4. Grade I invasive ductal carcinoma

Role of PET/CT in Breast Cancer

PET-CT useful ONLY in

(a) inflammatory breast cancer
(b) > 3 cm large breast cancer
(c) stage II/III breast cancer

Staging of Breast Cancer

(1) Initial staging
◊ PET/CT is efficient for locally advanced + inflammatory breast cancer

√ 40% of breast primaries NOT visualized
√ 61% sensitive + 80% specific for axillary nodes
√ unsuspected disease detected in mediastinal / internal mammary lymph nodes in 30%

(2) Restaging
◊ PET/CT performs better than all other imaging
√ 92–100% sensitive for recurrence, 72–82% specific (changes with time interval since therapy)
√ PET/CT may change clinical management in 36%

High SUV Values in Breast Cancer

(1) Ranking: infiltrating ductal carcinoma > infiltrating lobular carcinoma > ductal carcinoma in situ
(2) Estrogen receptor-negative tumor
(3) Cancer with poor prognosis: triple negative breast tumor (negative for estrogen + progesterone receptors + HER2/neu overexpression)

Distant Metastases in Breast Cancer

Soft-tissue lesion: mediastinal nodes (24%), liver (15%), supracentimetric lung nodules
Bone lesion:
(a) osteosclerotic: PET lacks sensitivity; downstaging with no FDG uptake (in 12%)
(b) osteolytic / mixed lesions: PET more efficient than CT / bone scintigraphy
◊ Bone scintigraphy may no longer be necessary!

Role of Stereotactic Biopsy

Indications: obviously malignant nonpalpable lesion, indeterminate likely benign lesion, anxiety over lesion
Targets: well-defined solid mass, indistinct / spiculated mass, clustered microcalcifications
Advantage: single-stage surgical procedure
Problematic: 3–5-mm small lesion, fine scattered microcalcifications, indistinct density, area of architectural distortion
Sensitivity: 85–99% with core needle biopsy (100% specific), 68–93% with fine-needle aspiration (88–100% specific)
Indication for excision:
(a) anatomic reason: lesion close to chest wall, lesion in axillary tail, very superficial lesion
(b) pathologic reason:
1. Radial scar suspected (in up to 28% associated with tubular carcinoma)
2. Atypia / atypical hyperplasia (in 49–61% associated with malignancy)
3. Carcinoma in situ (in 9–20% associated with invasion)
4. Branching microcalcifications suggestive of DCIS with comedo necrosis

Miss rate: 3–8% for stereotactic biopsy, 3% for surgery

Incidental Breast Cancer Detection by CT

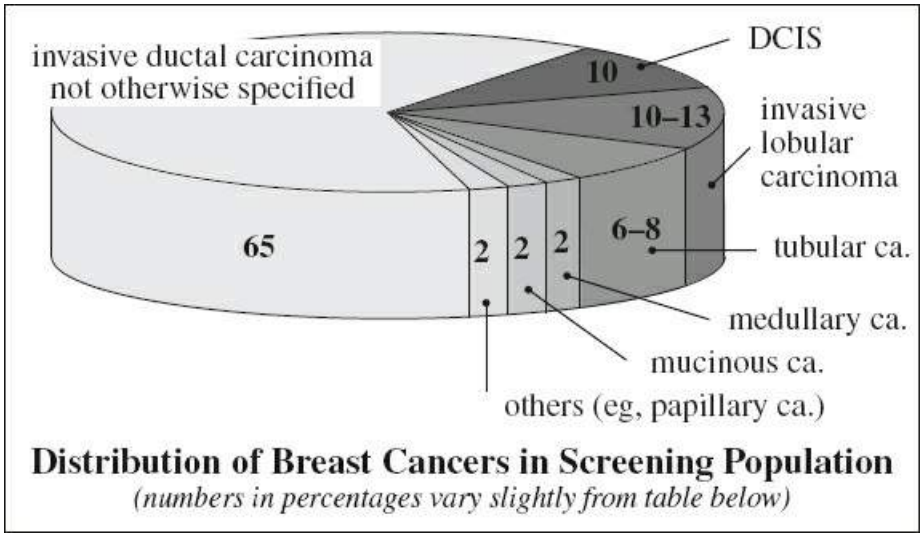
› highly predictive features:
√ irregular margins, irregular shape, rim enhancement

√ washout pattern on postcontrast images
√ diffuse regional enhancement

› most accurate sign:
√ spiculated + irregular margin

Categories of Breast Cancer

A. Invasive ductal carcinoma (NOS) + DCIS 85%
B. Other types of malignancy 15%
(a) Invasive lobular carcinoma (ILC)



Distribution of Breast Cancers in Screening Population
(numbers in percentages vary slightly from table below)

(b) Well-differentiated subtypes of IDC
1. Tubular carcinoma
2. Mucinous carcinoma
3. Medullary carcinoma
4. Papillary carcinoma

(c) Cancers of stromal origin
1. Phyllodes tumor
2. Angiosarcoma
3. Osteosarcoma
4. Adenoid cystic carcinoma

(d) Metastatic disease (0.5–2.0%)
1. NHL
2. Malignant melanoma
3. Metastatic carcinoma
4. Rhabdomyosarcoma
5. Leukemia

Origin: terminal ductal lobular unit (TDLU);
terminal duct → ductal carcinoma (85%)
acinus → lobular carcinoma (10–12%)
stroma → fibrosarcoma, liposarcoma, angiosarcoma, phylloides sarcoma

Staging of Breast Cancer

(a) primary tumor

(b) lymph nodes:

› anatomy

› signs of malignancy

Internal mammary node metastases usually occur after axillary involvement indicating stage N3b / IIIC.

Isolated internal mammary node metastases occur in 1–5% of breast cancers usually from a deep / medial lesion indicating N2b disease.

(c) distant metastasis = stage IV disease

◊ 4% of patients present with distant metastases and of those 10% have lesions at multiple sites

Location: bone, lung, brain, liver

Prognosis: 22% 5-year survival rate

(c) AJCC stage (American Joint Committee on Cancer)

Stage 0	TisN0M0
Stage IA	T1N0M0
Stage IB	T0–T1 with N^{1mi} and M0
Stage IIA	T0–T1 with N1M0 / T2N0M0
Stage IIB	T2N1M0 / T3N0M0.
Stage IIIA	T0–T2 with N2M0 / T3 with N1–N2 + M0
Stage IIIB	T4 with N0–N2 and M0
Stage IIIC	any T with N3M0.
Stage IV	M1 with any T + any N

NONINVASIVE BREAST CANCER (15 %)

= malignant transformation of epithelial cells lining mammary ducts + lobules confined within boundaries of basement membrane

Rx: few data are available to provide insight into proper treatment

Ductal Carcinoma In Situ (DCIS)

= highly heterogeneous group of intraductal carcinomas (“cancer waiting to become malignant”)

= nonobligate precursor to invasive cancer

◊ 30% become invasive over 10 years

Incidence: 20–25% of all cancers in screening population; 70% of noninvasive carcinomas

T Descriptors in TNM Staging of Breast Cancer	
Descriptor	*Definition (= tumor size + locoregional invasion)*
Tis	Carcinoma in situ: DCIS, LCIS, Paget disease of nipple (not associated with invasive carcinoma / carcinoma in situ in underlying breast parenchyma)
T1	all invasive tumors ≤ 20 mm
T1mi	Tumor ≤ 1 mm
T1a	Tumor > 1 mm but ≤ 5 mm
T1b	Tumor > 5 mm but ≤ 10 mm
T1c	Tumor > 10 mm but ≤ 20 mm
T2	Tumor > 20 mm but ≤ 50 mm *mnemonic:* "**T2 over 2** cm"
T3	Tumor > 50 mm
T4	Any tumor size with extension to chest wall / skin (invasion of dermis alone does not qualify)
T4a	extension to chest wall = involvement of ribs /serratus anterior muscle / intercostal muscles (pectoralis muscle invasion alone does not qualify)
T4b	ulceration, ipsilateral satellite skin nodules ± skin edema (= peau d'orange without meeting classic criteria for inflammatory breast cancer)
T4c	T4a + T4b
T4d	inflammatory carcinoma (IBC)
Size of largest tumor determines stage, if > 1 malignancy in same breast. Tumor size is most accurately measured by MRI (size is underestimated by 14% on mammo and by 18% on US)	

N Descriptors in TNM Staging of Breast Cancer	
Descriptor	*Definition (metastases to ...)*
N1	ipsilateral level I–II axillary lymph nodes
N2	
N2a	clinically "fixed" / matted N1
N2b	ipsilateral internal mammary lymph nodes in the absence of axillary nodes
N3	
N3a	ipsilateral infraclavicular (level III) lymph nodes
N3b	ipsilateral level I–II axillary + internal mammary nodes
N3c	ipsilateral supraclavicular nodes
Biopsy the most suspicious lymph node! √ lymph node anatomy √ imaging criteria of malignancy	

Age-adjusted prevalence: 32.5÷100,000 women (2005); 88÷100,000 women 50–64 years
Age: most > 55 (40–60) years
Path: heterogeneous group of malignancies with proliferation of malignant cells lining

TDLU + duct

Histo: proliferation of malignant epithelial cells that line a TDLU without invasion through basement membrane → duct diameter increases from 90 µm to 360 µm

Subgroups: comedonecrosis (often); non-comedocarcinomas (solid, papillary, micropapillary, cribriform)

Nuclear grade: low, intermediate, high

Van Nuys Classification (most reproducible):

Group 1: low / intermediate grade <u>without</u> necrosis

Group 2: low / intermediate nuclear grade <u>with</u> necrosis

Group 3: <u>high nuclear grade</u>

Van Nuys group 1 lesions more likely manifest as noncalcified abnormalities than higher-grade lesions!

Associated with: ADH + invasive ductal carcinoma

N.B.: by definition not capable of metastasizing to regional lymph nodes, HOWEVER axillary metastases in 1.3–13%

Risk factors: increasing age, family history, high breast density, postmenopausal hormone use

- may persist for years without palpable abnormality (in screening population)
- palpable mass (12%) / Paget disease of nipple / nipple discharge (in 12% of symptomatic patients)

◊ 50% of DCIS are > 5 cm in size

◊ Histologic size of DCIS is independent of histologic subgroup

◊ Almost all "comedo" type DCIS contain significant microcalcifications

◊ DCIS often involves the nipple + subareolar ducts

◊ Calcifications in ductal orientation like "string of beads"

Multicentricity: in 8–47% (increasing with tumor size)

Multifocality: in 27%

Multicentricity	Multifocality
> 1 focus in <u>different breast quadrants</u> with a minimum distance of 2 cm → mastectomy	> 2 foci in <u>same breast quadrant</u> → breast conservation therapy
mnemonic: "**C** before **D**" = Centricity for Different quadrants	

Average size: 10–15 mm

Mammo (27–95% sensitive):

√ microcalcifications (in 90%):

› in 75% sole finding

› in 15% associated with soft-tissue component

Shape: amorphous; coarse; heterogeneous; fine pleomorphic (most common)

Distribution: clustered / linear / segmental

√ fine linear / fine linear branching (high-grade DCIS)

√ amorphous microcalcifications (low-grade DCIS)

√ soft-tissue mass / asymmetry (10%):

◊ more frequently associated with low-grade DCIS

√ dominant mass with well-defined margin (14%)
√ ill-defined indistinct obscured mass (2%)
√ architectural distortion (7–13%)
√ soft-tissue abnormality + calcifications (14%)
√ invisible (6%)

US:
√ microcalcifications:
√ associated with ductal changes (most common)
√ echogenic regions without duct changes / mass
√ intraductal mass ± multiple punctate echogenic foci within dilated duct
√ solid mildly hypoechoic irregularly shaped intraparenchymal mass with indistinct / microlobulated margins + normal acoustic transmission
√ pseudomicrocystic appearance

MR (60–100% sensitive, 18–100% FN [!]):

DCIS Grade	*MR Sensitivity*
high	98%
intermediate	91%
low	80%

Sensitivity for DCIS is much higher for MRI (92%) than for mammography (56%)!

◊ Preoperative MR evaluation is utilized in women with newly developed breast cancer to discover:
(a) extent of disease and tumor margins
(b) ipsilateral multicentric involvement
(c) contralateral disease (in 3.3%)

√ hypo- to isointense to surrounding parenchyma on T1WI + fatsat T2WI
◊ Not helpful in decision whether to biopsy clustered microcalcifications or not!

CEMR:

Morphology of DCIS on Enhanced MRI

Type	*Definition*	*Frequency*
NME	nonmass-like enhancement of an area that is not a mass	60–81%
mass	3-dimensional space-occupying lesion of enhancement	14–41%
focus	< 5 mm region of enhancement	1–12%

High likelihood of cancer:
√ clumped linear (beady, string of pearls) ductal / segmental enhancement (HALLMARK)
√ linear enhancement adjacent to synchronous malignant mass

Enhancement pattern of DCIS:

The internal enhancement pattern of nonmass-like DCIS is commonly clumped or heterogeneous (50% vs. 20%)

√ nonmass-like (60–81%) enhancement (NME) pattern:
√ clumped (41–64%)

√ internally heterogeneous (16–29%) / homogeneous (16%)
√ reticular / dendritic (9%), stippled (8%), punctate (3%)
√ oval / round masslike (14–41%) enhancement pattern:
√ irregular (14–83%) / spiculated (0–92%) / smooth (4–8%) mass margins

DCIS most frequently manifests as an irregular mass!

√ homogeneous (9–25%) / heterogeneous (9–67%) internal enhancement / rim enhancement (0–8%)
√ focal (1–12%) enhancement pattern
√ no enhancement (in 5–10%)

Enhancement distribution of DCIS:
√ segmental (42%), focal (33%), diffuse (9%), linear-ductal (9%), regional (6%)

A segmental distribution is the most common pattern accounting for 33–77% of all DCIS!

Enhancement kinetics of DCIS:
√ initial period: fast (49–68%), medium (20%), slow (20%)
√ delayed period: plateau (20–52%), washout (28–44%), persistent (20–30%)
◊ There is no pathognomonic kinetic pattern:
› lower-grade lesions tend to show steep initial period + washout
› higher-grade lesions tend to show persistent increase

The most common enhancement kinetics for DCIS are a fast initial phase with a delayed-phase plateau!

Prognosis: 96–98% 10-year survival rate

Rx: (1) Simple / modified mastectomy: cure rate of 98%; reserved for tumor > 5 cm or multicentric / diffuse disease
(2) Local excision alone (breast-conserving Rx): local recurrence in 4 years:
› 19% for poorly differentiated
› 10% for moderately differentiated
› 0% for well differentiated
(3) Lumpectomy + radiotherapy: 7% rate of recurrence

Treatment problems:
◊ Underestimation of extent of disease in 30% for mammography and in 19% for MRI!

MRI provides an accurate assessment of the extent of DCIS (89%) compared to mammo (55%) and US (47%) OR an overestimation!

1. Occult invasion in 5–20% of patients
2. Multifocality in 30%
3. Multicentricity in 14% of lesions < 25 mm, in 100% of lesions > 50 mm
4. Axillary metastases in 1–2%

Increased risk of recurrent DCIS:
(1) Positive margins after surgery
(2) Residual synchronous foci of DCIS

Presentation: 50% as invasive cancer; 20% as distant metastases in 10 years

High Nuclear Grade DCIS ("comedo type")

Prevalence: 60% of all DCIS
Precursor: none; one stage de novo development
Path: "comedo" = pluglike appearance of necrotic material that can be expressed from the cut surface
[*comedo* , Latin = worm of waxy material that can be squeezed from a blackhead believed to feed (*edere* = to eat) on the body]
Characteristics:
› nuclear grade: large / intermediate nuclei, numerous mitoses, aneuploidy
› growth pattern: predominantly solid cell proliferation; atypically papillary / micropapillary / cribriform
[*cribriform*, Latin = small holes or open spaces like a sieve)
› necrosis: extensive (HALLMARK) ← rapid growth
› calcifications (90%): dystrophic / amorphous within necrosis in center of dilated ductal system outlining most of the lobe in classic solid growth pattern
• estrogen-receptor + progesterone-receptor negative
• overexpression of ErbB-2 oncogene product and P53 suppressor gene mutation
• often symptomatic lesion with nipple discharge
√ ductal system enlarged to 300–350 µm
√ linear / branching pattern of calcifications scattered in a large part of lobe / whole lobe
√ large solid high-density casting calcifications (fragmented, coalesced, irregular) in solid growth pattern
√ "snake skin–like" / "birch tree flowerlike" dotted casting calcifications within necrosis of micropapillary / cribriform growth pattern
√ palpable dominant mass without calcifications (very unusual)
√ nipple discharge (rare)
Prognosis: higher recurrence rate than noncomedo-group

Low Nuclear Grade DCIS ("noncomedo type")
Prevalence: 40% of all DCIS
Precursor lesion: atypical ductal hyperplasia (ADH) with slight / moderate / severe atypia
◊ 52–56% of ADH at core biopsy are associated with malignancy at excision!
Characteristics:
› nuclear grade: monomorphic small round nuclei, few / no mitoses
› growth pattern: predominantly micropapillary / cribriform; atypically solid cell proliferation (often coexist)
› necrosis: not present in classic micropapillary / cribriform growth pattern
› calcifications (50%): laminated / psammoma-like ← active secretion by malignant cells into duct lumen
√ fine granular "cotton ball" calcifications in cribriform growth pattern
√ coarse granular "crushed stone" / "broken needle tip" / "arrowhead" calcifications in less common solid growth pattern
◊ Size of "noncomedo" DCIS often underestimated mammographically (? ← lower density of calcifications at periphery of lesion)!

√ powdery calcifications (45%)
√ palpable dominant mass without calcifications (intracystic papillary carcinoma, multifocal papillary carcinoma in situ)
√ nonpalpable asymmetric density with architectural distortion
√ occasionally serous / bloody nipple discharge + ductal filling defects on galactography

Risk of recurrence: 2%

Prognosis: 30% eventually develop into invasive cancer

Dx: surgical biopsy

◊ Core needle biopsy could result in diagnosis of only proliferative breast disease that is usually intermixed!

Lobular Carcinoma In Situ (LCIS)

= arises in epithelium of blunt ducts of mammary lobules

◊ NOT a precancerous lesion – BUT a marker for an increased risk of subsequent invasive cancer in either breast! ("Risk factor waiting to become malignant")

Prevalence: 0.8–3.6% in screening population; 3–6 % of all breast malignancies; 25% of all noninvasive carcinomas; high incidence during reproductive age → decreasing with age

Age: most 40–54 years (earlier than DCIS / invasive tumors)

Histo: monomorphous small cell population filling + expanding ductules of the lobule

◊ Synchronous invasive cancer in 5%!

• not palpable
√ mammographically occult
√ may atypically present as a noncalcified mass (in 7%), calcifications + mass (in 10%), asymmetric opacity (2%)

MR:

› T1WI:
√ isointense to breast parenchyma
› enhanced T1WI:
√ ill-defined enhancement with nonspecific intensity curves

◊ High frequency of multicentricity (50–70%) + bilaterality (30%)!

Dx: incidental microscopic finding depending on accident of biopsy (performed for unrelated reasons + findings)

Prognosis:

◊ LCIS serves as a marker of increased risk for developing invasive carcinoma in <u>either</u> breast!

◊ 20–30% develop invasive ductal > lobular carcinoma within 20 years after initial diagnosis
◊ 1% per year lifetime risk for invasive malignancy

Rx: recommendations range from observation (with follow-up examinations every 3–6 months + annual mammograms) to uni- / bilateral simple mastectomy

Intracystic Papillary Carcinoma In Situ (0.5–2%)

= rare variant of noncomedo DCIS

Age: usually older postmenopausal woman; peak 34–52 years
Histo: papillary fronds within the wall of a cystically dilated duct; (partial) absence immunohistochemical marker p63 for myoepithelial cell layer
- well-circumscribed + freely movable
- aspiration yields straw-colored / dark red / brown fluid ← ruptured capillaries in cyst wall / necrosis of tumor cells; reaccumulation of fluid within 3–4 weeks
- fluid cytology negative for cancer in 80%

Size: 1.9 (range, 0.4–7.5) cm
√ solid intracystic mass on US
√ round benign appearing mass with sharply circumscribed lobulated borders on mammography
√ intracystic mass on pneumocystography
√ fast growth ← accumulation of fluid + proliferation of neoplastic cells
Rx: lumpectomy
Prognosis: 10-year disease-free survival rate of 91%
DDx on mammogram: mucinous / medullary carcinoma, hematoma, metastasis

INVASIVE BREAST CANCER (85%)

= cancer cells outside mammary ducts / TDLUs after penetrating basement membrane
Pathophysiology:
malignant cells of ~ 1 billion cells = 1 cm^3 (= critical mass) outgrow their nutrient supply inside confines of basement membrane → tumor elaborates
(1) angiogenic factor stimulating growth of new arterial channels (neovascularity) and
(2) proteolytic enzyme weakening / dissolving basement membrane
Subtypes: estrogen receptor, progesterone receptor, Her2 (= **H**uman **e**g**fr 2**), CK5/6 (= CytoKeratin 5/6), EGFR (= **E**pidermal **G**rowth **F**actor **R**eceptor)
Growth rate: average doubling time of 110–150 (range, 25–1000) days
√ **mass** = 3-dimensional lesion apparent on 2 views:
√± spicules = extension of malignant cells
√ focal **asymmetry** = confined parenchymal area of similar shape
› without identifiable borders in 2 views
› with definable border on 1 view
√ architectural **distortion** = alteration of anticipated normal orderly undulating curvilinear breast parenchyma into straight or converging lines / a convexity / acute angle:
√ surrounding corona of radiolucency
√ nipple retraction / skin retraction
√ tenting / flattening / shrinking
√ bulging contour
√ edema (lymphatic obstruction) + skin thickening
√ adenopathy
MR:
√ peripheral / rim enhancement
Prognosis:

Tumor size	Survival at 10 years after diagnosis
< 1 cm	95% (independent on tumor grade)
1–2 cm	85%
2–5 cm	60% (dependent on tumor grade)

A reduction of breast cancer mortality is possible through detection of small invasive cancers!

Infiltrating / Invasive Ductal Carcinoma (65%)

= NO SPECIAL TYPE / NOT OTHERWISE SPECIFIED (NOS)

◊ Most frequently encountered breast malignancy

◊ 10% false-negative ratio

Age: any age; peaks between 50 and 60 years

Histo:

grade I = well-differentiated

grade II = moderately differentiated

grade III = poorly differentiated

◊ Strong fibrotic component!

- palpable: 70% are first palpated by the patient
- larger by palpation than on mammogram (Leborgne's law)
- often poorly movable + indolent

Location: multifocal in 15%; bilateral in 5%

Mammo:

√ spiculated (36%) / irregular mass = PRINCIPAL FINDING

√ developing asymmetry

√ lobulated / round / oval mass

√ increased central density

√ ± malignant calcifications (45–60%)

US:

√ ill-defined hypoechoic mass with intermediate hyperechoic margins

√ central / peripheral acoustic shadowing

√ ductal extension (HIGHLY SPECIFIC)

√ perilesional hypervascularity

<u>less common:</u>

√ irregular cystic lesion with surrounding round / tubular hypoechoic areas (= ductal extension)

√ intraductal mass

√ ill-defined spiculated hyperechoic mass with acoustic shadowing

CT:

√ dense spiculated mass

√ marked early and / or peripheral enhancement

MR (88–98% sensitive)

› T1WI:

√ isointense to parenchyma; hypointense to fat

› enhanced T1WI:

√ round / ovoid / spiculated lesion with ill-defined margins
√ ring enhancement in up to 50% with centripetal progression
√ strong (60%) / moderate (35%) / mild (5%) contrast uptake
√ plateau (most frequent) / wash-out (often) / continuous increase (rare) on postinitial phase
√ dilated veins draining the tumor

› T2WI:
√ moderately hyperintense ← viable tumor cells in tumor periphery
√ hyperintense ← central area of necrosis / infarction

On T2WI areas of tumor infarction + necrosis exhibit high SI, viable tumor cells show moderately high SI!

Infiltrating / Invasive Lobular Carcinoma (10–15%)

= neoplasm arising from terminal ductules of breast lobules
= ILC
◊ 2nd most common form of invasive breast cancer
◊ 30–50% of patients will develop a second primary in same / opposite breast within 20 years

Median age: 45–56 years; 2% of breast cancers in women < 35 years; 11% of breast cancers in women > 75 years

Multiplicity: multicentric (30%) + bilateral (6–28%)
◊ Relatively high frequency of bilaterality!

Histo: straight single file of uniform small cells with round oval nuclei + scanty cytoplasm growing around ducts, vessels, and lobules with lack of cohesiveness + without destruction of anatomic structures ("Indian files, targetoid growth pattern) like a spiderweb resulting in subtle changes in architecture; little desmoplastic stromal reaction

Grade: 20% grade I, 64% grade II, 16% grade III

Spread: by diffuse infiltration with little disruption of underlying anatomy

Metastases: peritoneum, retroperitoneum, gynecologic organs, GI tract, carcinomatous meningitis
◊ Consider ILC in women presenting with ascites, hydronephrosis, pelvic masses!

- palpable in 69%:
  - area of subtle thickening / induration
  - skin / nipple retraction
  - large rubbery / indiscrete firm mass / fine nodularity
- decreasing breast size; aching / pulling sensation

Mammo (57–81% sensitive):

◊ Mammogram often underestimates tumor size relative to physical finding + histology; highest FN rate of all invasive breast cancers (up to 19%)

√ solitary inhomogeneous mass (44–65%):
√ with spiculated / ill defined margins (40%)
√ round well-circumscribed (1–3–11%)

√ opacity equal to / lower than normal fibroglandular tissue
√ architectural distortion (= retraction of normal glandular tissue with thickening + disturbance of fibrous septa) in 10–15–34%
√ focal asymmetry (= ill-defined area of increased density without central tumor nidus) in 8–16–19%
◊ May be evident on ONLY one standard view: CC (typically better compressed) > ML > MLO!
√ global asymmetry with unilateral increase in parenchymal volume (1–11–14%)
√ "shrinking breast" = in large tumor breast size appears mammographically smaller compared to contralateral side due to decreased compliance + compressibility
• physical size at inspection symmetric + unchanged
√ microcalcifications (0–24%)
√ retraction of skin (25%) + nipple (26%)
√ skin thickening
√ normal / benign finding (8–16%)
US (68–98% sensitive):
√ irregular / angular hypoechoic mass with heterogeneous internal echoes + ill-defined / spiculated margins + posterior acoustic shadowing (54–61%):
√ circumscribed shadowing mass (pleomorphic ILC)
√ focal shadowing without a discrete mass (classic ILC)
√ rarely hyperechoic mass
MR (83–100% sensitive):
◊ Additional unexpected ipsilateral lesions (in 32%) + contralateral lesion (in 7%):
√ dominant lesion surrounded by multiple small enhancing foci
› T1WI:
√ isointense to parenchyma
› enhanced T1WI:
√ moderate / strong initial enhancement
√ postinitial plateau (frequently) / wash-out (rare) / delayed maximum enhancement (typical)
√ lack of mass effect + amorphous asymmetry
√ ring enhancement of nodular tumor form (in up to 50%)
√ enhancing solitary irregular / angular mass with spiculated / ill-defined margins (31–43%)
√ multiple small enhancing foci with interconnected enhancing strands
√ enhancing septa
› T2WI:
√ iso- to hypointense to breast parenchyma
Dx: core biopsy (controversial) may help in surgical planning prior to surgical excision
Rx: frequently associated with positive margins at excision
Prognosis: survival rate slightly higher than for usual type of invasive ductal carcinomas
DDx: radial sclerosing lesion

Adenoid Cystic Carcinoma (0.1–0.4%)
Histo: mixed glandular + stromal material with predominantly basaloid cells in a variable

architectural pattern (solid, cribriform, tubular, trabecular); microcystic areas formed by coalescent spaces in dilated glands (in 25%)

√ well-defined irregular mass with parallel growth
√ smooth macrolobulated / indistinct margins
√ architectural distortion
√ asymmetric density

US:
√ heterogeneous hypoechoic irregular mass

MR:
√ variable signal intensity on T2WI
√ predominantly persistent enhancement kinetics

Prognosis: excellent

Tubular Carcinoma (< 2%)

= well-differentiated low nuclear-grade ductal carcinoma

Multiplicity: multicentric (28%), bilateral (12–38%)
(a) low grade: bilateral in 1÷3
(b) high grade: bilateral in 1÷300

Associated with: lobular carcinoma in situ in 40%

Median age: 44–49 years

• positive family history in up to 40%; nonpalpable

Mean size: 8 mm (up to 17 mm in diameter)

√ high-opacity nodule with spiculated margins:
√ spicules often longer than central mass
√ may be stable for years
√ associated microcalcifications (50%)
√ multicentric (28%), bilateral (12–38%)

US:
√ hypoechoic solid mass + ill-defined margins + posterior acoustic shadowing

MR:
› T1WI:
√ stellate hypointense lesion well seen in fat
› enhanced T1WI:
√ stellate tumor with moderate / strong initial uptake
√ ring enhancement rare
√ postinitial plateau (frequent) / wash-out (rare) / continuous increase (very rare)
› T2WI:
√ iso- / slightly hypointense to parenchyma
√ occasional peritumoral edematous zone

Prognosis: 97% 10-year survival

DDx: radial scar (histologically α-smooth muscle / maspin staining of myoepithelial cells)

Medullary Carcinoma (2%)

= SOLID CIRCUMSCRIBED CARCINOMA

◊ Fastest growing breast cancer!

◊ Often associated with BRCA gene!
Prevalence: < 5% of all breast carcinomas; 11% of breast cancers in women < 35 years
Path: well-circumscribed mass with nodular architecture + lobulated contour; central necrosis is common in larger tumors; reminiscent of medullary cavity of bone
Histo: poorly differentiated cells with scant stroma + intense lymphoplasmacytic infiltration (reflecting host resistance); propensity for syncytial growth; no glands
Mean age: 46–54 years
• softer than average breast cancer
• often palpable tumor ← rapid growth
Mean size: 2–3 cm
√ well-defined round / oval noncalcified uniformly dense mass (← hemorrhage) with lobulated margin
√ may have partial / complete "halo" sign
US:
√ hypoechoic homogeneous / mildly heterogeneous mass with some degree of through transmission
√ distinct / indistinct margins
√ large central cystic component
MR:
√ irregular internal architecture (no septa!)
› T1WI:
√ well-circumscribed hypointense lesion difficult to detect in parenchyma
› enhanced T1WI:
√ moderately / strongly enhancing round / ovoid lesion with smooth edge
√ homogeneous internal enhancement (← high cellularity) / (occasionally) ring enhancement
√ postinitial type II plateau pattern (frequent) / wash-out (occasionally) / continuous increase (rare)
› T2WI:
√ iso- or mildly hypointense to parenchyma
DDx: myxoid fibroadenoma
Prognosis: 92% 10-year survival rate

Metaplastic Carcinoma (< 1%)
= metaplastic conversion of ductal carcinoma into nonglandular growth pattern of squamous / spindle / heterogeneous mesenchymal cells
Prevalence: < 1% of all newly diagnosed breast cancers; < 5% of invasive breast cancers
Histo: spectrum from poorly differentiated ductal to keratinizing squamous cell carcinoma
Age: > 50 years
• rapidly growing palpable mass
√ predominantly circumscribed noncalcified mass of high density
US:
√ round lobular mass with well-circumscribed microlobulated margin
√ ± complex internal echogenicity with solid + cystic components ← necrosis / cystic degeneration

MR:
› enhanced T1WI:
√ rimlike enhancement
√ postinitial type III wash-out pattern in enhancing peripheral portion
› T2WI:
√ high signal intensity ← necrosis, cystic degeneration, myxoid matrix, intratumoral hemorrhage, loose edematous stroma

Mucinous / Colloid Carcinoma (1–7%)

= well-differentiated low nuclear-grade ductal carcinoma with large amount of extracellular epithelial mucus

Prevalence: 1–7% of all invasive breast cancers

Histo:

(a) pure form: aggregates of tumor cells floating in abundant pools of extracellular mucin (gelatinous / colloid fluid) → less aggressive slow growth

(b) mixed form: contains areas of infiltrating ductal carcinoma not surrounded by mucin

Age: 7% of all carcinomas in women > 75 years; 1% of breast cancers in women < 35 years

• "swish" / "crush" sensation during palpation
• 60% estrogen-receptor positive
√ well-circumscribed usually lobulated round / ovoid mass of low density:
√ poorly defined margins on spot compression
√ pleomorphic clustered / clumped amorphous / punctate calcifications (rare)
√ may enlarge fast (through mucin production)

US:
√ heterogeneous mass with mixture of solid + cystic components
√ posterior acoustic enhancement (common)
√ posterior acoustic shadowing (uncommon)

MR:
› T1WI:
√ well-circumscribed lobulated lesion of variable intensity ← differences in protein concentration
› enhanced T1WI:
√ typically type I persistent enhancement pattern
√ very strong (usually) / moderate (occasionally) / slight (rare) initial uptake
√ postinitial plateau (frequent) / wash-out (occasionally) / continuous increase (very rare)
√ rarely ring enhancement
› T2WI:
√ homo- / heterogeneously hyperintense mass ← predominant mucin component

Prognosis: excellent (unless of mixed form)

Papillary Carcinoma (1–2%)

= rare ductal carcinoma arising from benign papilloma

N.B.: Do not confuse with micropapillary / cribriform growth pattern of ductal carcinoma

Histo: multilayered papillary projections extending from vascularized stalks; no myoepithelial layer (as in benign lesions); neurosecretory granules + positive CEA-reactivity in 85% (absent in benign lesions)

Types:

(a) intraductal papillary carcinoma (often multiple)

(b) intracystic papillary carcinoma = in situ malignancy

(c) invasive carcinoma with papillary growth pattern (microscopic frond formation)

Mean age: 63–67 (range, 25–89) years; peak of 40–75 years

- slow growing palpable central mass (67%)
- nipple discharge (22–34%) often tinged with blood
- rich in estrogen and progesterone receptors

Location: single nodule in central portion of breast; multiple nodules extending from subareolar area to periphery of breast

Size: average diameter of 2–3 cm

√ multinodular pattern (55%) = lobulated mass / cluster of well-defined contiguous nodules

√ solitary well-circumscribed round / ovoid mass of equal or high density ← hemorrhage into cystic space

√ usually confined to single quadrant

√ associated microcalcifications in 60%

√ multiple filling defects / disruption of an irregular duct segment / complete obstruction of duct system at galactography

US:

√ cyst with an intracystic mass of lobulated smooth margins + acoustic enhancement

√ complex mass

√ ± blood flow on color Doppler

MR:

› T1WI:

√ well-circumscribed hypointense retroareolar lesion

› enhanced T1WI:

√ strong initial enhancement + postinitial wash-out (type II washout pattern) / (less often) plateau

√ ring enhancement possible

› T2WI:

√ well-circumscribed lesion of intermediate intensity in signal-intense cyst

Prognosis: 90% 5-year survival after simple mastectomy + axillary node dissection

DDx: solitary central duct papilloma; multiple peripheral benign papillomas

Intraductal Papillary Carcinoma

Path: growth within dilated ducts surrounded by zone of fibrosis without cystic component

√ single / multiple clusters of microcalcifications (most common feature)

MR:

√ clumped areas of enhancement

Distribution: focal / ductal / segmental / regional

√ intratumoral high T2 signal ← microcystic components

Intracystic Papillary Carcinoma

Prevalence: 2–5% of all breast cancers
Origin: dilated duct
Path: friable bosselated well-circumscribed mass within a cystic space (0.3–2.0%) / without a cyst as solid variant
Histo: epithelial frond-forming growth pattern supported by a fibrovascular core lined by ≥ 1 layer of epithelial malignant cells; incomplete / absent myoepithelial cell layer identified by immunohistochemical marker p63
Average age: 70 (range, 27–99) years

- asymptomatic; slowly enlarging palpable mass
- bloody nipple discharge (22–34%)

Location: retroareolar; multifocal
√ round / oval well-circumscribed mass
√ spiculation
√ nipple retraction
US / MR:
√ cystic mass ± septa
√ intracystic solid papillary mass with peripheral fronds projecting from cyst wall into lumen
√ thick fibrotic cyst wall
√ fluid-debris level ← spontaneous hemorrhage
√ positive color Doppler flow
√ posterior acoustic enhancement ← fluid component
√ fluid component serous (low signal on T1WI + high signal on T2WI) / frequently hemorrhagic (high signal on T1WI + T2WI)
√ marked enhancement of mural nodule + cyst wall + septa
Dx: surgical excision to document invasion at tumor periphery
Prognosis: 10-year survival rate approaches 100%
DDx: cyst, mucinous / medullary carcinoma, hematoma, metastasis

Paget Disease of the Nipple (5%)

[Paget, Sir James Paget, 1st Baronet (1814–1899), English surgeon at St. Bartholomew's Hospital, London, England and one of the founders of scientific medical pathology; first described in 1874]
= uncommon manifestation of breast cancer characterized by infiltration of the nipple epidermis by adenocarcinoma
◊ NEARLY ALWAYS a sign of underlying breast malignancy!
Origin: likely from preexisting DCIS / invasive ductal cancer
Prevalence: 1–3% of all breast cancers
Age: all ages; peak between 40 and 60 years

- nipple changes (32%): eczema, erythema of nipple + areola, scaly / flaky skin, nipple erosion, nipple ulceration, nipple inversion, retraction of nipple and areola, bloody discharge:
  ◊ Median delay of correct diagnosis by 6–11 months as features suggest a benign diagnosis of eczema!

- nipple changes + palpable mass / thickening of breast (45%)
- palpable mass / thickening of breast only (14%)
- nipple itching, ± serous / sanguineous nipple discharge

Histo: Paget cell = large round cell with pale clear abundant cytoplasm + enlarged pleomorphic nucleus invading epidermis; histologically and biologically similar to comedocarcinoma

Histogenesis:

(1) Epidermotropic theory = subareolar cancer cells break away from malignancy → migrate through milk ducts along basal membrane → enter nipple and areola

(2) Intraepidermal transformation theory = in situ malignant transformation / degeneration of existing cells

Associated with:

extensive invasive (30%) / in situ ductal carcinoma (60%) limited to one duct in subareolar area / remote + multicentric

Staging: Paget disease associated with breast carcinoma should be categorized on the basis of parenchymal disease!

The mammographic appearance is normal in 22–50%!

@ nipple-areolar complex
- √ nipple / areolar / skin thickening
- √ nipple retraction
- √ dilated duct
- √ linearly distributed subareolar malignant microcalcifications
- √ discrete retroareolar soft-tissue mass / masses

@ breast parenchyma
- √ discrete mass(es) > 2 cm from nipple-areolar complex elsewhere in breast with asymmetry, architectural distortion, diffuse malignant calcifications

MR:

› T1WI:
- √ flattening / thickening of mamillary region

› enhanced T1WI:
- √ variable initial uptake: absent / mild / intense
- √ postinitial plateau / wash-out
- √ asymmetric enhancement of nipple
- √ retroareolar lymphatic enhancement

› T2WI:
- √ rarely asymmetric areolar hyperintensity

Dx: full-thickness biopsy of nipple + areola → followed by radiologic evaluation to detect an underlying malignancy;

cytologic smear of a weeping nipple secretion

Prognosis: survival rate with palpable mass similar to infiltrating duct carcinoma; 85–90% 10-year survival rate without palpable mass; positive axillary nodes in 0–13%

Inflammatory Breast Carcinoma (IBC)

= clinical entity with diffuse erythema + edema involving > ⅓ of breast skin ± angiolymphatic

tumor emboli
Prevalence: 2–5% of breast cancers
Average age: 52 years
Histo: no specific type
◊ Tumor invasion of dermal lymphatics demonstrated in only 60% of specimens!
Staging: T4d (T4b if < ⅓ of breast skin involved)
◊ 20–40% risk of distant metastases at time of Dx
N.B.: dermal lymphatic invasion alone is NOT necessary / sufficient for a diagnosis of IBC
Location: L > R breast; bilaterality in 30–55%
◊ Metastatic at time of presentation in 20%!
Site: often dorsal + central within breast
• rapid symptomatic development > ⅓ of breast surface:
  • palpable tumor (63%); nipple retraction (13%)
  • diffuse erythema + edema of skin (13–64%)
  • erysipeloid edge = peau d'orange edema of skin (13%)
• palpable axillary adenopathy (in up to 91%)
√ NO fluid collection (DDx to abscess)
√ tumor mass ± malignant-type calcifications
√ dense edematous breast
√ stromal coarsening (50%)
√ thickening of Cooper ligaments
√ extensive skin thickening (71%)
CT:
√ marked skin thickening + peripheral enhancement
PET/CT (superior in staging + restaging of IBC):
√ detection of primary breast lesion, skin involvement
√ extent of lymph node metastases for radiation therapy planning: ipsilateral axillary, subpectoral, infra- and supraclavicular, internal mammary (25%)
√ detection of unexpected distant metastases
MR (most accurate modality):
› T1WI:
√ unilateral breast enlargement
√ skin thickening
› enhanced T1WI:
√ patchy asymmetric enhancement of parenchyma + Cooper ligaments
√ strong increased uptake in thickened skin:
√ "punched-out" sign = patchy nodular enhancement of skin at different points in time + different locations
√ strong increased uptake in tumor infiltrated parenchyma:
√ occasionally delineation of primary tumor
› T2WI:
√ diffuse increase in intensity compared to contralateral breast (= prepectoral edema)
√ sometimes hypovascular tumor surrounded by nontumoral edema

Dx: skin punch biopsy

◊ MRI can help identify a biopsy target to confirm Dx.
Both tissue diagnosis & clinical evidence of inflammatory disease are required for a diagnosis of IBC.

Rx: multimodal: neoadjuvant chemotherapy + surgery (ie, modified radical mastectomy) + radiation therapy ± further adjuvant medical therapy with anti-HER antibody / hormonal therapy

Prognosis: 25–50% 5-year survival; median survival time of 7 months (untreated) + 18 months (after radical mastectomy)

DDx:

1. Mastitis
   √ often arises in subareolar area
   (a) infectious mastitis (test treatment for 2–3 weeks with macrolide antibiotic azithromycin, eg, Zithromax Z-pak®)
   (b) inflammatory mastitis (connective tissue disease, SLE, psoriasis)
   (c) granulomatous mastitis
2. Breast abscess
3. Edema (lymphedema, venous obstruction from cardiac pacemakers / dialysis catheters, vascular stenosis / malformation, nephrogenic systemic fibrosis)
4. Ruptured epidermal inclusion / sebaceous cyst associated with skin trauma / follicular inflammation
5. Iatrogenic (prior radiation Rx)
   • localized scleroderma-type skin reaction (rare) = radiation-induced morphea [*morpheus*, Greek = God of dreams or maker of shapes]
   √ skin thickening + fat necrosis
6. Recurrent breast cancer
7. Noninflammatory locally advanced breast cancer (LABC)

   • onset of symptoms usually longer than 3 months with slow progression

   ◊ 10% risk of distant metastases at time of Dx
   Average age: 66 years
8. Metastasis: melanoma, GI cancer, ovarian cancer, lymphoma / leukemia

Pregnancy-Associated Breast Cancer

= PABC = breast cancer that occurs during pregnancy / within 1 year of delivery
Frequency: 1÷3,000–10,000 pregnancies; 3% of all breast malignancies
Path: high rates of inflammatory tumor; lymph node involvement (in > 50%)
Histo: high-grade tumor (in > 50%); high prevalence of hormone-receptor–negative and HER2/neu–positive tumors ← aggressive biologic growth pattern
• palpable mass, swelling, erythema, diffuse breast enlargement
√ same radiologic features as for non-PABC
Mammo:
√ required to detect malignant microcalcifications, multifocality, multicentricity, bilaterality
Sensitivity: lower in pregnant / lactating patients ← increased glandular density

Recommendation: Try to avoid mammography during 1st trimester – evaluate breast disease with US instead!

Risk to fetus: malformations may occur with exposure to > 0.05 Gy of radiation

Dose: standard 2-view mammography of each breast performed with abdominal shielding subjects fetus to only 0.004 Gy of radiation

◊ Abdominal shielding can be performed during pregnancy with minimal / NO risk to fetus!

MR: MRI should be avoided during pregnancy!

Breast biopsy: cytologic diagnosis of breast lesions during pregnancy and lactation should be avoided – use core biopsy instead!

Prognosis: tendency for larger more advanced neoplasms at diagnosis → poorer outcome ← delayed diagnosis + aggressive growth pattern; recurrence common within 2–3 years

BREAST CYST

Frequency: most common single cause of breast lumps between 35 and 55 years of age

Age: any; most common in later reproductive years + around menopause

Histo: cyst wall lined by single layer of

(a) flattened epithelial cells
- cyst fluid with Na+/ K+ ratio ≥ 3

(b) epithelial cells with apocrine metaplasia → secretory function
- cyst fluid with Na+/K+ ratio < 3

Cause: fluid cannot be absorbed ← obstruction of extralobular terminal duct by fibrosis / intraductal epithelial proliferation

- size changes over time

◊ A simple cyst in a male is suspicious because benign cystic disease typically does not occur in men!

Simple Breast Cyst

√ well-defined flattened oval / round (if under pressure) mammographic mass + surrounding halo (DDx: well-defined solid mass)

√ solitary / multiple

√ needle aspiration of fluid (proof) + postaspiration mammogram as new baseline

US (98–100% accuracy):

◊ Correlate with palpation / mammogram as to size, shape, location, surrounding tissue density!

√ spherical / ovoid lesion with anechoic center

√ well-circumscribed thin echogenic capsule

√ posterior acoustic enhancement (may be difficult to demonstrate in small / deeply situated cysts)

√ thin edge shadows

√ occasionally multilocular ± thin septations / cluster of cysts

MR:

› T1WI:

√ well-circumscribed hypointense lesion without discernible cyst wall; well seen within adipose parenchyma; poorly seen in normal parenchyma

› enhanced T1WI:

√ no change in SI; improved demarcation ← enhancement of surrounding parenchyma

› T2WI:

√ well-circumscribed hyperintense lesion with homogeneous internal texture (detectable at a diameter of ~ 2 mm)

Pneumocystogram (for symptomatic cysts)

√ air remains mammographically detectable for up to 3 weeks

√ therapeutic effect of air insufflation (equal to 60–70% of aspirated fluid volume): no cyst recurrence in 85–94% (40–45% cyst recurrence without air insufflation)

Complex / Complicated Breast Cyst

= any cyst that does not meet criteria of simple cyst

Cause: fibrocystic changes (vast majority), infection, malignancy (extremely rare)

◊ 0.3% of all breast cancers are intracystic

◊ A complex cystic mass in a male should prompt Bx!

◊ Patients with apocrine cysts are at greater risk to develop breast cancer!

√ uniformly thick wall + tenderness = inflammation / infection

√ diffuse low-level internal echoes (= "foam" cyst):

(a) with mobility upon increase in power output

= subcellular material like protein globs, floating cholesterol crystals, cellular debris

(b) without mobility upon increase in power output

= cells like foamy macrophages, apocrine metaplasia, epithelial cells, pus, blood

√ fluid-debris level

Rx: aspiration to rule out blood / pus

√ thick septation / eccentric wall thickening further characterized by:

› protruding ill-defined outer margin

› convex microlobulated inner margin ("mural nodule")

› nonmobile mass with coarse heterogeneous echotexture

› color Doppler flow within thickening

Rx: treated like solid nodule

√ spongelike cluster of microcysts

Rx: treated like solid nodule

MR:

› T1WI:

√ hyper- / isointense cyst content (hemorrhage) ± sign of sedimentation

› enhanced T1WI:

√ thick ring-enhancing cyst wall (inflammation)

√ slight contrast uptake in surrounding tissue (= reactive hyperemia)

Rx: complete aspiration (assures benign cause), core needle biopsy (if partially / nonaspiratable)

DDx: artifactual scatter in superficial / deep small cysts, fibroadenoma, papilloma, carcinoma

Cyst Aspiration

- inspection of cyst fluid:
  (a) normal: turbid greenish / grayish / black fluid
  (b) abnormal: straw-colored clear fluid / dark blood

√ needle moves within nonaspiratable complex cyst

Processing of fluid:

(1) Fluid without blood should be discarded
(2) Bloody fluid should be examined cytologically

CARCINOMA OF MALE BREAST

Incidence: 1.3÷100,000 per year (in 2000); 2,600 new cases / year with 440 deaths (in 2016); 1% of all breast cancers; 0.17% of all male cancers

◊ 3.7% of male breast carcinomas occur in men with Klinefelter syndrome!

Peak age: 60–69 (mean, 59) years

At risk: males with chronically increased estrogen levels

1. Advanced age
2. Klinefelter syndrome (20- to 50-fold risk over normals): XXY chromosomes
3. Liver dysfunction: cirrhosis, schistosomiasis, malnutrition
4. Genetic predisposition: BRCA2 > BRCA1 mutation, family history in 1st-degree male / female relative (in up to 30%)
5. Testicular atrophy: injury, mumps orchitis, undescended testes
6. Radiation therapy to chest (latent period of 12–35 years)
7. Occupational heat exposure (diminished testicular function)
8. Jewish background

◊ Gynecomastia is NOT a risk factor!

Histo: same as in females; invasive ductal carcinoma NOS (80–85%), associated DCIS (35–50%), infiltrating mammary carcinoma with mixed features, invasive papillary carcinoma (2 x more than in women); invasive lobular carcinoma distinctly uncommon (tubular structures usually not found in male breast)

- breast swelling, bloody nipple discharge (25%)
- firm painless irregular mass ± associated gynecomastia
- nipple retraction, skin ulceration / thickening

Location: L > R breast; bilateral in < 1%

Site: retroareolar / upper-outer-quadrant

Mammo (screening not feasible ← low incidence):

√ high-density irregular mass:
  √ spiculated / lobulated / microlobulated margin resembling scirrhous carcinoma of female breast
  √ usually located eccentrically

√ microcalcifications (in only 13–30%): fewer + less linear (= more scattered) + more round + coarser than in female

√ solid nodules / papillary projections arising along a cyst wall (= papillary carcinoma)

√ enlarged axillary nodes (in 50% at time of presentation)

US:

√ invasive ductal carcinoma appears as a solid hypoechoic subareolar mass of irregular shape with spiculated / microlobulated margins, eccentric to the nipple!

√ metastases to pleura, lung, bone, liver

Delay in diagnosis from onset of symptoms: 6–18 months

Rx: simple / modified radical mastectomy + sentinel node biopsy, hormonal manipulation (85% estrogen receptor and 75% progesterone receptor positive)

Prognosis: 5-year survival rate for stage 1 = 82–100%, for stage 2 = 44–77%, for stage 3 = 16–45%, for stage 4 = 4–8% (same as for women!)

DDx: breast abscess, gynecomastia, epidermal inclusion cyst

DERMATOPATHIC LYMPHADENOPATHY

= benign reactive lymphadenopathy within breast associated with cutaneous rashes

Cause: exfoliative dermatitis, erythroderma, psoriasis, atopic dermatitis, skin infection)

Histo: follicular pattern retained, germinal centers enlarged, enlarged paracortical area with pale-staining cells (lymphocytes, Langerhans cells, interdigitating reticulum cells)

• mobile nontender firm subcutaneous nodules

Location: often bilateral

Site: predominantly upper outer quadrant

√ regional subcentimeter masses with central / peripheral radiolucent notches

DESMOID TUMOR (MAMMARY FIBROMATOSIS)

= LOW-GRADE FIBROSARCOMA = AGGRESSIVE FIBROMATOSIS

= rare tumor without metastatic potential

Incidence: over 100 isolated cases reported

Histo: spindled fibroblasts + myofibroblasts forming interlacing fascicles entrapping ducts + lobules; actin positive, variably positive for desmin + S-100; nuclear expression of β-catenin

May be associated with: trauma, surgery, Gardner syndrome, familial adenomatous polyposis, familial multicentric fibromatosis

M÷F = 3÷1

• painless firm mobile mass

• ± skin retraction, dimpling, nipple retraction

Size: 0.5–10 cm

√ spiculated mass without calcifications

√ hypoechoic mass with spiculated / irregular / microlobulated margins

√ low to intermediate SI on T1WI + variable SI on T2WI

√ benign progressive kinetic enhancement pattern (common)

MRI is the optimal modality for assessment of chest wall involvement, given its superior soft-tissue resolution and the locally aggressive nature of fibromatosis!

Prognosis: 27–29% recurrence rate

DIABETIC (FIBROUS) MASTOPATHY

= rare fibroinflammatory breast disease
Cause: long-standing type 1 diabetes → increased resistance of collagen to normal degradation
Histo: stromal sclerosis with an increased number of spindle cells, scattered epithelial cells and perivascular dense lymphocytic infiltrate
Age: young woman, 20 years after onset of diabetes
• firm to hard nontender breast mass
√ nonspecific discrete mass / regional asymmetry of dense tissue
US:
√ single / multiple bilateral masses hypoechoic to SQ fat
√ hypovascular / avascular on color flow imaging
√ posterior acoustic shadowing
Dx: (frequently required) core biopsy
DDx: breast cancer

DUCT ECTASIA

= nonspecific dilatation of one / more ducts > 2 mm / of ampullary duct segment > 3 mm
Cause: ?; periductal inflammation; malignancy
• occasionally nipple discharge / retraction
• palpable mass, pain / tenderness
(a) benign
Location: central
√ retroareolar serpentine radiodense structures converging on the nipple-areolar complex
√ anechoic smooth-walled branching structures tapering toward the periphery
√ filled with fluid / thick inspissated secretions or cellular debris ± movement of particulate matter
√ ± coarse smooth-bordered rod-/ cigar-shaped calcifications pointing toward the nipple
(b) malignant features
Location: peripheral
√ irregularity of duct margin
√ focal thickening of duct wall
√ adjacent hypoechoic tissue

An echogenic intraductal mass within an ectatic duct warrants biopsy to exclude malignancy!

DDx: blocked duct (during lactation); inflammatory infiltrate (masslike intraductal lesions); periductal mastitis (premenopausal, periductal enhancement)

EPIDERMAL INCLUSION CYST

= most common benign cutaneous / subcutaneous lesion

Origin: infundibulum (uppermost portion) of hair follicle

Cause: ?

(a) spontaneous: congenital, ? squamous metaplasia of ductal epithelium

(b) trauma (breast core biopsy, reduction mammoplasty → displacement of epidermis during surgery

Path: cyst filled with keratin

Histo: wall lined by stratified squamous epithelium

- palpable skin cyst with tiny visible skin opening:
  - smooth round nodule attached to skin with "blackhead" (= blackened pore = clogged hair follicle), movable against underlying tissue
- occasional whitish discharge from opening + subsequent decompression of palpable mass

√ circumscribed isodense or high-density mass

√ contiguous with dermis (tangential view)

√ ± calcifications

US:

√ hypoechoic well-circumscribed solid / cystic lesion

√ heterogeneous content ← variable amounts of internal keratinous debris and granulation tissue:

√ ± internal whorled / onion-ring appearance (= lamellated keratinous material)

√ ill-defined margins + peripheral vascularity if inflamed

Dx: CHARACTERISTIC imaging findings

◊ NO biopsy ← increased risk of inflammatory response

DDx: sebaceous cyst (indistinguishable)

FAT NECROSIS OF BREAST

= TRAUMATIC LIPID CYST = OIL CYST

= nonsuppurative saponification of fat by tissue lipase ← local destruction of fat cells with release of lipids + hemorrhage + fibrotic proliferation

Etiology: direct external trauma (seat belt injury), lumpectomy, reduction mammoplasty, implant removal, breast reconstruction, irradiation, nodular panniculitis (Weber-Christian disease), ductal ectasia of chronic mastitis, foreign body reaction (to silicone / paraffin injection)

Prevalence: 0.5% of breast biopsies

At risk: middle-aged obese women with fatty pendulous breasts

Histo: cavity with oily material surrounded by "foam cells" (= lipid-laden macrophages)

- history of trauma in 40% (eg, prior surgery, radiation > 6 months ago, reduction mammoplasty, lumpectomy)
- usually clinically occult
- firm, slightly fixed tender / painless mass
- skin retraction (50%); yellowish fatty fluid on aspiration

Location: anywhere; more common in superficial periareolar region; near biopsy site / surgical

scar
√ early: ill-defined irregular spiculated dense mass
√ later: well-circumscribed mass with translucent areas at center (= homogeneous fat density of oil cyst) surrounded by thin pseudocapsule (in old lesion)
√ calcifies in 4–7% (= liponecrosis macrocystica calcificans):
√ occasionally curvilinear / eggshell calcification in wall
√ fine spicules of low density vary with projection
√ localized skin thickening / retraction possible
US:
√ hypo- / anechoic mass with ill- / well-defined margins ± acoustic shadowing
√ occasionally echogenic ± acoustic shadowing
√ complex cyst with mural nodules / echogenic bands
MR:
› T1WI:
√ signal intensity nearly isointense to fat
√ round lesion with hyperintense fat signal (oil cyst)
√ signal loss with macrocalcifications
› enhanced T1WI:
√ localized ill-defined area of moderate enhancement + continuous postinitial increase (= granulation tissue) within 6 months after trauma
√ rim-enhancement / no enhancement in late lesion / oil cyst
› T2WI:
√ ill-defined hyperintense area (= reactive edema of fresh lesion)
√ round lesion with central SI of fat (in oil cyst)
DDx: breast cancer (indistinguishable from carcinoma if associated with distortion, skin thickening, retraction), breast abscess

Weber-Christian Disease

= nonsuppurative panniculitis with recurrent bouts of inflammation = areas of fat necrosis, involving subcutaneous fat + fat within internal organs
• accompanied by fever + nodules over trunk and limbs

FIBROADENOMA

= ADULT-TYPE FIBROADENOMA
= estrogen-induced benign fibroepithelial tumor originating from TDLU; forms during adolescence; pregnancy and lactation are growth stimulants; regression after menopause (mucoid degeneration, hyalinization, involution of epithelial components, calcification)
Frequency: 3rd most common type of breast lesion after fibrocystic disease + carcinoma; most common benign solid tumor in women of childbearing age (~ 10%)
Mean age: 30 (range, 13–80) years; most common breast tumor under age 25 years
Hormonal influence:
slight enlargement at end of menstrual cycle + during pregnancy; regresses after menopause; may occur in postmenopausal women receiving estrogen replacement therapy
Path: well-circumscribed smooth / mildly lobulated mass with well-demarcated interface

between stroma + uninvolved parenchyma (NO capsule)

Histo: concurrent proliferation of fibrous stroma + glandular epithelium

(a) intracanalicular fibroadenoma: dense stroma compressing ducts into slitlike space

(b) pericanalicular fibroadenoma: NO duct compression

(c) combination

◊ Cellular FA = highly cellular predominantly epithelial elements in younger woman

◊ Fibrous FA = acellular predominantly fibrotic elements in older postmenopausal woman

- slowly enlarging firm rubbery, smooth, sometimes lobulated, freely movable mass
- in 35% not palpable; NO skin fixation
- rarely tender / painful; clinical size = radiographic size

Size: 1–5 cm (in 60%)

Location: multifocal in 15–25%; bilateral in 4%; often located in upper outer quadrant

√ circular / oval-shaped lesion of low density

√ nodular / lobulated contour when larger (= areas with different growth rates)

√ well-defined smooth discrete margins (indistinguishable from cysts when small)

√ often with "halo" sign

√ smoothly contoured calcifications of high + fairly equal density in 3% ← necrosis from regressive changes in older women:

(a) peripheral subcapsular myxoid degeneration

√ peripheral marginal ring- / dotlike calcifications that coalesce over time

(b) central myxoid degeneration

√ "popcorn" type of calcification (PATHOGNOMONIC)

(c) small calcifications within ductal elements

√ pleomorphic / dystrophic linear ± branching pattern

Dx: biopsy may be necessary

◊ Calcifications enlarge as soft-tissue component regresses!

US:

√ round (3%) / oval (96%) mass with long axis parallel to chest wall with length-to-depth ratio of > 1.4 (in carcinomas usually < 1.4)

√ hypoechoic similar to fat lobules (80–96%) / hyperechoic / mixed pattern / anechoic / isoechoic compared with adjacent fibroglandular tissue

√ homogeneous (48–89%) / inhomogeneous (12–52%) texture

√ regular (57%) / lobulated (15–31%) / irregular (6–58%) contour

√ "hump and dip" sign = small focal contour bulge immediately contiguous with a small sulcus (57%)

√ intratumoral bright echoes (10%) = macrocalcifications

√ posterior acoustic enhancement (17–25%) / acoustic shadow without calcifications (9–11%)

√ echogenic halo (capsule) with lateral shadowing

√ slight compressibility of tumor

√ avascular / some central vascularity on color flow imaging

MR:

› T1WI:

√ iso- / mildly hypointense compared to parenchyma
√ more obvious in fatty tissue
√ endotumoral signal loss ← macrocalcifications
› enhanced T1WI:
√ very strong enhancement (with proportionately larger epithelial component)
√ postinitial continuous increase / plateau
√ endotumoral septa with mild contrast uptake
› T2WI:
√ high SI (for tumor with proportionately larger epithelial component) in 50%
√ occasionally endotumoral septations ← fibrotic component
√ iso- / slightly hypointense compared to breast parenchyma (for predominantly fibrotic tumor) in 50%

Management: follow-up in 6 month to assess interval growth
Cx: spontaneous infarction (esp. during 3rd trimester of pregnancy / after delivery) ← intravascular thrombosis
DDx: phyllodes tumor (rapid growth, recurrence of fibroadenoma, cellular fibroadenoma in postmenopausal patient); adenosis tumor / florid adenosis

Juvenile / Giant / Cellular Fibroadenoma

= fibroadenoma > 5 cm in diameter / weighing > 500 g
Frequency: 7–8% of all fibroadenomas; multiple / bilateral in 10–25%
Cause: hyperplasia + distortion of normal breast lobules ← hormonal imbalances between estradiol + progesterone levels
Age: any (mostly in adolescent girls); most often in African-American girls
Histo: more glandular + more stromal cellularity than adult type of fibroadenoma; ductal epithelial hyperplasia
• rapidly enlarging well-circumscribed nontender mass
• dilated superficial veins, stretched skin ± ulceration
√ discrete mass with rounded borders
√ ± cleftlike depressions and tiny cysts (similar to phyllodes tumor)
MR:
› T1WI:
√ iso- to slightly hypointense round / oval mass difficult to separate from normal breast parenchyma
› enhanced T1WI:
√ strong enhancement with sharp demarcation from surrounding tissue + endotumoral septations
› T2WI:
√ typically hyperintense
Cx: infarction → edema, hemorrhage
DDx: medullary / mucinous / papillary carcinoma / carcinoma within fibroadenoma

Tubular Adenoma

= variant of pericanalicular fibroadenoma with florid epithelium like in adenosis

FIBROCYSTIC CHANGES

= MAZOPLASIA = MASTITIS FIBROSA CYSTICA = CHRONIC CYSTIC MASTITIS = CYSTIC DISEASE = GENERALIZED BREAST HYPERPLASIA = DESQUAMATED EPITHELIAL HYPERPLASIA = FIBROADENOMATOSIS = MAMMARY DYSPLASIA = SCHIMMELBUSCH DISEASE = FIBROUS MASTITIS = MAMMARY PROLIFERATIVE DISEASE

◊ Not a disease since it is found in 72% of screening population > 55 years of age

◊ The College of American Pathologists suggests use of the term "fibrocystic changes / condition" in mammography reports!

Prevalence: most common diffuse breast disorder; in 51% of 3,000 autopsies

Age: 35–55 years

Etiology: exaggeration of normal cyclical proliferation + involution of the breast with production + incomplete absorption of fluid by apocrine cells ← hormonal imbalance

Histo:

(1) overgrowth of fibrous connective tissue = stromal fibrosis, fibroadenoma
(2) cystic dilatation of ducts + cyst formation (in 100% microscopic, in 20% macroscopic)
(3) hyperplasia of ducts + lobules + acini = adenosis; ductal papillomatosis

• asymptomatic with macrocystic disease
• fullness, tenderness, pain in microcystic disease
• palpable nodules + thickening
• symptoms occur with ovulation
• regression with pregnancy + menopause

√ individual round / ovoid cysts with discrete smooth margins
√ lobulated multilocular cyst
√ enlarged nodular pattern (= fluid-distended lobules + extensive extralobular fibrous connective tissue overgrowth)
√ "teacup-like" curvilinear thin calcifications with horizontal beam + low-density round calcifications in craniocaudal projection = milk of calcium (4%)
√ "oyster pearl–like" / psammoma-like calcifications
√ "involutional type" calcifications = very fine punctate calcifications evenly distributed within one / more lobes against a fatty background ← mild degree of hyperplasia in subsequently atrophied glandular tissue

US:

√ ductal pattern, ductectasia, multiple cysts of varying size, ill-defined focal echogenic lesions with / without posterior sound attenuation

MR:

› T1WI:
√ hypointense compared to intramammary adipose tissue
√ interspersed hypointense cysts of varying sizes

› enhanced T1WI:
√ patchy to diffuse increased enhancement (correlating with degree of adenosis)
◊ Avoid scheduling patient during 1st and 4th week of menstrual cycle / under HRT
√ continuous rise after postinitial phase

› T2WI:
√ occasionally diffusely increased SI (in 2nd half of menstrual cycle / under HRT)

√ interspersed hyperintense cysts of varying sizes

Risk for invasive breast carcinoma:

A. NO INCREASED RISK (70%)
   1. Nonproliferative lesions: adenosis, florid adenosis, apocrine metaplasia without atypia, macro- / microcysts, duct ectasia, fibrosis, mild hyperplasia (more than 2 but not more than 4 epithelial cells deep), mastitis, periductal mastitis, squamous metaplasia
   2. Fibroadenoma

B. SLIGHTLY INCREASED RISK (1.5–2 times):
   1. Moderate + florid solid / papillary hyperplasia
   2. Papilloma with fibrovascular core
   3. Sclerosing adenosis

C. MODERATELY INCREASED RISK (5 times):
   Ductal / lobular atypical hyperplasia (= borderline lesion with some features of carcinoma in situ)

D. HIGH RISK (8–11 times):
   1. Atypical hyperplasia + family history of breast cancer
   2. Ductal / lobular carcinoma in situ

Classification of Fibrocystic Changes

Grade	*Frequency*	*Histological Category*	*Breast Cancer Risk*
I	70%	Nonproliferative lesion	0
II	25%	Proliferative lesion without atypia	2x
III	5%	Proliferative lesion with atypia	4–5x

Adenosis

Age: all

Path: lobulocentric lesion derived from TDLU with distortion and effacement of underlying lobules

Histo: epithelial and myoepithelial proliferation of ductules + lobules with nuclear pleomorphism + increase in cell size

√ increase in size of TDLUs to 3–7 mm

√ "snowflake pattern" of widespread ill-defined nodular densities

√ often round intralobular microcalcifications / milk of calcium (less common + less extensive than in sclerosing adenosis)

US:

√ adenosis lobules are sonographically iso- to mildly hypoechoic compared with fat

MR:

√ no abnormalities on T1WI / T2WI

√ usually strong, occasionally branching contrast uptake in focal areas of adenosis

DDx: malignancy

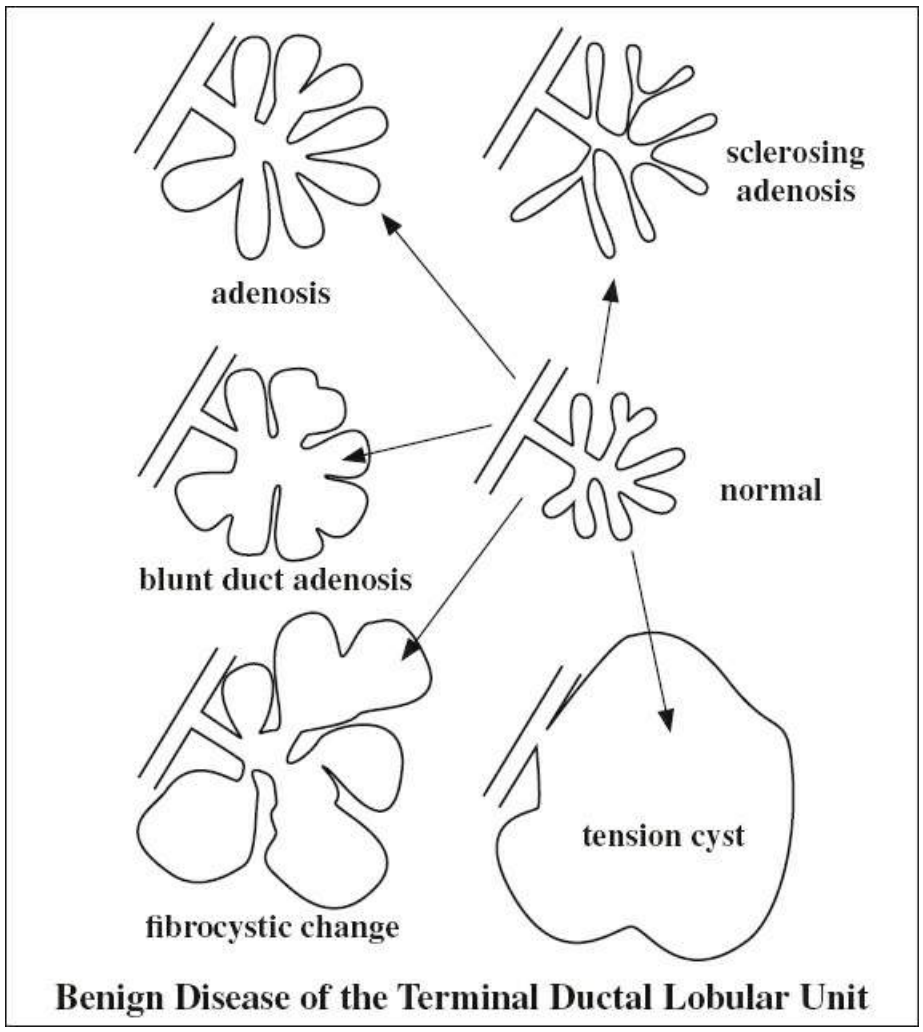
Sclerosing Adenosis

Path: myoepithelial proliferation + reactive stromal fibrosis
Histo: stromal sclerosis involving > 50% of all TDLUs, which become elongated + distorted + compressed by sclerosis
DDx: tubular carcinoma (absence of basement membrane + myoepithelial cells); radial scar (more extensive fibrosis + central fibrocollagenous scar)

- palpable mass (rare) = "adenosis tumor"

Rarely associated with: lobular carcinoma in situ > ductal carcinoma in situ

◊ Sclerosing adenosis is not a risk factor / precursor of breast cancer!



Benign Disease of the Terminal Ductal Lobular Unit

√ punctate calcifications of calcium oxalate casts forming in obstructed acini in 50%

(a) focal form
- √ "rosettes" = focal cluster of microcalcifications occupying all acini of one / several TDLUs
- √ architectural distortion
- √ focally dense breast → as a nodule / spiculated lesion

(b) diffuse form
- √ adenosis + diffusely scattered "starry night" calcifications

√ diffusely dense breast

DDx: other spiculated lesions

Adenosis Tumor = Florid Adenosis

Average age: 30 years

Histo: focal proliferation of ductules and lobular glands with hyperplasia of epithelial + myoepithelial cells

• firm clinically discrete / ill-defined mass

√ nodular mass usually < 2 cm in diameter

√ ± microcalcifications

DDx: fibroadenoma

Gestational & Secretory Hyperplasia

(a) gestational (= related to pregnancy):

Histo: calcifications in lobular acini

√ round microcalcifications in a diffuse / focal distribution (most commonly)

(b) secretory (= related to lactation)

Histo: ductal hyperplasia

√ irregular microcalcifications in a linear distribution + branching pattern closely resembling malignancy (less commonly)

(c) coexistence of both types of microcalcifications

DDx: pseudolactational hyperplasia (same radiologic-pathologic findings in nonpregnant nonlactating women)

Fibrosis

√ round / oval clustered microcalcifications with smooth contours + associated fine granular calcifications filling lobules

Atypical Lobular Hyperplasia

= proliferation of round cells of LCIS type growing along terminal ducts in permeative fashion (pagetoid growth) between benign epithelium + basal myoepithelium BUT NOT completely obliterating terminal ductal lumina / distending lobules (as in lobular carcinoma in situ)

√ no mammographic correlate

Atypical Ductal Hyperplasia

= low-grade intraductal proliferation with partial / incompletely developed features of noncomedo DCIS

√ frequent calcifications

Sclerosing Lobular Hyperplasia

= FIBROADENOMATOID MASTOPATHY

= benign proliferative lesion

Path: enlarged lobules, increased number of intralobular ductules, sclerosis of intralobular septa

Mean age: 32 years; black woman
• palpable circumscribed mass
√ resembles noncalcified fibroadenoma

FIBROUS NODULE OF BREAST

= FIBROUS DISEASE OF THE BREAST = FIBROUS DISEASE = FOCAL FIBROSIS OF THE BREAST = FIBROUS MASTOPATHY = FIBROUS TUMOR OF THE BREAST
Frequency: 3–4% of benign masses; 8% of surgical breast specimens
Histo: focally dense collagenous stroma surrounding atrophic epithelium; NONSPECIFIC
Age: 20–50 years; only 8% postmenopausal
• palpable / nonpalpable mass: edge merges into surrounding dense tissue
Location: unilateral (80–85%) / bilateral (15–20%)
√ circumscribed (55%) / indistinct (32%) margin
√ suggestive of malignancy (11%): irregular shape, spiculated margin, posterior acoustic shadowing
DDx: fibroadenoma, malignancy

GALACTOCELE

= retention cyst of fatty material in areas of cystic duct dilatation appearing during / (more commonly) shortly after lactation
◊ Most common benign breast lesion in lactating women!
Cause: ? abrupt suppression of lactation / obstructed milk duct
Path: smooth-walled cyst lined by simple cuboidal to columnar apocrine-type epithelium filled with milky fluid; often accompanied by inflammatory / necrotic debris ← leakage of cyst fluid
Age: occurs during / shortly after lactation; may occur in children of either gender
• enlarging painless mass; thick inspissated milky fluid (colostrum)
Location: retroareolar area; uni- / bilateral
√ large radiopaque lesion of water density (1st phase)
√ smaller lesion of mixed density + SPECIFIC fat-water level with horizontal beam (2nd phase)
√ pseudohamartoma = NO physical separation of fat + water ← high viscosity of milk
√ pseudolipoma = small radiolucent lesion resembling lipoma
√ ± fluid-calcium level
US:
√ heterogeneous complex mass / cyst with a mixture of low + high internal echogenicity ← hypoechoic water component + hyperechoic fat component
√ hyperechoic-hypoechoic fat-fluid level ← fresh milk
√ well-defined solid-appearing mass with posterior acoustic enhancement + highly echogenic material
MR:
√ enhancement of wall + septations
Cx: infection (relatively common)
Dx: diagnostic + therapeutic aspiration of milky fluid

GIGANTOMASTIA

= very rare condition characterized by massive enlargement of both breasts

Incidence: 1÷100,000 pregnancies

Etiology: ? abnormal response to hormonal stimulation during pregnancy

• dramatic growth of breasts up to 4–6 kg per breast → dyspnea

√ radiologic studies NOT required

Cx: tissue necrosis, ulceration, infection, hemorrhage

Rx: bromocriptine administration; surgical intervention (reduction mammoplasty / simple mastectomy with posterior reconstruction) if disorder progresses

GYNECOMASTIA

= benign usually reversible excessive development of male breast

◊ NOT a risk factor for development of breast cancer!

◊ Most common disease in males

Cause:

(1) Hormonal stimulation by excess estrogens or decreased androgens
   (a) neonate: influence from maternal estrogens crossing placenta
   (b) puberty: high estradiol levels
      Prevalence: in up to 60–75% of healthy adolescents
      Age: 1 year after onset of puberty (13–14 years)
      Prognosis: subsides within 1–2 years
   (c) senescence: decline in serum testosterone levels of elderly
   (d) hypogonadism (Klinefelter syndrome, anorchism, acquired testicular failure (eg, testicular neoplasm), pituitary hormone deficiency

(2) Other hormonal disorders obesity (increased conversion of testosterone to estrogen), hyperthyroidism

(3) Neoplasm: hepatoma (with estrogen production), feminizing adrenocortical tumor, gonadotropin-secreting tumor (hepatoblastoma, fibrolamellar carcinoma, choriocarcinoma), pituitary tumor (prolactinoma), estrogen-producing testicular tumor (Sertoli / Leydig cell tumor), hyperthyroidism, testicular feminization syndrome, neurofibromatosis I

(4) Systemic disorders
advanced alcoholic cirrhosis, hemodialysis in chronic renal failure, chronic pulmonary disease (emphysema, TB), malnutrition

Gynecomastia versus Male Breast Cancer		
Feature	*Gynecomastia*	*Breast Cancer*
Age	peripubertal + > 50 years	> 60 years
Clinical	soft tender; mobile mass	soft / firm nontender / nonmobile mass
Site	central	eccentric
Location	(commonly) bilateral	(usually) unilateral
Mammo	fan- / flame-shaped density	discrete mass, calcifications, skin thickening, nipple retraction, axillary adenopathy

(5) Drug-induced
marijuana, anabolic steroids, corticosteroids, leuprolide acetate (Lupron Depot®), estrogen treatment for prostate cancer, thiazide diuretics, cimetidine, omeprazole, digitalis, spironolactone, reserpine, isoniazid, ergotamine, diazepam, tricyclic antidepressants

(6) Idiopathic

mnemonic: CODES
Cirrhosis
Obesity
Digitalis
Estrogen
Spironolactone

Frequency: 85% of all male breast masses
Age: neonatal period; adolescent boys (40%); men > 50 years (32%)
Histo: hyperplasia (= increased number) of ducts, proliferation of duct epithelium, periductal edema, fibroplastic stroma, adipose tissue

- breast enlargement
- (usually) uni- (less common) bilateral breast tenderness, subjective burning sensation
- palpable firm nodules > 2 cm in subareolar region

Location: bilateral (63%), left-sided (27%), right-sided (10%)
Site: concentric to the nipple-areola complex
Pattern:

Gynecomastia has 3 radiographic patterns: nodular, dendritic, diffuse, which reflect the underlying pathologic changes.

(a) nodular gynecomastia: in early florid phase
- symptoms for less than 1 year

Histo: hyperplasia of intraductal epithelium + periductal inflammation + stromal edema
√ hypoechoic subareolar nodule of disk / fan shape ± hypervascularity
√ indistinct borders
Prognosis: reversible if stimulus eliminated

(b) dendritic gynecomastia: during quiescent fibrotic phase
- symptoms for more than 1 year

Histo: fibrous gynecomastia with more hyalinized fibrous stroma + dilated ducts

√ flame-shaped subareolar density with linear projections interdigitating into deeper adipose tissue
√ fingerlike projections extending into retroareolar breast
Prognosis: irreversible ← fibrosis

(c) diffuse glandular gynecomastia
• often 2° to exposure to high-dose exogenous estrogen
√ heterogeneously dense breasts
√ combination of nodular + dendritic gynecomastia

US:
√ hypoechoic echotexture
√ absence of posterior acoustic enhancement
√ mild prominence of subareolar ducts in nodular / poorly defined / flame-shaped distribution (focal type)
√ homogeneously dense breast (diffuse type)

MR:
√ hypointense retromamillary area
√ no / slight contrast enhancement

Rx: surgical removal; discontinuation of offending drug

DDx: **pseudogynecomastia** (= fatty proliferation without glandular elements in obese males); breast cancer (hard / firm to palpation, usually unilateral, frequently not central to nipple-areola complex)

HAMARTOMA OF BREAST

= FIBROADENOLIPOMA = LIPOFIBROADENOMA = ADENOLIPOMA

Prevalence: 2 –16 ÷ 10,000 mammograms

Mean age: 45 (range, 27–88) years

Histo: normal / dysplastic mammary tissue composed of dense fibrous tissue + variable amount of fat, delineated from surrounding tissue without a true capsule

• soft, often nonpalpable (60%)

Location: retroareolar (30%), upper outer quadrant (35%)

√ round / ovoid well-circumscribed mass usually > 3 cm
√ mixed density with mottled center (2° to fat) = "slice of sausage" pattern
√ thin smooth pseudocapsule (= thin layer of surrounding fibrous tissue)
√ "halo" sign = peripheral radiolucent zone ← compression of surrounding tissue
√ may contain calcifications

MR:
› T1WI:
√ well-circumscribed round / oval / lobulated lesion with pseudocapsular demarcation:
√ intermediate intensity for parenchymal component
√ high intensity for lipomatous component
√ low intensity for cystic component
› enhanced T1WI:
√ no / strong enhancement in parenchymal component with continuous postinitial increase (dependent on vascularization)

› T2WI:
√ intermediate intensity for parenchymal + lipomatous components
√ high intensity for cystic component

DDx: liposarcoma, Cowden disease

HEMANGIOMA OF BREAST

= rare tumor in breast

Incidence: up to 11% at autopsies

Histo: dilated endothelium-lined vascular channels filled with erythrocytes; negative for S-phase kinase-associated protein 2; low value for Ki-67

Classification: capillary / cavernous

• may be palpable

Location: within superficial tissue; parallel to chest wall

√ circumscribed oval / macrolobulated mass ± calcifications

US:

√ well-defined hypoechoic / ill-defined hyperechoic mass (DDx: fibroadenoma; complex cyst)

MR:

√ ovoid mass with intermediate SI on T1WI (similar to fibroglandular tissue) ± peripheral areas of ↑ signal ← fat
√ hyperintense on T2WI ← cavernous / cystic spaces with slow-flowing blood
√ low–signal-intensity foci ← calcification / flow void / fibrosis / thrombosis
√ early diffuse enhancement (DDx: angiosarcoma)
√ delayed central fill-in enhancement

Clue: excessive bleeding during core biopsy

DDx: low-grade angiosarcoma (skin discoloration, large palpable lesion, positive for S-phase kinase-associated protein 2, value for Ki-67 > 175 on pathology)

HEMATOMA OF BREAST

= area of localized hemorrhage

Cause: (1) Surgery / biopsy (most common)
(2) Blunt trauma
(3) Coagulopathy: leukemia, thrombocytopenia
(4) Anticoagulant therapy

√ well-defined ovoid mass (= hemorrhagic cyst)
√ ill-defined mass with diffuse increased density ← edema + hemorrhage)
√ adjacent skin thickening / prominence of reticular structures
√ regression within several weeks leaving
(a) no trace
(b) architectural distortion
(c) incomplete resolution
√ calcifications (occasionally)

US:

√ complex hypoechoic mass with internal echoes dependent on age of hematoma:

√ hyperechoic (in acute stage + occasionally before resolution)
√ hypoechoic to anechoic (= hematoma progression)

MR:

› T1WI:
√ homogeneous high signal ± sedimentation (fresh)
√ low SI + peripheral ring of high signal (deoxyhemoglobin of subacute hematoma)

› enhanced T1WI:
√ no uptake within hematoma
√ moderate diffuse reactive enhancement surrounding hematoma + continuous postinitial increase

› T2WI:
√ homogeneous low signal intensity (fresh)
√ low SI + peripheral ring of low SI

Dx: resolution on short-term follow-up; biopsy

JUVENILE PAPILLOMATOSIS

= distinctive rare benign clinical-pathologic entity that characteristically involves young patients

Frequency: low but increasing

Path: 1–8 cm tumor composed of many aggregated cysts of < 2 cm with interspersed dense stroma ("swiss cheese disease"); calcifications common

Histo: multiple macrocysts lined by flat duct epithelium / epithelium with apocrine metaplasia, sclerosing adenosis, ductectasia; marked papillary hyperplasia of duct epithelium with often extreme atypia

Mean age: 23 (range, 12–48) years

• localized palpable firm tumor; no nipple discharge
• family history of breast cancer in 28–58% (affected first-degree relative in 8%; in one / more relatives in 28–53%)

√ usually negative mammogram / asymmetric density
√ ± microcalcifications
√ marked enhancement with benign enhancement profile on MR

US:

√ ill-defined hypoechoic masses filled with multiple cysts of variable size clearly demarcated from surrounding normal parenchyma

Prognosis: development of synchronous (4%) / metachronous (5–15%) breast cancer after 8–9 years

Recommendation: follow-up of female relatives ← development of carcinomas in nearly 50%

Dx: may be suspected with core biopsy

Rx: complete surgical excision requiring negative margins

DDx: fibroadenoma

LACTATING ADENOMA

= newly discovered painless benign breast mass during pregnancy / lactation

Etiology: ?

(a) adenomatous / lactational transformation of preexisting fibroadenoma / tubular adenoma / lobular hyperplasia
(b) de novo neoplasm unique to pregnancy

Path: well-circumscribed yellow spherical mass with lobulated surface + rubbery firm texture and without capsule

Histo: pure adenoma composed of secretory lobules lined by granular and foamy to vacuolated cytoplasm separated by scant stromal components of connective tissue

• firm rubbery smooth slightly lobulated freely movable mass
• may enlarge rapidly during first 2 trimesters
• usually painless unless infarction has occurred

Size: typically < 3 cm

Mammo (insensitive ← increased breast density during pregnancy):
√ mass of equal / slightly decreased density = fat content of milk ← lactational hyperplasia
√ punctate calcifications may be present

US:
√ usually benign features:
√ homogeneously hypoechoic / isoechoic mass
√ smooth lobulations + well-defined margins
√ long axis parallel to chest wall
√ posterior acoustic enhancement
√ occasionally malignant features:
√ irregular angulated margins
√ posterior acoustic shadowing
√ fibrous septa may be present
√ ± small central hyperechoic foci (= fat within milk)
√ increased vascularity by Doppler

Dx: biopsy

Cx: infarction → painful breast mass

Prognosis: regression after completion of breast feeding

Rx: excision if without spontaneous resolution / with pain

DDx: fibroadenoma; complex cyst; tubular adenoma (rare, typically in young woman); galactocele (after cessation of breast feeding); phyllodes tumor; lymphoma; breast carcinoma (1÷1,300–1÷6,200 pregnancies)

LIPOMA OF BREAST

= usually solitary unilateral asymptomatic slow-growing lesion
◊ Most common benign tumor of male breast

Prevalence: extremely rare

Histo: encapsulated tumor containing mature fat cells

Mean age: 45 years + post menopause

• clinically often occult; soft, freely movable, well delineated
√ usually > 2 cm
√ radiolucent tumor easily seen in dense breast; almost invisible in fatty breast
√ discrete thin radiopaque line (= capsule), seen in most of its circumference

√ displacement of adjacent breast parenchyma
√ calcification with fat necrosis (extremely rare)
√ may enlarge in response to hormonal stimulation
US:
√ homogeneously hypo-, iso- or mildly hyperechoic lesion
√ posterior acoustic enhancement possible
√ ± encapsulated margin
√ no internal / peripheral vascularity
MR:
› T1WI:
√ well-circumscribed hyperintense lesion
√ ± thin hypointense capsule
√ no contrast enhancement
› T2WI:
√ signal intensity equivalent to subcutaneous fat
DDx: fat lobule surrounded by trabeculae / suspensory ligaments; fat necrosis

Angiolipoma of Breast

= rare fat-containing tumor
Frequency: 5–17% of all benign fatty tumors
Path: mature adipocytes intermixed with vascular proliferation; NO malignant potential
(a) infiltrative type
(b) noninfiltrative type: in breast
Histo: vascular lesion with cellular atypia + mitotic activity; HALLMARK of scattered microthrombi in small blood vessels
Location: back, neck, shoulder, rare in breast
• faint skin discoloration
√ solid circumscribed mass without characteristic imaging finding
√ asymmetry with mixed density (= soft-tissue density interspersed with fat density)
US:
√ iso- to hyperechoic / hypoechoic mass with internal vascularity
Dx: biopsy required to make diagnosis
DDx: lipoma; fibroadenolipoma (hamartoma)

LYMPHOMA OF BREAST

A. PRIMARY LYMPHOMA
= extranodal lymphoma of the breast without prior history of lymphoma / leukemia
Prevalence: 0.12–0.53% of all breast malignancies; 2.2% of all extranodal lymphomas
• asymptomatic
B. SECONDARY LYMPHOMA
◊ One of the most common metastatic lesion in the breast!
• fever, pain
Histo: B-cell NHL (majority), Hodgkin disease, leukemia (CLL), plasmacytoma
Age: 50–60 years; M < F

Location: right-sided predominance; 13% bilateral
√ well / incompletely circumscribed round / oval lobulated mass / masses
√ infiltrative with poorly defined borders
√ NO calcifications / spiculations
√ skin thickening + trabecular edema
√ bilateral axillary adenopathy in 30–50%
US:
√ oval / round homo- / heterogeneously hypoechoic mass(es)
√ sharply defined / poorly defined borders
√ posterior acoustic shadowing / enhancement
Prognosis: 3.4% 5-year disease-free survival for all stages; 50% remission rate with aggressive chemotherapy
Recurrence: mostly in contralateral breast / other distant sites
DDx: circumscribed breast carcinoma, fibroadenoma, phylloides tumor, metastatic disease

Pseudolymphoma
= lymphoreticular lesion as an overwhelming response to trauma

MAMMARY DUCT ECTASIA

= PLASMA CELL MASTITIS = VARICOCELE TUMOR OF BREAST = MASTITIS OBLITERANS = COMEDOMASTITIS = PERIDUCTAL MASTITIS = SECRETORY DISEASE OF BREAST
= rare aseptic inflammation of subareolar area
Pathogenesis (speculative):
(1) Stasis of intraductal secretion → duct dilatation + leakage of inspissated material into parenchyma → aseptic chemical mastitis (periductal mastitis); the extravasated material is rich in fatty acids → nontraumatic fat necrosis
(2) Periductal inflammation → damage to elastic lamina of duct wall → duct dilatation
Histo: ductal ectasia, heavily calcified ductal secretions; infiltration of plasma cells + giant cells + eosinophils
Mean age: 54 years; may develop in young children
• often asymptomatic; bloody nipple discharge in children
• breast pain, nipple retraction, mamillary fistula, subareolar breast mass
Location: subareolar, often bilateral + symmetric; may be unilateral + focal
√ dense triangular mass with apex toward nipple
√ duct dilatation = distended ducts connecting to nipple
√ periphery blending with normal tissue
√ multiple often bilateral dense round / oval a few mm long calcifications with lucent center + polarity (= linear orientation toward subareolar area / nipple)
(a) periductal
√ oval / elongated calcified ring around dilated ducts with very dense periphery (= surrounding deposits of fibrosis + fat necrosis)
(b) intraductal
√ fairly uniform linear, often rod-shaped / sausage-shaped / needle-shaped calcifications of wide caliber, occasionally branching (within ducts / confined to duct walls)

√ nipple retraction / skin thickening may occur
Sequelae: cholesterol granuloma
DDx: breast cancer

MAMMOPLASTY

= COSMETIC BREAST SURGERY

Augmentation Mammoplasty

◊ Most frequently performed plastic surgery in USA
Frequency: 307,180 procedures in 2011 (70% for cosmetic reasons, 30% for reconstruction); 5,083,717 American women have breast implants (estimate for 2010) = 4.9% (census data)
Methods:

1. Injection augmentation (no longer practiced): paraffin, silicone, fat from liposuction
   Cx: tissue necrosis resulting in dense, hard, tender breast masses; lymphadenopathy; infection; granuloma formation (= siliconoma)
2. Implants (prepectoral / subpectoral)
   (a) spongelike masses of Ivalon®, Etheron®, Teflon®
   (b) Silicone elastomer (silastic) smooth / textured shell containing silicone oil / saline: > 100 varieties of dimethylpolysiloxane
   › single lumen of polymerized methyl polysiloxane with smooth / textured outer silicone shell / polyurethane coating
   › double lumen with inner core of silicone + outer chamber of saline
   › "reverse double-lumen" = inner saline-filled lumen surrounded by silicone-filled envelope
   › triple lumen

Silicone breast implants were FDA-approved for primary breast augmentation in 2006.

   (c) expandable implant ± intraluminal valves = saline injection into port with gradual tissue expansion for breast reconstruction
   Location: retroglandular / subpectoral
3. Autogenous tissue transplantation
   (for breast reconstruction) with musculocutaneous flap: transverse rectus abdominis muscle (TRAM), latissimus dorsi, tensor fasciae latae, gluteus maximus

Mammographic technique for implants:

1. Two standard views (CC and MLO views) for most posterior breast tissue
   ◊ 22–83% of fibroglandular breast tissue obscured on standard views by implant depending on size of breast + location of implant + degree of capsular contraction!
   ◊ The false-negative rate of mammography increases from 10–20% to 41% in patients with implants!
2. Two Eklund (= implant displacement) views (CC and 90° LAT views) for compression views of anterior breast tissue = "push-back" view = breast tissue pulled anteriorly in front of implant while implant is pushed posteriorly + superiorly thus excluding most of the implant

Mammographic sensitivity for breast cancer detection: 45% with augmentation versus 67% without

augmentation

MR technique for implants:

Physical principle: resonant frequencies of water, fat (~ 220 Hz lower than water) and silicone (~ 100 Hz lower than fat) differ

Most effective sequence: inversion recovery (IR), which suppresses fat

(a) with additional suppression of water = pure depiction of silicone

(b) with additional suppression of silicone = pure depiction of saline component

Orientation: axial + sagittal (2 angulations mandatory)

Cx of silicone-gel–filled implant:

Screening MRI for asymptomatic implant rupture at 3 years after implantation followed by 2-year intervals!

◊ Increase of complication rate with **augmentation** (desire for a larger breast) > **reconstruction** (after mastectomy) > **revision** (subsequent surgery in 15–25%)

1. **Capsular fibrosis** (100%)
   = normal host response to wall off foreign body
   √ low-intensity implant shell + fibrous capsule cannot be differentiated on MR
   √ physiologic fluid may occupy space between implant shell + fibrous capsule
   √ radial folds (normal) = hypointense lines emanating from the fibrous capsule-shell junction as a wrinkle
   √ gently undulating circumferential contour (normal)
2. **Contracture** (12–20%): more frequent with retroglandular implants → increasing with time
   • distortion of breast contour, hardening of breast
   • tightness, pain
   √ crenulated contour (US helpful)
   √ capsular calcifications at periphery of prosthesis
   √ focal bulge = herniation of a locally weakened fibrous capsule
   √ fibrous capsule delineated by US (unleaked silicone is echolucent)
   √ extensive periprosthetic calcifications

   MR (low specificity):
   √ rounded implants with transverse diameter < 2x the anteroposterior diameter
   √ marked thickening of fibrous capsule
   √ signal-free periprosthetic zone of macrocalcifications
   √ complete absence of radial folds
   √ contrast enhancement ← granulomatous inflammation

   Rx: not health hazard; capsulotomy (release); capsulectomy (removal of scar tissue)
2. **Implant migration**
   Cause: overdistension of implant pocket at surgery
3. **Rupture of prosthesis**
   = hole / tear in implant shell observed at surgery
   Implant failure: 11% after 5 years, 49% after 12 years, 95% after 20 years
   Cause: violation of elastomer shell during surgery (years 1–5); mechanical / fatigue (years 5–10)
   Result: total / partial / no collapse of shell

- change in contour / location of implant
- flattening of implant, breast pain

4. **"Gel bleed" = silicone leaching** (100% = normal condition as all implants bleed)
   = leakage of microscopic quantities of silicone oil through semiporous but intact barrier shell made of silicone elastomer
   √ silicone-equivalent signal within keyhole-shaped terminal bend of radial folds + between capsule and implant shell
   Dx: microscope
5. Infection / hematoma formation
6. Localized pain / paresthesia

N.B.: NO association between silicone breast implants and connective tissue disease / malignancy

Intracapsular Rupture

= broken implant casing, which swims within silicone gel contained by intact fibrous capsule

Frequency: 80–90% of all ruptures

Mammo (11–23% sensitive, 89–98% specific):
√ bulging / peaking of implant contour (DDx: herniation through locally weakened capsule)

US (59–70% sensitive, 57–92% specific, 49% accurate):
√ "stepladder" sign = series of parallel horizontal echogenic straight / curvilinear lines inside implant (= collapsed implant shell floating within silicone gel)
√ heterogeneous aggregates of low- to medium-level echogenicity (65% sensitive, 57% specific)

N.B.: visualization of internal lumen within anechoic space in double-lumen implants can be confused on US with intracapsular rupture

MR (81–94% sensitive, 93–97% specific, 84% accurate):
√ multiple curvilinear low–signal-intensity lines often parallel to fibrous capsule (corresponding to collapsed prosthesis shell inside the silicone-filled fibrous capsule):
  √ "linguine" sign = multiple hypointense wavy lines within implant (= pieces of free-floating collapsed envelope), 100% PPV
  √ in incomplete rupture "inverted teardrop" / "noose" / "keyhole" / "lariat (= lasso)" sign = loop-shaped hypointense structure contiguous with implant envelope (= small focal invagination / fold of shell with silicone on either side)
  [*la reata*, Spanish = lasso]
  DDx: radial fold (extending from periphery perpendicular to surface directed toward center of implant)
√ "water droplet" / "salad-oil" sign = appearance of multiple droplets of fluid of extracapsular origin / saline-containing envelope within lumen of silicone implant (DDx: 1–2 droplets may be normal; after injection of saline / Betadine® / antibiotics / steroids)

Extracapsular Rupture

= extrusion + migration of silicone droplets through tear in both implant shell + fibrous capsule

Frequency: up to 20% of all ruptures

• palpable breast masses

US:

√ "snowstorm" / "echogenic noise" pattern = markedly hyperechoic nodule with well-defined anterior + indistinct echogenic noise posteriorly (= free silicone droplets mixed with breast tissue)

√ highly echogenic area with acoustic shadowing

√ hypoechoic masses almost indistinguishable from cysts + usually surrounded by echogenic noise (= large to medium-sized collections of free silicone) with low-level internal echoes

MR:

√ discrete hypointense foci on fat-suppressed T1WI + hyperintense signal on water-suppressed T2WI in continuity with / separate from implant

√ "linguine" sign = sign of associated intracapsular rupture

Mammography:

√ lobular / spherical dense area of opacities adjacent to / separate from silicone implant

√ rim calcifications

EXTRACAPSULAR SPREAD OF SILICONE

Source: gel bleed, implant rupture (11–23%) more common with thinner shell + older implants

• silicone lymphadenopathy

• paresthesia of arm ← nerve impingement ← fibrosis surrounding silicone migrated to axilla / brachial plexus

• silicone nipple discharge (rare)

• migration to arm (→ constrictive neuropathy of radial nerve), subcutaneous tissue of lower abdominal wall, inguinal canal

√ migration to ipsilateral chest wall + axillary nodes

√ silicone droplets in breast in 11–23% (97% specific, 5% sensitive)

Siliconoma = Silicone Granuloma

= collection of silicone within breast parenchyma surrounded by a foreign-body granulomatous reaction

Histo: granuloma formation + fibrosis

Location: typically at edge of breast implant

√ hyperechoic mass with fine internal echoes

√ "dirty" posterior acoustic shadowing / "snowstorm" pattern of acoustic scattering

Reduction Mammoplasty

= removal of excess fat + glandular tissue + skin

Purpose:

(1) Aesthetics to achieve desired breast size

(2) Relief of back pain
(3) Restore chest symmetry after contralateral lumpectomy
√ swirled architectural distortion (in inferior breast best seen on mediolateral view)
√ postsurgical distortion
√ residual isolated islands of breast tissue
√ fat necrosis
√ dystrophic calcifications
√ asymmetric tissue oriented in nonanatomic distribution

MASTITIS

Acute Mastitis

= infection of the breast with primary ascending canalicular + secondary interstitial spread
Cause: mammary duct obstruction / ectasia; cellulitis; immunocompromised state; nipple injury
Pathogen: S. aureus (most commonly)
Histo: acute + chronic inflammatory infiltration, fibrosis, occasional multinucleated giant cells
Age: any; most commonly in lactating woman
• tender swollen erythematous breast (DDx: inflammatory ca.)
• enlarged painful axillary lymph nodes
• fever (5–12–47%), elevated ESR, leukocytosis
√ diffuse increased density
√ diffuse skin thickening
√ swelling of breast
√ enlarged axillary lymph nodes
√ rapid resolution under antibiotic therapy
US:
√ increased echogenicity in fat lobules
√ hypoechoic thick-walled complex multiloculated collection + acoustic enhancement = abscess
√ increased peripheral color Doppler flow
MR:
√ circumscribed area of low signal intensity on T1WI
√ strong initial enhancement + postinitial plateau
Cx: abscess, fistula

Puerperal Mastitis (14–59%)

= LACTATIONAL MASTITIS
= usually interstitial infection during lactational period
(a) through infected nipple crack / skin abrasion
(b) hematogenous
(c) ascending via ducts = galactophoritis
Prevalence: 1–24% of breast-feeding women
At risk: primipara (65% of cases)

Risk factor: milk stasis = excellent culture medium
Organism: S. aureus > Streptococcus (from nose + throat of nursing infant)
√ imaging NOT required
√ skin and trabecular thickening from breast edema
Cx: abscess (in 5–11%) in first 12 weeks after birth / at time of weaning
Rx: continue breast feeding under conservative therapy to disengorge ducts (unless contraindicated by type of antibiotic!); amoxicillin-clavulanate / cloxacillin; incision + drainage

Nonpuerperal Mastitis (41–86%)
= outside breast-feeding period
Organism: Streptococcus, E. coli
1. Infected cyst
2. Purulent mastitis with abscess formation
3. Plasma cell mastitis
4. Nonspecific mastitis

CENTRAL NONPUERPERAL MASTITIS
= PERIAREOLAR MASTITIS (most common)
Cause: complication of periductal mastitis
Pathophysiology:
squamous metaplasia of cuboidal epithelium → keratin plugs → central acute inflammatory infiltrate → obstruction of lactiferous ducts → secondary infection → cutaneous fistula
At risk: smoker
Prognosis: recurrence in 25–40%

PERIPHERAL NONPUERPERAL MASTITIS
At risk: diabetes, rheumatoid arthritis, steroid medication, recent breast intervention

Granulomatous Mastitis
= very rare chronic inflammatory process
Median age: 41 years (most commonly during post partum / post lactation period)
Histo: noncaseating nonvasculitic granulomatous inflammatory reaction centered on lobules
under exclusion of:
TB, fungal infection, sarcoidosis, Wegener granulomatosis, granulomatous reaction associated with carcinomas
Organism: Corynebacterium (in up to 75%)
• acute onset of a distinct firm / hard tender painful mass sparing subareolar region; nipple retraction
√ focal asymmetric density (most frequently)
√ dense breast tissue / mass with benign / malignant features
√ reactive enlargement of axillary nodes (in up to 15%)
US:
√ multiple clustered contiguous tubular hypoechoic lesions
√ ± large hypoechoic mass

Prognosis: spontaneous healing over time; corticotherapy

METASTASIS TO BREAST

Prevalence: 0.5–3% of all malignant breast tumors; 5% of all male breast cancers
Mean age: 43 years
Intramammary primary:
commonly located in contralateral breast
Extramammary primary:
malignant melanoma > NHL > lung cancer (small- and large-cell types) > sarcoma > carcinoma of ovary, stomach, kidney, prostate
◊ In up to 40% no known history of primary cancer!
in children: rhabdomyosarcoma, acute leukemia, NHL
Location: subcutaneous fat rather than glandular tissue; bilaterality in up to 30%
√ round homogeneous mass with smooth margin
√ solitary mass, esp. in upper outer quadrant
√ usually multiple masses
√ skin adherence (25%) ± skin thickening
√ axillary node involvement (40%)
√ NO calcifications
US:
√ hypervascularity in a predominantly echogenic mass (in 64% of breast lymphoma, in 99% of melanoma)

Hemorrhagic Metastasis to Breast

1. Malignant melanoma
2. RCC
3. Choriocarcinoma
4. Kaposi sarcoma

MONDOR DISEASE

= rare usually self-limited thrombophlebitis of subcutaneous veins (mostly thoracoepigastric v.) of the breast / anterior chest wall
Cause: unknown; trauma, physical exertion, surgery, breast cancer, inflammation, dehydration
May be associated with: carcinoma (in up to 12%), DVT
• painful tender palpable cordlike structure
• skin dimpling, erythema
Location: usually lateral aspect of breast
√ linear ropelike tubular superficial structure ± beading
√ rarely calcification of vein
US:
√ superficial hypoechoic tubular structure containing low-level internal echoes (= thrombus)
Prognosis: resolves spontaneously in 2–4 weeks

MYOFIBROBLASTOMA

= SPINDLE CELL TUMOR OF BREAST = SPINDLE CELL LIPOMA = FIBROMA = MYOGENIC STROMAL TUMOR = SOLITARY FIBROUS TUMOR = ATYPICAL VARIANT OF LEIOMYOMA
= rare benign stromal tumor
Age: 6th–7th decade
May be associated with: gynecomastia
• slow growing unilateral painless mobile mass
Path: bands of hyalinized collagen separating short fascicles of bland spindle cell with pseudoencapsulation of peripherally compressed fibrous tissue; positive for muscle-specific actin + α-smooth muscle actin + desmin
Size: 1–4 cm
√ well-defined round / ovoid dense mass
US:
√ solid well-circumscribed homogeneously hypoechoic mass
√ occasionally ill-defined with posterior acoustic shadowing
MR:
√ homogeneous enhancement (similar to fibroadenoma) with nonenhancing internal septations on T2WI

NIPPLE ADENOMA

= FLORID PAPILLOMATOSIS = EROSIVE ADENOMATOSIS = SUPERFICIAL PAPILLARY ADENOMATOSIS
= uncommon variant of intraductal papilloma involving nipple
• bloody discharge, crusting, nodularity
• tenderness, swelling, erythema (resembling Paget disease)
Rx: complete local excision

PAPILLOMA OF BREAST

= proliferation of ductal epithelial tissue on a fibrovascular stalk within a duct
Prevalence: rare; 1–2% of all benign tumors
Age: 30–77 years (juvenile papillomatosis = 20–26 years); may occur in men
Histo: hyperplastic proliferation of ductal epithelium; lesion may be pedunculated / broad-based; connective tissue stalk covered by epithelial cells proliferating in the form of apocrine metaplasia / solid hyperplasia → may cause duct obstruction + distension to form an intracystic papilloma; immunohistochemical marker p63 for myoepithelial cell layer present in a complete layer
Mammo:
√ negative mammogram / intraductal nodules in subareolar area
√ may be associated with coarse microcalcifications
Galactography:
√ dilated duct with distorting intraluminal filling defect / complete duct obstruction
US:
√ solid round / oval / slightly lobulated well-circumscribed hypoechoic mass in dilated duct
√ ± hypervascularity on color Doppler
MR:
› T1WI:

√ round / oval tumor with signal isointense to parenchyma (usually not detectable on precontrast T1WI)
√ homo- / heterogeneous contrast enhancement stronger than surrounding parenchyma
√ continuous postinitial increase / occasionally plateau

Cx: invasive papillary carcinoma / DCIS (lesion > 1 cm, location > 3 cm from nipple, patient age > 50 years)

Rx: surgical excision (because of low risk of upgrade to DCIS)

Prognosis: in 24% recurrence after surgical treatment

Central Solitary Papilloma

= NOT premalignant

Location: major subareolar duct; bilateral in 25%

- asymptomatic
- spontaneous usually bloody / serous (9–48%) / clear nipple discharge (52–88–100%):

◊ Most common cause of serous / serosanguinous nipple discharge!

- "trigger point" = nipple discharge produced upon compression of area with papilloma
- intermittent mass disappearing with discharge

√ asymmetrically dilated single duct

Peripheral Multiple Papillomas

= INTRADUCTAL PAPILLOMATOSIS

Age: perimenopausal

Location: within terminal ductal lobular unit; bilateral in up to 14%

In 10–38% associated with:
atypical ductal hyperplasia, lobular carcinoma in situ, DCIS (papillary + cribriform intraductal cancers), invasive cancer, sclerosing adenosis, radial scar

√ segmental distribution with dilated duct extending from beneath the nipple (20%)

PHYLLODES TUMOR

[*phyllon*, Greek = leaf → phyllodes = leaflike]

Prevalence: 1÷6,300 examinations; 0.3–1.5% of all breast neoplasms; 3% of all fibroadenomas

Mean age: 45 years (5th–6th decade); occasionally in women < 20 years of age

Histo: similar to fibroadenoma but with increased cellularity + pleomorphism of its stromal elements (wide variations in size, shape, differentiation); fibroepithelial tumor with leaflike growth pattern = branching projections of tissue within cleftlike spaces lined with layers of myoepithelial and ductal epithelium; cavernous structures contain mucus, cystic degeneration + hemorrhage
Subtypes: (a) benign (b) borderline (c) malignant

- sense of fullness
- rapidly enlarging breast mass; periods of remission
- huge, firm rubbery, mobile, discrete, lobulated, smooth mass
- thinning + livid discoloration of skin, wide veins, shining skin → skin ulceration / invasion of chest wall

Size: 1–20 cm

Mammo:
- √ large homogeneous noncalcified isodense mass with smooth polylobulated margins mimicking fibroadenoma
- √ rapid growth to large size (> 6–10 cm), may fill entire breast
- √ occasional "halo" sign ← compression of surrounding tissue

US:
- √ round / lobulated hypoechoic mass with smooth margins
- √ heterogeneous internal echoes without acoustic shadowing
- √ anechoic fluid-filled clefts in large tumors (DDx from fibroadenoma)

MR:
- › T1WI:
  - √ hypo- / isointense to parenchyma
  - √ hypointense regions of cystic / necrotic changes (occasionally)
- › enhanced T1WI:
  - √ strong initial uptake in solid tumor component
  - √ continuous increase / plateau in postinitial phase
  - √ increasing demarcation of nonenhancing cystic components (mass-in-mass morphology)
- › T2WI:
  - √ iso - to hyperintense to breast parenchyma
  - √ hyperintense regions of cystic / necrotic changes (occasionally) = "slit-like" cystic channels

Dx: excisional biopsy ← histopathology of core biopsy may mimic hypercellular fibroadenoma

Cx: malignant degeneration (25%)

DDx: fibroadenoma (uncommon in postmenopausal woman)

Benign Phyllodes Tumor

= FIBROADENOMA PHYLLODES = GIANT FIBROADENOMA

= benign giant form of intracanalicular fibroadenoma

Histo: low mitotic activity (0–4 mitoses / 10 HPF)

Cx: in 5–10% degeneration into malignant fibrous histiocytoma / fibro- / lipo- / leiomyo- / chondro- / osteosarcoma with local invasion + hematogenous metastases to lung, pleura, bone (axillary metastases quite rare)

Prognosis: 15–20% recurrence rate after excision

Malignant Phyllodes Tumor (16–30%)

= PHYLLODES SARCOMA = CYSTOSARCOMA PHYLLODES = ADENOSARCOMA

= rare fibroepithelial neoplasia

Histo: high mitotic activity (> 5 mitoses / 10 HPF) in a predominantly sarcomatous differentiation (angio-, chondro-, myo-, osteo-, liposarcoma); rare transformation into metaplastic breast cancer (squamous cell carcinoma in 1%)

√ ± coarse / eggshell calcifications

√ type III washout pattern in solid tumor portion

Prognosis: hematogenous spread in 20% (lung > bone > heart > liver) as late as 12 years after initial Rx; 20% local relapse rate; 65% 5-year survival; death in 30%

Rx: wide excision (without axillary node dissection); radiation + chemotherapy not useful

PSEUDOANGIOMATOUS STROMAL HYPERPLASIA

= PASH = benign hormonally stimulated mesenchymal myofibroblastic proliferation of mammary stroma

Spectrum: from focal incidental findings to clinically and mammographically evident breast masses

Histo: (a) incidental focal microscopic finding in 23% of all breast specimens
(b) tumoral form (rare)

Tumoral Form of PASH

Age: 4th–5th decade (range, 14–67 years); frequently in pre- and perimenopausal women

Associated with: gynecomastia in men (in 20–47%); immunosuppressive condition (eg, HIV); neurofibromatosis type 1

Path: well-defined mass with pseudocapsule

Histo: proliferating myofibroblasts creating slit-like anastomosing spaces positive for vimentin + CD34 (+ muscle actin + desmin); ER + PR positive in 95%; similar in appearance to low-grade angiosarcoma

Pathogenesis: high density of progesterone receptors

- single palpable movable painless firm rubbery mass
- may grow rapidly

Mean size: 4.2 (range, 1–12) cm

Mammo:

√ dense well / partially circumscribed noncalcified mass
√ rarely indistinct / spiculated border

US:

√ hypoechoic solid ovoid mass with long axis parallel to chest wall:
  √ slightly heterogeneous texture ± echogenic component
  √ rarely predominantly hyperechoic
√ ± circumscribed margins
√ ± small cystic component
√ usually no posterior phenomena

MR:

√ commonly persistent (type 1) or less frequently plateau (type 2) / washout (type 3) enhancement

Rx: excision for symptomatic / growing mass

Prognosis: recurrence after excisional biopsy (in 5–18%) requires 1–2 cm excisional margins; concurrent DCIS / invasive carcinoma in surrounding tissue (in 4–10%)

DDx: fibroadenoma; phyllodes tumor; angiosarcoma (slitlike spaces with atypical cell nuclei containing erythrocytes, positive for CD31 + factor VIII)

RADIAL SCAR

= SCLEROSING DUCT HYPERPLASIA = INDURATIVE MASTOPATHY = FOCAL FIBROUS DISEASE = BENIGN SCLEROSING DUCTAL PROLIFERATION = INFILTRATING EPITHELIOSIS = NONENCAPSULATED

SCLEROSING LESION

= benign proliferative breast lesion (malignant potential is controversial) unrelated to prior surgery / trauma

Prevalence: 0.1–2.0÷1,000 screening mammograms; in 2–16% of mastectomy specimens

Cause: ? localized inflammatory reaction, ? chronic ischemia with slow infarction

Path: "scar" = sclerotic center composed of acellular connective tissue (= fibrosis) and elastin deposits (= elastosis); entrapped ductules with intact myoepithelial layer in sclerotic core; corona of distorted ducts + lobules composed of benign proliferations (sclerosing adenosis, ductal hyperplasia, cyst formation, papillomatosis)

In up to 50% associated with:

tubular carcinoma, comedo carcinoma, invasive lobular carcinoma + contralateral breast cancer

◊ Avoid frozen section, fine-needle aspiration, core needle biopsy (controversial)!

• rarely palpable

√ mean diameter of 0.33 cm (range, 0.1–0.6 cm)

√ typically no central mass (BUT: irregular noncalcified mass often with architectural distortion)

√ variable appearance in different projections (= radial scars are typically planar in configuration)

√ oval / circular translucent areas at center

√ very thin long spicules, clumped together centrally

√ radiolucent linear structures (= fat) paralleling spicules ("black star" appearance)

√ no skin thickening / retraction

MR:

› T1WI:

√ stellate lesion with SI equal to parenchyma (difficult / impossible to visualize within parenchyma; good in adipose tissue)

› enhanced T1WI:

√ slight to moderate uptake with nonspecific curve

› T2WI:

√ no characteristic finding

Rx: surgical excision required for definitive diagnosis

DDx: carcinoma, postsurgical scar, fat necrosis, fibromatosis, granular cell myoblastoma

SARCOMA OF BREAST

Frequency: < 1% of malignant mammary lesions

Age: 45–55 years

Histo: fibrosarcoma, rhabdomyosarcoma, osteogenic sarcoma, mixed malignant tumor of the breast, malignant fibrosarcoma and carcinoma, liposarcoma

• rapid growth (4–6 cm at time of detection)

√ smooth / lobulated large dense mass

√ well-defined outline

√ palpated size similar to mammographic size

Angiosarcoma of Breast

= rare highly malignant endovascular breast tumor

Prevalence: 200 cases in world literature; 0.05% of all malignant breast tumors; 8% of all breast sarcomas

Age: 3rd–4th decade of life

Histo: hyperchromatic neoplastic endothelial cells; network of communicating vascular spaces

stage I: cells with large nucleoli

stage II: endothelial lining displaying tufting + intraluminal papillary projections

stage III: mitoses, necrosis, marked hemorrhage (= "blood lakes")

Immunohisto: factor VIII-related antigen, CD34, ulex-lectin antigen, desmin, vimentin, S-phase kinase-associated protein 2

Metastasis: hematogenous spread to lung, skin, SQ tissue, bone, liver, spleen, omentum, adrenal, gland, psoas muscle, brain, ovary; NO lymphatic spread

• rapidly enlarging painless immobile breast mass

Laterality: bilateral angiosarcoma (often in pregnancy)

Mammo:

√ normal (in 33%)

√ ill-defined / circumscribed lobulated round / oval mass

√ ± coarse calcifications

US:

√ skin thickening + nipple retraction

√ large solitary hypo- / hyperechoic heterogeneous mass

√ diffuse mixed echotexture without definable mass (38%)

√ well- / ill-defined multilobulated nonspiculated border

√ hyperechoic areas (← hemorrhage) ± acoustic shadowing

√ hypervascularity on color Doppler

MR:

√ heterogeneous mass with low SI on T1WI + intermediate to high SI on T2WI

√ pronounced early arterial enhancement with higher pathologic tumor grade

√ prolonged enhancement ← blood-filled vascular spaces

√ small focus of enhancement in irradiated thickened skin

PET/CT (useful for initial staging + surveillance):

√ FDG-avid

Biopsy: fine-needle aspiration / punch biopsies not diagnostic or misleading → excisional biopsy

Prognosis: dismal with 1.2–3.1 years median survival; 15% overall 5-year survival rate

Rx: simple mastectomy without axillary lymph node dissection

DDx: phylloides tumor, lactating breast, juvenile hypertrophy

◊ Frequently misdiagnosed as lymph- / hemangioma (negative for S-phase kinase-associated protein 2)

Secondary Angiosarcoma of Breast

Prevalence: 0.9–1.6÷1000 after radiation therapy

Risk factor: breast-conserving therapy accompanied by radiation therapy
Cause: radiogenic DNA mutations, genetic predisposition, congenital, idiopathic, traumatic factors; **Stewart-Treves syndrome** = angiosarcoma arising in region of chronic lymphedema
Age: > 65 years
Types:
(a) postradiation angiosarcoma (more common)
(b) lymphedema-associated cutaneous angiosarcoma (less common)
Criteria for radiation-associated neoplasm:
(a) site of origin within / adjacent to field of prior irradiation
(b) significant amount of radiation (25–80 Gy)
(c) interval of > 3–4 years since time of irradiation
(d) secondary sarcoma histologically different from primary neoplasm
Mean age: 65 years
• palpable mass
• skin macules / papules / vesicles → ulceration + edema
• change in skin color → blue, red, purple discoloration often accompanied by ecchymotic / telangiectatic /erythematous / eczematous component

Dermatofibrosarcoma Protuberans

= uncommon locally aggressive mesenchymal tumor; rarely in breast
Incidence: 5÷1,000,000 persons annually
Origin: dermis
Age: early / middle adulthood
Histo: CD34-positive spindle cell malignancy of typically storiform arrangement containing short fascicles within myxoid + hyalinized stromal background
• slow growing erythematous indurated subcutaneous nodule
√ hyperdense mass; NO calcifications; NO fat
US:
√ heterogeneously hypoechoic ovoid mass
√ parallel orientation
√ predominantly circumscribed microlobulated margins
√ scattered areas of internal vascularity
MR:
√ homogeneous mass T1-isointense to breast parenchyma
√ hyperintense mass on T2WI
√ intense enhancement
Prognosis: 20–50% recurrence rate
Rx: surgical excision with 2–3 cm wide margin

Liposarcoma of Breast

Prevalence: 0.7% of all breast cancers; 15% of all sarcomas
• slowly enlarging painful unilateral mass
• NO axillary lymphadenopathy; NO skin change
Median size: 8 cm

Histo: lipoblasts with scalloped irregular hyperchromatic nuclei + intracytoplasmic vacuoles indenting the nucleus confirm diagnosis
√ large encapsulated circumscribed hyperdense mass ± irregular margins
US:
√ heterogeneous hyperechoic echotexture
Rx: wide surgical excision

Pleomorphic Hyalinizing Angiectatic Tumor of Breast

= PHAT
= rare low-grade mesenchymal tumor of uncertain lineage
Histo: nonencapsulated mass with sheets of spindle + pleomorphic cells alternating with clusters of thin-walled ectatic vasculature surrounded by fibrin + collagen; positive for vimentin; variably positive for CD34, CD99, factor XIIIa and vascular endothelial growth factor
Location: lower extremity; breast
• slow-growing painless subcutaneous mass
√ large well-circumscribed retroareolar mass
√ NO calcifications
US:
√ ill-defined heterogeneous mass + flow on color Doppler
MR:
√ large solid + complex cystic mass:
√ hypointense SI on T1WI
√ hyperintense SI on T2WI
√ homogeneous enhancement
DDx: hematoma, Kaposi sarcoma

SEBACEOUS CYST

= epithelial cyst ← obstructed sebaceous gland arising from outer root sheath of hair follicle
Prevalence: less common dermal lesion than epidermal inclusion cyst
Location: dermis ± expansion into subcutaneous fat;
axilla / sternum (= **steatocystoma**) with flattened sebaceous gland lobules in relation to cyst wall
◊ NOT readily distinguishable from epidermal inclusion cyst by imaging / clinical features
Size: 0.8–10.0 cm in diameter
√ circumscribed round / oval mass of low (fatty) to variable density
US:
√ circumscribed mixed (commonly) / hyperechoic (occasionally) solid mass
√ cystic / solid depending on the internal contents
√ contiguous with dermis on tangential view
√ exiting hypoechoic track toward skin surface
DDx: epidermal inclusion cyst (indistinguishable)

SEROMA OF BREAST

= localized postoperative fluid collection of wound serum
Average size: 3.9 (range, 0.7–8.3) cm
√ oval / round mass with convex (outward-bulging) margins
√ slowly diminishes in size (= contraction)
√ evolution into scar by 1 year after surgery
√ occasionally reaccumulates / persists
US:
√ fluid collection ± solid echogenic component
CT:
√ hypo- / isodense lesion
MR:
› T1WI:
√ circumscribed area of mildly hypointense signal
› enhanced T1WI:
√ smooth ≤ 5 mm thin rim enhancement of surrounding parenchyma
› T2WI:
√ hyperintense area of fluid retention
Dx: gradual resolution / persistence on follow-up
DDx: indistinguishable from hematoma

HEART AND GREAT VESSELS

DIFFERENTIAL DIAGNOSIS OF CARDIOVASCULAR DISORDERS

Approach to Congenital Heart Disease		
	Acyanotic	*Cyanotic*
	√ enlarged main pulmonary artery	√ concave main pulmonary artery
Increased Pulmonary BF	L-R shunts	Admixture lesions = bidirectional shunts = T-lesions
+ increased C/T ratio	VSD	Transposition
	ASD	Truncus arteriosus
	PDA	TAPVR
	ECD	Tricuspid atresia (without RVOT obstruction)
	PAPVR	"Tingles" (single ventricle / atrium)
Normal Pulmonary Blood Flow	LV outflow obstruction	
+ normal C/T ratio	AS	
+ pulmonary venous HTN	Coarctation	
	Interrupted aortic arch	
	Hypoplastic left heart	
	LV inflow obstruction	
	Obstructed TAPVR	
	Cor triatriatum	
	Pulmonary vein atresia	
	Congenital MV stenosis	
	Muscle disease	
	Cardiomyopathy	
	Myocarditis	
	Anomalous LCA	
Decreased Pulmonary BF		R-to-L shunts
+ normal C/T ratio		+ nonrestrictive intracardiac shunt
		Tetralogy of Fallot
		Tricuspid atresia (with PS + nonrestrictive ASD)
		Pulmonary atresia + nonrestrictive VSD
+ increased C/T ratio		+ restrictive intracardiac shunt
		Pulmonary atresia + ASD without VSD
		PS with ASD / patent foramen ovale
		Tricuspid atresia + PS + restrictive ASD
		Trilogy of Fallot
		Ebstein anomaly
		Congenital tricuspid insufficiency

CONGENITAL HEART DISEASE

Incidence of CHD in Liveborn Infants

Overall incidence: 8–9÷1000 livebirths

◊ Most common CHD: bicuspid aortic valve (2%) [usually not recognized before late infancy / childhood]

◊ ASD + VSD + PDA account for 45% of all CHD
◊ 12 lesions account for 89% of all CHD:
Ventricular septal defect 30.3%
Patent ductus arteriosus 8.6%
Pulmonic stenosis 7.4%
Ostium secundum defect 6.7%
Coarctation of aorta 5.7%
Aortic stenosis 5.2%
Tetralogy of Fallot 5.1%
Transposition 4.7%
Endocardial cushion defect 3.2%
Hypoplastic right ventricle 2.2%
Hypoplastic left heart syndrome 1.3%
TAPVR 1.1%
Truncus arteriosus 1.0%
Single ventricle 0.3%
Double outlet right ventricle 0.2%

High-risk pregnancy:
(1) Previous sibling with CHD: 2–5%
(2) Previous 2 siblings with CHD: 10–15%
(3) One parent with CHD: 2–10%

Congenital Abnormality of Aortic Valve

1. **Bicuspid aortic valve**
   ◊ Most common congenital cardiac anomaly!
2. Unicuspid / unicomissural aortic valve
   = single commissure in (commonly) L posterior position
   Incidence: 0.02%
   Cx: early aortic stenosis, aneurysmal dilatation of ascending aorta
3. Quadricuspid aortic valve
   Incidence: 200 cases reported
   Cx: regurgitation
4. Aneurysmal dilatation of sinus of Valsalva
   Cause: (a) congenital: connective tissue disorder (Marfan), aortic insufficiency, bicuspid aortic valve, VSD
   (b) acquired: infection (endocarditis, syphilis, TB), medial degeneration, trauma, hypertension

Congenital Abnormality of Mitral Valve

1. Endocardial cushion defect
2. Parachute mitral valve (Shone syndrome)

CHD Presenting in 1st Year of Life

1. VSD

2. d-Transposition of great vessels
3. Tetralogy of Fallot
4. Isolated coarctation
5. Patent ductus arteriosus
6. Hypoplastic left heart syndrome

Most common causes for CHF + PVH in neonate:

1. Left ventricular failure ← outflow obstruction
2. Obstruction of pulmonary venous return

Presenting Age in CHD		
Age	*Severe PVH*	*PVH + Shunt Vascularity*
0–2 d	Hypoplastic left heart	Hypoplastic left heart
	Aortic atresia	TAPVR above diaphragm
	TAPVR below diaphragm	Complete transposition
	Myocardiopathy in IDM	
3–7 d	PDA in preterm infant	
7–14 d	CoA + VSD / PDA	Coarctation of aorta
	Aortic valve stenosis	Peripheral AVM
	Peripheral AVM	
	Endocardial fibroelastosis	
	Anomalous LCA	

CHD Compatible with Relatively Long Life

1. Mild tetralogy: mild pulmonic stenosis + small VSD
2. Valvular pulmonic stenosis: with relatively normal pulmonary circulation
3. Transposition of great vessels: some degree of pulmonic stenosis + large VSD
4. Truncus arteriosus: delicate balance between systemic + pulmonary circulation
5. Truncus arteriosus type IV: large systemic collaterals
6. Tricuspid atresia + transposition + pulmonic stenosis
7. Eisenmenger complex
8. Ebstein anomaly
9. Corrected transposition without intracardiac shunt

Classic Signs of Congenital Cardiovascular Anomalies

1. “Boot-shaped” heart
2. “Box-shaped” cardiomegaly
3. “Egg-on-a-string” sign
4. “Figure-of-3” and reverse “figure-of-3” sign
5. “Gooseneck” sign
6. “Scimitar” sign
7. “Snowman” sign

Juxtaposition of Atrial Appendages

1. Tricuspid atresia with transposition

2. Complete transposition
3. Corrected transposition of great arteries
4. DORV

Continuous Heart Murmur

1. PDA
2. AP window
3. Ruptured sinus of Valsalva aneurysm
4. Hemitruncus
5. Coronary arteriovenous fistula

Syndromes with CHD

5 p – (Cri-du-chat) Syndrome

Incidence of CHD: 20%

DiGeorge Syndrome

= congenital absence of thymus + parathyroid glands

1. Conotruncal malformation
2. Interrupted aortic arch

Down Syndrome

= MONGOLISM = TRISOMY 21

1. Endocardial cushion defect (25%)
2. Membranous VSD
3. Ostium primum ASD
4. AV communis
5. Cleft mitral valve
6. PDA
7. 11 rib pairs (25%)
8. Hypersegmented manubrium (90%)

Ellis-van Creveld Syndrome

Incidence of CHD: 50%

• polydactyly

√ single atrium

Holt-Oram Syndrome

= UPPER LIMB-CARDIAC SYNDROME

Incidence of CHD: 50%

1. ASD
2. VSD
3. Valvular pulmonary stenosis
4. Radial dysplasia

Hurler Syndrome

Cardiomyopathy

Ivemark Syndrome

Incidence of CHD: 100%

• asplenia

√ complex cardiac anomalies

Klippel-Feil Syndrome

Incidence of CHD: 5%

1. Atrial septal defect
2. Coarctation

Marfan Syndrome

= ARACHNODACTYLY

1. Annuloaortic ectasia
2. Aortic aneurysm
3. Aortic regurgitation
4. Pulmonary aneurysm

Noonan Syndrome

1. Pulmonary stenosis
2. ASD
3. Hypertrophic cardiomyopathy

Osteogenesis Imperfecta

1. Aortic valve insufficiency
2. Mitral valve insufficiency
3. Pulmonic valve insufficiency

Postrubella Syndrome

• low birth weight, deafness, cataracts, mental retardation

1. Peripheral pulmonic stenosis
2. Valvular pulmonic stenosis
3. Supravalvular aortic stenosis
4. PDA

Trisomy 13–15

VSD, tetralogy of Fallot, DORV

Trisomy 16–18

VSD, PDA, DORV

Turner Syndrome (XO)

= OVARIAN DYSGENESIS

Incidence of CHD: 35%

1. Coarctation of the aorta (in 15%)
2. Bicuspid aortic valve
3. Dissecting aneurysm of aorta

Williams Syndrome

= IDIOPATHIC HYPERCALCEMIA

- peculiar elfinlike facies, mental + physical retardation
- hypercalcemia (not in all patients)

1. Supravalvular aortic stenosis (33%)
2. ASD, VSD
3. Valvular + peripheral pulmonary artery stenosis
4. Aortic hypoplasia, stenoses of more peripheral arteries

SHUNT EVALUATION

Evaluation of L-to-R Shunts

A. AGE

› Infants:

(1) Isolated VSD
(2) VSD with CoA / PDA / AV canal
(3) PDA
(4) Ostium primum

› Children / adults:

(1) ASD
(2) Partial AV canal with competent mitral valve
(3) VSD / PDA with high pulmonary resistance
(4) PDA without murmur

B. SEX

99% chance for ASD / PDA in female patient

C. CHEST WALL ANALYSIS

√ 11 pair of ribs + hypersegmented manubrium → Down syndrome
√ pectus excavatum + straight back syndrome + funnel chest → prolapsing mitral valve
√ rib notching

D. CARDIAC SILHOUETTE

√ absent pulmonary trunk:
corrected transposition with VSD; pink tetralogy
√ left-sided ascending aorta:
corrected transposition with VSD
√ tortuous descending aorta:
aortic valve incompetence + ASD
√ huge heart:
persistent complete AV canal (PCAVC); VSD + PDA; VSD + mitral valve incompetence
√ enlarged left atrium:
intact atrial septum; mitral regurgitation (endocardial cushion defect, prolapsing mitral valve + ASD)

Differential Diagnosis of L-R Shunts						
	RA	*RV*	*PA*	*LA*	*LV*	*Prox. Ao*
ASD	↑	↑	↑	↔	↔	↔
VSD	↔	↑	↑	↑	↑	↔
PDA	↔	↔	↑	↑	↑	often ↑

Shunt with Normal Left Atrium

A. Precardiac shunt
   1. Anomalous pulmonary venous connection

B. Intracardiac shunt
   1. ASD (8%)
   2. VSD (25%)

C. Postcardiac shunt
   1. PDA (12%)

Aortic Size in Shunts

A. Extracardiac shunts
   √ aorta enlarged + hyperpulsatile
   1. PDA

B. Pre- and intracardiac shunts
   √ aorta small but not hypoplastic
   1. Anomalous pulmonary venous return
   2. ASD
   3. VSD
   4. Common AV canal

Left-to-Right Shunts Missed on Echocardiography

1. Sinus venosus defect
2. Patent ductus arteriosus
3. Anomalous pulmonary venous return

SITUS

= "position / site / location" referring to the position of the atria and viscera relative to the midline

Segmental Analysis of CHD

= 3-part **Van Praagh notation** of congenital heart disease corresponding to atria & ventricles & great vessels

◊ Only one type of situs anomaly is possible in any patient!

Step 1. **Visceroatrial situs** {X,_,_}:

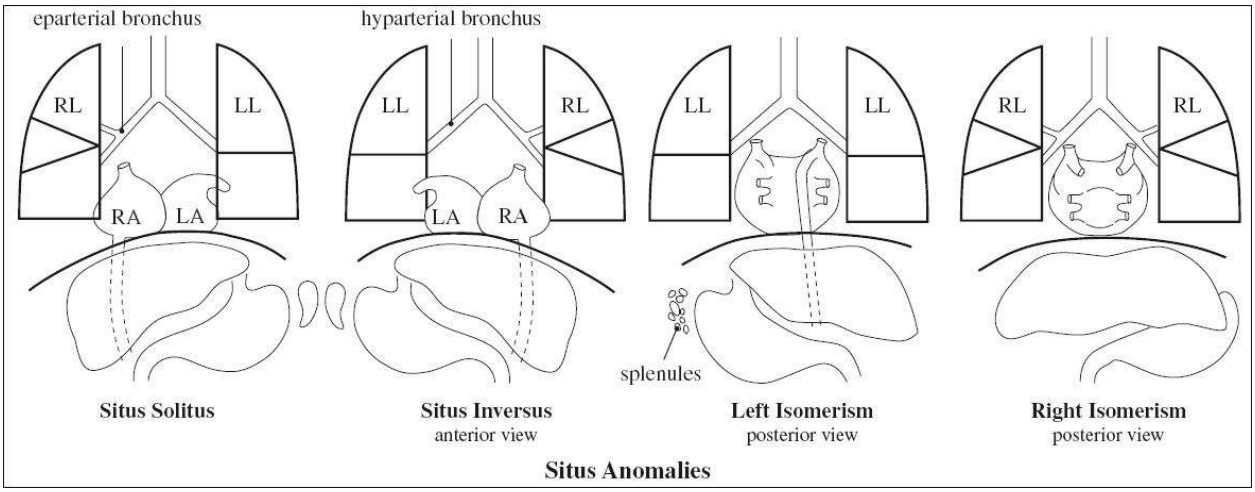
solitus ={S}, inversus = {I}, ambiguus = {A}

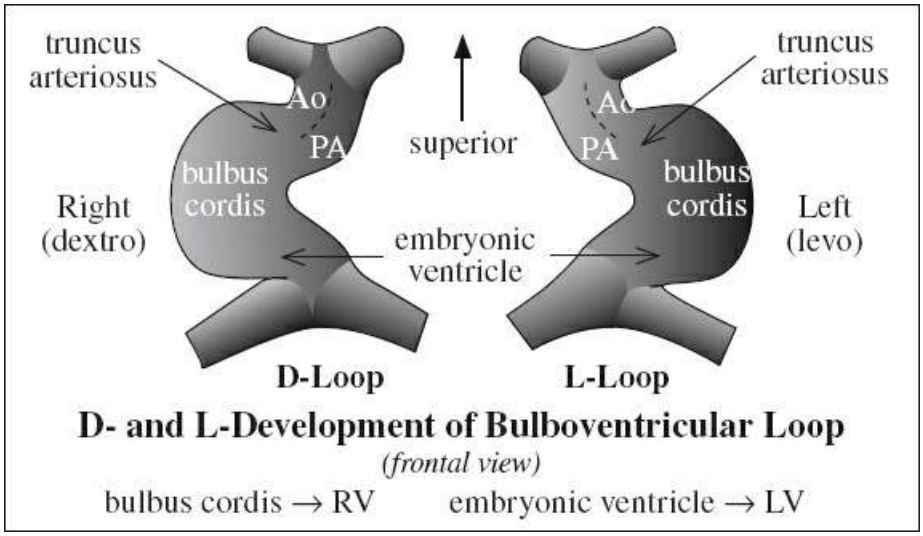
(a) establish <u>atrial situs</u> by morphology of atrial appendages
   √ broad blunt (triangular) appendage = RA
   √ narrow pointed tubular (fingerlike) appendage = LA
   ◊ Morphologic RA is on patient's right side

(b) establish atrial situs by lung morphology:
› morphologic RT lung
√ main RT lung bronchus is eparterial
› morphologic LT lung
√ main LT bronchus is hyparterial

The relationship between main RT + LT bronchi and pulmonary arteries is a reliable indicator of atrial arrangement.

(c) establish <u>visceral situs:</u>
√ largest lobe of liver on RT; stomach + spleen on LT
(b) establish <u>thoracoabdominal situs:</u>
√ supradiaphragmatic IVC connects to anatomic RA





√ RT lung + largest lobe of liver on right side

Supradiaphragmatic IVC / coronary sinus usually drain into anatomic RA (= rule of venoatrial concordance)

◊ Atrial + thoracoabdominal situs are usually concordant!

Step 2. **Ventricular loop orientation** {_,X,_}:

Embryology:

components of craniocaudal tube are truncus arteriosus (future great vessels), bulbus cordis (future right ventricle), embryonic LV, primitive atria, sinus venosus; tube curves toward right (D-loop) placing RV to right of LV

(a) identify morphologic RV and LV

(b) determine location of RV relative to LV

Hand rule: approaching heart from anteriorly place right / left hand in RV with palm against IVS. If right thumb is in inflow tract + right fingers in outflow tract = D-loop

Step 3. **Position of great vessels** {_,_,X}:

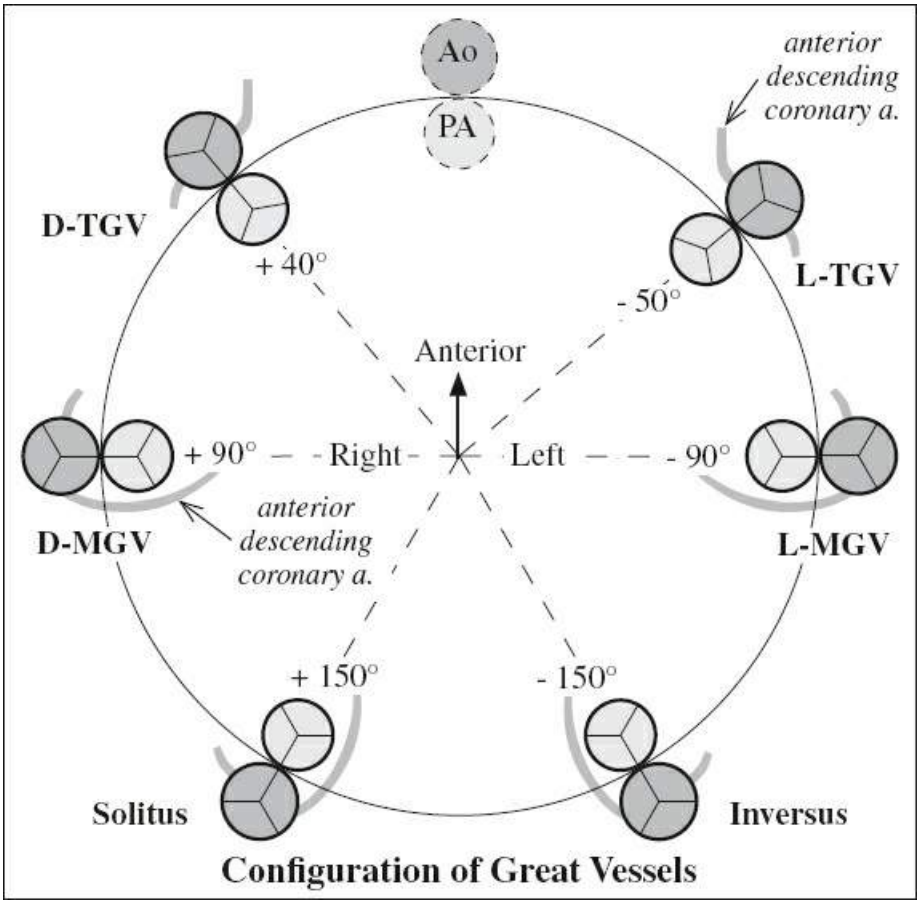
(a) identify morphologic aorta (Ao supplies at least 1 coronary artery + most systemic arteries) and main pulmonary artery (MPA supplies right + left pulmonary artery)

(a) designate position of Ao relative to MPA at level of aortic + pulmonic valves:

› normal or inverse position: solitus ={S}, inversus = {I}

› transposition of great arteries: dextrotransposition = {D-TGV}, levotransposition = {L-TGV}

› malposition if both arteries override / originate from same ventricle: Ao rightward from MPA = {D-MGV}, Ao leftward from MPA = {L-MGV}



Configuration of Great Vessels

Situs Solitus = Normal / Usual Situs

Right side	*Left side*
√ systemic atrium	√ pulmonary atrium
√ trilobed lung	√ bilobed lung
√ liver	√ stomach
√ gallbladder	√ single spleen
√ IVC	√ aorta

Associated with:

(a) levocardia : 0.6–0.8% chance for CHD

(b) dextrocardia : 95% chance for CHD

SITUS ANOMALY

Associated with: CHD, primary ciliary dyskinesia, abdominal anomalies (eg, intestinal malrotation)

Situs Inversus

= mirror-image arrangement of situs solitus

Frequency: 0.01%Associated with:

(a) dextrocardia = situs inversus totalis (usual variant): 3–5% chance for CHD (eg, Kartagener syndrome in 20%)

(b) levocardia (extremely rare): 95% chance for CHD

Left side	*Right side*
√ systemic atrium	√ pulmonary atrium
√ trilobed lung	√ bilobed lung
√ liver	√ stomach
√ gallbladder	√ single spleen
√ IVC	√ aorta

Situs Ambiguus = Heterotaxy

[*heteros*, Greek = other / different; *taxis*, Greek = arrangement]

= visceral malposition + dysmorphism associated with indeterminate atrial arrangement

Associated with: CHD in 50–100%

Subclassification:

1. Asplenia syndrome = double / bilateral right-sidedness
2. Polysplenia syndrome = double / bilateral left-sidedness

Bronchial Situs

Classification:

1. Right bronchial isomerism
   √ bilateral eparterial upper lobe bronchi = morphologically right lung
2. Left bronchial isomerism
   √ bilateral hyparterial upper lobe bronchi = morphologically left lung

The relationship of the upper lobe bronchus to the ipsilateral pulmonary artery is the most

reliable marker of bronchial situs at CT *for details see Anatomy and Function of Lung*

Less reliable: number of lobes, ratio of left to right main bronchial lengths, bronchial branching pattern

Cardiac Malposition

= location of heart other than within left hemothorax in situs solitus or within left hemithorax when other organs are ambiguous

◊ Determined by base-apex axis; no assumption is made regarding cardiac chamber / vessel arrangement

In general, cardiac and situs anomalies are less frequently found with a concordant position of the cardiac apex, stomach, and aortic arch.

A. POSITION OF CARDIAC APEX
   1. Levocardia = apex directed leftward
   2. Dextrocardia = apex directed rightward
   3. Mesocardia = vertical / midline heart (usually with situs solitus)

   √ atrial septum characteristically bowed into LA in cardiac situs solitus with dextrocardia + cardiac situs inversus with levocardia (DDx: juxtapositioned atrial appendages)

Cardiac Position as Predictor of CHD	
Visceroatrial Situs	*Frequency of CHD*
Situs solitus	
with levocardia	< 1%
with dextrocardia	**95%**
Situs inversus	
with dextrocardia	3–5%
with levocardia	**100%**
Situs ambiguus	
with left isomerism (polysplenia)	90%
with right isomerism (asplenia)	99–100%

   ◊ Does not imply a particular internal structure / specific location of other thoracoabdominal organs!

B. CARDIAC DISPLACEMENT
   by extracardiac factors (eg, lung hypoplasia, pulmonary mass)
   1. Dextroposition
      suggests hypoplasia of ipsilateral pulmonary artery (PAPVR implies scimitar syndrome)
   2. Levoposition
   3. Mesoposition

C. CARDIAC INVERSION
   = alteration of normal relationship of chambers
   1. D-bulboventricular loop
   2. L-bulboventricular loop

D. TRANSPOSITION
= alteration of anterior-posterior relationship of great vessels

CYANOTIC HEART DISEASE

Chemical cyanosis = $PaO_2 \leq 94\%$

Clinical cyanosis = $PaO_2 \leq 85\%$

◊ Decrease in hemoglobin delays detectability!

Most common cause of cyanosis:

› in newborn: transposition of great vessels

› in child: tetralogy of Fallot!

N.B.: tricuspid atresia = the great mimicker

Increased Pulmonary Blood Flow with Cyanosis

= ADMIXTURE LESIONS

= bidirectional shunt with 2 components:

(a) mixing of saturated blood (L-R shunt) and unsaturated blood (R-L shunt)

(b) NO obstruction to pulmonary blood flow

Evaluation process:

√ cardiomegaly

√ increased pulmonary blood flow

√ concave main pulmonary artery:

√ PA segment absent = transposition

√ PA segment present:

(a) L atrium normal (= extracardiac shunt) = TAPVR

(b) L atrium enlarged (= intracardiac shunt) = truncus arteriosus

N.B.: Overcirculation + cyanosis = complete transposition until proven otherwise!

Admixture Lesions = T-lesions

mnemonic: 5 T's + CAD

Transposition of great vessels = complete TGV ± VSD

◊ Most common cause for cyanosis in neonate

Tricuspid atresia with or without transposition + VSD

◊ 2nd most common cause for cyanosis in neonate

Truncus arteriosus

Total anomalous pulmonary venous return (TAPVR) above diaphragm:

(a) supracardiac

(b) cardiac (coronary sinus / right atrium)

"**T**ingle" = single ventricle

Common atrium

Aortic atresia

Double-outlet right ventricle (DORV type I) / Taussig-Bing anomaly (DORV type II)

Clues:

√ skeletal anomalies: Ellis-van Creveld syndrome (truncus / common atrium)

√ polysplenia: common atrium

√ R aortic arch: persistent truncus arteriosus
√ ductus infundibulum: aortic atresia
√ pulmonary trunk seen: supracardiac TAPVR; DORV; tricuspid atresia; common atrium
√ ascending aorta with leftward convexity: single ventricle
√ dilated azygos vein: common atrium + polysplenia + interrupted IVC; TAPVR to azygos vein
√ left-sided SVC: vertical vein of TAPVR
√ "waterfall" right hilum: single ventricle + transposition
√ large left atrium (rules out TAPVR)
√ prominent L heart border: single ventricle with inverted rudimentary RV; levoposition of appendage of RA (tricuspid atresia + transposition)
√ age of onset ≤ 2 days: aortic atresia

Decreased Pulmonary Blood Flow with Cyanosis

= two components of
(a) impedance of blood flow through right heart ← obstruction / atresia at pulmonary valve / infundibulum
(b) R-to-L shunt

• pulmonary circulation maintained through systemic arteries / PDA
√ normal / decreased pulmonary blood flow
√ concave main pulmonary artery
√ cardiomegaly
√ restrictive intracardiac R-to-L shunt

mnemonic: P2 TETT
Pulmonic stenosis with ASD
Pulmonic atresia
Tetralogy of Fallot
Ebstein anomaly
Tricuspid atresia with pulmonic stenosis
Transposition of great vessels with pulmonic stenosis

A. SHUNT AT VENTRICULAR LEVEL
1. Tetralogy of Fallot
2. Tetralogy physiology (associated with pulmonary obstruction):
› complete / corrected transposition
› single ventricle
› DORV
› tricuspid atresia (PS in 75%)
› asplenia syndrome

√ prominent aorta with L / R aortic arch; inapparent pulmonary trunk
√ normal RA (without tricuspid regurgitation)
√ normal-sized heart ← escape mechanism into aorta

Clues:
1. Skeletal anomaly (eg, scoliosis): tetralogy (90%)
2. Hepatic symmetry: asplenia
3. Right aortic arch: tetralogy, complete transposition, tricuspid atresia

4. Aberrant right subclavian artery: tetralogy
5. Leftward convexity of ascending aorta: single ventricle with inverted right rudimentary ventricle, corrected transposition, asplenia, JAA (tricuspid valve atresia)

B. SHUNT AT ATRIAL LEVEL

mnemonic: PET

1. **P**ulmonary stenosis / atresia with intact ventricular septum
2. **E**bstein malformation + Uhl anomaly
3. **T**ricuspid atresia (ASD in 100%)

√ moderate to severe cardiomegaly
√ RA dilatation
√ RV enlargement ← massive tricuspid incompetence
√ inapparent aorta
√ left aortic arch

Pulmonary Venous Hypertension with Cyanosis

(a) during 1st week of life

1. Hypoplastic left heart syndrome
   √ marked cardiomegaly
2. TAPVR below diaphragm
   √ normal cardiac size

(b) during 2nd week of life

3. Aortic coarctation
4. Aortic atresia

(c) during 4th–6th week of life

5. Critical aortic stenosis
6. Endocardial fibroelastosis
7. Anomalous origin of LCA
8. Atresia of common pulmonary vein

ACYANOTIC HEART DISEASE

Increased Pulmonary Blood Flow without Cyanosis

= indicates L-R shunt with increased pulmonary blood flow (shunt volume > 40%)

A. WITH LEFT ATRIAL ENLARGEMENT
indicates shunt distal to mitral valve = increased volume without escape defect

1. VSD (25%): small aorta in intracardiac shunt
2. PDA (12%): aorta + pulmonary artery of equal size in extracardiac shunt
3. Ruptured sinus of Valsalva aneurysm (rare)
4. Coronary arteriovenous fistula (very rare)
5. Aortopulmonary window (extremely rare)

B. WITH NORMAL LEFT ATRIUM indicates shunt proximal to mitral valve = volume increased with escape mechanism through defect

1. ASD (8%)
2. Partial anomalous pulmonary venous return (PAPVR) + sinus venosus ASD

3. Endocardial cushion defect (ECD) (4%)

Normal Pulmonary Blood Flow without Cyanosis

A. OBSTRUCTIVE LESION
   1. Right ventricular outflow obstruction
      (a) at level of pulmonary valve: subvalvular / valvular / supravalvular pulmonic stenosis
      (b) at level of peripheral pulmonary arteries:
          peripheral pulmonary stenosis
   2. Left ventricular inflow obstruction
      (a) at level of peripheral pulmonary veins:
          pulmonary vein stenosis / atresia
      (b) at level of left atrium: cor triatriatum
      (c) at level of mitral valve:
          supravalvular mitral stenosis, congenital mitral stenosis / atresia, "parachute" mitral valve
   3. Left ventricular outflow obstruction
      (a) at level of aortic valve:
          anatomic subaortic stenosis, functional subaortic stenosis (IHSS), valvular aortic stenosis, hypoplastic left heart, supravalvular aortic stenosis
      (b) at level of aorta:
          interruption of aortic arch, coarctation of aorta

B. CARDIOMYOPATHY
   1. Endocardial fibroelastosis
   2. Hypertrophic cardiomyopathy
   3. Glycogen storage disease

C. HYPERDYNAMIC STATE
   1. Noncardiac AVM: cerebral AVM, vein of Galen aneurysm, large pulmonary AVM, hemangioendothelioma of liver
   2. Thyrotoxicosis
   3. Anemia
   4. Pregnancy

D. MYOCARDIAL ISCHEMIA
   1. Anomalous left coronary artery
   2. Coronary artery disease (CAD)

ACQUIRED HEART DISEASE

√ LA enlargement = MV disease
√ dilated ascending aorta = aortic valve disease
√ RA enlargement = tricuspid valve disease

Pressure Overload

1. Systemic hypertension
2. Aortic stenosis
3. Mitral stenosis

Decreased Compliance

1. Myocardial infarction
2. Hypertrophic cardiomyopathy
3. Restrictive cardiomyopathy

Volume Overload

1. Aortic insufficiency
2. Mitral insufficiency
3. Tricuspid insufficiency

Systolic Anterior Motion of Mitral Valve

1. Hypertrophic Cardiomyopathy
2. Hypertensive heart
3. Diabetes mellitus
4. Acute myocardial infarction
5. Mitral valve dysfunction / repair

Concentric Left Ventricular Hypertrophy

1. Symmetric hypertrophic cardiomyopathy

Approach to Acquired Heart Disease

Criteria	*Mild–Moderate Cardiomegaly*	*Moderate–Severe Cardiomegaly*
C/T ratio	0.45–0.55	> 0.55
LA enlargement	pressure overload	volume overload
	mitral stenosis	mitral insufficiency
	decreased LV compliance	
	hypertrophic cardiomyopathy	
	restrictive cardiomyopathy	
Enlarged ascending aorta	pressure overload	volume overload
	aortic stenosis	aortic insufficiency
Normal LA + aorta	myocardial	myocardial
	acute infarction	dilated cardiomyopathy
	hypertrophic cardiomyopathy	ischemic cardiomyopathy
	restrictive cardiomyopathy	
	pericardial	pericardial
	constrictive pericarditis	pericardial effusion

2. Amyloidosis
3. Cardiac sarcoidosis
4. **Athlete's heart**
   √ ↑ LV mass, ↑ LV diastolic cavity dimension, ↑ LV wall thickness
   √ lack of areas of delayed myocardial hyperenhancement
   Dx (80% sensitive, 99% specific):
   LV Thicknessdiastole ÷ Volumeend-diastole (corrected to body surface area) < 0.15 mm/m2/mL
5. **Fabry disease**
   = rare X-linked autosomal recessive metabolic storage disorder caused by lysosomal a-galactosidase
   √ concentric thickening of LV wall
   √ delayed hyperenhancement of LV midwall on CEMR
6. Adaptive LV hypertrophy: hypertension, aortic stenosis

CARDIOMEGALY

1. CHF
2. Multivalvular disease
3. Pericardial effusion
   √ absence of pulmonary venous hypertension + hydrostatic edema

Cardiothoracic Ratio

= widest transverse cardiac diameter ÷ widest inside thoracic diameter
= primarily a measure of LV dilatation

< 0.45	normal
0.45–0.55	mild cardiomegaly
> 0.55	moderate / severe cardiomegaly

Falsely normal: with LV enlargement in up to 66%, moderate enlargement of LA + RV
Falsely elevated: in expiration, in recumbent position

Vascular Pedicle Width

= distance on a horizontal line between (1) point where right mainstem bronchus + SVC cross and (2) point where left subclavian artery crosses horizontal line

48 ± 5 mm	normal
> 53 mm	in 60% of cardiogenic edema, in 85% of volume overload

Cardiomegaly in Newborn

A. NONCARDIOGENIC
   (a) metabolic:
      1. Ion imbalance in serum levels of sodium, potassium, and calcium
      2. Hypoglycemia
   (b) decreased ventilation
      1. Asphyxia
      2. Transient tachypnea
      3. Perinatal brain damage

(c) erythrocyte function
    1. Anemia
    2. Erythrocythemia
(d) endocrine
    1. Glycogen storage disease
    2. Thyroid disease: hypo- / hyperthyroidism
(e) infant of diabetic mother
(f) arteriovenous fistula
    1. Vein of Galen aneurysm
    2. Hepatic angioma
    3. Chorioangioma

B. CARDIOGENIC
    1. Arrhythmia
    2. Myo- / pericarditis
    3. Cardiac tumor
    4. Myocardial infarction
    5. Congenital heart disease

Abnormal Heart Chamber Dimensions

A. LEFT VENTRICULAR VOLUME OVERLOAD
    1. VSD
    2. PDA
    3. Mitral incompetence
    4. Aortic incompetence
B. LEFT VENTRICULAR HYPERTROPHY
    1. Coarctation
    2. Aortic stenosis
C. RIGHT VENTRICULAR VOLUME OVERLOAD
    1. ASD
    2. Partial APVR / total APVR
    3. Tricuspid insufficiency
    4. Pulmonary insufficiency
    5. Congenital / acquired absence of pericardium
    [6. Ebstein anomaly] – not truly RV
D. RIGHT VENTRICULAR HYPERTROPHY
    1. Pulmonary valve stenosis
    2. Pulmonary hypertension
    3. Tetralogy of Fallot
    4. VSD
E. Fixed subvalvular aortic stenosis
F. Hypoplastic left / right ventricle, common ventricle
G. Congestive cardiomyopathy

Right Atrial Enlargement

Cause: tricuspid stenosis / regurgitation, ASD, atrial fibrillation, dilated

cardiomyopathy, Ebstein anomaly, pulmonary atresia

◊ RA enlarges in rightward + posterior direction

PA CXR:

√ prominent round superior border at junction with SVC

√ > 5.5 cm from midline to most lateral RA margin

√ > 2.5 cm from right vertebral margin

√ > 50% vertical height of RA compared with cardiovascular mediastinal height (from top of aortic arch to base of heart)

LAT CXR:

√ sharp horizontal interface with lung above RV

√ displacement of heart posterior to IVC mimicking LV enlargement

Right Ventricular Enlargement

Cause: pulmonary valve stenosis, cor pulmonale, ASD, tricuspid regurgitation, dilated cardiomyopathy, secondary to LV failure

◊ RV enlarges in anterior, superior + leftward direction causing levorotation of heart

PA CXR:

◊ Only extreme dilatation causes recognizable signs on frontal view!

√ straightening / convexity of left upper cardiac contour

√ upturned cardiac apex

√ left upper cardiac margin parallels left mainstem bronchus as a long convex curvature

√ increased distance between left upper cardiac margin + left mainstem bronchus

√ small appearance of rotated aortic arch + SVC

√ large appearance of main pulmonary artery

LAT CXR (most sensitive view):

√ filling of retrosternal air space by prominent convexity of anterior heart border > ⅓ of distance from sternodiaphragmatic angle to the point where trachea meets sternum

Left Atrial Enlargement

Cause:

(a) acquired: mitral stenosis / regurgitation, LV failure, LA myxoma

(b) congenital: VSD, PDA, hypoplastic left heart

◊ LA enlarges in multiple directions

PA CXR:

√ right retrocardiac double density with inferomedial curvature (earliest sign)

√ > 7.0 (female) / 7.5 (male) cm distance between midpoint of undersurface of left mainstem bronchus + right lateral LA shadow

√ left retrocardiac double density

√ > 75° splaying of carina with horizontal orientation of distal left mainstem bronchus

√ enlarged left-convex left atrial appendage ± calcifications (← rheumatic heart disease in 90%)

LAT CXR:

√ increased convexity of posterosuperior cardiac margin

√ posterosuperior atrial convexity crosses vertical plane formed by tracheal midline + upper lobe bronchus

√ posterior displacement of barium-filled esophagus
√ posterior displacement of LUL bronchus

Left Ventricular Enlargement

Cause:

(a) pressure overload: hypertension, aortic stenosis
(b) volume overload: aortic or mitral regurgitation, VSD
(c) wall abnormalities: LV aneurysm, hypertrophic cardiomyopathy

◊ LV enlarges in posterior, inferior + leftward direction

PA CXR:

√ leftward displacement of downturned cardiac apex = left ventricular configuration
√ depression of left hemidiaphragm + gastric bubble (with diaphragmatic inversion)

LAT CXR:

√ increased convexity of posteroinferior cardiac margin
√ posterior cardiac margin projects > 1.8 cm posterior to IVC measured at a point 2 cm above intersection of IVC with right hemidiaphragm (Hofman-Rigler rule)

Flattening / Inversion of Interventricular Septum

= position determined by pressure difference between RV + LV
√ normally convex shape with slight right-sided bulge during ventricular filling (LV diastolic pressure > RV pressure)

(a) RV volume / pressure overload:
1. ASD
2. Acute / chronic cor pulmonale

(b) pericardial abnormality:
1. Cardiac tamponade (↑ pericardial pressure)
2. Constrictive pericarditis (↓ pericardial compliance)

Enlargement of Coronary Sinus

Conditions Causing RA Dilatation

1. Tricuspid stenosis / regurgitation
2. Right ventricular dysfunction (failure): CHF, cardiomyopathy, atrial fibrillation, atrioventricular node reentrant tachycardia
3. Severe pulmonary hypertension
4. Right atrial hypertension
5. Cardiac tamponade

Congenital Structural Anomaly

(a) increased volume of systemic venous blood
(1) persistent left SVC draining into coronary sinus
(2) interrupted IVC with hemiazygos continuation to a left SVC / hepatic veins connecting directly into coronary sinus

The coronary sinus dilates most commonly due to a left SVC draining into the coronary sinus!

(b) L-to-R shunt: oxygenated blood

› low-pressure shunt:
1. Interatrial shunt (= coronary sinus-ASD) LA → unroofed coronary sinus

An unroofed coronary sinus is a complete / partial wall defect partitioning the coronary sinus from the left atrium!

2. TAPVR

› high-pressure shunt:
3. Coronary arteriovenous fistula

Small Coronary Sinus

A. ACQUIRED
1. Atrial systole
2. Lipomatosis
3. Small heart
4. Stenosis

B. CONGENITAL
1. Atresia
2. Hypoplasia: corrected TGA
3. Unroofed coronary sinus
4. CHD: corrected TGA, tetralogy of Fallot, Ebstein

Neonatal Cardiac Failure

A. LEFT-SIDED OBSTRUCTIVE LESIONS
1. Segmental hypoplasia of aorta
2. Critical coarctation of the aorta
3. Aortic valve stenosis
4. Asymmetrical septal hypertrophy / hypertrophic obstructive cardiomyopathy
5. Mitral valve stenosis
6. Cor triatriatum

B. VOLUME OVERLOAD
1. Congenital mitral valve incompetence
2. Corrected transposition with left (= tricuspid) AV valve incompetence
3. Congenital tricuspid insufficiency
4. Ostium primum ASD

C. MYOCARDIAL DYSFUNCTION / ISCHEMIA
1. Nonobstructive cardiomyopathy
2. Anomalous origin of LCA from pulmonary trunk
3. Primary endocardial fibroelastosis
4. Glycogen storage disease (Pompe disease)
5. Myocarditis

D. NONCARDIAC LESIONS
1. AV fistulas: hemangioendothelioma of liver, AV fistula of brain, vein of Galen aneurysm, large pulmonary AV fistula
2. Transient tachypnea of the newborn
3. Intraventricular / subarachnoid hemorrhage

4. Neonatal hypoglycemia (low birth weight, infants of diabetic mothers)
5. Thyrotoxicosis (transplacental passage of LATS hormone)

Congestive Heart Failure & Cardiomegaly

mnemonic: Ma McCae & Co.

Myocardial infarction
anemia
Malformation
cardiomyopathy
Coronary artery disease
aortic insufficiency
effusion
Coarctation

Congenital Cardiomyopathy

mnemonic: CAVE GI

Cystic medial necrosis of coronary arteries
Aberrant left coronary artery / Absent coronary artery
Viral myocarditis
Endocardial fibroelastosis
Glycogen storage disease (Pompe)
Infant of diabetic mother / Ischemia

Delayed Myocardial Hyperenhancement on MRI

A. Ischemic heart disease (MI)
B. Nonischemic
    1. Dilated / hypertrophic cardiomyopathy
    2. Myocarditis
    3. Sarcoidosis
    4. Systemic sclerosis
    5. Endocardial fibroelastosis
    6. Fabry disease
    7. Chagas disease
    8. RV pressure overload
    9. Amyloidosis
    10. Cardiac transplantation
    11. Uremia

Subendocardial Enhancement

1. Ischemic heart disease
2. Amyloidosis
3. Löffler endocarditis (hypereosinophilic syndrome)

Transmural Enhancement

1. Ischemic heart disease
2. Myocarditis

Subepicardial Enhancement

1. Myocarditis

Mesocardial Enhancement

= delayed enhancement in midinterventricular septum

1. Hypertrophic cardiomyopathy
2. Dilated cardiomyopathy

Nodular Patchy Enhancement

1. Amyloidosis
2. Myocarditis
3. Cardiac sarcoidosis

Cardiac Accumulation of FDG

Myocardial Uptake

1. Physiologic FDG uptake ← depending on levels of blood glucose and free fatty acids
   √ none / diffuse / focal uptake in walls of ventricles
   Remedy: uptake suppressed by low-carbohydrate dinner followed by 12-hour fast
2. Drug interaction
   (a) lowering uptake:
   › Bezafibrate for treating hyperlipidemia
   › Levothyroxine (thyroid hormone)
   (b) increasing uptake:
   › benzodiazepines: Diazepam
3. Sarcoidosis
   √ hypermetabolic myocardial foci in nonperivascular distribution
4. Biventricular chemotherapy-induced cardiomyopathy
   √ increased metabolic activity in ventricular myocardium
5. Ventricular enlargement associated with systemic + pulmonary hypertension and valvular heart disease
   √ diffuse uniform increase in myocardial activity
6. Inflammatory myocarditis
7. Endocarditis ← infected valve
8. Neoplasia: sarcoma, metastasis (breast, lung, melanoma, lymphoma), myxoma
9. Coronary artery disease ← shift from fatty acid metabolism to glucose utilization ← ischemia

ATRIAL UPTAKE

1. Atrial fibrillation
2. Radiofrequency ablation for atrial fibrillation
3. Crista terminalis: ? physiologic

Pericardial Uptake

1. Post–radiation pericarditis
2. Malignant pericardial effusion

3. Epipericarditis
4. Lipomatous hypertrophy interatrial septum

CARDIAC TUMOR

◊ Extremely rare; often asymptomatic until very large!

- symptoms of cardiopulmonary diseases:
  - congestive heart failure: dyspnea, orthopnea, peripheral edema, paroxysmal nocturnal dyspnea
  - palpitations, heart murmur, cough, chest pain
- symptoms caused by peripheral emboli to cerebral / systemic / coronary circulation: syncope
- weight loss, fever, malaise

Location: intracavitary (obstruction, emboli), intramural (arrhythmia), pericardial (tamponade)

CXR:

√ cardiomegaly, pericardial effusion
√ signs of CHF
√ abnormal cardiac contour
√ pleural effusion

DDx: thrombus, pericardial and bronchogenic cyst, intrathoracic neoplasm, gastrointestinal hernia

Primary Heart Tumor

Prevalence: 0.002–0.250%; 0.001–0.030% (autopsy series)

Benign Heart Tumor in Adults (75%)

◊ More common than malignant neoplasms

1. Myxoma (with almost 50% the most common primary cardiac tumor; 25% of all cardiac tumors)
2. Papillary fibroelastoma (10% of all primary cardiac tumors; with 75% most common valvular tumor)
3. Lipoma (10% of all cardiac tumors)
4. Hydatid cyst (uncommon):
   √ localized bulge of left cardiac contour
   √ curvilinear / spotty calcifications (resembling myocardial aneurysm)

Cx: may rupture into cardiac chamber / pericardium

Malignant Heart Tumors (25%)

Prevalence: 25% of all cardiac tumors in adults;
10% of all cardiac tumors in children

1. Sarcomas
2. Rhabdomyosarcoma
3. Lymphoma (rare)
4. Pericardial mesothelioma
5. Malignant teratoma
6. Multiple cardiac myxomas

Secondary (Metastatic) Heart Tumor

◊ Most common cause of a neoplastic cardiac mass!

Age: typically > 60 years with disseminated tumor

Prevalence: metastatic÷primary disease = 30÷1; 10–12% of cancer patients develop metastases to the heart (autopsy)

Origin: lung, breast, esophagus, melanoma, lymphoma, leukemia

◊ Melanoma has the highest prevalence of cardiac seeding of any neoplasm!

- asymptomatic (frequently)
- arrhythmia (most common clinical sign)
- chest wall pain ← transient ischemic attack
- CHF (shortness of breath, fatigue, peripheral edema)

Site:

(a) peri- / epicardium (most common): lung > breast > lymphoma > leukemia > breast > esophagus

(b) myocardium: malignant melanoma; secondary extension to myocardium from epicardium

◊ Most common sites for myocardial lesions are LV free wall + interventricular septum (= greatest myocardial mass)

(c) endocardial / intracavitary (in only 5%)

(d) transvenous extension: RCC, hepatoma, adrenal adenocarcinoma

√ nonspecific imaging features

ECHO: iso- / hyperechoic

US/CT/MR: enhancement

MR: T1-hypointense + T2-hyperintense

Exception: T1-hyperintensity of melanoma, hemorrhagic lesion

Prognosis: death (⅓) ← cardiac tamponade / CHF / coronary artery invasion, sinoatrial node invasion

Cavoatrial Tumor Extension

= neoplasm arising in infradiaphragmatic sites

1. Hepatocellular carcinoma
   extension into hepatic veins / IVC (7.5%), into RA (4%)
2. RCC
   invasion of renal vein / IVC (5–15%), into RA (1%)
4. Wilms tumor
   into renal veins / IVC (4–10%), into RA (1%)
5. Adrenocortical carcinoma
6. Uterine leiomyoma
7. Leiomyosarcoma of IVC
8. Osteogenic sarcoma of pelvis

N.B.: sudden death may occur when tumor in RA intermittently obstructs tricuspid valve leading to low cardiac output

Congenital Cardiac Tumor

The majority of primary cardiac tumors in children are benign, rhabdomyoma and fibroma accounting

for 70%!

Prevalence: 1÷10,000

1. Rhabdomyoma (58%): usually multiple masses
2. Teratoma (20%): intrapericardiac, extracardiac
   √ multicystic mass
3. Cardiac fibroma (12%)
4. Cardiac hemangioma

Cardiac Tumor by Location

A thrombus is the most common cause of a cardiac mass!

A. ENDOCARDIAL / INTRACAVITARY
   1. Myxoma
   2. Thrombus
   3. Myofibroblastic sarcomas (MFH, leiomyo- sarcoma, fibrosarcoma, myxosarcoma)

B. VALVULAR
   1. Papillary fibroelastoma
   2. Valve vegetations
   3. Thrombus
   4. Myxoma

C. MYOCARDIAL / INTRAMURAL
   1. Rhabdomyoma of heart
   2. Cardiac fibroma

D. ENDO- / MYO- / EPICARDIAL
   1. Cardiac lipoma
   2. Cardiac sarcoma
   3. Lymphoma of heart

Left Atrial Mass

1. Myxoma
2. Thrombus
3. Septal lipoma

Right Atrial Mass

1. Thrombus
2. Myxoma
3. Hypernephroma
4. Eustachian valve
5. Chiari network
6. Angiosarcoma

Left Ventricular Mass

1. Thrombus
2. Papillary muscle
3. Rhabdomyoma
4. Metastasis

5. Fibroma

Right Ventricular Mass

1. Thrombus
2. Rhabdomyoma
3. Secondary deposit
4. Angiosarcoma

Mitral Valve Mass

(a) frequent

1. **Idiopathic mitral annular calcification** (most common)
   Cx: caseous degeneration of annulus
   CT:
   √ well-defined peripherally calcified mass
   √ central region of variable attenuation
   MR:
   √ hypointense mass on all sequences
2. Vegetation, usually infective (2nd most common) ← rheumatic disease / mitral valve prolapse / mitral valve prosthesis
3. Thrombus
4. Papillary fibroelastoma

(b) rare:

1. Myxoma
2. Lymphoma
3. Sarcoma
4. Metastasis

Myocardial Fat

= focal area of attenuation < 20 HU / fat-suppression on MR

1. Physiologic fat: ↑ in degree with age
   Prevalence: 16–43% on CT; 85% on autopsy; ↑ with age
   Location: anterolateral free wall + RVOT
   Site: outer half of RV wall → extension toward endocardium sparing subendocardium
   √ increase of total myocardial thickness: RV > LV

Physiologic RV myocardial fat is most frequent on anterolateral free wall, i.e. basal superior wall > middle superior wall > RVOT!

2. Healed myocardial infarct
   = replacement of scar by fat; usually > 6 months after MI
   Prevalence: 22–62% with history of MI
   Location: subendocardial region of culprit coronary a.
   √ thin linear / curvilinear configuration
3. Arrhythmogenic RV cardiomyopathy
4. Cardiac lipoma
5. Lipomatous hypertrophy of interatrial septum
6. Tuberous sclerosis complex

7. Dilated cardiomyopathy

CARDIAC CALCIFICATIONS

Detected by:

fluoroscopy (at low-beam energies ≤ 75 kVp is 57% sensitive) < digital subtraction fluoroscopy < conventional CT < ultrafast CT (96% sensitive)

@ Coronary arteries

@ Cardiac valves

◊ Valvar calcification means stenosis — its amount is proportionate to degree and duration of stenosis!

1. **Aortic valve**

◊ Valve calcium best seen on lateral view!

◊ Good correlation between amount of calcium and degree of stenosis:

› heavy calcification = significant stenosis

› no calcification = aortic stenosis unlikely

Cause: congenital bicuspid valve (70–85%) > atherosclerotic degeneration > rheumatic aortic stenosis (rare), syphilis, ankylosing spondylitis

Location: above + anterior to a line connecting carina + anterior costophrenic angle (lateral view)

(a) **Congenital bicuspid aortic valvular stenosis**

• calcium first detected at an average age of 28 years

◊ In patients < 30 years aortic valve calcifications are mostly due to a bicuspid aortic valve!

√ usually extensive cluster of heavy densely calcific deposits:

√ nearly circular calcification with interior linear bar (DIAGNOSTIC)

√ poststenotic dilatation of ascending aorta

(b) **Isolated rheumatic aortic stenosis**

• calcium first detected at an average age of 47 years

◊ In patients 30–60 years of age aortic valve calcification suggests rheumatic valve disease!

√ cluster of heavy dense calcific deposits without bicuspid contour

(c) **Degenerative aortic stenosis**

• calcium first detected at an average age of 54 years

◊ In patients > 65 years aortic valve calcification in 90% due to atherosclerosis!

√ curvilinear shape of calcium outlining tricuspid leaflets

√ diffuse dilatation + tortuosity of aorta (NO poststenotic dilatation)

2. **Mitral valve** (MV)

Cause: rheumatic heart disease (virtually always), infected endocarditis, tumor attached to mitral valve, mitral valve prolapse

Location: inferior to a line connecting carina + anterior costophrenic angle (on lateral view)

• calcium first detected in early 30s when patients become overtly symptomatic

◊ a severely calcified MV is usually stenotic, but MV stenosis frequently exists without

calcium
√ delicate calcification similar to coronary arteries (DDx: calcium in RCA / LCX)
√ superior-to-inferior motion

3. **Pulmonic valve**
Cause: tetralogy of Fallot, pulmonary stenosis, atrial septal defect
√ calcific pattern similar to calcified mitral valve

4. **Tricuspid valve** (extremely rare)
Cause: rheumatic heart disease, septal defect, tricuspid valve defect, infective endocarditis

@ Annulus
= valve rings serve as fibrous skeleton of the heart for attachment of myocardial fibers + cardiac valves

1. **Mitral annulus**
Cause: degenerative (physiologic in elderly)
Age: > 65 years; M÷F = 1÷4
May be associated with: mitral valve prolapse
Commonly associated with:
aortic valve calcium (= aortic stenosis), hypertension, hypertrophic cardiomyopathy; NOT MV dysfunction
√ dense bandlike calcification starting at posterior aspect + progressing laterally frequently forming a "reversed C" / "O" / "U" / "J"
Cx: mitral insufficiency (← impaired anterior mitral leaflet); atrial fibrillation; heart block (← infiltration into posterior wall conduction pathway)
Prognosis: doubles risk of stroke

2. **Aortic annulus**
√ usually in combination with degenerative aortic valve calcification → NO effect on valve function

3. **Tricuspid annulus**
Associated with: long-standing RV hypertension
Location: right AV groove
√ bandlike C-shaped configuration

@ **Pericardium**
Cause: idiopathic pericarditis, rheumatic fever (5%), TB, viruses, uremia, trauma, radiotherapy to mediastinum
Location: calcification over less pulsatile right-sided chambers along diaphragmatic surface, atrioventricular grooves, pulmonary trunk
√ clumpy amorphous calcium deposits, frequently in atrioventricular groove
√ diffuse eggshell calcification sparing LA (not covered by pericardium)
Cx: constrictive pericarditis
◊ 50% of patients with constrictive pericarditis show pericardial calcifications!

@ **Myocardium**
Cause: infarction, aneurysm, rheumatic fever, myocarditis
Frequency: in 8% post myocardial infarction; M > F
Location: apex / anterolateral wall of LV (coincides with LAD vascular distribution +

typical location of LV aneurysms)

√ thin curvilinear contour outlining the aneurysm

√ shaggy laminated calcification suggests calcification of associated mural thrombus

√ coarse amorphous calcifications caused by trauma, cardioversion, infection, endocardial fibrosis

@ **Interventricular septum**

Location: triangular fibrous area between mitral + tricuspid annuli (= trigona fibrosa) representing the basal segment of interventricular septum, closely related to bundle of His

Always associated with:

heavy calcification of mitral annulus / aortic valve

Cx: heart block

@ **Left atrial wall**

Cause: rheumatic endocarditis

(a) diffuse sheetlike form

• patient usually in CHF + atrial fibrillation

√ curvilinear calcification sparing interatrial septum + posterolateral wall on right side

√ shaggy nodular deposits in atrial appendage

Cx: mural thrombus formation + emboli

◊ LA wall calcification indicates atrial fibrillation!

(b) localized form

√ nodular calcific scar in posterior wall (= MacCallum patch) ← injury from a forceful jet in mitral valve insufficiency

[William George MacCallum (1874–1944), one of the first graduates of the Johns Hopkins Medical School in 1897, professor of pathology at Columbia University and Johns Hopkins University]

@ **Cardiac tumor**

atrial myxoma (in 5–10% calcified), rhabdomyoma, fibroma, angioma, osteosarcoma, osteoclastoma

@ **Endocardium**

Cause: cardiac aneurysm, thrombus, endocardial fibroelastosis

@ **Pulmonary artery**

Cause: severe precapillary arterial pulmonary hypertension (pHTN), syphilis

@ **Ductus arteriosus**

(a) in adults: indicates patency of ductus with associated long-standing precapillary arterial pHTN

(b) in children: ductus likely closed

√ calcium deposition in ligament of Botallo

[Leonardo Botallo (1530–1600), Italian surgeon and anatomist in the French royal medical service in Paris]

Coronary Artery Calcification

◊ The amount of coronary calcification correlates with the extent of atherosclerosis!

◊ The absence of coronary calcifications implies the absence of angiographically significant coronary vessel stenosis!

Cause: (1) Arteriosclerosis of intima
(2) Mönckeberg medial sclerosis (exceedingly rare)

Histo: calcified subintimal plaques

Pathophysiology:
injury to endothelium → allows circulating histiocytes to lodge in vessel wall → transformation into macrophages; these accumulate lipids ("fatty streaks" beneath surface endothelium); lipids calcify; the thin fibrous cap overlying lipid deposits may rupture allowing circulating blood to mount a thrombogenic reaction resulting in narrowing of lumen

◊ Calcium is deposited as calcium hydroxyapatite in hemorrhagic areas within atheromatous plaques!

Location: **"coronary artery calcification triangle"**
= triangular area along mid left heart border, spine, and shoulder of LV containing calcifications of left main coronary artery + proximal portions of LAD + LCX

Frequency (autoptic): LAD (93%), LCX (77%), main LCA (70%), RCA (69%)

CXR (detection rate up to 42%):
√ parallel calcified lines (lateral view)
◊ Indicates more severe coronary artery disease

Fluoroscopy: (promoted as inexpensive screening test)
(a) asymptomatic population
› calcifications in 34% in asymptomatic male individuals
› in 35% of patients with calcifications exercise test will be positive (without calcifications only in 4% positive)
› calcifications indicate > 50% stenosis (72–76% sensitive, 78% specific); frequency of coronary artery calcifications with normal angiogram increases with age; predictive value in population < 50 years as good as exercise stress test
(b) symptomatic population
› in 54% of symptomatic patients with ischemic heart disease
◊ In symptomatic patients 94% specificity for obstructive disease (> 75% stenosis) of at least one of the three major vessels!

CT:
(a) electron beam: threshold of +130 HU
(b) spiral CT: threshold of +90 HU

Clinical outcome:
(a) for coronary calcifications detected at fluoroscopy: 5.4% event risk at 1 year (vs. 2.1% without calcification)
(b) for electron beam CT a calcification score of ≥ 100 is highly predictive in identifying patients with events

Prognosis: 58% (87%) 5-year survival rate with (without) calcifications

PERICARDIUM

Pericardial Compressive Syndromes

1. Cardiac tamponade
2. Constrictive pericarditis ← loss of elasticity ← scarring
3. Concomitant effusive-constrictive pericarditis
   = constrictive physiology + coexisting pericardial effusion
   • central venous pressure remains elevated after drainage of pericardial effusion

Pericardial Thickening

= pericardial thickness ≥ 4 mm

◊ Pericardial thickening / calcifications are NOT DIAGNOSTIC of constrictive pericarditis! It requires symptoms of physiologic constriction / restriction.

A. PERICARDITIS WITH RESTRICTION
   • clinical findings of heart failure
   1. Constrictive pericarditis

B. PERICARDITIS WITHOUT RESTRICTION
   • NO clinical findings of heart failure
   √ enhancement of thickened pericardium indicates inflammation
   1. Acute pericarditis
   2. Uremia
   3. Rheumatic heart disease
   4. Rheumatoid arthritis
   5. Sarcoidosis
   6. Mediastinal irradiation

Pericardial Effusion

= pericardial fluid > 50 mL

• dyspnea, fatigue, symptoms of cardiac tamponade (50%)

Etiology:

A. SEROUS FLUID = transudate
   congestive heart failure, hypoalbuminemia (liver insufficiency), renal failure, irradiation, Dressler syndrome, postpericardiotomy syndrome, myxedema, drug-induced pericarditis

B. BLOOD = hemopericardium
   (a) iatrogenic: cardiac surgery / catheterization, anticoagulants, chemotherapy, radiation
   (b) trauma: penetrating / nonpenetrating
   (c) acute myocardial infarction / rupture of free wall
   (d) aneurysm rupture of left ventricle / coronary artery
   (e) rupture of ascending aorta / pulmonary trunk / ruptured aortic dissection
   (f) coagulopathy
   (g) neoplasm (30%): mesothelioma, sarcoma, teratoma, fibroma, angioma, metastasis (lung, breast, lymphoma, leukemia, melanoma)

C. LYMPH
   neoplasm, congenital, cardiothoracic surgery, obstruction of hilum / SVC

D. FIBRIN = exudate
(a) infection: viral, pyogenic, tuberculous
(b) renal insufficiency: 18% in acute uremia; 51% in chronic uremia; dialysis patient
(c) collagen vascular disease: SLE, rheumatoid arthritis, acute rheumatic fever
(d) hypersensitivity: Dressler syndrome

mnemonic: CUM TAPPIT RV
Collagen vascular disease
Uremia
Metastasis
Trauma
Acute myocardial infarction
Purulent infection
Post MI syndrome
Idiopathic
Tuberculosis
Rheumatoid arthritis
Virus

CXR:
√ normal with fluid < 250 mL / in acute pericarditis
√ "water bottle configuration" = symmetrically enlarged cardiac silhouette
√ loss of retrosternal clear space
√ "fat-pad" sign = separation of retrosternal from epicardial fat line > 2 mm (in 15%) by water density
√ rapidly appearing cardiomegaly + normal pulmonary vascularity
√ "differential density" sign = increase in lucency at heart margin ← slight difference in contrast between pericardial fluid + heart muscle
√ diminished cardiac pulsations

CT:
√ effusion of greater than water density = hemopericardium, malignancy, purulent effusion, hypothyroid state
√ effusion of low attenuation = chylopericardium
√ pericardial thickening > 4 mm suggests pericarditis

MR:
√ effusion hypointense on T1WI + hyperintense on T2WI = simple transudate
√ effusion hyperintense on T1WI + hypointense on T2WI = proteinaceous / hemorrhagic fluid
√ septations + debris + pericardial thickening = complex effusion as in inflammatory pericarditis of uremia / TB

ECHO:
√ separation of epi- and pericardial echoes extending into diastole (rarely behind LA)
√ volume estimates by M-mode:
(a) separation only posteriorly = < 300 mL
(b) separation throughout cardiac cycle = 300–500 mL
(c) plus anterior separation = > 1000 mL

Pneumopericardium

Etiology: shearing mechanism of injury of the heart during blunt trauma

Path: tear in fibrous pericardium, usually along course of phrenic nerve, allows pneumomediastinal air to enter

√ thick shaggy soft-tissue density of fibrous pericardium separated by air from cardiac density

√ air limited to distribution of pericardial reflection

Tension Pneumopericardium

= intrapericardial pressure > 265 mm H_2O (normal intrapericardial pressure = 50–100 mm H_2O)

◊ MEDICAL EMERGENCY!

Cause: blunt / penetrating trauma, iatrogenic, positive pressure ventilation (barotrauma), pericarditis with gas-forming organisms, direct extension of inflammatory process from adjacent structures, fistulous communication with air-containing structures, extension of pneumomediastinum

- chest pain, dyspnea, cyanosis, hypotension, tachycardia
- cardiac tamponade + hemodynamic compromise

CXR:

√ "halo" sign = continuous rim of air outlining the heart borders

√ "small heart" sign = sudden substantial decrease in size of cardiac silhouette

CT:

√ substantial amount of air in pericardial cavity

√ compression + displacement of heart:

√ collapse of heart chambers

√ flattening of anterior heart border

√ distension of IVC

Rx: needle pericardiocentesis / placement of drain

Pericardial disease

A. CONGENITAL
   1. Pericardial cyst / diverticulum
   2. Pericardial defect

B. ACQUIRED
   1. Pericardial effusion
   2. Cardiac tamponade
   3. Inflammatory pericarditis
   4. Constrictive pericarditis

C. PERICARDIAL PSEUDOMASS

cystic lesion, hematoma, gossypiboma (= foreign body granuloma around surgical sponge), complex organized effusion, abundant epicardial fat, epicardial fat necrosis

D. TRUE PERICARDIAL MASS

Pericardial neoplasms are rarely asymptomatic usually presenting with nonspecific diverse symptoms:

- exertional dyspnea, chest pain, cough, palpitations

- fatigue, night sweats, fever
- facial / lower-extremity edema

due to: pericarditis, pericardial effusion, invasion of adjacent structures

(a) **Primary pericardial tumor** (extremely rare)
1. Pericardial mesothelioma
2. Pericardial sarcoma: angio-, lipo-, rhabdomyo-, synovial sarcoma, undifferentiated sarcoma
3. Pericardial lymphoma
4. Pericardial teratoma
5. Pericardial fibroma, hemangioma, lipoma

(b) Secondary pericardial tumor (in 10–12%):
› direct invasion by neoplasm of lung, mediastinum (lymphoma), heart (angiosarcoma)
› hematologic spread from malignant melanoma, lymphoma, breast cancer
› venous extension from renal cell carcinoma, HCC

Cx: (1) invasion of mediastinal structures
(2) regional / distant metastases
(3) pericardial effusion
(4) cardiac tamponade
(5) compression of vascular structures / cardiac chambers
(6) encasement of vital structures
(7) involvement of coronary arteries
(8) myocardial infarction
(9) diastolic dysfunction
(10) constrictive physiology

PULMONARY VASCULARITY

Normal Pulmonary Vasculature

A. VASCULAR DISTRIBUTION
√ pulmonary vessels within upper perihilum approximate ⅓ of total vascularity
√ pulmonary vessels within lower perihilum approximate ⅔ of total vascularity

B. VASCULAR TAPERING
√ pulmonary vessels taper near transition of middle ⅓ to outer ⅓ of lung

C. VASCULAR CALIBER
√ straight / slightly concave main pulmonary artery contour (mild convexity is normal in young females)
√ pulmonary trunk measures < 4.5 cm (leftward distance from vertical line at carina to most lateral aspect of main pulmonary artery contour)
√ right interlobar / intermediate pulmonary artery measures 10–15 (9–14) mm in males (females) on PA radiographs
√ pulmonary vessel size < 1–2 mm in extreme lung periphery
√ artery within 1st anterior intercostal space measure ≤ 3 mm

CT:

√ upper limits of normal for main pulmonary artery = 3 cm

Normal Pulmonary Vascularity & Normal-sized Heart

mnemonic: MAN

Myocardial ischemia
Afterload (= pressure overload problems)
Normal

Increased Pulmonary Vasculature

A. OVERCIRCULATION

= shunt vascularity = arterial + venous overcirculation

(a) congenital heart disease (most common)
  (1) L-R shunts
  (2) Admixture cyanotic lesions

(b) high-flow syndromes
  (1) Thyrotoxicosis
  (2) Anemia
  (3) Pregnancy
  (4) Peripheral arteriovenous fistula

√ diameter of right descending pulmonary artery larger than trachea just above aortic knob

√ increased size of vessels (veins + arteries) larger than accompanying bronchus (= "kissing cousin" sign), best seen just above hila on AP view

Evaluation of Pulmonary Vasculature on ERECT Chest Film

	Normal	*PAH*	*PVH*	*Overload*
Distribution (UL÷LL)	1÷2	1÷2	1÷1 or 1÷2	1÷1
Vessel tapering	middle–outer 1/3	variably pruned	outer third	outer third
Vascular caliber		increased	increased	increased
Artery-to-bronchus ratio:				
upper lung	0.85 ± 0.15		1.50 ± 0.25	1.62 ± 0.31
lower lung	1.34 ± 0.25		0.87 ± 0.20	1.56 ± 0.28
Vessel margins (edema)	sharp	sharp	obscured	obscured

√ enlarged hilar vessels (lateral view)

√ visualization of vessels below 10th posterior rib

B. PULMONARY VENOUS HYPERTENSION

√ redistribution of flow (not seen in younger children)

√ indistinctness of vessels with Kerley lines (= interstitial edema)

√ fine reticulated pattern

√ alveolar edema

C. PRECAPILLARY HYPERTENSION
- √ enlarged main + right and left pulmonary arteries
- √ abrupt tapering of pulmonary arteries

D. PROMINENT SYSTEMIC / AORTOPULMONARY COLLATERALS
1. Tetralogy of Fallot with pulmonary atresia (= pseudotruncus)
2. VSD + pulmonary atresia (single ventricle, complete transposition, corrected transposition)
3. Pulmonary-systemic collaterals
   - √ coarse vascular pattern with irregular branching arteries (from aorta / subclavian arteries)
   - √ small central vessels despite apparent ↑ in vascularity

Decreased Pulmonary Vascularity
= obstruction to pulmonary flow
- √ vessels reduced in size and number
- √ hyperlucent lungs
- √ small pulmonary artery segment + hilar vessels

PULMONARY ARTERY

Invisible Main Pulmonary Artery
A. UNDERDEVELOPED = RVOT obstruction
1. Tetralogy of Fallot
2. Hypoplastic right heart syndrome (tricuspid / pulmonary atresia)

B. MISPLACED PULMONARY ARTERY
1. Complete transposition of great vessels
2. Persistent truncus arteriosus

Major Aortopulmonary Collateral Arteries
= systemic pulmonary supply via aortic branches
1. Pulmonary atresia with VSD = severe form of tetralogy of Fallot
2. Tetralogy of Fallot
3. Transposition of great arteries
4. Double-outlet right ventricle
5. Truncus arteriosus

Decreased Diameter of Pulmonary Artery
1. Lung cancer
   - ◊ Tumor extending > 180° of arterial circumference of main pulmonary artery indicates unresectability!
2. Mediastinal fibrosis
3. Takayasu arteritis
4. Chronic thromboembolic disease

Unequal Pulmonary Blood Flow

1. Tetralogy of Fallot
   √ diminished flow on left side (hypoplastic / stenotic pulmonary artery in 40%)
2. Persistent truncus arteriosus (esp. type IV)
   √ diminished / increased blood flow to either lung
3. Pulmonary valvular stenosis
   √ increased flow to left lung ← jet phenomenon

Dilatation of Pulmonary Artery

1. Idiopathic dilatation of pulmonary trunk
2. Pulmonic valve stenosis
   √ poststenotic dilatation of trunk + left pulmonary artery
3. Pulmonary regurgitation
   (a) severe pulmonic valve insufficiency
   (b) absence of pulmonic valve (may be associated with tetralogy)
4. Congenital L-to-R shunts
5. Pulmonary arterial hypertension
6. Aneurysm: mycotic / traumatic
7. Intravascular pulmonary metastases

Filling Defect in Pulmonary Artery

1. Thromboembolism (99%)
2. Nonthrombotic embolus: fat droplets, bubbles of air / nitrogen, tumor, foreign bodies (talc, polymethylmethacrylate particles)
   ◊ Particles mostly too small to be visualized
3. Primary sarcoma

PULMONARY VEIN

Congenital Anomalies of Pulmonary Veins

A. ANOMALIES IN NUMBER
   1. Anomalous unilateral single pulmonary vein = **meandering pulmonary vein**
      √ serpentine tubular opacity adjacent to lung hilum
      DDx: scimitar syndrome, AVM, lung nodule

B. ANOMALIES IN DIAMETER
   2. Congenital unilateral pulmonary vein stenosis / atresia
      √ small lung with ipsilateral mediastinal deviation
      √ reticular opacities with Kerley B lines
      DDx: pulmonary neoplasm, fibrosing mediastinitis
   3. Pulmonary vein varix

C. ANOMALIES IN DRAINAGE
   4. TAPVR
   5. PAPVR
   6. Scimitar syndrome
   7. Sinus venosus defect
   8. Malposition of septum primum

9. Cor triatriatum

Pulmonary Vein Stenosis / Obstruction

Mechanism: extrinsic compression / invasion

1. Radiofrequency ablation for atrial fibrillation (1–10%)
2. Surgery: heart surgery, correction of APVR, lung transplantation
3. Neoplastic infiltration: lung primary, atrial tumor, primary sarcoma
4. Fibrosing mediastinitis
5. Benign inflammatory process: sarcoidosis, tuberculosis

Pulmonary Vein Calcification

1. Rheumatic mitral valve disease (long-term): associated with atrial fibrillation, considerable LA dilatation, high prevalence of dyspnea, female predominance
2. Chronic renal failure: (= deposits of extraskeletal metastatic calcium) associated with cardiac arrhythmia

PULMONARY HYPERTENSION (pHTN)

= sustained mean pulmonary arterial pressure of ≥ 25 mmHg at rest / > 30 mmHg with exercise
= pulmonary capillary wedge pressure ≤ 15 mmHg determined by right heart catheterization

Right heart catheterization is the reference standard for pulmonary HTN because it enables direct measurement of pulmonary pressure, resistance, and cardiac output!

Normal: resting mean pulmonary artery pressure ≤ 20 mmHg

Cause: elevated precapillary pulmonary resistance + normal pulmonary venous pressure (= pulmonary wedge pressure ≤ 15 mmHg)

Pathophysiology:

reduction in cross-sectional area of the pulmonary vascular bed → chronic elevation in pulmonary arterial pressure → RV hypertrophy → RA dilatation → abnormal septal motion impairing LV function → RV dilatation → tricuspid regurgitation → decreased cardiac output → right heart failure

In severe pulmonary hypertension the hypertrophied RV is of spherical shape with a greater cross-sectional area than the LV resulting in abnormal septal motion that impairs left ventricular function.

◊ The most useful noninvasive parameters to assess RV function: RV volume + RV ejection fraction measured at cardiac MR imaging!

Histo: intimal cellular proliferation + medial hypertrophy in walls of muscular arteries

Classification by anatomic level:

A. PRECAPILLARY CAUSE

= changes limited to pulmonary arterial circulation @ level of muscular arteries

1. Chronic thromboembolic pulmonary disease as a complication of single or multiple undiagnosed (? %) / diagnosed (4%) acute symptomatic pulmonary thromboembolic events
2. In-situ pulmonary arterial thrombotic disease (polycythemia, sickle-cell disease)
3. Widespread pulmonary embolism by intravascular
   (a) malignant cells (= tumor emboli) in cancer of kidney, liver, stomach, breast,

prostate, ovary, malignant melanoma, choriocarcinoma, right atrial myxoma

(b) parasites (= parasitic emboli), commonly of Schistosoma mansoni

(b) foreign material, eg. talcosis of IV drugs

◊ Fat, amniotic fluid, septic emboli rarely produce clinically significant PAH!

4. Pulmonary vasculitis: eg, collagen vascular disease (especially scleroderma), CREST, HIV
5. Longstanding cardiac L-to-R shunt = Eisenmenger syndrome with reversal into R-to-L shunt: VSD (in 10%), ASD (in 5%), PDA, TGV
6. Alveolar hypoventilation syndromes
7. Primary pHTN (idiopathic)

B. PULMONARY PARENCHYMAL DISEASE

= mechanical interference with small pulmonary arteries (classified under precapillary cause)

(a) hypoxic lung disease:

1. Chronic obstructive pulmonary disease
2. Interstitial pulmonary fibrosis (in 46% PAH)
3. Ventilatory failure ← thoracic cage deformity (kyphoscoliosis, thoracoplasty, restrictive pleural disease), diaphragmatic disorder, neuromuscular disease, spinal cord injury

(b) connective tissue disorder:

1. Scleroderma (PAH in 12%)
2. CREST variant of scleroderma (calcinosis, Raynaud phenomenon, esophageal motility disorder, sclerodactyly, telangiectasia)
3. Polymyositis, dermatomyositis, systemic lupus erythematosus, rheumatoid arthritis

(c) infection:

1. HIV (6–12 x compared to general population)
2. Sarcoidosis
3. Tuberculosis

C. **P**OSTCAPILLARY CAUSE

= PULMONARY VENOUS HYPERTENSION

= findings located in pulmonary venous circulation + between capillary bed and left atrium

1. Elevated left atrial pressure: usually MV disease, chronic left heart failure, left atrial tumor / thrombus
2. Fibrosing mediastinitis → narrowing of pulmonary veins, which may also affect precapillary vessels
3. Pulmonary venoocclusive disease: idiopathic
4. Pulmonary capillary hemangiomatosis

• often not clinically recognized until advanced stage
• nonspecific symptoms: exertional dyspnea, fatigue, syncope

ECG with Doppler (79–100% sensitive, 68–98% specific):

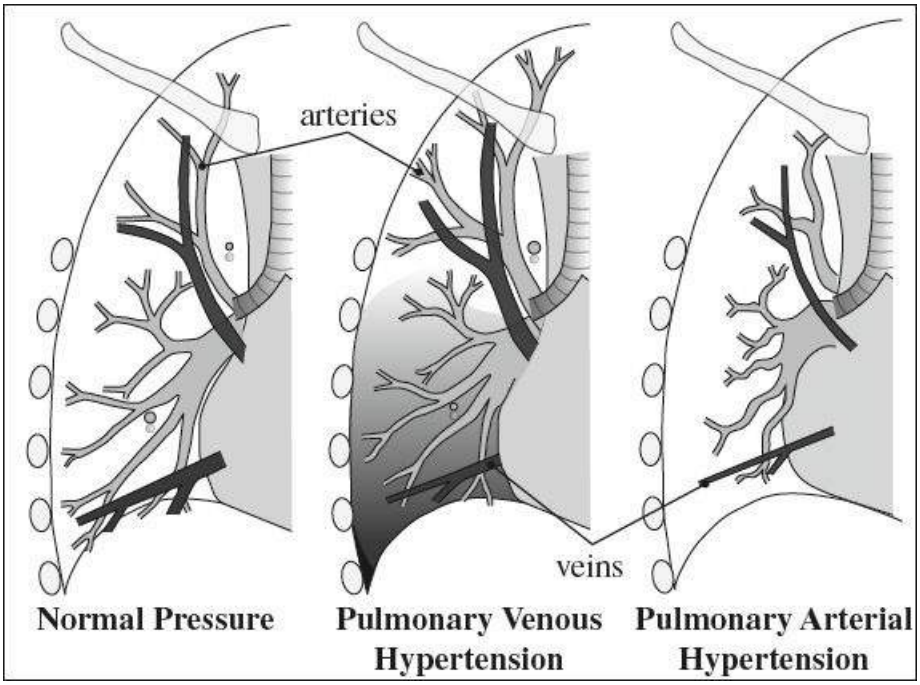
√ systolic pulmonary artery pressure
√ tricuspid regurgitant jet velocity

CXR:

√ may be normal in early stage
√ central pulmonary arterial dilatation
√ pruning of peripheral arteries
√ ↑ diameter of right interlobar artery: > 16 (> 15) mm in men (women) measured from its lateral margin to interlobar bronchus
√ ↓ retrosternal air space (LAT view) by RV enlargement

NUC (V/Q scan):

◊ A normal V/Q scan rules out chronic thromboembolic disease (modality of choice)!



√ normal / diffuse patchy perfusion defects in severe pHTN

CT pulmonary angiogram:

√ <u>vascular signs:</u>
- √ widest short-axis diameter of pulmonary trunk ≥ 29 mm (87% sensitive, 89% specific, 97% PPV) measured on transverse sections at level of PA bifurcation
  CAVE: in pulmonary fibrosis PA dilatation occurs without pHTN
- √ diameter ratio of distal pulmonary trunk to ascending aorta (measured at same level) > 1 (96% PPV, 92% specific) independent of systolic-diastolic variations with strong correlation in patients < 50 years
- √ diameter of main left + right pulmonary artery > 16 mm (= poor indicator of pulmonary arterial hypertension)
- √ segmental artery-to-bronchus ratio > 1 in 3 of 4 lobes (100% specific)
- √ "pruning" / tapering of peripheral pulmonary arteries
  = ↓ in caliber of smaller muscular arteries (← vasocon-striction) + disproportionate increase in caliber of central fibrous arteries (← sustained increase in flow by a factor of > 2)
- √ pulmonary veins

(a) small: ← precapillary pulmonary HTN
(b) enlarged: ← left-sided heart disease

√ enlargement of bronchial systemic arteries to > 1.5 mm: chronic thromboembolic pHTN (73%) > primary pHTN (14%)

√ vascular complications:

√ subpleural pulmonary infarcts (with elevated pulmonary venous pressure / underlying malignancy)

√ calcified plaques of central pulmonary arteries (PATHOGNOMONIC)

√ dissection / massive apposition thrombus of central pulmonary arteries

√ <u>lung parenchymal signs</u> (HRCT):

√ centrilobular ground-glass nodules (common in idiopathic pHTN)

Histo: cholesterol granulomas ← ingestion of RBCs by macrophages following repeated episodes of pulmonary hemorrhage

√ ***geographic mosaic pattern*** of lung attenuation ← regional variations in lung perfusion without dilatation of bronchi:

√ hyperdense areas containing large caliber vessels (= ↑ vessel diameter in areas of hyperattenuation)

N.B.: increase in density = increase in vessel caliber

√ hypodense areas containing small caliber vessels ← tapering of peripheral vessels in areas of hypoattenuation

◊ MOST COMMON + SPECIFIC SIGN of chronic pulmonary thromboembolism!

√ <u>mediastinal & cardiac signs:</u>

√ right heart hypertrophy + dilatation:

√ RV myocardial thickness > 4 mm

√ straightening / leftward bowing of interventricular septum

√ right heart dilatation = ratio of RV÷LV > 1÷1 at midventricular level on axial image

√ RA enlargement

√ dilatation of tricuspid valve annulus

√ dilatation of IVC + coronary sinus

√ reflux of contrast medium into IVC + hepatic veins (usefulness diminishes with injection rate > 3 mL/sec)

√ mild pericardial thickening + pericardial effusion

√ adenopathy + septal lines + ground-glass opacities suggestive of pulmonary venoocclusive disease

√ NO increase of pulsations in middle third of lung

Dana Point Classification of Pulmonary Hypertension (2008) *(based on similar pathophysiologic traits)*	
Group	*Description*
1	*Pulmonary arterial hypertension* (paHTN)
1.1	Idiopathic pulmonary arterial hypertension
1.2	Heritable
1.3	Drug / toxin induced
1.4	Associated with connective tissue disease, HIV infection, portopulmonary hypertension, CHD, schistosomiasis, chronic hemolytic anemia
1.5	Persistent pulmonary hypertension in newborn
1'	Pulmonary veno-occlusive disease / pulmonary capillary hemangiomatosis
2	pHTN due to *left heart failure*: systolic / diastolic dysfunction, valvular disease
3	pHTN due to *lung disease / hypoxia*: chronic obstructive pulmonary disease, interstitial lung disease, mixed restrictive + obstructive disease, sleep-disordered breathing, alveolar hypoventilation disorder, chronic high altitude exposure
4	pHTN due to *chronic thromboembolic disease*
5	pHTN with unclear *multifactorial* mechanisms: hematologic disorders (myeloproliferative disorder, splenectomy); systemic disorder (sarcoidosis, Langerhans cell histiocytosis, lymphangioleiomyomatosis, neurofibromatosis, vasculitis); metabolic disorder (glycogen storage disease, Gaucher disease, thyroid disorder); others (tumoral obstruction, fibrosing mediastinitis, chronic renal failure on dialysis)
': distinct category not completely separated from PAH but difficult to categorize	

√ functional parameter:
- √ reduced right pulmonary artery distensibility (= change in cross-sectional area between systole and diastole) of < 16.5% (86% sensitive, 96% specific) measured as (Areamax – Areamin) ÷ Area max • 100
  - ◊ Strong correlation with mean pulmonary artery pressure!
- √ decrease in RV ejection fraction

MR (steady-state free precession cine):
- √ RV hypertrophy (in almost 100% if RV systolic pressure exceeds 70 mmHg):
  - √ mean thickness of RV wall = 6 mm
  - √ ventricular mass index (= RV mass ÷ LV mass) > 0.6
- √ RV dilatation:
  - √ mean RV end-diastolic volume = 80 mL
  - √ tricuspid regurgitation ← dilatation of tricuspid valve annulus
- √ enlargement of RA + IVC + SVC
- √ septum straight / bowed leftward
- √ diminished RV ejection fraction (mean of 45%)

√ reduced distensibility of main pulmonary artery (mean of 8%)
√ systolic intraluminal signals in pulmonary arteries ← slow flow correlating with severity of PAH:
√ mean average velocity < 11.7 cm/sec (93% sensitive, 82% specific) on phase-contrast imaging

Angio (reference standard):
◊ Right heart catheterization = the only test that confirms pHTN!
√ direct measurement pulmonary pressure + resistance + cardiac output

Cx: central arterial thrombosis, premature atherosclerosis of central elastic + muscular pulmonary arteries, aneurysmal dissection of pulmonary arteries, hypertrophy + dilatation of right side of heart

Dx: clinical assessment of hemodynamic parameters, medical history, histologic findings

Pulmonary Arterial Hypertension (PAH)

= precapillary pHTN

Pathogenesis:

A. HYPERKINETIC CAUSES
1. L-to-R shunt
2. High cardiac output states: thyrotoxicosis, chronic anemia
3. Diffuse pulmonary arteriovenous shunts: hereditary hemorrhagic telangiectasia (Osler-Weber-Rendu), pregnancy, polysplenia syndrome, liver cirrhosis, complex cardiac malformations

B. OBLITERATIVE CAUSES
(a) vascular = precapillary pHTN:
1. Primary plexogenic pulmonary arteriopathy = Primary pHTN
2. Arteritis (eg, Takayasu)
3. Embolization
› chronic thromboembolic disease
› tumor
√ lymphangitic carcinomatosis
› parasites, eg, schistosomiasis
√ hepatosplenomegaly
› talc crystals
√ micronodular opacities
√ perihilar fibrotic masses
4. Persistent fetal circulation
5. Pulmonary capillary hemangiomatosis

(b) pleuropulmonic disease
1. Chronic interstitial lung disease = cor pulmonale:
COPD, emphysema, chronic bronchitis, asthma, bronchiectasis, malignant infiltrate, granulomatous disease, cystic fibrosis, end-stage fibrotic lung, S/P lung resection, idiopathic hemosiderosis, alveolar proteinosis, alveolar microlithiasis
2. Pleural disease + chest deformity: fibrothorax, thoracoplasty, kyphoscoliosis

(c) vasoconstriction

1. Chronic alveolar hypoxia
   = hypoxic pulmonary arterial hyperperfusion:
   chronic high altitude; sleep apnea; chronic hypercapnea ← hypoventilation ← neuromuscular disease / obesity
3. Portopulmonary hypertension (in 5% of patients with liver cirrhosis and portal hypertension)

(c) vasodilatation
1. Hepatopulmonary syndrome (in 20% of patients with liver cirrhosis) ← excessive vascular production of vasodilator nitric oxide

C. CHRONIC PULMONARY VENOUS HYPERTENSION

Cor Pulmonale

mnemonic: TICCS BEV

Thoracic deformity
Idiopathic: primary pulmonary hypertension (1%)
Chronic pulmonary embolism
COPD
Shunt: ASD, VSD, etc
Bronchiectasis
Emphysema
Vasculitis

Pulmonary Venous Hypertension (PVH)

= INCREASED VENOUS PULMONARY PRESSURE = VENOUS CONGESTION
= postcapillary pHTN = primary findings located within pulmonary venous circulation between capillary bed + LA

Dx: uniform / widely variable elevation of pulmonary capillary wedge pressure (PCWP) > 15 mmHg

Cause:

A. LV INFLOW TRACT OBSTRUCTION
√ normal-sized heart with right ventricular hypertrophy
√ prominent pulmonary trunk
@ proximal to mitral valve:
√ normal-sized left atrium
› pulmonary veins
1. TAPVR below the diaphragm
2. Pulmonary venoocclusive disease
3. Stenosis of individual pulmonary veins
4. Atresia of common pulmonary vein

› mediastinum
1. Fibrosing mediastinitis (may also affect precapillary vessels)
2. Constrictive pericarditis

› left atrium
1. Cor triatriatum
2. Left atrial mass: thrombus, myxoma, sarcoma, metastasis

3. Supravalvular ring of left atrium

@ at mitral valve level = mitral valve stenosis

√ enlarged left atrium

1. Rheumatic mitral valve stenosis ± regurgitation (99%)

√ enlarged left atrial appendage

2. Congenital mitral valve stenosis
3. Parachute mitral valve (= single bulky papillary muscle)

B. LEFT VENTRICULAR FAILURE (more common)

(a) ABNORMAL PRELOAD with secondary mitral valve incompetence (= volume overload)

1. Aortic valve regurgitation
2. Eisenmenger syndrome (= R-to-L shunt in VSD)
3. High-output failure:
   noncardiac AVM (cerebral AVM, vein of Galen aneurysm, large pulmonary AVM, hemangioendothelioma of liver, iatrogenic), thyrotoxicosis, anemia, pregnancy

(b) ABNORMAL afterload (= pressure overload)
= LV outflow tract obstruction

1. Hypoplastic left heart syndrome
2. Aortic stenosis (supravalvular, valvular, anatomic subaortic)
3. Interrupted aortic arch
4. Coarctation of the aorta

(c) DISORDERS OF CONTRACTION AND RELAXATION

1. Endocardial fibroelastosis
2. Glycogen storage disease (Pompe disease)
3. Cardiac aneurysm
4. Cardiomyopathy
   › congestive (alcohol)
   › hypertrophic obstructive cardiomyopathy, particularly in IDM
   (1) Asymmetric septal hypertrophy
   (2) Idiopathic hypertrophic subaortic stenosis

(d) MYOCARDIAL ISCHEMIA

1. Anomalous left coronary artery
2. Coronary artery disease

Histo:

(a) primary changes: venous medial hypertrophy + intimal proliferation, marked thickening of venous internal elastic lamina

(b) secondary changes: capillary bed congestion with adjacent vascular proliferation, interlobular septal and pleural edema + fibrosis, lymphatic dilatation, alveolar hemosiderosis, paraseptal venous infarcts adjacent to complete venous occlusion

Cx: secondary pulmonary arterial hypertension

CT:

√ interlobular septal thickening

√ pleural effusion

√ pulmonary edema
√ vascular redistribution (on coronal reformatted images!)
√ dilated left atrium (with left-sided heart disease)

CXR:
√ equalization of pulmonary vascularity: PCWP 13–15 mmHg
√ cephalization of pulmonary vascularity: PCWP 16–18 mmHg
√ interstitial pulmonary edema (PCWP 19–24 mmHg)
= fluid within peribronchovascular connective tissue:
√ peribronchial thickening / cuffing
√ indistinct vessel margins
√ Kerley B lines = short horizontal reticulations within lateral subpleural lung bases
√ Kerley A lines = 3–4-cm-long lines of interlobular septal thickening radiating from hila to mid and upper lung zones
√ perihilar haze = hilar interstitial edema
√ thickened pleural fissures / pseudoeffusion = fluid within subpleural connective tissue
√ small pleural effusions
√ alveolar pulmonary edema (PCWP ≥ 25 mmHg)
= bilateral perihilar and basilar airspace opacification

HEART VALVES

Pathology of Cardiac Valves

1. Degenerative disease
2. Inherited cause
3. Postrheumatic heart disease

AORTA

Enlarged Aorta

Definition: diameter > 50% above high end of normal range (depending on age + sex + body size + segment)

PA CXR:
√ aortic knob > 4.0 cm measured from indented trachea to most lateral margin of aorta
√ right convex contour above RA margin + lateral displacement of SVC (= dilatation of ascending aorta)

A. INCREASED VOLUME LOAD
1. Aortic insufficiency
2. PDA

B. POSTSTENOTIC DILATATION
1. Valvular aortic stenosis

C. INCREASED INTRALUMINAL PRESSURE
1. Coarctation
2. Systemic hypertension

D. MURAL WEAKNESS / INFECTION
1. Cystic media necrosis: Marfan / Ehlers-Danlos syndrome

2. Congenital aneurysm
3. Syphilitic aortitis
4. Mycotic aneurysm
5. Atherosclerotic aneurysm (compromised vasa vasorum)

E. LACERATION OF AORTIC WALL
1. Traumatic aneurysm
2. Dissecting hematoma

Enlarged Aortic Root

A. COMMON CAUSES
1. Connective tissue disorder: eg, Marfan syndrome, Ehlers-Danlos syndrome
2. Bicuspid aortic valve
3. **Loeys-Dietz syndrome:**
inherited autosomal dominant disorder with typically severe + widespread arterial disease
Cx: aortic dissection at small aortic diameter
4. Hypertension
5. Atherosclerosis: aneurysm typically diffuse + fusiform; descending > ascending aorta; root typically spared

B. LESS COMMON CAUSES
1. Infection: eg, syphilis
2. Vasculitis: eg, Takayasu arteritis, giant cell arteritis
3. Trauma
4. **Familial thoracic aneurysm disease:**
mostly autosomal dominant of variable expression + penetrance → aneurysm at significantly younger age
5. Turner syndrome

Aortic Wall Thickening

1. Intramural hematoma
= aortic dissection without intimal tear
2. Aortitis segments of aortic arch + branch vessels
3. Atherosclerotic plaque
√ irregular narrowing of aortic lumen
4. Adherent thrombus

Aortitis

A. Infectious aortitis

B. Idiopathic conditions
1. Idiopathic aortitis (pathologic diagnosis only)
2. Idiopathic inflammatory aortic aneurysm
3. Idiopathic retroperitoneal fibrosis

C. Noninfectious aortitis = vasculitis
Segment: mostly affecting ascending aorta
(a) rheumatic diseases commonly causing aortitis

1. Takayasu arteritis
2. Ankylosing spondylitis
3. Giant cell arteritis (GCA)
4. Cogan syndrome
5. Relapsing polychondritis

(b) rheumatic diseases uncommonly causing aortitis
1. Rheumatoid arthritis
2. Seronegative spondyloarthropathies
3. Behçet disease
4. SLE

(c) rheumatic diseases rarely causing aortitis
1. Sarcoidosis
2. Antineutrophil cytoplasmic antibody–associated aortitis: Wegener granulomatosis, polyarteritis nodosa
3. Juvenile rheumatoid arthritis

Rheumatic diseases with an > 10% prevalence of aortitis include Takayasu arteritis, GCA, long-standing ankylosing spondylitis, Cogan syndrome, relapsing polychondritis.

Acute Aortic Syndrome

1. Intramural hematoma
2. Penetrating atherosclerotic ulcer
3. Aortic dissection with overt false lumen

Narrowing of Abdominal Aorta in Childhood

1. Takayasu arteritis
2. Fibromuscular dysplasia
3. Prior radiation therapy
4. Neurofibromatosis-1
5. Williams syndrome
6. Midaortic syndrome

Aortic Calcifications

Intimal Calcification

Cause: part of atherosclerotic plaque
Associated with: inflammatory cells, lipid, vascular smooth muscle cells
Site: within perimeter of internal elastic lamina
√ discrete punctate lesion on radiograph

Medial Calcification

Cause: aging, diabetes, end-stage renal disease, neuropathy, genetic syndromes
Associated with: elastin + vascular smooth muscle cells
√ linear deposit along elastic lamellae resembling railroad tracks (when severe)

Vascular Rings

= anomaly characterized by encirclement of trachea + esophagus by aortic arch + branches

Prevalence: < 1% of all congenital cardiac defects

Cause: abnormal persistence / regression of 1 of 6 embryonic aortic arches

A. Usually symptomatic vascular ring
   - chronic stridor, wheezing, recurrent pneumonia
   - dysphagia, failure to thrive

   1. Double aortic arch with R descending aorta + L ductus arteriosus
   2. R aortic arch with R descending aorta + aberrant L subclavian artery + persistent L ductus / ligamentum arteriosum

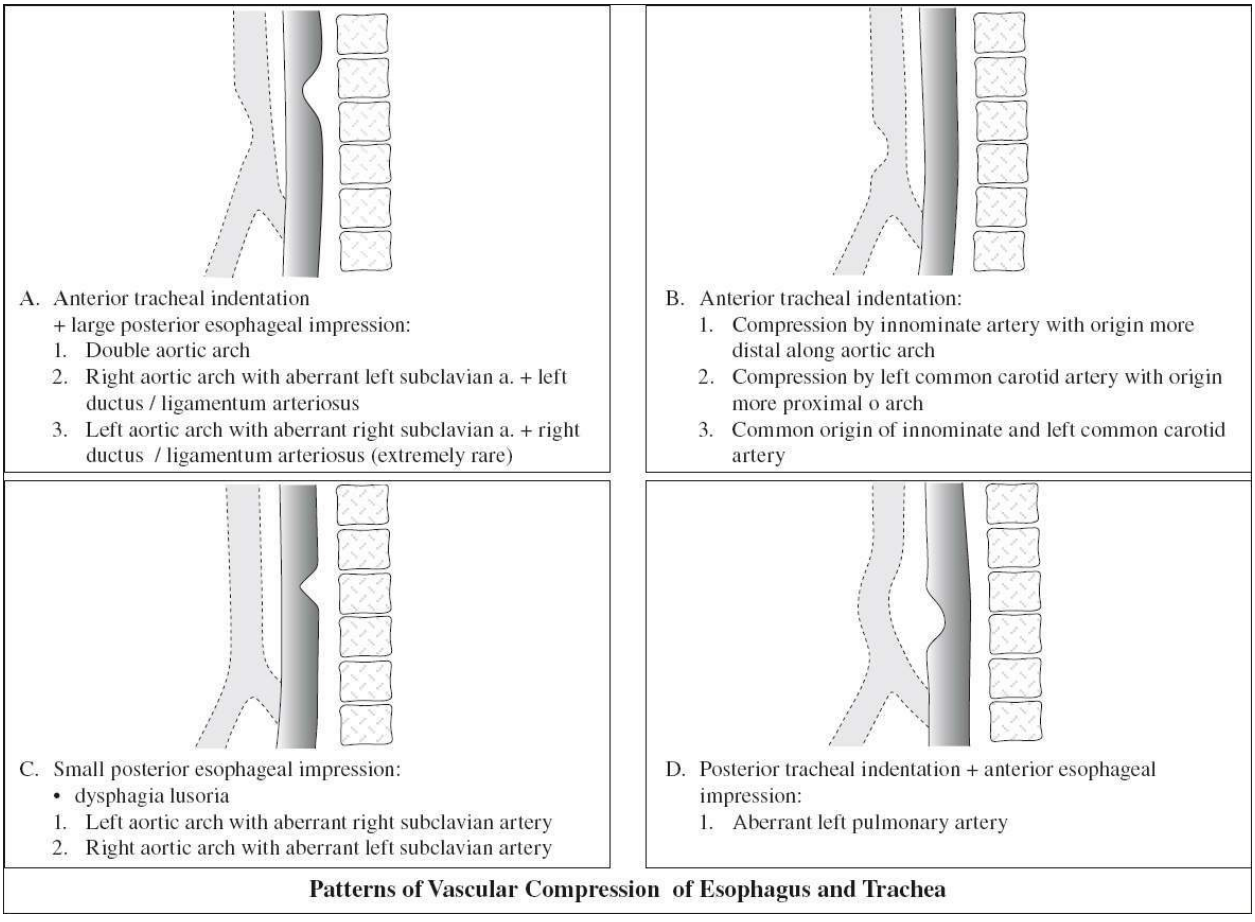
      N.B.: left obliterated ductus arteriosus (= **ligament of Botallo**) passes from L pulmonary artery to descending aorta / L subclavian artery

      - symptoms + radiographic findings identical to double aortic arch

      √ indentation on right lateral esophageal wall (by aortic arch)
      √ impression on the anterolateral esophageal wall (by ligament of Botallo)
      √ origin of L subclavian artery frequently dilated

   3. L arch with L descending aorta + R ductus / ligamentum
   4. Aberrant L pulmonary artery = "pulmonary sling"

Frequency of CXR findings:



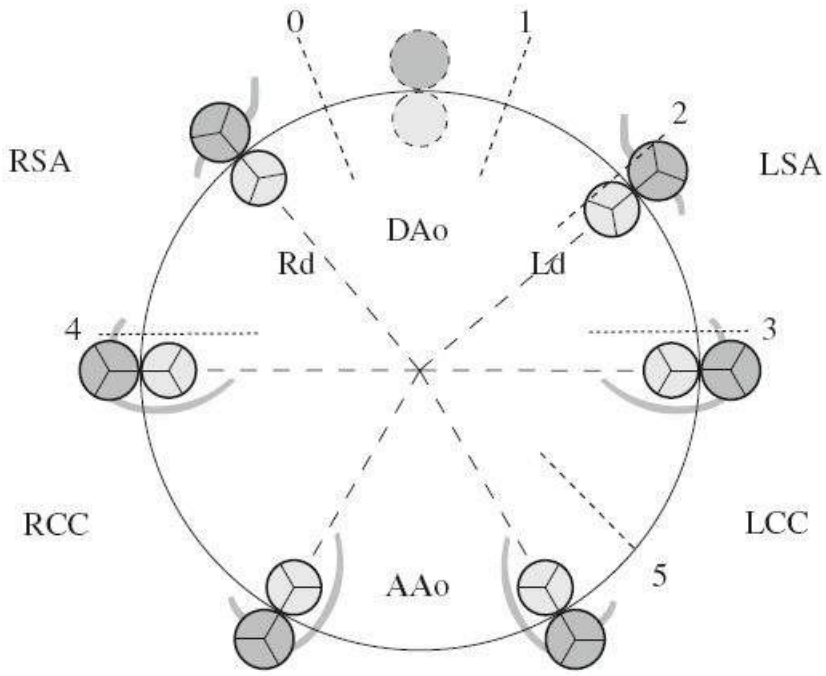
Patterns of Vascular Compression of Esophagus and Trachea

- › frontal CXR:
  - √ right aortic arch (85%)
  - √ focal indentation of distal trachea (73%)
- › lateral CXR:
  - √ anterior tracheal bowing (92%)
  - √ increased retrotracheal opacity (79%)
  - √ focal tracheal narrowing (77%)

B. Occasionally symptomatic lesions
   1. Anomalous R innominate artery
   2. Anomalous L common carotid artery / common trunk
   3. R aortic arch with L descending aorta + L ductus / ligamentum

C. Usually asymptomatic lesions
   1. L aortic arch + aberrant R subclavian artery
   2. L aortic arch with R descending aorta
   3. R aortic arch with R descending aorta + mirror-image branching
   4. R aortic arch with R descending aorta + aberrant L subclavian artery
   5. R aortic arch with R descending aorta + isolation of L subclavian artery
   6. R aortic arch with L descending aorta + L ductus / ligamentum

Complete Vascular Rings



Edwards' Hypothetical Aortic Arch Development

RSA	= right subclavian a.	AAo	= ascending aorta
LSA	= left subclavian a.	DAo	= descending aorta
RCC	= right common carotid a.	Rd	= right ductus
LCC	= left common carotid a.	Ld	= left ductus

0 = normal left aortic arch

1 = right aortic arch with mirror-image branching; ductus from pulmonary a. to left brachiocephalic / subclavian a. = no vascular ring

2 = right aortic arch with mirror-image branching; ductus from pulmonary a. to descending aorta = complete vascular ring

3 = right aortic arch with aberrant left subclavian a.; ductus from pulmonary a. to descending aorta (most common complete vascular ring)

4 = left aortic arch with aberrant right subclavian a.

5 = right aortic arch with aberrant left brachiocephalic artery; ductus from pulmonary a. to descending aorta (very uncommon)

2 + 3 = right aortic arch with isolated left subclavian a. (very uncommon)

1. Double aortic arch (55%)
2. R aortic arch + aberrant L subclavian a. + L ligamentum arteriosum (12–25%)
3. R aortic arch with mirror-image branching + retroesophageal L ligamentum arteriosum

4. L aortic arch + R descending aorta, R subclavian artery + R ligamentum arteriosum

Abnormal Left Ventricular Outflow Tract

LVOT = area between IVS + aML from aortic valve cusps to mitral valve leaflets

1. Membranous subaortic stenosis
   = crescent-shaped fibrous membrane extending across LVOT + inserting at aML
   √ diffuse narrowing of LVOT
   √ abnormal linear echoes in LVOT space (occasionally)
2. Prolapsing aortic valve vegetation
3. Narrowed LVOT (< 20 mm)
   (a) Long-segment subaortic stenosis
      √ aortic valve closure in early systole with coarse fluttering
      √ high-frequency flutter of mitral valve in diastole (aortic regurgitation)
      √ symmetric LV hypertrophy
   (b) ASH / IHSS
      √ asymmetrically thickened septum bulging into LV + LVOT
      √ systolic anterior motion of aML (SAM)
   (c) Mitral stenosis
   (d) Endocardial cushion defect

Obstruction of Left Ventricular Outflow Tract

1. Bicuspid aortic valve
2. Coarctation of aorta
3. Subvalvular aortic stenosis
4. Supravalvular aortic stenosis

VENA CAVA

Vena cava anomalies

Persistent Left SVC

= BILATERAL SVCS

Prevalence: 0.3–0.5% of general population; 3–11% of patients with CHD
◊ Most common congenital thoracic venous anomaly

Etiology: failure of involution of left anterior + left common cardinal veins + left horn of sinus venosus

Origin: confluence of left IJV + subclavian vein

Course: lateral to aortic arch, anterior to left hilum

Terminus: drains into enlarged coronary sinus (in 92%) / into LA (in 8%) creating a R-to-L shunt (increased prevalence of CHD)

Associated with:

(a) Right SVC (82–90%) normal / small = SVC duplication
(b) Bridging vein connecting right + left SVC (35–55%)
(c) Absence of right SVC (in 10–18%): → increased incidence of CHD (ASD, VSD, tetralogy of Fallot, bicuspid aortic valve, aortic coarctation, mitral atresia, cor

triatriatum, azygos continuation of IVC)

√ persistent left SVC should be suspected when a dilated coronary sinus is seen at cross-sectional imaging

√ left SVC arises from confluence of left subclavian and jugular veins + traverses caudally lateral to aortic arch
√ left SVC lies anterior to left hilum → traverses along ligament of Marshall → drains into RA via dilated coronary sinus
√ CVC placement into left SVC may be mistaken for arterial / mediastinal / pleural placement (frontal CXR)
√ hemiazygos arch formed by left superior intercostal vein + persistent left SVC (20%)
√ left brachiocephalic vein: present in 25–35%; absent / small in 65%

Circumaortic Left Renal Vein

Prevalence: 1.5–8.7%
Etiology: persistence of anterior intersubcardinal + posterior intersupracardinal anastomosis
√ venous collar encircling aorta
√ superior left renal vein crosses aorta anteriorly
√ inferior left renal vein receives left gonadal vein + crosses aorta posteriorly 1–2 cm below the superior left renal vein
Significance: preoperative plan for nephrectomy

Duplicated IVC

= DOUBLE IVC
Prevalence: 0.2–3%
Etiology: persistence of both supracardinal veins
√ small / equal-sized left IVC formed by left iliac vein
√ crossover to right IVC via left renal vein / or more inferiorly
√ crossover usually anterior / rarely posterior to aorta
Significance: recurrent pulmonary embolism after IVC filter placement
DDx: left gonadal v./ a., inferior mesenteric v.

DOUBLE IVC WITH RETROAORTIC RIGHT RENAL VEIN AND AZYGOS CONTINUATION OF IVC

Etiology: persistence of left supracardinal v. and dorsal limb of renal collar + regression of ventral limb + failure of formation of right subcardinal-hepatic anastomosis

DOUBLE IVC WITH RETROAORTIC RIGHT RENAL VEIN AND HEMIAZYGOS CONTINUATION OF IVC

Etiology: persistence of left lumbar + thoracic supracardinal v. + left suprasubcardinal anastomosis + failure of formation of right subcardinal-hepatic anastomosis
√ right IVC and right renal vein join the left IVC and continue cephalad as the hemiazygos vein
√ hemiazygos vein follows alternative pathways:
(a) crosses posterior to aorta at T8-9 and joins the rudimentary azygos vein
(b) continues cephalad + joins coronary vein via persistent left SVC
(c) accessory hemiazygos continuation to left brachiocephalic vein

√ hepatic segment of IVC drains into right atrium

Left IVC

= TRANSPOSITION OF IVC = SOLITARY LEFT IVC

Prevalence: 0.2–0.5%

Etiology: persistence of left + regression of right supracardinal vein

√ left IVC usually joins left renal vein

√ crossover as left renal vein usually anterior / rarely posterior to aorta

DDx: left-sided paraaortic adenopathy

Significance: difficult transjugular access to infrarenal IVC filter placement

Retroaortic Left Renal Vein

Prevalence: 1.8–2.1%

Etiology: persistence of posterior intersupracardinal anastomosis + regression of anterior intersubcardinal anastomosis

√ crossover usually below / occasionally at level of right renal vein

SVC Obstruction / Stricture

- SVC syndrome

A. INTRINSIC CAUSE long-standing CVCs, transvenous pacemaker, postoperative / postradiation effects, fibrin sheath, bland / tumor thrombus

B. EXTRINSIC CAUSE
compression from malignancy (small cell + non–small cell lung cancer, lymphoma, metastatic lymphadenopathy, tracheal malignancy), mediastinal mass, fibrosing mediastinitis, lymphadenopathy, ascending aortic aneurysm

IVC Obstruction

A. INTRINSIC OBSTRUCTION
   (a) neoplastic (most frequent)
      1. Renal cell carcinoma (in 10%), Wilms tumor
      2. Adrenal carcinoma, pheochromocytoma
      3. Pancreatic carcinoma, hepatic adenocarcinoma
      4. Metastatic disease to retroperitoneal lymph nodes (carcinoma of ovary, cervix, prostate)
   (b) nonneoplastic
      1. Idiopathic
      2. Proximally extending thrombus from femoroiliac veins
      3. Systemic disorders: coagulopathy, Budd-Chiari syndrome, dehydration, infection (pelvic inflammatory disease), sepsis, CHF
      4. Postoperative / traumatic phlebitis, ligation, plication, clip, cava filter, severe exertion

B. INTRINSIC CAVAL DISEASE
   (a) neoplastic
      1. Leiomyoma, leiomyosarcoma, endothelioma
   (b) nonneoplastic

1. Congenital membrane

C. EXTRINSIC COMPRESSION
   (a) neoplastic
      1. Retroperitoneal lymphadenopathy (adults) ← metastatic disease, lymphoma, granulomatous disease (TB)
      2. Renal + adrenal tumors (children)
      3. Hepatic masses
      4. Pancreatic tumor
      5. Tumor-induced desmoplastic reaction (eg, metastatic carcinoid)
   (b) nonneoplastic
      1. Hepatomegaly
      2. Tortuous aorta / aortic aneurysm
      3. Retroperitoneal hematoma
      4. Massive ascites
      5. Retroperitoneal fibrosis

D. FUNCTIONAL OBSTRUCTION
   1. Pregnant uterus
   2. Valsalva maneuver
   3. Straining / crying (in children)
   4. Supine position with large abdominal mass

E. COLLATERAL PATHWAYS
   1. Deep pathway: ascending lumbar veins to azygos vein (right) + hemiazygos vein (left) + intravertebral, paraspinal, extravertebral plexus (Batson plexus)
   2. Intermediate pathway: via periureteric plexus + left gonadal vein to renal vein
   3. Superficial pathway: external iliac vein to inferior epigastric vein + superior epigastric vein + internal mammary vein into subclavian vein
   4. Portal pathway: retrograde flow through internal iliac vein + hemorrhoidal plexus into inferior mesenteric vein + splenic vein into portal vein

Reflux of Contrast Media

IVC Reflux

1. Cardiac tamponade
2. Tricuspid regurgitation
3. Hypovolemic / cardiogenic shock
4. Pulmonary embolism

Azygos Vein Reflux

= sign of raised central venous pressure

1. Pulmonary arterial hypertension
2. Massive pulmonary embolism
3. Cor pulmonale
4. Ischemic right heart failure
5. Cardiac tamponade
5. Tumoral obstruction of main pulmonary artery

6. Bilateral pneumothoraces
7. Positive pressure ventilation for ARDS

INFLAMMATORY CARDIOVASCULAR DISEASE

@ Myocardium
   1. Cardiac sarcoidosis
   2. Myocarditis

@ Peri- & Epicardium
   1. Pericarditis
   2. Epipericarditis

@ Vessels
   1. Atherosclerosis
   2. Vasculitis

Eosinophilic Diseases with Cardiac Involvement

1. Eosinophilic heart disease
2. Churg-Strauss syndrome
3. Early giant cell myocarditis
4. Drug-induced hypersensitivity reaction
5. Parasitic infection
6. Tropical endomyocardial fibrosis
7. Malignancy

Vasculitis

= inflammation and necrosis of vessel wall

A. LARGE-VESSEL VASCULITIS
   1. Giant cell arteritis (= temporal arteritis)
   2. Takayasu arteritis
   5. Ankylosing spondylitis
   6. Reiter syndrome

B. MEDIUM-SIZED–VESSEL VASCULITIS
   1. Polyarteritis nodosa
   2. Kawasaki disease
   3. Relapsing polychondritis
   4. Drug-induced vasculitis:
      › methamphetamine
      › cocaine: neurovascular, cardiovascular complications, aortic dissection, venous thrombosis, mesenteric artery thrombosis, renal infarction

C. SMALL-VESSEL VASCULITIS
   (a) ANCA-associated small-vessel vasculitis (= antineutrophil cytoplasmic autoantibodies)
      1. Granulomatosis with polyangiitis = Wegener granulomatosis
      2. Eosinophilic granulomatosis with polyangiitis = Churg-Strauss syndrome
      3. Microscopic polyangiitis
   (b) immune-complex small-vessel vasculitis

1. IgA vasculitis = Henoch-Schönlein purpura
2. Essential cryoglobulinemic vasculitis
3. Cutaneous leukocytoclastic angiitis

others: lupus, rheumatoid, Sjögren, Behçet, Goodpasture, serum sickness, drug-induced, hypocomplementemic urticaria

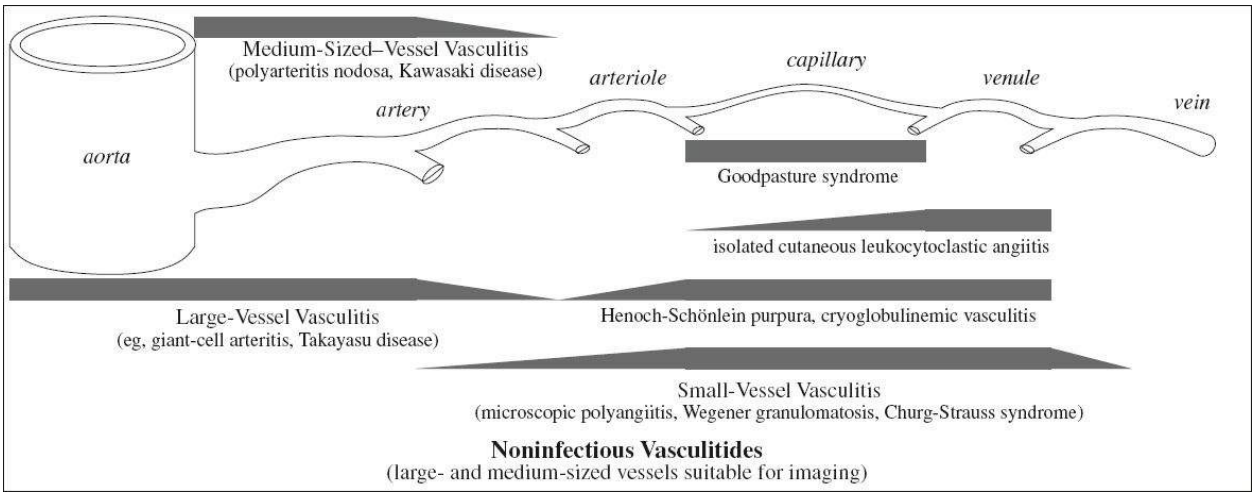
(c) inflammatory bowel disease vasculitis

D. VARIABLE-SIZED–VESSEL VASCULITIS
1. Behçet disease
2. Cogan syndrome

E. SINGLE-ORGAN VASCULITIS
1. Primary angiitis of CNS (PACNS)

F. VASCULITIS OF A SYSTEMIC DISEASE
1. Systemic lupus erythematosus (SLE)
2. Sjögren syndrome
3. Rheumatoid arthritis
4. APLA (antiphospholipid antibody) syndrome
5. Scleroderma

G. VASCULITIS WITH PROBABLE ETIOLOGY
1. Infection-induced vasculitis
2. Acute septic meningitis
3. Mycobacterium tuberculosis
4. Neurosyphilis
5. Viral: HIV-related vasculitis, varicella-zoster vasculopathy



Major Pediatric Vasculitides with Major Sites of Involvement		
Type	*Predilection Site*	*EULAR-PRES Criteria (European League Against Rheumatism - Paediatric Rheumatology European Society)*
Takayasu arteritis	aortic arch & branches, pulmonary arteries	Angio: characteristic abnormalities + absent peripheral pulses / claudication, blood pressure discrepancy in any limb, bruits, HTN, elevated acute phase reactants
Kawasaki disease	coronary arteries	fever > 5 days + bilateral conjunctival injection, changes of lips & oral cavity, cervical lymphadenopathy, polymorphous exanthem, changes in peripheral extremities / perineal area
Polyarteritis nodosa	GI tract, kidneys	Angio: abnormalities of medium to small-sized arteries with systemic necrotizing vasculitis + skin involvement, myalgia, HTN, peripheral neuropathy, renal involvement (proteinuria, hematuria, impaired function)
Granulomatosis with polyangiitis	upper + lower respiratory tract, kidneys	upper airway involvement + laryngotracheobronchial stenosis + pulmonary & renal involvement, histopathologic granulomatous inflammation, ANCA positivity
Henoch-Schönlein purpura	gut, skin , kidneys	purpura / petechiae with lower limb predominance + arthritis / arthralgia, abdominal pain, renal involvement (hematuria, proteinuria), IgA deposition

6. Fungal: mucormycosis aspergillosis
7. Parasitic: cysticercosis
8. Malignancy-induced vasculitis
9. Drug-induced vasculitis
10. Radiation-induced vasculitis

Classification of Childhood Vasculitis

European League against Rheumatism (EULAR) & Paediatric Rheumatology European Society (PRES)

Incidence: 23÷100,000 annually

The 2 most common types of primary pediatric vasculitis are Henoch-Schönlein purpura (49%) and Kawasaki disease (23%).

A. LARGE VESSEL
   1. Takayasu Arteritis
B. MEDIUM VESSEL
   1. Kawasaki disease
   2. Polyarteritis nodosa
   3. Cutaneous polyarteritis
C. SMALL-VESSEL GRANULOMATOUS
   1. Wegener granulomatosis
   2. Eosinophilic granulomatosis with polyangiitis
D. SMALL-VESSEL NONGRANULOMATOUS
   1. Henoch-Schönlein purpura
   2. Microscopic polyangiitis
   3. Isolated cutaneous leukocytoclastic vasculitis
   4. Hypocomplementemic urticarial vasculitis
E. OTHERS
   1. Behçet disease
   2. Vasculitis associated with connective tissue disease
   3. Secondary to infection, malignancy, drugs
   4. Isolated vasculitis of CNS
   5. Cogan syndrome

Multiple Aneurysms

1. Polyarteritis nodosa
   - fever, malaise, weight loss, myalgia
   - proteinuria, hematuria
2. Rheumatoid vasculitis
   - advanced rheumatoid arthropathy
3. Systemic lupus erythematosus
   - arthritis, photosensitivity
   - malar rash, discoid rash, oral ulcers
4. Churg-Strauss syndrome
5. Heroin / methamphetamine abuse
6. Wegener granulomatosis
7. Scleroderma
   - skin thickening, induration and tightness
8. Diabetes
9. Giant cell temporal arthritis (rare)

VASCULAR TUMORS & MALFORMATIONS

Classification of International Society for the Study of Vascular Anomalies (ISSVA)

Vascular Tumors

= true neoplastic lesion with cellular proliferation and hyperplasia characterized by rapid early proliferative stage and later involuting stage

1. Infantile hemangioma
2. Congenital hemangioma
3. Kaposiform hemangioendothelioma
4. Tufted angioma
5. Hemangiopericytoma
6. Pyogenic granuloma
7. Spindle cell hemangioendothelioma

Developmental Vascular Malformations

= error of vascular morphogenesis → collection of dysplastic abnormally dilated arteries, veins, capillaries, lymphatics characterized by

- greater conspicuity with age ← steady growth commensurate with patient growth (puberty, pregnancy, trauma, surgery may cause growth spurts)
- NO spontaneous involution / regression

1. **Slow-flow** vascular malformation
   √ absence of flow voids on SE images
   DDx: low-signal-intensity striations, septa, thrombosed vessels, phleboliths
   (a) Venous malformation
   (b) Lymphatic malformation
   (c) Capillary malformation
2. **High-flow** vascular malformation
   Frequency: 10% of malformations in extremities

√ presence of signal voids demonstrating enhancement and high-signal-intensity foci on GRE images

(a) Arteriovenous malformation

(b) Congenital arteriovenous fistula

Characterization:

√ NO blood flow = lymphatic malformation

√ venous flow ONLY:

√ WITH phlebolith = venous malformation

√ NO phlebolith = low-flow vascular malformation

Rx: sclerotherapy

1. Klippel-Trénaunay syndrome
2. Sturge-Weber syndrome
3. Blue rubber bleb nevus
4. Proteus syndrome
5. Gorham-Stout syndrome
6. Maffucci syndrome

√ arterial flow:

(a) WITH mass = vascular tumor

1. PHACE syndrome
2. Kasabach-Merritt syndrome

(b) NO mass = high-flow vascular malformation

Rx: arterial embolization

1. Parkes Weber syndrome
2. Hereditary hemorrhagic telangiectasia
3. Vascular metameric syndrome
   (a) Wyburn-Mason syndrome
   (b) Cobb syndrome

Serpentine High-Flow Vascular Channels on MRI

1. Hemangioendothelioma
2. Hemangiopericytoma
3 Angiosarcoma
4. Rhabdomyosarcoma
5. Synovial sarcoma
6. Alveolar soft-part sarcoma
7. Extraskeletal Ewing sarcoma

LYMPH FLOW DISORDERS

1. Lymphatic dysplasia
2. Lymphedema

PRIMARY HYPERCOAGULABLE STATES

= THROMBOPHILIA

• DVT of extremities / pulmonary embolism

(a) Qualitative defect / quantitative ↓ in an antithrombotic protein:
› antithrombin III
› protein C
› protein S
› Trousseau phenomenon in cancer: HCC, pancreatic ca.
(b) Increased level of a prothrombotic protein
› activated protein C resistance (Factor V Leiden)
› G20210A prothrombin gene mutation

SUDDEN CARDIAC DEATH IN YOUNG ADULTS

= death from unexpected circulatory arrest within 1 hour of onset of symptoms ← usually a result of cardiac arrhythmia

Incidence: 1–2÷1000

Age range: 18–35 years

- precipitated by:
  - ventricular tachycardia / fibrillation (75–80%)
  - bradyarrhythmia (15–20%) = AV block, asystole

Cause:

A. ANOMALOUS CORONARY ARTERY
   1. Interarterial / intramural course
   2. LCA arising from pulmonary artery
   3. Coronary artery fistula

B. PRIMARY CARDIOMYOPATHY
   1. Hypertrophic / dilated / noncompaction cardiomyopathy
   2. Lysosomal / glycogen storage disease
   3. Arrhythmogenic right ventricular hypertrophy

C. INHERITED ARRHYTHMIA SYNDROME
   1. Long / short QT syndrome
   2. Brugada syndrome
   3. Catecholaminergic polymorphic ventricular tachycardia

D. VALVULAR DISEASE
   1. Mitral valve prolapse
   2. Aortic stenosis

E. CONGENITAL HEART DISEASE
   1. L- and D-transposition of great vessels
   2. Tetralogy of Fallot
   3. Single left ventricle

In order of frequency:

hypertrophic cardiomyopathy > anomalous coronary artery with an interarterial / intramural course > arrhythmogenic right ventricular cardiomyopathy (ARVC)

CARDIAC SURGERY

Surgical Procedures

A. AORTICOPULMONARY WINDOW SHUNT
= side-to-side anastomosis between ascending aorta and left pulmonary artery (reversible procedure)
→ tetralogy of Fallot

B. BLALOCK-HANLON PROCEDURE
= surgical creation of ASD
→ complete transposition

C. BLALOCK-TAUSSIG SHUNT
= end-to-side anastomosis of subclavian artery to pulmonary artery, performed ipsilateral to innominate artery / opposite to aortic arch
MODIFIED BLALOCK-TAUSSIG SHUNT uses synthetic graft material such as polytetrafluoroethylene (Gore-Tex®) in an end-to-side anastomosis between subclavian artery + ipsilateral branch of pulmonary artery
→ tetralogy of Fallot, tricuspid atresia with pulmonic stenosis

D. FONTAN PROCEDURE
= systemic flow of venous blood to lungs without passing through any ventricle
(1) External conduit from right atrium to pulmonary trunk (= venous return enters pulmonary artery directly)
(2) Closure of ASD: floor constructed from flap of atrial wall and roof from piece of prosthetic material
→ tricuspid atresia

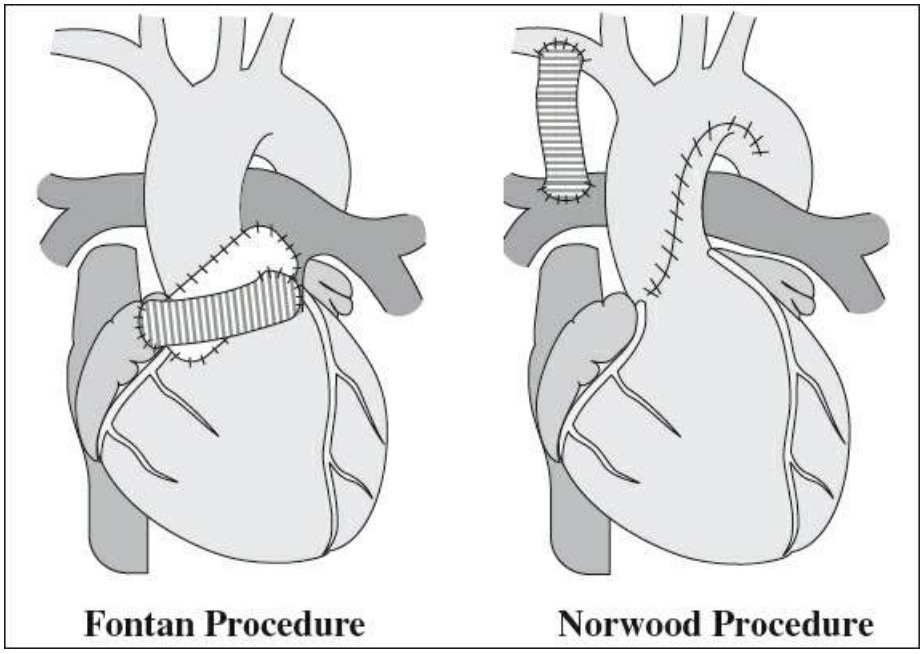
E. GLENN SHUNT
= end-to-side shunt between distal end of right pulmonary artery and SVC; reserved for patients with cardiac defects in which total correction is not anticipated
→ tricuspid atresia

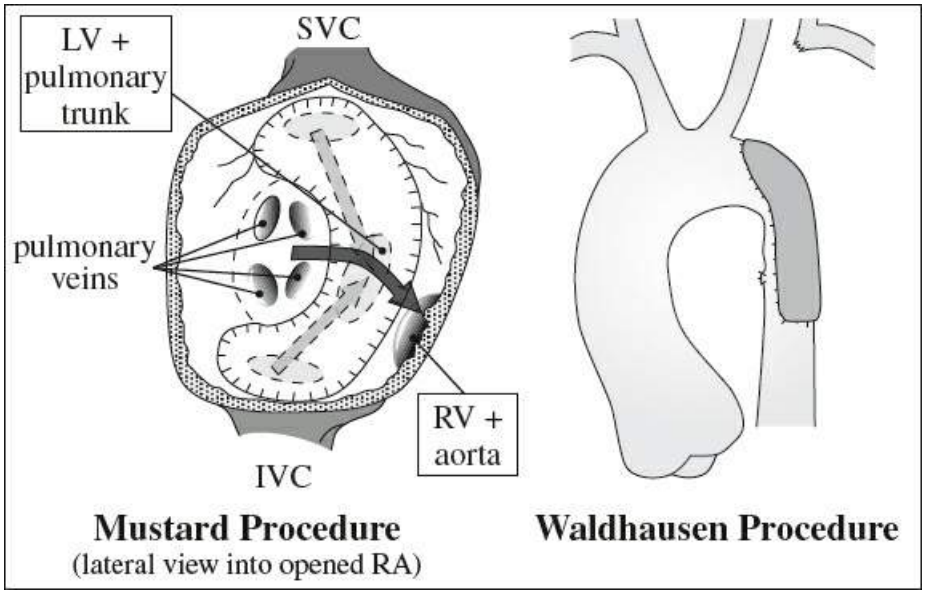
F. NORWOOD PROCEDURE
(1) Construction of "neoaorta" from aortic arch + descending aorta + main pulmonary artery supplying coronary and systemic circulation
(2) Communication between RV as systemic ventricle and systemic circulation
(3) Shunt between innominate artery + main pulmonary artery to control pulmonary arterial blood flow
(4) Excision of distal ductus arteriosus + atrial septum to prevent pulmonary venous hypertension
→ hypoplastic left heart syndrome

G. POTT SHUNT
= side-to-side anastomosis between descending aorta + left pulmonary artery
→ tetralogy of Fallot

H. MUSTARD PROCEDURE
(a) removal of atrial septum
(b) pericardial baffle placed into common atrium such that systemic venous blood is rerouted into LV and pulmonary venous return into right ventricle and aorta
→ complete transposition

I. RASHKIND PROCEDURE
= balloon atrial septostomy





→ complete transposition

J. RASTELLI PROCEDURE
external conduit (Dacron) with porcine valve connecting RV to pulmonary trunk
→ transposition

K. WALDHAUSEN PROCEDURE
= subclavian artery used to augment aortic lumen
= SUBCLAVIAN FLAP ANGIOPLASTY
(a) ligation of left subclavian artery at origin of left vertebral artery ± ligation of vertebral artery
(b) lateral incision of subclavian artery with extension into aortic isthmus
(c) excision of diaphragm of coarctation

(d) subclavian artery flap folded down into incision
→ coarctation

L. WATERSTON-COOLEY SHUNT
= side-to-side anastomosis between ascending aorta and right pulmonary artery;
(a) extrapericardial (WATERSTON)
(b) intrapericardial (COOLEY)
→ tetralogy of Fallot

Heart Valve Prosthesis

(a) mechanical valve requiring long-term anticoagulation
1. Starr-Edwards
√ caged ball
◊ Predictable performance from large long-term experience
2. Björk-Shiley / Lillehei-Kaster / St. Jude
√ tilting disk
◊ Excellent hemodynamics, very low profile, durable

(b) tissue (biologic) valve of limited durability
3. Hancock / Carpentier-Edwards (= porcine xenograft) Ionescu-Shiley (= bovine xenograft)
◊ Low incidence of thromboembolism, no hemolysis, central flow, inaudible

Postoperative Thoracic Deformity

A. ON RIGHT SIDE
1. Systemic-PA shunt: Blalock-Taussig shunt, Waterston-Cooley shunt, Glenn shunt, central conduit shunt
2. Atrial septectomy: Blalock-Hanlon procedure
3. VSD repair: through RA
4. Mitral valve commissurotomy

B. ON LEFT SIDE
1. PDA
2. Coarctation
3. PA banding
4. Mitral valve commissurotomy
5. Systemic-PA shunt: Blalock-Taussig shunt, Pott shunt

Postoperative Complications of Mitral Valve Surgery

1. Paravalvular abscess
2. Valvular vegetation
3. Pseudoaneurysm
4. Restricted leaflet excursion
5. Dehiscence of valve prosthesis / annuloplasty band
6. LCx artery injury

PULSUS ALTERNANS

= alternating arterial pulse height with regular cardiac rhythm

1. Intrinsic myocardial abnormality
   severe left ventricular dysfunction (CHF, aortic valvular disease, hypothermia, hypocalcemia, hyperbaric stress, ischemia)
2. Alternating end-diastolic volumes abnormalities in venous filling + return (obstructed venous return, IVC balloon

CARDIAC CONDUCTION DEVICES (CCD)

Components of CCD

A. Pulse generator hardware, programmable software, lithium iodide battery (5–10-year lifespan)
B. Leads for pacemaker / ICD
   1. Conductor
   2. Insulation: silicone rubber / polyurethane
   3. Electrode(s): uni- / bipolar
   4. Lead tip fixation in cardiac trabeculae:
      (a) passive: prongs, tines, fins, helix, cone
      (b) active: helical screw
   5. Proximal terminal connector pin → well seated in connector block

Cardiac Pacemaker

= electronic device providing small electrical stimuli for cardiac contraction as substitute for sinoatrial node activity in wall of RA near junction with SVC

Indication: periods of bradycardia / arrhythmia caused by disruption of electric conduction pathway (degenerative aging of SA node / AV node / conduction tissue, myocardial infarction)

A. Temporary epicardial electrode
B. **Single-chamber pacemaker** = 1 lead pacing RV / RA
   Placement:
   1. Apex of RV
      = single-lead intramyocardial electrode
      Indication: problematic conduction pathway
   2. Into RA (uncommon)
      Indication: SA node dysfunction, aberrant SA focus
B. **Dual-chamber pacemaker** = 2 leads pacing RV + RA
   Placement:
   1. 1 lead in RA
   2. 1 lead into apex of RV
   Indication: coordination of signals to atria + ventricles
C. **Biventricular pacemaker** = 3 leads pacing RV + LV ± RA
   Purpose: more efficient pumping action with simultaneous contraction of LV + RV
   Indication: moderate to severe drug-refractory CHF associated with inter- / intraventricular dyssynchrony; weakened enlarged heart
   Placement:
   1. 1 lead into apex of RV

2. 1 lead through coronary sinus into a posterior / lateral cardiac vein for LV
3. 1 lead into RA

= right atrial-biventricular synchronous pervenous device

Rx: cardiac resynchronization therapy (CRT) in combination with implantable defibrillator into appendage of RA

Implantable Cardioverter-Defibrillator (ICD)

= AUTOMATIC IMPLANTABLE CARDIOVERTER-DEFIBRILLATOR (AICD)

= electronic device generating a large amount of electrical energy to defibrillate the heart back into a normal rhythm

Indication: tachydysrhymthia (ventricular tachycardia / ventricular fibrillation) to prevent cardiac arrest

√ single lead with 2 shock coils

Placement:

1. 1 shock coil at junction of brachiocephalic vein + SVC
2. 1 shock coil into RV

Preferred Lead Implant Sites

1. Right atrial pacemaker lead

   Location: electrode tip in right atrial appendage

   √ electrode tip pointing upward + anteriorly

   √ electrode tip may be shaped into a preformed "J loop"

   √ slight redundancy of lead desirable to avoid tension during deep inspiration / arm movement

2. Right ventricular pacemaker / ICD lead

   Location: electrode tip in apex of RV

   √ electrode tip to left of spine (frontal view)

   √ electrode tip pointing anteriorly (lateral view)

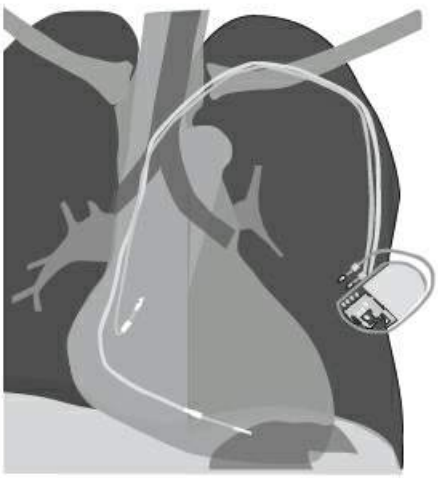
   √ (rarely) electrode tip intended for RVOT

3. Left ventricular pacemaker lead

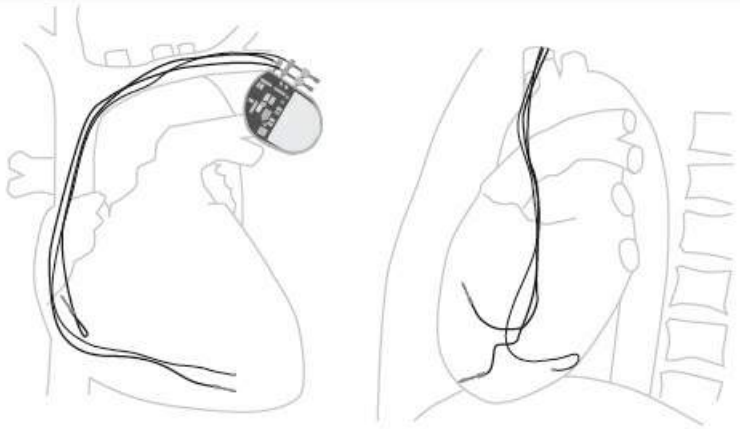
   Location: electrode tip in cardiac vein along lateral / posterior free wall of LV

   √ electrode tip posteriorly (lateral view)

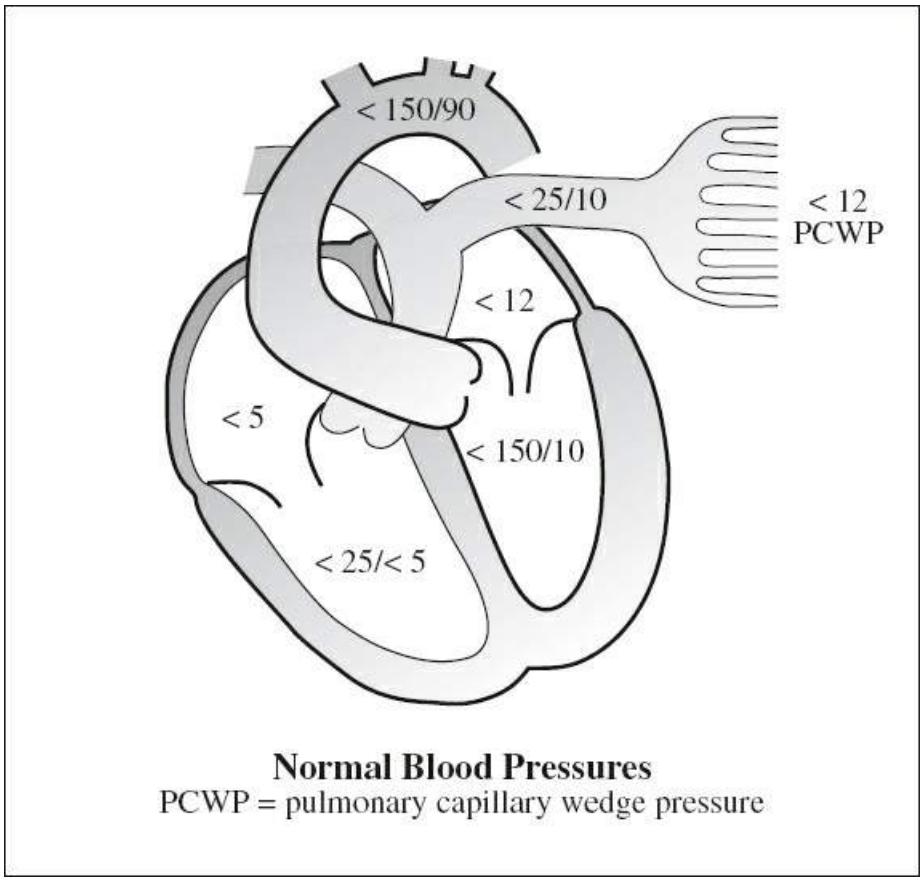
   √ inferiorly + laterally (frontal view)



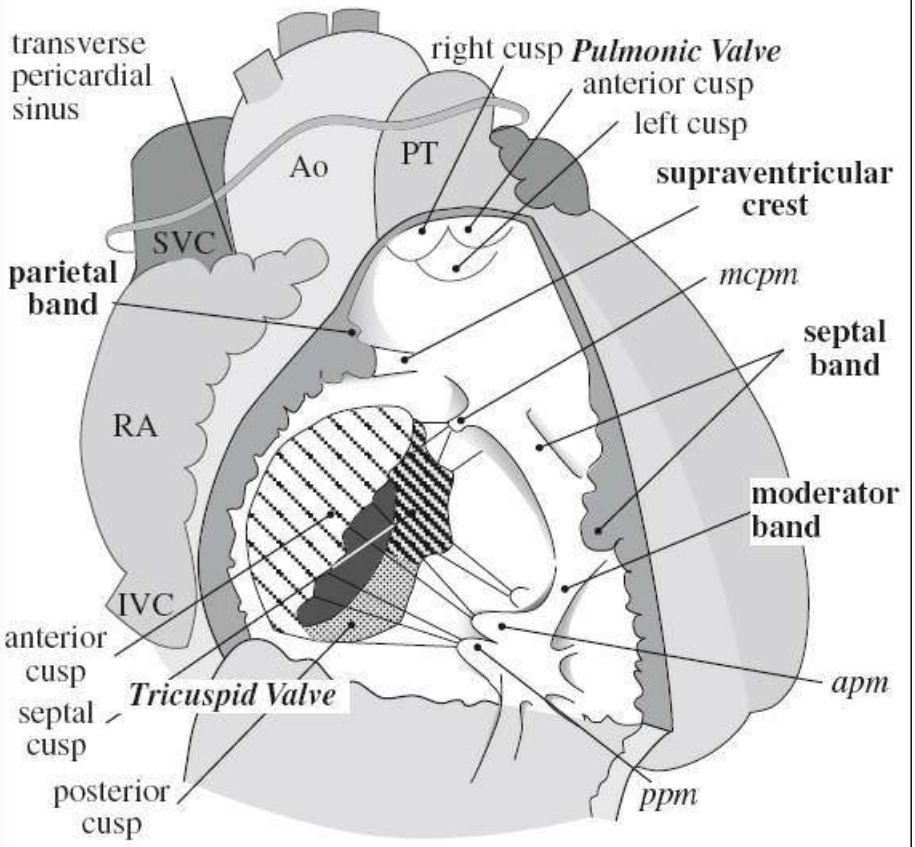
Dual-Chamber Cardiac Pacemaker



Biventricular Pacemaker
(dual chamber pacemaker with leads in RV + LV + RA)



Normal Blood Pressures
PCWP = pulmonary capillary wedge pressure



Right Ventricle Viewed from Front

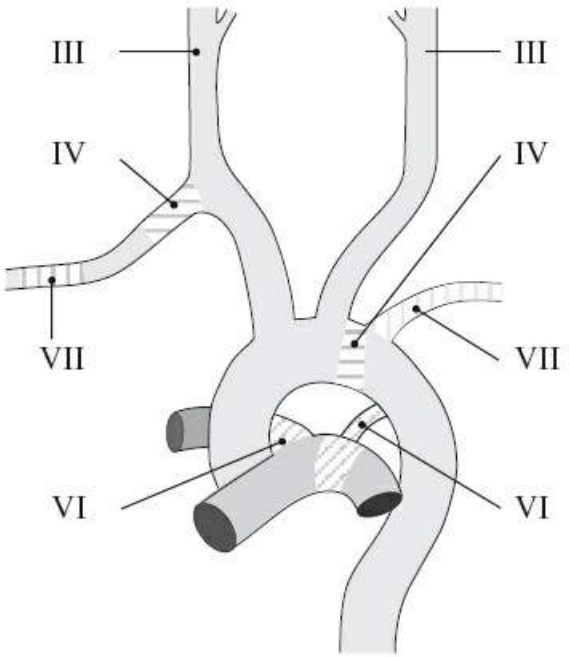
Demarcation between posteroinferior inflow portion and anterosuperior outflow portion by prominent muscular bands forming an almost circular orifice (parietal band, crista supraventricularis, septomarginal trabeculae (= septal band and moderator band)

apm = anterior papillary muscle attaches near apex of RV with chordae tendineae for anterior & posterior cusps
Anterior papillary muscle originates from moderator band!

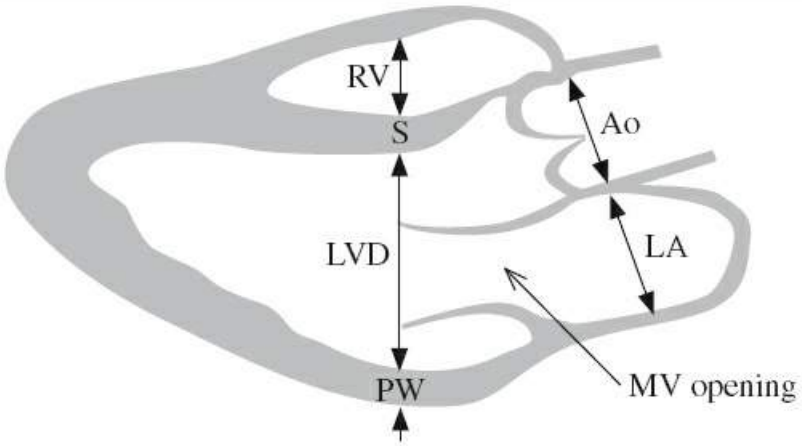
mcpm = medial supracristal (conal) papillary muscle arises from septal band with chordae tendineae for anterior & medial cusps

ppm = posterior *papillary muscle* attaches near apex of RV with chordae tendineae for posterior & medial cusps

Ao = aorta IVC = inferior vena cava PT = pulmonic trunk
RA = right atrium SVC = superior vena cava

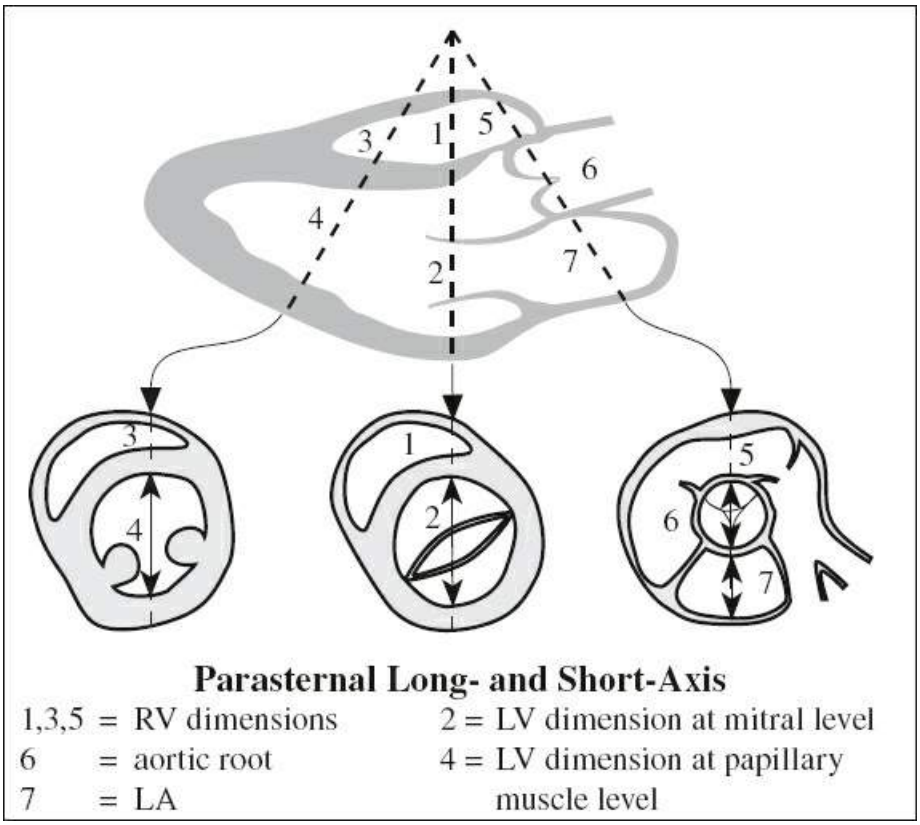


Development of Major Blood Vessels
numbers refer to embryologic aortic arches
(most portions of aortic arches I, II and V regress)
mnemonic: **Aor** from **Four**



Parasternal Long-Axis View

Ao = aorta	PW = posterior wall
LA = left atrium	RV = right ventricle
LVD = left ventricular diameter	S = septum



Parasternal Long- and Short-Axis

1,3,5 = RV dimensions
6 = aortic root
7 = LA
2 = LV dimension at mitral level
4 = LV dimension at papillary muscle level

HEART SIZE

Cardiothoracic Ratio

= CT ratio = widest transverse cardiac diameter ÷ widest inside thoracic diameter

< 0.5 = normal in > 1 month old (45% sensitive, 85% specific, 59% accurate)

< 0.6 = normal in < 1 month old

Purpose: measurement of LV dilatation

Dependent on:

- lung volume: CT ratio enlarges in expiration
- patient position: CT ratio increases on supine film

Pitfalls:

› no change unless LV volume increases by > ²/₃

› no change in moderate enlargement of LA / RV

CARDIAC IMAGING PLANES

Vertical Long Axis

= parasagittal plane along long axis of LV

Best assessment of:

1. LA and LV (relationship)
2. Inferior + anterior walls of LV myocardium
3. Bicuspid MV (structure & function) versus LV

4. LV (structure & function)
4. LA appendage and coronary sinus

Horizontal Long Axis / 4-Chamber View

= horizontal plane bisecting all 4 chambers

Best assessment of:

1. Chamber size and valve position
2. Septal + apical + lateral LV walls
3. AV valve (subjective assessment in cine mode)
4. Ventricular function (subjective assessment)
5. LA size (quick measurement)

Three-Chamber View

= oblique long-axis view optimizing visualization of LV, LA, aortic root, MV, aortic valve

Best assessment of:

1. LV outflow tract, aortic valve, aortic root, proximal ascending thoracic aorta
2. Posteromedial papillary muscles arising from LV free (lateral) wall
3. Chordae tendineae of MV

Short Axis View

= oblique coronal plane across barrel of LV lumen

1. Basal, middle, apical portions of LV myocardium
2. LV size (easy assessment)
3. LV myocardial contractility (easy assessment)

CARDIAC REPORTING

1. Coronary arteries: origin, course, segmental anatomy
2. Dominance and size of LAD artery, LCx artery, and RCA
3. Number of diagonal + marginal branches
4. Size of heart + cardiac chambers
5. LV function with ejection fraction and wall motion
6. End-diastolic + end-systolic LV volume
7. LV myocardial mass + thickness

HEART VALVES

Embryology:

semilunar valves develop simultaneously with formation of RV + right ventricular outflow tract (RVOT) from conotruncal endocardial cushions around distal part of conus

Heart Valve Positions

PA CXR:

reference line = oblique line drawn from distal left mainstem bronchus to right cardiophrenic angle

√ aortic valve resides in profile superior to this line overlying the thoracic spine

√ pulmonic valve just inferior to left mainstem bronchus

√ mitral valve resides inferior to this line centrally located within cardiac silhouette
√ tricuspid valve inferior to this line more basilar and midline

LAT CXR:

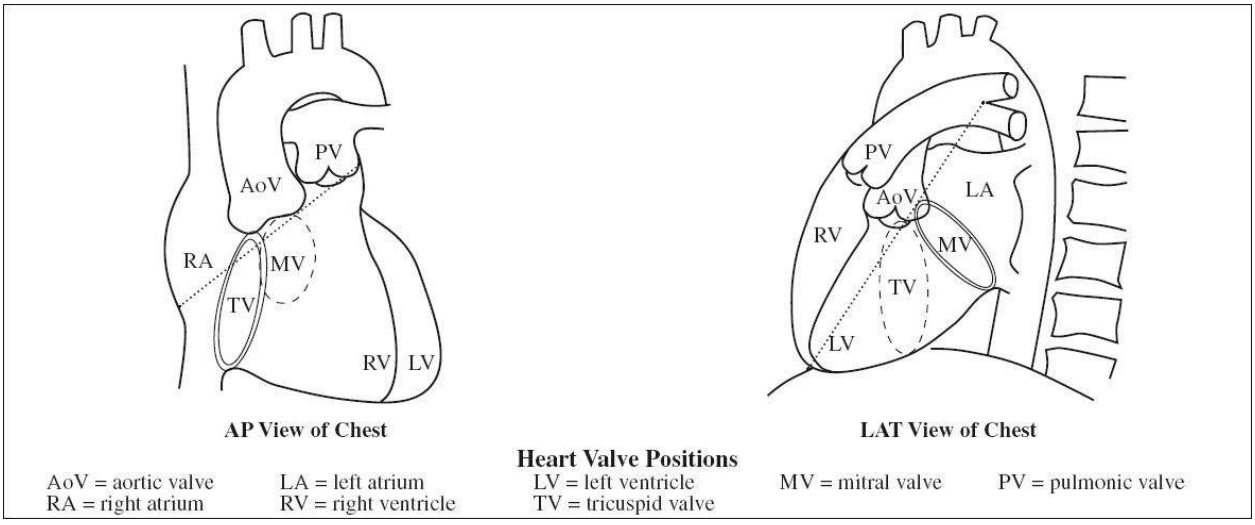
reference line = oblique line drawn from carina / right pulmonary artery shadow to anterior cardiophrenic sulcus

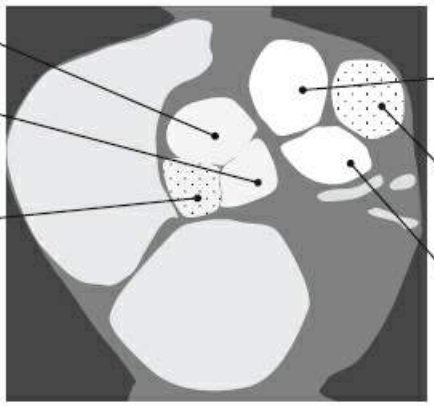
√ aortic valve resides superior to this line
√ pulmonic valve anterior + superior to aortic valve
√ mitral valve resides inferoposteriorly to this line
√ tricuspid valve inferior to this line anteriorly

Aortic Valve

= separates LV outflow tract from ascending aorta by a valve composed of annulus, commissures and usually 3 (range, 1 – 4) thin semilunar valve leaflets / cusps

(a) right cusp: inferior to right coronary sinus + origin of RCA
(b) left cusp: inferior to left coronary sinus + origin of LCA





Attitudinal CT of Semilunar Valves & Cusps

intrathoracic attitudinal view versus *heart-centric short-axis view*

left-facing sinus	= left anterolateral	= *anterior*
right-facing sinus	= right anterolateral	= *right posterior*
nonfacing sinus	= posterior	= *left posterior*

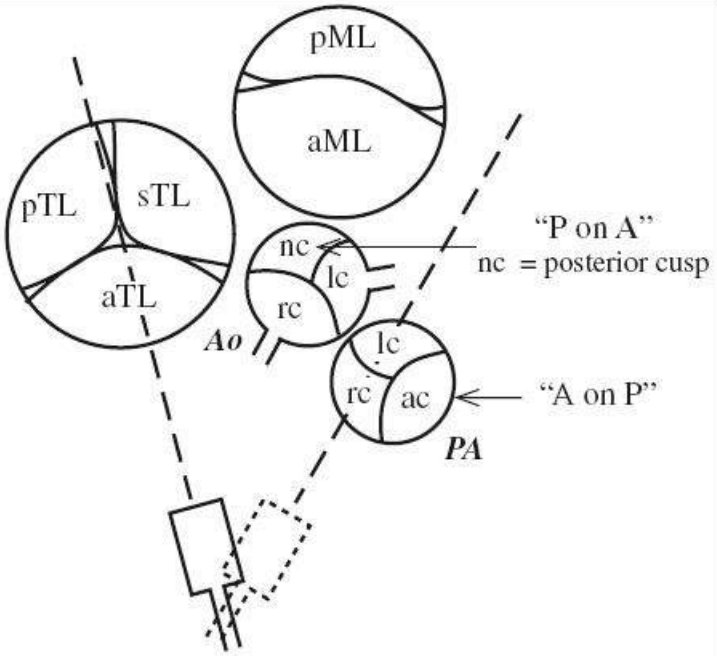


Diagram of the Relationship of the Four Cardiac Valves in Cross Section

aTL, pTL, sTL = anterior, posterior, septal (medial) tricuspid valve leaflets

Attachment of chordae tendineae:

- anterior papillary muscle attach to aTL + pTL
- posterior papillary muscle attach to pTL + sTL
- medial (conal) papillary muscle attach to aTL + sTL

aML, pML = anterior, posterior mitral valve leaflet

Attachment of chordae tendineae:

- anterior + posterior papillary mm. both attach to aML + pML

rc, lc, nc (Ao) = right, let, noncoronary cusps of aortic valve

rc, lc, ac (PA) = right, left, anterior cusps of pulmonary artery

Echocardiogram of Aortic Root		
Aortic root dimension	measured at end-diastole at R-wave of ECG	2.1–4.3 cm
increased in:	aneurysm of aorta, aortic insufficiency	
Aortic cusp separation		1.7–2.5 cm
decreased in:	aortic stenosis, low stroke volume	
increased in:	aortic insufficiency	
Left atrial diameter	measured at moment of mitral valve opening	2.3–4.4 cm
Eccentricity index of aortic valve cusps	ratio of anterior to posterior dimension (rarely used)	<1.3
Ratio of LA-to-aortic root dimension		0.87–1.11

(c) posterior / noncoronary cusp

Nodules of Arantius = thickened fibrous bulge at center of each free cusp margin forming central coaptation area

Commissures = junctions of cusps at attachment to aortic wall at level of sinotubular junction

Area: 2.5 –4.0 cm^2

Aortic valve planimetry is optimal during midsystole = 20% of R-R interval or 50–100 msec from R-wave peak!

Mitral Valve

= bicuspid valve (= 2 leaflets) anchored on mitral valve annulus + connected to LV papillary muscles by chordae tendineae; MV and aortic valve share fibrous continuity

Area: 4–6 cm^2

Circumference: 10 cm

Embryology: develops during 5th–15th week of gestation

Papillary Muscles of Mitral Valve

Origin: lateral wall of LV

(a) anterolateral papillary muscle

(b) posteromedial papillary muscle (single blood supply)

Prognosis: vulnerable to ischemia + rupture

Mitral Valve Annulus

= D-shaped ring within L atrioventricular groove; imbedded within myocardium as part of cardiac skeleton

(a) straight border = anterior portion of annulus; in fibrous continuity with aortic valve + heart skeleton

(b) curved border = posterior portion of annulus: attached to pliant endocardium

Function: site of valve leaflet attachment

Border: LCx artery + coronary sinus

Mitral Valve Leaflets

Normal thickness: < 5 mm

(a) semicircular anterior leaflet attaches to ⅓ of annulus + forms part of LVOT
Segments: lateral A1, middle A2, medial A3

(b) crescentic posterior leaflet
Segments: lateral P1, middle P2, medial P3

Mitral valve components are best evaluated on reformatted 2-chamber long-axis images perpendicular to the valve during middiastole = 65% of R-R interval for open mitral valve and 5% of R-R for closed mitral valve!

Pulmonic / Pulmonary Valve

= separates RV outflow tract from main pulmonary artery by a semilunar valve composed of 3 cusps (similar to aortic valve although separate from atrioventricular valve)

mnemonic: A cusp on P and P cusp on A anterior cusp (short-axis view) ← pulmonic valve posterior (noncoronary) cusp ← aortic valve

(a) anterior cusp
(b) right cusp
(b) left cusp

Area: 2.0 cm^2 / m2 of body surface area

Tricuspid Valve

= right atrioventricular valve separating RA from RV; anchored on tricuspid valve annulus + connected to RV papillary muscles by chordae tendineae; composed of 3 (range, 2 to 4) leaflets

Crista supraventricularis: muscular ridge that separates TV from pulmonary valve

(a) septal leaflet
(b) anterior leaflet
(b) posterior leaflet

VENTRICLES

Right Ventricle

Trabeculae: coarse

Papillary muscles: attached to interventricular septum + free wall; apical moderator band

Differentiating features of RV (from LV):

1. Heavily trabeculated apex
2. Well-developed infundibulum
3. Septal papillary muscles
4. Lack of fibrous continuity of AV valve + outflow tract

Moderator Band

= muscular band extending from interventricular septum to base of anterior papillary muscle

Function: part of right bundle branch conduction system

Right Ventricular Outflow Tract (RVOT)

= smooth muscular infundibulum / conus inferior to PV

In the right ventricle, trabeculae are coarse, and presence of an apical moderator band is CHARACTERISTIC!

Left Ventricle

Trabeculae: thin, delicate, smooth septal surface
Papillary muscles: attached to free wall only

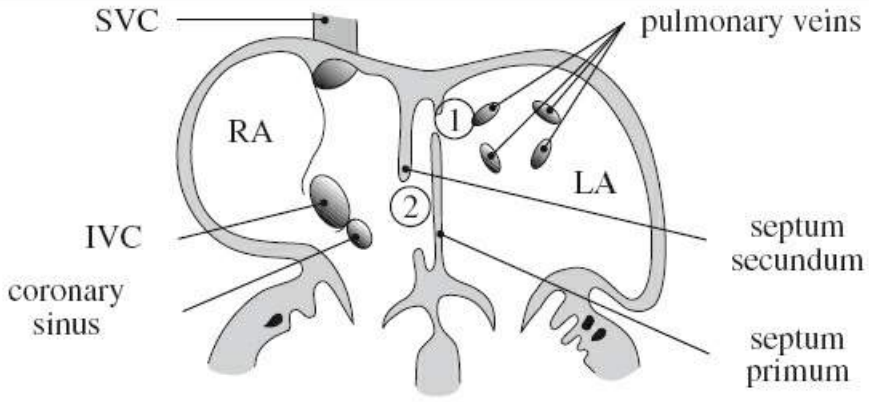
ATRIA

Embryology of Atrial Septa

1. **Septum primum** = thin partition dividing primitive atrium into right and left atria at 4th week; membrane grows from dorsal atrial wall toward endocardial cushion → ultimately forms thin flap valve of fossa ovalis
2. **Ostium primum** = temporary orifice between septum primum + endocardial cushions close to AV valves; it becomes obliterated by 5th week
3. **Ostium secundum** = multiple small coalescing fenestrations in center of septum primum
4. **Septum secundum** = stiff membrane developing on right side of septum primum growing from right atrial roof → ultimately forms thicker limbus of fossa ovalis
5. **Foramen ovale** = orifice limited by septum secundum + septum primum
6. **Foramen ovale flap** = lower edge of septum primum (patent in 6%, probe-patent in 25%); not considered an ASD

Right Atrium (RA)

Components:



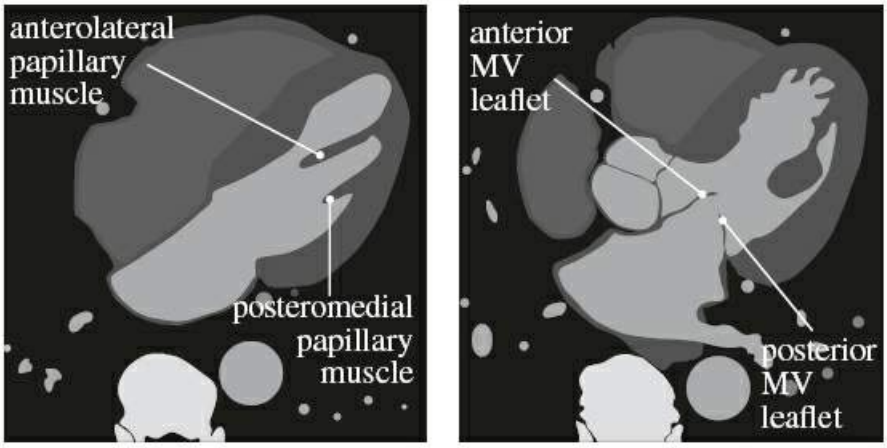
Normal Newborn Heart

Atrial septum consists of two components

(a) right side: septum secundum (muscular, firm) with posterior opening = foramen ovale

(b) left side: septum primum (fibrous, thin) with anterior opening = ostium secundum

1 = ostium primum 2 = ostium secundum



Papillary Muscles of MV **LV Outflow Tract**

Axial Diastolic Images of Left Ventricle

(Contrast-enhanced ECG-gated)

Echocardiogram of Right and Left Ventricle		
RV end-diastolic dimension	at R-wave of ECG	0.7–2.3 cm
increased in:	RV volume overload	
Septal thickness	end-diastolic thickness at R-wave of ECG	0.9 ± 0.06 cm
decreased in:	CAD	
increased in:	asymmetric septal hypertrophy, IHSS	
LV end-diastolic dimension	at R-wave of ECG	4.6 ± 0.54 cm
LVPW thickness	end-diastolic thickness at peak of R-wave	0.94 ± 0.09 cm
increased in:	LV hypertrophy	
LV end-systolic dimension		2.9 ± 0.5 cm
IVS÷LVPW thickness		<1.3
Fractional shortening	(EDD - ESD)/EDD x 100	
for LV		25–42%
for IVS		28–62%
for LVPW		36–70%

Morphologic Characteristics of Cardiac Ventricles		
Feature	*Right ventricle*	*Left ventricle*
Septum	moderator, septal and parietal bands	smooth septal surface
Trabeculae	coarse	thin and fine
Papillary muscles	attach to free wall and IVS	attach to free wall only
AV valve	tricuspid	bicuspid

Morphologic Characteristics of Cardiac Atria		
Feature	*Right Atrium*	*Left Atrium*
Appendage	blunt with broad connection to RA trapezoidal shape	small with narrow connection to RA fingerlike tubular shape
Blood from	coronary sinus and IVC	pulmonary veins
Pectinate muscle	extends outward toward AV canal	within tubular appendage
Myocardial component	crista terminalis and tenia sagittalis	none

(1) appendage
(2) venous part
(3) vestibule

Embryology: originates from primitive trabeculated RA (persists as RA appendage) + from sinus venosus forming smooth-walled portion of RA

Right Atrial Appendage

= triangular superior extension of RA that wraps around aortic root

√ pyramidal shape with narrow base

Rx: right atrial lead tip is typically placed at right atrial appendage for pacemaker / internal cardiac defibrillator

Sinus Venosus

› located in posterolateral wall of RA between orifices of SVC and IVC

(a) right horn: gives rise to crista terminalis, eustachian ridge, thebesian valve

(b) left horn: gives rise to coronary sinus

Vestibule of Right Atrium

= smooth muscular rim surrounding tricuspid orifice

Crista Terminalis

= prominent fibromuscular ridge separating smooth-walled venous part of posterior RA (= sinus venosus) from trabeculated muscle fibers of appendage anteriorly

Variations: in size + extent among individuals

Location: junction of sinus venosus and primitive RA

Clinical significance:

thickening of crista terminalis → development of atrial flutter + focal right tachycardias (⅔ arise in crista terminalis) → target for catheter RF ablation

√ vertically oriented smooth muscular ridge varying in size + thickness amongst individuals:

√ small thin valvelike / broad-based structure

√ may be large ← fatty infiltration of crista terminalis in lipomatous hypertrophy of the atrial septum

√ superiorly arches anterior to the orifice of the SVC

√ extends to area of anterior interatrial groove

√ merges with interatrial bundle (= Bachmann bundle)

√ indistinct inferior border located near IVC orifice merging with small trabeculations of inferior portion of cavotricuspid isthmus

› gives rise to thick muscle bundles

(a) anterior pectinate muscles fanning out anteriorly

(b) septum spurium = most prominent anterior pectinate muscle (in 80%) arising from crista terminalis

Mean thickness: 4.5 mm

Sinoatrial Node

= subepicardial spindle-shaped structure as source of cardiac impulse (= dominant pacemaker)

Length: 20 ± 3 mm

Location: in myocardium at superior cavoatrial junction between crista terminalis and

SVC

√ surrounds sinoatrial nodal artery, which may course centrally (70%) / eccentrically within node

Koch Triangle

Location: at orifice of coronary sinus

Borders:

› posteriorly: fibrous extension from eustachian valve (tendon of Todaro) = Todaro-eustachian ridge

› anteriorly: attachment of septal leaflet of tricuspid valve

› inferiorly: coronary sinus

› at apex: central fibrous body of heart (= site of penetration of His bundle)

› midportion: contains compact AV node (fast pathway)

› base: bordered by coronary sinus ostium + septal isthmus (= area between edge of coronary sinus ostium + septal tricuspid valve); contains slow pathway

◊ Septal isthmus = frequently target for ablation of slow pathway in AV node reentrant tachycardia!

AV Node

Location: within Koch triangle

Borders:

› coronary sinus ostium

› septal leaflet of tricuspid valve

› tendon of Todaro = fibrous band connecting eustachian and thebesian valves

[Francesco Todaro (1839–1918), Italian professor of anatomy at the Universities of Messina and Rome]

Importance: electrophysiologists frequently modify this node in dual atrioventricular nodal pathways → AV nodal reentrant tachycardia

Terminal Groove / Sulcus Terminalis

= fat-filled groove on epicardial side corresponding internally to crista terminalis close to cavoatrial junction

› location of sinus node + terminal segment of sinoatrial nodal artery

Eustachian Valve

[Bartolomeo Eustachi (1500 or 1514–1574), one of the founders of the science of human anatomy in Rome, Italy]

= valve of inferior vena cava (guarding entrance into IVC)

Function: directs flow toward foramen ovale

Location: junction of RA and IVC; inserts medially onto eustachian ridge (= border between oval fossa + coronary sinus)

› directs blood from IVC to foramen ovale in fetus

› free border continues as tendon of Todaro

√ thin linear structure, not routinely imaged

◊ Rarely an unusually large muscular valve may pose an obstacle to passage of a catheter!

Cavotricuspid Isthmus

= area between IVC + tricuspid valve of highly variable isthmian anatomy

◊ Target of catheter ablation as treatment of choice for isthmus-dependent atrial flutter!

N.B.: obstacles to successful ablation may be a large eustachian ridge, aneurysmal pouches, or a concave deformation of the entire isthmus

Thebesian Valve

= valve of coronary sinus

[Adam Christian Thebesius (1686–1732), anatomist and municipal physician in Hirschberg, Silesia]

Prevalence: in 80% of cadaveric specimens

Function: prevents reflux from RA into coronary sinus

Location: entry of coronary sinus into RA

Morphology: complete circular (30%), crescentic (35%), absent (20%), threadlike (2%), fenestrated (10%)

√ thin semilunar fold at anteroinferior rim of coronary sinus ostium

Mechanical barrier: large eustachian valve / ridge (25%), > 5 mm deep subthebesian recess (45%), hypoplastic coronary sinus ostium, large thebesian valve

Subthebesian Pouch

= subeustachian sinus = sinus of Keith

= pouchlike atrial wall inferior to orifice of coronary sinus

Depth: 4.3 ± 2.1 (range, 1.5–9.4) mm

◊ Substrate for reentrant circuit during atrial flutter

N.B.: main source of RF procedural difficulty

Interatrial Septum

Septum = wall that can be removed without exposing heart cavity to extracardiac structures

Parts: flap valve of foramen ovale (septum primum) + part of its anteroinferior margin

◊ Superior rim of fossa (septum secundum = infolded wall between SVC and right pulmonary veins) is not a true septum!

√ thin septum that is difficult to image

√ may contain small amount of fat sparing fossa ovalis

DDx: Lipomatous hypertrophy of interatrial septum

√ characteristic dumbbell shape ← sparing of fossa ovalis

√ abnormal amount of fat in older / obese adults

Fossa Ovalis

= circular indentation in interatrial septum

Variant: patent fossa ovalis / foramen ovale

PATENT FORAMEN OVALE

= PATENT FOSSA OVALIS

Prevalence: 15%

Function: can result in R-to-L shunt

Associated with:
paradoxical emboli, cryptogenic stroke, hypoxemia in patients with obstructive sleep apnea, increased risk for decompression sickness, increased risk for atrial fibrillation after cardiac surgery
√ demonstrated by contrast-enhanced echocardiography

Left Atrium (LA)

Components: venous component, vestibule, appendage
Embryology: originates from primitive trabeculated LA (persists as LA appendage) + from pulmonary veins forming smooth-walled portion of LA
√ smooth walled venous + septal component + vestibule
√ ridge of smooth muscle (± bulbous tip) at junction of LA appendage and entrance of left superior pulmonary vein

Venous Component of Left Atrium
= located posteriorly → pulmonary vein orifices at each corner

Left Atrial Vestibule
= surrounds the mitral orifice

Left Atrial Appendage
= arises from superolateral aspect of LA
√ rough trabeculated surface of tubular shape
√ projects anteriorly over proximal LCx artery
√ 3.5–6.5 mm thick superior wall / dome
Cx: narrow neck predisposes to thrombus deposition

Atrial Appendages

√ linear filling defects (R > L) = pectinate muscles fibers running parallel to each other measuring > 1 mm (in 97%)
DDx: thrombus in LA

CORONARY ARTERIES

Anatomy of Left Coronary Artery (LCA)

arises from left (posterior) coronary sinus (= left sinus of Valsalva) near sinotubular ridge; passes to left and posterior to pulmonary trunk

1. **Left main coronary artery** (LM)
   Segments: ostium to bifurcation = 5–20 mm short stem
   › bifurcates into LAD + LCx
   › trifurcates (in 15%) = ramus intermedius (RI) branch coursing laterally toward LV free wall similar to D1
2. **Left anterior descending** (LAD)
   Course: within anterior interventricular groove toward apex
   Supply: majority of LV + anterolateral papillary muscle ± small branches to anterior RV wall

Segments:
- › proximal: from left main bifurcation to origin of 1st septal branch
- › midportion: from 1st septal branch to an acute angle (may coincide with origin of 2nd septal perforator)
  - – otherwise split halfway between 1st septal perforator and apex into:
    - › middle LAD
    - › distal LAD
- › apical segment = termination of LAD

(a) **Diagonal** perforating branches (D1, D2, etc) arise from LAD, course over anterolateral wall of LV
Supply: LV free wall
mnemonic: **D**iagonals course **d**ownward from LA**D**

(b) **Septal** perforating branches (S) course medially toward anterior interventricular septum
Supply: majority of interventricular septum + AV bundle + proximal bundle branch

3. **Left circumflex artery** (LCx) travels within left atrioventricular sulcus (groove); terminates at obtuse (blunt / round) margin of heart

(a) **Obtuse marginal** (lateral) branches (OM1, OM2, etc) for lateral wall of LV

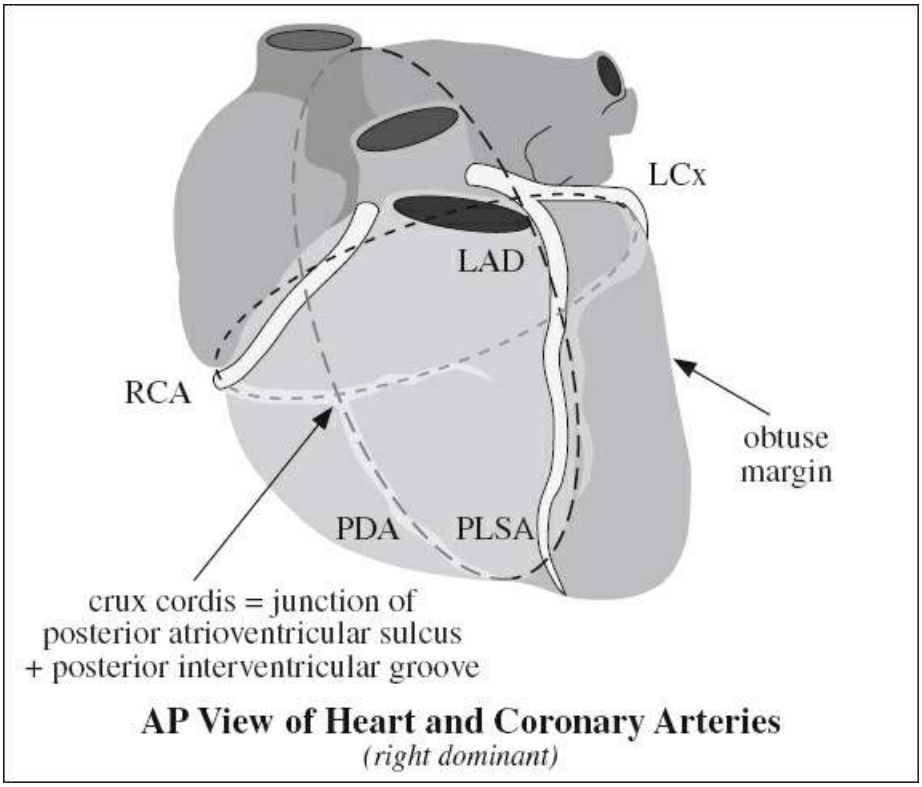
(b) Left atrial circumflex artery (LACX) for atrium

(c) variably: branches to posterolateral + posterior descending artery supplying diaphragmatic portion of LV (= left dominance)

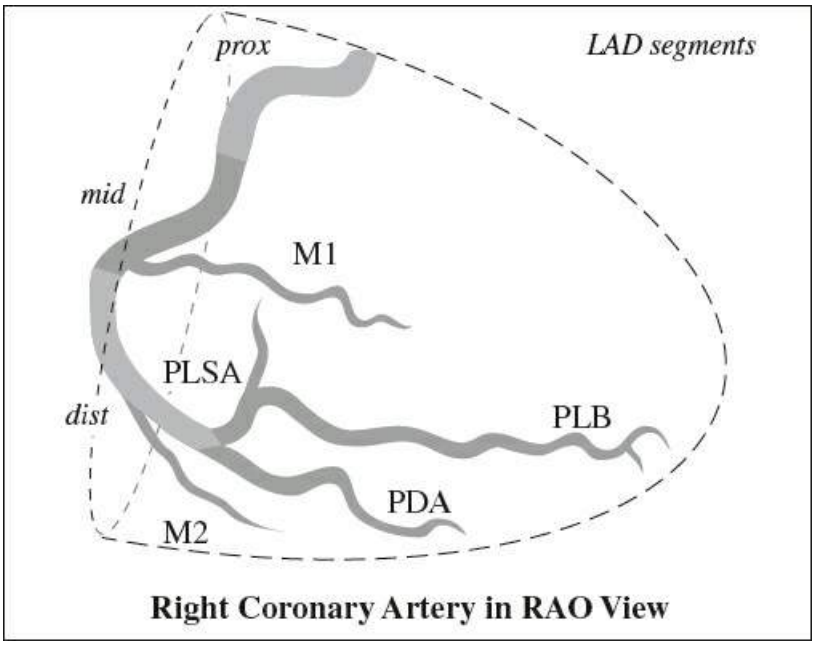
Supply: LV free wall + variable portion of anterolateral papillary muscle

Terminology from surface perspective of apical view:
- › rounded obtuse margin of heart formed mainly by LV
- › sharp angle = acute margin of heart formed mainly by RV

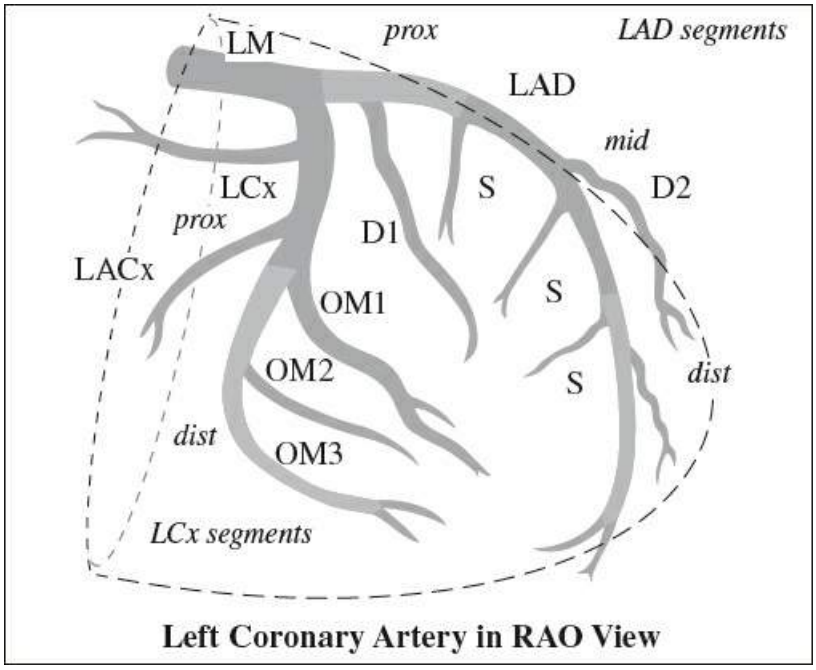
Segments: proximal + distal (based on origin of large obtuse marginal branches)



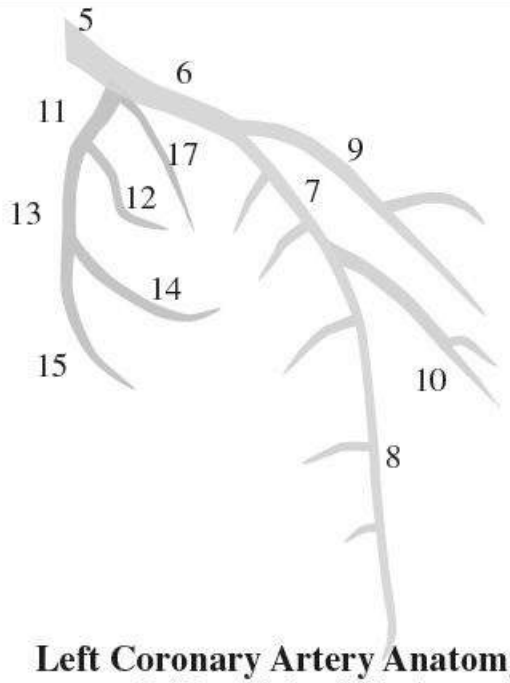
AP View of Heart and Coronary Arteries
(right dominant)



Right Coronary Artery in RAO View



Left Coronary Artery in RAO View

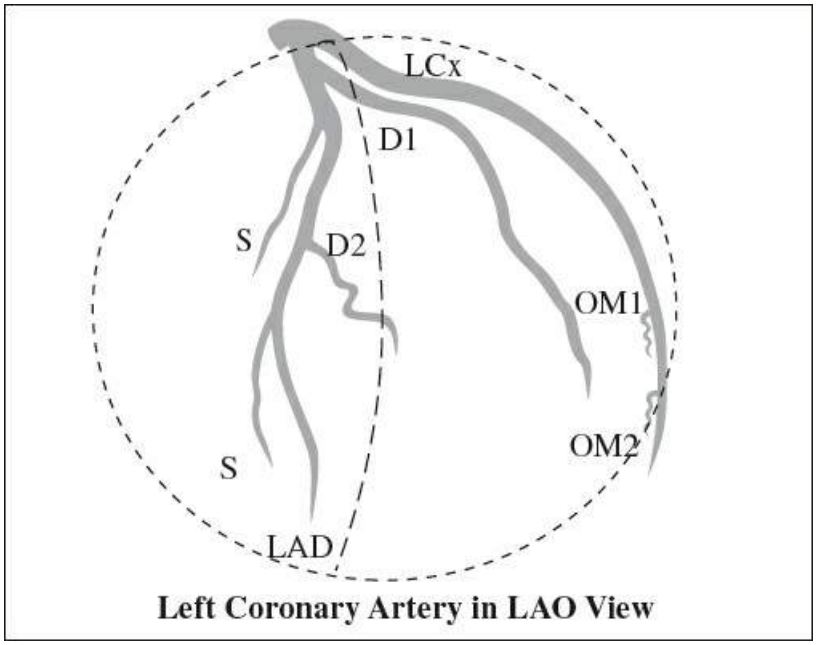


Left Coronary Artery Anatomy

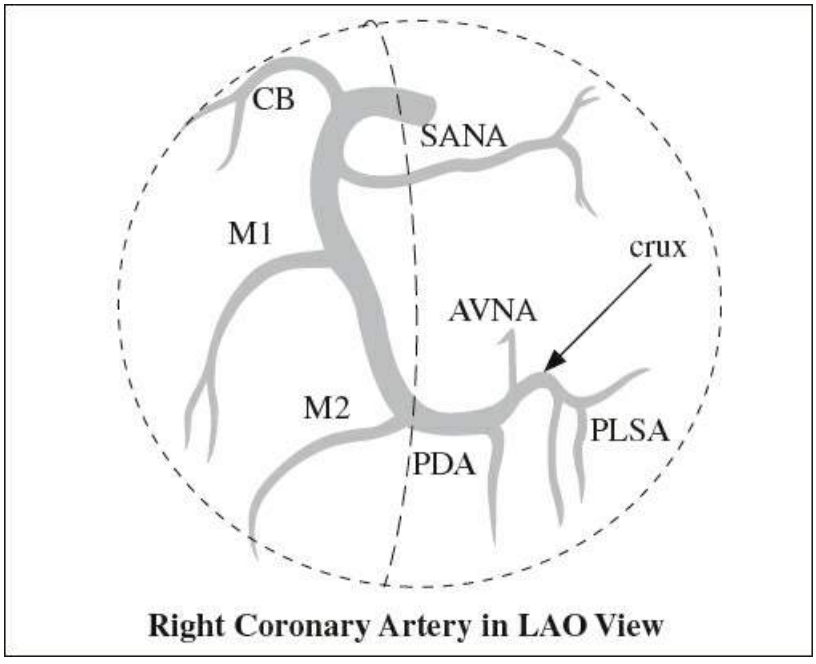
(LAO cranial projection)

17-Segment Classification by American Heart Association

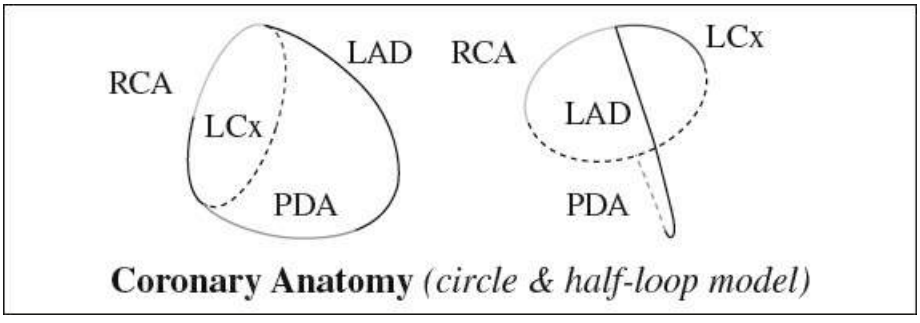
5 = main artery
6 = proximal segment of LAD branch
7 = middle segment of LAD branch
8 = distal segment of LAD branch
9 = first diagonal branch
10 = second diagonal branch
12 = proximal segment of LCx artery
13 = middle segment of LCx artery
14 = second obtuse marginal branch of LCx
15 = distal segment of LCx artery
17 = intermediate branch



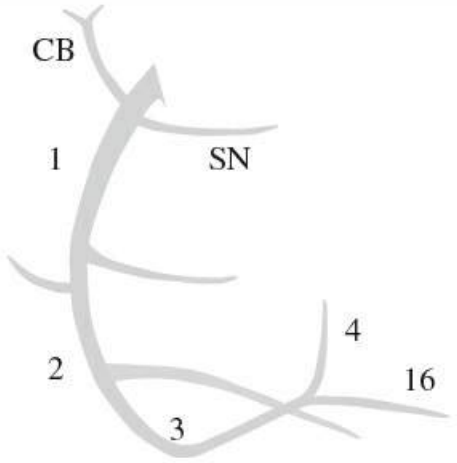
Left Coronary Artery in LAO View



Right Coronary Artery in LAO View



Coronary Anatomy *(circle & half-loop model)*

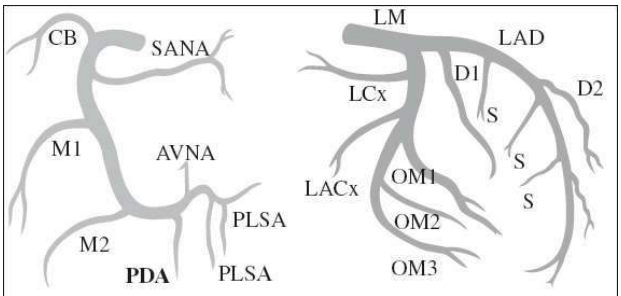


Right Coronary Artery Anatomy

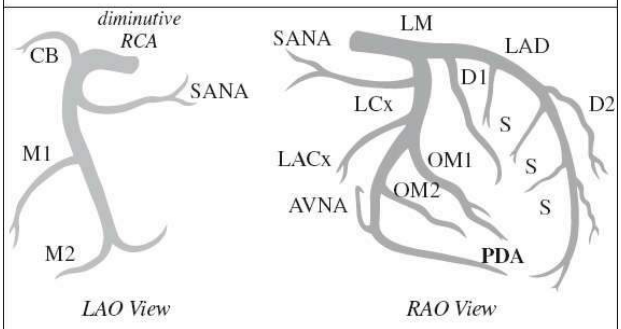
(RAO cranial projection)

17-Segment Classification by American Heart Association

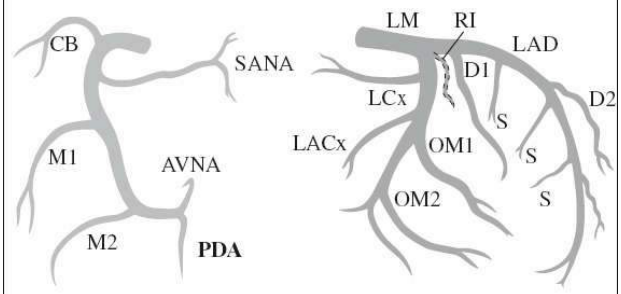
1	=	proximal segment of main artery
2	=	middle segment of main artery
3	=	distal segment of main artery
4	=	posterior descending branch
16	=	posterior left ventricular branch
SN	=	sinonodal branch
CB	=	conal branch



Right Dominant Circulation



Left Dominant Circulation



Balanced Circulation

Coronary Artery Angiograms of Varying Dominance

AVNA = atrioventricular node artery
CB = conus branch artery
D1 = 1st diagonal artery
D2 = 2nd diagonal artery
LACx = left atrial circumflex artery
LAD = left anterior descending artery
LCx = left circumflex artery
LM = left main coronary artery
M1 = 1st acute marginal branch artery
M2 = 2nd acute marginal branch artery
OM1 = 1st obtuse marginal artery
OM2 = 2nd obtuse marginal artery
PDA = posterior descending artery
PLB = posterolateral branch
PLSA = posterolateral segment artery
R = ramus intermedius (in 15%)
S = septal branch
SANA = sinoatrial node artery

Anatomy of Right Coronary Artery (RCA)

arises from right (anterior) coronary sinus → passes to right + posteriorly to pulmonary artery → travels downward within right atrioventricular sulcus (groove) → rounds the acute margin of the heart toward crux

Terminology based on posterior surface view of heart:

crux cordis = cross formed by
› AV groove (transecting a line formed by)
› posterior interventricular + interatrial sulci
[*crux*, Latin = cross, junction]

Segments:

› proximal: ostium to halfway to acute margin of heart
› mid:
› distal: acute angle of heart to origin of PDA

1. **Conus artery** (CB)
   = 1st branch of RCA (in 50–60% of patients); may originate directly from coronary sinus of aorta (in 30–35%)
   √ forms circle of Vieussens = anastomosis with LAD
   Supply: RVOT = conus arteriosus
2. **Sinoatrial node artery** (SANA)
   = 2nd branch of RCA (in 60%) / from LCx (in 40%)
   √ courses along anterior interatrial groove toward superior cavoatrial junction
   √ at cavoatrial junction circling either anteriorly (precaval) / posteriorly (retrocaval) to enter node
3. **Marginal branches** (M1, M2, etc) have an anterior course
   › **acute marginal branch** = at junction of middle + distal RCA
   Supply: RV
4. **Posterior descending artery** (PDA)
   = origin of PDA determines coronary artery dominance
   Origin: usually RCA near crux (in 70%) / distal acute marginal branch (= right dominance)
   Supply: posterior third of ventricular septum + diaphragmatic segment of LV + posteromedial papillary muscle
5. **Atrioventricular node artery** (AVNA)
   = small branch to AV node
   Origin: apex of U-turn of distal RCA (80–87%) / terminal portion of LCx (8–13%) / both RCA and LCx (2–10%)
   Supply: posterior interventricular septum, interatrial septum, AV node, His bundle
   √ penetrates base of posterior interatrial septum at crux
   √ may course beneath endocardium near ostium of coronary sinus + septal isthmus
   ◊ High risk for AV nodal artery coagulation during RF ablation!
6. **Posterolateral segment arteries** (PLSA)
   supplies posterolateral wall of LV

Coronary Artery Territory

septum	=	LAD
anterior wall	=	LAD
lateral wall	=	LCx
posterior wall	=	RCA
inferior / diaphragmatic wall	=	RCA
apex + inferolateral wall	=	watershed areas

Coronary Artery Dominance

Whichever artery crosses the crux of the heart and gives off the posterior descending artery (PDA) is considered the dominant coronary artery!

= artery that supplies the inferior portion of LV
- › RCA in 70–85% (= right dominance)
- › LCx in 7–10% (= left dominance)
- › RCA + LCx = codominance / balanced supply (7–8%)

Coronary Arteriography

◊ Average coronary artery diameter: 4 mm (M); 3 mm (F)

Contrast agents:

1. Monomeric ionic contrast material:
   (a) negative inotropic = depression of myocardial contractility ← hyperosmolality of sodium + decrease in total calcium
   (b) peripheral vasodilatation
2. Meglumine diatrizoate (contains small quantities of sodium citrate + EDTA)
3. Nonionic contrast material = slight increase in LV contractility

Dose: 3–10 mL

Mortality: 0.05%

Risk factors associated with death:

1. Multiple ventricular premature contractions
2. Congestive heart failure
3. Systemic hypertension
4. Severe triple-vessel coronary artery disease (highest risk)
5. LV ejection fraction < 30%
6. Left main coronary artery stenosis

Clues for projection:

45–70° LAO:
- √ ribs slanting to left side of image
- √ catheter in descending aorta on right side of image

15–30° RAO:
- √ ribs slanting to right side of image
- √ catheter in descending aorta on left side of image

Technique:

◊ 20–30° of cranial / caudal angulation variably used

Catheter in left coronary orifice:

(a) LAO + caudocranial angulation:

proximal ⅓ of LAD + origin of first diagonal branch

(b) LAO + craniocaudal angulation = "spider view":
LCA, proximal LCx, first marginal / diagonal branches

(c) RAO + craniocaudal angulation:
proximal third of LCx + origin of its branches

(d) RAO + caudocranial angulation:
separation of LAD from diagonal branches

Catheter in right coronary artery orifice: LAO ± RAO

False-negative interpretation:

(1) Eccentric lesion in 75%
(2) Foreshortening of vessel
(3) Overlap of other vessels remedied by angulated projections: improved diagnosis (50%), upgrade to more significant stenosis (30%), lesion unmasked (20%)

Coronary Artery Collaterals

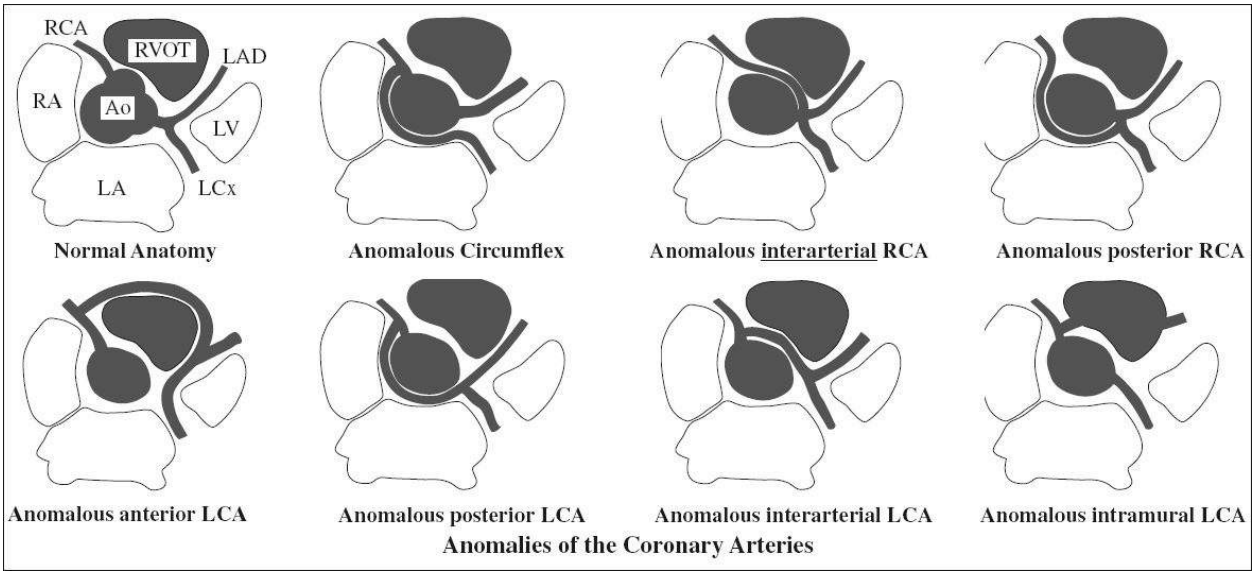
A. INTRACORONARY COLLATERALS
= filling of a distal portion of an occluded vessel from the proximal portion
√ tortuous course outside the normal path

B. INTERCORONARY COLLATERALS
= between different coronary arteries / between branches of the same artery
Location: on epicardial surface, in atrial / ventricular septum, in myocardium

1. Proximal RCA to distal RCA
   (a) by way of acute marginal branches
   (b) from sinoatrial node artery (SANA) to atrio-ventricular node artery (AVNA) = Kugel collateral
2. RCA to LAD
   (a) between PDA and LAD through ventricular septum / around apex
   (b) conus artery (1st branch of RCA) to proximal part of LAD
   (c) acute marginals of RCA to right ventricular branches of LAD
3. Distal RCA to distal LCx
   (a) posterolateral segment artery of RCA to distal LCx (in AV groove)
   (b) AVNA of RCA to LCx (through atrial wall)
   (c) posterolateral branch of RCA to obtuse marginal branches of LCx (over left posterolateral ventricular wall)
4. Proximal LAD to distal LAD
   (a) proximal diagonal to distal diagonal artery of LAD
   (b) proximal diagonal to LAD directly
5. LAD to obtuse marginal of LCx

Coronary Artery Anomalies

Prevalence: 0.3–1.3%; in 4–25% responsible for nontraumatic sudden death in young adults



Coronary Artery Anomaly of Hemodynamic Significance

= 2nd most common cause of sudden cardiac death among young adults

1. ALCAPA = most serious anomaly
2. Origin from opposite sinus of Valsalva / opposite coronary artery + interarterial / intramural course
3. Congenital coronary artery fistula

Coronary Artery Atresia

1. Congenital atresia of left main coronary artery
   √ fibrous connection between LAD-LCx junction + left coronary cusp
2. Atresia of right coronary artery
3. Atresia of left circumflex coronary artery

Anomaly of Coronary Artery Origin

1. High takeoff point from aorta (6%)
   = origin of RCA / LCA above the junctional zone between sinus + tubular part
   ◊ May be difficult to cannulate!
2. Multiple ostia
   (a) RCA + conus branch arise separately
   (b) LAD + LCx arise separately without LCA (0.41%)
3. Single coronary artery (0.0024–0.0440%)
4. Anomalous origin from pulmonary artery
5. Origin of coronary artery from opposite sinus / noncoronary sinus
   (a) RCA arising from left coronary sinus (0.03–0.17%)
   (b) LCA arising from right coronary sinus (0.09–0.11%)
   (c) LCx / LAD arising from right coronary sinus (0.32–0.67%)
   (d) LCA / RCA arising from noncoronary sinus
   may take the following course:
   › <u>interarterial</u> "malignant" course (between aorta + pulmonary trunk) just above pulmonary valve

◊ Most common clinically significant coronary artery anomaly → compression of coronary artery between aorta and PA → acute ischemia / arrhythmia → sudden cardiac death

√ anomalous artery surrounded by epicardial fat

› trans-septal: subpulmonic / beneath RVOT

› prepulmonic: anterior to RVOT

› retroaortic: posterior to aorta

› intramural: LCA within aortic wall → compression throughout cardiac cycle

√ slitlike coronary artery lumen

√ impaired coronary artery blood flow

Among 6.3 million military recruits 64 patients died from a cardiac cause: 54% had a left main coronary artery arising from the right sinus of Valsalva with an interarterial course!

Anomaly of Coronary Artery Course

1. Myocardial bridging
   = band of myocardial muscle overlying a segment of a coronary artery
2. Duplication of arteries: eg, LAD

Anomaly of Termination of Coronary Artery

1. Coronary artery fistula
2. Coronary arcade
   = angiographically demonstrable communication between RCA and LCA in the absence of a coronary artery stenosis
   √ prominent straight connection near crux
   DDx: tortuous collateral vessel
3. Extracardiac termination
   Cause: atherosclerotic CAD
   Receiver: bronchial, internal mammary, pericardial, anterior mediastinal, superior / inferior phrenic, intercostal arteries

EMBRYOGENESIS OF VEINS

Time of development: 6th–8th week of embryonic life

Origin: 3 main paired venous systems drain into sinus venosus

A. Vitelline (omphalomesenteric) venous system:
   blood from yolk sac to sinus venosus invagination separates left horn of sinus venous from LA

B. Umbilical venous system blood from chorionic villi to sinus venosus via ductus venosus

C. Intraembryonic cardinal venous system
   = continuous appearance + regression of 3 paired embryonic veins

(1) Cardinal veins

(a) <u>anterior</u> cardinal vein drains the cranial (cephalic) region

› part of left anterior cardinal vein→ left superior intercostal vein + adjacent left brachiocephalic vein

(b) <u>posterior</u> cardinal vein drains caudal portion of embryo (body of embryo +

mesonephros + anterior extremities)

Location: dorsolateral part of urogenital fold

› right posterior cardinal vein→ part of azygos vein

(c) right + left <u>common</u> cardinal veins (= ducts of Cuvier) formed by confluence of anterior + posterior cardinal veins

› right common cardinal vein→ superior vena cava

› right horn of sinus venosus → posterior wall of RA

› left horn of sinus venosus → coronary sinus

› regressing left common cardinal vein → ligament / vein of left atrium (vein of Marshall)

(d) vessel connecting right + left superior cardinal veins → left brachiocephalic vein

(2) Subcardinal veins drain urogenital system of metanephros + suprarenal glands

Location: ventromedial to posterior cardinal veins + ventrolateral to aorta

› intersubcardinal anastomoses form anterior to aorta below superior mesenteric artery and connect left + right subcardinal veins

(3) Supracardinal veins

drain body wall via intercostal veins

Location: dorsomedial to posterior cardinal vein + dorsolateral to aorta

› CRANIAL

(a) azygos vein on the right
drains 4–11 right intercostal veins

(b) portion of superior intercostal vein drains 2–3 left intercostal veins

(c) accessory hemiazygos drains 4–7 left intercostal veins

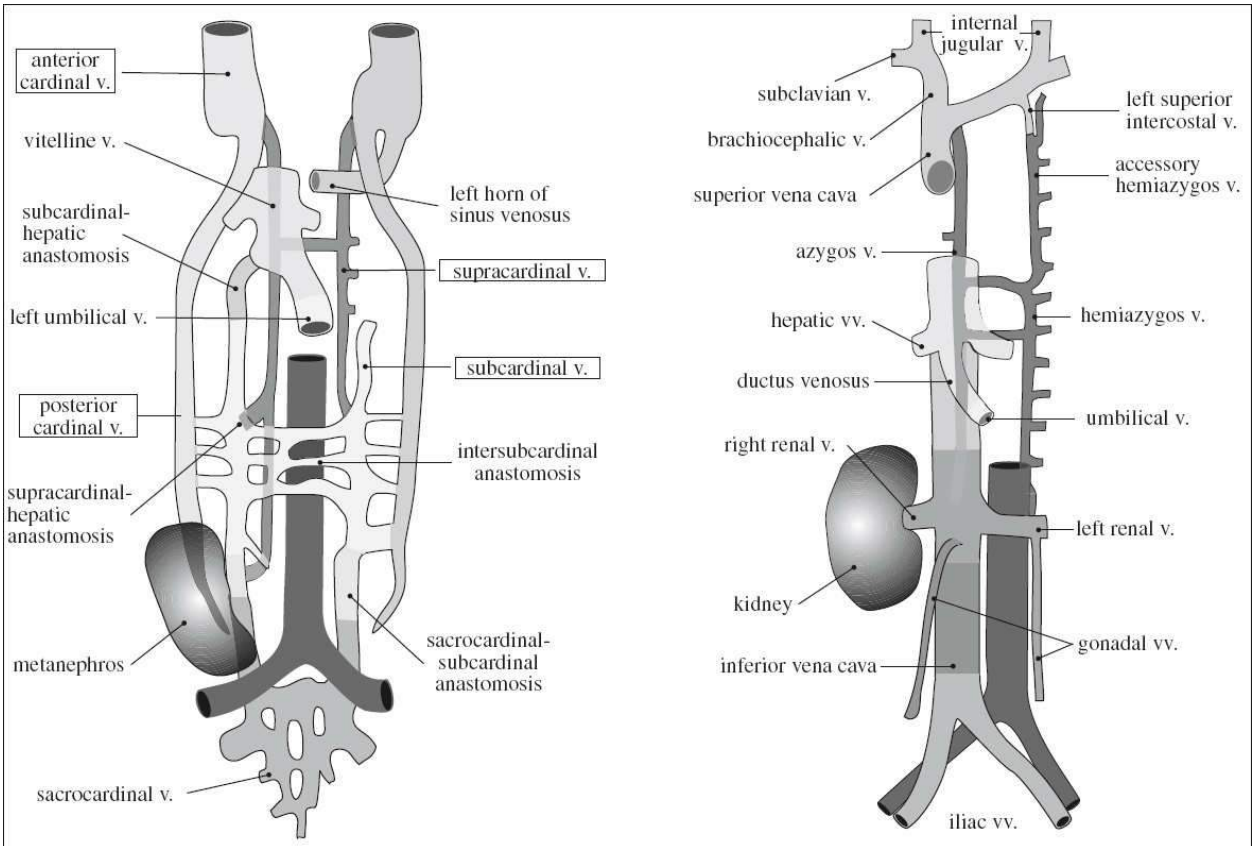
(d) hemiazygos vein drains left 8–11 intercostal veins

› CAUDAL: lumbar veins

Superior Vena Cava

Embryology: right common cardinal vein + proximal aspect of right anterior cardinal vein + right horn of sinus venosus form right superior vena cava

› Left common cardinal vein + proximal part of left anterior cardinal vein form left superior vena cava



Development of the Major Venous System
vitelline vein ⇒ hepatic segment of IVC; right subcardinal-hepatic anastomosis ⇒ suprarenal segment of IVC
right supracardinal-subcardinal anastomosis ⇒ renal segment of IVC; right abdominal supracardinal vein ⇒ infrarenal segment of IVC
thoracic supracardinal vein ⇒ azygos and hemiazygos veins

› Left superior vena cava involutes with development of innominate vein → ligament of Marshall

Origin: formed by confluence of right + left brachiocephalic vv.
Mean length: 7.1 ± 1.4 cm
Diameter: 2.1 ± 0.7 cm (in adults)
Shape on cross-section: major axis (1.5–2.8 cm), minor axis (1–2.4 cm)
Area threshold: < 1.07 cm^2 → obstruction / compression
CECT:
√ excellent uniform enhancement of SVC 60–75 seconds after injection of contrast agent into a peripheral vein
√ nonenhanced blood from contralateral veins and azygos vein can mimic a thrombus

Congenital Anomalies of SVC

1. Persistent left SVC

Inferior Vena Cava

1. Hepatic = posthepatic segment
   Origin: terminal part of right vitelline vein
2. Suprarenal segment

Origin: subcardinal-hepatic anastomosis

3. Renal segment
   Origin: part of right subcardinal vein + supracardinal-subcardinal anastomoses
4. Infrarenal segment
   Origin: right supracardinal / sacrocardinal vein

Congenital Anomalies of the IVC

1. Absence of hepatic segment of IVC with azygos continuation
2. Absence of infrarenal IVC with azygos / hemiazygos continuation
3. Duplication of IVC with azygos / hemiazygos continuation

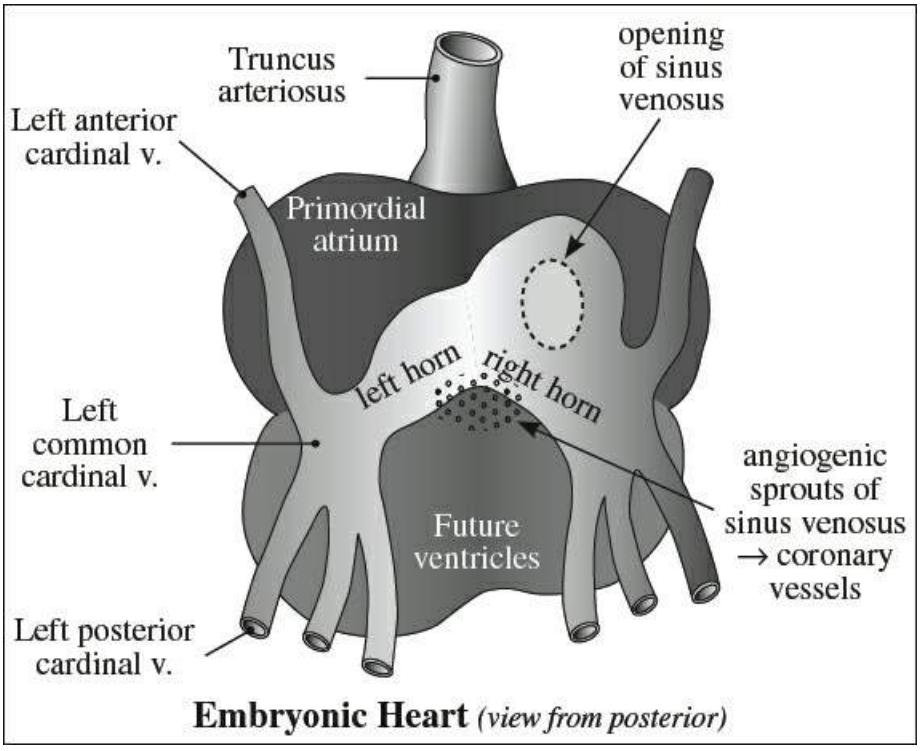
CARDIAC VEINS

Classification:

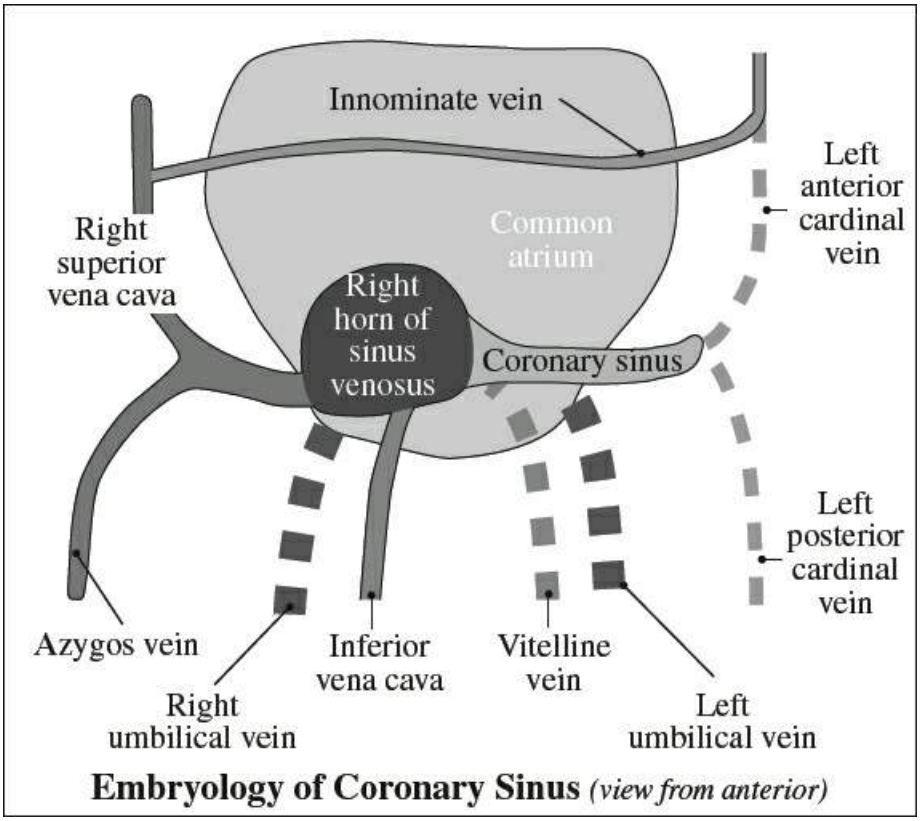
A. Greater cardiac (epicardial) venous system 70%
   › coronary sinus tributaries: 50% coronary sinus, anterior + posterior interventricular v., great cardiac v., small cardiac v., oblique vein of Marshall, atrial + septal vv.
   › noncoronary sinus tributaries: 20% anterior RV v., LA + RA vv., superior septal vv.

B. Smaller cardiac (intramural) venous system: 30% venoluminal, arterioluminal, venosinusoidal, arteriosinusoidal (= thebesian vessels 2 ° to arterial component)

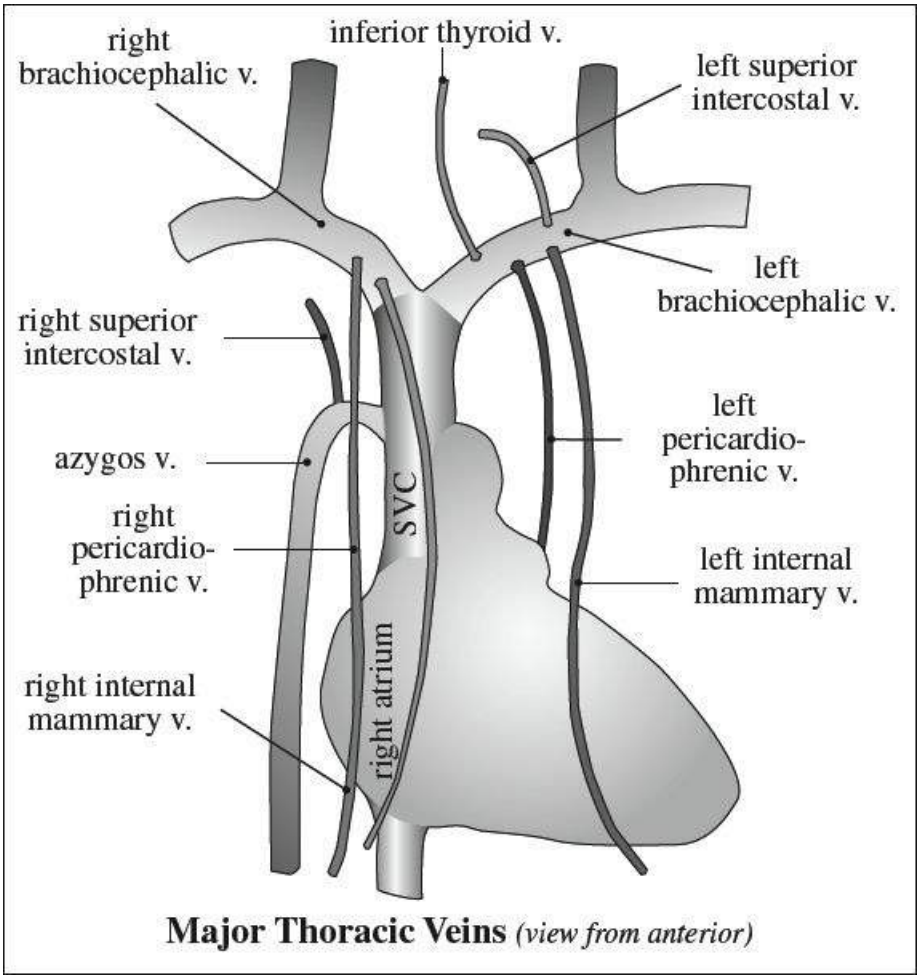
C. Compound cardiac venous system: venous tunnels of RA, sinoatrial node v., atrioventricular node v., RA wall v., ventricular septal v.



Embryonic Heart *(view from posterior)*



Embryology of Coronary Sinus *(view from anterior)*



Major Thoracic Veins *(view from anterior)*

Coronary Sinus

= distal portion of great cardiac vein

Origin: left horn of sinus venosus + adjacent left common cardinal vein receiving cardiac veins

› right horn of sinus venosus persists as venous portion of right atrium

Ostium: in RA medial to IVC + just superior to septal leaflet of tricuspid valve; guarded by thebesian valve

Length: 30–50 mm (in 75%)

Function: collects blood from left marginal vein; left posterior ventricular vein; small, middle, great, oblique cardiac veins

Clinical significance:

(1) Catheterization easiest via SVC ← sharp angle between coronary sinus and LA

(2) For cardiac resynchronization therapy (= implantation of automatic cardioverter-defibrillator for treatment of heart failure) a LV pacer lead is usually placed into posterior vein of LV / left marginal vein

(3) Conduit for catheter treatment of arrhythmias

Congenital Anomalies of Coronary Sinus

(a) variations

› in morphology: diverticulum (common at inferior aspect at junction with middle cardiac vein)
› in shape: wind sock (40%), tubular (50%), filiform (10%), varicoid, bifid
› in course: straight (16%), gently curved (62%), high-riding (22%)

Significance: difficult cannulation for mapping, ablation, left ventricular pacing; rarely of hemodynamic consequence

(b) enlargement
(c) absence / atresia: associated with heterotaxy syndromes + complex CHD
(d) atretic coronary sinus ostium
› with persistent left SVC
› with communication to LA

Coronary Sinus-Great Cardiac Vein Junction

Location: within 10 mm of each other
(1) Valve of Vieussens (in 65–85%) located 32 ± 5 mm from coronary sinus ostium
(2) Annular narrowing of external surface (20%) ← sphincterlike thickening of myocardial sleeve of coronary sinus
(3) Proximal / adjacent to oblique vein of Marshall

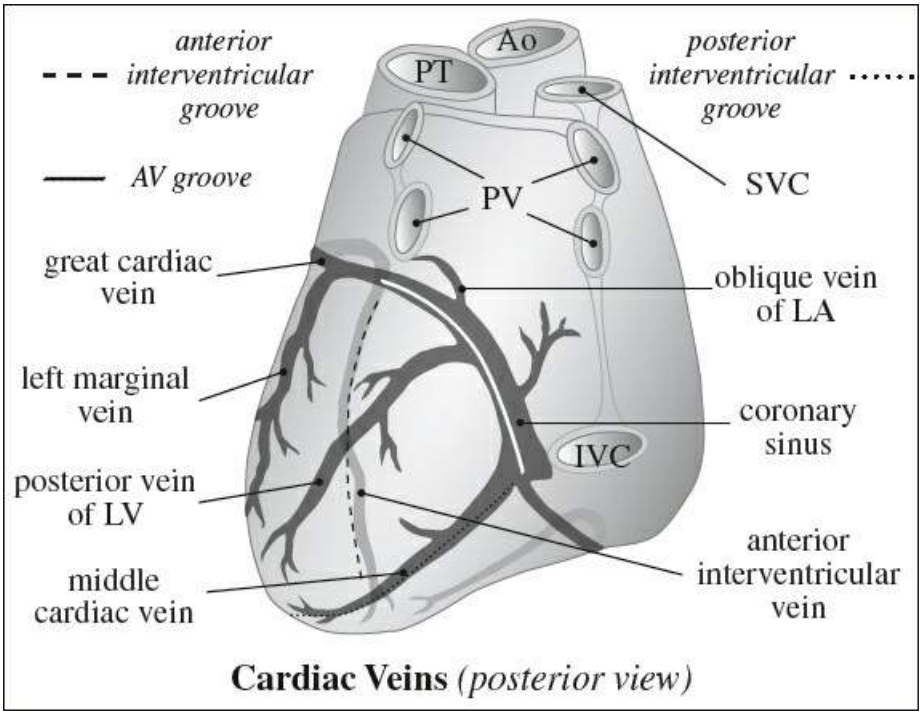
Valve of Vieussens: bi- / unicuspid (65%) or incomplete valve; present in 80%; cause of obstruction to cannulation

[Raymond Vieussens (1635–1715), French anatomist and pioneer in cardiology, head physician at Hôtel Dieu Saint-Éloi in Montpellier]

The 3 most constant anatomic landmarks of GCV-CS junction:
(1) orifice of the oblique vein of Marshall,
(2) valve of Vieussens,
(3) left margin of myocardial sleeve of coronary sinus

Great Cardiac Vein (GCV)

Location: inferior aspect of the heart in AV groove before emptying into RA
Course: crosses LAD + LCx
Drains: anterior interventricular septum, anterior surfaces of both ventricles, part of LA, cardiac apical region
Size: 45 mm long; 10–12 mm in diameter
Ostium: valve of Vieussens
Branches:



(1) Inferior interventricular (IIV) / posterior interventricular / middle cardiac vein
Location: posterior interventricular sulcus from apex to base of heart
Terminus: coronary sinus 1 cm from ostium
Drains: inferior walls of ventricles + cardiac apex + posterior $^{2}/_{3}$ of septum

(2) Left posterior / posterolateral vein of LV
Prevalence: 95%; single v. (60%), up to 3 veins
Terminus: coronary sinus (75%), GCV (25%)

(3) Left (obtuse) marginal vein
Prevalence: 70–95%
Terminus: GCV (80%), coronary sinus (20%)
Drains: much of LV myocardium

(4) Great cardiac vein
Location: left AV groove with LCx artery

(5) Anterior interventricular vein
Location: anterior interventricular groove from base of heart toward apex adjacent to LAD

Variability in Cardiac Veins

1. Absence of left marginal vein (15%)
2. Absence of posterior vein of LV (45%)

Variability in Great Cardiac Vein

@ beginning of coronary sinus
1. Oblique vein of Marshall = outer constriction
2. Vieussens valve = internal constriction

@ crossing of muscular LCx

√ kink in vein → luminal obstruction of great cardiac v.

PERICARDIUM

= double-walled sac (2-layered membrane) that envelops all cardiac chambers + origin of great vessels without direct attachment to heart

Pericardial thickness: 0.4–1.0 mm (1.2–1.7 mm by MRI; 0.7–2.0 mm by CT)

Function: regulates normal ventricular compliance by minimizing dilatation of RV + RA; physically protects heart by production of fluid + surfactants; limits displacement of heart within mediastinum; acts as pressure transducer between pleural space + cardiac chambers (augments systemic venous return + RV filling during inspiration)

A. FIBROUS / PARIETAL PERICARDIUM = FIBROSA
   = tough outer parietal layer that is mildly stretched
   √ attaches to sternum + proximal great vessels
   √ intrapericardial location of ascending aorta, main pulmonary artery, portions of venae cavae, most of PVs

B. SEROUS / VISCERAL PERICARDIUM = serosa
   = **epicardium**
   = delicate inner visceral layer forming a completely closed sac around the pericardial cavity; consists of a single layer of mesothelial cells
   • intimately connected to heart + epicardial fat

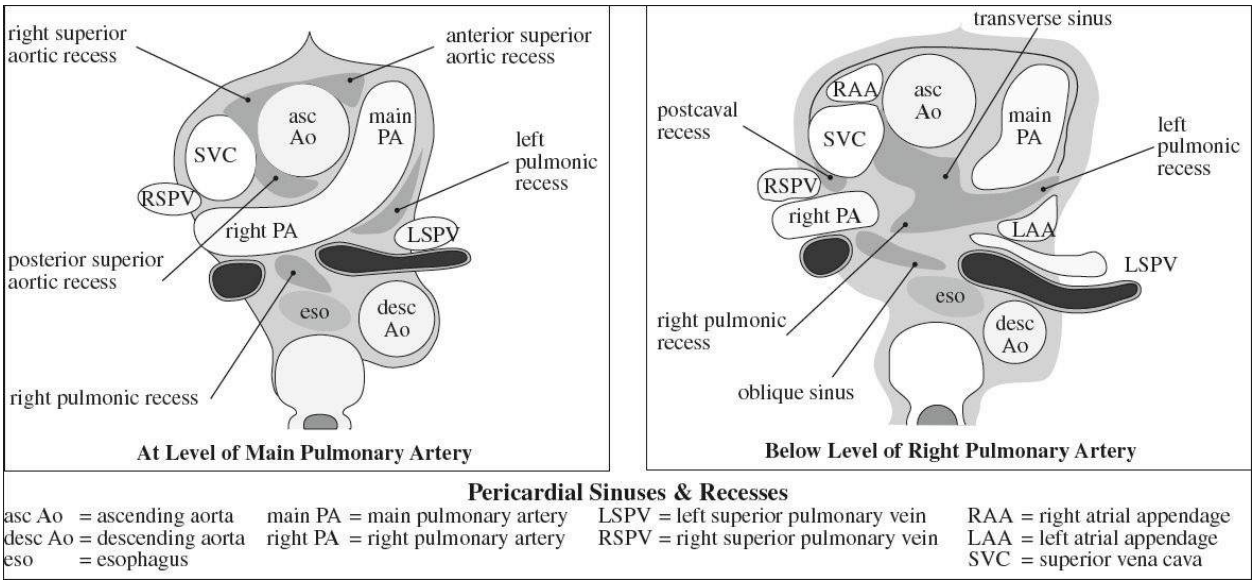
C. PERICARDIAL CAVITY
   = space between visceral and parietal pericardium
   √ sac contains 15–50 mL of serous fluid produced by mesothelial cells that line serosa
   √ normal intrapericardial pressure = 50–100 mm H_2O

Pericardial Sinuses and Recesses

= extensions of pericardial cavity

* = percentages give depiction on HRCT

A. Recesses of pericardial cavity proper
   1. Postcaval recess 23%*



√ behind and right lateral to SVC

2. Right pulmonic vein recess 29%*
   √ behind and right lateral to SVC
3. Left pulmonic vein recess 60%*
   √ behind and right lateral to SVC

B. Transverse sinus
   √ posterior to ascending aorta and pulmonary trunk + above left atrium 95%*
   1. Superior (aortic) recess
      √ along ascending aorta; may be divided into anterior, posterior, right lateral portion
      DDx: aortic dissection on NECT
   2. Left pulmonic recess
      √ below left pulmonary artery + posterolateral to proximal right pulmonary artery
   3. Right pulmonic recess
      √ below right pulmonary artery + above left atrium
   4. Inferior aortic recess
      √ between ascending aorta + inferior SVC / right atrium
      √ extending down to level of aortic valve

C. Oblique sinus 89%*
   √ behind left atrium + anterior to esophagus
   √ separated from transverse sinus by double reflection of pericardium (and fat) between right + left superior pulmonic veins
   1. Posterior pericardial recess 67%*
      √ behind distal right pulmonary artery + medial to bronchus intermedius

DDx: lymph nodes, esophageal / thymic process, vascular abnormality, pericardial cyst / tumor

Epicardial Fat

Thickness: increased in obesity

Asymmetric distribution: 3–4 x more along RV compared to left heart

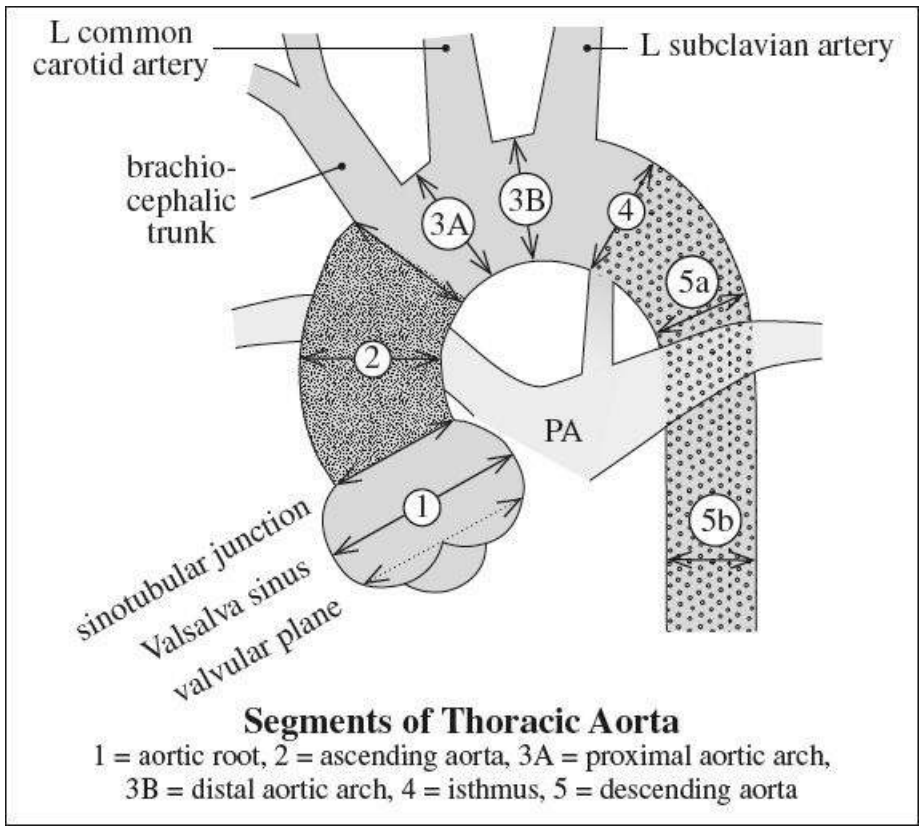
- can directly influence atherogenesis by free diffusion of fatty acids + adipokines into wall of coronary arteries

ANATOMY OF AORTA

Segments: Aortic root → Ascending aorta → Transverse aortic arch → Isthmus → Descending aorta

Aortic Root

(a) **Aortic annulus** = aortic valvular plane



Segments of Thoracic Aorta
1 = aortic root, 2 = ascending aorta, 3A = proximal aortic arch, 3B = distal aortic arch, 4 = isthmus, 5 = descending aorta

[*anulus* (diminutive of anus), Latin = small ring]
= firm fibrous band at aortoventricular junction surrounding and supporting aorta + valve leaflets

(b) **Aortic valve sinus** = Valsalva sinus
= 3 subtle dilatations of aortic root between aortic valve annulus + sinotubular ridge; associated with right + left + noncoronary cusp

(c) **Sinotubular junction** = landmark between aortic root and tubular portion of ascending aorta

Sinus of Valsalva

[Antonio Valsalva (1666 – 1723), professor of anatomy in Bologna, Italy and president of the Academy of the Sciences]
= 3 subtle outward bulges of aortic root wall between aortic valve annulus + sinotubular

ridge, each associated with corresponding right, left, noncoronary aortic valve cusp

Embryology: left + right truncoconal swellings develop along inferior end of truncus arteriosus during 5th week of embryogenesis → septation of truncus into anterior pulmonary + posterior aortic channels → each ventricular outflow tract contains 3 tubercles → form cusps of aortic and main pulmonary artery → formation of Valsalva sinuses + aortic valve leaflets (5th–9th weeks)

Aortic Diameter

Measurements are to be taken orthogonally to aortic lumen ← off-axis measurements overestimate the true diameter

(average diameter increases with age) underlined are points of standard aortic measurements (represented by thick arrows in drawing)

1. Sinotubular junction 36 mm
2. Ascending aorta (1 cm proximal to arch)
   Location: aortic root → origin of right brachiocephalic a.
   Diameter: always < 4 cm at any age
   › Midascending aorta = midpoint between 35 mm sinoaortic junction + proximal aortic arch
3. **Aortic arch**
   Location: right brachiocephalic artery → attachment of ligamentum arteriosum
   › aorta @ origin of brachiocephalic trunk 29 mm
   (A) proximal aortic arch:
   = immediately distal to innominate artery from right brachiocephalic artery → left subclavian artery
   (B) distal (mid)aortic arch:
   = immediately distal to left common carotid a.
4. Aortic isthmus = left subclavian artery → attachment of ligamentum arteriosum
5. Descending thoracic aorta
   Location: attachment of ligamentum arteriosum → aortic hiatus at diaphragm
   Diameter: always < 3 cm at any age
   (a) proximal descending aorta: 26 mm
   2 cm distal to left subclavian artery
   (b) middescending aorta: 25 mm
   (c) distal descending aorta: 24 mm
   @ diaphragm = 2 cm above celiac axis origin
6. Abdominal aorta @ celiac axis origin
7. Abdominal aorta @ most cephalic renal artery
8. Abdominal aorta @ most caudal renal artery
9. Infrarenal abdominal aorta
   (a) 15 mm below caudal renal artery
   (b) aorta just above bifurcation

Aortic Arch Branching Patterns

1. "Standard" branching pattern (65–75%) brachiocephalic trunk, left CCA, left subclavian

artery
2. Common origin of brachiocephalic trunk + left CCA (13%)
3. Bovine aortic arch (9%)
   = origin of left CCA from brachiocephalic trunk
4. Vertebral artery (usually left) arising from aortic arch (3%)
5. Left and right brachiocephalic trunks (1%)
6. Aberrant right subclavian artery as the last branch of the aortic arch (< 1%)

Cervical Aortic Arch

Associated with: right aortic arch (in ²/₃)

• pulsatile neck mass, upper airway obstruction, dysphagia
√ mediastinal widening
√ absence of normal aortic knob
√ aortic arch near lung apex
√ tracheal displacement to opposite side + anteriorly
√ apparent cutoff of tracheal air column ← crossing of descending aorta to side opposite of arch

DDx: carotid aneurysm

Aortic Isthmus Variants

Aortic Isthmus

= narrowing of the aorta in newborn between left subclavian artery and ductus arteriosus

Age: up to 2 months of age

Prognosis: aortic isthmus disappears ← cessation of flow through ductus arteriosus + increased flow through narrowed region

Aortic Spindle *(16%)*

= congenital narrowing of the aorta at the ligamentum arteriosum with distal fusiform dilatation
√ smooth circumferential bulge below isthmus in first portion of descending aorta

Ductus Diverticulum

= convex focal bulge along anterior undersurface of aortic isthmus

Origin: remnant of enlarged mouth of ductus arteriosus / result of traction from ligamentum arteriosum

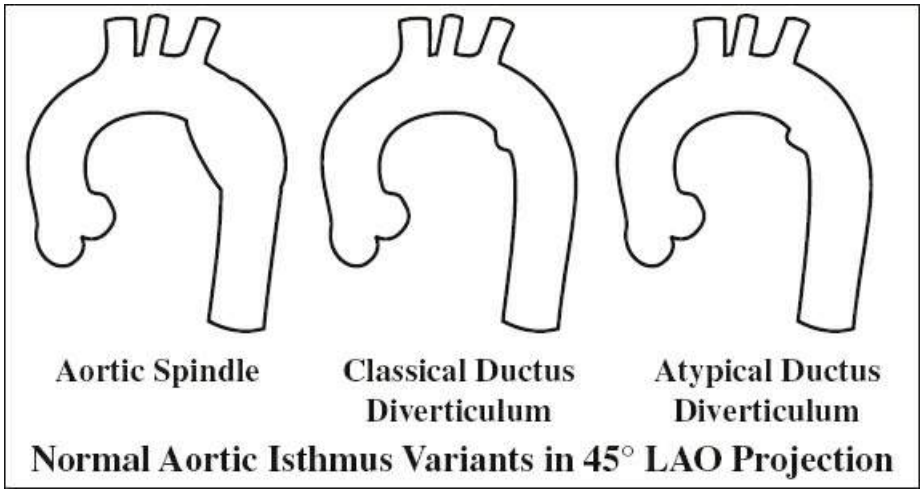
Frequency: in 33% of infants, in 9% of adults

√ focal bulge with smooth uninterrupted margin and obtuse angle with aortic wall:
  √ gently sloping symmetric shoulders (classic ductus diverticulum)
  √ shorter steeper slope superiorly + more gentle slope inferiorly (atypical ductus diverticulum)

DDx: posttraumatic pseudoaneurysm

Ductus Arteriosus

Origin: left 6th aortic arch



Normal Aortic Isthmus Variants in 45° LAO Projection

Location: connects proximal descending aorta (immediately distal to origin of left subclavian artery) with left pulmonary artery (at level of junction with main pulmonary artery)

Function: shunting of blood away from lungs (during fetal life)

Normal ductus physiology in mature infant:

↑ arterial oxygen pressure → constriction + closure of duct

◊ Functional closure ← muscular contraction within 10–18–48 hours after birth

◊ Anatomic closure ← subintimal fibrosis + thrombosis: in 35% by 2 wks; in 90% by 2 mo; in 99% by 1 year

Cx: premature closure → heart failure, fetal hydrops

PULMONARY VESSELS

Pulmonary Artery

1. Diameter of root: < 35 mm
2. Diameter at level of bifurcation: < 28 mm

Location: near bronchus

Pulmonary Veins

= 2 (superior + inferior) veins from R and L lung drain into either side of LA with separate ostia

Embryology: during first 2 months of fetal life lungs drain into systemic veins; these obliterate when common primitive pulmonary vein (developed from primitive LA) fuses with primitive lung

Pulmonary venous trunk:

= - distance from ostium to 1st-order branch:

Length: (a) superior pulmonary vein: 21.6 ± 7.5 mm

(b) inferior pulmonary vein: 14.0 ± 6.2 mm

Pulmonary vein ostium:

(a) superior pulmonary vein: 19–20 mm

(b) inferior pulmonary vein: 16–17 mm

Drainage:
RUL + RML → right superior pulmonary v.
LUL + lingula → left superior pulmonary v.
RLL / LLL → right / left inferior pulmonary v.

Variations of Pulmonary Vein Anatomy (in 38%)

1. Conjoined (common) left / right pulmonary vein (25%)
2. Supernumerary vein
   › separate right middle pulmonary vein draining RML:
   √ aberrant insertion with perpendicular orientation to posterior left atrial wall
   Mean size of ostium: 9.9 ± 1.9 mm
   Strong association with: atrial fibrillation
3. Early branching of pulmonary vein (< 1 cm)

Clinical significance:
LA muscle (as a focus of ectopic electrical activity) can extend into venous ostia → atrial fibrillation → treatment with radiofrequency catheter ablation

Pulmonary veins contribute to the origination and maintenance of atrial fibrillation, most commonly with a focus in the left superior pulmonary vein!

◊ Alert cardiologist about variant anatomy of additional pulmonary veins prior to RF ablation!

COLLATERAL CIRCULATION OF HAND

Vascular supply to hand is predominantly through ulnar a. with connections to radial artery via superficial + deep palmar arches

Blood supply: (1) Radial a. (2) Ulnar a. ± (3) Median a. (4) Interosseous a.

Circuits:

› at level of carpus
(1) Anterior carpal arch
(2) Posterior carpal arch

› at midcarpal level (with blood supply to fingers)
(3) Superficial palmar arch (larger)
= anastomosis between termination of ulnar a. + palmar branch of radial a.
√ origin to 3 common palmar digital arteries
(4) Deep palmar arch (smaller)
= anastomosis between termination of radial a. + palmar branch of ulnar a.
√ proximal to superficial arch
√ crosses bases of metacarpal bones
√ origin to 3 palmar metacarpal branches

Variations of arterial termination:

(1) Complete superficial palmar arch (66–96%)
= supplies all fingers + ulnar side of thumb
(2) Incomplete superficial palmar arch (4–7%)
= supplies all fingers + NO supply of thumb
(3) Distal end of superficial palmar arch of ulnar artery communicates with radial artery

(34%)
(4) Complete palmar arch + anastomosis to superficial palmar branch of radial artery (10%)
(5) Complete deep palmar arch (77–97%)
(6) Radial artery dominance
(7) Malformations of ulnar artery

Allen Test

= good clinical indicator of relative contribution of radial + ulnar arteries to circulation of hand

Purpose:
(1) Continuity assessment of palmar arch
(2) Test for arterial disease: thrombangiitis obliterans, scleroderma, occupational vasospastic disease
(3) Radial artery harvest of the nondominant arm for coronary artery bypass grafting (CABG)
(4) Prior to puncture / insertion of monitoring catheters into radial artery (19–92% incidence of occlusion after cannulation)

Pathophysiology: obliteration of one circulation → distal hypoperfusion + ↓ pressure + ↓ resistance → augmented flow in the opposite artery

Clinical Allen Test

Requirement: conscious cooperative patient

Technique: assessment of capillary refilling after active "exsanguination" of hand (= repetitive clenching into fist) under simultaneous compression of both radial and ulnar arteries followed by relaxed extension of fingers and release of one artery (more common)

N.B.: AVOID hyperextension of wrist or hand!

Results:
(1) Normal = complete capillary refilling and blush of entire hand within 6 sec. following release of arterial compression of one artery
(2) Incomplete continuity of palmar arch = any portion of hand without capillary refilling
(3) Occlusion of released artery = no capillary refilling of entire hand

◊ Considerable rate of false-positive and false-negative results!

Doppler Allen Test

◊ Independent of patient cooperation!

Technique: Doppler velocity detector placed on radial / ulnar artery at wrist before and during a period of compression of the opposite artery

Results:

Normal: arterial velocity increases in response to compression of opposite artery

Abnormal: absence of velocity increase indicates a lack of continuity between radial + ulnar circulation (= interruption of palmar arch)

Modified Allen Test For Radial Artery Harvest

Technique:

Doppler examination with recording of PSV (peak systolic velocity) + EDV (end diastolic velocity) of

(a) subclavian a., axillary a., brachial a., radial a. (at wrist), ulnar a. (at wrist)
(b) superficial palmar arch of radial a. (at imaginary line following proximal segment of 2nd metacarpal bone)
(c) princeps pollicis a. (medial aspect of base of thumb)
(d) 2nd common palmar digital a. (between heads of 2nd + 3rd metacarpal bones)
(i) 3rd common palmar digital a. (between heads of 3rd + 4th metacarpal bones)

Patient position: supine after a 10-min rest at standard room temperature

Criteria for safe radial artery harvest:

(1) Over 20% increase in systolic-diastolic flow rate in ulnar artery (suggests good arterial compliance to receive the entire flow from the brachial artery)
(2) Flow reversal in superficial palmar arch (indicates anatomic continuity of superficial palmar arch)
(3) Stable flow in 3rd common palmar digital a. (good palmar circulation)
(4) Up to 70% flow reduction in 2nd common palmar digital a.
(5) Up to 30% flow reduction in 1st common palmar digital a.

Contraindication to removal (6%):

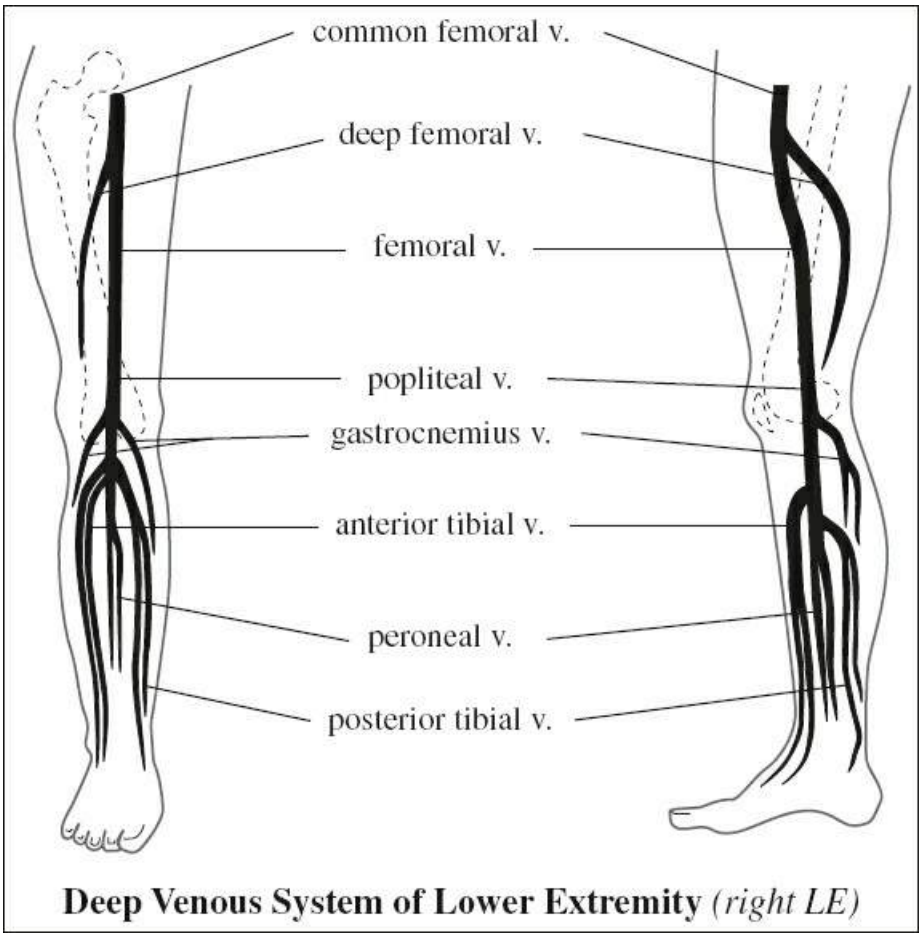
(1) Absence of expected increases in PSV and EDV in ulnar artery (MAIN CONTRAINDICATION)
(2) Atherosclerosis of upper limb arteries (1.6%)
◊ Patients are susceptible to catastrophic embolic episodes with a single artery supplying the forearm!
(3) Raynaud disease
(4) Disappearance of flow in superficial palmar arch

VENOUS SYSTEM OF LOWER EXTREMITY

Deep Veins of Lower Extremity

3 paired stem veins of the calf accompany the arteries as venae commitantes + anastomose freely with each other:

1. **Anterior tibial veins**
   draining blood from dorsum of foot, running within extensor compartment of lower leg close to interosseous membrane
2. **Posterior tibial veins**
   formed by confluence of superficial + deep plantar veins behind ankle joint
3. **Peroneal veins**
   directly behind + medial to fibula
4. Calf veins
   (a) **Soleus muscle veins**
   baggy valveless veins in soleus muscle (= sinusoidal veins); draining into posterior tibial + peroneal veins or lower part of popliteal vein
   (b) **Gastrocnemius veins**
   thin straight veins with valves; draining into lower + upper parts of popliteal vein



Deep Venous System of Lower Extremity *(right LE)*

5. **Popliteal vein**
   formed by stem veins of lower leg
6. **Femoral / superficial femoral vein**
   continuation of popliteal vein; receives deep femoral vein about 9 cm below inguinal ligament
7. **Deep femoral vein**
   draining together with superficial femoral vein into common femoral vein; may connect to popliteal vein (38%)
8. **Common femoral vein**
   formed by confluence of deep + superficial femoral vein; becomes external iliac vein as it passes beneath inguinal ligament

Superficial Veins of Lower Extremity

1. **Great (greater) saphenous vein** (GSV)
   formed by union of veins from medial side of sole of foot with medial dorsal veins; ascends in front of medial malleolus; passes behind medial condyles of tibia + femur
   (a) **Posterior arch vein**
   connected to deep venous system by communicating veins
   (b) **Anterior superficial tibial vein** = Anterior arch vein from lateral malleolus along lateral edge of tibia across tibia to join greater saphenous vein at upper ⅓ of calf

(c) **Posteromedial superficial thigh vein**
often connects with upper part of lesser saphenous vein
(d) **Anterolateral superficial thigh vein**
(e) Tributaries in fossa ovalis
› superficial inferior epigastric vein
› superficial external pudendal vein
› superficial circumflex iliac vein

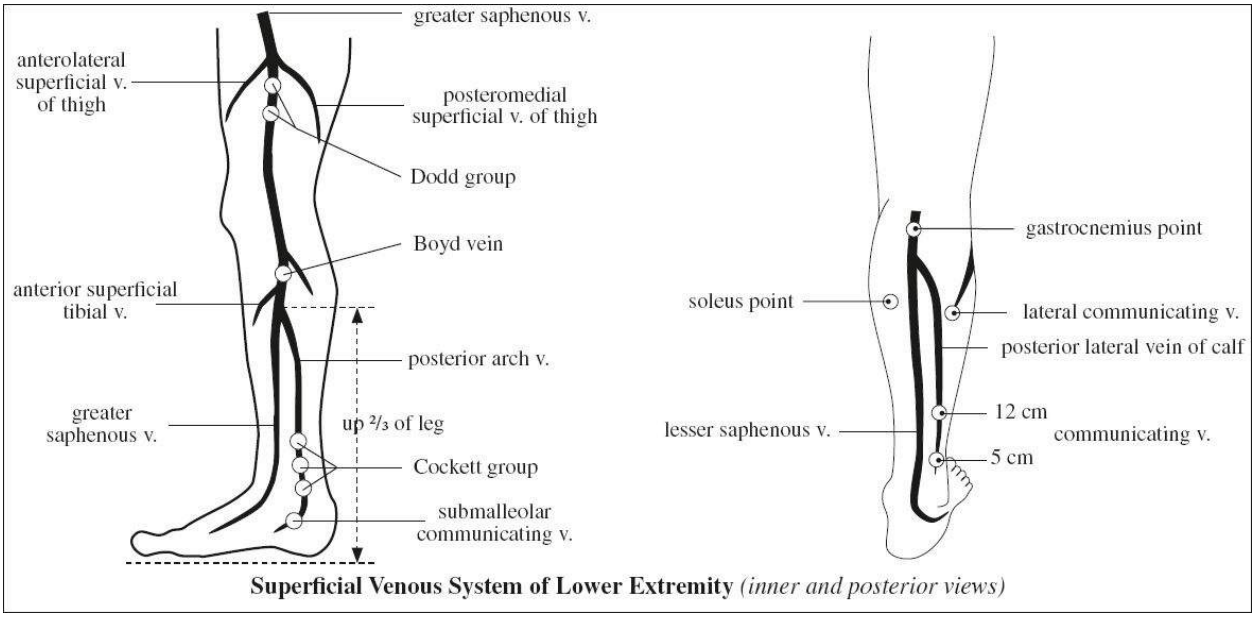
2. **Small (lesser) saphenous vein** (SSV)
originates at outer border of foot behind lateral malleolus as continuation of dorsal venous arch; enters popliteal vein between heads of gastrocnemius in popliteal fossa within 8 cm of knee joint (60%) or joins with greater saphenous vein via posteromedial / anterolateral superficial thigh vein (20%)

Communicating = Perforating Veins

> 100 veins in each leg

A. MEDIAL
1. Submalleolar communicating vein
2. **Cockett group**
group of 3 veins located 7, 12, 18 cm above the tip of medial malleolus connecting posterior arch vein with posterior tibial vein
3. **Boyd vein**
located 10 cm below knee joint connecting main trunk of greater saphenous vein to posterior tibial veins
4. **Dodd group**
group of 1 or 2 veins passing through Hunter canal (= subsartorial canal) to join greater saphenous vein with superficial femoral vein

B. LATERAL
1. **Lateral communicating vein**
located from just above lateral malleolus to junction of lower-to-mid thirds of calf connecting lesser saphenous vein with peroneal veins



Superficial Venous System of Lower Extremity *(inner and posterior views)*

2. **Posterior mid-calf communicating veins**
   located posteriorly 5 + 12 cm above os calcis joining lesser saphenous vein to peroneal veins
3. **Soleal + gastrocnemius points**
   joining short saphenous vein to soleal / gastrocnemius veins

PHASICITY

[*phasis* , Greek = speech]

= description of fluctuating / undulating cyclic (phasic) flow events (= velocity changes of acceleration, deceleration, direction) in a vessel audible by Doppler / graphically depicted as a Doppler waveform

Cause: pressure gradients generated by cardiac ± respiratory activity and exerted on the "column" of blood within the interrogated vessel segment

Origin: audible Doppler sounds created by changes in flow acceleration

Antegrade flow may be either toward or away from the transducer, depending on the spatial relationship of the transducer to the vessel. Therefore, antegrade flow may be displayed above or below the baseline.

Ambiguous terminology:

1. Flow direction: above / below baseline (favored)
2. Points of inflection = modulation of pitch (original)

PULSATILITY

= assessment of vascular resistance (increased resistance reduces diastolic flow)

◊ Can be assessed in vessels too small / tortuous to be imaged (Doppler angle unnecessary)!

◊ Index should be calculated for each of several cardiac cycles (5 heartbeats adequate) an average value taken

S = A = maximal systolic shift

D = B = end-diastolic frequency shift

1. Full pulsatility index of Gosling (PIF) = $1/A0_2\ SAi_2$
2. Simplified pulsatility index (PI) = (S - D)/mean
3. Resistance index (RI) = Pourcelot index
   = (S - D)/S or 1 - (D/S)
4. Stuart index = A/B ratio = S/D ratio
5. B/A ratio = B(100%)/A

High-Resistance Arteries

1. External carotid arteries
2. Extremity arteries
3. Fasting mesenteric arteries

Low-Resistance Arteries

1. Internal carotid arteries
2. Hepatic arteries
3. Renal arteries
4. Testicular arteries

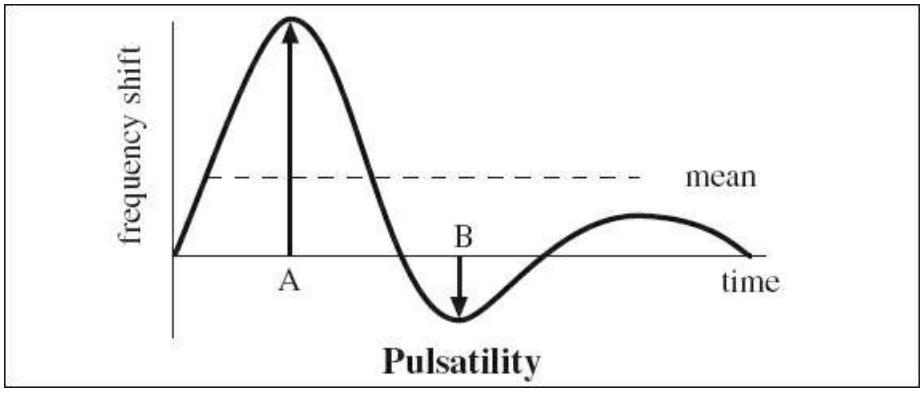
HEMOGLOBIN

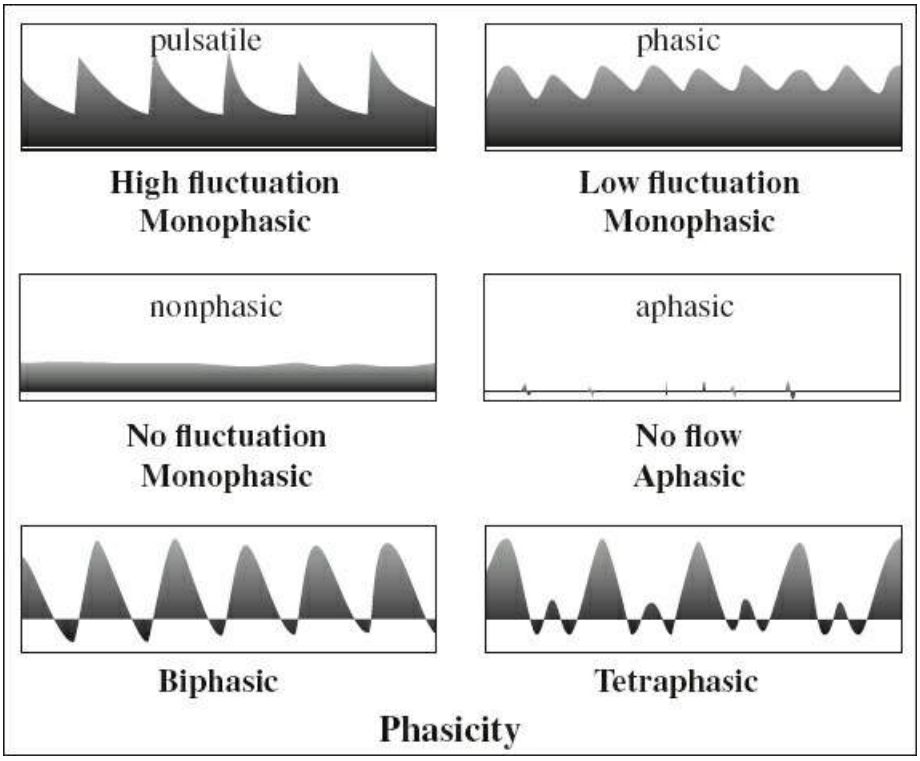
composed of 4 globular protein subunits + porphyrin ring holding an Fe2+ ion

in fetus: Hb F

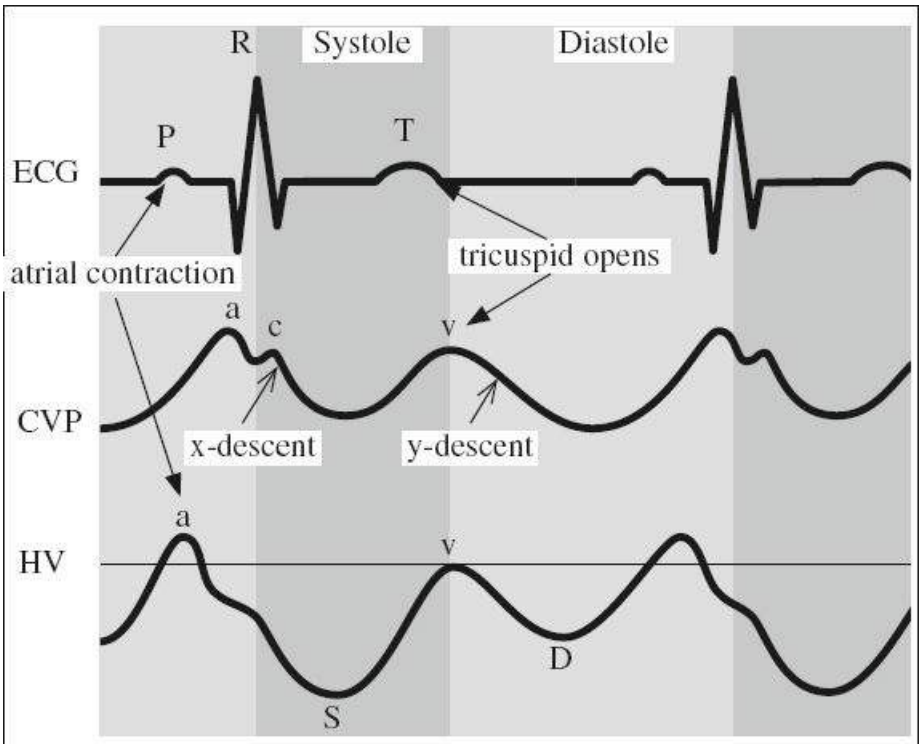
in adult: Hb A, Hb A2, Hb F

Variants: Hb H (β4).
Hb S (α2βS2)
Hb C (α2βC2)
Hb SA
Hb SC





pulsatile
phasic
High fluctuation
Monophasic
Low fluctuation
Monophasic
nonphasic
aphasic
No fluctuation
Monophasic
No flow
Aphasic
Biphasic
Tetraphasic
Phasicity



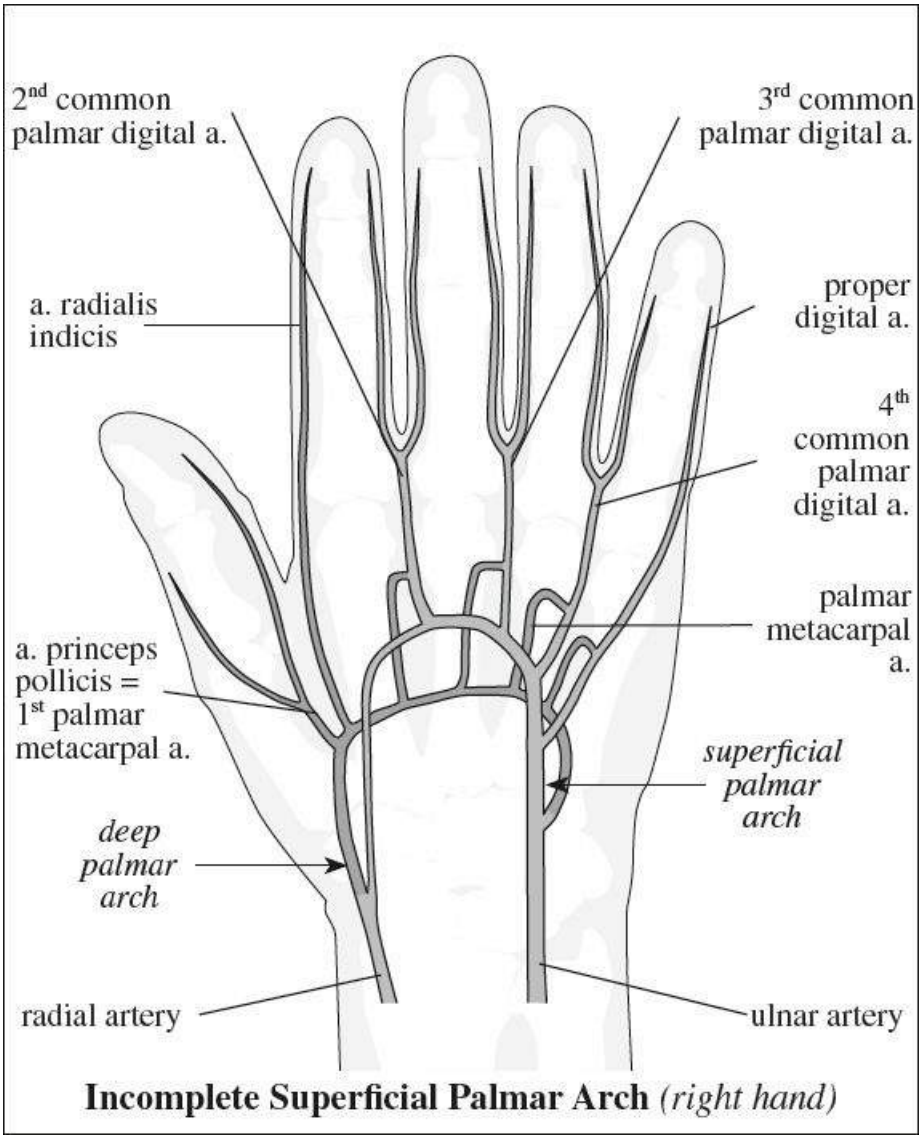
Time-correlated electrocardiographic (ECG), central venous pressure (CVP) and hepatic venous (HV) Waveform

S wave = trough correlates with peak negative pressure created by downward motion of AV annulus toward cardiac apex during midsystole

v wave = peak correlates with opening of tricuspid valve as the point of transition from systole to diastole; caused by RA overfilling against a closed tricuspid valve; occurs in <50% of patient

D wave = trough correlates with rapid early diastolic RV filling caused by opening of the tricuspid valve + blood flow from RA into RV; equal to / smaller than *S* wave

a wave = retrograde *a* wave at end-diastole caused by contraction of RA; in 66% of patients



Incomplete Superficial Palmar Arch *(right hand)*

Hb A (96–98%)

= in **A**dult composed of 4 subunits of polypeptides Hb α1, Hb α2, Hb β, Hb β

Genes & Locus:

HBA1 on chromosome 16p13.3

HBA2 on chromosome 16p13.3

HBB on chromosome 11p15.5

tetramer α2β2 composed of

- 2 α globin chains (141 amino acids)
- 2 β globin chains (146 amino acids)

Hb A_2 (1.5–3.5%)

tetramer α2δ2 composed of

- 2 α globin chains
- 2 δ globin chains

Hb F

in **F**etus + in F-cells of the adult

tetramer α2γ2 composed of

- 2 α globin chains
- 2 γ globin chains

• greater affinity to oxygen than Hb A

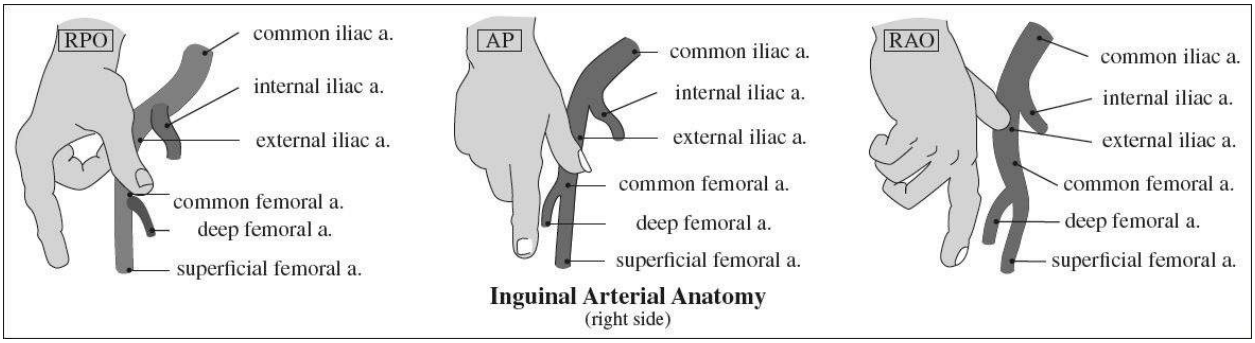
Lymphatics



Inguinal Arterial Anatomy
(right side)

CARDIOVASCULAR DISORDERS

ABERRANT LEFT PULMONARY ARTERY

= LEFT PULMONARY ARTERY SLING = ANOMALOUS ORIGIN OF LEFT PULMONARY ARTERY

Embryology: failure of development / obliteration of left 6th aortic arch (= vascular pedicle for left lung); left lung parenchyma maintains a connection with right lung leading to development of a collateral branch of the right pulmonary artery to supply the left lung

Site: left PA passes above right mainstem bronchus + between trachea and esophagus on its way to left lung (= sling around proximal right main bronchus + distal trachea)

Age at presentation: neonate to adulthood

Classification:

(1) Normal bronchial pattern

(2) Malformation of bronchotracheal tree

Associated with:

(a) "napkin-ring trachea" = absent pars membranacea (50%)

(b) stenosis of long tracheal segment

(c) PDA (most common), ASD, persistent left SVC

- stridor (most common), wheezing, apneic spells, cyanosis
- respiratory infection, feeding problems

√ deviation of trachea to left

√ "inverted-T" appearance of mainstem bronchi = horizontal course ← lower origin of right mainstem bronchus

√ anterior bowing of right mainstem bronchus

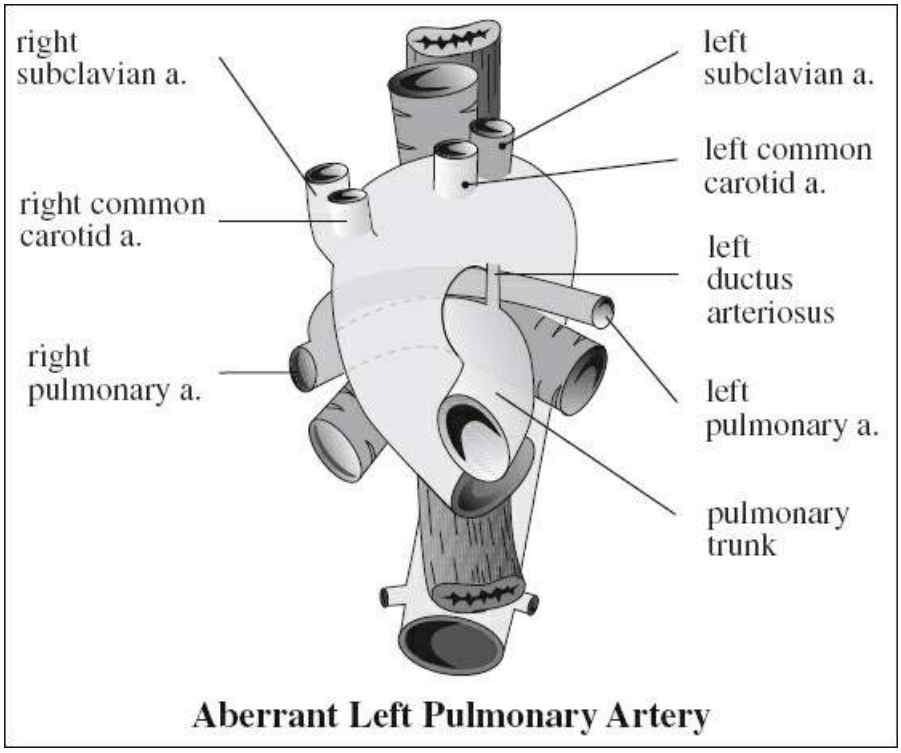
√ "carrot-shaped trachea" = narrowing of tracheal diameter in caudad direction resulting in functional tracheal stenosis

√ obstructive emphysema / atelectasis of RUL + LUL

√ low left hilum

√ separation of trachea + esophagus at hilum by soft-tissue mass

√ anterior indentation on esophagram



Aberrant Left Pulmonary Artery

AMYLOIDOSIS

= extracellular deposits of insoluble fibrillar protein (most commonly amyloid AL = light chain) in myocardial interstitium

Incidence: AL amyloidosis (50%); AA amyloidosis (2%);
isolated myocardial amyloid deposition (in 25% of autopsied patients > 85 years of age)

Path: commonly involvement of all 4 chambers

- asymptomatic / fatigue, weakness
- angina, CHF (diastolic dysfunction ⇉ restrictive cardiomyopathy), arrhythmia

CXR:
- √ normal / generalized cardiomegaly
- √ pulmonary congestion
- √ pulmonary deposits of amyloid

NUC:
- √ striking uptake of ^{99m}Tc-pyrophosphate greater than bone (50–90%)

ECHO:
- √ granular sparkling appearance of myocardium
- √ LV wall thickening
- √ decreased LV systolic + diastolic function

MR:
- √ diffuse decrease in SI on T1WI
- √ diffuse pattern of ventricular myocardial hypertrophy
- √ increase in thickness of interatrial septum + right atrial free wall > 6 mm (SPECIFIC)
  [DDx: ischemic heart disease thins myocardium]

CEMR:
√ predominant late enhancement of entire subendocardial circumference (HIGHLY SPECIFIC + SENSITIVE)

Dx: endomyocardial Bx with potential for severe complications

ANOMALOUS (INNOMINATE) BRACHIOCEPHALIC ARTERY COMPRESSION SYNDROME

= origin of R innominate (brachiocephalic) artery to the left of trachea coursing to the right
√ anterior tracheal compression
• ablation of right radial pulse by rigid endoscopic pressure
√ posterior tracheal displacement
√ focal collapse of trachea at fluoroscopy
√ pulsatile indentation of anterior tracheal wall by innominate artery on MR
Rx: surgical attachment of innominate artery to manubrium

ANOMALOUS LEFT CORONARY ARTERY

= **A** NOMALOUS ORIGIN OF **L** EFT **C** ORONARY **A** RTERY FROM **P** ULMONARY **A** RTERY SYNDROME = ALCAPA = BLAND-WHITE-GARLAND SYNDROME

Prevalence: 1÷300,000 live births; 0.25–0.50% of congenital heart defects

◊ One of the most common causes of myocardial ischemia + infarction in children!

Age: infancy / early childhood; adulthood (rare)
In 5% associated with: ASD, VSD, aortic coarctation
Location: LCA arises from left inferolateral aspect of main pulmonary artery just beyond pulmonary valve
Hemodynamics:
postnatal fall in pulmonary arterial pressure → perfusion of LCA drops (= "coronary steal") → L-to-R shunt (= collateral circulation from RCA with flow reversal in LCA)
› adequate collateral circulation = lifesaving
› inadequate collateral circulation = myocardial infarction
› large collateral circulation = volume overload of heart
• ECG: anterolateral infarction
√ LCA arising from the main pulmonary artery (HALLMARK) along its left inferolateral aspect just beyond pulmonic valve
√ coronary steal into PA
√ left ventricular wall motion abnormalities, mostly global hypokinesis
Rx: (1) Ligation of LCA at its origin from pulmonary trunk
(2) Ligation of LCA + graft of left subclavian artery to LCA
(3) Creation of an AP window + baffle from AP window to ostium of LCA
DDx: endocardial fibroelastosis; dilated cardiomyopathy; viral cardiomyopathy (NO shocklike symptoms)

A. INFANT TYPE
• symptomatic about 8 weeks after birth:
• failure to thrive, profuse sweating, dyspnea, pallor
• atypical chest pain while eating / crying
√ massive cardiomegaly during newborn period:

√ dilatation of LV ← chronic myocardial ischemia
√ enlargement of LA
√ congestive heart failure
√ mitral insufficiency ← myocardial infarction
√ normal pulmonary vascularity / redistribution
Prognosis: if untreated death within 1st year (in up to 90%)

B. ADULT TYPE (rare)
= sufficient right-to-left coronary artery collaterals
• asymptomatic, continuous murmur (if collaterals large)
• ischemic cardiomyopathy, malignant dysrhythmia
√ massively enlarged and tortuous collateral circulation from RCA to LCA ← increased flow:
√ abundant intercoronary collaterals on epicardial surface
√ development of dilated bronchial artery collaterals
Cx: chronic left ventricular subendocardial ischemia → malignant ventricular dysrhythmia
Prognosis: sudden cardiac death (in 80–90%)

ANOMALOUS PULMONARY VENOUS RETURN

= complete / partial failure of developing lung to connect with primitive common pulmonary vein retaining connections to primitive splanchnic system of cardinal veins (L-to-R shunt)

Total Anomalous Pulmonary Venous Return

= TAPVR = entire pulmonary venous return directed to RA = admixture lesion because of the combination of cyanosis + increased pulmonary vascularity (L-to-R and R-to-L shunt) = absent connection of pulmonary veins with LA

Embryology: persistence of primitive splanchnic pulmonary veins connecting to fetal cardinal systemic veins + failure of primitive common pulmonary vein to develop from posterior LA wall

◊ Usually isolated defect!

May be associated with:
asplenia; ASD / patent foramen ovale (necessary for survival); bronchopulmonary sequestration; pulmonary arteriovenous malformation; cystic adenomatoid malformation

Types: according to termination of anomalous pulmonary veins

I	supracardiac level	55%
II	cardiac level	30%
III	infracardiac / infradiaphragmatic level	13%
IV	termination at ≥ 2 levels (= mixed type)	2%

Prevalence: 2% of CHD

Age: symptomatic in 1st year of life

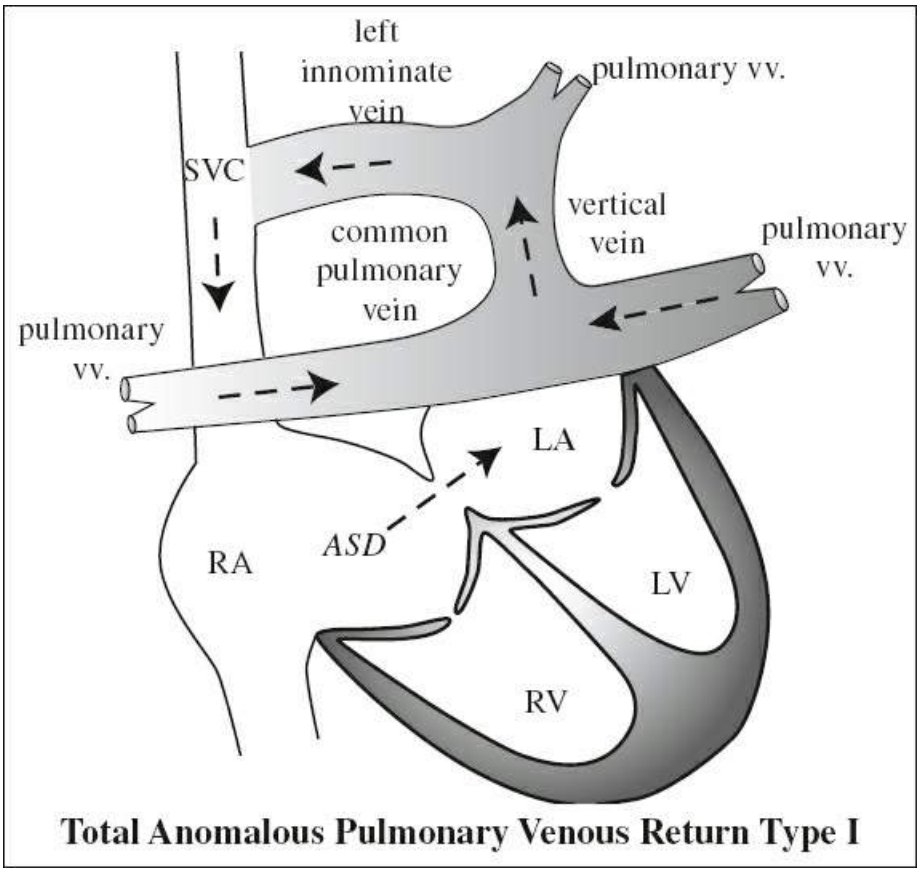
• cyanosis and congestive heart failure typically develop in the early neonatal period

Hemodynamics:
obstruction along the pulmonary venous pathway

RA ↔	RV ↔	Main PA ↔
Pulm vessels ↑		
LA ↔	LV ↔	Ao ↔

MR:

√ "retroatrial" sign = presence of veins posterior to LA
√ small LA without pulmonary venous connections
√ patent foramen ovale / ASD



Total Anomalous Pulmonary Venous Return Type I

√ anomalous vein with variable location

In most potentially clinically unstable neonates with TAPVR, complete anatomic delineation of the defect is possible with echocardiography alone!

Overall prognosis: 75% mortality rate within 1 year of birth if untreated

Supradiaphragmatic TAPVR *(85%)*

Hemodynamics:

› functional L-to-R shunt from pulmonary veins to RA
› increased pulmonary blood flow (= overcirculation)
› obligatory R-to-L shunt via usually patent foramen ovale / ASD → restores oxygenated blood to left side
› normal systemic venous pressure with increased flow through widened SVC

› after birth CHF secondary to
(a) mixture of systemic + pulmonary venous blood in RA
(b) volume overload of RV

Age: presentation < 1 years of age

In 30% associated with: other cardiac lesions, asplenia

• cyanosis, neck veins undistended (shunt level distally)
• R ventricular heave (= increased contact of enlarged RV with sternum)
• systolic ejection murmur (large shunt volume)

√ overall heart size notably normal:
√ slightly enlarged RV (= volume overload with time)
√ normal / enlarged RA
√ normal LA (= ASD acts as escape valve)

√ increased pulmonary blood flow (= overcirculation)

SUPRACARDIAC TAPVR (55%)

= drainage of pulmonary veins into a horizontally oriented confluence posterior to LA → ascending vertical vein posterior to left atrial appendage + usually anterior to left pulmonary a. → left brachiocephalic (innominate) vein / right or left persistent SVC / azygos vein

√ "figure of 8" / "snowman" configuration of cardiac silhouette:
√ "head of snowman" = dilated vertical vein on left + innominate vein on top + SVC on right
√ "body of snowman" = heart with enlarged RA

√ pretracheal density on lateral film (= left vertical vein)

= 4 anomalous pulmonary veins converge behind LA forming a common vertical vein, which passes anterior to left PA + left main bronchus to join
(a) innominate vein (most commonly)
(b) left brachiocephalic vein
(c) right SVC
(d) azygos vein

√ extrinsic venous obstruction if vertical vein courses between left PA anteriorly + left main bronchus posteriorly (10%)

CARDIAC TAPVR (30%)

= drainage of pulmonary veins into coronary sinus (80%) / RA / SVC / (often obstructed) azygos vein

ECHO:
√ "whale's tail" appearance ← dilated pulmonary veins and coronary sinus

Sub- / Infradiaphragmatic / Infracardiac TAPVR *(13%)*

= drainage of pulmonary veins into vertically oriented confluence posterior to LA → portal vein / ductus venosus / IVC / hepatic veins / left gastric vein; R-to-L shunt through ASD

Age: presentation in neonatal period with severe CHF

• intense cyanosis + respiratory distress

Hemodynamics: constriction of descending pulmonary vein by diaphragm en route through

esophageal hiatus → (in > 90%) pulmonary venous hypertension + RV pressure overload

Associated with: asplenia syndrome (80%), polysplenia

√ pulmonary veins join to form a common vertical descending vein ("inverted fir tree") posterior to LA:

√ vertical vein lies anterior to esophagus + descends through esophageal hiatus

√ low anterior indentation on barium-filled esophagus

√ connects (most commonly) to portal vein at confluence of splenic v. + superior mesenteric v.

√ unique appearance of pulmonary edema + pulmonary venous congestion with normal-sized heart (DDx: hyaline membrane disease)

√ thymic atrophy + depression of diaphragm

Cx: obstruction of pulmonary venous return in > 90%

Prognosis: death within a few days of life

Mixed Type of TAPVR *(2%)*

= with various connections to R side of heart (6%) at ≥ 2 levels, most commonly (a) vertical vein drains into left innominate (brachiocephalic) vein (b) anomalous vein(s) from right lung drain into RA / coronary sinus

Partial Anomalous Pulmonary Venous Return

= PAPVR = ≥ 1 pulmonary veins drain into systemic venous system / RA rather than LA (= L-to-R shunt)

Embryology: early atresia / malposition of central pulmonary v.

Prevalence: 0.3–0.7% of patients with CHD

Age: presentation later in life than TAPVR

N.B.: venous return almost never obstructed!

May be associated with: may occur in isolation

(1) Atrial septal defect (25%)

(a) RUL pulmonary vein (66%) enters SVC, RA, azygos vein, coronary sinus, IVC

Age: more common in children

◊ in 90% of patients with sinus venosus type ASD

◊ 50% of patients with PAPVR have a high sinus venosus type ASD near orifice of SVC

√ RUL vein courses in a horizontal direction

(b) LUL pulmonary vein (33%) enters brachiocephalic vein / coronary sinus

Age: more common in adults as incidental finding

Frequently associated with: ostium secundum type ASD (10–15%)

√ vertical mediastinal density lateral to aortic knob extending upward and medially with smooth curvilinear border (DDx: persistent left SVC)

(2) Hypogenetic lung as a component of congenital pulmonary venolobar / scimitar syndrome

• acyanotic and often asymptomatic

• ASD symptomatology (if ≥ 50% of pulmonary venous flow)

√ radiographic findings similar to ASD

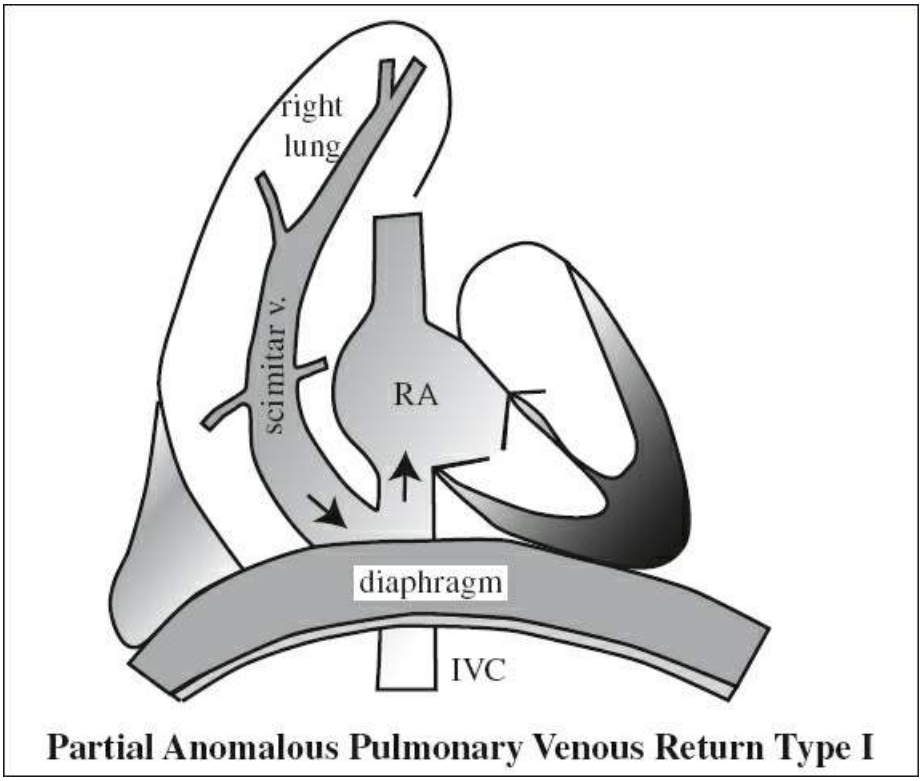
√ anomalous course of draining vein
√ enlargement of draining site: SVC, IVC, azygos vein
CECT:
√ nodular / tubular opacity (= anomalous vein), which opacifies in phase with pulmonary vein
Prognosis: near normal life expectancy

Scimitar Syndrome

= HYPOGENETIC LUNG SYNDROME = CONGENITAL PULMONARY VENOLOBAR SYNDROME
[*scimitar* = Persian or Turkish sword with curved blade]
= lower part / all of the hypogenetic lung is drained by an anomalous vein → L-to-R shunt
Hemodynamics: insignificant L-to-R shunt
Components: systemic supply + drainage of RLL
(1) Anomalous arterial supply of right lower lobe from abdominal aorta = systemic arterialization of the lung <u>without sequestration</u> (= pseudosequestration)
(2) Scimitar vein
(3) Hyopoplasia of right lung with dextroposition of heart:
(4) → Hypo- / aplasia of right pulmonary artery
Associated with: CHD (47–90%, most commonly ASD), extralobar sequestration, horseshoe lung, pulmonary AVM, bronchogenic cyst, accessory diaphragm
◊ High incidence of sinus venosus ASD with right upper lobe PAPVR

- asymptomatic (for shunt of < 50% of pulmonary flow) / pulmonary to systemic blood flow (Qp÷Qs) ≥ 1.5÷1
- acyanotic (until pulmonary arterial HTN occurs)
- heart murmur, fatigue, dyspnea

Location: almost exclusively on right side (1 case on left)



Partial Anomalous Pulmonary Venous Return Type I

CXR:

√ tubular structure paralleling the right heart border in an outward curved configuration of a Turkish sword increasing in diameter as the vein descends (PA view)

Site: middle of right lung to cardiophrenic angle

√ hypoplastic ipsilateral lung

√ small ipsilateral pulmonary hilum ← hypoplasia / aplasia of pulmonary artery

√ shift of heart + mediastinum into right chest

√ hyperinflated and hyperlucent contralateral lung

MR/CT:

The amount of L-to-R shunting is quantifiable by MR with cine phase-contrast flow analysis of the aorta and main pulmonary artery to estimate the Qp/Qs ratio!

√ systemic arterialization of right lung (without sequestration) ← anomalous artery from abdominal aorta / visceral artery

√ scimitar vein drains any / all lobes of right lung and connects to:

› infradiaphragmatic IVC (33%)

› suprahepatic IVC (22%)

› hepatic veins

› portal vein (11%)

› azygos vein

› coronary sinus

› right atrium (22%)

› left atrium = "meandering pulmonary vein"

◊ Drainage into suprahepatic portion of IVC / right atrium may be a clue for

interruption of intrahepatic portion of IVC!

Prognosis: normal / near-normal life span

Rx: anomalous vein / veins anastomosed to LA + repair of ASD

Sinus Venosus Defect

= SINUS VENOSUS–TYPE ATRIAL SEPTAL DEFECT

= unroofing of right pulmonary veins into SVC / IVC

N.B.: sinus venosus atrial septal defect is a misnomer since the true atrial septum is not involved

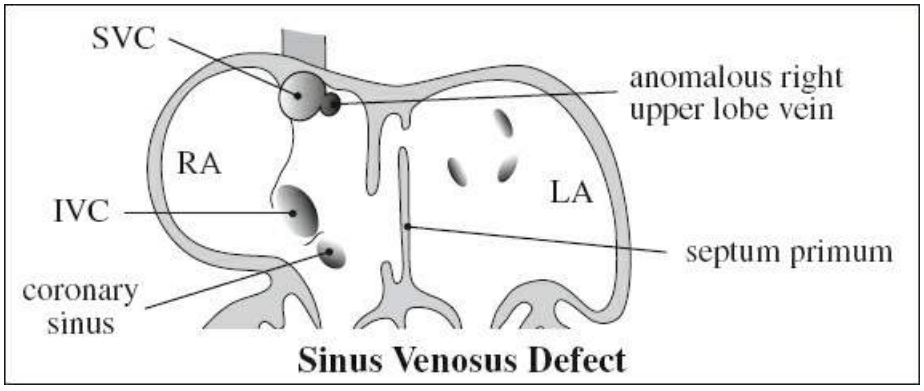
Types:

1. Sinus venosus defect of the SVC type
   = unroofing of the right <u>upper</u> pulmonary vein (RUPV) into SVC = defect of the superior inlet portion of extraseptal atrial wall separating SVC–right atrial junction from posterosuperior aspect of LA = drainage of RUPV into SVC
   Location: superior to fossa ovalis near entrance of superior vena cava (SVC straddles ASD)
2. Sinus venosus defect of the IVC type
   = unroofing of the right <u>lower</u> pulmonary vein (RLPV) into IVC

<u>variable:</u> involvement of the right middle pulmonary vein (RMPV) can occur with either type

Function: R-to-L shunt similar to large ASD

- symptoms of right ventricular volume overload:



Sinus Venosus Defect

- fatigue, dyspnea, arrhythmia, heart murmur

Associated with:

partial anomalous pulmonary venous return in 90% (RUL pulmonary veins connect to SVC / right atrium), Holt-Oram syndrome, Ellis-van Creveld syndrome

AORTIC ANEURYSM

An aneurysm is defined as a vessel segment with a diameter of > 150% of the diameter of a normal adjacent segment + involving < 50% of the total vessel length!

Cause:

1. Aortic dissection (53%)

2. Atherosclerosis (29–80%): descending aorta; usually multiple
3. Traumatic (15–20%): descending aorta; ← transection
4. Congenital (2%): aortic sinus, post coarctation, ductus diverticulum
5. Syphilis (4%): ascending aorta + arch
6. Mycotic infection = bacterial dissection; anywhere
7. Cystic media necrosis (Marfan / Ehlers-Danlos syndrome, annuloaortic ectasia): ascending aorta
8. Aortitis = inflammation of media + adventitia: Takayasu arteritis, giant cell arteritis, relapsing polychondritis, rheumatic fever, rheumatoid arthritis, ankylosing spondylitis, Reiter syndrome, psoriasis, ulcerative colitis, systemic lupus erythematosus, scleroderma, Behçet disease, ulcerative colitis, radiation
9. Increased pressure: systemic hypertension, aortic valve stenosis
10. Abnormal volume load: severe aortic regurgitation

Pathophysiology:
intimal injury of aortic wall → lipid-laden macrophage + lymphocyte infiltration → inflammatory cells secrete cytokines → activation of multiple proteolytic cascades → degradation of collagen + elastin within tunica media → weakening + dilatation of aortic wall

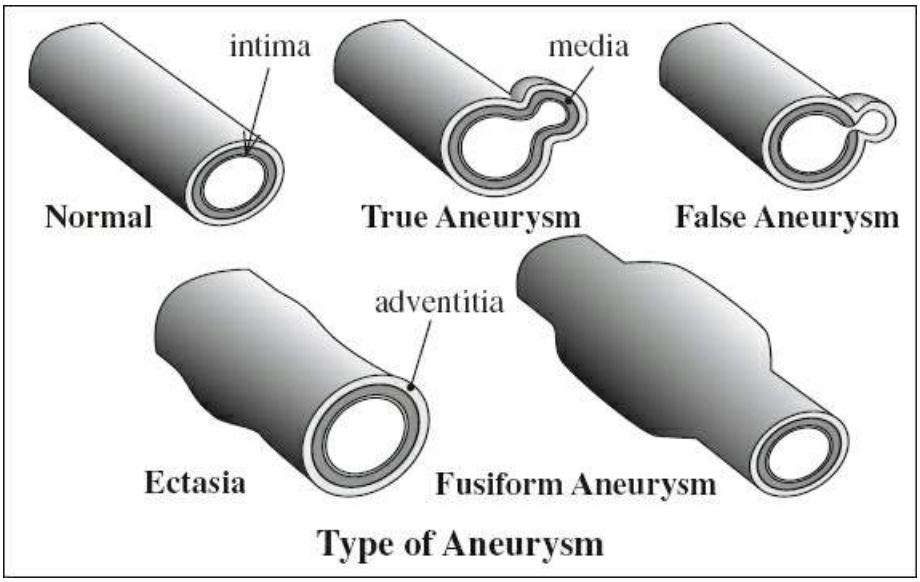
Location: abdominal aorta (31%), ascending aorta (22%), arch (12%), descending thoracic aorta (8%), thoracoabdominal (3%)

TRUE ANEURYSM

= permanent dilatation of all 3 layers (intima + media + adventitia) of weakened but intact wall

Fusiform Aneurysm (80%)

[*fusus* , Latin = spindle (tapered at each end)]
= longitudinal measurement > transverse diameter
Cause: atherosclerotic degeneration
√ circumferential involvement of wall over longer arterial segment
√ NO definable neck



√ NO relation to proximal stenosis

Saccular Aneurysm (20%)

[*saccus*, Latin = sack, pouch]

= transverse diameter > longitudinal measurement

Cause: penetrating ulcer / inflammation / infection

√ berry-like outpouching of portion of wall

√ frequently distal to area of proximal stenosis

√ often multisegmental

Cx: prone to thrombosis and rupture

FALSE ANEURYSM = PSEUDOANEURYSM

= loss of wall integrity with transition from 3-layered wall to an outwardly single/double layer

Cause: trauma, penetrating atheroclerotic ulcer, infection (= "mycotic" aneurysm)

Pathophysiology: escaped blood contained by adventitia / perivascular connective tissue + organized blood

Histo: disruption of the external elastic membrane

√ saccular dilatation with a narrow neck

ARTERIAL ECTASIA

= diffuse dilatation

Type I diffuse dilatation of 2–3 vessels

Type II ectasia of 1 vessel + aneurysm in another

Type III solitary ectatic vessel

Abdominal Aortic Aneurysm (AAA)

= focal widening > 3 cm (ultrasound literature); twice the size of normal aorta / > 4 cm [Bergan, Ann Surg 1984]

Normal size of abdominal aorta > 50 years of age:

14–21 [12–19] mm in men [women]

Prevalence: 1.4–8.2% in unselected population; in 6% > 80 years of age; in 6–20% of patients with signs of atherosclerotic disease; M > F; Whites÷Blacks = 3÷1

Cause: structural defect; ? genetic (10-fold ↑ in risk as 1st- degree relative of patient with AAA); copper deficiency

Risk factors: male sex, age > 75 years, white race, prior vascular disease, hypertension, cigarette smoking, family history, hypercholesterolemia

Age: > 60 years; M÷F = 5–9÷1

Associated with:

(a) visceral + renal artery aneurysm (2%)
(b) isolated iliac + femoral artery aneurysm (16%):
common iliac (89%), internal iliac (10%), external iliac (1%)
(c) stenosis / occlusion of celiac trunk / SMA (22%)
(d) stenosis of renal artery (22–30%)
(e) occlusion of inferior mesenteric artery (80%)
(f) occlusion of lumbar arteries (78%)

Growth rate of aneurysm of 3–6 cm in diameter:
0.39 cm annually

• asymptomatic (30%), abdominal mass (26%) / pain (37%)

◊ Imaging should provide information about:

(a) anatomic considerations of aneurysm:
» size
» proximal extent, which determines the site of clamping of the aorta (eg, origin of renal arteries)
» course of the left renal vein (retroaortic?)
(b) aneurysm growth rate
(c) findings of aneurysm instability

Location: infrarenal (91–95%) with extension into iliac arteries (66–70%)

◊ The infrarenal abdominal aorta has a lower concentration of elastin + vasa vasorum making it vulnerable to aneurysm formation!

Plain film:
√ mural calcification (75–86%)

US:
√ > 98% accuracy in size measurement

NCCT:
√ perianeurysmal fibrosis (10%) → ± ureteral obstruction

CECT:

(a) ruptured aneurysm
√ anterior displacement of kidney
√ extravasation of contrast material
√ fluid collection / hematoma within posterior pararenal + perirenal spaces
√ free intraperitoneal fluid
√ perirenal "cobwebs"
(b) contained leak
√ laminated mural calcification

√ periaortic mass of mixed / soft-tissue density
√ lateral "draping" of aneurysm around vertebral body
√ indistinct aortic wall (unreliable)
√ focal discontinuity of calcifications (unreliable)

A patchy discontinuous intimal calcification is common in stable and unstable aneurysms.

Angio (AP + LAT filming):
√ focally widened aortic lumen > 3 cm
√ apparent normal size of lumen ← mural thrombus (11%)
√ mural clot (80%)
√ slow antegrade flow of contrast medium

Cx:
(1) Aortic rupture (25%)
(2) Peripheral embolization
(3) Infection
(4) Spontaneous occlusion of aorta

Prognosis: 17% 5-year survival without surgery, 50–60% 5-year survival with surgery

Rx: (1) Excision of aneurysm + aortic interposition graft (4–5% surgical mortality for nonruptured, 30–80% for ruptured aneurysm)
(2) Endovascular aneurysm repair (70%) with post-repair complications of graft migration > 5 mm, graft kinking / fracture, persistent endoleak

Postoperative Cx:
(1) Left colonic ischemia (1.6%) with 10% mortality
(2) Renal failure (14%)
(3) 0–8% mortality rate for elective surgery

Acute Aortic Aneurysm Rupture

◊ Leading cause of death (4,500 annually) in USA in 1.3% of men > 65 years

Risk factors: female sex (M÷F = 1÷4), larger baseline aneurysm diameter, hypertension, continued tobacco use, low 1-second forced expiratory volume, history of cardiac / renal transplant

Risk for aneurysm rupture:
directly related to aneurysm size + rate of enlargement

Increased risk of aneurysm rupture: size > 6 cm

Aneurysm Size vs. Likelihood of Rupture

< 4 cm	10%	5–7 cm	25%
4–5 cm	23%	7–10 cm	46%
		> 10 cm	60%

› growth > 5 mm / 6 months

The most accurate + reproducible bidimensional aneurysm measurements are those that are orthogonal to a center line through the aorta.

• pain + tenderness
◊ The exact moment of rupture is unpredictable
• sudden severe abdominal pain ± radiating into back

• faintness, syncope, hypotension

Site:

(1) into retroperitoneum: commonly on left
(2) into GI tract: massive GI hemorrhage
(3) into IVC: rapid cardiac decompensation

CT:

√ high-attenuation crescent within mural thrombus = acute contained rupture / impending rupture
√ retroperitoneal hematoma ± extension into perirenal space / pararenal space / psoas muscle / peritoneum

CECT:

√ active extravasation into thrombosed portion

Prognosis: 64–94% die before reaching hospital

Rx: most vascular surgeons electively repair a typical fusiform abdominal aortic aneurysm if > 5.4 cm

Chronic Contained Aortic Aneurysm Rupture

= aortic wall no longer fully intact with hemorrhage enclosed by a thrombus and/or retroperitoneal soft tissues

• hemodynamically stable
• ± previous episode of abdominal pain

Angio:

√ absent parenchymal stain = avascular halo
√ displacement + stretching of aortic branches

CT:

√ loss of periaortic fat planes:
  √ commonly posterolateral focal area of soft-tissue attenuation intimately associated with aorta
√ "draped aorta" sign = posterior aortic wall not identifiable as distinct from adjacent structures / closely apposed to adjacent vertebral body contour
√ new saccular outpouching (= focal breach) of aneurysm wall in the region that appears draped on AXIAL view
√ anterior vertebral body scalloping ← chronic repetitive aortic pulsations and pressure

N.B.: contained rupture is unrelated to aneurysm size

Impending Aortic Aneurysm Rupture

A focal discontinuity of a circumferential calcified intimal plaque and outward displacement may indicate a contained rupture at NECT. A contained rupture is definite if the finding is new.

√ increasing size of aneurysm

Laplace law:

T (circumferential wall tension) = P (transmural pressure) • r (vessel radius)

√ thinning of thrombus = decreasing thrombus volume with progressive enlargement of flow lumen ← lysis of thrombus (thrombus protects against rupture)

√ focal discontinuity in circumferential wall calcifications ← focal plaque erosion = unstable aneurysm
√ "crescent" sign = periluminal curvilinear area of hyperattenuation in aneurysm wall / thrombus (= acute intramural hematoma) is 93% specific:
  √ attenuation higher than intraluminal blood on NECT
  √ attenuation higher than psoas muscle on CECT
√ ± perianeurysmal fat stranding

With bolus tracking a large aneurysm may not fully opacify, which can result in suboptimal enhancement of the aortic branches.

Extravasation indicative of active hemorrhage may not be apparent in a large rupturing aneurysm during the early arterial phase but rather during the late arterial / venous phase after the aneurysm has filled with contrast.

Indication for surgical repair:
√ diameter of > 5–6–7 cm
√ enlargement rate of ≥ 10 mm annually

Atherosclerotic Aneurysm of Abdominal Aorta

◊ There is no consensus regarding the definition of an atherosclerotic AAA!

Frequency: most common cause of aortic aneurysms; leading cause of thoracic aortic aneurysm

Histo: diseased intima with secondary degeneration + fibrous replacement of media → ultimately wall of aneurysm composed of acellular + avascular connective tissue

Pathophysiology:
progressive weakening of media → vessel dilatation + increased tension of vessel wall (law of Laplace = tensile stress varies with product of blood pressure and radius of vessel); compromise of mural vascular nutrition (vasa vasorum) → further degeneration + progressive dilatation

Age: elderly; M > F

- asymptomatic (most)
- chest pain; symptoms related to compression of adjacent structures (dysphagia, hoarseness, lobar atelectasis, pneumonia, parenchymal hemorrhage, superior vena cava syndrome)

Location: distal abdominal aorta (66%) > iliac a. > popliteal a. > common femoral a. > aortic + descending thoracic aorta > carotid a. > ascending aorta

Site:
(1) Infrarenal aorta (associated with thoracic aneurysm in 29%)
(2) Descending thoracic aorta distal to left subclavian artery
(3) Thoracoabdominal aorta

√ fusiform (80%), saccular (20%)
√ frequently contain calcified thrombus with irregular inner contour

Cx: rupture (cause of death in 50%): usually unrestrained + fatal in thoracic location

Degenerative Aneurysm

= medial degeneration

Most common cause of aneurysm in ascending aorta

Cause:
(1) Genetically transmitted metabolic disorder: Marfan syndrome, Ehlers-Danlos syndrome
(2) Acquired: result of repetitive aortic injury + repair associated with aging

Idiopathic Inflammatory Aortic Aneurysm

= defined as triad of
(1) thickened wall of aneurysm
(2) extensive perianeurysmal + retroperitoneal fibrosis
(3) dense adhesions of adjacent abdominal organs

Cause: slow leakage from aneurysm related to periaortic retroperitoneal fibrosis and autoimmune diseases (rheumatoid arthritis, systemic lupus erythematosus, giant cell arteritis)

Frequency: 5–25% of all AAAs; rare in ascending aorta + aortic arch

Mean age: 62–68 years; M÷F = 6÷1 to 30÷1

- abdominal / back pain; weight loss + anorexia (20–41%)
- elevated ESR (40–88%), fever
- tender pulsatile abdominal mass (15–30%)

Comorbidities: arterial hypertension (34–69%), arterial occlusive disease (10–47%), diabetes mellitus (3–13%), coronary artery disease (33–55%)

Size: usually small at presentation because of early symptomatology

CECT (83% sensitive, 99% specific):
√ rind of homogeneous soft-tissue density surrounding aorta anteriorly + laterally sparing posterior wall
√ delayed contrast enhancement of soft-tissue component (DDx from hematoma)

MR:
√ periaortic inflammation and adventitial fibrosis
√ turbulent intraluminal flow

US:
√ sonolucent halo around aorta

PET:
√ grading extent of inflammation

Cx: (1) Entrapment of ureters (10–21%) + hydronephrosis
(2) Aortic-sigmoid colon fistula + bleeding
(3) Secondary bacterial infection (eg, Salmonella)
(4) Enlargement + rupture irrespective of size (lower rate than in noninflammatory aneurysm)

Prognosis: 23% mortality during surgical repair

Leaking Aortic Aneurysm

- acute chest pain

At risk for rupture: symptomatic > asymptomatic aneurysm; mycotic aneurysm; thoracic aortic aneurysm > 6 cm

MR:

√ irregular aneurysm wall
√ extra-aortic blood
√ pleural effusion containing high SI on T1WI (methemoglobin)
√ admixture of lower-intensity blood products + fat in mediastinum

Cx: rupture into left pleural space (descending thoracic aorta); rupture into pericardium/mediastinum (ascending thoracic aorta)

Mycotic (Infected) Aneurysm

[mycotic = misnomer used by Osler in 1885 describing a mushroom-shaped aneurysm associated with endocarditis]

= false (majority) / true aneurysm that is prone to rupture

Frequency: 0.7–2.6% of all aortic aneurysms

Age: > 5th decade; M > F

Location: (a) aorta: suprarenal (70%) > infrarenal > descending thoracic > thoracoabdominal > juxtarenal > ascending aorta near sinus of Valsalva
(b) other arteries: abdominal visceral artery > intracranial artery > lower / upper extremity a.

A mycotic aneurysm of the aortic root and sinus of Valsalva may be associated with infectious endocarditis, uni- / bicuspid aortic valve, and infected prosthetic aortic valve!

A. PRIMARY MYCOTIC ANEURYSM (rare) unassociated with any demonstrable intravascular inflammatory process

B. SECONDARY MYCOTIC ANEURYSM
= aneurysm due to nonsyphilitic infection

Predisposing factors:
(1) Atherosclerosis
(2) Aortic trauma ← accidents, aortic valve surgery, arterial graft, coronary artery bypass surgery, intravascular catheter, arterial catheterization, joint prosthesis

Risk factors:
(1) IV drug abuse
(2) Sepsis
(3) Bacterial endocarditis (12%)
(4) Immunocompromise (malignancy, alcoholism, corticosteroid therapy, chemotherapy, autoimmune disease, diabetes)

Mechanism:
(a) hematogenous:
› septicemia with abscess formation via vasa vasorum
› septicemia with abscess formation via vessel lumen
(b) direct extension from adjacent infection: osteomyelitis of sternum or spine, renal or psoas abscess → weakening + destruction part of the aortic wall
(c) traumatic / iatrogenic: intima laceration (trauma, atherosclerosis, coarctation)

Organism: S. aureus (53%) > E. coli > Salmonella (33-50%) > nonhemolytic Streptococcus > Listeria > Haemophilus, Pneumococcus, Gonococcus, Mycobacterium (contiguous spread from spine / lymph nodes)

Histo: loss of intima + destruction of internal elastic lamella; varying degrees of destruction

of muscularis of media + adventitia
- frequently insidious → late-stage septic shock
- persistent fever, leukocytosis ← bacteremia (positive blood culture in only 53%); NO acute chest pain

Size: 1–11 cm

√ CHARACTERISTIC saccular formation (> 90%) with lobular contour arising eccentrically from aortic wall

√ rapid enlargement (faster expansion rate compared with atherosclerotic aneurysm as short as 7 days)

√ interrupted ring of aortic wall calcification

√ periaortic fat stranding / fluid / gas collection

√ adjacent vertebral / sternal osteomyelitis (rare)

√ periaortic / psoas abscess

√ adjacent reactive lymph node enlargement

Cx: (1) Life-threatening rupture + hemorrhage (50–75%)
(2) Uncontrolled sepsis if untreated

Rx: prompt surgery

Prognosis: 67% overall mortality

Syphilitic Aneurysm

= sexually transmitted chronic systemic infection caused by spirochete Treponema pallidum

= tertiary stage of syphilis consisting of neurosyphilis, gumma, cardiovascular involvement

Spectrum:

1. Uncomplicated syphilitic aortitis
2. Syphilitic aortic aneurysm (mostly saccular)
3. Syphilitic aortic valvulitis (aortic regurgitation)
4. Syphilitic coronary ostial stenosis

N.B.: dissection (uncommon) ← scarring of media

Frequency: 12% of patients with untreated syphilis

Onset: 5–30 years after initial spirochete infection

Histo: chronic inflammation of vasa vasorum → obstruction of vasa vasorum → nutritional impairment of aortic media → focal destruction of aortic media with loss of elastic + smooth muscle fibers replaced by scar

- positive venereal disease research laboratory (VDRL) test
- positive microhemagglutination assay - Treponema pallidum (MHA-TP) test

Location: ascending aorta (36–60%), aortic arch (34%), proximal descending aorta (25%), distal descending aorta (5%), aortic sinuses (< 1%)

√ asymmetric enlargement of aortic sinuses (DDx to annuloaortic ectasia with symmetric enlargement)

√ saccular (75%) / fusiform (25%) aneurysm

√ TYPICAL pencil-thin dystrophic aortic wall calcification (up to 40%) most severe in ascending aorta, frequently obscured by thick coarse irregular calcifications of secondary atherosclerosis

√ early sternal erosion affecting mainly right side of manubrium + medial end of right

clavicle
√ narrowing of coronary ostia (subintimal scarring)
Prognosis: death ← aortic rupture in 40%; death ← myocardial infarction within 6–8 months of onset of symptoms if untreated
Rx: penicillin

Thoracic Aortic Aneurysm

Most common vascular cause of mediastinal mass!
◊ 10% of mediastinal masses are of vascular origin!
Definitions:
diameter of 4 – 5 cm = **aortic ectasia**
diameter of > 5 cm = **aortic aneurysm**
Frequency: 25% of all aneurysms
Cause: atherosclerosis (29%), aortic dissection (53%), aortitis (8%), cystic medial necrosis (6%), syphilis (4%)
◊ Bicuspid aortic valve = independent risk factor!
Associated with: hypertension, coronary artery disease, abdominal aneurysm (30%)
Mean age: 65 years; M÷F = 3÷1
• substernal / back / shoulder pain (26%)
• SVC syndrome ← venous compression)
• dysphagia ← esophageal compression)
• stridor, dyspnea ← tracheobronchial compression)
• hoarseness ← recurrent laryngeal nerve compression)
Location: arch > descending aorta
√ mediastinal mass with proximity to aorta
√ wide tortuous aorta:
√ annual growth rate of 0.07–0.42 cm
√ curvilinear peripheral calcifications (75%)
√ circumferential / crescentic mural thrombus
N.B.: Angio may show normal caliber ← mural thrombus!
Cx:
(1) Rupture into mediastinum, pericardium, either pleural cavity, airway, esophagus
Median size at rupture-dissection:
5.9 cm for ascending aorta,
7.2 cm for descending aorta
√ high-attenuation fluid
(2) Aortobronchopulmonary fistula
√ consolidation of lung adjacent to aneurysm
◊ Most aneurysms rupture when > 10 cm in size
Prognosis: 1-year survival 57%; 3-year survival 26%; 5-year survival 19% (60% die from ruptured aneurysm, 40% die from other causes)
Rx: operative repair should be considered
for ascending aorta at > 5.5 cm
for descending aorta at > 6.5 cm
for Marfan syndrome > 5.0 cm

at annual growth rate > 1.0 cm

Surgical mortality: 9% for elective + 22% for emergent surgery

Annuloaortic Ectasia

= dilated sinuses of Valsalva with effacement of sinotubular junction

Cause: Marfan syndrome, idiopathic (30%), homocystinuria, Ehlers-Danlos syndrome, osteogenesis imperfecta

√ pear-shaped aorta

Valsalva Sinus Aneurysm

= aneurysm originating from a coronary sinus above aortic annulus

Prevalence: in 0.09% of autopsies; in 0.15%–3.50% of heart surgeries

Types:

(a) congenital: localized weakness of elastic lamina at junction of aortic media and annulus fibrosus in Marfan and Ehlers-Danlos syndrome

(b) acquired: infectious disease (bacterial endocarditis, syphilis, tuberculosis); degenerative (atherosclerosis, cystic medial necrosis); deceleration injury; aortic valve replacement

Associated with: supracristal VSD (30%–60% of patients), aortic insufficiency (20%–30%), bicuspid aortic valve (10%), coronary anomalies

Age: 35.4 (range, 4 days–96) years; M÷F = 2÷1 to 4÷1; Eastern/Asian÷Western countries = 5÷1

- asymptomatic (14%)
- cardiac murmur (57%), dyspnea (56%), chest pain
- insidiously progressive heart failure ← volume overload

Location: (a) right coronary sinus (72%)
(b) noncoronary sinus (22%
(c) coronary sinus (6%)

ECHO: diagnostic in 90%

Imaging criteria for a Valsalva sinus aneurysm include
(1) origin above aortic annulus
(2) saccular shape
(3) normal dimensions of adjacent aortic root and ascending aorta!

Cx:

(a) rupture (66%):
1. Aortic regurgitation (in 30–50%)
2. Aortocardiac shunt with RV (56%), RA (30%), RVOT (9%), LV (2%), interventricular septum (2%), LA (1%), extracardiac space (rare)

(b) mass effect:
1. Aortic regurgitation
2. Impaired function of tricuspid / mitral valve
3. Occluded / partially obstructed RVOT
4. Dissection into interventricular septum
5. Compression / occlusion of a coronary artery → myocardial ischemia

Surgery is indicated for asymptomatic patients without another underlying cardiovascular condition or disease, when aortic root measures ≥ 5.5 cm

DDx: prolapsing aortic cusp (below annulus)

Traumatic Aortic Pseudoaneurysm

= CHRONIC AORTIC PSEUDOANEURYSM

◊ 2nd most common form of thoracic aortic aneurysm

◊ Most common type occurring in young patients

Frequency: 2.5% of patients who survive initial trauma of acute aortic transection

√ usually calcified

√ may contain thrombus

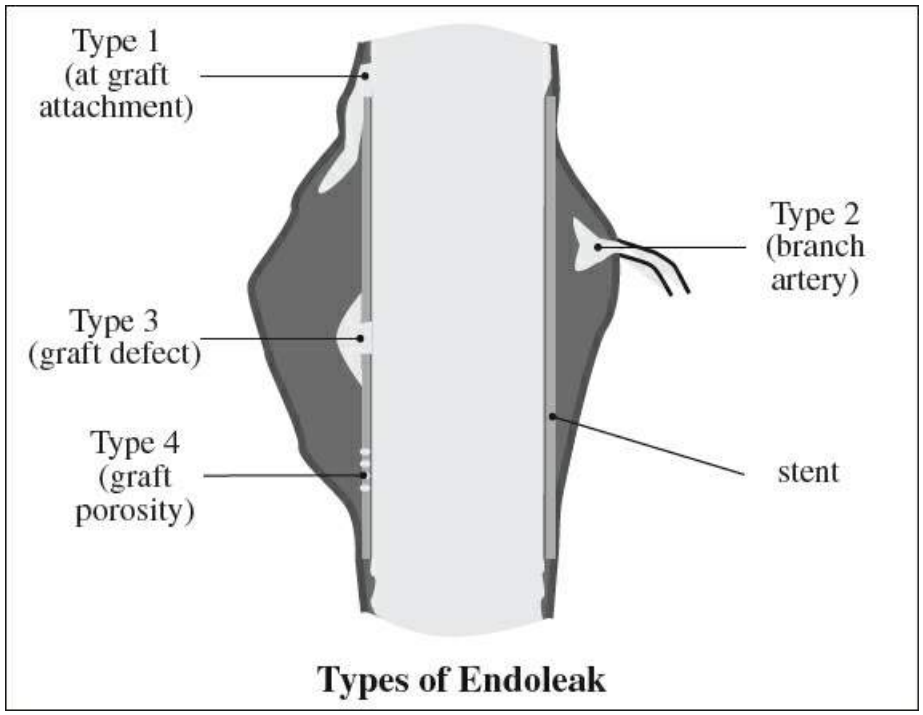
Cx: (1) Progressive enlargement

(2) Rupture (even years after insult)

Complications of Endovascular Stent-Graft Repair

1. **Endoleak** (2–45%)

   = leakage into the aneurysm outside stent-graft



Types of Endoleak

Type 1 = incomplete fixation of stent-graft to aortic wall at the proximal / distal attachment site

Type 2 = retrograde flow via parent artery (eg, lumbar / inferior mesenteric artery) in up to 24%

◊ High rate of spontaneous resolution if aneurysmal sac size remains stable

Type 3 = endograft defect with disruption of either metallic support / fabric

Type 4 = porous graft (uncommon)

Type 5 = endotension = aneurysm expansion > 5 mm without demonstrable endoleak (← nonvisualized endoleak, ultrafiltration of blood across graft membrane, thrombus as ineffective barrier)

2. Graft kinking
   Cause: diminishing diameter of aneurysm after stent-graft implantation also decreases length of aneurysm
   Associated with: distal migration of stent-graft
3. Graft infection
   √ interval development of perigraft soft-tissue attenuation / air
   Rx: antibiotics + total excision of infected graft
4. Graft thrombosis (3–19%)
   = intraluminal circular / semicircular thrombus
   Prognosis: spontaneous shrinkage, development of complete thrombosis
5. Graft occlusion
6. Shower embolism (4–17%)
   Cause: mural thrombus dispersed by delivery system
   Prognosis: perioperative death
7. Colon necrosis
   Cause: occlusion of inferior mesenteric a. by stent-graft
8. Aortic dissection
   Cause: retrograde injury by delivery system

AORTIC DISSECTION

= spontaneous longitudinal separation of aortic intima and adventitia by circulating blood having gained access to and splitting the media of the aortic wall

◊ Most common ACUTE EMERGENCY condition of the aorta!

Incidence: 3÷1,000 (more common than all ruptures of thoracic + abdominal aorta combined); 1÷205 autopsies; 2,000 cases annually in USA

Peak age: 60 years (range 13–87 years); M÷F = 3÷1

Predisposed: cystic medial necrosis / disease of aortic wall

◊ Starts in fusiform aneurysms in 28%

◊ Does not occur in aneurysms < 5 cm in diameter

1. Hypertension (60–90%)
2. Marfan syndrome (5–16%)
3. Ehlers-Danlos syndrome
4. Turner syndrome
5. Noonan syndrome
6. Polycystic kidney disease
7. Osteogenesis imperfecta
8. Valvular aortic stenosis
9. Coarctation
10. Bicuspid aortic valve
11. S/P prosthetic valve / other cardiovascular procedure
12. Blunt trauma (rare)

13. Inflammatory collagen vascular disease
14. Relapsing polychondritis
15. Aortitis (eg, Takayasu disease, SLE)
16. Behçet disease
17. Patient on corticosteroids
18. Cocaine abuse
19. Family history of dissection
20. Personal history of aortic aneurysm (2–12%)
21. Atherosclerosis of aorta (24–42%)
22. Pregnancy
    ◊ In women 50% of dissections occur during pregnancy!

N.B.: NOT syphilis

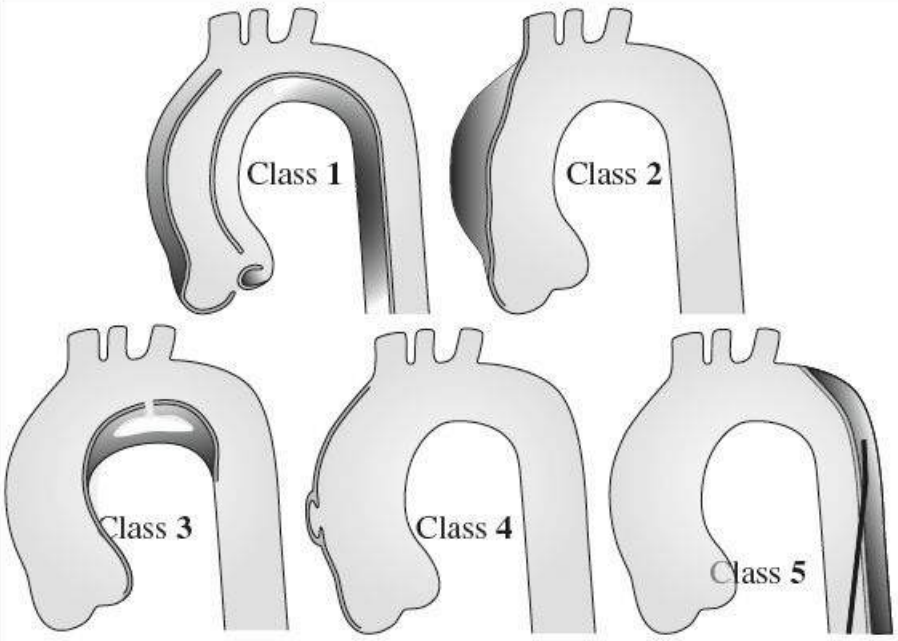
Path: destruction of media leads to formation of a false channel:

(1) Transverse tear in weakened intima (95–97%)
    ◊ The diagnosis relies primarily on visualization of an intimal flap + blood flow within a false lumen
(2) Primary hemorrhage into aortic wall WITHOUT intimal tear (3–5–13%) = atypical noncommunicating aortic dissection

Pathogenesis:

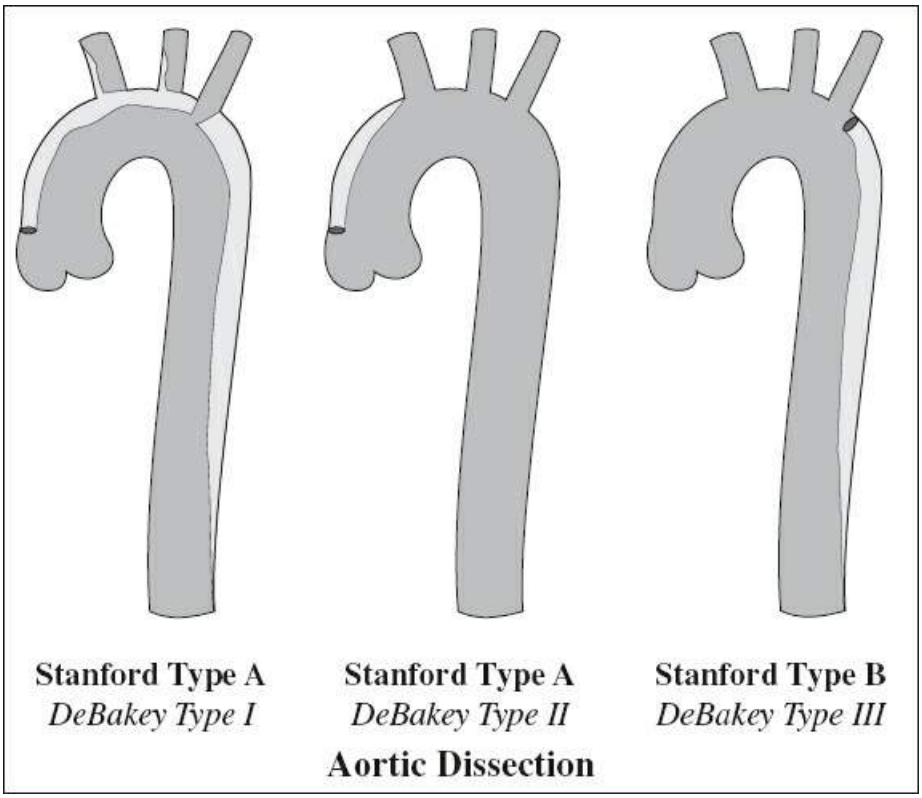
intimal tear results from combination of the following factors:

(a) media degeneration decreases cohesiveness of aortic wall
(b) persistent motion ← beating heart stresses aortic wall



Variants of Aortic Dissection *(Svensson LG)*

Class	*Description*
1	Separation of intima/media; dual lumina (classic)
2	Intramural hematoma separation of intima/media; angiographically no intraluminal tear or flap
3	Intimal tear without hematoma (limited dissection) and eccentric bulge
4	Atherosclerotic penetrating ulcer; ulcer usually penetrating to adventitia with localized hematoma
5	Iatrogenic/traumatic dissection



(c) hypertension accentuates hydrodynamic forces

The classic intimal flap is seen in ~ 70% of aortic dissections.

Pathophysiology:

luminal pressures:

intimal tear allows blood to enter media (= false lumen) with pressure in false lumen ≥ pressure in true lumen → collapse of true lumen + expansion of false lumen → possible compression + obstruction of true lumen;

degree of dilatation of false lumen depends on

(a) blood pressure
(b) depth of medial dissection plane,
(c) percentage of involved wall circumference;

flow direction in false lumen: antegrade / retrograde

effect on branch vessel:

(a) static obstruction = intimal flap enters branch-vessel origin without reentry point
(b) dynamic obstruction = intimal flap prolapses into / covers branch vessel like a curtain

fate of false lumen:

may remain patent / thrombose / recommunicate with true lumen through fenestrations / rupture into potential spaces (pericardial, pleural, peritoneal)

Definition of acute versus chronic dissection:

(a) acute aortic dissection = symptoms present for < 14 days
(b) chronic aortic dissection = symptoms present for ≥ 14 days

- sharp tearing intractable anterior / posterior chest pain (75–95%) radiating to jaw, neck, low back (DDx: myocardial infarction)

- murmur ± bruit (65%) from aortic regurgitation
- malperfusion symptoms:
  - asymmetric peripheral pulses + blood pressures (59%)
  - absent femoral pulses (25%), reappearing after reentry
  - pulse deficit: in up to 50% of type A dissection, in 16% of type B dissection; persistent oliguria, anuria
  - neurologic deficits (5–25%): hemiplegia, paraparesis ← compromise of anterior spinal artery of Adamkiewicz
- hemodynamic shock (25%)
- congestive heart failure (rare) ← acute aortic insufficiency:
  - diastolic murmur (40–50%)
- recurrent arrhythmias / right bundle branch block
- signs of pericardial tamponade: clouded sensorium, extreme restlessness, dyspnea, distended neck veins

Types:

DeBakey Classification:

Type I (29–34%) = ascending aorta + portion distal to arch
Type II (12–21%) = ascending aorta only
Type III (50%) = descending aorta only
subtype III A = up to diaphragm
subtype III B = below diaphragm

Stanford Classification: based on need for surgical therapy

Type A (60–70%) = ascending aorta ± arch in first 4 cm
Type B (30–40%) = descending aorta only

mnemonic: **A a**ffects **a**scending **a**orta and **a**rch; **B b**egins **b**eyond **b**rachiocephalic vessels; I = II + III

Flow velocities (average):

- 13.4 cm/second in true lumen
- 3.1 cm/second in false lumen
- retrograde flow more common in false lumen

Location of dissection flap (following helical flow pattern):

› on right anterolateral wall of ascending aorta just distal to aortic valve (65%)
› on posterosuperior wall of transverse aortic arch (10%)
› on left posterolateral wall of upper descending aorta distal to left subclavian artery (20%)
› more distal aorta (5%) usually terminating in left iliac artery (80%) / right iliac artery (10%) [involvement of left renal artery in 50%]
◊ An exit / distal tear / reentry occurs in 10%!

Imaging characteristics of true lumen:

√ usually smaller and oval / semiround
√ in continuity with undissected portion of aorta
√ higher concentration of contrast
√ ribbonlike

Imaging characteristics of false lumen:

√ SPECIFIC "cobweb" sign = slender linear areas of low attenuation ← residual ribbons of

media
√ "beak" sign at cross-sectional imaging = wedge of hematoma creating space for propagation of false lumen
√ rewinding around true lumen on axial plane
√ may become thrombosed

Atypical configurations of intimal flap:
√ circumferential intimal flap ← dissection of entire intima
√ filiform intimal flap creating an extremely narrow true lumen ± ischemic complications
√ mural calcification of false lumen (in chronic dissection)
√ three-channel aorta (= "Mercedes-Benz" sign) ← two false channels ← secondary dissection of one channel
◊ Multibarreled aortic dissections (9% of all aortic dissections) have a significantly poorer survival!
√ intimointimal intussusception → "windsock" appearance

Secondary signs of aortic dissection:
√ internal displacement of intimal calcification
√ delayed enhancement of false lumen
√ widening of aorta and mediastinum
√ pleural / pericardial hematoma

CXR (best assessment by comparison with serial films):
√ normal CXR in 10–25–40%
√ "calcification" sign = inward displacement of atherosclerotic plaque by > 4–10 mm from outer aortic contour (7%)
N.B.: can only be applied to contour of descending aorta due to projection; may be misleading in presence of periaortic soft-tissue mass / hematoma
√ disparity in size between ascending + descending aorta
√ irregular wavy contour / indistinct outline of aorta
√ widening of superior mediastinum to > 8 cm ← hemorrhage / enlarging false channel (40–80%)
√ cardiac enlargement ← LV hypertrophy / hemopericardium
√ left pleural effusion (27%)
√ atelectasis of lower lobe
√ rightward displacement of trachea / endotracheal tube

ECHO:
(a) transesophageal echocardiography (TEE): 95–100% sensitive + 77–97% specific
◊ Ultrasound can be performed at bedside!
False-positive (33%): reverberation artifacts from calcified aortic wall
(b) transthoracic US: 59–85% sensitive + 63–96% specific for type A dissection; poorer for type B
(c) intravascular US (in conjunction with aortography) to differentiate true from false lumen
√ intimal flap (seen in more than one view)
√ pericardial fluid
√ aortic insufficiency
False-positives: reverberation echoes from aneurysmal ascending aorta / calcified atheromatous plaque, postoperative periaortic hematoma

Angio (86–88% sensitive, 75–94% specific):

◊ Largely replaced by noninvasive cross-sectional imaging techniques

Superior to any other technique in demonstrating

› entry + reentry points (in 50%)

› branch vessel involvement + coronary arteries

› aortic insufficiency

√ visualization of intimal / medial flap (75–79%) = linear radiolucency within opacified aorta

√ "double barrel aorta" (87%) = opacification of two aortic lumens

√ abnormal catheter position outside anticipated aortic course

√ compression of true lumen by false channel (72–85%)

√ aortic valvular regurgitation (30%)

√ increase in aortic wall thickness > 6–10 mm

√ obstruction of aortic branches: left renal artery (25–30%)

√ ulcerlike projections caused by truncated branches

√ slower blood flow in false lumen

False-negative: complete thrombosis / very slow blood flow of false channel (10%), intimal flap not tangential to x-ray beam

False-positive: thickening of aortic wall due to aneurysm, aortitis, adjacent neoplasm / hemorrhage

NECT:

√ high attenuation within aortic wall 2° to:

(a) high-attenuation of false lumen (slow flow / thrombosis)

(b) presence of intramural hematoma

√ intimal flap separating two aortic channels (may be seen without contrast in anemic patients)

CECT (87–100% sensitive, 87–100% specific):

within 4 hours (if patient responds rapidly to medical Rx); detection as accurate as angio with single-level dynamic scanning (cardiac gating desirable to avoid overdiagnosis)

√ intimal flap separating two aortic channels

√ crescentic high-attenuation clot within false lumen

√ internally displaced intimal calcification (DDx: calcification of thrombus on luminal surface or within)

√ entry tear = most proximal split / discontinuity in intimal flap

False-negative: inadequate contrast opacification, thrombosed lumen misinterpreted as aortic aneurysm with mural thrombus

False-positive: perivenous streaks ← beam hardening + motion, cardiac / aortic motion artifacts; opacified normal sinus of Valsalva; normal pericardial recess mistaken for thrombus; mural thrombus in a fusiform aortic aneurysm; periaortic fibrosis; anemia with apparent high attenuation of aortic wall

MR (95–100% sensitive, 90–100% specific):

Advantage: large field of view in any plane; contrast material NOT necessary

Disadvantage: longer imaging time; difficulty monitoring acutely ill patients; image degradation from motion (uncooperative patient, atrial fibrillation)

SE images:

√ intimal flap of medium intensity outlined by signal voids of rapidly flowing blood in true + false lumen

√ intimal flap more difficult to detect in the presence of slow flow / thrombus ← false lumen has intermediate intensity instead of flow void

√ "cobwebs" (25%) traversing the corners of the false lumen = bands of medial elastic lamellae spanning the junction of the dissecting septum with outer wall of false lumen

GRE images:

√ lower-intensity intimal flap between high-intensity channels of flowing blood

√ intermediate signal from thrombosed lumen

√ aortic valve insufficiency = conical area of signal loss from aortic valve into LV during systole ← intravoxel dephasing caused by turbulence

Cx:

(1) Retrograde dissection (in Stanford type A)
  (a) aortic insufficiency
  (b) occlusion of coronary artery (8%)
  (c) internal rupture into RV, LA, vena cava, pulmonary artery producing a large L-to-R shunt

(2) Occlusion / transient obstruction of major aortic branches (in up to 27%)
  (a) static obstruction
    √ flap enters branch-vessel origin
  (b) dynamic obstruction = flap spares branch-vessel origin but covers it like a curtain
    √ collapsed true lumen outlined by a C-shaped flap envelope which is concave toward false lumen (= ischemic configuration)

(3) External rupture of aorta into mediastinum, pleural cavity / pericardial sac (75%), right ventricle, left atrium, vena cava, pulmonary artery: 70% mortality (= most common cause of death within 24 hours)
  NECT: √ hyperattenuating mediastinal / pericardial / pleural fluid collection
  CECT: √ extravasation of vascular contrast material

(4) Development of aneurysm (15%) of the true / false lumen

◊ Organs may receive their blood supply through either the true or false lumen or both!

Rx:

(1) Reducing peak systolic pressure to 120–70 mmHg (adequate ONLY for type III = B, which rarely progresses proximally):
  Cx: death from rupture of aortic aneurysm in 46% of hypertensive + 17% of normotensive patients
  Survival rate: 40–70% with medical / surgical management

(2) Immediate surgical graft reinforcement of aortic wall (Type I, II = A) preventing rupture + extension into aortic root → progressive aortic valve insufficiency
  Nonsurgical survival rate: < 10%
  Postsurgical mortality: 10–35%
  Cx: myocardial infarction, stroke, respiratory insufficiency, pulmonary embolism, aortic rupture, pseudoaneurysm, graft infection

Prognosis without Rx:

immediate death (3%); death within: 1 day (20–30%), 1 week (50–62%), 3 weeks (60%), 1 month (75%), 3 months (80%), 1 year (80–95%)

Prognosis with Rx:

5–10% mortality rate following timely surgery;
40% 10-year survival rate after leaving hospital

Death from thoracic aortic dissection may occur ← acute aortic regurgitation; ← major aortic branch obstruction; ← pericardial tamponade; ← aortic rupture into pericardium / left pleural cavity / mediastinum.

DDx: penetrating ulcer of thoracic aorta (= atherosclerotic lesion of mid-descending aorta with ulceration extending through intima into aortic media)

AORTIC HYPOPLASIA

Prevalence: 5–10% of congenital cardiac lesions

Cause: fibrous ridge deformity of aortic media + intima protruding into aortic lumen → prominent posterior infolding of aortic lumen that may extend laterally → eccentric narrowing of aortic lumen

Genetics: usually sporadic; increased frequency among patients with Turner syndrome (13–15%)

• CHF in neonatal period (in 50%) = 2nd most common cause of heart failure in newborns

Definition:

(a) external diameter of proximal arch segment < 60%
(b) external diameter of distal arch segment < 50%
(c) external diameter of isthmic segment < 40% compared to external diameter of ascending aorta

√ patent ductus arteriosus

Hemodynamics:

fetus : no significant change because only 10% of cardiac output flows through aortic isthmus
neonate : determined by how rapidly the ductus closes; without concurrent VSD overload of LV leads to CHF in 2nd / 3rd week of life

Prognosis: 11% mortality prior to 6 months of age

Rx: ages 3–5 years are ideal time for operation (late enough to avoid restenosis + early enough before irreversible hypertension occurs); surgical correction past 1 year of age decreases operative mortality drastically

Risk of surgery: 3–11% perioperative mortality

Procedures:

1. Resection + end-to-end anastomosis
2. Patch angioplasty
3. Subclavian artery used as flap (Waldhausen procedure)

Postsurgical Cx:

1. Residual coarctation (in 32%)
2. Subsequent obstruction (rare)
3. Mesenteric arteritis: 2–3 days after surgery ← paradoxical hypertension from increased plasma renin
   • abdominal pain, loss of bowel control

4. Chronic persistent hypertension

DDx: Normal (gradual tapering of distal aortic arch + isthmus during first 3 months of life)

Tubular Aortic Hypoplasia

= combination of abnormally small diameter + increased length (> 5 mm in infants) between aortic arch segments

AORTIC PROSTHETIC GRAFT INFECTION

Frequency: 1.3–6% of prosthetic graft procedures

Classification:

(1) PERIGRAFT INFECTION (2–6%)
- groin swelling, heat, tenderness, pulsatile mass, draining sinus tract; fever, chills, leukocytosis

(2) AORTOENTERIC FISTULA (0.6–2%)
- acute / chronic GI bleeding (may be occult), sepsis

- may be temporally remote (up to 10 years): median time of 3 years to manifestation (70% occur > 1st year)
- intracavitary signs: malaise, back pain, fever, elevated sedimentation rate, hydronephrosis, ischemia from clotted graft

Normal postoperative course:

√ ring of fat attenuation in early postoperative period < 5 mm between aneurysm wall and graft

◊ Complete resolution of hematoma by 3 months

◊ Disappearance of ectopic gas complete by 4–7 weeks

CT (94% sensitive, 85% specific, 91% accurate):

√ perigraft fluid

√ perigraft soft-tissue attenuation with indistinctness of graft margins

√ ectopic gas ← fistulous communication with bowel / gas-producing organism

√ pseudoaneurysm (25%)

√ focal bowel wall thickening → indicates fistula

√ > 5 mm soft tissue between graft + surrounding wrap (beyond 7th postoperative week)

√ focal discontinuity of calcified aneurysmal wrap

False positives:

perigraft hematoma in early postoperative period, pseudoaneurysm (in 15–20%)

NUC:

√ uptake of ^{99m}Tc-hexametazine labeled leukocytes (drawbacks: not performed quickly, hepatobiliary excretion)

Prognosis: 17–75% mortality; 30–50% morbidity

Dx: positive culture from needle aspirate (incubation period must be up to 14 days as organisms may be slow-growing)

AORTIC REGURGITATION / INSUFFICIENCY

Cause:

A. PRIMARY DISEASE OF ASCENDING AORTA distorting aortic root (more common)

(a) dilatation of aortic annulus
1. Idiopathic dilatation (most common cause)
2. Atherosclerosis ← systemic hypertension
3. Aortic aneurysm
4. Rheumatoid arthritis and variants:
   › Ankylosing spondylitis (5–10%)
   › Reiter disease
   › Psoriatic arthritis
5. Familial connective tissue disease:
   mnemonic: HOME
   › Homocystinuria
   › Osteogenesis imperfecta
   › Marfan syndrome (most common cause < 40 years of age)
   › Ehlers-Danlos syndrome
6. Relapsing polychondritis
7. Seronegative spondyloarthropathy: eg, Behçet
8. Syphilitic aortitis

(b) laceration of aorta

Classification of Aortic Regurgitation in Adults			
Classification	*Regurgitant Volume (mL/beat)*	*Regurgitant Fraction (%)*	*Valve Orifice Area (cm2)*
Mild	< 30	< 30	< 0.10
Moderate	30–59	30–49	0.10–0.29
Severe	≥ 60	≥ 50	> 0.30

1. Deceleration trauma → aortic dissection
2. Prosthetic valve: mechanical break, thrombosis, paravalvular leak

B. INTRINSIC AORTIC VALVE DISEASE impairing leaflet function (less common)
1. Congenital bicuspid valve
   N.B.: Most common cause in developed nations
2. Rheumatic endocarditis
   N.B.: Most common cause in developing world
3. Bacterial endocarditis (perforation / prolapse of cusp)
4. Rupture of congenitally fenestrated cusp
5. Myxomatous valve associated with cystic medial necrosis
6. Atherosclerotic degeneration
   ◊ Severely calcified aortic valves are often regurgitant
7. Connective tissue disorder: Marfan syndrome
8. Ergot toxicity, anorectic drugs
9. Systemic inflammation: lupus erythematosus, Crohn disease, Takayasu arteritis, giant cell arteritis
10. Aortic valve prolapse

Pathogenesis: LV volume overload → progressive enlargement of diastolic + systolic LV dimensions → increase in myocardial fiber length + increase in stroke volume;

decompensation occurs if critical limit of fiber length is reached

- "water-hammer pulse" = twin-peaked pulse
- systolic ejection murmur + high-pitched diastolic murmur
- Austin Flint murmur = soft mid-diastolic or presystolic bruit

√ LV enlargement (cardiothoracic ratio > 0.55) + initially normal pulmonary vascularity (DDx: congestive cardiomyopathy, pericardial effusion):
  √ LV wall may appear thin even with ventricular hypertrophy
√ normal aorta (in intrinsic valve disease)
√ dilatation of aorta (in systemic disease):
  √ ± calcification of ascending aorta (in aortic wall disease)
  √ ± enlarged aortic arch + tortuous descending aorta
√ increased pulsations along entire aorta

ECHO:
  √ aortic root dilatation
  √ CHARACTERISTIC high frequency flutter of aML (occasionally pML) during first $^{2}/_{3}$ of diastole
  √ high frequency diastolic flutter of IVS (uncommon)
  √ diastolic flutter of aortic valve (SPECIFIC, but rare)
  √ premature aortic valve opening (high diastolic LV pressure)
  √ decreased MV opening (aML pushed posteriorly by regurgitant aortic jet)
  √ premature closure of mitral valve (high diastolic LV pressure produces MV closure before beginning of systole in severe acute aortic insufficiency)
  √ LV dilatation + large amplitude of LV wall motion (volume overload, increased ejection fraction):

End-systolic LV diameter	Action
< 50 mm	yearly follow-up
50–54 mm	4- to 6-month follow-up
> 55 mm	valve replacement

Doppler:
  √ decrease of slope of peak diastolic to end-diastolic velocity > 3 m/sec2 in severe aortic regurgitation
  √ area of regurgitant flow visible by color Doppler
  √ ratio of width of regurgitant beam to width of aortic root is good predictor of severity (on color Doppler)

AORTIC RUPTURE

= blood leakage through aortic wall

1. Spontaneous rupture of aortic aneurysm
   Pathogenesis: small clefts occur at a fragile site within inner thrombus gradually expanding to outer layer of thrombus with gradual seepage of flowing blood into mural thrombus + aneurysmal wall

   CT:
     √ high-attenuation "crescent" sign (71%)
2. Spontaneous rupture of descending thoracic aorta

Predisposed: hypertension and atherosclerosis, NO preformed aneurysm!
Pathogenesis: pressure atrophy of media ← overlying intimal atheromatous plaque causing localized ballooning of aortic wall prior to perforation

3. Traumatic rupture / transection of thoracic aorta
   Cause: blunt trauma to thoracic aorta

AORTIC STENOSIS

Aortic valve area decreased to < 0.8 cm^2 = 0.4 $cm^2/m2$ BSA (normal 2.5–4.0 cm^2)

A. ACQUIRED AORTIC STENOSIS
   1. Rheumatic valvulitis: from postinflammatory fusion (almost invariably associated with mitral valve disease)
      N.B.: Most common cause worldwide
   2. Fibrocalcific senile aortic stenosis (degenerative)
      N.B.: Most common cause in developed countries
   3. Takayasu aortitis
   4. Radiation aortitis
   5. Aortic dissection
   6. Infected aortic aneurysm with abscess
   7. Pseudoaneurysm from laceration
   8. Atherosclerosis (rare)
   9. Syphilitic aortitis (rare)

B. CONGENITAL AORTIC STENOSIS (most common)
   = most frequent CHD associated with IUGR
   Location:
   1. Subvalvular AS (15–30%)
   2. Valvular AS (60–70%)
   3. Supravalvular AS (rare)
   Cause:
   1. Bicuspid aortic valve → predisposed to early stenosis
   2. Williams syndrome
   3. Neurofibromatosis
   4. Rubella
   5. Mucopolysaccharidosis
   6. Hypoplastic left heart syndrome

Pathogenesis:
gradual decrease in valve area → ↑ gradient across valve → ↑ LV afterload LV → hypertrophy and diminished LV compliance; ↑ muscle mass may outstrip coronary blood supply (subendocardial myocardial ischemia with angina → fibrosis); LV decompensation with impaired contractility + compliance → LV dilatation + pulmonary venous congestion

Aortic stenosis increases afterload on LV → compensatory LV hypertrophy, which initially minimizes wall stress and maintains cardiac output!

- asymptomatic for many years (until valve area 1 cm^2)

Severity of Aortic Stenosis in Adults			
Classification	*Aortic Jet velocity (m/sec)*	*Mean Pressure Gradient (mmHg)*	*Valve Orifice Area (cm^2)*
Normal	≤ 2.0	< 5	3.0–4.0
Mild	< 3.0	< 25	> 1.5
Moderate	3.0–4.0	25–40	1.0–1.5
Severe	> 4.0	> 40	< 1.0

- angina, dyspnea, syncope, heart failure, systolic murmur
- diminished aortic component of 2nd heart sound
- sudden death in severe stenosis (20%) after exercise (diminished flow in coronary arteries causes ventricular dysrhythmias + fibrillation); carotid pulsus parvus et tardus

√ poststenotic dilatation of ascending aorta (in 90% of acquired, in 70% of congenital AS)
√ normal-sized / enlarged LV (small LV chamber with thick walls)
@ in adults > 30 years
  √ calcification of aortic valve (best seen on RAO); indicates gradient > 50 mmHg:
    √ severe aortic calcifications = "porcelain aorta" → technically difficult / impossible valve replacement
  √ ectasia / aneurysmal dilatation of ascending aorta (NO correlation with severity of stenosis)
  √ calcification of mitral annulus
  √ "left ventricular configuration" = concavity along mid left lateral heart border + increased convexity along lower left lateral heart border
@ in children / young adults
  √ prominent ascending aorta
  √ left ventricular heart configuration
@ in infancy:
  √ left ventricular stress syndrome

CT:
  √ thickening + calcification of cusps
  √ reduction of aortic valve area

ECHO:
  √ thickened + calcified aortic valve with multiple dense cusp echoes throughout cardiac cycle (right > noncoronary > left coronary cusp)
  √ decreased separation of leaflets in systole with ↓ opening orifice: 13–14 mm = mild AS; 8–12 mm = moderate AS; < 8 mm = severe AS
  √ ± doming in systole
  √ dilated aortic root
  √ increased thickness of LV wall ← concentric LV hypertrophy
  √ hyperdynamic contraction of LV (in compensated state)
  √ decreased mitral EF slope ← reduced LV compliance
  √ LA enlargement
  √ increased aortic valve gradient (Doppler)
  √ decreased aortic valve area (unreliable)

DDx: calcification of aortic annulus in elderly / calcified coronary artery ostium (thickened cusp echoes only in diastole)

Prognosis: depends on symptomatology (angina, syncope, CHF → 2–3 years average survival w/o surgery)

Cx: aortic valve replacement (for symptomatic patient with substantial ventricular dysfunction)

Subvalvular Aortic Stenosis

= SUBAORTIC STENOSIS

A. ANATOMIC / FIXED SUBAORTIC STENOSIS

Associated with: cardiac defects in 50% (usually VSD)

Type I : thin 1–2-mm membranous diaphragmatic stenosis, usually located within 2 cm or less of valve annulus

Type II : thick collarlike stenosis

Type III : irregular fibromuscular stenosis

Type IV : "tunnel subaortic stenosis" = fixed tunnel-like narrowing of LVOT = excessive thickening of only upper ventricular septum with normal mitral valve motion

B. FUNCTIONAL / DYNAMIC SUBAORTIC STENOSIS

1. Asymmetric septal hypertrophy (ASH)
2. Idiopathic hypertrophic subaortic stenosis (IHSS)
3. Hypertrophic obstructive cardiomyopathy (HOCM) may occur in infants of diabetic mothers

√ no dilatation of ascending aorta

√ asymmetrically thicker ventricular septum than free wall of LV (95%)

√ normal / small left + right ventricular cavities (95%)

√ lucent subaortic filling defect in systole

√ focal convexity of left upper-mid cardiac margin = anterior aspect of ventricular septum (rare)

ECHO:

√ coarse systolic flutter of valve cusps

√ opening of leaflets followed by rapid inward move in mid systole, leaflets may remain in partially closed position through latter portion of systole (to appose borders of the flow jet)

√ systolic anterior motion of mitral valve

Cx: mitral regurgitation ← abnormal position of anterolateral papillary muscle preventing complete closure of MV in systole

Valvular Aortic Stenosis

= fusion of commissures between cusps

Degree: mild: > 0.7 cm^2; moderate: 0.5–0.7 cm^2; severe: < 0.5 cm^2

Congenital types:

(1) Bicuspid / unicuspid (in 95%): in 0.7–2.0% of population; M > F; commonly associated with aortic coarctation

◊ Valve degenerates a decade earlier compared with tricuspid configuration!

◊ Aortic ectasia ← marfanoid-type wall weakness + eccentric poststenotic jet

(2) Tricuspid (5%)

(3) Dysplastic thickened aortic cusps

@ IN INFANT with critical aortic stenosis:

- intractable CHF in first days / weeks of life with severe dyspnea; may simulate neonatal sepsis

Associated with: L-to-R shunts (ASD, VSD)

√ marked cardiomegaly ← thickened wall of LV
√ pulmonary venous hypertension
√ decreased ejection fraction
√ doming of thickened valve cusps
√ dilated ascending aorta

Rx: emergency surgical dilatation

@ IN CHILD:

- asymptomatic until late in life

√ normal pulmonary vascularity
√ LV configuration with normal size of heart
√ large posterior noncoronary cusp, smaller fused right + left cusps
√ doming of thickened valve cusps
√ eccentric jet of contrast

DDx of Valvular Aortic Stenoses

	Congenital	*Rheumatic*	*Degenerative*
Clinically apparent	< 30 years	30–60 years	> 65 years
Valve calcifications			
1st appearance	25 years	47 years	54 years
Ca^{2+} pattern	nodular / bicuspid	nodular	nodular / tricuspid
on CXR	> 90% (40–65 y)	< 10%	> 90% (> 65 y)
Aortic ectasia	ascending Ao	ascending Ao	entire Ao

√ poststenotic dilatation of ascending aorta

@ IN ADULT

√ valvular calcifications (in 60% of > 24 years of age)

ECHO:

√ increase in echoes from thickened deformed leaflets (maximal during diastole)
√ decrease in leaflet separation

Supravalvular Aortic Stenosis

= focal / diffuse narrowing of aorta starting at sinotubular junction + often involving entire ascending aorta (15%)

Types:

(a) localized hourglass narrowing just above aortic sinuses
(b) discrete fibrous membrane above sinuses of Valsalva
(c) diffuse tubular hypoplasia of ascending aorta + branching arteries

Genetics: (rare) sporadic form / autosomal inherited: mutation of elastin gene on

chromosome 7q11.23

Path: reduction + disorganization of elastin fibers within aortic media accompanied by hypertrophied smooth muscle cells and increased collagen content → reduced elasticity + increased shear stress

Associated with:

› peripheral PS
› valvular AS (in 50%): commonly bicuspid aortic valve
› discrete subvalvular aortic stenosis (in 16%)
› Williams-Beuren syndrome
› Marfan syndrome
› infantile hypercalcemia syndrome

√ small ascending thoracic aorta
√ dilatation + tortuosity of coronary arteries (may undergo early atherosclerotic degeneration 2° to high pressure)

ECHO:

√ narrowing of supravalvular aortic area (normal root diameter: 20–37 mm)
√ normal movement of cusps
√ left ventricular myocardial hypertrophy
√ bicuspid aortic valve

AORTOENTERIC FISTULA

= life-threatening condition

Mortality: approaches 100% without prompt surgery

Primary Aortoenteric Fistula (rare)

= complication of atherosclerotic aortic aneurysms WITHOUT previous aortic surgery / trauma

Incidence: 0.007÷1,000,000 annually

Predisposed: syphilis, TB, mycotic infection, collagen vascular disease

√ ectopic gas adjacent to / within aorta (KEY FINDING)
√ obliteration of fat plane between aorta and bowel
√ ± hematoma in retroperitoneum / bowel wall or lumen

Secondary Aortoenteric Fistula (more frequent)

= complication of aortic reconstructive surgery / stent graft

Incidence: 0.6%–2.0% annually

Time interval since surgery: 2 weeks to 10 years

Cause: complication of advanced perigraft infection

• GI bleeding (80%) preceded by "herald bleeds"
• abdominal pain (30%), back pain (15%), sepsis (44%)
• groin mass (12%), abdominal pulsatile mass (6%)

Location: horizontal + ascending duodenum (80%)

√ loss of fat plane between aorta and adjacent bowel, pseudoaneurysm, disruption of aortic wall:
  √ tethering / puckering of bowel wall toward aorta
√ perigraft soft-tissue edema, fluid / hematoma:

N.B.: resolution within 2–3 months after surgery

√ hyperattenuating fluid collection / mass acute = hematoma / partially thrombosed pseudoaneurysm

Strongly suggestive CT findings:

√ ectopic gas

N.B.: may be normal immediately after surgery

Cave: abnormal 3–4 weeks after surgery = sign of perigraft infection / fistulization

√ focal bowel wall thickening (challenging if involved bowel loop not distended)

√ breach of the aortic wall

√ extravasation of contrast material into bowel lumen (extremely rare but most SPECIFIC)

√ leakage of enteric contrast into periaortic space (rare)

CT features of perigraft infection should raise concern about the possibility of a secondary aortoenteric fistula.

Angio: usually no vascular abnormality

DDx: (1) Perigraft infection without fistulization

(2) Retroperitoneal fibrosis

(3) Infected (mycotic) aortic aneurysm

(4) Infectious aortitis

Aortoesophageal Fistula

= rare life-threatening subtype of intramural hematoma

Frequency: 3.5% of all deaths ← upper esophageal bleeding

Cause:

(a) aortic condition (75%): ruptured aneurysm, ruptured atheromatous plaque, penetrating ulcer, prosthetic grafting / reconstructive surgery

(b) esophageal condition: foreign body ingestion, malignancy, corrosive esophagitis

CT:

√ enhancing subepithelial esophageal mass with fistulous tract between aorta + esophagus

AORTOPULMONIC WINDOW

= AORTOPULMONARY WINDOW

= large round / oval communication between left wall of ascending aorta + right wall of pulmonary trunk / right pulmonary artery

Aortopulmonic window has well-defined separate aortic and pulmonary valve apparatuses unlike in truncus arteriosus!

Prevalence: 0.1% of all CHD

Cause: defect in septation process with incomplete fusion / malformation of right / left conotruncal rings

• clinically resembles PDA with frequent CHF

Mori classification:

Type I = proximal communication near semilunar valves (70–96%)

Type II = distal communication near pulmonary bifurcation at level of right pulmonary artery (14–25%); associated with type A of interrupted aortic arch

Type III = total absence of aortopulmonary septum (5%)

Associated with: other congenital cardiac anomalies (in up to 44%)

CXR:

√ shunt vascularity
√ cardiomegaly ← LA + LV enlarged
√ diminutive aortic knob
√ prominent pulmonary trunk ← arterial pHTN

Angio (left ventriculogram / aortogram in AP / LAO projection):

√ defect several mm above aortic valve
√ pulmonary valve identified (DDx to truncus arteriosus)

Rx: surgery (pulmonary artery flap, pericardial patch); nonsurgical (Amplatzer device implantation)

ARTERIOSCLEROSIS OBLITERANS

= ASO = HARDENING OF THE ARTERIES

Prevalence: 2.7% (in 1.0% of < 60 years of age, in 3.4% of ≥ 65 years of age); 2.4 million people in USA; in 1978 12% of autopsies had ASO as leading cause of death (excluding MI)

Etiology: unknown

Contributing factors: aging, diabetes (16–44%), hypertension, atherosclerosis

Effect of hyperlipidemia:

(a) high-density lipoproteins (HDL) have a protective effect: carry 25% of blood cholesterol
(b) low-density lipoproteins (LDL): carry 60% of cholesterol

Histo: deposition of lipids, blood products, carbohydrates, begins as disruption of intimal surface; fatty streaks (as early as childhood); fibrous plaques (as early as 3rd decade); thrombosis, ulceration, calcification, aneurysm

Age: 50–70 years; M > F (after menopause)

Clinical classification:

(1) Intermittent claudication = ischemic symptoms with exercise: in calf, thigh, hip, buttock
(2) Ischemic symptoms at rest (indicative of multisegment dz)

- cramping / burning / aching pain; cold extremity; paresthesia
- trophic changes: hair loss, thickened nails
- ulcer, gangrene; decreased / absent pulses

Location: medium + large arteries; frequently at bifurcations; most frequently affected sites are:

› superficial femoral artery within adductor canal (diabetics + nondiabetics)
› aortoiliac segment (nondiabetics)
› tibioperoneal trunk (diabetics)

Prognosis:

ASO accelerated by diabetes (34% will require amputation), hypertension, lipoprotein abnormalities, heart disease (= ↓ cardiac output → polycythemia → ↑ blood viscosity), chronic addiction to tobacco (11.4% will require amputation), intermittent claudication (5–

7% require amputation if nondiabetic = 1–2% annually), ischemic ulcer / rest pain (19.6% require amputation)

ATRIAL SEPTAL DEFECT

◊ Most common congenital cardiac defect after bicuspid aortic valve!

Frequency: 8–10–14% of all CHD; M÷F = 1÷3

Age: presentation frequently > age 40 secondary to benign course

(a) mildly symptomatic (60%): dyspnea, fatigue, palpitations

(b) severely symptomatic (30%): cyanosis, heart failure

Hemodynamics:

no hemodynamic perturbance in fetus; after birth physiologic ↑ in LA pressure + greater compliance of RA and RV create L-to-R shunt (shunt volume ~ 3–4 times that of systemic blood flow); volume overload of RV is well tolerated in childhood, → leads to RV dilatation, right heart failure; diastolic pressure differences in atria determine direction of shunt; pulmonary pressure remains normal for decades; after 40 years of age onset of pulmonary hypertension → increased R-to-L shunting (Eisenmenger syndrome); pulmonary hypertension in young adulthood (6%)

RA	↑	RV	↑	Main PA	↑
Pulm. vessels	↑				
LA	↔	LV	↔	Ao	↓/↔

- repeated respiratory infections; feeding difficulties
- atrial arrhythmias: atrial flutter + atrial fibrillation increases with age; thromboembolism
- asymptomatic; occasionally discovered by routine CXR
- fixed splitting of second heart sound with accentuation of pulmonary component (ejection murmur grade II/VI) heard at 2nd left intercostal space along PA
- ECG: right axis deviation + some right bundle branch block
- exertional dyspnea after development of pulmonary arterial hypertension (= Eisenmenger syndrome)
- cyanosis may occur (shunt reversal to R-to-L shunt), typically during 3rd–4th decade
- right heart failure in patients > 40 years; right ventricular heave

Types of ASD: ostium secundum > ostium primum > sinus venosus > unroofed coronary sinus

CXR:

√ normal (if shunt < 2 x systemic blood flow)

√ overcirculation = increase in pulmonary blood flow (if pulmonary-to-systemic blood flow ≥ 2÷1)

√ cardiomegaly:

√ heart small compared with pulmonary vascularity = closing shunt

√ heart large compared with pulmonary vascularity = intercurrent myocardial / aortic disease

√ loss of visualization of SVC ← clockwise rotation of heart ← RV hypertrophy

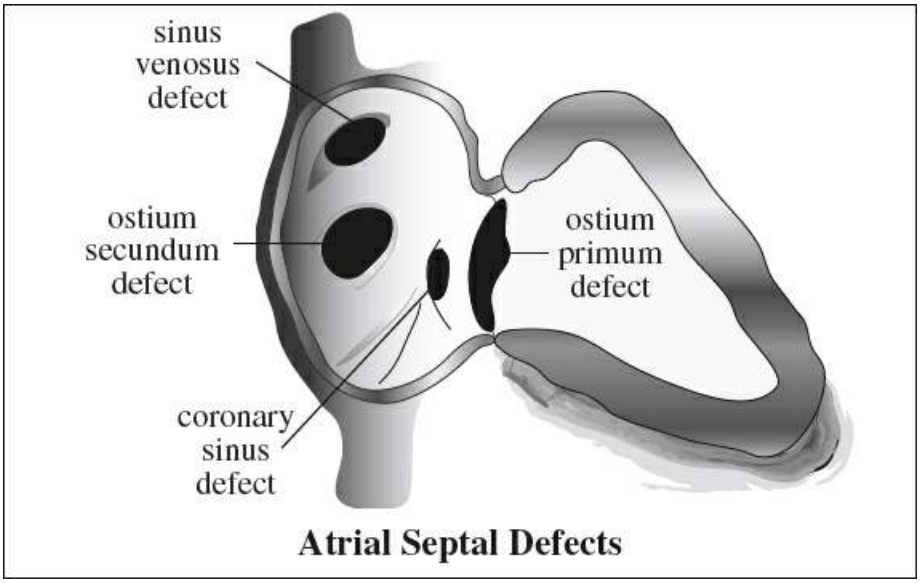
√ small appearing aorta with normal aortic knob

√ normal size of LA after shunt reversal ← immediate decompression into RA (in Eisenmenger syndrome):

√ enlargement of PA + central pulmonary arteries
√ RV enlargement
√ "hilar dance" = increased pulsations of central pulmonary arteries (DDx: other L-to-R shunts)

ECHO:
√ paradoxical interventricular septal motion ← RV volume overload
√ direct visualization of ASD (= lack of echoes of atrial septum) in subcostal view
√ diastolic blood flow from interatrial septum crossing RA + tricuspid valve directly observed by color Doppler

MR:
√ discrete area of interruption of the normal intermediate-intensity interatrial septum
CAVE: normal thinning of fossa ovalis can cause drop-out of atrial signal
√ area of signal loss from atrial septum into RA ← turbulent jet on GRE
√ ratio of stroke volumes in aorta to PA (measurement of flow volume on cine phase-contrast images)



Angio:
√ RA fills with contrast shortly after LA is opacified (on levophase of pulmonary angio in AP or LAO projection)
√ injection into RUL pulmonary vein to visualize exact size + location of ASD (LAO 45° + C-C 45°)

Prognosis:
(1) Mortality: 0.6% in 1st decade; 0.7% in 2nd decade; 2.7% in 3rd decade; 4.5% in 4th decade; 5.4% in 5th decade; 7.5% in 6th decade; median age of death is 37 years
(2) Spontaneous closure: 22% in infants < 1 year; 33% between ages 1 and 2 years; 3% in children > 4 years

Cx: (1) Tricuspid insufficiency ← dilatation of AV ring
(2) Mitral valve prolapse

(3) Atrial fibrillation (in 20% 1st presenting symptom in patients > age 40)

Rx: (if vascular changes still reversible = resistance of pulmonary-to-systemic system ≤ 0.7)

1. Surgical patch closure
2. Rashkind foam + stainless steel prosthesis

Indication for surgery (1% surgical mortality):

1. RA and RV enlargement ± symptoms
2. Paradoxical emboli
3. Pulmonary-to-systemic flow ratio > 1.5

Beneficial ASD

= secundum type ASD serves essential compensatory function in:

1. Tricuspid atresia
   RA blood reaches pulmonary vessels via ASD + PDA; improvement through Rashkind procedure
2. TAPVR
   significant shunt volume only available through ASD (VSD / PDA much less reliable)
3. Hypoplastic left heart
   systemic circulation maintained via RV with oxygenated blood from LA through ASD into RA

Ostium Secundum Defect

= persistent opening at site of foramen ovale

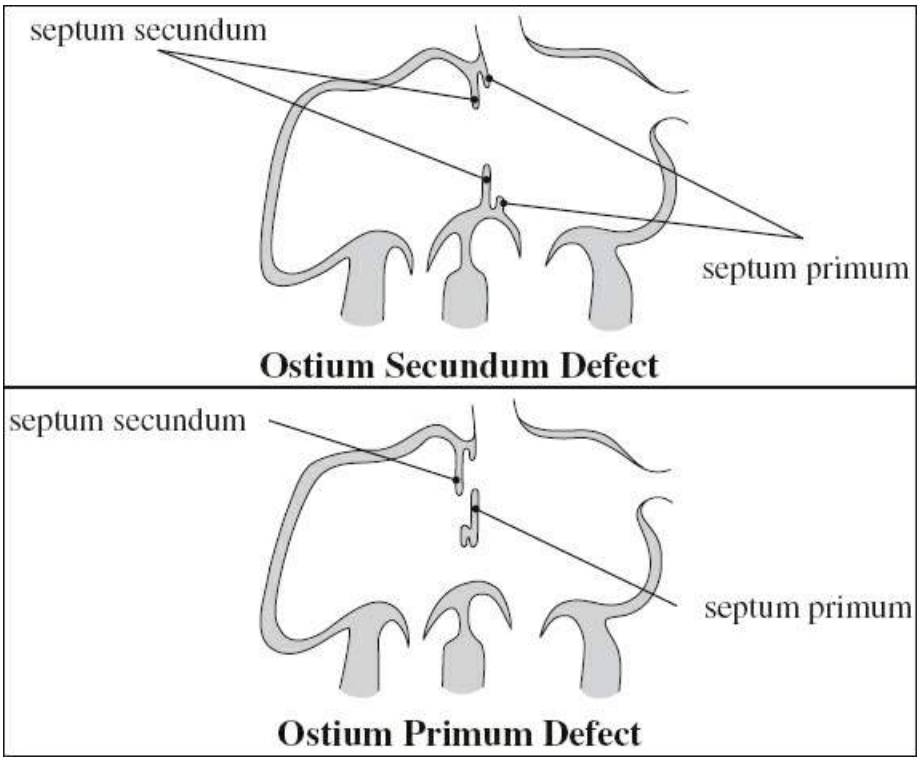
Cause: exaggerated resorptive process of septum primum → absence / fenestration of foramen ovale flap (Chiari network)

Location: in the center of the atrial chamber at fossa ovalis

Size: large defect of 1–3 cm in diameter

May be associated with:

prolapsing mitral valve (20–30%), pulmonary valve stenosis, tricuspid atresia, TAPVR, hypoplastic left heart, interrupted aortic arch



√ large direct communication between atria

Prognosis: often spontaneous closure by 2 years of age if diameter < 6 mm and if discovered in neonate

DDx: patent foramen ovale (interatrial connection of variable width + length)

Ostium Primum Defect

= defect of atrioventricular endocardial cushion

Location: lower end of septum inferior to fossa ovalis (at outlet portion of atrial septum) adjacent to atrioventricular valves

Almost always associated with:

Down syndrome, cleft mitral valve, common atrioventricular canal complex, anterior fascicular block

√ cardiomegaly + pulmonary vascular congestion

ECHO:

- √ direct visualization of abnormality
- √ measurement of flow and shunt size
- √ evaluation for valvular regurgitation
- √ both AV valves at same level (tricuspid valve usually more apically located than mitral valve)
- √ enlargement RA + RV + PA ← secondary pulmonary arterial hypertension

Unroofed Coronary Sinus

= CORONARY SINUS DEFECT

Cause: lack of septation between left atrium and coronary sinus → left-to-right shunt

Spectrum: multiple fenestrations in coronary sinus to complete atresia of thebesian valve
√ normal coronary sinus typically absent (unroofed)
√ dilated coronary sinus
√ connection between coronary sinus and left atrium
√ persistent SVC drains directly into LA

Malposition of Septum Primum

= anomalous drainage of right pulmonary vein into RA (= to right of leftward deviated septum primum)
Pathophysiology: lack of left heart filling → left heart hypoplasia
Associated with: heterotaxy, polysplenia, complex CHDs

Lutembacher Syndrome

= ASD + mitral stenosis

AZYGOS CONTINUATION OF IVC

= INTERRUPTED IVC WITH AZYGOS / HEMIAZYGOS CONTINUATION = ABSENCE OF THE HEPATIC SEGMENT OF THE IVC WITH AZYGOS CONTINUATION
Prevalence: 0.6%
Etiology: formation failure of right subcardinal-hepatic venous anastomosis → atrophy of right subcardinal vein → shunting of blood from supracardinal-subcardinal anastomosis to cranial portion of supracardinal vein (= retrocrural azygos vein)
May be associated with:
polysplenia syndrome (common), asplenia syndrome (rare), indeterminate situs (= situs ambiguus), persistent left SVC, dextrocardia, transposed abdominal viscera, duplicated IVC, retroaortic left renal vein, congenital pulmonary venolobar syndrome
√ absence of hepatic ± infrahepatic IVC:
  √ drainage of hepatic veins into RA via supra- / posthepatic segment of IVC (N.B.: IVC shadow present on LAT CXR!)
√ drainage of iliac + renal veins via azygos / hemiazygos vein:
  √ right renal artery crosses anterior to "IVC" on US
√ both gonadal veins drain into ipsilateral renal vein (since postcardinal-subcardinal anastomosis does not contribute to formation of IVC)
CXR:
  √ enlargement of azygos arch to > 7 mm
  √ widening of right paraspinal stripe contiguous with azygos arch (= enlarged paraspinal + retrocrural azygos veins)
  √ widening of left paraspinal stripe (= enlarged hemiazygos v.)
CT / MR:
  √ intensely enhancing well-defined tubular structure behind diaphragmatic crura paralleling aorta
DDx: right-sided paratracheal mass with retrocrural adenopathy

BACTERIAL ENDOCARDITIS

Incidence: 1.7–6.2÷100,000 annually in developed countries

Predisposed:

1. Native valve disease:
   (a) bicuspid aortic valve:
   responsible for 50% of aortic valvular bacterial endocarditis
   (b) rheumatic valve disease
   (c) mitral valve prolapse with mitral regurgitation
2. Prosthetic valve:
   4% incidence of bacterial endocarditis; mitral valve > aortic valve
   √ exaggerated valve motion (= disintegration of suture line + regurgitation)
3. Most CHD (VSD, TOF) except ostium secundum ASD
4. Previous endocarditis
5. Intravenous drug use:
   endocarditis of tricuspid valve → multiple septic pulmonary emboli
6. Central venous catheter
7. Other sources of infection: poor dentition, long-term hemodialysis, diabetes mellitus, HIV infection

Major criteria:

1. Oscillating valvular mass
2. Abscess
3. Dehiscent prosthetic valve

Minor criteria:

1. Pseudoaneurysm
2. Septic infarction

Valve Vegetations

Manifestations:
(1) Embolic phenomena
(2) Valvular regurgitation

CT:
√ peripheral cavitary (septic) lung nodules → assess for right-sided valvular vegetations

ECHO:
√ usually discrete focal echodensities with sharp edges; may show fuzzy / shaggy nonuniform thickening of cusps (vegetations) in systole + diastole
√ may appear as shaggy echoes that prolapse when the valve is closed (DDx to mitral valve prolapse)

ECG-gated CT (97% sensitive, 88% specific):
√ routinely depicts vegetations > 1 cm in diameter
√ depicts perivalvular abscess + pseudoaneurysm
√ septic + peripheral emboli

Cx: bundle-branch block, fistulation, refractory sepsis
(a) left: peripheral embolism, stroke, brain abscess
(b) right: septic pulmonary embolism, infarction

BEHÇET DISEASE

[Hulusi Behçet (1889–1948), dermatologist in Istanbul, Turkey]
= rare multisystemic chronic relapsing inflammatory vasculitis of variable-sized vessels in multiple organs of unknown origin

Countries: worldwide, most common in eastern Mediterranean countries, eastern rim of Asia; highest prevalence in Turkey with 80–370÷100,000

Histo: nonspecific necrotizing vasculitis with deposition of immune complexes in walls of small blood vessels

Associated with: human leukocyte antigen HLA-B51; genetic mutations including factor V Leiden → hyper-coagulability; triggered by microbial antigens

Age at onset: 3rd decade; M÷F = 2÷1

TRIAD of

1. Orogenital ulcers
2. Ocular inflammatory disease
3. Cutaneous lesions

Diagnostic criteria:

(1) Recurrent oral ulcers = aphthous stomatitis (95–100%)

plus 2 major criteria

(2) Recurrent genital ulcers (65–90%): ulcers on penis + scrotum / vulva + vagina

(3) Ocular inflammation (35–70%): anterior + posterior uveitis, relapsing iridocyclitis, hypopyon, choroiditis, papillitis, retinal vasculitis

(4) Skin lesion (40–50%):

› erythema nodosum, pseudofolliculitis, papulopustular lesions, acneiform nodules

› positive pathergy test (10–50%): pustule formation 24–48 hours after skin prick

Major criteria: buccal + genital ulceration, ocular inflammation, skin lesions

Minor criteria: thrombophlebitis, GI + CNS lesions, arthritis, family history

@ Joints

• arthritis (30–80%)

√ mild nondestructive arthritis

Rx: systemic corticosteroids for disease exacerbation

DDx: Reiter syndrome, Stevens-Johnson syndrome, SLE, ulcerative colitis, ankylosing spondylitis

Gastrointestinal Behçet Disease (5–42–60%)

Path: lymphocytic vasculitis of venules of bowel wall → chronic inflammation + intestinal ulceration

• abdominal pain + diarrhea (50%)

@ Esophagus (rarely involved)

√ single / multiple erosions / ulcerations

√ diffuse esophagitis, esophageal stenosis

√ mucosal dissection, intramural hematoma

√ downhill esophageal varices ← thrombotic occlusion of SVC → fibrosing mediastinitis → mediastinal collateral vessels draining into esophageal, coronary, hepatic veins + IVC

• hematemesis, SVC syndrome

@ Small bowel

Location: terminal ileum (most common), often together with proximal cecum
√ geographic large collar-button–shaped deep ulcer
√ aneurysmal dilatation of terminal ileum
√ cecal mass
Cx: perforation, fistula, hemorrhage

@ Large intestine
Location: ascending colon (most common)
√ multiple discrete punched-out ulcers throughout colon mimicking Crohn disease

Neurologic Behçet Disease (5–21–50%)
= develops > 10 years after onset of Behçet disease
Path: inflammatory cellular infiltrate around peripheral small venules + arterioles ← demyelination + edema

@ Parenchymal Neurobehçet (80%)
Location: brainstem (cerebral peduncles, pons) > thalamus > basal ganglia > centrum semiovale > peri-ventricular region, spinal cord, cranial nerve
√ isolated / confluent irregular T2 hyperintense foci of circular / linear / crescent shape that are iso- or hypointense relative to brain parenchyma on T1WI
DDx: multiple sclerosis (smaller + less extensive lesions), brainstem infarction, dilated perivenular spaces
√ atypically space-occupying lesion masquerading as unilateral brain tumor
DDx: lymphoma, other malignant tumor, abscess
√ leptomeningeal enhancement ← cranial nerve palsy /meningoencephalitis
Cx: small / (occasionally) large infarction

@ Nonparenchymal Neurobehçet (20%)
√ cerebrovascular disorders:
√ dural sinus thrombosis (5–25%) → raised intracranial pressure
√ multiple arterial aneurysm
√ arterial dissection / occlusion (rare)
√ aseptic meningitis (0.05–8.00%)

Cardiac Behçet Disease (1–16%)
= develops within 10 years after onset of Behçet disease
√ endocarditis, myocarditis, pericarditis
√ endomyocardial fibrosis
√ coronary artery disease, myocardial infarction
√ intracardiac thrombosis
√ aneurysm of sinus of Valsalva, periaortic pseudoaneurysm
√ valve dysfunction, conduction system disturbances

Vascular Behçet Disease (5–30–45%)
@ Veins (25%): migratory thrombophlebitis
√ subcutaneous / superficial venous thrombophlebitis
√ mediastinal widening ← edema ← thrombosis of SVC
√ thrombosis of IVC, veins in upper extremities

√ deep vein thrombosis in lower extremities
√ Budd-Chiari syndrome (3%)
√ portal vein thrombosis (9%)

@ Systemic arteries (3%)
√ saccular arterial aneurysm formation (⅓)
Histo: perivascular inflammatory cell infiltration → occlusion of vasa vasorum → transmural necrosis of wall → severe destruction of elastic fibers in media → perforation of vessel wall
Location: ascending thoracic aorta > aortic arch > abdominal aorta > pulmonary > femoral > coronary > subclavian > popliteal arteries
√ arterial occlusion/ pulseless disease (⅔)

@ Pulmonary artery
√ increased perihilar radiopacity ← pulmonary artery aneurysm
Location: artery to RLL > RPA > LPA
◊ Most common cause of pulmonary artery aneurysm!
√ in situ pulmonary artery thrombosis
√ pulmonary artery thromboembolism ← DVT ← hypercoagulable state

Thoracic Behçet Disease (1–8%)

@ Lung
√ multiple subpleural wedge-shaped / ill-defined increased opacities ← areas of pulmonary infarction ← hemorrhage / parenchymal necrosis
√ ill-defined ground-glass opacities with consolidation = hemorrhage ← ruptured pulmonary artery aneurysm
√ pleural effusion

BICUSPID AORTIC VALVE

= single fused commissure at birth resulting in 2 separate cusps of unequal size (usually fused L + R coronary cusps)

Sievers classification: based on
(a) number of raphes
(b) position of cusps and raphes

Prevalence: 1–2% in general population
◊ Most common congenital cardiac anomaly!

Genetics: autosomal dominant with incomplete penetrance

Histo: cystic medial degeneration; ↑ levels of matrix metalloproteinases; ↓ levels of fibrillin-1 in aortic wall

Bicuspid aortic valve patients have an aortopathy similar to Marfan syndrome with an increased propensity for aortic dilatation, aneurysm, dissection, and rupture!

Associated with: dilatation of aortic root (50%) + ascending aorta + transverse arch aortic; CoA

Cx: stenosis, regurgitation, endocarditis, aneurysmal dilatation of ascending aorta, aortic dissection

Recommendation: monitoring of aortic size with echocardiography / CT / MRI

BUERGER DISEASE

= THROMBANGIITIS OBLITERANS

[Leo Buerger (1879–1943), Austrian-American pathologist, surgeon and urologist at Mount Sinai Hospital, Beth David Hospital, Bronx Hospital, and Wyckoff Heights Hospital, Brooklyn, New York]

= idiopathic recurrent segmental obliterative vasculitis of small + medium-sized peripheral arteries + veins (panangiitis)

Frequency: < 1% of all chronic vascular diseases; more common in Israel, Orient, India

Etiology: unknown

Histo:

(a) acute stage: multiple microabscesses within fresh / organizing thrombus; all layers of vessel wall inflamed but intact; internal elastic lamina may be damaged; multinucleated giant cells within microabscesses (PATHOGNOMONIC)

(b) subacute stage: thrombus organization with little residual inflammation

(c) chronic stage: lumen filled with organized recanalized thrombus, fibrosis of adventitia binds together artery, vein, and nerve

Associated with: cigarette smoking (95%)

- instep claudication ± distal ulceration (symptoms abate on cessation of smoking + return on its resumption)
- Raynaud phenomenon (33%)

Location: legs (80%), arms (10–20%)

Site: starts in palmar + plantar vessels with proximal progression

√ superficial + deep migratory thrombophlebitis (20–33%)
√ arterial occlusions, tapered narrowing of arteries
√ abundant corkscrew-shaped collaterals
√ direct collateral following the path of the original artery (Martorell sign) in 80%
√ skip lesions = multiple segments involved with portions of arterial wall remaining unaffected
√ absence of generalized arteriosclerosis / arterial calcifications (90%)

CARDIAC ARREST

= sudden cessation of cardiac pump function

CT:

√ layering of static blood within heart + great vessels
√ hematocrit effect ← sedimentation of RBCs
√ good depiction of cardiac anatomy ← NO cardiac motion

CECT:

√ contrast pooling in dependent portion of venous system (right atrium, hepatic veins)
√ no contrast in pulmonary artery + left heart structures

Rx: prompt cardiopulmonary resuscitation

CARDIAC FIBROMA

= FIBROMATOSIS = FIBROUS HAMARTOMA = FIBROELASTIC HAMARTOMA

= congenital neoplasm / hamartoma of the heart

Prevalence: 100 cases reported; 2nd most common benign cardiac neoplasm of childhood (after

rhabdomyoma)

Mean age: 13 (range, 0–56) years; 33% in children < 1 year of age / in utero; 15% in adolescents + adults

Increased prevalence in: Gorlin (basal cell nevus) syndrome

- heart failure, cardiac murmur (⅓), ventricular arrhythmia
- NO embolism; asymptomatic (⅓)

Path: 2–10-cm large <u>single</u> round bulging well-circumscribed tumor within ventricular myocardium; foci of calcification / ossification (50%)

Histo: collection of fibroblasts interspersed among large amounts of collagen; numerous elastic fibers (> 50%); NO foci of cystic change / hemorrhage / necrosis

Location: ventricular septum > left ventricular free wall

√ cardiomegaly
√ focal cardiac bulge ← tumor in free ventricular wall
√ may be pedunculated
√ centrally cystic degeneration (rare)
√ ± pericardial effusion

ECHO:

√ noncontractile echogenic heterogeneous solid mass:
√ mean diameter > 5 cm; may obliterate cardiac chamber
√ multifocal dystrophic central tumor calcifications
√ affected myocardium hypokinetic

DDx: focal hypertrophic cardiomyopathy, hypertrophy of ventricular septum

CT:

√ homogeneous mural mass of soft-issue attenuation
√ sharply marginated / infiltrative
√ calcifications (25%)
√ variable enhancement

MR:

√ iso- / hypointense homogeneous discrete mural mass / myocardial thickening on T1WI
√ homogeneously hypointense on T2WI
√ no / little hetero- or homogeneous enhancement

Prognosis:

(1) Sudden death ← arrhythmia ← invasion / compression of cardiac conduction system
◊ 2nd most common primary cardiac tumor associated with sudden death (after endodermal heterotopia of AV node)
(2) May remain stable in size for years

Fibromas often are single lesions that do not regress, unlike rhabdomyomas!

Cx: fetal hydrops ← obstruction, pericardial effusion, fetal arrhythmia, fetal death

Rx: surgical excision / partial resection

DDx in infants: rhabdomyoma (multiple masses)

DDx in children: rhabdomyosarcoma (no calcification, cystic or necrotic tumor, invasion of pulmonary veins or pericardial space)

CARDIAC HEMANGIOMA

= rare benign vascular tumor of the heart
Prevalence: 5–10% of benign cardiac tumors
Association: Kasabach-Merritt syndrome (multiple systemic hemangiomas, recurrent thrombocytopenia, consumptive coagulopathy)
Path: predominantly intramural spongy mass / well-circumscribed endocardial-based soft mass growing into pericardial space; may contain fat
Histo: capillary (= small capillary-like vessels); cavernous (= multiple thin-walled dilated vessels); arteriovenous (= thick-walled dysplastic arteries + veins + capillaries)
• asymptomatic; dyspnea on exertion, chest pain, right-sided CHF
• arrhythmia, syncope, pericarditis, sudden death
Location: any chamber
√ mass-occupying lesion impinging upon cardiac cavities
√ ± pericardial effusion
US:
√ hyperechoic mass
CT:
√ heterogeneous intensely enhancing mass
MR:
√ heterogeneously iso- / hypointense on T1WI
√ hyperintense / occasionally hypointense on T2WI
√ inhomogeneous hyperintense enhancement pattern
Angio:
√ vascular blush in capillary + arteriovenous type
√ no enhancement for cavernous type
Prognosis: spontaneous regression possible
Rx: surgical resection (for symptomatic lesion)

CARDIAC INJURY

Frequency: 25% of traumatic deaths related to heart injury
◊ Congestive heart failure, pulmonary edema, cardiogenic shock, new cardiac murmur, pericardial friction should prompt evaluation for cardiac injury!

In blunt trauma, a triad of hyperdense pericardial effusion + distention of IVC and renal vv. + hypodense periportal fluid suggests cardiac tamponade!

Blunt Cardiac Injury

= most common type of cardiac injury after blunt thoracic trauma, but difficult to diagnose
Cause: MVC, fall, explosion, work-related accident, recreational activity, CPR
Location: RV (35%), LV (25%), RA atrium (33%), LA (14%), aorta (14%)
Associated with: rib fracture (83%), pneumothorax (39%), hemothorax (31%), lung contusion (13%), fracture of clavicle (13%), sternum (10%)

Myocardial Concussion

= mildest form of cardiac injury without proved myocardial cell damage / morphologic injury = myocardial stunning

- NO chemical abnormalities; NO elevated enzymes
- ± arrhythmia

ECHO:

√ segmental wall motion abnormalities

Myocardial Contusion

Frequency: 10–75%

Site: anterior surface of heart (RV > LV)

- precordial pain and dyspnea with varying ECG changes
- elevated cardiac enzymes:
  - › creatine kinase (> 90% sensitive, < 6% specific)
  - › serum cardiac troponin (> 90% sensitive + specific): level proportional to extent of myocardial damage

√ distinct boundary between normal + contused tissue

√ patchy necrosis + hemorrhage → eventually heal to form patchy and irregular fibrosis

ECHO:

√ increased myocardial echogenicity

√ focal systolic hypokinesis

NUC: not found to be helpful

Cx: arrhythmia, low cardiac output, ventricular septal defect, ventricular rupture, valvular dysfunction

◊ Extensive myocardial contusion + hemopericardium may be present without external signs of thoracic trauma

Myocardial Rupture

Frequency: 0.3–1.1% (in ER), 36–65% (in autopsy)

Site: right side of heart

- refractory hypotension + tachycardia

√ pericardial effusion → tamponade → cardiac arrest

√ myocardial disruption:

√ traumatic VSD typically occurs in the apical interventricular septum ← anteroposterior cardiac compression between sternum and thoracic spine.

√ extravasation of IV contrast into pericardial space

Prognosis: 33% surgical mortality, excellent long-term prognosis in survivors

Pericardial Injury / Rupture

Location of tear: longitudinal path along phrenic nerve

√ pericardial effusion

√ pneumopericardium ← pericardial tear (in 0.3–0.5%)

√ delayed traumatic diaphragmatic hernia

√ focal pericardial dimpling + discontinuity

√ lung interposition between aorta + pulmonary artery / heart + diaphragm / RA + RVOT

Cx: partial / complete trans-defect cardiac herniation

CARDIAC HERNIATION

N.B.: life-threatening condition (33–47% survival rate)

Prevalence: in 64% of pericardial ruptures
√ contour abnormality of heart = deformed ventricular silhouette
√ cardiac displacement into either hemithoracic cavity
√ pericardial sac "empty" = delineated by air / filled with loops of gas-containing bowel
Cx: strangulation of cardiac structures ← constrictive pericardial defect

CARDIAC LUXATION

= cardiac herniation and volvulus
Frequency: in 28% of pericardial ruptures
• change in electrical axis of heart
√ cardiac displacement:
√ leftward deviation of the myocardial septum
√ torsion along IVC + great vessels = strangulation of entire heart
√ entrapment of LA + LV
√ cardiac herniation through pericardial defect
√ pneumopericardium, esp. if associated with pneumothorax
Cx: SVC obstruction, right heart strain
Mortality rate: up to 67%

Coronary Artery Injury

Frequency: < 2% of blunt chest trauma
Site: LAD > RCA >> left circumflex artery
Path: intimal tear → dissection → thrombosis
• hypotension, ventricular arrhythmias
• acute myocardial infarction + ST-segment elevation
Rx: percutaneous transluminal angioplasty + stenting
Cx: rapid tamponade

Traumatic Valvular Dysfunction

Site: aortic > mitral > tricuspid valve
Pathophysiology:
(1) direct blunt cardiac trauma → abrupt increase in intracardiac chamber pressure against closed valve → maximal transvalvular gradient
(2) sudden rise in intraabdominal pressure → waterhammer effect to L > R heart
√ pulmonary edema ← new onset heart failure
@ Aortic valve
√ tear / avulsion from annulus of aortic valve cusp (esp. noncoronary cusp)
@ Mitral valve
Site: rupture of papillary muscle > chordae tendineae > tear of leaflet
@ Tricuspid valve (rare)
Site: rupture of chordae tendineae > tear of anterior papillary muscle > tear of leaflet

Penetrating Cardiac Injury

Cause: stabbing (knives), gunshot (handgun)
Location: RV (62%), LV (38%)

In penetrating chest trauma, CT is useful for depicting hemopericardium (100% sensitive, > 96% specific), pneumopericardium, intrapericardial hernia, and cardiac compression by a mediastinal hematoma.

Mortality: prehospital (94%), in-hospital (50%), gunshot (81–90%), stabbing (16–67%)
Cause of death: hemorrhagic shock (78%), cardiac tamponade (22%)

CARDIAC LIPOMA

= very rare benign neoplasm; 2nd most common cardiac tumor
Prevalence: 60 reported cases
Age: wide range; typically in adults
Path: encapsulated spherical / elliptical solitary mass, often very large (up to 4,800 g) by the time they come to clinical attention; multiple lipomas in CHD, tuberous sclerosis
Histo: mature adipocytes surrounded by capsule
Associated with: tuberous sclerosis (with multiple lipomas)
• mostly asymptomatic
• dyspnea (in intracavitary lipoma ← blood flow obstruction, in pericardial lipoma ← displacement of lung)
• arrhythmia ← involvement of conduction system
• right heart failure ← direct obstruction of tricuspid valve / vena cava with large lipoma
Location: broad-based from
(a) epicardial surface growing into pericardial space
(b) endocardial surface growing into cardiac chamber
(c) interatrial septum (atrioventricular grooves)
√ cardiomegaly, globular-shaped heart
√ echogenic / hypoechoic broad-based nonmobile mass
√ round mass with smooth contour
CT:
√ homogeneous mass of ≤ −50 HU in cardiac chamber / pericardial space
MR:
√ mass similar to adjacent subcutaneous / mediastinal fat:
√ homogeneously hyperintense on T1WI
√ intermediate to high signal intensity on T2WI
√ ± few thin septations
√ uniform drop in signal intensity with fat saturation
√ NO contrast enhancement
PET:
√ NO FDG activity
Rx: surgical resection

CARDIAC PARAGANGLIOMA

= extremely rare, usually benign sporadic neoplasm arising from intrinsic cardiac sympathetic paraganglial (chromaffin) cells
Prevalence: < 50 cases
Mean age: 40 (range, 18–85) years

- catecholamine-producing tumor (in the majority):
  - headache, arterial hypertension, palpitations, flushing
  - elevated levels of urinary norepinephrine, vanillylmandelic acid, total metanephrine, plasma norepinephrine, epinephrine

Associated with:

(a) additional paragangliomas (in 20%) in carotid body, adrenal gland, bladder, paraaortic

(b) metastases to bone (in 5%)

Path: 2–14 cm large encapsulated / poorly circumscribed and infiltrative highly vascular mass; necrotic in 60%

Histo: monomorphic tumor composed of nests of paraganglial cells (= "Zellballen") surrounded by sustentacular cells

Location: posterior wall of left atrium > roof of left atrium > atrial cavity > interatrial septum > ventricle

Site : epicardial surface of the base of the heart with tendency to involve coronary arteries

CXR:

√ middle mediastinal mass splaying carina simulating left atrial enlargement (for typically located tumor)

ECHO:

√ large echogenic left atrial mass

√ compression of SVC, encasement of coronary arteries

DDx: myxoma (broad base of attachment, softer)

NUC (^{131}I- or ^{123}I-MIBG):

√ for total body imaging with a sensitivity of 90%

NECT:

√ circumscribed / ill-defined heterogeneous mass:

√ hypoattenuating

√ isoattenuating to cardiac structures (may be missed)

√ ± tumor calcifications

√ ± extracardiac extension

CECT:

Cave: Premedicate patient with alpha- and beta-blockers as contrast material can trigger a hypertensive crisis!

√ markedly enhancing mass adherent to / involving left atrium / anterior to aortic root

√ central area of low attenuation (in 50%) from necrosis

MR:

√ mass iso- / hypointense to myocardium on T1WI

√ very hyperintense mass on T2WI

√ intense often heterogeneous enhancement

CARDIAC SARCOMA

◊ Most common primary malignant tumor of the heart!

Mean age: 41 years; extremely rare in infants + children

(a) right-sided heart inflow obstruction (tumor in right atrium)

1. Angiosarcoma (37–80%)

(b) mitral valve obstruction (tumor in left atrium)

2. Undifferentiated sarcoma (24–37%)
3. Malignant fibrous histiocytoma (11–24%)
4. Leiomyosarcoma (1–9%): predilection for left atrium; tends to invade pulmonary veins + mitral valve

Age: 5–10 years earlier than other sarcomas

5. Primary cardiac osteogenic sarcoma (3–9%)

DDx: myxoma (at fossa ovalis)

• dyspnea, pericardial tamponade, arrhythmia, syncope, peripheral edema, sudden death
• embolic phenomena, chest pain, pneumonia, fever
√ contrast enhancement, areas of hemorrhage, central necrosis

CXR:

√ cardiomegaly, RA enlargement
√ CHF
√ pleural effusion, pericardial effusion
√ focal cardiac mass
√ pulmonary consolidation

PET:

√ difficult identification of sarcoma if myocardial FDG activity is high

Metastatic to: lung, lymph nodes, bone, liver, brain, bowel, spleen, adrenal gland, pleura, diaphragm, kidney, thyroid, skin

Prognosis: mean survival of 3 month to 1 year

Dx: invasion of adjacent cardiac chambers + pericardium (DDx: benign mass)

Clue for subtypes:

√ macroscopic fat favors liposarcoma
√ calcifications favor fibrosarcoma
√ right atrial location favors angiosarcoma

Angiosarcoma (37–80%)

Frequency: most common cardiac malignancy of adulthood

Age: typically in middle-aged men

Path: frequently hemorrhagic + necrotic mass, often adherent to pericardium → pericardial effusion

Histo: mesenchymal cells characterized by ill-defined vascular spaces lined by atypical endothelial cells

• chest pain, right heart failure, supraventricular arrhythmia
• fever, weight loss; pericardial tamponade = bloody fluid on pericardiocentesis (rarely with malignant cells)

Spread to: right ventricle, lung, vena cava, liver (in 66–89% at presentation)

Location: right atrial free wall + involvement of pericardium (80%)

(a) well-defined large mass protruding into a cardiac chamber

√ usually originating from RA with sparing of atrial septum
√ areas of central necrosis communicating with cardiac chamber
√ disruption of fat planes, pericardial thickening / nodularity
√ low-attenuation mass on CT

√ heterogeneous contrast enhancement
√ heterogeneous MR signal:
√ "cauliflower appearance" = local nodular predominantly hyperintense areas interspersed within areas of intermediate SI on T2WI
√ central areas of necrosis

(b) diffusely infiltrative mass extending along epicardial surface
√ obliterated pericardial space (hemorrhage + necrotic tumor debris)
√ "sunray appearance" = linear contrast enhancement along vascular lakes on MR

Prognosis: poor (← late patient presentation); median survival of 6 months

Leiomyosarcoma of Heart (1–9%)

Location: predilection for left atrium; multiple (in 30%); tends to invade pulmonary veins + mitral valve
Age: 5–10 years earlier than other sarcomas
• dyspnea, CHF ← mitral valve obstruction
√ iso- to hypointense on T1WI + hyperintense on T2WI
√ marked contrast enhancement

Primary Osteogenic Sarcoma of Heart (3–9%)

= OSTEOSARCOMA OF HEART = CARDIAC OSTEOSARCOMA
Frequency: rare; 3–9% of primary cardiac sarcomas
Histo: osteo- / chondro- / fibroblastic differentiation
Location: left atrium sparing fossa ovalis
√ broad base of attachment with invasive behavior
√ dense calcifications (frequent) on CT
√ heterogeneously hypointense on T1WI
√ hyperintense on T2WI
DDx: metastatic osteosarcoma, myxoma

Rhabdomyosarcoma of Heart

Frequency: most common primary cardiac malignancy of childhood
Histo: embryonal type (in children + adults); pleomorphic type (in adults)
Location: no specific chamber with tendency to involve valves; multiple sites
• CHF (common)
MR:
√ isointense to myocardium on T1WI
√ central areas of low SI ← tumor necrosis
√ homogeneous enhancement

Undifferentiated Sarcoma (24–37%)

= PLEOMORPHIC SARCOMA = ROUND CELL SARCOMA = SPINDLE CELL SARCOMA
Frequency: 2nd most common cardiac malignancy
Age: 45 years (range, neonates to elderly)
• pulmonary congestion
Location: left atrium

√ large irregular hypodense intracavitary mass
√ polypoid mass isointense to myocardium
√ thickening / irregularity of myocardium ← tumor infiltration
√ tendency to involve valves
√ hemorrhagic mass replacing the pericardium (similar to angiosarcoma)

CARDIAC TAMPONADE

= PERICARDIAL TAMPONADE
◊ Cardiac tamponade is a clinical diagnosis!
= significant compression of heart by fluid / blood / pus / gas / tissue (= benign or malignant neoplasia) contained within pericardial sac → impaired diastolic filling of ventricles

In blunt trauma, the triad of hyperdense pericardial effusion + distention of IVC and renal veins + hypodense periportal fluid suggests cardiac tamponade!

Hemodynamics:
incremental ↑ in intrapericardial volume exceeds limit of pericardial stretch → ↑ intrapericardial pressure → compression of heart → ↑ diastolic filling pressures + ↓ volumes of cardiac chambers → severe hemodynamic impairment (= ↓ stroke volume) → reduced cardiac output → ↓ arterial blood pressure + ↓ coronary blood flow

Intrapericardial pressure: normally equals intrapleural pressure; pathologically equals cardiac chamber pressure
◊ With rapid fluid accumulation as little as 200 mL of fluid can cause cardiac tamponade!

Dx: clinical suspicion confirmed by echocardiography

Rate of accumulation versus pericardial volume:
(a) rapid / acute: 100–200 mL
(b) slow / gradual: up to 1,000–1,500 mL

- Beck triad:
  - muffled "distant" heart sounds
  - jugular venous distention ← ↑ central venous pressure
  - falling blood pressure / hypotension
- compensatory mechanisms:
  - tachycardia, increased contractility
  - vasoconstriction: cool legs, arms, ears, nose, peripheral cyanosis
- pulsus paradoxus = exaggerated drop in systolic arterial pressure > 10 mmHg during inspiration (← ↑ in right heart filling during inspiration at the expense of left heart filling)
  DDx: massive pulmonary thromboembolism, obstructive lung disease, profound hemorrhagic shock / other forms of severe hypotension
- shortness of breath
- ECG: reduced voltage, ST elevation, PR depression, nonspecific T-wave abnormalities

CXR:
√ normal lung fields + normal pulmonary vascularity
√ rapid enlargement of heart size (requires > 200 mL of pericardial effusion):
  √ global cardiomegaly with "water bottle" cardiac silhouette
  √ mediastinal widening

- √ hilar mass
- √ ± epicardial "fat pad" sign:
  - √ curvilinear fat density displaced posteriorly from sternum by pericardial effusion on LAT view
- √ ± tension pneumopericardium:
  - √ "small heart" sign = substantial decrease in size of cardiac silhouette

ECHO (imaging method of choice):

- √ cardiac chamber compression:
  - √ RV collapse during early diastole ← pericardial pressure exceeds RV pressure (38–48% sensitive, 84–100% specific)
  - √ inward movement of RA wall during late diastole + early systole lasting for > 30% of cardiac cycle (55–60% sensitive, 50–68% specific)
  - √ highly specific collapse of LA during late diastole (late sign in 25%)
- √ exaggerated respiratory variation in mitral + tricuspid inflow ← increased ventricular coupling
- √ distended inferior vena cava (IVC plethora) → NO decrease in diameter of proximal IVC by > 50% after deep inspiration / sniff
- √ Doppler flow velocity paradoxus = exaggerated paradoxical increase of right versus decrease of left transvalvular inflow velocities during early diastole
- √ compression of intrapericardial pulmonary trunk + thoracic IVC → indentation of RA at level of IVC junction anteriorly
- √ paradoxical motion of the interventricular septum → during inspiration sharply toward left, during expiration to right
- √ swinging motion of heart inside pericardial sac

Limitations of ECHO:

1. High rate of false-positive findings ← adjacent pathologic conditions simulating pericardial effusions: pleural effusion, lower lobe atelectasis, pericardial + intracardiac mass, other mediastinal lesions
2. Difficulty in identifying blood clot within pericardium
3. Differentiation of small fluid collections from pericardial thickening
4. Differentiation of fluid in the anterior and posterior spaces around the heart from epicardial fat
5. Identification of loculations in complex pericardial collections

CT:

- √ various attenuation values:
  - √ fat (chylopericardium)
  - √ simple serous fluid (underlying heart failure, renal failure, nonhemorrhagic carcinomatous involvement)
  - √ greater than water (hemopericardium, malignancy, purulent exudates, myxedematous effusion associated with hypothyroidism)
- √ signs of pericardial thickening:
  - √ presence of nodular areas
  - √ typically anterior location
  - √ lack of change at decubitus positioning

- √ pericardial contrast enhancement
- √ extrapericardial venous changes:
  - √ SVC enlargement: SVC diameter ≥ adjacent thoracic aorta
  - √ IVC enlargement: diameter > twice that of adjacent aorta
  - √ distension of hepatic + renal veins
  - √ reflux of contrast medium into azygos vein + IVC
  - √ periportal lymphedema
  - √ hepatomegaly
- √ intrapericardial venous changes:
  - √ compression of coronary sinus
  - √ compression of pulmonary trunk
  - √ compression of short intrathoracic segment of IVC (extrapericardial posteriorly, but covered by pericardium anteriorly)
- √ "flattened heart" sign ← pericardial fluid / tissue (↑ intrapericardial pressure → transient reversal of transmural left ventricular pressure during diastole):
  - √ flattening of anterior heart surface with ↓ in AP diameter
  - √ straightening of the right cardiac contour
  - √ inversion of wall with concave deformity of RA / RV
- √ RV + LV of equal size ← equalization of ventricular pressures
- √ angulation / bowing / inversion of interventricular septum

MR:

- ◊ Limited role due to emergent life-threatening disease!
- √ detection of pericardial effusions as small as 30 mL
- √ swinging heart and paradoxical septal bounce (cine MR)

Doppler-US:

- √ distension of IVC + hepatic veins with diastolic flow reversal (= hepatopetal flow)
- √ episodes of high-velocity hepatopetal flow separated by long intervals of minimal flow

Rx: needle pericardiocentesis (95% success with anterior effusion > 10 mm) / surgical pericardial drainage (intrapericardial bleeding, purulent effusion, clotted hemopericardium)

DDx: effusive-constrictive pericarditis

Malignant Pericardial Disease

- √ mass arising from / contiguous with pericardium
- √ obliteration of normal tissue planes between paracardiac mass and heart / pericardium
- √ compression + narrowing of cardiac chambers by pericardial effusion / mass
- √ hyperattenuating pericardial effusion ← hemorrhage / debris with fluid usually > 20 HU
- √ irregular enhancing nodular pericardial thickening
- √ signs of right-sided heart failure
- √ often evidence of primary malignancy of breast / lung

Rx: emergent pericardiocentesis ± drain placement

CARDIAC THROMBUS

A thrombus is the most common cause of a cardiac mass!

Cardiac thrombi in children are more commonly associated with indwelling central venous catheters, less likely with congenital heart disease or dilated cardiomyopathy.

A. Left atrial thrombus
Associated with: mitral valve disease
• atrial fibrillation
Site: atrial appendage
√ atrial dilatation
√ irregular / lobulated border
√ microcavitations
√ laminated appearance

B. Right atrial thrombus

Cause: underlying coagulation disorders / atrial arrhythmias / central venous catheters / pacemaker leads / mechanical tricuspid valve

Incidence: 4–7% with suspected pulmonary embolism
√ hyperechoic mass (DDx: crista terminalis, myxoma)
√ absence of mobility
√ multiple lesions favor thrombus
Prognosis: 80–100% mortality in untreated patients
◊ Large right atrial mobile thrombi are life-threatening!
Rx: anticoagulation, thrombectomy, thrombolysis, surgical resection
DDx: cardiac myxoma

C. Left ventricular thrombus
Site: region of ventricular dyskinesia / aneurysm ← prior myocardial infarction
√ usually NO enhancement:
√ peripheral enhancement ← neovascularization in chronic thrombus
√ homogeneous attenuation on CT
√ heterogeneous signal on SE MR images
√ low-signal intensity on GRE MR images
DDx: myxoma (heterogeneous texture on CT)

CARDIOMYOPATHY

= mechanical / electrical dysfunction of myocardium exhibiting inappropriate ventricular hypertrophy + dilatation
Prevalence: 1÷5439 in USA
Cause:

A. PRIMARY / INTRINSIC CARDIOMYOPATHY
(a) genetic
1. Hypertrophic cardiomyopathy
2. Arrhythmogenic RV dysplasia
3. Noncompaction cardiomyopathy
4. Glycogen storage disease
5. Conduction defects
6. Mitochondrial myopathy
7. Ion channel disorders

(b) acquired
1. Inflammatory (myocarditis)
2. Stress provoked
3. Peripartum
4. Tachycardia induced
5. Infants of diabetic mothers

(c) mixed
1. Dilated cardiomyopathy
2. Restrictive cardiomyopathy

B. SECONDARY CARDIOMYOPATHY (majority of cases)
= characterized by multiorgan involvement
(a) infiltrative: amyloidosis, Gaucher disease, Hurler disease, Hunter disease
(b) storage: hemochromatosis, Fabry disease, glycogen-storage disease type II, Niemann-Pick disease
(c) toxicity: drugs, heavy metals, chemical agents
(d) endomyocardial: endomyocardial fibrosis, hypereosinophilic syndrome (Löffler endocarditis)
(e) inflammatory: sarcoidosis
(f) endocrine: diabetes mellitus, hyperparathyroidism, hyper- / hypothyroidism, pheochromocytoma, acromegaly
(g) neurologic: Friedreich ataxia, Duchenne-Becker muscular dystrophy, myotonic dystrophy, neurofibromatosis, tuberous sclerosis
(h) autoimmune: SLE, dermatomyositis, rheumatoid arthritis, scleroderma, polyarteritis nodosa
(i) electrolyte imbalance: deficiencies of potassium, phosphate, magnesium; anorexia nervosa; laxative abuse
(j) cancer therapy: anthracyclines (doxorubicin), cyclophosphamide, radiation

Dilated and Ischemic Cardiomyopathy

= CONGESTIVE CARDIOMYOPATHY

Etiology:

1. Idiopathic
2. Myocarditis: viruses, bacteria
3. Alcoholism
4. Pregnancy / post partum
5. Endocardial fibroelastosis = thickened endocardium + reduced contractility
6. Infants of diabetic mothers
7. Inborn error of metabolism: glycogenosis, mucolipidosis, mucopolysaccharidosis
8. Coronary artery disease: myocardial infarction, anomalous origin of L coronary artery, coronary calcinosis
9. Muscular dystrophies

• tendency for CHF when EF < 40%
√ global 4-chamber enlargement
√ poor ventricular contractility (= reduced EF)
√ LA enlargement without enlargement of LA appendage

√ bilateral atrioventricular valve insufficiency

ECHO:

√ enlarged LV with global hypokinesis

√ IVS + LVPW of equal thickness with ↓ motion amplitude

√ low-profile / "miniaturized" mitral valve

√ mildly enlarged LA ← elevated end-diastolic LV pressure

√ enlarged hypokinetic right ventricle

Dilated Cardiomyopathy

= dilatation + impaired contraction of LV or LV + RV

Prevalence: 36÷100,000 in USA

Cause:

1. Idiopathic (50%)
   (a) familial (20–35%): autosomal dominant / recessive, maternal, X chromosome–linked trait
3. Injury: coronary artery disease, systemic disease, nutritional deficiency, excessive consumption of alcohol, anthracyclines, catecholamines
4. Infection: viral, bacterial, fungal, rickettsial
5. Neuromuscular syndromes: Duchenne muscular dystrophy, Friedreich ataxia

Histo: patchy loss of myocytes with progressive replacement by interstitial fibrosis + eccentric hypertrophy of adjacent uninvolved cells

Hemodynamics: ↑ diastolic volume, ↑ systolic volumes, ↓ ejection fraction

• congestive heart failure, progressive dyspnea, orthopnea

◊ 3rd most common cause of heart failure after ischemia + valvular disease

◊ Most common cause of heart failure in the young

• arrhythmias, thromboembolism

√ biventricular dilatation

√ global ventricular hypokinesia

√ myocardial wall thinning (= diastolic wall thickness < 5.5.mm)

√ increase in myocardial mass

√ mitral / tricuspid regurgitation, atrial enlargement

√ intracardiac thrombus

Risk factor of sudden death: LV ejection fraction < 35%

Rx: ICD placement (for LV ejection fraction of ≤ 35%)

DDx: CAD, myocarditis, cardiac sarcoidosis

Hypertrophic Cardiomyopathy (10%)

= genetic disorder of cardiac muscle characterized by hypertrophy of LV in the absence of cardiac / systemic disease with subsequently decreasing size of LV cavity

Phenotypes (variable penetrance + expression):

1. Asymmetric (septal) HCM 60–70%
2. Apical HCM 2–25%
3. Symmetric (concentric) HCM in up to 42%
4. Midventricular HCM
5. Masslike HCM

Prevalence: 2÷1,000 (one of the most common genetic disorders)

Etiology: mutation in one of sarcomeric genes with autosomal dominant transmission (> 60%); sporadic form

Histo: myocyte disarray + interstitial fibrosis; dysplasia of small intramural coronary arterioles ← increased pressure from adjacent hypertrophic myocytes

Age: 3rd–5th decade; occasionally infants + elderly

- asymptomatic, fatigue, systolic murmur
- dyspnea on exertion (75%) ← impaired diastolic function ← impaired LV filling + preserved systolic function:
  - elevated LV diastolic pressure
- angina (66%) ← LV outflow obstruction + decreased flow through intramural coronary arteries
- syncope ← arrhythmia / decreased cardiac output during exercise because of LV outflow obstruction
- high voltage + inverted T waves at ECG
- sudden cardiac death in children (5% risk annually)

Risk factors of sudden cardiac death:

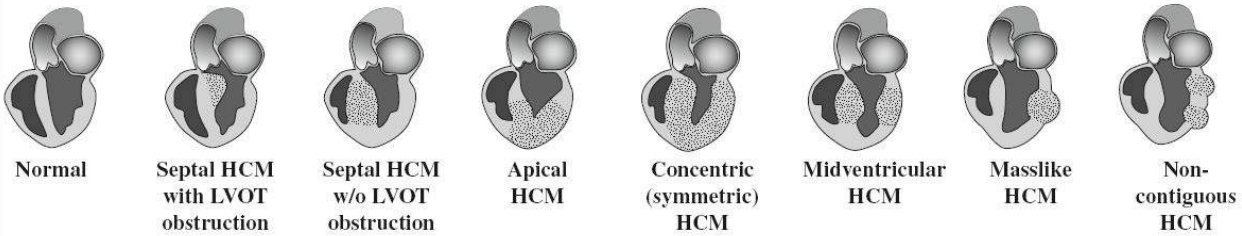
(1) Family history of sudden cardiac death
(2) Unexplained syncope
(3) Nonsustained ventricular tachycardia = greater than 3 beats at ≥ 120 bpm
(4) Hypotensive / blunted blood pressure response to exercise = rise of systolic pressure < 20 mmHg

Risk factors identified on cardiac imaging:

(1) LV wall thickness of ≥ 30 mm
(2) LVOT obstruction with gradient of ≥ 30 mmHg at rest or ≥ 50 mmHg with provocation
(3) LV dilatation with depressed ejection fraction
(4) Fibrosis
(5) Perfusion defect
(6) Reduced functional reserve flow

Role of imaging:

(1) Establish diagnosis
(2) Monitor gene carriers without phenotypic hypertrophic cardiomyopathy for development of the disease
(3) Screen family members of affected individuals
(4) Help stratify risk for sudden cardiac death
(5) Evaluate for complications



Phenotypes of Hypertrophic Cardiomyopathy (HCM)

There is a linear relationship between maximal myocardial thickness + risk for sudden cardiac death: maximal myocardial thickness of > 30 mm → indication for ICD placement!

Location:

› asymmetric septal hypertrophy = ratio of septal to inferolateral wall thickness of ≥ 1.3
› apical / midventricular hypertrophy
› focal masslike hypertrophy
› right ventricular hypertrophy

√ LV wall hypertrophy > 15 mm at end-diastole; often asymmetric / segmental / discontinuous
√ NO dilatation of LV cavity → decreasing in size
√ normal heart size
√ diastolic dysfunction:
  √ reduced LV compliance with relatively preserved systolic function and normal LV ejection fraction
√ LA enlargement ← mitral insufficiency ← abnormal mitral valve apparatus (in 30%) / diastolic dysfunction
√ prominent left midheart border (septal hypertrophy)
√ ± mild pulmonary venous hypertension

MR:

Cardiac MR imaging is a powerful imaging modality for differentiating HCM from other cardiomyopathies!

√ marked thickening of LV wall + small LV cavity
√ myocardial crypts at base of LV
√ average end-diastolic thickness of septal + posterolateral wall = 23.5 mm + 11.4 mm; ratio 2.1
√ increased LV mass (estimated by cine MR)
√ large + prolonged signal void from site of obstruction toward aortic valve within normally high-intensity flowing blood ← turbulent flow during systole
√ substantially elevated ejection fraction
√ prolonged systolic contact of the anterior mitral valve leaflet with septum ← elongation of anterior MV leaflet
√ systolic flow void from mitral valve into left atrium ← mitral valve regurgitation (on cine MR)
√ impairment of LV relaxation (= abnormal LV stiffness) → poor early diastolic filling

CEMR:

√ delayed hyperenhancement of hypertrophic myocardium (in 80%), on average 10% of

overall LV myocardial volume

ECHO (modality of choice):

√ IVS ≥ 15 mm thick; posterolateral wall > 11 mm thick; IVS÷LVPW thickness > 1.3÷1

√ systolic anterior motion of mitral valve (SAM) → narrowed LVOT during systole

√ dynamic LVOT obstruction ← hypertrophy of basal septum + SAM:

√ increased LVOT gradient with late systolic peaking on Doppler

√ midsystolic closure of aortic valve

√ hyperdynamic ventricular contraction → high LV ejection fraction

√ impaired myocardial relaxation

Dx: LV wall thickness ≥ 15 mm at end-diastole (without explanation); 12–14 mm = borderline values of mild dz

Prognosis: 1–6% annual mortality rate (sudden death in young patients); progressive LV dilatation, atrial arrhythmia, intractable CHF

Hypertrophic cardiomyopathy is the most common cause of sudden cardiac death in young adults and athletes!

Rx: beta-blockers, calcium antagonists, myomectomy of hypertrophied septum, septal alcohol ablation, cardiac transplantation, ICD (effective prevention of cardiac death)

DDx: athlete's heart

Apical Hypertrophic Cardiomyopathy

= myocardial wall thickening confined to apical portion of LV with sparing of septum

Age: middle-aged men

- usually clinically benign (no obstruction to LV flow), rarely associated with sudden cardiac death
- frequently complicated by hypertension
- giant (negative) inverted T-wave

Dx: (1) Absolute apical wall thickness > 15 mm (typically most evident in anteroseptal myocardium) *or*

(2) $\text{Thickness}_{\text{apical wall}} \div \text{Thickness}_{\text{basal LV wall}} = 1.3–1.5$

√ spade-like deformity of LV cavity at end-diastole (best seen on vertical long axis view)

Specific Cx: apical infarction resulting in aneurysm formation (= burned-out apex)

At risk for: thrombus formation, thromboembolism

Prediction of adverse outcome:

√ significant amount of delayed enhancement (> 5%)

Arrhythmogenic Right Ventricular Cardiomyopathy

= ARRHYTHMOGENIC RV DYSPLASIA

= heritable genetic progressive replacement of RV myocardium by fibrofatty tissue

- palpitations, fatigue, heart failure syncope, chest pain
- sustained monomorphic ventricular tachycardia with left bundle-branch block during exercise
- sudden cardiac death with physical exertion (rare)

Prevalence: 1÷1,000–1÷5,000; increase during 15–20 years of age; familial in up to 50%

Age: adolescence to middle-aged; M÷F = 3÷1
Location: triangle of dysplasia = between RV outflow tract + RV apex + diaphragmatic aspect of RV beneath posterior leaflet of tricuspid valve
Site: progression from epicardium to endocardium
Path: segmental / diffuse transmural loss of (RV >> LV > interventricular septum) myocardium with replacement by fibrofatty tissue; saccular aneurysm in triangle of dysplasia (in up to 50%)
√ almost imperceptibly thin free wall of RV
√ dilatation of RV (body + RVOT)
√ regional RV akinesia / dyskinesia / dyssynchrony
ECHO:
√ RVOT ≥ 29 mm on parasternal long axis view
√ RVOT ≥ 32 mm on parasternal short axis view
√ reduction of RV ejection fraction to ≤ 45%
√ increased RV end-diastolic volume index
CT:
√ myocardial fat in RV trabeculae + moderator band (difficult DDx: abundant epicardial fat)
√ conspicuous trabeculae
√ scalloped / bulging appearance of RV free wall

Functional and structural assessment of the RV is more reliable than fibrofatty changes!

MR:
√ fatty infiltration of RV / (rarely) epicardial LV free wall
√ aneurysm formation of RV
√ ratio of RV end-diastolic volume to body surface area ≥ 100 (90) mL/m2 for male (female) on parasternal long axis view
√ reduction of RV ejection fraction to ≤ 45%
√ "accordion" sign = corrugated pattern to RV wall ← RV akinesia / dyskinesia / dyssynchronous contraction

A diagnosis of ARVC requires these RV findings: dilatation, wall motion abnormalities, scalloped / bulging free wall, and myocardial fat in free wall, trabeculae, moderator band, interventricular septum!

Rx: avoidance of strenuous exercise, β blocker, ICD placement, antiarrhythmic Rx, catheter ablation
DDx: (1) Physiologic myocardial fat (normal myocardial thickness + size of RV)
(2) Healed MI (coronary artery territory, subendocardial location)
(3) Cardiac sarcoidosis (left / biventricular enlargement)
(4) Unrecognized shunt lesion: ASD, PAPVR
(5) Pectus excavatum (restricted motion of basolateral + inferolateral RV wall, narrowing of RV base with relative enlargement of RV apex + RVOT)

Asymmetric Septal Hypertrophy (ASH)

= IDIOPATHIC HYPERTROPHIC SUBAORTIC STENOSIS (IHSS) = SUBAORTIC STENOSIS

Asymmetric septal hypertrophy is the most common morphologic variant of HCM (60–70%). The ventricular septum is disproportionately enlarged, most commonly involving the anteroseptal myocardium. Septal hypertrophy can be limited to subaortic / midventricular / apical regions.

◊ Most common + clinically significant form!

Dx: The normal thickness of the LV is ≤ 11 mm measured during diastole.
(1) Septal thickness ≥ 15 mm (typically most evident in anteroseptal myocardium) *or*
(2) Thickness $_{\text{septum}}$ ÷ Thickness $_{\text{inferior LV wall}}$ > 1.5 at midventricular level

Clinical distinction:

1. Hypertrophic obstructive cardiomyopathy
   = gradient between LV outflow tract + aorta at rest and/or with provocation
   Cause: systolic anterior motion of MV leaflets + midsystolic contact of MV leaflets with IVS
   √ peak systolic pressure gradient at rest ≥ 50 mmHg
2. Nonobstructive cardiomyopathy
   = no systolic obstruction of LV outflow tract

Hemodynamics:

› LV hypertrophy → subaortic stenosis → abnormal diastolic function → myocardial ischemia
› rapid blood flow through narrow outflow tract → anterior leaflet of mitral valve displaced anteriorly toward septum during systole (**Venturi effect**)
› concomitant mitral regurgitation ← displaced MV leaflets with incomplete leaflet apposition

• mitral regurgitation
√ basal / upper part of LV septum disproportionately thickened
√ anterolateral wall of LV often also abnormally thick

CEMR:
√ midwall patchy or punctate midwall hyperenhancement in thickened myocardium in a noncoronary distribution

Rx: septal myomectomy / alcohol ablation

MIDVENTRICULAR CARDIOMYOPATHY

= rare variant of asymmetric HCM
• ventricular arrhythmia, myocardial necrosis
• systemic embolism
√ hypertrophy of middle ⅓ of LV wall
√ apposition of midventricular wall → obstruction
May be associated with: apical aneurysm ← increased systolic pressure in apex

Symmetric / Concentric Hypertrophic Cardiomyopathy

= HYPERTENSIVE HYPERTROPHIC CARDIOMYOPATHY
= concentric LV hypertrophy with a small cavity WITHOUT evidence of secondary causes
• commonly in older women
(a) midventricular
(b) diffuse

(c) apical
√ marked concentric LV hypertrophy
√ small LV cavity
DDx: Concentric LV hypertrophy

Masslike Hypertrophic Cardiomyopathy
= focal segmental hypertrophic cardiomyopathy
√ parallels homogeneous SI + perfusion of normal myocardium
DDx: neoplasm

Noncompaction Cardiomyopathy

= sponge myocardium
= rare congenital myocardial disorder caused by intrauterine arrest of endomyocardial compaction → persistence of embryonic myocardium
Prevalence: in 0.05% of adult echocardiograms
Path: noncompacted subendocardial myocardium comprises numerous prominent trabeculations; deep intertrabecular recesses extend into compacted myocardial layer
• asymptomatic; supraventricular / ventricular arrhythmia
• congestive heart failure, embolic event, sudden cardiac death
Location: primarily LV + concomitant RV involvement (41%)
Site: from apex along lateral + inferior wall to mid portion of left ventricle
MR:
√ overall increased myocardial thickness:
√ 2-layers of thin compacted subepicardial layer (C) + thick noncompacted subendocardial layer (NC)
√ NC÷C ratio of > 2.3 in end-diastole (on 2D Steady State Free Precession imaging)
ECHO:
√ maximal end-systolic NC÷C ratio of > 2 (short-axis view)

Restrictive Cardiomyopathy

= intrinsic myocardial disease that impairs the myocardial ability to relax normally + impairs ventricular filling
Etiology: (a) idiopathic: endomyocardial fibroelastosis, drugs, anthracyclines, carcinoid
(b) infiltrative disease: amyloidosis, sarcoidosis, hemochromatosis, Fabry disease, glycogen storage disease, Löffler's hypereosinophilic endocarditis, Gaucher disease
Hemodynamics: reduced myocardial compliance → ↑ ventricular pressure with small increases in volume → ↓ diastolic ventricular filling → diastolic heart failure with preservation of systolic function
• increasing dyspnea + exercise intolerance
• palpitations, syncopal attacks, conduction disturbances
√ varying degrees of pulmonary venous hypertension
√ dilatation of RA + IVC reflecting high RV filling pressure (DDx: constrictive pericarditis)
√ ± LA enlargement
ECHO:

√ reduced early + late diastolic annular velocities

Diagnostic key imaging features:
√ left ventricular hypertrophy
√ delayed enhancement of myocardium at MRI
√ normal pericardium

Prognosis: 70% 5-year mortality rate after initial manifestation of symptoms
DDx: constrictive pericarditis

CHRONIC VENOUS STASIS DISEASE

= CHRONIC VENOUS INSUFFICIENCY

= insufficiency / incompetence of venous valves in deep venous system of lower extremity

Cause:

(a) postphlebitic valvular incompetence: short thickened valves ← scar formation ← destruction of valve apparatus

(b) primary valvular incompetence: shallow elongated redundant valve cusps prevent effective closure

Associated with: incompetent venous valves in calf ← pressure dilatation from stasis in deep venous system leading to superficial vein varicosities

- edema (= fluid exudation from increased capillary pressure), induration; aching pain
- ulceration ← minor trauma + decreased diffusion of oxygen ← fibrin deposits around capillaries
- skin hyperpigmentation (= breakdown products of exudated RBCs)

√ venous reflux on descending venography with Valsalva:

(a) 82% in deep venous system alone

(b) 2% in saphenous vein alone

(c) 16% in both

bilateral in 75%

Grade:

1 = minimal incompetence = to level of upper thigh

2 = mild incompetence = to level of lower thigh

3 = moderate incompetence = to level of knee

4 = severe incompetence = to level of calf veins

CHURG-STRAUSS SYNDROME

= ALLERGIC ANGIITIS AND GRANULOMATOSIS = EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS

= rare multisystemic disorder with necrotizing vasculitis of small vessels associated with extravascular eosinophilic granulomas occurring exclusively in patients with asthma + peripheral eosinophilia = variant of polyarteritis nodosa

Etiology: ? hypersensitivity response to an inhaled agent

Incidence: 1–7÷1,000,000 annually

Mean age: 28 (range, 20–40) years; M÷F = 1÷1

Clinical phases (CLASSIC TRIAD):

(1) Prodromal: asthma, allergic rhinitis, sinus pain, headaches

(2) Eosinophilic: peripheral blood (> 30%) and tissue hypereosinophilia with Löffler syndrome (almost in 100%)

(3) Systemic small-vessel granulomatous vasculitis: usually developing within 3 years of onset of asthma

Path: (1) Necrotizing vasculitis

(2) Eosinophilic tissue infiltration

(a) eosinophilic pneumonia
(b) eosinophilic gastroenteritis

(3) Extravascular "allergic" granulomas / eosinophilic abscesses

Diagnostic criteria of American College of Rheumatology (at least 4 must be present):
(1) Asthma (in older patient)
(2) Eosinophilia > 10% of WBC differential count
(3) Polyneuropathy
(4) Migratory / transient pulmonary opacities
(5) Paranasal sinus abnormalities
(6) Extravascular eosinophils at biopsy

- fever, malaise, gastrointestinal symptoms, arthralgias
- p-ANCA (perinuclear antineutrophil cytoplasmic autoantibodies) in 40–70%
- elevated rheumatoid factor in 52%

√ vascular aneurysms + thrombosis

@ Lung (most frequent): intraalveolar hemorrhage
- √ normal CXR (25%)
- √ often transient peripheral widespread nonsegmental air-space opacities without zonal predominance
- √ diffuse miliary nodules:
  - √ nodules may coalesce up to 2 cm (rare)
  - √ cavitation is atypical (and suggests infection)
- √ eosinophilic pleural effusions (29%)

HRCT:
- √ subpleural consolidation / ground-glass attenuation in a lobular distribution (59%)
- √ bilateral centrilobular nodules
- √ diffuse interstitial reticular / reticulonodular opacities
- √ interlobular septal thickening
- √ bronchial wall thickening
- √ uni- / bilateral pleural (30%)

<u>less common:</u>
- √ hyperinflation
- √ mediastinal / hilar lymphadenopathy
- √ pericardial effusion

@ Skin (2nd most frequent): palpable purpura, macular / papular erythematous rash, subcutaneous nodules

@ GI tract (20%): ulceration, hemorrhage, perforation
- diarrhea, bleeding, obstruction
- √ mesenteric vasculitis (= polyarteritis nodosa)
- √ eosinophilic gastroenteritis (= bowel wall infiltration by eosinophils)

@ Heart (up to 47%): coronary vasculitis with myocardial infarction, myocarditis, acute pericarditis with pericardial tamponade (accounting for 50% of deaths)

◊ Higher frequency of cardiac involvement than in Wegener granulomatosis

@ CNS (commonly involved)
- diffuse peripheral neuritis, mononeuritis multiplex
- cranial nerve palsy (frequent): ischemic optic neuropathy

• confusion, seizures, coma (in severe cases)
√ micro- or macrohemorrhages of cerebral ischemia

@ Kidney:
• renal artery-induced hypertension, hematuria
√ focal segmental glomerulonephritis
◊ Less frequent + less severe renal disease compared with Wegener granulomatosis + microscopic polyangiitis

@ Muscles & joints: myalgia, joint pain

Prognosis: 85% 5-year survival; death from intraabdominal /cardiac complications, cerebral hemorrhage, renal failure, status asthmaticus

Rx: corticosteroids, cyclophosphamide

DDx: (1) Chronic eosinophilic pneumonia (no granulomatous arteritis, no extrapulmonary lesions, homogeneous peripheral airspace consolidation)
(2) Wegener granulomatosis (solitary / multiple nodules with cavitation)
(3) Hypereosinophilic syndrome

COARCTATION OF AORTA

= CoA = JUXTADUCTAL COARCTATION
= short aortic narrowing at level of ligamentum arteriosum

Former Classification:
(a) adult / postductal / localized type of aortic coarctation
(b) infantile / preductal / diffuse type of aortic coarctation

Prevalence: 7% of congenital heart disease; M÷F = 1.5÷1; rare in Blacks

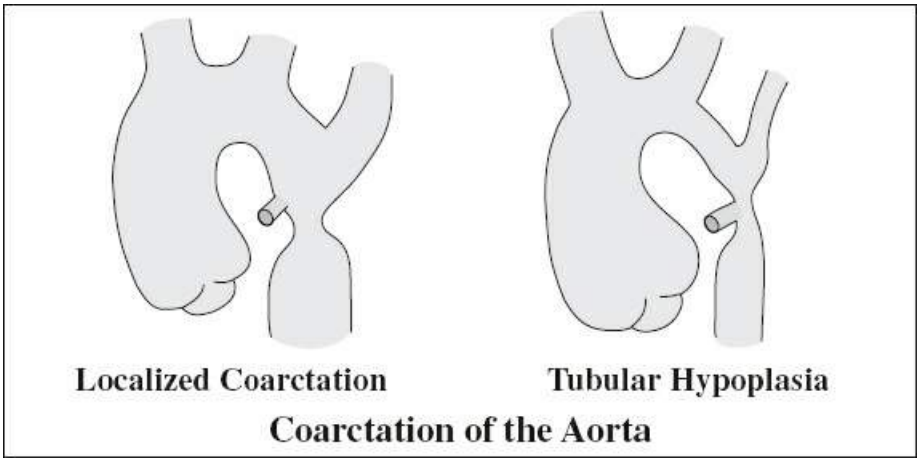
Cause: hemodynamic hypothesis (= abnormal preductal flow); ductal hypothesis (= ectopic ductal tissue extending into aorta)

◊ Usually solitary lesion (in 82%)!

May be associated with:
1. Bicuspid aortic valve (22–42%), which may result in calcific aortic valve stenosis (after 25 years of age) + bacterial endocarditis
2. Intracardiac malformations:
   › PDA (33%), VSD (15%), ASD, TGV
   › aortic stenosis / insufficiency
   › ostium primum defect
   › truncus arteriosus, double-outlet right ventricle
   › Shone complex = LVOT obstruction + parachute mitral valve
   › aortic hypoplasia: isolated isthmic hypoplasia, isolated aortic arch hypoplasia, isthmic + aortic arch hypoplasia
3. Noncardiac malformations (13–15%): Turner syndrome
4. Intracranial berry aneurysms (10%)
5. Mycotic aneurysm distal to CoA

Path: juxta- / periductal narrowing ± extension into aortic arch and isthmus

Histo: cystic medial necrosis (common), intimal thickening with fragmentation of elastin and increased collagen deposition → gradually thickening of media and ↓ luminal diameter



Coarctation of the Aorta

Location: most frequent in juxtaductal portion of arch
• systemic arterial hypertension in upper extremities
• incidental finding late in life with differential pressures between upper + lower extremities
• systolic murmur; ductus usually closed
√ shelflike lesion at any point along the aortic arch
√ poststenotic aortic dilatation
√ juxtaductal aortic narrowing
√ collateral circulation via subclavian artery and its branches:
› thoracoacromial trunk › thyrocervical trunk
› anterior spinal artery › descending scapular artery
› lateral thoracic artery › transverse cervical artery
› internal mammary artery
→ draining into external iliac + intercostal arteries
Cx: wall changes predispose to infective endarteritis, intimal dissection, aortic aneurysm
Prognosis: 75% mortality by 46 years of age
Cause of death: CHF (26%), aortic rupture (21%), complications of endocarditis (18%), intracranial hemorrhage (12%)
Rx: prosthetic overlay, tube graft, aortoplasty, percutaneous balloon angioplasty ± stent placement
DDx: pseudocoarctation

Symptomatic CoA

◊ Second most common cause of CHF in neonate (after hypoplastic left heart)
Onset:
(a) toward the end of 1st week of life in "critical stenosis"
(b) more commonly presents in older child
• lower extremity cyanosis (in tubular hypoplasia)
• left ventricular failure (usually toward end of 1st week of life)
CXR:
√ generalized cardiomegaly
√ increased pulmonary vascularity (L-to-R shunt through PDA / VSD)
√ pulmonary venous hypertension / edema

√ "figure-of-3" sign hidden by thymus

Asymptomatic CoA

• headaches ← hypertension; claudication ← hypoperfusion
√ "figure-of-3" sign (in 50–66% of adults)
= indentation of left lateral margin of aortic arch in the region of aortic-pulmonic window resembling the number 3 on frontal CXR view:
√ dilatation of left subclavian artery + prestenotic aorta
√ indentation at site of aortic stenosis
√ dilatation of poststenotic aorta
√ "reverse figure-of-3" sign = indentation of esophageal contour during barium esophagram on LAO view
√ elevated left ventricular apex ← LV hypertrophy
√ collateral vessels bypassing coarctation:
√ dilatation of brachiocephalic vessels + aorta proximal to stenosis
√ obscuration of superior margin of aortic arch
@ superior epigastric arteries
@ internal mammary arteries
√ scalloped contouring of soft-tissues posterior to sternum (= dilated tortuous internal mammary arteries) on LAT CXR (in 28%)
@ intercostal arteries
√ inferior rib notching (in 75%; mostly in adults over age 20; unusual before age 6)
Location: ribs 3–8 (most pronounced in 3rd + 4th ribs, less pronounced in lower ribs); 1st + 2nd rib do not participate because they have arteries originating from the costocervical trunk
Site: central + lateral thirds of posterior ribs
(a) bilateral
(b) unilateral on left side: left aortic arch with aberrant right subclavian artery below CoA
(c) unilateral on right side: right aortic arch and anomalous left subclavian artery below CoA

CONGENITAL ABSENCE OF PULMONARY VALVE

= massive regurgitation between pulmonary artery and RV
In 90% associated with: VSD, tetralogy of Fallot (50%)
• cyanosis (not in immediate newborn period)
• repeated episodes of respiratory distress; continuous murmur
• ECG: right ventricular hypertrophy
√ prominent main, right, and left pulmonary artery
√ RV dilatation (increased stroke volume)
√ partial obstruction of right / left mainstem bronchus ← compression by vessel
√ right-sided aorta (33%)

CONGESTIVE HEART FAILURE

Congestive Left Heart Failure

= increase in circulating blood volume with diminishing cardiac function → elevation of microvascular pressure of lung

Frequency: most common cause of interstitial + airspace edema of lungs

Cause:

(a) back pressure from LV: long-standing systemic hypertension, aortic valve disease, coronary artery disease, cardiomyopathy, myocardial infarction

(b) obstruction proximal to LV: mitral valve disease, LA myxoma, cor triatriatum

Histo:

(1) Interstitial phase: fluid in loose connective tissue around conducting airways and vessels + engorgement of lymphatics

(2) Alveolar phase: increase in alveolar wall thickness

(3) Alveolar airspace phase: alveoli filled with fluid with loss of alveolar volume; pulmonary fibrosis upon organization of intraalveolar fibrin (if chronic)

• LA pressure / pulmonary venous pressure > 12 mmHg (measured by wedging a pulmonary artery catheter [PAWP])

√ enlarged heart:

√ enlargement of LA (mitral stenosis)

√ enlargement of LA + LV (mitral regurgitation)

√ enlargement of LV (aortic valve disease)

1. **Flow inversion = cephalization of pulmonary vessels**

Cause: chronic elevation of LA pressure (as in left heart failure / mitral valve disease)

Pathophysiology:

long-standing ↑ of LA pressure → ↑ in atriovenous reflux; initially ↑ LA pressure is met with an ↑ tonus of LA wall (= absence of atrial enlargement in acute left heart failure); → eventually LA enlarges → inciting a protective atrial-pulmonary-vascular reflex vasospasm → narrowing of lower lobe vessels and ↓ atriovenous reflux

• pulmonary artery wedge pressure 13–17 mmHg

√ basal oligemia (= arterial + venous constriction)

√ hyperemia of upper lobes:

√ vessel diameter equal to / greater than comparable lower zone vessels

√ upper zone arteries wider than accompanying bronchus

√ vessel diameter in 1st anterior intercostal space > 3 mm

N.B.: flow inversion is never seen in pulmonary edema of renal failure / overhydration / low oncotic pressure

2. **Interstitial pulmonary edema** (invariably precedes alveolar edema) = engorgement of interstitium

• NO abnormal physical finding

• hypoxemia (ventilation-perfusion inequality)

• pulmonary artery wedge pressure > 17 mmHg

√ perihilar haze = loss of sharp definition of vascular markings in large perihilar interstitium

√ thickening of interlobular septa (Kerley lines)

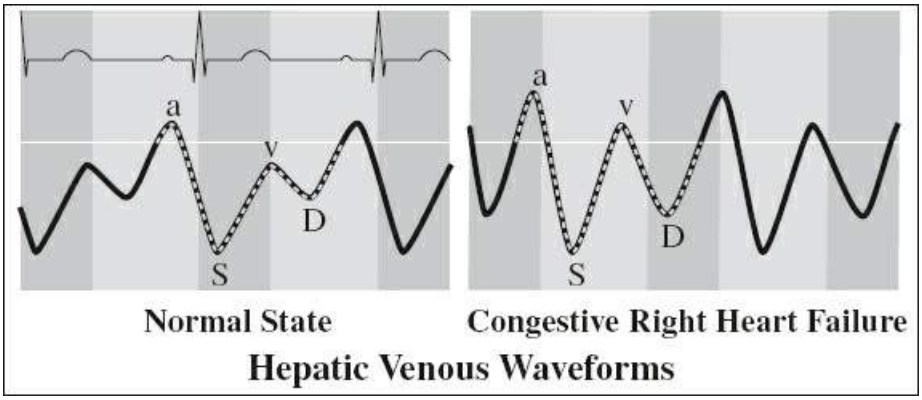
√ peribronchial cuffing = poorly defined increased bronchial wall thickness

√ thickening of interlobar fissures ← fluid accumulation in subpleural connective tissue layer
√ usually right pleural effusion (if PAWP > 20 mmHg)

3. **Alveolar pulmonary edema = airspace edema**
   Cause: acute LA pressure elevation → volume of capillary filtration exceeds that of lymphatic drainage
   • severe dyspnea / orthopnea; tachypnea + cyanosis
   • dry cough / copious frothy sputum
   • hypoxemia ← vascular shunting
   √ pulmonary venous pressure > 20 mmHg
   √ poorly defined patchy acinar opacities
   √ coalescence of acinar consolidation, particularly in medial ⅓ of lung
   √ air bronchograms
   √ butterfly / bat-wing distribution of consolidation (= consolidated hilum + uninvolved lung cortex)
   √ always coexists with interstitial pulmonary edema
4. **Generalized oligemia**
   Cause: aortic valvular disease

Congestive Right Heart Failure

• pitting edema of lower extremities
√ abnormal hepatic vein Doppler spectrum:
  √ abnormally tall *a* wave (increased right atrial pressure + volume toward end-diastole)
  √ abnormally tall *v* wave (increased right atrial pressure + volume toward end systole) of hepatic vein waveform
  √ normal relationship between *S* and *D* waves



Extrathoracic Manifestations of CHF

@ Hepatobiliary
  √ GB wall edema
  √ periportal edema
  √ enlarged IVC

CORONARY ARTERY FISTULA

= direct precapillary connection between branch of coronary a. + lumen of heart chamber / systemic or pulmonary circulation

Prevalence: 0.05–0.25% of coronary angiographies; 0.002% of general population

Cause: congenital (most), posttraumatic, iatrogenic

Hemodynamics: L-to-R shunt; pulmonary÷systemic blood flow = < 1.5÷1 (usually)

Involved coronary artery:

RCA (in 50–60%), LCA (in 40–42%), both (in < 5%)

Drain into:

RV (in 41–45%), RA (in 26%), pulmonary artery (in 15–17%), coronary sinus (7%), SVC

- asymptomatic (commonly LCA, small fistula)
- audible continuous heart murmur

√ may have normal CXR (in small shunts)

√ cardiomegaly + shunt vascularity (in large shunts)

Angio:

√ dilated tortuous coronary artery with anomalous connection

√ single (most) / multiple communications / network of fine vessels

Cx: myocardial ischemia / sudden cardiac death (in large shunt), CHF, endocarditis, arrhythmia, rupture, embolization

Rx: observation, surgical ligation, transcatheter embolization

COR TRIATRIATUM

= rare congenital anomaly in which a fibromuscular septum with a single stenotic / fenestrated / large opening separates the embryologic common pulmonary vein from the LA:

(1) proximal / accessory chamber lies posteriorly receiving pulmonary veins (= primitive common pulmonary vein)

(2) distal / true atrial chamber lies anteriorly connected to left atrial appendage + emptying into LV through mitral valve

Embryology: failure of common pulmonary vein to incorporate normally into left atrium → persistence of primitive splanchnic connections

Associated with: ASD, PDA, anomalous pulmonary venous drainage, left SVC, VSD, tetralogy of Fallot, atrioventricular canal

- symptoms of pulmonary venous obstruction clinically similar to mitral valve stenosis:
  - pulmonary hypertension, heart failure with pulmonary edema
  - dyspnea, hemoptysis, failure to thrive
  - frequent pulmonary infections

√ pulmonary venous distention + interstitial edema + dilatation of pulmonary trunk + pulmonary arteries (in severe obstruction)

√ enlarged RA + RV

√ mild enlargement of LA

Angio:

√ dividing membrane on levophase of pulmonary arteriogram

MR:

√ accessory chamber (representing the common pulmonary vein) communicates with LA through a stenosed opening

√ accessory chamber lies always above level of LA appendage

Prognosis (if untreated):

usually fatal within first 2 years of life; 50% 2-year survival; 20% 20-year survival

Flow gradient across stenosis + RV pressures are the most important pieces of information to assess the degree of pulmonary venous obstruction!

Rx: surgical excision of obstructing membrane

DEEP VEIN THROMBOSIS (DVT)

Incidence: ~ 600,000 new cases annually in USA; 1÷100 patients with DVT dies (= 15% of in-hospital deaths); 6–7 million stasis skin changes; in 0.5% cause of skin ulcers

Pathogenetic factors:

1. Hypercoagulability
2. Decreased blood flow / stasis
3. Intimal injury
4. Decreased fibrinolytic potential of veins
5. Platelet aggregation

Risk factors:

1. Surgery, esp. on legs / pelvis: orthopedic (45–50%) especially total hip replacement > 50%), gynecologic (7–35%), neurosurgery (18–20%), urologic (15–35%), general surgery (20–25%)
2. Severe trauma
3. Prolonged immobilization: hemiplegic extremity, paraplegia + quadriplegia, casting / orthopedic appliances
4. Malignancy (risk factor 2.5) = Trousseau phenomenon
5. Obesity (risk factor 1.5)
6. Diabetes
7. Pregnancy (risk factor 5.5) with peak at 36 weeks and for 8–12 weeks post partum
   Cause: progesterone-induced venodilation, pelvic venous compression by gravid uterus
8. Medication: birth control pills, estrogen replacement, tamoxifen (risk factor 3.2)
9. Decreased cardiac function: congestive heart failure, myocardial infarction (20–50%; risk factor 3.5)
10. Inflammatory bowel disease
11. Age > 40 years (risk factor 2.2)
12. Varicose veins
13. Previous DVT (risk factor 2.5)
14. Patients with blood group A > blood group 0
15. Polycythemia
16. Smoking

Pathologic terminology:

"***organized thrombus***" = transition to a vascularized lesion of connective tissue adherent to vessel wall

"***recanalized thrombus***" = vascular channel network within an organized clot reducing it to septations of collagen and elastic fibers often lined by endothelium

Location:

1. Dorsal veins of calf (± ascending thrombosis)
2. Iliofemoral veins (± descending thrombosis)
3. Peripheral + iliofemoral veins simultaneously
4. rare: internal iliac, ovarian, ascending lumbar veins

Side: L÷R = 7÷3 ← compression of left common iliac vein by left common iliac artery (arterial pulsations lead to chronic endothelial injury with formation of intraluminal spur (in 22% of autopsies + in 90% of patients with DVT)

- Local symptoms ← obstruction / phlebitis usually only when (a) thrombus occlusive, (b) clot extends into popliteal / more proximal vein (14–78% sensitivity, 4–21% specificity):
  - warmth, swelling (measurement of circumference)
  - deep crampy pain in affected extremity: worse in erect position, improved while walking
  - tenderness along course of affected vein
  - Homans sign = calf pain with dorsal flexion of foot
  - Payr sign = pain upon compression of sole of foot
  - ◊ ⅔ of deep vein thromboses are clinically silent:
    - ◊ DVT diagnosed ante mortem in < 30%
    - ◊ Only 10–33% of patients with fatal PE are symptomatic for DVT
  - ◊ Clinically suspected DVT accurate in only 26–45%:
    - ◊ DVT symptomatology due to other causes in 15–35%
    - ◊ Negative bilateral venograms in 30% of patients with angiographically detected pulmonary emboli (**big bang** theory = clot embolizes in toto to the lung leaving no residual in vein)

Venography (89% sensitive, 97% specific, 11% FN, 5% FP):

◊ venography aborted / nondiagnostic in 5%

Risk: postvenography phlebitis (1–2%), contrast reaction, contrast material-induced skin slough, nephropathy

√ intraluminal filling defect constant on all images

√ nonfilling of calf veins

√ inadequate filling of common femoral vein and external + common iliac veins

B-Mode US (88–100% sensitive, 92–100% specific, > 90% accurate for DVT in thigh and popliteal veins):

A. ACUTE DEEP VEIN THROMBOSIS
   - √ NO complete luminal collapse with venous compression (DDx: deformity + scarring from prior DVT; technical difficulties in adductor canal + distal deep femoral vein)
   - √ visualization of clot within vein (DDx: slow flowing blood; machine noise):
     - √ homogeneous poorly echogenic / anechoic substance within venous lumen
     - √ smooth border of thrombus
   - √ < 75% increase in diameter of common femoral vein during Valsalva
   - √ venous diameter at least twice that of adjacent artery suggests thrombus < 10 days old

B. SUBACUTE / CHRONIC DEEP VEIN THROMBOSIS
   - √ echogenic material within venous lumen
   - √ irregular surface of thrombus
   - √ incomplete compressibility of vein

Doppler US:

√ absence of spontaneity (= any waveform recording): NOT RELIABLE in peripheral veins

√ continuous venous signal = absence of phasicity (= no cyclic variation in flow velocity with respiration, ie, ↓ in expiration and ↑ in inspiration) is SUSPICIOUS for proximal obstruction

√ attenuation / absence of augmentation (= no increase in flow velocity with distal compression) indicates venous occlusion / compression in intervening venous segments

√ pulsatile venous flow is a sign of congestive heart failure / pericardial effusion / cardiac tamponade / pulmonary embolism with pulmonary hypertension

NEMR:

N.B.: limited by flow signal artifacts

√ high SI / absence of low SI flow within vein on true FISP sequence

√ low-signal–intensity filling defect in a high-signal-intensity patent vein on true FISP sequence

√ absence of normal low-signal–intensity flow void in a patent vessel on T2WI

√ variable signal intensity on T1WI depending on age of luminal blood products

Venous Occlusion Plethysmography:

= temporary obstruction of venous outflow by pneumatic cuff around mid-thigh inflated above venous pressure → progressive increase in blood volume in lower leg; upon release of cuff → limb quickly returns to resting volume with prompt venous runoff; limb blood volume changes are measured by impedance plethysmography in which a weak alternating current is passed through the leg; the electrical resistance varies inversely with blood volume; current strength is held constant so that voltage changes directly reflect blood volume changes

› 87–95–100% sensitive, 92–100% specific for above-knee DVT

› 17–33% sensitive for below-knee DVT

√ ↓ initial rise in venous capacitance (= venous volume)

√ delay in venous outflow (= "fall" of curve) measured at 3 sec

False positives (6%): severe cardiopulmonary disease, pelvic mass, reduced arterial inflow

False negatives: calf vein thrombosis, small thrombus

^{125}I-Labeled Fibrinogen:

› 90% sensitive for calf vein thrombus

› 60–80% sensitive for femoral vein thrombus

› insensitive for thrombus in upper thigh / pelvis

Risk: results not available for several days, possible virus transmission

False positives: hematoma, inflammation, wound, old small thrombus isolated in common femoral / iliac v.

Cx:

(1) **Pulmonary embolism** (50%): in 90% from lower extremity / pelvis; in 60% with proximal "free-floating" / "widow-maker" thrombus; occurs usually between 2nd to 4th (7th) day of thrombosis

Source of pulmonary emboli:

multiple sites (⅓), cryptogenic in 50%;

(a) lower extremity (46%)
(b) inferior vena cava (19%)
(c) pelvic veins (16%)
(d) mural heart thrombus (4.5%)
(e) upper extremity (2%)

Likelihood of pulmonary embolism:
77% for iliac veins, 35–67% for femoropopliteal vein, 0–46% for calf veins

(2) **Postphlebitic syndrome** in 20% of cases with DVT ← valvular incompetence ← recanalization to a smaller lumen with focal wall changes

(3) **Phlegmasia** [*phlegma* , Greek = inflammation; *dolens* , Latin = painful] = blanching of skin (phlegmasia **alba dolens**) / blue leg (phlegmasia **cerulea dolens**) → severely impaired venous drainage → acute limb ischemia → gangrene

Prognosis: tibial / peroneal venous thrombi resolve spontaneously in 40%, stabilize in 40%, propagate into popliteal vein in 20%

Prophylaxis: intermittent compression of legs, heparin, warfarin

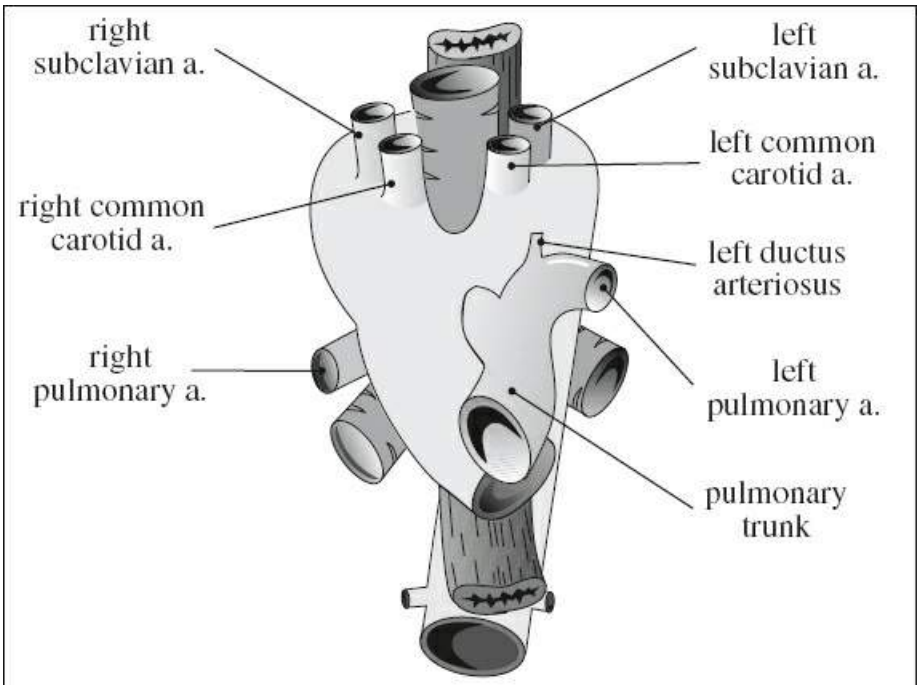
Rx:

(1) Heparin IV

(2) Systemic anticoagulation (warfarin) for ≥ 3 months decreases risk of recurrent DVT in initial 3 months from 50% to 3% + fatal pulmonary embolism from 30% to 8%; necessity for anticoagulation in DVT of calf veins is CONTROVERSIAL

(3) Caval filter (10–15%) in patients with contraindication / complication from anticoagulation or progression of DVT / PE despite adequate anticoagulation

DDx: pseudothrombophlebitis (= signs + symptoms of DVT produced by popliteal cyst / traumatic hematoma)



Double Aortic Arch

DOUBLE AORTIC ARCH

◊ Most common + serious type of a complete vascular ring; usually isolated condition

Embryology: failure of regression of both right + left embryonic 4th arches, joined to form dorsal aorta

Types:

1. Dominant right (posterior) arch (75%)
2. Dominant left (anterior) arch (20%)
3. Symmetric arches of same size (5%)

The less dominant arch is atretic in ⅓ !

Frequency: 55% of all vascular rings

Age: usually detected in infancy

- usually asymptomatic; stridor, dyspnea, recurrent pneumonia
- dysphagia (less common than respiratory symptoms, more common after starting baby on solids)

Location: descending aorta in 75% on left, in 25% on right side; smaller arch anterior in 80%; right arch larger + more cephalad than left in 80%

√ two separate arches arise from single ascending aorta

√ each arch joins to form a common descending aorta

√ trachea in midline:

- √ impressions may be present on both sides of trachea: usually R > L (in older children)
- √ trachea narrowed and displaced posteriorly with small anterior impression

Esophagram:

- √ broad horizontal posterior indentation at the level of 3rd / 4th thoracic vertebra ← right arch crossing obliquely to join left
- √ bilateral esophageal indentations with a reversed S-shaped configuration (= right indentation higher than left)

CT:

- √ "four-artery" sign = each arch gives rise to 2 dorsal subclavian + 2 ventral carotid arteries evenly spaced around trachea on section cephalad to aortic arch

DDx: right arch with aberrant left subclavian artery (when dominant arch on right indistinguishable by esophagram)

DOUBLE-OUTLET RIGHT VENTRICLE

= DORV = TAUSSIG-BING HEART

= most of the aorta + pulmonary artery arise from the RV ← maldevelopment of conotruncus

Prevalence: 127÷1,000,000 live births

Hemodynamics:

similar to: VSD, tetralogy of Fallot, transposition of great arteries, single ventricle, atrioventricular atresia

fetus: NO CHF in utero (in absence of other obstructing anomalies)

neonate: ventricular work overload → CHF

Associated with: VSD (100%), pulmonary stenosis / atresia (75%), mitral stenosis / atresia, PDA

◊ location of VSD affects physiologic function and classification relative to semilunar valves into subaortic (50%), subpulmonic (30%), uncommitted, doubly committed

√ NO continuity between mitral valve + adjacent semilunar valve (PATHOGNOMONIC)

√ aorta posterior / parallel / anterior to pulmonary artery:

√ aorta and pulmonary artery side by side with aorta in D-malposition on the right (most frequent)

√ aorta overriding the interventricular septum with predominant connection to RV

√ normal / hypoplastic / absent LV

DUCTUS ARTERIOSUS ANEURYSM

= fusiform aneurysm of ductus arteriosus, usually patent toward aorta + completely / incompletely occluded toward pulmonary a.

Prevalence: < 100 cases

Classification:

(a) according to age: infantile, childhood, adult type

(b) according to cause: congenital, infectious, traumatic

Pathogenesis: ? delay in closure, ? myxoid degeneration of ductus wall, ? abnormal elastic fibers

Age: most < 2 months of age

• dyspnea, tachypnea, hoarseness

√ pulmonary artery displaced anteromedially

√ distal aortic arch displaced laterally

CXR:

√ left upper mediastinal mass in aorticopulmonary window

√ tracheal displacement to right + anteriorly / posteriorly

√ consolidation of adjacent lung (compression, fibrosis, hemorrhage)

CT:

√ contrast-enhancing mass in classic location

ECHO:

√ cystic mass with pulsatile flow

Cx: rupture, dissection, infection, thromboembolic disease, phrenic nerve compression

Prognosis: usually fatal (without prompt surgery)

EBSTEIN ANOMALY

[Wilhelm Ebstein (1836–1912), internist in Breslau, Germany]

◊ Most common cause of congenital tricuspid regurgitation.
=atrialization of RV (HALLMARK) = apical / downward displacement of septal + posterior leaflets of dysplastic tricuspid valve into inflow portion of RV

RV is divided into:

(a) a large superior atrialized inflow portion with thin ventricular wall (incorporating part of the RV into the RA), and

(b) a small inferior functional chamber with shortened chordae tendineae

Valve morphology:

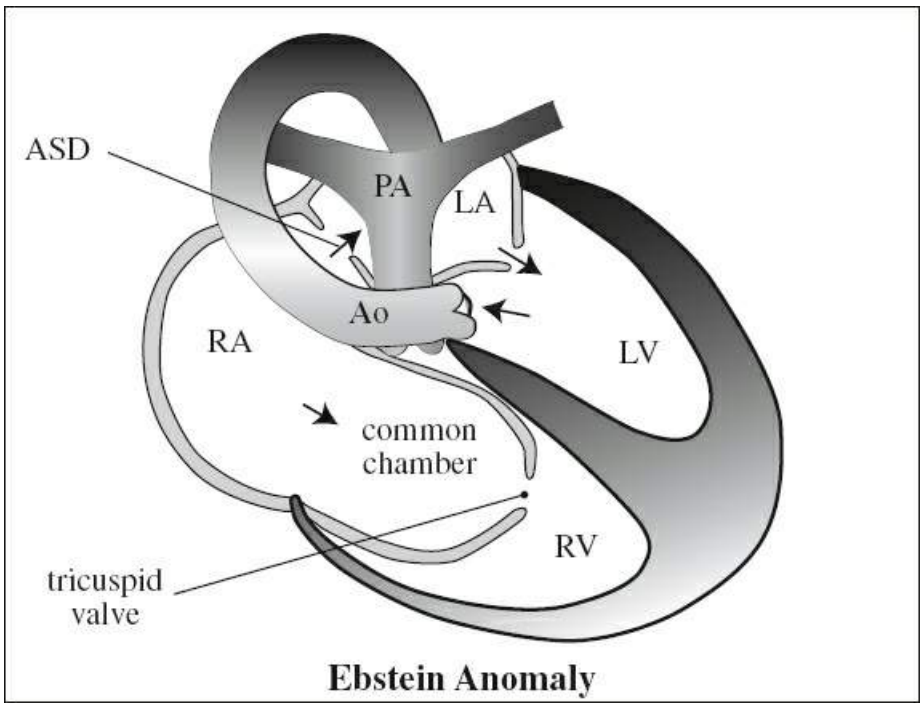
inappropriately low attachment of posterior ± septal malformed defective tricuspid valve leaflets; only anterior leaflet attaches normally to tricuspid annulus, but may be dysplastic / sail-like

Etiology: oral lithium therapy during pregnancy (10%)

◊ 0.5–0.7% of all CHD!

Hemodynamics:

tricuspid valve insufficiency → tricuspid regurgitation ("ping-pong" volume) + severely dilated RA; RA dilatation stretches interatrial septum → incompetence of foramen ovale (R-to-L shunt) in 75%



Ebstein Anomaly

RA	↑	RV	↓	Main PA	↔
Pulm. vessels	↔/↓				
LA	↔	LV	↔	Ao	↔

Associated with: ostium-secundum–type ASD / patent foramen ovale (R-to-L shunt), VSD, PDA, pulmonary atresia

- symptoms and prognosis depend on amount of tricuspid regurgitation, right ventricular function, and cyanosis:

- ± cyanosis in neonatal period (depending on degree of R-to-L shunt): may improve / disappear postnatally with decrease in pulmonary arterial pressure
- CHF in utero / in neonate (in 50%)
- systolic murmur (tricuspid insufficiency)
- **Wolff-Parkinson-White syndrome** (10%) = paroxysmal supraventricular tachycardia / right bundle branch block (responsible for sudden death)
  Cause: conduction system develops during formation of tricuspid valve adjacent to it

Ebstein anomaly is the ONLY cyanotic CHD in which aorta and pulmonary trunk are hypoplastic (= smaller than normal)!

√ "box-shaped / funnel-like" cardiomegaly:
  √ extreme RA enlargement ← insufficient tricuspid valve forming a common right ventriculoatrial chamber
  √ dilated right ventricular outflow tract
√ IVC + azygos dilatation ← tricuspid regurgitation
√ normal LA
√ calcification of tricuspid valve may occur
√ distance of septal leaflet to anterior mitral valve leaflet:
  √ > 15 mm in child < 14 years of age
  √ > 20 mm in adult
  √ > 0.8 mm/cm^2 of body surface area = DIAGNOSTIC

MR:
  √ marked right atrial enlargement
  √ small right ventricle ± dilatation of RV infundibulum

ECHO:
  √ large "sail-like" tricuspid valve structure within dilated right heart
  √ tricuspid regurgitation identified by Doppler ultrasound

Prognosis: sudden death ← fatal atrial arrhythmia; 50% infant mortality; 13% operative mortality

Survival rate: 70% at 2 years, 50% at 13 years; survival into adulthood if valve functions normally

Rx: 1. Digitalis + diuretics
2. Tricuspid valve prosthesis

EISENMENGER COMPLEX

= EISENMENGER DEFECT
= (1) high VSD ± overriding aorta with hypoplastic crista supraventricularis
  (2) RV hypertrophy
  and as consequence of increased pulmonary blood flow:
  (3) → dilatation of pulmonary artery + branches
  (4) → intimal thickening + sclerosis of small pulmonary arteries + arterioles
• cyanosis appears in 2nd + 3rd decade with shunt reversal

EISENMENGER SYNDROME

= EISENMENGER REACTION
= development of high pulmonary vascular resistance after many years of L-to-R shunt (ASD, PDA, VSD) → ↑ pulmonary blood flow → bidirectional (= balanced) shunt and ultimately → shunt reversal (R-to-L shunt)

Etiology:
pulmonary microscopic vessels undergo reactive muscular hypertrophy, endothelial thickening, in situ thrombosis, tortuosity + obliteration; once initiated, pulmonary hypertension accelerates vascular reaction → increasing pulmonary hypertension in a vicious cycle

with RV failure + death

Path: adaptive anastomotic pathways connect plexiform lesions of pulmonary arterial vessels to bronchial arteries supplying terminal bronchioles + vasa vasorum of pulmonary arteries

Pathologic classification of severity (Heath & Edwards):

Grade I = medial hypertrophy of muscular pulmonary arteries and arterioles
- potentially reversible

Grade II = grade I + intimal proliferation in small muscular arteries and arterioles
- potentially reversible

Grade III = grade II + intimal laminar fibrosis + progressive vessel obliteration
- borderline for reversibility

Grade IV = occlusion of vessels with progressive aneurysmal dilatation of small arteries nearby
- irreversible

Grade V = tortuous "glomeruloid" channels within proliferation of endothelial cells (= plexiform + angiomatoid lesions)
- irreversible

Grade VI = thrombosis + necrotizing arteritis
- irreversible

CXR:
- √ pronounced dilatation of central pulmonary arteries (pulmonary trunk, main pulmonary a., intermediate branches)
- √ pruning of peripheral pulmonary arteries
- √ enlargement of RV + RA (proportionate to volume overload)
- √ LA + LV return to normal size (with decrease of L-to-R shunt ← markedly elevated pulmonary vascular resistance)
- √ normal pulmonary veins (unless superimposed cardiac volume overload):
  - √ pulmonary veins NOT distended ← NO increase in pulmonary blood flow)
  - √ NO redistribution of pulmonary veins (normal venous pressure)

CT:
- √ massive aneurysmal dilatation of pulmonary trunk
- √ linear calcification + thrombus in central pulmonary arteries
- √ atheromatous calcification of pulmonary arteries
- √ mural calcification / aneurysmal dilatation of ductus arteriosus (in case of patent ductus arteriosus)

Dx: measurement of pulmonary artery pressure + flow via catheter

Rx: heart-lung transplant

ENDOCARDIAL CUSHION DEFECT

= ECD = ATRIOVENTRICULAR SEPTAL DEFECT
= PERSISTENT OSTIUM ATRIOVENTRICULARE COMMUNE
= PERSISTENT COMMON ATRIOVENTRICULAR CANAL

= persistence of primitive atrioventricular canal + anomalies of AV valves ← interruption of normal development of endocardial tissues

Frequency: 4% of all cases of CHD

Endocardial cushion = forms lower portion of atrial septum, upper portion of interventricular septum + septal leaflets of MV and TV

Cause: deficiency of conus + sinus portions of interventricular septum → narrowing of left ventricular outflow tract

A. INCOMPLETE / PARTIAL ECD

= (1) Ostium primum ASD
(2) Separate tricuspid + mitral valves with cleft in anterior mitral valve leaflet / trileaflet
(3) Accessory short chordae tendineae arising from anterior MV leaflet insert directly into crest of deficient ventricular septum

√ left atrioventricular valve usually has 3 leaflets with a wide cleft between anterior + septal leaflet

√ **"gooseneck"** deformity on LV angiography = concavity of IVS below MV + elongation and narrowing of LVOT ← downward attachment of anterior MV leaflet close to interventricular septum by accessory chordae tendineae

√ communication between LA–RA or LV–RA, occasionally LV–RV

√ right atrioventricular valve usually normal

B. TRANSITIONAL / INTERMEDIATE ATRIOVENTRICULAR CANAL (uncommon)

= (1) Ostium primum ASD
(2) High membranous VSD
(3) Wide clefts in septal leaflets of both AV valves
(4) Bridging tissue between anterior + posterior common leaflet of both AV valves

C. COMPLETE ECD = AV COMMUNIS = COMMON AV CANAL

= (1) Ostium primum ASD above
(2) Posterior inlet membranous VSD below
(3) One AV valve common to RV + LV with 5–6 leaflets
(a) anterior common "bridging" leaflet
(b) two lateral leaflets
(c) posterior common "bridging" leaflet

Type 1 = chordae tendineae of anterior bridging leaflet attached to both sides of ventricular septum

Type 2 = chordae tendineae of anterior leaflet attached medially to anomalous papillary muscle within RV, but unattached to septum

Type 3 = free-floating anterior leaflet with chordae attachments to septum; only type becoming symptomatic in infancy!

Associated with:

(1) Down syndrome:
in 25% of trisomy 21 an ECD is present;
in 45% of ECD trisomy 21 is present
(2) Asplenia, polysplenia

√ common atrioventricular orifice

√ oval septal defect consisting of a low ASD + high VSD

√ atrial septum secundum usually spared ("common atrium" if absent)

√ frequently associated with mesocardia / dextrocardia

Hemodynamics:

fetus: atrioventricular valves frequently incompetent leading to regurgitation + CHF

neonate: L-to-R shunt after decrease of pulmonary vascular resistance resulting in pulmonary hypertension

• incomplete right bundle branch block (distortion of conduction tissue); left-anterior hemiblock

CXR:

◊ Radiographic findings similar to ASD, but more marked

√ increased pulmonary vascularity (= shunt vascularity)

√ redistribution of pulmonary blood flow (mitral regurgitation)

√ enlarged pulmonary artery

√ diminutive aorta ← L-to-R shunt

√ cardiac enlargement out of proportion to pulmonary vascularity ← L-to-R shunt + mitral insufficiency

√ enlarged RV + LV

√ enlarged RA ← LV blood shunted to RA

√ normal-sized LA ← ASD

ECHO:

√ visualization of ASD + VSD + valve + site of insertion of chordae tendineae

√ paradoxical anterior septal motion ← ASD

√ atrioventricular insufficiency + shunts identified by Doppler ultrasound

Angio:

AP projection:

√ "gooseneck deformity" (in diastole) ← deficiency of conus and sinus portion of interventricular septum below mitral valve with narrowing of LVOT

√ cleft in anterior leaflet of mitral valve (in systole)

√ mitral regurgitation

Hepatoclavicular projection in 45° LAO + C-C 45° (= 4-chamber view):

√ best view to demonstrate LV-RA shunt

√ best view to demonstrate VSD (inflow tract + posterior portion of interventricular septum in profile)

LAT projection:

√ irregular appearance of superior segment of anterior mitral valve leaflet over LVOT

Prognosis: 54% survival rate at 6 months, 35% at 12 months, 15% at 24 months, 4% at 5 years; 91% long-term survival with primary intracardiac repair, 4–17% operative mortality

ENDOCARDIAL FIBROELASTOSIS

= diffuse endocardial thickening of LV + LA ← deposition of collagen + elastic tissue

Etiology:

(1) ? Viral infection

(2) Secondary endocardial fibroelastosis
= subendocardial ischemia in critical LVOT obstruction: aortic stenosis, coarctation, hypoplastic left heart syndrome

• sudden onset of CHF during first 6 months of life
√ mitral insufficiency:
  (a) involvement of valve leaflets
  (b) shortening + thickening of chordae tendineae
  (c) distortion + fixation of papillary muscles
√ enlarged LV (= dilatation of hypertrophied LV) ← mitral regurgitation
√ restricted LV motion
√ enlarged LA
√ pulmonary venous congestion + pulmonary edema
√ LLL atelectasis ← compression of left lower lobe bronchus by enlarged LA
Prognosis: mortality almost 100% by 2 years of age

Carcinoid Heart Disease

Etiology: secretion of 5-hydroxytryptamine by tumor cells metastatic to liver → deposition of fibrous tissue on endocardial surfaces of right heart
Prevalence: in up to 60% of patients with carcinoid syndrome
Location: both tricuspid and pulmonary valve leaflets + corresponding subvalvular apparatus
√ thickening of valve leaflets and cusps → eventually retracted + shortened + immobile
√ thickening + fusion of chordae
Cx: valvular regurgitation, valvular stenosis

EOSINOPHILIC HEART DISEASE

= manifestation of hypereosinophilic syndrome
Cause: active damage of endomyocardium by toxic cationic proteins released after degranulation of infiltrated eosinophils
Pathophysiology: Fibrous tissue deposition within endocardium + adjacent myocardium along inflow tracts and apices of one / both ventricles → rigidity of ventricular walls, papillary muscles, atrioventricular valves
Phases:
(1) Acute necrosis
  • palpitations, dyspnea, fever, malaise
(2) Mural thrombosis
  • infarction ← thromboembolism
  • DVT ← hypercoagulable state
(3) Fibrosis
  • right / left ventricular dysfunction, valvular incompetence, thromboembolic episodes, organ dysfunction

MR:
√ ventricular wall thickening
√ regional wall motion abnormalities
√ extensive myocardial hyperintensity on T2WI
CEMR (10-min delay):
√ CHARACTERISTIC 3-layered appearance of ventricular wall:
√ outer normal nulled (black) myocardium

√ adjacent enhancing hyperintense subendocardium ← fibrosis
√ innermost nonenhancing mural thrombus

√ pericardial effusion with variable degree of pericardial enhancement ← pericarditis (rare)

ECHO / CT:

√ endocardial thickening, cardiac mural thrombus
√ restrictive ventricular diastolic (filling) dysfunction ← reduced size, atrial enlargement, atrioventricular valve incompetence
√ nonenhancing intracardiac mural thrombus
√ fibrotic endocardial thickening

FIBROMUSCULAR DYSPLASIA

= nonatherosclerotic noninflammatory angiopathy of unknown pathogenesis caused by proliferation of muscular + fibrous elements in middle- and small-caliber arteries

Prevalence: 0.6–1.1%; < 1% of cerebral angiographies

Age: children + young adults < 30–40 years; ²/₃ > 50 years; M÷F = 1÷3 to 1÷4

• hypertension, progressive renal insufficiency, neurologic deficits
• decreased peripheral pulses, bruit, asymmetric limb pressures

Location:

@ Craniovertebral arteries (25–30%):
cervical + intracranial ICA (85%), extracranial carotid artery (30%), vertebral artery (7–10%); both anterior + posterior circulations (8%); bilateral (60–65%)
Site: adjacent to C1-C2
Associated with: brain ischemia (up to 50%), intracranial aneurysms (up to 30%), intracranial tumors (30%), bruits, trauma

@ Abdominal aorta:
renal artery (60–75%), other aortic branches (in 1–2%: celiac a., hepatic a., splenic a., mesenteric a., iliac artery)
◊ Simultaneous involvement of renal / muscular arteries in 3%

1. **Intimal Fibroplasia** (1–2%)
= INTIMAL HYPERPLASIA
• progressive
Path: circumferential / eccentric fibrous tissue between intima + internal elastic lamina
Age: children + young adults; M÷F = 1÷1
Site: main renal artery + major segmental branches; often bilateral
√ focal narrow annular radiolucent band
√ smooth tubular stenosis
√ poststenotic fusiform dilatation
Cx: spontaneous dissection
DDx: atherosclerosis, Takayasu arteritis

2. **Medial Fibroplasia** (60–85%)
= fibromuscular hyperplasia = medial fibroplasia with microaneurysms
Age: 20–50 years; typically affects women; common cause of renal artery stenosis in children
Path: multiple fibromuscular ridges + severe mural thinning with loss of smooth muscle

+ internal elastic lamina

Site: mid + distal renal artery + branches; bilateral in 50%

√ "string-of-beads" sign = alternating areas of weblike stenoses + aneurysms (which exceed the normal diameter of the artery)

√ single tubular focal stenosis

Cx: dissection

3. **Perimedial Fibroplasia** (rare)

= SUBADVENTITIAL FIBROPLASIA

Age: young females

Path: fibroplasia of outer 1/2 of media replacing external elastic lamina

Site: distal (mostly right) main renal artery

√ long irregular stenosis

√ beading = NO aneurysm formation (diameter of beads not wider than normal diameter of artery)

4. **Medial Hyperplasia** (5–15%)

= FIBROMUSCULAR HYPERPLASIA

Path: smooth muscle + fibrous tissue hyperplasia within arterial media

Site: main renal artery and branches

√ long smooth concentric tubular narrowing

DDx: Takayasu arteritis, sclerosing arteritis, vessel spasm, arterial hypoplasia

5. **Adventitial Fibroplasia** (< 1%)

= SUBADVENTITIAL / PERIADVENTITIAL HYPERPLASIA

Path: adventitial + periarterial proliferation in fibrofatty tissue

Site: main renal artery, large branches

√ long segmental stenosis

<u>added to original 5 types:</u>

6. **Medial Dissection** (5–10%)

Path: new channel in outer ⅓ of media within external elastic lamina

Site: main renal artery + branches

√ false channel, aneurysm

7. **Atypical Fibromuscular Dysplasia**

(= ? variant of intimal fibroplasia)

√ web = smooth / corrugated mass involving only one wall of vessel + projecting into lumen

DDx: atherosclerotic disease, posttraumatic aneurysm

VARIANT: **Segmental mediolytic arteriopathy**

= rare noninflammatory disease of small + medium arteries

Histo: focal segmental disruption of medial smooth muscle cells with mediolysis

√ string-of-beads appearance

√ irregular stenoses + aneurysms

Cx: dissection (in 3%), macroaneurysm formation, intramural hemorrhage, subarachnoid hemorrhage

Prognosis: tends to remain stable / minimal progression of lesions in 20% causing decline in renal function

Rx: (1) Resection of diseased segment with end-to-end anastomosis
(2) Replacement by autogenous vein graft, excision + repair by patch angioplasty
(3) Transluminal balloon angioplasty (90% success rate with very low restenosis rate)

FLAIL MITRAL VALVE

Cause:
(1) Ruptured chordae tendineae in rheumatic heart disease, ischemic heart disease, bacterial endocarditis
(2) Ruptured head of papillary muscle in acute myocardial infarction, chest trauma

Location: chordae to leaflet from posteromedial papillary muscle (single vessel blood supply)
√ deep holosystolic posterior movement of leaflet
√ random anarchic motion pattern of flail parts in diastole
√ excessively large amplitude of opening of aML

HENOCH-SCHÖNLEIN PURPURA

[Eduard Heinrich Henoch (1820–1910, pediatrician in Berlin and director of the first children's hospital in Germany]
[Johann Lukas Schönlein (1793–1864), German physician in Bamberg, the cradle of German hospital medicine, and at the University of Würzburg, where he introduced bedside teaching]
= I G A VASCULITIS
= most common systemic allergic hypersensitivity-related acute small-vessel vasculitis in children

Incidence: 20÷100,000 annually; mostly occurring in winter
Precipitated by: bacterial (b-hemolytic Streptococcus) / viral infection (URI in 50%), allergies, insect sting, drugs (eg, penicillin, sulfonamides, aspirin), certain foods
Cause: deposition of IgA-dominant immune complexes in vessel walls (venules, capillaries, arterioles)
Peak age: 7 (range, 3–15) years + adults > 20 years (in up to 30%); M÷F = 1.5÷1.0
◊ Most common vasculitis 4–7 years of age
Path: acute leukocytoclastic small-vessel vasculitis with IgA deposits at dermoepidermoid junction and renal mesangium

- often begins as an upper respiratory tract infection
- 3–4 weeks mean duration of symptoms; at least 1 recurrence (⅓)

@ Skin disease
- nonthrombocytopenic petechial / maculopapular skin rash
- palpable purpura concentrated in dependent / pressure-bearing regions of lower extremities + buttocks + extensor surfaces of arms (95–100%)

@ Joint disease (60–84%)
- arthralgias / arthritis of large joints

@ GI tract involvement (57–65–76%)
- may precede skin rash / within 1 week of onset of rash
- colicky abdominal pain ± diarrhea, nausea, vomiting
- GI bleeding ± melena

√ multifocal short-segment (< 15 cm) small bowel wall thickening of 7–12 mm (← intramural hemorrhage + edema) with skipped areas (DDx from other types of vasculitis)
√ "comb" sign = hypervascular engorged vasa recta
√ intestinal dilatation
√ ± bowel ulceration
√ mesenteric fat stranding + adenopathy of < 1.5 cm

@ Renal disease (20–100%)
- microscopic hematuria + proteinuria in 50%
- nephrotic syndrome in 10%
- proliferative glomerulonephritis with IgA deposits demonstrated by immunofluorescence (in up to ⅓)

√ normal / bilaterally enlarged kidneys
√ increased echogenicity of renal cortex
√ ± intramural hematoma of urinary bladder / ureter

@ Scrotal disease (15–37%)
√ mostly bilateral scrotal wall thickening
√ epididymal enlargement, reactive hydrocele
√ ± orchitis

@ CNS (rare)
√ hypertensive / uremic encephalopathy
√ focal ischemic / hemorrhagic lesions

Cx: (1) Bowel infarct / perforation / irreducible ileocecal intussusception (1–3–5%)
(2) Renal insufficiency (10–20%), end-stage renal disease (5%)

Dx: 4 diagnostic criteria:
(1) Age < 20 years at onset
(2) Palpable purpura
(3) Gastrointestinal bleeding
(4) Biopsy evidence of granulocytes around small arteriolar + venular walls (skin biopsy)

Rx: supportive; high doses of corticosteroids and azathioprine; IV immunoglobulin therapy
◊ Radiologic diagnosis avoids unnecessary surgery!

Prognosis: self-limiting without requiring treatment in 37% of adults + 60% of children

Mortality: 60% during 1st year of life

DDx: SLE (multiple segments of symmetric bowel thickening in jejunum + ileum, bowel dilatation, increased attenuation of mesentery, ascites); Yersinia enterocolitis (terminal ileum involved); Crohn disease (erythema nodosum + pyoderma gangrenosum)

HEMANGIOMA

= true neoplasm with vascular channels lined by proliferating endothelial cells

Infantile Hemangioma

= CAPILLARY HEMANGIOMA

Prevalence: 2–3% in all children; higher in prematurity
◊ Most common vascular tumor of infancy

Age: normally not visible at birth; manifest during first few weeks after birth; often evident by 3 months of age; M÷F = 1÷3 to 1÷5

Histo:

(a) proliferating phase = hyperplastic proliferating endothelial cells forming syncytial masses with ↑ metabolic turnover and ↑ number of mast cell
- strawberry-like pulsatile warm mass
- in first few weeks of life
- rapid growth with subsequent regression

(b) involuting phase = thinning of endothelial lining with progressive perivascular deposition of fibrofatty tissue
- slow constant regression into grayish dark red mass
- regression completed by age 7–10 years

Location: face and neck (60%), trunk (25%), extremity (15%)

- subcutaneous strawberry-like bluish-red mass with bruit, pulsatility and warmth
- rapid growth during first few months (= proliferating phase)

MR:

√ well-defined lobulated mass with high SI on T2WI
√ intermediate SI on T1WI
√ flow voids within high-flow feeding arteries and draining veins on SE images
√ high signal intensity on GRE images
√ NO perilesional edema
√ early intense uniform enhancement without AV shunting
√ heterogeneous lesion with foci of increased SI intensity on T1WI (= fatty replacement) + less avid enhancement during involuting phase

Rx: usually none; needed when symptomatic / in region with possible secondary loss of function or lifetime aesthetic impairment: propranolol / embolization / surgery

Congenital Hemangioma

Age: present at birth (fully grown); M÷F = 1÷1

(a) rapidly involuting congenital hemangioma
- complete regression during first 2 years of life

(b) noninvoluting congenital hemangioma
- growth proportional to that of child without regression

MR:

√ similar to infantile hemangioma

HETEROTAXY SYNDROME

[*hetero*, Greek = different; *taxis*, Greek = arrangement]

= CARDIOSPLENIC SYNDROMES

= situs ambiguus with a spectrum of various congenital truncal abnormalities + frequently cardiac malformations from asplenia to polysplenia

Embryology:

primary defect in lateralization with disruption of complete separation of cardiac chambers during 20–30 days of gestation

Inheritance: multifactorial (autosomal dominant, autosomal recessive, X-linked recessive)
Individualized approach of classification:
describes all critical structures by analyzing
(a) position of atria
(b) position of venous drainage below diaphragm relative to midline
(c) position of aorta relative to midline
(d) position of the stomach + presence of malrotation
(e) position of liver + gallbladder
(f) position of cardiac apex
(g) presence, appearance, and number of spleens
(h) presence of bi- / trilobed lungs

Asplenia Syndrome

= BILATERAL RIGHT-SIDEDNESS = RIGHT ISOMERISM
= IVEMARK SYNDROME

Prevalence: 1÷1,750–1÷40,000 livebirths; M > F
Associated with:
(a) CHD (in 50%):
TAPVR (almost 100%), endocardial cushion defect (85%), single ventricle (51%), TGA (58%), pulmonary stenosis / atresia (70%), dextrocardia (42%), mesocardia, VSD, ASD, absent coronary sinus, common atrium, common hepatic vein
(b) GI anomalies:
Partial / total situs inversus, annular pancreas, agenesis of gallbladder, ectopic liver, esophageal varices, duplication + hypoplasia of stomach, Hirschsprüng disease, hindgut duplication, imperforate anus
(c) GU anomalies (15%):
Horseshoe kidney, double collecting system, hydroureter, cystic kidney, fused / horseshoe adrenal, absent left adrenal, bilobed urinary bladder, bicornuate uterus
(d) Cleft lip / palate, scoliosis, single umbilical artery, lumbar myelomeningocele

- cyanosis in neonatal period / infancy (if severe cyanotic CHD)
- severe respiratory distress; Howell-Jolly bodies = RBC inclusions in patients with absent spleen

@ Lung
√ right bronchial isomerism:
√ bilateral trilobed lungs = bilateral minor fissures (SPECIFIC)

Heterotaxy Syndromes		
	Asplenia = bilateral right-sidedness	*Polysplenia = bilateral left-sidedness*
Clinical		
Presenting age	newborn / infant	infant / adult
Sex predominance	male	female
Cyanosis	severe	usually absent
Heart disease	severe	moderate / none (5–10%)
Howell-Jolly / Heinz bodies	present	absent
Spleen scan	no spleen	multiple small spleens
Characteristic ECG	none	abnormal P-wave vector
Prognosis	poor	good
Mortality	high	low
Plain radiograph		
Lung vascularity	decreased	normal / increased
Aortic arch	right / left	right / left
Cardiac apex	right / left / midline	right / left
Bronchi	bilateral eparterial	bilateral hyparterial
Minor fissure	possibly bilateral	none / normal
Stomach	midline / right / left	right / left
Liver	symmetrical / R / L	in various positions
Malrotation of bowel	yes (microgastria)	yes
Cardiography		
Coronary sinus	usually absent	sometimes absent
Atrial septum	common atrium (100%)	ASD (84%)
AV valve	atresia / common valve	normal / abnormal MV
Single ventricle	44%	infrequent
IVS	VSD	VSD common
Great vessels	d- / l-transposition (72%)	normal relationship
Pulmonary stenosis	the rule	frequent
Pulmonary veins	TAPVR	PAPVR (42%) TAPVR (6%)
Single coronary a.	19%	
SVC	bilateral (53%)	bilateral (33%)
IVC-aorta relationship	same side of spine	normal
IVC	normal	interrupted (84%) / normal
Azygos vein	inapparent	continuation R / L

√ bilateral eparterial bronchi (MR / tomogram):
√ main bronchus passes superior to ipsilateral main pulmonary artery
√ pulmonary arteries inferior to bronchi (on PA view) + projecting anterior to trachea (on LAT view)
√ diminished pulmonary vascularity / pulmonary venous hypertension (TAPVR below diaphragm)

@ Heart & great vessels
√ bilateral systemic / right morphologic atria with broad-based appendages
√ ipsilaterality of abdominal aorta + IVC
= juxtaposed "piggybacked" IVC (aorta usually posterior) (MOST RELIABLE INDICATOR)
√ bilateral SVC

@ Abdomen
√ asplenia = absent spleen (risk of sepsis)
√ midline liver = centrally located "bridging" liver = hepatic symmetry
√ variably located stomach (on right / left side / in central position) and small (microgastria)
√ cardiac apex discordant from stomach + liver

Prognosis: up to 90% mortality by end of 1st year of life

Polysplenia Syndrome

= BILATERAL LEFT-SIDEDNESS = LEFT ISOMERISM

Age: presentation in infancy / adulthood; M < F

Associated with:

(a) CHD (> 50%):
APVR (70%), dextrocardia (37%), ASD (37%), ECD (43–65%), pulmonic valvular stenosis (23%), TGA (13–17%), DORV (13–20%)
• no / mild CHD in most patients

(b) GI abnormalities:
esophageal atresia, tracheoesophageal fistula, gastric duplication, preduodenal portal vein, duodenal webs + atresia, short bowel, mobile cecum, malrotation, semiannular pancreas, biliary atresia, absent GB

(c) GU anomalies (15%):
renal agenesis, renal cysts, ovarian cysts

(d) Vertebral anomalies, common celiac trunk–SMA

• CHF ← L-to-R shunt; heart murmur, occasional cyanosis
• leftward / superiorly directed P-wave vector
• heart block ← endocardial cushion defect
• extrahepatic biliary obstruction
√ absence of IVC (on LAT CXR)
√ large azygos vein (on AP CXR) may mimic aortic arch

@ Lung
√ left bronchial isomerism:
√ bilateral morphologic left lungs with 2 lobes (55–68%), normal (18%), bilateral R-sided lungs (7%)

√ bilateral hyparterial bronchi = main bronchus passes inferior to ipsilateral main pulmonary artery:
√ arteries projecting superior to bronchi (on PA view) + posterior to tracheobronchial tree (on LAT view)
√ normal / increased pulmonary vascularity
√ absence of middle lobe fissure

@ Heart & great vessels
√ bilateral pulmonary / left morphologic atrium with pointed tubular narrow-based appendages
√ cardiac apex on right / in midline
√ bilateral SVC (50%)
√ interruption of hepatic segment of IVC with azygos / hemiazygos continuation in 65–70% (MOST CONSISTENT FINDING)

@ Abdominal heterotaxy (56%)
√ polysplenia = presence of ≥ 2 spleens (usually two major + indefinite number of splenules) located on both sides of the mesogastrium (esp. greater curvature of stomach)
√ midline centrally located liver = hepatic symmetry
√ absence of gallbladder (50%)
√ variably located stomach → always on same side of spleen(s)
√ malrotation of bowel (80%)
√ preduodenal portal vein

OB-US:
√ absence of intrahepatic IVC
√ aorta anterior to spine in midline
√ "double vessel" sign = 2 vessels of similar size in paraspinous location posterior to heart = aorta + azygos vein on left / right side of spine

Prognosis: 50% mortality by 4 months; 75% mortality by 5 years; 90% mortality by midadolescence

HYPOPLASTIC LEFT HEART SYNDROME

= SHONE SYNDROME = AORTIC ATRESIA
= underdevelopment of left side of heart characterized by
(a) hypoplastic / atretic aortic valve
√ subvalvar aortic stenosis
(b) hypoplastic / atretic mitral valve
√ parachute mitral valve = all chordae tendineae arise from single fused papillary muscle
√ supravalvar mitral ring
(c) hypoplastic LV ← endocardial fibroelastosis
(d) hypoplastic ascending aorta
√ aortic coarctation
(e) normally related great vessels

Prevalence: 0.2÷1,000 live births; M÷F = 2÷1
◊ 4th most common cardiac malformation manifesting in 1st year of life (after VSD, TGV,

tetralogy of Fallot)
◊ Most common cause of CHF in neonate
◊ Responsible for 25% of all cardiac deaths in 1st week of life

Hemodynamics:
pulmonary venous blood in LA faces an atretic / stenotic MV (= pulmonary venous outflow obstruction) → flow diverted to RA through herniated foramen ovale / ASD (L-to-R shunt); RV supplies (a) pulmonary artery, (b) ductus arteriosus, (c) descending aorta (antegrade flow), (d) aortic arch + ascending aorta + coronary circulation (retrograde flow) → RV work overload + CHF

Associated malformations:
coarctation of aorta, PDA, patent foramen ovale, dilated pulmonary artery, VSD, dilated RA, enlarged RV, double-outlet right ventricle, endocardial fibroelastosis

- severe CHF ← RV volume + pressure overload:
  - characteristically presents within first few hours of life
- ashen gray color / dusky complexion ← systemic underperfusion ← inadequate atrial L-to-R shunt
- myocardial ischemia ← decreased perfusion of aorta [= "common coronary artery"] + coronary arteries):
  - cardiogenic shock, metabolic acidosis (when ductus arteriosus closes)

CXR:
√ hypoplastic / normal / enlarged cardiac silhouette:
√ prominent right atrial border
√ ± absence of left ventricular silhouette
√ ± thymic atrophy
√ interstitial + alveolar pulmonary edema ← pulmonary venous hypertension with severely restrictive interatrial communication in 80%
√ normal pulmonary vasculature (with wide nonrestrictive interatrial communication in 20%)

OB-US (may be missed < 22 weeks GA):
√ small left ventricular cavity (apex of LV and RV should be at same level)
√ hypoplastic ascending aorta
√ aortic coarctation (in 80%)
√ diastolic flow reversal in narrow ascending aorta is DIAGNOSTIC

ECHO:
√ normal / enlarged LA
√ slitlike / small / normal LV
√ enlarged RA
√ herniation + prolapse of foramen ovale flap into RA
√ hypoplastic ascending aorta (< 5 mm = aortic atresia)
√ absent / grossly distorted mitral valve echoes

Angio:
√ retrograde flow in ascending aorta + aortic arch + coronary arteries via PDA
√ stringlike ascending aorta < 6 mm in diameter
√ massive enlargement of RV + RVOT

Prognosis: almost 100% fatal by 6 weeks

Time of diagnosis: 32% pre-, 65% 1–4 days postnatally

Rx: (1) Prostaglandin E1 → patency of ductus arteriosus

(2) Hypoventilation (increase in CO_2 maintains high pulmonary vascular resistance)

(3) Nitroprusside IV (decreases systemic vascular resistance)

(4) Norwood procedure = palliative attempt

(5) Cardiac transplant

HYPOPLASTIC RIGHT VENTRICLE

= PULMONARY ATRESIA WITH INTACT VENTRICULAR SEPTUM

= underdeveloped right ventricle ← pulmonary atresia in the presence of an intact interventricular septum

Type I = small RV ← competent tricuspid valve (more common)

Type II = normal / large RV ← incompetent tricuspid valve

Hemodynamics:

fetus: L-to-R atrial shunt through foramen ovale; retrograde flow through ductus arteriosus into pulmonary vascular bed

neonate: closure of ductus → cyanosis, acidosis, death

√ small right ventricular cavity (apex of RV + LV should be at same level)

√ atresia of pulmonary valve

√ hypoplastic proximal pulmonary artery

√ secundum atrial septal defect (frequently associated)

Rx: prostaglandin E1 infusion + valvotomy + systemic-pulmonary artery shunt

IDIOPATHIC DILATATION OF PULMONARY TRUNK

= CONGENITAL ANEURYSM OF PULMONARY ARTERY

Age: adolescence; M < F

• asymptomatic; systolic ejection murmur (in most cases)

√ dilated main pulmonary artery causes a round bulge at the mediastinal border simulating a mass

√ normal peripheral pulmonary vascularity

√ normal pulmonary arterial pulsations

√ NO lateralization of pulmonary flow

Dx per exclusion:

1. Absence of shunts, CHD, acquired disease
2. Normal RV pressure
3. No significant pressure gradient across pulmonic valve

Prognosis: nonprogressive

DDx: (1) Marfan syndrome

(2) Takayasu arteritis

INFECTIOUS AORTITIS

= inflammation of aorta caused by bacterium / virus / fungus

The aorta is normally very resistant to infection. However, an abnormal aortic wall as occurs with atherosclerotic disease, preexisting aneurysm, cystic medial necrosis, diabetes, vascular malformation, medical devices, or surgery, makes it susceptible to infection!

Organism:

1. Bacterial: Staphylococcus > Streptococcus > Salmonella, Clostridium septicum (exceedingly rare, but strongly associated with GI / hematologic malignancy)
2. Luetic = syphilis
3. Mycobacterial = Mycobacterium tuberculosis
4. Viral: eg, HIV infection / AIDS

√ thickening of aortic wall + intramural gas (KEY FEATURE)

N.B.: aorta may appear normal on imaging

Rx: empiric antibiotic therapy against S. aureus and gram-negative rods

DDx: infected aortic aneurysm (dilated aorta prone to rupture)

Syphilitic Aortitis

= LUETIC AORTITIS

Prevalence: in 10–15% of untreated patients (accounts for death in ⅓)

Path: periaortitis (via lymphatics), mesaortitis (via vasa vasorum) = primarily disease of media leading to secondary injury of intima, which predisposes the intima to premature calcific atherosclerosis

Age: 40–65 years

Site: ascending aorta (36%), aortic arch (24%), descending aorta (5%), sinus of Valsalva (1%), pulmonary artery

√ thick aortic wall ← fibrous + inflammatory tissue

√ saccular (75%) / fusiform (25%) dilatation of ascending aorta:

√ small saccular aneurysm often protrudes from fusiform aneurysm

√ fine pencil-like calcifications of intima (15–20%) in ascending aorta, late in disease

Cx: (1) Stenosis of coronary ostia ← intimal thickening

(2) Aortic regurgitation (syphilitic valvulitis), rare

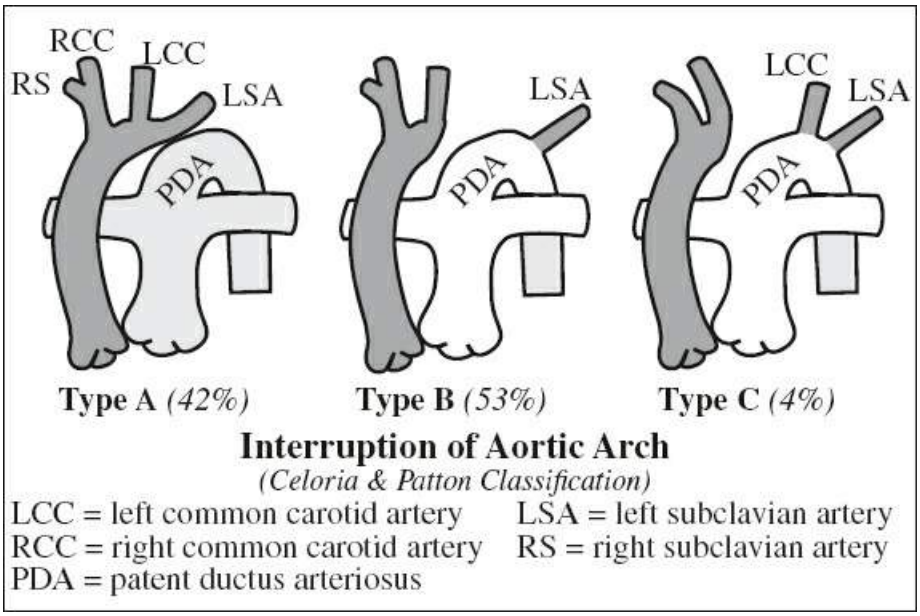
DDx: Degenerative calcification of ascending aorta (older population, no aneurysm, no aortic regurgitation)

INTERRUPTION OF AORTIC ARCH

= IAA = rare congenital anomaly with complete luminal and anatomic discontinuity between ascending + descending aorta

Prevalence: 1% of CHD

◊ Common cause of death in neonatal period after physiologic closure of PDA (4–10 days)



Trilogy: (1) Luminal discontinuity between ascending + descending thoracic aorta
(2) VSD (in 90%)
(3) PDA (pulmonary blood supplies lower part of body) in nearly 100%

Cause: ? altered hemodynamics through 4th aortic arch / teratogenic exposure

Genetics: chromosome 22q11.2 deletion (50%), DiGeorge syndrome (= hypocalcemia and T-cell defects ← thymic hypoplasia in 42%)

Forms: (a) Simple IAA

(b) Complex IAA (in ⅓) associated with:

1. Bicuspid aortic valve
2. Muscular subaortic stenosis
3. Truncus arteriosus
4. Aortopulmonary window
5. ASD
6. Transposition of great arteries
7. Double-outlet right ventricle
8. Functional single ventricle
9. Complete anomalous pulmonary venous return

• presents with CHF

Location:

Type A: distal to left subclavian artery (13–42%)
Type B: between left CCA and subclavian artery (53–84%)
Type C: between innominate and left CCA (3–4%)

√ dilatation of right atrium + ventricle
√ dilatation of pulmonary artery
√ ascending aorta much smaller than pulmonary artery
√ arch formed by pulmonary artery + ductus arteriosus gives the appearance of a low aortic arch
√ aortic knob absent

√ trachea in midline
√ NO esophageal impression
√ retrosternal clear space increased (small size of ascending aorta)
√ increased pulmonary vascularity ← L-to-R shunt
√ aberrant right subclavian artery arising from right side of proximal descending thoracic aorta
Cx: hypoperfusion with acute renal failure + metabolic acidosis
Prognosis: 59–70% overall survival rate by 16 years of age
Rx: prostaglandin E1 in neonatal period (to keep the ductus arteriosus open); cardiac surgery during 1st year of life (with 15–20% mortality)

INTERRUPTION OF PULMONARY ARTERY

= pulmonary trunk continues only as one large artery to one lung while systemic aortic collaterals supply the other side
Cause: abnormal development of 6th aortic arch in utero
Associated with: CHD (particularly if interruption on left side):
1. Tetralogy of Fallot
2. Scimitar syndrome = congenital pulmonary venolobar syndrome
3. PDA, VSD
4. Pulmonary hypertension

Collateral supply:
1. Arteries arising from arch + ascending aorta
2. Bronchial vessels
3. Intercostal vessels
4. Branches from subclavian artery (internal mammary artery)

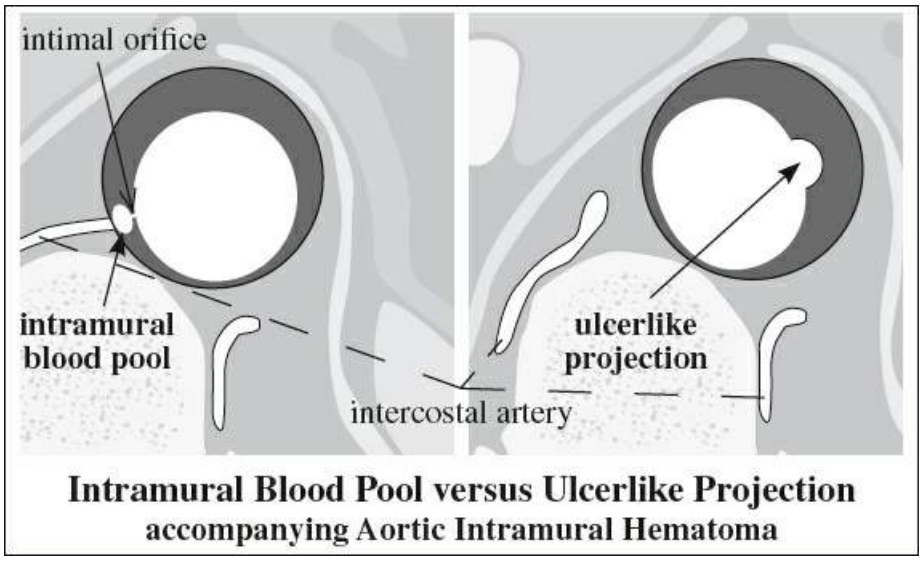
Location: usually opposite from aortic arch; R > L pulmonary artery
CXR:
√ hypoplastic ipsilateral lung
√ lung opacity similar to normal lung / slightly increased
√ volume loss of affected hemithorax:
  √ small ipsilateral chest
  √ mediastinal shift toward involved lung
  √ ipsilateral shift of anterior junction line
  √ ± elevation of ipsilateral hemidiaphragm
  √ ipsilateral narrowed intercostal spaces
  √ absent / diminutive appearance of pulmonary hilum with "comma-shaped" small distorted hilar shadow
  √ occasionally rib notching
√ hyperexpanded + hyperlucent contralateral lung with herniation into smaller hemithorax
√ asymmetry of pulmonary vascularity
√ normal respiratory motion (normal aeration of hypoplastic lung)

CECT:
√ affected pulmonary artery completely absent / terminates within 1 cm of its origin
√ reconstitution of more peripheral pulmonary arteries ← collateral vessels
√ multiple linear opacities perpendicular to pleural surface (= transpleural systemic

collateral vessels)
√ serrated pleural thickening (= enlarged intercostal + transpleural arteries)
NUC:
√ absent perfusion with normal aeration
Angio:
√ absent pulmonary artery
Cx: recurrent pulmonary infection, hemorrhage, hemoptysis (10%), mild exertional dyspnea, pulmonary hypertension (19–25%)
Rx: Surgical anastomosis between proximal + distal pulmonary artery (to prevent progressive pulmonary hypertension with dyspnea, cyanosis, hemoptysis, death)
DDx: (1) Hemitruncus
(2) Swyer-James syndrome (ipsilateral air trapping, reduced ventilation + perfusion)
(3) Chronic thromboembolic occlusion
(4) Takayasu arteritis
(5) Mediastinal fibrosis
(6) Hypogenetic lung syndrome (abnormal bronchial branching pattern)

INTRAMURAL AORTIC HEMATOMA (3–13%)

= ATYPICAL AORTIC DISSECTION = IMH
= aortic dissection without demonstrable intimal flap / penetrating aortic ulcer
Cause: rupture of vasa vasorum; in 94% spontaneous; in 6% traumatic (? early stage of limited dissection or thrombosis of false lumen)
Pathophysiology:
rupture of vasa vasorum → hemorrhage into aortic media → intramural blood clot → weakening of aortic wall; no detectable flow within the "false channel"
Median age: 68 years
Risk: hypertension (53%)
• signs + symptoms + classification identical to classic aortic dissection:
• chest pain / back pain or both (in 80%)
◊ IMH detected in 5–20% of patients presenting with signs of classic aortic dissection
Stanford classification: in 57% type A; in 43% type B
May be associated with: pericardial / pleural effusion, mediastinal hematoma
√ NO intimal tear / flap at initial imaging
√ NO penetrating atherosclerotic ulcer
NECT (necessary):



Intramural Blood Pool versus Ulcerlike Projection accompanying Aortic Intramural Hematoma

√ DIAGNOSTIC eccentric cuff / crescent of aortic wall > 7 mm thick with a density of 60–70 HU:
- √ attenuation identical to intraluminal blood after 1 week
- √ decreased thickness within a few weeks
- √ complete resolution within 1 year

√ displacement of intimal calcifications maintaining a semicircular / circular curvilinear configuration

CECT:

√ nonenhancing mural region of low attenuation with smooth border maintaining a constant circumferential relationship with aortic wall

√ predictors of outcome:
- (a) maximal aortic diameter,
- (b) maximal axial thickness of hematoma,
- (c) minimum + maximum transverse aortic diameter at level of maximal thickness of intramural hematoma

MR:

◊ Review source images!

√ crescent-shaped eccentric wall thickening

√ T2 white blood imaging:
- √ hyperintense signal (< 7 days of age)
- √ intermediate signal intensity (≥ 7 days)

√ subacute / chronic hematoma on T1 black blood imaging:
- √ subacute isointense (= oxyhemoglobin)
- √ hyperintense hematoma (= methemoglobin)

Aortography: not useful!

Cx: (1) Ulcerlike projection with progression to open dissection
(2) Saccular or fusiform aneurysmal dilatation
(3) Rupture

Rx: (1) Emergency surgical repair for type A hematoma (probably represents early stage

with development of classic aortic dissection)

(2) Observation for type B hematoma (may heal completely)

Mortality: 21% (similar to classic aortic dissection)

DDx:

(1) Acutely thrombosed false lumen of dissection (opacification of true + false lumina; intimal flap; multilayered pattern of increasing attenuation; linear configuration of intimal calcifications; tendency to spiral longitudinally around aorta)

(2) Aortitis (segmental mural thickening of aorta + branch vessels interspersed with normal segments)

(3) Acute aortic hematoma of fusiform aortic aneurysm with hyperattenuating crescent (= sign of impending rupture)

(4) Atheromatous mural thrombus (irregular intraluminal surface in segment of dilated aorta, abdominal location, multiple sites)

(5) Penetrating atherosclerotic ulcer (small focal contrast-enhanced outpouching of intima + adjacent subintimal hematoma, located in abdominal / descending thoracic aorta, associated with extensive atherosclerosis)

(6) Intramural blood pool

= intramural contrast-medium filled pool

√ tiny intimal orifice ± connection with intercostal / lumbar artery

Prognosis: good

(7) Focal periaortic soft-tissue mass (circumferential involvement with irregular external border)

(a) Idiopathic retroperitoneal fibrosis

(b) Periaortic lymphoma

(8) Aortic motion artifact simulating type A IMH

ISCHEMIC HEART DISEASE

= CORONARY ARTERY DISEASE (CAD)

Incidence: 1.5 million annually; leading cause of death in industrial nations

Prognosis: 28.7÷1,000 men annually; 3.1÷1,000 deaths annually

• **Acute Coronary Syndrome**

(a) transmural myocardial infarction

(b) subendocardial myocardial infarction

(c) unstable angina

Likelihood of Myocardial Ischemia	*Preferred Imaging Modality*
high	Catheter angiography
moderate	ECG-gated SPECT
low	Coronary CT angiography

CXR:

√ often normal

√ coronary artery calcification

√ pulmonary venous hypertension following acute infarction (40%)

√ LV aneurysm

A. NONINVASIVE TESTING
   1. Noninvasive testing is of marginal benefit when disease prevalence is < 0.2 / > 0.7
   2. Concordant ^{201}Thallium and stress ECG are greater predictors of disease probability than either one used alone and/or when discordant
   3. Sequential ^{201}Thallium and stress ECG are most useful to establish the diagnosis of CAD when pretest prevalence is intermediate + test results are concordant

B. INVASIVE TESTING
   1. Nonstress Myocardial Perfusion Study (^{99m}Tc-Sestamibi) administered during acute chest pain: 99% NPV, 92% sensitive for early diagnosis

Coronary CTA / Triple CTA		
Risk category	*CT Interpretation*	*Clinical Guideline*
High	Coronary calcium score > 400 > 70% stenosis in any vessel > 50% stenosis in left main	Admission
Medium	Coronary calcium score 100–400 30–70% stenosis in any vessel	Cardiology consultation
Low	Coronary calcium score < 100	Follow-up with cardiology
Negative	Normal scan	Follow-up with regular MD
Results are negative / in low risk category in 75%!		

Pitfalls: breast attenuation, diaphragmatic attenuation (repeat study in prone position)

   2. ECHO (90% sensitive, 53–78% specific for infarction)
      √ region of dilatation with disturbance of wall motion:
      (1) Akinesis = no wall motion
      (2) Hypokinesis = reduced wall motion
      (3) Dyskinesis = paradoxical systolic expansion
      (4) Asynchrony = disturbed temporal sequence of contraction
   3. Coronary angiography: 1.2 million procedures annually
   4. Coronary CTA
   5. Cardiac PET/CT

Imaging of Coronary Artery Disease

(1) DIRECTLY with <u>myocardial perfusion imaging</u> providing a pictorial representation of the relative perfusion of viable myocardial tissue using exercise + rest physiology images
   (a) ^{201}Tl chloride SPECT imaging (92% sensitive, 68% specific)
   (b) ^{99m}Tc-sestamibi / tetrofosmin SPECT imaging (89% sensitive, 90% specific)
   (c) PET

(2) INDIRECTLY with <u>imaging of ventricular function</u>,
i.e., evaluation of wall motion + ejection fraction
   (a) multigated acquisition studies (MUGA)
      › ^{99m}Tc-labeled RBCs

› ^{99m}Tc-human serum albumin

(b) first-pass radionuclide angiography

› sodium pertechnetate

› diethylenetriamine pentaacetic acid (DTPA)

› sulfur colloid

› ^{195m}Au (gold)

› ^{191m}Ir (iridium)

(3) SIMULTANEOUS assessment of myocardial perfusion + ventricular function
= first-pass radionuclide angiography + gated SPECT perfusion imaging

Interpretation:

A. NORMAL MYOCARDIUM

√ homogeneous perfusion

√ similar appearance at rest + with exercise

B. ISCHEMIC VIABLE MYOCARDIUM

√ normal perfusion at rest

√ relative hypoperfusion with exercise (= reversible defect)

DDx:

(1) Reversible septal defect in left bundle branch block

(2) Differing soft-tissue attenuation artifact

C. MYOCARDIAL INFARCTION

√ reduced muscle mass

√ absent / reduced uptake at rest + with exercise (= fixed defect)

DDx: (1) "**Hibernating myocardium**" = chronic myocardial hypoperfusion producing abnormal regional ventricular function

(2) Soft-tissue attenuation artifacts

√ marked variability in LV tracer uptake of inferior wall (diaphragmatic attenuation) + anterior wall (breast attenuation)

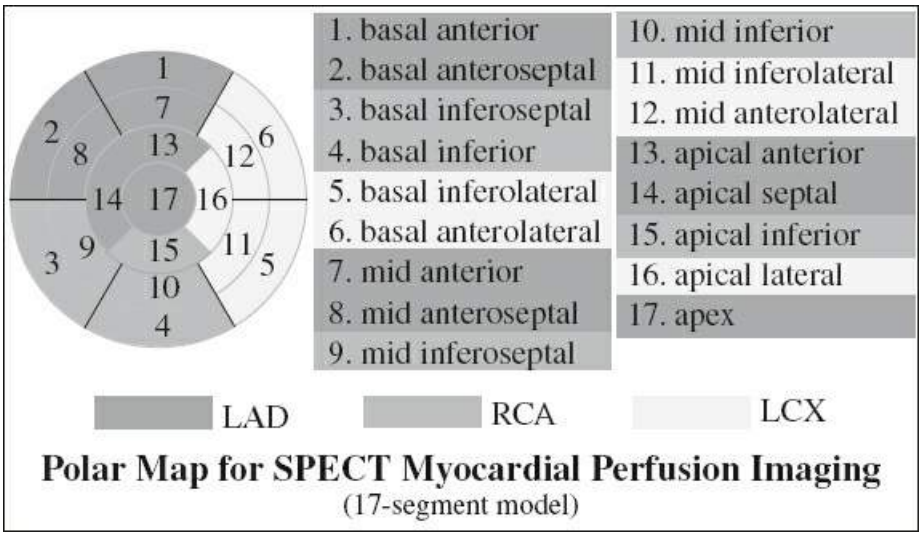
(3) Infiltrative disorders

DDx of a mild fixed defect:

1. Scar
2. Hibernating myocardium
3. Attenuation artifact

Myocardial Viability Assessment

1. Perfusion



» ^{201}Tl rest injection with redistribution images preferable to sestamibi
√ uptake > 50% of maximum

2. Metabolic activity
» FDG may provide best assessment (normal myocardium uses fatty acids as chief metabolic substrate, but can switch to glucose metabolism)
√ enhanced glucose uptake by ischemic but viable myocardium

Analysis of Perfusion Defect

Report must address: location, size, severity, reversibility of a perfusion defect

(1) TYPE OF PERFUSION ABNORMALITY
√ fixed defect
= myocardial scar / severe myocardial ischemia
√ reversible defect
= perfusion abnormality on poststress images normalizes on resting images
√ partially reversible defect
= 20–30% improvement in regional activity

(2) LOCATION OF PERFUSION ABNORMALITY described with regard to
(a) LV wall
→ anterior, septal, inferior, lateral, apical
◊ Avoid "posterior" as it has been variably assigned to the lateral wall (LCX) or basal inferior wall (RCA)
(b) expected coronary vascular territory involvement

(3) DEGREE OF REVERSIBILITY OF PERFUSION DEFECT
√ cross-hatching of perfusion defect on stress image-based polar map
√ improvement by ≥ 2 points in SSS / absolute SSS of 0 or 1 on rest images

◊ If an area of infarcted myocardium with a fixed defect has perfusion of greater than 50% of the database norm, it is considered to be at least partially viable

(4) SIZE / EXTENT OF PERFUSION DEFECT

Size of Myocardial Perfusion Defect	
Description	*Size of Total LV Volume*
small	5–10%
medium	15–20%
large	20–40%
extensive	> 40%

(5) SEVERITY OF PERFUSION DEFECT

» Qualitative

- mild = 10% reduction of peak tracer activity, of unknown clinical significance
- moderate
- severe

» Semiquantitative Segmental Scoring for more accurate + more consistent reporting

- Summed rest score (SRS)
- Summed stress score (SSS

Semiquantitative Segmental Scoring		
Score	*Reduction in Perfusion*	*Decrease from Norm*
0	normal / no difference	0%
1	equivocal / mild	< 40%
2	moderate	40–60%
3	severe	> 60%
4	absent perfusion	no activity

Myocardial Perfusion SPECT for Detection and Management of CAD			
	Normal	*Mildly Abnormal*	*Moderately Severely Abnormal*
Summed Stress Score	< 4	4–8	> 8
Likelihood of Coronary Artery Disease	low	high	high
Risk of Myocardial Infarction	low	intermediate	intermediate
Risk of Cardiac Death	low	low	intermediate

Risk for Future Hard Cardiac Events	
Risk	*Summed Stress Score*
Normal	0–3
Low risk	4–7
Intermediate risk	8–12
High risk	> 12

- Summed difference score (SDS) = SRS - SSS

= measure of reversibility (≥ 2-grade improvement represents substantial ischemia)

(a) no / mild ischemia = SDS ≤ 4
(b) determines risk for future hard cardiac even

QUANTITATIVE ANALYSIS
= using a reference profile (= database normalized to specific gender, radiopharmaceutical, and population) perfusion data is displayed as a polar map / bull's-eye projection / circumferential profile serving as a "second observer"
√ blackout map (most popular) = perfusion values below a threshold (usually of 2.5 SD below mean) displayed in black
√ cross-hatched areas = area above threshold value but with abnormal perfusion during stress indicating reversible defect

Common Artifacts in Myocardial Perfusion Imaging

1. Patient motion artifact
   ◊ Motion ≥ 2 pixels is unacceptable!
   (a) superior → inferior
   (b) laterally
   (c) "upward creep" ← increase of respiratory excursion after strenuous exercise
   √ heart in different locations on adjacent SPECT projection images
   √ "apical flame / hurricane" sign = artifactual perfusion defect in apical septum + mild offset of septal aspect of LV relative to lateral aspect + tail of activity extending superiorly from distal LV on short-axis views resembling depiction of a hurricane on weather maps
   Remedy: (1) repeat imaging without delay / reinjection → ^{99m}Tc-labeled radiotracers remains relatively fixed for as long as 2 hours
   (2) use of motion correction software → eliminates misregistration due to slight / moderate motion
2. Misregistration artifact
   = patient motion between sequential acquisition of low-dose CT data obtained for attenuation correction and SPECT image
   Remedy: use of coregistration software for precise superimposition of CT + SPECT
3. Left bundle branch block artifact
   Effect: decrease in septal blood flow at higher heart rate ← asynchronous septal contraction ← perturbed activation sequence + incomplete relaxation of septum during diastole
   √ apparent septal defect typically sparing apex and anterior wall (often more pronounced during stress induced by exercise / dobutamine instead of vasodilators that have a limited effect on heart rate)
   √ asynchronous / hypokinetic / paradoxical septal wall motion with preserved septal wall thickness
4. Normal prominent apical thinning
   √ apparent perfusion defect with matching stress and rest perfusion pattern
   ◊ Best seen on vertical and horizontal long-axis images + polar map display
   √ normal wall motion + normal wall thickness
5. Lung activity increased ← severe left ventricular dysfunction

6. RV uptake usually RV intensity 50% of peak LV intensity; ↑ in
   (a) RV hypertrophy ← pulmonary HTN
   (b) globally reduced LV uptake
7. Extracardiac activity
   › skin / clothing contamination
   › intense subdiaphragmatic activity from liver / GI tract ← hepatobiliary excretion of ^{99m}Tc-labeled radiotracers

   Effect: (1) Scatter radiation → apparent increased perfusion in inferior myocardial wall masking true perfusion defect
   (2) Normalized to highest count activity apparent LV activity relatively low → simulating extensive perfusion defect

   √ ramp artifact
   = band of pixels with negative counts around hot objects during SPECT reconstruction

   Remedy: (1) Repeat acquisition after delay → clearance of radiotracer superimposed on heart
   (2) Repeat imaging in prone position
   (3) Combination of vasodilator administration with low-level exercise protocol → reduction of splanchnic blood flow may prevent subdiaphragmatic activity
   (4) Patient drinks water to clear stomach

   › neoplastic lesion lung, breast, sarcoma, lymphoma, thymoma, parathyroid tumor, thyroid abnormality, kidney tumor, liver tumor
8. Attenuation (in up to 40% of all studies)
   › overlapping breast tissue (women)
   › diaphragm (men) → affects inferior myocardial wall

   Effect: artifactual activity decrease in anterior myocardial wall ± septal and lateral walls

   Clue: (1) Apparent perfusion defect present on stress-rest set of images (without change in position)
   (2) Normal LV wall motion and wall thickness
   (3) Noncoronary distribution of abnormality
   (4) Large dense breasts at cinematic review of raw images

   Remedy: (1) Attenuation correction method: like low-dose breath-hold CT on hybrid SPECT/CT
   (2) Repeat imaging in prone position

KAPOSIFORM HEMANGIOENDOTHELIOMA

= vascular neoplasm of borderline malignancy + intermediate aggressiveness
Associated with: Kasabach-Merritt syndrome
Location: extremity, trunk, head and neck
Spread: to regional lymph nodes (rare)
MR:
√ ill-defined margins with involvement of multiple tissue planes + destructive changes

√ small feeding + draining vessels
√ hemosiderin deposits
DDx: infantile hemangioma

KAWASAKI DISEASE

= MUCOCUTANEOUS LYMPH NODE SYNDROME
= acute febrile generalized multisystem vasculitis of unknown cause involving medium-sized (large + small) arteries with a HALLMARK predilection for coronary arteries
◊ Leading cause of acquired pediatric heart disease in developed countries; 2nd most common pediatric vasculitis
Incidence: 20.8÷100,000 annually in children < 5 years of age; highest in Asian countries (Japan, Korea)
Cause: unknown; probable activation of immune system by an infectious trigger in a genetically susceptible host
Histo: necrotizing panvasculitis
Age: < 5 years of age (in 85%); peak age of 2–3 years; M÷F = 1.6÷1.0
Associated with: polyarthritis (30–50%), aseptic meningitis (25%), hepatitis (5–10%), pneumonitis (5–10%)
Seasonal variation: peaks in winter
Clinical phases:
(1) Acute phase (lasts 11 days): fever, nonexudative bulbar conjunctivitis, erythema of lips + oral mucosa, rash; ± pericarditis, myocarditis, abdominal pain, ascites, GB hydrops
(2) Subacute phase (lasts 2 weeks): resolution of fever, coronary artery aneurysms may develop; highest risk of sudden cardiac death
(3) Convalescent phase: 4–8 weeks after onset

- abrupt onset of high fever > 5 days
- mucosal reddening: injected fissured lips, injected pharynx, strawberry tongue in 99%
- maculopapular rash on extensor surfaces (99%)
- bilateral nonpurulent conjunctivitis (96%)
- erythema of palms + soles with desquamation (88%)

@ Cardiovascular system (⅓)
1. Coronary artery abnormality (15–25%)
◊ Perform cardiac ECHO at diagnosis, at 2 weeks, and at 6–8 weeks after onset of illness!
√ mild coronary artery dilatation (in up to 50%)
√ **coronary artery aneurysm**: LCA (⅔), RCA (⅓); proximal segment in 70%; as early as 3 days after onset of illness; 48% regress, 37% diminish in size
Risk factors: male sex, extremes of age, prolonged fever, delay in diagnosis, persistent fever after treatment
√ coronary artery stenosis (39%) ← thrombus formation in aneurysm with intimal thickening
√ coronary artery occlusion (8%) in aneurysms > 9 mm
2. Myocarditis (25%)

3. Pericarditis
4. Valvulitis
5. Atrioventricular conduction disturbance

Coronary artery involvement is the most characteristic manifestation of Kawasaki disease. Other medium-sized muscular arteries may also be involved.

@ CNS
√ subdural effusion
√ cerebral infarction, atrophy
√ lesion with reversible T2 hyperintensity in splenium of corpus callosum + subcortically
√ posterior reversible encephalopathy syndrome

@ Neck
• firm nonfluctuant cervical lymphadenopathy (82%), unresponsive to antibiotics
√ typically unilaterally enlarged nonsuppurative lymph nodes

@ Abdomen
√ intestinal pseudoobstruction
√ focal colitis
√ bowel infarction → ischemic stricture
√ transient gallbladder hydrops (15%)

Prognosis: 0.4–3.0% mortality (from myocardial infarction / myocarditis with congestive heart failure / rupture of coronary artery aneurysm)

Rx: aspirin (100 mg/kg per day) + gamma globulin

DDx: infantile polyarteritis

LEFT AORTIC ARCH WITH ABERRANT RIGHT SUBCLAVIAN ARTERY

= right subclavian artery arises as 4th branch from proximal descending aorta = arteria lusoria

Prevalence: 0.4–2.3% of population; in 37% of Down syndrome children with CHD;

◊ Most common congenital aortic arch anomaly!

Associated with: (1) Absent recurrent pharyngeal nerve (2) CHD in 10–15%

• asymptomatic / **dysphagia lusoria** (rare)
[*lusoria* = *lusus naturae,* Latin = freak / mutant / monster of nature]

Course: (a) behind esophagus (80%)
(b) between esophagus + trachea (15%)
(c) anterior to trachea (5%)

√ soft-tissue opacity crossing the esophagus obliquely upward toward the right shoulder (PATHOGNOMONIC)
√ masslike opacity in right paratracheal region
√ rounded opacity arising from superior aortic margin posterior to trachea + esophagus on LAT CXR
√ dilated origin of aberrant right subclavian artery (in up to 60%) = **diverticulum of Kommerell** = remnant of embryonic right arch
√ unilateral L-sided rib notching (if aberrant right subclavian artery arises distal to

coarctation)

LIPOMATOUS HYPERTROPHY OF INTERATRIAL SEPTUM

= LHIAS = excessive deposition of brown fat in interatrial septum

Prevalence: 3%; ↑ with older age

Associated with: obesity, pulmonary emphysema

Dx: thickening of interatrial septum > 2 cm (transverse diameter)

Histo: unencapsulated infiltration of adipocytes (brown fat) between atrial muscle cells, NOT true neoplasm

Brown fat: increased vascularity + high density of mitochondria → generation of heat

- commonly asymptomatic, more commonly female

Site: at level of fossa ovalis BUT with sparing of fossa ovalis

√ fatty mass of dumbbell shape ← sparing of fossa ovalis

√ no contrast enhancement

√ increase in mediastinal and epicardial fat

√ ± focally increased FDG activity = mean SUV of 1.84 (range, 0.48–3.48) ← metabolically active brown fat

DDx: potential imaging pitfall suggesting infectious /inflammatory / neoplastic lesion

Cx: supraventricular arrhythmias, vena caval obstruction

LEIOMYOSARCOMA OF IVC

= rare slow growing neoplasm; < 300 patients in literature

◊ Most common primary tumor of the IVC

◊ 2nd most frequent retroperitoneal neoplasm in adults

Age: 5th–6th decade; M÷F = 1÷2 to 1÷3

Growth patterns: extraluminal (62%), intraluminal (5%), combined extra- and intraluminal (33%)

Histo: atypical interlaced pattern with sweeping bundles of spindle-shaped cells with elongated / occasionally truncated blunt-ended nuclei

- most common:
  - exhaustion, abdominal pain, weight loss
  - abdominal mass / swelling, nausea, vomiting
- late stage:
  - abdominal distention, changes in defecation habits
  - shortness of breath ← decreased cardiac return
  - leg edema, back / radicular pain, frequent urination
  - elevated liver functions, jaundice

Location:

(a) upper IVC = hepatic vein to right atrium (24%) → Budd-Chiari syndrome from sudden / gradual occlusion of hepatic veins / IVC / both

(b) middle IVC = hepatic to renal veins (42%) → nephrotic syndrome

(c) lower IVC = infrarenal area (34%) → lower extremity edema

(d) entire length of IVC (10–17%)

Spread to: liver, lung, lymph nodes, brain, peritoneum; skin, soft tissue, bone, kidney, omentum

(less common)
◊ Distant seeding in 40% at presentation!

√ lobulated well-defined heterogeneous tumor exhibiting signs of hemorrhage
√ rarely necrotic predominantly cystic mass
√ venous dilatation + total / near-complete vessel obstruction
√ calcification unusual
√ collateral pathways bypassing IVC: hemiazygos, azygos
√ tumor extension from IVC into right atrium / pulmonary artery

US:
√ blood flow in IVC / hepatic veins may be absent / reversed / turbulent (depending on degree of obstruction)
√ tumor vascularity (DDx from bland thrombus)

CT:
√ irregular contrast enhancement of tumor
√ mass of intermediate attenuation mass

Prognosis: local recurrence (40–77%)

DDx: retroperitoneal tumor compressing / invading IVC; bland thrombus

DDx of tumor extension into right atrium:
renal cell carcinoma, hepatocellular carcinoma

LYMPHATIC DYSPLASIA

Primary Lymphatic Dysplasia

• uni- / bilateral swelling of lower / upper extremities
› resembles other angiodysplastic syndromes:
1. Klippel-Trénaunay-Servelle syndrome
= venous + lymphatic abnormalities
2. Klippel-Trénaunay-Weber syndrome
= venous + lymphatic + arterial disturbances
3. Milroy disease
= inherited autosomal disorder with high penetrance characterized by lymphedema of one / both lower /upper extremities, face, other body parts

Secondary Lymphatic Dysplasia

= obstruction of lymph flow from an acquired cause

Cause:
1. Treatment of cancer: obliteration of lymph nodes by excision or irradiation
◊ Lymphedema may appear months to years after treatment ← gradual deterioration in intrinsic contractile force of lymphatic wall / valve incompetence
2. Filariasis
= nematode (Wuchereria bancrofti, Brugia malayi) resides within peripheral lymphatic vessels + nodes + obstructs lymph flow
• elephantine / pachydermatous extremities / genitalia
• chyluria, hydrocele, chylous reflux (chylometrorrhagia, chylous vesicles), genital edema, massive breast engorgement

3. Long-standing venous disease / following venous stripping
4. Lymphatic obstruction by cancer, Kaposi sarcoma
5. Lymphatic inflammation: topical use of Cantharone ® (for eradication of plantar warts); injection treatment of varicosities
6. Minor trauma to soft tissue / bone
7. Sedentary condition: eg, confinement to wheelchair
8. Morbid obesity
9. Lymphedema tarda
   = congenital lymphedema with delayed manifestation secondary to superimposed secondary cause

LYMPHEDEMA

Primary Lymphedema

• no history of cancer chemotherapy, nodal extirpation / irradiation, severe trauma

Age: birth to > 25 years

Cause: primary / acquired lymphatic disorder

√ complete absence / delay of radiotracer transport

√ absence / paucity of lymphatic collectors (truncal flow)

√ intense dermal dispersion / backflow

• chylous skin vesicles; external leakage of milky lymph

√ lymphatic dysplasia may involve viscera

Pitfall: subcutaneous injection leads to factitious failure of radiotracer movement

Congenital Lymphedema

Age: birth to 5 years

Lymphedema Precox

Age: puberty to 25 years

(a) congenital

√ lack of lymph collectors, dermal diffusion, delayed transport

(b) acquired

√ intact collectors, rapid regional transport, delayed dermal diffusion

Secondary Lymphedema

√ prominent lymphatic trunks:

√ long-standing lymphatic obstruction leads to "die-back" (obliteration) of lymphatics ← intraluminal coagulum-gel deposition / reactive inflammation

√ dermal diffusion (backflow) of variable intensity

√ delayed radiotracer transport

√ faintly visualized regional lymph nodes

LYMPHOMA OF HEART

PET:

√ difficult to differentiate from normal myocardial uptake

DDx: (1) Metastasis: lung cancer, malignant melanoma

(2) Cardiac angiosarcoma (involving large areas of heart, more aggressive with penetration of valves + great vessels, central necrosis, prominent enhancement)

Secondary Cardiac Lymphoma

Prevalence: in 16–28% on autopsy for NHL; pericardial involvement more frequent than for primary; more common in immunocompromised patients

Secondary cardiac involvement by lymphoma, either through direct extension or via hematogenous spread, is more common than primary cardiac lymphoma.

Primary Cardiac Lymphoma

= lymphoma that involves only heart ± pericardium at time of diagnosis (extremely rare)

Mean age: 60 (range, 13–90) years

Predisposed: immunocompromised patients, esp. AIDS

Path: multiple firm nodules; contiguous invasion of pericardium

Histo: typically NHL: well-differentiated B-cell lymphoma, follicular center cell lymphoma, diffuse large cell lymphoma, undifferentiated Burkitt-like lymphoma

The most common symptoms of cardiac lymphoma are dyspnea, congestive heart failure, pericardial effusion, hemopericardium, arrhythmias and nonspecific EKG abnormalities (AV block).

- chest pain; unresponsive rapidly progressive heart failure
- cardiac tamponade, SVC syndrome

Location: RA > RV > LV > LA > atrial septum > ventricular septum; > 1 chamber (75%)

When infiltration beyond the myocardium occurs, the right atrium is most commonly involved, with subsequent venous extension leading to SVC / IVC thrombosis.

A curious feature of cardiac lymphoma:

√ tendency of tumor to extend along epicardial surfaces → primarily encasing adjacent structures like coronary arteries and aortic root!

√ massive pericardial effusion

CXR:

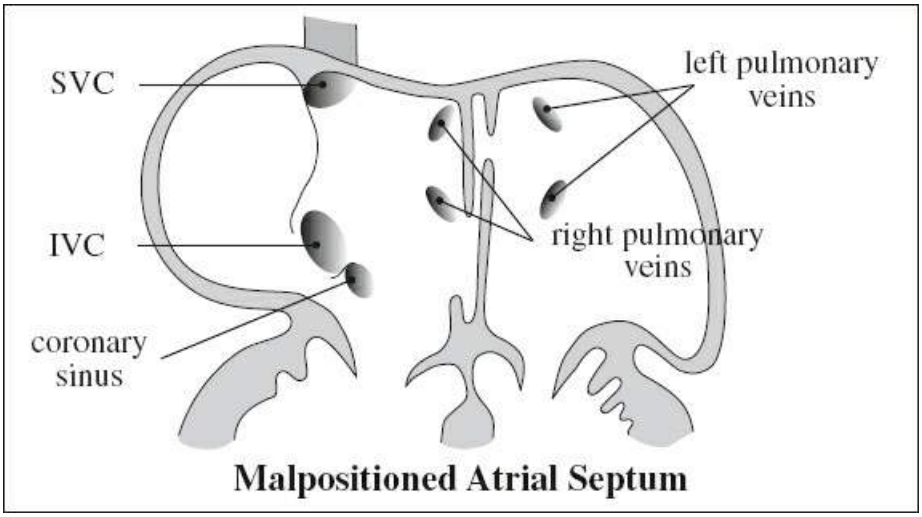
√ cardiomegaly

√ signs of CHF

√ massive pericardial effusion

ECHO:

√ hypoechoic myocardial masses in RA / RV



√ pericardial effusion

CT:

√ hypo- / isoattenuating masses relative to myocardium

√ heterogeneous enhancement of masses

MR:

√ poorly marginated heterogeneous lesions of iso- to hypointensity relative to myocardium on T1WI

√ heterogeneously hyperintense to myocardium on T2WI

√ heterogeneous enhancement with gadolinium with areas of low enhancement in center of lesion

Dx: positive cytology in pericardial fluid (in 67%); exploratory thoracotomy with biopsy of cardiac tissue

Prognosis: invariably very poor

Primary Effusion Lymphoma

= PEL = BODY CAVITY LYMPHOMA

Prevalence: 4% of all HIV-associated NHL

Associated with: concomitant diagnosis of Kaposi sarcoma

Histo: unique subgroup of B-cell lymphoma with features of both high-grade anaplastic and B-cell immunoblastic lymphoma

CXR: √ cardiomegaly

CT: √ massive pericardial effusion

MALPOSITION OF SEPTUM PRIMUM

= anomalous drainage of normally connected pulmonary veins ← leftward deviation / curvature of septum primum

Associated with: complex congenital heart defects, heterotaxy, polysplenia

√ leftward curvature of atrial septum

√ anomalous drainage of right upper pulmonary vein into RA

Variations: ± right lower pulmonary vein ± left pulmonary veins (in extreme degrees of

malposition)
√ ± left heart hypoplasia ← lack of left heart filling
Rx: resection + repositioning of atrial septum in a more normal position

MAY-THURNER SYNDROME

= ILIAC VEIN COMPRESSION SYNDROME = ILEOCAVAL COMPRESSION SYNDROME = COCKETT SYNDROME
[Robert May (1912–1984), surgeon in Innsbruck, Austria]
[Josef Thurner (1927–????), pathologist in Salzburg, Austria]
= obstruction of left common iliac vein caused by crossing of right common iliac artery
Pathophysiology:
(a) extrinsic : physical entrapment with compression of left common iliac vein (CIV) by right common iliac artery against underlying vertebral body → chronic venous stagnation → chronic left lower extremity swelling ± thrombosis of left iliac vein + femoral vein
(b) intrinsic: chronic repetitive pulsatile force of the right common iliac artery → intimal hypertrophy → formation of endovascular spur (= intravenous web / band) in left CIV
Path: spurlike projection in proximal left CIV in 22% (autopsy), in 49–62% of left iliofemoral thrombosis
Risk factors: surgery, injury, pregnancy, oral contraceptive use
Incidence: 0.2% annually in patients evaluated for venous thrombosis of left lower extremity
Age: 2nd–4th decade; M < F
• persistent left lower extremity swelling without obvious cause
• exertional pain
• varicose veins, venous eczema, hyperpigmentation
√ compression of left common iliac vein on CT / venography
√ tortuous pelvic venous collaterals joining contralateral veins
Prognosis: 60% of individuals with May-Thurner syndrome develop postthrombotic syndrome at some time during their lives
Cx: deep vein thrombosis (L÷R = 5÷1), chronic venous stasis ulcer; pulmonary embolism; phlegmasia cerulea dolens
Rx: (1) Endovascular stent after catheter-directed thrombolysis (95% success rate)
(2) Surgery: vein-patch angioplasty, relocation of right common iliac artery behind vein / IVC, contralateral saphenous vein bypass graft to ipsilateral common femoral vein with creation of a temporary AV fistula (Palma crossover)

MEDIAN ARCUATE LIGAMENT COMPRESSION

= MALS = CELIAC AXIS COMPRESSION SYNDROME = DUNBAR SYNDROME
= dynamic compression of celiac artery (± superior mesenteric artery) by median arcuate ligament → relieved by caudal movement of celiac artery with inspiration
Cause: abnormally cephalad origin of celiac artery / abnormally low median arcuate ligament
Median arcuate ligament:
archlike fibrous band connecting diaphragmatic crura on both sides of aortic hiatus passing
(a) usually superior to celiac axis at L1
(b) low anteriorly over celiac axis (in 10–24%)

Age: 30–84 years; M÷F=2÷3; especially young thin women
Incidence: 50–60% stenosis in 5–12% of healthy adults during inspiration / in 16% during expiration
• often postprandial epigastric pain, weight loss
• abdominal bruit with expiration
◊ Isolated compression of celiac axis during expiration may not be clinically significant!
CTA, DSA, MRA:
√ focal narrowing in proximal celiac axis (more prominent in expiration → superior movement of aorta + celiac artery
◊ Narrowing observed during inspiration → likely clinically significant!
√ superior indentation of proximal celiac a. creating a CHARACTERISTIC "hooked" appearance (SAG plane!)
√ direct visualization of median arcuate ligament
√ poststenotic dilatation of celiac a.
√ collateral filling via SMA + pancreaticoduodenal arcades
√ absence of atherosclerotic changes in adjacent aorta and proximal celiac segment
US:
√ peak systolic velocity in celiac artery ≥ 250 cm/s (70–99% stenosis) or in SMA ≥ 275 cm/s (70–99% stenosis)
√ normalization of elevated velocity during deep inspiration / standing upright position
Dx: lateral aortography / reformatted MDCT
Rx: surgical division of median arcuate lig. (50% long-term cure) ± celiac artery stenting (does not always relieve symptoms)
DDx: fixed celiac stenosis (atherosclerosis, vasculitis)

MICROSCOPIC POLYANGIITIS

= MICROSCOPIC POLYARTERITIS = HYPERSENSITIVITY VASCULITIS = LEUKOCYTOCLASTIC VASCULITIS
= pauci-immune necrotizing small-vessel angiitis without granulomatous inflammation
Path: necrotizing arteritis identical to polyarteritis nodosa but in vessels smaller than arteries (= arterioles, venules and capillaries)
Trigger: drugs (eg, penicillin), microorganisms, heterologous proteins, tumor antigens
• hemoptysis, hematuria, proteinuria
• abdominal pain, GI bleeding, muscle pain + weakness
• ANCA (antineutrophil cytoplasmic autoantibodies) in > 80%
• negative serologic tests for hepatitis B
Location: skin, mucous membranes, lung, brain, heart, GI tract, kidney, muscle
◊ Most common cause of pulmonary-renal syndrome!
@ Kidney
√ glomerulonephritis (90%)
@ Lung
√ pulmonary infiltrates ← capillaritis
@ CNS (involved in 37–72%)
√ mononeuritis multiplex

√ cerebral hemorrhage, nonhemorrhagic cerebral infarction
√ pachymeningitis
√ variable degrees of small-vessel disease involving white and gray matter

Rx: removal of offending agent

MITRAL REGURGITATION

= MITRAL INSUFFICIENCY

= most common manifestation of mitral valve dysfunction of any component (mitral valve annulus, leaflets, chordae tendineae, papillary muscle)

Hemodynamics:

during LV systole → backward flow of blood from LV into LA → ⇑ volume of blood under elevated pressure → dilatation of LA; ⇑ increase in LV diastolic volume with little increase in LV diastolic pressure (= increase in preload without increase in afterload = ↑ ejection fraction + ↑ LV stroke volume)

Quantification of Severity of Mitral Regurgitation:

Degree	*Regurgitant Volume [mL/beat]*	*Regurgitant Fraction [$Vol_{regurge}$ / Vol_{stroke}]*
Mild	< 30	< 30%
Moderate	30–59	30–49%
Severe	> 60	> 50%

The severity of mitral regurgitation can be quantified with CT / MRI by calculating the regurgitant volume and regurgitant fraction!

ECHO:

√ left ventricular volume overload:
  √ normal-sized / enlarged LV
  √ increased septal + posterior wall motion
√ increased EF slope
√ early closure of aortic valve (LV stroke volume partially lost to LA)
√ left atrial enlargement (in chronic MV insufficiency)
√ bulging of interatrial septum to the right during systole

Rx: surgical valve repair / replacement (if LV ejection fraction < 60% / LV end-systolic diameter > 40 mm)

Acute Mitral Regurgitation

Cause:

1. Spontaneous rupture of chordae tendineae
2. Myocardial infarction → rupture / dysfunction of papillary muscle (posteromedial > anterolateral papillary muscle)
3. Bacterial (= infectious) endocarditis with rupture of chordae tendineae / leaflet perforation
4. Periprosthetic valve leak

• markedly elevated LA pressure

√ pulmonary venous hypertension with engorged pulmonary vessels and cephalization (less

than with mitral stenosis)
√ symmetric interstitial / alveolar pulmonary edema:
√ asymmetric right upper lobe edema (9%) ← preferential flow of regurgitant jet into pulmonary vein of RUL (PATHOGNOMONIC)
√ limited cardiac enlargement

Chronic Mitral Regurgitation

Cause:

1. Rheumatic heart disease ← acute rheumatic fever
   (a) isolated: frequently seen in children
   (b) uncommon in adults (mostly combined with stenosis)
2. Mitral valve prolapse syndrome
3. Atrial myxoma
4. Coronary artery disease = ischemic cardiomyopathy → regional wall motion abnormality, LV / annular dilatation → functional mitral regurgitation
5. Idiopathic hypertrophic subaortic stenosis (IHSS)
6. Myxomatous degeneration of mitral valve: eg, Marfan syndrome, SLE
7. Mitral annulus calcification
8. Dilated / hypertrophic obstructive / amyloid cardiomyopathy → severe dilatation of LV → dilatation of mitral ring
9. Congenital heart disease: short / abnormally inserted chordae tendineae; persistent ostium primum ASD with cleft mitral valve; corrected transposition with Ebstein-like anomaly

√ massively dilated left atrium:
√ posterior LA wall calcification (McCallum patch)
√ enlarged LA appendage (with history of previous rheumatic heart disease)
√ elevation of left mainstem bronchus
√ enlarged pulmonary arteries ← venous hypertension
√ marked LV enlargement (cardiothoracic ratio > 0.55)
√ left heart failure
√ mitral annular calcification (frequent)

MITRAL STENOSIS

= characterized by fusion of edges of anterior + posterior leaflets along commissure

Cause: rheumatic heart disease (5–15 years after initial episode of rheumatic fever); carcinoid syndrome; eosinophilic endocarditis; rheumatoid arthritis; SLE; mass obstructing LV inflow (tumor, atrial myxoma, thrombus); congenital (parachute MV, double-orifice MV)

Mitral stenosis caused by rheumatic disease may have distinctive morphologic features unlike those of mitral stenosis produced by other causes!

M÷F = 1÷8

Hemodynamics:

increasing transvalvular pressure gradient (with mitral valve area of < 2.5 cm^2) → rise in LA + pulmonary vascular pressure throughout systole and into diastole → compensatory dilation of LA + pulmonary venous hypertension; development of medial hypertrophy + intimal

sclerosis in pulmonary arterioles → postcapillary pulmonary arterial hypertension; RV hypertrophy; tricuspid regurgitation; RV dilatation; right heart failure

May be associated with: ASD = Lutembacher syndrome (in 0.6%) causing L-to-R shunt

- history of rheumatic fever (in 50%)
- dyspnea on exertion, orthopnea, paroxysmal nocturnal dyspnea ← pulmonary hypertension; atrial fibrillation
- systemic embolization from thrombosis of atrial appendage

Stages (according to degree of pulmonary venous hypertension):

Stage 1 : loss of hilar angle, redistribution
Stage 2 : interstitial edema
Stage 3 : alveolar edema
Stage 4 : hemosiderin deposits + ossification

Quantification of Severity of Mitral Stenosis:

Degree	*Valve Area in Diastole [cm^2]*	*Mean Diastolic Gradient [mmHg]*
Normal	4.0–6.0	0
Mild	1.6–3.9	< 5
Moderate	1.0–1.5	5–10
Severe	< 1.0	> 10

Quantifiable parameters of severity of mitral stenosis are planimetric valve area + mean diastolic gradient across the valve on velocity-encoded phase-contrast cine images!

@ Left heart
√ enlarged LA ± wall calcification:
√ "double density" seen through right upper cardiac border (AP view)
√ bulge of superior posterior cardiac border below carina (lateral view)
√ splaying of mainstem bronchi
√ esophagus displaced toward right + posteriorly
√ dilated left atrial appendage (not present with retracting clot), in 90% associated with rheumatic heart disease

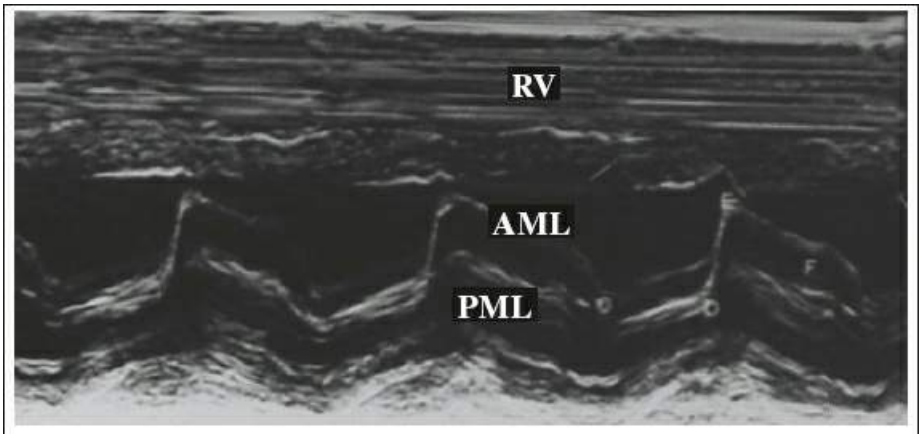
◊ Dilatation of left atrial appendage + calcification = rheumatic heart disease!

√ calcification of valve leaflets in 60% of severe mitral stenosis, usually > 50 years of age (DDx: calcification of mitral annulus, calcified chronic LA thrombus)
√ normal / undersized LV ← LV hypertrophy
√ small aorta ← decrease of forward cardiac output

@ Right heart
√ prominent pulmonary artery segment ← precapillary pulmonary hypertension
√ RV hypertrophy
√ dilatation of RV ← tricuspid insufficiency / pulmonary hypertension
√ increase in cardiothoracic ratio
√ diminution of retrosternal clear space
√ IVC pushed backward (lateral view)

@ Lung
√ pulmonary arterial enlargement ← pulmonary hypertension

√ pulmonary vascular cephalization = redistribution of pulmonary blood flow to upper lobes (= postcapillary pressure 16–19 mmHg):
  √ diameter of pulmonary artery > corresponding bronchus
  √ diameter of upper lobe vessels > lower lobe vessels
√ interstitial pulmonary edema (= postcapillary pressure 20–25 mmHg)
  DDx: interstitial fibrosis / deposition of hemosiderin-laden macrophages (= "brown induration") of chronic mitral valve stenosis
√ alveolar edema (= postcapillary pressure 25–30 mmHg)



M-mode Echogram in Mitral Valve Stenosis
anterior tracking of posterior mitral valve leaflet (pML)

DDx: diffuse alveolar hemorrhage = diffuse confluent acinar / ground-glass areas of increased opacity sparing the lung periphery (= "window frame" effect)
√ pulmonary hemosiderosis:
  √ 1–3 mm ill-defined nodules
  √ fine / coarse reticular areas of increased opacity with bias for middle and lower lungs
√ pulmonary ossification (3–13%) = densely calcified 1–3–5 mm nodules (± trabeculae) mainly in middle and lower lungs

ECHO:
√ thickening of leaflets toward free edge (fibrosis, calcification)
√ flattening of EF slope = MV remains open throughout diastole ← persistently high LA pressure (crude index of severity of MV stenosis)
√ diastolic anterior tracking of pML in 80% ← diastolic anterior pull by larger + more mobile aML
√ diastolic doming of MV leaflets
√ commissure fusion = increased echodensity + decreased leaflet motion at level of commissure
√ <u>area reduction of MV orifice:</u> *(see under Quantification)* (reproducible to within 0.3 cm^2)
√ shortening + fibrosis of chordae tendineae
√ abnormal septal motion = early diastolic dip of IVS due to rapid filling of RV (in severe MV stenosis)
√ slowed LV filling pattern of small LV

√ dilatation of LA (> 5 cm increases risk of atrial fibrillation + left atrial thrombus)
√ DE opening amplitude reduced to < 20 mm indicating loss of valve pliability (DDx: low cardiac output state)
√ absent A-wave common (atrial fibrillation)
√ increase in valve gradient + pressure halftime on Doppler

Rheumatic Mitral Stenosis

√ "fish-mouth" appearance of thickened valve with commissural fusion on short-axis images
√ "hockey-stick" appearance of bowed thickened fibrotic anterior leaflet during diastole on 2- / 4-chamber images

Rx: (1) Commissurotomy / balloon valvuloplasty if valves pliable + calcium absent + MV regurgitation absent
(2) Valve replacement for symptomatic patients with severely stenotic valves

DDx: (1) Pseudomitral stenosis in decreased LV compliance (decreased EF slope, normal leaflet thickness + motion)
(2) Rheumatic mitral insufficiency (indistinguishable findings + evidence of LV volume overload)
(3) LA myxoma (mass behind MV + in LA)
(4) Low cardiac output (apparent small valve orifice)

Lutembacher Syndrome

= rheumatic mitral valve stenosis + ASD

MITRAL VALVE PROLAPSE

= MVP = systolic bowing of mitral leaflet ≥ 2 mm beyond annular plane into atrium
◊ Most common cause of nonischemic mitral regurgitation
At increased risk for: ventricular arrhythmia, sudden death
Prevalence: 2–6% of general population; 5–20% of young women; ? autosomal dominant inheritance
Age: commonly 14–30 years
Terminology:
(1) **billowing** leaflet = bowing of leaflet body
(2) **flail** leaflet = prolapse of free leaflet edge
Classification:
(1) **MVP syndrome** = systolic click + mid- to late-systolic murmur and classic echocardiographic criteria
Age: young woman
• benign clinical course
(2) **Myxomatous mitral valve disease** = thickened redundant valve leaflets (most common cause of MVP and mitral valve surgery)
= "Floppy mitral valve" = elongation of cusps + chordae tendineae → redundant valve tissue → prolapse into LA during systole
Age: older man
• higher risk for complications, frequently needing repair

Path: myxomatous proliferation of middle layer of MV leaflets, surface fibrosis of MV leaflets, thinning of chordae tendineae, myxomatous annulus

Associated with: Barlow syndrome = straight back syndrome

(3) **Secondary MVP**:

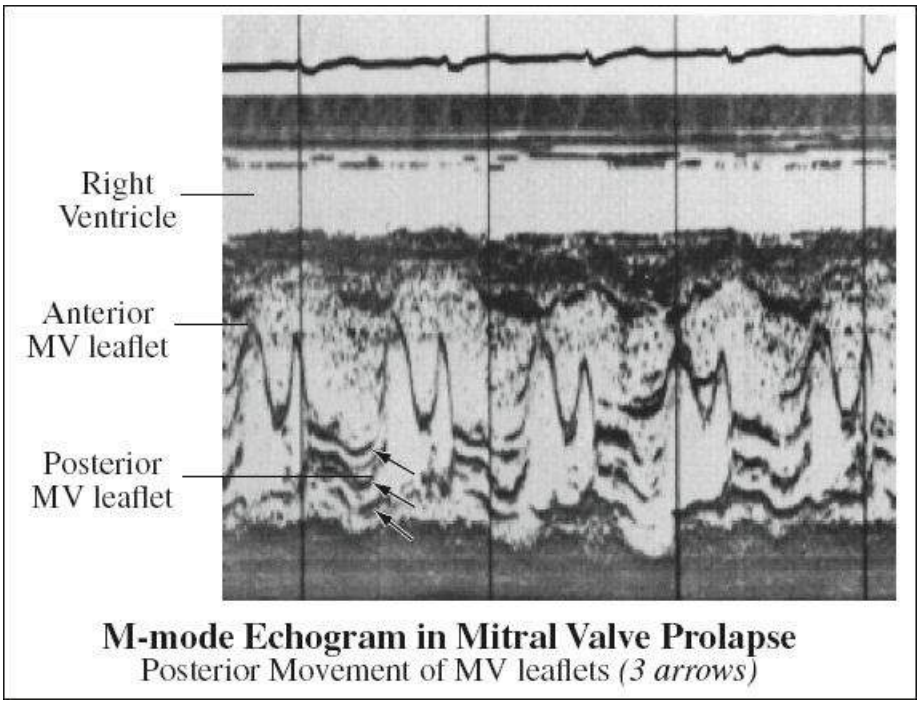
Associated with:

(a) Connective tissue disease: Marfan syndrome (MVP in 91%), Ehlers-Danlos syndrome (in 6%)

(b) CHD: ASD (MVP in 10%), coarctation of aorta (MVP in 2%)

(c) Skeletal abnormalities: scoliosis, straightening of thoracic spine, narrow anteroposterior chest dimension, pectus excavatum deformity of sternum

(d) ischemia / infarction with papillary muscle dysfunction / rupture or rupture of chordae tendineae, rheumatic mitral insufficiency, infective endocarditis, hypertrophic cardiomyopathy, primary pulmonary hypertension, tricuspid valve prolapse, ADPKD



M-mode Echogram in Mitral Valve Prolapse
Posterior Movement of MV leaflets *(3 arrows)*

To decrease mortality preoperative detection of coexisting coarctation of the aorta is important in patients with mitral regurgitation!

- arrhythmia, palpitation, chest pain, light-headedness, syncope
- responsible for midsystolic click + late systolic murmur (when associated with mitral regurgitation)

Location: middle scallop of posterior leaflet (P2 segment)

√ LA NOT enlarged (unless associated with significant mitral regurgitation)

ECHO:

√ interruption of CD line with bulge toward left atrium:

√ abrupt midsystolic posterior buckling of both leaflets (classic pattern)

√ "hammocklike" pansystolic posterior bowing of both leaflets
√ multiple scallops on mitral valve leaflets (short-axis parasternal view)
√ valve leaflets may appear > 5 mm thick (myxomatous degeneration + valve redundancy)
√ ± flail leaflet = eversion of mitral leaflet tip into atrium during systole (← rupture of chordae tendineae)
√ mitral valve leaflets passing > 2 mm posterior to plane of mitral annulus (apical 4-chamber view)
√ hyperactive atrioventricular groove
√ mitral annulus may be dilated > 4.7 cm^2

CT / MR:
√ leaflet thickness > 5 mm + flail leaflet

2- and 3-chamber views are preferred when assessing mitral valve prolapse!

DDx: (1) Pericardial effusion (systolic posterior displacement of MV leaflets + entire heart)
(2) Bacterial endocarditis (mimicked by locally thickened + redundant leaflets)

MYOCARDIAL INFARCTION

= MI = myocardial cell death ← prolonged ischemia overwhelming cellular repair mechanisms

Cause: luminal thrombosis (frequent) superimposed on coronary atherosclerosis, coronary spasm, embolism, > arteritis, dissection, congenital abnormalities, hypercoagulable states, cocaine

Pathophysiology:
↓ perfusion → ↓ tissue oxygenation → ↓ phosphocreatine → repolarization abnormalities → diastolic dysfunction → systolic dysfunction → ↓ adenosine triphosphate → edema → tissue necrosis

Time of dysfunction: loss of contractility (at 60 sec): loss of viability (at 20–40 min)

Wavefront phenomenon:
myocardial ischemia → zone of subendocardial infarction → extension to midmyocardial zone → transmural infarction (from subendocardial to subepicardial layers)

Size of infarct: microscopic < 10% of myocardium
moderate 10–30% of myocardium
large > 30% of myocardium

Incidence: 1,500,000 annually in USA resulting in 500,000 deaths (50% occur in asymptomatic individuals)

Peak age: 40–65 years; more severe + lethal in women

• ST-segment elevation MI (STEMI)
• atrioventricular block (common with inferior wall infarction as AV nodal branch originates from RCA); complete heart block has worse prognosis because it indicates a large area of infarction

CXR:
√ normal-sized heart (84–95%) in acute phase, if previously normal
√ cardiomegaly: high incidence of congestive heart failure with anterior wall infarction, multiple myocardial infarctions, double- and triple-vessel CAD, LV aneurysm

CECT:

√ perfusion defect within 60–90 sec after bolus injection
√ delayed enhancement of infarcted tissue peaking at 10–15 min (← accumulation of iodine in ischemic cells), size of enhanced area correlates well with size of infarct

MR:
√ no change / mildly decreased SI of myocardium on T1WI (= edema of myocardium)
√ high-intensity focus + wall thickening in region of acute infarction on T2WI ← myocardial edema
√ LV wall thinning + decreased SI on T2WI (in remote infarction)
√ increased intracavitary signal ← slow flow caused by stasis of blood adjacent to infarcted myocardium
√ regional wall-motion abnormalities on cine images
√ pericardial effusion (25%), possibly hemorrhagic

CEMR:
√ hyperenhancement = pooling of gadolinium within region of infarction on delayed images 20–30 min post injection:
  √ higher volume of distribution ← increased extracellular space ← myocyte death with membrane disintegration / cell rupture
  √ increased intracellular entry of gadolinium
  √ slow wash-in and washout ← capillary plugging
√ highlighting of infarcted tissue with contrast using magnetic susceptibility to selectively suppress signals from normal myocardium

Delayed-enhancement imaging is the most important technique + most accurate method for diagnosing MI or nonischemic cardiomyopathies, quantifying scar, assessing viability, and evaluating thrombus!

Cx: myocardium is prone to rupture during 3rd–14th day post infarction
Prognosis: 90–95% survival for hospital admissions

Left Ventricular Failure (60–70%)
• "cardiac shock" = systolic pressure < 90 mmHg
◊ Signs of pulmonary venous hypertension are a good predictor of mortality (> 30% if present, < 10% if absent)
√ progressive enlargement of heart
√ haziness + indistinctness of pulmonary arteries
√ ↑ size of right descending pulmonary artery > 17 mm
√ pleural effusion
√ septal lines
√ perihilar ± peripheral parenchymal clouding
√ alveolar pulmonary edema
Mortality: 30–50% with mild LV failure; 44% with pulmonary edema; 80–100% with cardiogenic shock; 8% in absence of LV failure

Ventricular Aneurysm (in 12–15% of survivors of MI)
= saccular protrusion of LV wall of mechanically weak necrotic / scarred fibrotic wall
Location: anterior + apical walls (70–85%)
√ wide-mouthed protrusion with thrombus (in 50%)

√ calcification of wall and thrombus
√ akinetic / dyskinetic wall section during systole
√ delayed hyperenhancement ← scarring
Cx: heart failure, ventricular arrhythmia, thromboembolism

Myocardial Rupture (in 3–20% of infarcts)

At increased risk: first MI, female, ≥ 60 years, multivessel disease, transmural MI involving 20% of wall, poor collateral supply, absence of ventricular hypertrophy, delayed initiation of thrombolytics

Path: myocardial rupture contained by parietal pericardium + thrombus + scar tissue = pseudoaneurysm (mouth smaller than actual size of aneurysmal segment) → high risk of expansion + rupture (30–45%)

• occurs usually on 3rd–5th day post MI

Location: free wall > septum; LV > RV; commonly at apex

√ enlargement of heart (slow leakage of blood into pericardium)

CEMR (delayed-enhancement MRI):

√ loss of continuity of myocardium with irregular margins
√ pericardial enhancement
√ dyskinetic section during systole + diastole

Prognosis: cause of death in 13% of all infarctions; mortality almost 100%

DDx: true aneurysm (mouth larger than size of aneurysmal segment; dyskinetic wall section during systole only)

Rupture of Papillary Muscle (1%)

Cause: infarction of posteromedial papillary muscle in inferior MI (common) / anterolateral papillary muscle in anterolateral MI (uncommon)

• sudden onset of massive mitral insufficiency
• unresponsive to medical management
√ abrupt onset of severe persistent pulmonary edema
√ asymmetric PVH in right upper lobe
√ minimal LV enlargement / normal-sized heart
√ NO dilatation of LA ← immediate decompression into pulmonary veins

Prognosis: 70% (80–90%) mortality within 24 hours (2 weeks)

Rupture of Interventricular Septum (0.5–2%)

= VENTRICULAR SEPTAL RUPTURE

• occurs usually within 2–21 days with rapid onset of L-to-R shunt
• Swan-Ganz catheterization: increase in oxygen content of RV, capillary wedge pressure may be within normal limits

Location: typically at apex

√ right-sided cardiac enlargement
√ engorgement of pulmonary vasculature:
√ asymmetric PVH of right upper lobe
√ NO pulmonary edema (DDx to ruptured papillary muscle)

Prognosis: 24% mortality within 24 hours; 87% mortality (> 90%) within 2 months (1 year)

Rx: emergency surgery (VSD patch repair + coronary artery bypass grafting)

Dressler Syndrome (3–4%)

= POSTMYOCARDIAL INFARCTION SYNDROME = LATE PERICARDITIS

Etiology: autoimmune reaction to myocardial infarction

Onset: 2–3 weeks (range 1 week–several months) following infarction

- relapses occur as late as 2 years after initial episode
- pleuritic chest pain, fever

√ thickening of pericardium
√ pericardial effusion
√ pleural effusion
√ pneumonitis

Right Ventricular Infarction

◊ RV involved in 33% of left inferior myocardial infarction
√ decreased RV ejection fraction
√ accumulation of ^{99m}Tc-pyrophosphate

Prognosis: in 50% RV ejection fraction returns to normal within 10 days

Cx: (1) Cardiogenic shock (unusual)
(2) Elevation of RA pressure
(3) Decrease of pulmonary artery pressure

MYOCARDITIS

= acute / chronic inflammation of the myocardium

Cause:

1. Infection: viral (Coxsackie B, other enteroviruses, herpesvirus, adenovirus, parvovirus B19, Epstein-Barr virus); bacterial (diphtheria, Streptococcus); parasitic (Trypanosoma cruzi)
2. Autoimmune process
3. Cardiotoxic drugs: anthracyclines, trastuzumab, catecholamines, chemotherapy
4. Hypersensitivity reaction
5. Myocardial infarction / mechanical injury / radiation Rx

Histo: lymphocytic infiltration associated with myocyte injury in the absence of ischemia

- usually asymptomatic; acute chest pain
- atrial / ventricular arrhythmias
- rapid recent onset of heart failure
- cardiogenic shock, sudden cardiac death (12%)
- CK-MB (creatine kinase - myocardial b fraction specific for heart muscle) with high specificity but limited sensitivity
- troponin I more often elevated than CK-MB

Sequela: dilated cardiomyopathy (in up to 10%)

Echocardiography (low sensitivity):

√ normal heart function or global / regional LV hypokinesis

MR:

√ patchy diffuse / nodular hyperenhancement in nonvascular distribution up to 4 weeks after infection ← inflammation and cell necrosis

Location: inferior and inferolateral myocardial segments

Site: subepicardial / midmyocardial

√ increased T2 signal

√ wall motion abnormalities in affected regions

Benefit: biopsy guidance to areas of higher pathologic yield

PET/CT:

√ increased metabolic activity in myocardium ← microvascular + myocyte damage + changes in fatty-acid metabolism

Dx: endomyocardial biopsy

MYXOMA

= most common benign primary cardiac tumor (true neoplasm) in adults; 40–50% of all cardiac tumors

Mean age: 50 (range, 11–82) years; 90% of patients are between ages 30 and 60 years; M÷F = 1÷1.7 to 1÷4

Etiology: ? overgrowth of trapped embryologic rest

Classification: sporadic type (most frequent); familial type (mean age of 24 years); complex type = Carney syndrome

Path: (a) papillary / villous pedunculated friable gelatinous tumor

(b) round / ovoid lobular smooth sessile tumor (25%) with firm surface
◊ No infiltration of underlying tissues!

Histo: composed of myxoma cells (= ovoid nucleus with large / inconspicuous nucleoli + abundant eosinophilic cytoplasm) forming rings / syncytia / cords; hypocellular amorphous acid mucopolysaccharide matrix in areas without fibrosis; hemorrhage and hemosiderin; fibrosis, calcifications (56%); covered by a mono-layer of endothelial cells (= endocardial tumor)

Mean size: 5.7 (range, 0.6–12.0) cm

- short history + rapid progression; dyspnea, chest pain
- constitutional symptoms (30%):
  - fever, malaise, weight loss, myalgia, arthralgia, lethargy
  - leukocytosis, anemia, elevated ESR, petechiae
  - hypergammaglobulinemia

  Cause: ? autoimmune phenomenon
- positional symptoms (ie, change with position) due to hemodynamic obstruction:
  - arrhythmia (20%), heart murmur
  - congestive heart failure (valve obstruction); syncope
- embolization (30–40%) to CNS, coronary artery, aorta, kidney, spleen, extremities, pulmonary artery ← tumor fragments / accumulated thrombus

Location: LA (75–80%); RA (10–20%); ventricle (5%); biatrial ← growth through fossa ovalis

Site: attached to interatrial septum by small stalk adjacent to or in fossa ovalis (75%) / to wall of cardiac chambers / to valve surfaces; may protrude into ventricle causing partial obstruction of atrioventricular valve

√ small myxomas produce no CXR findings
√ cardiomegaly
√ atrial obstruction (mimicking valvular stenosis)
√ persistent defect in atrium / diastolic defect in ventricle

A. LEFT ATRIAL MYXOMA (75–80%) with obstruction of mitral valve:
   √ pulmonary venous hypertension:
      √ pulmonary vascular redistribution
      √ interstitial pulmonary edema
   √ enlargement of LA
   √ NO enlargement of atrial appendage
   √ ossific lung nodules

   Cx: systemic emboli (27%) in 50% to CNS (= stroke / "mycotic" aneurysm) ← thrombotic nature of mass

B. RIGHT ATRIAL MYXOMA (10–20%) with obstruction of tricuspid valve:
   - peripheral edema, hepatic congestion, ascites ← potential obstruction of systemic venous return

   √ tumor calcification: R > L
   √ enlargement of RA
   √ prominent SVC, IVC, azygos vein
   √ decreased pulmonary vascularity
   √ pleural effusion (occasionally)

Cx: pulmonary emboli ← thrombotic nature of mass

ECHO: (2D-ECHO is study of choice)
- √ tumor attached by narrow stalk → transvalvular prolapse (DDx to thrombus)
- √ tumor mobility:
  - √ prolapse across AV valve during diastole
- √ tumor distensibility
- √ hyperechoic spherical mass:
  - √ internal hypoechoic areas (= hemorrhage, necrosis)
  - √ speckled echogenic foci (= calcifications)
  - √ frondlike surface projections

Doppler:
- √ valvular regurgitation

M-mode findings of only historical interest:
- √ dense echoes appearing posterior to aML soon after onset of diastole
- √ pML obscured
- √ tumor echoes can be traced into LA
- √ dilated LA
- √ reduced E-F slope

CT:
- √ well-defined spherical / ovoid intraluminal filling defect
- √ lobular / smooth surface contour
- √ tumor attenuation lower than unopacified blood ← gelatinous component
- √ heterogeneous texture ← hemorrhage, necrosis, cyst formation, fibrosis, calcification (16%), ossification

MR:
- √ heterogeneous signal intensity:
  - √ iso- / hypointense on T1WI relative to myocardium
  - √ hyperintense areas on T1WI ← older hemorrhage
  - √ (nearly always) markedly hyperintense on T2WI ← myxomatous tissue
  - √ areas of decreased SI ← calcifications, hemosiderin deposits, fibrous tissue
- √ heterogeneous contrast enhancement:
  - √ increased SI ← vascularity and inflammation
  - √ decreased SI ← necrotic areas
- √ CHARACTERISTIC mobility ± prolapse through AV valve (best seen on 4-chamber horizontal long-axis cine MRI) ← suspended by narrow stalk

PET:
- √ very low-grade / no significant FDG activity

Rx: urgent surgical excision ± valvuloplasty / valve replacement

Cx: malignant transformation (exceedingly rare)

Prognosis: 5–14% recurrence rate (multifocal myxomas); isolated cases of metastatic disease

DDx: (1) Thrombus (more likely in posterior location in LA and LV, NO contrast enhancement, NO transvalvular prolapse)

(2) Papillary fibroelastoma (also arises from narrow stalk, much smaller, different SI characteristics)

(3) Other cardiac tumors: sarcoma, malignant mesenchymoma, metastasis

Carney Complex

= CARNEY SYNDROME = COMPLEX MYOMA

[J. Aidan Carney (–), pathologist at Mayo Clinic, Rochester, Minnesota]

= autosomal-dominant inherited syndromic disorder

Prevalence: 7% of all myxomas; 150 patients identified since 1985 worldwide

Age: younger than patients with sporadic myxoma

- endocrine overactivity:
  - Cushing syndrome; sexual precocity; acromegaly

(a) Cardiac myxomas: multifocal (66%), outside left atrium, recurring at an increased rate after resection

(b) Hyperpigmented skin lesions: lentigines, ephelides, blue nevi

(c) Extracardiac tumors:

1. Pituitary adenoma
2. Myxoid fibroadenoma of the breast
3. Psammomatous melanotic schwannoma
4. Testicular tumor: large-cell calcifying Sertoli cell tumor
5. Primary pigmented nodular adrenocortical hyperplasia

N.B.: not related to Carney triad (pulmonary hamartomas, extraadrenal paragangliomas, gastric leiomyosarcoma)

NUTCRACKER PHENOMENON

= RENAL VEIN ENTRAPMENT SYNDROME

= entrapment of left renal vein (LRV) between SMA and aorta (= anterior nutcracker) / between aorta and underlying vertebral body in retroaortic LRV (*posterior* nutcracker)

Anterior nutcracker syndrome may occur simultaneously with SMA syndrome. Both are associated with a thin / asthenic body habitus, rapid weight loss, and loss of retroperitoneal fat.

Prevalence: rare (unknown);

◊ Insignificant anatomic compression is present in 72% of the general population!

Normal anatomy:

SMA arises from aorta at L1-2 forming an aortomesenteric angle (AMA) of 28–65°; duodenum is cushioned by retroperitoneal fat in mesenteric root maintaining an aortomesenteric space / diameter (AMD) of 10–34 mm

Pathophysiology:

squeezed left renal vein → increased venous pressure → intra- and extrarenal hypertensive valveless venous collaterals

(a) → increased capillary pressure → hematuria

(b) → reflux into left gonadal vein

» female: ovarian vein → congestion in ovarian and parametrial venous plexus = **pelvic congestion syndrome** (vulvar + pelvic + thigh varices, postcoital ache, pelvic pain, dysmenorrhea, dyspareunia)

» male: testicular vein → left-sided **varicocele**

Pathogenesis: steep angulation of SMA relative to aorta can predispose to nutcracker

syndrome → simultaneous SMA syndrome

Age: 3rd–4th decade; M < F

• intermittent asymptomatic mild microhematuria
• severe gross hematuria → passage of ureteral blood clots → left flank pain
• mild to severe orthostatic proteinuria

√ compression of left renal vein + prestenotic dilatation
√ reflux into dilated adrenal + gonadal veins
√ hilar + periureteric + perirenal + pelvic venous collaterals
√ decreased aortomesenteric space (AMD) of 3 mm
√ decreased aortomesenteric angle (AMA) of < 16°

US:
√ venous flow velocity of > 100 cm/s (78% sensitive, 100% specific)
√ peak systolic velocity ratio of > 4.7 at point of renal vein compression compared to hilar renal vein (100% sensitive, 90% specific)

IVP:
√ indentations / scalloping of renal pelvis / ureter ← enlarged retroperitoneal varices

Retrograde venography:
√ renal venous–caval pressure gradient > 3 mmHg (less than 1 mmHg in healthy subjects)

Rx: (1) Expectant: hyperalimentation in thin patient < 18 years
(2) Surgery (in severe cases): renal vein transposition, venous stent placement, left nephrectomy, renal autotransplantation to iliac fossa

PAPILLARY FIBROELASTOMA

= FIBROELASTIC PAPILLOMA = PAPILLOMA / MYXOMA / FIBROMA OF VALVES = GIANT LAMBL EXCRESCENCE
= MYXOFIBROMA = HYALINE FIBROMA
= rare benign excrescence predominantly affecting surface of cardiac valves

Prevalence: 25% of all cardiac valvular tumors (most common valvular tumor); 10% of all primary cardiac tumors (2nd most common primary benign cardiac neoplasm after myxoma + similar to lipoma)

Peak age: 7th and 8th decade; M÷F = 1÷1

Cause: ? reactive process, ? hamartoma

Path: gelatinous mass with "sea anemone" appearance ← multiple delicate branching papillary fronds attached to endocardium by short thin pedicle

Histo: avascular papilloma = avascular connective tissue composed of fibrous core + lined by a single layer of endothelium; scattered smooth muscle cells within papillary projections

• mostly asymptomatic (incidental finding at autopsy, surgery, echocardiography, cardiac catheterization)
• chest pain, dyspnea, embolic events (TIA / stroke from thrombi collecting on tumor)
• NO valvular dysfunction ← away from free edge of valve

Location: cardiac valves (> 90%): aortic (29%) > mitral (25%) > tricuspid (17%) > pulmonary valve (13%)

Site: NOT at free edge of valve
(a) AV valve: nonvalvular endocardial surface of atrium (frequently) / ventricle (16%)

(b) semilunar valve: nonvalvular endocardial surface of aorta

Size: usually < 1.0–1.5 cm in diameter (may be as large as 5 cm)

ECHO:

√ homogeneous mobile pedunculated mass:

√ elongated strandlike projection / well-defined head

√ CHARACTERISTIC stippled edge with a "shimmer / vibration" at interface between tumor and surrounding blood (DDx: amorphous thrombus)

√ flutters / prolapses with cardiac motion

√ turbulent blood flow

CT:

√ slightly hypoattenuating mass

MR: difficult to visualize on static fast SE images

√ intermediate SI / hypointense compared to myocardium

√ mobile mass (on cine gradient-echo images)

Rx: surgical excision ± leaflet repair / valve replacement

DDx: vegetation (destruction of valvular leaflets, valvular incompetence, fever, murmur, embolic events, small vessel vasculitis); thrombus; myxoma (slightly larger)

PATENT DUCTUS ARTERIOSUS

= PDA = persistence of left 6th aortic arch permeable ≥ 3 months after birth = L-to-R shunt

Prevalence: 9 (range, 5–10)% of all CHD; M÷F = 1÷2; in 1÷2,000 full-term infants, higher in prematurity

Cause: failure of immature ductus arteriosus to close ← persistent postnatal hypoxia + failure of ductus contraction

Associated with:

prematurity, birth asphyxia, high-altitude birth, maternal rubella syndrome, VSD, coarctation, trisomy 18 + 21, 4p syndrome, single gene mutation (Carpenter syndrome, Holt-Oram syndrome), X-linked mutations (incontinentia pigmenti)

Morphologic types (useful to select closure device):

A. (conical): √ ampulla at aortic end (most common type)

B. (window): √ ductus narrows at aortic end

C. (tubular): √ NO narrowing / constrictions

D. (complex): √ ductus with multiple constrictions

E. (elongated): √ bizarre configuration; constriction away from pulmonary artery end

Hemodynamics of PDA:

increased volume of blood flows from aorta → through PDA → pulmonary artery → lungs → left side of heart

→ pulmonary artery → lungs → left side of heart

RA	↔	RV	↔	Main PA	↑
Pulm. vessels	↑				
LA	↔/↑	LV	↔/↑	Ao	↑

- mostly asymptomatic; continuous murmur
- congestive heart failure (rare), usually by 3 months of age if L-to-R shunt large

• bounding peripheral pulses ← intraaortic pressure runoff through PDA

CXR (mimics VSD):

√ enlarged pulmonary artery segment
√ increase of pulmonary vasculature; less flow directed to LUL
√ ↑ ascending aorta + aortic arch (thymus may obscure this)
√ LA + LV enlargement
√ enlarged RV (only with pulmonary hypertension)
√ prominent ductus infundibulum (diverticulum)
= prominence between aortic knob + pulmonary a. segment
√ obscured aortopulmonary window
√ "railroad track" = calcified ductus arteriosus

ECHO:

√ LA÷Ao ratio ≥ 1.2÷1 (signalizes significant L-to-R shunt)

Angio:

√ catheter course from RA to RV, main pulmonary artery, PDA, descending aorta
√ communication from aorta (distal to left subclavian artery) → left pulmonary artery (on AP / LAT / LAO aortogram)

PDA in Premature Infant

premature infant not subject to medial muscular hypertrophy of small pulmonary artery branches (which occurs in normal infants subsequent to progressive hypoxia in 3rd trimester)

• CHF

Cause:

(a) pulmonary artery pressure remains low without opposing any L-to-R shunts (PDA / VSD)
(b) ductus arteriosus remains open ← hypoxia in RDS

√ recurrence of alveolar airspace filling after resolution of RDS
√ granular pattern of hyaline membrane disease becomes more opaque
√ enlargement of heart (masked by positive pressure ventilation)

Rx:

(a) Medical therapy:
(1) Supportive oxygen, diuretics, digitalis
(2) Avoid fluid overload (NOT to increase shunt volume)
(3) Antiprostaglandins = indomethacin opposes prostaglandins, which are potent duct dilators
(b) Surgical ligation

Beneficial PDA

= compensatory effect of PDA (= decreasing shunt volume) in:

1. Tetralogy of Fallot
cyanosis usually occurs during closure of duct shortly after birth
2. Eisenmenger pulmonary hypertension
PDA acts as escape valve shunting blood to descending aorta
3. Interrupted aortic arch
supply of lower extremity via PDA

Nonbeneficial PDA

in L-to-R shunts (VSD, aortopulmonic window) a PDA increases shunt volume

PENETRATING AORTIC ULCER

= PENETRATING ATHEROSCLEROTIC ULCER OF THE AORTA

= PAU = atherosclerotic ulcer that penetrates deep through intima and internal elastic lamina into media rendering the aortic wall unstable ← complication of aortic atherosclerosis

Prevalence: uncommon

Cause: new intimal disruption

Age: elderly with hypertension, hyperlipidemia and severe atherosclerosis; M÷F = 4÷1

- often asymptomatic
- chest pain that may radiate to back (29%) WITHOUT pulse difference, aortic regurgitation, CNS symptoms
- occasional distal ischemia ← embolic event

Location: middle / distal ⅓ of descending thoracic aorta (70%); abdominal aorta (30%)

√ localized contrast-medium filled pouch widely communicating with true lumen
√ extensive atherosclerotic disease + ectasia
√ lack of compression of the aortic lumen
√ intramural hematoma (thoracic >> abdominal aorta)
√ NO intimal flap

CECT:

√ focally ulcerated plaque
√ adjacent subintimal hematoma (DDx from intraluminal thrombus / atherosclerotic plaque not possible):
√ inward displacement of calcified intima (common)
√ thickening / enhancement of adjacent aortic wall

MR (valuable for patients in renal failure):

√ focal excavation of aortic wall
√ subacute hematoma in aortic wall of high SI on T1WI + T2WI (methemoglobin) either localized or mimicking type 3 dissection

Angio:

√ ulcerated atherosclerotic plaque
√ aortic wall thickening

Cx:

(1) Ulcer expansion
(2) Aortic dissection (7%) ← intramural hemorrhage:
  (a) localized / extensive
  (b) communicating "double-barreled" / thrombosed
(3) Saccular / fusiform aortic aneurysm (30%) ← stretching of aortic wall
(4) Aortic rupture (40%)

Prognosis: poor and negatively modified by diameter of abdominal aorta, bidimensional size of ulcer, severity of intimal calcification

Rx: (1) Antihypertensive medication, analgesics
(2) Excision of ulcer + aortic interposition graft (for recurrent symptoms /

pseudoaneurysm formation)

DDx: (1) Aortic dissection (intimal flap, patent false lumen)
(2) Atheroma / chronic intramural thrombus (low SI on T1WI + T2WI)
(3) Intramural blood pool

PERICARDIAL CYST

Etiology:
(a) defect in embryogenesis of celomic cavities
(b) sequelae of pericarditis

Frequency: 1÷100 000; 13–17% of all mediastinal cysts
◊ Most common congenital cystic mediastinal lesion

Histo: benign unilocular lesion composed of connective tissue + lined by single layer of mesothelial cells

Age: 30–40 years; M÷F = 3÷2

- asymptomatic (50%)
- chest pain (severe if torsed), dyspnea, cough (in < ⅓)

Location: 90% of pericardial cysts contact diaphragm ± extension into major fissure; R÷L = 3÷1 to 3÷2
(a) right cardiophrenic angle (65%)
(b) left cardiophrenic angle (25%)
(c) mediastinum (10%)

CT:
√ well-defined nonenhancing homogeneous lesion of water attenuation values (20–40 HU)
√ no internal septa / nodules
√ ± proteinaceous fluid of intermediate attenuation
√ ± hemorrhagic content of increased attenuation

√ encapsulated round / ovoid triangular mass usually 3–8 cm (range, 1–28 cm) in diameter:
√ change in location = pedunculated migrating cyst
√ change in shape with change in location ← compressible

MRI:
√ intermediate to low signal intensity on T1WI
√ high signal intensity on T2WI

√ proteinaceous cyst:
√ high SI on T1WI
√ intermediate to low signal intensity on T2WI
√ no restricted diffusion on DWI + high signal on ADC map
√ hemorrhagic cyst:
√ high SI on T1WI
√ susceptibility on GRE

Rx: surgical resection / percutaneous drainage if
(a) individual symptomatic (b) complication present
(c) diagnosis uncertain (d) pathology needed

DDx: congenital cyst (thymic, bronchogenic, neurenteric, duplication cyst); cystic tumor

Pericardial Diverticulum

= focal outpouching of pericardial sac
√ direct communication with pericardial cavity
√ change in size + shape with respiration / body position

PERICARDIAL DEFECT

= CONGENITAL ABSENCE OF PERICARDIUM
= failure of pericardial development ← premature atrophy of left duct of Cuvier (cardinal vein), which fails to nourish the left pleuropericardial membrane during embryogenesis

Frequency: 1÷13,000; M÷F = 3÷1
Mean age at detection: 21 years (range, newborn to 81 years)
Location:

A. PARTIAL ABSENCE (91%)
  (a) complete absence on left side 35%
  (b) foraminal defect on left side 35%
  (c) diaphragmatic pericardial aplasia 17%
  (d) foraminal defect on right side 4%
B. TOTAL BILATERAL ABSENCE (9%)

In 30% associated with:

(1) Bronchogenic cyst (30%)
(2) VSD, PDA, mitral stenosis
(3) Diaphragmatic hernia, sequestration

• mostly asymptomatic
• symptoms ← entrapment / incarceration of cardiac structures:
  • palpitations, tachycardia, dyspnea, dizziness, syncope
  • positional discomfort while lying on left side
  • nonspecific intermittent chest pain: lack of pericardial cushioning, torsion of great vessels, tension on pleuro-pericardial adhesions, pressure on coronary arteries by rim of pericardial defect
• ECG: right axis deviation, right bundle branch block
√ variations in size:
  › small foraminal defect = no abnormality
  › large defect = herniation of cardiac structures / lung
  › complete absence = levoposition of heart
√ absence of left pericardial fat-pad
√ levoposition of heart + aortic knob with lack of visualization of right heart border while trachea remains at midline
√ prominence / focal bulge in the area of RVOT, main pulmonary artery, left atrial appendage
√ sharp margination + elongation of left heart border
√ insinuation of lung between heart + left hemidiaphragm
√ insinuation of lung between aortic knob + pulmonary artery
√ increased distance between heart + sternum ← absence of sternopericardial ligament (cross-table lateral projection)
√ pneumopericardium following pneumothorax

√ NO tracheal deviation

CT + MR:

√ excessive levorotation + displacement of heart

√ cardiac indentation at location of defect

◊ Direct visualization of left pericardium NOT possible!

Cx: cardiac strangulation

Rx: foraminal defect requires surgery because of

(a) herniation + strangulation of left atrial appendage → infarction of appendage

(b) herniation of LA / LV

(c) compression of left coronary artery especially during exercise → cardiac ischemia

(1) Closure of defect with pleural flap

(2) Resection of pericardium

PERICARDIAL MESOTHELIOMA

= PRIMARY MALIGNANT PERICARDIAL MESOTHELIOMA

= malignant primary neoplasm arising from mesothelial cells of the pericardium

Prevalence: 0.0022% at autopsy; < 1% of all mesotheliomas; 50% of all primary pericardial tumors

◊ Most common primary malignancy of pericardium!

Mean age: 46 (range, 2–78) years; M÷F = 2÷1

Path: multiple coalescing pericardial masses with obliteration of pericardial space; myocardial invasion is rare

Histo: epithelial > biphasic (mixed) > fibrous (spindle cell); biphasic tumor composed of epithelial areas forming tubulopapillary structures (resembling carcinoma) and spindled areas (resembling sarcoma)

- chest pain, cough, dyspnea, palpitations
- signs of constrictive pericarditis, cardiac tamponade
- conduction abnormalities ← myocardial infiltration

CXR:

√ cardiac enlargement with irregular contour

√ diffuse mediastinal enlargement

CT / MR:

√ irregular diffuse pericardial thickening / cardiac encasement by soft-tissue masses

√ ± invasion of adjacent vascular + anatomic structures

√ pericardial effusion

√ heterogeneous enhancement with involvement of parietal + visceral layers of pericardium

PET:

√ hypermetabolic activity

Dx: pericardiocentesis → hemorrhagic fluid, malignant cells (in only 20%)

Rx: palliative surgery + radiation therapy

Prognosis: 6 weeks – 15 months survival, regardless of therapy

PERICARDIAL TERATOMA

= benign germ cell neoplasm

Age: infants + children
Histo: derivatives of all 3 germ cell layers (neuroglia, cartilage, skeletal muscle, liver, intestine, pancreas, glandular tissue)
Location: within pericardial sac connected to a great vessel via a pedicle; intramyocardial (rare)
• respiratory distress, cyanosis ← pericardial tamponade + compression of SVC, RA, aortic root, PA
CXR:
√ enlarged cardiomediastinal silhouette
√ formed calcified teeth
US:
√ intrapericardial heterogeneous complex multilocular cystic mass:
√ intrinsic echogenic foci (= calcifications)
√ pericardial effusion
√ fetal hydrops (ascites, pleural effusion, subcutaneous edema, polyhydramnios)
MR:
√ large mass of heterogeneous signal intensity
Rx: emergent pericardiocentesis (life-threatening lesion); urgent surgical excision
Prognosis: good

PERICARDITIS

Etiology:
A. IDIOPATHIC (85%, 2nd most common cause today)
B. NONIDIOPATHIC (15%)
(a) infectious / inflammatory
1. Virus (Coxsackie B, influenza)
2. Bacterium
3. Tuberculosis (formerly most common etiology)
◊ TB is major cause in developing countries + in HIV-immunocompromised patients
3. Fungus / parasite
4. Connective tissue disease: rheumatoid arthritis, lupus erythematosus
(b) traumatic
1. Cardiac surgery (most frequent today)
2. Radiotherapy to mediastinum: breast cancer, mediastinal tumor
3. Percutaneous coronary intervention, pacemaker insertion, catheter ablation
4. Acute myocardial infarction
› **Epistenocardiac pericarditis**
= inflammation in close temporal relationship to acute transmural infarction
Frequency: 10% of patients with acute MI
Cause: pericardial spread of infarct-related inflammation
› Dressler syndrome
(c) autoimmune disorder (5%)
(d) uremia = chronic renal failure

(e) neoplastic (5%) = tumor invasion by carcinoma of breast / lung, lymphoma / leukemia, sarcoma, mesothelioma

Constrictive Pericarditis

= PERICARDIAL CONSTRICTION
= fibrous thickening of pericardium interfering with filling of ventricular chambers via restriction of heart motion
Age: 30–50 years; M÷F = 3÷1
Etiology: infection, trauma, radiation, postoperative status
Hemodynamics of decreased compliance of pericardium:
(a) dissociation between intracardiac + intrathoracic pressure → isolates heart from normal respiratory changes
(b) increased ventricular coupling
(c) increased cardiac filling pressures with equalization of atrial + ventricular pressures

- dyspnea + weakness, peripheral edema, neck vein distension
- abdominal enlargement (ascites + hepatomegaly)
- pericardial knock sound = loud early-diastolic sound
- **Kussmaul sign** = failure of venous pressure to fall (= elevation of jugular venous pressure) with inspiration
- prominent X and Y descent on venous pressure curve

◊ Other causes of right heart failure must be excluded first, ie, pulmonary hypertension, severe tricuspid insufficiency, myocardial infarction

Diagnostic key imaging features):
√ pericardial thickening + enhancement + calcifications
√ biatrial enlargement + tubular ventricles

@ Pericardium
Location: most pronounced over RV + anterior AV groove + posterior surface of LV
√ irregular thickening of pericardium
√ linear / plaquelike pericardial calcifications (27%) as a nonspecific response to chronic inflammation

@ Heart
√ flattened tubular shape of cardiac cavities
√ uni- / bilateral atrial enlargement
√ small atria; occasionally compensatory dilatation of nonconstricted portions, eg, LA enlargement (20%)
√ normal / small-sized heart (enlargement only due to preexisting disease)
√ straightening of heart borders:
√ straight / concave on right side
√ squared on left side
√ pericardial tenting
√ increase in ejection fraction (small EDV)

@ Veins (↑ cardiac filling pressure)
√ dilatation of SVC (77%), IVC, azygos vein (69%), hepatic veins

@ Lung & abdomen

√ normal pulmonary vascularity / pulmonary venous hypertension (43%)
√ pleural effusion (34% bilateral, 26% right PE)
√ ascites

CT:
√ pericardial thickening to 4 mm ± 1 mm in reversible constrictive pericarditis
√ thinning of pericardium to 2 mm ± 1 mm in end-stage irreversible chronic fibrosing pericarditis
√ reflux of contrast into coronary sinus
√ flattening of RV with narrow tubular configuration
√ sigmoid-shaped curvature of interventricular septum toward left

MR:
√ pericardial thickening ≥ 4 mm (suggestive) and > 5–6 mm (highly specific)
◊ Maximal pericardial thickness in constrictive pericarditis has a wide range of 1–17 mm!
◊ Up to 20% of patients have normal thickness of ≤ 2 mm
◊ Degree of pericardial thickening is only weakly related to degree of cardiac constriction!
√ pericardium of intermediate SI similar to myocardium sandwiched between high-signal epicardial and mediastinal fat (on T1WI); most easily identified anterior to RV > RA > free wall of LV
√ often small LV + tubular appearing RV
√ dilatation of RA + IVC reflecting high RV filling pressure (DDx: restrictive cardiomyopathy)
√ flattened / sigmoid-shaped septum
√ NO pericardial enhancement in end stage of disease

Phase-contrast MRI:
√ tricuspid valve inflow: ↑ early filling + ↓ / absent late filling
√ IVC: ↓ / absent forward or reversed systolic flow; ↑ early diastolic flow; late reversed diastolic flow
√ RV filling ↑ on inspiration + LV filling ↑ on expiration
√ "**septal bounce**" = flattening / inversion of septum during early diastolic ventricular filling ← increased ventricular coupling:
√ most pronounced at onset of inspiration
√ right-sided septal shift at onset of expiration

ECHO (nonspecific features):
√ thickening of pericardium (not reliably demonstrated unless pericardial fluid present)
√ immobile pericardium
√ rapid early filling of LV
√ rapid early filling motion followed by flat posterior wall motion during diastasis period (= period between early rapid filling and atrial contraction)
√ premature opening of pulmonic valve

Cx: protein-losing enteropathy ← increased pressure in IVC + portal vein

Rx: antiinflammatory drugs; pericardiectomy = surgical stripping of pericardium

DDx: (a) restrictive physiology:

1. Cardiac tamponade
2. Restrictive cardiomyopathy: eg, amyloid

(b) nonrestrictive physiology:
1. S/P recent cardiac surgery
2. Organized intrapericardial hematoma

Epipericarditis

= EPIPERICARDIAL FAT NECROSIS
= uncommon benign condition of unknown cause that manifests with acute pleuritic chest pain and no prodrome
• focal chest pain varying with changes in patient's position
• normal levels of troponin
CT:
√ focally increased attenuation within epipericardial fat
PET/CT:
√ low-grade FDG uptake
Rx: antiinflammatory medication
Prognosis: symptoms and image findings resolve over time

Inflammatory Pericarditis

Prevalence: 1% of autopsies
Clinical course: acute / subacute / recurrent / chronic
√ pericardial thickening + enhancement + fluid
√ mild to moderate increase / NO increase in FDG uptake

Acute Pericarditis

Cause: mnemonic: MUSIC
Myocardial infarction (acute)
Uremia
Surgery (cardiac)
Infection
Cancer

Histo: inflamed pericardial layers composed of highly vascularized granulation tissue with fibrin deposition

• typical often severe chest pain
• pericardial friction rub (← pericarditis sicca)
• elevated serologic markers of inflammation (eg, C-reactive protein); widespread ST elevation

CT:
√ thickening of pericardial layers
√ diffuse enhancement of pericardium
√ pericardial effusion ± loculations

MR:
√ edema on STIR
√ enhancement of pericardium ± surrounding fat ± myocardium

Cx: (1) Progression to chronic sclerosing pericarditis (< 0.5% for viral pericarditis, relatively frequent for purulent + tuberculous pericarditis)

(2) Myocarditis = atypical ECG changes, transient regional / global wall motion abnormalities, increase in cardiac enzymes

Rx: NSAID

Chronic Pericarditis

Histo: fibroblasts + collagen deposition

Subtypes: (1) Chronic sclerosing pericarditis

(2) Chronic fibrosing pericarditis

√ irregularly thickened pericardial layers

√ loculated pericardial effusion

Cx: stiff pericardium → constrictive pericarditis

PERSISTENT DUCTUS VENOSUS (rare)

= portosystemic shunt ← failure of ductus closure during the 1st week of life (usually immediately after birth in full-term neonate)

Anatomy: ductus arises from posterior aspect of left PV (opposite umbilical vein opening) and drains into HV

Associated with: prematurity, CHD

PERSISTENT FETAL CIRCULATION

= PERSISTENT PULMONARY HYPERTENSION OF THE NEWBORN

= delay in transition from intra- to extrauterine pulmonary circulation

Cause: primary disorder related to birth asphyxia; concurrent parenchymal lung disease (meconium aspiration, pneumonia, pulmonary hemorrhage, hyaline membrane disease, pulmonary hypoplasia); concurrent cardiovascular disease; hypoxic myocardial injury; hyperviscosity syndromes)

• labile pO2

√ structurally normal heart

POLYARTERITIS NODOSA

= PERIARTERITIS NODOSA = PAN

= systemic necrotizing inflammation of medium-sized + small muscular arteries WITHOUT glomerulonephritis or vasculitis in arterioles, capillaries, venules

Frequency: 4–9÷1,000,000 annually(rare); 70÷1,000,000 annually in patients with hepatitis B

Etiology: ? deposition of immune complexes

Mean age: 55 (range, 8–81) years; M÷F = 2÷1 3% of childhood vasculitides in USA

Path: focal panmural necrotizing vasculitis with nodules along the vessel walls; mucoid degeneration + fibrinoid necrosis begins within media; multiple small aneurysms of small + medium-sized arteries; absence of vasculitis in vessels other than arteries (DDx: necrotizing angiitis, mycotic aneurysm)

Histo: polymorphonuclear cell infiltrate in all layers of arterial wall + perivascular tissue (acute phase), mononuclear cell infiltrate, intimal proliferation, thrombosis, perivascular

inflammation (chronic stage)

Associated with: hepatitis B + HIV antigenemia

- low-grade fever, malaise, abdominal pain, weight loss
- myalgia (over weeks), arthralgia, hypertension
- elevated ESR, thrombocytosis, anemia
- positive for hepatitis B surface antigen (up to 30%)
- positive perinuclear ANCA titers; mononeuritis multiplex

Location: all organs may be involved, kidney (70–90%), heart (65%), liver (50–60%), spleen (45%), pancreas (25–35%), GI tract, CNS (cerebrovascular accident, seizure), skin

@ Kidney (involved in 70–80–90%)

- painless hematuria, nephrotic syndrome (proteinuria)
- acute / chronic renal failure

√ irregular nephrogram
√ radiolucent cortical areas
√ prolonged washout of contrast material
√ multiple small intrarenal microaneurysms (at bifurcation of interlobar / arcuate arteries)
√ aneurysms may disappear (thrombosis) or appear in new locations
√ arterial narrowing + thrombosis (chronic / healing stage)
√ multiple small cortical infarcts

CECT:

√ lobulated renal contour + irregular thinning ← prior cortical infarcts
√ multiple hypoattenuating bands (arterial occlusion)

Cx: intrarenal / subcapsular / perinephric hemorrhage ← rupture of aneurysm

@ Chest (involved in 70%)

- CHF, myocardial infarction

√ cardiac enlargement / pericardial effusion (14%)
√ pleural effusion (14%)
√ pulmonary venous engorgement (21%)
√ massive pulmonary edema (4%)
√ linear densities / platelike atelectasis (10%)
√ wedge-shaped / round peripheral infiltrates of nonsegmental distribution (14%) simulating thromboembolic disease with infarction
√ cavitation may occur
√ interstitial pneumonitis in lower lung fields

@ Liver (involved in 50–66%)

√ prolonged washout of contrast material ← increase in peripheral hepatic arterial resistance + hepatic infarcts

@ GI tract (involved in 50–70%)

Location: small intestine > mesentery > colon

- abdominal pain, nausea, vomiting (66%)

√ ulcer formation, GI bleeding (6%)
√ bowel perforation (5%), intestinal infarction (1.4%)
√ pneumatosis intestinalis ± portal venous gas

@ Skeletal muscle (involved in 39%)

- myalgia, arthralgia (50%), limb claudication

√ aneurysms of lumbar + intercostal arteries (19%)
√ lower extremity ischemia (16%)
@ Skin (involved in 20%)
• palpable purpura, infection, ischemic ulcer
• tender subcutaneous nodules (15%)
• peripheral neuropathy (= mononeuritis multiplex)
@ CNS (involved in 10%)
√ sulci of high-signal-intensity on FLAIR image
√ leptomeningeal enhancement on T1WI
Angiography (61–89% sensitive, 90% specific, 55% PPV, 98% NPV, 80% true-positive rate):
√ multiple (> 10) aneurysms of small + medium-sized arteries typically at branching points as a result of pannecrosis of the internal elastic lamina in 50–60% (HALLMARK):
√ 1–5 mm saccular aneurysms in 60–75%
√ fusiform aneurysms / arterial ectasia
◊ Aneurysms are found in 12–94% of polyarteritis nodosa
√ luminal irregularities (in up to 90%)
√ stenoses of arteries
√ arterial occlusions + organ infarcts (98%)
DDx: rheumatoid vasculitis, drug abuse, systemic lupus erythematosus, Churg-Strauss syndrome
Dx: angiography, tissue biopsy
Cx: renin-mediated hypertension, renal failure, hemorrhage ← aneurysm rupture (9%), organ infarction ← vessel thrombosis: gangrene of fingers / toes
Prognosis: clinical course lasts several months to > 1 year; relapse in 40% with median interval of 33 months; 13% 5-year survival rate if untreated
Rx: immunosuppression with corticosteroids + cyclophosphamide (increases 5-year survival rate to 48–90%)

Polyarteritis Nodosa of Childhood

Frequency: 3% of childhood vasculitides in USA
Mean age: 9 years
• history of recent URI
May be associated with: familial Mediterranean fever
Types:
(1) Systemic polyarteritis nodosa (57%)
= malaise, fever, weight loss, myalgia, abdominal pain, arthralgia
Organs: skin, MSK, kidney, GI, heart, CNS, lung
• livido reticularis, subcutaneous nodules
• peripheral gangrene
Cx: visceral hemorrhage ← ruptured aneurysm, bowel infarction
(2) Cutaneous polyarteritis nodosa (30%)
= benign course
Involved organs: skin, MSK WITHOUT internal organs
(3) Hepatitis B-associated polyarteritis nodosa (< 5%) more typical for adults
Dx: CLASSIC angiographic findings of aneurysm, stenosis, occlusion of medium-sized to

small muscular arteries ← necrotizing vasculitis
Location: predominantly renal + mesenteric + hepatic arteries
Renal DSA (digital subtraction angiography):
√ aneurysms in small to medium-sized renal arteries (40%)
√ segmental narrowing
√ variations in arterial caliber
√ pruning of peripheral vascular tree
Mortality rate: 1–4%

POPLITEAL ARTERY ENTRAPMENT SYNDROME

= vascular compression syndrome of popliteal artery (PopA)
Prevalence: 0.165% of young males entering military service
Prevalence: 35 cases in American surgical literature; bilateral in 22–67%
Normal anatomy: PopA courses between the two heads of gastrocnemius muscle = lateral to medial head of gastrocnemius muscle (medGastroc)
Aberrant anatomy:
(1) medial course of PopA around medGastroc
(2) lateral insertion of medGastroc on distal femur
(3) accessory slip of gastrocnemius m. (30%; most common)
(4) hypertrophy / accessory slip of gastrocnemius muscle
(4) fibrous band of popliteus muscle
Pathophysiology:
flow unimpeded when muscle relaxed; increased arterial angulation with muscle contraction (early); progressive intimal hyperplasia ("atheroma" = misnomer) ← microtrauma in area of repeated arterial compression; ultimately occlusion / thrombosis within aneurysm (late)
Age peaks: 17 and 47 years; < 35 years in 68%; M÷F = 9÷1 to 15÷1
• unilateral claudication + exercise-induced leg pain (90%):
  • slowly progressive, esp. during periods of prolonged standing
• acute ischemia of leg with permanent occlusion of popliteal a. (late)
Pulse volume recording (PVR with 40% false-positive results):
√ posterior tibial pulse obliterated during active plantar flexion against resistance / dorsiflexion of foot
  ◊ 50% of general population has some narrowing of PopA!
√ ankle-arm index reduced during active muscle contraction
√ Doppler waveforms of posterior tibial artery diminished during muscle contractions
Angio (biplanar views with hyperextended knee):
√ medial deviation of artery (29%), popliteal stenosis (11%), poststenotic dilatation (8%)
Dx:
√ arteriography with typical medial deviation of popliteal artery before + after gastrocnemius contraction
√ popliteal artery thrombosis / occlusion
Cx: popliteal artery aneurysm
DDx: cystic adventitial disease of popliteal artery, arterial embolism, premature arteriosclerosis, popliteal aneurysm with thrombosis, popliteal artery trauma, popliteal

artery thrombosis, Buerger disease, spinal cord stenosis (= neurogenic claudication)

POSTRHEUMATIC HEART DISEASE

Cause: infection by group A streptococcus → acute rheumatic fever (= systemic inflammatory infection) involving heart, joints, skin, SQ tissue

Path: pancarditis with vegetations forming predominantly on mitral + aortic valve → scarring of chronic inflammation → valvular deformity

• manifestation after latency of 20–25 years

Location: mitral valve > aortic valve

Cx: valvular malfunction (stenosis / insufficiency) → volume overload of proximal cardiac chamber → ventricular damage + remodeling

PRIMARY PULMONARY HYPERTENSION

= PLEXOGENIC PULMONARY ARTERIOPATHY = ppHTN

= idiopathic precapillary cause of pulmonary hypertension (pHTN)

Diagnosis per exclusion:

NO identifiable cause; clinically unexplained progressive pulmonary arterial hypertension without evidence for thromboembolic disease / pulmonary venoocclusive disease

At risk: portal hypertension (with / without liver disease); autoimmune disorders (Raynaud disease, collagen vascular disease); pregnancy; HIV infection; aminorex fumarate (appetite suppressant) ingestion

Histo: plexogenic arteriopathy (HALLMARK) = intimal cell proliferation with focal disruption of internal elastic lamina and media by glomeruloid small vascular channels that ramify into alveolar septal capillaries (75%); acute + organizing intraluminal thrombi (50%)

Age: 3rd decade (range, 20–45 years); M÷F = 1÷3

• gradual onset of progressive dyspnea on exertion (60%)

• easy fatigability, syncope, angina, hyperventilation, hemoptysis

• Raynaud phenomenon, symptoms of cor pulmonale

√ right ventricular enlargement ← hypertrophy + dilatation

√ dilatation of central pulmonary arteries

CXR:

- √ prominent central pulmonary arteries:
  - √ enlarged pulmonary trunk
  - √ right descending pulmonary artery > 25 mm wide
- √ pulmonary vascularity:
  - √ oligemia + rapidly tapering vessels
  - √ overcirculation + vascular distension

CT:

- √ enlargement of central pulmonary arteries:
  - √ diameter of main pulmonary artery > 29 mm (87% sensitive, 89% specific) measured at scan plane of bifurcation at right angle to its long axis just lateral to ascending aorta
  - √ segmental artery-to-bronchus ratio > 1÷1
  - √ pulmonary artery-to-aorta ratio (rPA) > 1
- √ abrupt decrease in caliber of segmental + subsegmental arteries (at outer to medial ⅓ of

lung mantle)
√ small tortuous peripheral vessels = plexogenic arteriopathy
√ absence of detectable intraluminal thrombi
in severe cases:
√ wall-adherent apposition thrombus in central pulmonary aa.
√ pericardial effusion (worse prognosis)
√ focal perivascular groundglass opacities in peripheral / perihilar distribution

HRCT:
√ patchy mosaic pattern of lung attenuation ← regional variations in lung perfusion (rare):
√ hyperdense areas containing large caliber vessels
√ hypodense areas containing small caliber vessels

MR:
√ reversal of interventricular septal curvature
√ direct linear correlation between mean pulmonary artery pressure (PAP) and ratio of main pulmonary artery caliber to descending aorta (MPA/AO)
√ abnormal intravascular signal in 92% on gated T1WI ← slow arterial flow ← ↑ pulmonary vascular resistance

NUC:
√ normal / low-probability V/Q scans

Angio:
√ symmetrically enlarged central arteries
√ diffuse pattern of abruptly tapering + pruned subsegmental vessels
√ filamentous / "corkscrew" peripheral arteries
√ subpleural collaterals (occasionally)
√ bronchial artery dilatation is uncommon (14%) in primary pHTN for unknown reasons and is useful for differentiation from chronic thromboembolic disease.

Prognosis: death in 2–5 years; 34% 5-year survival
Rx: vasodilators, calcium channel blockers, diuretics, anticoagulants; lung / heart-lung transplantation

PSEUDOCOARCTATION

= AORTIC KINKING
= elongated redundant thoracic aorta with acute kink / anterior buckling just distal to origin of left subclavian artery at ligamentum arteriosum
= variant of coarctation without a pressure gradient
Age: 12–64 years
Associated with: hypertension, bicuspid aortic valve, PDA, VSD, aortic / subaortic stenosis, single ventricle, ASD, anomalies of aortic arch branches
• asymptomatic; ejection murmur
• NO pressure gradient across the buckled segment

CXR:
√ anteromedial deviation of aorta
√ "chimney-shaped" high aortic arch (in children)
√ rounded / oval soft-tissue mass in left paratracheal region + superior to presumed normally

positioned aortic arch ← elongation of ascending aorta + aortic arch (in adults)
√ anterior displacement of esophagus
√ NO rib notching / dilatation of brachiocephalic arteries / LV enlargement / poststenotic dilatation

CT/MR:
√ shelflike lesion at any point along the aortic arch
√ poststenotic aortic dilatation

Angio:
√ high position of aortic arch
√ "figure 3" sign = notch in descending aorta at attachment of short ligamentum arteriosum

DDx: true coarctation, aneurysm, mediastinal mass

PULMONARY ARTERY PSEUDOANEURYSM

= tear / disruption of layers of vessel wall with extravasation of blood contained by adventitia / clot / compressed surrounding tissue

Prevalence: rare

Cause:

A. TRAUMA
   1. Improper placement of Swan-Ganz catheter
   2. Penetrating / blunt (rare) trauma
B. INFECTION:
   1. Mycotic aneurysm ← endovascular seeding from endocarditis / direct extension from necrotizing pneumonia
   2. Mycobacterial aneurysm (= Rasmussen aneurysm)
   3. Syphilitic aneurysm
C. VASCULAR ABNORMALITY: cystic medial necrosis, Behçet disease, Marfan syndrome, Takayasu disease
D. OTHER: septic emboli, neoplasm

Associated with: patent ductus arteriosus

• hemoptysis ← leakage of blood into bronchial tree

CXR:
√ stable / increasing focal lung mass

CT:
√ enhancing round lung mass isointense to central pulmonary a.

Cx: 100% mortality with rupture

PULMONARY ATRESIA

= CONGENITAL ABSENCE OF PULMONARY ARTERY

= atretic pulmonary valve with underdeveloped pulmonary artery distally

May be associated with: hypogenetic lung

CXR:
√ small hemithorax of normal radiodensity
√ mediastinal shift to affected side
√ elevation of ipsilateral diaphragm

√ reticular network of vessels on affected side ← systemic collateral circulation from bronchial arteries
√ rib notching from prominence of intercostal arteries ← large transpleural collateral vessels

OB-US:
√ small / enlarged / normal right ventricle
√ progressive atrial enlargement ← tricuspid regurgitation
√ flow reversal in ductus arteriosus + main pulmonary artery (most reliable)

Proximal Interruption of Pulmonary Artery

= AGENESIS OF PULMONARY ARTERY
= atresia of mediastinal portion of right / left pulmonary artery (usually opposite the side of the aortic arch) with distal pulmonic circulation supplied by aortopulmonary collaterals / bronchial arteries
• recurrent infections, dyspnea, pulmonary hypertension
• hemoptysis (10%) ← ruptured systemic collateral vessels
(a) Interrupted left pulmonary artery
Associated with: right aortic arch + severe CHD (including tetralogy of Fallot)
(b) Interrupted right pulmonary artery (more common), generally as isolated finding

CT:
√ complete absence of mediastinal portion of affected pulmonary artery
√ short pulmonary a. terminating within 1 cm of its origin
√ hypoplastic ipsilateral lung + hyperinflated contralateral lung rotating across midline
√ abundant systemic collaterals to affected lung ← dilated bronchial arteries, subclavian artery, intercostal arteries
√ linear peripheral lung opacities = transpleural vascular collaterals

Pulmonary Atresia with Ventricular Septal Defect

= part of spectrum of tetralogy of Fallot (TOF)

Pulmonary Atresia with Intact Interventricular Septum

Associated with: ASD → R-to-L shunt
Type I : NO remaining RV, NO tricuspid regurgitation
√ moderately ↑ RA (depending on size of ASD)
Type II : normal RV with tricuspid regurgitation
√ massive enlargement of RA
√ cardiomegaly ← increase in size of LV + RA
√ concave / small pulmonary artery segment
√ diminished pulmonary vascularity
Rx: prolonged infusion of prostaglandin E, stent placement into ductus, modified Blalock-Taussig shunt, atrial septotomy, transpulmonary valvotomy

PULMONIC INSUFFICIENCY / REGURGITATION

Pathophysiology:
forward blood flow may be maintained ← contraction of RA + pumping of systemic venous return from left heart

Cause:

(a) normal (in 30%) if trivial / mild
(b) bi- and quadricuspid valve
(c) dilatation of valve: pulmonary hypertension, Marfan syndrome, syphilis
(d) damage of cusps: carcinoid heart disease, rheumatic heart disease, infectious endocarditis
(e) after surgical / percutaneous treatment for pulmonary stenosis and repair of TOF

CT:

√ inadequate apposition of cusp at end-diastole
√ dilatation of pulmonic ring + pulmonary artery
√ RV dilatation + hypertrophy

MR / ECHO:

√ ± late diastolic forward flow in pulmonary trunk with each atrial contraction → regurgitant flow usually < 50%

Measurement of pulmonary regurgitant fraction:

√ accurately quantified with through-plane (true transverse with < 15° angulation) velocity mapping
= $\text{Volume}_{\text{regurgitant}} \times 100 / \text{Volume}_{\text{forward}}$ [%]
◊ A regurgitant fraction of ≥ 40% is considered severe!

PULMONIC (PULMONARY) STENOSIS

Frequency: pulmonary artery stenosis without VSD in 8% of all CHD

Embryology: infundibulum formed from proximal portion of bulbis cordis; pulmonary valves develop in 6th–9th week from outgrowth of 3 tubercles

• mostly asymptomatic; cyanosis / heart failure
• loud systolic ejection murmur
√ systolic doming of pulmonary valve (= incomplete opening)
√ normal / diminished / increased pulmonary vascularity (depending on presence + nature of associated malformations)
√ enlarged pulmonary trunk + left pulmonary artery (= poststenotic dilatation)
√ prominent left pulmonary artery + normal right pulmonary a.
√ hypertrophy of RV with reduced size of RV chamber:
√ elevation of cardiac apex
√ increased convexity of anterior cardiac border on LAO
√ diminution of retrosternal clear space
√ cor pulmonale
√ mild enlargement of LA (reason unknown)
√ calcification of pulmonary valves in older adults (rare)

Prognosis: death at mean age of 21 years if untreated

Shape of pulmonary stenosis:

(1) Dome-shaped valve (40–60%) with normal leaflets
(2) Dysplastic thickened immobile cusps (20–30%)
(3) Supravalvular narrowing with deep bottle-shaped sinuses + hourglass deformity (16%)
(4) Bicuspid (0.1%) / quadricuspid (0.2%) pulmonary valve
(5) Dome-shaped valve with dysplastic leaflets

Subvalvular Pulmonic Stenosis

A. INFUNDIBULAR PULMONIC STENOSIS
typically in tetralogy of Fallot

B. SUBINFUNDIBULAR PULMONIC STENOSIS
= hypertrophied anomalous muscle bundles crossing portions of RV
Associated with: VSD (73–85%)
(a) low type: courses diagonally from low anterior septal side to crista posteriorly
(b) high type: horizontal defect across RV below infundibulum

√ late-peaking jet
√ no dilatation of PA because of dissipation of RV force through elongated area of obstruction

Valvular Pulmonic Stenosis / Pulmonary Valve Stenosis

Cause:
(a) congenital (95%):
› isolated (most often)
› associated with other congenital anomalies:
» tetralogy of Fallot (bicuspid pulmonary valve)
» Noonan syndrome (dysplastic pulmonary valve)
» LEOPARD syndrome (= **l**entigines, **e**lectrocardiographic anomalies, **o**cular hypertelorism, **p**ulmonary stenosis, **a**bnormalities of genitalia, **r**etardation of growth, **d**eafness)
(b) acquired: metastatic carcinoid, rheumatic fever, infective endocarditis, prosthetic valve, RVOT conduit

1. CLASSIC / TYPICAL PULMONIC VALVE STENOSIS (95%)
= commissural fusion of pulmonary cusps → funnel shape with small circular orifice
Age of presentation: childhood
• pulmonic click
• ECG: hypertrophy of RV
√ <u>dome-shaped</u> valve:
√ mobile valve with 2–4 raphes
√ incomplete separation of valve cusps
√ jet of contrast through small central orifice
√ dilated main + left pulmonary artery
Rx: balloon valvuloplasty (for peak instantaneous gradient above 50 mmHg)

2. DYSPLASTIC PULMONIC VALVE STENOSIS (5%)
= thickened redundant immobile distorted cusps ← myxomatous tissue
• NO click
√ cauliflower-like thickening at free margin of leaflets
√ NO poststenotic dilatation
Rx: surgical resection of redundant valve tissue
Hemodynamics: obstruction of RV systolic ejection with pressure burden on RV

RA	↔/↑	RV	↑	Main PA	↑
Pulm. vessels	↔			LPA	↑
LA	↔	LV	↔	Ao	↔

CXR:
√ normal pulmonary vascularity
√ normal-sized heart
√ enlargement of main + left pulmonary artery
CT:
√ poststenotic enlargement of main + left PA
√ normal size of right PA (not exposed to turbulent jet from stenotic valve due to 90° angle from main PA)
√ RV hypertrophy
√ bowing of interventricular septum to the left
√ decreased mobility of pliable + thin valve leaflets
Angio:
√ increase in trabecular pattern of RV
√ hypertrophied crista supraventricularis (lateral projection)

Supravalvular Pulmonic Stenosis

60% of all pulmonic valve stenoses
Site of narrowing: sinutubular junction, pulmonary trunk, pulmonary bifurcation, one / both main pulmonary arteries, lobar pulmonary artery, segmental pulmonary artery
Shape of narrowing:
(a) localized with poststenotic dilatation
(b) long tubular hypoplasia
May be associated with:
(1) Valvular pulmonic stenosis, supravalvular aortic stenosis, VSD, PDA, systemic arterial stenoses
(2) Familial peripheral pulmonic stenoses + supravalvular aortic stenosis
(3) **Williams-Beuren syndrome**: autosomal dominant multisystem disorder with supravalvular AS (in 71%), MV prolapse, PS, peculiar facies
(4) Ehlers-Danlos syndrome
(5) **Postrubella syndrome**: peripheral pulmonic stenoses, valvular pulmonic stenosis, PDA, low birth weight, deafness, cataract, mental retardation
(6) Tetralogy of Fallot / critical valvular pulmonic stenosis

Peripheral Pulmonary Artery Stenosis

Frequency: 5% of all pulmonary artery stenoses with an intact ventricular septum

RAYNAUD SYNDROME

= episodic digital ischemia in response to cold / emotional stimuli
Pathogenesis:
(1) Increase in vasoconstrictor tone
(2) Low blood pressure
(3) Slight increase in blood viscosity
(4) Immunologic factors (4–81%)
(5) Cold provocation

- exaggerated response of digit to cold / emotional stress:
  - numbness + loss of tactile perception
  - demarcated pallor / cyanosis
- hyperemic throbbing during rewarming
- sclerodactyly; small painful ulcers at tip of digit

Raynaud Disease

= PRIMARY VASOSPASM = SPASTIC FORM OF RAYNAUD SYNDROME

= exaggerated cold-induced constriction of smooth muscle cells in otherwise normal artery

Cause: ? acquired adrenoreceptor hypersensitivity

May be associated with: reflex sympathetic dystrophy, <u>early stages</u> of autoimmune disorders

Age: most common in young women

- usually affects all fingers of both hands equally

√ normal segmental arm + digit pressures at room temperature

√ peaked digit volume pulse = rapid rise in systole, anacrotic notch just before the peak, dicrotic notch high on the downslope

PPG:

√ flat-line tracing at low temperatures (10°–22°C) with sudden reappearance of normal waveform at 24–26°C = "threshold phenomenon"

Raynaud Phenomenon

= SECONDARY VASOSPASM WITH OBSTRUCTION

= OBSTRUCTIVE FORM OF RAYNAUD SYNDROME

= digital artery occlusion ← stenotic process in normally constricting artery / associated with an abnormally high blood viscosity

Cause:

1. Atherosclerosis (most frequent)
   (a) embolization from an upstream lesion
   (b) occlusion of major arteries supplying arm
2. Arterial trauma
3. <u>End stage</u> of many autoimmune disorders:
   eg, scleroderma, rheumatoid arthritis, systemic lupus erythematosus
4. Takayasu disease
5. Buerger disease
6. Drug intoxication: ergot, methysergide)
7. Dysproteinemia
8. Primary pulmonary hypertension
9. Myxedema

- normal vasoconstrictive response to cold

√ reduced segmental arm + digit pressures at room temperature

PPG (76% sensitivity, 92% specificity):

√ flat-line / barely detectable tracing at low temperature with gradual increase of amplitude upon rewarming

Hand magnification angiography:

1. Baseline angiogram with ambient temperature
2. Stress angiogram immediately following immersion of hand in ice water for 20 seconds

RECREATIONAL DRUG ABUSE

= INTRAVENOUS DRUG ABUSE

Incidence: 35,000,000 > 12 years of age admit to cocaine use at least once in their lifetime; 6,000,000 in a year, 2,300,000 in a month; 8,000,000 have used "crack"

◊ Cocaine is the most commonly used illicit drug + most frequent cause of drug-related deaths

Drugs:

nasal insufflation of cocaine, smoking of alkaloidal cocaine ("freebase", "crack"), amphetamines, amphetamine derivatives (3,4-methylenedioxymethamphetamine [MDMA] = "ecstacy"), opiates, cannabis, inhaled volatile agents (amyl and butyl nitrites = "poppers"), industrial solvents (toluene)

Complications secondary to:

(a) physical / mechanical effects of method of administration (eg, injection technique + choice of injection site [eg, "groin hit" into femoral vein; "pocket shot" into jugular, subclavian, brachiocephalic vein])
(b) chemical / pharmacologic effects of drug or combination of drugs (eg, heroin + cocaine / Talwin®)
(c) effects of adulterants / filler agents (eg, heroin is mixed ["cut"] with quinine, baking soda, sawdust)
(d) microbiologic sequelae (septic preparation)
(e) social + behavioral consequences

Cardiovascular Complications of Drug Abuse

A. Cardiac complications
   1. Acute myocardial ischemia + infarction
      Cause: intense coronary vasoconstriction, platelet activation (cocaine)
      Drug: amphetamines, cocaine
   2. Arrhythmia
   3. Dilated cardiomyopathy (often reversible)
      Cause: chronic drug abuse
   4. Endocarditis (esp. of tricuspid valve)
      Cause: bacteremia (most commonly S. aureus) with nonsterile IV administration

B. Arterial complications
   1. Aortic dissection
      Cause: systemic hypertension + positive inotropic + chronotropic cardiac effects of cocaine
   2. Arterial occlusion
      (a) at injection site ← intimal damage, thrombosis, spasm
      (b) distal to injection site ← embolization, spasm
   3. Pseudoaneurysm
   4. Mycotic aneurysm

5. Arteriovenous fistula
4. Embolization of infectious agent / foreign body / air through inadvertent arterial injection ("hit the pink")

C. Venous complications
1. Deep vein thrombosis (DVT) (after superficial veins have been exhausted)
"groin hit" into femoral vein; "pocket shot" into jugular, subclavian vein, brachiocephalic vein
2. Septic thrombophlebitis
3. Intravenous migration of needle to heart / lungs

Respiratory Complications of Drug Abuse

1. Bronchitis, epiglottitis, sinusitis
Drug: nasal insufflation of cocaine hydrochloride, smoking of alkaloidal cocaine (freebase, crack)
2. Nasal septal perforation = "cocaine nose"
Cause: ischemic necrosis from chronic cocaine use
3. Pneumonia
Cause: aspiration during altered consciousness, anesthetic effect of cocaine on pharynx
4. Pulmonary edema
Drug: opiate overdose, IV use of cocaine hydrochloride, smoking of crack cocaine, amphetamine, MDMA
Cause: cardiogenic, neurogenic pulmonary edema ← CNS effects of drug, direct toxic effect on alveolar-capillary membrane, immune response activation
5. Pulmonary hemorrhage
Drug: crack cocaine
6. Bland / septic pulmonary embolism
Cause: DVT, septic thrombophlebitis, tricuspid valve endocarditis
7. Pulmonary granulomatosis
Drug: insoluble filler agents in oral medications abused intravenously like talc (magnesium silicate), starch, cellulose
8. Emphysema
Drug: marijuana, IV abuse of methylphenidate (Ritalin)
9 Hemo- / pyo- / pneumothorax
Cause: attempted subclavian / jugular vein puncture ("pocket shot"), rupture of drug-related bulla, rupture of peripheral pulmonary abscess, inhalational maneuvers during crack / cannabis use

Neurologic Complications of Drug Abuse

1. Intracranial hemorrhage
Cause: sympathomimetic effect of → systemic vasoconstriction → increased cardiac output → severe acute hypertension
N.B.: in 50% underlying vascular lesion
Drug: esp. alkaloidal form of cocaine, amphetamine
2. Ischemic stroke
Cause: vasoconstrictive effects; platelet activation of cocaine; vasculitis in amphetamine

+ cocaine; embolic events in endocarditis / injection of particulate material

Drug: cocaine, MDMA, heroin

3. Posterior reversible encephalopathy syndrome (PRES)
   Drug: cocaine, amphetamine
4. Diffuse cerebral edema
   Cause: anoxic brain injury after drug-induced cardiac arrest, severe respiratory depression in opiate overdose, fulminant multiorgan failure in drug overdose
5. Toxic leukoencephalopathy
   Drug: inhalation of heroin vapor (pyrolysate) heated on tinfoil ("chasing the dragon"); inhalant abuse of industrial solvent toluene
6. Cerebral atrophy (esp. frontal lobes)
   Cause: chronic drug abuse
7. CNS infection
   Cause: left-sided endocarditis

Soft-tissue Complications of Drug Abuse

1. Cellulitis from subcutaneous injection ("skin popping") after exhausting all venous access
2. Pyomyositis
3. Necrotizing fasciitis
4. Abscess: esp. iliopsoas
5. Hematoma
6. Foreign bodies
7. Lymphadenopathy

Skeletal Complications of Drug Abuse

1. Osteomyelitis
   (a) direct contamination: eg, pubic bone ("groin hit") / clavicle ("pocket shot")
   (b) hematogenous: spine most commonly affected
2. Septic arthritis: sacroiliac, sternoclavicular, symphysis pubis, acromioclavicular, hip, knee, wrist
3. Diskitis

Cx: 1. Spinal epidural abscess in 5–18% ← vertebral osteomyelitis
2. Cord compression ← collapsed vertebral body

Visceral Complications of Drug Abuse

A. Gastrointestinal complications
   1. Severe colonic ileus resulting in chronic constipation + fecal impaction ← opiates
      Cx: stercoral colitis ← pressure necrosis; perforation of rectum / sigmoid colon
   2. Mesenteric ischemia / infarction (cocaine, amphetamines)
   3. Colonic pseudoobstruction
   4. Necrotizing enterocolitis
   5. Liver abscess

B. Genitourinary complications
   1. Acute renal toxicity
   2. Rhabdomyolysis

3. Renal infarction
4. Focal / segmental glomerulosclerosis ← heroin abuse
5. Distal tubular renal acidosis ← toluene abuse
6. Amyloidosis

C. Acquired viral infection
Cause: sharing of contaminated needles
1. HIV (in 5–10%)
2. Hepatitis B + C (20–59%)

RHABDOMYOMA OF HEART

= benign myocardial hamartoma
Prevalence: most common cardiac tumor in infancy + childhood (up to 90%)
Age: usually discovered < 1 year of age
Path: well-circumscribed intramural lobulated nodule / multiple < 1 mm nodules (= rhabdomyomatosis)
Histo: "spider cells" = enlarged vacuolated cells with high glycogen content + central nucleus surrounded by clear cytoplasm and radial extensions
Associated with: congenital heart disease

With cardiac rhabdomyomas tuberous sclerosis is found in 60–80%. With tuberous sclerosis > 50% have rhabdomyomas!

- asymptomatic (incidental detection at prenatal US)
- murmur, arrhythmia
- heart failure ← obstruction of left ventricular outflow tract / reduction of enddiastolic volume / decreased contractility
- supraventricular tachycardia ← accessory conductive pathways within tumor

Presentation: cardiac rhabdomyomas may precede skin lesions (hypopigmented "ash-leaf" macules) and neuroradiologic findings (subependymal nodules, cortical tubers) by months or years!

Location: multifocal (in up to 90%); ventricular wall with intramural growth + tendency to involve interventricular septum; atrial wall (rare)
Average size: 3–4 cm; up to 10 cm in diameter
US (good for small intramural lesions):
√ fetal nonimmune hydrops
√ solid echogenic sessile mass ± intracavitary component bulging into ventricular outflow tract / atrioventricular valve
√ diffuse myocardial thickening (with multiple small lesions)
MR (complimentary to US):
√ tumor iso- to marginally hyperintense on T1WI
√ hyperintense to myocardium on T2WI
√ hypointense to myocardium after contrast enhancement
Prognosis: may regress spontaneously in patients < 4 years old
Rx: surgical excision for life-threatening symptoms
DDx: fibroma (solitary centrally calcified + cystic tumor, in ventricular myocardium, associated with Gorlin syndrome); teratoma (single intrapericardial multicystic mass);

hemangioma (arise from right atrium, pericardial effusion, skin hemangiomas)

RIGHT AORTIC ARCH (RAA)

Prevalence: 1–2%

Embryology: persistence of right aortic arch and right descending aorta + regression of left aortic arch

Course: to right of trachea + esophagus, over right mainstem bronchus; crosses lower thoracic spine; passes through left hemidiaphragm

Incidence of right aortic arch in CHD:

1. Truncus arteriosus 35%
2. Pulmonary atresia 25%
3. Tetralogy of Fallot 25%
4. Tricuspid atresia 15%
5. DORV 12%
6. TGV 8%
7. Large VSD 2%

Rare anomalies:

1. Corrected transposition
2. Pseudotruncus
3. Asplenia
4. Pink tetralogy

RAA with Aberrant Left Subclavian Artery

= RAA with ALSA + left ligamentum arteriosum

Embryology: interruption of embryonic left arch between left CCA + left subclavian artery

◊ Most common type of right aortic arch anomaly

Prevalence: 1 ÷ 2,500; 35–72% of right aortic arch anomalies

◊ 2nd most common cause of vascular rings (12–25%) after double aortic arch

Associated with: congenital heart disease in 5–12%:

1. Tetralogy of Fallot (⅔ = 8%)
2. ASD ± VSD (¼ = 3%)
3. Coarctation (1/12 = 1%)

- usually asymptomatic (loose ring around trachea + esophagus)
- may be symptomatic in infancy / early childhood:
  - wheezing + stridor provoked by bronchitis + tracheal edema
  - dysphagia (50% of children and adults)
- may be symptomatic in adulthood provoked by torsion of aorta

√ left common carotid artery is first branch of ascending aorta

√ left subclavian artery arises from descending aorta via the remnant of the left dorsal aortic root (= lusorian artery)

√ bulbous configuration of origin of LSA (= remnant of embryonic left arch) = retroesophageal aortic diverticulum = **diverticulum of Kommerell** (N.B.: originally described as diverticular outpouching at origin of right subclavian artery with left aortic arch):

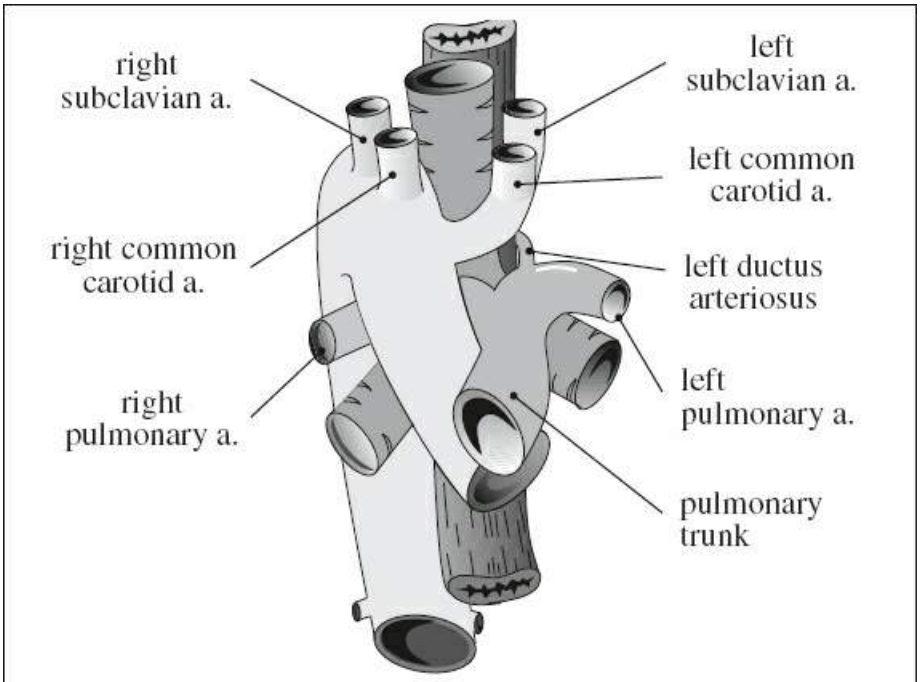
[Burckhard Friedrich Kommerell (1901-1990), chief of radiology at the Charité University Clinic in Berlin and radiologist in Heidelberg, Germany]

√ small rounded density left lateral to trachea

√ impression on left side of esophagus simulating a double aortic arch (by aortic diverticulum or ductus / ligamentum arteriosum)

√ vascular ring (= left ductus extends from aortic diverticulum to left pulmonary artery):

√ impression on tracheal air shadow (by right aortic arch)



Right Aortic Arch with Mirror-image Branching

√ right esophageal indentation (by right aortic arch)

√ masslike density silhouetting top of aortic arch just posterior to trachea on LAT CXR ← aberrant left subclavian artery

√ broad posterior impression on esophagus ← left subclavian artery / aortic diverticulum

√ small anterior impression on trachea ← left common carotid artery

√ descending aorta on right side

CT:

√ "four artery" sign = 2 dorsal subclavian arteries and 2 ventral carotid arteries evenly spaced around trachea

Right Aortic Arch with Mirror-image Branching

◊ 2nd most common aortic arch anomaly: 24–60%

= interruption of embryonic left arch between left subclavian artery and descending aorta; retroesophageal left ductus arteriosus / lig. arteriosum

Interruption of Left Aortic Arch Distal to Ductus Arteriosus = Type 1 (common)

Associated with: cyanotic CHD in 98%:

1. Tetralogy of Fallot (87%)
2. Multiple defects (7.5%)
3. Truncus arteriosus (2–6%)
4. Transposition (1–10%)
5. Tricuspid atresia (5%)
6. ASD ± VSD (0.5%)

◊ 25% (37%) of patients with tetralogy of Fallot (truncus arteriosus) have a right aortic arch!

√ NO vascular ring, NO retroesophageal component

√ NO structure posterior to trachea

√ R arch impression on tracheal air shadow

√ NORMAL barium swallow

Interruption of Left Aortic Arch Proximal to Ductus Arteriosus = Type 2 (rare)

= true vascular ring (if duct persists); rarely associated with CHD

RAA with Isolated Left Subclavian Artery

◊ 3rd most common right aortic arch anomaly: 2%

= interruption of embryonic left arch between
(a) left CCA and left subclavian artery and
(b) left ductus and descending aorta
resulting in a connection of left subclavian artery with left pulmonary artery

Associated with: tetralogy of Fallot

√ left common carotid artery arises as the first branch

√ left subclavian artery attaches to left pulmonary artery through PDA

√ NO vascular ring, NO retroesophageal component

• congenital subclavian steal syndrome

RAA with Aberrant Left Brachiocephalic Artery

Similar in appearance to R aortic arch + aberrant L subclavian artery

SINGLE VENTRICLE

= UNIVENTRICULAR HEART = DOUBLE INLET SINGLE VENTRICLE

= failure of development of interventricular septum ± absence of one atrioventricular valve (mitral / tricuspid atresia) ± aortic / pulmonic stenosis

Associated with: TGV or DORV

• conduction defect ← aberrant anatomy of conduction system

√ 2 atrioventricular valves connected to a main ventricular chamber

√ the single ventricle may be a LV (85%) / RV / undetermined

√ a second rudimentary ventricular chamber may be present, which is located anteriorly (in left univentricle) / posteriorly (in right univentricle):
√ rudimentary chamber ± connection to one great artery

√ may be associated with tricuspid / mitral atresia

SPLENIC ARTERY ANEURYSM

= most frequent of visceral artery aneurysms
Etiology: medial degeneration with superimposed atherosclerosis, congenital, mycotic, pancreatitis, trauma, portal hypertension (in 7–10% ← high flow rate)
Predisposed: women with ≥ 2 pregnancies (88%)
May be associated with: fibromuscular disease (in 20%)
M÷F = 1÷2
• usually asymptomatic / pain, GI bleeding
Location: intra- / extrasplenic
√ calcified wall of aneurysm (²/₃)
Cx: rupture of aneurysm (6–9%, higher during pregnancy) especially if > 1.5 cm in diameter
Mortality: up to 76%
DDx: renal artery aneurysm, tortuous splenic artery

SUBCLAVIAN STEAL SYNDROME

= stenosis / obstruction of subclavian artery near its origin with flow reversal in ipsilateral vertebral artery at the expense of the cerebral circulation
Frequency: 2.5% of all extracranial arterial occlusions
Etiology:
(a) congenital: interruption of aortic arch, preductal infantile coarctation, hypoplasia of left aortic arch, hypoplasia / atresia / stenosis of an anomalous left subclavian artery with right aortic arch, coarctation with aberrant subclavian artery arising distal to the coarctation
(b) acquired: atherosclerosis (94%), dissecting aneurysm, chest trauma, embolism, tumor thrombosis, inflammatory arteritis (Takayasu, syphilitic), ligation of subclavian artery in Blalock-Taussig shunt, complication of coarctation repair, radiation fibrosis
Average age: 59–61 years; M÷F = 3÷1; Whites÷Blacks = 8÷2
Associated with: additional lesions of extracranial arteries in 81%
• lower systolic blood pressure by > 20–40 mmHg on affected side
• delayed weak / absent pulse in ipsilateral extremity
• signs of vertebrobasilar insufficiency (40%):
  • syncopal episodes initiated by exercising the ischemic arm
  • headaches, nausea, vertigo, ataxia
  • mono-, hemi-, para-, quadriparesis, paralysis
  • diplopia, dysphagia, dysarthria, paresthesias around mouth
  • uni- / bilateral homonymous hemianopia
• signs of brachial insufficiency (3–10%):
  • intermittent / constant pain in affected arm precipitated by increased activity of that arm
  • paresthesia, weakness, coolness, numbness, burning in fingers + hand; fingertip necrosis
Location: L÷R = 3÷1
Color Doppler:
√ reversal of vertebral artery flow → augmented by arm exercise / reactive hyperemia (= blood pressure cuff inflated above systolic pressure for 5 min)
Angio:
√ subclavian stenosis / occlusion (aortic arch injection)
√ reversal of vertebral artery flow (selective injection of contralateral subclavian / vertebral

artery)

CAVE: "false steal" = transient retrograde flow in contralateral vertebral artery caused by high-pressure injection

Rx: bypass surgery, PTA (good long-term results)

Partial Subclavian Steal Syndrome

= retrograde flow in systole + antegrade flow in diastole

Occult Subclavian Steal Syndrome

= reverse flow seen only after provocative maneuvers, ie, ipsilateral arm exercise of 5 min / 5 min inflation of sphygmomanometer > systolic blood pressure levels

SUPERIOR MESENTERIC ARTERY SYNDROME

= ARTERIOMESENTERIC DUODENAL COMPRESSION SYNDROME = WILKIE SYNDROME = CHRONIC DUODENAL ILEUS = BODY CAST SYNDROME

= rare cause of duodenal obstruction ← compression of 3rd portion of duodenum between SMA and aorta; probably representing a functional reflex dilatation

Normal anatomy: see "nutcracker phenomenon"

Cause: congenital, weight loss, visceroptosis ← loss of abdominal muscle tone (as in pregnancy), asthenic build, exaggerated lumbar lordosis, prolonged bed rest in supine position

Pathophysiology:

(1) rapid severe weight loss ← cachexia (AIDS, malabsorption, cancer); catabolic condition (burns, major surgery); eating disorder (anorexia nervosa); drug abuse; post bariatric surgery → loss of retroperitoneal fat → decrease in angle (AMA) + space (AMD) → duodenal compression

(2) Post scoliosis surgery → lengthening of spine → increased tension on mesentery → decreased AMA and AMD

(3) Applied external abdominal pressure (body / hip spica cast)

(4) Anatomic variant: insertional variation of ligament of Treitz / low origin of SMA → more cranial disposition of duodenum → acute AMA

Frequency: 0.1–0.3% of barium studies

Age: 10–39 years; M÷F = 1÷2

- postprandial epigastric pain and fullness relieved by lying prone / in left lateral decubitus position
- nausea, repetitive vomiting, weight loss, anorexia
- severe esophagitis + gastritis ← stasis / chronic obstruction

Angio / sagittal MR / reformatted CT (test of choice):

√ narrowing of angle between SMA + aorta to 6–22° (AMA)

√ reduced distance between SMA + aorta to 2–8 mm (AMD)

Upper GI:

√ megaduodenum = pronounced dilatation of 1st + 2nd portion of duodenum + frequently dilated stomach (best seen in supine position)

√ vertical linear compression defect in transverse portion of duodenum overlying spine

√ abrupt change in caliber distal to compression defect

√ antiperistaltic waves proximal to obstruction
√ delayed gastroduodenal emptying
√ relief of obstruction by postural change into prone knee-elbow position

Rx: (1) conservative: fluid + electrolyte resuscitation, nasojejunal feeding, small liquid meals, prone / left lateral decubitus patient position, restoration of retroperitoneal fat through hyperalimentation)

(2) surgery: duodenojejunostomy, gastrojejunostomy, Strong procedure (= lysis of ligament of Treitz with derotation of bowel)

SUPERIOR VENA CAVA SYNDROME

= obstruction of SVC with development of collateral pathways

Etiology:

A. MALIGNANT LESION (78–97%)
   1. Bronchogenic carcinoma (50–80%)
   2. Lymphoma (2–20%)
   3. Metastatic mediastinal nodes (← commonly breast ca.)
   4. Mediastinal germ cell tumor
   5. Malignant thymoma

B. BENIGN LESION
   1. Granulomatous mediastinitis: usually histoplasmosis, sarcoidosis, TB
   2. Substernal goiter
   3. Ascending aortic aneurysm
   4. Pacer wires / central venous catheter (23%)
   5. Constrictive pericarditis

Collateral routes:

1. Esophageal venous plexus = "downhill varices" (predominantly upper $^{2}/_{3}$ of esophagus)
2. Azygos + hemiazygos veins
3. Accessory hemiazygos + superior intercostal veins = "aortic nipple" (visualization in normal population in 5%)
4. Lateral thoracic veins + umbilical vein
5. Vertebral veins

• head and neck edema (70%), headache, dizziness, syncope
• cutaneous enlarged venous collaterals, proptosis, tearing
• with benign etiology: slower onset + progression, both sexes at 25–40 years of age
• with malignancy: rapid progression within weeks, mostly males at 40–60 years of age
• dyspnea, cyanosis, chest pain, hematemesis (11%)

√ superior mediastinal widening (64%)
√ encasement / compression / occlusion of SVC
√ dilated cervical + superficial thoracic veins (80%)
√ SVC thrombus

NUC:

√ increased tracer uptake in quadrate lobe + posterior aspect of medial segment of left lobe ← umbilical pathway toward liver when injected in upper extremity

TAKAYASU ARTERITIS

= PULSELESS DISEASE = AORTITIS SYNDROME

= AORTOARTERITIS = IDIOPATHIC MEDIAL AORTOPATHY = AORTIC ARCH SYNDROME = MARTORELL SYNDROME

= idiopathic chronic relapsing necrotizing obliterative segmental large-vessel panarteritis affecting mainly elastic arteries (aorta > main aortic branches > pulmonary arteries) limited to persons usually < 50 years of age

◊ The only form of aortitis that produces stenosis / occlusion of the aorta!

Etiology: probably cell-mediated autoimmune process

Prevalence: 1÷1,000,000; 2.2% (at autopsy)

Incidence: 2.6÷1,000,000 annually (USA)

Geography: common in Asia, Mediterranean basin, South Africa, Latin America; rare in Europe + North America

Age: 12–66 years; M÷F = 1÷8; especially in Asians

◊ Primary large-vessel vasculitis in children and adults!

◊ 3rd most common form of childhood vasculitis!

Histo: (a) Acute stage: granulomatous infiltrative process focused on elastic fibers of media of arterial wall consisting of multinucleated giant cells, lymphocytes, histiocytes, plasma cells; perivascular cuffing of vasa vasorum

(b) Fibrotic stage (weeks to years): progressive fibrosis of vessel wall resulting in constriction from intimal proliferation / thrombotic occlusion / aneurysm formation (← extensive destruction of elastic fibers in media); → ultimately fibrosis of intima + adventitia

◊ Morphologically indistinguishable from temporal arteritis!

Clinical stages: often overlapping ← relapsing course

» prepulseless / systemic / early phase

Duration: few months – 1 year

- nonspecific systemic signs + symptoms: fever, night sweats, weakness, weight loss, myalgia, arthralgia

◊ Mean interval of 8 years between onset of symptoms + Dx

» vascular inflammatory phase

» pulseless / occlusive / late phase

- signs + symptoms of ischemia of limb (arm claudication, pulse deficit, bruits, discrepant blood pressures)
- renovascular hypertension, abdominal angina
- visual symptoms

- neurologic symptoms: transient ischemic attack, stroke, hypertensive encephalopathy
- erythrocyte sedimentation rate (ESR) > 20 mm/hour in 80%

The diagnosis of Takayasu arteritis is based on clinical information, laboratory evaluation, and diagnostic imaging, because a large-vessel biopsy cannot be performed.

Numano classification: involvement usually bilateral

Type I : branches of aortic arch = brachiocephalic trunk + carotid arteries + subclavian arteries

Type II : combination of type I + III
IIa : ascending aorta / aortic arch ± branches
IIb : descending thoracic aorta ± ascending aorta / aortic arch with its branches
Type III : entire descending aorta ± renal arteries
Type IV : abdominal aorta ± renal arteries
Type V : entire aorta with branches
C / P(+) = involvement of coronary / pulmonary arteries
Commonly involved: left subclavian artery (< 50%), left common carotid artery (20%), brachiocephalic trunk, renal arteries, celiac trunk, superior mesenteric a., pulmonary a.
Infrequently involved: axillary, brachial, vertebral, iliac arteries (usually bilaterally), coronary arteries

Angiography / DSA:
◊ Difficult catheterization / risk of ischemic complications ← increase in coagulation!
√ arterial wall thickening + contrast enhancement
√ full-thickness calcification (= chronic disease)
√ mural thrombi
Dx: involvement of > 2 medium-sized branch vessels

CXR:
√ widened supracardiac shadow > 3.0 cm
√ wavy / scalloped appearance of lateral margin of descending aorta
√ aortic calcifications (15%) commonly in aortic arch + descending aorta
√ focal decrease of pulmonary vascularity

NECT:
√ high-attenuation arterial walls of variable thickness
√ calcifications in aorta + its branches

CT angiography (95% sensitive, 100% specific):
√ concentric thickening of vessel wall > 3 mm:
√ "double ring" appearance = poorly enhanced internal ring (= swollen intima) + enhancing outer ring (= inflamed media and adventitia)
√ mural thrombus, stenosis, occlusion
√ vessel ectasia, aneurysm, ulcer
√ typically linear wall calcifications after > 5 years (usually sparing ascending aorta)

MR:
› acute / active inflammatory phase:
√ thickened enhancing arterial wall (on fat-suppressed T1)
√ mural edema of arterial wall (STIR) = measure of disease activity
√ bright T2 signal around inflamed vessel
√ mural thrombus, multilevel stenosis
√ thickening of aortic valve cusps
√ pericardial effusion
› late phase:
√ dilatation of ascending aorta

√ segmental dilatation with stenotic regions of CCA + subclavian artery
√ complete occlusion of supra-aortic arteries at their origin, + multiple collaterals
» luminal changes: multifocal stenoses, fusiform vascular dilatation, mural thrombi, collateral vessel formation

US:
√ "macaroni sign" long segment of smooth homogeneous concentric wall thickening
√ increased intimal-medial thickness = reliable marker for disease activity

@ Aorta (common involvement)
Location: abdominal aorta > descending thoracic > arch
√ long + diffuse / short + segmental irregular stenosis / occlusion of major branches of aorta near their origins
√ stenotic lesions of descending thoracic > abdominal aorta
√ frequent skipped lesions
√ abundant collateralization (late phase)
√ aneurysmal dilatation of ascending aorta + arch (= diffusely dilated lumen with irregular contours) → aortic insufficiency
√ fusiform / saccular aortic aneurysms (10–15%) (common in descending thoracic + abdominal aorta)
Cx: rapid aneurysm expansion → aortic rupture (33%)

@ Brachiocephalic arteries
√ multisegmented dilatation of carotid artery producing segmental septa
√ diffuse homogeneous circumferential thickening of vessel wall in proximal common carotid artery
√ increase in flow velocity + turbulence
√ distal CCA, ICA, ECA spared with dampened waveforms

@ Pulmonary arteries (50–80%)
Location: segmental + subsegmental (common); lobar + main pulmonary arteries (uncommon)
◊ often late manifestation of disease
√ dilatation of pulmonary trunk (19%)
√ nodular thrombi (3%)
√ "pruned tree" appearance / flame-shaped stenosis of pulmonary arteries (66%)
√ unilateral occlusion / aneurysm of pulmonary artery
√ systemic-pulmonary artery shunts
CT angio:
√ wall thickening with enhancement (acute)
√ luminal + mural calcium deposition (chronic)
√ pulmonary artery stenosis / occlusion (chronic)

@ Coronary arteries (in up to 20%)

Cx: (1) Cerebrovascular accidents (10–20%)
(2) Heart failure ← aortic regurgitation

DDx: atherosclerosis; temporal arteritis (CCA not involved); fibromuscular dysplasia (in ICA not CCA); idiopathic carotid dissection (ICA); syphilitic aortitis (calcification of ascending aorta)

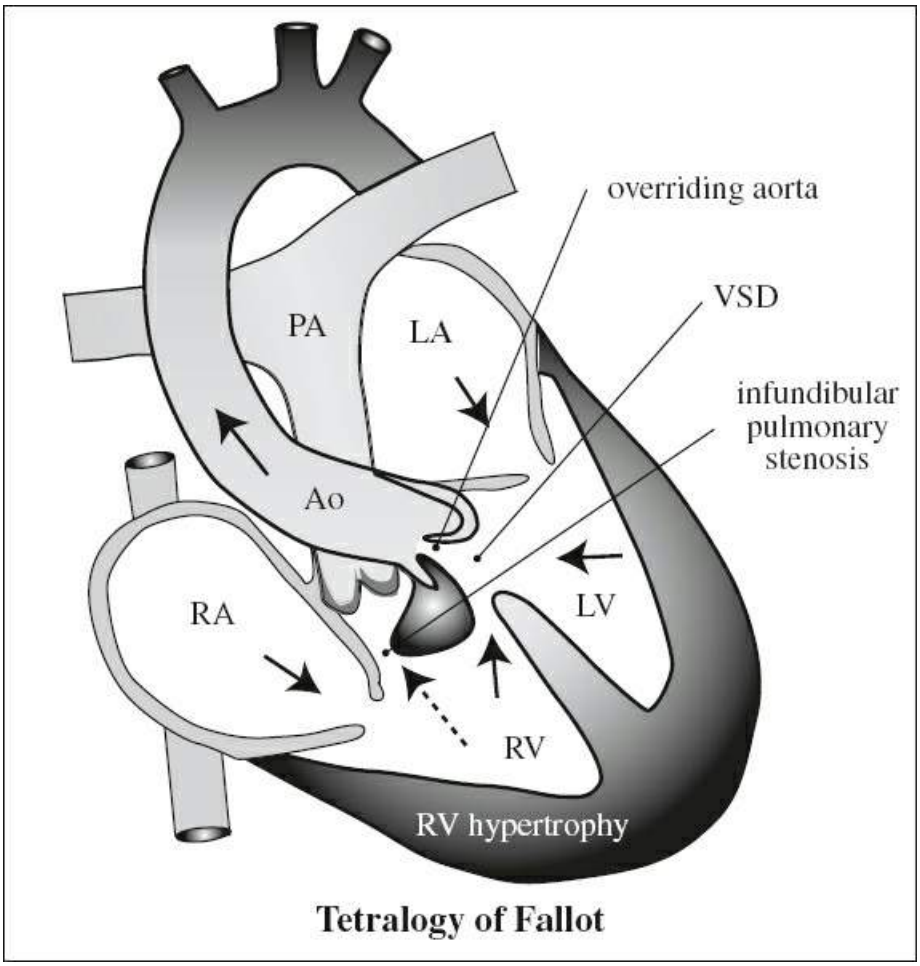
Rx: high-dose glucocorticoids, angioplasty after decline of active inflammation

TEMPORAL ARTERITIS

= CRANIAL / GRANULOMATOUS ARTERITIS
= POLYMYALGIA RHEUMATICA = GIANT CELL ARTERITIS (poor choice because Takayasu disease is also a giant cell arteritis)
= systemic chronic granulomatous vasculitis

Giant cell arteritis is a chronic vasculitis that affects large and medium-sized vessels, usually involving the superficial cranial arteries. It is closely related to polymyalgia rheumatica.

Incidence: 20÷100,000 annually;
◊ Most common form of aortitis in North America!
Age: usually limited to persons > 50 years of age
Histo: closely related to polymyalgia rheumatica
(a) acute stage: granulomatous infiltrative process focused on elastic fibers of arterial wall (internal elastic lamina) consisting of multinucleated giant cells, lymphocytes, histiocytes, plasma cells
(b) fibrotic stage (weeks to years): progressive fibrosis of vessel wall resulting in constriction from intimal proliferation / thrombotic occlusion / aneurysm formation
◊ Morphologically indistinguishable from Takayasu arteritis!
Age peak: 65–75 years; M÷F = 1÷3
› prodromal phase of flulike illness of 1–3 weeks:
• malaise, low-grade fever, weight loss, myalgia
• unilateral headache (50–90%), facial pain
› chronic stage:
• jaw claudication (while chewing + talking)
• neuroophthalmic manifestations: visual impairment /diplopia / blindness; palpable tender temporal artery
• polymyalgia rheumatica (50%) = intense myalgia of shoulder + hip girdles
• erythrocyte sedimentation rate (ESR) of 40–140 mm/hour (HALLMARK)
Location:
any artery of the body; mainly medium-sized branches of aortic arch (10%), external carotid artery branches (particularly superficial temporal / occipital artery); vertebral artery; coronary arteries; mesenteric arteries; extracranial arteries below neck (9%): subclavian > axillary > brachial > profunda femoris > forearm > calf



Note: intracranial ICA + intracranial vertebral artery are not involved as internal elastic lamina ceases to exist 5 mm distal to entry point through dura mater

Distribution: commonly bilateral + symmetric

√ long smooth stenotic arterial segments with skip areas

√ smooth tapered occlusions with abundance of collateral supply

√ absence of atherosclerotic changes

CT angiography:

√ luminal changes: stenosis, occlusion, dilatation

√ mural thrombus, aneurysm formation, mural calcifications

MR angiography:

√ edema of arterial wall (STIR) = measure of disease activity

√ smooth tapering proximal + distal to lesion

US:

√ "halo" sign = diffusely thickened hypoechoic arterial wall

√ ± turbulent flow + stenosis of affected vessel

PET (56% sensitive, 98% specific):

√ abnormal uptake in aortic arch + large thoracic arteries

@ Aorta

√ anuloaortic ectasia + ascending aortic aneurysm that may extend into aortic arch (late

complication)
√ aortic valve insufficiency, acute dissection
√ abdominal aortic aneurysm

Cx: stroke in vertebrobasilar territory (rare)

Dx: biopsy of palpable temporal artery

Prognosis: disease may be self-limiting (1–2 years); 10% mortality within 2–3 years

TETRALOGY OF FALLOT

[Etienne-Louis Arthur Fallot (1850–1911), physician of forensic medicine and hygiene in Marseille, France]

= underdevelopment of pulmonary infundibulum ← unequal partitioning of conotruncus = anterior malalignment of conal septum

Frequency: 8–11% of all CHD; most common cyanotic CHD

Prevalence: 3.3÷100,000 live births

TETRAD:

1. Large VSD immediately below aortic valve
2. Right ventricular hypertrophy (in long-standing untreated disease) ← elevated RV systolic pressure
3. Overriding aorta straddling VSD and receiving blood from both ventricles
4. Obstruction of right ventricular outflow tract: usually of pulmonary infundibulum, occasionally pulmonic valve atresia

mnemonic: Don't DROP the baby

Defect: VSD
Right ventricular hypertrophy
Overriding aorta
Pulmonary stenosis

Embryology:

abnormal spiraling caudad growth of truncoconal ridges in 3rd–4th week causes unequal partitioning of the conotruncus into a small underdeveloped anteromedial pulmonary infundibulum + large posterolateral LV outflow tract

Hemodynamics:

fetus: pulmonary blood flow supplied by retrograde flow through ductus arteriosus with absence of RV hypertrophy / IUGR

neonate: R-to-L shunt bypassing pulmonary circulation with decrease in systemic oxygen saturation (cyanosis); pressure overload + hypertrophy of RV ← pulmonic-infundibular stenosis

RA	↔/↑	RV	↑	Main PA	↓
Pulm. vessels	↓			LPA	↑
LA	↔	LV	↔	Ao	↑

Systemic pulmonary supply:

via major aortopulmonary (systemic-pulmonary) collaterals

Associated with:

1. Bicuspid pulmonic valve (40%)

2. Stenosis of left pulmonary artery (40%)
3. Right aortic arch (25%) with mirror-image branching
4. Tracheoesophageal fistula
5. Down syndrome
6. Forked ribs, scoliosis
7. Anomalies of coronary arteries in 10% (single RCA / LAD from RCA)

- cyanosis by 3–4 months of age (concealed at birth by PDA)
- dyspnea on exertion, clubbing of fingers and toes
- "squatting position" when fatigued → ↑ pulmonary blood flow
- "episodic spells" = loss of consciousness
- polycythemia, lowered pO2 values, systolic murmur in pulmonic area

CXR:

√ coeur en sabot (boot-shaped heart)
[*sabot* , French = wooden shoe / clog]
= uplifting of cardiac apex due to (1) right ventricular hypertrophy + (2) small / absent main pulmonary artery (in 65%) accentuated by large lung volume + small thymus + lordotic projection

√ pronounced concavity in region of pulmonary artery trunk ← small / absent PA

√ marked reduction in caliber + number of pulmonary arteries ← reduced blood flow to lungs:

√ asymmetric pulmonary vascularity

√ reticular pattern with horizontal course usually in periphery (= prominent collateral circulation of bronchial vessels + pleuropulmonary connections)

√ enlarged aorta

√ right-sided aortic arch in 25%

OB-US:

√ dilated aorta overriding the interventricular septum

√ usually perimembranous VSD

√ mildly stenotic RV outflow tract

√ NO RV hypertrophy in midtrimester

ECHO:

√ discontinuity between anterior aortic wall + interventricular septum (= overriding of the aorta)

√ small left atrium

√ RV hypertrophy with small right ventricular outflow tract

√ widening of the aorta

√ thickening of right ventricular wall + interventricular septum

Prognosis: spontaneous survival without surgical correction in 50% (10%) up to age 7 (21) years

Rx: surgery in early childhood

(a) palliative

1. Blalock-Taussig shunt = end-to-side anastomosis of subclavian to pulmonary artery opposite aortic arch [64% (55%) survival rate at 15 (20) years]
2. Pott operation on left = anastomosis of left PA with descending aorta

3. Waterston-Cooley procedure = anastomosis between ascending aorta + right pulmonary artery
4. Central shunt = Rastelli procedure = tubular synthetic graft between ascending aorta + pulmonary artery

(b) corrective open cardiac surgery = VSD-closure + reconstruction of RV outflow tract by excision of obstructing tissue (82% survival rate at 15 years)

Operative mortality: 3–10%

Pink Tetralogy

= infundibular hypertrophy → minimal RVOT obstruction + VSD (3%) with predominantly L-to-R-shunt → no cyanosis

Pentalogy of Fallot

= tetralogy + ASD

Trilogy of Fallot (infantile presentation)

(1) Severe pulmonic valvular stenosis
(2) Hypertrophy of RV
(3) ASD with R-to-L shunt (increased pressure in RA forces foramen ovale open)

THORACIC OUTLET SYNDROME

= neurovascular syndrome caused by compression of subclavian vessels + brachial plexus between chest and arm

Prevalence: 0.3–8.0%

Age: 20–40 years; M÷F = 1÷3 to 1÷4

Thoracic outlet: above 1st rib and behind clavicle

(a) interscalene triangle = most medial space
◊ In 50% responsible for neurologic compression!
Borders: anterior scalene muscle (anteriorly), middle scalene muscle (posteriorly), medial surface of 1st rib (inferiorly)
Content: subclavian artery, 3 divisions of brachial plexus

(b) costoclavicular space
◊ Most frequent site of vascular compression!
◊ In 50% responsible for neurologic compression!
Borders: middle ⅓ of clavicle (superiorly), subclavius muscle (anteriorly), 1st rib + middle scalene muscle (posteriorly)
Content: subclavian vein

(c) retropectoralis minor / subcoracoid space
◊ Rare site of compression!
Borders: pectoralis minor muscle (anteriorly), subscapularis muscle (posteriorly + superiorly), anterior chest wall (posteriorly + inferiorly)
Content: axillary vessels, 3 cords of brachial plexus

Arm abduction: → narrowing of thoracic inlet in costoclavicular + retropectoralis minor spaces

Cause:

A. CONGENITAL / ANATOMIC
   1. Cervical rib (< 1% of general population)
   2. Scalene muscle anomaly
      (a) hypertrophy of anterior scalene muscle = **scalenus anticus syndrome** (most common)
      (b) common origin of anterior + middle scalene mm.
      (c) passage of brachial plexus through substance of anterior scalene muscle
      (d) supernumerary scalenus minimus muscle (rare) extending from transverse process of 7th cervical vertebra to 1st rib with insertion between brachial plexus + subclavian artery
   4. Anomalous 1st rib = unusually straight course with narrowing of costoclavicular space
   5. Elongated transverse process of C7
   6. Congenital fibromuscular bands

B. ACQUIRED / POSTTRAUMATIC
   1. Fracture of clavicle / 1st rib (34%) with nonanatomic alignment / exuberant callus
   2. Posttraumatic fibrosis of scalene muscles
   3. Slender body habitus
      = long neck, sagging / drooping shoulders ← backpacking
   4. Muscular body habitus
      = arterial compression in pectoralis minor tunnel affecting weight lifter, swimmer, tennis player
   5. Supraclavicular tumor (lipoma, neurogenic tumor) / lymphadenopathy

Neurogenic Thoracic Outlet Syndrome (95%)

- pain in forearm + hand that increases upon elevation and abduction of arm (sustained reaching overhead)
- paresthesias of hand + fingers (C8 + T1) in ulnar nerve distribution with numbness, "pins and needles" in 95%
- arm pain in radial nerve distribution (C5-C7 roots) and pain in neck, ear, upper chest, upper back
- numbness, weakness, thenar wasting

Rx: physical therapy; NSAID; muscle relaxants

Venous Thoracic Outlet Syndrome (4%)

- arm swelling, distention of superficial veins, cyanosis, pain

Paget-von Schrötter Syndrome

[Leopold von Schrötter (1837–1908), director of the world's first laryngological clinic at Vienna General Hospital and head of the department of internal medicine]

= EFFORT THROMBOSIS

= primary thrombosis of subclavian vein at costoclavicular junction (= subtype of thoracic outlet syndrome)

Incidence: 1–2÷100,000 annually

Cause: repetitive / vigorous activity

Rx: catheter-mediated thrombolysis (initially) + surgical decompression of

costoclavicular junction

Arterial Thoracic Outlet Syndrome (1%)

- decreased skin temperature, discoloration of hand
- intermittent claudication of fingers (from ischemia)
- hyperabduction maneuver with obliteration of radial pulse (34%)
- Raynaud phenomenon (40%): episodic constriction of small vessels
- supraclavicular bruit (15–30%)
- **Roos test** = repeated clenching of fist with abducted + externally rotated arms
- Adson test = palpation of radial pulse with patient sitting upright, hands on thigh, neck hyperextended, head turned toward affected side
- **Wright test** = diminution of pulse during hyperabduction of arms

Bidirectional Doppler:

1. **Adson maneuver** (for scalenus anticus muscle)
   = hold deep inspiration while neck is fully extended + head turned toward ipsilateral and opposite side
2. Costoclavicular maneuver (compression between clavicle + 1st rib) = exaggerated military position with shoulders drawn back and downward
3. Hyperabduction maneuver (compression by humeral head / pectoralis minor muscle) = extremity monitored through range of 180° abduction

√ complete cessation of flow in one position

Photoplethysmography:

1. Photo pulse transducer secured to palmar surface of one fingertip of each hand
2. Arterial pulsations recorded with arm in
   (a) neutral position
   (b) extended 90° to side
   (c) 180° over the head
   (d) in "military" position with arms at 90° + shoulders pressed back

√ complete disappearance of pulse in one position

Angio:

√ abnormal course of distal subclavian artery
√ focal stenosis / occlusion
√ poststenotic dilatation of distal subclavian artery
√ aneurysm
√ stress test: bandlike / concentric constriction
√ mural thrombus ± distal embolization
√ venous thrombosis / obstruction

Positional CTA (with adducted + then hyperabducted arms):

√ vascular compression
√ collateral arterial circulation

MR:

√ denervation-related fatty atrophy of muscles
√ effacement of fat planes around compressed plexus
√ abnormal intramuscular course of brachial plexus components

Rx: thrombolytic therapy + concomitant anticoagulation (in acute thrombosis); NOT

endoluminal stent; surgery

DDx: Cervical disk disease, radiculopathy, spinal cord tumor, trauma to brachial plexus, arthritis, carpal tunnel syndrome, Pancoast tumor, peripheral arterial occlusive disease, aneurysm, causalgia, thromboembolism, Raynaud disease, vasculitis

TRANSPOSITION OF GREAT ARTERIES

Complete Transposition of Great Arteries

= TGA = D-TRANSPOSITION

= great vessels originate from inappropriate ventricle:

(1) Aorta originates from morphologic RV with an infundibulum

(2) Pulmonary artery originates from morphologic LV

(3) Normal position of atria + ventricles

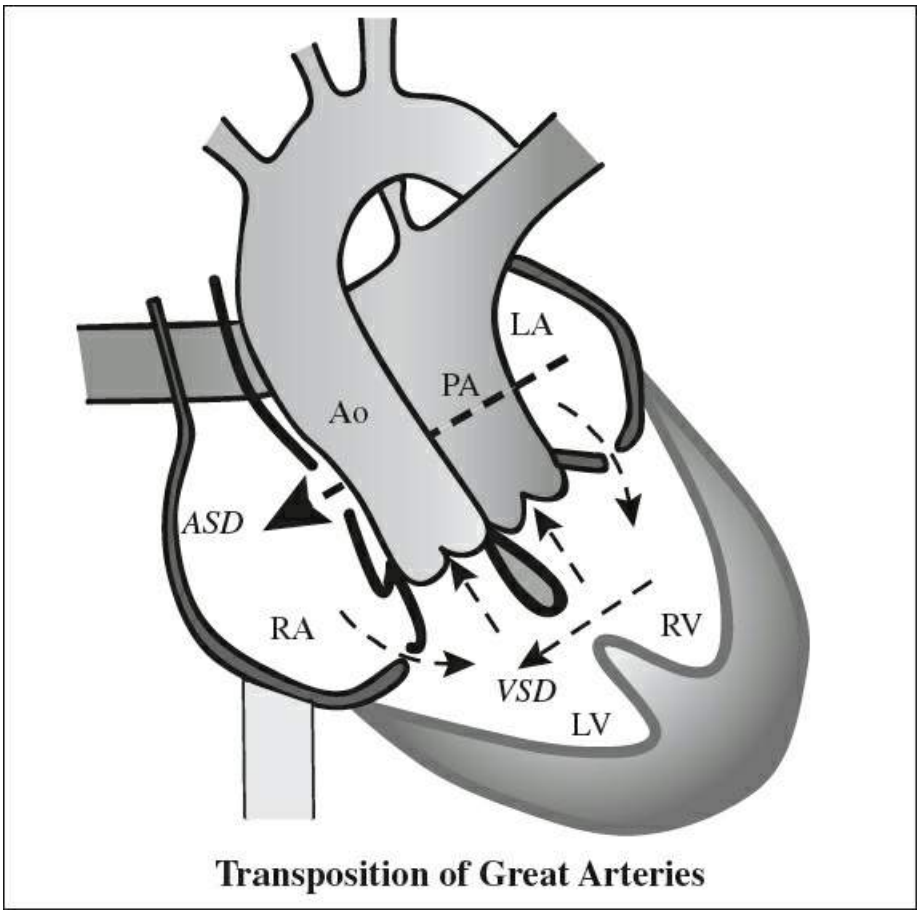
Embryology: failure of the aorticopulmonary septum (= truncoconal ridges) to follow a spiral course

Frequency: 5–7% of all CHD

In 10% associated with: a syndrome / extracardiac malformation; in 90% isolated

VARIATIONS:

1. Complete TGA + intact interventricular septum



Transposition of Great Arteries

2. Complete TGA + VSD: CHF due to VSD
3. Complete TGA + VSD + PS: PS prevents CHF = longest survival

Hemodynamics:

fetus : no hemodynamic compromise with normal birth weight

neonate : mixing of the 2 independent circulations necessary to sustain life

Admixture of blood from both circulations via:

(1) PDA (carries aortic blood into pulmonary artery)

Prognosis: worst when PDA closes → increase in volume of pulmonary blood flow

(2) ASD / patent foramen ovale (allows saturated blood to enter RA from LA)

(3) VSD (in 50%)

RA	↑	RV	↑	Main PA	↔
Pulm. vessels	↑				
LA	↔	LV	↔	Ao	↔

Associated with: diabetic mothers

- cyanosis: most common cause for cyanosis in neonate; 2nd most common cause of cyanosis after tetralogy of Fallot

- symptomatic 1–2 weeks following birth

CXR:

√ "egg-on-a-string" appearance of heart (on frontal CXR):

√ abnormal convexity of RA border (= "egg")

√ narrow superior mediastinum (= "string" = MOST CONSISTENT SIGN):

√ PA situated to the right of its normal location

√ PA obscured by aorta

√ stress-induced thymic atrophy

√ hyperaeration

√ cardiac enlargement beginning 2 weeks after birth (= "egg on its side") following closure of PDA:

√ enlargement of right heart

√ enlargement of LA (with VSD)

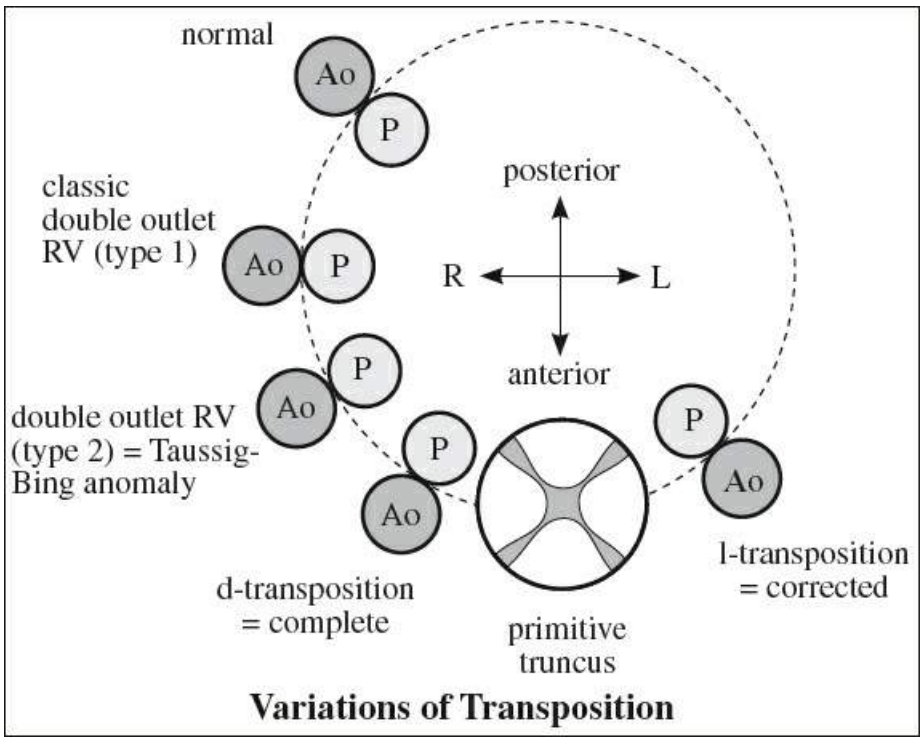
√ absent pulmonary trunk (99%) = PA located posteriorly in midline

√ increased pulmonary blood flow (if not associated with PS) → enlargement of LA

√ midline aorta (30%) / ascending aorta with convexity to the right

√ right aortic arch in 3% (difficult assessment due to midline position + small size)

OB-US:



Variations of Transposition

√ great arteries arise from ventricles in a parallel fashion
√ aorta anterior + to right of pulmonary artery (in 60%; rarely side by side)

Prognosis: overall 70% survival rate at 1 week, 50% at 1 month, 11% at 1 year by natural history

Rx:

(1) Prostaglandin E1 administration to maintain ductal patency
(2) Rashkind procedure = balloon septostomy to create ASD
(3) Blalock-Hanlon procedure = surgical creation of ASD
(4) Mustard operation (corrective) = removal of atrial septum + creation of intraatrial baffle directing the pulmonary venous return to RV + systemic venous return to LV; 79% 1-year survival rate; 64–89% 5-year survival

Corrected Transposition of Great Arteries

= CONGENITALLY CORRECTED TRANSPOSITION = L-TRANSPOSITION = VENTRICULAR INVERSION
= anomalous looping of the bulboventricular loop (= primordial ventricles) associated with lack of spiral rotation of conotruncal septum characterized by

(1) Transposition of great arteries (= aorta anterior + to right of PA)
(2) Inversion of ventricles (LV on right side, RV on left side):
  (a) RA connected to morphologic LV
  (b) LA connected to morphologic RV
(3) AV valves + coronary arteries follow their corresponding ventricles

Hemodynamics: functionally corrected abnormality

Associated with:

(1) Usually perimembranous VSD (in > 50%)
(2) Pulmonic stenosis (in 50%)

(3) Anomaly of left (= tricuspid) atrioventricular valves (Ebstein-like) → insufficiency
(4) Dextrocardia (high incidence)

• NO cyanosis, atrioventricular block (malalignment of atrial + ventricular septa)

CXR:
√ abnormal convexity / straightening in upper portion of left heart border (ascending aorta arising from inverted RV)
√ inapparent aortic knob + descending aorta (overlying spine)
√ inapparent pulmonary trunk (rightward posterior position) = PREMIER SIGN
√ humped contour of lower left heart border with elevation above diaphragm (anatomic RV)
√ apical notch (= septal notch)
√ increased pulmonary blood flow (if shunt present)
√ pulmonary venous hypertension (if left-sided AV valve incompetent)
√ LA enlargement

MR:
√ posterior cardiac chamber has moderator band + muscular infundibulum (morphologic RV)

Angio:
√ original LV on right side: smooth-walled, cylinder- / cone-shaped with high recess emptying into aorta (= venous ventricle)
√ original RV on left side: bulbous, triangular shape, trabeculated chamber with infundibular outflow tract into pulmonary trunk (= arterial ventricle)

OB-US:
√ great arteries arise from ventricles in a parallel fashion
√ aortic valve separated from tricuspid valve by a complete infundibulum
√ fibrous continuity between pulmonic valve + mitral valve

Prognosis: (unfavorable ← additional cardiac defects); 40% (30%) 1-year (10-year) survival rate

TRAUMATIC AORTIC INJURY

= AORTIC LACERATION = BLUNT TRAUMA TO THORACIC AORTA
= laceration that disrupts the physical integrity of > 1 structural layer of the aorta
Incidence: > 100,000 people in USA annually
Cause: rapid deceleration (high-speed MVA > 48 km/hour with unrestrained driver or ejected passenger, fall from height > 3 m) / crushing chest injury
Pathomechanism: horizontal / vertical deceleration with shear between fixed arch and mobile descending aorta, hydrostatic force, osseous pinch between spine and sternum

Extent of laceration:

1. Incomplete rupture (15%)
   ◊ Aorta goes on to rupture completely within 24 hours in 50% of patients!
   › INTIMA
   (a) intimal hemorrhage without tear
   (b) transverse laceration of intima with hemorrhage (= **intimal tear / flap = traumatic**

aortic dissection)
Minimal aortic injury (10%) = intimal flap of < 10 mm without significant periaortic hematoma

› MEDIA
tear into media with subadventitial hematoma (40–60%)

› ADVENTITIA
(a) periaortic hemorrhage (± aortic injury)
(b) **traumatic pseudoaneurysm** = laceration of intima + media + adventitia with locally contained periadventitial hematoma

2. Complete rupture (85%) = transmural extension of laceration = **aortic transection** = **traumatic aortic rupture**
• exsanguination before patient reaches a hospital

Length of tear: circumferential tear (in majority)
Site: at aortic attachment
(1) Aortic isthmus (88–95%): brachiocephalic arteries + ligamentum arteriosum fix aorta in this region
Site: within 2 cm of origin of left subclavian artery
(2) Aortic arch with avulsion of brachiocephalic trunk (4.5%)
(3) Aortic root immediately above aortic valve (5–9%)
Cx: aortic valve rupture, coronary artery laceration, hemopericardium + cardiac tamponade; NO mediastinal hematoma
(4) Aortic hiatus in diaphragm (1–3%)
◊ Most often posteriorly (in noncircumferential tear)

Acute Thoracic Aortic Injury

Prevalence: 10–16–20% of all fatalities in high-speed deceleration accidents
• severe chest pain: precordial (ascending aorta), neck-jaw (aortic arch), interscapular (descending thoracic aorta)
• anterior chest wall contusion, dyspnea, dysphagia
• blood pressure changes:
  • unexplained hypotension
  • scapulothoracic syndrome = decreased / absent upper extremity pulses
  • acute coarctation syndrome = decreased / absent lower extremity + normal upper extremity pulses with upper extremity hypertension + systolic murmur in 2nd left parasternal interspace

CXR (53–100% sensitive, 1–60% specific, 4–20% PPV):

◊ A normal anteroposterior upright CXR virtually excludes acute thoracic aortic injury (96–98% NPV)!

N.B.: There are no plain CXR findings of aortic injury (since aortic integrity is maintained by intact adventitia)! The sources of <u>mediastinal hematoma</u> are frequently the azygos, hemiazygos, internal thoracic, paraspinal and intercostal vessels!
◊ Aortic injury is the cause of mediastinal hematoma in only 12.5%!

√ normal admission CXR in 28% (radiographic signs may not develop until 6–36 hours): supine CXR is very INACCURATE for mediastinal widening

Most specific and valuable signs:
- √ deviation of nasogastric / endotracheal tube to the right of T3-T4 spinous process (12–100% sensitive, 80–95% specific)
- √ depression of left mainstem bronchus anteroinferiorly > 40° below the horizontal + toward right (in 53%)
- √ indistinct / blurred aortic contour at arch / descending aorta (53–100% sensitive, 21–55% specific)

√ mediastinal widening > 8 cm at level of origin of left subclavian artery (present in 75–92%; 90–95% sensitive, 5–10% specific):
- √ mediastinal width to chest width > 0.25

√ obscuration of aortopulmonary window (40–100% sensitive, 56–83% specific)
√ widened left paraspinal "stripe" > 5 mm (12–83% sensitive, 89–97% specific)
√ thickening of right paratracheal stripe > 4–5 mm ← hematoma between pleura + trachea
√ left / right "apical pleural cap" sign in 37%
← extrapleural hematoma along brachiocephalic vessels
√ tracheal compression + displacement toward right (61%)
√ rapidly accumulating commonly left-sided hemothorax without evident rib fracture ← break in mediastinal pleura
√ fractures of 1st + 2nd rib (17%)

mnemonic: BAD MEAT
Bronchus depression (left main)
Aortic silhouette shaggy
Death in 80–90%
Mediastinal widening
Enteric (nasogastric) tube displacement
Apical cap
Tracheal shift

NECT screening (90–100% sensitive, 19–45% specific, 0–50% PPV, 94–100% NPV):
√ mediastinal fluid often of high density
√ obliteration of aorta-fat interface with increased attenuation ← mediastinal / periaortic hematoma

Source of blood: small veins, vasa vasorum of aortic wall

◊ A negative CT examination for mediastinal hemorrhage has an almost 100% NPV for aortic injury!

False positive:
residual thymic tissue, periaortic atelectasis, pericardial recess, patient motion, streak artifacts, volume averaging of pulmonary artery, pleural effusion adjacent to descending aorta, sternal + spinal fracture

CECT (100% sensitive, 92–99% specific, 0–39% FP, 0.7% FN):
Multidetector CT: 100 mL at 4 mL/sec with bolus tracking; 1–2 mm collimation for 3D reconstruction with 50% overlap

Disadvantages: CT delays surgery
Advantages: unsuspected injuries are discovered (pulmonary contusion, pneumothorax, pericardial effusion, rib fracture)

√ intraluminal low-density filling defect:
  √ linear = intimal flap
  √ polypoid = clot
√ contour deformity of outer aortic wall = pseudoaneurysm
√ contour deformity of inner aortic wall:
  √ intramural hematoma
  √ pseudocoarctation = abrupt tapering of the diameter of descending aorta compared with ascending aorta
√ extravasation of contrast material (extremely rare)

False positive:
pulsation artifact (aortic valve leaflets, wall of ascending aorta, cardiac motion), streak artifact ← high-density contrast in brachiocephalic vein, volume averaging, prominent periaortic bronchial / mediastinal vessels, atherosclerotic pseudoaneurysm, small ductus diverticulum

Transesophageal echocardiography:
(in 2–15% technically unsuccessful, 57–63% sensitive, 84–91% specific):
√ intimal flap
√ intraluminal thick stripes
√ pseudoaneurysm
√ aortic occlusion (= pseudocoarctation)
√ fusiform aneurysm
√ aortic wall hematoma

Advantage: portable, relatively fast

Disadvantage: operator dependent with false negatives for ascending aorta + aortic arch

Aortography (92% sensitive, 98–100% specific):

Technique: LAO + RAO projection; high-flow pigtail catheter; 50 mL at 35 mL/sec

Morbidity: 1.7% (iatrogenic extension of flap, entry of guidewire into pseudoaneurysm)

Delay: 147 minutes between admission and angio

True positive: in 17–20% of mediastinal hematomas angio demonstrates acute traumatic aortic injury!

False negative: small transverse intimal tears may be missed!
√ resistance in advancing guide wire
√ intimal irregularity, linear defect, filling defect = intimal flap = posttraumatic dissection (5–10%)
√ intramural injury:
  √ thickening of aortic wall
  √ posttraumatic coarctation
√ transmural laceration:
  √ contained extravasation = traumatic false aneurysm
  √ free extravasation = aortic rupture

DDx: ductus diverticulum (in 10% of normals), aortic spindle, infundibula of brachiocephalic arterial branches; volume averaging with left brachiocephalic vein / left superior intercostal vein / right bronchial arteries (vs. intimal flap); artifact from physiologic streaming / mixing of contrast material; athero-sclerotic aortic ulceration; atheromatous plaque; syphilitic aortic aneurysm

Recommendations for work-up:
(1) Normal well-defined mediastinal + aortic contours on CXR: no further imaging
(2) Stable patient:
angio CT of chest + CT of head, abdomen, pelvis
(3) Unstable patient + unequivocally abnormal CXR / strong clinical evidence of aortic injury:
angio CT / emergency surgery

Rx: (1) Antihypertensive medication
(2) Stent graft for high-risk patients
(3) Surgical repair : 20–54% mortality, 5–10% morbidity ← paraplegia

Prognosis:
(1) 80–90% fatal at scene of accident
◊ Mortality rises rapidly within first 24 hours
(2) 10–20% reach hospital
← formation of periaortic hematoma + false aneurysm contained by adventitia ± surrounding connective tissue
(a) without intervention: 30% (40–50%) dead within 6 (24) hours; 90% dead within 4 months; chronic false aneurysm may develop in 2–5% at isthmus / descending aorta
(b) with surgical repair: 60–70% survive; surgical mortality rate of 9–44% varies with degree of hemodynamic instability + severity of associated injuries + magnitude of aortic laceration
Cx: postoperative paraplegia (9%) ← aortic cross clamping > 30 minutes
(3) Chronic pseudoaneurysm (1%): potentially unstable

Chronic Posttraumatic Aortic Pseudoaneurysm

= aneurysm that exists for > 3 months

Risk: amount of wall fibroplasia following rupture usually not sufficient to prevent subsequent rupture until at least 3 months after initial traumatic episode

Prevalence: 2–5% of patients surviving aortic transection > 24–48 hours

- symptom-free period of months to years (in 11% > 10 years)
- delayed clinical symptoms: 42% (85%) within 5 (20) years consisting of chest pain, back pain, dyspnea, cough, hoarseness, dysphagia, systolic murmur

Location: descending aorta at level of lig. arteriosum filling the aorticopulmonary window (most commonly)

√ well-defined rounded mass in left paramediastinal region
√ ± inferior displacement of left mainstem bronchus

Cx: CHF, partial obstruction of aortic lumen, bacterial endocarditis, aortoesophageal fistula, aortic dissection, obstruction of tracheobronchial tree, systemic emboli

Prognosis: enlargement + eventual rupture;
10-year survival rate: 85% with surgical repair, 66% without surgical repair

TRICUSPID ATRESIA

2nd most common cause of pronounced neonatal cyanosis (after transposition) characterized by
(1) Absent tricuspid valve
(2) ASD

(3) Small VSD (in most patients)

Frequency: 1.5% of all CHD

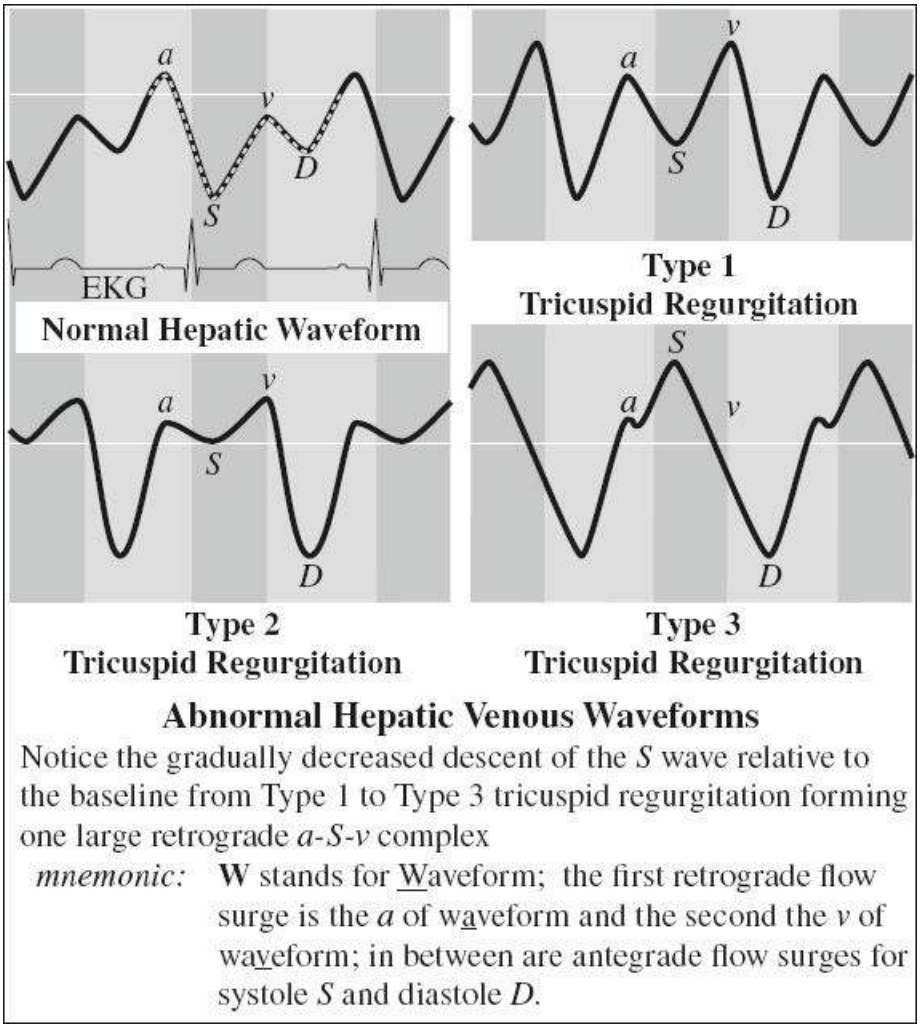
Embryology: imbalanced tissue proliferation + resorption results in absence of valvular tissue

1. TRICUSPID ATRESIA WITHOUT TRANSPOSITION (80%)
   (a) without PS, (b) with PS, (c) with pulmonary atresia
2. TRICUSPID ATRESIA WITH TRANSPOSITION
   (a) without PS, (b) with PS [most favorable combination], (c) with pulmonary atresia

◊ Usually small VSD + PS (75%) restrict pulmonary blood flow

Hemodynamics:

absent tricuspid valve forces blood from an enlarged RA through an ASD into LA (R-to-L shunt); pulmonary blood flow limited by pulmonary valvular stenosis



RA	↑	RV	↓	Main PA	↓
Pulm. vessels	↓				
LA	↑	LV	↑	Ao	↑

- progressive cyanosis from birth on, increasing with crying = OUTSTANDING FEATURE (inverse relationship between degree of cyanosis + volume of pulmonary blood flow)

• pansystolic murmur (VSD)
• ECG: left-axis deviation

CXR (typical cardiac contour):

√ heart size ranges from normal to moderately enlarged (depending on volume of pulmonary blood flow and size of RA)
√ left rounded contour = enlargement + hypertrophy of LV
√ right rounded contour = enlarged RA
√ flat / concave pulmonary segment
√ normal / decreased pulmonary vascularity
√ typical flattening of right heart border with transposition (in 15%)

Prognosis: may survive well into early adulthood

Rx:

(1) Blalock-Taussig procedure (if pulmonary blood flow decreased in infancy)
(2) Glenn procedure = shunt between IVC + right PA (if total correction not anticipated)
(3) Fontan procedure = external conduit from RA to pulmonary trunk + closure of ASD (if pulmonary vascular disease has not developed)

TRICUSPID REGURGITATION / INSUFFICIENCY

Cause:

RV dilatation is the most common cause of tricuspid regurgitation, with dilatation of the tricuspid annulus causing improper coaptation of the valve leaflets.

A. SECONDARY = dilatation of RV + annulus ← elevated pulmonary artery pressure
   1. Left heart failure
   2. Pulmonary vascular disease
   3. Chronic lung disease ← pulmonary hypertension
   4. Carcinoid syndrome
   ◊ Mild / trace of tricuspid regurgitation is normal!
B. PRIMARY = lesion of intrinsic valve apparatus (chordae tendineae / leaflets / annulus / papillary muscles)
   1. Rheumatic heart disease
   2. Bacterial endocarditis
   3. Tricuspid valve prolapse
   4. Papillary muscle dysfunction: myocardial infarction, trauma, (metastatic) carcinoid heart syndrome
   6. Connective tissue disorder: Marfan syndrome
   7. Congenital heart disease: Ebstein anomaly, atrioventricular cushion defect
   8. Pacemaker leads
   9. Radiation therapy, certain drug-based treatments

• exhaustion and fatigue
• symptoms of right heart failure: peripheral edema, ascites

√ normal / reduced pulmonary vascularity
√ cardiomegaly ← RA + RV hypertrophy and enlargement
√ distension of IVC > SVC

Doppler ECHO:

√ systolic reversal of hepatic vein flow with normal sinus rhythm
√ dilatation of RA
√ flattening / leftward bowing of interventricular septum during diastole
√ vena contracta (= smallest stream diameter) width > 0.7 cm
√ color flow jet area > 10 cm^2
√ proximal isovelocity surface area radius > 0.9 cm
√ decreased *S* wave = *S* wave no longer as deep as the *D* wave, gradually rising with degree of regurgitation
√ one large *a*-*S*-*v* complex in severe incompetence

CT:
√ RV displaced to the left
√ interventricular septum bowed to the left
√ hepatic venous congestion
√ emphysema, pulmonary hypertension, left heart disease

Prognosis: if untreated → RV dysfunction, congestive hepatopathy, cardiac cirrhosis

TRICUSPID STENOSIS

= thickening + fusion of tricuspid valve apparatus

Cause:
1. (Nearly always) rheumatic heart disease:
   √ often accompanied by mitral + aortic valve disease
   √ NO valve calcifications
2. Infectious endocarditis: IV drug users
3. Congenital abnormalities
4. Fabry disease
5. Whipple disease
6. Metastatic carcinoid syndrome
7. Pacemaker-related complications

• fatigue, dyspnea, congestion, right heart failure with elevated jugular pressure, hepatomegaly, ascites
• arrhythmias ← severe right atrial enlargement

CXR:
√ RA enlargement + dilatation of both venae cavae
√ normal pulmonary arteries

ECHO (findings of hemodynamic significance):
√ mean transvalvular pressure gradient of > 5 mmHg (clinically most relevant)
√ inflow time-velocity integral > 60 cm
√ pressure half-time > 190 msec
√ valve area by continuity equation of < 1 cm^2

CT:
√ thickened tricuspid valve leaflets: shortening of chordae tendineae + fusion of edges of leaflets
√ narrowed valve annulus
√ RA dilatation

√ enlargement of superior + inferior venae cavae
√ hepatic venous congestion
Cx: often coexisting tricuspid regurgitation exacerbating RA enlargement → increasing risk for arrhythmia

TROUSSEAU SYNDROME

= PARANEOPLASTIC THROMBOEMBOLISM

Prevalence: 1–11%; higher in terminally ill cancer patients

Tumors: mucin-secreting adenocarcinoma of GI tract and pancreas (most common), lung, breast, ovary, prostate

Pathogenesis: (?)

(a) tumors activate coagulation + depress anticoagulant function
(b) cancer cells cause injury to endothelial lining, activate platelets + coagulation

Type of lesion: (1) Venous thrombosis
(2) Arterial thromboembolism
(3) Nonbacterial thrombotic endocarditis

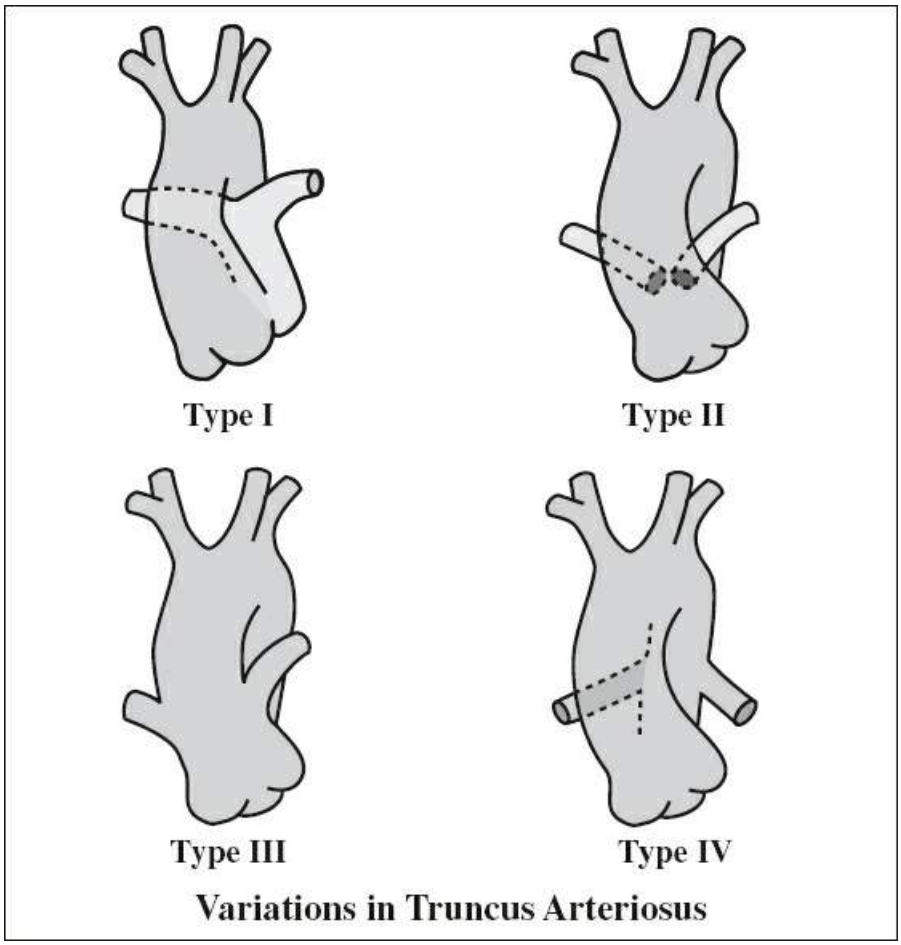
◊ Patients with thromboembolism have an increased incidence of occult malignancy!

Prevalent criteria:

› absence of apparent cause for thromboembolism
› age > 50 years
› multiple sites of venous thrombosis
› simultaneous venous + arterial thromboembolism
› resistance to oral anticoagulant therapy
› associated other paraneoplastic syndromes
› regression of thromboembolism with successful treatment of cancer

• disorders of consciousness ← cerebral emboli
• muscular pain + weakness ← emboli to skeletal muscle
• decompensated disseminated intravascular coagulation
√ deep vein thrombosis
√ pulmonary embolism
√ nonbacterial thrombotic endocarditis (echocardiography)

Rx: (1) Heparin (more successful than warfarin)
(2) Greenfield filter



Variations in Truncus Arteriosus

TRUNCUS ARTERIOSUS

= PERSISTENT TRUNCUS ARTERIOSUS = SINGLE OUTLET OF THE HEART = COMMON ARTERIAL TRUNK

= septation failure of the conotruncus characterized by

(1) Single great artery arising from the heart (larger than the aorta at a comparable age)
(2) Giving rise to coronary, pulmonary, and systemic arteries
(3) Overriding the ventricular septum
(4) Large VSD

Prevalence: 1% of CHD detected in fetus; 94÷1,000,000 live births

Collett & Edwards classification:

Type I	(50%)	=	both pulmonary arteries arise from a short pulmonary trunk distal to truncal valve
Type II	(25%)	=	separate origin of both pulmonary arteries from posterior aspect of truncus
Type III	(10%)	=	separate origin of both pulmonary arteries at lateral aspect of truncus
Type IV		=	pseudotruncus
Subtype A		=	infundibular VSD present
Subtype		=	VSD absent

B

Associated with:

(1) Right aortic arch (in 35%)
  ◊ Right aortic arch + cyanosis + shunt vascularity = TRUNCUS
(2) Genetic abnormality: chromosome 22q11 deletion, DiGeorge syndrome
(3) Interrupted aortic arch / coarctation (11–14%)
(4) Forked ribs

Hemodynamics:

admixture lesion (R-to-L and L-to-R shunt across VSD) with volume of pulmonary blood flow inversely related to degree of pulmonary vascular resistance

fetus : CHF only with incompetent valve ← massive regurgitation from truncus to ventricles

neonate : L-to-R shunt after decrease in pulmonary resistance (massive diversion of flow to pulmonary district) → CHF (ventricular overload) / pulmonary hypertension with time

RA	↔	RV	↑	Trunk	↑
Pulm. vessels	↑				
LA	↔	LV	↑		

- moderate cyanosis (degree inversely related to volume of pulmonary blood flow), apparent with crying
- severe CHF within first days / months of life (in large R-to-L shunt); wide pulse pressure
- systolic murmur (similar to VSD)
- early diastolic murmur (with truncal insufficiency)

CXR:

√ cardiomegaly:
  √ increased volume of both ventricles
  √ enlarged LA (50%) ← increased pulmonary blood flow
√ wide mediastinum ← large "aortic shadow" = truncus arteriosus
√ "waterfall / hilar comma" sign = elevated right hilum (30%); elevated left hilum (10%)
√ concave pulmonary segment (50%) = type I has left convex pulmonary segment
√ markedly ⇑ pulmonary blood flow, may be asymmetric

ECHO:

√ single arterial vessel overriding the interventricular septum (DDx: tetralogy of Fallot)
√ frequently dysplastic single semilunar valve with 3–6 leaflets (most commonly tricommissural = 3 leaflets)
  √ truncal valve may be stenotic
  √ truncal valve insufficiency with age (in 25%)

Dx: (often stenotic / insufficient) truncal valve with 2–5 cusps + atretic pulmonary valve + flow direction

Prognosis: 40% (20%) 6-month (1-year) survival rate

Rx: Rastelli procedure (30% no longer operable at 4 years of age) = (a) artificial valve placed high in RVOT and attached via a Dacron graft to main pulmonary artery (b) closure of VSD (5% mortality rate)

DDx: aortopulmonary window (2 separate valves)

Hemitruncus

= rare acyanotic anomaly characterized by
  (a) one pulmonary artery (commonly right PA) arises from truncus
  (b) one pulmonary artery arises from RV / supplied by systemic collaterals

Associated with: PDA (80%), VSD, tetralogy (usually isolated to left PA)

Pseudotruncus Arteriosus

= TRUNCUS TYPE IV

= severe form of tetralogy of Fallot with atresia of the pulmonary trunk; entire pulmonary circulation through bronchial collateral arteries (NOT a form of truncus arteriosus in its true sense); characterized by
  (1) Pulmonary atresia
  (2) VSD with R-to-L shunt
  (3) RV hypertrophy

Associated with: right aortic arch in 50%

• cyanosis
√ concavity in area of pulmonary segment
√ commalike abnormal appearance of pulmonary artery
√ absent normal right + left pulmonary artery (lateral chest film)
√ esophageal indentation posteriorly ← large systemic collaterals
√ prominent hilar + intrapulmonary vessels (= systemic collaterals)
√ "coeur en sabot" = RV enlargement
√ prominent ascending aorta with hyperpulsations

VASCULAR MALFORMATION

Arteriovenous Malformation

= nidus composed of multiple dysplastic vascular channels connecting feeding arteries with draining veins in the absence of a normal capillary bed

Age: present at birth in the early quiescent stage; not usually evident until childhood / adulthood

Growth: proportionate increase in size with child growth

Exacerbation: hormonal changes (puberty, pregnancy) / thrombosis, infection, trauma

• red pulsatile warm mass with thrill
• high-output congestive heart failure

MR:
  √ NO well-defined mass
  √ large serpentine flow voids on SE images / high-signal-intensity foci on GRE images = enlarged feeding arteries + draining veins
  √ decreased marrow signal intensity on T1WI ← intraosseous extension of lesion
  √ areas of high signal intensity on T1WI ← hemorrhage, intravascular thrombosis, flow-related enhancement

CEMR:
  √ contrast material rise time of 5–10 seconds
  √ early venous filling

Cx: bone overgrowth, arterial steal phenomenon, cutaneous ischemia

Congenital Arteriovenous Fistula

= single vascular channel between an artery and a vein
Cause: arrested vascular embryonic development
Location: extremity, neck, face
MR:
√ large signal voids on SE images or high-signal-intensity foci on GRE images without a well-defined mass ← arterial + venous components
DDx: chronic secondary AVF (with time enlarging supplying arteries + draining veins ← strong flow)

Capillary Malformation

= area of congenital ectasia of thin-walled small-caliber vessels of the skin (dermis / mucous membrane)
Age: present at birth in 0.3% of children
Associated with:
(1) Sturge-Weber syndrome
(2) Klippel-Trénaunay syndrome
(3) Parkes Weber syndrome
• cutaneous lesion of red discoloration
Location: predominantly in head & neck
MR (MRI not usually required ← clinical diagnosis):
√ subtle skin thickening ± occasional increased subcutaneous thickness

Lymphatic Malformation

Prevalence: 2nd most common type of vascular malformation after venous malformation
Cause: sequestered lymphatic sacs that fail to communicate with peripheral draining channels
Age: discovered in first 2 years of life
Path: infiltrative lesion permeating fat planes + involving multiple tissues consisting of chyle-filled cysts lined with endothelium
Commonly associated with: other vascular malformations
• smooth noncompressible soft-tissue mass with rubbery consistency:
A. MACROCYSTIC lymphatic malformation = cysts of variable size > 2 mm in diameter
• smooth translucent multiple masses beneath normal skin
√ rim + septal enhancement without central filling of cystic structures
B. MICROCYSTIC lymphatic malformation = cysts of < 2 mm in size on background of solid matrix
• permeation of skin
• diffuse soft-tissue thickening + surrounding lymphedema
√ NO significant enhancement
√ occasionally diffuse enhancement ← septal enhancement of small nonperceptible cysts / venous component in mixed venous-lymphatic malformation
Location: neck (70–80%); axillary region (20%); extremities (rare)
Site: posterior cervical triangle

MR:
√ lobulated septated mass with intermediate to decreased SI on T1WI + increased signal intensity on T2WI + STIR
√ internal fluid-fluid levels (common)

Venous Malformation

= simple slow-flow malformation + abnormal venous network
= "cavernous hemangioma" (misnomer)
Path: lesion may permeate across tissue planes and invade multiple adjacent tissues; connection to adjacent physiologic veins via narrow tributaries
Histo: small + large dysplastic postcapillary thin-walled vascular channels with sparse smooth muscle and variable amounts of hamartomatous stroma, thrombi, phleboliths
Age: childhood / early adulthood (present at birth)
• skin level: faint blue soft compressible nonpulsatile mass
  • enlarging with Valsalva maneuver + in dependent position
  • decreasing with elevation of extremity + local compression
• deep level: pain, impaired mobility, skeletal deformity
Location: head & neck (40%), extremities (40%), trunk (20%)
Associated with:
(1) Blue rubber bleb nevus syndrome
(2) Proteus syndrome
(3) Maffucci syndrome
√ absence of enlarged feeding vessels / arteriovenous shunting
√ lack of arterial + early venous enhancement
√ slow gradual filling with contrast material (contrast material rise time of about 90 seconds) + CHARACTERISTIC nodular enhancement of tortuous vessels during delayed venous phase
MR:
√ septated lesion of intermediate to decreased SI on T1WI:
  √ heterogeneous SI on T1 ← thrombosis / hemorrhage
√ increased signal intensity on T2WI and STIR
√ occasionally internal fluid-fluid levels ← hemorrhage / high protein content
√ small low-signal-intensity foci on all pulse sequences ← phleboliths
Dx: low-flow malformation based on absence of flow voids on SE images
Rx: sclerotherapy after lack of evident connection between malformation and deep venous system

VENTRICULAR ANEURYSM

A. CONGENITAL LEFT VENTRICULAR ANEURYSM
rare, young Black adult
(1) Submitral type:
  √ bulge at left middle / upper cardiac border
(2) Subaortic type:
  √ small + not visualized
  √ heart greatly enlarged (from aortic insufficiency)

B. ACQUIRED LEFT VENTRICULAR ANEURYSM

= complication of myocardial infarction, Chagas disease

- may be asymptomatic + well tolerated for years
- occasionally associated with persistent heart failure, arrhythmia, peripheral embolization

True Ventricular Aneurysm

= circumscribed noncontractile outpouching of ventricular cavity with broad mouth + localized dyskinesis

Cause: sequelae of transmural myocardial infarction

Location:

(a) left anterior + anteroapical: readily detected (anterior + LAO views)

(b) inferior + inferoposterior: less readily detected (steep LAO + LPO views)

Detection rate: 50% by fluoroscopy; 96% by radionuclide ventriculography; frequently not visible on CXR

√ localized bulge of heart contour = "squared-off" appearance of mid left lateral margin of heart border

√ localized paradoxical expansion during systole (CHARACTERISTIC)

√ rim of calcium in fibrotic wall (chronic), rare

√ akinetic / severely hypokinetic segment

√ left ventriculography in LAO, RAO is diagnostic

√ wide communication with heart chamber (NO neck)

Cx: wall thrombus with embolization

Prognosis: rarely ruptures

Pseudoaneurysm of Ventricle

= FALSE ANEURYSM

= left ventricular rupture contained by fused layers of visceral + parietal pericardium / extracardiac tissue

(a) cardiac rupture with localized hematoma contained by adherent pericardium; typically in the presence of pericarditis

(b) subacute rupture with gradual / episodic bleeding

Etiology: trauma, myocardial infarction

Location: typically at posterolateral / diaphragmatic wall of LV

√ left retrocardiac double density

√ diameter of mouth smaller than the largest diameter of the globular aneurysm

√ delayed filling

Cx: high risk of delayed rupture (infrequent in true aneurysms)

VENTRICULAR SEPTAL DEFECT

Most common CHD (25–30%):

(a) isolated in 20%

(b) with other cardiac anomalies in 5% (PDA, CoA)

◊ Acyanotic L-to-R shunt + right aortic arch (in 2–5%) = VSD

Embryology:

single ventricular chamber divides into two by fusion of membranous portion of ventricular

septum + endocardial cushions + bulbis cordis (= proximal part of truncus arteriosus) between 4th–8th week

1. MEMBRANOUS = PERIMEMBRANOUS VSD (75–80%)
   Location: posterior + inferior to crista supraventricularis near commissure between right and posterior (= noncoronary) aortic valve cusps
   May be associated with:
   small aneurysms of membranous septum commonly leading to decrease in size of membranous VSD (their presence does not necessarily predict eventual complete closure)
2. SUPRACRISTAL = CONAL VSD (5–8%)
   ◊ Crista supraventricularis = inverted U-shaped muscular ridge posterior + inferior to pulmonary valve
   (a) RV view = VSD just beneath pulmonary valve with valve forming part of superior margin of defect
   (b) LV view = VSD just below commissure between R + L aortic valve cusps
   Cx: right aortic valve cusp may herniate into VSD → aortic insufficiency
3. MUSCULAR VSD (5–10%)
   May consist of multiple VSDs; bordered entirely by myocardium
   Location: (a) inlet portion
   (b) trabecular portion
   (c) infundibular / outlet portion
4. ATRIOVENTRICULAR CANAL TYPE
   = ENDOCARDIAL CUSHION TYPE = POSTERIOR VSD (5–10%)
   Location: adjacent to septal + anterior leaflet of mitral valve; rare as isolated defect

Hemodynamics:
small bidirectional shunt during fetal life (similar pressures in RV + LV); after birth pulmonary arterial pressure ↓ and systemic arterial pressure ↑ with development of L-to-R shunt

Classification:

"Maladie de Roger"
= small restrictive VSD with defect < 1 cm; little / no hemodynamic significance with normal pulmonary artery pressure, normal pulmonary vascular resistance
- asymptomatic
- holosystolic heart murmur at 4th left rib interspace

√ normal plain film
Prognosis: spontaneous closure

Moderate Shunt
VSD defect < 75% of aortic diameter (1–1.5 cm); systolic LV pressure > systolic RV pressure; intermediate pulmonary artery pressure; normal pulmonary vascular resistance

Heart size	↑	Main PA	↔ to ↑
Pulm. vessels	↔ to ↑	LA	↑

- respiratory infections, mild dyspnea

√ slight prominence of pulmonary vessels (45% shunt)
√ slight enlargement of LA
Prognosis: spontaneous closure in large percentage

Nonrestrictive Large Shunt

VSD defect > 75% of aortic diameter; systolic LV pressure = systolic RV pressure (pulmonary vascular disease + hypertension increases RV pressure); pulmonary artery pressure approaching systemic levels; slightly increased pulmonary vascular resistance; pulmonary blood flow 2–4 times systemic flow

Heart size	↑	Main PA	↑
Pulm. vessels	↑	LA	↑

- bouts of respiratory infections
- feeding problems, failure to thrive
- CHF soon after birth ← RV overload

√ prominent pulmonary segment + vessels (= shunt vascularity)

√ calcification of pulmonary arteries
= PATHOGNOMONIC for pulmonary arterial hypertension

√ enlargement of LA + LV

√ normal / small thoracic aorta

Eisenmenger syndrome

large VSD eventually leads to shunt reversal (R-to-L shunt) ← irreversible increase in pulmonary vascular resistance (= intima + medial hyperplasia) when pulmonary vascular resistance > 0.75 of systemic vascular resistance

RA	↑	RV	↑	Main PA	↑
Pulm. vessels	↓/↑				
LA	↑ to ↔	LV	↑ to ↔	Ao	↑ to ↔

Frequency: 10% of large VSDs by 2 years of age

- cyanotic, but less symptomatic; CHF rare

√ eventual decrease of pulmonary vessel caliber

√ eventual decrease in size of LA + LV

NATURAL HISTORY OF VSD causing reduction in pulmonary blood flow:

1. Spontaneous closure
   in 40% within first 2 years of life; 60% by 5 years (65% with muscular VSD, 25% with membranous VSD); with small (large) VSD in 50% (10%)
2. RVOT obstruction
   infundibular hypertrophy in 3% = pink tetrad
3. Prolapse of right aortic valve cusp
   = aortic valve insufficiency

CXR (with increase in size of VSD):

√ variable appearance ← variations in defect size

√ enlargement of LA

√ enlargement of pulmonary artery segment

√ enlargement of LV

√ RV hypertrophy

√ increase in pulmonary blood flow (if > 45% of pulmonary blood flow from systemic circulation)

√ Eisenmenger reaction

ECHO:
√ prolapse of aortic valve cusp (in supracristal VSD)
√ deformity of aortic cusp (in membranous VSD)
√ lack of echoes in region of interventricular septum with sharp edges (DDx: artifactual dropout with sound beam parallel to septum); muscular VSD difficult to see
√ LA enlargement
Angio:
Projections:
(a) LAO 60° C-C 20° for membranous + anterior muscular VSD
(b) LAO 45° C-C 45° (hepatoclavicular) for posterior endocardial cushion + posterior muscular VSD
(c) RAO for supracristal VSD + assessment of RVOT
√ RVOT / pulmonary valve fill without filling of RV chamber (in supracristal VSD)
Rx:
(a) large VSD + left heart failure at 3 months of age: aim is to delay closure until child is 18 months of age; pulmonary-to-systemic blood flow > 2÷1 requires surgery before pulmonary hypertension becomes manifest
1. Digitalis + diuretics
2. Pulmonary artery banding
3. Patching of VSD: surgical approach through RA / through RV for supracristal VSD
(b) small VSDs without increase in pulmonary arterial pressure are followed

WEGENER GRANULOMATOSIS

[Friedrich Wegener (1907–1990), German pathologist in Berlin, Breslau and Lübeck describes rhinogenic granulomatosis in 1936]
= GRANULOMATOSIS WITH POLYANGIITIS
= ANCA-positive systemic vasculitis that affects small arteries characterized by systemic necrotizing granulomatous destructive angiitis
Incidence: 3÷100,000 annually in USA
Path: peribronchial necrotizing granulomas + vasculitis not intimately related to arteries with little / NO deposition of immunoglobulins / complement components (pauci-immune)
Mean age of onset: 40–50 years (range of all ages); M÷F = 2÷1; majority in Whites (90%)
Mean age in childhood: 14 (range 4–17) years; M < F
CLASSIC TRIAD:
(1) Upper airway granulomatous inflammation
◊ The most common presenting symptoms (in up to 67%): rhinitis, sinusitis, otitis media, nasal mucosa ulcer, bone deformity, subglottic stenosis
(2) Lower respiratory tract involvement
(3) Necrotizing glomerulonephritis
• circulating antineutrophil cytoplasmic antibodies (cANCA) directed against proteinase 3 + myeloperoxidase (found in neutrophils) in up to 90%
• rarely eosinophilia (DDx: Churg-Strauss syndrome)
• constitutional symptoms: fever, malaise, weight loss
Location: upper respiratory tract + sinuses in > 90%; kidneys in 85%

◊ Prone to venous thrombosis in lower extremities ← antiphospholipid antibodies

@ Pulmonary disease (94%)
- intractable cough (occasionally with hemoptysis)
- chest pain, dyspnea
- anemia, decrease in serum iron + ferritin levels (in diffuse alveolar hemorrhage)

Path: vasculitis of medium-sized and small pulmonary arteries + veins + capillaries, geographic necrosis, granulomatous inflammation

√ bilateral interstitial reticulonodular opacities, most prominent at lung bases (earliest stage)

√ randomly distributed irregular masses / nodules of varying sizes (5 mm to 10 cm), especially in lower lung fields (69%) usually sparing apices:
- √ usually < 10 masses, solitary in up to 25%
- √ cavitation of > 2-cm nodules with thick wall + irregular shaggy inner lining (25–50%)

√ bilateral multifocal patchy air-space opacities (in up to 50%):
- √ acute airspace pneumonia
- √ intraalveolar pulmonary hemorrhage

√ smooth / nodular thickening of subglottic / tracheal / bronchial wall producing stenosis with oligemia + emphysema + lobar / segmental atelectasis (60%)

√ uni- / bilateral pleural effusion (usually exudative) in 10–20%

√ focal pleural thickening = acute / chronic fibrinous pleuritis

√ reactive hilar / mediastinal lymphadenopathy (unusual)

√ interstitial pulmonary edema ± cardiomegaly (from renal / cardiac involvement)

CT:
- √ nodules in peribronchovascular distribution:
  - √ central cavitation in nodules > 2 cm in diameter
  - √ feeding vessels entering nodules (= angiocentric distribution)
- √ pleura-based wedge-shaped lesions (= infarcts)
- √ ground-glass opacity and consolidation (= pulmonary hemorrhage / infection) in up to 50%:
  - √ in a bilateral perihilar + peribronchovascular distribution
  - √ waxing and waning
  - √ air bronchogram in dense consolidation
  - √ CT "halo" sign (= rim of ground-glass attenuation surrounding a pulmonary lesion) due to adjacent parenchymal hemorrhage (in up to 15%)
  - √ CT "atoll" / "reverse halo" sign = central ground-glass opacity surrounded by a rim of opacified lung ← organizing pneumonia reaction in periphery of focal hemorrhage
- √ radiating linear scarring, spiculation + pleural tags of nodules and masses (prominent feature!)

Cx: (1) Dangerous airway stenosis (15% of adults, 50% of children)
(2) Massive life-threatening pulmonary hemorrhage
(3) Spontaneous pneumothorax (rare)

@ Tracheobronchial stenosis (16–23%)
- stridor ← tracheal inflammation + sclerosis

Location: subglottic portion of trachea (most often)

√ uni- / multifocal / segmental subglottic / tracheobronchial stenosis:
√ 2–4 cm long segment
√ smooth / nodular circumferential wall thickening of posterior membrane of trachea
√ ± intra- and extraluminal soft-tissue masses

@ Renal disease (85%) focal glomerulonephritis in 20–40% at presentation, as disease progresses in 80–90%
Histo: focal necrosis, crescent formation, paucity/ absence of immunoglobulin deposits
• may present as overt acute renal failure
√ large echogenic kidneys (early)
√ small shrunken echogenic kidney (late in renal failure)

@ Paranasal sinuses (91%)
Location: maxillary antra most frequently
• sinus pain, purulent sinus drainage, rhinorrhea
√ thickening of mucous membranes of paranasal sinuses
√ gradual reduction in sinus volume
√ residual lumen filled with material of ground-glass opacity
√ periantral soft-tissue infiltration
√ bone thickening + sclerosis of sinus walls ← chronic obstruction + inflammation
Cx: invasion of orbital fat + extraocular muscles + optic nerve ± local bone destruction

@ Nasopharynx (64%)
• chronic nasal obstruction (may be misdiagnosed as chronic sinusitis)
• epistaxis from nasal mucosal ulceration
• necrosis of nasal septum, saddle nose deformity
√ partial / complete erosion of nasal septum
√ truncated + shortened turbinates
√ progressive destruction of turbinates + lateral nasal wall (DDx: relapsing polychondritis)
√ destruction of hard palate with sinonasal-oral fistulas
√ granulomatous masses filling nasal cavity

@ CNS (involved late in 22–35%)
• central / peripheral neuritis
√ cerebral lesions ← intracranial extension of granulomas located in nasal cavity + paranasal sinuses
√ necrotizing cerebral vasculitis (nearly always with active sinusitis / otitis / lung disease)
√ leptomeningeal enhancement
√ nonspecific isolated enhancing intracranial / spinal lesions

@ Other organ involvement:
(a) Joints (67%): migratory polyarthropathy
(b) Ear (61%): otitis media
(c) Eye (58%): ocular inflammation, proptosis
(d) Skin + muscle (45%): inflammatory nodular skin lesions, cutaneous purpura
(e) Heart + pericardium (12–28%):
coronary vasculitis (rare), pancarditis, valvular lesions
Cx: acute pericarditis (6%), dilated congestive cardiomyopathy, acute valvular insufficiency with pulmonary edema, cardiac arrest ← ventricular arrhythmia, myocardial infarction

(f) Splenic disease
(g) GI tract (10%):
- abdominal pain, diarrhea, blood loss
√ ischemia, inflammation, ulceration, perforation

Cx: (1) Hypertension
(2) Uremia
(3) Facial nerve paralysis

Dx: (1) Lung / renal biopsy
(2) c-ANCA: 96% sensitive for generalized disease, 99% specific

Prognosis: death within 2 years from renal (83%) / respiratory failure; 90–95% mean 5-year survival under Rx

Rx: corticosteroids, cytotoxic drugs (cyclophosphamide), renal transplantation; 75–93% remission with therapy

DDx: Churg-Strauss (asthma, 47% cardiac involvement, less severe renal + sinus disease, p-ANCA); Goodpasture syndrome; SLE; mixed connective tissue disease; microscopic polyangiitis

Limited Wegener Granulomatosis

= Wegener granulomatosis largely confined to lung WITHOUT renal / upper airway involvement

Dx: c-ANCA (96% sensitive, 99% specific)

M < F

Prognosis: more favorable than classical Wegener's

Midline Granuloma

= mutilating granulomatous + neoplastic lesions limited to nose + paranasal sinuses with very poor prognosis; considered a variant of Wegener granulomatosis WITHOUT the typical granulomatous + cellular components

LIVER, BILE DUCTS, PANCREAS AND SPLEEN

DIFFERENTIAL DIAGNOSIS OF HEPATIC, BILIARY, PANCREATIC AND SPLENIC DISORDERS

RIGHT UPPER QUADRANT PAIN

A. BILE DUCTS
   1. Biliary colic / bile duct obstruction
   2. Acute cholecystitis / cholangitis

B. LIVER
   1. Acute hepatitis:
      (a) alcoholic, viral, drug-related, toxic
      (b) steatohepatitis
   2. Hepatic abscess
   3. Hepatic tumor: metastases, hepatocellular carcinoma, hemangioma, focal nodular hyperplasia, hepatic adenoma
   4. Hemorrhagic cyst
   5. Hepatic congestion: acute hepatic congestion, Budd-Chiari syndrome
   6. Perihepatitis = Fitz-Hugh-Curtis syndrome

C. PANCREAS
   1. Acute pancreatitis

D. INTESTINES
   1. Acute appendicitis
   2. Peripyloric ulcer
   3. Small bowel obstruction
   4. Irritable bowel
   5. Colitis / ileitis
   6. Intestinal tumor

E. LUNG
   1. Pneumonia
   2. Pulmonary infarction

F. KIDNEY
   1. Acute pyelonephritis
   2. Ureteral calculus
   3. Renal / perirenal abscess
   4. Renal infarction
   5. Renal tumor

G. OTHERS
   1. Costochondritis
   2. Herpes zoster

LIVER

Diffuse Liver Disease

A. Infectious
   1. Hepatitis
   2. Candidiasis
   3. Sarcoidosis
B. Reparative
   1. Cirrhosis
C. Infiltrative
   1. Iron deposition: hemochromatosis
   2. Fat deposition: fatty liver
   3. Glycogen storage disease
   4. Wilson disease
D. Vascular
   1. Intrahepatic shunts
   2. Budd-Chiari syndrome
   3. Right-sided CHF
   4. Portal vein thrombosis
   5. Venoocclusive disease
E. BILIARY
   1. Caroli disease
   2. Cholangitis: primary sclerosing cholangitis

Diffuse Hepatic Enlargement = Hepatomegaly

A. METABOLIC
   1. Fatty infiltration
   2. Amyloid
   3. Wilson disease
   4. Gaucher disease
   5. Von Gierke disease
   6. Niemann-Pick disease
   7. Weber-Christian disease
   8. Galactosemia
B. MALIGNANCY
   1. Lymphoma
   2. Diffuse metastases
   3. Diffuse HCC
   4. Angiosarcoma
C. INFLAMMATION / INFECTION
   1. Hepatitis
   2. Mononucleosis
   3. Miliary TB, histoplasmosis
   4. Malaria
   5. Syphilis

6. Leptospirosis
7. Chronic granulomatous disease of childhood
8. Sarcoidosis

D. VASCULAR
1. Passive congestion

E. OTHERS
1. Early cirrhosis
2. Polycystic liver disease

Hepatosplenomegaly

1. Disorders associated with extramedullary hematopoiesis + hemolytic anemia
2. Metabolic storage disease
3. Viral infection
4. Sarcoidosis
5. Leukemia, lymphoma, myeloproliferative disease

Hepatic Gas

Hepatic gas may be indicative of serious acute disease or simply an incidental finding of no clinical significance. Knowledge of the clinical history and clues on images may allow to determine its clinical relevance.

A. NONIATROGENIC
1. Liver abscess
2. Mesenteric infarction, necrotizing enterocolitis, colitis → portal venous gas
3. Hepatic artery thrombosis in liver transplant
4. Inflammatory bowel disease
5. Abdominal trauma
6. Emphysematous cholecystitis, ascending cholangitis

B. IATROGENIC

Hepatic gas is to be expected after therapeutic interventions like surgery, embolization, or tumor ablation.

1. Biliary gas: sphincterotomy / choledochojejunostomy
2. Colonoscopy, barium enema examination
3. Liver biopsy
4. Hepatic artery embolization: chemoembolization, brachytherapy, posttraumatic embolization
4. Percutaneous tumor ablation
5. Migration of hepatic venous gas: femoral venous / spinal / epidural catheter or lumbar puncture
6. Oxidized cellulose sponge (SURGICEL®)

Hepatic venous gas may be seen after placement of a femoral central venous catheter and aggressive fluid resuscitation.

Increased Liver Attenuation

= abnormal deposits of substances with high atomic numbers

√ normal liver density on NECT: 55–65 HU

A. IRON

√ density of iron-laden liver on NECT: > 72–80 HU

(a) diffuse iron deposition

› hepatocyte deposition

1. Genetic hemochromatosis
2. Erythropoietic hemochromatosis: intravascular hemolysis, paroxysmal nocturnal hemoglobulinuria
3. Bantu siderosis
4. Cirrhosis

› recticuloendothelial deposition

4. Transfusional iron overload

(b) focal iron accumulation

1. Hemorrhagic metastases: choriocarcinoma, melanoma
2. Hepatic adenoma
3. Siderotic regenerative nodules of cirrhosis
4. Focal hemochromatosis

B. COPPER

Wilson disease

C. IODINE

Amiodarone (= antiarrhythmic drug with 37% iodine by weight)

√ 95–145 HU (range of normal for liver 30–70 HU)

D. GOLD

Colloidal form of gold for therapy of rheumatoid arthritis

E. THOROTRAST

Alpha-emitter with atomic number of 90

F. THALLIUM

Accidental / suicidal ingestion of rodenticides (lethal dose is 0.2–1.0 gram)

G. ACUTE MASSIVE PROTEIN DEPOSITS

H. GLYCOGEN STORAGE DISEASE

mnemonic: GG CHAT

Gold therapy
Glycogen storage disease
Cyclophosphamide
Hemochromatosis / hemosiderosis
Amiodarone
Thorotrast

Generalized Increase in Liver Echogenicity

1. Fatty liver
2. Steatohepatitis
3. Cirrhosis (fibrosis + fatty liver)
4. Chronic hepatitis
5. Vacuolar degeneration

Marked Decrease in Hepatic T2 Signal Intensity

= paramagnetic effect of intracellular iron deposition (ferritin, hemosiderin)

◊ Signal intensity of pancreas does not help distinguish between primary + secondary hemochromatosis!

1. Primary / hereditary hemochromatosis (dietary iron)
2. Secondary hemochromatosis
   √ bone marrow of low SI (DDx: myelofibrosis)
3. Transfusional siderosis (RES)
   √ bone marrow of low signal intensity
   √ decreased T2 signal in spleen
4. Intravenous administration of ultrasmall superparamagnetic iron oxide

PERIHEPATIC SPACE

Perihepatic Fat Attenuation

1. Spontaneous rupture of cystic ovarian teratoma
2. Lipoma / liposarcoma
3. Pseudolipoma
   = detached degenerating epiploic appendage lodged between diaphragm and superior aspect of liver
3. Juxtacaval fat
   = medial to IVC near hepatic venous confluence
   Prevalence: 0.5% of CTs in adults
4. Omental infarction
5. Intrahepatic omental packing

Perihepatitis

= inflammation of peritoneal capsule of liver

√ hepatic capsular enhancement

A. Infection
   1. Fitz-Hugh-Curtis syndrome
   2. Perforated cholecystitis
   3. Perforated hepatic abscess
   4. Tuberculous peritonitis
B. Inflammation
   1. SLE
   2. Radiation therapy
C. Tumor = peritoneal carcinomatosis
D. Pseudoperihepatitis
   = low liver density simulates capsular enhancement
   1. Fatty liver

LIVER MASS

◊ Hepatic masses account only for 5–6% of all intraabdominal masses in children!

Primary Benign Liver Tumor

A. EPITHELIAL TUMORS
   (a) hepatocellular
      1. Hepatic adenoma
      2. Focal nodular hyperplasia
      3. Nodules in cirrhosis: regenerative nodule, dysplastic nodule
      2. Nodular regenerative hyperplasia
   (b) cholangiocellular
      1. Hepatic cyst
      2. Bile duct hamartoma
      3. Peribiliary cyst
      4. Biliary cystadenoma
      5. Caroli disease
      3. Biliary papillomatosis
B. MESENCHYMAL TUMORS
   (a) tumor of adipose tissue
      1. Hepatic lipoma
      2. Hepatic myelolipoma
      3. Hepatic angiomyolipoma
   (b) tumor of muscle tissue
      1. Leiomyoma
   (c) tumor of blood vessels
      1. Infantile hemangioendothelioma
      2. Hemangioma
      3. Peliosis hepatis
   (d) tumor of neural crest
      1. Hepatic paraganglioma
   (e) mesothelial tumor
      1. Benign mesothelioma
C. MIXED TISSUE TUMOR
   1. Mesenchymal hamartoma
   2. Hepatoblastoma
   3. Benign teratoma
D. MISCELLANEOUS
   1. Adrenal rest tumor
   2. Pancreatic rest
E. PSEUDOLESION
   1. Focal fatty infiltration
   2. Focal fat sparing
   3. Confluent hepatic fibrosis

Pediatric Benign Liver Mass

1. Infantile hemangioendothelioma
2. Mesenchymal hamartoma

infrequent:

3. Focal nodular hyperplasia
4. Hepatocellular adenoma
5. Nodular regenerative hyperplasia

Primary Malignant Liver Tumor

◊ Hepatic malignancies are the most common GI malignancy in children, but account for < 2% of all pediatric malignancies!

A. EPITHELIAL TUMOR
   (a) hepatocellular
      1. Hepatoblastoma (7%)
      2. Hepatocellular carcinoma (75%)
   (b) cholangiocellular (6%)
      1. Cholangiocarcinoma
      2. Biliary cystadenocarcinoma

B. MESENCHYMAL TUMOR
   (a) tumor of blood vessels
      1. Angiosarcoma
      2. Epithelioid hemangioendothelioma
      3. Kaposi sarcoma
   (b) other tumor
      1. Embryonal sarcoma
      2. Fibrosarcoma

C. TUMOR OF MUSCLE TISSUE
   1. Leiomyosarcoma
   2. Embryonal rhabdomyosarcoma of the biliary tree

D. MISCELLANEOUS
   1. Carcinosarcoma
   2. Teratoma
   3. Yolk sac tumor
   4. Carcinoid
   5. Squamous carcinoma
   6. Primary lymphoma

Pediatric Malignant Liver Mass

A. PRIMARY
   1. Hepatoblastoma
   2. Hepatocellular carcinoma
   3. Fibrolamellar carcinoma
   4. Undifferentiated (embryonal) sarcoma
   5. Epithelioid hemangioendothelioma
   6. Embryonal rhabdomyosarcoma

B. SECONDARY (metastasis)
   ◊ Most common neoplasm involving liver
   Origin: neuroblastoma, Wilms tumor, lymphoma

Solitary Liver Lesion

A. Benign tumor
   1. Cavernous hemangioma
   2. Adenoma
   3. Focal nodular hyperplasia
   4. Mesenchymal hamartoma

B. Infection
   1. **Pyogenic abscess**
   2. Echinococcal cyst
   3. Inflammatory pseudotumor

C. Trauma
   1. Hematoma
   2. Traumatic cyst

D. Malignant tumor
