Printed in China

Library of Congress Cataloging-in-Publication Data

Names: Dähnert, Wolfgang, author.
Title: Radiology review manual / Wolfgang Dähnert.
Description: Eighth edition. | Philadelphia : Wolters Kluwer, [2017] |
Includes bibliographical references and index.
Identifiers: LCCN 2016044206 | ISBN 9781496360724
Subjects: | MESH: Radiography | Diagnosis, Differential | Diagnostic Imaging
| Outlines
Classification: LCC RC78.17 | NLM WN 18.2 | DDC 616.07/572–dc23
LC record available at https://lccn.loc.gov/2016044206

This work is no substitute for individual patient assessment based upon healthcare professionals' examination of each patient and consideration of, among other things, age, weight, gender, current or prior medical conditions, medication history, laboratory data and other factors unique to the patient. The publisher does not provide medical advice or guidance and this work is merely a reference tool. Healthcare professionals, and not the publisher, are solely responsible for the use of this work including all medical judgments and for any resulting diagnosis and treatments.

Given continuous, rapid advances in medical science and health information, independent professional verification of medical diagnoses, indications, appropriate pharmaceutical selections and dosages, and treatment options should be made and healthcare professionals should consult a variety of sources. When prescribing medication, healthcare professionals are advised to consult the product information sheet (the manufacturer's package insert) accompanying each drug to verify, among other things, conditions of use, warnings and side effects and identify any changes in dosage schedule or contraindications, particularly if the medication to be administered is new, infrequently used or has a narrow therapeutic range. To the maximum extent permitted under applicable law, no responsibility is assumed by the publisher for any injury and/or damage to persons or property, as a matter of products liability, negligence law or otherwise, or from any reference to or use by any person of this work.

“If a little knowledge is dangerous, where is the man who has so much to be out of danger!”

T.H. Huxley, 1825–1895 from Elementary Instruction in Physiology published in 1877

“It is the tragedy of the world that no one knows what he doesn’t know — and the less a man knows, the more sure he is that he knows everything”

Joyce Cary, British author 1888–1957

“Nothing in the world can take the place of persistence.

Talent will not; nothing is more common than unsuccessful men with talent. Genius will not; unrewarded genius is almost a proverb.

Education will not; the world is full of educated derelicts.

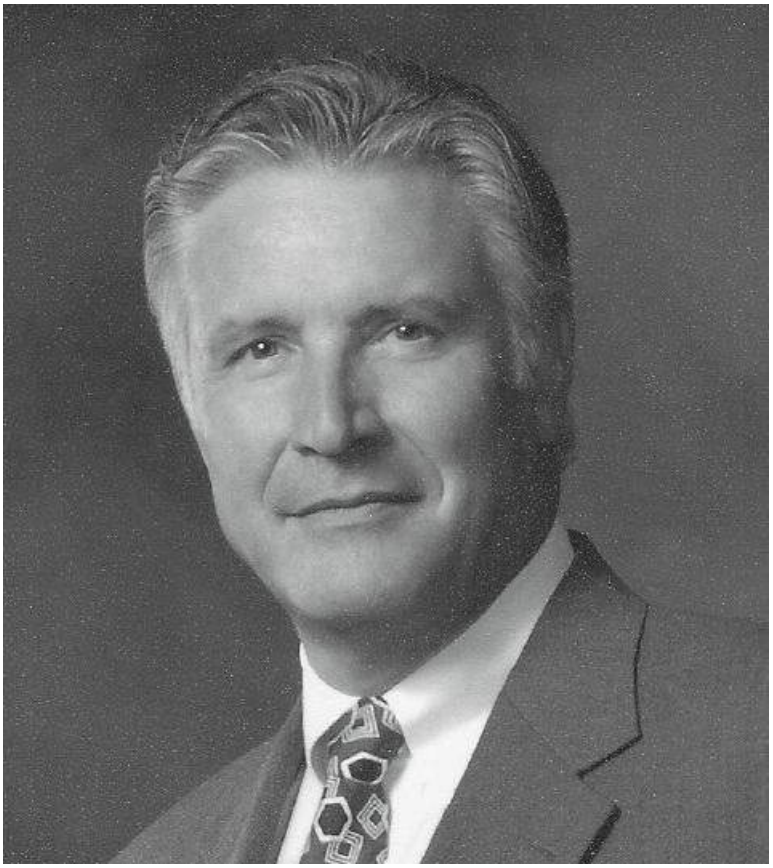
Persistence and determination alone are omnipotent."

Calvin Coolidge 1872–1933

Vice President 1921–1923

President 1923–1929

About the Author



Wolfgang Dähnert, M.D.

Wolfgang Dähnert was born in Hamburg, Germany. After graduating from the Wilhelm-Gymnasium High School in Braunschweig, Lower Saxony, in 1966 he enlisted into the German Air Force for four years. After his discharge from the armed services he studied medicine at the Heinrich-Heine Universität in Düsseldorf, North Rhine-Westphalia, for his preclinical years and at the Johannes-Gutenberg Universität in Mainz, Rhineland-Palatinate, for his clinical years. He graduated from medical school in 1975 and received his doctor of medicine degree shortly thereafter based on his dissertation "Pulse Flow Photocytometry of Prostate Punch Biopsies". A one-year rotating internship in urology, internal medicine and sports medicine at the Johannes-Gutenberg Universität and at the municipal Dr. Horst Schmidt Klinik in Wiesbaden was followed by a one-year residency in general surgery at the Deutsches Rotes Kreuz Krankenhaus in Mainz, Germany. In 1978 he switched to begin a residency in radiology at the municipal and teaching hospital in Darmstadt, Hesse, under the directorship of Prof. H.K. Deininger. He continued his education in diagnostic

and therapeutic radiology at the Johannes-Gutenberg Universität in Mainz under the directorship of Prof. Manfred Thelen and Prof. Rolf W. Günther receiving his German certification for radiology in 1982. Dr. Dähnert started a 2-year fellowship in ultrasound and computed tomography at the Johns Hopkins Hospital in Baltimore in 1984 under the leadership of Roger Sanders / Ulrike Hamper and Stanley Siegelman / Elliot Fishman and was appointed Clinical Instructor in 1986. In 1985 he sat for the federal licensing exam, and in 1987 took his oral exam in diagnostic radiology in Louisville, Kentucky. The American Board of Radiology had approved a 2-year fellowship program for him in lieu of a residency in radiology. The foundation of Radiology Review Manual was laid during the three years at Hopkins while preparing for the ABR exam. Between 1987 and 1989 he worked as Assistant Professor of Radiology in ultrasound at Thomas Jefferson Hospital in Philadelphia under Barry Goldberg. During this period in Philadelphia Radiology Review Manual was taken to fruition culminating in the publication of its first edition in 1991. Dr. Dähnert joined Clinical Diagnostic Radiology & Nuclear Medicine in Phoenix, AZ, in 1989 as director of ultrasound. This group practice of approximately 25 mostly fellowship-trained radiologists served three center city hospitals and their affiliated residency program in radiology, the latter at St. Joseph's Hospital and Medical Center, before it ceased operations in 2006 brought about by a fiscally unsustainable management style and culture. In September of 2004 Dr. Dähnert relocated to Green Bay, Wisconsin, joining a group of eight radiologists as part of a multispecialty group practice at Aurora BayCare Medical Center, the northern hub of Aurora Health Care, one of Wisconsin's largest private-sector employers.

PREFACE

Since the first publication of Radiology Review Manual in 1990 momentous changes have occurred in radiology. We have progressed from films developed in the dark-room to images on a computer screen. We have gone from an initially voluntary lifetime certificate of qualification to a never-ending process of proving to the public that our knowledge, skills, and clinical ability in the area of radiology has kept apace with the times. The first ABR Core Examination took place in October 2013. It tests knowledge and comprehension of anatomy, pathophysiology, physics and all aspects of diagnostic radiology including breast, cardiac, gastrointestinal, interventional, musculoskeletal, neuroradiology, nuclear, pediatric, reproductive/endocrinology, thoracic, urinary, vascular, computed tomography, magnetic resonance, radiography/fluoroscopy, ultrasound, physics, safety and radioisotope safety. The first Certifying Examination was in fall 2015.

Given the predominant practice pattern in the United States I estimate that General Radiology makes up at least 10% to 20% of the work a radiologist with subspecialty training is asked to perform. This is true for the vast majority of radiology practices, with the possible exception of those practices that employ more than 20 radiologists. Our clinical colleagues expect from us a depth of medical knowledge and familiarity with all imaging modalities suitable to address their clinical questions, regardless of our favored subspecialty. To remain relevant to them we need to stay current at their level.

Commensurate with an explosion of knowledge in medicine the number of pages for this volume have more than doubled, while radiologists have been squeezed between knowing more and reading faster. Radiology Review Manual has developed over the years from a simple preparatory text for the “oral boards” to something that has kept pace with my own growth in radiology. Since 1987 and between editions I have never stopped working on this book: new (eg, genetic) insights were added, variations in categorizations amended, words tweaked, numbers changed, and statements clarified. It is my humble attempt to put into a single reference much of the information that is or could be relevant to my practice and, hopefully, also yours. The decision for inclusions or omissions herein have always been governed by my own practical needs. We have conducted a survey among radiology residents to help us with the decision what topics to delete in an effort to diminish the number of pages. The results showed such a wide variation in opinions that I didn’t have the guts to wield the eraser at all. A single author book does not require collaboration, and thankfully I didn’t have to defend this decision.

The popularity of the “green giant” or the “green bible”, as it has been dubbed by residents, and the continued impressive number of sales and several translations into other languages confirms the usefulness of this type of publication. The outline style chosen for the sake of conserving space provides only an extract of information and may, at times, jeopardize the intended meaning of statements without any prior background knowledge of the subject. Accordingly, be careful, this book is not intended for the uninitiated.

How to use this book:

I have selected one of many possible ways to organize a book of this size and scope with the intent

to cover all modalities and provide room for growth and change over time. The material is presented anatomically from head to heel (when possible) to avoid duplications and save space. Systemic diseases have been forced into this topographical scheme rather than occupying a separate section. Departing from prior editions, NUC imaging findings are now relegated to the respective entity. A general section has been introduced that also includes some aspects about techniques in nuclear medicine in addition to contrast media, statistics, sedation, analgesia, and local anesthesia. As in the 6th edition I hope we can again use the inside of the cover pages to provide immediate access for accepted therapies of contrast reactions.

The organization within the individual chapters follows the practical approach of reading images. Often the initial step of image interpretation is to scrutinize for a radiologic pattern that may help suggest the disease process at hand. Therefore, differential diagnoses of radiologic patterns are presented in the first section of a chapter. Occasionally, important clinical signs and their differential diagnoses, relevant to the practice of radiology, are included in the first portion of a chapter as well. Lists of differential diagnoses can be presented in many fashions. There is no right or wrong way, but there certainly is a chaotic versus an organized approach. Accordingly, an attempt is made to categorize differential diagnostic considerations or etiologies of certain diseases in a manner digestible for recapitulation. It is a common experience that this is not always possible, logically satisfactory, or complete.

The majority of this book deals with disease entities presented in the last section of a chapter. The disease entities are presented in alphabetical order and headed by their most commonly used name with other designations listed below. Not infrequently and without explanations name switches occur from one publication to another. As a radiologic diagnosis should be entertained in context with its probability to be correct, percentages in regard to frequency of signs and symptoms are included liberally, often giving the lowest and the highest number found in the literature. The truth may be somewhere in between for nonselected patient populations, and occasionally a third number is provided between the high and low number as the most frequently cited. I had to arbitrate choices when different or contradictory results are found in the literature – unfortunately, an occurrence not at all infrequent.

This latest edition includes text on a gray background to guide the reader toward an emphatic statement made by a speaker or author on a particular topic.

These two sections in each chapter are separated by a few pages of functional, anatomic, or embryologic aspects. Mnemonics (which I personally abhor) have been liberally added. The index, which selectively refers to those pages with significant information, concludes the manual and is usually the starting point for many. The index also includes so-called “buzz words” that are miraculously attached to diseases.

Acknowledgement:

Various sources are responsible for the content: individuals (named in prior editions), ACR syllabi, handouts from various CME courses, major textbooks, hand-written notes taken during lectures, feed-back from board examinees and most importantly the journals dedicated to imaging with brilliant review articles, in particular the practice-oriented publication of Radiographics. Accordingly, the material in this book is a compilation and extraction of other’s work presented from my perspective of relevance and perhaps with omissions of my ignorance. Our radiologic ancestors, mentors, teachers and scientists alike, throughout the world deserve our admiration and gratitude for the collective knowledge passed on to us for the benefit of our profession and our

patients. I realize, in retrospect, that the omission of references may present a problem when certain statements appear unlikely and their verification has to be left to the user. For my defense, I can say that I have tried to extract all data as diligently as possible.

I sincerely hope that Radiology Review Manual will serve you in your preparation for the board exam, in teaching situations, and particularly in your daily work assignments — the way it continues to help me.

Green Bay, August 2016

CONTENTS

ABBREVIATIONS

√	radiologic sign
•	clinical sign, symptom
=	equals, is
≠	is not
@	at anatomic location of
/	or, per
+	and, plus, with
±	with or without
<	less than
>	more than, over
›	separation of points
»	method
◊	important comment
→	leads to, is followed by
←	due to, 2° to, caused by
↑	increased
⇑	much increased
↓	decreased
⇓	much decreased
↔	unchanged
~	about, approximately
÷	ratio
1°	primary
2°	secondary
2-D	two-dimensional
3-D	three-dimensional
5-HIAA	5-hydroxyindole acetic acid

aa.	**arteries**
AAA	abdominal aortic aneurysm
AAAs	abdominal aortic aneurysms
ABC	aneurysmal bone cyst
ABER	abduction + external rotation
ABO	blood group
ABR	American Board of Radiology

AC	abdominal circumference
ACA	anterior cerebral artery
ACE	angiotensin I–converting enzyme
ACEI	angiotensin-converting enzyme inhibitor
ACL	anterior cruciate ligament
aCom	anterior communicating artery
ACR	American College of Radiology
ACTH	adrenocorticotropic hormone
ADC	apparent diffusion coefficient
ADH	antidiuretic hormone; atypical ductal hyperplasia
ADPKD	adult polycystic kidney disease
AF-AFP	amniotic fluid alpha-fetoprotein
AFI	amniotic fluid index
AFP	alpha-fetoprotein
AICA	anterior inferior cerebellar artery
AIDS	acquired immune deficiency syndrome
AIP	acute interstitial pneumonia
AJCC	American Joint Committee on Cancer
ALARA	as low as reasonably achievable
AlkaPhos	alkaline phosphatase
ALL	acute lymphoblastic leukemia
ALPSA	**a**nterior **l**abroligamentous **p**eriosteal **s**leeve **a**vulsion
ALSA	aberrant left subclavian artery
ALT	alanine aminotransferase
AMA	antimitochondrial antibody
AML	acute myeloblastic leukemia; angiomyolipoma
aML	anterior mitral valve leaflet
AMLs	angiomyolipomas
ANA	antinuclear antibodies
ANCA	antineutrophil cytoplasmic autoantibodies
Angio	angiography
ANT	anterior
Ao	aorta
AP	anteroposterior; arterial phase; alkaline phosphatase
APA	aldosterone producing adenoma
aPL-ab	antiphospholipid antibody
approx.	approximately
APUD	amine precursor uptake and decarboxylation
APUDomas	endocrine cells tumors
APVR	anomalous pulmonary venous return

APW	absolute percentage washout
ARA-C	arabinoside C
ARDS	acute respiratory distress syndrome
ARF	acute renal failure
AS	aortic stenosis
ASA	acetylsalicylic acid
ASD	atrial septal defect
ASH	asymmetric septal hypertrophy
AST	aspartate aminotransferase
ATN	acute tubular necrosis
ATP	adenosine triphosphate
AV	arteriovenous; atrioventricular
AVF	arteriovenous fistula
AVM	arteriovenous malformation
AVMs	arteriovenous malformations
AVN	avascular necrosis
AVNA	atrioventricular node artery
Ba	barium
BAH	bilateral adrenal hyperplasia
BAL	bronchoalveolar lavage
BALT	bronchus-associated lymphoid tissue
BCG	bacille Calmette-Guérin
BCNU	bis-chloronitrosourea
BDI	basion-dens interval
BE	barium enema
BF	blood flow
b.i.d.	*bis in die*, Latin = twice per day
BIDA	butyl iminodiacetic acid
BI-RADS	Breast Imaging Reporting and Data System
BIH	benign intracranial hypertension
BKG	background
BKG_{counts}	background counts
BLC	biceps-labral complex
BLL	benign lymphoepithelial lesions
BMD	bone marrow density
BOOP	bronchiolitis obliterans organizing pneumonia
BP	blood pressure
BPD	biparietal diameter
BPH	benign prostatic hyperplasia

bpm	beats per minute
BPP	biophysical profile
Bq	Becquerel (1 Bq = one nucleus decays per sec)
BRCA	breast cancer suppressor gene
BSA	body surface area
BSO	bilateral salpingo-oophorectomy
Bx	biopsy
Ca	calcium
Ca2+	calcium ion
c-ANCA	cytoplasmic pattern of antineutrophil cytoplasmic autoantibodies
CA-125	cancer antigen 125
CABG	coronary artery bypass grafting
CAD	coronary artery disease
CADASIL	cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy
CAM	cystic adenomatoid malformation
CBD	common bile duct
CBF	cerebral blood flow
cBPD	corrected biparietal diameter
CBV	cerebral blood volume
CC	craniocaudad
CCA	common carotid artery
CCK	cholecystokinin
CCMC	common carpometacarpal joint
CCNU	1-(2-Chloroethyl)-3-cyclohexyl-1-nitrosourea
CD4	specialized lymphocyte responsible for cell-mediated immunity
CDC	Center for Disease Control
CDH	Congenital Diaphragmatic Hernia
CEA	carcinoembryonic antigen
CECT	contrast-enhanced computed tomography
CEMR	contrast-enhanced MR
CF	cystic fibrosis
CFI	color flow imaging
CFTR	cystic fibrosis transmembrane regulator gene
cGy	centigray = rad
CHAOS	Congenital high airway obstruction syndrome
CHD	common hepatic duct; congenital heart defect
CHF	congestive heart failure
CLL	chronic lymphatic leukemia

cm	centimeter
cm^2	square centimeter
cm^3	cubic centimeters
CMC	carpometacarpal
CME	continuing medical education
CML	chronic myelogenous leukemia
CMV	Cytomegalovirus
CN	cranial nerve
CNS	central nervous system
CO	carbon monoxide
CoA	coarctation of aorta
COPD	chronic obstructive pulmonary disease
COW	circle of Willis
CP	cerebellopontine
CPA	cerebellopontine angle
CPAP	continuous positive airway pressure
CPD	cardiopulmonary disease
CPDN	cystic partially differentiated nephroblastoma
cpm	counts per min
CPPD	calcium pyrophosphate dihydrate
CPR	cardiopulmonary resuscitation
cps	counts per sec
cRCC	conventional renal cell cancer; cystic renal cell cancer
CRF	chronic renal failure
CRL	crown rump length
CRT	cathode ray tube
CSF	cerebrospinal fluid
CSI	chemical shift imaging
CST	contraction stress test
C/T	cardiothoracic ratio
CT	computed tomography
CTA	computed tomography angiogram
CVA	cerebrovascular accident
CVC	central venous catheter
CVJ	craniovertebral junction
CVS	chorionic villus sampling
CWP	coal worker's pneumoconiosis
Cx	complication
CXR	chest x-ray
CXRs	chest x-rays

d	day(s)
D5W	solution of 5% dextrose in water
DCBE	double-contrast barium enema
DCIS	ductal carcinoma in situ
DDH	developmental dysplasia of hip
DDx	differential diagnosis
DES	diethylstilbestrol
DEXA	dual energy X-ray absorptiometry
DFSP	dermatofibrosarcoma protuberans
DIC	disseminated intravascular coagulation
DIDA	diethyl iminodiacetic acid
DIP	desquamative interstitial pneumonia; distal interphalangeal
DISH	diffuse idiopathic skeletal hyperostosis
DISIDA	diisopropyl iminodiacetic acid
dist	distal
DIT	diiodotyrosine
DLCL	diffuse large cell lymphoma
D_LCO	diffusion capacity of lung for carbon monoxide
DMSA	dimercaptosuccinic acid
DORV	double outlet right ventricle
DPLD	diffuse parenchymal lung disease
DSA	digital subtraction angiography
DTPA	diethylenetriamine pentaacetic acid
DVT	deep vein thrombosis
DWI	diffusion weighted images
Dx	diagnosis
dz	disease
EAC	external auditory canal
EBV	Epstein-Barr virus
EC-cells	enterochromaffin cells
ECA	external carotid artery
ECD	endocardial cushion defect; ethyl cysteinate dimer
ECF	extracellular fluid
ECG	electrocardiogram
ECHO	echocardiogram; enteric cytopathic human orphan (virus)
ECMO	extracorporeal membrane oxygenation
EDD	enddiastolic diameter
EDTA	ethylenediaminetetraacetic acid

EDV	enddiastolic volume
EEG	electroencephalogram
EF	ejection fraction
EFW	estimated fetal weight
EG	eosinophilic granuloma
eg	exempli gratia
EGA	estimated gestational age
EHDP	ethylene hydroxydiphosphonate
EKG	electrocardiogram
ELISA	enzyme-linked immunosorbent assay
EMA	epithelial membrane antigen
ENT	ear, nose and throat
ErbB	epidermal growth factor receptor gene
ERC	endoscopic retrograde cholangiography
ERCP	endoscopic retrograde cholangiopancreatography
ERPF	effective renal plasma flow
ERV	expiratory reserve volume
ESD	endsystolic diameter
esp.	especially
ESR	erythrocyte sedimentation rate
EtOH	ethanol
ESV	end-systolic volume
F	female; fluorine
Fab	fragment antigen binding
FAI	femoroacetabular impingement
FAP	familial adenomatous polyposis
FDA	Federal Drug Administration
FDG	fluorodeoxyglucose
Fe^{2+}	ferrous ion
Fe^{3+}	ferric state
FEV	forced expiratory volume
FEV_1	FEV at 1 sec
FEV_3	FEV at 3 sec
FHM	fetal heart motion
FIGO	Fédération Internationale de Gynécologie et d'Obstétrique
FISH	fluorescence in situ hybridization
FK-506	code number for tacrolimus
FL	femur length
FLAIR	fluid-attenuated inversion recovery sequence

FLASH	fast low-angle shot
FN	false negative
FNAB	fine needle aspiration biopsy
FNH	follicular nodular hyperplasia
FOOSH	fall on outstretched hand
FP	false positive
Fr	French = unit of linear measure of circumference (1 F = 1/3 mm ≈ 1 mm in diameter)
FRC	functional residual capacity
FS	fractional shortening
FSE	fast spin echo
FSH	follicle stimulating hormone
FVC	forced vital capacity
FWHM	full-width at half-maximum
Fx	fracture
GA	gestational age
GB	gallbladder
GBM	glioblastoma multiforme
GCT	giant cell tumor; granulosa cell tumor
GCTs	giant cell tumors
Gd	gadolinium
GDA	gastroduodenal artery
GE	gastroesophageal
GER	gastroesophageal reflux
GERD	gastroesophageal reflux disease
GFR	glomerular filtration rate
GH	growth hormone
GHA	glucoheptonate
GI	gastrointestinal
GIST	gastrointestinal stromal tumor
GMP	guanosine monophosphate
GMRH	germinal matrix–related hemorrhage
GN	glomerulonephritis
GNRH	gonadotropin releasing hormone
GRASS	gradient recalled acquisition in steady state
GRE	gradient refocused echo
GS	gestational sac
GSV	great saphenous vein
GnRH	gonadotropin releasing hormone

GU	genitourinary
Gy	1 gray = absorption of 1 joule of ionizing radiation by 1 kilogram of matter = 1 J • kg^{-1} = 1 m2 • sec^{-2}
γGT	gamma-glutamyltransferase
HAART	highly active antiretroviral therapy
HAGL	humeral avulsion of the glenohumeral ligament
Hb	hemoglobin
HBME-1	mouse monoclonal antibody to mesothelioma
HBP	high blood pressure
HBV	hepatitis B virus
HC	head circumference
HCC	hepatocellular carcinoma
HCCs	hepatocellular carcinomas
hCG	human chorionic gonadotropin
HCl	hydrochloric acid
Hct	hematocrit
HD	Hodgkin disease
HELLP	hemolysis, elevated liver enzymes, low platelets
Hg	mercury
HHV_8	human herpes virus type 8
HIAA	hydroxyindole acetic acid
HIDA	hepatic 2,6-dimethyl iminodiacetic acid
HIE	hypoxic ischemic encephalopathy
Histo	histology
HIV	human immunodeficiency virus
HL	Hodgkin lymphoma
HLA	human leukocyte antigen
HMB-45	monoclonal antibody against human melanoma black
HMPAO	hexamethylpropyleneamine oxime = exametazime
HNP	herniated nucleus pulposus
HOCM	hypertrophic obstructive cardiomyopathy; high-osmolar contrast media
HPF	high power field (400 x magnification)
HPO	hypertrophic pulmonary osteoarthropathy
HPS	hypertrophic pyloric stenosis
HPT	hyperparathyroidism
HPV	human papilloma virus
hr	hour(s)
HRCT	high-resolution CT
HRT	hormone replacement therapy

HSA	human serum albumin
HSG	hysterosalpingography
HSV	herpes simplex virus
HTN	hypertension
HU	Hounsfield unit
HV	hepatic vein
HypoPT	hypoparathyroidism
Hx	history
IAA	interruption of aortic arch
IAC	internal auditory canal
ICA	internal carotid artery
ICBT	intercostal bronchial trunk a.
ICP	intracranial pressure
IDA	iminodiacetic acid
IDC	invasive ductal carcinoma
IDDM	insulin-dependent diabetes mellitus
IDM	infant of diabetic mother
ie	id est
IgA	Immunoglobulin A
IgE	Immunoglobulin E
IgG	Immunoglobulin G
IGL	inferior glenohumeral ligament
IGHLC	inferior glenohumeral labroligamentous complex
IGL	inferior glenohumeral ligament
IgM	immunoglobulin M
IHSS	idiopathic hypertrophic subaortic stenosis
IIP	idiopathic interstitial pneumonia
ILC	invasive lobular carcinoma
IM	intramuscular
IMA	inferior mesenteric artery
IMH	intramural hematoma
IMV	inferior mesenteric vein
In	indium
inf	inferior
intermed	intermediate
IPF	idiopathic pulmonary fibrosis
IPH	idiopathic pulmonary hemosiderosis; intraparenchymal hemorrhage
IPMT	intraductal papillary mucinous tumor
IQ	intelligence quotient

IR	inversion recovery
IRP	international reference preparation
IRU	inferior radioulnar joint
IRV	inspiratory reserve volume
IS	iliosacral; international standard
IU	international unit = amount of a substance, based on measured biological activity or effect
IUD	intrauterine device
IUGR	intrauterine growth retardation
IUP	intrauterine pregnancy
IV	intravenous
IVC	inferior vena cava
IVDA	intravenous drug abuse
IVH	intraventricular hemorrhage
IVP	intravenous pyelogram
IVS	intraventricular septum
IVU	intravenous urogram
JAA	juxtaposition of atrial appendages
KCC	Kulchitsky cell carcinoma
kDa	atomic weight in terms of kilodaltons
keV	1 kiloelectron volt = 1.60217646 × 10-16 joules
kV	kilovolt
kVp	kilovolt peak
KUB	kidney + ureter + bladder on one film
L	left
L-DOPA	3-(3,4-dihydroxyphenyl)-levo-alanin
LA	left atrium
LAD	left anterior descending
LAO	left anterior oblique
LAT	lateral
LATS	long-acting thyroid stimulating
lbs	pounds (*Libra pondo*, Latin)
LCA	left coronary artery
LCH	Langerhans cell histiocytosis
LCIS	lobular carcinoma in situ
LCL	lateral collateral ligament
LCx	left circumflex coronary artery

LDH	lactate dehydrogenase
LE	lupus erythematosus
LES	lower esophageal sphincter
LFTs	liver function tests
LGA	large for gestational age
LGE	late gadolinium-induced enhancement
LH	luteinizing hormone
LHBB	long head of biceps brachii
LHRH	luteinizing hormone releasing hormone
lig.	ligament
ligg.	ligaments
LIP	lymphocytic interstitial pneumonitis
LL	lower lobes
LLL	left lower lobe
LLQ	left lower quadrant
LM	left main coronary artery; lateromedial
LMP	last menstrual period
Lnn	lymph nodes
LOCM	low-osmolar contrast media
LPA	left pulmonary artery
LPD	lymphoproliferative disease
LPO	left posterior oblique
LPV	left portal vein
L/S	Lecithin-Sphingomyelin (ratio)
LSA	left subclavian artery
LSD	lysergic acid diethylamide
LUL	left upper lobe
LUQ	left upper quadrant
LV	left ventricle
LVEF	left ventricular ejection fraction
LVET	left ventricular ejection time
LVFT1	left ventricular fast filling time
LVOT	left ventricular outflow tract
LVPW	left ventricular posterior wall

M	male
m	meter
m.	muscle
MA	menstrual age
MAA	macroaggregated albumin

MAG	mercaptoacetyltriglycine
MAI	Mycobacterium avium intracellulare
MALT	mucosa-associated lymphoid tissue
Mammo	mammography
max.	maximum
MBC	maximum breathing capacity
MBq	mega Becquerel = 106 Bq
MCA	middle cerebral artery
MCDK	multicystic dysplastic kidney
mCi	millicurie (1 mCi = 3.7×10^7 disintegrations per sec)
MCP	metacarpophalangeal
MCL	medial collateral ligament
MDMA	3,4-methylenedioxymethamphetamine
MDP	methylene diphosphonate
MEA	multiple endocrine adenomas
MED	medial
MELAS	**M**itochondrial myopathy, **E**ncephalopathy, **L**actic acidosis, **A**nd **S**trokelike episodes
MEN	multiple endocrine neoplasms
mEq	milliequivalent
mets	metastases
MFH	malignant fibrous histiocytoma
MGL	middle glenohumeral ligament
mGy	absorbed energy of ionizing radiation (1 Gy = 1 J • kg^{-1} = 1 m^2 • sec^{-2})
MHA	microhemagglutination assay
MIBG	metaiodobenzylguanidine
MIBI	methoxyisobutylisonitril
min.	minimum
min	minute(s)
MIP	maximum intensity projection
MIT	monoiodotyrosine
mIU	1 • 10^{-6} IU
ML	middle lobe
MLCN	multilocular cystic nephroma
MLO	mediolateral oblique
mm.	muscles
MMAA	mini-microaggregated albumin colloid
MMFR	maximal midexpiratory flow rate
mo	month(s)
MoM	multiple of mean

MPA	main pulmonary artery
MPS	mucopolysaccharidosis
MPV	main portal vein
MR	magnetic resonance
MRA	magnetic resonance angiography
MRCP	magnetic resonance cholangiopancreatography
MRV	magnetic resonance venography
MS-AFP	maternal serum - fetoprotein
mSv	millisievert (1 Sv = 1 J/kg)
MT	metatarsal
MTP	metatarsophalangeal
MTT	mean transit time
MUGA	multiple gated acquisition
MV	mitral valve
MVA	motor vehicle accident
MVC	motor vehicle collision
Myelo	myelography
NASCET	North American symptomatic endarterectomy trial
N.B.	nota bene
NCCT	noncontrast CT
NECT	nonenhanced computed tomography
NF1	neurofibromatosis type 1
NG	nasogastric
NHL	non-Hodgkin lymphoma
NIDDM	non-insulin dependent diabetes mellitus
nn.	nerves
NMLE	non-masslike enhancement
NOS	not otherwise specified
npl	neoplasm
NPO	nulla per os
NPV	negative predictive value
NRC	Nuclear Regulatory Commission
NSAID	nonsteroidal antiinflammatory drug
NSAIDs	nonsteroidal antiinflammatory drugs
NSIP	nonspecific interstitial pneumonia
NST	nonstress test
NTD	neural tube defect
NTDs	neural tube defects
NUC	nuclear medicine

OB	**obstetrical**
OB-US	obstetrical ultrasound
OBL	oblique
OEIS	omphalocele, (bladder) exstrophy, imperforate anus, spinal defects
OFD	occipitofrontal diameter
OHSS	ovarian hyperstimulation syndrome
OI	osteogenesis imperfecta
OIH	orthoiodohippurate
OKC	odontogenic keratocyst
P	phosphorus
p-ANCA	perinuclear antineutrophil cytoplasmic autoantibodies
PA	posteroanterior; pulmonary artery
PACs	premature atrial contractions
PAH	para-aminohippurate; precapillary pulmonary arterial hypertension
PALM	premature with accelerated lung maturity
PAP	primary atypical pneumonia; pulmonary alveolar proteinosis
PAPVR	partial anomalous pulmonary venous return
PAS	periodic acid Schiff
PASH	pseudoangiomatous stromal hyperplasia
Path	pathology
PAVM	pulmonary arteriovenous malformation
PAWP	pulmonary artery wedge pressure
PBF	pulmonary blood flow
PCA	posterior cerebral artery
PCKD	polycystic kidney disease
PCL	posterior cruciate ligament
pCom	posterior communicating artery
PCP	Pneumocystis carinii pneumonia
PCWP	pulmonary capillary wedge pressure
PD	posterior descending artery
PDA	patent ductus arteriosus
PE	pulmonary embolism
PEEP	positive end expiratory pressure
PEP	preejection period
PET	positron emission tomography, pancreatic endocrine tumor
PFT	pulmonary function tests
pHPT	primary hyperparathyroidism
PHPV	persistent hyperplastic primary vitreous

PHypoPT	pseudohypoparathyroidism
PICA	posterior inferior cerebellar artery
PID	pelvic inflammatory disease
PIE	pulmonary infiltrate with eosinophilia; pulmonary interstitial emphysema
PIOPED	prospective investigation of pulmonary embolus detection
PIP	proximal interphalangeal
PIPIDA	paraisopropyl iminodiacetic acid
PLCH	pulmonary Langerhans cell histiocytosis
PLSA	posterolateral segment artery
pML	posterior mitral valve leaflet
PMMA	polymethylmethacrylate
PMN	polymorphonuclear
PMNs	polymorphonuclears
PMT	photomultiplier tube
PNET	primitive neuroectodermal tumor
PNST	peripheral nerve sheath tumor
PO	*per os*, Latin = by mouth
pO_2	oxygen pressure
POST	posterior
PPD	purified protein derivative
PPG	photoplethysmography
PPHypoPT	pseudopseudohypoparathyroidism
ppm	parts per million
PPROM	preterm premature rupture of membranes
PPV	positive predictive value; positive-pressure ventilation
pRCC	papillary renal cell cancer
preval	prevalence
p.r.n.	*pro re nata*, Latin = as the circumstance arises
PS	pulmonary stenosis
PSA	prostate-specific antigen
PSS	progressive systemic sclerosis
PSV	peak systolic velocity
PTA	percutaneous transluminal angioplasty
PTC	percutaneous transhepatic cholangiography
PTH	parathyroid hormone
pTL	posterior tricuspid valve leaflet
PTU	propylthiouracil
PV	portal vein; pulmonary valve
PVC	polyvinyl chloride
PVCs	premature ventricular contractions

PVH	pulmonary venous hypertension
PVL	periventricular leukomalacia
PVNS	pigmented villonodular synovitis
PVP	portal venous phase
PVR	pulse volume recording; postvoid residual
PYP	pyrophosphate
QPS	quantitative perfusion SPECT
R	right
RA	rheumatoid arthritis; right atrium
RAA	right aortic arch; right atrial appendage
rad	radiation absorbed dose, in 1975 replaced by gray (Gy)
RAIU	radioactive iodine uptake
RAO	right anterior oblique
Rb	Rubidium
RB-ILD	respiratory bronchiolitis-associated interstitial lung disease
RBC	red blood cell
RBCs	red blood cells
RCA	right coronary artery
RCC	renal cell carcinoma
RCCs	renal cell carcinomas
RDS	respiratory distress syndrome
rel.	relative
RES	reticuloendothelial system
RHV	right hepatic vein
RI	resistive index
RIBA	recombinant immunoblot assay
RIND	reversible ischemic neurologic deficit
RISA	radioiodine serum albumin
RLAT	right lateral
RLL	right lower lobe
RLQ	right lower quadrant
RML	right middle lobe
RMS	root mean square
ROC	receiver operating characteristic
ROI	region of interest
ROIs	regions of interest
RPF	renal plasma flow
RPO	right posterior oblique

RPV	right portal vein
RPW	relative percentage washout
RSV	respiratory syncytial virus
RTA	renal tubular acidosis
RUL	right upper lobe
RUQ	right upper quadrant
RV	residual volume; right ventricle
RVOT	right ventricular outflow tract
RVT	renal vein thrombosis
Rx	therapy
S1Q3T3	prominent S wave in lead I + Q wave and inverted T wave in lead III
S/P	status post
SAE	subcortical arteriosclerotic encephalopathy
SAG	sagittal
SAH	subarachnoid hemorrhage
SBE	subacute bacterial endocarditis
SBFT	small bowel follow-through
SBO	small bowel obstruction
SCC	squamous cell carcinoma
SCBE	single-contrast barium enema
SCLC	small cell lung cancer
SCMM	sternocleidomastoid muscle
S/D	systolic / diastolic (ratio)
SD	standard deviation
SDS	summed difference score
SE	spin echo
Sens	sensitivity
SGA	small for gestational age
SGL	superior glenohumeral ligament
sHPT	secondary hyperparathyroidism
SI	signal intensity
SIJ	sacroiliac joint
SIS	Second International Standard
SLAP	superior labral tear from anterior to posterior
SLE	systemic lupus erythematosus
SMA	superior mesenteric artery
SMV	superior mesenteric vein
Sn	stannum
SNHL	sensorineural hearing loss

SOB	shortness of breath
S/P	status post
Specif	specificity
SPECT	single photon emission
SPIO	superparamagnetic iron oxide
SQ	subcutaneous
SRS	summed rest score
SSS	summed stress score
STH	somatotrophic hormone
STIR	short tau inversion recovery
supp	suppositorium, suppository
Surg	surgery
SUV	standardized uptake values
SVC	superior vena cava
SVCs	superior venae cavae
T1WI	T1-weighted image
T2WI	T2-weighted image
TAH	total abdominal hysterectomy
TAPVR	total anomalous pulmonary venous return
TB	tuberculosis
TBG	thyroxin-binding globulin
Tc	Technetium
TCC	transitional cell carcinoma
TDLU	terminal ductal lobular unit
TDLUs	terminal ductal lobular units
TE	echo time
TEF	tracheoesophageal fistula
TGA	transposition of great arteries
TGV	transposition of great vessels
tHPT	tertiary hyperparathyroidism
TIA	transitory ischemic attack
TIAs	transitory ischemic attacks
TLC	total lung capacity
Tm	transport maximum across tubular cells
T_{max}	time to maximum peak
TMB-IDA	2,4,6-trimethylbromo-acetanilide iminodiacetic acid
TN	true negative
TNF	tumor necrosis factor
TNM	tumor nodes metastasis

TOA	tuboovarian abscess
TOF	tetralogy of Fallot; time of flight
TORCH	toxoplasmosis, rubella, cytomegalovirus, herpes virus
TP	true positive
TPN	total parenteral nutrition
TPROM	term premature rupture of membranes
TR	repetition time
TRH	thyrotropin-releasing hormone
TRV	transverse
TSC	tuberous sclerosis
TSH	thyroid-stimulating hormone
TURP	transurethral resection of prostate
TV	tidal volume
UA	umbilical artery
UCL	ulnar collateral ligament
uE3	unconjugated estriol
UGI	upper gastrointestinal series
UICC	Union Internationale Contre le Cancer
UIP	usual interstitial pneumonia
UL	upper lobe
UPJ	ureteropelvic junction
URI	upper respiratory infection
US	ultrasound
USA	United States of America
USP	United States Pharmacopoeia
USP XX	United States Pharmacopoeia, 20th edition
UTI	urinary tract infection
UTIs	urinary tract infections
UVJ	ureterovesical junction
Uvol	urine volume
VACTERL	vertebral, **a**norectal, **c**ardiovascular, **t**racheo-**e**sophageal fistula, **r**enal, **l**imb anomalies
VC	vital capacity
VCUG	voiding cystourethrogram
VDRL	venereal disease research laboratory
vHL	Von Hippel-Lindau disease
VIP	vasoactive intestinal peptides
VMA	vanillylmandelic acid

VP	ventriculoperitoneal
V/Q	ventilation perfusion
VR	Virchow-Robin space
vs.	versus
VSD	ventricular septal defect
VSDs	ventricular septal defects
VUR	vesicoureteral reflux
vv.	venae, veins
WAGR	Wilms tumor, aniridia, genital abnormalities, mental retardation
WBC	white blood cell
WBCs	white blood cells
WDHA	watery diarrhea, hypokalemia, achlorhydria
WDHH	watery diarrhea, hypokalemia, hypochlorhydria
WM	white matter
wk	week(s)
w/o	without
WPW	Wolff-Parkinson-White
wt/vol	weight/volume percent = amount of solute in g per amount of solution in mL
XGP	xanthogranulomatous pyelonephritis
YS	yolk sac
yr	year(s)

TREATMENT OF ADVERSE CONTRAST REACTIONS[1]

PRINCIPLES OF TREATMENT

1. Give high doses of oxygen
2. Infuse physiologic fluids
3. Establish adequate airway
4. Monitor heart rate & blood pressure

◊ No therapeutic role in acute adverse reaction: antihistamines, H_2 antagonists, corticosteroids

VASOVAGAL REACTION

- **hypotension** (systolic blood pressure < 80 mmHg) **with** sinus **bradycardia** (pulse < 60 bpm)
- dizziness, diaphoresis
- loss of consciousness

⇒ Monitor vital signs

⇒ Leg elevation > 60° + Trendelenburg position

⇒ Secure airway + **O_2** 6–10 L/min

⇒ Secure IV access + rapid IV infusion of isotonic Ringer's lactate / normal saline

if symptoms persist, add:

⇒ **atropine** slowly IV 0.6–1.0 mg

⇒ Repeat atropine every 3–5 min slowly IV up to a total dose of 0.04 mg/kg (3 mg) in adults [pediatric: 0.02 mg/kg IV; starting dose: min. 0.1 mg, max. 0.6 mg; may repeat to total dose of 2 mg]

DERMAL CONTRAST REACTION

- hives = urticaria
- itching = pruritus
- flushing
- facial angioedema (= nonpruritic SQ edema of eyelid / peroral)

Mild Urticaria

⇒ Discontinue injection if not completed

⇒ No treatment needed in most cases

⇒ H_1-antihistamine, ie

diphenhydramine (Benadryl®) PO/IM/IV 25–50 mg

or

hydroxyzine (Vistaril®) PO/IM/IV 25–50 mg

Severe Urticaria

add H_2-antihistamine:

⇒ **cimetidine** (Tagamet®) 300 mg PO / slowly IV (diluted in 20 mL D5W solution)

[pediatric: 5–10 mg/kg diluted in 20 mL D5W solution]
or
ranitidine (Zantac®) 50 mg PO / slowly IV (diluted in 20 mL D5W solution)

if widely disseminated:
⇒ IV line started + kept open (with normal saline / Ringer's lactate)
⇒ **epinephrine IV** (1÷10,000) IV slowly over 2–5 min 1.0 mL (= 0.1 mg) if no cardiac contraindication

NAUSEA / VOMITING

may be the 1st signs of a more severe reaction
⇒ watch patient closely

RESPIRATORY DISTRESS

- wheezing (inconsequential)
- bronchoconstriction (life-threatening)
- laryngeal edema (life-threatening)

Facial / Laryngeal Edema

⇒ **epinephrine SQ** (1÷1,000) 0.1–0.2 mL (= 0.1–0.2 mg)
or – if patient hypotensive –
epinephrine (1÷10,000) slowly IV 1.0 mL (= 0.1 mg)
Repeat after 15 min up to a maximum of 1.0 mg
⇒ **O_2** 6–10 L/min (via mask)
monitor: ECG; O_2 saturation (pulse oximeter); BP

If not responsive to therapy:
⇒ Seek assistance (CODE team)
⇒ Consider intubation

Bronchospasm (isolated)

⇒ **O_2** 6–10 L/min (by mask, not nasal prongs)
monitor: ECG; O_2 saturation (pulse oximeter); BP
⇒ β_2-agonist metered dose inhaler in 2–3 deep inhalations: **metaproterenol** (Alupent®) / **terbutaline** (Brethaire®) / **albuterol** (Proventil®)
NOT: diphenhydramine as it thickens secretions

If unrelieved
with normal blood pressure + stable bronchospasm
⇒ **epinephrine SQ** (1÷1,000) 0.1–0.2 mL (= 0.1–0.2 mg); may give 0.3 mg
[pediatric: 0.01 mg/kg up to 0.3 mg max.]
with decreased blood pressure + progressive bronchospasm
⇒ **epinephrine IV** (1÷10,000) slowly over 2–5 min IV 1.0 mL (= 0.1 mg)
[pediatric: 0.01 mg/kg IV]
Repeat after 15 min up to a maximum of 1.0 mg

Alternatively

⇒ **aminophylline** 6 mg/kg IV in D5W over 15–20 min (loading dose); then 0.4–1.0 mg/kg/hr

Cx: hypotension, cardiac arrhythmia

or

terbutaline 0.25–0.50 mg IM/SQ

⇒ 200–400 mg hydrocortisone IV

if unsuccessful, may require intubation

if anxiety exacerbates bronchospasm, sedation with 5–10 mg Demerol IV

⇒ Call for assistance (CODE team) for severe bronchospasm / if O_2 saturation persists < 88%

TREATMENT OF ADVERSE CONTRAST REACTIONS[2]

ANAPHYLACTOID REACTION

= acute rapidly progressing generalized systemic reaction characterized by multisystem involvement

- tachycardia (pulse > 100 bpm)
- hypotension (systolic blood pressure < 80 mmHg)
- dizziness, diaphoresis
- loss of consciousness

Hypotension with Tachycardia

⇒ leg elevation > 60° + Trendelenburg position
⇒ monitor: ECG; pulse oximeter; BP
⇒ **O_2** 6–10 L/min (via mask, not nasal prongs)
⇒ rapid IV infusion of isotonic Ringer's lactate / normal saline
⇒ suction as needed

if poorly responsive to fluid therapy add vasopressors
⇒ call CODE
⇒ **epinephrine IV** (1÷10,000) slowly over 2–5 min IV 1.0 mL (= 0.1 mg);
[pediatric: 0.02 mg/kg IV; starting dose of min. 0.1 mg to max. 0.6 mg; may repeat to 2 mg total dose]
repeat after 15 min up to a maximum of 1.0 mg (titrated to effect)
⇒ dopamine

if still poorly responsive:
⇒ transfer to ICU

in adults without IV access:
⇒ **epinephrine SQ** (1÷1,000) 0.3 mL (= 0.3 mg)

in infants / children:
⇒ epinephrine SQ (1÷1,000) with body weight determining the correct dose

Seizure / Convulsion

⇒ protect patient from injury
⇒ monitor airway from obstruction by tongue
⇒ suction as needed
⇒ **O_2** 6–10 L/minute (by mask)

if uncontrolled:
⇒ **diazepam** (Valium®) 5.0 mg / **midazolam** (Versed®) 2.5 mg IV
⇒ monitor: ECG, O_2 saturation (pulse oximeter), BP

if longer effect needed:
⇒ obtain consultation

⇒ **phenytoin** (Dilantin®) infusion 15–18 mg/kg at 50 mg/minute
⇒ consider CODE for intubation

Pulmonary Edema

⇒ Elevate torso
⇒ Apply rotating tourniquets for venous compression
⇒ **O_2** 6–10 L/minute (via mask)
⇒ **furosemide** (Lasix®) 40 mg IV, slow push
⇒ Consider morphine
⇒ Transfer to ICU
⇒ Corticosteroids optional

SEVERE HYPERTENSION

⇒ monitor: ECG, pulse oximeter, BP
⇒ IV fluids very slowly to maintain venous access
⇒ **nitroglycerin** 0.4 mg tablet sublingual; may repeat x 3; topical 1–2" strip of 2% ointment
⇒ **sodium nitroprusside** arterial line (infusion pump necessary to titrate)
⇒ transfer to ICU

for pheochromocytoma:

⇒ **phentolamine** (Regitin®)
Adult dose: 5.0 mg IV; Pediatric dose: 1.0 mg IV

ANGINA

⇒ **O_2** 6–10 L/min (via mask, not nasal prongs)
⇒ IV fluids, very slowly
⇒ **nitroglycerin** 0.4 mg, sublingually; may repeat q 15 minutes
⇒ **morphine** 2 mg IV

AIR EMBOLISM

- air hunger, dyspnea, expiratory wheezing, cough
- chest pain, pulmonary edema, tachycardia, hypotension
- stroke ← decreased cardiac output / paradoxical air embolism / pulmonary AVM / R-to-L intracardiac shunt

Rx: ⇒ 100% **O_2** administration
⇒ left lateral decubitus position

CONTRAST EXTRAVASATION

= escape of contrast material from vascular lumen + infiltration of interstitial tissue during injection

Incidence: 0.1–0.4%; no direct correlation with injection flow rate (although frequent with power injectors)

Risk: fragile veins, IV catheter indwelling for many days, multiple puncture attempts during IV placement

Effect: (a) acute inflammatory response (peaking in 24–48 hrs) related to hyperosmolality of

contrast material

(b) compartment syndrome

(c) ulceration + tissue necrosis (as early as 6 hours)

(d) fibrosis

(e) muscle atrophy

- may be asymptomatic; edema, erythema
- swelling, tightness, tenderness, stinging, burning pain

Evaluate for:

(1) Skin injury (blanching, discoloration)
(2) Nerve compromise
(3) Vascular compromise

Dx: (1) Palpate catheter venipuncture site during initial seconds of injection
(2) Ask patient to report any sensation of pain / swelling at injection site

Severe Cx (uncommon): compartment syndrome, skin ulceration, tissue necrosis

Rx: (1) Elevation of affected extremity above heart → decrease capillary hydrostatic pressure
(2) Cold compress → decreases cellular uptake
(3) Warm compress → vasodilatation promotes absorption
(4) Discharge with instructions to watch for symptoms that indicate a need for surgical evaluation
(5) Surgical consultation if
› extravasation > 50 mL
› ↑ in swelling / pain after 2–4 hours
› ↓ in capillary refill time
› change in sensation (paresthesia) in affected limb
› skin ulceration / blistering
(5) Documentation in medical record
(6) Notification of referring physician
(7) 24-hour follow up (phone call, examination)

MUSCULOSKELETAL SYSTEM

DIFFERENTIAL DIAGNOSIS OF MUSCULOSKELETAL DISORDERS

UNIVERSAL DIFFERENTIAL DIAGNOSIS

mnemonic: VINDICATE

Vascular and cardiac
Infectious, **I**nflammatory
Neoplasm
Drugs
Iatrogenic, **I**diopathic, **I**ntoxication
Congenital
Autoimmune, **A**llergic
Trauma
Endocrine and metabolic

DIAGNOSTIC GAMUT OF BONE DISORDERS

Conditions to be considered = "dissect bone disease with a DIATTOM"

Dysplasia + **D**ystrophy
Infection
Anomalies of development
Tumor + tumorlike conditions
Trauma
Osteochondritis + ischemic necrosis
Metabolic disease

Dysplasia = disturbance of bone growth
Dystrophy = disturbance of nutrition

LIMPING CHILD

Limping Child at 1–4 Years

A. CONGENITAL
   1. Developmental dysplasia of hip
B. TRAUMATIC
   1. Toddler's fracture
   2. Nonaccidental trauma
   3. Other fractures
   4. Foreign body
C. INFLAMMATORY
   1. Diskitis

2. Septic arthritis
3. Osteomyelitis
4. Transient synovitis of hip

Limping Child at 4–10 Years

A. TRAUMATIC
B. INFLAMMATORY
   1. Septic arthritis
   2. Osteomyelitis
   3. Transient synovitis of hip
   4. Diskitis
   5. Juvenile rheumatoid arthritis
C. VASCULAR
   1. Legg-Perthes disease

Limping Child at 10–15 Years

A. TRAUMATIC
   1. Stress fracture
   2. Osteochondritis dissecans
   3. Osgood-Schlatter disease
B. INFLAMMATORY
   1. Juvenile rheumatoid arthritis
   2. Ankylosing spondylitis
   3. Septic arthritis
   4. Osteomyelitis
C. HORMONAL
   1. Epiphyseolysis of femoral head

DELAYED BONE AGE

A. CONSTITUTIONAL
   1. Familial
   2. IUGR
B. METABOLIC
   1. Hypopituitarism
   2. Hypothyroidism
   3. Hypogonadism (Turner syndrome)
   4. Cushing disease, steroid therapy
   5. Diabetes mellitus
   6. Rickets
   7. Malnutrition
   8. Irradiation of brain (for cerebral tumor / ALL)
C. SYSTEMIC DISEASE
   1. Congenital heart disease
   2. Renal disease
   3. GI disease: celiac disease, Crohn disease, ulcerative colitis

4. Anemia
5. Bone marrow transplantation (< 5 years of age)

D. SYNDROMES
1. Trisomies
2. Noonan disease
3. Cornelia-de-Lange syndrome
4. Cleidocranial dysplasia
5. Lesch-Nyhan disease
6. Metatropic dwarfism

UPTAKE PATTERN IN BONE LESIONS

Superscan

Cause:

A. METABOLIC
1. Renal osteodystrophy
2. Osteomalacia
√ randomly distributed focal sites of intense activity
= Looser zones = pseudofractures
= Milkman fractures (most characteristic)
3. Hyperparathyroidism
√ focal intense uptake ← site of brown tumors
4. Hyperthyroidism
→ rate of bone resorption > rate of bone formation (= decrease in bone mass)
• hypercalcemia (occasionally)
• elevated alkaline phosphatase
√ radiographically NOT visible
√ susceptible to fracture

B. Widespread bone lesions
1. Diffuse skeletal metastases: prostate, breast, multiple myeloma, lymphoma, lung, bladder, colon, stomach (most frequent)
2. Myelofibrosis / myelosclerosis
3. Aplastic anemia, leukemia
4. Waldenström macroglobulinemia
5. Systemic mastocytosis
6. Widespread Paget disease

√ diffusely increased activity in bones: particularly prominent in axial skeleton, calvarium, mandible, costochondral junctions (= "rosary beading"), sternum (= "tie sternum"), long bones
√ increased metaphyseal + periarticular activity
√ increased bone-to-soft-tissue ratio
√ "absent kidney" sign = little / no activity in kidneys but good visualization of urinary bladder
√ femoral cortices become visible

CAVE: scan may be interpreted as normal, particularly in patients with poor renal function!

Hot Bone Lesions

mnemonic: NATI MAN

Neoplasm
Arthropathy
Trauma
Infection
Metastasis
Aseptic **N**ecrosis

Long Segmental Diaphyseal Uptake

A. BILATERALLY SYMMETRIC
   1. Hypertrophic pulmonary osteoarthropathy
   2. Thigh / shin splints = mechanical enthesopathy
   3. Ribbing disease
   4. Engelmann disease = progressive diaphyseal dysplasia

B. UNILATERAL
   1. Inadvertent arterial injection
   2. Melorheostosis
   3. Chronic venous stasis
   4. Osteogenesis imperfecta
   5. Vitamin A toxicity
   6. Osteomyelitis
   7. Paget disease
   8. Fibrous dysplasia

Doughnut Sign of Bone Lesion

= radiotracer accumulation at periphery of bone lesion with little activity at its center

1. Aneurysmal bone cyst
2. Giant cell tumor
3. Chondrosarcoma
4. Telangiectatic osteosarcoma

Photon-deficient Bone Lesion

= decreased radiotracer uptake

A. Interruption of blood flow in local bone
   = vessel trauma or vascular obstruction by thrombus / tumor
   1. Early osteomyelitis
   2. Radiation therapy
   3. Posttraumatic aseptic necrosis
   4. Sickle cell crisis

B. Replacement of bone by destructive process
   1. Metastases (most common cause): central axis skeleton > extremity, most commonly in carcinoma of kidney + lung + breast + multiple myeloma

2. Primary bone tumor (exceptional)

mnemonic: HM RANT

Histiocytosis X
Multiple myeloma
Renal cell carcinoma
Anaplastic tumors (reticulum cell sarcoma)
Neuroblastoma
Thyroid carcinoma

Radionuclide Uptake in Benign Bone Lesions

A. NO TRACER UPTAKE
   1. Bone island
   2. Osteopoikilosis
   3. Osteopathia striata
   4. Fibrous cortical defect
   5. Nonossifying fibroma

B. INCREASED TRACER UPTAKE
   1. Fibrous dysplasia
   2. Paget disease
   3. Eosinophilic granuloma
   4. Melorheostosis
   5. Osteoid osteoma
   6. Enchondroma
   7. Exostosis

BONE SCLEROSIS

Diffuse Osteosclerosis

mnemonic: 5 M'S To PROoF

Metastases
Myelofibrosis
Mastocytosis
Melorheostosis
Metabolic: hypervitaminosis D, fluorosis, hypothyroidism, phosphorus poisoning
Sickle cell disease
Tuberous sclerosis
Pyknodysostosis, Paget disease
Renal osteodystrophy
Osteopetrosis
Fluorosis

Acquired Syndromes with Increased Bone Density

1. Renal osteodystrophy
2. Osteoblastic metastases
3. Paget disease of bone

4. Erdheim-Chester disease
5. Myelofibrosis
6. Sickle cell disease

Constitutional Sclerosing Bone Disease

1. Progressive diaphyseal dysplasia
2. Infantile cortical hyperostosis
3. Melorheostosis
4. Osteopathia striata
5. Osteopetrosis
6. Osteopoikilosis
7. Pachydermoperiostosis
8. Pyknodysostosis
9. Van Buchem disease
10. Williams syndrome

Sclerosing Bone Dysplasia

Endochondral bone formation:

primary spongiosa forms at 7th week of embryogenesis → resorption around 9th week with conversion into secondary spongiosa → osteoclastic remodeling into trabeculae + medullary cavity

Target sites for endochondral bone formation:

tubular + flat bones, vertebrae, skull base, ethmoids, ends of clavicle

Intramembranous ossification:

= transformation of mesenchymal cells into cortical bone without intervening cartilaginous matrix beginning at 9th week of fetal life to beyond closure of growth plates

Target sites for intramembranous bone formation:

cortex of tubular + flat bones, calvaria, upper facial bones, tympanic temporal bone, vomer, medial pterygoid process

A. DYSPLASIA OF ENDOCHONDRAL OSSIFICATION (PRIMARY SPONGIOSA)
   = failure in resorption + remodeling of primary immature spongiosa by osteoclasts
   √ accumulation of calcified cartilage matrix packing the medullary cavity
   1. Osteopetrosis
   2. Pyknodysostosis

B. DYSPLASIA OF ENDOCHONDRAL OSSIFICATION (SECONDARY SPONGIOSA)
   = errors in resorption + remodeling of secondary spongiosa
   √ focal densities / striations along trabecular bone
   1. Osteopoikilosis
   2. Osteopathia striata

C. DYSPLASIA OF INTRAMEMBRANOUS OSSIFICATION
   = disequilibrium between periosteal bone formation + endosteal bone resorption
   1. Progressive diaphyseal dysplasia
   2. Hereditary multiple diaphyseal sclerosis
   3. Hyperostosis corticalis generalisata
   4. Diaphyseal dysplasia with anemia

5. Oculodento-osseous dysplasia
6. Trichodento-osseous dysplasia
7. Kenny-Caffey syndrome

D. MIXED SCLEROSING DYSPLASIAS = OVERLAP SYNDROME

(a) predominantly endochondral disturbance

1. Dysosteosclerosis
2. Metaphyseal dysplasia (Pyle disease)
3. Craniometaphyseal dysplasia
4. Frontometaphyseal dysplasia

(b) predominantly intramembranous defects

1. Melorheostosis
2. Craniodiaphyseal dysplasia
3. Lenz-Majewski hyperostotic dwarfism
4. Progressive diaphyseal dysplasia

Nonhereditary Sclerosing Dysplasia

1. Intramedullary osteosclerosis
2. Melorheostosis
3. Overlap syndromes
   = disorder of endochondral + intramembranous ossification
   Combination: melorheostosis + osteopoikilosis + osteopathia striata

Solitary Osteosclerotic Lesion

A. DEVELOPMENTAL

1. Bone island

B. VASCULAR

1. Old bone infarct
2. Aseptic / ischemic / avascular necrosis

C. HEALING BONE LESION

(a) trauma: callus formation in stress fracture
(b) benign tumor: fibrous cortical defect / nonossifying fibroma; brown tumor; bone cyst
(c) malignant tumor: lytic metastasis after radiation, chemotherapy, hormone therapy

D. INFECTION / INFLAMMATION
(low-grade chronic infection / healing infection)

1. Osteoid osteoma
2. Chronic / healed osteomyelitis: bacterial, tuberculous, fungal
3. Sclerosing osteomyelitis of Garré
4. Granuloma
5. Brodie abscess

E. BENIGN TUMOR

1. Osteoma
2. Osteoblastoma
3. Ossifying fibroma
4. Healed fibrous cortical defect
5. Enchondroma / osteochondroma

F. MALIGNANT TUMOR
   1. Osteoblastic metastasis: prostate, breast
   2. Lymphoma
   3. Sarcoma: osteo-, chondro-, Ewing sarcoma

G. OTHERS
   1. Sclerotic phase of Paget disease
   2. Fibrous dysplasia

Cortical Sclerotic Lesion in Child

1. Osteoid osteoma
2. Stress fracture
3. Chronic osteomyelitis
4. Healed fibrous cortical defect

Multiple Osteosclerotic Lesions

A. FAMILIAL
   1. Osteopoikilosis
   2. Enchondromatosis = Ollier disease
   3. Melorheostosis
   4. Multiple osteomas: associated with Gardner syndrome
   5. Osteopetrosis
   6. Pyknodysostosis
   7. Osteopathia striata
   8. Chondrodystrophia calcificans congenita
   9. Multiple epiphyseal dysplasia = Fairbank disease

B. SYSTEMIC DISEASE
   1. Mastocytosis = urticaria pigmentosa
   2. Tuberous sclerosis

Bone-within-bone Appearance

= endosteal new bone formation

1. Normal
   (a) thoracic + lumbar vertebrae (in infants)
   (b) growth recovery lines (after infancy)
2. Infantile cortical hyperostosis (Caffey)
3. Sickle cell disease / thalassemia
4. Congenital syphilis
5. Osteopetrosis / oxalosis
6. Radiation
7. Acromegaly
8. Paget disease
9. Gaucher disease

mnemonic: BLT PLT RSD RSD

Bismuth ingestion

Lead ingestion

Thorium ingestion
Petrosis (osteopetrosis)
Leukemia
Tuberculosis
Rickets
Scurvy
D toxicity (vitamin D)
RSD (reflex sympathetic dystrophy)

Dense Metaphyseal Bands

mnemonic: DENSE LINES
D-vitamin intoxication
Elemental arsenic + heavy metals: lead, bismuth, phosphorus
Normal variant
Systemic illness
Estrogen to mother during pregnancy
Leukemia
Infection (TORCH), **I**diopathic hypercalcemia
Never forget healed rickets
Early hypothyroidism (cretinism)
Scurvy, congenital **S**yphilis, **S**ickle cell disease
also: methotrexate therapy

OSTEOPENIA

= decrease in bone quantity maintaining normal quality
√ increased radiolucency of bone:
√ vertical striations in vertebral bodies
√ accentuation of tensile + compressive trabeculae of proximal femur
√ reinforcement lines (= bone bars) crossing marrow cavity about knee
√ cortical resorption of 2nd metacarpal:
√ measuring outer cortical diameter (W) and width of medullary cavity (m) at mid portion of bone and reporting combined cortical thickness (CCT = W + m)
√ subperiosteal tunneling

Categories:

A. DIFFUSE OSTEOPENIA
1. Osteoporosis = decreased osteoid production
2. Osteomalacia = undermineralization of osteoid
3. Hyperparathyroidism
4. Multiple myeloma / diffuse metastases
5. Drugs
6. Mastocytosis
7. Osteogenesis imperfecta

B. REGIONAL OSTEOPENIA

Osteoporosis

= reduced bone mass of normal composition secondary to
(a) osteoclastic resorption (85%): trabecular, endosteal, intracortical, subperiosteal
(b) osteocytic resorption (15%)

Prevalence: 7% of all women aged 35–40 years;
12% for males + females aged 50–79 years;
◊ Most common of all metabolic bone disorders; 14 million worldwide by 2020

Classification:

(a) Primary / involutional osteoporosis ← cumulative bone loss as people age and undergo sex hormone changes
1. Type I (postmenopausal) osteoporosis
= accelerated trabecular bone resorption ← estrogen deficiency
Fracture pattern: spine and wrist
2. Type II (senile) osteoporosis
= proportionate loss of cortical and trabecular bone
Fracture pattern: hip, proximal humerus, tibia, pelvis

(b) Secondary osteoporosis (in 20–30%) = consequence of various medical conditions / use of certain medications

Etiology:

A. CONGENITAL DISORDERS
1. Osteogenesis imperfecta
◊ The only osteoporosis with bending of bones!
2. Homocystinuria

B. IDIOPATHIC (bone loss begins earlier + proceeds more rapidly in women)
1. Juvenile osteoporosis: < 20 years
2. Adult osteoporosis: 20–40 years
3. Postmenopausal osteoporosis: > 50 years
(40–50% lower trabecular bone mineral density in elderly than in young women)
4. Senile osteoporosis: > 60 years
progressively decreasing bone density at a rate of 8% (3%) in females (males) per year

C. NUTRITIONAL DISTURBANCES scurvy; calcium deficiency; protein deficiency (nephrosis, chronic liver disease, alcoholism, anorexia nervosa, kwashiorkor, starvation, malnutrition, malabsorption)

D. ENDOCRINOPATHY Cushing disease, hypogonadism (Turner syndrome, eunuchoidism), hyperthyroidism, hyperparathyroidism, acromegaly, Addison disease, diabetes mellitus, pregnancy, paraneoplastic phenomenon in liver tumors

E. RENAL OSTEODYSTROPHY
decrease / same / increase in spinal trabecular bone; rapid loss in appendicular skeleton

F. IMMOBILIZATION = disuse osteoporosis

G. COLLAGEN DISEASE, RHEUMATOID ARTHRITIS

H. BONE MARROW REPLACEMENT infiltration by lymphoma / leukemia (ALL), multiple myeloma, diffuse metastases, marrow hyperplasia ← hemolytic anemia

I. DRUG THERAPY
corticosteroids, heparin (15,000–30,000 U for > 6 months), methotrexate, excessive alcohol consumption, smoking, Dilantin, aromatase inhibitors, gonadotropin-releasing hormone antagonist

J. RADIATION THERAPY

K. LOCALIZED OSTEOPOROSIS
immobilization / disuse, Sudeck dystrophy, transient osteoporosis of large joints, regional migratory osteoporosis of lower extremities

- serum calcium, phosphorus, alkaline phosphatase frequently normal
- hydroxyproline may be elevated during acute stage

Significant predictors of osteoporotic fractures:

1. Age
2. History of fracture
3. Failed chair test (= inability to rise from a chair in 3 successions without using arms)
4. Fall within past 12 months

Clinical manifestation:

(1) Vertebral compression fracture (HALLMARK)
(2) Femoral fracture: neck + intertrochanteric region
(3) Fracture of distal radius (Colles) and tibia

Technique of Bone Densitometry:

(1) **Single-Photon Absorptiometry** measures primarily cortical bone of appendicular bones, single-energy ^{125}I radioisotope source
Site: distal radius (= wrist bone density), os calcis
Dose: 2–3 mrem
Precision: 1–3%

(2) **Dual-Photon Absorptiometry** radioactive energy source with 2 photon peaks; should be reserved for patients < 65 years of age because of interference from osteophytosis + vascular calcifications
Site: vertebrae, femoral neck
Dose: 5–10 mrem
Precision: 2–4%

(3) **Single X-ray Absorptiometry**
= area projectional technique for quantitative bone density measurement
Site: distal radius, calcaneus
Dose: low
Precision: 0.5–2%

(4) **Dual Energy X-ray Absorptiometry (DXA / DEXA)**
= quantitative digital radiography
◊ Most widely used & most precise technique!
◊ Standard of reference for diagnosis of osteoporosis in conjunction with *Fracture Risk Assessment Tool* at http://www.shef.ac.uk/FRAX/ for results of a 10-year probability of a major osteoporotic fracture in hip, spine, proximal humerus, distal

forearm

Technique:

» mobile x-ray source composed of 2 different photon energy levels (constant + pulsed) moves together with detection system
» rectilinear / fan-beam scanners
» attenuation values of soft tissues are subtracted, leaving only the attenuation values of bone
» lateral scanning of spine increases accuracy without superimposition of posterior elements + marginal osteophytes + vascular calcifications

Advantage:

(1) low radiation dose with higher radiation flux than radioisotope source of dual-photon absorptiometry
(2) uses sites where osteoporotic fractures occur
(3) low cost; ease of use; rapidity of measurement

Limitation of 2-dimensional (areal) technique:

(1) no distinction between cortical + trabecular bone
(2) no discrimination between changes secondary to bone geometry + increased bone density
(3) regulatory oversight for ionizing radiation

Site: (a) lumbar spine (L1–L4)
(b) proximal femur (total hip, femoral neck, trochanter, Ward area)
(c) calcaneus (95% trabecular bone)
(d) forearm (suboptimal ← mostly cortical bone)

Dose: < 3 mrem

Precision: 1–2%

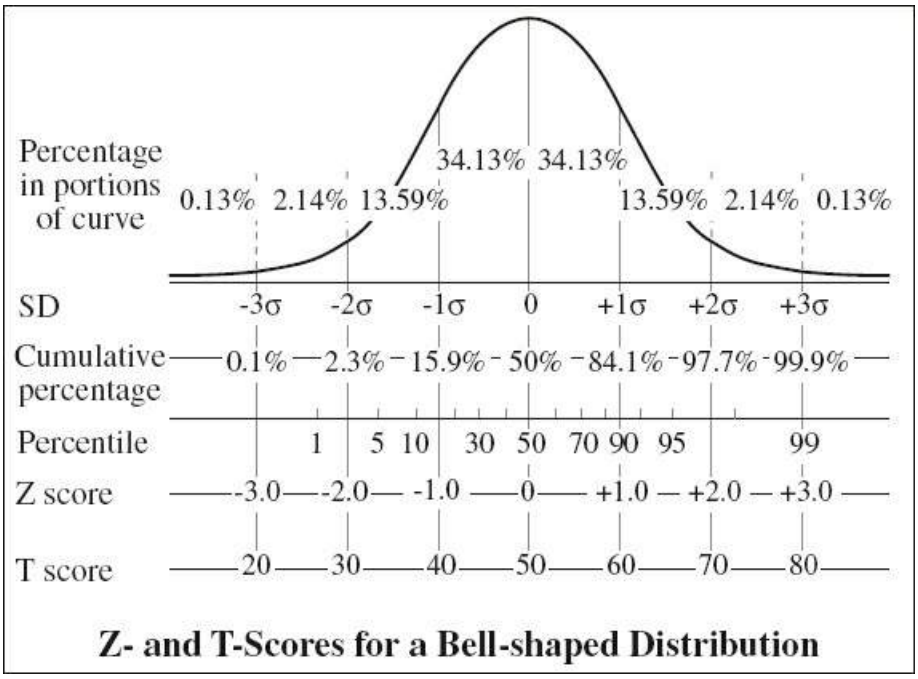
Data collected:

BMD (bone marrow density) value (g/cm^2)
T-score = how far is the score from the mean of 50 with a SD of 10 compared with young adults 20–30 years of age (= peak of bone mass)
Z-score = location of a score compared to age-matched + gender-matched controls in a distribution with a mean of 0 and a SD of 1.0; particularly important in patients aged > 75 years

Interpretation:

normal (≥ –1.0); osteopenia (< –1.0 but > –2.5); osteoporosis (≤ –2.5); severe osteoporosis (≤ –2.5 with a fragility fracture)

Pitfalls:



Z- and T-Scores for a Bell-shaped Distribution

› weekly phantom calibration to detect scanner drift
› improper patient positioning (decentering of lumbar spine, abduction / external rotation of hip)
› improper numbering of vertebrae, placement of intervertebral markers, detection of bone edges
› blurring / irregular contour of bone margins ← patient motion
› anatomic artifacts from
(a) superimposed disease: degenerative disk disease, compression fracture, postsurgical defect, overlying atherosclerotic calcifications
(b) implanted devices: stent + vena cava filter, GI barium, hardware, vertebroplasty cement
(c) external objects: piercing, bra clips, metallic buttons
◊ Results from different scanners not interchangeable ← differences in scanners and software programs

(5) **Quantitative Computed Tomography**
= determines true volumetric density (mg/cm^3) by providing separate estimates of trabecular + cortical bone BMD over 2–4 vertebrae (T12–L4)
• high-turnover cancellous bone is important for vertebral strength and has high responsiveness
• trabecular bone + low-turnover compact bone can be measured separately
Advantage:
› allows separate analysis of trabeculae + cortices
› selective assessment of metabolically active trabecular bone in center of vertebral body
› better sensitivity than projectional methods (DXA)
› exclusion of structures not contributing to spine mechanical resistance

Disadvantage:
› high radiation dose
› poor precision limited to longitudinal assessment
› high costs
› high degree of operator dependence
› need for considerable amount of space
› limited scanner access

Pitfalls affecting measurements:
myelofibrosis + hematopoietic disorders + fat

Technique:
» use of low-dose commercial CT scanner
» compared to external bone mineral reference phantom that is scanned simultaneously with patient to calibrate CT attenuation measurements
» 10-mm–thick section with gantry angle correction through center of vertebral body
» results expressed as absolute values / Z and T scores

Site: vertebrae L1–L3, other sites

Use: assessment of vertebral fracture risk; measurement of age-related bone loss; follow-up of osteoporosis + metabolic bone disease

(a) single energy: 300–500 mrem; 6–25% precision
(b) dual energy: 750–800 mrem; 5–10% precision

◊ Most sensitive technique!

(6) **Peripheral Quantitative CT**

= exact 3-dimensional localization of target volumes with multisection data acquisition capability covering a large volume of bone

Site: distal radius

(7) **Quantitative Heel Ultrasound**

= determines US stiffness index(SI) using formula

SI = 0.67 • BUA [dB/MHz] + 0.28 • SOS [m/s] – 420 SOS = speed of sound BUA = broadband ultrasound attenuation for 200–600 kHz

as a risk assessment independent from DEXA

◊ Fracture risk increases with decrease in SI

Precision: 2.2%

Disadvantage: lack of sensitivity, equipment drift

Location: axial skeleton (lower dorsal + lumbar spine), proximal humerus, neck of femur, wrist, ribs

Radiographs:

◊ Radiographs: insensitive prior to bone loss of 25–30%
◊ Bone scans do NOT show a diffuse increase in activity
√ increased radiolucency = decreased number + thickness of trabeculae = osteopenia ("poverty of bone"):
√ relatively prominent primary trabeculae ← initially selective loss of secondary trabeculae
√ juxtaarticular osteopenia with trabecular bone predominance (eg, distal radius + proximal femur):
√ accentuation of compressive + tensile trabeculae

√ sparsely trabeculated region in inferomedial femoral neck between converging primary and secondary compressive groups = **Ward triangle**

◊ Trabecular bone responds to metabolic changes faster than cortical bone

√ cortical thinning (endosteal + intracortical + periosteal resorption):

√ scalloping of inner cortical margin

√ widening of marrow canal

√ prominent longitudinal cortical striations = tunneling

√ irregular definition of outer bone surface

◊ Most specific finding of high bone turnover

√ delayed fracture healing with poor callus formation (DDx: abundant callus formation in osteogenesis imperfecta + Cushing syndrome)

Cx: fracture for 1÷2 women + 1÷4 men > age 50 years

(1) Fractures at sites rich in labile trabecular bone (eg, vertebrae, wrist) in postmenopausal osteoporosis

(2) Fractures at sites containing cortical + trabecular bone (eg, hip) in senile osteoporosis

Rx: calcitonin, sodium fluoride, diphosphonates, parathyroid hormone supplements, estrogen replacement

Osteoporosis of Spine

Clinical manifestation:

- vertebral compression fracture occurring
  (a) spontaneously
  (b) during lifting / bending / coughing
  (c) load simply caused by muscle contraction
- progressive loss of stature → shortening of paraspinal musculature requiring prolonged active contraction for maintenance of posture → pain from muscle fatigue

Location: thoracolumbar junction (T12, L1), midthoracic area (T7, T8)

√ diminished radiographic density

√ vertical striations = rarefaction of trabeculae ← marked thinning of secondary horizontal (transverse) trabeculae + relative accentuation of primary vertical trabeculae along lines of stress

√ accentuation of endplates

√ "picture framing" (= accentuation of cortical outline with preservation of external dimensions ← endosteal + intracortical resorption

√ <u>anterior wedge fracture</u> resulting in spinal deformity:

√ kyphosis ← multiple fractures in 20–30%

◊ The greater the degree of osteoporosis the greater the number of fractures!

√ "dowager's hump"

√ reduction in thoracic and abdominal space →

- impaired pulmonary function
- protuberant abdomen
- alteration in body shape

√ <u>endplate fracture</u> = compression deformity with reduction in mid height + protrusion of intervertebral disks:

√ biconcavity of vertebra
√ Schmorl nodes

√ crush fracture = reduction of overall height of a vertebra relative to adjacent vertebrae:
√ height loss > 4 mm (posterior height is normally 1–3 mm more than anterior height for thoracic vertebra)
√ decreased height of vertebrae → loss of body height
√ absence of osteophytes

MR:
√ heterogeneously hyperintense SI on T1WI:
√ focal fatty marrow usually has a round morphology
√ round lesions coalesce to involve entire vertebral body
√ variable T2 signal intensity

Osteoporosis of Appendicular Skeleton

@ Hand (on industrial hard-copy film)
√ corticomedullary index = evaluation of cortical thickness of 2nd metacarpal bone
Digital X-ray Radiogrammetry (DXR)
= digitized PA radiograph with automatic segmentation of cortex + medulla of midshafts of 2nd + 3rd + 4th metacarpal bones → average cortical thickness + average bone width in region of interest
Advantage: high reproducibility; capacity to predict future fracture; widely available; inexpensive; low radiation dose

@ Femur
√ Singh classification system = trabeculae in proximal femur disappear in predictable sequence

@ Calcaneus
√ Jhamaria index = lateral radiograph of calcaneus

Osteomalacia

= accumulation of excessive amounts of uncalcified osteoid with bone softening + insufficient mineralization of osteoid due to
(a) high remodeling rate: excessive osteoid formation + normal / little mineralization
(b) low remodeling rate: normal osteoid production + diminished mineralization

Etiology:
(1) dietary deficiency of vitamin D3 + lack of solar irradiation
(2) deficient metabolism of vitamin D:
› chronic renal tubular disease
› chronic administration of phenobarbital (alternate liver pathway)
› diphenylhydantoin (interferes with vitamin D action on bowel)
(3) decreased absorption of vitamin D:
› malabsorption syndromes (most common)
› partial gastrectomy (self-restriction of fatty foods)
(4) diminished deposition of calcium in bone
› diphosphonates (for treatment of Paget disease)

Histo: excess of osteoid seams + decreased appositional rate

- bone pain / tenderness; muscular weakness
- serum calcium slightly low / normal
- decreased serum phosphorus
- elevated serum alkaline phosphatase

√ uniform osteopenia
√ fuzzy indistinct trabecular detail of endosteal surface
√ coarsened frayed trabeculae decreased in number + size
√ thin cortices of long bone
√ bone deformity from softening:
  √ hourglass thorax
  √ bowing of long bones
  √ acetabular protrusion
  √ buckled / compressed pelvis
  √ biconcave vertebral bodies
√ increased incidence of insufficiency fractures
√ pseudofractures = Looser zones
√ mottled skull

Localized / Regional Osteopenia

1. Disuse osteoporosis / atrophy
   Etiology: local immobilization secondary to
   (a) fracture (more pronounced distal to fracture site)
   (b) neural paralysis
   (c) muscular paralysis
2. Reflex sympathetic dystrophy = Sudeck dystrophy
3. Regional migratory osteoporosis, transient regional osteoporosis of hip
4. Rheumatologic disorders
5. Infection: osteomyelitis, tuberculosis
6. Osteolytic tumor
7. Lytic phase of Paget disease
8. Early phase of bone infarct and hemorrhage
9. Burns + frostbite

Bone Marrow Edema

= hypointense on T1WI + hyperintense on T2WI relative to fatty marrow

1. Trauma
   (a) "bone bruise"
   (b) radiographically occult acute fracture
   (c) recent surgery
2. Infection = osteomyelitis
3. Aseptic arthritis
4. Osteonecrosis = early stage of AVN
5. Neuropathic osteoarthropathy
6. Reflex sympathetic dystrophy (some cases)
7. Transient osteoporosis of hip

8. Infiltrative neoplasm

Transverse Lucent Metaphyseal Lines

mnemonic: LINING

Leukemia
Illness, systemic (rickets, scurvy)
Normal variant
Infection, transplacental (congenital syphilis)
Neuroblastoma metastases
Growth lines

Frayed Metaphyses

mnemonic: CHARMS

Congenital infections (rubella, syphilis)
Hypophosphatasia
Achondroplasia
Rickets
Metaphyseal dysostosis
Scurvy

MYELOPROLIFERATIVE DISORDERS

= autonomous clonal disorder initiated by an acquired pluripotential hematopoietic stem cell

Types:

1. Polycythemia vera
2. Chronic granulomatous / myelogenous leukemia
3. Essential idiopathic thrombocytopenia
4. Agnogenic myeloid metaplasia (= primary myelofibrosis + extramedullary hematopoiesis in liver + spleen)

Pathophysiology:

› self-perpetuating intra- and extramedullary hematopoietic cell proliferation without stimulus
› trilinear panmyelosis (RBCs, WBCs, platelets)
› myelofibrosis with progression to myelosclerosis
› myeloid metaplasia = extramedullary hematopoiesis (normocytic anemia, leukoerythroblastic anemia, low platelet count, reticulocytosis, normal / reduced WBC count)

BONE TUMOR

Role of Radiologist

1. Is there a lesion?
2. Is it a bone tumor?
3. Is the tumor benign or malignant?
4. Is a biopsy necessary?
5. Is histologic diagnosis consistent with radiographic image?

Assessment of Bone Tumor

A systematic approach is imperative for assessment of a bone tumor with attention to size, number, and location of lesions; margins and zone of transition; periosteal reaction; matrix mineralization; soft-tissue component.

1. **Age** (and gender) of patient
2. Precise tumor **location**
   (a) transverse: medullary, cortical, juxtacortical
   (b) longitudinal: epi-, meta-, diaphyseal
3. Pattern of **bone destruction / aggressiveness**
   (a) nonaggressive
      √ well-defined sharp margins
      √ smooth solid-appearing periosteal reaction
   (b) aggressive infiltrative osseous process
      √ broad zone of transition
      √ poorly defined borders
      √ disrupted / "sunburst" appearance
      DDx: destructive metabolic / infectious process
4. Lesion **matrix**
   √ "rings-and-arcs" appearance = chondral origin
   √ opaque cloud-like matrix = osseous mineralization
   √ osteolytic lesion → FEGNOMASHIC
   √ CT for cortical continuity / disruption

Action Following Bone Tumor Assessment

A. BENIGN
   1. Diagnosis certain: no further work-up necessary
   2. Asymptomatic lesion with highly probable benign diagnosis may be followed clinically
   3. Symptomatic lesion with highly probable benign diagnosis may be treated without further work-up

B. CONFUSING LESION
   not clearly categorized as benign or malignant; needs staging work-up

C. MALIGNANT: needs staging work-up

Staging work-up:

Bone scan: identifies polyostotic lesions (eg, multiple myeloma, metastatic disease, primary osteosarcoma with bone-forming metastases, histiocytosis, Paget disease)

Chest CT: identifies metastatic deposits + changes further work-up and therapy

Local staging with MR imaging:
   (1) Margins: encapsulated / infiltrating
   (2) Compartment: intra- / extracompartmental
   (3) Intraosseous extent + skip lesions
   (4) Soft-tissue extent (DDx: hematoma, edema)
   (5) Joint involvement

(6) Neurovascular involvement

Local assessment with CT imaging:

√ matrix / rim calcifications

VESSEL AND NERVE INVOLVEMENT

√ tumor encasement of neurovascular bundle by

– 180–360° = indicates infiltration by tumor

– 90–180° = indeterminate for infiltration by tumor

– 0–90° = infiltration by tumor unlikely

Tumorlike Conditions

1. Solitary bone cyst
2. Juxtaarticular ("synovial") cyst
3. Aneurysmal bone cyst
4. Nonossifying fibroma; cortical defect; cortical desmoid
5. Eosinophilic granuloma
6. Reparative giant cell granuloma
7. Fibrous dysplasia (monostotic; polyostotic)
8. Myositis ossificans
9. "Brown tumor" of hyperparathyroidism
10. Massive osteolysis

Pseudomalignant Appearance

1. Osteomyelitis
2. Aggressive osteoporosis

Pattern of Bone Tumor Destruction / Aggressiveness

A. GEOGRAPHIC BONE DESTRUCTION

Cause: (a) slow-growing usually benign tumor

(b) rarely malignant: plasma cell myeloma, metastasis

(c) infection: granulomatous osteomyelitis

√ well-defined smooth / irregular margin

√ narrow zone of transition

B. MOTH-EATEN BONE DESTRUCTION

Cause: (a) rapidly growing malignant bone tumor

(b) osteomyelitis

√ less well-defined / demarcated lesional margin

√ broad zone of transition

mnemonic: H LEMMON

Histiocytosis X

Lymphoma

Ewing sarcoma

Metastasis

Multiple myeloma

Osteomyelitis

Neuroblastoma

C. PERMEATIVE BONE DESTRUCTION
Cause: aggressive bone tumor with rapid growth potential (eg, Ewing sarcoma)
√ poorly demarcated lesion imperceptibly merging with uninvolved bone
√ broad zone of transition

Size, Shape, and Margin of Bone Tumors

◊ Primary malignant tumors are larger than benign tumors
√ elongated lesion (= greatest diameter of > 1.5 times the least diameter): Ewing sarcoma, histiocytic lymphoma, chondrosarcoma, angiosarcoma
√ sclerotic margin (= reaction of host tissue to tumor)

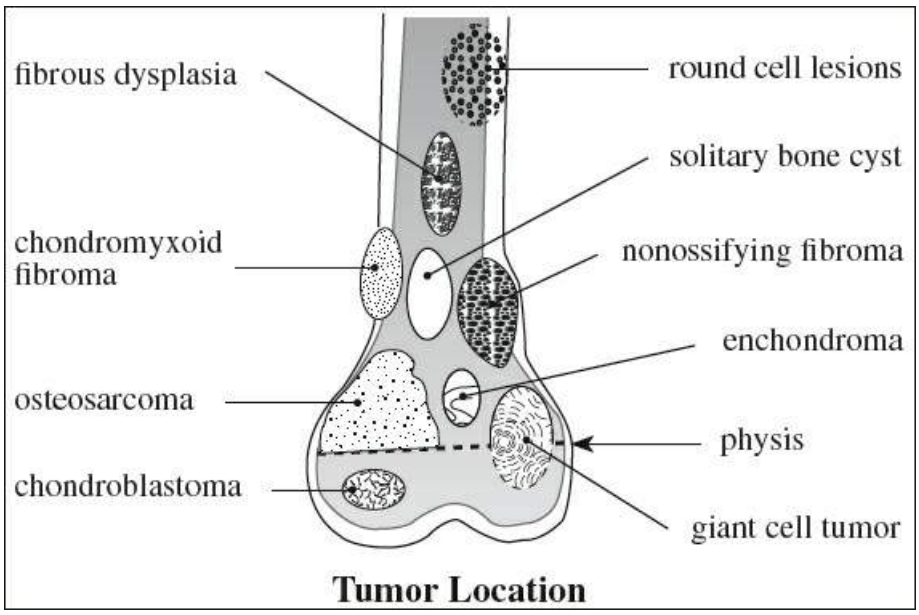
Tumor Position in Transverse Plane

A. CENTRAL MEDULLARY LESION
1. Enchondroma
2. Solitary bone cyst

B. ECCENTRIC MEDULLARY LESION
1. Giant cell tumor
2. Osteogenic sarcoma, chondrosarcoma, fibrosarcoma
3. Chondromyxoid fibroma

C. CORTICAL LESION
1. Nonossifying fibroma
2. Osteoid osteoma

D. PERIOSTEAL / JUXTACORTICAL LESION
1. Juxtacortical chondroma / osteosarcoma
2. Osteochondroma
3. Parosteal osteogenic sarcoma



Tumor Location

Tumor Position in Longitudinal Plane

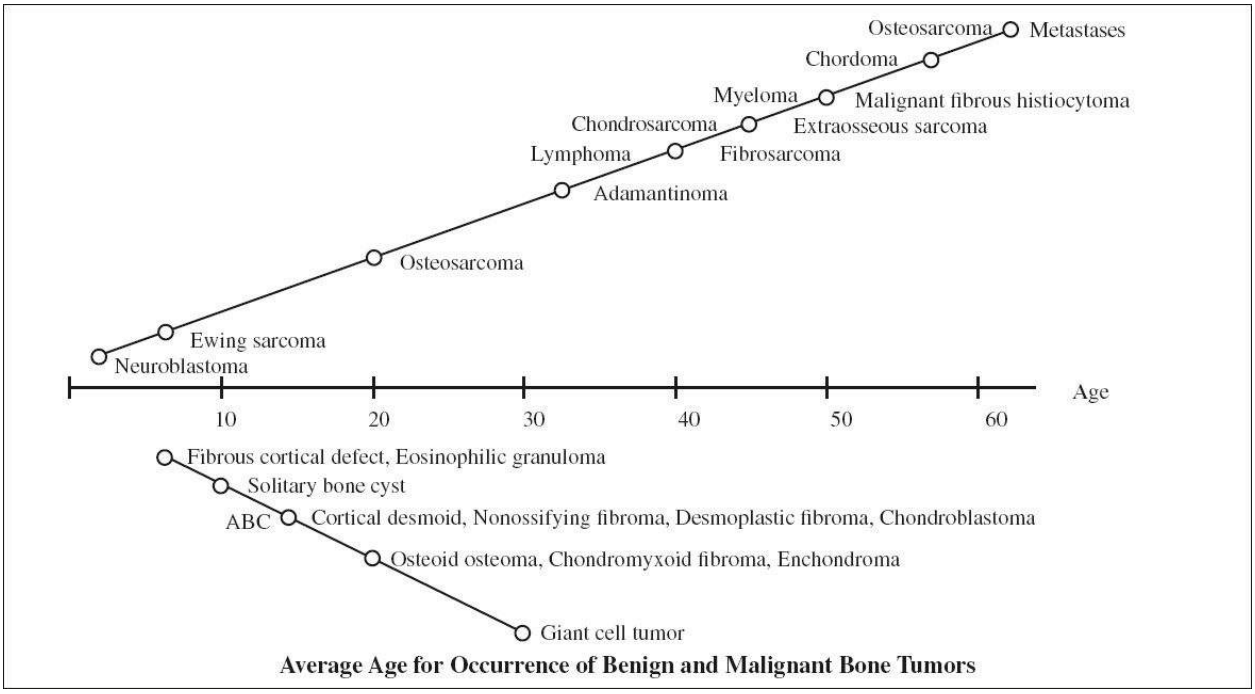
A. EPIPHYSEAL LESION
   1. Chondroblastoma (prior to closure of growth plate)
   2. Intraosseous ganglion, subchondral cyst
   3. Giant cell tumor (originating in metaphysis)
   4. Clear cell chondrosarcoma
   5. Fibrous dysplasia
   6. Abscess

   mnemonic: CAGGIE
      Chondroblastoma
      Aneurysmal bone cyst
      Giant cell tumor
      Geode
      Infection
      Eosinophilic granuloma
         [after 40 years of age throw out "CEA" and insert metastases / myeloma]

B. METAPHYSEAL LESION
   1. Nonossifying fibroma (close to growth plate)
   2. Chondromyxoid fibroma (abutting growth plate)
   3. Solitary bone cyst
   4. Osteochondroma
   5. Brodie abscess
   6. Osteogenic sarcoma, chondrosarcoma

C. DIAPHYSEAL LESION
   1. Round cell tumor (eg, Ewing sarcoma)
   2. Nonossifying fibroma
   3. Solitary bone cyst
   4. Aneurysmal bone cyst
   5. Enchondroma
   6. Osteoblastoma
   7. Fibrous dysplasia

   mnemonic: FEMALE
      Fibrous dysplasia
      Eosinophilic granuloma
      Metastasis
      Adamantinoma



Average Age for Occurrence of Benign and Malignant Bone Tumors

Leukemia, **L**ymphoma
Ewing sarcoma

Tumors Localizing to Hematopoietic Marrow

1. Metastases
2. Plasma cell myeloma
3. Ewing sarcoma
4. Histiocytic lymphoma

Diffuse Bone Marrow Abnormalities in Childhood

A. REPLACED BY TUMOR CELLS
   (a) metastatic disease
      1. Neuroblastoma (in young child)
      2. Lymphoma (in older child)
      3. Rhabdomyosarcoma (in older child)
   (b) primary neoplasm
      1. Leukemia

B. REPLACED BY RED CELLS
   = red cell hyperplasia = reconversion
   (a) severe anemia: sickle cell disease, thalassemia, hereditary spherocytosis
   (b) chronic severe blood loss
   (c) marrow replacement by neoplasia
   (d) treatment with granulocyte-macrophage colony stimulating factor

C. REPLACED BY FAT
   1. Myeloid depletion = aplastic anemia

D. REPLACED BY FIBROUS TISSUE

1. Myelofibrosis

Incidence of Bone Tumors

◊ 80% of bone tumors are correctly determined on the basis of age alone!

Most Frequent Benign Bone Tumor

1. Osteochondroma 20–30%
2. Enchondroma 10–20%
3. Simple bone cyst 10–20%
4. Osteoid osteoma
5. Nonossifying fibroma
6. Aneurysmal bone cyst 5%
7. Fibrous dysplasia
8. Giant cell tumor

Most Frequent Malignant Bone Tumor

A. Bone malignancy
   1. Metastasis
B. Primary bone malignancy
   1. Multiple myeloma
   2. Osteosarcoma
   3. Chondrosarcoma
   4. Ewing sarcoma
C. Primary bone malignancy in children & adolescents
   1. Osteosarcoma
   2. Ewing sarcoma

Sarcomas by Age

mnemonic: **E**very **O**ther **R**unner **F**eels **C**rampy **P**ain **O**n **M**oving

Ewing sarcoma	0–10 years
Osteogenic sarcoma	10–30 years
Reticulum cell sarcoma	20–40 years
Fibrosarcoma	20–40 years
Chondrosarcoma	40–50 years
Parosteal sarcoma	40–50 years
Osteosarcoma	60–70 years
Metastases	60–70 years

EWING SARCOMA FAMILY

1. Ewing sarcoma of bone
2. Extraskeletal Ewing sarcoma
3. Primitive neuroectodermal tumor
4. Askin tumor

Malignancy with Soft-tissue Involvement

mnemonic: **M**y **M**other **E**ats **C**hocolate **F**udge **O**ften
Metastasis
Myeloma
Ewing sarcoma
Chondrosarcoma
Fibrosarcoma
Osteosarcoma

Tumor Matrix of Bone Tumors

Cartilage-forming Bone Tumors

√ centrally located ringlike / flocculent / flecklike radiodensity

A. BENIGN
   1. Enchondroma
   2. Parosteal chondroma
   3. Chondroblastoma
   4. Chondromyxoid fibroma
   5. Osteochondroma

B. MALIGNANT
   1. Chondrosarcoma
   2. Chondroblastic osteosarcoma

Bone-forming Tumors

√ inhomogeneous / homogeneous radiodense collections of variable size + extent

A. BENIGN
   1. Osteoma
   2. Osteoid osteoma
   3. Osteoblastoma
   4. Ossifying fibroma

B. MALIGNANT
   1. Osteogenic sarcoma

Fibrous Connective Tissue Tumors

A. BENIGN FIBROUS BONE LESIONS
   (a) cortical
      1. Benign cortical defect
      2. Avulsion cortical irregularity
   (b) medullary
      1. Herniation pit
      2. Nonossifying fibroma
      3. Ossifying fibroma
      4. Congenital generalized fibromatosis
   (c) corticomedullary
      1. Nonossifying fibroma
      2. Ossifying fibroma
      3. Fibrous dysplasia

4. Cherubism
5. Desmoplastic fibroma
6. Fibromyxoma
7. Benign fibrous histiocytoma

B. MALIGNANT
1. Fibrosarcoma

Tumors of Histiocytic Origin

A. LOCALLY AGGRESSIVE
1. Giant cell tumor
2. Benign fibrous histiocytoma

B. MALIGNANT
1. Malignant fibrous histiocytoma

Tumors of Fatty Tissue Origin

A. BENIGN
1. Intraosseous lipoma
2. Parosteal lipoma

B. MALIGNANT
1. Intraosseous liposarcoma

◊ Lipomas follow the SI of subcutaneous fat in all sequences!

Tumors of Vascular Origin

< 1% of all bone tumors

A. BENIGN
1. Hemangioma
2. Glomus tumor
3. Lymphangioma
4. Cystic angiomatosis
5. Hemangiopericytoma

B. MALIGNANT
1. Malignant hemangiopericytoma
2. Angiosarcoma = hemangioendothelioma

Metastatic sites: lung, brain, lymph nodes, other bones

Tumors of Neural Origin

A. BENIGN
1. Solitary neurofibroma
2. Neurilemmoma

B. MALIGNANT
1. Neurogenic sarcoma = malignant schwannoma

Bone Tumors with Fluid-Fluid Levels

1. Aneurysmal bone cyst
2. Telangiectatic osteosarcoma
3. Giant cell tumor

4. Chondroblastoma
5. Fibrous dysplasia

Round Cell Tumor

Location: arises in midshaft
√ osteolytic lesion
√ reactive new bone formation
√ NO tumor new bone
mnemonic: LEMON
Leukemia, **L**ymphoma
Ewing sarcoma, **E**osinophilic granuloma
Multiple myeloma
Osteomyelitis
Neuroblastoma

INTRAOSSEOUS LESION

Bubbly Bone Lesion

mnemonic: FOGMACHINES
Fibrous dysplasia, **F**ibrous cortical defect
Osteoblastoma
Giant cell tumor
Myeloma (plasmacytoma), **M**etastases from kidney, thyroid, breast
Aneurysmal bone cyst / **A**ngioma
Chondromyxoid fibroma, **C**hondroblastoma
Hyperparathyroid brown tumor, **H**emangioma, **H**emophilia, **H**istiocytosis X
Infection (Brodie abscess, Echinococcus, coccidioidomycosis)
Nonossifying fibroma
Eosinophilic granuloma, **E**nchondroma, **E**pithelial inclusion cyst
Solitary bone cyst
mnemonic: FEGNOMASHIC
Fibrous dysplasia
Enchondroma / **E**osinophilic granuloma
Giant cell tumor
Nonossifying fibroma
Osteoblastoma
Metastasis, **M**yeloma
Aneurysmal bone cyst
Simple bone cyst
Hyperparathyroidism
Infection
Chondroblastoma, **C**hondromyxoid fibroma

Infectious Bubbly Lesion

1. Brodie abscess (Staph. aureus)

2. Coccidioidomycosis
3. Echinococcus
4. Atypical mycobacterium
5. Cystic tuberculosis

Blowout Lesion

A. METASTASES
   Carcinoma of thyroid, kidney, breast
B. PRIMARY BONE TUMOR
   1. Fibrosarcoma
   2. Multiple myeloma (sometimes)
   3. Aneurysmal bone cyst
   4. Hemophilic pseudotumor

Nonexpansile Well-demarcated Bone Defect

Unilocular Well-demarcated Bone Defect

1. Fibrous cortical defect
2. Nonossifying fibroma
3. Simple unicameral bone cyst
4. Giant cell tumor
5. Brown tumor of HPT
6. Eosinophilic granuloma
7. Enchondroma
8. Epidermoid inclusion cyst
9. Posttraumatic / degenerative cyst
10. Pseudotumor of hemophilia
11. Intraosseous ganglion
12. Histiocytoma
13. Arthritic lesion
14. Endosteal pigmented villonodular synovitis
15. Fibrous dysplasia
16. Infectious lesion

Multilocular Well-demarcated Bone Defect

1. Aneurysmal bone cyst
2. Giant cell tumor
3. Fibrous dysplasia
4. Simple bone cyst

Expansile Unilocular Well-demarcated Osteolysis

1. Simple unicameral bone cyst
2. Enchondroma
3. Aneurysmal bone cyst
4. Juxtacortical chondroma
5. Nonossifying fibroma

6. Eosinophilic granuloma
7. Brown tumor of HPT

Poorly Demarcated Osteolytic Lesion

Osteolytic Lesion <u>without</u> Periosteal Reaction

A. NONEXPANSILE
   1. Metastases from any primary neoplasm
   2. Multiple myeloma
   3. Hemangioma

B. EXPANSILE
   1. Chondrosarcoma
   2. Giant cell tumor
   3. Metastasis from kidney / thyroid

Osteolytic Lesion <u>with</u> Periosteal Reaction

1. Osteomyelitis
2. Ewing sarcoma
3. Osteosarcoma

Mixed Sclerotic and Lytic Lesion

Mixed Bone Lesion <u>without</u> Sequestrum

1. Osteomyelitis
2. Tuberculosis
3. Ewing sarcoma
4. Metastasis
5. Osteosarcoma

Mixed Bone Lesion <u>with</u> Button Sequestrum

√ bone opacity surrounded by a well-defined lucent area

common:

1. Osteomyelitis
2. Eosinophilic granuloma
3. Fibrosarcoma, desmoplastic fibroma, MFH
4. Lymphoma

uncommon:

partially calcified intraosseous lipoma, tuberculous osteitis, radiation necrosis, metastatic carcinoma, fibrous dysplasia, dermoid & epidermoid cyst, hemangioma, meningioma

Trabeculated Bone Lesion

1. Giant cell tumor: delicate thin trabeculae
2. Chondromyxoid fibroma: coarse thick trabeculae
3. Nonossifying fibroma: lobulated
4. Aneurysmal bone cyst: delicate, horizontally oriented trabeculae

5. Hemangioma: striated radiating trabeculae

Lytic Bone Lesion Surrounded by Marked Sclerosis

mnemonic: BOOST

Brodie abscess
Osteoblastoma
Osteoid osteoma
Stress fracture
Tuberculosis

Multiple Lytic Lesions

mnemonic: FEEMHI

Fibrous dysplasia
Enchondromas
Eosinophilic granuloma
Metastases, **M**ultiple myeloma
Hyperparathyroidism (brown tumors), **H**emangiomas
Infection

Multiple Lytic Lesions in Child

1. Histiocytosis X
2. Metastatic neuroblastoma / leukemia
3. Fibrous dysplasia
4. Enchondromatosis
5. Rare: cystic angiomatosis, multifocal osteomyelitis

Lytic Bone Lesion in Patient < 30 Years of Age

mnemonic: CAINES

Chondroblastoma
Aneurysmal bone cyst
Infection
Nonossifying fibroma
Eosinophilic granuloma
Solitary bone cyst

Lytic Bone Lesion on Both Sides of Joint

mnemonic: SAC

Synovioma
Angioma
Chondroid lesion

Multiple Bone Lesions with Soft-tissue Tumor

1. Neurofibromatosis & fibroxanthomas
2. Maffucci syndrome = enchondromatosis & hemangioma
3. Mazabraud syndrome = fibrous dysplasia & myxoma
4. Metastases

(a) Multiple myeloma
(b) Malignant melanoma
(c) Lymphoma

Osteoblastic Bone Lesion

A. BENIGN
   1. Bone island
   2. Osteoma
   3. Osteoid osteoma

B. MALIGNANT
   1. Osteosarcoma
   2. Parosteal sarcoma

Widespread Osteosclerotic Lesions

1. Metastases: prostate, breast, lung, bladder, pancreas, stomach, colon, carcinoid, brain
2. Paget disease
3. Sarcoma
4. Myelofibrosis
5. Mastocytosis

BONE OVERGROWTH

Bone Overdevelopment

1. Marfan syndrome
2. Klippel-Trénaunay syndrome
3. Nerve territory-oriented macrodactyly
   (a) Macrodystrophia lipomatosa
   (b) Fibrolipomatous hamartoma with macrodactyly

Erlenmeyer Flask Deformity

= expansion of distal end of long bones, usually femur

1. Gaucher disease, Niemann-Pick disease
2. Hemolytic anemia: thalassemia, sickle cell
3. Osteopetrosis
4. Heavy metal poisoning
5. Metaphyseal dysplasia = Pyle disease
6. Rickets
7. Fibrous dysplasia
8. Down syndrome
9. Achondroplasia
10. Rheumatoid arthritis
11. Hypophosphatasia
12. Leukemia

mnemonic: TOP DOG
Thalassemia

Osteopetrosis
Pyle disease
Diaphyseal aclasis
Ollier disease
Gaucher disease

PERIOSTEAL REACTION / PERIOSTITIS

1. Trauma, hemophilia
2. Infection
3. Inflammatory: arthritis
4. Neoplasm
5. Congenital: physiologic in newborn
6. Metabolic: hypertrophic osteoarthropathy, thyroid acropachy, hypervitaminosis A
7. Vascular: venous stasis

Solid Periosteal Reaction

= reaction to periosteal irritant
√ even + uniform thickness > 1 mm
√ persistent + unchanged for weeks
Patterns:
(a) thin: eosinophilic granuloma; osteoid osteoma
(b) dense undulating: vascular disease
(c) thin undulating: pulmonary osteoarthropathy
(d) dense elliptical: osteoid osteoma; long-standing malignant disease (with destruction)
(e) cloaking: storage disease; chronic infection

Interrupted Periosteal Reaction

= pleomorphic, rapidly progressing process undergoing constant change
(a) buttressing = periosteal bone formation merges with underlying cortex: eosinophilic granuloma
(b) laminated = "onion skin": acute osteomyelitis; malignant tumor (osteosarcoma, Ewing sarcoma)
(c) radiating spicules = "sunburst": osteosarcoma; Ewing sarcoma; chondrosarcoma; fibrosarcoma; leukemia; metastasis; acute osteomyelitis
(d) perpendicular spicules = "hair-on-end": Ewing sarcoma
(e) amorphous: malignancy (deposits may represent extension of tumor / periosteal response); osteosarcoma
(f) Codman triangle: hemorrhage; malignancy (osteosarcoma, Ewing sarcoma); acute osteomyelitis; fracture
[Ernest Armory Codman (1869–1940), orthopedic surgeon at Massachusetts General Hospital, Harvard Medical School]

Symmetric Periosteal Reaction in Adulthood

1. Venous stasis (lower extremity)
2. Hypertrophic osteoarthropathy
3. Pachydermoperiostosis
4. Thyroid acropachy
5. Fluorosis
6. Rheumatoid arthritis
7. Psoriatic arthritis
8. Reiter syndrome
9. Idiopathic-degenerative

Periosteal Reaction in Childhood

(a) benign

1. Physiologic (up to 35%): symmetric involvement of diaphyses during first 1–6 months of life
2. Nonaccidental trauma = battered child syndrome
3. Infantile cortical hyperostosis: < 6 months of age
4. Hypervitaminosis A
5. Scurvy
6. Osteogenesis imperfecta
7. Congenital syphilis

(b) malignant

1. Multicentric osteosarcoma
2. Metastases from neuroblastoma + retinoblastoma
3. Acute leukemia

mnemonic: PERIOSTEAL SOCKS

Physiologic, Prostaglandin
Eosinophilic granuloma
Rickets
Infantile cortical hyperostosis
Osteomyelitis
Scurvy
Trauma
Ewing sarcoma
A-hypervitaminosis
Leukemia + neuroblastoma
Syphilis
Osteosarcoma
Child abuse
Kinky hair syndrome
Sickle cell disease

Periosteal Reaction in Infant

› before 6 months of age

1. Infantile cortical hyperostosis

2. Physiologic
3. Extracorporeal membrane oxygenation

› after 6 months of age

1. Hypervitaminosis A
2. Scurvy
3. Rickets

› anytime during infancy

1. Nonaccidental trauma
2. Syphilis
3. Metastatic neuroblastoma / leukemia
4. Prostaglandin therapy: within 40 days
5. Sickle cell dactylitis

DDx: motion artifact

Enthesopathy

[*en*, Greek = in; *thesis*, Greek = position]

Enthesis = osseous attachment of tendon composed of 4 zones, ie, tendon itself + unmineralized fibrocartilage + mineralized fibrocartilage + bone

Cause:

1. Degenerative disorder
2. Seronegative arthropathies: ankylosing spondylitis, Reiter disease, psoriatic arthritis
3. Diffuse idiopathic skeletal hyperostosis
4. Acromegaly
5. Rheumatoid arthritis (occasionally)

Location: at site of tendon + ligament attachment

√ bone proliferation (enthesophyte)
√ calcification of tendon + ligament
√ erosion

BONE TRAUMA

Childhood Fractures

1. Greenstick fracture
2. Bowing fracture
3. Traumatic epiphyseolysis
4. Battered child syndrome
5. Epiphyseal plate injury

Pseudarthrosis in Long Bones

1. Nonunion of fracture
2. Fibrous dysplasia
3. Neurofibromatosis
4. Osteogenesis imperfecta
5. Congenital: clavicular pseudarthrosis

Exuberant Callus Formation

1. Steroid therapy / Cushing syndrome
2. Neuropathic arthropathy
3. Osteogenesis imperfecta
4. Congenital insensitivity to pain
5. Paralysis
6. Renal osteodystrophy
7. Multiple myeloma
8. Battered child syndrome

EPIPHYSIS

Premature Epiphyseal Ossification

@ Proximal femoral and humeral epiphyses
   1. Jeune asphyxiating thoracic dysplasia
   2. Ellis-van Creveld chondroectodermal dysplasia

Epiphyseal / Apophyseal Lesion

1. Chondroblastoma
2. Brodie abscess
3. Fungal / tuberculous infection
4. Langerhans cell histiocytosis
5. Osteoid osteoma
6. Chondromyxoid fibroma
7. Enchondroma
8. Bone cyst
9. Foreign-body granuloma

mnemonic: ICEBAGS

Infection
Chondroblastoma (age <40)
Eosinophilic granuloma
Brown tumor
Aneurysmal bone cyst
Giant cell tumor
Subchondral cyst

Subarticular Lesion

(a) T2 hypo- to isointense matrix
   1. Giant cell tumor

(b) T2 hyperintense matrix
   2. Solitary subchondral cyst
   3. Intraosseous ganglion
   4. Brodie abscess
   5. Clear cell chondrosarcoma

Stippled Epiphyses

1. Normal variant
2. Avascular necrosis
3. Hypothyroidism
4. Chondrodysplasia punctata
5. Multiple epiphyseal dysplasia
6. Spondyloepiphyseal dysplasia
7. Hypoparathyroidism
8. Down syndrome
9. Trisomy 18
10. Fetal exposure to warfarin / hydantoin
11. Homocystinuria (distal radial + ulnar epiphyses = PATHOGNOMONIC)
12. Zellweger cerebrohepatorenal syndrome

Physeal / Metaphyseal Widening & Irregularity

1. Rickets
2. Hypophosphatasia
3. Metaphyseal chondroplasia

Epiphyseal Overgrowth

1. Juvenile rheumatoid arthritis
2. Hemophilia
3. Healed Legg-Perthes disease
4. Tuberculous arthritis
5. Pyogenic arthritis (chronic)
6. Fungal arthritis
7. Epiphyseal dysplasia hemimelica
8. Fibrous dysplasia of epiphysis
9. Winchester syndrome

Epiphyseolysis

= SLIPPED EPIPHYSIS (zone of maturing hypertrophic cartilage affected, NOT zone of proliferation)

1. **Idiopathic / juvenile epiphyseolysis**
   Age: 12–15 years (? puberty-related hormonal dysregulation)
   • adiposogenital type; tall stature
2. Renal osteodystrophy
3. Hyperparathyroidism in chronic renal disease
4. Hypothyroidism
5. Radiotherapy

JOINTS

Approach to Arthritis

mnemonic: ABCDE'S

Alignment
Bone mineralization
Cartilage loss
Distribution
Erosion
Soft tissues

Signs of Arthritis

Prevalence of arthritis: 15% of population in USA

Conventional x-ray:

√ narrowing of radiologic joint space:
  (a) uniform = inflammatory arthritis
  (b) nonuniform = degenerative arthritis

√ evidence of disease on both sides of joint:
  √ osteopenia
  √ subchondral sclerosis
  √ erosion
  √ subchondral cyst formation
  √ malalignment

√ joint effusion

√ joint bodies

NUC:

√ increase in regional blood flow (active disease)

√ distribution of disease

MR:

√ bone marrow edema = predictor of erosions

√ Gd-DTPA enhancement of synovium (active disease)

√ radiographically occult extraarticular inflammation = tenosynovitis + enthesitis

√ irregularity + narrowing of articular cartilage

Classification of Arthritides

A. SEPTIC ARTHRITIS
   1. Tuberculous
   2. Pyogenic
   3. Lyme arthritis
   4. Fungal arthritis: Candida, Coccidioides immitis, Blastomyces dermatitidis, Histoplasma capsulatum, Sporothrix schenckii, Cryptococcus neoformans, Aspergillus fumigatus

   N.B.: Tuberculous + fungal arthritis show *Phemister triad* (1) prominent osteoporosis, (2) slower rate of destruction, and (3) less joint narrowing than a pyogenic infection

B. COLLAGEN / COLLAGEN-LIKE DISEASE
   1. Rheumatoid arthritis
   2. Ankylosing spondylitis
   3. Psoriatic arthritis

4. Rheumatic fever
5. Sarcoidosis

C. BIOCHEMICAL ARTHRITIS
1. Gout
2. Chondrocalcinosis
3. Ochronosis
4. Hemophilic arthritis

D. DEGENERATIVE JOINT DISEASE = Osteoarthritis

E. TRAUMATIC
1. Secondary osteoarthritis
2. Neurotrophic arthritis
3. Pigmented villonodular synovitis

F. ENTEROPATHIC ARTHROPATHY
(a) INFLAMMATORY BOWEL DISEASE
1. Ulcerative colitis (in 10–20%)
2. Crohn disease (in 5%): peripheral arthritis increases with colonic disease
3. Whipple disease (in 60–90% transient intermittent polyarthritis: sacroiliitis, spondylitis)

◊ Resection of diseased bowel is associated with regression of arthritic symptomatology!

(b) INFECTIOUS BOWEL DISEASE
Infectious agents: Salmonella, Shigella, Yersinia

(c) after intestinal bypass surgery

Spondyloarthritis with Positive HLA-B 27 Histocompatibility Complex

1.	Ankylosing spondylitis	95%
2.	Reiter disease	80%
3.	Arthropathy of inflammatory bowel disease	75%
4.	Psoriatic spondylitis	70%
5.	Normal population	10%

Monoarthritis

Destructive Monoarthritis

◊ Any destructive monoarthritis should be regarded as infection until proved otherwise!

A. SEPTIC ARTHRITIS

B. Monoarticular presentation of a systemic arthritis
1. Rheumatoid arthritis
2. Gout
3. Amyloidosis
4. Seronegative arthritis

C. Joint tumor
1. PVNS
2. Synovial chondromatosis
3. Articular hemangioma

Nonseptic Monoarthritis

1. Gout
2. Milwaukee shoulder
3. Rapidly destructive articular disease
4. Amyloid arthropathy
5. Hemophilic arthropathy
6. Primary synovial osteochondromatosis
7. Pigmented villonodular synovitis
8. Neuropathic arthropathy
9. Foreign-body synovitis

Arthritis without Demineralization

1. Gout
2. Neuropathic arthropathy
3. Psoriasis
4. Reiter disease
5. Pigmented villonodular synovitis

mnemonic: PONGS

Psoriatic arthritis
Osteoarthritis
Neuropathic joint
Gout
Sarcoidosis

Arthritis with Demineralization

mnemonic: HORSE

Hemophilia
Osteomyelitis
Rheumatoid arthritis, Reiter disease
Scleroderma
Erythematosus, systemic lupus

Deforming Nonerosive Arthropathy

1. Collagen-vascular disease, especially SLE
2. Rheumatoid arthritis (rare)
3. Rheumatic fever (Jaccoud arthritis) (rare)

Arthritis with Periostitis

1. Juvenile rheumatoid arthritis
2. Psoriatic arthritis
3. Reiter syndrome
4. Infectious arthritis

Premature Osteoarthritis

mnemonic: COME CHAT

Calcium pyrophosphate dihydrate arthropathy
Ochronosis
Marfan syndrome
Epiphyseal dysplasia
Charcot joint = neuroarthropathy
Hemophilic arthropathy
Acromegaly
Trauma

Synovial Disease with Decreased Signal Intensity

= blooming" artifact of low SI on gradient-echo pulse sequences ← magnetic susceptibility artifact of hemosiderin

1. Pigmented villonodular synovitis
2. Rheumatoid arthritis
3. Hemophiliac arthropathy
4. Synovial hemangioma

Chondrocalcinosis

mnemonic: WHIP A DOG
Wilson disease
Hemochromatosis, **H**emophilia, **H**ypothyroidism, 1° **H**yperparathyroidism (15%), **H**ypophosphatasia, Familial **H**ypomagnesemia
Idiopathic (aging)
Pseudogout (CPPD)
Arthritis (rheumatoid, postinfectious, traumatic, degenerative), **A**myloidosis, **A**cromegaly
Diabetes mellitus
Ochronosis
Gout

mnemonic: 3 C's

Crystals	CPPD, sodium urate (gout)
Cations	calcium (any cause of hypercalcemia), copper, iron
Cartilage degeneration	osteoarthritis, acromegaly, ochronosis

Subchondral Cyst

= SYNOVIAL CYST = SUBARTICULAR PSEUDOCYST
= NECROTIC PSEUDOCYST = GEODES

Etiology: bone necrosis allows pressure-induced intrusion of synovial fluid into subchondral bone; in conditions with synovial inflammation

Cause by mnemonic: COORS
CPPD
Osteoarthritis
Osteonecrosis
Rheumatoid arthritis
Synovial tumor

√ size of cyst usually 2–35 mm
√ may be large + expansile (especially in CPPD)
DDx: (1) Giant cell tumor
(2) Pigmented villonodular synovitis
(3) Metastasis
(4) Intraosseous ganglion
(5) Brown tumor of hemophilia

Periarticular Calcified Mass

1. Calcinosis of chronic renal failure = uremic tumoral acalcinosis = secondary tumoral calcinosis = tumoral calcification
2. Tumoral calcinosis

Periarticular Cyst

= cyst located in the vicinity of a synovial joint

1. Ganglion
   = mucin-containing cyst arising from tendon sheath / joint capsule / bursa / subchondral bone lined by flat spindle-shaped cells
2. Synovial cyst
   = cyst continuous with joint capsule lined by synovial cells (term is used by some synonymously with ganglion)
3. Meniscal cyst
   = associated with meniscal tear, in > 90% of a tear with horizontal component
4. Bursa
   = synovial lining, forms in area of friction, may communicate with joint

Loose Intraarticular Bodies

1. Osteochondrosis dissecans
2. Synovial osteochondromatosis
3. Chip fracture from trauma
4. Severe degenerative joint disease
5. Neuropathic arthropathy

Rice Bodies

= subset of loose bodies as a nonspecific response to chronic synovial inflammation resembling polished rice

1. Rheumatoid arthritis
2. Juvenile rheumatoid arthritis
3. Tuberculous arthritis

Pathogenesis:
(1) microinfarction of synovium / detachment of hypertrophied synovium → sloughed synovium falls into joint space → coated with fibrinogen
(2) precipitate of fibrin + fibronectin / core of mononuclear cells, blood cells and amorphous material

MRI:

√ well-defined nodules of intermediate SI on T1WI + relatively low intensity on T2WI

DDx:

(1) Synovial osteochondromatosis (monoarticular, large joint, hyperintense cartilage components on T2WI)

(2) Pigmented villonodular synovitis (monoarticular, large joint, hemosiderin deposition)

Intraarticular Mass

A. PROLIFERATIVE SYNOVIAL PROCESS
   1. Lipoma arborescens
   2. Synovial osteochondromatosis
   3. Pigmented villonodular synovitis
   4. Rheumatoid arthritis

B. INFECTIOUS GRANULOMATOUS DISEASE
   1. Tuberculous arthritis
   2. Coccidioidomycosis arthritis

C. DEPOSITION DISEASE
   1. Gout
   2. Amyloid arthropathy

D. VASCULAR MALFORMATION
   1. Synovial hemangioma
   2. Arteriovenous malformation

E. MALIGNANCY
   1. Synovial chondrosarcoma
   2. Synovial sarcoma
   2. Synovial metastasis: primary lung cancer

F. Peculiar joint anatomy
   1. Cyclops lesion

Intraarticular Process with Cortical Erosion

1. Pigmented villonodular synovitis
2. Synovial osteochondromatosis
3. Rheumatoid arthritis
4. Gout
5. Synovial hemangioma
6. Lipoma arborescens

Erosions of DIP Joints

1. Inflammatory osteoarthritis
2. Psoriatic arthritis
3. Gout
4. Multicentric reticulohistiocytosis
5. Hyperparathyroidism
6. Frostbite
7. Septic arthritis

Articular Disorders of Hand and Wrist

1. **Osteoarthritis** = degenerative joint disease
   = abnormal stress with minor + major traumatic episodes
   Target areas: DIP, PIP, 1st CMC, trapezioscaphoid; bilateral symmetric / asymmetric
   √ joint space narrowing
   √ subchondral eburnation
   √ marginal osteophytes + small ossicles
   √ radial subluxation of 1st metacarpal base
   ◊ Radiocarpal joint normal unless history of trauma
2. **Erosive osteoarthritis** = inflammatory osteoarthritis
   Age: predominantly middle-aged / postmenopausal women
   • acute inflammatory episodes
   Target areas: DIP, PIP, 1st CMC, trapezioscaphoid; bilateral symmetric / asymmetric
   √ central erosions combined with osteophytes = subchondral "gull wing" erosions
   √ joint space narrowing + sclerosis
   √ rare ankylosis
3. **Psoriatic arthritis**
   = rheumatoid variant / seronegative spondyloarthropathy; peripheral manifestation in monoarthritis / asymmetric oligoarthritis / symmetric polyarthritis
   Target areas: all hand + wrist joints (commonly distal); bi- / unilateral asymmetric polyarticular changes
   √ "mouse ears" marginal erosions
   √ intraarticular osseous excrescences
   √ new bone formation ± fusion
   √ osteoporosis may be absent
4. **Rheumatoid arthritis**
   = synovial proliferative granulation tissue = *pannus*
   Target areas: PIP (early in 3rd), MCP (earliest changes in 2nd + 3rd), all wrist joints (early in RC, IRU), ulnar styloid; both hands in relative symmetric fashion
   √ fusiform soft-tissue swelling
   √ regional periarticular osteoporosis
   √ diffuse loss of joint space
   √ marginal + central poorly defined erosions
   √ joint deformities
5. **Gouty arthritis**
   • monosodium urate crystals in synovial fluid
   • asymptomatic periods from months to years
   Target areas: commonly CCMC + all hand joints
   √ development of chronic tophaceous gout = lobulated soft-tissue masses
   √ well-defined eccentric erosions with overhanging edge (often periarticular) + sclerotic margins
   √ preservation of joint spaces
   √ absence of osteoporosis
   √ most extensive changes in common carpometacarpal compartment:
   √ scalloped erosions of bases of ulnar metacarpals

6. **Calcium pyrophosphate dihydrate crystal deposition disease = CPPD**
   Target areas: MCP (2nd, 3rd), radiocarpal; bilateral symmetric / asymmetric changes
   √ chondrocalcinosis + periarticular calcifications:
      √ calcification of triangular fibrocartilage
   √ "degenerative changes" in unusual locations:
      √ narrowing ± obliteration of space between distal radius and scaphoid ± fragmentation of surfaces
      √ scapholunate separation
      √ destruction of trapezioscaphoid space
   √ no erosions
   √ + large osteophytes = hemochromatosis
7. **SLE**
   = myositis, symmetric polyarthritis, deforming nonerosive arthropathy, osteonecrosis
   Target areas: PIP, MCP
   √ reversible deformities
8. **Scleroderma** = progressive systemic sclerosis (PSS)
   Target areas: DIP, PIP, 1st CMC
   √ tuft resorption
   √ soft-tissue calcifications

Arthritis Involving Distal Interphalangeal Joints

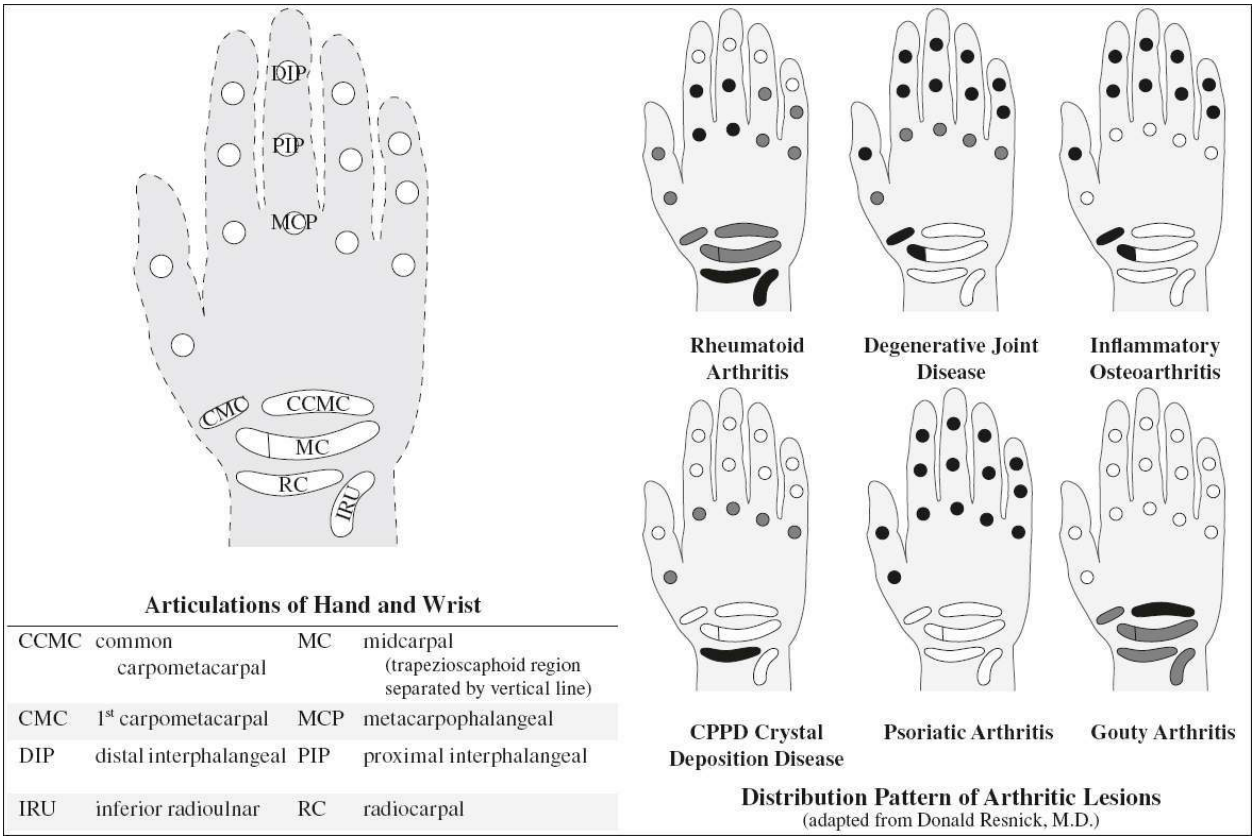
mnemonic: "POEM"
Psoriatic arthritis
Osteoarthritis
Erosive osteoarthritis
Multicentric reticulohistiocytosis

Ankylosis of Interphalangeal Joints

mnemonic: "S - Lesions"
1. P**s**oriatic arthritis
2. Ankylo**s**ing spondylitis
3. Ero**s**ive osteoarthritis
4. **S**till disease

Arthritis of Interphalangeal Joint of Great Toe

1. Psoriatic arthritis



Articulations of Hand and Wrist

CCMC	common carpometacarpal	MC	midcarpal (trapezioscaphoid region separated by vertical line)
CMC	1st carpometacarpal	MCP	metacarpophalangeal
DIP	distal interphalangeal	PIP	proximal interphalangeal
IRU	inferior radioulnar	RC	radiocarpal

Distribution Pattern of Arthritic Lesions
(adapted from Donald Resnick, M.D.)

2. Reiter disease
3. Gout
4. Degenerative joint disease

RIBS

Thoracic Deformity

Pectus Carinatum = Pigeon Breast

= anterior displacement of sternum

Frequency: 1÷1500 live births; in 25% familial

In > 30% associated with: scoliosis

Types:

(a) chondrogladiolar deformity = protrusion of middle + lower sternum
[*gladiolus*, Latin, diminutive for *gladius* = sword]

(b) chondromanubrial deformity (Currrarino-Silverman syndrome) = protrusion of manubrium + upper sternum
[*manubrium*, Latin = a handle]

• shortness of breath, exercise intolerance

√ increase in AP diameter

√ pectus index (TRV diameter ÷ AP diameter of chest): < 1.42–1.98

Pectus Excavatum = Funnel Chest

= posterior depression of sternum with reduction of prevertebral space compressing heart against spine

Frequency: 1÷400 to 1÷1000 live births; M÷F = 4÷1

Cause: rapid misdirected growth of lower costal cartilages

◊ Most common congenital deformity of the sternum

◊ Most frequently an isolated anomaly (45% familial)!

May be associated with:

prematurity, homocystinuria, Marfan syndrome, Poland syndrome, Noonan syndrome, fetal alcohol syndrome, congenital heart disease

In > 20% associated with: scoliosis

• decreased total lung capacity

• decreased cardiac stroke volume

√ depressed position of sternum (LATERAL)

√ indistinct right heart border mimicking right middle lobe process (FRONTAL) = leftward displacement + axial rotation of heart

√ decreased heart density (FRONTAL)

√ leftward displacement of heart mimicking cardiomegaly (FRONTAL)

√ horizontal course of posterior portion of ribs

√ accentuated downward course of anterior portions of ribs (FRONTAL)

CT:

√ pectus index (TRV diameter ÷ AP diameter of chest): > 2.56 ± 0.35

Rx: surgical correction with pectus index > 3.25

Barrel Chest

= large sagittal diameter of thorax

Cause: COPD, emphysema

√ lateral segments of ribs elongated + straight pointing vertical (FRONTAL)

√ square shape on cross section (CT)

Congenital Rib Anomalies

Prevalence: 1.4%

1. **Cervical rib** (0.2–1–8%)

   M< F

   • usually asymptomatic

   • thoracic outlet syndrome (due to elevation of floor of scalene triangle with decrease of costoclavicular space):

   ◊ 10–20% of symptomatic patients have a responsible cervical rib

   ◊ 5–10% of complete cervical ribs cause symptoms

   May be associated with: Klippel-Feil anomaly

   √ uni- / bilateral

   √ may fuse with first ribs anteriorly

   √ adjacent transverse process angulated inferiorly

   Cx: aneurysmal dilatation of subclavian a.

   DDx: elongated transverse process of 7th cervical vertebra; hypoplastic 1st thoracic rib

2. **Forked / bifid rib** (0.6%) = duplication of anterior portion

Location: 4th rib (most often)
May be associated with: Gorlin basal cell nevus syndrome
◊ A single bifid rib is most commonly a normal incidental finding!

3. **Rib fusion** (0.3%)
   May be associated with: vertebral segmentation anomalies
   Location: 1st + 2nd rib / several adjacent ribs
   Site: posterior / anterior portion
4. **Bone bridging** = focal joining by bone outgrowth
   Cause: congenital / posttraumatic
   Location: anywhere along one pair of ribs / several adjacent ribs
   √ complete bridging / pseudarthrosis
5. **Rudimentary / hypoplastic rib** (0.2%)
   Location: 1st rib (usually)
   √ transverse process angulated superiorly
   DDx: cervical rib
6. **Pseudarthrosis of 1st rib** (0.1%)
   √ radiolucent line through mid portion with dense sclerotic borders
7. **Intrathoracic / pelvic rib** (rare)
8. **Abnormal number of ribs**
   (a) supernumerary: trisomy 21, VATER syndrome
   (b) 11 pairs: normal individuals (5–8%); trisomy 21 (33%); cleidocranial dysplasia; camptomelic dysplasia

Short Ribs

1. Thanatophoric dysplasia
2. Jeune asphyxiating thoracic dysplasia
3. Ellis-van Creveld chondroectodermal dysplasia
4. Short rib-polydactyly syndromes (Saldino-Noonan, Majewski, Verma-Naumoff)
5. Achondroplasia
6. Achondrogenesis
7. Mesomelic dwarfism
8. Spondyloepiphyseal dysplasia
9. Enchondromatosis

Rib Lesions

A. BENIGN RIB TUMOR
   1. Fibrous dysplasia (most common benign lesion)
      √ predominantly posterior / lateral location
      √ expansile remodeling of protracted length of bone
      √ typical ground-glass appearance
   2. Enchondroma (2nd most common)
      √ at costochondral junction
      √ high SI on T2WI + lobulated contour
   3. Osteochondroma / exostosis (8%):
      √ at costochondral / costovertebral junction

Associated with: spontaneous hemothorax

4. Langerhans cell histiocytosis (eosinophilic granuloma)
   - age < 30 years
   √ "black hole" on CT of lower density
   √ aggressive features like periostitis + cortical breakthrough + soft-tissue mass
5. Benign cortical defect
6. Hemangioma of bone
7. Giant cell tumor
   √ low to intermediate SI on T1WI + T2WI
8. Aneurysmal bone cyst
   √ lobulated septated mass with thin well-defined rim of low SI + fluid levels
9. Osteoblastoma
10. Osteoid osteoma
11. Chondroblastoma
    √ at costovertebral / costochondral junction
12. Enostosis = bone island (0.4%)
13. Paget disease
14. Brown tumor of HPT
15. Xanthogranuloma
16. Nonossifying fibroma = fibroxanthoma
    √ eccentric intracortical location, smaller in size
    √ spontaneous regression with age

B. PRIMARY MALIGNANT RIB TUMOR
1. Chondrosarcoma (33%)
2. Plasmacytoma
3. Lymphoma
4. Osteosarcoma (1.3%)
5. Fibrosarcoma
6. Primitive neuroectodermal tumor / Askin tumor

C. SECONDARY MALIGNANT RIB TUMOR
› *in adult:* 1. Metastasis (most common malignant lesion)
2: Multiple myeloma
3: Desmoid tumor
› *in adult:* 1. Ewing sarcoma (most common malignant rib tumor of children and adolescents)
2: Metastatic neuroblastoma

D. TRAUMATIC RIB DISORDER
1. Healing fracture
2. Radiation osteitis

DDx: pulmonary nodule

E. AGGRESSIVE GRANULOMATOUS INFECTIONS
= osteomyelitis

Expansile Rib Lesion

mnemonic: O FEEL THE CLAMP

Osteochondroma (25% of all benign rib tumors)
Fibrous dysplasia
Eosinophilic granuloma
Enchondroma (7% of all benign rib tumors)
Lymphoma / **L**eukemia
Tuberculosis
Hematopoiesis
Ewing sarcoma
Chondromyxoid fibroma
Lymphangiomatosis
Aneurysmal bone cyst
Metastases
Plasmacytoma

Abnormal Rib Shape

Rib Notching on Inferior Margin

= minimal concave scalloping / deep ridges along the neurovascular groove with reactive sclerosis

◊ Minor undulations in the inferior ribs are normal!

◊ The medial third of posterior ribs near transverse process of vertebrae may be notched normally!

A. ARTERIAL
Cause: intercostal aa. function as collaterals to descending aorta / lung
(a) Aorta: coarctation (usually affects ribs 4–8; rare before age 8 years), thrombosis
(b) Subclavian artery: Blalock-Taussig shunt
(c) Pulmonary artery: pulmonary stenosis, tetralogy of Fallot, absent pulmonary artery

B. VENOUS
Cause: enlargement of intercostal veins
(a) AV malformation of chest wall
(b) Superior vena cava obstruction

C. NEUROGENIC
1. Intercostal neuroma
2. Neurofibromatosis type 1
3. Poliomyelitis / quadriplegia / paraplegia

D. OSSEOUS
1. Hyperparathyroidism
2. Thalassemia
3. Melnick-Needles syndrome

Unilateral Rib Notching on Inferior Margin

1. Postoperative Blalock-Taussig shunt (subclavian to pulmonary artery)
2. Coarctation between origin of innominate a. + L subclavian a.
3. Coarctation proximal to aberrant subclavian a.

Rib Notching on Superior Margin

1. Rheumatoid arthritis
2. Scleroderma
3. Systemic lupus erythematosus
4. Hyperparathyroidism
5. Restrictive lung disease
6. Marfan syndrome

Dysplastic Twisted Ribbon Ribs

1. Osteogenesis imperfecta
2. Neurofibromatosis

Bulbous Enlargement of Costochondral Junction

1. Rachitic rosary
2. Scurvy
3. Achondroplasia
4. Hypophosphatasia
5. Metaphyseal chondrodysplasia
6. Acromegaly

Wide Ribs

1. Marrow hyperplasia (anemias)
2. Fibrous dysplasia
3. Paget disease
4. Achondroplasia
5. Mucopolysaccharidoses

Slender Ribs

1. Trisomy 18 syndrome
2. Neurofibromatosis

Dense Ribs

1. Tuberous sclerosis
2. Osteopetrosis
3. Mastocytosis
4. Fluorosis
5. Fibrous dysplasia
6. Chronic infection
7. Trauma
8. Subperiosteal rib resection

Hyperlucent Ribs

Congenitally Lucent Ribs

1. Osteogenesis imperfecta
2. Achondrogenesis
3. Hypophosphatasia
4. Camptomelic dysplasia

Acquired Lucent Ribs

1. Cushing disease
2. Acromegaly
3. Scurvy

CLAVICLE

Absence of Outer End of Clavicle

1. Rheumatoid arthritis
2. Hyperparathyroidism
3. Posttraumatic osteolysis
4. Metastasis / multiple myeloma
5. Cleidocranial dysplasia
6. Gorlin basal cell nevus syndrome

Penciled Distal End of Clavicle

mnemonic: SHIRT Pocket

Scleroderma
Hyperparathyroidism
Infection
Rheumatoid arthritis
Trauma
Progeria

Destruction of Medial End of Clavicle

mnemonic: MILERS

Metastases
Infection
Lymphoma
Eosinophilic granuloma
Rheumatoid arthritis
Sarcoma

SHOULDER

Shoulder Instability

= recurrent subluxation / dislocation of humeral head out of the glenoid socket during activities causing symptoms

Stabilizer: inferior glenohumeral ligament-labrum complex = IGHLC (most important); anterior labrum-ligament complex

Lesions after first anterior dislocation:

(1) traumatic, unidirectional, Bankart, surgical (TUBS)

Age: < 40 years

- fall on outstretched hand (FOOSH)

√ capsulolabral avulsion (Bankart lesion / its variants)
√ anterior-inferior instability

(2) **a**traumatic, **m**ultidirectional, **b**ilateral, **r**esponding to rehabilitation, **i**nferior capsular shift (AMBRI)
Age: > 40 years
√ tear of supraspinatus tendon (33%)
√ fracture of greater tuberosity (33%)
√ subscapularis avulsion from humerus (33%)

Instability lesions:
√ detachment of anteroinferior labrum:
√ scapular periosteum disrupted = Bankart lesion:
√ without bone fragment = soft Bankart
√ with bone fragment = osseous Bankart
√ scapular periosteum intact:
√ labrum displaced = ALPSA
√ labrum not displaced = Perthes lesion
√ fractured articular cartilage = GLAD
√ avulsion of humeral detachment of inferior glenohumeral ligament = HAGL
√ detachment of posterior labrum

Fluid in Subcoracoid Bursa

1. Isolated subcoracoid bursitis
2. Inadvertent injection of contrast material into bursa
3. Posttraumatic inflammatory response with tears of rotator cuff + rotator interval

WRIST

Carpal Angle

= angle of 130° formed by tangents to proximal row of carpal bones

A. DECREASED CARPAL ANGLE (< 124°)
1. Turner syndrome
2. Hurler syndrome
3. Morquio syndrome
4. Madelung deformity

B. INCREASED CARPAL ANGLE (> 139°)
1. Down syndrome
2. Arthrogryposis
3. Bone dysplasia with epiphyseal involvement

HAND

Axiality: determined after limb extension at right angle to long axis of body

preaxial = lateral (radial) aspect of upper limb or medial (tibial) aspect of lower limb

postaxial = medial (ulnar) aspect of upper limb or lateral (fibular) aspect of lower limb

Metacarpal Sign

= relative shortening of 4th + 5th metacarpals

√ tangential line along heads of 5th + 4th metacarpals intersects 3rd metacarpal

1. Idiopathic
2. Pseudo- and pseudopseudohypoparathyroidism
3. Basal cell nevus syndrome
4. Multiple epiphyseal dysplasia
5. Beckwith-Wiedemann syndrome
6. Sickle cell anemia
7. Juvenile chronic arthritis
8. Gonadal dysgenesis: Turner + Klinefelter syndrome
9. Ectodermal dysplasia = Cornelia de Lange syndrome
10. Hereditary multiple exostoses
11. Peripheral dysostosis
12. Melorheostosis

mnemonic: **P**ing **P**ong **I**s **T**ough **T**o **T**each

Pseudohypoparathyroidism
Pseudopseudohypoparathyroidism
Idiopathic
Trauma
Turner syndrome
Trisomy 13–18

Brachydactyly

= shortening / broadening of metacarpals ± phalanges

1. Idiopathic
2. Trauma
3. Osteomyelitis
4. Arthritis
5. Turner syndrome
6. Osteochondrodysplasia
7. Pseudohypoparathyroidism, Pseudopseudohypoparathyroidism
8. Mucopolysaccharidoses
9. Cornelia de Lange syndrome
10. Basal cell nevus syndrome
11. Hereditary multiple exostoses

Clinodactyly

= curvature of finger in mediolateral plane

1. Normal variant
2. Down syndrome
3. Multiple dysplasia
4. Trauma, arthritis, contracture

Polydactyly

Frequently associated with:

1. Carpenter syndrome
2. Ellis-van Creveld syndrome
3. Meckel-Gruber syndrome
4. Polysyndactyly syndrome
5. Short rib-polydactyly syndrome
6. Trisomy 13

Syndactyly

= osseous ± cutaneous fusion of digits

1. Apert syndrome
2. Carpenter syndrome
3. Down syndrome
4. Neurofibromatosis
5. Poland syndrome
6. Others

FINGER

Benign Lesion of Finger

(a) cartilage matrix
1. Enchondroma
2. Enchondromatosis
3. Periosteal / juxtacortical chondroma
4. Chondromyxoid fibroma
5. Chondroblastoma

(b) bone matrix
1. Osteochondroma
2. Hereditary multiple exostoses
3. Subungual exostosis
4. Florid Reactive Periostitis
5. Bizarre parosteal osteochondromatous proliferation
6. Osteoid osteoma
7. Aneurysmal bone cyst
8. Giant cell tumor

(b) mimics of primary osseous lesion
1. Glomus tumor
2. Epidermal inclusion cyst
3. Systemic disease: sarcoidosis, tophaceous gout, brown tumor of hyperparathyroidism, rheumatoid arthritis ± pressure erosion from overlying rheumatoid nodule
4. Infection

Lucent Lesion in Finger

A. BENIGN TUMOR
1. Enchondroma
2. Epidermoid inclusion cyst
3. Giant cell tumor
4. Reparative granuloma
5. Sarcoidosis
6. Glomus tumor (rare)

others: aneurysmal bone cyst, brown tumor, hemophilic pseudotumor, solitary bone cyst, osteoblastoma

B. MALIGNANT PRIMARY TUMOR (exceedingly rare)

(a) osseous malignancy
1. Chondrosarcoma
   ◊ Most common primary malignant bone tumor of the hand!
2. Osteosarcoma
3. Fibrosarcoma
4. Hemangioendotheliosarcoma
5. Ewing sarcoma

(b) nail bed malignancy

1. Squamous cell carcinoma
2. Malignant melanoma

C. MALIGNANT SECONDARY TUMOR
1. Metastasis from lung > genitourinary tract > breast

mnemonic: GAMES PAGES
Glomus tumor
Arthritis (gout, rheumatoid)
Metastasis (lung, breast)
Enchondroma
Simple cyst (inclusion)
Pancreatitis
Aneurysmal bone cyst
Giant cell tumor
Epidermoid
Sarcoid

Dactylitis

= expansion of bone with cystic changes
1. Tuberculous dactylitis (= spina ventosa)
2. Pyogenic / fungal infection
3. Syphilitic dactylitis
4. Sarcoidosis
5. Hemoglobinopathies
6. Hyperparathyroidism
7. Leukemia

Resorption of Terminal Tufts

A. TRAUMA
1. Amputation
2. Burns, electric injury
3. Frostbite
4. Vinyl chloride poisoning

B. NEUROPATHIC
1. Congenital indifference to pain
2. Syringomyelia
3. Myelomeningocele
4. Diabetes mellitus
5. Leprosy

C. COLLAGEN-VASCULAR DISEASE
1. Scleroderma
2. Dermatomyositis
3. Raynaud disease

D. METABOLIC
1. Hyperparathyroidism

E. INHERITED

1. Familial acroosteolysis
2. Pyknodysostosis
3. Progeria = Werner syndrome
4. Pachydermoperiostosis

F. OTHERS
1. Sarcoidosis
2. Psoriatic arthropathy
3. Epidermolysis bullosa

Subungual Tumors

A. Benign solid tumor
1. Glomus tumor
2. Subungual exostosis
3. Soft-tissue chondroma
4. Keratoacanthoma
5. Hemangioma
6. Lobular capillary hemangioma

B. Benign cystic lesion
1. Epidermal cyst
2. **Mucoid cyst**
= cyst containing hyaluronic acid + related to osteoarthritis of DIP joint

C. Malignant tumor
1. Squamous cell carcinoma
2. Malignant melanoma

Acroosteolysis

1. Acroosteolysis: (a) acquired
(b) familial
2. Massive osteolysis
3. Essential osteolysis
4. Ainhum disease

Acquired Acroosteolysis

mnemonic: PETER's DIAPER SPLASH

Psoriasis, **P**orphyria
Ehlers-Danlos syndrome
Thrombangiitis obliterans
Ergot therapy
Raynaud disease
Diabetes, **D**ermatomyositis, **D**ilantin therapy
Injury (thermal + electrical burns, frostbite)
Arteriosclerosis obliterans
PVC (polyvinyl chloride) worker
Epidermolysis bullosa
Rheumatoid arthritis, **R**eiter syndrome

Scleroderma, **S**arcoidosis
Progeria, **P**yknodysostosis
Leprosy, **L**esch-Nyhan syndrome
Absence of pain
Syringomyelia
Hyperparathyroidism
also in: yaws; Kaposi sarcoma; pachydermoperiostosis

√ lytic destructive process involving distal + middle phalanges
√ NO periosteal reaction
√ epiphyses resist osteolysis until late

Acroosteosclerosis

= focal opaque areas + endosteal thickening

1. Incidental in middle-aged women
2. Rheumatoid arthritis
3. Sarcoidosis
4. Scleroderma
5. Systemic lupus erythematosus
6. Hodgkin disease
7. Hematologic disorders

Fingertip Calcifications

1. Scleroderma / CREST syndrome
2. Raynaud disease
3. Systemic lupus erythematosus
4. Dermatomyositis
5. Calcinosis circumscripta universalis
6. Hyperparathyroidism

HIP

Snapping Hip Syndrome

A. INTRAARTICULAR
   1. Osteocartilaginous bodies
B. EXTRAARTICULAR = tendon slippage
   1. Fascia lata / gluteus maximus over greater trochanter
   2. Iliopsoas tendon over iliopectineal eminence
   3. Long head of biceps femoris over ischial tuberosity
   4. Iliofemoral ligament over anterior portion of hip capsule

Increase in Teardrop Width

√ increase in distance between teardrop + femoral head
Cause: hip joint effusion
√ increase in mediolateral size of teardrop
Cause: hip dysplasia, chronic hip joint effusion during skeletal maturation

Protrusio Acetabuli

= acetabular floor bulging into pelvis
√ center-edge angle of Wiberg of > 40°
√ medial wall of acetabulum projecting medially to ilioischial line by > 3 mm (in males) / > 6 mm (in females)
√ crossing of medial + lateral components of pelvic "teardrop" (U-shaped radiodense area medial to hip joint)
Anatomy:
(a) lateral aspect = articular surface of acetabular fossa
(b) medial aspect = anteroinferior margin of quadrilateral surface of ilium)
√ obscured "teardrop" sign = pelvic teardrop obscured by femoral head

A. UNILATERAL
1. Tuberculous arthritis
2. Trauma
3. Fibrous dysplasia

B. BILATERAL
1. Rheumatoid arthritis
2. Paget disease
3. Osteomalacia

mnemonic: PROT
Paget disease
Rheumatoid arthritis
Osteomalacia (HPT)
Trauma

Pain with / after Hip Prosthesis

= pain in groin / thigh after hip arthroplasty
Prevalence of pain: 40%; ~ 120,000 hip arthroplasties per year in USA

1. Postoperative hematoma
Incidence: 1.7% (within first 2 weeks)
Cx: wound dehiscence, infection
2. Heterotopic ossification
Incidence: 50–60% (within 8 weeks after surgery)
Risk factors: male gender, DISH, history of heterotopic ossification, osteoarthritis with preexisting heterotopic bone, ankylosing spondylitis
• loss of motion ← ossifications bridging the joint
3. Trochanteric bursitis
4. Prosthetic / periprosthetic / cement fracture
• audible crack during tapping of stem (intraoperative!)
Incidence: in up to 18%
Predisposition: osteoporosis, osteolysis, stress shielding (= bone resorption due to decreased stress to bone) typically at base of greater trochanter and calcar
5. Dislocation
Risk factors: component malposition, imbalance of tissue tension, implant design, surgical approach, extent of surgical soft-tissue dissection, small femoral

head, failure of abductor mechanism

(a) posterior joint instability disruption of posterior joint capsule + short external rotator muscles / muscle atrophy

(b) anterior joint instability excessive acetabular cup anteversion > 30° → impingement of femoral neck onto posterior rim of acetabular component → creation of posterior lever mechanism forcing femoral head out anteriorly

6. Synovitis
   (a) nonspecific mechanical irritation
      √ small amount of joint fluid without debris
      √ thin synovial lining
   (b) polyethylene wear-induced = polymeric debris
      √ slowly progressive typically bulky osteolysis
      √ expansion of hip pseudocapsule by thick + particulate-appearing synovitis
   (c) adverse local tissue reaction (metal hypersensitivity, metallosis)
      √ synovial thickness > 7 mm
   (d) infection *(see below)*
7. Iliopsoas impingement syndrome & tendinopathy
   Incidence: 4.3%
   Cause:
      (a) idiopathic
      (b) prominent oversized / malpositioned acetabular component
      (c) retained cement
      (d) excessively long iliac screws
      (e) femoral head larger than native head
   √ gluteus medius and minimus tendon thickening / tear
8. **Aseptic loosening**
   = complete loss of implant fixation
   Frequency: 50% of prostheses after 10 years; 30% require revision
   Cause:
      (a) mechanical wear + tear of components
      (b) small-particle disease
         Path: particulate debris incites inflammatory / immune reaction → unsuccessful enzymatic destruction of debris → cytokines and proteolytic enzymes damage bone and cartilage → osteolysis
         Histo: synovium-like pseudomembrane of histiocytes (95% of specimens), giant cells (80%), lymphocytes and plasma cells (25%), neutrophils (< 10%)
   √ thin and enlarging > 2 mm radiolucent area around component / between cement mantle + bone
   √ NEW radiolucent area < 2 mm
   √ increasing osteolysis (due to particulate debris with foreign body granuloma)
   √ increasingly wide / asymmetric periprosthetic radiolucency
   √ endosteal scalloping around femoral stem
   √ pedestal formation = bone sclerosis distal to prosthetic tip in medullary canal ← micromotion

√ bead shedding = punctate pieces of metal around in-growth component
√ fractured cement mantle
√ fractured acetabular cup screw
√ newly tilted / migrated acetabular cup
√ rotated / migrated / toggled femoral stem:
  √ subsidence (= distal migration) of prosthesis (up to 5 mm is normal for noncemented femoral component in first few months)
  √ "sinking" of femoral flange into lesser trochanter
√ contrast medium between points of fixation
√ motion of components on stress views / fluoroscopy
√ inflammatory benign solid soft-tissue mass / pseudotumor around metal-on-metal implants

Rx: 30% require single-stage revision arthroplasty

9. **Infection of Hip Prosthesis** (= septic loosening)

Frequency: 0.3–1.7–9.0%; < 2% of primary arthroplasties; < 5% of revisions

Organism: Staphylococcus epidermidis (31%), Staphylococcus aureus (20%), Streptococcus viridans (11%), Escherichia coli (11%), Enterococcus faecalis (8%), group B streptococcus (5%)

Time of onset: ⅓ within 3 months, ⅓ within 1 year, ⅓ > 1 year

Path: bacteria bind to implant

Histo: neutrophils present in large numbers

Rx: excisional arthroplasty + protracted course of antimicrobial therapy + revision arthroplasty

• clinical signs of infection often absent

Plain film:
  √ "aggressive" osteolysis with ill-defined margins ← particulate debris with foreign body granuloma / abscess
  √ periostitis = periosteal new bone (100% specific, 16% sensitive for infection)
  √ periarticular fluid collection with irregular walls communicating with joint (CT arthrography) and sinus track to skin

NUC (83% sensitive, 88% specific): *(see below)*

PET:
  √ NO advantage over bone marrow imaging as a combination of ^{111}In-labeled leukocytes and ^{99m}Tc sulfur colloid

Arthrography:
  √ irregularity of joint pseudocapsule
  √ filling of nonbursal spaces / sinus tracts / abscess cavities

Aspiration of fluid under fluoroscopy (12–93% sensitive, 83–92% specific for infection):
  • joint aspiration: high number of FP + FN
  √ injection of contrast material to confirm intraarticular location

Evaluation of Total Hip Arthroplasty

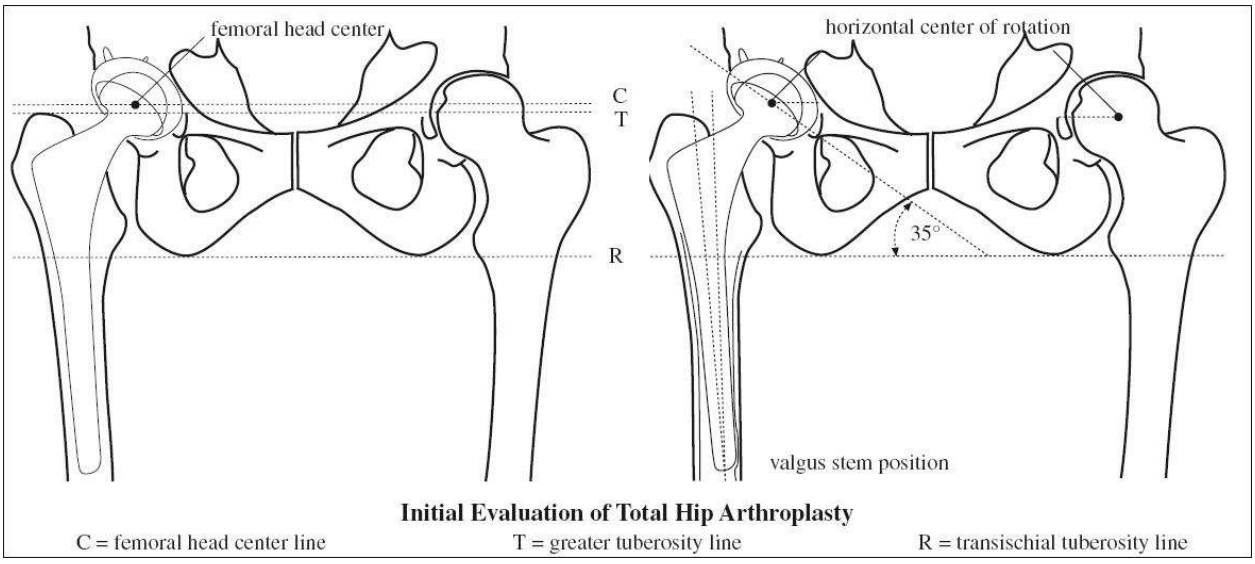
MEASUREMENTS

Reference line: transischial tuberosity line (R)

1. Leg length = vertical position of acetabular component

= comparing level of greater / lesser tuberosity (T) with respect to line R
High placement: shorter leg, less effective muscles crossing the hip joint
Low placement: longer leg, muscles stretched to point of spasm with risk of dislocation

2. Vertical center of rotation
   = distance from center of femoral head (C) to line R
3. Horizontal center of rotation
   = distance from center of femoral head (C) to teardrop / other medial landmark
   Lateral position: iliopsoas tendon crosses medial to femoral head center of rotation increasing risk of dislocation
4. Lateral acetabular inclination = horizontal version
   = angle of cup in reference to line R (40° ± 10° desirable)
   Less angulation: stable hip, limited abduction
   Greater angulation: risk of hip dislocation
5. Acetabular anteversion (15° ± 10° desirable)
   = lateral radiograph of groin
   Retroversion: risk of hip dislocation
6. Varus / neutral / valgus stem position
   Varus position: tip of stem rests against lateral endosteum, increased risk for loosening
   Valgus position: tip of stem rests against medial endosteum, not a significant problem
7. Femoral neck anteversion works synergistically with acetabular anteversion, true angle assessed by CT
8. Cup overhang > 12 mm associated with iliopsoas impingement, assessed by CT



9. Unfavorable position of screw tip eg, abutting the L5 nerve root in sciatic notch

Type of Hip Prosthesis

A. Hemiprosthesis
   √ preservation of acetabular cartilage + subchondral bone plate

√ only femoral stem is fixed by
(a) bone cement (polymethylmethacrylate)
(b) press-fit / in-growth with textured surface facilitating in-growth of trabecular bone

1. Unipolar head
= 1 articulation between metal implant head + native acetabular cartilage
2. Bipolar head
= 2 articulations to improve range of motion:
(a) between inner head + liner of bipolar head
(b) between bipolar head (shell) + acetabulum
√ smooth outer surface
√ slightly greater than hemispheric shape
√ no screw holes

B. Total prosthesis (mostly for treatment of arthritis)
√ acetabulum reamed
1. Conventional
√ screw holes in acetabular cup
2. Resurfacing = replacing articulating surfaces of hip joint and removing very little bone
√ small acetabular cup in pelvic socket
√ femoral head component seated with a pegged stem inside a preserved femoral neck

Radiographic Findings in Total Hip Arthroplasty

A. NORMAL
√ irregular cement-bone interface
= normal interdigitation of PMMA (polymethylmethacrylate) with adjacent bone remodeling providing a mechanical interlock
◊ PMMA is not a glue!
√ thin lucent line along cement-bone interface
= 0.1–1.5-mm thin connective tissue membrane ("demarcation") along cement-bone interface accompanied by thin line of bone sclerosis

B. ABNORMAL
√ wide lucent zone at cement-bone interface
= ≥ 2-mm lucent line along bone-cement interface due to granulomatous membrane
Cause: component loosening ± reaction to particulate debris (eg, PMMA, polyethylene)
√ lucent zone at metal-cement interface along proximal lateral aspect of femoral stem
= suboptimal metal-cement contact at time of surgery / loosening
√ well-defined area of bone destruction (= histiocytic response, aggressive granulomatous disease)
Cause: granulomatous reaction as response to particulate debris / infection / tumor
√ asymmetric positioning of femoral head within acetabular component
Cause: acetabular wear / dislocation of femoral head / acetabular disruption / liner displacement / deformity

√ cement fracture
Cause: loosening

Scintigraphy for Prosthetic Failure

√ increased uptake of bone agent, ^{67}Gallium, ^{111}Indium-labeled leukocytes, complementary technetium-labeled sulfur colloid + combinations

(1) ***Bone Scintigraphy*** (high NPV):
› negative
√ periprosthetic uptake indistinguishable from surrounding nonarticular bone = no prosthetic abnormality (= high NPV)
› positive for infection / loosening:
√ diffuse intense uptake around femoral component (= generalized osteolysis unreliable in separating infection from loosening)
√ diffuse periprosthetic uptake favors infection
√ focal uptake at distal tip of femoral component in > 1 year old prosthesis = aseptic loosening
› nonspecific:
√ periprosthetic activity generally decreases with time:
√ variable uptake patterns in 1st year after implantation
√ persistent uptake > 1 year is frequent in cementless / porous-coated hip replacements

(3) ***Sequential bone/gallium scintigraphy*** (60–80% accurate, modest improvement over bone scintigraphy alone):
› negative for infection:
√ gallium distribution normal regardless of findings on bone imaging
√ spatially congruent distribution of both radiotracers + gallium intensity less than bone tracer
› inconclusive:
√ spatially congruent radiotracer distribution + similar uptake intensity for both radiotracers
› positive for infection:
√ spatially incongruent distribution of the 2 radiotracers
√ gallium uptake intensity exceeds that of bone agent

(4) ***Labeled leukocyte scintigraphy***:
› positive for infection:
√ intensity exceeds that of a reference point
√ activity outside normal distribution

(5) ***Combined labeled leukocyte–marrow scintigraphy*** = WBC/sulfur colloid scintigraphy (study of choice):
Accuracy: 88–98%
Concept: ^{99m}Tc-sulfur colloid maps aberrantly located normal bone marrow as a point of reference for leukocyte tracer
› positive for infection:
√ labeled leukocyte activity without corresponding sulfur colloid activity ← osteomyelitis stimulates WBC uptake + depresses sulfur colloid uptake

› negative for infection:
√ spatially congruent distribution of both radiotracers / any other pattern of uptake

KNEE

Bone Contusion Pattern

√ edema of mid portion of lateral femoral condyle
Cause: **pivot shift injury** = valgus load + external rotation of tibia / external rotation of femur applied to various states of flexion (noncontact injury)
Predisposed: skier, football player
Associated with injury of:
(1) anterior cruciate lig. (midsubstance > femoral attachment > tibial attachment site)
(2) posterior joint capsule + arcuate ligament
(3) posterior horn of lateral / medial meniscus
(4) medial collateral ligament

√ ± edema of posterior patellar surface
Cause: dashboard injury = force upon anterior proximal tibia with knee in flexed position
Associated with:
(1) rupture of posterior cruciate lig. (midsubstance > femoral attachment > tibial attachment site)
(2) tear of posterior joint capsule
(3) fracture / osteochondral injury of patella
(4) injury of hip

√ "kissing" bone contusion pattern = anterior aspect of tibial plateau + anterior aspect of femoral condyle
Cause: **hyperextension injury** = direct force upon anterior tibia while foot is planted / indirect force of forceful kicking motion
Associated with:
(1) injury to posterior / anterior cruciate lig.
(2) meniscal injury
(3) dislocation of knee
(4) popliteal neurovascular injury
(5) complete disruption of posterolateral complex

√ edema in lateral aspect of femoral condyle ← direct blow

√ small area of edema in medial femoral condyle ← avulsive stress to medial collateral ligament
Predisposed: football player
Cause: **clip injury** = pure valgus stress with knee in mild flexion
Associated with injury of:
(1) medial collateral ligament (at femoral attachment site
(2) anterior cruciate ligament
(3) medial meniscus
(4) combination of all three = methyl triad

√ anterolateral aspect of lateral femoral condyle

√ inferomedial aspect of patella
Predisposed: teenaged / young adult athletes with shallow trochlear groove
Cause: **lateral patellar dislocation** = twisting motion with knee in flexion + quadriceps contraction
Associated with injury of:
(1) medial retinaculum
(2) medial patellofemoral ligament (near femoral attachment site) most important stabilizing structure)
(3) medial patellotibial ligament

Double PCL sign on MRI
1. Bucket-handle tear of medial / lateral meniscus
2. Ligament of Humphrey
3. Torn ACL
4. Fracture fragments
5. Osteophyte
6. Loose body

Absent bow-tie sign
1. Bucket-handle tear of medial meniscus
2. Congenitally hypoplastic / ring-shaped meniscus
3. Small meniscus in child / petite adult
4. Partial meniscectomy
5. Arthritic degeneration

Unique Tibial Lesions
1. Fibrous dysplasia
2. Ossifying fibroma
3. Adamantinoma

Tibiotalar Slanting
= downward slanting of medial tibial plafond
1. Hemophilia
2. Still disease
3. Sickle cell disease
4. Epiphyseal dysplasia
5. Trauma

FOOT

Abnormal Foot Positions
A. FOREFOOT
1. **Varus** = adduction
= axis of 1st metatarsal deviated medially relative to axis of talus
2. **Valgus** = abduction

= axis of 1st metatarsal deviated laterally relative to axis of talus

3. **Inversion** = supination
   = inward turning of sole of foot
4. **Eversion** = pronation
   = outward turning of sole of foot

B. HINDFOOT

talipes = any deformity of the ankle and hindfoot
[*talus*, Latin = ankle; *pes*, Latin = foot]

1. Equinus
   = hindfoot abnormality with reversal of calcaneal pitch so that the heel cannot touch the ground
2. Calcaneal foot
   = very high calcaneal pitch so that forefoot cannot touch the ground
3. Pes planus = flatfoot
   = low calcaneal pitch + (usually) heel valgus + forefoot eversion
4. Pes cavus
   = high calcaneal pitch (fixed high arch)

Clubfoot = Talipes Equinovarus

Common severe congenital deformity characterized by

- equinus of heel (reversed calcaneal pitch)
- heel varus (talocalcaneal angle of almost zero on AP view with both bones parallel to each other)
- metatarsus adductus (axis of 1st metatarsal deviated medially relative to axis of talus)

1. Arthrogryposis multiplex congenita
2. Chondrodysplasia punctata
3. Neurofibromatosis
4. Spina bifida
5. Myelomeningocele

Rocker-bottom Foot = Vertical Talus

√ vertically oriented talus with increased talocalcaneal angle on lateral view
√ dorsal navicular dislocation at talonavicular joint
√ heel equinus
√ rigid deformity

Associated with: Arthrogryposis multiplex congenita; spina bifida; trisomy 13–18

Talar Beak = Hypertrophied Talar Ridge

1. Talocalcaneal type of tarsal coalition
2. Diffuse idiopathic skeletal hyperostosis (DISH)
3. Acromegaly
4. Rheumatoid arthritis

Heel Pad Thickening

= heel pad thickening > 25 mm (normal < 21 mm)

mnemonic: MAD COP

Myxedema
Acromegaly
Dilantin therapy
Callus
Obesity
Peripheral edema

Soft-tissue Masses of Foot + Ankle

A. NONTUMORAL
   (a) synovial proliferations
      1. Pigmented villonodular synovitis (PVNS)
      2. Giant cell tumor (GCT) of tendon sheath
   (b) posttraumatic
      1. Plantar fasciitis
   (c) inflammatory
   (d) uncertain origin
      1. Ganglion cyst
      2. Epidermoid cyst
      3. Morton neuroma
      4. Florid reactive periostitis
      6. Rheumatoid nodules
B. BENIGN TUMORS
   1. Plantar fibromatosis
   2. Deep fibromatosis
   3. Infantile digital fibromatosis
   4. Hemangioma
   5. Nerve sheath tumor
   6. Lipoma, angiolipoma

SOFT TISSUES

Categories of Soft-tissue Masses

A. Neoplastic
   Incidence: 300÷100,000 / year; benign÷malignant = 100÷1
   (a) benign (most frequent)
      1. Lipoma
      2. Hemangioma
      3. Desmoid tumor
      4. Ganglion cyst
      5. Pigmented villonodular synovitis
      6. Neurofibroma (5%)
      7. Lipoblastoma
   (b) malignant
      Frequency: 1% of all cancers in adults, increasing with age

1. Malignant fibrous histiocytoma
2. Liposarcoma

B. Inflammatory
C. Traumatic
D. Vascular

Superficial Soft-tissue Mass

A. MESENCHYMAL TUMOR
   (a) cutaneous
      1. Dermatofibrosarcoma protuberans
   (b) subcutaneous
      1. Lipoma / liposarcoma
      2. Angioma (hemangioma, lymphangioma, mixed)
      3. Peripheral nerve sheath tumor
      4. Malignant fibrous histiocytoma
      5. Leiomyosarcoma
      6. Epithelioid sarcoma
   (c) fascial
      1. Nodular fasciitis
      2. Fibromatosis

B. SKIN APPENDAGE LESION
   1. Epidermal inclusion cyst
   2. Pilomatricoma
   3. Eccrine cystadenoma / hydrocystoma
      = cystic ectasia of dermal portion of eccrine duct
   4. Cylindroma (head, neck, scalp in women)
   5. Syringoma (eyelids, upper cheek)

C. METASTATIC TUMOR
   ◊ 5–10% of all cancer patients develop skin metastases
   1. Carcinoma
      mnemonic: BLOCK
         Breast
         Lung
         Ovary
         Colon
         Kidney
   2. Melanoma (in 30% of melanoma patients)
   3. Myeloma (in < 5% of multiple myeloma patients)

D. OTHER TUMORS & TUMORLIKE LESION
   1. Myxoma
      √ homogeneous fluidlike signal intensity
   2. Lymphoma
   3. Granuloma annulare

E. INFLAMMATORY LESION
   1. Cellulitis

= inflammation / infection of cutis + subcutis without gross suppuration
√ thickened skin with reticulated fluidlike SI

2. Fasciitis
   = inflammation / infection of fascia
   √ fascial thickening + enhancement
3. Adenitis
   √ intermediate SI on non–fat-suppressed T2WI
4. Abscess
   = confined focal collection of pus or necrotic tissue + WBCs + bacteria
   √ fluidlike signal intensity + rim of enhancement
5. Phlegmon
   = poorly defined region with edema-like pattern and indistinct margins

Histologic Classification of Soft-tissue Lesions

A. FATTY
   1. Lipoma
   2. Angiolipoma
   3. Liposarcoma

B. FIBROUS
   1. Fibroma
   2. Nodular fasciitis
   3. Aggressive fibromatosis / desmoid
   4. Fibrosarcoma

C. MUSCLE
   (a) skeletal muscle tumor
      1. Rhabdomyoma
      2. Rhabdomyosarcoma
   (b) smooth muscle tumor
      1. Leiomyoma
      2. Leiomyosarcoma

D. VASCULAR
   1. Hemangioma
   2. Kaposiform hemangioendothelioma
   3. Kaposi sarcoma
   4. Hemangiopericytoma
   5. Hemangiosarcoma
   6. Glomus tumor
   7. Myopericytoma

E. LYMPH
   1. Lymphangioma
   2. Lymphangiosarcoma
   3. Lymphadenopathy in lymphoma / metastasis

F. SYNOVIAL
   1. Nodular synovitis
   2. Pigmented villonodular synovitis

3. Synovial sarcoma

G. NEURAL
1. Neurofibroma
2. Neurilemmoma
3. Ganglioneuroma
4. Malignant neuroblastoma
5. Neurofibrosarcoma

H. CARTILAGE AND BONE
1. Myositis ossificans
2. Extraskeletal osteoma
3. Extraskeletal / soft-tissue chondroma
4. Mesenchymal chondrosarcoma
5. Extraskeletal osteosarcoma

I. UNCERTAIN DIFFERENTIATION
1. Intramuscular myxoma
2. Ossifying fibromyxoid tumor
3. Synovial sarcoma
4. Primitive neuroectodermal tumor
5. Extraskeletal Ewing sarcoma

Most Frequent Benign Soft-tissue Tumors

8 pathologic diagnoses make up 70% of all benign tumors!

1. Lipoma 16%
2. Fibrous histiocytoma 13%
3. Nodular fasciitis 11%
4. Neurogenic neoplasm 10%
5. Hemangioma 7%
6. Fibromatosis 7%
7. PVNS / giant cell tumor of tendon sheath 4%
8. Ganglion cyst

Most Frequent Malignant Soft-tissue Tumors

7 pathologic diagnoses make up 80% of all malignant tumors!

1. Undifferentiated pleomorphic sarcoma (= malignant fibrous histiocytoma) 29%
2. Liposarcoma 14%
3. Nonspecific spindle cell sarcoma 12%
4. Leiomyosarcoma 8%
5. Malignant peripheral nerve sheath tumor 6%
6. Dermatofibroma protuberans 6%
7. Synovial sarcoma 5%

Fat-containing Soft-tissue Masses

A. BENIGN LIPOMATOUS TUMORS
1. Lipoma
2. Intra- / intermuscular lipoma

3. Synovial lipoma
4. Lipoma arborescens = diffuse synovial lipoma
5. Neural fibrolipoma = fibrolipomatous tumor of nerve
6. Macrodystrophia lipomatosa

B. LIPOMA VARIANTS
1. Lipoblastoma
2. Lipomatosis
   (a) Madelung disease
   (b) Mediastinal lipomatosis
   (c) Pancreatic lipomatosis
   (d) Pelvic lipomatosis
3. Hibernoma

C. MALIGNANT LIPOMATOUS TUMOR
1. Liposarcoma

D. OTHER FAT-CONTAINING TUMORS
1. Hemangioma
2. Elastofibroma dorsi

E. LESIONS MIMICKING FAT-CONTAINING TUMORS
1. Myxoid tumors: intramuscular myxoma, extraskeletal myxoid chondrosarcoma, myxoid malignant fibrous histiocytoma
2. Neural tumors: neurofibroma, neurilemmoma, malignant schwannoma
   √ 73% have tissue attenuation less than muscle
3. Hemorrhage

Benign Fibrous Soft-Tissue Tumors

So-called Fibrohistiocytic Tumors

1. Benign fibrous histiocytoma
2. Diffuse-type giant cell tumor
3. Malignant fibrous histiocytoma

Benign Myofibroblastic Proliferations

1. Nodular fasciitis
2. Proliferative fasciitis / myositis
3. Fibroma of tendon sheath
4. Keloid and hypertrophic scar
5. Elastofibroma

Musculoskeletal Fibromatoses

= wide range of clinicopathologic conditions with benign proliferation of fibrous tissue characterized by infiltrative growth pattern and tendency to recur locally

SUPERFICIAL FASCIAL FIBROMATOSES

1. Palmar fibromatosis (Dupuytren disease)
2. Plantar fibromatosis (Ledderhose disease)
3. Penile fibromatosis (Peyronie disease)

4. **Knuckle pads**
   = focal fibrous thickening dorsally at PIP / MCP joint
5. Juvenile aponeurotic fibroma
6. Infantile digital fibromatosis

Deep Musculoaponeurotic Fibromatoses

1. Desmoid-type fibromatosis
2. Abdominal wall fibromatosis
3. Mesenteric fibromatosis
4. Retroperitoneal fibromatosis
5. Pelvic fibromatosis
6. Gardner syndrome fibromatosis

Childhood Fibromatosis

1. Fibromatosis colli
2. Lipofibromatosis
3. Calcifying aponeurotic fibroma
4. Inclusion body fibromatosis
5. Infantile myofibromatosis
5. Juvenile aponeurotic fibroma
6. Infantile digital fibromatosis

Cystlike T2-hyperintense Soft-tissue Lesions on MRI

Cause: (a) true cyst
(b) internal tumor necrosis
(c) high extracellular water content = edema
(d) extracellular matrix of high water + protein content = myxoid stroma

A. TRULY CYSTIC LESION
   1. Synovial cyst
   2. Ganglion cyst
   2. Distended bursa
   3. Postsurgical collection + hematoma
   4. Skin appendage: eg, epidermal inclusion cyst
   5. Lymphatic malformation
   6. Hydatid cyst

B. BENIGN SOLID LESION
   1. Myxoma
   2. Peripheral nerve sheath tumor
   3. Vascular lesions: hemangioma, vascular malformation
   4. Glomus tumor

C. MALIGNANT SOLID LESION
   1. Malignant fibrous histiocytoma = undifferentiated pleomorphic sarcoma
   2. Myxoid sarcoma:
      › myxofibrosarcoma
      › myxoid liposarcoma
      › extraskeletal myxoid chondrosarcoma

3. Synovial sarcoma
4. Metastasis

Myxomatous Lesions of Soft Tissue

= tumor with abundance of extracellular mucoid material
√ mimicker of cysts ← high water content

A. BENIGN
   1. Intramuscular myxoma
      √ perilesional edema + rim of fat
   2. Synovial cyst
      √ communication with joint / tendon sheath
   3. Bursa
   4. Soft-tissue ganglion
      √ communication with joint / tendon sheath
   5. Benign peripheral nerve sheath tumor: neurofibroma, schwannoma
      √ "entering-and-exiting-nerve" sign

B. MALIGNANT
   1. Myxoid liposarcoma
      √ intralesional fat
   2. Myxoid leiomyosarcoma
   3. Myxoid chondrosarcoma
      √ internal chondroid matrix
   4. Ossifying fibromyxoid tumor
      √ incomplete peripheral ossification
   5. Myxofibrosarcoma

C. SYNDROMES
   1. Mazabraud syndrome

Extraskeletal Osseous + Cartilaginous Tumors

A. OSSEOUS SOFT-TISSUE TUMORS
   √ cloudlike "cumulus" type of calcification
   1. Myositis ossificans
   2. Fibrodysplasia ossificans progressiva
   3. Soft-tissue osteoma
   4. Extraskeletal osteosarcoma
   5. Myositis ossificans variants
      (a) Panniculitis ossificans
      (b) Fasciitis ossificans
      (c) Fibroosseous pseudotumor of digits

B. CARTILAGINOUS SOFT-TISSUE TUMORS
   √ arcs and rings, spicules and floccules of calcification
   1. Synovial osteochondromatosis
   2. Soft-tissue chondroma
   3. Extraskeletal chondrosarcoma

DDx:

(1) Synovial sarcoma
(2) Benign mesenchymoma
= lipoma with chondroid / osseous metaplasia
(3) Malignant mesenchymoma
= 2 or more unrelated sarcomatous components
(4) Calcified / ossified tophus of gout
(5) Ossified soft-tissue masses of melorheostosis
(6) Tumoral calcinosis
(7) **Pilomatricoma** = calcifying epithelioma of Malherbe
• lesion arises from hair matrix cells with slow growth confined to the subcutaneous tissue of the face, neck, upper extremities
√ central sandlike calcifications (84%)
√ peripheral ossification (20%)

Soft-tissue Uptake of Bone Agents

A. Physiologic
1. Breast
2. Kidney: accentuated uptake with dehydration, antineoplastic drugs, gentamicin
3. Bowel: surgical diversion of urinary tract

B. Faulty preparation with radiochemical impurity
(a) free pertechnetate (TcO_4^-)
Cause: introduction of air into the reaction vial
√ activity in mouth (saliva), salivary glands, thyroid, stomach (mucus-producing cells), GI tract (direct secretion + intestinal transport from gastric juices), choroid plexus
(b) ^{99m}Tc-MDP colloid
Cause: excess aluminum ions in generator eluate / patient ingestion of antacids; hydrolysis of stannous chloride to stannous hydroxide, excess hydrolyzed technetium
√ diffuse activity in liver + spleen

C. Neoplastic condition
(a) benign tumor
1. Tumoral calcinosis
2. Myositis ossificans
(b) primary malignant neoplasm
1. Extraskeletal osteosarcoma / soft-tissue sarcoma: bone forming
2. Neuroblastoma (35–74%): calcifying tumor
3. Breast carcinoma
4. Meningioma
5. Bronchogenic carcinoma (rare)
6. Pericardial tumor
(c) metastases with extraosseous activity
1. to liver: mucinous carcinoma of colon, breast carcinoma, lung cancer, osteosarcoma
mnemonic: LE COMBO

Lung cancer
Esophageal carcinoma
Colon carcinoma
Oat cell carcinoma
Melanoma
Breast carcinoma
Osteogenic sarcoma

2. to lung: 20–40% of osteosarcomas metastatic to lung demonstrate ^{99m}Tc-MDP uptake
3. Malignant pleural effusion, ascites, pericardial effusion

D. Inflammation
1. Inflammatory process (abscess, pyogenic / fungal infection):
   (a) adsorption onto calcium deposits
   (b) binding to denatured proteins, iron deposits, immature collagen
   (c) hyperemia
2. Crystalline arthropathy (eg, gout)
3. Dermatomyositis, scleroderma
4. Radiation: eg, radiation pneumonitis
5. Necrotizing enterocolitis
6. Diffuse pericarditis
7. Bursitis
8. Pneumonia

E. Trauma
1. Healing soft-tissue wounds
2. Rhabdomyolysis:
   crush injury, surgical trauma, electrical burns, frostbite, severe exercise, alcohol abuse
3. Intramuscular injection sites:
   especially Imferon® (= iron dextran) injections with resultant chemisorption; meperidine
4. Ischemic bowel infarction (late uptake)
5. Hematoma: soft tissue, subdural
6. Heterotopic ossification
7. Myocardial contusion, defibrillation, unstable angina pectoris
8. Lymphedema

F. Metabolic
1. Hypercalcemia (eg, hyperparathyroidism):
   (a) uptake enhanced by alkaline environment in stomach (gastric mucosa), lung (alveolar walls), kidneys (renal tubules)
   (b) uptake with severe disease in myocardium, spleen, diaphragm, thyroid, skeletal muscle
2. Diffuse interstitial pulmonary calcifications: hyperparathyroidism, mitral stenosis
3. Amyloid deposits

G. Ischemia / necrosis with dystrophic soft-tissue calcifications

@ Spleen: infarct (sickle cell anemia in 50%), microcalcifications ← lymphoma, thalassemia major, hemosiderosis, glucose-6-phosphate-dehydrogenase deficiency

@ Liver: massive hepatic necrosis
@ Heart: transmural myocardial infarction, valvular calcification, amyloid deposition
@ Muscle: traumatic / ischemic skeletal muscle injury
@ Brain: cerebral infarction (damage of blood-brain barrier)
@ Kidney: nephrocalcinosis
@ Vessels: calcified wall, calcified thrombus

Soft-tissue Calcification

Metastatic / Metabolic Calcification

= deposit of calcium salts in normal tissue
(1) as a result of elevation of Ca x P product above 60–70
(2) with normal Ca x P product after renal transplant

Location: lung (alveolar septa, bronchial wall, vessel wall), kidney, gastric mucosa, heart, peripheral vessels

Cause:

(a) Skeletal deossification
1. 1° HPT
2. Ectopic HPT production (lung / kidney tumor)
3. Renal osteodystrophy + 2° HPT
4. Hypoparathyroidism
5. Prolonged immobilization

(b) Massive bone destruction
1. Widespread bone metastases
2. Plasma cell myeloma
3. Leukemia

(c) Hypercalcemia
1. Primary hyperparathyroidism
2. Hypervitaminosis D
3. Milk-alkali syndrome
4. Sarcoidosis
5. Hydroxyapatite deposition disease
6. IV administration of calcium salts

(d) Idiopathic hypercalcemia

(e) Hyperuricemia
1. Tophaceous gout

Dystrophic Calcification

= deposit of calcium salts in tissue damaged by injury / inflammation (with local electrolyte / enzyme alterations) in presence of normal serum Ca + P level

Cause:

(a) Metabolic disorder without hypercalcemia
1. Renal osteodystrophy with 2° HPT
2. Hypoparathyroidism
3. Pseudohypoparathyroidism

4. Pseudopseudohypoparathyroidism
5. Gout
6. Pseudogout = chondrocalcinosis
7. Ochronosis = alkaptonuria
8. Diabetes mellitus

(b) Connective tissue disorder
1. Scleroderma = progressive systemic sclerosis
2. Dermato- and polymyositis
3. Systemic lupus erythematosus
4. Mixed connective tissue disorders

(c) Trauma
1. Neuropathic calcifications
2. Frostbite
3. Myositis ossificans progressiva

(d) Infestation
1. Cysticercosis
2. Dracunculosis (guinea worm)
3. Loiasis
4. Bancroft filariasis
5. Hydatid disease
6. Leprosy

(e) Vascular disease
1. Atherosclerosis
2. Media sclerosis (Mönckeberg)

DDx of Soft-Tissue Calcifications

Metastatic Calcifications	*Dystrophic Calcifications*	*Calcinosis*
Hyperpara-thyroidism	Soft-tissue tumor: lipoma, sarcomas (synovial, osteo~, chondro~)	Idiopathic tumoral calcinosis
Hypopara-thyroidism	Inherited disorder: Ehlers-Danlos, pseudoxanthoma	Calcinosis interstitialis universalis
Milk-alkali syndrome	Parasitic infection	Calcinosis in SLE, scleroderma, juvenile dermatomyositis
Excessive vitamin D	Tophaceous gout	
Sarcoidosis		
Paraneoplastic hypercalcemia		
Destructive bone disease		

3. Venous calcifications
4. Tissue infarction (eg, myocardial infarction)

(f) Miscellaneous
1. Ehlers-Danlos syndrome
2. Pseudoxanthoma elasticum
3. Werner syndrome = progeria
4. Calcinosis (circumscripta, universalis, tumoral calcinosis)

(g) Neoplastic disease
1. Synovial sarcoma
2. Osteosarcoma
3. Chondrosarcoma
4. Necrotic tumor

(h) Degenerative disease
1. Calcium pyrophosphate deposition disease
2. Calcific tendonitis (in 3% of adults)
Location: shoulder > hip > elbow > wrist > knee
3. Calcific bursitis

(i) Metaplasia
1. Synovial osteochondromatosis

GENERALIZED CALCINOSIS

(a) Collagen vascular disorders
1. Scleroderma
2. Dermatomyositis

(b) Idiopathic calcinosis universalis

Idiopathic Calcification

1. Tumoral calcinosis
   - normal calcium + elevated phosphate levels

Interstitial Calcinosis

Calcinosis Circumscripta

- firm white commonly ulcerating dermal papules / plaques / subcutaneous nodules extruding a chalky white material of hydroxyapatite

1. Acrosclerosis: granular deposits around joints of fingers and toes, fingertips
2. Scleroderma + CREST syndrome: acrosclerosis and absorption of ends of distal phalanges
3. Dermatomyositis: extensive subcutaneous deposits
4. Varicosities: particularly in calf
5. 1° Hyperparathyroidism: infrequently periarticular calcinosis
6. Renal osteodystrophy with 2° hyperparathyroidism: extensive vascular deposits even in young individuals
7. Hypoparathyroidism: occasionally around joints; symmetrical in basal ganglia
8. Vitamin D intoxication: periarticular in rheumatoid arthritis (puttylike); calcium deposit in tophi

Calcinosis Universalis

= progressive disease of unknown origin
Age: children + young adults
Associated with: poly- and dermatomyositis
√ diffuse plaque- / sheetlike calcium deposits in skin and subcutis; sometimes in tendons + muscles + fascia
√ NO true bone formation

Soft-tissue Ossification

= formation of trabecular bone

1. Myositis ossificans progressiva / circumscripta
2. Paraosteoarthropathy
3. Soft-tissue osteosarcoma
4. Parosteal osteosarcoma
5. Posttraumatic periostitis = periosteoma
6. Surgical scar
7. Severely burned patient

Connective Tissue Disease

= CTD = [COLLAGEN VASCULAR DISEASE]

= heterogeneous group of immunologically mediated systemic inflammatory disorders that may affect various organs but share a number of clinical + laboratory features

- Features:
  (a) relatively specific: arthritis, myositis, Raynaud phenomenon with digital ulceration, tethered skin in extremities + trunk, malar rash sparing nasolabial folds, morning stiffness
  (b) relatively nonspecific: polyarthralgias (most common initial symptom), myalgias, mottling of extremities, muscle weakness + tenderness
- Laboratory findings:
  (a) relatively specific: ANA in peripheral rim / nucleolar pattern, anti-DNA, elevated muscle enzyme
  (b) relatively nonspecific: ANA in homogeneous pattern, anti-single-stranded DNA, positive rheumatoid factor

Types and most distinctive features:

1. Rheumatoid arthritis positive rheumatoid factor, prominent morning stiffness, symmetric erosive arthritis
2. Systemic lupus erythematosus malar rash, photosensitivity, serositis, renal disorders with hemolytic anemia, leukopenia, lymphopenia, thrombocytopenia, positive ANA
3. Sjögren syndrome dry eyes + mouth, abnormal Schirmer test
4. Progressive systemic sclerosis
   Raynaud phenomenon, skin thickening of distal extremities proceeding to include proximal extremities + chest + abdomen, positive ANA in a nucleolar pattern
5. Polymyositis, dermatomyositis heliotrope rash over eyes, proximal muscle weakness, elevated muscle enzymes, inflammation at muscle biopsy
6. Mixed connective tissue disease

Thoracic imaging pattern: *(see table)*

Muscle

MR signal intensity of normal muscle:

√ higher than water + lower than fat on T1WI

√ much lower than water + fat on T2WI

Intramuscular Mass

A. NEOPLASM

B. INFECTION / INFLAMMATION

1. Intramuscular abscess
2. Focal myositis = benign inflammatory pseudotumor
3. Necrotizing fasciitis
4. Sarcoidosis

√ nodules with central star-shaped area of fibrosis surrounded by granuloma

C. MYONECROSIS

1. Sickle cell crisis
2. Poorly controlled diabetes
3. Compartment syndrome
4. Crush injury
5. Severe ischemia
6. Intraarterial chemotherapy
7. **Rhabdomyolysis** = severe muscle injury with loss of integrity of muscle cell membranes

Cause: trauma, severe exercise, ischemia, burn, toxin, IV heparin therapy, autoimmune inflammation

Frequency of Thoracic CT Findings of Connective Tissue Disease

	Mixed Connective Tissue Disease	*Dermatomyositis Polymyositis*	*Progressive Systemic Sclerosis*	*Juvenile Idiopathic Arthritis*	*Systemic Lupus Erythematosus (SLE)*

Cx: renal damage from myoglobulinemia, tetany, compartment syndrome

D. TRAUMA
   1. Intramuscular hematoma (eg, severe muscle strain, laceration, contusion, spontaneous)
   2. Myositis ossificans traumatica

Muscle Edema

√ muscle hyperintensity on STIR images

A. INFLAMMATION
   1. Dermatomyositis
   2. Polymyositis
   4. Radiation therapy: straight sharp margins, involves muscle + subcutaneous fat
   5. Early stage of myositis ossificans

B. CELLULAR INFILTRATE
   1. Lymphoma

C. INFECTION
   1. Bacterial / infectious myositis
      (a) direct extension from adjacent infection (eg, osteomyelitis, subcutaneous abscess)
      (b) hematogenous
   2. Inclusion body myositis (probably due to paramyxovirus infection) resembling polymyositis

D. RHABDOMYOLYSIS
   1. Sport / electric injury
   2. Diabetic muscular infarction
   3. Focal nodular myositis
   4. Metabolic myopathy: eg, phosphofructokinase deficiency, hypokalemia, alcohol overdose
   5. Viral myositis

E. TRAUMA
   1. **Subacute muscle denervation**
      Time of onset: 2–4 weeks after denervation
      Mechanism:
      spinal cord injury, poliomyelitis, peripheral nerve injury / compression (ganglion cyst, bone spur), Graves disease, neuritis

2. Muscle contusion (from direct blow)
3. **Muscle strain** (= injury at musculotendinous junction from overly forceful muscle contraction)
   Predilection for: hamstring, gastrocnemius m., biceps brachii m.)
4. **Delayed-onset muscle soreness**
   = overuse injury becoming symptomatic hours / days after overuse episode
5. **Compartment syndrome**
   = increased pressure within indistensible space of confining fascia leading to venous occlusion, muscle + nerve ischemia, arterial occlusion, tissue necrosis
   Cause: trauma, burns, heavy exercise, extrinsic pressure, intramuscular hemorrhage
   • severe pain
   • dysfunction of sensory + motor nerves passing through affected compartment
   Rx: urgent fasciotomy
6. Sickle cell crisis

Fatty Infiltration of Muscle

1. Chronic stage of muscle denervation (eg, poliomyelitis, stroke, peripheral nerve injury)
2. Chronic disuse (eg, chronic tendon tear, severe osteoarthritis)
3. Late stage of severe muscle injury
4. Long-term high-dose corticosteroid medication affecting truncal muscles

MUSCULOSKELETAL INFECTION

At risk: IV drug abuse, HIV, sickle cell disease, diabetes, peripheral vascular disease, immunocompromised, cancer, alcoholism, organ transplants

1. **Cellulitis**
   = acute infection of dermis + SQ tissue
   • pain, erythema, edema, warmth
   CT:
   √ skin thickening
   √ septation of SQ fat
   √ thickening of underlying superficial fascia
   Dx: clinical assessment
   DDx: heart failure
2. Necrotizing fasciitis
3. Soft-tissue abscess
   Cause: methicillin-resistant S. aureus (MRSA, 51%)
   √ well-demarcated fluid collection with peripheral pseudo-capsule showing rim enhancement
   DDx: cellulitis, fasciitis (no rim enhancement)
4. Infectious myositis
5. Osteomyelitis
6. Septic arthritis
7. Septic bursitis

TENDON

MRI Spectrum of Tendon Pathology

1. Tendinosis
   √ fusiform thickening of tendon + ↑ SI on PDWI + T1WI
   √ ↑ SI on T2WI ← severe intrasubstance degeneration
2. Tenosynovitis
   √ fluid + synovial proliferation within tendon sheath
3. Peritendinosis
   √ fluid in adjacent soft tissues
4. Tendon rupture
   (a) partial rupture
      √ focal areas of fiber discontinuity often outlined by fluid
   (b) complete rupture
      √ complete fiber discontinuity (= disruption) of tendon
      √ fluid outlining retracted proximal + distal stumps
5. Tendon entrapment
6. Tendon instability: subluxation / dislocation

Tendon Rupture

Location: quadriceps, Achilles tendon, rotator cuff, biceps brachii

Cause:

A. Traumatic

B. Spontaneous

= rupture during movement and activity that usually does not damage the musculotendinous unit

Risk factors: hyperparathyroidism, chronic renal failure, gout, Reiter syndrome, obesity, leukemia, rheumatoid arthritis, diabetes mellitus, systemic lupus erythematosus, infection, metabolic diseases, psoriasis, steroid abuse / injections, Marfan syndrome, tumors, immobilization

Classification and findings on MR:

(a) partial tear
   √ increased signal within tendon on T1WI + T2WI with extension to surface of tendon
   √ focal / diffuse enlargement or atrophy
   √ partial disruption of tendon fibers
   √ focal intratendinous fluid
   √ tendon enhancement

(b) complete tear
   √ discontinuity + separation of torn ends of tendon
   √ interposed edema + hemorrhage

FIXATION DEVICES

Internal Fixation Devices

A. Screws

1. Cannulated screw = hollow shaft screw inserted over guide pin (K-wire = Kirschner wire)
   Use: fracture of femoral neck
2. Cortical screw = shallow finely threaded over entire length, blunt tip
   Use: fixation of plates anchored in bone cortex
3. Cancellous screw = wide thread diameter with varying length of smooth shank between head + threads
   Use: compression across fracture site anchored in soft medullary bone
4. Malleolar screw = partially threaded
5. Herbert screw = cannulated screw threaded on both ends with wider pitch of proximal portion causing fragment compression, no screw head
   Use: scaphoid + other carpal bone fractures
6. Interference screw = short, fully threaded, cancellous thread pattern, self-tapping tip, recessed head
   Use: within tunnel holding bone graft of ACL and PCL reconstruction
7. Acutrak screw = cannulated screw fully threaded with variable thread pitch causing fragment compression, submerged without screw head
   Use: scaphoid fracture
8. Dynamic hip screw = lag screw telescopes (= free to slide) within hollow metal barrel of angular side plate allowing impaction of fracture without perforation of subarticular cortex
   Use: intertrochanteric, subtrochanteric, subcapital fracture
9. Knowles pin
   Use: proximal femoral neck fracture with tenuous blood supply
10. Radiolucent absorbable polycarbonate screw = "stealth hardware"

B. Washer
   1. Flat washer = increase surface area over which force is distributed
   2. Serrated washer = spiked edges used for affixing avulsed ligaments / small avulsion fractures

C. Plates
   › compression plate
   Use: compression of tension side of stable fractures
   › neutralization plate = protects fracture from bending, rotation + axial-loading forces
   › buttress plate = support of unstable fractures in compression / axial loading
   1. Straight plate
      (a) straight plate with round holes
      (b) dynamic compression plate (DCP) = oval holes
      (c) tubular plate = thin pliable plate with concave inner surface
      (d) reconstruction plate = thin pliable / malleable plate to allow bending, twisting, contouring
   2. Special plates
      T-shaped, L-shaped, Y-shaped, cloverleaf, spoon, cobra, condylar blade plate, dynamic compression screw system

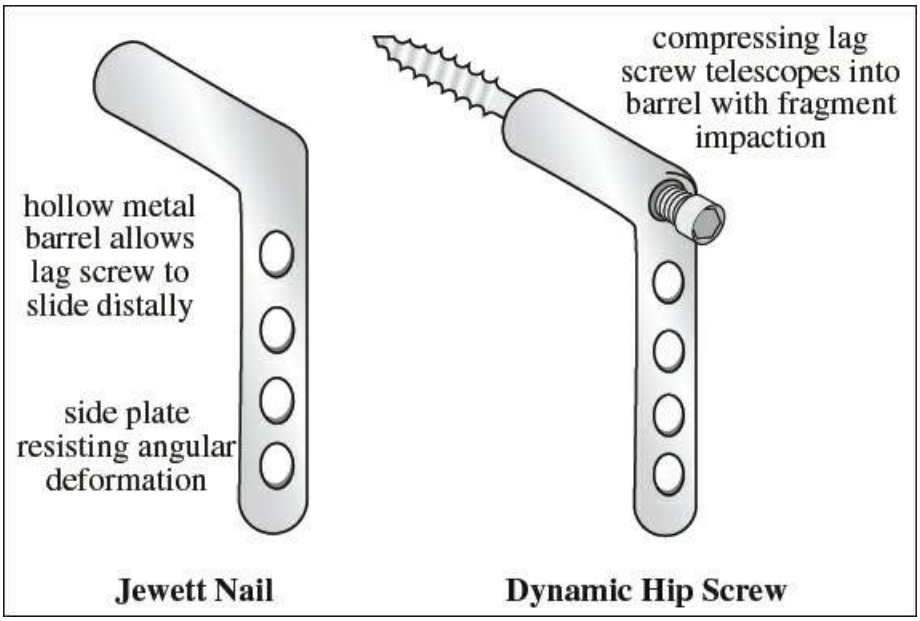
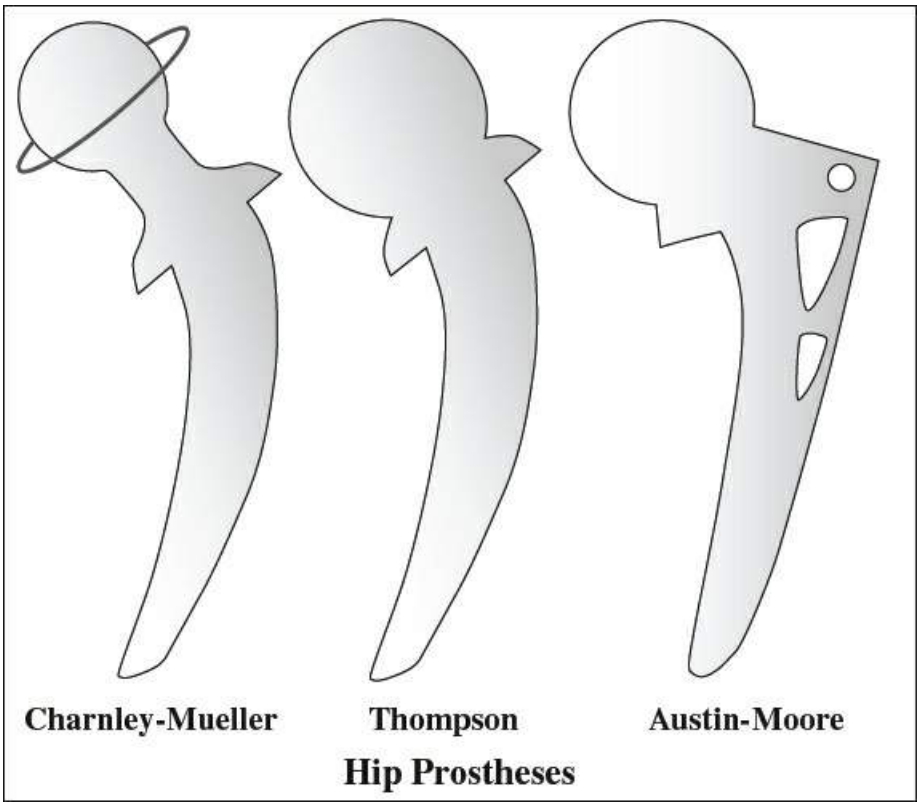
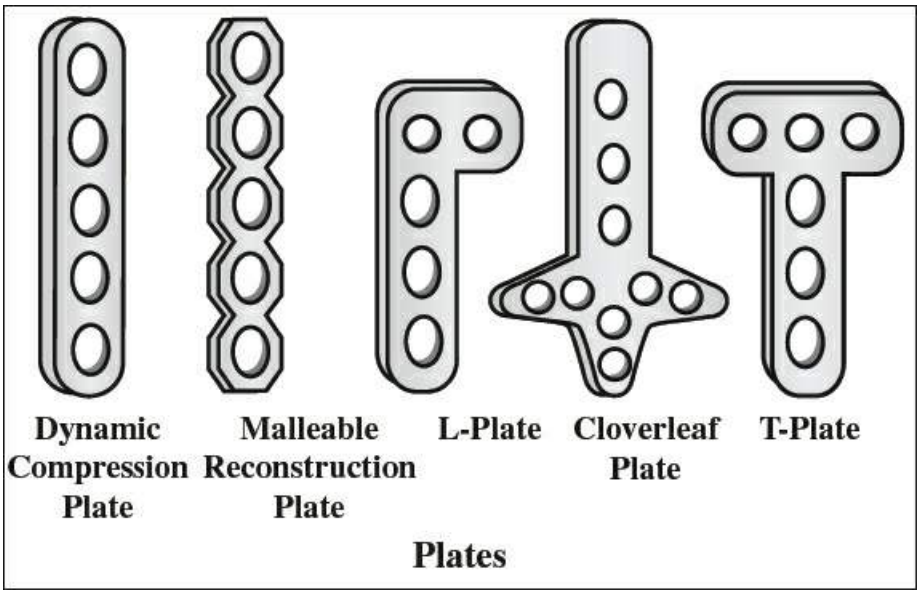
Screws



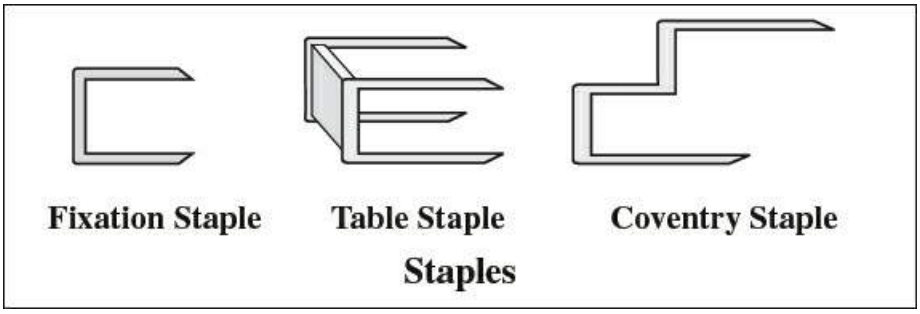
compressing lag screw telescopes into barrel with fragment impaction
hollow metal barrel allows lag screw to slide distally
side plate resisting angular deformation
Jewett Nail
Dynamic Hip Screw

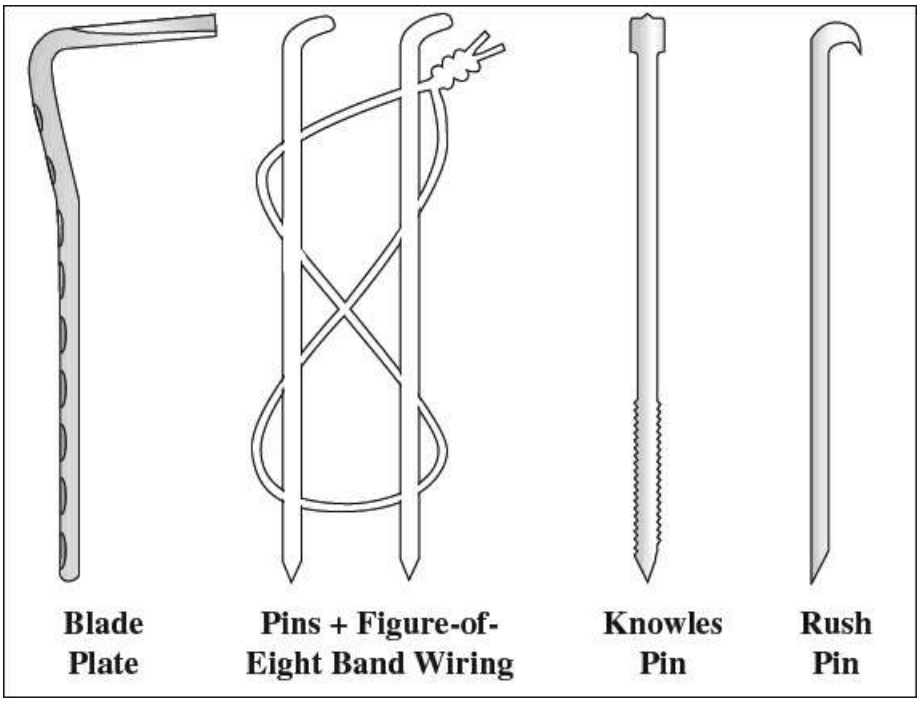


Hip Prostheses



Plates





D. Staples
Fixation = bone = epiphyseal = fracture staples with smooth / barbed surface
› Coventry = stepped osteotomy staple
› stone = table staple

E. Wires
1. K wire (= Kirschner wire) = unthreaded segments of extruded wire of variable thickness
Use: temporary fixation
2. Cerclage wiring = wire placed around bone
Use: fixation of comminuted patellar fracture, holding bone grafts in position
3. Tension band wiring = figure-of-eight wire placed on tension side of bone
Use: olecranon / patellar fractures

External Fixation Devices

= smooth / threaded pins / wires attached to an external frame

(a) unilateral pin = enters bone only from one side
1. Steinmann pin = large-caliber wire with pointed tip

2. Rush pin = smooth intramedullary pin
3. Schanz screw = pin threaded at one end to engage cortex, smooth at other end to connect to external fixation device
4. Knowles pin (for femoral neck fracture)

(b) transfixing pin = passes through extremity supported by external fixation device on both ends

Intramedullary Fixation Devices

Use: diaphyseal long bone fractures

(a) nail / pin= driven into bone without reaming

(b) rod = solid / hollow device with blunted tip driven into reamed channel (reaming disrupts blood supply and may decrease the rate of fracture healing)

(c) interlocking nail = accessory pins / screws / deployable fins placed to prevent rotation

1. Rush pin = beveled end + hooked end
   Use: fibular shaft / tubular bone fractures
2. Ender nail = chisel-like end + oval in cross section; usually 3–4 at a time pushed through a cortical hole up or down the shaft across fracture under fluoroscopic control
   Use: humeral shaft
3. Sampson rod = slightly curved rigid rod with fluted surface
4. Küntscher nail = cloverleaf in cross section with rounded tip
   Use: tibial / femoral shaft fracture
5. Zickel nail
   Use: subtrochanteric fracture

ANATOMY AND METABOLISM OF BONE

BONE MINERALS

Bone composition: highly metabolic tissue consisting of type I collagen (40%) + hydroxyapatite (45%) + water (15%)

Bone mass: function of

(a) peak bone mass attained in 3rd decade of life influenced by dietary calcium intake during adolescence, sex hormone status (male > female), nutrition, physical activity, genetic factors (Blacks > Whites > Asians)

(b) rate of age-related bone loss = endosteal + Haversian resorption + loss of cancellous bone (particularly in vertebrae) without replacement by new bone

Bone resorption: in the elderly due to

(a) estrogen deficiency = rate increased at menopause

(b) diminished fractions of bioavailability for testosterone

(c) vitamin D insufficiency → secondary hyperparathyroidism

(d) declining levels of physical activity

(e) reduced serum levels of insulin-like growth factors

Calcium

A. 99% in bone

B. serum calcium

(a) protein-bound fraction (albumin)

(b) ionic (pH-dependent) 3% as calcium citrate / phosphate

Absorption: facilitated by vitamin D

Excretion: related to dietary intake; > 500 mg/24 hours (= hypercalciuria)

Phosphorus

Absorption: requires sodium; decreased by aluminum hydroxide gel in gut

Excretion: increased by estrogen, parathormone decreased by vitamin D, growth hormone, glucocorticoids

BONE MARROW

4th largest organ, 5% of body weight

Components: trabeculae, hematopoietic cells, fat cells, stroma, and RES cells, sinusoids

(a) **Red marrow**

= hematopoietically active (by EGA of 20 weeks) with a rich + extensive vascular supply, composed of erythrocyte + leukocyte + platelet precursors

› in adolescence: 40% fat, 40% water, 20% protein

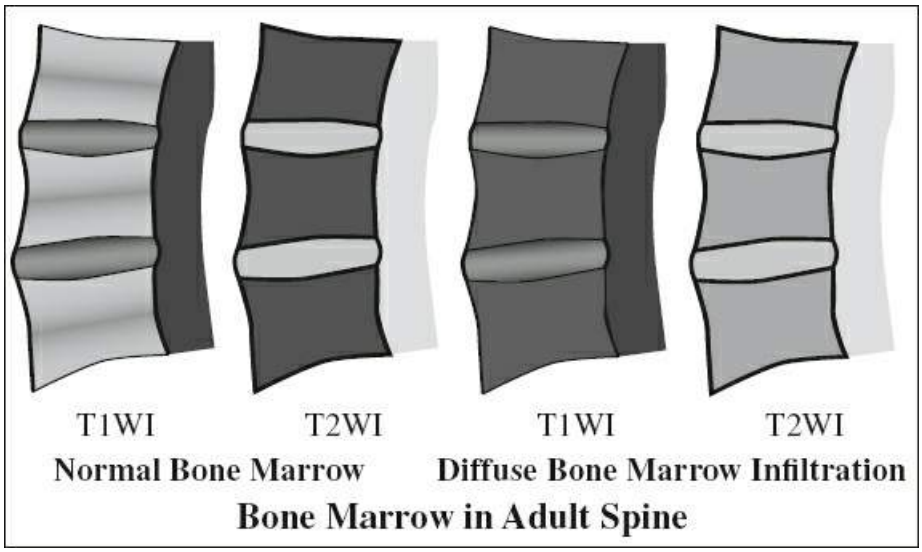
› at age 70: 60% fat, 30% water, 10% protein

(b) **Yellow / fatty marrow**

with a sparse vascular network

› composed of 80% fat, 15% water, 5% protein

Distribution: conversion from red to fatty marrow throughout life



@ birth: marrow contains primarily hematopoietically active cells

@ 1 year: 1st conversion in phalanges of feet

@ puberty: conversion in diaphyses of long bones

@ 1st 2 decades: conversion begins in appendicular skeleton progressing to axial skeleton; conversion in long bones begins in diaphysis > distal metaphysis > proximal metaphysis

@ 3rd decade: residual red marrow remains in skull, spine, flat bones (clavicle, sternum, scapula, ribs), proximal 25–30% of humerus and femur; acetabulum superiorly + medially > ilium > around sacroiliac joints

NUC:

(1) Labeled leukocyte scintigraphy

(2) Bone marrow scintigraphy

MR:

Anatomic sites for MRI marrow screening:

› spine (SAG images)

› pelvis + femora (COR images)

√ red marrow:

√ iso- / slightly hyperintense compared with muscle on T1WI + T2WI (longer T1 relaxation time)

√ hypointense compared with fatty marrow (shorter T2 relaxation time)

√ yellow marrow:

√ isointense compared with subcutaneous fat on T1WI (relatively short T1 relaxation time compared with water)

√ T2-iso- / hypointense compared with subcutaneous fat

√ hyperintense compared with muscle on T2WI (long T2 relaxation time compared with water)

◊ Differences in SI are maximized on T1WI but diminished on T2WI

◊ Marrow signal iso- / hypointense to muscle + disk on T1WI in adults is abnormal!
◊ After 10 years of age red marrow is hyperintense to muscle on T1WI
◊ Fat-suppressed T2-FSE and STIR are very sensitive for pathology!

Bone Marrow Reconversion

= reversal of yellow to red marrow

1. Obesity
2. Pulmonic pathology
3. Smoking
4. High altitude
5. High-performance athletes
6. GCSF (granulocyte stimulating factor)

Parathormone Function		
	PTH Action	*Net Effect*
Principal function:	phosphate diuresis resorption of Ca + P from bone	Serum: increase in Ca decrease in P
Secondary function:	resorption of Ca from gut reabsorption of Ca from renal tubule	Urine: increase in Ca increase in P

HORMONES

Parathormone

= key modulator of calcium homeostasis

Origin: chief cells of 4 parathyroid glands

Major stimulus: low levels of serum calcium ions (action requires vitamin D presence)

Target organs:

BONE: mobilization of calcium at bone surface ← ↑ in osteoclastic activity

KIDNEY: (a) ↑ renal tubular absorption of calcium
(b) ↓ tubular reabsorption of phosphate (+ amino acids) = phosphaturia
(c) ↑ hydroxylation of 25-OH vitamin D *(see below under vitamin D metabolism)*

GUT: ↑ absorption of calcium + phosphorus

Major function:

- increase of serum calcium levels
- increase in serum alkaline phosphatase (50%)

Vitamin D Metabolism

required for

(1) adequate calcium absorption from gut
(2) synthesis of calcium-binding protein in intestinal mucosa
(3) parathormone effect (→ stimulation of osteoclastic + osteocytic resorption of bone)

Biochemistry:

inactive form of vitamin D3 present through diet / exposure to sunlight (photoconversion of 7-dehydrocholesterol in skin to cholecalciferol)

› vitamin D3 is converted into **25-OH-vitamin D3** by liver

› 25-OH-vitamin D3 is converted into **1,25-OH vitamin D3** (biologically most active form = hormone) by kidney

(a) ↑ intestinal absorption of calcium

(b) binds to intranuclear receptors within bone → production of mediators for calcium mobilization + mineralization of organic matrix

Stimulus for conversion: (1) Hypophosphatemia
(2) PTH elevation

Action:

(a) BOWEL: (1) ↑ absorption of calcium from bowel
(2) increased absorption of phosphate from distal small bowel

(b) BONE: (1) proper mineralization of osteoid
(2) mobilization of calcium + phosphate (potentiates parathormone action)

(c) KIDNEY: (1) ↑ absorption of calcium from renal tubule
(2) ↑ absorption of phosphate from renal tubule

(d) CELL: binds to receptor on nucleus → activation of genes involved in calcium homeostasis

Calcitonin

secreted by parafollicular cells of thyroid

Major stimulus: increase in serum calcium

Target organs:

(a) BONE: (1) inhibits parathormone-induced osteoclasis by reducing number of osteoclasts
(2) enhances deposition of calcium phosphate; responsible for sclerosis in renal osteodystrophy

(b) KIDNEY: inhibits phosphate reabsorption in renal tubule

(c) GUT: increases excretion of sodium + water into gut

Major function: decreases serum calcium + phosphate

PHYSIS

= Growth Plate

Four distinct zones of cartilage in longitudinal layers

(1) Germinal zone = small cells
adjacent to epiphyseal ossification center

(2) Zone of proliferation = flattened cells
arranged in columns

(3) Zone of hypertrophy = swollen vacuolated cells
(a) zone of maturation
(b) zone of degeneration
(c) zone of provisional calcification

(4) Zone of primary and secondary spongiosa

NORMAL SHOULDER JOINT ANATOMY

Acromion Types

Normal anatomic variants can cause compression with an increased incidence of rotator cuff tears with type II and type III acromions according to cadaveric studies

Suprascapular Nerve

= mixed motor and sensory peripheral nerve

Origin: upper trunk of brachial plexus (roots of C5 and C6, variably from C4)

Course: deep to omohyoid m. and trapezius m. → *suprascapular notch* (beneath superior transverse scapular ligament) → supraspinatus fossa → around scapular spine → *spinoglenoid notch* → infraspinatus fossa

Innervation:

(a) supraspinatus m. (motor); glenohumeral joint + acromioclavicular joint + rotator cuff + posterior $^{2}/_{3}$ of joint capsule (sensory)

(b) infraspinatus m. (motor)

Rotator Cuff Muscles

mnemonic: SITS

Supraspinatus
Infraspinatus
Teres minor
Subscapularis

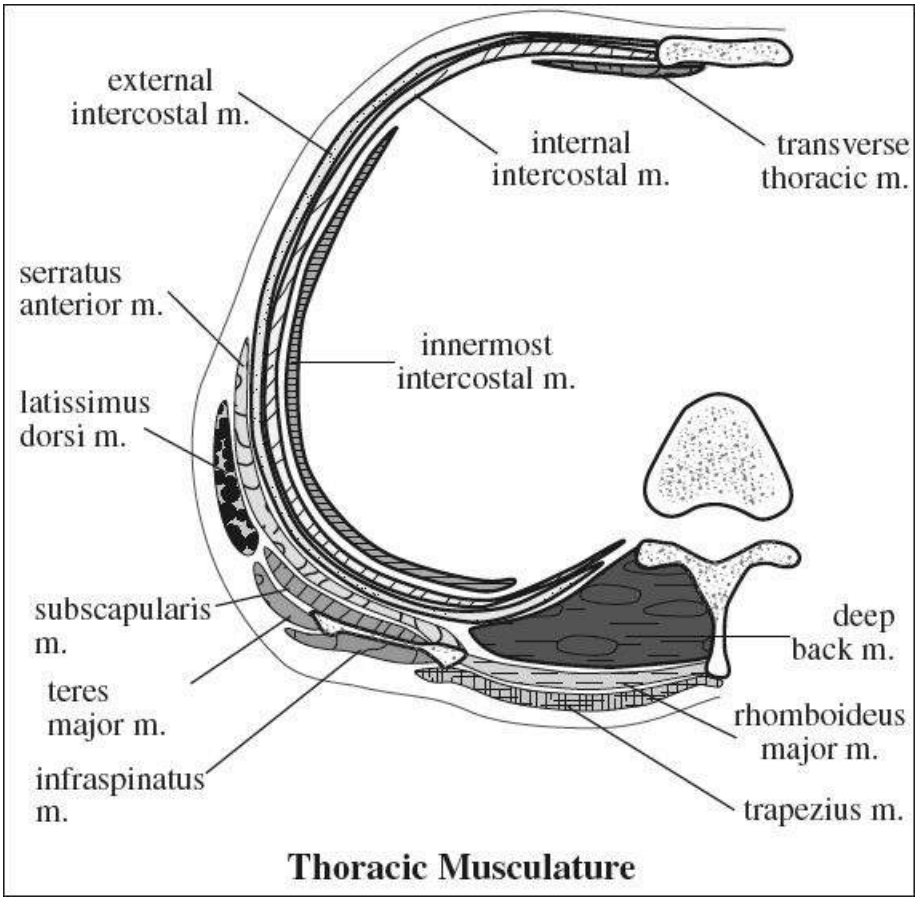
Glenoid Labrum

= 4-mm–wide triangular fibrocartilaginous rim (= extension of the glenoid fossa) with considerable variation in shape

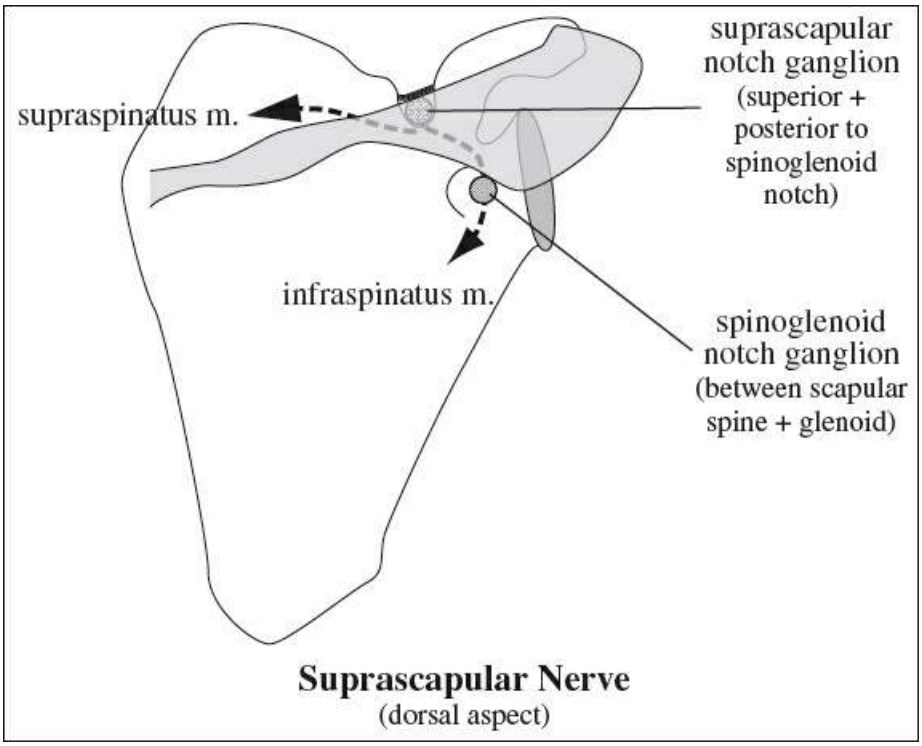
Function: stabilizes glenohumeral joint by deepening and increasing surface area of glenoid fossa and providing attachment for glenohumeral ligaments and tendon of long head of biceps

√ low SI on all pulse sequences; susceptible to magic angle artifact at 55°

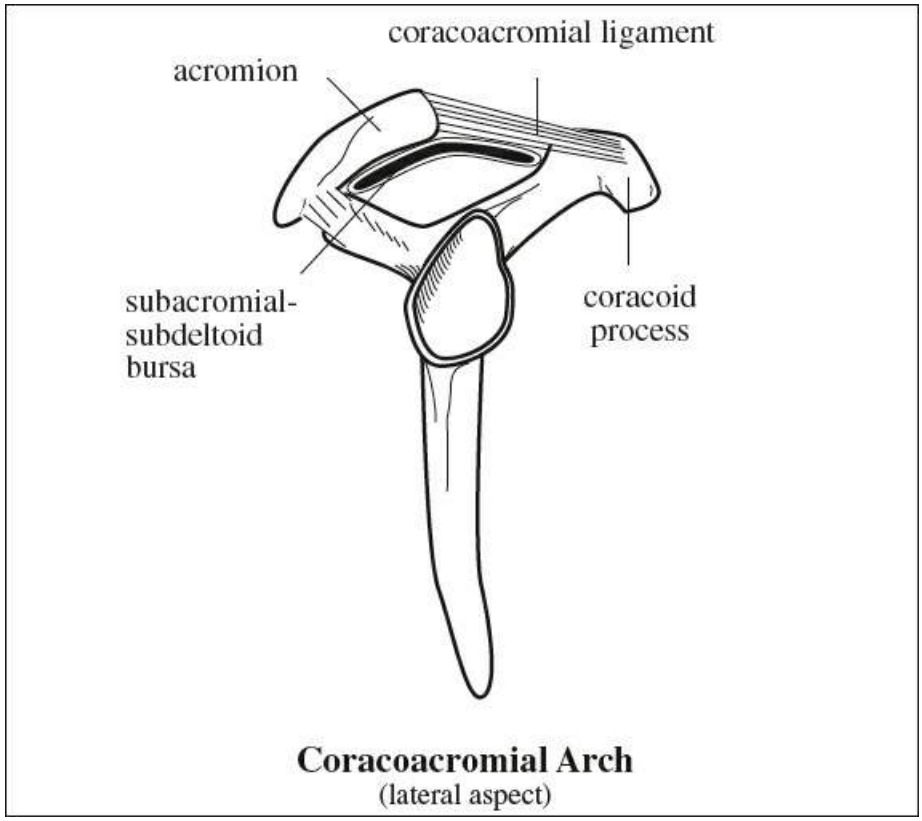
√ variations in attachment above epiphyseal line (= junction of upper + middle thirds of glenoid body fossa): limited to sector from 11 to 3 o'clock (anterior = 3 o'clock, posterior 9 o'clock, superior 12 o'clock, inferior 6 o'clock):



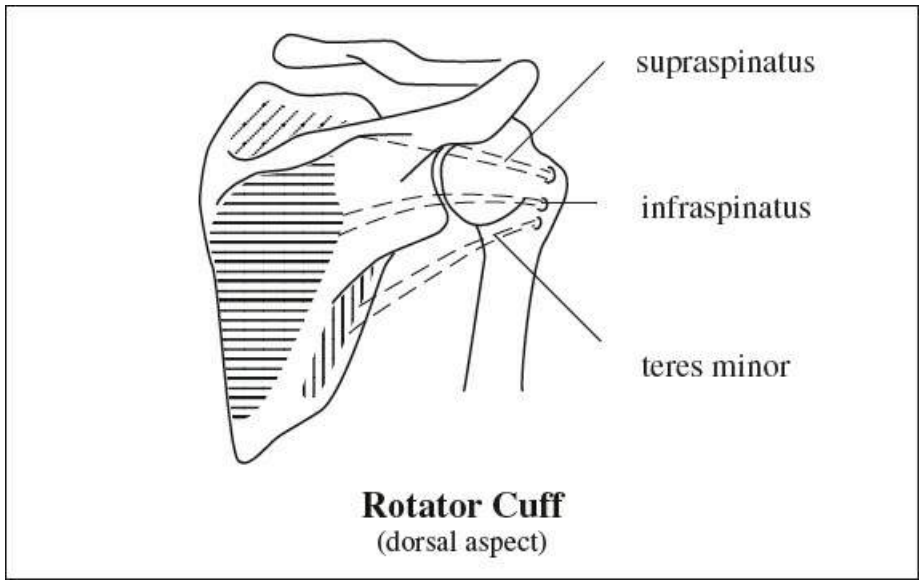
Thoracic Musculature



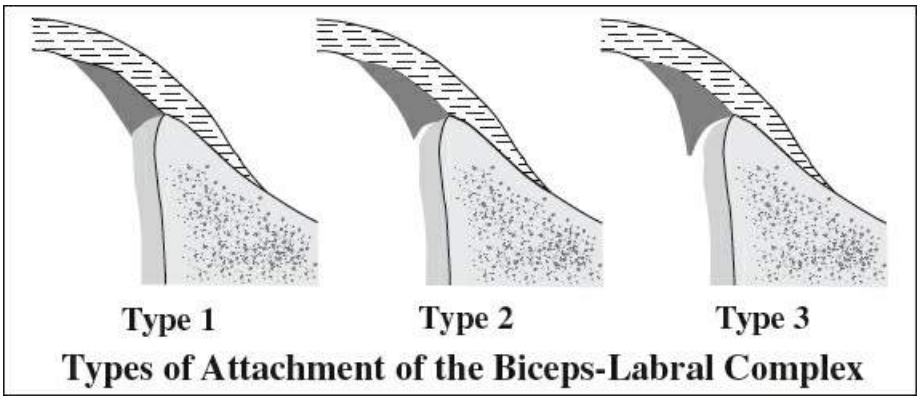
Suprascapular Nerve
(dorsal aspect)



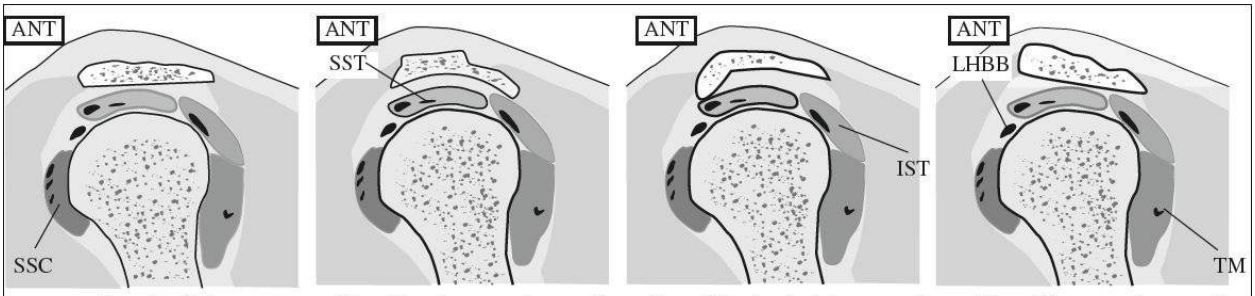
Coracoacromial Arch
(lateral aspect)



Rotator Cuff
(dorsal aspect)



Types of Attachment of the Biceps-Labral Complex



Acromion Types

(on sagittal view of shoulder)

IST = infraspinatus, LHBB = long head of biceps brachii tendon, SSC = subscapularis, SST = supraspinatus, TM = teres minor

Muscle Attachments of Shoulder

Name of Muscle	*Origin*	*Insertion*
Deltoid	lateral third of clavicle	deltoid tuberosity of humerus
	lateral border of acromion	deltoid tuberosity of humerus
	lower part of spinous process of scapula	deltoid tuberosity of humerus
Subscapularis	medial ²/₃ of costal surface of scapula	superior aspect of lesser tubercle of humerus
Pectoralis major		
› clavicular portion	medial half of clavicle	crest of greater tubercle of humerus
› sternocostal portion	manubrium + corpus of sternum	crest of greater tubercle of humerus
› abdominal portion	anterior sheath of rectus abdominis	crest of greater tubercle of humerus
Pectoralis minor	2nd / 3rd–5th ribs	superomedial aspect of coracoid process
Biceps brachii		
› long head	supraglenoid tubercle of scapula	tuberosity of radius
› short head	tip of coracoid process	tuberosity of radius
Coracobrachialis	tip of coracoid process	medial surface of middle third of humerus
Supraspinatus	supraspinatus fossa of scapula	greater tubercle of humerus, highest facet
Infraspinatus	infraspinatus fossa of scapula	greater tubercle of humerus, middle facet
Teres minor	upper ²/₃ of lateral border of scapula	greater tubercle of humerus, lower facet
Teres major	dorsum of inferior angle of scapula	inferior crest of lesser tubercle of humerus

- √ occasionally partially deficient anterosuperiorly
- √ labrum continuous with glenoid articular cartilage inferior to epiphyseal line
- √ triangular / rounded shape on cross-sectional image:
  - √ round / cleaved / flat larger anterior labrum
  - √ flat / round smaller posterior labrum

√ blends superiorly with biceps tendon

Superior Sublabral Sulcus / Recess

= variations in depth of sulcus between osseous glenoid rim + labrum

Location: 12 o'clock position at the site of biceps tendon attachment (in sagittal plane); NOT posterior to labral attachment of long head of biceps

Size: consistently 1–2 mm wide throughout its length

Types of attachment of biceps-labral complex (BLC):

(1) BLC firmly adherent to superior pole of glenoid without sulcus / sublabral foramen

(2) small sulcus = BLC attached several mm medially; hyaline cartilage beneath labrum; may be continuous with sublabral foramen which is anterior to BLC

(3) deep probe-patent sulcus = meniscoid labrum with large sulcus between labrum and hyaline cartilage

√ may be continuous with sublabral foramen

√ best visualized on oblique coronal CT / MR

DDx: type II SLAP lesion (more lateral in oblique coronal plane)

Biceps Brachii

= muscle with 2 separate origins

Short Head of Biceps Brachii Muscle

Function: ineffectual elevator of the arm

Origin: apex of coracoid process (together with coracobrachialis tendon)

Course: extraarticular

Insertion: radial tuberosity (conjoined distal tendon of the short and long head)

Long Head of Biceps Brachii Muscle

Function: ineffectual elevator of the arm

Origin: supraglenoid tubercle of scapula ± posterosuperior glenoid labrum

Course: traverses rotator interval + descends through intertubercular sulcus (bicipital groove)

Insertion: radial tuberosity (conjoined distal tendon of the short and long head)

Tendon of Long Head of Biceps Brachii

√ attached to anterosuperior aspect of glenoid rim with fibers to

(a) anterosuperior labrum (biceps-labral complex)

(b) posterosuperior labrum (biceps-labral complex)

(c) supraglenoid tubercle

(d) base of coracoid process

√ exits joint through intertubercular groove

√ secured to intertubercular groove by transverse lig.

√ surrounded by slinglike band of CHL superiorly and superior GHL anteriorly

Coracohumeral Ligament

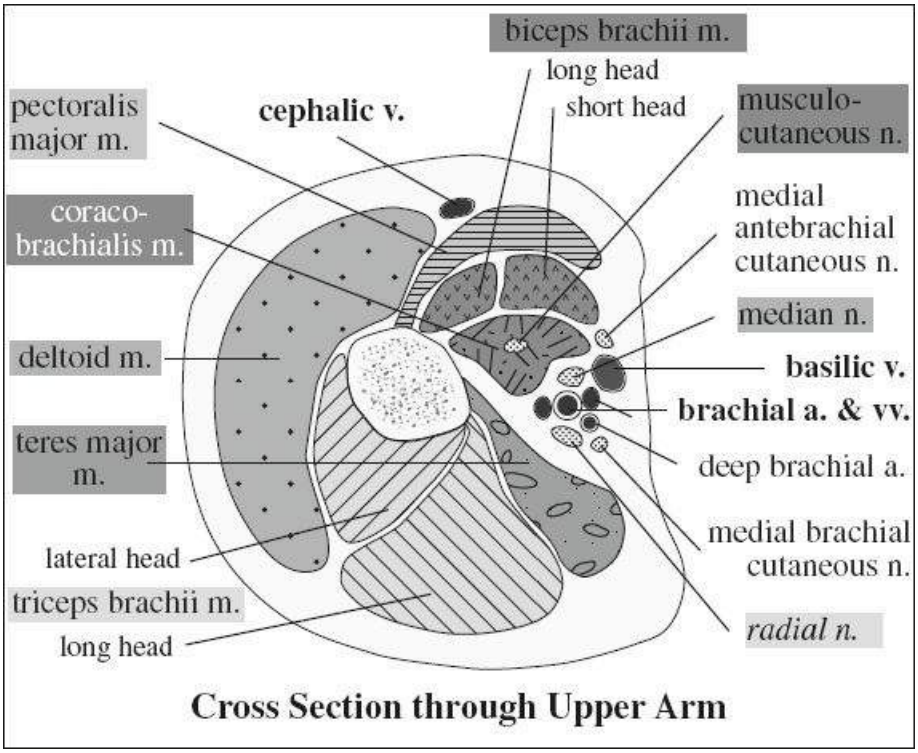
= most superficial capsular structure of rotator interval blending with fibers of subscapularis + supraspinatus tendons at their insertions forming roof of rotator interval with

(a) larger (lateral) band
Insertion: greater tuberosity + fibers of supraspinatus tendon
(b) smaller (medial) band crosses over biceps tendon + forms anterior covering around biceps tendon blending with fibers of subscapularis tendon
Insertion: proximal aspect of lesser tuberosity

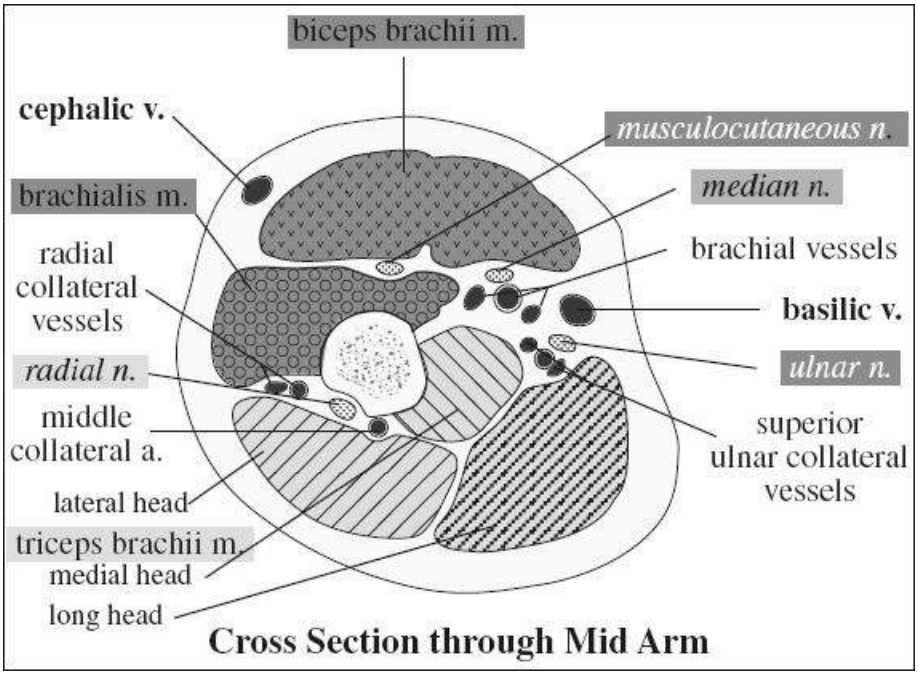
Origin: lateral aspect of base of coracoid process

Course: runs parallel to superior glenohumeral lig. posteriorly + laterally to fuse with joint capsule

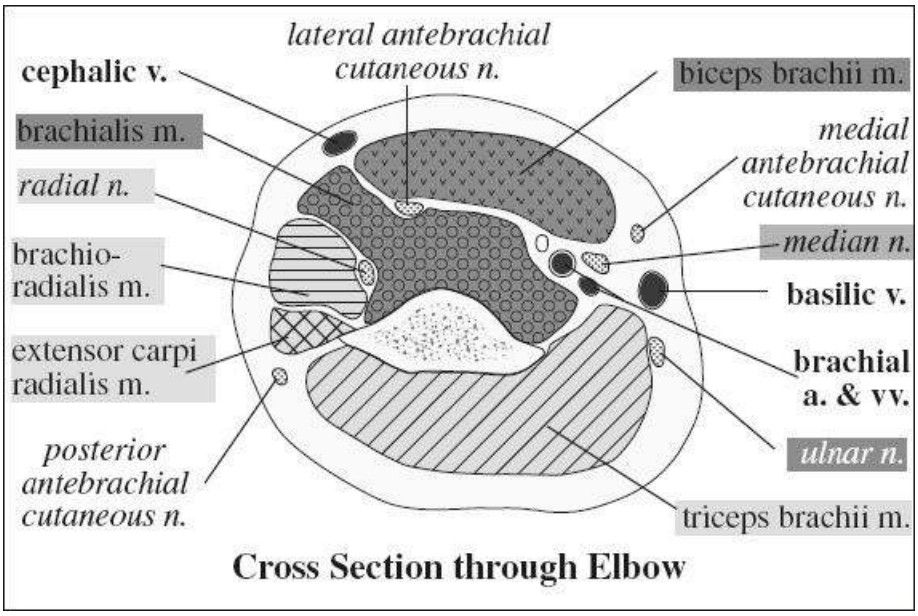
Variations of insertion:
(a) into rotator interval
(b) to supraspinatus tendon / subscapularis tendon
(c) to supraspinatus + subscapularis tendons



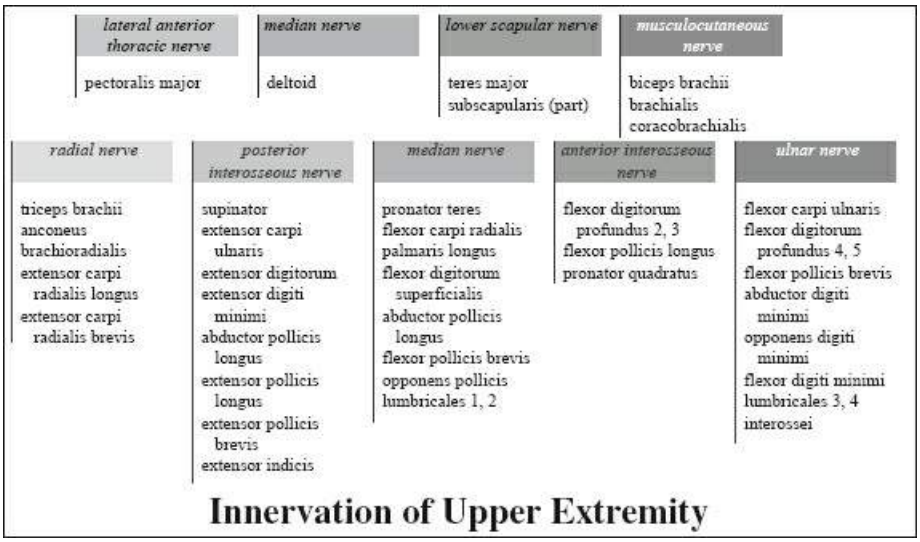
Cross Section through Upper Arm



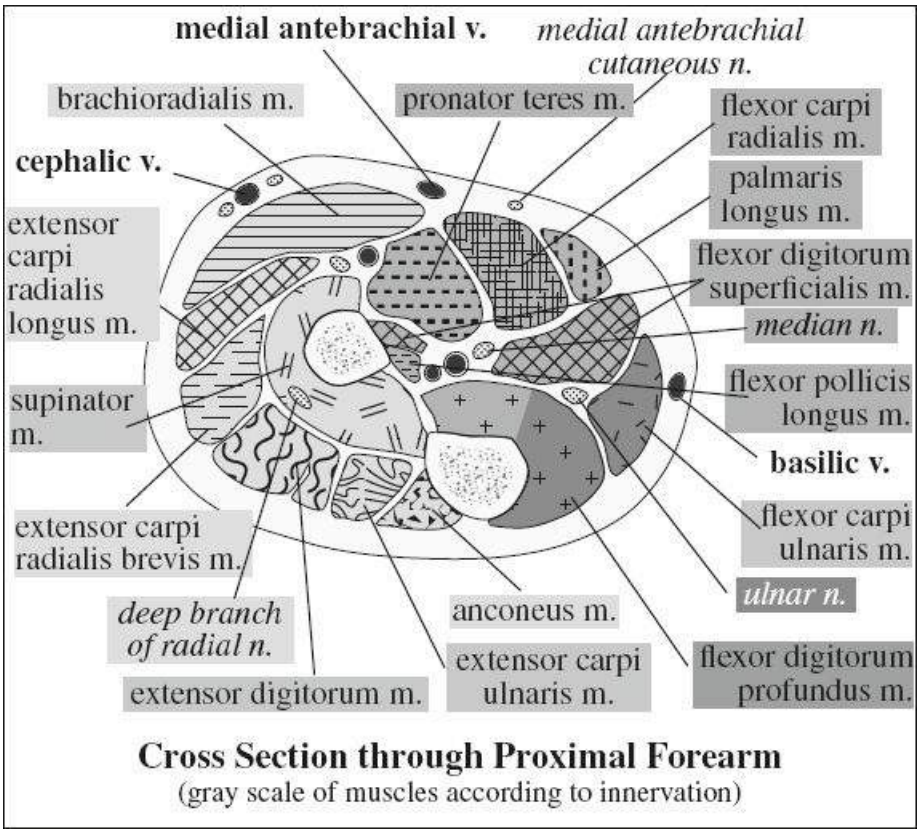
Cross Section through Mid Arm



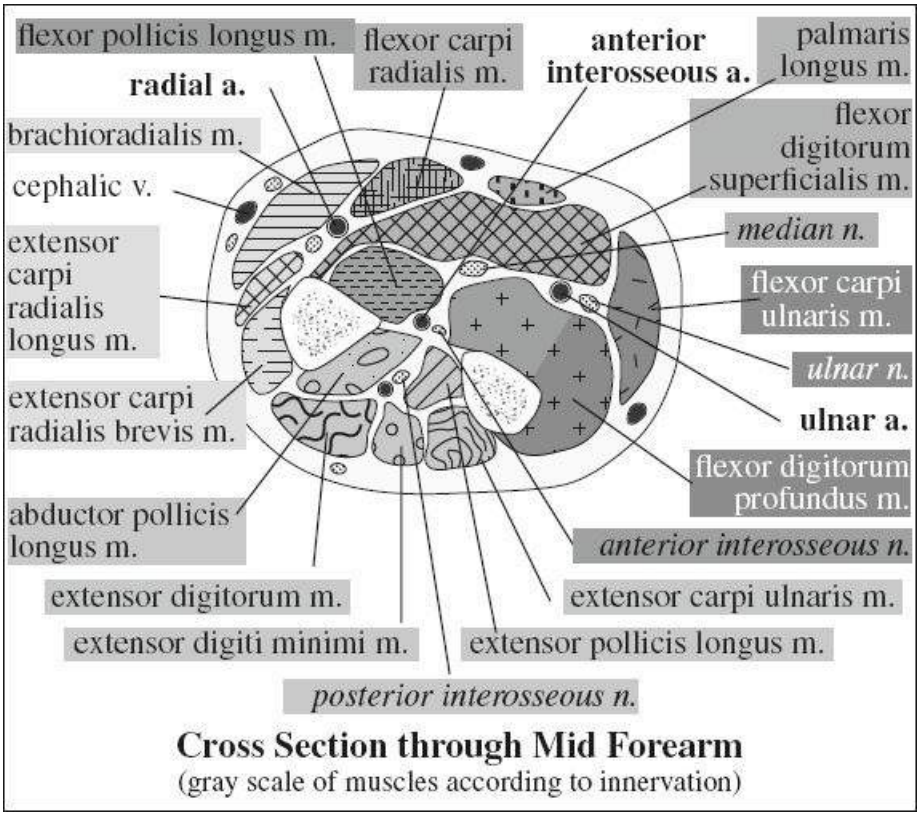
Cross Section through Elbow



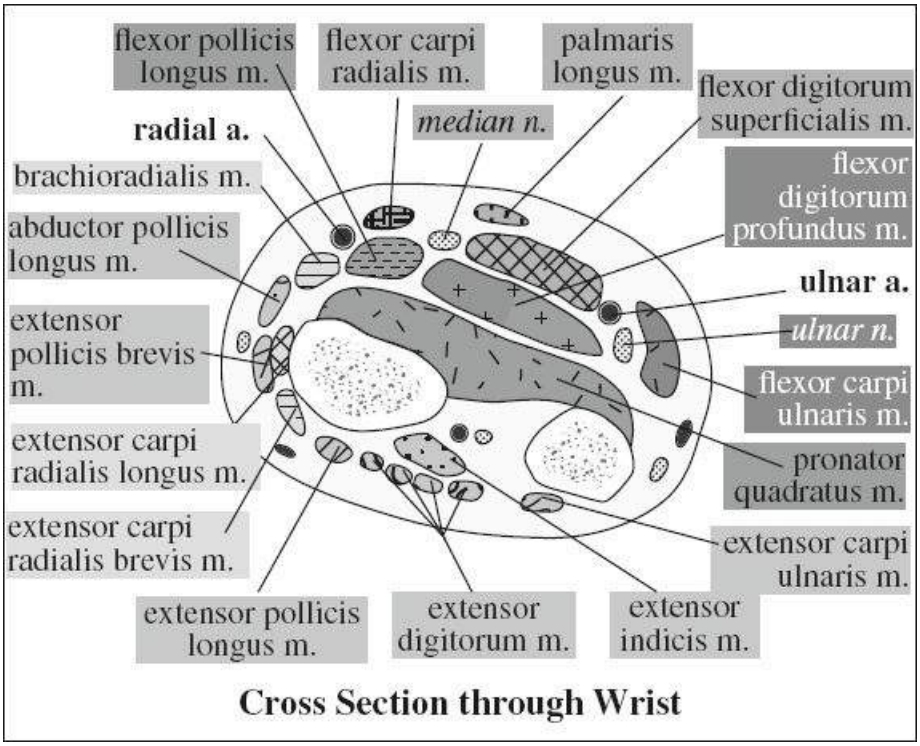
Innervation of Upper Extremity



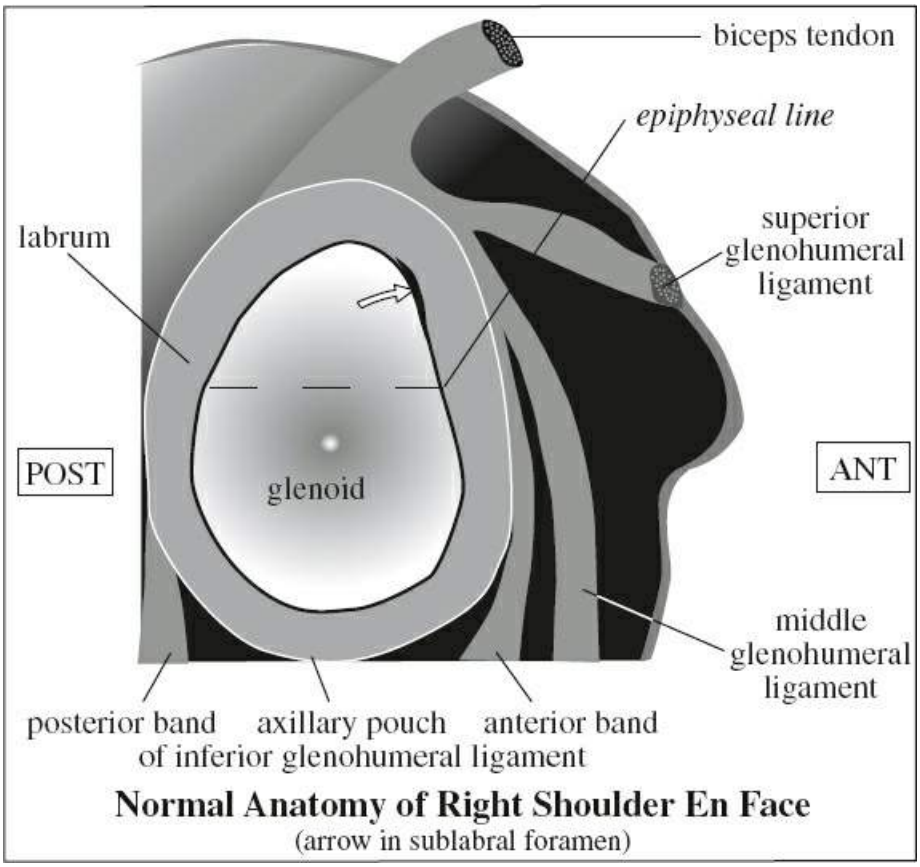
Cross Section through Proximal Forearm
(gray scale of muscles according to innervation)



Cross Section through Mid Forearm
(gray scale of muscles according to innervation)

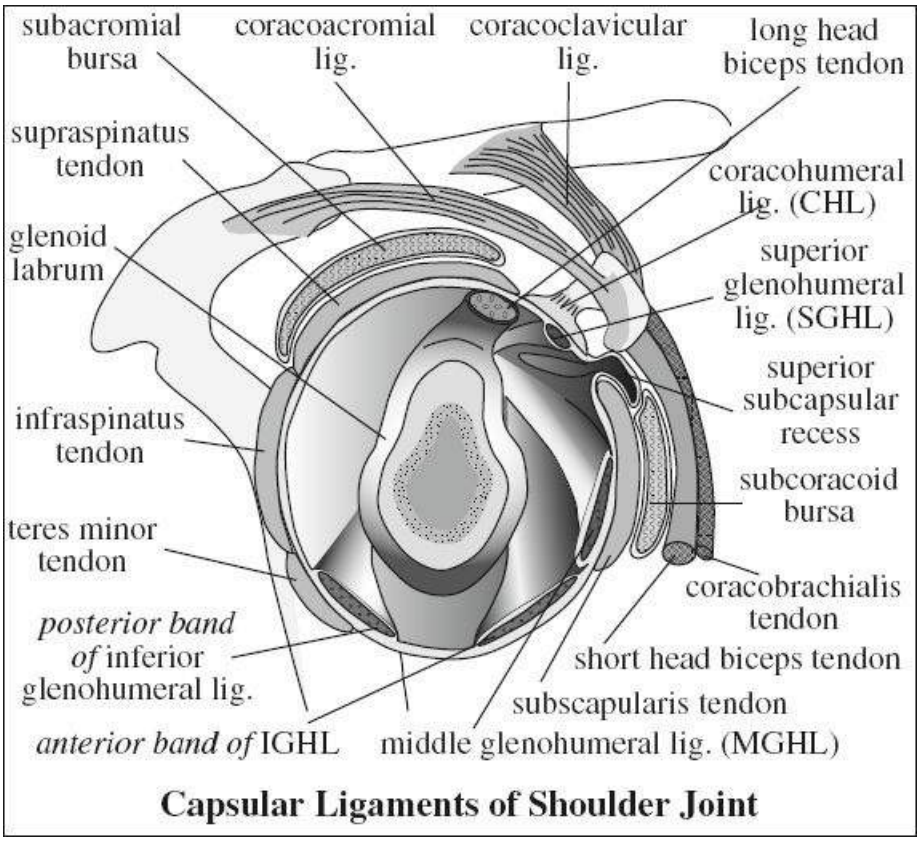


Cross Section through Wrist



Normal Anatomy of Right Shoulder En Face
(arrow in sublabral foramen)

Buford Complex



Capsular Ligaments of Shoulder Joint

Coracoacromial Ligament

= strong triangular fibrous band that extends from coracoid process to acromion forming protective arch superficial to rotator cuff

Rotator Interval

= triangular space between superior border of subscapularis tendon + anterior border of supraspinatus tendon

= portion of glenohumeral joint capsule that is not reinforced by overlying rotator cuff muscles

Apex: combined fibers from subscapularis tendon with contributions from supraspinatus tendon and CHL + posterior lamina of tendon of pectoralis major muscle ("transverse ligament") bridging bicipital groove

Base: coracoid process with origin of coracohumeral lig. medially

Content: intraarticular portion of long biceps tendon, coracohumeral ligaments

Glenohumeral Ligaments

= thickened collagenous bands of joint capsule functioning as shoulder stabilizers

Superior Glenohumeral Ligament (SGHL)

= most consistently identified capsular ligament

Function: passive restraint to inferior translation of adducted shoulder

Origin: superior glenoid tubercle (= upper pole of glenoid cavity) just anterior to origin of biceps tendon and base of coracoid process

Course: passes between supraspinatus + subscapularis in plane perpendicular to middle glenohumeral ligament + parallel to coracoid process
Insertion: lesser tuberosity at bicipital groove
√ merges with coracohumeral ligament in rotator cuff interval
√ best visualized on transverse CT / MR

Middle Glenohumeral Ligament (MGHL)
= varies most in size + attachment; may be absent
Function: limits anterior translation with external rotation + moderate abduction
Origin: medially on scapular neck / superior portion of anterior glenoid rim
Course: obliquely from superomedial to inferolateral
Insertion: medial from lesser tuberosity at anterior aspect of anatomic neck
• taught during external rotation
√ blends into capsular sheath of subscapularis tendon
√ may be thick + cordlike
√ best visualized on sagittal / transverse CT / MR

Inferior Glenohumeral Ligament (IGHL)
= important stabilizer of anterior shoulder joint
Function: resists anteroinferior glenohumeral translation
Course: from anteroinferior labrum to humeral metaphysis
• ligament + labrum function as single unit
= **inferior glenohumeral labral-ligamentous complex** *(IGHLC)*
• taught during ABER position
√ attaches to inferior $^{2}/_{3}$ of the circumference of the entire labrum for a variable distance
√ forms sleeve of continuous tissue with glenoid rim, capsule, periosteum, humeral metaphysis
√ best visualized on MR arthrography / joint effusion
Parts:
1. Anterior band of IGHL = thickened anterior-superior extent of ligament
◊ Critical to passive joint stabilization!
2. Axillary pouch
3. Posterior band of IGHL (usually thinner)

Normal Anatomic Variants of Shoulder

Sublabral Foramen = Sublabral Hole
= sublabral hole between labrum + glenoid
Prevalence: 12% of individuals
Location: 2 o'clock position anterior to biceps tendon attachment
√ may coexist with sublabral recess
DDx: labral tear (isolated tears are rare in this region)

Buford Complex
= cordlike thickening of middle glenohumeral ligament directly attaching to anterosuperior glenoid + absence of anterosuperior labrum

Prevalence: 1.5% of individuals
Location: 2 o'clock position anterior to biceps tendon attachment
√ course of middle glenohumeral ligament can be followed on serial images from origin to insertion
√ may coexist with sublabral recess
DDx: displaced anterosuperior labral fragment

Cysts and Bursae of Shoulder

1. Subacromial-subdeltoid bursa
2. Superior subscapular recess / subscapularis bursa
   Location: between subscapularis muscle + anterior surface of scapula with extension above superior margin of subscapularis tendon
   (a) **Foramen of Weitbrecht**
   = opening between SGHL and MGHL
   (b) **Foramen of Rouvière**
   = opening between MGHL and IGHL
3. Subcoracoid bursa
   Location: between anterior surface of subscapularis muscle + coracoid process with extension along merged tendons of coracobrachialis m. + short head of biceps
   √ no communication with glenohumeral joint
   √ ± communication with subacromial-subdeltoid bursa
   √ often associated with rotator cuff + interval tears
4. AC joint cyst
5. Glenoid labral cyst

ELBOW

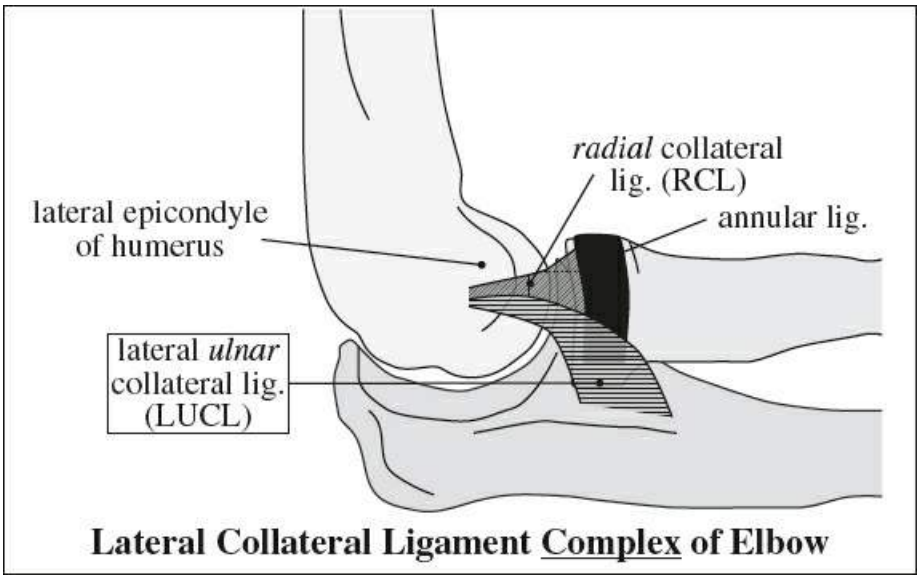
Elbow Joint Stabilizers

A. Medial / (ulnar) collateral ligament complex (MCL)
   Origin: anteroinferior margin of medial epicondyle
   (a) anterior bundle (functionally important): inserts on sublime tubercle (= anteromedial aspect of coronoid process) – resists valgus forces
   (b) posterior bundle
   (c) transverse (oblique) bundle = Cooper lig.
B. Lateral / radial collateral ligament complex
   Origin: inferior margin of lateral epicondyle
   1. Radial collateral ligament (RCL)
      Insertion: on annular ligament
   2. Lateral ulnar collateral ligament (LUCL): functionally important – resists varus forces
      Insertion: distal to tubercle of crista supinatoris ulnae
   3. Annular ligament

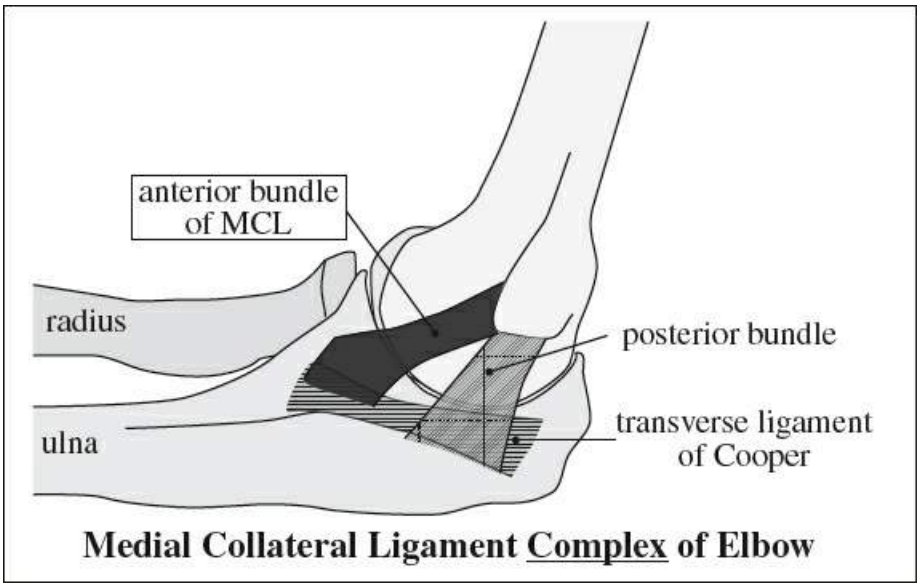
Functionally primary stabilization:

1. Ulnohumeral articulation
2. Anterior bundle of MCL
3. LUCL

Functionally secondary stabilization:

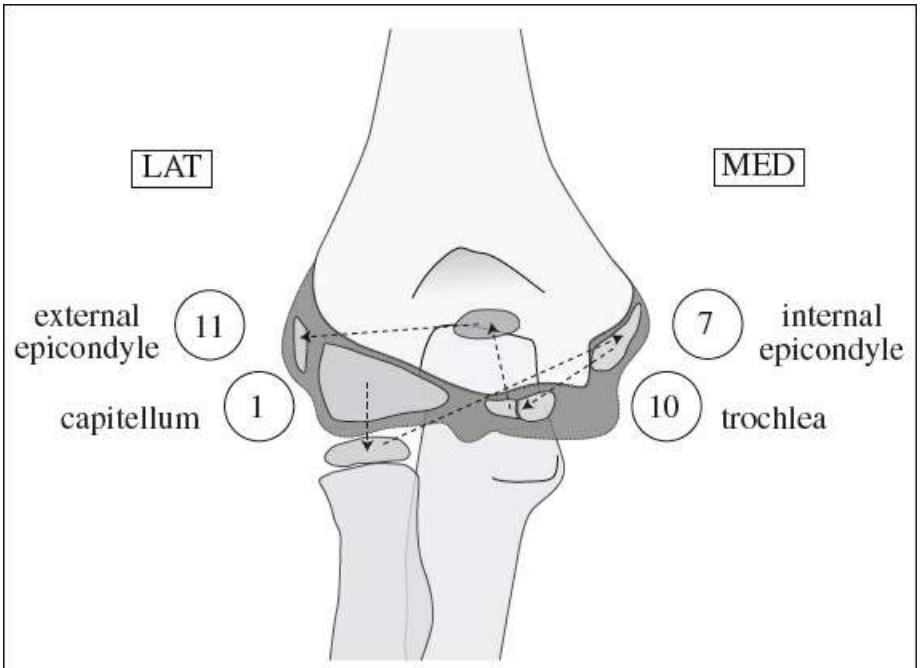


Lateral Collateral Ligament Complex of Elbow



Medial Collateral Ligament Complex of Elbow

Occurrence of Bone Centers at Elbow		
mnemonic: CRITOE		
Capitellum	**1** yr	(M 1–11 m, F 1–26 m)
Radial head	4 yrs	(3–6 yrs)
Internal (medial) humeral epicondyle	**7** yrs	(M 5–8 yrs, F 7–9 yrs)
Trochlea	**10** yrs	(M 7–11 yrs, F 8–13 yrs)
Olecranon	10 yrs	(9–10 yrs)
External (lateral) humeral epicondyle	**11** yrs	(F 8–11 yrs, M 9–13 yrs)



Occurrence of Bone Centers in Elbow *(numbers in years)*
mnemonic: "Nelson's X: 1, 7, 10, 11 years"

1. Radiocapitellar articulation
2. Common flexor-pronator tendon
3. Common extensor tendon
4. Joint capsule

Cysts and Bursae of Elbow

1. Olecranon bursa
2. Medial + lateral epicondylar bursa
3. Cubital tunnel bursa
4. Biceps tendon bursa
   (a) Bicipitoradial bursa
   Location: lateral to biceps insertion
   • posterior interosseous nerve compression
   (b) Interosseous bursa
   Location: medial to biceps insertion
   • median nerve compression
5. Ganglion

CARPAL BONES

mnemonic: **S**ome **L**overs **T**ry **P**ositions **T**hat **T**hey **C**an't **H**andle

proximal row	*distal row*
Scaphoid	**T**rapezium

Lunate	**T**rapezoid
Triquetrum	**C**apitate
Pisiform	**H**amate

◊ Remember that trapezium comes before trapezoid in the dictionary as well!

◊ Spaces between carpal bones: ≤ 3 mm wide (internal comparison with capitolunate joint)

Scaphoid

[*scaphion*, Greek = boat]

◊ The largest bone of proximal carpal row!

Function: acts as an intercalated segment between lunate proximally + trapezium and trapezoid distally

Division: proximal third; middle third with waist; distal third with tuberosity on palmar surface

Blood supply: branches of radial artery enter bone near midportion / waist dorsally → perfusion of mid to proximal 70–80% of scaphoid + proximal pole supplied by end artery in retrograde fashion

Lunate

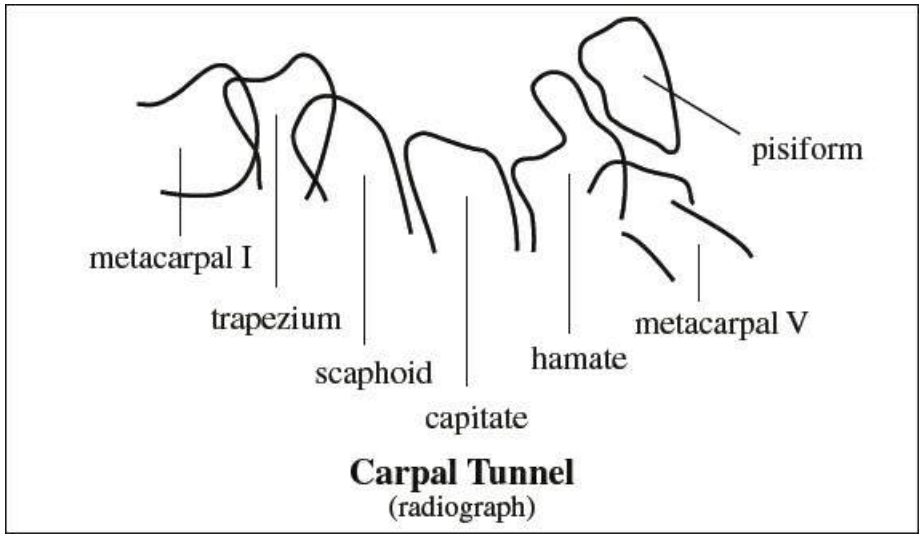
[*luna*, Latin = moon]

= moon-shaped configuration on LAT view

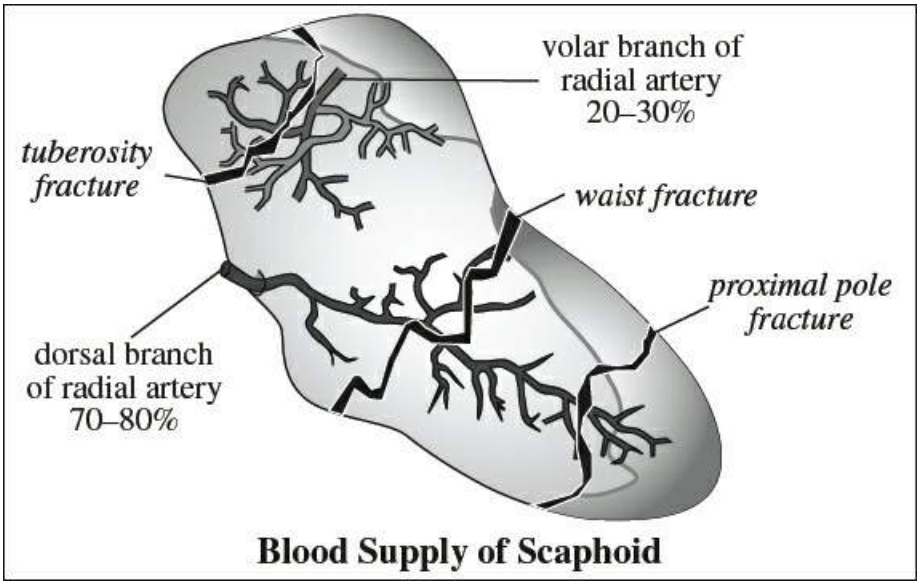
Parts: body, volar pole, dorsal pole

Function: acts as keystone of proximal carpal row

Blood supply: single vessel (20%); 2 nonarticular nutrient arteries with consistent intraosseous anastomosis (80%)



Carpal Tunnel
(radiograph)



Blood Supply of Scaphoid

Carpal Bone Blood Supply

◊ Blood vessels frequently enter distal half of bone putting proximal bone at risk for avascular necrosis!

Single arterial supply	scaphoid, capitate, lunate (in 20%)
Two nutrient arteries without intraosseous anastomosis	trapezoid, hamate
Two nutrient arteries with intraosseous anastomosis	trapezium, triquetrum, pisiform, lunate (in 80%)

Ulnar Variance

= HULTEN VARIANCE = RADIOULNAR INDEX
= relative lengths of distal articular surfaces of radius and ulna

Definition:

» neutral = both surfaces at same level = equal length of ulna + radius
» positive = ulnar surface distal to radial surface = long ulna
◊ Gymnasts have a predilection for a positive ulnar variance!
Risk: (1) ulnar impaction (→ chondral fibrillation, chondromalacia, degenerative arthritis)
(2) ligamentous and carpal disturbances (→ TFCC tear, focal chondral lunate injury)
» negative = ulnar surface proximal to radial surface = short ulna
◊ Most children aged 12–16 years have a negative ulnar variance!

Effect of wrist position:

(a) increase of ulnar variance
1. maximum forearm pronation
2. firm grip

(b) decrease of ulnar variance
1. maximum forearm supination

2. cessation of grip

Radiographic standard view of unloaded wrist: posteroanterior, neutral forearm rotation, elbow flexed 90°, shoulder abducted 90°

Guyon Canal

[Jean Casimir Félix Guyon (1831–1920), 1st French chair in urology at University of Paris]

= canalis nervi ulnaris = loge de Guyon (French)

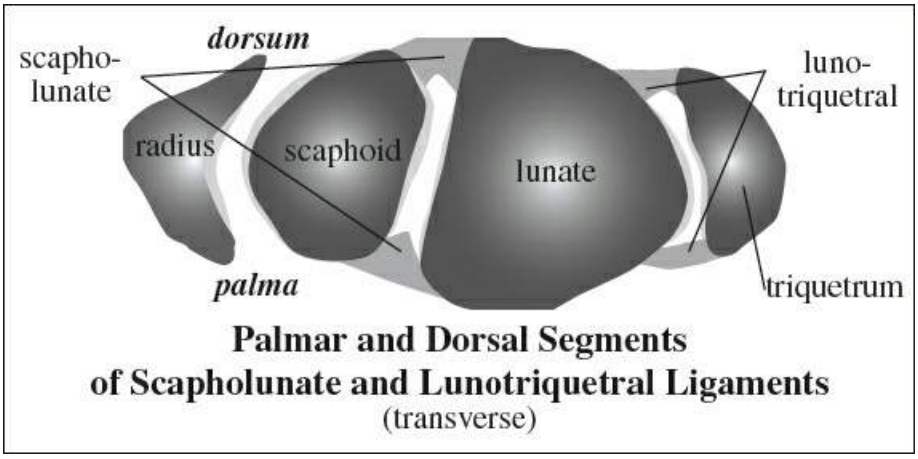
= small superficial tunnel-like structure at base of *hypothenar*

Floor: depression between pisiform + hook of hamate

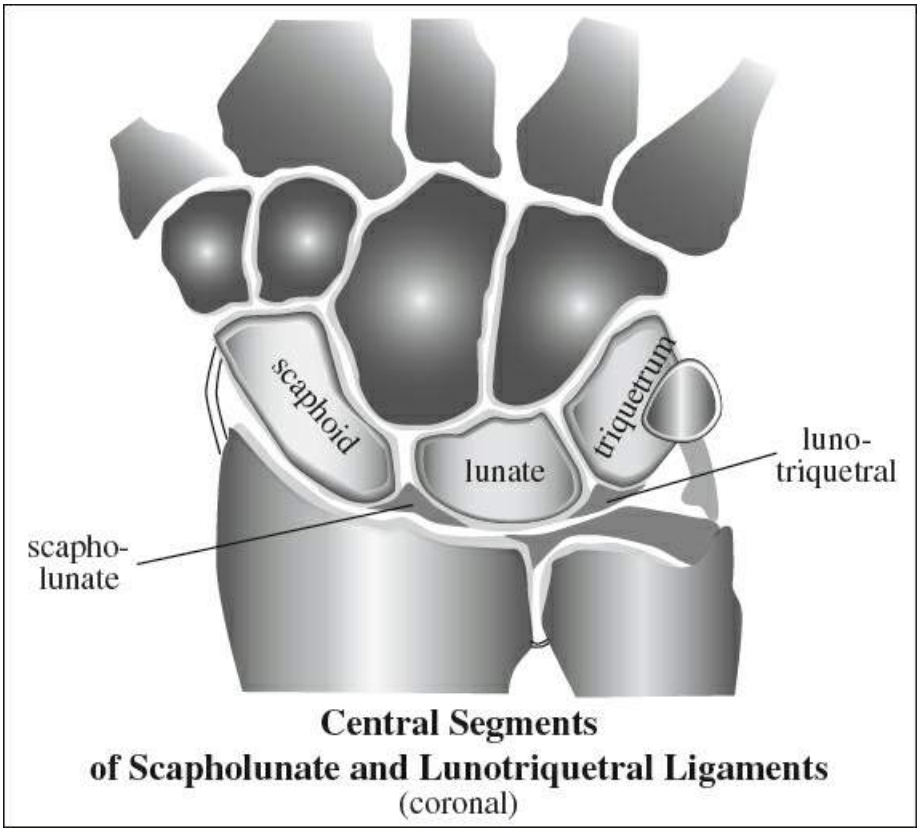
Roof: volar carpal ligament and pisohamate ligament; retinaculum flexorum manus; flexor carpi ulnaris m.

Contents: ulnar nerve with bifurcation into superficial and deep branches; ulnar artery

Clinical significance: site for compression injury by anomalous muscle, ganglion, hamate fracture



Palmar and Dorsal Segments of Scapholunate and Lunotriquetral Ligaments
(transverse)



Central Segments
of Scapholunate and Lunotriquetral Ligaments
(coronal)

Important Stabilizing Wrist Ligaments

◊ Important for carpal stability!

A. Intrinsic = between carpal bones
   1. Scapholunate lig.
   2. Lunotriquetral lig.

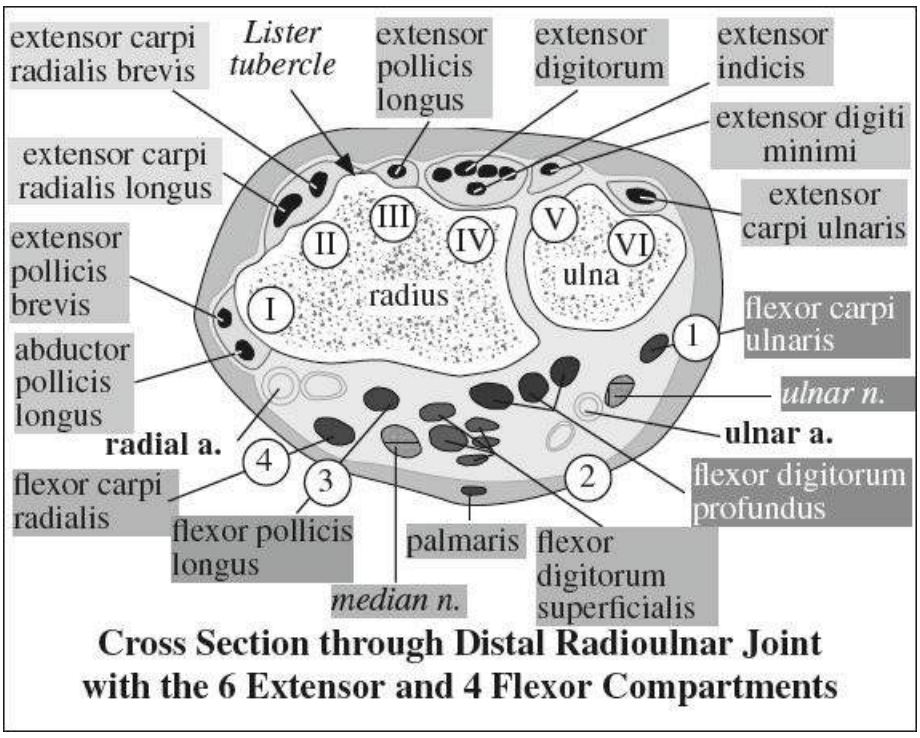
B. Extrinsic = between carpal + metacarpal bones or between carpal bones + radius / ulna
   (a) Palmar: carpal stability
      1. Radial collateral lig.
      2. Radiolunotriquetral lig. (RLTL): preventing ulnar translation
      3. Radioscaphocapitate lig. (RSCL): keeps scaphoid in position
   (b) Dorsal radiocarpal ligg.: prevent perilunate instability + volar intercalated segment instability
   (c) Dorsal intercarpal ligg.: prevent perilunate instability + dorsal intercalated segment instability

HIP

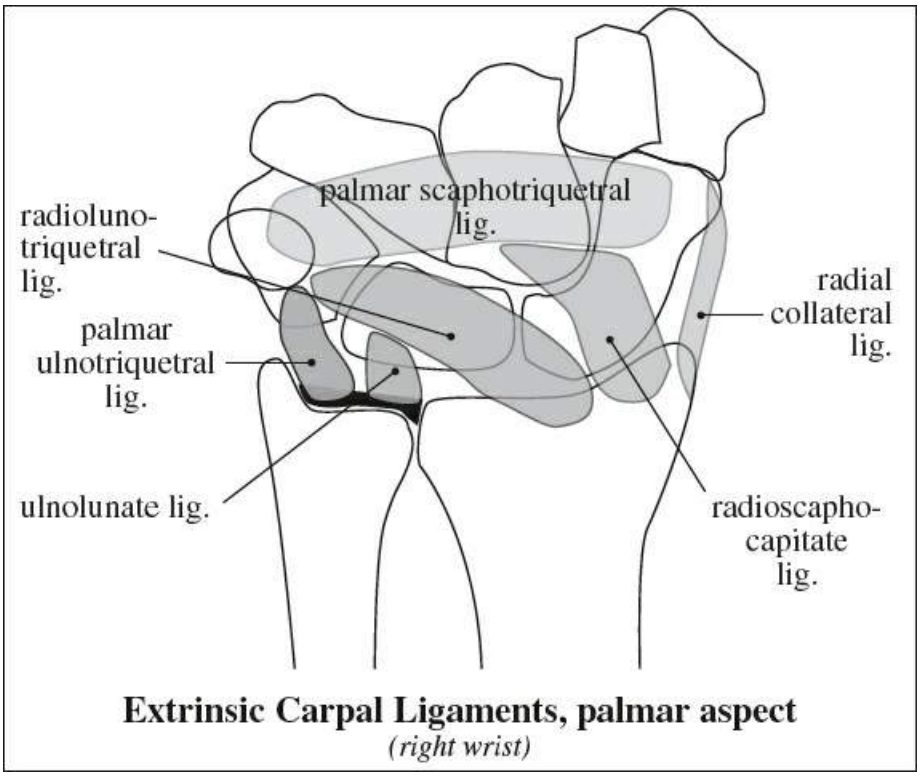
Cysts and Bursae of Hip

1. Iliopsoas bursa
   Location: surrounds iliopsoas tendon
   √ largest bursa in body
   √ communication with hip in 15%

2. Greater trochanteric bursae
   (a) Trochanteric bursa
   Location: covers posterior facet, beneath gluteus maximus muscle + iliotibial tract
   (b) Subgluteus medius bursa



Cross Section through Distal Radioulnar Joint with the 6 Extensor and 4 Flexor Compartments



Extrinsic Carpal Ligaments, palmar aspect

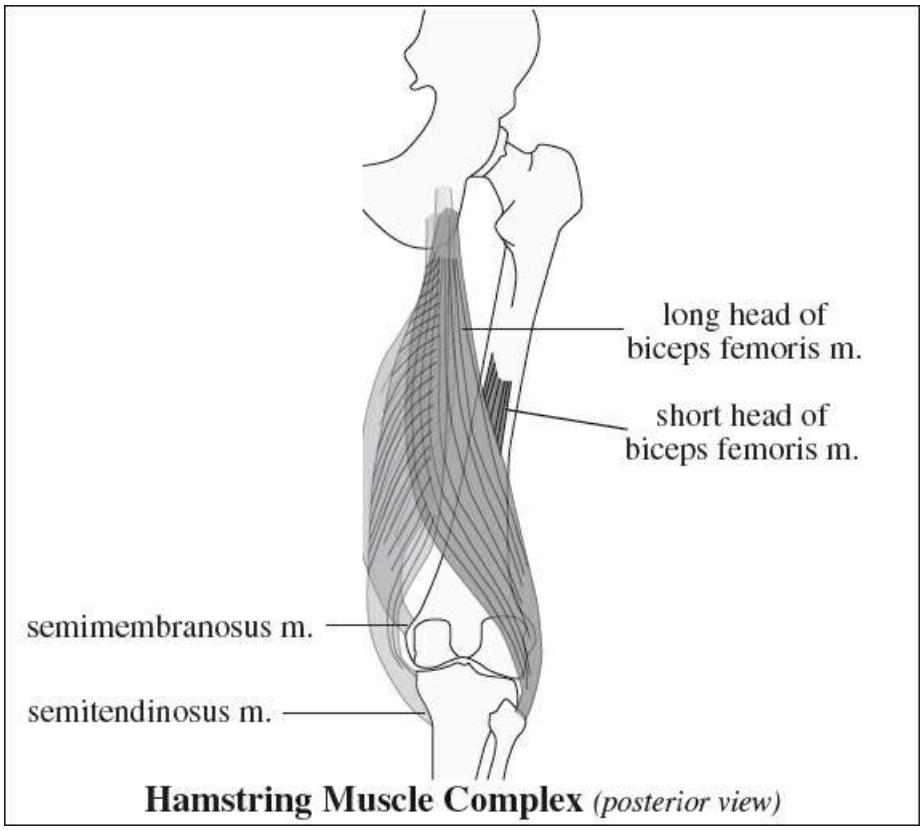
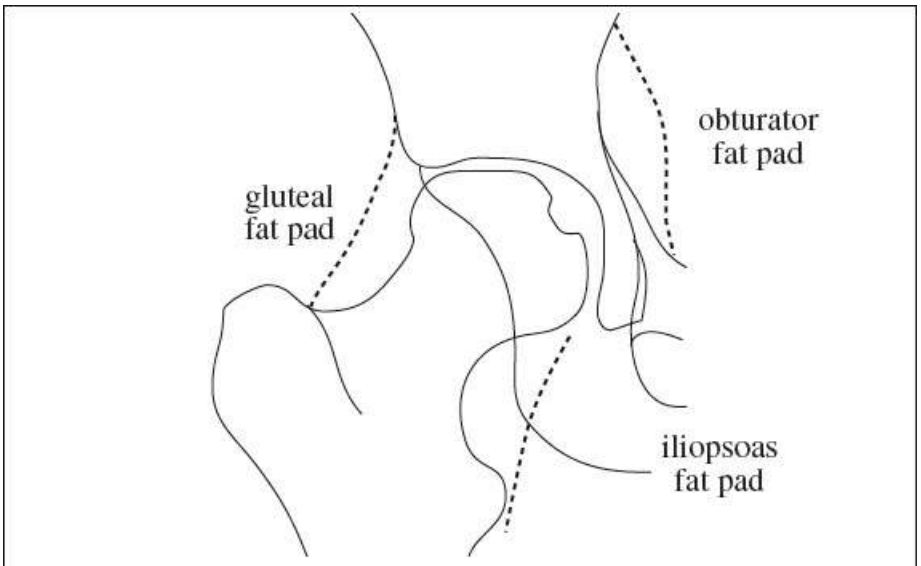
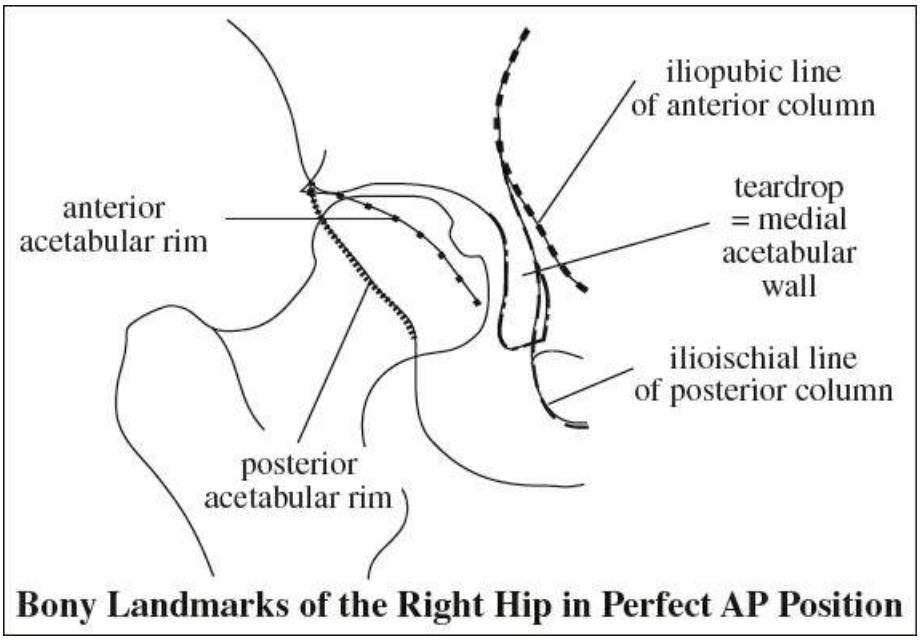
Acetabular Anatomy *(lateral aspect)*



Hamstring Muscle Complex *(posterior view)*

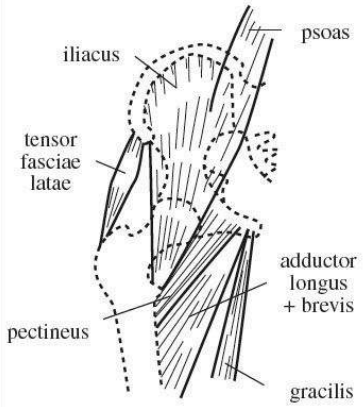


Fat Pads of the Right Hip in Perfect AP Position



Bony Landmarks of the Right Hip in Perfect AP Position

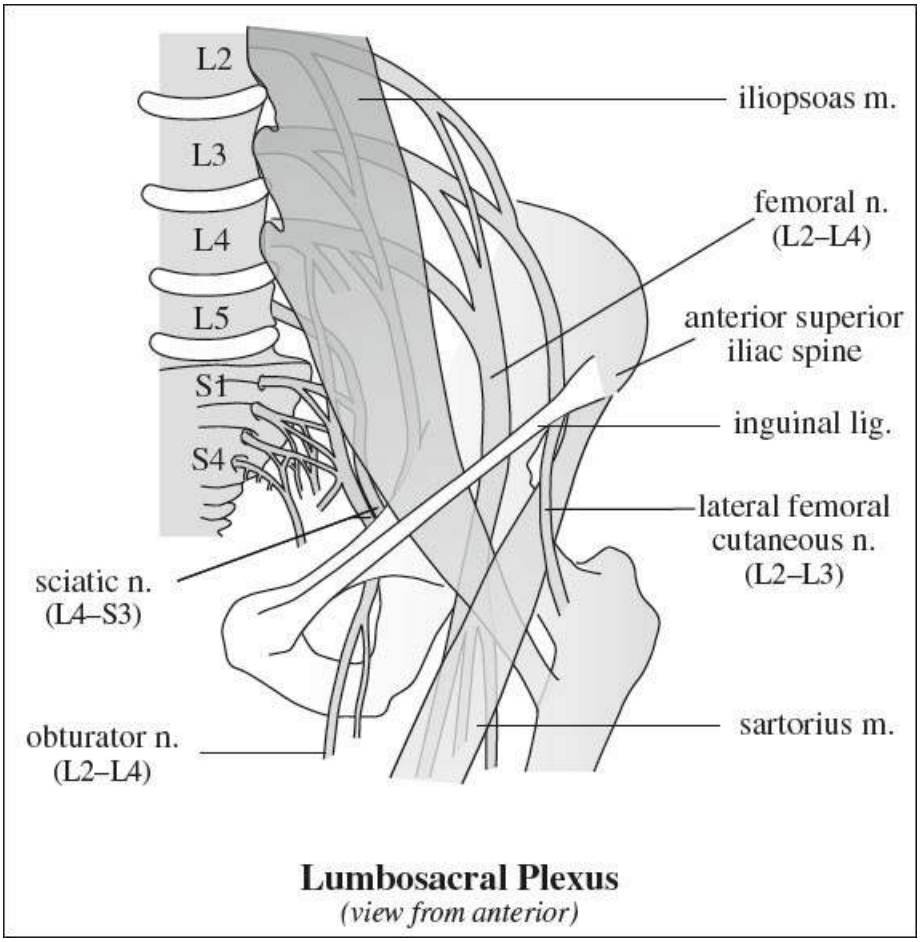
Innervation of Pelvis & Thigh Muscles	
Supplying Nerve	*Muscles Innervated*
Sacral plexus	piriformis, inferior gemellus, superior gemellus,obturator internus, quadratus femoris
Femoral nerve	iliopsoas, pectineus, quadriceps (rectus femoris, vastus lateralis, vastus medialis, vastus intermedius), sartorius
Obturator nerve	adductor brevis, adductor longus, anterior head of adductor magnus (also supplied by sciatic nerve), obturator externus, gracilis
Sciatic nerve	
› tibial division	long head of biceps femoris, semitendinosus, semimembranosus, adductor magnus
› peroneal division	short head of biceps femoris
Superior gluteal n.	gluteus medius, gluteus minimus, tensor fasciae latae
Inferior gluteal n.	gluteus maximus



Hip Flexors

Muscle Attachments of Thigh

Name of Muscle	*Origin*	*Insertion*
Gracilis	inferior pubic ramus	pes anserinus
Semimembranosus	ischial tuberosity	medial tibial condyle
Semitendinosus	ischial tuberosity	pes anserinus
Biceps femoris		
› long head	ischial tuberosity	fibular head
› short head	lateral linea aspera	fibular head
Adductor		
› longus	superior pubic ramus	medial linea aspera
› magnus	inferior pubic ramus	medial linea aspera
Sartorius	anterior superior iliac spine	pes anserinus
Quadriceps		
› rectus	anterior inferior iliac spine	patellar tendon
› vastus lateralis	greater trochanter	patellar tendon
› vastus medialis	medial intertrochanteric line	patellar tendon
Iliopsoas		
› iliacus	ilium	lesser trochanter
› psoas	lumbar spine	lesser trochanter
Tensor fasciae latae	anterior superior iliac spine	anterolateral tibia



Lumbosacral Plexus
(view from anterior)

Location: covers superior portion of lateral facet, beneath lateral portion of gluteus

medius m.

(c) Subgluteus minimus bursa

Location: covers superomedial portion of anterior facet, beneath + medial to gluteus minimus m.

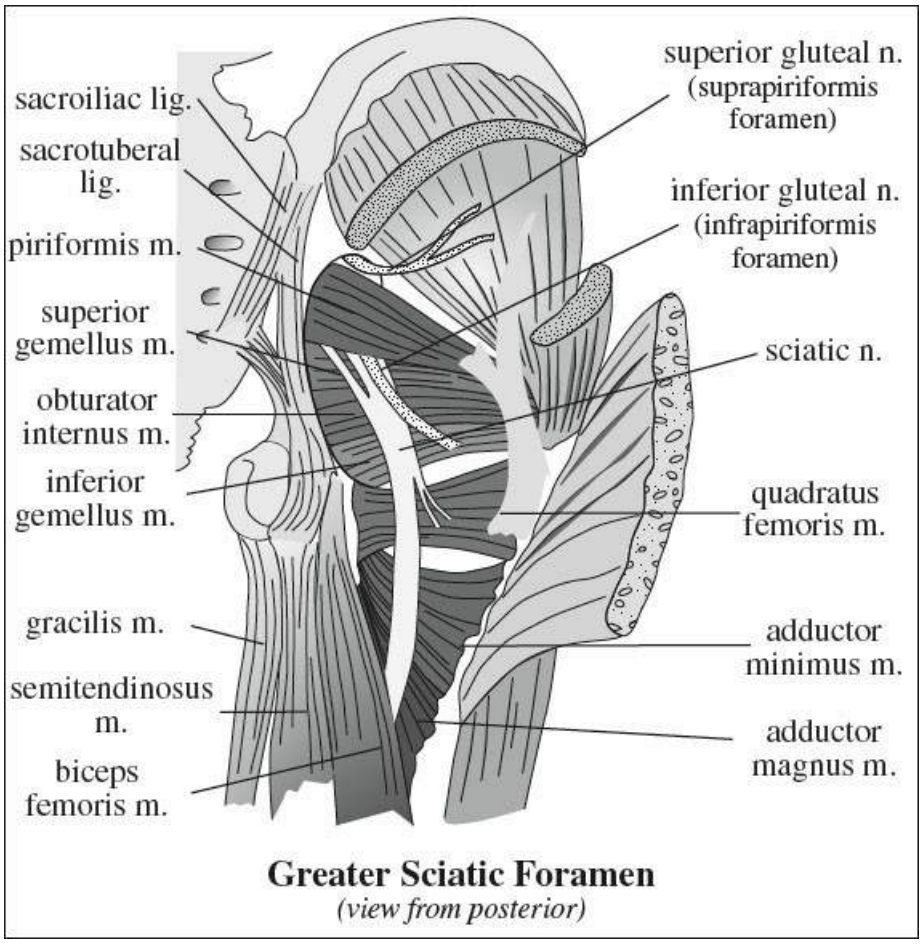
3. Ischiotrochanteric bursa
4. Obturator externus bursa

Location: posteroinferior communication of hip joint capsule

5. Ischial bursa (= weaver's bottom)
6. Paralabral cyst

Iliotibial Tract

Function: primary stabilizing structure of anterolateral knee together with lateral capsular ligaments



Greater Sciatic Foramen
(view from posterior)

Consists of:

1. Distal extension of superficial + deep layers of fascia lata
2. Tensor fasciae latae
3. Gluteus maximus m.
4. Gluteus medius m.

Insertion:

(a) supracondylar tubercle of lateral femoral condyle
(b) intermuscular septum of distal femur (deep component)
(c) **Gerdy Gerdy**, Pierre Nicolas (1797–1856), surgeon in Paris tubercle (main site of superficial component) = anterolateral tubercle of tibia
[Pierre Nicolas Gerdy (1797–1856), surgeon in Paris]
(d) patella + patellar ligament

Hamstring Muscle Complex

◊ Most frequently injured muscle!

(a) medial hamstring

Function: flexion + medial rotation of knee joint as thigh is swung forward and hip extended

1. Semimembranosus m.

Origin: superolateral aspect of ischial tuberosity (beneath semitendinosus m.)
Course: medial + anterior to other hamstring muscles with connections to tendons of adductor magnus m. + long head of biceps m.
Insertion: via 5 tendinous arms on
› medial tibial condyle (anterior[1] + direct[2] + inferior[3] arm) deep to tibial collateral ligament
› posterior oblique lig. (capsular[4] arm)
› arcuate lig. (oblique popliteal lig.[5])
Innervation: single branch off tibial division of sciatic n.

2. Semitendinosus m.

Origin: inferomedial impression of upper portion of ischial tuberosity *conjoined with* long head of biceps femoris m.
Insertion: Gerdy tubercle *conjoined* with gracilis m.
Innervation: tibial n. (2 separate branches)

(b) lateral hamstring

Function: flexion + lateral rotation of knee joint

3. Biceps femoris m.

Insertion: head of fibula, lateral condyle of tibia, fascia of leg
(a) long head
Origin: medial facet of ischial tuberosity
Innervation: tibial portion of sciatic n.
(b) short head (does not cross 2 joints, may be absent)
Origin: lateral linea aspera + lateral supracondylar line + intermuscular septum
Used as: landmark to distinguish between proximal and distal hamstring injuries
Innervation: peroneal division of sciatic n.

KNEE

Knee Extensors

= quadriceps muscle consisting of

1. Vastus medialis m.
2. Vastus lateralis m.

3. Vastus intermedius m.
4. Rectus femoris m.

Insertion: combined as quadriceps tendon on patella

Pes Anserinus

[*pes*, Latin = foot; *anser*, Latin = goose]

= tendinous configuration of 3 flexors + medial rotators of knee joint attaching inferomedially to tibial tuberosity

mnemonic: **S**ay GraceSe before eating goose

Sartorius tendon (anterior)

Gracilis tendon (middle)

Semitendinosus tendon (posterior)

Patella Alta

= high-riding patella as normal anatomic variant

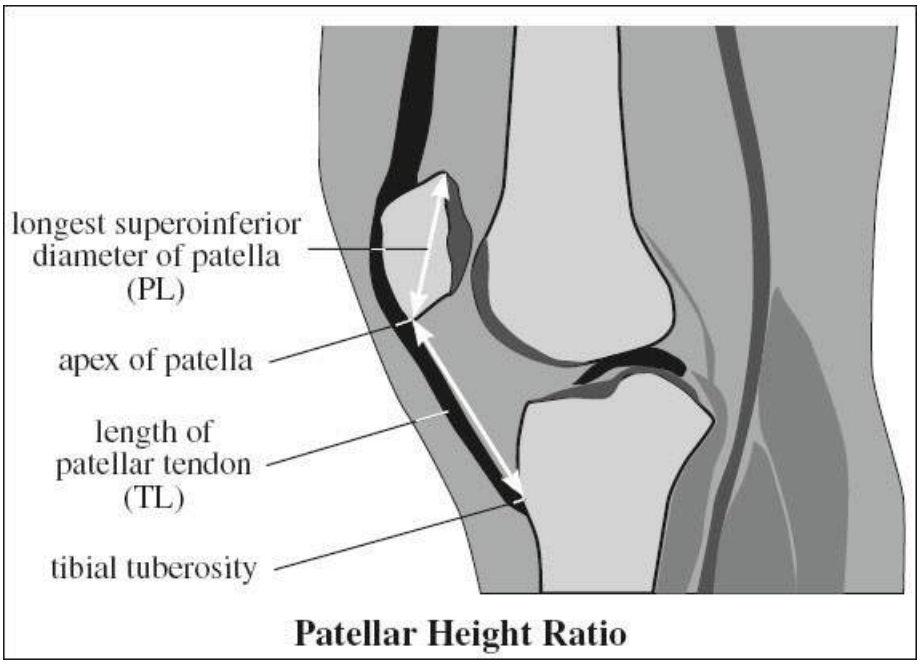
Cause: patellar tendon too long → reduced patellar contact area → patellar dislocation

◊ High-riding patella in 25% of patients with acute patellar dislocation

• mostly asymptomatic

MR measurement:

patellar height ratio (Insall-Salvati index) = TL÷PL = patellar tendon length (TL) divided by superoinferior diameter of patella (PL) 1.1 ± 0.1 = normal; >1.3(M) or >1.5 (F) = patella alta; <0.74 (M) or <0.79 (F) = patella baja (infera)



Cruciate Ligaments

◊ Both cruciate ligaments are intracapsular but extrasynovial!

Anterior Cruciate Ligament (ACL)

Function: limits anterior tibial translation
Origin: inner face of lateral femoral condyle
Insertion: noncartilaginous region of anterior aspect of intercondylar eminence of tibia
Anatomy: several distinct bundles of fibers
(1) large posterior bulk = spiraling together at femoral origin
(2) small anteromedial bundle diverging at tibial insertion

√ thin solid taut dark band (sagittal MR with knee in extension) almost parallel to intercondylar roof (= Blumensaat line):
√ with knee extension posterolateral band taut
√ with increasing flexion:
anteromedial band becomes more taut + posterolateral band more lax

√ thin hypointense band parallel to inner aspect of lateral femoral condyle + fanlike configuration toward tibial spine (coronal MR)

√ thin ovoid hypointense band proximally, elliptical configuration distally with higher intensity (axial MR)

√ greater SI than posterior cruciate ligament (due to anatomy)

Posterior Cruciate Ligament (PCL)

Function: limits posterior tibial translation
Origin: in a depression posterior to intercondylar region of tibia below joint surface
Insertion: most distal + anterior aspect of inner face of medial femoral condyle

√ thick dark band slightly posteriorly convex (arclike course on sagittal MR with knee in extension)

√ medial to ACL (coronal MR)

Collateral Ligaments of Knee Joint

Medial (Tibial) Collateral Ligament

Origin: just distal to adductor tubercle of femur
Insertion: anteromedial face of tibia distal to level of tibial tubercle about 5 cm below joint line

(a) deep portion:
› meniscofemoral ligament
› meniscotibial ligaments

(b) superficial portion
› vertical band from femoral epicondyle to pes anserinus
› posterior oblique ligament = posterior oblique band from femoral epicondyle to semimembranosus tendon

√ deep and superficial dark bands separated by a thin bursa + fatty tissue (on coronal MR)

Lateral (Fibular) Collateral Ligament

Origin: lateral aspect of lateral femoral condyle
Insertion: styloid process of fibular head

√ bicipital tendon + iliotibial band join lateral collateral lig.

Arcuate Complex

Function: provides posterolateral stabilization
Consists of: lateral (fibular) collateral ligament
+ biceps femoris tendon
+ popliteus muscle and tendon
+ popliteal meniscal ligament
+ popliteal fibular ligament
+ oblique popliteal ligament
+ arcuate ligament
+ fabellofibular ligament
+ lateral gastrocnemius muscle

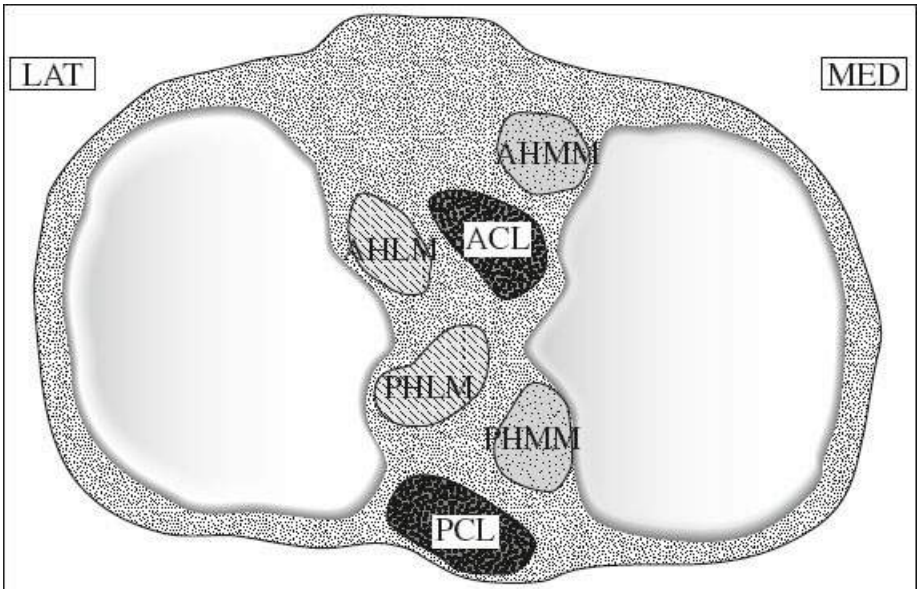
Posteromedial Corner of Knee

1. Semimembranosus tendon
   Attachment: infraglenoid tubercle of posteromedial tibia; posterior joint capsule; posterior horn of medial meniscus
2. Posterior joint capsule
3. Posterior oblique ligament

Menisci

= wedge-shaped semilunar fibrocartilaginous structures
Function: absorb shock, distribute axial load, assist in joint lubrication, facilitate nutrient distribution
Margin: (a) superior concave surface conforming to femoral condyle → increase in contact area
(b) inferior flat base that attaches to central tibial plateau via anterior + posterior root ligament anchors → maintain normal meniscal position + biomechanical function
(c) thick peripheral portion
(d) tapered central free edge
Composition: collagen bundles oriented in
(1) circumferential (longitudinal) type I collagen bundles parallel to long axis of meniscus → hoop strength resisting axial load + preventing meniscal extrusion
(2) radial thin fibers perpendicular to longitudinal bundles forming a lattice → tying bundles together + providing structural support
Subdivision into thirds:
» anterior horn
» meniscal body
» posterior horn
Attachment:
» posterior root
» anterior root
@ lateral meniscus (LM)
√ striated / comb-like appearance of anterior horn ← intimate association between anterior root of lateral meniscus + ACL insertion site
@ medial meniscus (MM)

√ anomalous insertion paralleling ACL → mimicks MM tear
√ anterior root may insert along anterior margin of tibia → mimicks MM subluxation



Attachment of Cruciate Ligaments and Menisci on Tibial Plateau

ACL	anterior cruciate ligament
AHMM	anterior horn of medial meniscus
AHLM	anterior horn of lateral meniscus
PCL	posterior cruciate ligament
PHMM	posterior horn of medial meniscus
PHLM	posterior horn of lateral meniscus

√ peripheral attachment to deep fibers of medial collateral ligament → meniscus less mobile

Imaging:

› on sagittal images of menisci:
√ "bow-tie" structure peripherally
√ opposing triangles centrally
√ posterior horn larger than anterior horn for MM
√ anterior + posterior horns of similar size + shape for LM
› on coronal images:
√ triangular shape through body of meniscus
√ wedge-shaped through horn of meniscus
› on axial images:
√ open C-shaped configuration of medial meniscus
√ increase in width from anterior to posterior

Variants mimicking a tear:

1. **Transverse meniscal (geniculate) ligament** (83–90%)
= thin fibrous band that connects and stabilizes the anterior horns of the menisci

√ overrides superior aspect of menisci before completely fusing to menisci
DDx: anterior root tear
Dx: Trace cross section of transverse ligament through infrapatellar fat pad on more central SAG images!

2. **Meniscofemoral ligaments** (MFL) in 89–93%
   (a) **Wrisberg** ligament
   √ posterior to posterior cruciate ligament
   (b) **Humphrey** ligament
   √ anterior to posterior cruciate ligament
   mnemonic: **under** the **hump** (of the PCL)
   Origin: superior + medial aspect of posterior horn of lateral meniscus
   Insertion: lateral aspect of medial femoral condyle
   Function: assist PCL + help control mobility of posterior horn of lateral meniscus during knee flexion + extension
   √ demonstrated in ⅓ of cases on SAG images; usually limited to single most medial image!
3. **Popliteomeniscal fascicles** (visualized in 90%)
   (a) anteroinferior fascicle = floor of popliteal hiatus
   (b) posterosuperior fascicle = roof of popliteal hiatus
   = synovial-lined fibrous bands that attach to posterior horn of lateral meniscus + help form popliteal hiatus
   Function: stabilize posterior horn
4. **Popliteal hiatus**
   = separates lateral meniscus from joint capsule
   √ above posterior aspect of lateral meniscus on most superficial SAG slice!
   √ popliteal tendon moves behind + inferior to meniscus on adjacent deeper SAG sections!
5. **Oblique meniscomeniscal ligament** (1–4%)
   = connects meniscal horns in X-wise fashion on AXIAL image
   (a) medial oblique meniscomeniscal ligament
   √ anterior horn of medial meniscus to posterior horn of lateral meniscus
   (b) lateral oblique meniscomeniscal ligament
   √ anterior horn of lateral meniscus to posterior horn of medial meniscus
   √ traverses intercondylar fossa between ACL and PCL

Anatomic Variants of Menisci

1. **Diskoid meniscus**
   = abnormally shaped enlarged meniscus with further central extension onto tibial articular surface
   Prevalence: 1.5–3% for lateral meniscus; 0.12–0.3% for medial meniscus
   Side: lateral÷medial meniscus = 10÷1
   Age: children, adolescents
   √ body of meniscus measures ≥ 15 mm on midline coronal image
   √ ≥ 3 bow-tie shapes on contiguous sagittal (4-mm-thick) sections
   √ diffuse intrameniscal signal intensity ← increased meniscal vascularity

2. **Meniscal flounce**
   = rippled appearance of free nonanchored inner edge of medial meniscus
   Prevalence: 0.2–0.3% of asymptomatic knees
3. Meniscal ossicle (rare)
   Cause: developmental, degenerative, posttraumatic
   Location: posterior horn of MM
   √ calcification on radiograph mimicks loose body
   √ increased signal intensity can mimic a tear
4. Chondrocalcinosis
   Prevalence: 5– 15% (increasing with age)
   √ calcifications on radiograph
   √ increased signal intensity → lowers sensitivity and specificity for detection of meniscal tear

Posterolateral Corner Structures

= arcuate complex

1. Fibular collateral ligament
2. Arcuate ligament
3. Popliteus musculotendinous complex
4. Popliteofibular ligament
5. Fabellofibular ligament
6. Posterolateral capsule

Popliteus Musculotendinous Complex

Origin: posteromedial tibial surface proximal to soleal line forming floor of popliteal fossa

Course: forms long strong **popliteal tendon** that passes underneath posterolateral joint capsule + arcuate ligament (extracapsular); enters knee through popliteal hiatus posteroinferiorly behind posterior horn of lateral meniscus; passes beneath lateral collateral ligament + tendon of biceps femoris
= *intracapsular – extraarticular – extrasynovial*

Attachment: popliteal notch on lateral aspect of lateral femoral condyle; anteroinferior to proximal attachment of lateral collateral ligament on lateral epicondyle

Function: in non–weight-bearing state primary internal rotator of tibia on femur; in weight-bearing state external rotator of femur on leg

√ fluid-filled popliteus bursa surrounds popliteus muscle and tendon

Fibular Collateral Ligament

= (TRUE) LATERAL COLLATERAL LIGAMENT

Origin: lateral femoral epicondyle

Attachment: lateral aspect of fibular head + neck anterior and distal to fibular styloid process; often conjoined insertion with biceps femoris tendon

Function: simple passive restraint

√ extracapsular WITHOUT meniscal attachment

Arcuate Ligament

= Y-shaped inconstant thickening of posterolateral capsule
(a) lateral limb inserts into posterolateral joint capsule
(b) medial limb extends medially over popliteus muscle to oblique popliteal ligament

Popliteofibular Ligament

= attachment of popliteus tendon to fibular head
Origin: popliteus tendon near myotendinous junction
Attachment: posterior aspect of fibular styloid process posteromedial to the biceps insertion
Function: one of the strongest lateral stabilizers in knee

Fabella (present in 20%)

= sesamoid bone in lateral head of gastrocnemius muscle
Function: anchors fabellofibular ligament

FABELLOFIBULAR LIGAMENT (present in 40%)

Origin: fabella
Attachment: styloid process of fibular head posterior to arcuate ligament + lateral to popliteofibular ligament / to lateral femoral condyle (in absence of fabella)

Cysts and Bursae of the Knee

1. Suprapatellar bursa
2. Popliteal bursa
3. Pes anserine bursa
4. Semimembranosus-tibial collateral ligament bursa
5. Prepatellar bursa
6. Infrapatellar bursa
7. Tibial collateral ligament bursa
8. Tibiofibular joint cyst
9. Popliteus bursa
10. Meniscal cyst
11. Cruciate ligament cyst
12. Ganglion (mucinous degeneration of ACL)

ANKLE & FOOT

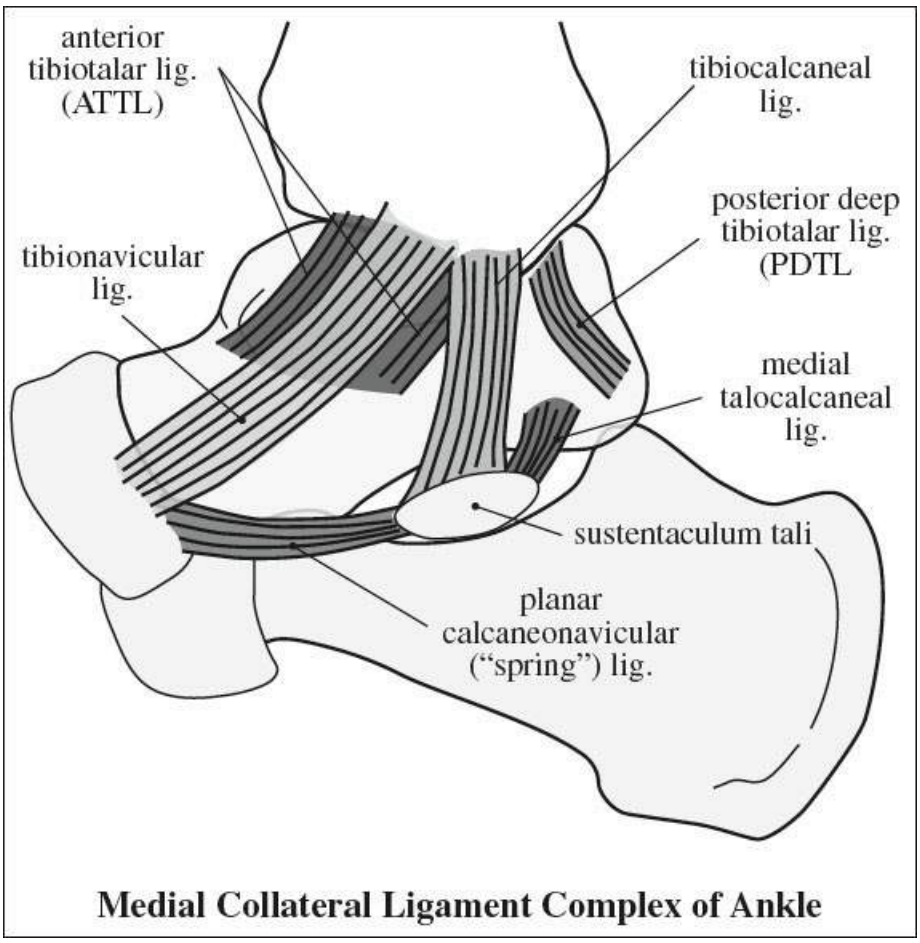
Ligamentous Stabilizers of Ankle

Deltoid Ligament

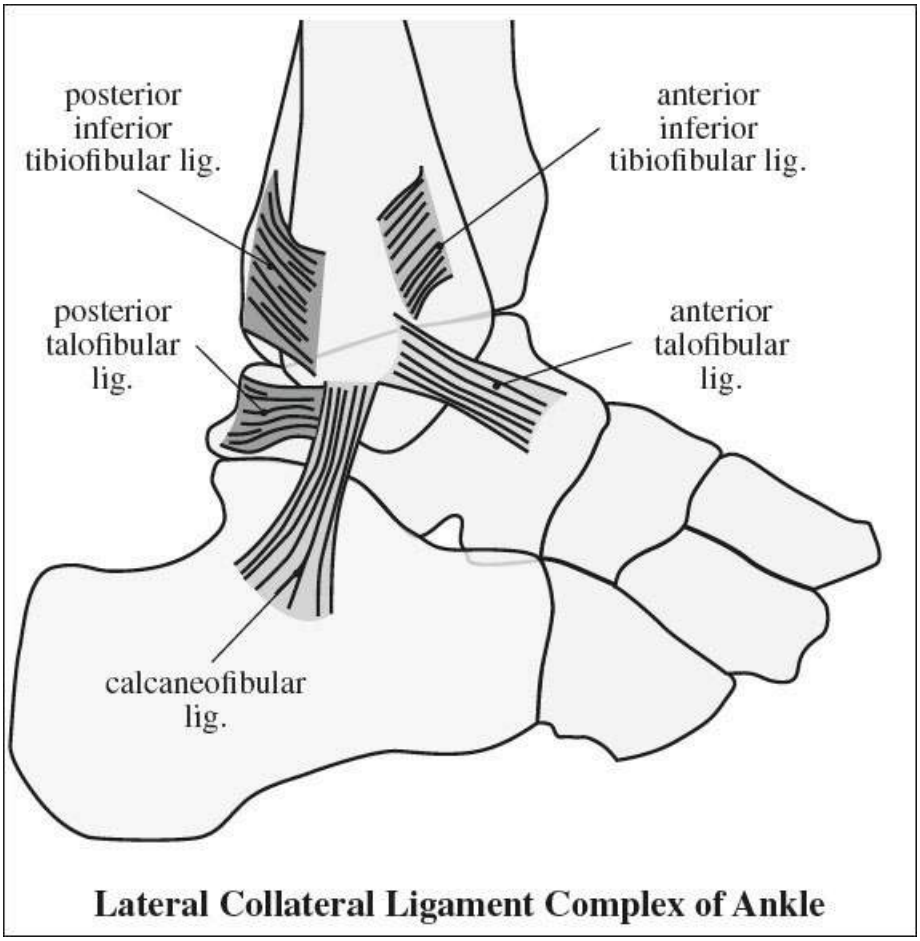
= MEDIAL COLLATERAL LIGAMENT OF ANKLE
Function: main stabilizer against valgus force / pronation force / rotational force on talus
Components:
(a) superficial layer:
Origin: anterior colliculus of medial malleolus
1. Tibiocalcaneal ligament

Distal attachment: calcaneus

2. Tibionavicular ligament
   Distal attachment: os naviculare
3. Posterior superficial tibiotalar ligament
   Distal attachment: talus
4. Tibiospring ligament
   Distal attachment: joins superomedial oblique band of spring lig. proper (= calcaneonavicular lig.)
   Function: stabilizer for talocalcaneonavicular joint + medial plantar arch



Medial Collateral Ligament Complex of Ankle



Lateral Collateral Ligament Complex of Ankle

(b) deep layer = intraarticular, covered by synovium
Origin: intercollicular (= malleolar) groove + posterior colliculus of medial malleolus

1. Anterior tibiotalar ligament (ATTL)
2. Posterior deep tibiotalar ligament (PDTL)

Deltoid ligament rupture is rare without additional injuries to the ankle ← uncommon occurrence of eversion ankle sprains and due to intrinsic thickness of the ligament.

Lateral Collateral Ligament Complex (LCL)

◊ 85% of all ankle sprains involve these ligaments!

1. Anterior talofibular ligament (ATFL)
2. Posterior talofibular ligament (PTFL)

The anterior talofibular ligament is the weakest and most frequently injured among the 3 components of the lateral collateral ligament complex.

3. Calcaneofibular ligament (CFL)

In inversion sprains, the calcaneofibular ligament is usually sequentially torn after the anterior talofibular ligament. If the anterior talofibular ligament is normal, then an isolated tear of the CFL is unlikely.

Syndesmotic Ligament Complex

binding tibia + fibula

1. Anterior-inferior tibiofibular (AITFL)
   Attachment: slightly above talofibular ligaments = above level of talotibial joint line
   ◊ One of the most commonly injured ligaments in the ankle!
2. Posteroinferior tibiofibular (PITFL)
3. Transverse tibiofibular ligament
4. Interosseous membrane

Anterior Ankle Tendons

Anterior Tibialis

= most medial and largest extensor of ankle with appearance of tendon at junction of middle to distal ⅓

Function: 80% of foot dorsiflexion; helps support longitudinal arch; aids in foot supination and inversion

Origin: proximal third of lateral tibia, lateral tibial condyle, interosseous membrane, deep fascia, intermuscular septum

Insertion: bifid = medial cuneiform (dominant slip) + 1st metatarsal base (thin slip)

Tendon fixation: superior + inferior extensor retinaculum (with oblique superomedial and oblique inferomedial bands)

Extensor Hallucis Longus

Function: extension of hallux

Origin: middle half of fibula + interosseous membrane; becomes tendinous at distal ⅓ of tibia

Insertion: dorsomedial surface of distal phalangeal base of hallux

Course: descends vertically between anterior tibial and extensor digitorum longus muscles deep to superior + inferior extensor retinaculi

Extensor Digitorum Longus

Function: extension of phalanges; contributes to foot dorsiflexion

Origin: lateral tibial condyle, proximal ¾ of anterior fibula, interosseous membrane, deep fascia, intermuscular septa

Insertion: dorsal aspect of middle + distal phalanges of 2nd through 5th digits

Course: behind superior extensor retinaculum

Posterior Ankle Tendons

Achilles Tendon

Size: 7 mm in AP thickness (largest tendon of the body)

Origin: gastrocnemius + soleus muscle

√ surrounded by loose paratenon without tendon sheath

Plantaris Tendon

√ parallels Achilles tendon anteromedially

Insertion: Achilles tendon. calcaneus, plantar fascia

Medial Flexor Tendons

Posterior Tibialis Tendon

Function: plantar flexion + inversion of foot; support for medial longitudinal arch of the foot

Size: twice the size of flexor digitorum longus tendon

Course: posterior + beneath medial malleolus (used as pulley) + flexor retinaculum; continues medial to subtalar joints

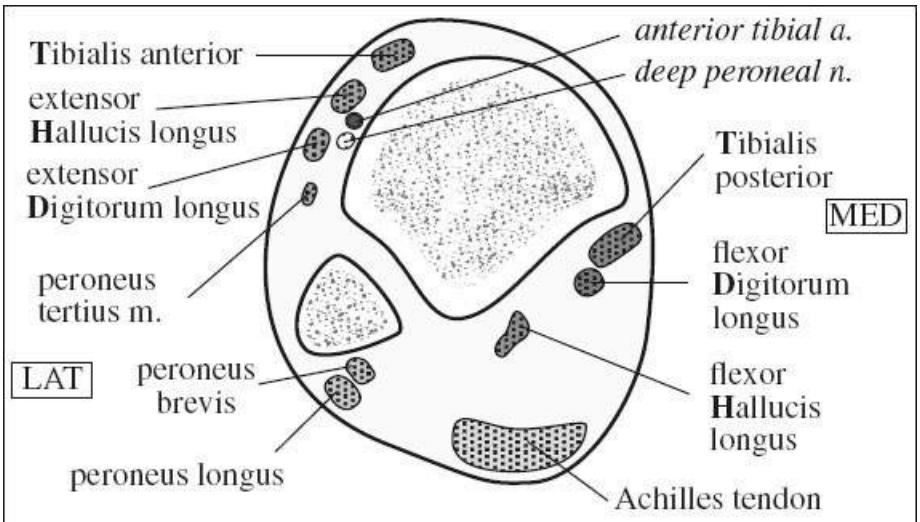
(a) largest anterior tendon component

Insertion: navicular tuberosity + plantar capsule of navicular-cuneiform joint + plantar aspect of medial cuneiform bone

Variation: ossified accessory navicular bone (in 25%) embedded into tendon

(b) deep middle (tarsometatarsal) tendon component

Insertion: 2nd and 3rd cuneiform bones + cuboid bone + 2nd to 4th (± 5th) metatarsal bases



Cross Section through Ankle

mnemonic for posterior tendons: "**T**om, **D**ick and **H**arry from medial to lateral"

Tibialis posterior
Digitorum longus (flexor)
Hallucis longus (flexor)

mnemonic for anterior ankle compartment - medial to lateral:

"**T**he **H**ospitals **A**re **N**ot **D**irty **P**laces"

Tibialis anterior tendon (extensor)
Hallucis longus (extensor)
Artery (anterior tibial)
Nerve (deep peroneal)
Digitorum longus (extensor)
Peroneus tertius

mnemonic for peroneus tendons at the ankle:

"**P**eroneus **L**ongus is **P**osterior and **L**ateral from peroneus brevis"

(c) posterior tendon component

Origin: proximal tendon

Insertion: anterior aspect of sustentaculum tali

Tendon sheath: ends 1–2 cm proximal to navicular insertion

Flexor Digitorum Longus Tendon

Course: pierces medial intermuscular septum in medial-to-lateral direction; travels obliquely superficial (plantar) to flexor hallucis longus tendon; receives insertion of quadratus plantae muscle as it splits into four separate tendons giving rise to lumbrical muscles

Insertion: bases of 2nd – 5th distal phalanges

Flexor Hallucis Longus Tendon

Course: groove beneath posterior process of talus, beneath sustentaculum tali; pierces medial inter- muscular septum in medial-to-lateral direction; courses through fibro-osseous tunnel between tibial + fibular sesamoid bones of great toe

Insertion: base of distal phalanx of hallux

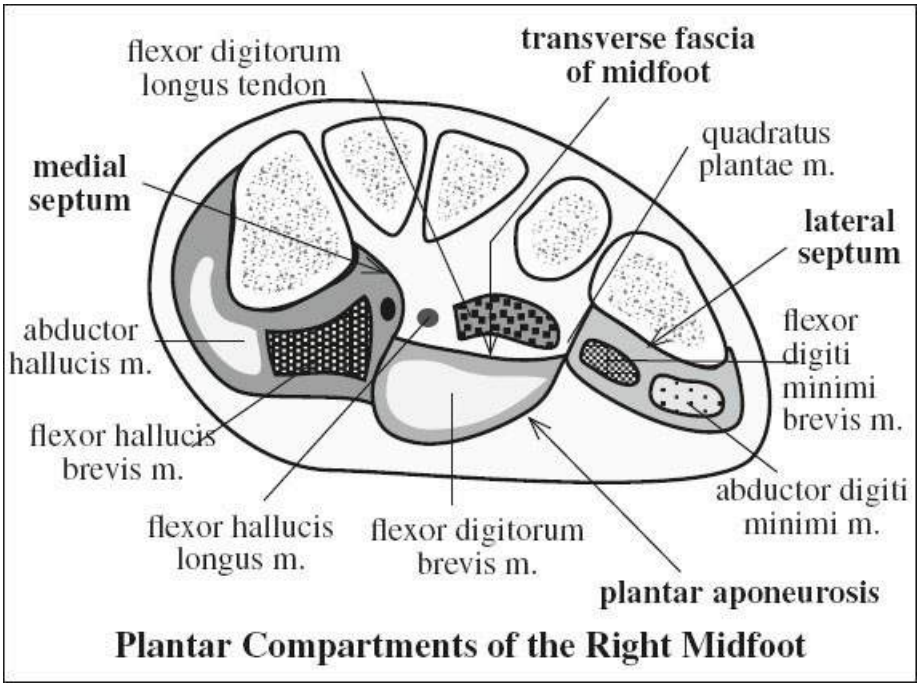
Flexor digitorum and hallucis longus tendons cross at the level of the navicular bone forming the master knot of Henry!

Peroneus Longus Tendon

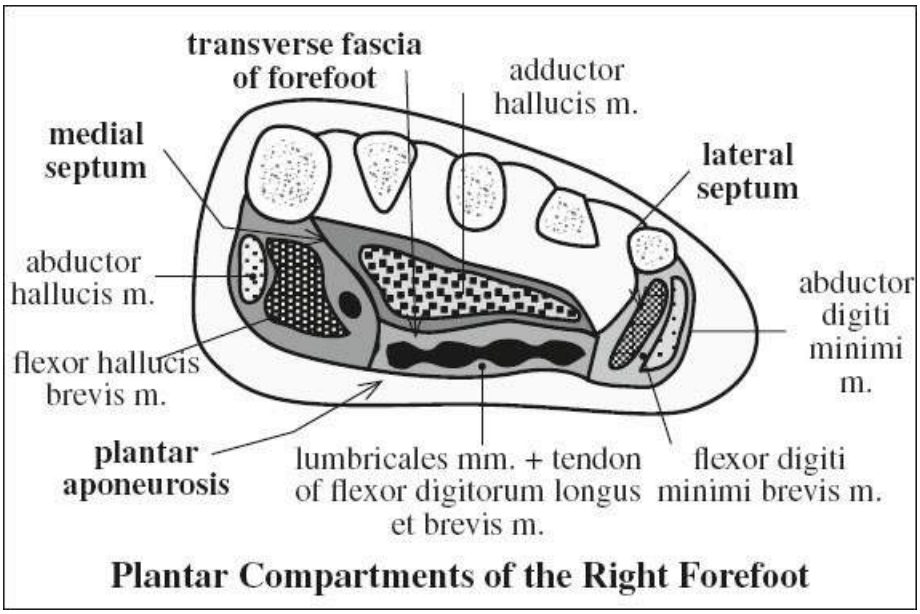
The peroneus longus tendon is located posterolateral to peroneus brevis tendon in retromalleolar groove!

Function: plantar flexion of 1st ray of foot + ankle and eversion of ankle; important stabilizer of ankle

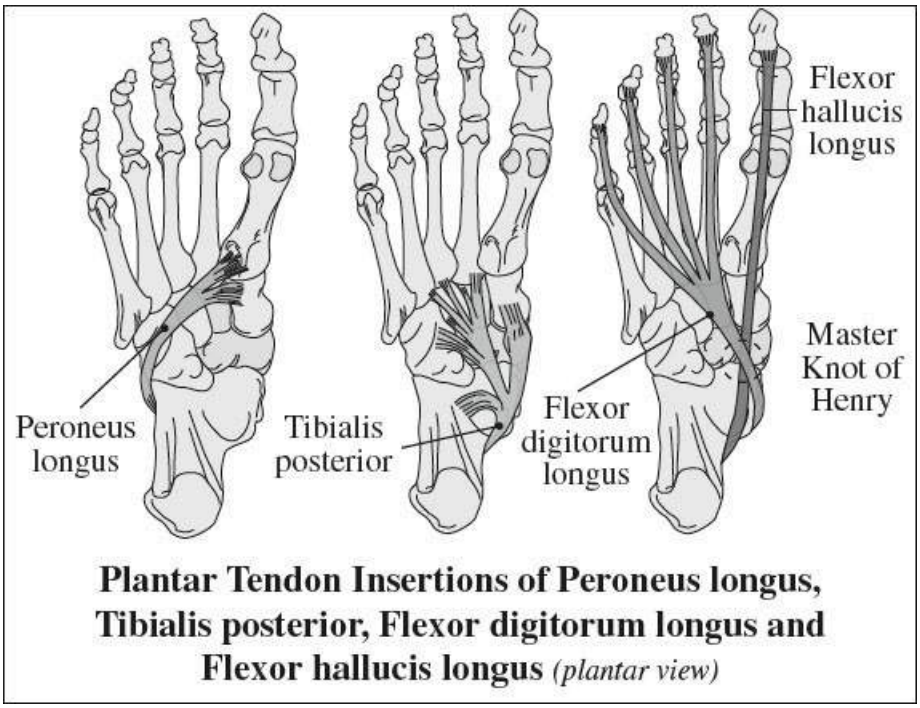
Insertion: fan-shaped onto lateral tubercle at base of 1st MT + plantar aspect of 1st cuneiform bone + base of 2nd MT bone + 1st dorsal interosseous muscle



Plantar Compartments of the Right Midfoot



Plantar Compartments of the Right Forefoot



Plantar Tendon Insertions of Peroneus longus, Tibialis posterior, Flexor digitorum longus and Flexor hallucis longus *(plantar view)*

Course: posterior to lateral malleolus in retromalleolar groove; posterolateral to peroneus brevis tendon; beneath cuboid bone through cuboid fibro-osseous tunnel / groove; oblique anteromedial orientation while crossing plantar aspect of foot

Variant: os peroneum (20%) = accessory ossicle embedded in peroneus longus tendon at level of calcaneocuboid joint

N.B.: Tenosynovial effusion within plantar peroneus longus tendon sheath is uncommon

Fluid in plantar peroneus longus tendon sheath is highly suggestive of tenosynovitis!

Cysts and Bursae of the Ankle and Foot

1. Malleolar bursa
2. Retrocalcaneal bursa
3. Tendo-Achilles bursa
4. Tarsal tunnel ganglion
5. Sinus tarsi bursa
6. Intermetatarsal bursae

Foot Compartments

(a) medial compartment
Border: medial septum (extending from plantar aponeurosis to navicular bone, medial cuneiform bone, plantar surface of 1st metatarsal bone)
Content: abductor hallucis muscle + flexor hallucis brevis muscle + flexor hallucis longus tendon

(b) lateral compartment
Border: lateral septum (extending from plantar aponeurosis to medial surface of 5th metatarsal bone)
Content: abductor muscle + short flexor muscle + opponens muscle of 5th toe

(c) central compartment
Border: medial + lateral septa; communicates directly with posterior compartment of calf; subdivided by horizontal septa: adductor hallucis muscle separated from quadratus plantae muscle
Content: flexor digitorum brevis m. + flexor digitorum longus tendon + quadratus plantae muscle + lumbricales mm. + adductor hallucis muscle

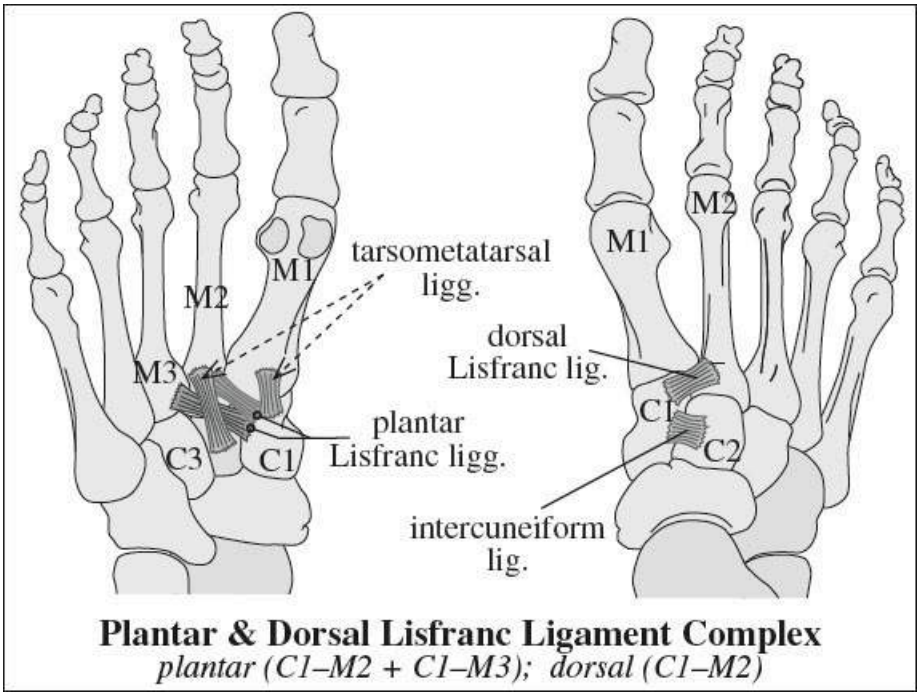
(d) deep subcompartment
Border: transverse fascia of forefoot; separated from quadratus plantae muscle
Content: adduct hallucis muscle

Lisfranc Joint Complex

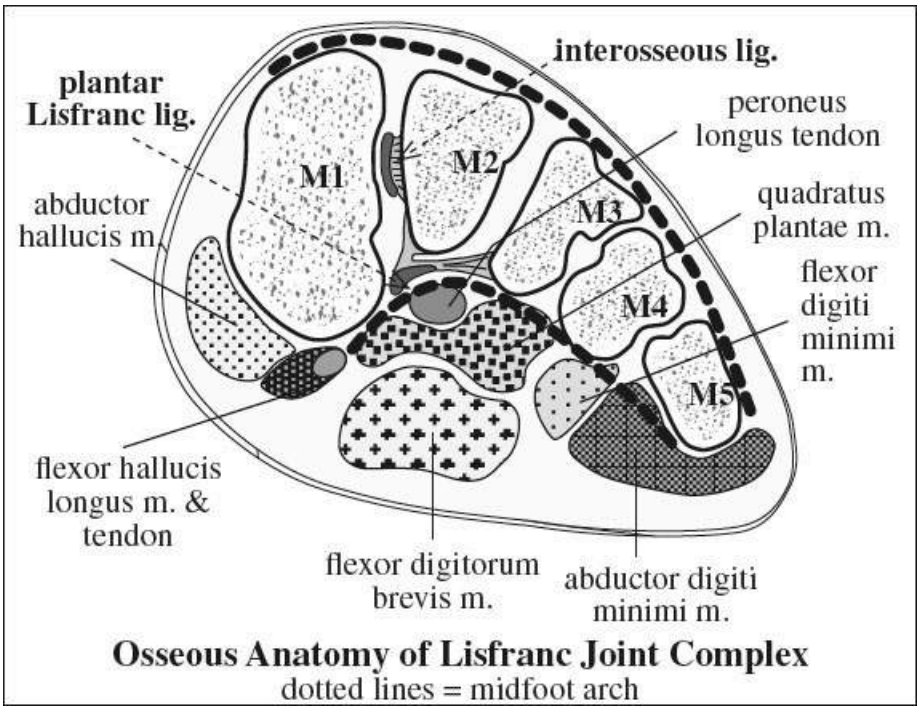
= articulation between nine bones of forefoot and midfoot:
- 5 metatarsals (M1–M5) → contribute to plantar arch (M2–M4 bases of trapezoidal morphology at cross section and M2 base representing osseous "keystone")
- 3 cuneiforms (C1–C3)
- cuboid

Three separate synovial articulations:
- lateral column = most mobile articulation of M4 + M5 with cuboid
- middle column = most rigid articulations of M2 + M3 with C2 + C3
- medial column = rigid articulation between C1 and M1

Location of Common Synovial Recesses and Bursae		
Joint	*Recess or Bursa*	*Location*
Shoulder	Subscapularis	between scapula + subscapularis muscle, extending above + (sometimes) anterior to subscapularis tendon
	Subacromial-subdeltoid	between deltoid muscle + joint capsule, extending underneath acromion + coracoacromial ligament
	Subcoracoid	between anterior surface of subscapularis tendon + coracoid
Elbow	Olecranon	posterior to olecranon process of ulna
	Bicipitoradial	between distal biceps tendon + proximal radius
Hip	Trochanteric	between gluteus maximus / iliotibial tract + posterior facet of greater trochanter
	Iliopsoas	between anterior aspect of hip joint + iliopsoas tendon
	Obturator externus	between superior margin of obturator externus + posteroinferior hip joint capsule
Knee	Gastrocnemius-semimembranosus	posteromedial knee, extending between distal tendon of semimembranosus + proximal tendon of medial head of gastrocnemius
	Suprapatellar	between posterior surface of patella + prefemoral fat pad
	Prepatellar	subcutaneous tissues anterior to patella
	Pes anserine	deep to distal tendons of sartorius, gracilis, semitendinosus as they insert on medial aspect of proximal tibia
Ankle & foot	Retrocalcaneal	between Achilles tendon + posterosuperior surface of calcaneus
	Intermetatarsal	between metatarsal heads



Plantar & Dorsal Lisfranc Ligament Complex
plantar (C1–M2 + C1–M3); dorsal (C1–M2)



Osseous Anatomy of Lisfranc Joint Complex
dotted lines = midfoot arch

Talus

= 2nd largest tarsal bone; ²/₃ of surface covered with articular cartilage

› head of talus

Anterior articulation: Talonavicular joint

Inferior articulation: Anterior talocalcaneal (subtalar) joint

› neck of talus

Inferior surface: tarsal canal opening laterally into sinus tarsi

› talar body

Inferior (subtalar) articulations:

(1) Posterior (lateral) facet: larger articulation

(2) Middle (medial) facet: sustentaculum

Superior articulation: talar dome / trochlea

(1) tibiotalar joint

Lateral articulation: fibula

(1) posterior facet of posterior talocalcaneal (subtalar) joint

› posterior process

(a) medial tubercle

(b) lateral tubercle

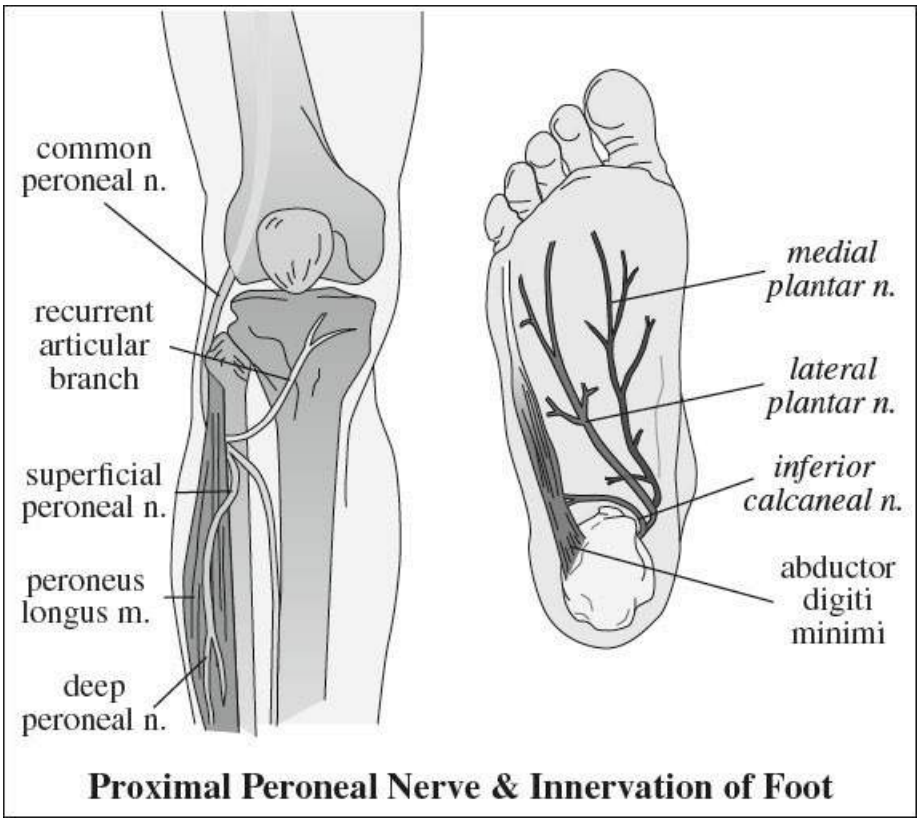
» elongated = Stieda process

» nonfused = os trigonum (prevalence of 2–50%)

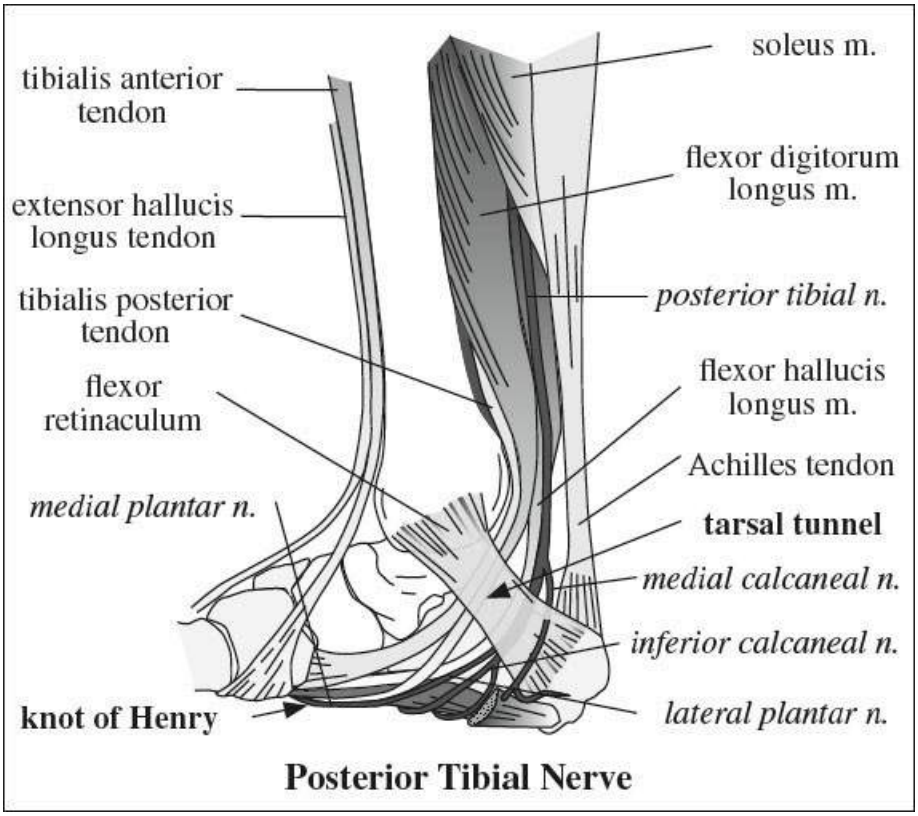
(c) groove between both: for flexor hallucis longus tendon

Blood supply:

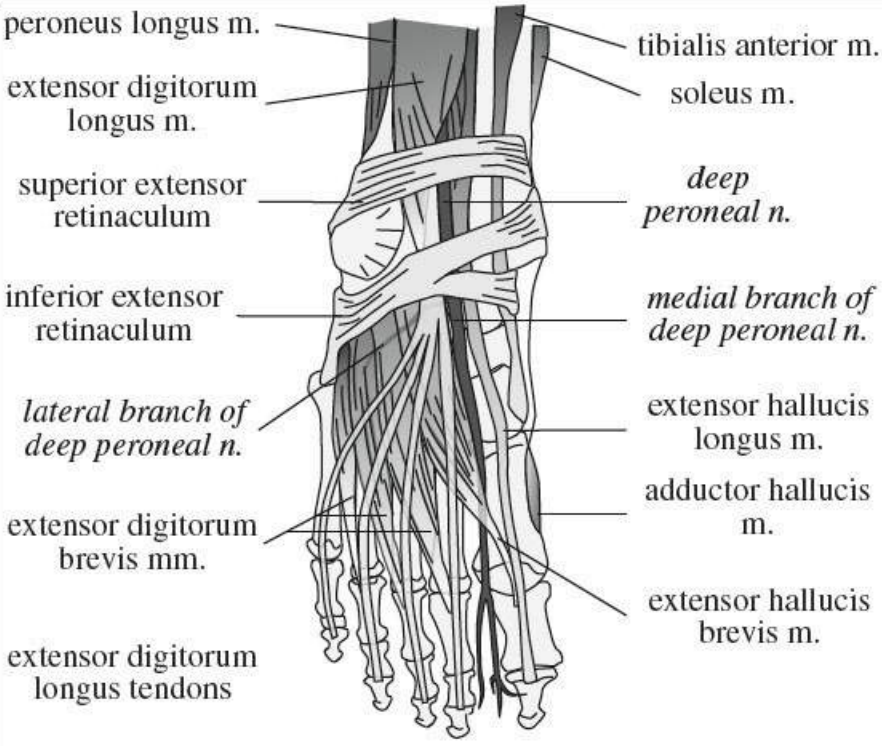
(1) Anterior tibial (dorsalis pedis) artery



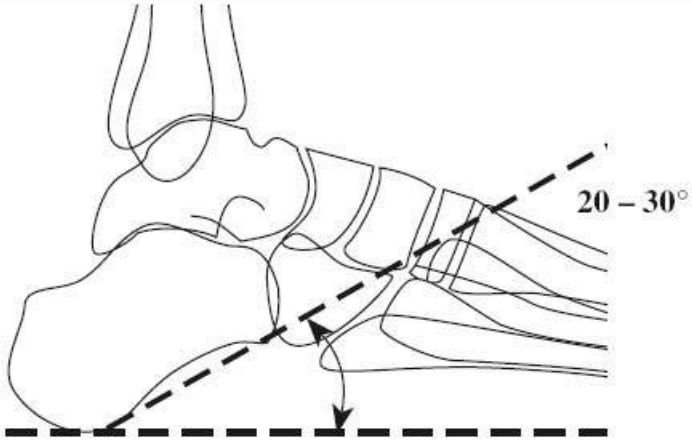
Proximal Peroneal Nerve & Innervation of Foot



Posterior Tibial Nerve

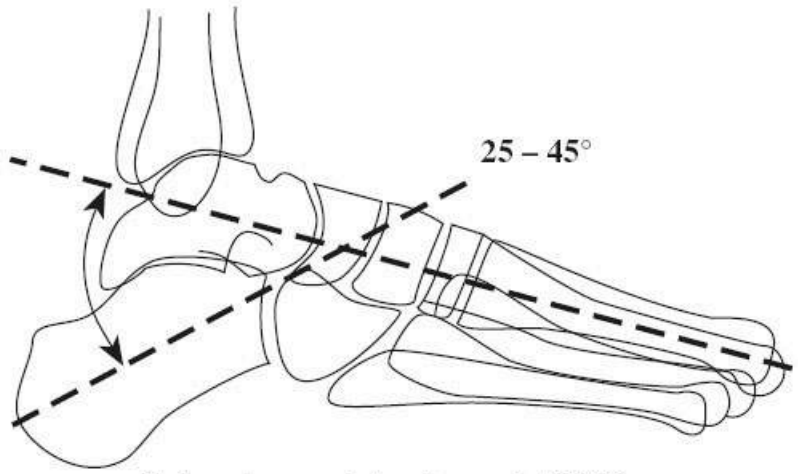


Distal Peroneal Nerve



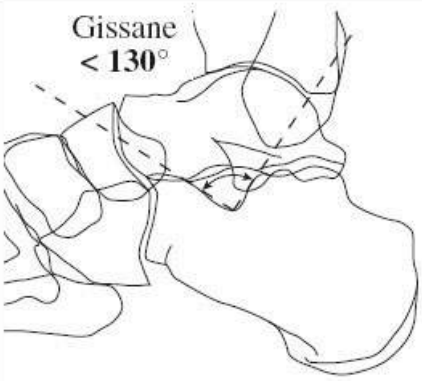
Calcaneal Pitch
= Calcaneal Inclination Angle

= determines longitudinal arch of foot;
angle between line drawn along the inferior border of calcaneus connecting the anterior and posterior prominences + line representing the horizontal surface



Talocalcaneal Angle on LAT View

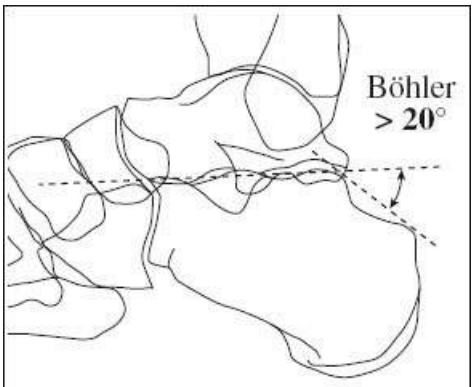
= angle between lines drawn through mid-transverse planes of talus + calcaneus; the midtalar line parallels the longitudinal axis of the first metatarsal



Angle of Gissane

[William Gissane (1898–), trauma surgeon in Birmingham, England]

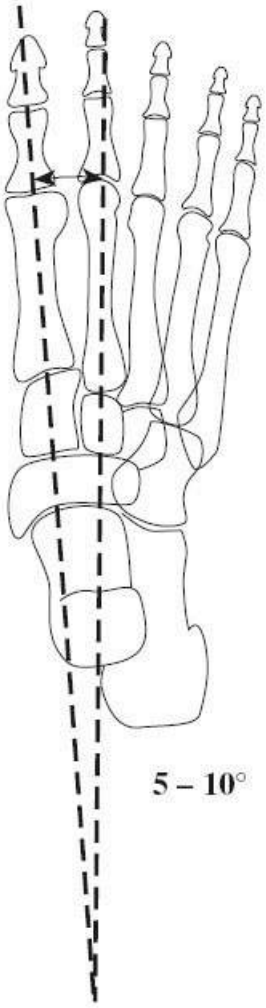
= formed by intersection of downward + upward slopes of calcaneal superior surface, located inferior to lateral process of talus



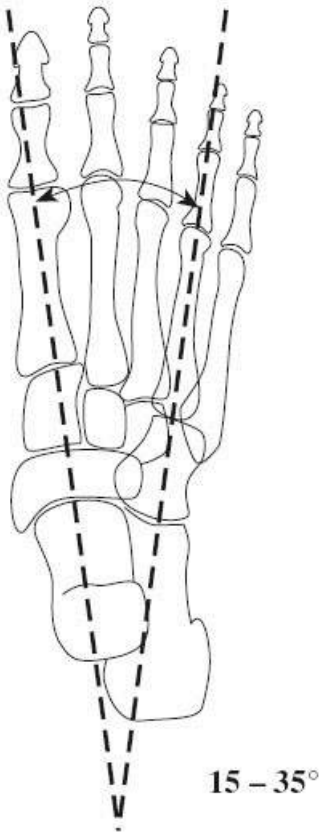
Angle of Böhler

[Lorenz Böhler (1885–1973), trauma surgeon in Vienna, Austria]

= formed by intersection of (a) a line from the highest point of posterior calcaneal tuberosity to the highest point of posterior facet and (b) a line from highest point of anterior process to the highest point of posterior facet



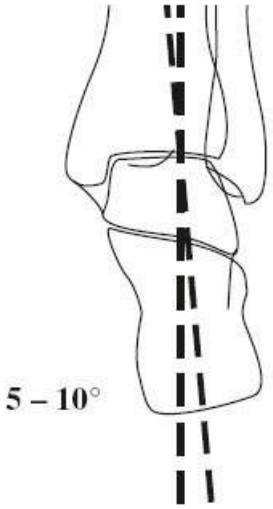
Intermetatarsal Angle
= amount that 1st + 2nd metatarsals diverge from each other



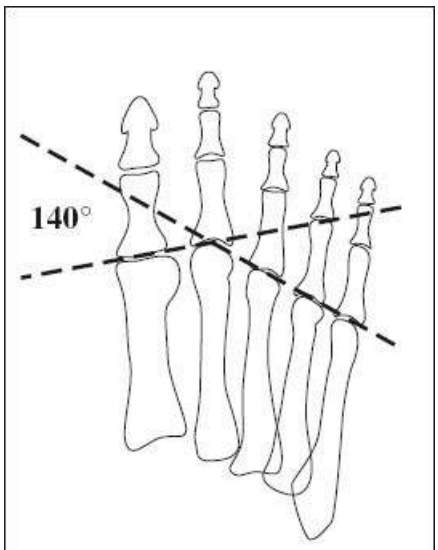
Talocalcaneal Angle on AP View

= KITE ANGLE

= the midtalar and midcalcaneal lines parallel the 1^{st} + 4^{th} metatarsals; angle is greater in infants



Heel Valgus
cannot be measured directly on radiographs but inferred from the talocalcaneal angle and estimated on coronal CT sections

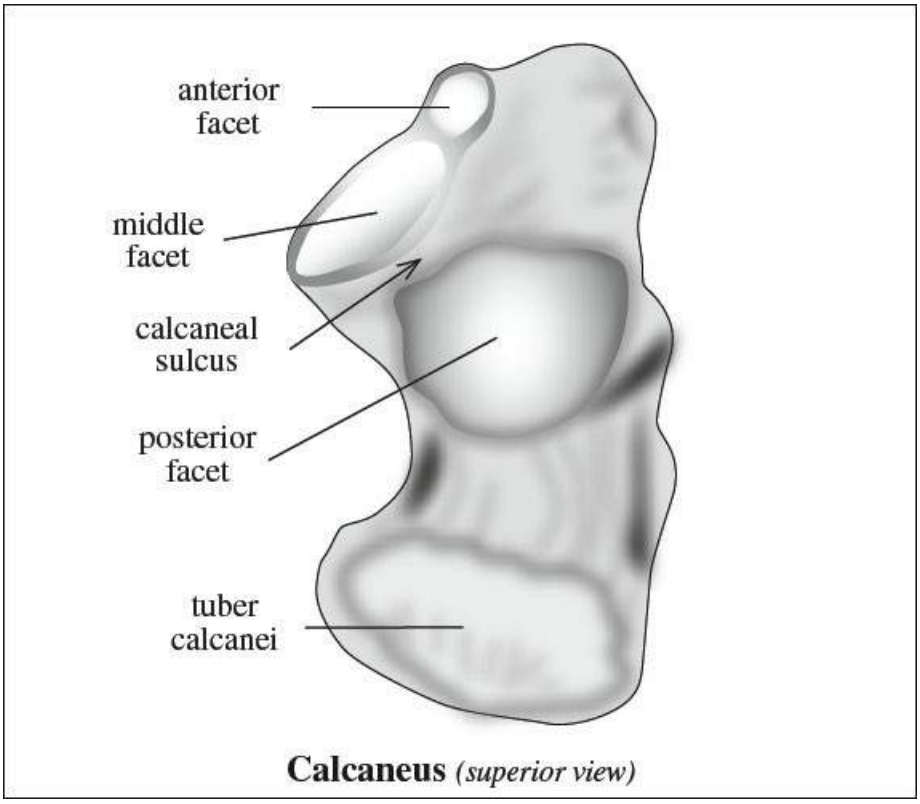


Angle of Metatarsal Heads
= obtuse angle formed by lines tangential to metatarsal heads

(2) Posterior tibial artery → artery of tarsal canal
(3) Peroneal a. → peroneal perforating branch / lateral tarsal artery → tarsal sinus artery

Calcaneus

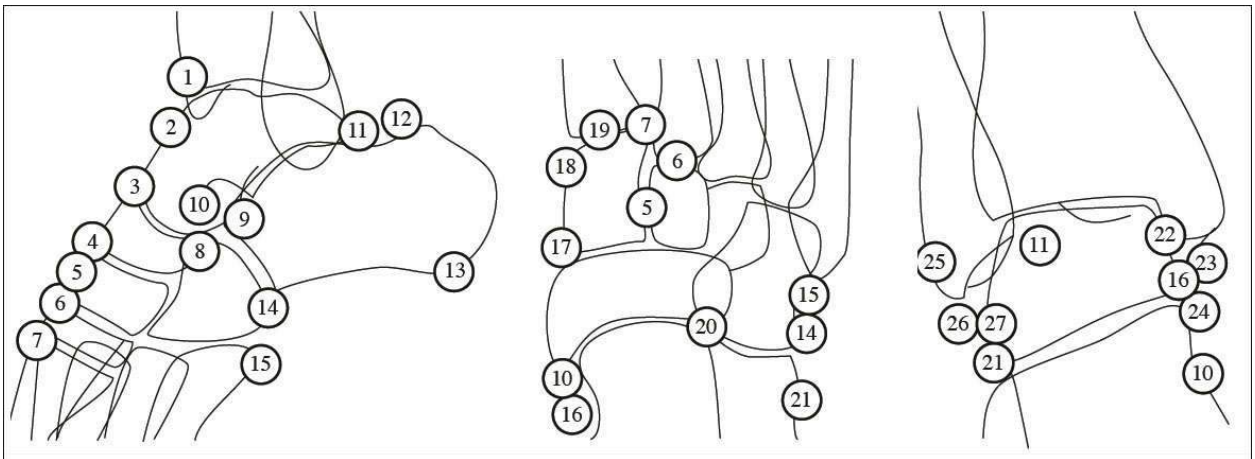
Articulations:
(a) superiorly – subtalar joint:
(1) Anterior talar facet
› supported by calcaneal beak
› articulates with anterior talar facet
(2) Middle talar facet
› articulates with middle talar facet
› supported by sustentaculum tali
calcaneal sulcus = groove between middle and posterior facet
sinus tarsi = canal between calcaneal sulcus and talus
(3) Posterior talar facet
thalamic portion = condensed cortical bone inferior to posterior facet
(b) anteriorly – calcaneocuboid joint
(4) triangular cuboidal facet
Lateral surface: flat + subcutaneous
› peroneal tubercle (centrally located)
» centrally = attachment of calcaneofibular ligament centrally
» anterosuperiorly = attachment of lateral talocalcaneal ligament



Calcaneus *(superior view)*

Medial surface:

› talar support by
  » interosseous lig. + medial talocalcaneal lig.
› *sustentaculum tali* at anterior aspect of medial surface
  » groove inferior to sustentaculum transmits tendon of flexor hallucis longus
› neurovascular bundle



Accessory Ossicles of the Foot

1	Os talotibiale	10	Os tibiale externum	19	Os cuneometatarsale I plantare
2	Os supratalare	11	Trigonum	20	Cuboides secundarium
3	Os supranaviculare	12	Os accessorium supracalcaneum	21	Os trochleare calcanei
4	Os infranaviculare	13	Os subcalcis	22	Sesamoid talus – int. malleolus
5	Os intercuneiforme	14	Os peroneum	23	Os subtibiale
6	Os cuneometatarsale II dorsale	15	Os vesalianum	24	Os sustentaculi
7	Os intermetatarsale	16	Talus accessorius	25	Os retinaculi
8	Secondary cuboid	17	Os cuneonaviculare mediale	26	Os subfibulare
9	Calcaneus secundarius	18	Sesamum tibiale anterius	27	Talus secundarius

BONE AND SOFT-TISSUE DISORDERS

ACHONDROGENESIS

= autosomal recessive lethal chondrodystrophy characterized by extreme micromelia, short trunk, large cranium

Triad: (1) severe short-limb dwarfism
(2) lack of vertebral calcification
(3) large head with normal / decreased calvarial ossification

Birth prevalence: 2.3÷100,000

Path: disorganization of cartilage

A. TYPE I = Parenti-Fraccaro disease
= defective enchondral + membranous ossification
√ complete lack of ossification of calvarium + spine + pelvis
√ absent sacrum + pubic bone
√ extremely short long bones without bowing: especially femur, radius, ulna
√ thin ribs with multiple fractures (frequent)

B. TYPE II = Langer-Saldino disease
= defective enchondral ossification only
√ good ossification of skull vault
√ nonossification of lower lumbar vertebrae + sacrum
√ short + stubby horizontal ribs without fractures

• often subcutaneous edema
√ irregular flared metaphyses: esp. humerus
√ short trunk with narrow chest + protruding abdomen
√ redundant soft tissues
√ polyhydramnios (common)
√ increase in HC÷AC ratio

Prognosis: lethal often in utero / within few hours or days after birth (← respiratory failure)

DDx: often confused with thanatophoric dwarfism

ACHONDROPLASIA

Heterozygous Achondroplasia

◊ Prototype of rhizomelic dwarfism!

= autosomal dominant / sporadic (80%) disease with quantitatively defective endochondral bone formation; related to advanced paternal age; epiphyseal maturation + ossification unaffected

Prevalence: 1÷26,000–66,000 births; M < F ◊ Most common of lethal bone dysplasias!

• normal intelligence + motor function
• neurologic defects
• classically circus dwarfs

@ Skull
- flat nasal bridge (= hypoplastic base of skull)
- macrocephaly + brachycephaly with enlarged bulging forehead (= nonprogressive hydrocephalus)
- relative prognathism

√ large calvarium with frontal bossing
√ depression of nasion
√ broad mandible
√ constricted basicranium + small foramen magnum:
  √ communicating hydrocephalus caused by obstruction of basal cisterns + aqueduct

Cx: apnea + sudden death ← compression of spinal cord and lower brain stem

@ Chest
√ anteroposterior narrowing of chest
√ short anteriorly flared concave ribs
√ squaring of inferior scapular margin

@ Spine
√ hypoplastic bullet- / wedge-shaped vertebra:
  √ rounded anterior beaking of vertebra in upper lumbar spine (DDx: Hurler disease)
  √ decreased vertebral height
√ scalloped posteriorly concave vertebral margin
√ scoliosis:
  √ thoracolumbar angular kyphosis (gibbus)
  √ exaggerated sacral lordosis
√ stenosis of lumbar spine:
  √ narrowing of interpedicular space ← laminar thickening
  √ ventrodorsal narrowing of spine ← short pedicles
  √ bulging / herniation of intervertebral disks
√ wide intervertebral foramina

@ Pelvis
- protuberant abdomen; prominent buttocks
- rolling gait from backward tilt of pelvis and hip joints

√ square flattened iliac bones = tombstone configuration
√ "champagne glass"-shaped pelvic inlet
√ lack of flaring of iliac wings
√ horizontal acetabula (= flat acetabular angle)
√ small sacrosciatic notch

@ Extremities
- trident hand = separation of 2nd + 3rd digit and inability to approximate 3rd + 4th finger; short stubby limbs + fingers
- limited range of motion of elbow

√ predominantly rhizomelic micromelia of long bones (ie, femur, humerus):
  √ "trumpet" appearance of long bones = shortening with disproportionate metaphyseal flaring (= actually normal width of metaphysis)
  √ short femoral necks
  √ limb bowing

√ "ball-in-socket" epiphysis = broad V-shaped distal femoral metaphysis in which epiphysis is incorporated
√ high position of fibular head (= disproportionately long fibula)
√ short ulna with thick proximal + slender distal end
√ brachydactyly (short tubular bones of hand + feet), especially short proximal + middle phalanges

OB-US (diagnosable > 21st–27th week GA):
√ shortening of proximal long bones: femur length < 99th percentile between 21 and 27 weeks MA
√ increased BPD, HC, HC÷AC ratio
√ decreased FL÷BPD ratio
√ normal mineralization, no fractures
√ normal thorax + normal cardiothoracic ratio
√ three-pronged (= trident) hand = 2nd + 3rd + 4th finger of similarly short length without completely approximating each other (= PATHOGNOMONIC)

Cx: (1) Hydrocephalus + syringomyelia (small foramen magnum)
(2) Recurrent ear infection (poorly developed facial bones)
(3) Neurologic complications (compression of spinal cord, lower brainstem, cauda equina, nerve roots): → apnea and sudden death
(4) Crowded dentition + malocclusion

Prognosis: long life
DDx: various mucopolysaccharidoses

Homozygous Achondroplasia

= hereditary autosomal dominant disease with severe features of achondroplasia (= disproportionate limb shortening, more marked proximally than distally)
Risk: marriage of two achondroplasts to each other
√ large cranium with short base + small face
√ flattened nose bridge
√ short ribs with flared ends
√ hypoplastic vertebral bodies
√ decreased interpedicular distance
√ short squared innominate bones
√ flattened acetabular roof
√ small sciatic notch
√ short limb bones with flared metaphyses
√ short, broad, widely spaced tubular bones of hand
Prognosis: often stillborn; lethal in neonatal period (← respiratory failure)
DDx: thanatophoric dysplasia

Pseudoachondroplasia

= part of osteochondroplasias
Prevalence: 4÷1,000,000
Etiology: mutation of genes encoding for cartilage oligomeric matrix protein (COMP) on

chromosome 19 (closely related to multiple epiphyseal dysplasia)

Age at presentation: 2–4 years

- normal facial features and intelligence
- mean adult height 118 (range, 82–130) cm
- disturbance of gait; joint laxity

@ Skull: normal

@ Spine
  - √ persistent oval-shaped vertebral bodies
  - √ anterior beaking, platyspondyly, scoliosis
  - √ odontoid dysplasia
  - √ disk space widening

@ Extremities
  - √ short long bones with flared metaphyses
  - √ small irregular flared epiphyses with delayed development
  - √ coxa vara = medial beaking of proximal femoral neck (CHARACTERISTIC)
  - √ genu valgum, genu varum, genu recurvatum
  - √ shortening + widening of phalanges and metacarpals + metatarsals

@ Pelvis
  - √ widened triradiate cartilage

Cx: premature osteoarthritis

DDx: (1) Achondroplasia (large head with prominent frontal region + depressed bridge of nose, normal epiphyses, trident hands)

(2) Multiple epiphyseal dysplasia (near normal pelvis)

(3) Spondyloepiphyseal dysplasia congenita (hip joints more affected + near normal extremities)

(4) Diastrophic dwarfism (joint contractures and scoliosis at birth / in early infancy)

(5) Metatropic dwarfism (dumbbell-shaped long bones + flattened vertebrae in infancy, less epiphyseal involvement)

ACROOSTEOLYSIS, FAMILIAL

dominant inheritance

Age: onset in 2nd decade; M÷F = 3÷1

- sensory changes in hands + feet
- destruction of nails; joint hypermobility
- swelling of plantar of foot with deep wide ulcer + ejection of bone fragments

@ Skull
  - √ wormian bones
  - √ craniosynostosis
  - √ basilar impression
  - √ protuberant occiput
  - √ resorption of alveolar processes + loss of teeth

@ Spine
  - √ spinal osteoporosis ± fracture

√ kyphoscoliosis + progressive decrease in height

DDx: Hyperparathyroidism

ACROMEGALY

Etiology: excess growth hormone ← eosinophilic adenoma / hyperplasia in anterior pituitary

• gigantism in children: advanced bone age + excessive height (DDx: Sotos syndrome of cerebral gigantism = large skull, mental retardation, cerebral atrophy, advanced bone age)

√ osseous enlargement (phalangeal tufts, vertebrae)

√ flared ends of long bone

√ cystic changes in carpals, femoral trochanters

√ osteoporosis

@ Hand

• spadelike hand

√ widening of terminal tufts

@ Skull

√ prognathism (= elongation of mandible) in few cases

√ sellar enlargement + erosion

√ enlargement of paranasal sinuses: large frontal sinuses (75%)

√ calvarial hyperostosis: especially inner table

√ enlarged occipital protuberance

@ Vertebrae

√ posterior scalloping in 30% ← pressure of enlarged soft tissue

√ anterior new bone

√ loss of disk space (weakening of cartilage)

@ Soft tissue

√ heel pad > 25 mm

@ Joints

√ premature osteoarthritis (commonly knees)

ACTINOMYCOSIS

= chronic suppurative infection characterized by formation of multiple abscesses, draining sinuses, abundant granulation tissue ← mucosal disruption + low tissue oxygen tension

Organism: Actinomyces israelii / naeslundii / odontolyticus / viscosus / meyeri / gerencseriae / eriksonii, gram-positive non–acid-fast anaerobic pleomorphic small branching filamentous bacterium with proteolytic activity, superficially resembling the morphology of a hyphal fungus (Gömöri methenamine silver stain-positive filaments); closely related to mycobacteria

◊ Actinomycotic infections are polymicrobial!

Pathogenesis: trauma / surgery / foreign body → disruption of mucosal barrier → bacterial entry into deep tissues → <u>fibrotic lesion</u> spreading beyond fascial planes → <u>abscess formation</u> centrally → <u>draining sinus tracts</u> extending from abscess to skin / adjacent organs

Spread:

(a) contiguous: production of proteolytic enzymes allow crossing of normal anatomic barriers

(b) hematogenous

No lymphatic spread ← size of organism!

Histo: (a) mycelial form in tissue as yellow tangled filaments of actinomyces = diagnostic sulfur granules seen as round / oval horseshoe-shaped basophilic masses with a radiating fringe of eosinophilic clubs

(b) rod-shaped bacterial form = opportunistic pathogens that normally inhabit oropharynx (dental caries, gingival margins, tonsillar crypts) + GI tract + female genital tract

At risk: very poor dental hygiene, immunosuppressed patient, prolonged use of IUD, bisphosphonate therapy

Location: mandibulofacial > intestinal > lung

Clinical types:

(1) Mandibulo- / cervicofacial actinomycosis (50–65%)

Origin: odontogenic

At risk: poor dental hygiene, recent dental extraction, dental caries, oromaxillofacial trauma, chronic tonsillitis, otitis, mastoiditis, osteonecrosis from irradiation / bisphosphonate therapy

• draining cutaneous sinuses

• "sulfur granules" in sputum / exudate = colonies of organisms arranged in circular fashion = mycelial clumps with thin hyphae 1–2 mm in diameter

√ destruction of mandible (most frequent bone involved) around tooth socket = osteomyelitis of mandible

Site: angle of jaw, submandibular region, cheek, submental space, masticator space, temporomandibular joint

√ no new-bone formation

√ spread into soft tissues at angle of jaw + into neck ignoring normal fascial planes

√ no / few reactive regional lymph nodes

– acute form:

√ soft-tissue swelling / painful pyogenic abscess / mass

– subacute to chronic form:

√ painless indurated mass ± spread to skin often accompanied by draining sinus tracts

(2) Pleuropulmonary / thoracic actinomycosis (15–30%)

Cause: (a) aspiration of infected material from oropharynx

(b) hematogenous spread

(c) direct extension into mediastinum from cervicofacial infection (extremely rare)

(d) transdiaphragmatic / retroperitoneal spread

Predisposed: alcoholics

Histo: masses of PMN leukocytes containing round actinomycotic / sulfur granules surrounded by a rim of granulation tissue

@ Lung

• draining chest wall sinuses ← spread through fascial planes

Predisposed: areas of parenchymal destruction and bronchiectasis ← prior TB / other organisms (= tendency of actinomyces for invasion of devitalized tissue)

√ enhancing extensive transfissural chronic segmental airspace consolidation:
√ hypoattenuating areas + peripheral enhancement (= lung necrosis)
√ often adjacent pleural thickening
Site: usually unilateral + lower lobe predominance
√ multiple small cavitary lesions with ringlike enhancement (= abscesses)
√ fibrotic pleuritis
√ chronic pleural effusion / empyema (in > 50%)
√ rarely acute airspace pneumonia ← postobstructive endobronchial actinomycosis
DDx: carcinoma, TB, bacterial / fungal pneumonia

@ Vertebra + ribs
√ destruction of vertebra with preservation of disk + small paravertebral abscess without calcification (DDx to tuberculosis: disk destroyed, large abscess with calcium)
√ thickening of cervical vertebrae around margins
√ destruction / thickening of ribs

(3) Abdominopelvic / ileocecal / abdominal actinomycosis (20%)
Cause: appendicitis, colonic diverticulitis; penetrating trauma, gut surgery; prolonged IUD use > 2 years (25% of IUDs become eventually colonized with serious infections in 2–4%)
Location: initially localized to cecum / appendix
• fever, leukocytosis, mild anemia
• weight loss, nausea, vomiting, lower abdominal pain
• chronic sinus in groin, vaginal discharge
• yellow / brown sulfur granules on cervical Papanicolaou smear
√ concentric bowel wall thickening:
√ adjacent cystic / solid mass
√ surrounding invasive soft-tissue strands
√ strong enhancement of solid portions ← extensive dense fibrosis = hallmark of actinomycosis
√ fold thickening + ulcerations (resembling Crohn disease)
√ rupture of abdominal viscus (usually appendix)
√ fistula formation
√ rarely regional lymphadenopathy
√ usually no / minimal ascites
Cx: (1) abscess in liver (15%), retroperitoneum, psoas muscle, pelvis, tuboovarian abscess (containing yellow "sulfur granules" = 1–2-mm colony of gram-positive bacilli)
(2) hydronephrosis ← compression of ureter by pelvic abscess

(4) Mixed organs (10%)
@ Tubular bones of hands
√ destructive lesion of mottled permeating type
√ cartilage destruction + subarticular erosive defects in joints (simulating TB)
@ CNS (2–3%), skin, pericardium

Dx: anaerobic culture; species-specific antibodies

Rx: high doses of penicillin G + surgical débridement
DDx: malignancy, chronic granulomatous disease (TB, fungal infection)

ADAMANTINOMA

= (MALIGNANT) ANGIOBLASTOMA
= rare locally aggressive / low-grade malignancy of bone
Risk factors for malignant course:
male sex, young age at presentation, short duration of symptoms, pain at initial presentation, local recurrence
Histo: zonal architecture of neoplastic epithelial cells (reactive to cytokeratins) concentrated centrally in osteofibrous stroma that forms peripherally columnar cells in a palisade pattern; prominent vascularity; resembles ameloblastoma of the jaw
Age: 25–50 (range, 3–74) years, commonest in 2 nd –3 rd decade
Prevalence: < 0.5% of malignant bone tumors
• frequently history of trauma; local swelling ± pain
Location: middle ⅓ of tibia (90%), fibula, ulna, carpals, metacarpals, humerus, shaft of femur
Size: average length of 10 cm
√ eccentric round osteolytic lesion with sclerotic margin
√ multiple additional foci (= multicentricity) in continuity with major lesion (CHARACTERISTIC) in 27%
√ longitudinally oriented along anterior tibial diaphysis
√ narrow zone of transition, may show mottled density
√ slight bone expansion (frequent)
√ cortical breakthrough in 15%
√ synchronous fibular involvement in 5–10%
MR:
√ intermediate signal intensity relative to muscle on T1WI
√ intensity similar to fat on T2WI
√ marked homogeneous enhancement
Prognosis: tendency to recur after local excision (19%); after several recurrences pulmonary metastases may develop; 13% mortality rate
DDx: fibrous dysplasia (in child < 10 years of age, painless enlargement of tibia, anterior bowing, pathologic fracture, eccentric bubbly cortical lucency and expansion with spontaneous regression)

AINHUM DISEASE

= DACTYLOLYSIS SPONTANEA
[ainhum, Brazilian tribal language = fissure, saw, sword]
Etiology: unknown
Histo: hyperkeratotic epidermis with fibrotic thickening of collagen bundles below; chronic lymphocytic inflammatory reaction may be present; arterial walls may be thickened with narrowed vessel lumina
Frequency: up to 2%
Age: usually in males in 4th + 5th decades; Blacks (West Africa) + their American descendants;

M > F

- deep soft-tissue groove forming on medial aspect of plantar surface of proximal phalanx with edema distally
- painful ulceration may develop

Location: mostly 5th / 4th toe (rarely finger); near interphalangeal joint; mostly bilateral

√ sharply demarcated progressive bone resorption of distal / middle phalanx with tapering of proximal phalanx to complete autoamputation (after an average of 5 years)

√ osteoporosis

Rx: early surgical resection of groove with Z-plasty

DDx: (1) Neuropathic disorders (diabetes, leprosy, syphilis)
(2) Trauma (burns, frostbite)
(3) Acroosteolysis from inflammatory arthritis, infection, polyvinyl chloride exposure
(4) Congenitally constricting bands in amniotic band syndrome

AMYLOIDOSIS

= extracellular deposition of a chemically diverse group of protein polysaccharides in body tissues (abnormal folding + assembly of β2-microglobulin); tends to form around capillaries + endothelial cells of larger blood vessels causing ultimately vascular obliteration with infarction

β_2-microglobulin = low-molecular-weight serum protein not filtered by standard dialysis membranes

Incidence: 6–10÷100,000 annually in USA + western Europe

Path: stains with Congo red

At risk: patients on long-term hemodialysis

- bone pain (eg, shoulder pain)
- periarticular rubbery soft-tissue swelling + stiffness (shoulders, hips, fingers):
  - carpal-tunnel syndrome (commonly bilateral)
- Bence-Jones protein (without myeloma)

Amyloid Arthropathy

= synovial-articular pattern of amyloidosis

Associated with: chronic hemodialysis, plasma cell dyscrasia, rheumatoid arthritis, familial Mediterranean fever, chronic osteomyelitis

Location: cervical spine, hip, shoulder, elbow, knee, wrist; bilateral

√ juxtaarticular soft-tissue masses (amyloid deposited in synovium, joint capsule, tendons, ligaments) ± extrinsic osseous erosion

√ mild periarticular osteopenia

√ subchondral cysts + well-defined sclerotic margin

√ joint effusion

√ joint space preserved until late in course of disease

√ subluxation of proximal humerus + femoral neck

MR:

√ extensive deposition of abnormal soft tissue of low to intermediate SI on T1WI + T2WI covering synovial membrane, filling subchondral defects, extending into periarticular

tissue
√ low SI on T1WI + T2WI subjacent to vertebral endplates in lower cervical > thoracic / lumbar spine
√ joint effusion
DDx: inflammatory arthritis, PVNS

Diffuse Amyloid Marrow Deposition

√ generalized osteoporosis
√ coarse trabecular pattern (DDx: sarcoidosis)
√ pathologic collapse of vertebral body may occur

Amyloidoma

= localized destructive lesion of amyloidosis (rarest form)
Location: appendicular > axial skeleton
√ focal medullary lytic lesion with endosteal scalloping (± secondary invasion + erosion of articular bone)
Cx: pathologic fracture

ANEURYSMAL BONE CYST

= expansile pathologically benign lytic lesion of bone containing thin-walled cystic cavities filled with chronic blood products; name derived from roentgen appearance
Incidence: 1.4–2.3% of primary bone tumors
Etiology:
(a) primary ABC (65–99%):
› local circulatory disturbance ← trauma
› improper repair of traumatic subperiosteal hemorrhage
(b) secondary ABC (29–35%) hemorrhage into a preexisting bone lesion → venous obstruction / arteriovenous fistula:
› common: giant cell tumor (19–39%), osteoblastoma, angioma, chondroblastoma
› uncommon: fibrous dysplasia, fibrous histiocytoma, chondromyxoid fibroma, xanthoma (= nonossifying fibroma), eosinophilic granuloma, telangiectatic osteosarcoma, metastatic carcinoma, solitary bone cyst
Histo: lack of anaplasia
(a) "intraosseous arteriovenous malformation" with cystic honeycombed spaces filled with blood separated by spindle cell stroma + osteoclast-like giant cells and osteoid / bone production; mineralized chondroidlike material in 1/3; areas of free hemorrhage
(b) solid variant of ABC in 5–7%: proliferation of spindle cells
Types:
1. INTRAOSSEOUS ABC
= primary cystic / telangiectatic tumor of giant cell family, originating in bone marrow cavity, slow expansion of cortex; rarely related to history of trauma
2. EXTRAOSSEOUS ABC
= posttraumatic hemorrhagic cyst; originating on surface of bones, erosion through cortex into marrow

Peak age: peak age 16 (range, 10–30) years; in 75% < 20 years; F > M
- pain of relatively acute onset with rapid increase of severity over 6–12 weeks; ± history of trauma
- neurologic signs (radiculopathy to quadriplegia) if in spine

Location:
- @ spine (3–20%): thoracic (34%), lumbar (31%), cervical spine (22%), sacrum (13%); involvement of posterior elements with extension into vertebral body (75%); may involve two contiguous vertebrae (25%) / intervertebral disk / ribs / paravertebral soft tissues
- @ long bones: eccentric in metaphysis of femur, tibia, humerus, fibula
- @ pelvis

√ purely lytic eccentric radiolucency
√ aggressive expansile ballooning lesion of "soap-bubble" pattern + thin internal septations + trabeculations
√ rapid progression within 6 weeks to 3 months
√ sclerotic inner portion
√ almost invisible thin cortex (CT shows integrity)
√ tumor respects epiphyseal plate
√ no periosteal reaction (except when fractured)

CT:
- √ "blood-filled sponge" = fluid-fluid / hematocrit levels ← blood sedimentation (in 10–35%)
- √ ± mineralized chondroidlike material when abundant

MR:
- √ multiple cysts of different SI representing different stages of blood by-products:
  - √ heterogeneous fluid-fluid levels within loculations ← hemorrhage with sedimentation
  - √ ↑ signal intensity on T1WI ← methemoglobin
- √ low-SI rim ← intact thickened periosteal membrane
- √ heterogeneous enhancement:
  - √ smooth enhancement of internal septa

NUC:
- √ "doughnut" sign = moderate to intense radiotracer accumulation at lesion periphery (64%)

Angio:
- √ hypervascularity in lesion periphery (in 75%)

Prognosis: 20–30% recurrence rate

Rx: preoperative embolotherapy; complete resection; radiation therapy (subsequent sarcoma possible)

Cx: (1) Pathologic fracture (frequent)
(2) Extradural block with paraplegia

DDx: (1) Giant cell tumor (particularly in spine)
(2) Hemorrhagic cyst (end of bone / epiphysis, not expansile)
(3) Enchondroma
(4) Metastasis (renal cell + thyroid carcinoma)
(5) Plasmacytoma
(6) Chondro- and fibrosarcoma

(7) Fibrous dysplasia
(8) Hemophilic pseudotumor
(9) Hydatid cyst

ANGIOMATOSIS

= diffuse infiltration of bone / soft tissue by hemangiomatous / lymphangiomatous lesions
Age: first 3 decades of life
May be associated with:
chylothorax, chyloperitoneum, lymphedema, hepatosplenomegaly, cystic hygroma

A. OSSEOUS ANGIOMATOSIS (30–40%)
- indolent course

Location: femur > ribs > spine > pelvis > humerus > scapula > other long bones > clavicle
√ osteolysis with honeycomb / latticework ("hole-within-hole") appearance
√ may occur on both sides of joint
DDx: solitary osseous hemangioma

B. CYSTIC ANGIOMATOSIS
= extensive involvement of bone
Histo: endothelium-lined cysts in bone
Peak age: 10–15 years (range, 3 months to 55 years)
Location: long bones, skull, flat bones
√ size of 1–2 mm to several cm
√ multiple osteolytic metaphyseal lesions with fine sclerotic margins + relative sparing of medullary cavity
√ may show overgrowth of long bone
√ endosteal thickening
√ sometimes associated with soft-tissue mass ± phleboliths
√ chylous pleural effusion suggests fatal prognosis
DDx: (other polyostotic diseases like) histiocytosis X, fibrous dysplasia, metastases, Gaucher disease, congenital fibromatosis, Maffucci syndrome, neurofibromatosis, enchondromatosis

C. SOFT-TISSUE ANGIOMATOSIS (60–70%)
= VISCERAL ANGIOMATOSIS
- poor prognosis

D. ANGIOMATOUS SYNDROMES
Maffucci, Osler-Weber-Rendu, Klippel-Trénaunay-Weber, Kasabach-Merritt, Gorham

ANGIOSARCOMA

= aggressive vascular malignancy, frequently with local recurrence + distant metastases; M÷F = 2÷1
Origin: endothelial + mesenchymal cells
Histo: vascular channels surrounded by hemangiomatous / lymphomatous cellular elements with high degree of anaplasia
Associated with: **Stewart-Treves syndrome** = angiosarcoma with chronic lymphedema developing in postmastectomy patients

Location: skin (33%); soft tissue (24%); bone (6%): tibia (23%), femur (18%), humerus (13%), pelvis (7%)
◊ Most commonly in right atrium > retroperitoneum (IVC)
√ heterogeneously enhancing mass expanding involved vessel
DDx: hemangioendothelioma, hemangiopericytoma

Soft-Tissue Angiosarcoma

Risk factors: chronic lymphedema, previous radiation therapy, foreign bodies, immunosuppression
Associated with: NF1, Klippel-Trénaunay-Weber syndrome, Maffucci syndrome
Age: any age; peak incidence in 7th decade
MR:
√ intermediate signal intensity on T1WI
√ areas of high SI on T1WI ← hemorrhage
√ high SI on T2WI (← tumor necrosis + methemoglobin)
√ aggressive infiltration of adjacent tissue
√ intratumoral low SI on all pulse sequences ← high flow
√ intratumoral high SI on T2WI ← low flow
√ contrast enhancement ± central areas of necrosis

ANTERIOR TIBIAL BOWING

= WEISMANN-NETTER SYNDROME
[Robert-Julius Weismann-Netter (1894–1980)]
= congenital painless nonprogressive bilateral anterior leg bowing
Age: beginning in early childhood
• may be accompanied by mental retardation, goiter, anemia
√ anterior bowing of tibia + fibula, bilaterally, symmetrically at middiaphysis
√ thickening of posterior tibial + fibular cortices
√ minor radioulnar bowing
√ kyphoscoliosis
√ extensive dural calcification
DDx: Luetic saber shin (bowing at lower end of tibia + anterior cortical thickening)

APERT SYNDROME

= ACROCEPHALOSYNDACTYLY TYPE I
[Eugène Charles Apert (1868–1940), médecin des hôpitaux Hôtel-Dieu and at the Hôpital des Enfants-Malades]
Frequency: 5.5÷1,000,000 neonates
Etiology: autosomal dominant with incomplete penetrance; sporadic (in majority)
Associated with CNS anomalies:
megalocephaly, gyral abnormalities, hypoplastic white matter, heterotopic gray matter, frontal encephalocele, corpus callosal agenesis, Kleeblattschädel, cleft palate, ventriculomegaly (? related to skull base hypoplasia, rarely progressive)
• IQ varies depending on CNS anomalies (in 50% normal)

- otitis media (high prevalence)
- bifid uvula
- conductive hearing loss (common ← external + middle ear malformations)

@ Skull
- downturned mouth

√ brachycephalic skull (← coronal craniosynostosis) + flat occiput

√ widened metopic + sagittal sutures extending from glabella to posterior fontanel (closing between 2–4 years)

√ hypoplastic / retruded midface:

√ hypertelorism

√ shallow orbits with proptosis

√ underdeveloped paranasal sinuses

√ underdeveloped maxilla with prognathism

√ high pointed arch of palate

√ prominent vertical crest in middle of forehead (← increased intracranial pressure)

√ V-shaped anterior fossa ← elevation of lateral margins of lesser sphenoid

√ ± enlargement of sella

√ stylohyoid ligament calcification (38–88%)

√ cervical spine fusion (in up to 71%), commonly of 5th and 6th vertebrae

√ choanal stenosis

@ Hand & feet

√ severe symmetric syndactyly = fusion of distal portions of phalanges, metacarpals / carpals (most often of 2nd, 3rd + 4th digit)

√ absence of middle phalanges

√ missing / supernumerary carpal / tarsal bones

√ pseudarthroses

@ GU (10%)
- cryptorchidism

√ hydronephrosis

√ polycystic kidneys (rare)

√ bicornuate uterus (rare)

ARTERIOVENOUS FISTULA OF BONE

Etiology: (a) acquired (usually gunshot wound)
(b) congenital AVF

Location: lower extremity most frequent

√ soft-tissue mass

√ presence of large vessels

√ phleboliths (DDx: long-standing varicosity)

√ accelerated bone growth

√ cortical osteolytic defect (= large-vessel pathway into medulla)

√ increased bone density

ARTHROGRYPOSIS

= ARTHROGRYPOSIS MULTIPLEX CONGENITA
= nonprogressive congenital syndromic complex characterized by poorly developed + contracted muscles, deformed joints with thickened periarticular capsule and intact sensory system

Pathophysiology:
congenital / acquired defect of motor unit (anterior horn cells, nerve roots, peripheral nerves, motor end plates, muscle) early in fetal life with immobilization of joints at various stages in their development

Cause: ? neurotropic agents, toxic chemicals, hard drugs, hyperthermia, neuromuscular blocking agents, mytotic abnormalities, mechanical immobilization

Frequency: 0.03% of newborn infants; 5% risk of recurrence in sibling

Path: diminution in size of muscle fibers + fat deposits in fibrous tissue

Associated with:
(1) neurogenic disorders (90%)
(2) myopathic disorders
(3) skeletal dysplasias
(4) intrauterine limitation of movement (myomata, amniotic band, twin, oligohydramnios)
(5) connective tissue disorders

Distribution: all extremities (46%), lower extremities only (43%), upper extremities only (11%); peripheral joints >> proximal joints; symmetrical

• clubfoot; claw hand; congenital dislocation of hip
• diminished muscle mass; skin webs
√ flexion + extension contractures
√ osteopenia ± pathologic fractures
√ congenital dislocation of hip
√ carpal coalition
√ vertical talus
√ calcaneal valgus deformity

ASPHYXIATING THORACIC DYSPLASIA

= JEUNE DISEASE
= autosomal recessive dysplasia characterized by short narrow thorax and short limbs

Prevalence: 1÷100,000 to 1÷130,000 live births

Associated with: renal anomalies (hydroureter), PDA

• respiratory distress ← reduced thoracic mobility (abdominal breathing) + frequent pulmonary infections
• progressive renal failure + hypertension

@ Chest
  √ markedly narrow + elongated bell-shaped chest:
    √ chest diameter significantly decreased compared with that of the abdomen
    √ short horizontal ribs + flared irregular bulbous costochondral junction
  √ normal size of heart leaving little room for lungs
  √ "handle-bar clavicles" = horizontal clavicles at level of C6
@ Pelvis

√ trident morphology of acetabular roof ← retardation of ossification of triradiate cartilage
√ small iliac wings flared + shortened in cephalocaudal diameter ("wineglass" pelvis)
√ narrow sacrosciatic notches
√ short ischial + pubic bones
√ reduced acetabular angle + acetabular spurs
√ premature ossification of capital femoral epiphysis

@ Extremities
√ metaphyseal irregularity
@ thigh & arm
√ rhizomelic brachymelia (humerus, femur) = long bones shorter + wider than normal
√ proximal humeral + femoral epiphyses ossified at birth (frequently)
@ hand & foot
√ postaxial hexadactyly (occasionally)
√ shortening of distal phalanges
√ cone-shaped epiphyses

@ Visceral involvement
√ nephronophthisis (= medullary cystic renal disease) = enlarged kidneys with linear streaking on nephrogram → progressive renal failure (in adulthood)
√ pancreatic cysts
√ intrahepatic bile duct dilatation
√ intestinal malrotation
√ situs anomalies

OB-US:
√ proportionate shortening of long bones
√ small thorax with decreased circumference
√ increased cardiothoracic ratio
√ occasionally polydactyly
√ polyhydramnios

Prognosis: neonatal death in 80% (respiratory failure + infections)
DDx: Ellis-van Creveld syndrome

AVASCULAR NECROSIS

= AVN = OSTEONECROSIS = ASEPTIC NECROSIS
= consequence of reduced / completely interrupted blood supply to bone with death of cellular elements

Terminology (now often used interchangeably):
(1) Osteonecrosis = ischemic bone death ← sepsis
(2) Ischemic necrosis / avascular necrosis / aseptic necrosis = necrosis of epiphyseal + subarticular bone
(3) Bone infarction = necrosis of metaphyseal + diaphyseal bone

Cause: [common causes are underlined]
◊ NO predisposing factors in 25%!
A. Trauma / thermal injury → interruption of arteries
√ typically unilateral

@ Femoral head:
1. Femoral neck fracture (60–75%)
2. Dislocation of hip joint (25%)
3. Slipped capital femoral epiphysis (15–40%)

@ Carpal scaphoid:
4–6 months after fracture (in 10–15%), in 30–40% of nonunions of scaphoid fracture
Site: proximal fragment (most common)

@ humeral head (infrequent)
@ talus (after talar neck fracture)

B. Nontraumatic
√ bilateral (in 70–80%)
(a) Occlusion / embolization of artery
1. Thrombus: thromboembolic disease, sickle-cell disease (SS + SC hemoglobin), polycythemia rubra vera, pheochromocytoma (microscopic thrombotic disease)
2. Nitrogen bubbles: Caisson disease, astronauts
3. Fat: pancreatitis (intramedullary fat necrosis from circulating lipase), alcoholism
4. Thromboembolism, arteriosclerosis
5. Pregnancy

(b) Vessel wall disease:
1. Collagen-vascular disease: SLE, rheumatoid arthritis, polyarteritis nodosa, sarcoidosis
2. Infectious vasculitis
3. Arteriosclerosis

(c) Vascular compression by abnormal deposition of:
1. Fat: corticosteroid therapy (eg, renal transplant, Cushing disease), diabetes
2. Blood: hemophilia, trauma (fractures, dislocations)
3. Inflammatory cells: osteomyelitis, infection, Langerhans cell histiocytosis
4. Tumor cells: leukemia, lymphoma
5. Edema: radiation therapy, hypothyroidism, frostbite
6. Substances: Gaucher disease (vascular compression by lipid-filled histiocytes), gout

(d) Direct cell toxicity
1. Drug therapy: immunosuppressives, cytotoxics, biphosphonates
2. Radiation therapy

(e) Idiopathic
1. Spontaneous osteonecrosis of knee
2. Legg-Calvé-Perthes disease
3. Freiberg disease (repetitive microtrauma)
4. Hypopituitarism

mnemonic: PLASTIC RAGS x 2
Pancreatitis, **P**regnancy
Legg-Perthes disease, **L**upus erythematosus
Alcoholism, **A**therosclerosis
Steroids, **S**ickle-cell disease
Trauma, **T**hermal injury

Idiopathic (Legg-Perthes disease), **I**nfection
Caisson disease, **C**ollagen disease (SLE)
Rheumatoid arthritis, **R**adiation treatment
Alcoholism, **A**myloid
Gaucher disease, **G**out
Sickle cell disease, **S**pontaneous osteonecrosis of knee

mnemonic: GIVE INFARCTS
Gaucher disease
Idiopathic (Legg-Calvé-Perthes, Köhler, Chandler)
Vasculitis (SLE, polyarteritis nodosa, rheumatoid arthritis)
Environmental (frostbite, thermal injury)
Irradiation
Neoplasia (-associated coagulopathy)
Fat (prolonged corticosteroid use increases marrow)
Alcoholism
Renal failure + dialysis
Caisson disease
Trauma (femoral neck fracture, hip dislocation)
Sickle cell disease

Path:

(a) Stage of cell death: cellular ischemia / anoxia → death of hematopoietic cells (in 6–12 hours) > adipocytes > bone cells = osteoclasts and osteoblasts + osteocytes (in 12–48 hours)
  ◊ Chondrocytes are adapted to relatively low oxygen tension and do not become devitalized!

(b) Stage of ↑ vascularity / reparative phase (osteoclasis): trabecular resorption ← inflammatory fibrovascular infiltration + proliferation ← hyperemia mixed with areas of relatively increased trabecular density ← osteonecrosis

(c) Stage of substitution / reactive phase (= osteogenesis): mesenchymal cells differentiate to osteoblasts on surface of dead trabeculae synthesizing new bone layer → trabecular thickening + osteoclastic resorption of devitalized bone (= creeping zone of substitution)
  @ metadiaphyseal osteonecrosis: rim of sclerosis is frequently of undulating / serpentine morphology
  @ epiphyseal osteonecrosis: increased bone resorption at junction of reactive zone and subchondral bone plate + weight-bearing → early fracture of overlying cartilage

Age: 4th–6th decades of life; M÷F = 4–8÷1

- asymptomatic (majority of patients)
- reduced range of motion; pain ← increase in intramedullary pressure ← medullary bone marrow edema

Location: femoral head (most common), humeral head, femoral condyles, proximal tibia, distal femoral metadiaphysis, distal tibial metadiaphysis, scaphoid, lunate, talus

Radiography (positive only after several months of symptoms):
  √ preservation of joint space (DDx: arthritis)
  √ patchy areas of lucency and sclerosis:
    √ dense osteonecrotic bone ← lack of resorption relative to healthy osteopenic bone + new

bone laid down over necrotic trabeculae:
- √ sclerosis of serpentine / undulating morphology characteristically about lesion rim (more common in metadiaphyseal lesions)
- √ early areas of articular collapse (in epiphyseal osteonecrosis) typically at junction of serpentine sclerotic rim and articular surface

√ radiolucent rim around area of osteonecrosis ← absorption around necrotic bone:
- √ "crescent" sign = crescentic subchondral lucency = subchondral structural collapse of necrotic segment parallel to articular surface in weight-bearing portion with separation from overlying cartilage and attached subchondral bone plate (in epiphyseal osteonecrosis)

√ later findings:
- √ flattening of articular surface ← articular fragmentation + progressive articular collapse, secondary osteoarthritis
- √ increased bone density ← compression of osseous trabeculae ← microfracture of nonviable bone + calcification of dendritic marrow + creeping substitution = deposition of new bone

CT (less sensitive than MRI / NUC):

◊ May be utilized for staging of known disease

√ staging upgrades in 30% compared with plain films

√ serpentine / undulating sclerotic margin (late stage)

√ useful for detecting location of articular collapse + extent in epiphyseal osteonecrosis!

NUC (80–85% sensitivity in early stages):

◊ Bone marrow imaging (with radiocolloid) more sensitive than bone imaging (with diphosphonates)

◊ More sensitive than plain films in early AVN ← evidence of ischemia seen as much as 1 year earlier

◊ Less sensitive than MR except for SPECT

Technique: imaging improved with double counts, pinhole collimation

√ diffuse increased radionuclide activity in epiphyseal involvement with articular collapse + 2ndary osteoarthritis

√ very early: cold = photopenic defect on bone scan (blood flow, blood pool, static phase) + bone marrow scan ← interrupted blood supply

√ late: "doughnut" sign = cold spot surrounded by increased radionuclide uptake ← chronic reparative processes:
- (a) capillary revascularization + new-bone synthesis
- (b) degenerative osteoarthritis

MR:

MRI Classification of Aseptic Necrosis
(Mitchell Classification)

Stage	*T1*	*T2*	*Analogous to*
A	high	intermediate	fat
B	high	high	subacute blood
C	low	high	fluid/edema
D	low	low	fibrous tissue

Cx: Malignant transformation to sarcoma (exceedingly rare, exclusive to metaphysis / metadiaphysis): malignant fibrous histiocytoma (69%), osteosarcoma (17%), angiosarcoma (9%)

Cortical Infarction

◊ Requires compromise of
(a) nutrient artery and (b) periosteal vessels!

Age: particularly in childhood where periosteum is easily elevated by edema

√ avascular necrosis = osteonecrosis

√ osteochondrosis dissecans

Cx: (1) Growth disturbances
√ cupped / triangular / coned epiphyses
√ "H-shaped" vertebral bodies
(2) Fibrosarcoma (most common), malignant fibrous histiocytoma, benign cysts
(3) Osteoarthritis

Medullary Infarction

◊ Nutrient artery is the sole blood supply for diaphysis!

Location: distal femur, proximal tibia, iliac wing, rib, humerus

(a) Acute phase:
√ NO radiographic changes without cortical involvement
√ area of rarefaction
√ infarcted area T1 hypointense + T2 hyperintense
√ bone marrow scan: diminished uptake in medullary RES for long period of time
√ bone scan: photon-deficient lesion within 24–48 hours; increased uptake after collateral circulation established

(b) Healing phase (complete healing / fibrosis / calcification):
√ demarcation by zone of serpiginous / linear calcification + ossification parallel to cortex
√ dense bone indicating revascularization
√ focal lesion with fatty marrow SI centrally + surrounding hypointense rim (= reactive / sclerotic bone)

Avascular Necrosis / Adult Osteonecrosis of Hip

Incidence: 10,000–20,000 new cases annually in USA

◊ Involvement of one hip increases risk to contralateral hip to 70%!

Age: 20–50 years

Zonal anatomy (from articular surface to center of head):
› zone of cell death
› reactive interface / creeping zone of substitution
› zone of reinforcing trabecular bone
› zone of reactive marrow
› zone of normal marrow

Classification (Steinberg):

Stage 0 = normal
Stage I = normal / barely detectable trabecular mottling; abnormal bone scan / MRI
Stage IIA = focal sclerosis + osteopenia
Stage IIB = distinct sclerosis + osteoporosis + early "crescent" sign
Stage IIIA = subchondral undermining ("crescent" sign) + cyst formation
Stage IIIB = mild alteration in femoral head contour / subchondral fracture + normal joint space
Stage IV = marked collapse of femoral head + significant acetabular involvement
Stage V = joint space narrowing + acetabular degenerative changes

- hip / groin / thigh / knee pain; limited range of motion

MR (90–100% sensitive, 85% specific for symptomatic disease):
Prevalence of clinically occult disease: 6%

◊ MR imaging changes reflect the death of marrow fat cells (not death of osteocytes with empty lacunae)!
◊ Sagittal images particularly useful!

⇒ EARLY AVN:

The early standard MRI may be normal ← lack of edema / hemorrhage / bone marrow response while Gd-enhancement shows devascularized areas

√ decreased Gd-enhancement on short-inversion-recovery (STIR) images (very early)
√ bone marrow edema: extensive even when area of infarction is small (early)
√ low-SI band with sharp inner interface + blurred outer margin on T1WI within 12–48 hours (= mesenchymal + fibrous repair tissue, amorphous cellular debris, thickened trabecular bone) seen as
(a) band extending to subchondral bone plate
(b) complete ring (less frequent)
√ "double-line" sign on T2WI (in 80%) [MORE SPECIFIC] = juxtaposition of inner hyperintense band (vascularized granulation tissue) + outer hypointense band (chemical shift artifact / fibrosis and sclerosis)

⇒ ADVANCED AVN:
√ "pseudohomogeneous edema pattern" = large inhomogeneous areas of mostly decreased SI on T1WI
√ hypo- to hyperintense lesion on T2WI
√ contrast-enhancement of interface + surrounding marrow + within lesion

⇒ SUBCHONDRAL FRACTURE:
√ predilection for anterosuperior portion of femoral head (SAG images!)
√ cleft of low SI running parallel to the subchondral bone plate within areas of fatlike SI on T1WI
√ hyperintense band (= fracture cleft filled with articular fluid / edema) within the intermediate- or low-signal-intensity of necrotic marrow on T2WI
√ lack of enhancement within + around fracture cleft

⇒ COLLAPSE OF ARTICULAR SURFACE:

√ focal depression of subchondral bone with low SI on T2WI = fibrotic changes in infarcted bone marrow
√ loss of normal spherical contour of bone
√ incongruity of articular surfaces
Predisposition: increased thickness of reparative zone, increasing volume of joint effusion, presence of prominent surrounding edema, patient age > 40 years, body mass index ≥ 24 kg/m^2

Cx: early osteoarthritis through collapse of femoral head + joint incongruity in 3–5 years if left untreated
Best predictor: volume of femoral head involved; collapse in 43–87% with > 25–50% + in 0–5% with < 25–30% involvement of femoral head volume

Rx: (1) core decompression (for grade 0–II): most successful with < 25% involvement of femoral head
(2) osteotomy (for grade 0–II)
(3) arthroplasty / arthrodesis / total hip replacement (for grade > III)

DDx: (1) Transient osteoporosis of the hip = bone marrow edema syndrome (marked diffuse increased SI on long repetition time images + diffuse contrast enhancement, no reactive interface)
(2) Subchondral epiphyseal insufficiency fracture (low SI band in superolateral femoral head convex toward articular surface; speckled / linear hypointense areas, focal depression of epiphyseal contour)
(3) Spondyloarthropathy

Blount Disease

[Walter Putnam Blount (1900–1992), professor of orthopedics at Marquette Medical School, Milwaukee, Wisconsin]
= TIBIA VARA
= avascular necrosis of medial tibial condyle
Age: > 6 years
• limping, lateral bowing of leg
√ medial tibial condyle enlarged + deformed (DDx: Turner syndrome)
√ irregularity of metaphysis (medially + posteriorly prolonged with beak)

Calvé-Kümmel-Verneuil Disease

= VERTEBRAL OSTEOCHONDROSIS = VERTEBRA PLANA
= avascular necrosis of vertebral body
Age: 2–15 years
√ uniform collapse of vertebral body into flat thin disk
√ increased density of vertebra
√ neural arches NOT affected
√ disks are normal with normal intervertebral disk space
√ intravertebral "vacuum cleft" sign (PATHOGNOMONIC)
DDx: eosinophilic granuloma, metastatic disease

Freiberg Disease

[Albert Henry Freiberg (1868–1940), orthopedic surgeon in Cincinnati, Ohio]
= osteochondrosis of head of 2nd (3rd / 4th) metatarsal
Age: 10–18 years; M÷F = 1÷3
• metatarsalgia, swelling, tenderness
Early:
√ flattening, increased density, cystic lesions of metatarsal head
√ widening of metatarsophalangeal joint
Late:
√ osteochondral fragment
√ sclerosis + flattening of metatarsal head
√ increased cortical thickening

Kienböck Disease

= LUNATOMALACIA
[Robert Kienböck (1871–1953), radiologist in Vienna, Austria]
= avascular necrosis of lunate bone
Predisposed: individuals engaged in manual labor with repeated / single episode of trauma
Age: 20–40 year old males
Associated with: ulna minus variant (short ulna) in 75%
• progressive pain + soft-tissue swelling of wrist
Location: uni- > bilateral (usually right hand)
Classification (Lichtman):

Stage I	=	normal radiographs + abnormal MRI
Stage II	=	increased radiographic density with preservation of normal lunate shape
Stage IIIA	=	lunate sclerosis + collapse on radiographs
Stage IIIB	=	+ diminished carpal height and flexion of scaphoid
Stage IV	=	+ extensive carpal degenerative changes

Radiographs:
√ initially normal radiograph
√ osteonecrotic fracture of carpal lunate
√ increased density + altered shape + collapse of lunate
CT:
√ coronal fracture creating a dorsal and volar half
√ multiple lunate fragments
MR:
√ diffusely decreased T1 SI involving entire lunate
√ variable T2 / STIR signal intensity
Cx: scapholunate dissociation, ulnar deviation of triquetrum, degenerative joint disease in radiocarpal / midcarpal compartments
Rx: ulnar lengthening / radial shortening, lunate replacement

Köhler Disease

[Alban Köhler (1874–1947), radiologist in Wiesbaden, Germany and co-founder of Deutsche

Röntgengesellschaft in Berlin]
= avascular necrosis of tarsal scaphoid
Age: 3–10 years; boys
√ irregular outline
√ fragmentation
√ disklike compression in AP direction
√ increased density
√ joint space maintained
√ decreased / increased uptake on radionuclide study

Legg-Calvé-Perthes Disease

= COXA PLANA
[Arthur Thornton Legg (1874–1939), orthopedic surgeon in Boston]
[Jacques Calvé (1875–1954), orthopedic surgeon at Fondation Franco-Americaine de Berck, France]
[Georg Clemens Perthes (1869–1927), head of the surgical clinic in Tübingen, Germany]
= idiopathic avascular necrosis of femoral head in children; one of the most common sites of AVN; in 10–15% almost always metachronously bilateral
Incidence: 1÷10,000 children; increased with lower socioeconomic status, low birth weight, delayed skeletal maturation
Age: (a) 2–12 (peak, 5–6) years: M÷F = 3–5÷1
(b) adulthood: Chandler disease
Cause: trauma in 30% (subcapital fracture, epiphyseolysis, esp. posterior dislocation), closed reduction of congenital hip dislocation, prolonged interval between injury and reduction
Pathophysiology:
insufficient femoral head blood supply (epiphyseal plate acts as a barrier in ages 4–10; ligamentum teres vessels become nonfunctional; blood supply is from medial circumflex artery + lateral epiphyseal artery only); articular cartilage continues to grow ← supplied with nutrients from synovium
Stages:
I = histologic + clinical diagnosis without radiographic findings
II = sclerosis ± cystic changes with preservation of contour + surface of femoral head
III = loss of structural integrity of femoral head
IV = in addition loss of structural integrity of acetabulum

Radiographic Findings in Legg-Calvé-Perthes Disease (*Catterall Classification*)		
Group	*Radiographic Findings*	*Epiphyseal Involvement*
I	√ anterior portion of epiphysis involved √ NO metaphyseal reaction / sequestrum / subchondral fracture	< 25%
II	√ more extensive involvement of anterior portion of epiphysis √ sequestrum √ anterolateral metaphyseal reaction √ subchondral fracture line NOT extending to apex of epiphysis	< 50%
III	√ entire epiphysis dense √ diffuse metaphyseal reaction + widening of neck √ subchondral fracture line posteriorly	most
IV	√ epiphyseal flattening / mushrooming / collapse √ extensive metaphyseal reaction √ posterior remodeling of posterior head	total

- 1 week–6 months (mean 2.7 months) duration of symptoms prior to initial presentation: limp, knee pain
- decreased range of hip motion concerning abduction and internal rotation

NUC (may assist in early diagnosis):

√ decreased uptake (early) in femoral head = interruption of blood supply

√ increased uptake (late) in femoral head

(a) revascularization + bone repair

(b) degenerative osteoarthritis

√ increased acetabular activity associated with degenerative joint disease

X-RAY:

Early signs:

√ femoral epiphysis smaller than on contralateral side (96%) = epiphyseal growth deficit

√ sclerosis of femoral head epiphysis ← sequestration + compression (82%)

√ slight widening of joint space ← thickening of cartilage, failure of epiphyseal growth, presence of joint fluid, joint laxity (60%)

√ ipsilateral bone demineralization (46%)

√ alteration of pericapsular soft-tissue outline ← atrophy of ipsilateral periarticular soft tissues (73%)

√ radiolucency of lateral + medial metaphyseal areas of femoral neck

N.B.: NEVER destruction of articular cortex as in bacterial arthritis

Late signs:

√ delayed osseous maturation of a mild degree

√ "radiolucent crescent line" of subchondral fracture = small archlike subcortical lucency (32%)

√ subcortical fracture on anterior articular surface (best seen on frog leg view)
√ lateral subluxation of femoral head = lateral collapse of ossific nucleus
√ femoral head fragmentation
√ femoral neck cysts (from intramedullary hemorrhage in response to stress fractures)
√ loose bodies (only found in males)

Regenerative signs:
√ coxa plana = flattened collection of sclerotic fragments (over 18 months)
√ coxa magna = remodeling of femoral head to become wider + flatter in mushroom configuration to match widened metaphysis + epiphyseal plate

CT:
√ loss of "asterisk" sign (= starlike pattern of crossing trabeculae in center of femoral head) with distortion of asterisk and extension to surface of femoral head

MR (gold standard):
√ "asterisk" sign of marrow edema = normal marrow SI of femoral epiphysis replaced by low T1-SI + high T2-SI
√ low signal intensity on T1WI and T2WI = necrotic portion of superior epiphysis
√ "double-line" sign (80%) = sclerotic nonsignal rim between necrotic + viable bone edged by a hyperintense rim of granulation tissue
√ "crescent" sign ← subchondral fracture
√ prominent involvement of anterosuperior + lateral femoral head (often best seen on SAG images)
√ thickening of epiphyseal cartilage
√ synovial hypertrophy, joint effusion
√ fluid within fracture plane
√ absent enhancement of femoral head epiphysis
√ early increased diffusivity in affected femoral epiphysis
√ hip joint incongruity: lateral femoral head uncovering, labral inversion, femoral head deformity

NUC (3-phase bone scan):
√ initially no uptake of radiopharmaceutical on early dynamic images
√ increased activity in lateral pillar ← revascularization phase
√ increased activity at epiphyseal base near physis ← transphyseal neovascularization

US:
√ joint effusion, synovitis

Cx: severe degenerative joint disease in early adulthood

Rx: bed rest, abduction bracing (to reduce stress on infarcted head), physical therapy

Metadiaphyseal Osteonecrosis

√ well-defined serpentine hypointense rim surrounding a central region of fat SI on T1WI
√ "double line" sign = bands of low + high SI that course together in parallel surrounding a central region of low SI (= necrotic bone) on T2WI (virtually PATHOGNOMONIC)

Panner Disease

[Hans Jessen Panner (1871–1930), head of roentgenological clinic at Rikshospitalet, Copenhagen, Denmark]

(NOT osteonecrosis)
= benign self-limited disorder of fragmented ossification in epiphysis of humeral capitellum
Age: children 7–12 years of age

Preiser Disease

[Georg Karl Felix Preiser (1876–1913), orthopedic surgeon in Hamburg, Germany]
= nontraumatic spontaneous osteonecrosis of entire scaphoid

Scaphoid Osteonecrosis

= OSTEONECROSIS OF PROXIMAL POLE OF SCAPHOID
Cause: fracture through waist / proximal pole and nonunion
Incidence of proximal pole osteonecrosis:
(a) in > 60% of fracture nonunions of proximal $^{1}/_{3}$ of scaphoid
(b) in ~ 20% of midscaphoid fractures
X-RAY:
√ increased density of proximal scaphoid fracture fragment compared with distal scaphoid / adjacent carpal bones
√ often sclerotic rounded fracture margins (= nonunion)
√ frequently surrounding lucencies (= cysts)
NUC (bone scan):
√ decreased uptake in proximal pole
CT:
√ increased sclerosis + lack of normal trabeculae in proximal third of scaphoid
MR:
√ homogeneously decreased SI (≤ SI of skeletal muscle) at T1WI in proximal pole of scaphoid (71% sensitive, 74% specific)
√ < 20% enhancement in proximal pole (86% sensitive, 96% specific)
√ complete absence of enhancement in proximal pole (54–76% sensitive)
Cx: scaphoid nonunion advanced collapse (= persistent fracture nonunion, radioscaphoid joint space narrowing, sclerosis, osteophytes, potentially proximal pole collapse)

Spontaneous Osteonecrosis of Knee

= SONK
Cause: ? meniscal tear (78%), trauma with resultant microfractures, vascular insufficiency, degenerative joint disease, severe chondromalacia, gout, rheumatoid arthritis, joint bodies, intraarticular steroid injection (45–85%)
Age: 7th decade (range, 13–83 years)
• acute onset of pain
Location: weight-bearing medial condyle more toward epicondylus (95%), lateral condyle (5%), may involve tibial plateau
√ radiographs usually normal (within 3 months after onset)
√ positive bone scan within 5 weeks (most sensitive)
√ flattening of weight-bearing segment of medial femoral epicondyle
√ radiolucent focus in subchondral bone + peripheral zone of osteosclerosis
√ horizontal subchondral fracture (within 6–9 months) + osteochondral fragment

√ periosteal reaction along medial side of femoral shaft (30–50%)
Cx: osteoarthritis

Talar Avascular Necrosis

◊ Fractures involving the talar body have a higher prevalence of AVN
Risk of AVN:
(a) nondisplaced fracture
– talar neck fracture (Hawkins type I) 0–15%
(b) fracture with dislocation / subluxation of:
› subtalar joint (Hawkins type II) 20–50%
› ankle + subtalar joints (Hawkins type III) almost 100%
› subtalar + tibiotalar + talonavicular joints (Hawkins type IV fracture) 100%
√ increase in talar dome opacity / sclerosis
√ deformity + articular collapse + bone fragmentation
√ absent Hawkins sign = thin subchondral radiolucent line along talar dome (← disuse osteopenia) indicates an adequate blood supply

BASAL CELL NEVUS SYNDROME

= NEVOID BASAL CELL CARCINOMA (BCC) SYNDROME = GORLIN-GOLTZ SYNDROME
= syndrome of autosomal dominant inheritance characterized by
(1) multiple cutaneous basal cell carcinomas during childhood
(2) odontogenic keratocysts of mandible
(3) ectopic calcifications
(4) skeletal anomalies (midface hypoplasia, frontal bossing, prognathism)
Mean age: 19 years
• up to hundreds of skin-colored pink / tan dome-shaped papules resembling benign nevi; aggressive after puberty; may metastasize
Distribution: nose, mouth, chest, back; affected by solar + ionizing radiation
• shallow pitlike defects in palms + soles = deficient stratum corneum (85%)
• mental retardation
Genetics: mutation of patched 1 (PTCH) gene that codes for regulatory receptor in the important Sonic hedgehog signaling pathway + acts as a tumor suppressor gene in BCC + medulloblastoma
Association: high incidence of medulloblastoma in children (4–5%); ovarian fibroma (in 17%); cardiac fibroma (in 14%)
√ multiple aggressive uni- / multiloculated mandibular > maxillary cystic lesions = odontogenic keratocyst / keratocystic odontogenic tumor (in 75%)
√ anomalies of upper 5 ribs:
√ forked = bifid rib (most commonly 4th rib) in 26%
√ agenesis / supernumerary ribs
√ fusion of adjacent ribs
√ hypo- / dysplastic distorted splayed ribs
√ bifid spinous processes, spina bifida
√ scoliosis (cervical + upper thoracic)

√ hemivertebrae + block vertebrae
√ Sprengel deformity (scapula elevated, hypoplastic, bowed)
√ deficiency of lateral clavicle
√ brachydactyly
√ extensive early calcification of falx + tentorium (65%)
√ ectopic calcifications of subcutaneous tissue, ovaries, sacrotuberous ligaments, mesentery
√ bony bridging of sella turcica
√ macrocephaly

BATTERED CHILD SYNDROME

= CAFFEY-KEMPE SYNDROME = CHILD ABUSE = PARENT -INFANT TRAUMATIC STRESS SYNDROME = NON-ACCIDENTAL TRAUMA
◊ Most common cause of serious intracranial injuries in children < 1 year of age; 3rd most common cause of death in children after sudden infant death syndrome + true accidents
Prevalence: 1.7 million cases reported + 833,000 substantiated in USA in 1990 (45% neglected, 25% physically abused, 16% sexually abused children); resulting in 2,500–5,000 deaths per year; 5–10% of children seen in emergency rooms
Age: usually < 2 years
• skin burns, bruising, lacerations, hematomas (SNAT = suspected nonaccidental trauma)
@ Skeletal trauma (50–80%)
Site: multiple ribs, costochondral / costovertebral separation, acromion, skull, anterior-superior wedging of vertebra, tibia, metacarpus
Unusual sites: transverse fracture of sternum, lateral end of clavicles, scapula, vertebral compression, vertebral fracture dislocation, disk space narrowing, spinous processes
Other clues: bilateral acute fractures, fractures of lower extremities in children not yet walking
√ multiple asymmetric fractures in different stages of healing (repeated injury = HALLMARK)
√ exuberant callus formation at fracture sites
√ avulsion fracture of ligamentous insertion; frequently seen without periosteal reaction
@ Epiphysis
√ separation of distal epiphysis
@ Metaphysis
√ marked irregularity + fragmentation of metaphyses (DDx: osteochondritis stage of congenital syphilis; infractions of scurvy)
√ "corner" fracture (11%) = "bucket-handle" fracture = avulsion of an arcuate metaphyseal fragment overlying the lucent epiphyseal cartilage
Cause: sudden twisting motion of extremity (periosteum easily pulled away from diaphysis but tightly attached to metaphysis)
Location: knee, elbow, distal tibia, fibula, radius, ulna
@ Diaphysis
√ isolated spiral fracture (15%) of diaphysis ← external rotatory force applied to femur / humerus

√ extensive periosteal reaction from large subperiosteal hematoma apparent after 7–14 days following injury (DDx: scurvy, copper deficiency)
√ cortical hyperostosis extending to epiphyseal plate (DDx: not in infantile cortical hyperostosis)

@ Head trauma (13–25%)
◊ Most common cause of death + physical disability!
(1) Impact injury with translational force: skull fracture (flexible calvaria + meninges decrease likelihood of skull fractures), subdural hematoma, brain contusion, cerebral hemorrhage, infarction, generalized edema
(2) Whiplash injury with rotational force: shearing injuries + associated subarachnoid hemorrhage
• bulging fontanels, convulsions
• ocular lesions, retinal detachment

Skull film (associated fracture in 1%):
√ linear fracture > comminuted fracture > diastases (conspicuously absent)

CT:
√ subdural hemorrhage (most common): interhemispheric location most common
√ subarachnoid hemorrhage
√ epidural hemorrhage (uncommon)
√ cerebral edema: focal, multifocal, diffuse
√ acute cerebral contusion as ovoid collection of intraparenchymal blood with surrounding edema

MR:
◊ More sensitive in identifying hematomas of differing ages
√ white matter shearing injuries as areas of prolonged T1 + T2 at corticomedullary junction, centrum semiovale, corpus callosum

@ Visceral trauma (3%)
◊ Second leading cause of death in child abuse
Cause: crushing blow to abdomen (punch, kick)
Age: often > 2 years
√ small bowel / gastric rupture
√ hematoma of duodenum / jejunum
√ contusion / laceration of lung, pancreas, liver, spleen, kidneys
√ traumatic pancreatic pseudocyst

Cx: (1) Brain atrophy (up to 100%)
(2) Infarction (50%)
(3) Subdural hygroma
(4) Encephalomalacia
(5) Porencephaly

DDx: normal periostitis of infancy, long-term ventilator therapy in prematurity, osteogenesis imperfecta, congenital insensitivity to pain, infantile cortical hyperostosis, Menkes kinky hair syndrome, Schmid-type chondrometaphyseal dysplasia, scurvy, congenital syphilitic metaphysitis

BENIGN CORTICAL DEFECT

= developmental intracortical bone defect

Age: usually 1st–2nd decade; uncommon in boys < 2 years of age; uncommon in girls < 4 years of age

• asymptomatic

Site: metaphysis of long bone

√ well-defined intracortical round / oval lucency

√ usually < 2 cm long

√ sclerotic margins

Cx: pathologic / avulsion fracture following minor trauma (infrequent)

Prognosis: (1) Spontaneous healing resulting in sclerosis / disappearance

(2) Ballooning of endosteal surface of cortex = fibrous cortical defect

(3) Medullary extension resulting in nonossifying fibroma

BIZARRE PAROSTEAL OSTEOCHONDROMATOUS PROLIFERATION

= NORA LESION

= benign exophytic surface lesion of bone

Cause: ? reactive mass of heterotopic mineralization arising from periosteum of intact cortex without involvement of medullary canal

Location: small tubular bones of hands + feet; proximal and middle phalanges (92%); metacarpal bones (8%)

Site: diaphyses + metaphyses of phalanges

• painless progressive swelling of digit

• ± limited motion in proximity to a joint

√ well-marginated ossified broad-based lesion arising from bone cortex, usually without cortical erosion

√ cortical + medullary discontinuity from underlying host bone

√ periosteal reaction usually absent

MR:

√ uniformly enhancing T1-hypointense mass

√ mass of hyperintensity on T2WI

Rx: surgical excision with wide margins in symptomatic patient

Prognosis: 55% recurrence rate within 2 years of excision

DDx: osteochondroma (cortical + medullary continuity between host bone and mass)

BONE CONTUSION

= BONE BRUISE

= acute bone injury in children

Path: subcortical trabecular microfractures → intraosseous hemorrhage + edema without cortical fracture line

• chronic pain ← persistently elevated intraosseous pressure

Radiograph / CT:

√ invisible

MR (fat-suppression!):

√ high T2 signal intensity = marrow edema + hemorrhage

Prognosis: healing in 12–16 weeks (much longer than for a typical cortical fracture)

Cx: insufficiency fracture ← return to normal physical activity before complete healing

BONE ISLAND

= ENOSTOSIS = ENDOSTEOMA = COMPACT ISLAND
= FOCAL SCLEROSIS = SCLEROTIC BONE ISLAND
= CALCIFIED MEDULLARY DEFECT
= focal lesion of densely sclerotic (compact) bone nesting within spongiosa

Age: any age (mostly 20–80 years of age); grows more rapidly in children

Histo: nest of lamellar compacted bone with haversian system embedded within medullary canal

Pathogenesis: ? misplaced cortical hamartoma, ? developmental error of endochondral ossification as a coalescence of mature bone trabeculae with failure to undergo remodeling; not inherited

• asymptomatic

Location: ilium + proximal femur (88–92%), ribs, spine (1–14%), humerus, phalanges (not in skull)

Size: usually 2–10 mm; lesion > 2 cm in longest axis = giant bone island

√ round / oval / oblong solitary osteoblastic lesion with abrupt transition to surrounding normal trabecular bone:
  √ "brush border" = "thorny radiations" = sharply demarcated margins with feathery peripheral radiations (HALLMARK) blending with trabeculae of surrounding spongiosa
  √ long axis of bone island parallels long axis of bone

√ may demonstrate slow growth / decrease in size (32%)

√ NO involvement of cortex / radiolucencies / periosteal reaction

MR:
  √ low signal intensity at T1WI and T2WI

NUC:
  √ may show activity on bone scan (< 10%), esp. if large

Prognosis: may increase to 8–12 cm over years (40%); may decrease / disappear

DDx: (1) Osteoblastic metastasis (aggressive, break through cortex, periosteal reaction)
(2) Low-grade osteosarcoma (cortical thickening, extension beyond medullary cavity)
(3) Osteoid osteoma (pain relieved by aspirin, nidus)
(4) Benign osteoblastoma
(5) Involuted nonossifying fibroma replaced by dense bone scar
(6) Eccentric focus of monostotic fibrous dysplasia
(7) Osteoma (surface lesion)

BRUCELLOSIS

= multisystemic zoonosis of worldwide distribution; endemic in Middle East (Arabian Peninsula), South and Central America, Mediterranean region (Spain, Italy)

Organism: small gram-negative nonmotile, nonsporing, aflagellate, nonencapsulated

coccobacilli: Brucella abortus, B. suis, B. canis, B. melitensis

Mode of transmission:
handling contaminated animal products (in excreta of infected animals like urine, stool, milk, products of conception) or consuming dairy products from unpasteurized milk

Histo: small intracellular pathogens cause small noncaseating granuloma within RES

Location: commonest site of involvement is reticuloendothelial system; musculoskeletal system

• 1–3 weeks between initial infection + symptoms
  ◊ Radiologic evidence of disease in 69% of symptomatic sites!

@ Brucellar spondylitis (53% = most common site)
  Age: 40 years is average age at onset
  • pain, localized tenderness, radiculopathy, myelopathy
  Location: lumbar (71%) > thoracolumbar (10%) > lumbosacral (8%) > cervical (7%) > thoracic (4%)
  (a) focal form
    √ bone destruction at diskovertebral junction (anterior aspect of superior endplate)
    √ associated with bone sclerosis + anterior osteophyte formation + small amount of gas
  (b) diffuse form: entire vertebral endplate / whole vertebral body affected with spread to adjacent disks + vertebral bodies
    √ bone destruction associated with sclerosis
    √ small amount of disk gas (25–30%)
    √ facet joint involvement
    √ obliteration of paraspinal muscle-fat planes
    √ paraspinal abscess (smaller than in TB)
    √ no / minimal epidural extension
    DDx: TB (paraspinal abscess, gibbus)

@ Extraspinal disease
  (a) Brucellar synovitis (81%)
    Location: knee > sacroiliac joint > shoulder > hip > sternoclavicular joint > ankle > elbow
    Site: organism localized in synovial membrane
    • serosanguinous sterile joint effusion
    √ bilateral sacroiliitis
  (b) Brucellar destructive arthritis (9%)
    √ indistinguishable from tuberculous / pyogenic arthritis
  (c) Brucellar osteomyelitis (2%)
    • pain, tenderness, swelling
  (d) Brucellar myositis (2%)

Dx: serologic tests (enzyme-linked immunosorbent assay, counterimmunoelectrophoresis, rose bengal plate test

Rx: combination of aminoglycosides + tetracyclines

DDx: fibrous dysplasia, benign tumor, osteoid osteoma

CAISSON DISEASE

= DECOMPRESSION SICKNESS = THE BENDS

Etiology: during too rapid decompression (= reduction of surrounding pressure ← ascent from dive, exit from caisson / hyperbaric chamber, ascent to altitude) nitrogen bubbles form (nitrogen is more soluble in fat of panniculus adiposus, spinal cord, brain, bones containing fatty marrow)

- "the bends" = local pain in knee, elbow, shoulder, hip
- neurologic symptoms: paresthesia, major cerebral / spinal involvement
- "chokes" = substernal discomfort + coughing ← embolization of pulmonary vessels

Location: mostly in long tubular bones of lower extremity (distal end of shaft + epiphyseal portion); symmetrical lesions

√ early: area of rarefaction
√ healing phase: irregular new-bone formation with greater density
√ peripheral zone of calcification / ossification
√ ischemic necrosis of articular surface → secondary osteoarthritis

CALCIUM PYROPHOSPHATE DIHYDRATE DEPOSITION DISEASE

= CPPD = PSEUDOGOUT = FAMILIAL CHONDROCALCINOSIS
= metabolic arthropathy characterized by deposition of calcium pyrophosphate dihydrate crystals in articular + periarticular tissues
◊ Most common crystalline arthropathy

Chondrocalcinosis = term for intra-articular calcifications with involvement of hyaline articular cartilage and fibrocartilage

Types:
1. Osteoarthritic form (35–60%)
2. **Pseudogout** = acute synovitis (10–20%) mimicking gout attack
3. Rheumatoid form (2–6%)
4. Pseudoneuropathic arthropathy (2%)
5. Asymptomatic with tophaceous pseudogout (common)

Associated with: hyperparathyroidism, hypothyroidism, hemochromatosis, hypomagnesemia

Prevalence: widespread in older population; increasing with age; M÷F = 3÷2

- calcium pyrophosphate crystals in synovial fluid + within leukocytes (characteristic weakly positive birefringent rhomboid foci)
- acute / subacute / chronic joint inflammation

√ polyarticular chondrocalcinosis (in fibro- and hyaline cartilage)
√ large subchondral cyst (HALLMARK)
√ numerous intraarticular bodies (fragmentation of subchondral bone)
√ coalescing CPPD crystals → tophus-like deposits (rare) → significant articular destruction

Site: involvement of tendons, bursae, pinnae of the ear

- painful mass

√ joint space narrowing + extensive subchondral sclerosis
◊ CPPD arthropathy resembles osteoarthritis!

@ Hand

Distribution: 1 CMC; 2nd + 3rd MCP joints; bilateral symmetric

√ resembling degenerative joint disease (without DIP and PIP involvement)
√ small hook-like osteophytes at radial aspect of metacarpal heads 2 & 3

@ Wrist

Distribution: triangular fibrocartilage in distal radioulnar joints bilaterally, proximal carpal row joints at lunotriquetral + scapholunate ligaments

√ calcification (chondrocalcinosis) of triangular fibrocartilage

√ extensive narrowing / obliteration of joint space between distal radius + scaphoid → destruction of trapezioscaphoid space:

√ incorporation of scaphoid into articular surface of radius

√ prominent cysts

√ scapholunate separation (= ligament tear) → scapholunate advanced collapse (SLAC

@ Knee

Distribution: especially meniscus + cartilage of patellofemoral joint

√ medial femorotibial + patellofemoral compartments commonly involved simultaneously (as in osteoarthritis) but with greater osseous destruction + fragmentation

√ disproportionate narrowing of patellofemoral joint

@ Spine

√ chondrocalcinosis / calcifications of outer fibers of annulus fibrosus of lumbar spine resembling syndesmophytes; NEVER in nucleus pulposus

DDx: ochronosis (in nucleus pulposus)

√ vertical radiodense line in symphysis pubis

Other locations:

› pelvis (sacroiliac joint, symphysis)

› shoulder (glenoid), hip (labrum), elbow, ankle, acromioclavicular joint

CAMPTOMELIC DYSPLASIA

= sporadic / autosomal recessive dwarfism

Prevalence: 0.05÷10,000 births

Associated with:

1. Hydrocephalus (23%)
2. Congenital heart disease (30%): VSD, ASD, tetralogy, AS
3. Hydronephrosis (30%)

• pretibial dimple

√ macrocephaly, cleft palate, micrognathia (90–99%)

@ Chest & spine

√ absence / hypoplasia of scapula (92%)

√ narrow bell-shaped chest

√ hypoplastic vertebral bodies + nonmineralized pedicles (especially lower cervical spine)

@ Pelvis

√ vertically narrowed iliac bones

√ vertical inclination of ischii

√ wide symphysis

√ narrow iliac bones with small wings

√ shallow acetabulum

@ Extremities (lower extremity more severely affected)

√ dislocation of hips + knees

√ anterior bowing (= campto) of long bones: marked in tibia + moderate in femur

√ hypoplastic fibula
√ small secondary ossification center of knee
√ small primary ossification center of talus
√ clubfoot

OB-US:
√ bowing of tibia + femur
√ decreased thoracic circumference
√ hypoplastic scapulae
√ ± cleft palate

Prognosis: death usually < 5 months of age (within first year in 97%) ← respiratory insufficiency

CARPAL TUNNEL SYNDROME

= entrapment syndrome caused by chronic pressure on the median nerve within the carpal tunnel

Etiology:
(a) intrinsic: flexor tendon tendinitis or tenosynovitis, infiltrative disorder, mass, cyst, muscle hypertrophy (from repetitive wrist / finger flexion), anomalous origin of lumbrical muscles
(b) extrinsic: mass, carpal instability, Kienböck disease

Pathogenesis: probably ischemia with venous congestion (stage 1), nerve edema from anoxic damage to capillary endothelium (stage 2), impairment of venous and arterial blood supply (stage 3)

• nocturnal hand discomfort
• weakness, clumsiness, finger paresthesias

MR:
√ "pseudoneuroma" of median nerve = swelling of median nerve proximal to carpal tunnel
√ swelling of nerve within carpal tunnel
√ increased signal intensity of nerve on T2WI
√ volar bowing of flexor retinaculum
√ swelling of tendon sheath ← tenosynovitis
√ mass(es) within carpal tunnel
√ marked enhancement ← nerve edema ← breakdown of blood-nerve barrier
√ no enhancement (= ischemia) provoked by wrist held in an extended / flexed position

CARPENTER SYNDROME

= ACROCEPHALOPOLYSYNDACTYLY TYPE 2

autosomal recessive

• retardation; hypogonadism
√ patent ductus arteriosus
√ acro(oxy)cephaly
√ brachymesophalangia
√ soft-tissue syndactyly (hands + feet)
√ preaxial polysyndactyly of feet

CEREBROCOSTOMANDIBULAR SYNDROME

= rare bone disorder of uncertain transmission
• respiratory distress ← flail chest and airway abnormalities
√ 11 pairs of ribs:
  √ abnormal costovertebral articulations
  √ posterior ossification gaps resembling fractures
√ microcephaly
√ micrognathia
√ congenital heart disease
DDx: multiple fractures

CHONDROBLASTOMA

= CODMAN TUMOR = BENIGN CHONDROBLASTOMA = CARTILAGE-CONTAINING GIANT CELL TUMOR
= benign cartilaginous tumor with predilection for growing skeleton
Frequency: 1% of primary bone neoplasms (700 cases in world literature)
Age: peak in 2nd decade (range, 8–59 years); 10–26 years (90%); M÷F = 2÷1; occurs before cessation of enchondral bone growth
Path: derived from primitive cartilage cells
Histo: polyhedral chondroblasts + reactive multinucleated giant cells + nodules of pink amorphous material (= chondroid) = epiphyseal chondromatous giant cell tumor (resembles chondromyxoid fibroma); "chicken wire" calcification of matrix = pericellular deposition of calcification is virtually PATHOGNOMONIC
• symptomatic for months to years prior to treatment
• mild joint pain, tenderness, swelling (joint effusion)
• limitation of motion
Location:
(a) long bones (80%): proximal femur + greater trochanter (23%), distal femur (20%), proximal tibia (17%), proximal humerus (17%)
  ◊ ²/₃ in lower extremity, 50% about knee
  ◊ may occur in apophyses (minor + greater trochanter, patella, greater tuberosity of humerus)
(b) flat bones: near triradiate cartilage of innominate bone, rib (3%), vertebral body & posterior elements (1.4%)
(c) short tubular bones of hand + feet
Site: eccentric medullary, subarticular location with open growth plate (98% begin within epiphysis); tumor growth may continue to involve metaphysis (50%) + rarely diaphysis
√ oval / round eccentrically placed lytic lesion of epiphysis
√ 1–4 cm in diameter occupying < ½ of epiphysis
√ well-defined sclerotic margin, lobulated in 50%
√ stippled / irregular calcifications in 25–30–50% (cartilaginous clumps better visualized by CT)
√ intact scalloped cortical border
√ thick periosteal reaction in metaphysis (50%) / joint involvement
√ periostitis of adjacent metaphysis / diaphysis (30–50%)

√ growth plate open in majority of patients

MR:

◊ MR tends to overestimate extent + aggressiveness ← large area of reactive edema!

√ intermediate to low SI on T2WI relative to fat ← immature chondroid matrix, hypercellularity, calcifications, hemosiderin

√ extensive intramedullary signal abnormalities ← bone marrow edema

√ peripheral rim of very low signal intensity

√ hypointense changes on T1WI + hyperintense on T2WI in adjacent soft tissues (← muscle edema in 50%)

√ ± joint effusion

Prognosis: almost always benign; may become locally aggressive; rarely metastasizes

Dx: surgical biopsy

Rx: curettage + bone chip grafting (recurrence in 25%)

DDx: (1) Ischemic necrosis of femoral head (may be indistinguishable, more irregular configuration)

(2) Giant cell tumor (usually larger + less well demarcated, not calcified, older age group with closed growth plate)

(3) Chondromyxoid fibroma

(4) Enchondroma

(5) Osteomyelitis (less well-defined, variable margins)

(6) Aneurysmal bone cyst

(7) Intraosseous ganglion

(8) Langerhans cell histiocytosis (less well-defined, variable margins)

(9) Primary bone sarcoma

CHONDRODYSPLASIA PUNCTATA

= CONGENITAL STIPPLED EPIPHYSES = DYSPLASIA EPIPHYSEALIS PUNCTATA = CHONDRODYSTROPHIA CALCIFICANS CONGENITA

= group of syndromes characterized by abnormal calcific foci in areas of enchondral bone formation

Etiology: peroxisomal disorder characterized by fibroblast plasmalogen deficiency

Prevalence: 1÷110,000 births

Genetics: X-linked autosomal

› recessive = alterations in peroxisomal metabolism

› dominant = mutations in delta 8 sterol isomerase enzyme → abnormal cholesterol biosynthesis (cholesterol is essential to proper function of Sonic hedgehog class of embryonic signaling proteins)

Associated with: congenital ichthyosiform erythroderma = generalized erythema with characteristic feathery adherent hyperkeratotic scale

Radiograph:

√ calcific stippling of epiphyses (prior to normal epiphyseal ossification)

√ scoliosis, kyphosis

A. **Autosomal Recessive Chondrodysplasia Punctata**

= RHIZOMELIC TYPE

Associated with: CHD (common)

- craniofacial dysmorphism = flat face with small saddle nose
- congenital cataracts
- severe mental retardation, spastic tetraplegia
- thermoregulatory instability
- cleft palate

√ multiple small punctate calcifications of varying size in epiphyses (knee, hip, shoulder, wrist), base of skull, posterior elements of vertebrae, respiratory cartilage and soft tissues (neck, rib ends) before appearance of ossification centers

√ prominent symmetrical shortening of femur + humerus (rarely all limbs symmetrically affected)

√ congenital dislocation of hip

√ multiple flexion (joint) contractures of extremities

√ clubfeet

√ metaphyseal splaying of proximal tubular bones (in particular about knee)

√ thickening of diaphyses

√ prominent vertebral + paravertebral calcifications

√ coronal clefts in vertebral bodies

OB-US:

√ ascites, polyhydramnios

Prognosis: death usually < 1 year of age

DDx: Zellweger syndrome

B. **Conradi-Hünermann-Happle Syndrome**

= NONRHIZOMELIC TYPE

more common milder nonlethal variety

Genetics: mutation localized to Xp11.23 to EBP gene

- normal intelligence

√ more widespread but milder involvement as above

Prognosis: survival often into adulthood

Cx: respiratory failure (severe underdevelopment of ribs), tracheal stenosis, spinal cord compression

DDx: (1) Cretinism (may show epiphyseal fragmentation, much larger calcifications within epiphysis)

(2) Warfarin embryopathy

(3) Zellweger syndrome

CHONDROECTODERMAL DYSPLASIA

= ELLIS-VAN CREVELD SYNDROME = MESODERMAL DYSPLASIA

= autosomal recessive acromesomelic dwarfism

Prevalence: 120 cases; in inbred Amish communities

Associated with: congenital heart disease in 50% (single atrium, ASD, VSD)

- ectodermal dysplasia:
  - › scant / fine hair

› absent / hypoplastic brittle spoon-shaped nails
› irregular + pointed dysplastic teeth, partial anodontia, teeth may be present at birth
› congenital heart disease
• obliteration of maxillary mucobuccal space (thick frenula between alveolar mucosa + upper lip); strabismus
• genital malformations: epispadia, hypospadia, hypoplastic external genitalia, undescended testicles
√ hepatosplenomegaly
√ accelerated skeletal maturation
√ normal spine
@ Skull
√ wormian bones
√ cleft lip
@ Chest
√ elongated narrow thorax in AP + transverse dimensions exaggerating cardiac size
√ cardiomegaly ← frequently ASD / single atrium
√ short horizontal ribs + anterior osseous expansion → barrel-shaped chest
√ elevated clavicles
@ Pelvis
√ small flattened ilium
√ trident morphology of acetabular roof = indentation in roof + bony spur (almost PATHOGNOMONIC)
√ acetabular + tibial exostoses
@ Extremities
√ variety of micromelia (= thickening + mild shortening of all long bones):
√ acromelia = hypoplasia / absence of terminal phalanges
√ mesomelia = shortening of forearms + lower legs (radius + tibia > humerus + femur)
√ cone-shaped epiphyses
√ premature ossification of proximal humeral + femoral epiphyses
@ Upper extremity
√ "drumstick" forearm = swelling of proximal end of ulna + distal end of radius
√ anterior dislocation of radial head ← shortening of ulna
√ carpal / tarsal fusion = frequent fusion of two / more carpal (hamate + capitate) + tarsal bones (after complete ossification)
√ supernumerary carpal bones
√ postaxial polydactyly common (usually finger, rarely toe) ± syndactyly of hands + feet
@ Lower extremity
√ genu valgum:
√ slanting of proximal tibial metaphysis (← delayed development of tibial plateau)
√ excessive shortening of fibula
√ widening of proximal tibial shaft
√ medial tibial diaphyseal exostosis
OB-US:
√ proportional shortening of long bones
√ small thorax with decreased circumference

√ increased cardiothoracic ratio
√ ASD
√ polydactyly

Prognosis: death within first month of life in 33–50% ← respiratory / cardiac complications

DDx: asphyxiating thoracic dysplasia (difficult distinction); rhizomelic achondroplasia

CHONDROMALACIA PATELLAE

= pathologic softening of patellar cartilage leading to defects of surface (chondrosis) / osteoarthritis

Cause: trauma, tracking abnormality of patella

• anterior knee pain
• asymptomatic (incidental arthroscopic diagnosis)

MR (60% sensitive, 84% specific, 73% accurate):

√ focal areas of increased T2 / PD signal intensity of cartilage
√ partial / full-thickness cartilage loss
√ underlying marrow / bone reactive changes

CHONDROMYXOID FIBROMA

= rare benign cartilaginous tumor; initially arising in cortex

Frequency: < 1% of all bone tumors

Histo: chondroid + fibrous + myxoid tissue (related to chondroblastoma); may be mistaken for chondrosarcoma

Age: peak 2nd–3rd decade (range, 5–79 years); M÷F = 1÷1

• slowly progressive local pain, swelling, restriction of motion

Location: (a) long bones (60%): about knee (50%), proximal tibia (82% of tibial lesions), distal femur (71% of femoral lesions), fibula
(b) short tubular bones of hand + feet (20%)
(c) flat bones: pelvis, ribs (classic but uncommon)

Site: metaphyseal (47–53%), metadiaphyseal (20–43%), metaepiphyseal (26%), diaphyseal (1–10%), epiphyseal (3%); eccentric

Size: 1–10 cm in length; 4–7 cm in width

√ expansile ovoid lesion with radiolucent center + oval shape at each end of lesion
√ long axis parallel to long axis of host bone
√ geographic bone destruction (100%)
√ well-defined sclerotic margin (86%)
√ expanded shell = bulged + thinned overlying cortex (68%)
√ partial cortical erosion (68%)
√ scalloped margin (58%)
√ septations (57%) may mimic trabeculations
√ stippled calcifications within tumor in advanced lesions (7%)
√ NO periosteal reaction (unless fractured)

Prognosis: 25% recurrence rate following curettage

Cx: malignant degeneration distinctly unusual

DDx: (1) Aneurysmal bone cyst

(2) Simple bone cyst
(3) Nonossifying fibroma
(4) Fibrous dysplasia
(5) Enchondroma
(6) Chondroblastoma
(7) Eosinophilic granuloma
(8) Fibrous cortical defect
(9) Giant cell tumor

CHONDROSARCOMA

A. PRIMARY CHONDROSARCOMA
no preexisting bone lesion

B. SECONDARY CHONDROSARCOMA
= complication of a preexisting skeletal abnormality such as
1. Osteochondroma
2. Enchondroma
3. Parosteal chondroma

Spread: via marrow cavity / periosteum

Metastases (uncommon) to: lung, epidural space

May be associated with: Ollier disease, Maffucci syndrome, Paget disease

CT:
√ chondroid matrix mineralization of "rings and arcs" (CHARACTERISTIC) in 70%
√ nonmineralized portion of tumor hypodense to muscle (high water content of hyaline cartilage)
√ extension into soft-tissues

MR:
√ low to intermediate signal intensity on T1WI
√ high SI on T2WI + hypointense areas ← mineralization / fibrous septa
√ enhancement of fibrous septations

NUC:
√ bone scan uptake intensity compared to anterior iliac crest: greater (82%) + equal to (12%) + less than (6%)

DDx: enchondroma; osteochondroma (marrow + cortical contiguity with cartilage cap); chordoma (calcification at periphery of lesion); chondroblastoma (lytic lesion with thin sclerotic margin; malignant fibrous histiocytoma; metastasis (history of primary tumor)

Central Chondrosarcoma

= INTRAMEDULLARY CHONDROSARCOMA = ENDOSTEAL CHONDROSARCOMA

Frequency: 3rd most common primary bone tumor (after multiple myeloma and osteosarcoma); 20–27% of all primary malignant neoplasms; 8–17% of biopsied primary bone tumors

Path: lobular morphology with variable amounts of calcium; presence of fibrous bands at tumor-marrow interface suggests malignancy (DDx from atypical enchondroma)

Histo: arises from chondroblasts (tumor osteoid never forms)

Age: median 45 years; 50% > 40 years; 10% in children (rapidly fatal); M÷F = 2÷1
• hyperglycemia as paraneoplastic syndrome (85%)
Location: neck of femur, pubic rami, proximal humerus, ribs (19%), skull (sphenoid bone, cerebellopontine angle, mandible), sternum, spine (3–12%)
Site: central within medullary canal of meta- / diaphysis
√ expansile osteolytic lesion 1 to several cm in size
√ short transition zone ± sclerotic margin (well defined from host bone)
√ ± small irregular punctate / snowflake type of calcification; single / multiple
√ late: loss of definition + break through cortex:
  √ pathologic fracture (in 3–17% at initial presentation)
√ endosteal cortical thickening, sometimes at a distance from the tumor ← invasion of haversian system
√ presence of large soft-tissue mass
DDx: benign enchondroma, osteochondroma, osteosarcoma, fibrosarcoma

Peripheral Chondrosarcoma

= EXOSTOTIC CHONDROSARCOMA
= malignant degeneration of hereditary multiple osteochondromatosis and rarely of a solitary exostosis (beginning in cartilaginous cap of exostosis)
Frequency: 8% of all chondrosarcomas
Average age: 50–55 years for solitary exostosis; 25–30 years for hereditary multiple osteochondromatosis; M÷F = 1.5÷1
Histo: low histologic grade in 67–85%
• growth after skeletal maturity
• gradually increasing pain, often worse at night
• local swelling / palpable mass (45%)
Location: pelvis, hip, scapula, sternum, ribs, ends of humerus / femur, craniofacial bones
√ growth of a previously unchanged osteochondroma in a skeletally mature patient
√ unusually large soft-tissue mass (= hyaline cartilage cap) containing flocculent / streaky chondroid calcifications (CHARACTERISTIC):
  √ cartilage cap 1.5–12 cm (average, 5.5–6 cm) thick
    ◊ > 1.5 cm is suspect of malignant transformation
√ irregular / indistinct lesion surface:
  √ dense radiopaque center with streaks radiating to periphery + loss of smooth margin
√ focal regions of radiolucency in interior of lesion
√ erosion / destruction of adjacent bone
Metastases: in 3–7%, most commonly to lung
Rx: wide resection
Prognosis: 70–90% long-term survival
DDx: (1) Osteochondroma (densely calcified with multiple punctate calcifications)
(2) Parosteal osteosarcoma (more homogeneous density of calcified osteoid)

Clear Cell Chondrosarcoma

◊ Usually mistaken for chondroblastoma because of low grade malignancy (both tumors may be related)!

Histo: small lobules of tissue composed of cells with centrally filled vesicular nuclei surrounded by large clear cytoplasm
Age: 19–68 years, predominantly after epiphyseal fusion
Location: proximal femur, proximal humerus, proximal ulna, lamina vertebrae (5%); pubic ramus
Site: epiphysis
√ single lobulated oval / round sharply marginated lesion of 1–2 cm in size
√ surrounding increased bone density
√ aggressive rapid growth to over 3 cm
√ may contain calcifications
√ bone often enlarged
√ indistinguishable from conventional chondrosarcoma / chondroblastoma (slow growth over years)

Extraskeletal Chondrosarcoma

Extraskeletal Myxoid Chondrosarcoma (most common)
Mean age: 50 years (range 4–92 years); M > F
Histo: surrounded by fibrous capsule + divided into multiple lobules by fibrous septa; delicate strands of small elongated chondroblasts suspended in an abundant myxoid matrix; rare foci of mature hyaline cartilage
• slowly growing soft-tissue mass; pain + tenderness (33%)
◊ Metastatic in 40–45% at time of presentation!
Location: proximal extremities (thigh most common)
Site: deep soft tissues; subcutis (25%)
Size: usually between 4 and 7 cm in diameter
√ lobulated soft-tissue mass WITHOUT calcification / ossification / cartilaginous differentiation
√ usually ill-defined margins
√ usually heterogeneous tumor ← necrosis + hemorrhage
MR:
√ SI equal to muscle on T1WI + equal to fat on T2WI
√ may mimic a cyst / myxoma
√ rings + arcs on contrast-enhanced images ← lobulated growth pattern
Prognosis: 45% 10-year survival rate; 5–15 years survival after development of metastases

Extraskeletal Mesenchymal Chondrosarcoma
= MESENCHYMAL CHONDROSARCOMA
Frequency: 2–10% of all chondrosarcomas
◊ 50% of all mesenchymal chondrosarcomas arise in soft tissues
Histo: proliferation of small primitive mesenchymal cells with scattered islands of cartilage; hemangiopericytoma-like vascular pattern
Bimodal age distribution: M = F
(a) tumors of head + neck in 2nd–3rd decade (common): meninges, periorbital region

(b) tumors of thigh + trunk in 5th decade

• frequently metastasized to lungs + lymph nodes

√ matrix mineralization (50–100%) characterized as rings + arcs / flocculent + stippled calcification / dense mineralization

MR:

√ lobulated soft tissue mass with:

√ low signal intensity on T1WI

√ variable heterogeneous signal intensity on T2WI

√ curvilinear / stippled areas of low signal intensity ← chondroid matrix calcifications

√ complex heterogeneous enhancement

Prognosis: 25% 10-year survival rate

Synovial Chondrosarcoma

= extremely rare intraarticular malignant cartilaginous neoplasm

Etiology: ? de novo / metaplastic transformation of synovial osteochondromatosis

◊ Concurrent (and presumably preexistent) primary synovial chondromatosis in 50%

Age: 4th–7th decade

Histo: permeation of trabecular bone, spindle-shaped chondrocytes, myxoid change in cellular matrix, shift from normal cell clusters to sheets of tumor cells

• pain + muscle swelling / contracture in presence of a mass

Location: knee, hip, shoulder, smaller joints (rare)

Spread to: lung

√ lobulated intraarticular soft-tissue mass:

√ mass isointense on T1WI + hyperintense on T2WI

√ calcified bodies of low SI on all pulse sequences

√ classic juxtaarticular ring-and-arc pattern

√ multiple nodules with peripheral enhancement

√ features suggestive of malignancy:

√ cortical bone erosion / destruction with marrow invasion

√ widespread extraarticular extension of tumor beyond joint capsule

√ hematogenous (to lung) / regional lymphatic metastases

DDx: synovial osteochondromatosis (indistinguishable with the exception that evidence of metastatic disease allows a definitive diagnosis)

CLEIDOCRANIAL DYSOSTOSIS

= CLEIDOCRANIAL DYSPLASIA = MUTATIONAL DYSOSTOSIS

= autosomal dominant disease with delayed ossification of midline structures (particularly of membranous bone)

@ Skull

• large head

√ diminished / absent ossification of skull (in early infancy)

√ wormian bones

√ widened fontanels + sutures with delayed closure

√ persistent metopic suture

√ brachycephaly + prominent bossing
√ large mandible
√ high narrow palate (± cleft)
√ hypoplastic paranasal sinuses
√ delayed / defective dentition

@ Chest
√ hypoplasia / absence (10%) of clavicles: usually defective development of lateral (R > L) portion of clavicle (DDx: congenital pseudarthrosis of clavicle)
√ thorax may be narrowed + bell-shaped
√ supernumerary ribs
√ incompletely ossified sternum
√ hemivertebrae, spondylosis (frequent)

@ Pelvis
√ delayed ossification of bones forming symphysis pubis (DDx: bladder exstrophy)
√ hypoplastic iliac bones

@ Extremities
√ radius short / absent
√ elongated second metacarpals
√ pseudoepiphyses of metacarpal bases
√ short hypoplastic distal phalanges of hand
√ pointed terminal tufts
√ coned epiphyses
√ coxa vara = deformed / absent femoral necks
√ accessory epiphyses in hands + feet (common)

OB-US:
√ cephalopelvic disproportion → large fetal head + narrow birth canal of affected maternal pelvis necessitates cesarean section

COCCIDIOIDOMYCOSIS

Cause: inhalation of fungus Coccidioides immitis
Endemic to: Mexico, South America, southwestern USA
Histo: chronic granulomatous process in bones, joints, periarticular structures
Location: (a) bones: most frequently in metaphyses of long bones + medial end of clavicle, spine, ribs, pelvis / bony prominences of patella, tibial tuberosity, calcaneus, olecranon, acromion
(b) arthritis of weight-bearing joints (33%):
Location: ankle, knee, wrist, elbow
• "desert rheumatism" = immune-complex–mediated arthritis
(c) tenosynovitis of hand, bursitis

√ focal areas of destruction, formation of cavities (early) = bubbly bone lesion
√ bone sclerosis surrounding osteolysis (later, rare)
√ proliferation of overlying periosteum
√ destruction of vertebra with preservation of disk space
√ psoas abscess indistinguishable from tuberculosis, may calcify

√ joints rarely infected (usually monoarticular from direct extension of osteomyelitic focus): synovial effusion, juxtaarticular osteopenia, bone destruction, rice bodies, joint space narrowing late in disease, ankylosis
√ soft-tissue abscess (common)
DDx: tuberculosis

CONGENITAL INSENSITIVITY TO PAIN WITH ANHYDROSIS

= rare autosomal recessive disorder presumably on the basis of abnormal neural crest development
Age: presenting at birth
Prevalence: 15 reported cases
Path: absence of dorsal + sympathetic ganglia, deficiency of neural fibers < 6 μm in diameter + disproportionate number of fibers of 6–10 μm in diameter
• history of painless injuries + burns (DDx: familial dysautonomia, congenital sensory neuropathy, hereditary sensory radicular neuropathy, acquired sensory neuropathy, syringomyelia)
• abnormal pain + temperature perception
• burns, bruises, infections (common); absence of sweating
• biting injuries of fingers, lips, tongue; mental retardation
Criteria: (1) defect must be present at birth
(2) general insensitivity to pain
(3) general mental / physical retardation
√ epiphyseal separation in infancy → epiphyseal injuries → growth problems
√ metaphyseal fractures in early childhood
√ diaphyseal fractures in late childhood
√ Charcot joints = neurotrophic joints (usually weight-bearing joints) with effusions + synovial thickening
√ ligamentous laxity
√ bizarre deformities + gross displacement + considerable hemorrhage ← unnoticed fractures + dislocations
√ ± osteomyelitis + septic arthritis → may progress extensively
DDx: (1) Sensory neuropathies (eg, diabetes mellitus)
(2) Hysteria
(3) Syphilis
(4) Mental deficiency
(5) Syringomyelia
(6) Organic brain disease

CORNELIA DE LANGE SYNDROME

= AMSTERDAM DWARFISM
• mental retardation (IQ < 50); hirsutism; hypoplastic genitalia
• feeble growling cry; high forehead; short neck; arched palate
• bushy eyebrows meeting in midline + long curved eyelashes

• small nose with depressed bridge; upward tilted nostrils; excessive distance between nose + upper lip
√ small + brachycephalic skull
√ hypoplasia of long bones: upper extremity more involved
√ forearm bones may be absent
√ short radius + elbow dislocation
√ thumbs placed proximally (hypoplastic 1st metacarpal)
√ short phalanges + clinodactyly of 5th finger

CORTICAL DESMOID

= AVULSIVE CORTICAL IRREGULARITY = PERIOSTEAL / SUBPERIOSTEAL DESMOID = SUBPERIOSTEAL / CORTICAL ABRASION = SUBPERIOSTEAL CORTICAL DEFECT
= rare fibrous lesion of the periosteum
Peak age: 14–16 (range, 3–17) years; M÷F = 3÷1
Histo: shallow defect filled with proliferating fibroblasts, multiple small fragments of resorbing bone (microavulsions) at tendinous insertions
• no localizing signs / symptoms
Location: posteromedial aspect of medial femoral epicondyle along medial ridge of linea aspera at attachment of adductor magnus aponeurosis; ⅓ bilateral
√ area of cortical thickening
√ 1–2 cm irregular, shallow, concave saucerlike crater with sharp margin
√ lamellated periosteal reaction
√ localized cortical hyperostosis proximally (healing phase)
◊ May be confused with a malignant tumor (eg, osteosarcoma) / osteomyelitis!

CRI-DU-CHAT SYNDROME

= deletion of short arm of 5th chromosome (5 p)
• generalized dwarfism ← marked growth retardation
• failure to thrive
• peculiar high-pitched cat cry (hypoplastic larynx)
• antimongoloid palpebral fissures; strabismus
• profound mental retardation; round facies; low-set ears
Associated with: congenital heart disease (obtain CXR!)
√ agenesis of corpus callosum
√ microcephaly
√ hypertelorism
√ small mandible
√ faulty long-bone development
√ short 3rd, 4th, 5th metacarpals
√ long 2nd, 3rd, 4th, 5th proximal phalanges
√ horseshoe kidney
Dx: made clinically

CROUZON SYNDROME

= CRANIOFACIAL SYNOSTOSIS / DYSOSTOSIS
= Apert syndrome without syndactyly
= skull + cranial base deformities characterized by craniosynostosis, maxillary hypoplasia, shallow orbits, ocular proptosis, bifid uvula, cleft palate

Prevalence: 1÷25,000

Etiology: autosomal dominant inheritance (in 67%)

Associated intracranial anomalies:

anomalous venous drainage, hydrocephalus (often progressive), Chiari I malformation (71%)

- parrot-beak nose; strabismus; deafness; mental retardation
- dental abnormalities; bifid uvula
- acanthosis nigrans (= hyperpigmented hyperkeratotic lesions on neck + near joint flexures)

√ premature craniosynostosis: acro(oxy)cephaly / brachycephaly / scaphocephaly / trigonocephaly / "cloverleaf" skull
√ hypertelorism + exophthalmos ← shallow orbits
√ hypoplastic maxilla → relative prominence of mandible
√ cleft palate
√ calcification of stylohyoid ligament (in 50% of patients > 4 years of age)
√ C2–C5 spine abnormalities (in up to 40%)
√ elbow malformation (18%)
√ minor hand deformities (10%)
√ visceral anomalies (7%)
√ musculoskeletal deformities (7%) but no limb anomaly

OB-US:

√ cloverleaf appearance (coronal view) + bilateral frontal indentations (axial view) of skull
√ increased interorbital distance + ocular proptosis
√ mild ventriculomegaly

CRUCIATE LIGAMENT INJURY

A. COMPLETE TEAR
   √ failure to identify ligament
   √ amorphous area of high SI on T1WI + T2WI with inability to define ligamentous fibers
   √ focal discrete complete disruption of all visible fibers
B. PARTIAL / INTRASUBSTANCE TEAR
   √ abnormal SI within substance of ligament with some intact + some discontinuous fibers

Anterior Cruciate Ligament Injury (ACL Tear)

Frequency: in up to 69% of all patients undergoing arthroscopy; in up to 72% of acutely injured knees with hemarthrosis

Mechanism: twisting, valgus impaction + internal rotation, hyperextension of knee with foot planted (football) / lower leg forcibly externally rotated during knee flexion (fall backwards while skiing)

- pivot shift test (82–90% sensitive) = examiner applies valgus stress on internally rotated leg while flexing the knee; induced anterolateral rotary subluxation reduces spontaneously at 40° flexion with an audible "pop"
- "anterior drawer" sign (22–80% sensitive) = proximal tibia displaces anteriorly with the

knee flexed at 60°–90°

• Lachman test (77–99% sensitive) = same as "anterior drawer" sign with knee flexed at 10°–20°

Location: midsubstance of ligament / near femoral attachment (in adults) / avulsion of anterior intercondylar eminence or tibial spines (in children)

◊ If the ACL appears intact in one of the sagittal oblique sequences discordant findings in other sequences can be disregarded!

Site: intrasubstance tear near insertion of femoral condyle (frequently); bone avulsion (rarely)

√ loss of fiber continuity + abnormal fiber orientation on PD image

√ T2-hyperintense signal (= focal fluid collection / soft-tissue edema) replacing the tendon substance in acute tear

√ pseudomass (hematoma + torn fibers) in intercondylar notch near femoral attachment

√ concavity of anterior margin of ligament

√ nondisplaced avulsion fracture of tibial eminence in children (coronal T1WI)

Secondary signs (low sensitivity, high specificity):

√ anterior translation of tibia (= "anterior drawer" sign) by > 5 mm with respect to femur measured at midsagittal plane of lateral femoral condyle

√ "uncovering" of lateral meniscus = posterior displacement of posterior horn of lateral meniscus > 3.5 mm behind tibial plateau

√ bowed PCL ← increased laxity = angle between proximal + distal limbs of PCL < 105°

Associated signs:

› for anterolateral rotary instability (football, skiing):

√ bone bruise in lateral compartment (posterolateral tibia + terminal sulcus of lateral femoral condyle) in 40–90% on fat-suppressed T2WI

◊ ACL intact in 28% of adolescents with bone bruise

√ low-signal–intensity line surrounded by region of high-signal–intensity marrow edema in posterior aspect of lateral tibial plateau (= occult fracture) on STIR image

› for hyperextension injury:

√ bone contusion in anterior tibial plateau + femoral condyles

› varus stress with external rotation:

√ avulsion of joint capsule from lateral tibial rim (Segond fracture)

√ deepening of lateral femoral sulcus > 1.5 mm ← osteochondral impaction injury when femur strikes posterior tibial plateau

False-positive Dx:

(1) slice thickness / interslice gap too great

(2) adjacent fluid / synovial proliferation

(3) cruciate ganglion / synovial cyst

Associated injuries: meniscal tear (lateral > medial) in 65%

Rx: (1) conservative: strengthening of quadriceps muscle + brace for activities

(2) arthroscopic reconstruction with autograft (patellar tendon / combined semitendinosus and gracilis tendon) or allograft (cadaveric patellar / Achilles tendon)

Subacute ACL Tear

Definition: few weeks after injury

√ fibers better defined as hemorrhage + edema subside
√ change in fiber contour + angle of residual fragments

Chronic ACL Tear

Definition: months to years after injury

√ bridging fibrous scar within intercondylar notch (simulating an intact ligament with its low SI)
√ disorganized scar tissue instead of linear parallel fibers
√ major distal ACL fragment assumes a more horizontal orientation (= less steep than the roof of the intercondylar notch or Blumensaat line)
√ ACL may fuse to posterior cruciate ligament
√ complete absence of ligament

Partial ACL Tear *(15%)*

◊ Extremely difficult to diagnose! 40–50% of partial tears are missed on MR!
• positive Lachman test (in 12–30%)
√ MR primary signs positive for injury (in 33–43%)

Posterior Cruciate Ligament Injury (PCL)

Prevalence: 2–23% of all knee injuries

√ midsubstance of PCL most frequently involved (best seen on sagittal images)
√ bone avulsion from posterior tibial insertion (< 10%), best seen on lateral plain film

Mechanism:

(1) Direct blow to proximal anterior tibia with knee flexed (dashboard injury)
  √ midsubstance PCL tear
  √ injury to posterior joint capsule
  √ bone contusion at anterior tibial plateau + femoral condyles farther posteriorly
(2) Hyperextension of knee
  √ avulsion of tibial attachment of PCL (with preservation of PCL substance)
  √ ± ACL rupture
  √ bone contusion in anterior tibial plateau + anterior aspect of femoral condyles
(3) Severe ab- / adduction + rotational forces
  √ + injury to collateral ligaments

Associated with: coexistent ligamentous injury in 70%

joint effusion 64–65%
bone marrow injury 35–36%
medial meniscal tear 32–35%
lateral meniscal tear 28–30%
anterior cruciate ligament 27–38%
medial collateral ligament 20–23%
lateral collateral ligament 6–7%

◊ A PCL injury is isolated in only 30%!

• posterior tibial laxity
• difficult to evaluate arthroscopically unless ACL torn

DEEP MUSCULOAPONEUROTIC FIBROMATOSIS

= DESMOID TUMOR [desmos, *Greek* = band / tendon]
= AGGRESSIVE FIBROMATOSIS = DEEP FIBROMATOSIS
= MUSCULOAPONEUROTIC FIBROMATOSIS
= musculoaponeurotic mass characterized by fibrous soft-tissue proliferation disrupting adjacent muscle + soft-tissue planes

Frequency: 1.5–3.0% of all soft-tissue masses
Origin: connective tissue of muscle, fascia, aponeurosis
Genetics: trisomies on chromosomes 8 + 20 (in many cases)
Association: (a) sporadic
(b) familial polyposis, Gardner syndrome
Classification: according to location
Peak age: 3rd decade (range, puberty to 40 years)
Histo: elongated spindle-shaped cells of uniform appearance, separated by dense bands of collagen, infiltration of adjacent tissue (DDx: low-grade fibrosarcoma, reactive fibrosis)
Location: extraabdominal, abdominal wall, intraabdominal
• hormonally responsive + dependent on estrogen
Imaging appearance:
dependent on tissue composition (spindle cells, collagen, myxoid matrix) + vascularity; may change over time
CT:
√ well-circumscribed / ill-defined and infiltrating mass
√ isoattenuating to muscle (predominantly collagenous) / hypoattenuating (myxoid stroma)
√ striated / whorled appearance (alternating collagenous and myxoid stroma)
√ mild to moderate contrast enhancement during parenchymal phase ± delayed enhancement
MR:
(a) early-stage hypercellular and myxoid lesion
√ predominantly hyperintense lesion on T2WI
(b) mature collagenous lesion
√ decrease in signal intensity on T2WI
√ hypointense bands in 62% (= conglomeration of collagen bundles)
√ moderate to marked enhancement
Prognosis: rapid aggressive growth; 50% recurrence rate after local excision; spontaneous regression (rare); malignant transformation (rare)
DDx: (1) Malignant tumor: metastasis, soft-tissue sarcoma (fibro-, rhabdomyo-, synovio-, liposarcoma), malignant fibrous histiocytoma, lymphoma
(2) Benign tumor: neurofibroma, neuroma, leiomyoma, giant cell tumor of tendon sheath
(3) Acute hematoma

Abdominal Wall Fibromatosis

= Abdominal wall desmoid
= solitary slow-growing neoplasm characterized by its progressive, locally infiltrative, and

aggressive behavior

Frequency: similar to desmoid-type fibromatosis

◊ The most common abdominal wall soft-tissue neoplasm!

Cause: ? genetics; estrogenic hormones (← regression after menopause / oophorectomy); trauma + surgery (= **cicatricial fibromatosis** of cesarean section scar)

Associated with:

(1) Familial adenomatous polyposis

(2) Gardner syndrome

Peak age: 3rd decade; M÷F = 13÷87 esp. young woman of childbearing age

› during 1st year after childbirth

› during pregnancy

› with use of oral contraceptives

Path: solid firm mass with often infiltrative spiculated margin toward skeletal muscle and subcutis; positive for estrogen receptors (in 79%)

• palpable firm slowly growing deep-seated mass

Location: musculoaponeurosis of rectus abdominis / internal oblique muscle; occasionally external oblique m.

Average size: 3–7 cm in diameter

√ identical to desmoid-type fibromatosis

MR:

√ hypo- to isointense mass to muscle on T1WI

√ variable intensity on T2WI

√ infiltrative border

√ nonenhancing low-signal-intensity bands

√ "fascial tail" sign = linear extension along superficial fascia

CT:

√ ill-defined / well-circumscribed mass

√ iso- / hypoattenuating mass compared to muscle

√ ± enhancement

√ retraction, angulation, distortion of small / large bowel with mesenteric infiltration

US:

√ sharply defined + smoothly marginated mass of low / medium / high echogenicity

Prognosis: locally aggressive; 25–65% recurrence rate

Rx: local resection + radiotherapy, antiestrogen therapy

DDx: scar endometriosis

Intraabdominal Fibromatosis

Age: peak age in 3rd decade, 70% between 20 and 40 years of age; M÷F = 1÷3

Location: mesentery, retroperitoneum, pelvis

◊ Most common mesenteric primary tumor!

In 9–18% associated with: familial adenomatous polyposis (Gardner syndrome)

√ masslike with significant displacement of contiguous structures / infiltrative causing compressive encasement

Cx: compression / displacement of bowel / ureter; vascular occlusion and ischemia;

intestinal perforation

DDx: (1) Malignant neoplasm of the mesentery (lymphoma, metastasis, soft-tissue sarcoma, malignant fibrous histiocytoma)

(2) Inflammatory pseudotumor, extrapleural solitary fibrous tumor, GIST

Desmoid-type Fibromatosis

= AGGRESSIVE FIBROMATOSIS = MUSCULOAPONEUROTIC FIBROMATOSIS = EXTRAABDOMINAL DESMOID TUMOR

= common benign aggressively growing soft-tissue tumor arising from connective tissue of muscle, fascia, aponeurosis outside abdominal cavity of intermediate malignant potential

Frequency: 2–4÷1,000,000 per year

Peak age: 25–35 years (range, 2nd–4th decade); M÷F = 1÷1.8; more aggressive behavior in children than in adults

- painless soft-tissue mass with slow insidious growth
- decreased mobility, reduced joint motion
- neurologic complaints: numbness, tingling, sharp pain, motor weakness; history of trauma (30%)

Path: firm mass often with spiculated tumor margins infiltrating muscle + subcutaneous tissue

Histo: proliferation of uniform spindle-shaped fibroblasts → poorly defined fascicles within a collagenous stroma

Associated with: Gardner syndrome (1–2%)

Genetics: activation of b-catenin signaling pathway ← APC (adenomatous polyposis coli) gene mutation on long arm of chromosome 5q21-22 (in Gardner syndrome) or somatic b-catenin mutation

Location: shoulder + upper arm (28%), chest wall and paraspinal region (17%), thigh (12%), neck (8%), knee (7%), pelvis / buttock (6%), lower leg (5%), forearm / hand (5%), head (2%); synchronous multicentricity in same extremity (10–15%)

@ head & neck (7–27%): supraclavicular neck > face

Site: centered in an intermuscular location with rim of fat ("split-fat" sign)

Size: mostly 5–10 cm in diameter

◊ Imaging appearance depends on cellularity of lesion + amount of collagen and myxoid material within it

√ poorly circumscribed mass infiltrating surrounding soft tissues + fixation to underlying muscle / bone (often)

US:

√ poorly defined hypoechoic soft-tissue mass

√ ± posterior acoustic shadowing in large lesion

√ ± hypervascularity

CT:

√ homogeneous / heterogeneous attenuation

√ iso- / hyper- / hypodense compared to muscle

√ indistinct lesion margins (often)

√ variable degree of enhancement

MR:
√ poorly defined lesion with irregular margin (50%) ← invasion of fat / muscle
√ lobulated well-defined lesion (50%)
√ "fascial tail" sign = linear extension along fascial planes (83%)
√ slightly hyper- / iso- (90%) / hypointense relative to muscle on T1WI
√ hyperintense (hypercellular) / hyperintense with areas of low intensity (intermixed with fibrous components) / hypointense (hypocellular) on T2WI
√ heterogeneous texture ← linear + curvilinear strands of low SI on CEMR / T2WI (62–91%) ← collagen fibers
√ moderate to marked enhancement (90%)

@ Bone (6–37%)
√ extensive pressure erosion / cortical scalloping without extension into medullary canal
√ skeletal dysplasia of multicentric desmoid-type fibromatosis (19%):
√ Erlenmeyer flask deformity: polyostotic / on affected side only
√ cortical thickening, focal lucent lesions
√ bone islands, osseous excrescences
Bone scintigraphy:
√ increased uptake on blood flow + blood pool images
Angio:
√ marked vascular staining ← hypervascularity

@ Breast
• palpable firm / hard mass
• history of minor trauma / breast surgery
Location: pectoralis fascia
√ round / irregular noncalcified mass
√ indistinct / spiculated margins
√ retraction of pectoralis muscle, skin, nipple

Prognosis: 20–75% recurrence within 2 years after surgical excision depending on location + extent (up to 87% local recurrence in < 30 years of age; 20% recurrence rate in > 20 years of age)

Infantile Myofibromatosis / Myofibroma

= GENERALIZED HAMARTOMATOSIS = CONGENITAL MULTIPLE / GENERALIZED FIBROMATOSIS = MULTIPLE VASCULAR LEIOMYOMAS = DESMOFIBROMATOSIS = INFANTILE F / JUVENILE FIBROMATOSIS
= rare disorder characterized by proliferation of fibroblasts
Cause: unknown
Frequency: 22% of all myofibroblastic lesions in childhood
◊ Most common fibromatosis in childhood!
Path: well-marginated soft-tissue lesion with scarlike consistency ± infiltration of surrounding tissues
Size: 0.5–7.0 cm in diameter
Histo: spindle-shaped cells in short bundles and fascicles in periphery of lesion with features of both smooth muscle + fibroblasts; centrally hemangiopericytoma-like pattern with necrosis, hyalinization, calcification

Types: solitary÷multicentric form = 1÷2 to 4÷1

(1) Solitary lesion = **myofibroma**

Age: < 2 years of age; M > F

Histo: contractile myoid cells arranged around thin-walled blood vessels

Location (ordered in diminishing frequency):

› head & neck (⅓): scalp, forehead, orbit, oral cavity (tongue, mandible, maxilla, mastoid bone), parotid

› trunk > extremities

Site: skin muscle, SQ tissue (86%), bone (9%), GI tract (4%)

Prognosis: spontaneous regression in 100%; recurrence after surgical excision in 7–10%

(2) Multicentric disease (2–100 lesions) = **myofibromatosis**

Age: at birth (in 60%), < 2 years (in 89%); M < F

Location: lung (28%), heart (16%), GI tract (14%), pancreas (9%), liver (8%)

Site: skin (98%), subcutis (98%), muscle (98%), bone (57%), viscera (25–37%)

Prognosis: related to extent + location of visceral lesions with cardiopulmonary + GI involvement as harbingers of poor prognosis (death in 75–80%); spontaneous regression (33%)

• firm nontender painless nodules in skin, subcutis, muscle

• ± overlying scarring of skin with ulceration

@ Skeleton

Location: any bone may be involved; commonly in calvarium, femur, tibia, rib, pelvis, vertebral bodies; often symmetric

Site: metaphysis of long bones

Age: early infancy (usually not present at birth)

√ circumscribed eccentric lytic foci with smooth margins 0.5 –1.0 cm in size:

√ sparing of region immediately adjacent to epiphysis

√ well-defined with narrow zone of transition

√ osseous foci may increase in size and number

√ unusual osseous findings:

√ periosteal reaction, pathologic fracture

√ vertebra plana, kyphoscoliosis with posterior scalloping of vertebral bodies

√ with healing → little residual abnormality:

√ resolution of osteolysis

√ formation of sclerotic margin (initially no sclerosis)

√ ± mineralization of center

NUC (bone scan):

√ increased / little radiotracer uptake

DDx: (1) Langerhans cell histiocytosis (skin lesions)

(2) Neurofibromatosis (multiple masses)

(3) Osseous hemangiomas / lymphangiomatosis / lipomatosis

(4) Metastatic neuroblastoma

(5) Multiple nonossifying fibromas

(6) Enchondromatosis

(7) Hematogenous osteomyelitis (unusual organism)

(8) Fibrous dysplasia

@ Soft tissue

◊ Most common fibrous tumor in infants

√ round well- / ill-defined solid mass with central necrosis

√ central / peripheral solitary / multiple calcifications

√ prominent vascularity of skin lesions resembling hemangioma

US:

√ hypo- to isoechoic mass

√ thick peripheral wall / septa

√ anechoic / partially anechoic center

√ echogenic shadowing foci ← calcifications

CT:

√ attenuation similar to muscle / mildly increased

√ central area of low attenuation ± calcifications

√ peripheral enhancement

MR:

√ lesion isointense to muscle on T1WI:

√ mildly T1-hyperintense center of myofibroma

√ lesion hyperintense to muscle on T2WI

√ intense occasionally targetlike enhancement

DDx: (1) Neurofibromatosis

(2) Infantile fibrosarcoma, leiomyosarcoma

(3) Angiomatosis

@ Lung

√ interstitial fibrosis, reticulonodular infiltrates

√ discrete mass

√ generalized bronchopneumonia

@ GI tract

√ diffuse narrowing / multiple small filling defects

@ Orbit

Aggressive Infantile Fibromatosis

= childhood equivalent of deep fibromatosis

Age: first 2 years of life; rarely > 5 years of age; M > F

Histo: may mimic infantile fibrosarcoma

• firm nodular soft-tissue mass within skeletal muscle / fascia / periosteum

Location: head, neck (tongue, mandible, mastoid), shoulder, thigh, foot

DERMATOFIBROSARCOMA PROTUBERANS

= uncommon spindle cell tumor arising in dermis typically spreading into subcutaneous tissue + muscle

Frequency: 6% of all soft-tissue sarcomas

Age: mostly adolescence

Location: trunk (50%)

Site: classified as skin tumor (= cutaneous lesion)
CT:
√ well-defined nodular subcutaneous lesion without calcification
MR:
√ unmineralized small nodule / large mass
√ nonspecific signal intensity:
√ hypointense on T1WI
√ hyperintense relative to fat on T2WI
√ ± heterogeneous foci of hemorrhage, myxoid change, necrosis
√ linear extension along skin surface
√ moderate enhancement

DERMATOMYOSITIS

= most common inflammatory myopathy with diffuse nonsuppurative inflammation of striated muscle + skin
Cause: cell-mediated (type IV) autoimmune attack on striated muscle
Pathophysiology: damaged chondroitin sulfate no longer inhibits calcification
Path: atrophy of muscle bundles followed by edema and coagulation necrosis, fibrosis, calcification
Histo: mucoid degeneration with round cell infiltrates concentrated around blood vessels
Age: bimodal: 5–15 and 50–60 years; M÷F = 1÷2
• elevated muscle enzymes (creatinine kinase, aldolase)
• myositis-specific autoantibodies: anti-Jo-1
(a) anti-aminoacyl-tRNA synthetase
• arthritis, Raynaud phenomenon, fever, fatigue
• interstitial lung disease
Prognosis: requires prolonged treatment
(b) anti-Mi-2 antibodies:
• V-shaped chest rash (= shawl rash)
• cuticular overgrowth
Prognosis: good response to medication
(c) anti-signal recognition particle antibodies
• abrupt onset myositis ± heart involvement
@ Skeletal musculature
Location: thigh (vastus lateralis + intermedius m. with relative sparing of rectus + biceps femoris m.) > pelvic girdle > upper extremity > neck flexors > pharyngeal muscles
√ bilateral symmetric edema in pelvic + thigh muscles
√ fatty infiltration + muscle atrophy (over months to years)
√ sheetlike confluent calcifications in soft tissues of extremities (quadriceps, deltoid, calf muscles), elbows, knees, hands, abdominal wall, chest wall, axilla, inguinal region) in 75%
@ Skeleton
√ pointing + resorption of terminal tufts

√ rheumatoid-like arthritis (rare)
√ "floppy-thumb" sign
Cx: flexion contractures; soft-tissue ulceration

@ Chest
• aspiration pneumonia is the most common occurrence ← pharyngeal muscle weakness
• hypoventilation + respiratory failure ← respiratory muscle weakness
√ disseminated pulmonary infiltrates (reminiscent of scleroderma)
√ diaphragmatic elevation with reduced lung volumes + basilar atelectasis
√ interstitial fibrosis (5–30%), most severe at lung bases:
• may precede development of myositis
• associated with presence of anti-Jo-1 antibodies
Patterns: NSIP, cryptogenic organizing pneumonia, UIP, diffuse alveolar damage
√ fine reticular pattern progressing to coarse reticulonodular pattern + honeycombing
HRCT:
√ predominantly linear abnormalities + ground-glass attenuation
√ air-space consolidation in middle + lower lung zones with peribronchial + subpleural distribution

@ Myocardium
√ changes similar to those of skeletal muscle involvement

@ GI tract
• dysphagia ← progressive weakness of proximal striated m.
√ atony + dilatation of esophagus
√ atony of small intestines + colon

Clinical forms:
(1) ACUTE FORM = childhood-onset form
• fever, joint pain, lymphadenopathy, splenomegaly, subcutaneous edema
√ more severe dermatomyositis
Prognosis: death within a few months
(2) CHRONIC FORM = adult-onset form
= insidious onset with periods of spontaneous remission and relapse
• low-grade fever, muscular aches + pains, edema
• muscle weakness (1st symptom in 50%) ← active inflammation, necrosis, muscle atrophy with fatty replacement, steroid-induced myopathy
• skin erythema (1st symptom in 25%): **heliotrope rash** (= dusky blue-purple erythema of eyelids) with periorbital edema, **Gottron papules** (= raised scaly violaceous rash over knuckles, major joints and upper body)

Cx: increased prevalence of malignant neoplasms of lung, breast, prostate, ovary, GI tract, kidney
Dx: measurement of serum muscle enzyme concentration; electromyography; muscle biopsy (normal in up to 15%)

Polymyositis
= subacute myopathy with weakness of proximal muscles evolving over weeks / months without skin involvement
Age: 4th decade

DDx: dermatomyositis (involvement of skin)

DESMOPLASTIC FIBROMA

= INTRAOSSEOUS DESMOID TUMOR
= rare locally aggressive benign neoplasm of bone with borderline malignancy resembling soft-tissue desmoids / musculoaponeurotic fibromatosis
Prevalence: 107 cases in world literature
Histo: intracellular collagenous material in fibroblasts with small nuclei
Age: mean of 21 years (range, 15 months to 75 years); in 90% < 30 years; M÷F = 1÷1
• slowly progressive pain + local tenderness; palpable mass
Location: mandible (26%), ilium (14%), > 50% in long bones (femur [14%], humerus [11%], radius [9%], tibia [7%], clavicle), scapula, vertebra, calcaneus
Site: central meta- / diaphyseal (if growth plate open); may extend into epiphysis with subarticular location (if growth plate closed)
√ geographic (96%) / moth-eaten (4%) bone destruction without matrix mineralization
√ narrow (96%) / poorly defined (4%) zone of transition
√ no marginal sclerosis (94%)
√ residual columns of bone with "pseudotrabeculae" are CLASSIC (91%)
√ bone expansion (89%); may grow to massive size (simulating aneurysmal bone cyst / metastatic renal cell carcinoma)
√ breach of cortex + soft-tissue mass (29%)
Cx: pathologic fracture (9%)
Prognosis: 52% rate of local recurrence
Rx: wide excision
DDx: (1) Giant cell tumor (round rather than oval, may extend into epiphysis + subchondral bone plate)
(2) Fibrous dysplasia (occupies longer bone, contains mineralized matrix, often with sclerotic rim)
(3) Aneurysmal bone cyst (eccentric blowout appearance rather than fusiform)
(4) Chondromyxoid fibroma (eccentric with delicate marginal sclerosis + scalloped border)

DEVELOPMENTAL DYSPLASIA OF HIP (DDH)

= CONGENITAL DYSPLASIA OF HIP
= deformity of acetabulum ← disrupted relationship between femoral head and acetabulum
◊ Acetabular dysplasia (without femoral subluxation / dislocation) can be determined only by imaging!
Etiology:
A. Late intrauterine event (98%)
(a) mechanical:
– oligohydramnios (restricted space in utero)
– firstborn (tight maternal musculature)
◊ in 60% of patients with DDH
– breech position (hip hyperflexion results in shortening of iliopsoas muscle; L÷R =

4÷1)
◊ in 30–50% of patients with DDH
◊ only 2–4% of deliveries are breech

(b) physiologic (females are more sensitive to):
– maternal estrogen (not inactivated by immature fetal liver) blocks cross-linkage of collagen fibrils
– pregnancy hormone relaxin

B. Teratologic (2%) ← neuromuscular disorder (myelodysplasia, arthrogryposis) occurring during 12th–18th week GA

C. Postnatal onset (< 1%)

Prevalence: 0.15% of neonates (Australia 1%, Netherlands 3.7%, Poland 3.9%, Israel 5.9%, Austria 6.6%, Norway 16.9%)

Age: most dislocations probably occur after birth;
M÷F = 1÷4–1÷8; Caucasians > Blacks

Increased risk:

(1) infants born in frank breech position (25%; risk of breech÷vertex = 6–8÷1)
(2) congenital torticollis (10–20%)
(3) skull-molding deformities; scoliosis; generalized joint laxity (Larsen syndrome, Ehlers-Danlos syndrome, Down syndrome [5%]); neuromuscular disorders (eg, myelodysplasia, spina bifida, sacral agenesis, arthrogryposis multiplex)
(4) family history of DDH (6–20%): 6% risk for subsequent sibling of normal parents, 36% risk for subsequent sibling of one affected parent; 12% risk for patient's own children
(5) foot deformities [metatarsus adductus, clubfoot (2%)]
(6) neonatal hyperextension of hips: swaddling of infants in hip extension / strapping to cradle board

Anatomy: acetabulum has a small bony component + a large cartilaginous component at birth; acetabulum highly susceptible for modeling within first 6 weeks of age + less susceptible > 16 weeks of age

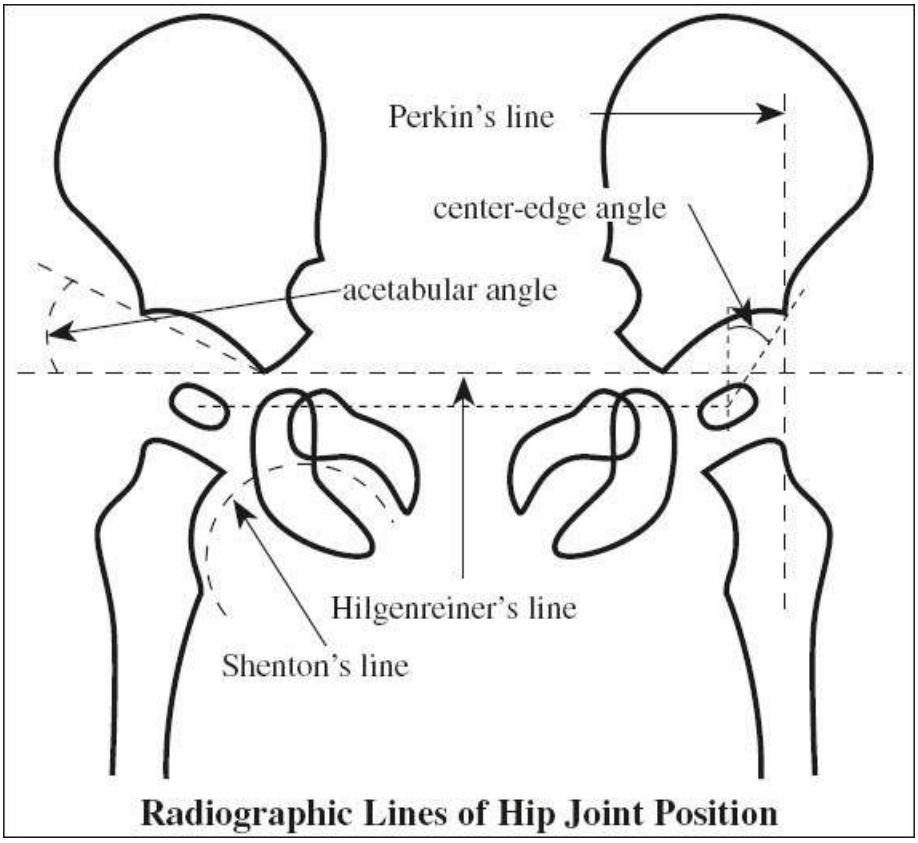
Classification:

1. Normal hip
2. Lax = subluxable hip
   ◊ Subluxability up to 6 mm is normal in newborns (still under influence of maternal hormones); decreasing to 3 mm by 2nd day of life
3. Concentric dislocatable unstable hip
   = joint laxity allowing nondisplaced femoral head to become subluxed / dislocated under stress
   Prevalence: 0.25–0.85% of all newborn infants (⅔ are firstborns)
   • Barlow positive
   √ slight increase in femoral anteversion
   √ mild marginal abnormalities in acetabular cartilage
   √ early labral eversion
   Prognosis: 60% will become stable after 1 week; 88% will become stable by age of 2 months
4. Decentered subluxed hip
   = femoral head shallow in location

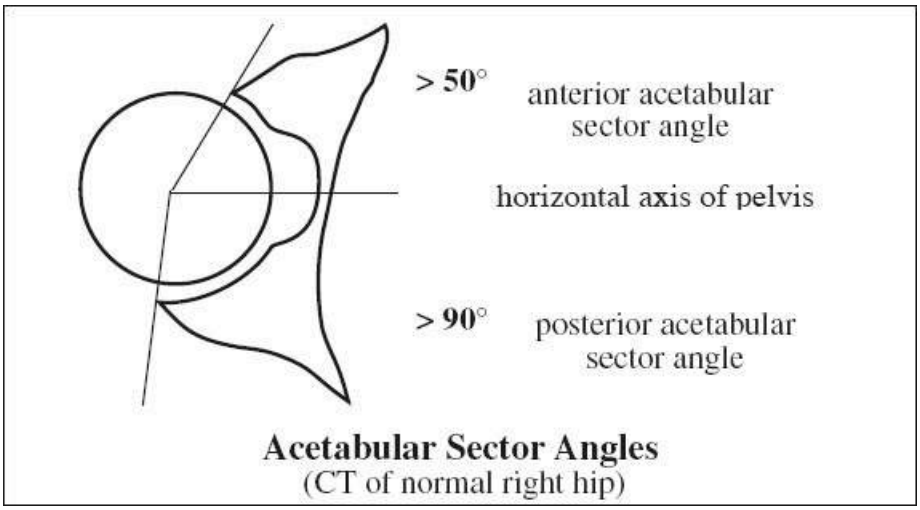
√ loss of femoral head sphericity
√ increased femoral anteversion
√ early labral inversion
√ shallow acetabulum

5. Eccentric dislocated hip
   = femoral head frankly displaced out of acetabulum
   (a) reducible = Ortolani positive
   (b) irreducible = Ortolani negative
   √ accentuated flattening of femoral head
   √ shallow acetabulum
   √ limbus formation (= inward growth + hypertrophy of labrum)

- "hip click" = usually result of joint capsule and tendon stretching + snapping (often confused with "hip clunk")
- positive examination result (up to 3 months of age):
  - positive Ortolani reduction test = reduction of dislocated femoral head into the acetabulum by lifting the flexed thigh + pushing the greater trochanter anteriorly; may be associated with audible "clunk"
  - positive Barlow dislocation test = posterior displacement of nondislocated proximal femur by progressive adduction with downward pressure (piston maneuver) on flexed hips and knees associated with audible "clunk"
- warning signs on physical examination:



Radiographic Lines of Hip Joint Position



Acetabular Sector Angles
(CT of normal right hip)

- limited hip abduction on affected side
- shortening of thigh on affected side:
  - asymmetric thigh / buttock creases
- Allis sign = Galeazzi sign = affected knee is lower with knees bent in supine position
- Trendelenburg test = visible drooping + shortening on dislocated side with child standing on both feet, then one foot

Location: left÷right÷bilateral = 11÷1÷4

Radiologic lines:

1. Line of Hilgenreiner
   = line connecting superolateral margins of triradiate cartilage
2. Acetabular angle / index
   = slope of acetabular roof = angle that lies between Hilgenreiner's line and a line drawn from most superolateral ossified edge of acetabulum to superolateral margin of triradiate cartilage
3. Perkin line
   = vertical line to Hilgenreiner's line through the lateral rim of acetabulum
4. Shenton curved line
   = arc formed by inferior surface of superior pubic ramus (= top of obturator foramen) + medial surface of proximal femoral metaphysis to level of lesser trochanter
   √ disruption of line (DDx: coxa valga)
5. Center-edge angle of Wiberg = angle subtended by one line drawn from the acetabular edge to center of femoral head + second line perpendicular to line connecting centers of femoral heads
   √ < 25° suggests femoral head instability

AP pelvic radiograph: > 4– 6 months of age (von Rosen view = legs abducted 45° + thighs internally rotated)

◊ Not reliable first 3 months of life!

√ proximal + lateral migration of femoral neck:

√ eccentric position of proximal femoral epiphysis (position estimated by a circle drawn with a diameter equivalent to width of femoral neck)

√ interrupted discontinuous arc of Shenton's line

√ line drawn along axis of femoral shaft will not pass through upper edge of acetabulum but intersect the anterior-superior iliac spine (during Barlow maneuver)
√ apex of metaphysis lateral to edge of acetabulum
√ femoral shaft above horizontal line drawn through the Y-synchondrosis
√ unilateral shortening of vertical distance from femoral ossific nucleus / femoral metaphysis to Hilgenreiner's line
√ femoral ossific nucleus / medial beak of femoral metaphysis outside inner lower quadrant of coordinates established by Hilgenreiner's + Perkin's lines

√ acetabular dysplasia = shallow incompletely developed acetabulum:
√ acetabular angle > 30° strongly suggests dysplasia
√ development of false acetabulum
√ delayed ossification of femoral epiphysis (usually evident by 4 months (range, 2nd–8th months) of life

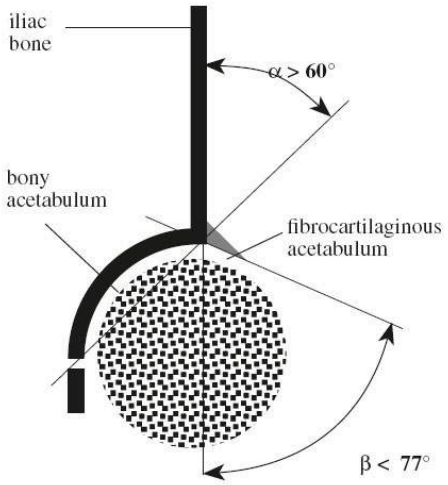
US (practical only):

Screening period: > 2 weeks and up to 4–6 months of age

◊ Instability often resolves spontaneously by 2 weeks of age!
◊ Examination impractical beyond 4–6 months of age

(1) static evaluation (popularized in Europe by Graf)
(2) dynamic evaluation (popularized in USA by Harcke)

@ Relationship of femoral head & acetabulum
√ femoral head position at rest in neutral position
√ hip instability under motion + stress maneuvers
√ dislocated (= eccentric) hip can be reduced (Ortolani positive):
√ hypoechoic femoral head not centered over triradiate cartilage between pubis + ischium (on transverse view)
√ increased amount of soft-tissue echoes ("pulvinar") between femoral head and acetabulum
√ cartilaginous acetabular labrum interposed between head and acetabulum (inverted labrum)



Coronal View of Left Hip

Sonographic Hip Types

Type	*Description*	*α Angle*	*β Angle*
1	mature hip	> 60°	
1A	narrow cartilaginous roof		< 55°
1B	wide cartilaginous roof		> 55°
2	deficient bony acetabulum		
2A	physiologic < 3 months	50–59°	
2B	delayed ossification > 3 months		
2C	concentric but unstable; critical range	43–49°	70–77°
2D	decentered = subluxed		> 77°
3	eccentric = dislocated	< 43°	
4	severe dysplasia with inverted labrum		

α angle = angle between straight lateral edge of ilium + bony acetabular margin (on coronal view); determines sonographic hip type

β angle = angle between straight lateral edge of ilium + fibrocartilaginous acetabulum; determines nuances of sonographic hip type

√ posterior + superior dislocation of head against ilium

√ "equator" sign = < 50% of femoral head lies medial to line drawn along iliac bone (on coronal view): > 58% coverage is normal; 58–33% coverage is indeterminate; < 33% coverage is abnormal

@ Femoral head

√ disparity in size of directly visualized unossified femoral head

√ disparity in presence + size of ossific nucleus

@ Acetabulum

√ delayed ossification of acetabular corner

√ wavy contour of bony acetabulum with only slight curvature

√ abnormally acute alpha angle (= angle between straight lateral edge of ilium + bony acetabular margin)

√ α > 60° in an infant is normal

√ α 55–60° can be normal < 4 weeks of age

√ α < 55° occurs in an immature acetabulum

◊ 4°–6° interobserver variation!

Prognosis: alpha-angle < 50° at birth / 50°–59° after 3 months indicates significant risk for dislocation without treatment; follow-up at 4-week intervals are recommended

CT (during cast treatment / attempted closed reduction):

√ sector angle = angle between line drawn from center of femoral head to acetabular rim + horizontal axis of pelvis (= reflects acetabular support)

√ anterior acetabular sector angle < 50°

√ posterior acetabular sector angle < 90°

Cx: (1) Degenerative joint disease

(2) Avascular necrosis of femoral head

Obstacles to reduction:

(1) Intraarticular obstacle to reduction

(a) pulvinar = fibrofatty tissue at apex of acetabulum
(b) hypertrophy of ligamentum teres
(c) labral hypertrophy / inversion

(2) Extraarticular obstacle to reduction (iliopsoas tendon impingement on anterior joint capsule with infolding of joint capsule)

Prognosis: 78% of hips become spontaneously normal by 4th week + 90% by 9th week; > 90% of abnormalities identified by ultrasound resolve spontaneously

Rx: (1) Flexion-abduction-external rotation brace (Pavlik harness) / splint / spica cast

(2) Femoral varus osteotomy

(3) Pelvic (Salter) / acetabular rotation

(4) Increase in acetabular depth (Pemberton)

(5) Medialization of femoral head (Chiari)

DIABETES MELLITUS

= multisystem disorder

Prevalence: 26 million (= 8.3% of population) in USA in 2010

Path: macro- and microvascular disease; neuropathy; increased susceptibility to infection

Sequelae: neuropathy, nephropathy, retinopathy

1. Genitourinary diabetes mellitus
2. Spinal disorders in diabetes
   (a) Dialysis-associated spondyloarthropathy
   (b) Pyogenic spondylodiskitis
   (c) Neuropathic spine
3. Musculoskeletal diabetes

Diabetic Foot

Diabetic neuropathy: 35% during lifetime

Neuropathic Joint of Diabetic Foot

= most common site of neuropathic joint in diabetes

Pathophysiology:

repetitive stress on insensitive foot → bone + joint disruption, valgus / varus deformity, joint instability → joint degeneration, subluxation, joint destruction

Prevalence: 5% of diabetic patients

Age: most commonly during 5th–7th decade

• grossly deformed usually painfree foot

Location: Lisfranc joint (60%), metatarsophalangeal joint (30%), tibiotalar joint (10%)

NUC:

√ labeled WBC accumulation in noninfected joint due to

(a) ↑ cytokine activity → conversion of yellow into red marrow (not due to infection)

(b) fracture → conversion of yellow into red marrow

Diabetic Foot Ulcer (mal perforans)

= focal skin interruption with elevated margins and associated soft-tissue defect

Cause: breakdown of callus / minor skin trauma (eg, toenail cutting)

Prevalence: 5% of US population

Lifetime risk among diabetics: 25%

Location:

@ typical sites: beneath heads of 1st + 5th metatarsal bones, tip of 1st toe, calcaneus, malleoli

@ additional sites due to neuropathic foot deformity: cuboid, midfoot (from arch collapse), dorsum of claw toe, heel

• poor healing ← vascular disease

• ESR > 70 mm/h (highly specific, 28% sensitive)

• bone contact during probing of ulcer (89% PPV, 56% NPV)

MR (in > 90% of diabetic osteomyelitis):

√ interruption of cutaneous signal (low PPV; higher PPV if ulcer > 2 cm^2 and > 3 mm

deep)= **ulcer**:
√ with low SI on T1WI + high SI on T2WI + intense peripheral enhancement (= **granulation tissue**)
√ reticulation of fat (of high T2 + intermediate T1 signal intensity) in area of soft-tissue swelling:
√ without enhancement = **edema**
√ with enhancement = **cellulitis**
√ focal ill-defined vaguely enhancing soft-tissue mass effect of low SI on T1WI + intermediate to high SI on T2WI replacing subcutaneous fat (= **phlegmon**)
√ focal fluid signal intensity with rimlike enhancement (= **abscess**)
√ sharply demarcated nonenhancing area of devitalized tissue ± peripheral enhancement = **dry gangrene**:
√ + multiple small foci of gas distributed along fascial planes displaying blooming artifact on T2 and GRE images = **wet gangrene**
√ thin linear soft-tissue signal with "tram-track" pattern of enhancing margins (high on T2WI) = **sinus tract**

Diabetic Osteomyelitis of Foot

Pathophysiology: pressure points → callus → ulceration → soft-tissue infection → osteomyelitis

X-ray (lags behind by 10–20 days):
◊ Repeat radiographs after 2–4 weeks!
√ bone destruction
√ periostitis
√ soft-tissue gas

NUC (80% accuracy for labeled leukocytes)

MR (modality of choice; 90% sensitive, 83% specific):
(a) primary osseous signs:
√ low marrow SI on T1WI + high marrow SI on T2WI (= bone marrow edema immediately adjacent to a soft-tissue infection / ulcer)
DDx: reactive osteitis (hyperintense on T2WI but not hypointense on T1WI) ← adjacent cortical (not medullary) / soft-tissue infection
√ marrow enhancement = infected viable tissue
◊ Estimated GFR should be > 30 mL/min before administering contrast medium!
√ ± cortical interruption / destruction
(b) secondary osseous signs:
√ periostitis = linear edema / enhancement along outer cortical margin
√ low-SI line (= calcified periosteum) separated from bone by high-SI layer (= fluid)
(c) secondary soft-tissue signs (in > 90%):
√ redistribution of fat away from planta of foot
√ **skin callus** = focal infiltration / mass within subcutaneous fat:
√ low SI on T1WI + enhancement
√ low to intermediate SI on T2WI
√ ± **adventitial bursitis** = thin flat fluid collection over osseous prominence with

preserved surrounding fat (DDx to abscess)

Location: same as for ulcers

√ tracking of ulcer / sinus track down to bone

Cx:

(1) Devitalized tissue without infection

√ focal often triangular sharply demarcated nonenhancing area of variable SI:

√ central tissue of usually high SI on T2WI + enhancing marginal zone = **dry gangrene**

√ multiple small foci of gas distributed along fascial planes displaying blooming artifact on T2WI + gradient-echo images = **wet gangrene**

(2) Bone infarct / necrosis

√ sharply demarcated nonenhancing marrow

(3) Spread of infection to foot compartments: tendon (tenosynovitis), joint (= septic arthritis), bone (= osteomyelitis)

Prognosis: 39–80% mortality rate at 5 years after diabetes-related amputation of lower extremity

DDx: Neuropathic osteoarthropathy (dislocation, disorganizaton, debris, destruction, density preserved, mildly symptomatic, joint effusion, multiple joints involved, marrow edema, periarticular enhancement; more common in ankle / Lisfranc / Chopart joints)

Diabetic Muscle Disorders

Diabetic Muscle Ischemia

= Diabetic muscle infarction / myonecrosis

Predisposed: long-standing poorly controlled diabetes

Path: fibrinous occlusion of arterioles + capillaries; muscle fiber necrosis + edema

Location: thigh, calf

Site: multiple noncontiguous foci of muscle involvement

- abrupt onset of severe pain + swelling
- palpable painful mass; NO leukocytosis / fever!

MRI:

√ muscle enlargement

√ edema of muscle + fascia

√ muscle enhancement + central nonenhancing region

Rx: glycemic control, analgesics, antiplatelet therapy

Prognosis: typically self-limited disorder responding to conservative therapy

DDx: infectious / inflammatory myositis, deep vein thrombosis, compartment syndrome

Diabetic Infectious Myositis

Cause: hematogenous spread of bacteria ← immune dysfunction in diabetic patients

- fever + leukocytosis with left shift, bacteremia

√ smooth-walled intramuscular abscess

√ rimlike enhancement

Rx: antibiotics, drainage

Diabetic Inflammatory Myositis

Cause: dermatomyositis, polymyositis, inclusion body myositis

• insidious gradually progressive proximal muscle weakness

Location: muscles in pelvis + thigh

√ bilateral symmetric edema

Dx: MRI-directed biopsy of affected muscle

Diabetic Muscle Denervation

Location: intrinsic muscles of foot (usually)

√ peripheral nerve distribution (!)

A. SUBACUTE

√ subacute T2 signal hyperintensity of affected muscle

√ maintained normal SI on T1WI

B. CHRONIC

√ reduced bulk + fatty infiltration of muscle on T1WI

DDx: diabetic muscle ischemia (fascial edema)

Diabetic Neuropathic (Charcot) Osteoarthropathy

Frequency: 1.4% of diabetics

Cause: repetitive trauma to insensate joint + autonomic dysfunction of blood flow

Pathophysiology: bone hyperemia → bone resorption → bone weakening; localized inflammation → bone destruction → joint subluxation → dislocation → foot deformity

Location: tarsometatarsal, subtalar, intertarsal, ankle joints

Eichenholtz classification:

stage 1: osteopenia, periarticular fragmentation, fracture, joint laxity with subluxation, capsular distension
• swollen erythematous foot

stage 2: absorption of bone debris, osseous fusion / osteosclerosis
• reduction in redness + warmth

stage 3: reconstruction + remodeling ± ankylosis of bone fragments, fixed rocker-bottom deformity
• absence of inflammation

NUC:

√ positive findings on blood-flow + blood-pool + delayed phase of 3-phase bone scan

√ combined leukocyte-bone marrow scintigraphy (procedure of choice) to separate from superimposed infection

MRI:

(a) acute

√ extensive soft-tissue edema

√ multiple foci of bone marrow + subchondral edema

√ enhancement far into medullary cavity

√ periarticular enhancement

√ subchondral cysts, articular erosions, joint effusion

(b) chronic

√ less inflammation + less enhancement
√ low marrow signal intensity (bone sclerosis)
√ bone debris, intraarticular bodies, ankylosis
√ joint subluxation + dislocation ← subchondral collapse

Cx: ulcers of midfoot → cuboid osteomyelitis

DIASTROPHIC DYSPLASIA

= DIASTROPHIC DWARFISM = EPIPHYSEAL DYSOSTOSIS

= severe rhizomelic dwarfism ← generalized disorder of cartilage followed by fibrous scars + ossifications

Genetics: autosomal recessive mutations in diastrophic dysplasia sulfate transporter gene located on chromosome 5q32–q33.1

Pathophysiology: disturbed sulfate transport → undersulfated proteoglycans in cartilage matrix

• diastrophic = "twisted" habitus; normal intellectual development
• "cauliflower ear" = ear deformity from inflammation of pinna
• laryngomalacia; lax + rigid joints with contractures

√ cleft palate (25%) + micrognathia

@ Axial skeleton
- √ cervical spina bifida occulta
- √ hypoplasia of odontoid
- √ severe progressive thoracolumbar kyphoscoliosis (not present at birth) + cervical kyphosis
- √ narrowed interpedicular space in lumbar spine
- √ short + broad bony pelvis
- √ posterior tilt of sacrum

@ Extremities
- √ shortening + metaphyseal widening of tubular bones
- √ severe micromelia (predominantly rhizomelic = humerus + femur shorter than distal long bones):
  - √ short and broad femoral neck
  - √ coxa vara (common)
- √ crescent-shaped flattened epiphysis (= retardation of epiphyseal ossification) with invagination of ossification centers into distal ends of femora
- √ multiple flexion contractures (notably of major joints)
- √ dislocation of one / more large joints (hip, elbow); lateral dislocation of patella
- √ clubfoot = severe talipes equinovarus:
  - √ medially bowed metatarsals + abduction of great toes
- √ deformity and shortening of metacarpals + phalanges:
  - √ ulnar deviation of hands
  - √ oval + hypoplastic 1st metacarpal bone + abducted proximally positioned thumb = "hitchhiker's thumb" (CHARACTERISTIC)
  - √ bizarre carpal bones with supernumerary centers
  - √ widely spaced fingers

OB-US:
√ proportionately shortened long bones
√ abducted / hitchhiker thumb
√ clubfeet
√ multiple joint flexion contractures
√ abnormal spinal curvature = scoliosis

Prognosis: death in infancy ← abnormal softening of tracheal cartilage

DIFFUSE IDIOPATHIC SKELETAL HYPEROSTOSIS

= DISH = FORESTIER DISEASE = ANKYLOSING HYPEROSTOSIS
= common ossifying diathesis characterized by bone proliferation at sites of tendinous + ligamentous attachment (enthesis)

Etiology:
(1) may be caused by altered vitamin A metabolism (elevated plasma levels of unbound retinol)
(2) long-term ingestion of retinoid derivatives for treatment of acne (eg, Accutane®); ? hypertrophic variant of spondylosis deformans

Age: > 50 years; M÷F = 3÷1

• pain, tenderness in extraspinal locations
• restricted motion of vertebral column
• hyperglycemia; positive HLA-B27 in 34%

√ increased incidence of hyperostosis frontalis interna

@ Spine
Location: middle + lower thoracic > lower cervical > entire lumbar spine
√ flowing ossification of at least 4 contiguous vertebral bodies:
√ osteophytes located anteriorly + laterally on right side (not on left because of aortic pulsations)
√ osteophytes largest at level of intervertebral disk
√ radiolucency beneath deposited bone
√ disk spaces well preserved, no apophyseal ankylosis, no sacroiliitis

@ Pelvis
√ bridge across superior aspect of symphysis pubis
√ ossification of iliolumbar + sacrotuberous + sacroiliac ligaments (high probability for presence of spinal DISH, DDx: fluorosis)
√ "whiskering" at iliac crest, ischial tuberosity, trochanters
√ broad osteophytes at lateral acetabular edge, inferior portions of sacroiliac joints

@ Extremities
√ big heel spurs (on plantar + posterior surface of calcaneus)
√ spur of olecranon process of ulna
√ spur on anterior surface of patella
√ ossification of coracoclavicular ligament, patellar ligament, tibial tuberosity, interosseous membranes

Cx: postoperative heterotopic bone formation (hip)

DDx: (1) Fluorosis (increased skeletal density)

(2) Acromegaly (posterior scalloping, skull features)

(3) Hypoparathyroidism

(4) X-linked hypophosphatemic vitamin D–resistant rickets

(5) Ankylosing spondylitis (squaring of vertebral bodies, coarser syndesmophytes, sacroiliitis, apophyseal alteration)

(6) Intervertebral osteochondrosis (vacuum phenomenon, vertebral body marginal sclerosis, decreased intervertebral disk height)

DISLOCATION

Hip Dislocation

Frequency: 5% of all dislocations

A. POSTERIOR HIP DISLOCATION (80–85%)

Mechanism: classical dashboard injury (= flexed knee strikes dashboard)

Associated with: fractures of posterior rim of acetabulum, femoral head

- adducted lower extremity flexed at hip

B. ANTERIOR HIP DISLOCATION (5–10%)

Mechanism: forced abduction + external rotation

Associated with: fractures of acetabular rim, greater trochanter, femoral neck, femoral head (characteristic depression on posterosuperior and lateral portion)

Subtypes: 1. anterior obturator dislocation
2. superoanterior / pubic hip dislocation

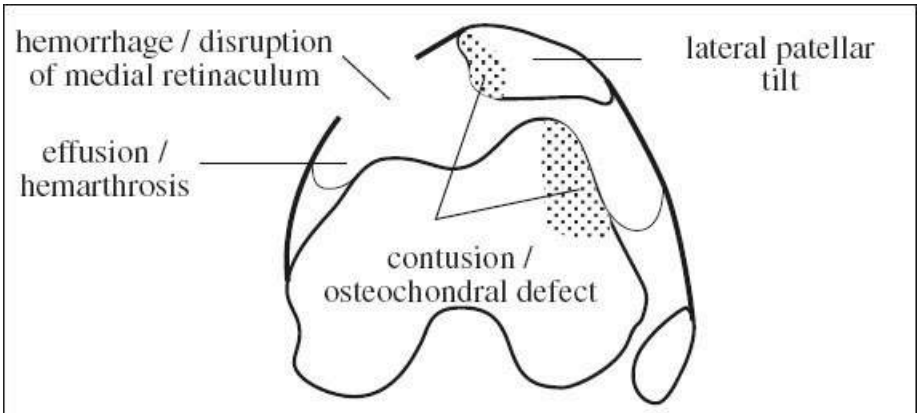
- lower extremity in external rotation

√ prominent lesser trochanter

√ obturator position of femoral head

C. CENTRAL ACETABULAR FRACTURE-DISLOCATION

Mechanism: force applied to lateral side of trochanter



MR Imaging Signs of Patellar Dislocation

Patellar Dislocation

= TRANSIENT LATERAL PATELLAR DISLOCATION

Frequency: 2–3% of all knee injuries

Mechanism: during attempt to slow forward motion while pivoting medially on a planted foot; internal rotation of femur on fixed tibia while knee is flexed + quadriceps contraction produces a net lateral force; direct blow (rare)

At risk: patellar dysplasia (with flattened articular surface); shallow trochlear groove of femur; passive lateral hypermobility of patella; dysplastic distal ⅓ of vastus medialis obliquus muscle; nail-patella syndrome

Associated with: medial meniscal tear / major ligamentous injury in 31%

Age: 13–20 years (young physically active person); M < F

• 50–75% not clinically diagnosed initially ← self-reduction!

√ lateral patellar tilt

√ hemarthrosis (most common cause of hemarthrosis in young conscripts)

√ concave impaction deformity of inferomedial patella (highly specific for prior patellar dislocation)

√ medial parapatellar ossification ← chronic instability with repetitive stress to medial patellofemoral ligament

MR:

√ "kissing" bone contusion / microfracture

√ osteochondral injury of anterolateral femoral condyle + medial patellar facet (90% sensitive):

√ intraarticular bodies (= avulsed osteochondral fragments of patella or lateral femoral condyle)

√ increased SI with sprain / disruption / avulsion of medial patellar retinaculum + medial patellofemoral ligament + medial patellotibial lig.

√ edema / hemorrhage within ± elevated vastus medialis obliquus muscle

√ knee joint effusion = fluid depth > 4 mm in suprapatellar recess (midline SAG image) or > 10 mm in lateral recess (on lateral SAG image):

√ hemarthros with fluid-fluid level (= sedimentation of blood components with low / intermediate T2 signal)

Rx: (1) Temporary immobilization + rehabilitation: successful in 75%

(2) Surgery: fixation of osteochondral fragments if > 1 cm^2, medial capsule repair, lateral retinacular release, vastus medialis et lateralis rearrangement, medial retinaculum reefing

Shoulder Dislocation

Sternoclavicular Dislocation *(3%)*

Posterior Sternoclavicular Dislocation

= posterior displacement of head of clavicle

Cause: blow to shoulder / medial clavicle

CECT confirms posterior sternoclavicular dislocation and may also disclose associated vascular injury.

Cx: injury to mediastinal blood vessels, trachea, esophagus

Anterior Sternoclavicular Dislocation

= anterior displacement of head of clavicle (more common but less serious type)

Cause: anterior blow to shoulder
• protruding clavicular head can be palpated
Cx: chronic pain, ankylosis, deformity
Rx: conservative therapy

Acromioclavicular Dislocation *(12%)*

Grade 1 (strain)
= stretching / partial tearing of acromioclavicular ligament fibers
√ soft-tissue swelling
√ stable AC joint without joint widening

Grade 2 (subluxation)
= disruption of acromioclavicular ligament + strain of coracoclavicular ligament
√ elevation of clavicle of < 100% of shaft width (weight-bearing!)
√ widening of AC joint

Grade 3 (superior dislocation)
= disruption of acromioclavicular + coracoclavicular ligg.
√ widening of AC joint
√ elevation of clavicle > 100% of shaft width

Grade 4 (posterior dislocation)
√ posterior position of clavicle with respect to acromion

Grade 5 (fascial injury)
√ penetration of clavicle through deltotrapezial fascia

Grade 6 (inferior dislocation)
√ inferior position of clavicle with respect to acromion

Glenohumeral Dislocation *(85%)*

◊ Glenohumeral joint dislocations make up > 50% of all dislocations!

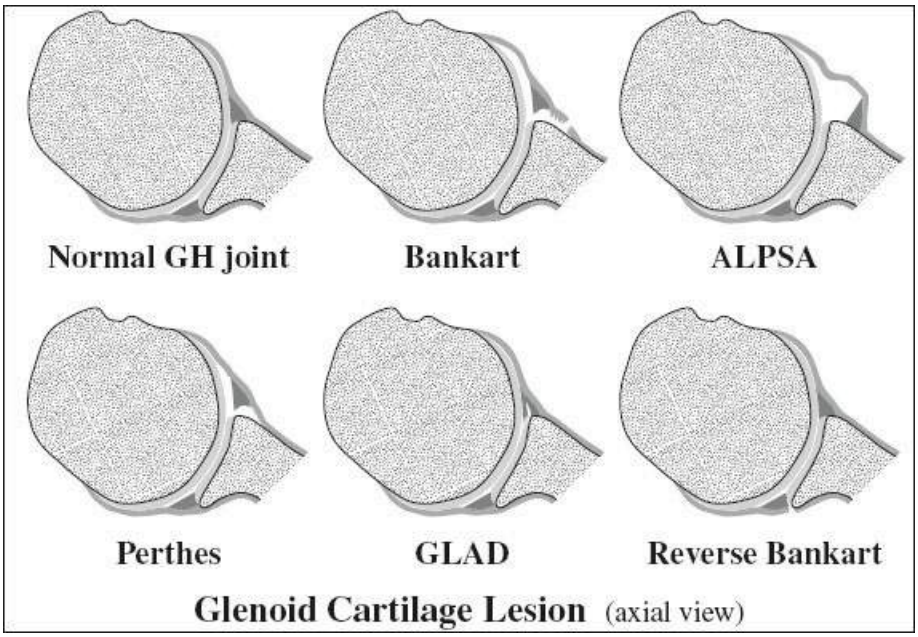
ANTERIOR / SUBCORACOID SHOULDER DISLOCATION

(85–95–98% of all shoulder dislocations)
Prevalence: up to 2% in general population
Types: subcoracoid, subglenoid, subclavicular, intrathoracic
Mechanism: external rotation + abduction (fall on outstretched arm); direct posterior blow in contact sport / forced ABER position)
Age: in younger individuals in their teens

(1) **Bankart lesion** = anterior capsulolabral avulsion
[Arthur Sydney Blundell Bankart (1879–1951), British orthopedic surgeon]
= detachment of glenoid labrum and joint capsule from anterior glenoid rim during anterior shoulder dislocation
√ detachment of anterior inferior glenohumeral labroligamentous complex (IGHLC = anterior-inferior glenoid labrum including labral insertion of inferior glenoid ligament) from glenoid at 3 to 6 o'clock position (= cartilaginous Bankart)
√ lifted disrupted scapular periosteum
√ labrum floats in anterior joint space

(a) Soft Bankart
√ no bony avulsion

(b) Osseous Bankart
√ fracture of anterior rim of glenoid



Shoulder instability increases with increasing size of the Bankart fragment. The redislocation rate is higher when the fragment involves > 20–25% of the glenoid surface area. A concomitant Hill-Sachs lesion reduces stability even further.

May be associated with:
√ fracture of greater tuberosity (15–35%)
√ fracture of coracoid process (3–13%)
√ **Hill-Sachs defect** / deformity (25–50–81%)
= depression / impacted fracture of posterolateral surface of humeral head at / above level of coracoid process ← impaction against anterior edge of glenoid rim in subglenoid type
[Harold Arthur Hill (1901–1973) and Maurice David Sachs (1909–1987), radiologists in San Francisco]

(2) **Perthes lesion** (variant of Bankart)
◊ easily overlooked on MR / arthroscopy → best detected in ABER position with traction on IGHL
√ labrum separated from articular cartilage
√ scapular periosteum stripped medially but with intact periosteal sleeve
√ nondisplaced avulsed labrum (DDx to ALPSA)

(3) **Glenoid Labrum Articular Disruption** (GLAD)
= combination of labral tear + cartilage defect
√ complete avulsion of anteroinferior glenoid labrum
√ small fragment of articular cartilage also detached
◊ chondral flaps best visualized on MR arthrogram

(4) **Humeral Avulsion of the Glenohumeral Ligament**

(HAGL) = failure at humeral attachment site
Prevalence: 52% in acute trauma; 2–9% of anterior glenohumeral instabilities
Age: 28 (range, 12–54) years; M÷F = 92÷8
√ "J / reversed J" sign (for RT / LT shoulder)
= detached end of anterior / posterior band of IGHL that falls inferiorly away from neck of humerus
√ extravasation of joint effusion / contrast material at the humeral insertion of disrupted capsule
Bony HAGL
√ avulsion of humeral cortex along with IGHL

(5) **Anterior Labroligamentous Periosteal Sleeve Avulsion** (ALPSA) = medialized Bankart
◊ best detected in ABER position
√ complete avulsion of anteroinferior glenoid labrum
√ avulsed scapular periosteum intact
√ labroligamentous complex rolls up + becomes displaced medially + inferiorly
• recurrent anterior humeral dislocations ← incompetent anterior band of IGHL
• can heal into a deformed labrum → difficult to diagnose

(6) **Reverse Bankart**
Prevalence: 2–4% of all shoulder instability
Mechanism: excessive force applied to adducted and internally rotated shoulder ← swimming, throwing, punching, convulsion
√ posterior labral tear

MRI (arthrography improves sensitivity to 89–99% and specificity to > 90%):
√ hemorrhagic effusion (in acute injury)
√ increased SI in anterior-inferior labrum + capsule (DDx: magic angle artifact)
√ discrete tear / fragmentation of labrum
√ ± tear of middle glenohumeral ligament
√ tear of degenerated supraspinatus tendon (in 33% of patients > 40 years of age)
√ tear of degenerated subscapularis tendon (in 33% of patients > 40 years of age)
√ myotendinous subscapularis strain / contusion
√ paralabral cysts are usually associated with labral tears; may cause denervation of suprascapular nerve simulating impingement syndrome (DDx: age-related degeneration)

Prognosis: significance of glenoid rim fracture is greater than of Hill-Sachs fracture
Cx: (1) Recurrent dislocations: inversely related to age (83% < 20 years; 16% > 40 years of age); M÷F = 3÷1
(2) Repeated dislocations ← incomplete / inadequate healing = chronic recurrent anterior shoulder instability
(3) Arthritis (with repeated subluxations)
Rx: (1) Conservative treatment for most
(2) Surgical fixation for young athletes

POSTERIOR SHOULDER DISLOCATION (2–5%)

Cause: (a) traumatic: convulsive disorders /electric shock therapy
(b) nontraumatic: voluntary, involuntary, congenital, developmental

Types: subacromial, subglenoid, subspinous

◊ In > 50% unrecognized initially + subsequently misdiagnosed as frozen shoulder!

◊ Average interval between injury and diagnosis is 1 year!

√ "rim" sign (66%) = distance between medial border of humeral head + anterior glenoid rim < 6 mm

May be associated with:

√ "trough" sign (75%) = "reverse Hill-Sachs"
= compression fracture of anteromedial humeral head (tangential Grashey view of glenoid!)

√ fracture of posterior glenoid rim

√ avulsion fracture of lesser tuberosity

MRI:

√ tear of subscapularis tendon

√ empty bicipital groove (= dislocated bicipital tendon)

Inferior Shoulder Dislocation (0.5%)

= LUXATIO ERECTA

= extremity held over head in fixed position with elbow flexed

Mechanism: severe hyperabduction of arm resulting in impingement of humeral head against acromion

√ humeral articular surface faces inferiorly

Cx: rotator cuff tear; fracture of acromion ± inferior glenoid fossa ± greater tuberosity; neurovascular injury

Superior Shoulder Dislocation (< 1%)

= humeral head driven upward through rotator cuff

May be associated with: fracture of humerus, clavicle, acromion

DDx: drooping shoulder (transient phenomenon after fracture of surgical neck of humerus ← hemarthrosis / muscle imbalance)

Gadolinium Shoulder Arthrography

» fluoroscopically guided needle insertion from an anterior approach

» confirmation of needle placement with iodinated contrast material

» injection of 12–20 mL of diluted gadolinium chelate solution:

- 0.1 mL of gadolinium DTPA (469 mg/mL) into
- 20 mL of bacteriostatic saline

» patient's arm and shoulder are moved through full range of motion

Biceps Tendon Dislocation

= total + permanent loss of contact between tendon and bicipital groove

Types:

(1) dislocation inside subscapularis tendon leaving anterior fascia intact

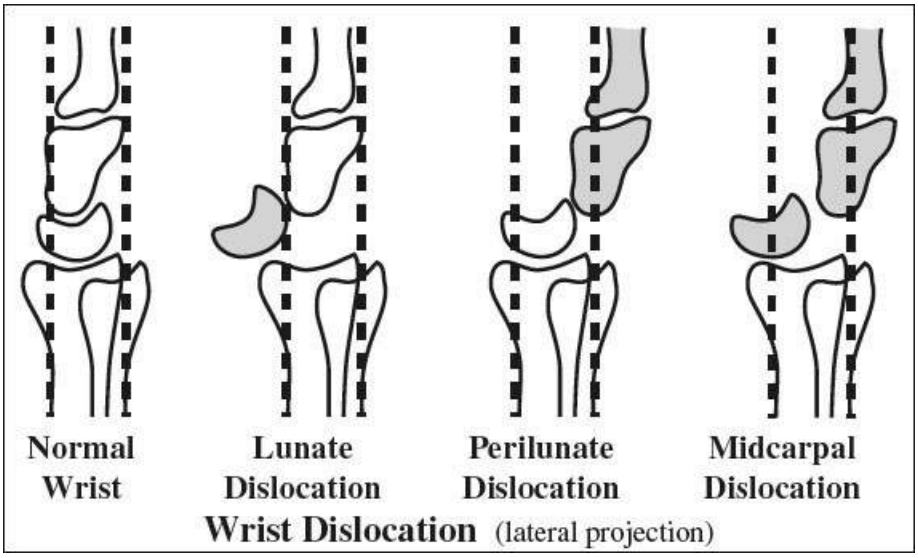
(2) intraarticular dislocation with complete tear of all insertions on lesser tuberosity but intact anterior fascia (lesion hidden in joint space)

(3) intraarticular dislocation with complete tear of all insertions on lesser tuberosity + anterior fascia
(4) dislocation over intact subscapularis tendon (= rupture of the supraspinatus tendon and CHL)

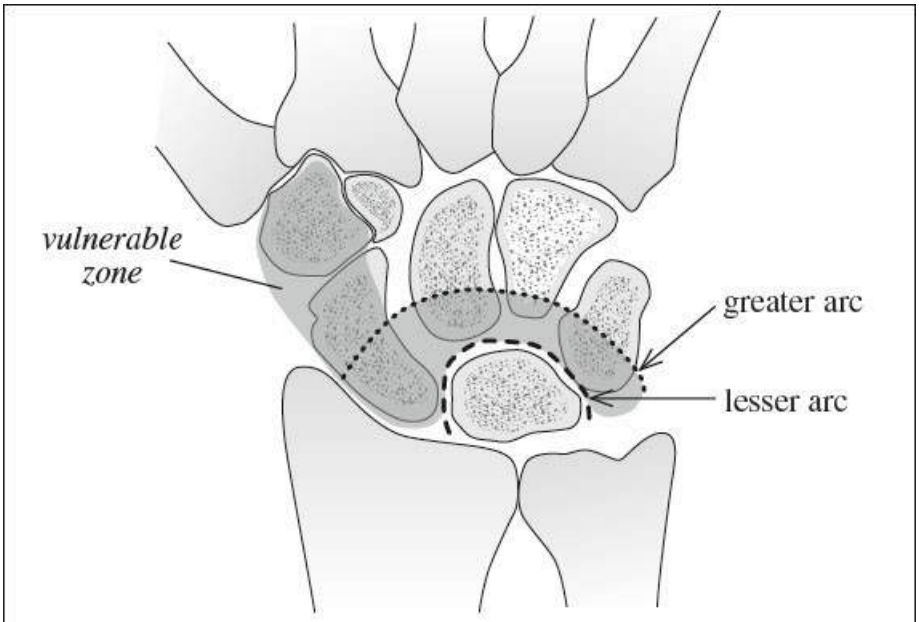
Associated with: tears of ligamentous pulley
Location: intraarticular extrasynovial (within reflection of synovial membrane)
MR:
√ dislocated biceps tendon medial to empty bicipital groove (axial image)
√ variably increased signal intensity
√ thickening, flattening, broadening of the tendon
√ fluid around displaced biceps tendon

Biceps Tendon Subluxation

= partial / transitional loss of contact between biceps tendon + bicipital groove
Direction:



Wrist Dislocation (lateral projection)



Fracture-Dislocation Zones of Wrist

(1) intraarticular
(2) between subscapularis tendon and CHL
(3) external to CHL
(4) intrasheath

Wrist / Carpal Dislocation

Mechanism: fall on outstretched hand
Frequency: 10% of all carpal injuries
◊ Up to 25% overlooked at initial examination!

Lunate Dislocation

= final stage of perilunate injury with highest degree of instablity
√ "spilled teacup" sign = lunate dislocated in volar direction (on LAT view)
√ rest of carpus assumes alignment with radius

Perilunate Dislocation

= dislocation of capitate head from concavity of distal lunate
Prevalence: 2–3 times more common than lunate dislocation
Mechanism: high-energy wrist hyperextension (MVC, fall from height, sports) with sequential injury of scapholunate → lunocapitate → lunotriquetral joints → complete dislocation
Average age: 30 years; M >> F
Associated with: fracture in 75%
√ disruption of carpal arcs (AP view)
√ Terry-Thomas sign = widening of space between scaphoid and lunate (AP view)
√ triangular lunate (AP view)
√ posterior dislocation of capitate head relative to lunate (LAT view)

GREATER ARC INJURY

= perilunate dislocation + fracture of scaphoid / trapezium / capitate / hamate / triquetrum
◊ Twice as common as lesser arc injury
◊ Most commonly transscaphoid perilunate dislocation
√ fracture of any carpal bone around lunate

LESSER ARC INJURY

= pure ligamentous disruption around lunate
√ most commonly dorsal dislocation
Rx: open reduction + internal fixation

Rotary Subluxation of Scaphoid

= Scapholunate dissociation
= tearing of interosseous ligaments of lunate, scaphoid, capitate
Mechanism: acute dorsiflexion of wrist; may be associated with rheumatoid arthritis
√ gap > 4 mm between scaphoid + lunate (PA view)
√ foreshortening of scaphoid
√ "ring" sign of distal pole of scaphoid

DOWN SYNDROME

= MONGOLISM = TRISOMY 21
Chromosomes: 95% nondisjunction, 5% translocation
Prevalence: 1÷870 live births, most common karyotype / chromosomal abnormality in USA
• mental retardation; hypotonia in infancy
• characteristic facies; Simian crease
@ Skull
√ hypotelorism
√ persistent metopic suture (40–79%) after age 10
√ hypoplasia of sinuses + facial bones
√ microcrania (brachycephaly)
√ delayed closure of sutures + fontanels
√ dental abnormalities (underdeveloped tooth No. 2)
√ flat-bridged nose
@ Axial skeleton
√ atlantoaxial subluxation (25%)
√ anterior scalloping of vertebral bodies
√ "squared vertebral bodies" = centra high and narrow
= positive lateral lumbar index (ratio of horizontal to vertical diameters of L2)
@ Chest
√ congenital heart disease (40%): endocardial cushion defect, VSD, tetralogy of Fallot
√ hypersegmentation of manubrium = 2–3 ossification centers (90%)
√ gracile ribs; 11 pairs of ribs (25%)
@ Pelvis (frontal view)
√ flaring of iliac wings (= rotation of iliac wings toward coronal plane at sacroiliac joints)

= "Mickey Mouse ears" / "elephant ears":
√ decreased iliac angle + index (in 70–80%)
√ flattening of acetabular roof (small acetabular angle)
√ elongated + tapered ischia
@ Extremities
√ metaphyseal flaring
√ clinodactyly (50%); widened space between first two digits of hands + feet
√ hypoplastic and triangular middle + distal phalanges of 5th finger = acromicria (DDx: normal individuals, cretins, achondroplastic dwarfs)
√ pseudoepiphyses of 1st + 2nd metacarpals
@ Gastrointestinal
√ umbilical hernia
√ "double bubble" sign (8–10%) = duodenal atresia / stenosis / annular pancreas
√ tracheoesophageal fistula
√ anorectal anomalies
√ Hirschsprüng disease

OB-US:

- advanced maternal age
  ◊ In 1÷385 live births for women > 35 years of age
  ◊ HOWEVER: 80% of fetuses with Down syndrome are born to mothers < 35 years of age
- quad test (2nd trimester maternal serum screening):
  (1) low (0.7 MoM) maternal alpha-fetoprotein (20–30%)
  (2) increased (2.04 MoM) hCG (DDx: decreased in trisomy 18)
  (3) decreased (0.79 MoM) unconjugated estriol (uE3)
  (4) decreased dimeric inhibin A levels
  ◊ Optimal time for test between 15 and 16 weeks GA
  ◊ Detects 75% of cases with Down syndrome with a 5% screen-positive rate
  Disadvantage: late performance in 2nd trimester, 25% of Down syndrome cases not detected, many amniocenteses unnecessarily recommended
- low pregnancy-associated plasma protein A (PAPP-A) at 10–14 weeks EGA

√ first-trimester ultrasound markers:
√ nuchal translucency
= measurement of space between spine and overlying skin on midsagittal view
Best time: 10w3d – 13w6d EGA
√ ≥ 5 mm during 14–18 weeks
√ ≥ 6 mm during 19–24 weeks
Cause: heart failure, abnormal extracellular matrix, abnormal lymphatic development
√ absent nasal bone
Best time: between 10 and 14 weeks EGA
√ absent / reversed Doppler flow in ductus venosus during atrial contraction
√ major structural malformations:
Best time: 18 weeks EGA
√ VSD / complete AV canal (50%)
√ cystic hygroma, resolved by 20th week MA (DDx: Turner syndrome, trisomy 18, trisomy 13, triploidy)

√ omphalocele
√ double bubble of duodenal atresia (8–10%), not apparent before 22 weeks GA
√ hydrothorax
√ mild cerebral ventricular dilatation
√ agenesis of corpus callosum
√ imperforate anus
√ minor markers:
√ elevated BPD / femur ratio ← short femur
√ ratio of measured-to-expected femur length ≤ 0.91 [expected femur length: –9.3105 + 0.9028 x BPD] (sensitivity 40%, specificity 95%, false-positive rate of 2–7%, 0.3% PPV for low-risk population [1÷700], 1% PPV for high-risk population [1÷250])
√ ratio of measured-to-expected humerus length ≤ 0.90 [expected humerus length: –7.9404 + 0.8492 x BPD] (1–2% PPV for low-risk population; 3% PPV for high-risk population)
√ flared iliac crest = iliac wings rotated toward coronal plane:
√ mean iliac angle at superiormost level of 95.6 ± 11.7° (compared to 76.4 ± 16.8° for euploid fetuses)
√ sandal-gap deformity = separation of great toe (45%)
√ hypoplasia of middle phalanx of 5th digit resulting in clinodactyly (= inward curve) in 60%
√ mild fetal pyelectasis (17–25%)
√ echogenic bowel at < 20 weeks GA (15%, in 0.6% of normals)
√ echogenic intracardiac focus, usually in left ventricle = thickening of papillary muscle (18%, in 5% of normals)
√ frontal lobe shortening (measured from the inner table of the frontal bone to the posterior margin of the thalamus)
√ brachycephaly
√ small cerebellum
√ IUGR (in 30%)
√ polyhydramnios

Cx: leukemia (increased frequency by 3–20 x)

DRUG-INDUCED MSK ANOMALIES

Aluminum

Source: dialysate containing a high concentration of aluminum, total parenteral nutrition, aluminum salts phosphate-binding antacids (to control hyperphosphatemia)

• aluminum serum level > 100 ng/mL
√ osteopenia → pathologic fractures
√ signs of osteomalacia (> 3 insufficiency fractures with predominant involvement of ribs)
√ widening of physis, fraying of metaphyses of long bones
√ avascular necrosis
√ lack of osteosclerosis
√ little evidence of subperiosteal resorption

Anticonvulsants

√ rickets, osteomalacia, osteoporosis
√ calvarial thickening + thickening of heel pad

Biphosphonates

= inorganic phosphates administered orally / IV

Use: decrease of bone pain + reduced complications in patients with metastatic lytic lesions, malignancy-induced hypercalcemia, multiple myeloma, Paget disease, osteoporosis

Pathophysiology: inhibition of endothelial proliferation → interruption of intraosseous circulation

@ Long bones
- √ bone-within-bone = bandlike metaphyseal sclerosis (in the maturing skeleton)
- √ atypical low-energy fractures:
  Location: proximal third of femur, distal to lesser trochanter, proximal to supracondylar flare
- √ transverse minimally comminuted fracture
- √ fracture fragment with medial spike / beak
- √ medial periosteal stress reaction + unicortical nipple (= focal thickening of lateral cortex)

@ Osteonecrosis of mandible
Location: mylohyoid ridge of mandible
Cause: spontaneous (increased risk with concurrent steroid therapy) / precipitated by trauma (tooth extraction)
May be associated with: infection by actinomyces
- painful / asymptomatic (occasionally)
- √ poorly marginated diffuse area of low attenuation with bilateral symmetric sclerosis

Corticosteroids

√ (most common cause of drug-induced) osteoporosis
√ insufficiency fractures
√ avascular necrosis + arthropathy

Deferoxamine

Use: removal of excess iron stores from multiple transfusions (treatment of severe β-thalassemia)

√ flattening of vertebrae → lower height percentile
√ irregular thickened cupped metaphyses (similar to rickets)

Fluorosis

Source of fluorides: high natural content in drinking water (parts of southeast Asia, South Africa); welding / manufacture of aluminum; medical drug therapy

√ sclerosis with granular pattern + thickened trabeculae
√ ossification of ligamentous insertions
√ osteophytic outgrowths around joints

√ increased bone fragility
√ diffuse periostitis

Lead

= Lead poisoning = **plumbism**

Source: paint, home-distilled liquors, folk remedies, cosmetics, industrial materials

Path: lead concentrates in metaphyses of growing bones (distal femur > both ends of tibia > distal radius) leading to failure of removal of calcified cartilaginous trabeculae in provisional zone

- loss of appetite, vomiting, constipation, abdominal cramps
- peripheral neuritis (adults), meningoencephalitis (children)
- anemia; lead line at gums (adults)

√ bands of increased density at metaphyses of tubular bones (only in growing bone):
  √ single transverse line of dense band
  √ bone-in-bone appearance
  - elevated serum levels (70–80 mg/dL)

√ lead lines may persist
√ clubbing if poisoning severe (anemia)

DDx: (1) Healed rickets
(2) Normal increased density in infants < 3 years old
(3) Hypervitaminosis D
(4) Healing leukemia
(5) Scurvy

Methotrexate

= dihydrofolate reductase inhibitor most often used in children for treatment of ALL / osteosarcoma / brain tumor

Methotrexate Osteopathy = syndrome that consists of
(1) bone pain (2) osteopenia (3) pathologic fractures

◊ Radiographic findings similar to scurvy:
  √ osteopenia:
    √ metaphyseal band of demineralization (simulating recurrent leukemia)
  √ broadening + increased density of the zone of provisional calcification
  √ sharply outlined epiphyses
  √ "corner" sign, ring epiphysis
  √ pathologic insufficiency fractures (most often metaphyseal)
  √ impaired healing of fractures
  √ NO massive subperiosteal hemorrhage

Prostaglandin E

Use: maintain patency of ductus arteriosus

√ periostitis = periosteal new bone growth

Location: symmetric involvement of long bones, ribs, clavicle, scapula, mandible

DDx: infantile cortical hyperostosis (Caffey disease); syphilis; effect of interleukin-11

therapy; scurvy; hypervitaminosis A

Retinoids
√ skeletal hyperostosis:
@ axial skeleton (esp. C-spine)
√ anterior vertebral osteophytes
√ ossification of anterior longitudinal ligament
√ osseous bridges between vertebrae
@ appendicular skeleton
√ calcification / ossification of coracohumeral ligament
√ enthesopathy
DDx: Diffuse idiopathic skeletal hyperostosis

Statins
√ muscle edema (= acute myositis)

Vitamin A
√ cortical thickening of tubular bones
√ cupping + fraying of metaphyses
√ irregularity of growth plates
√ premature fusion of ossification centers
DDx: Caffey disease (mandibular involvement, fever, > 4 months of age)

Vitamin D
√ generalized osteoporosis
√ metastatic calcifications in periarticular soft tissues

DYSCHONDROSTEOSIS
= LéRI-LAYANI-WEILL SYNDROME
= mesomelic long-bone shortening (forearm + leg); autosomal dominant; M÷F = 1÷4
• limited motion of elbow + wrist
√ bilateral Madelung deformity:
√ radial shortening in relation to ulna
√ bowing of radius laterally + dorsally
√ dorsal subluxation of distal end of ulna
√ carpal wedging between radius + ulna ← triangular shape of distal radial epiphysis + underdevelopment of ulna
DDx: pseudo-Madelung deformity (from trauma / infection)

DYSPLASIA EPIPHYSEALIS HEMIMELICA
= TREVOR DISEASE = TARSOEPIPHYSEAL ACLASIS
= uncommon skeletal developmental disorder representing an epiphyseal osteochondroma
Prevalence: 1÷1,000,000
Age: 2–4 years; M÷F = 3÷1
Cause: failure of normal progression of cellular cartilage breakdown (= aclasis); spontaneous

occurrence

Path: lobulated mass protruding from epiphysis with a cartilaginous cap

Histo: normal bone + hyaline cartilage with abundant enchondral ossification (= abnormal cellular activity at cartilaginous ossification center)

Types:

(1) Localized form = monostotic involvement: usually hindfoot and ankle

(2) Classic form (> 66%) = more than one area of involvement in a single extremity with characteristic hemimelic distribution: talus, distal femur, distal tibia

(3) Generalized / severe form = disease involving the whole lower extremity

√ pelvic involvement: femoral head, symphysis pubis, triradiate cartilage

√ hypertrophy of ipsilateral iliac bone

- antalgic (= pain-avoiding) gait; palpable mass
- varus / valgus deformity; limb length discrepancy
- limited joint mobility and function

Location: lower extremity (tarsus, knee, ankle); rare in upper extremity (humerus, ulna, scapula)

Site: restricted to medial OR lateral side of limb (= hemimelic), ie, medial÷lateral = 2÷1

@ Infant & toddler

√ premature appearance of an eccentric, lobulated, overgrown, asymmetric ossification center

√ stippled calcification of anomalous cartilage

@ Childhood

√ disorganized epiphyseal calcification accompanied by irregular ossification

√ osteochondroma-like growth from one side of epiphysis

√ premature closure of physis results in limb deformity and limb length discrepancy

√ irregular articular surface combined with angular deformity

√ undertubulation of bone as a consequence of secondary involvement of metaphysis

Cx: premature secondary osteoarthritis

DDx: osteochondroma

EHLERS-DANLOS SYNDROME

= group of autosomal dominant diseases of connective tissue characterized by abnormal collagen synthesis → excessive tissue fragility

Types: 10 types have been described that differ clinically, biochemically, and genetically

Age: present at birth; predominantly in males

- hyperelasticity of skin
- fragile brittle skin with gaping wounds and poor healing
- molluscoid pseudotumors over pressure points
- hyperextensibility of joints; joint contractures with advanced age
- bleeding tendency ← fragility of blood vessels
- blue sclera, microcornea, myopia, keratoconus, ectopia lentis

@ Soft tissues

√ multiple ovoid calcifications (2–10 mm) in subcutis / in fatty cysts (“spheroids”), most frequently in periarticular areas of legs

√ ectopic bone formation

@ Skeleton
- √ hemarthrosis (particularly in knee)
- √ malalignment / subluxation / dislocation of joints on stress radiographs
- √ recurrent dislocations: hip, patella, shoulder, radius, clavicle
- √ precocious osteoarthrosis (predominantly in knees)
- √ ulnar synostosis
- √ kyphoscoliosis
- √ spondylolisthesis
- √ spina bifida occulta

@ Chest
- √ diaphragmatic hernia
- √ panacinar emphysema + bulla formation
- √ tracheobronchomegaly + bronchiectasis

@ Arteries (= type IV of Ehlers-Danlos syndrome)
- √ aneurysm of great vessels, aortic dissection, aortic rupture, tortuosity of arch, ectasia of pulmonary arteries (in 60% by age 40)
- ◊ AORTOGRAPHY CONTRAINDICATED!
  (Cx following arteriography: aortic rupture, hematomas)

@ GI tract
- √ ectasia of gastrointestinal tract

ELASTOFIBROMA DORSI

= degenerative / reactive fibrous pseudotumor forming as a reaction to chronic mechanical friction

Frequency: in 24% of women + 11% of men > 55 years (autopsy study); in 2% of CT population

Average age: 60 (range, 41–80) years; M÷F = 1÷4

Histo: enlarged irregular serrated elastic hypereosinophilic fibers, collagen, scattered fibroblasts, occasional lobules of adipose tissue; lack of capsule

- slow growing, often asymptomatic + clinically inapparent
- stiffness (25%), moderate pain (10%) if > 5 cm in diameter
- clicking / snapping / clunking of scapula

Location: deep to serratus anterior + latissimus dorsi mm. at inferomedial border of scapula; R > L; bilateral in 10–66%
in < 1% at: greater trochanter, olecranon, thoracic wall

PET: incidental finding

CT:
- √ heterogeneous poorly defined lesion of soft-tissue attenuation similar to muscle

MR:
- √ well-defined heterogeneous intermediate-SI lesion similar to muscle on T1WI + T2WI
- √ interspersed streaks of fat intensity in fascicular pattern
- √ heterogeneous enhancement

Rx: local excision for symptomatic lesions

DDx: extraabdominal desmoid, neurofibroma, malignant fibrous histiocytoma

ENCHONDROMA

= benign cartilaginous growth in medullary cavity; bones preformed in cartilage are affected (NOT skull)

Frequency: 3–17% of biopsied primary bone tumors
◊ 2nd most common cartilage-containing tumor!

Etiology: continued growth of residual benign rests of cartilage displaced from the growth plate

Age: 10–30 years; M÷F = 1÷1

Histo: lobules of pure hyaline cartilage

• usually asymptomatic, painless swelling
• pain → suspect pathologic fracture

Location: (usually solitary; multiple = enchondromatosis)
(a) in 40% small tubular bones of hand (most frequent tumor here), distal + mid aspects of metacarpals, proximal / middle phalanges
◊ Most common benign tumor of the hand!
(b) proximal femur, proximal humerus, tibia, radius, ulna, foot, rib (3%)

Site: central within medullary canal + metaphyseal; epiphysis only affected after closure of growth plate

√ oval / round area of geographic destruction with lobulated contour + fine marginal line
√ chondroid matrix:
√ ground-glass appearance
√ dystrophic calcifications within small cartilage nodules / fragments of lamellar bone:
√ pinhead, flocculent, stippled "rings and arcs" pattern
√ bulbous expansion of bone with thinning of cortex in small tubular bones of phalanx, rib, fibula:
√ cortical endosteal scalloping
√ NO cortical breakthrough / periosteal reaction
√ Madelung deformity = bowing deformities of limb, discrepant length

MR:
√ low- to intermediate SI on T1WI
√ high SI on T2WI ← high water content of extracellular matrix
√ low-signal intensity matrix calcifications
√ normal fat marrow interspersed between cartilage nodules
√ peripheral enhancement pattern

CEMR:
√ peripheral nodular + septal enhancement ← avascular tumor

Cx: (1) Pathologic fracture → pain
√ may be better characterized on CT
(2) Malignant degeneration in long-bone enchondromas in 15–20% (severe new pain in an adult patient, interval growth at imaging, loss of marginal definition, cortical disruption, local periosteal reaction)

DDx: (1) Epidermoid inclusion cyst (phalangeal tuft, history of trauma, more lucent)
(2) Unicameral bone cyst (rare in hands, more radiolucent)

(3) Giant cell tumor of tendon sheath (commonly erodes bone, soft-tissue mass outside bone)

(4) Fibrous dysplasia (rare in hand, mostly polyostotic)

Enchondroma versus Chondrosarcoma in Appendicular Skeleton

	Enchondroma	*Intramedullary Chondrosarcoma*
Mean age and sex ratios	40 years; M÷F = 2÷3	50 years; M÷F = 11÷9
Palpable mass	28%	82%
Pain	40% (fracture associated)	95% (prolonged + increasing)
Lesion location	hands, feet	axial skeleton
Radiographic Features		
Site	diaphysis	metaphysis, epiphysis
Lesion size	< 5 cm	> 5–6 cm
Soft-tissue extension (MR)	3%	76%
Deep endosteal scalloping > ²/₃ of cortical thickness		90%
Periosteal reaction (X-ray)	3%	47%
Cortical destruction (CT)	8%	88%
Pathologic fracture (X-ray)	5%	27%
Endosteal scalloping > ²/₃ of length of lesion		79%
Cortical remodeling (X-ray)	15%	47%
Cortical thickening (X-ray)	17%	47%
Matrix mineralization (CT)	100%	94%
Small hyperintense T1 foci	65%	35%
Bone scintigraphy (↑ uptake c/w anterior iliac crest)	21%	82%

(5) Bone infarct

(6) Chondrosarcoma (exceedingly rare in phalanges, metacarpals, metatarsals)

ENCHONDROMATOSIS

= OLLIER DISEASE = DYSCHONDROPLASIA = MULTIPLE ENCHONDROMATOSIS

[Léopold Ollier (1830–1900), French orthopedic surgeon in Lyon]

= nonhereditary failure of cartilage ossification

Cause: derangement of cartilaginous growth resulting in migration of cartilaginous rests from epiphyseal plate into metaphysis where they proliferate

Prevalence: 1÷100,000 persons

Histo: persistent cartilage in bones formed by enchondral ossification

Mean age: 13 years

Association: juvenile granulosa cell tumor of ovary

• growth disparity with leg / arm shortening
• painless swelling, hand + foot deformity

Location: predominantly unilateral monomelic distribution (a) localized (b) regional (c) generalized

Site: metacarpals > phalanges

√ well-demarcated rounded radiolucencies / columnar streaks of decreased density from epiphyseal plate into diaphysis of long bones = cartilaginous rests

√ expansile remodeling of affected bone:
  √ clublike deformity / expansion of metaphyseal region
  √ predominant cortical thinning + endosteal scalloping
  √ bony spurs pointing toward the joint (DDx: exostosis points away from joint)

√ cartilaginous areas show punctate calcifications with age:
  √ matrix mineralization with TYPICAL arc-and-ring appearance of chondroid lesions

√ associated with dwarfing of the involved bone ← impairment of epiphyseal fusion

√ bowing deformities of limb bones → fracture

√ discrepancy in length = Madelung deformity (radius, ulna)

√ small bones of foot + hand: aggressive deforming tumors that may break through cortex ← tendency to continue to proliferate

√ fanlike radiation of cartilage from center to crest of ilium

Prognosis: skeletal findings often stabilize after puberty

Cx: sarcomatous transformation (in 5–50%): osteosarcoma (young adults); chondro- / fibrosarcoma (in older patients); mean age of 33 years
  ◊ ⇑ risk with tumor in long bones + axial skeleton
  ◊ ⇑ risk to develop multiple synchronous / metachronous chondrosarcomas

Maffucci Syndrome

[Angelo Maffucci (1847–1903), chief pathologist in Pisa, Italy]

= variant of Ollier disease

= rare nonhereditary early mesodermal dysplasia characterized by enchondromatosis + hemangiomatosis (= multiple low-flow vascular malformations [venous >> lymphatic])

Incidence: 180 cases confirmed

Histo of hemangioma:
spindle cell hemangioma > (originally described) cavernous hemangioma affecting SQ tissue of distal extremities

Age: 25% during 1st year of life; 45% prior to 6 years; 78% before puberty; M=F

Association: juvenile granulosa cell tumor of ovary

• multiple soft red-blue / skin-colored acral spongy subcutaneous nodules (= hemangiomas)
• swelling of dorsum of hand + foot (lymphatic form)
• normal intelligence

Location: unilateral involvement (50%) / marked asymmetry; distinct predilection for metaphyses of tubular bones of hand (88%) + foot (61%), lower leg (59%), femur (53%), humerus (42%), forearm (41%), pelvis (21%), vertebra (10%)

√ hemangioma + less commonly lymphangioma

√ phleboliths frequently present

√ striking tendency for enchondromas to be very large projecting into soft tissues

√ growth disturbance of long bones (common)

MR:

√ increased SI centrally on fluid-sensitive sequence ← myxoid change

Cx: (a) malignant transformation of

› enchondroma → chondrosarcoma / fibrosarcoma (15–20%)

› hemangioma → hemangiosarcoma / hemangio-endothelioma / lymphangiosarcoma (in 3–5%)

(b) ↑ prevalence of ovarian carcinoma, pancreatic ca., carcinoma, CNS glioma, gastrointestinal adenoca.

Prevalence of malignancy: 23–100% → lifelong follow-up

DDx: Ollier disease (without hemangiomas)

EPIDERMOID CYST

= INFUNDIBULAR CYST = SEBACEOUS CYST (misnomer)

= proliferation of surface epidermal cells within a circumscribed space in the dermis

Histo: production of keratin within closed space lined by surface epidermis

Associated with: nevoid basal cell syndrome (Gorlin syndrome) + high prevalence of epidermoid / dermoid cysts

• intradermal / subcutaneous mass

Location: anywhere; subungual (common)

√ small unilocular / (rarely) large multiloculated mass

US:

√ circumscribed circular / oval hypoechoic mass on US

√ often associated with hair follicle

MR:

√ isointense / slightly hypointense relative to muscle on T1WI

√ hyperintense with focal areas of decreased signal on T2WI

√ no appreciable enhancement

Epidermal Inclusion Cyst

= INTRAOSSEOUS KERATIN CYST = IMPLANTATION CYST

Age: 2nd–4th decade; M > F

Cause: trauma / migration of nail bed fragment → entrapment of epidermal fragments within other tissues

Path: encapsulated round / oval lesion lined by stratified squamous epithelium + filled with laminated keratin (soft white cheesy contents)

Histo: stratified squamous cells, keratin, cholesterol crystals

• history of trauma (implantation of epithelium under skin → secondary bone erosion); asymptomatic

• swelling of fingertip with redness, pain, sensation of heat

Location: superficially situated bones such as calvarium (typically in frontal / parietal bone), phalanx (usually terminal tuft of middle finger), L > R hand, occasionally in foot

√ well-defined round osteolysis with sclerotic margin

√ cortex frequently expanded + thinned
√ NO calcifications / periosteal reaction / soft-tissue swelling
√ ± wall calcification / ossification
√ pathologic fracture often without periosteal reaction

US:
√ round / oval an- or hypoechoic subungual mass with edge shadowing containing variably echogenic foci
√ no internal vascularity

MR:
√ well-defined round lesion of intermediate T1 + T2 SI
√ central debris + thin peripheral rim of enhancement
√ scalloping of distal phalanx underlying nail bed
√ extensive inflammation of surrounding soft tissue ← suggestive of lesion rupture

DDx: (a) in finger: glomus tumor, enchondroma (rare in terminal phalanx)
(b) in skull: infection, metastasis (poorly defined), eosinophilic granuloma (beveled margin)

EPIPHYSEOLYSIS OF FEMORAL HEAD

= SLIPPED CAPITAL FEMORAL EPIPHYSIS
= atraumatic fracture through hypertrophic zone of physeal plate

Frequency: 2÷100,000 people

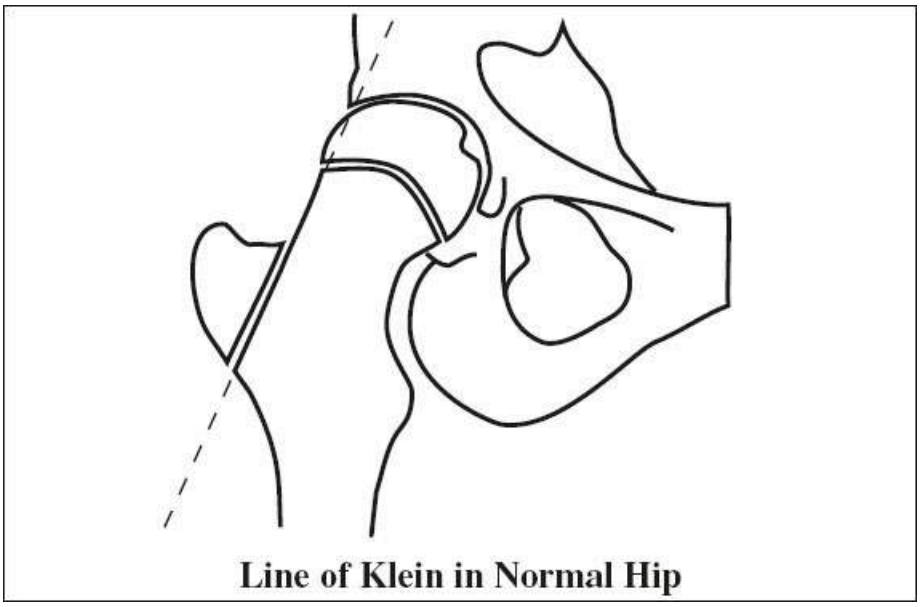
Etiology: growth spurt, renal osteodystrophy, rickets, childhood irradiation, growth hormone therapy, trauma (Salter-Harris type I epiphyseal injury)

Pathogenesis: widening of physeal plate during growth spurt + change in orientation of physis from horizontal to oblique increases shear forces

Mean age: 13 years for often overweight boys (range, 8–17 years), 11 years for girls; M÷F = 3÷1; Black > White

Associated with:
(a) malnutrition, endocrine abnormality, developmental dysplasia of hip (during adolescence)
(b) delayed skeletal maturation (after adolescence)

• hip pain (50%) / knee pain (25%) for 2–3 weeks



Line of Klein in Normal Hip

Location: usually unilateral; bilateral in 20–37% (at initial presentation in 9–18%)

√ widening of epiphyseal growth plate (preslip phase):
- √ irregularity + blurring of physeal physis
- √ demineralization of neck metaphysis

√ posteromedial displacement of head (acute slip):
- √ decrease in neck-shaft angle with alignment change of growth plate to a more vertical orientation
- √ line of Klein (= line drawn along superior edge of femoral neck) fails to intersect the femoral head
- √ epiphysis appears smaller ← posterior slippage: early slips are best seen on cross-table LAT view

CAVE: positioning into a frog leg view may cause further displacement

√ sclerosis + irregularity of widened physis (chronic slip):
- √ metaphyseal "blanch" sign = area of increased opacity in proximal part of metaphysis (healing response)

Grading (based on femoral head position):

mild = displaced by < ⅓ of metaphyseal diameter
moderate = displaced by ⅓–⅔ of diameter
severe = displaced by > ⅔ of metaphyseal diameter

Cx: (1) Chondrolysis = acute cartilage necrosis (7–10%)
= rapid loss of > 50% of thickness of cartilage
√ joint space < 3 mm

(2) Avascular necrosis of femoral head (10–15%): risk increases with advanced degree of slip, delayed surgery for acute slip, anterior pin placement, large number of fixation pins, subcapital osteotomy

(3) Pistol-grip deformity = broadening + shortening of femoral neck in varus deformity

(4) Degenerative osteoarthritis (90%)

(5) Limb-length discrepancy ← premature physeal closure

Rx: (1) limitation of activity
(2) prophylactic pinning
(3) osteotomy
◊ Attempted reductions increase risk of AVN!

EPITHELOID SARCOMA

Frequency: 1–2% of all soft-tissue sarcomas
Age: 10–35 years; M>> F
• firm solid nodule / multiple nodules
Location: forearm, hand, finger
◊ 21–29% of all malignant lesions of hand + wrist
√ soft-tissue mass ± speckled calcifications
√ cortical thinning / osseous erosion

ESSENTIAL OSTEOLYSIS

= progressive slow bone-resorptive disease
Histo: proliferation + hyperplasia of smooth muscle cells of synovial arterioles
√ progressive osteolysis of carpal + tarsal bones
√ thinned pointed proximal ends of metacarpals + metatarsals
√ elbows show same type of destruction
√ bathyrocephalic depression of base of skull
DDx: (1) Massive osteolysis = Gorham disease (local destruction of contiguous bones, usually not affecting hands / feet)
(2) Mutilating forms of rheumatoid arthritis
(3) Tabes dorsalis
(4) Leprosy
(5) Syringomyelia
(6) Scleroderma
(7) Raynaud disease
(8) Regional posttraumatic osteolysis
(9) Ulceromutilating acropathy
(10) Mutilating forms of rheumatoid arthritis
(11) Acrodynia mutilante (nonhereditary)

EWING SARCOMA / TUMOR

[James Stephen Ewing (1866–1943), American pathologist, first professor of pathology at Cornell University]
Frequency: 3% of all pediatric cancers; 2nd most common primary malignant bone tumor in children and adolescents after osteosarcoma; 4th most common bone tumor after multiple myeloma, osteosarcoma, chondrosarcoma
Incidence: 200 cases / year in USA; 1–3÷1,000,000 children

Histo: crowded sheets of small round cells (10–15 μm), uniformly sized + solidly packed invading medullary cavity and entering subperiosteum via Haversian canals producing osteolysis, periostitis, soft-tissue mass; glycogen granules present (DDx to reticulum cell sarcoma); absence of alkaline phosphatase (DDx to osteosarcoma)

DDx small round cells:

Ewing sarcoma, lymphoma, osteosarcoma, myeloma, neuroblastoma, embryonal rhabdomyosarcoma, eosinophilic granuloma

Immunohisto: positive for CD99 (MIC2, in 90%), vimentin, neuronspecific enolase, Leu7 (CD57), FL-1 protein

Peak age: 10–15 years (range, 5 months – 54 years); in 95% 4–25 years; in 30% < 10 years; in 39% 11–15 years; in 31% > 15 years; in 50% < 20 years; M÷F = 1.5÷1; Caucasians in 96%, Blacks in 0.5–2%

- severe localized pain (82–88%); soft-tissue mass / swelling (60%)
- fever (20–49%), leukocytosis; anemia (in early metastases)
- ↑ erythrocyte sedimentation rate (43%) simulating infection

Location:

femur (21%), ilium (13%), tibia (11%), humerus (10%), fibula (8%), hand or foot (5%), radius or ulna (4%), clavicle (2%)

(a) long bones in 60%: metadiaphysis (44–59%), middiaphysis (33%), metaphysis (15%), metaepiphyseal (6%), epiphysis (2%); extension into epiphysis (in up to 10%)

(b) flat bones in 40%:, ribs (in 7% > age 10; in 30% < age 10), vertebrae (in 3–10%, lumbar > thoracic > cervical spine), pelvis, sacrum (6%), scapula (5%), calvaria (1%), mandible or maxilla (1%), facial bones (0.5%), sternum (0.2%)

◊ > 20 years of age predominantly in flat bones

◊ < 20 years of age predominantly in cylindrical bones (tumor derived from red marrow)

√ 8–10 cm long aggressive lesion in shaft of long bone (62% lytic, 23% mixed density, 15% dense):

√ mottled "moth-eaten" to permeative destructive lesion (76–82%) with wide zone of transition in 96%

√ geographic bone destruction with wide zone of transition (= poor margination) in 15%

√ penetration into soft tissue (56–80%) with preservation of tissue planes (DDx: osteomyelitis with diffuse soft-tissue swelling)

√ early fusiform lamellated "onionskin" periosteal reaction (53–84%) / spiculated "sunburst" / "hair-on-end" (23%), Codman triangle

√ cortical thickening (21%) + saucerization (6%)

√ cortical destruction (19–42%) ± cortical sequestration

√ reactive sclerotic new bone (32–40%) of dense cloudlike osteoid appearance

√ pathologic fracture (15%)

√ expansile bone remodeling (13%)

CT:

√ density of soft-tissue component similar to muscle (98%):

√ commonly homogeneous

√ frequently asymmetrically circumferential

√ linear channels of low attenuation extending through dense cortex ← tumor extension along neurovascular + haversian channels (66%)

√ diffuse / peripheral nodular enhancement

MR (best modality):

√ homogeneous (73%) intermediate SI (95%) on T1WI

√ homogeneous (86%) low to intermediate (68%) SI on T2WI

√ heterogeneously high signal commonly in larger lesions ← hemorrhage + necrosis

√ marrow replacement (100%)

√ cortical destruction (92%)

√ associated asymmetrically circumferential soft-tissue mass (96%)

√ visible connection between medullary canal + soft-tissue component (74%)

√ diffuse / peripheral nodular enhancement

NUC:

√ ↑ uptake on bone scintigraphy (blood flow, blood pool, delayed imaging)

√ ↑ uptake on gallium scintigraphy

PET:

√ ↑ uptake of primary on PET with mean SUV of (a) 5.3 without metastases, (b) 11.3 with metastases

√ depiction of osseous metastasis (37–88% sensitive)

@ Ewing sarcoma of vertebra:

Prevalence: 3.5–15%

Mean age: 19 years; M÷F = 3÷2

Location: sacrum (55%), lumbar (25%), thoracic > cervical; > 1 segment involved (8%)

Site: (a) posterior elements (70%) with extension into vertebral body (86%)
(b) vertebral body (30%) with extension into posterior elements (83%)

√ large soft-tissue mass with invasion of spinal canal (91%)

√ disk spaces usually preserved

@ Ewing sarcoma of rib:

√ primarily lytic / sclerotic / mixture of lysis + sclerosis

√ disproportionately large inhomogeneous soft-tissue mass

√ large intrathoracic + minimal extrathoracic component

√ may spread into spinal canal via intervertebral foramen

Metastases to: lung, bones, regional lymph nodes in 11–30% at time of diagnosis, in 40–45% within 2 years of diagnosis

Cx: pathologic fracture (5–14%)

Prognosis: 60–75% 5-year survival

DDx: (1) Multiple myeloma (older age group)
(2) Osteomyelitis (duration of pain < 2 weeks)
(3) Eosinophilic granuloma (solid periosteal reaction)
(4) Osteosarcoma (ossification in soft tissue, near age 20, no lamellar periosteal reaction)
(5) Reticulum cell sarcoma (clinically healthy, between 30 and 50 years, no glycogen)
(6) Neuroblastoma (< age 5)
(7) Anaplastic metastatic carcinoma (> 30 years of age)
(8) Osteosarcoma

(9) Hodgkin disease

Extraskeletal Ewing Sarcoma

= aggressive tumor with high rate of recurrence
Origin: likely neuroectodermal
Prevalence: 15–20% of Ewing sarcoma of bone
Median age: 20 (range, 20 months–30 years)
• pain and tenderness (49%)
Location: paravertebral (32%), lower extremity (26%), chest wall (18%), retroperitoneum (11%), pelvis and hip (11%), upper extremity (3%), head & neck (nose, nasopharynx, parotid gland, cervical soft tissues)
Site: deep (92%), subcutaneous (8%)
Metastatic to: lung
√ 5–10 cm rapidly growing solitary soft-tissue tumor
√ well-defined pseudocapsule (35%), infiltrative growth (45%), neurovascular involvement (73%)
√ lesion calcification (25–30%)
√ extension to bone (25–42%): erosion of adjacent bone, cortical thickening, osseous invasion, aggressive periosteal reaction
√ no replacement of fatty bone marrow by tumor
√ hypervascular lesion by angiography, CT, MR
US:
√ hypoechoic lesion
CT:
√ mass of muscle density (87%)
√ hypoattenuating areas ← hemorrhage + cellular necrosis
MR:
√ heterogeneous mass of low to intermediate SI relative to muscle on T1WI
√ intermediate to high SI relative to muscle on T2WI
√ heterogeneous enhancement
√ serpentine hypointense high-flow vascular channels
PET:
√ ↑ uptake after injection with FDG

Ewing Sarcoma Family of Tumors

◊ Clinically, radiologically, and histologically very similar to PNET and Askin tumor!
Common karyotype abnormality = translocation between long arms of chromosomes 11 and 22 (t[11:22][q24;q12]) in 90%

EXTRAMEDULLARY HEMATOPOIESIS

= abnormal deposits of hematopoietic tissue outside bone marrow ← deficient bone marrow blood cell production
Etiology: prolonged erythrocyte deficiency due to
(1) destruction of RBCs:
congenital hemolytic anemia (sickle cell anemia, thalassemia, hereditary spherocytosis),

acquired hemolytic anemia, idiopathic severe anemia, erythroblastosis fetalis

(2) inability of normal blood-forming organs to produce RBCs: iron deficiency anemia, pernicious anemia, myelofibrosis, myelosclerosis, polycythemia vera, carcinomatous / leukemic / lymphomatous replacement depletion of bone marrow (chronic myelogenous leukemia, Hodgkin disease)

◊ NO hematologic disease in 25%

Histo: erythroid precursors in extramedullary sites

• absence of pain, bone erosion, calcification; chronic anemia

Sites: in areas of fetal erythropoiesis

@ Spleen

√ splenomegaly

√ focal isodense masses on enhanced CT

@ Liver, lymph nodes

@ Thorax: mediastinum, heart, thymus, pleura, lung

√ uni- / bilateral smooth lobulated paraspinal masses between T8 and T12

√ anterior rib ends expanded by masses

@ Spine

◊ Most commonly afflicted in thalassemia

• back pain, symptoms of spinal cord compression

√ coarsened trabeculation

√ extramedullary hematopoiesis in epidural space

@ Adrenal glands

@ Renal pelvis

@ Retroperitoneum (uncommon)

Site: perirenal (uncommon)

√ hyper- / isoattenuating masses in paravertebral region ± macroscopic fat on CT

√ hypointense mass on T1WI + T2WI ← red marrow / hemosiderin content

√ hyperintense on T1WI + T2WI ← fat tissue

√ variable mild enhancement

@ Gastrointestinal lymphatics

@ Dura mater (falx cerebri and over brain convexity)

√ expanded diploic space

@ Cartilage, broad ligaments

@ Thrombi, adipose tissue

@ Bone marrow reconversion = conversion of fatty to hematopoietic marrow

Sequence: vertebrae > flat bones of pelvis > long bones of extremities (proximal metaphysis > distal metaphysis > diaphysis)

√ lack of calcification / bone erosion

√ signs of hemochromatosis

FAMILIAL IDIOPATHIC ACROOSTEOLYSIS

= HAJDU-CHENEY SYNDROME

= rare bizarre entity of unknown etiology

Location: may be unilateral

• fingernails remain intact; sensory changes + plantar ulcers rare
√ pseudoclubbing of fingers + toes with osteolysis of terminal + more proximal phalanges
√ genu varum / valgum
√ hypoplasia of proximal end of radius
√ subluxation of radial head
√ scaphocephaly, basilar impression
√ wide sutures, persistent metopic suture, wormian bones, poorly developed sinuses
√ kyphoscoliosis
√ severe osteoporosis + fractures at multiple sites (esp. of spine)
√ protrusio acetabuli

FANCONI ANEMIA

= autosomal recessive disease with severe hypoplastic anemia + skin pigmentation + skeletal and urogenital anomalies
• skin pigmentation (melanin deposits) in 74% (trunk, axilla, groin, neck); microphthalmia (20%)
• anemia onset between 17 months and 22 years of age
• bleeding tendency (pancytopenia); hypogonadism (40%)
√ anomalies of radial component of upper extremity (strongly suggestive):
  √ absent / hypoplastic / supernumerary thumb
  √ hypoplastic / absent radius
  √ absent / hypoplastic navicular / greater multangular bone
√ slight / moderate dwarfism
√ minimal microcephaly
√ renal anomalies (30%): renal aplasia, ectopia, horseshoe kidney
Prognosis: fatal within 5 years after onset of anemia; patient's family shows high incidence of leukemia

FARBER DISEASE

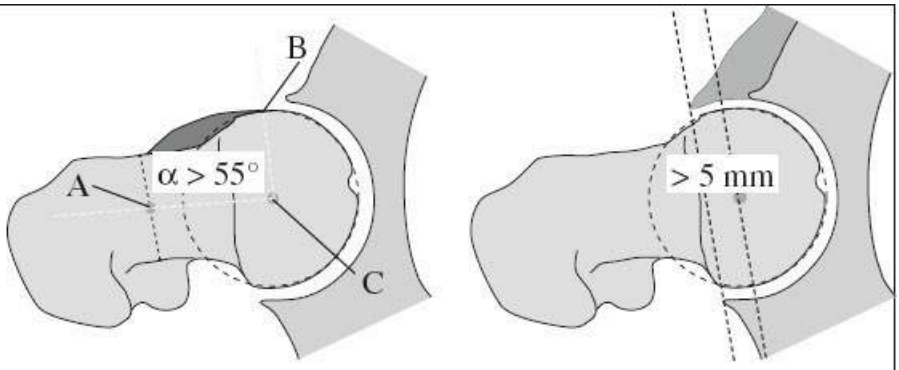
= DISSEMINATED LIPOGRANULOMATOSIS
Histo: foam cell granulomas; lipid storage of neuronal tissue (accumulation of ceramide + gangliosides)
• hoarse weak cry; subcutaneous + periarticular granulomas
• swelling of extremities; generalized joint swelling
• intermittent fever, dyspnea; lymphadenopathy
√ capsular distension of multiple joints (hand, elbow, knee)
√ juxtaarticular bone erosions from soft-tissue granulomas
√ subluxation / dislocation
√ disuse / steroid deossification
Prognosis: death from respiratory failure within 2 years

FEMOROACETABULAR IMPINGEMENT

= repetitive microtrauma due to an anatomic conflict between proximal femur + acetabular rim at extreme range of motion, especially hip flexion and internal rotation

Mean age: 20–45 yrs; in patients with increased physical activity; M÷F = 3÷2 to 9÷1
Prevalence: 10–15%
Cause: anatomic variations; developmental dysplasia of the hip; slipped capital femoral epiphysis; Legg-Calvé-Perthes; posttraumatic deformity
Pathophysiology:

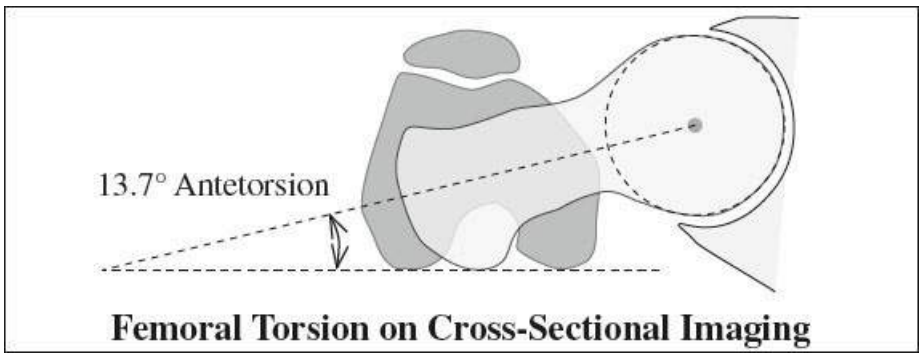
labrum caught between femoral head and acetabulum (impingement) → labral tear typically anterosuperiorly → chondral damage → secondary osteoarthritis (other causes of labral tears: trauma; capsular laxity; dysplasia; degeneration)



Femoroacetabular Impingement

A = center of the femoral neck at its narrowest point
B = point where the distance from the center of the femoral head to the peripheral contour of the femoral head exceeded the radius of the femoral head
C = center of femoral head
α = angle between line A–C and line B–C

Radial Sections perpendicular to Hip Joint Surface
for Imaging of Femoroacetabular Impingement



Femoral Torsion on Cross-Sectional Imaging

Types:

(1) Cam FAI (56% of all labral tears from sports injury)
= nonspherical shape of femoral head with reduced depth of femoral waist (= femoral waist deficiency) leads to abutment of femoral head-neck junction against acetabular rim

Age: athletic male 20–30 years

√ aspheric (= osseous bump) femoral head / head-neck junction (50%)
√ large areas of labral avulsion
√ broad areas of cartilage lesions often > 1 cm in width
√ carpet phenomenon = focal cartilage delamination
√ α-angle of > 55° (measured at the anterosuperior position on radial images rotated around center line of femoral neck)

N.B.: substantial overlap in α-angle measurements between volunteers and patients

(2) Pincer FAI (12% of all labral tears from sports injury)
= acetabular overcoverage limits range of motion

Cause: protrusio acetabuli, acetabular retroversion

Age: athletic woman 30–40 years

Associated with: increased femoral antetorsion

√ deep acetabulum (head center > 5 mm below rim)
√ acetabular retroversion = anterior acetabular rim overlaps posterior rim on AP
√ osseous bump deforming femoral head-neck junction (33%)
√ anterosuperior labral avulsion (pincer FAI)
√ thin rim of adjacent cartilage lesion often < 5 mm in width

(3) Mixed pattern (frequent)

- groin pain (83%) owing to initially activity overparticipation + later osteoarthritis; impaired ability to squat
- decreased range of motion (ROM)
- positive impingement test in supine position:

(a) anterior impingement (= groin pain during passive hip flexion + adduction + internal rotation)
(b) posterior impingement (= groin pain during hip extension + external rotation)

√ cystic / bony proliferative changes at femoral head-neck junction
√ ossicle along acetabular rim / os acetabuli

MR:
requires use of multiplanar capability to obtain radial sections perpendicular to surfaces of

hip joint → true cross section of cartilage + labrum without partial-volume effects

Cx: premature osteoarthritis initially with cartilage damage + labral tears

DDx: healthy young adult (common!), adult hip dysplasia, pseudoacetabular overcoverage in diffuse idiopathic skeletal hyperostosis (abnormal thoracolumbar spine) / ankylosing spondylitis (abnormal sacroiliac joints)

Rx: surgery in patients without osteoarthritis consisting of reshaping of femoral waist / trimming of acetabular rim / periacetabular osteotomy

FIBROCHONDROGENESIS

= autosomal recessive lethal short-limb skeletal dysplasia

Prevalence: 5 cases

√ severe micromelia + broad dumbbell-shaped metaphyses

√ flat + clefted pear-shaped vertebral bodies

√ short + cupped ribs

√ frontal bossing

√ low-set abnormally formed ears

Prognosis: stillbirth / death shortly after birth

DDx: (1) Thanatophoric dysplasia

(2) Metatropic dysplasia

(3) Spondyloepiphyseal dysplasia

FIBRODYSPLASIA OSSIFICANS PROGRESSIVA

= MYOSITIS OSSIFICANS PROGRESSIVA (misnomer since primarily connective tissues are affected)

= rare slowly progressive sporadic / autosomal dominant disease with variable penetrance characterized by remissions + exacerbations of fibroblastic proliferation, subsequent calcification + ossification of subcutaneous fat, skeletal muscle, tendons, aponeuroses, ligaments

Histo: edema with proliferating fibroblasts in a loose myxoid matrix; subsequent collagen deposition plus calcification + ossification of collagenized fibrous tissue in the center of nodules

Age: presenting by age 2 years (50%)

- initially subcutaneous painful masses on neck, shoulders, upper extremities
- progressive involvement of remaining musculature of back, chest, abdomen, lower extremities
- lesions may ulcerate and bleed
- muscles of back + proximal extremity become rigid followed by thoracic kyphosis
- inanition ← jaw trismus (masseter, temporal muscle)
- "wry neck" = torticollis ← restriction of sternocleidomastoid m.
- respiratory failure ← thoracic muscles affected
- conductive hearing loss ← fusion of middle ear ossicles

A. ECTOPIC OSSIFICATION

√ rounded / linear calcification in neck / shoulders, para-vertebral region, hips, proximal extremity, trunk, palmar and plantar fascia forming ossified bars + bony bridges

√ ossification of voluntary muscles, complete by 20–25 years (sparing of sphincters + head)

B. SKELETAL ANOMALIES
may appear before ectopic ossification
• clinodactyly
√ microdactyly of big toes (90%) and thumbs (50%)
= usually only one large phalanx present / synostosis of metacarpal + proximal phalanx (first sign)
√ phalangeal shortening of hand + foot (middle phalanx of 5th digit)
√ shortened 1st metatarsal + hallux valgus (75%)
√ shortened metacarpals + metatarsals
√ shallow acetabulum
√ short widened femoral neck
√ thickening of medial cortex of tibia
√ progressive fusion of posterior arches of cervical spine
√ narrowed AP diameter of cervical + lumbar vertebral bodies
√ ± bony ankylosis

CAVE: surgery is hazardous causing accelerated ossification at the surgical site

FIBROMA OF TENDON SHEATH

Histo: paucicellular tumor with scattered spindle-shaped myofibroblasts embedded in dense collagenous stroma + slitlike vascular channels and cleftlike spaces = crossover to giant cell tumor of tendon sheath

Mean age: 31 (range, 20–50) years; M÷F = 2÷1

Location: tendon sheath of upper extremity (fingers, hands, wrists) in 82%

Size: usually < 3 (range, 1–5) cm

• mostly painless soft-tissue mass

MR:
√ small hypointense nodule on all pulse sequences compared to muscle
√ areas of high signal intensity ← myxoid change
√ no / moderate / marked enhancement
√ attachment to tendon sheath

Rx: local excision (24% recurrence rate)

DDx: giant cell tumor of tendon sheath (blooming artifact ← hemosiderin deposition)

FIBROSARCOMA

Frequency: 4% of all primary bone neoplasm

Etiology:

A. PRIMARY FIBROSARCOMA (70%)
B. SECONDARY FIBROSARCOMA (30%)
1. following radiotherapy of giant cell tumor / lymphoma / breast cancer
2. underlying benign lesion: Paget disease (common); giant cell tumor, bone infarct, osteomyelitis, desmoplastic fibroma, enchondroma, fibrous dysplasia (rare)
3. dedifferentiation of low-grade chondrosarcoma

Histo: spectrum of well to poorly differentiated fibrous tissue proliferation; will not produce osteoid / chondroid / osseous matrix

Age: predominantly in 3rd–5th decade (range, 8–88 years); M÷F = 1÷1
Metastases to: lung, lymph nodes
• localized painful mass
Location: tubular bones in young, flat bones in older patients; femur (40%), tibia (16%) (about knee in 30–50%), jaw, pelvis (9%); rare in small bones of hand + feet or spinal column
Site: eccentric at diaphyseal-metaphyseal junction into metaphysis; intramedullary / periosteal

A. CENTRAL FIBROSARCOMA
= intramedullary
√ well-defined lucent bone lesion
√ thin expanded cortex
√ aggressive osteolysis with geographic / ragged / permeative bone destruction + wide zone of transition
√ occasionally large osteolytic lesion with cortical destruction, periosteal reaction + soft-tissue invasion
√ sequestration of bone may be present (DDx: eosinophilic granuloma, bacterial granuloma)
√ sparse periosteal proliferation (uncommon)
√ intramedullary discontinuous spread
√ no calcification
DDx: malignant fibrous histiocytoma, myeloma, telangiectatic osteosarcoma, lymphoma, desmoplastic fibroma, osteolytic metastasis

B. PERIOSTEAL FIBROSARCOMA
= rare tumor arising from periosteal connective tissue
Location: long bones of lower extremity, jaw
√ contour irregularity of cortical border
√ periosteal reaction with perpendicular bone formation may be present
√ rarely extension into medullary cavity

Cx: pathologic fracture (uncommon)
Prognosis: 20% 10-year survival
DDx: (1) Osteolytic osteosarcoma (2nd–3rd decade)
(2) Chondrosarcoma (usually contains characteristic calcifications)
(3) Aneurysmal bone cyst (eccentric blown-out appearance with rapid progression)
(4) Malignant giant cell tumor (begins in metaphysis extending toward joint)

FIBROUS CORTICAL DEFECT

= developmental abnormality classified as benign bone tumor
Prevalence: 30–35% of children; M÷F = 2÷1
Peak age: 7–8 (range, 2–20) years; mostly before epiphyseal closure
Histo: fibrous tissue from periosteum invading underlying cortex
• asymptomatic, usually incidental finding
In 5% associated with: neurofibromatosis
Location: metaphyseal cortex of long bone (near physis); multiple locations bilateral + symmetric in 50%

(a) femur (40%): posterior medial aspect of distal femur, proximal femur
(b) tibia (40%): proximal tibia
(c) fibula (10%)
(d) others: proximal humerus, ribs, ilium

Size: < 2 cm in largest diameter

Early stage:

√ circular / oval eccentrically located radiolucent area extending parallel to long axis of host bone
√ smooth lobulated / scalloped margins with well-defined thin rim of sclerosis
√ no periosteal reaction
√ high SI on T2WI (cystic component early stage) + low SI on T1WI
√ little / no uptake on bone scintigraphy

Late stage:

√ low SI on T2WI (progressive sclerosis + ossification) and on T1WI
√ sclerotic bone island (may be residue of incompletely involuted cortical defect in the adult)

Prognosis:

(a) involution over 2–4 years
(b) potential to grow and encroach on the medullary cavity leading to nonossifying fibroma (defined as > 2 cm in size)

DDx: Nonossifying fibroma

FIBROUS DYSPLASIA

= FIBROUS OSTEODYSTROPHY = OSTEODYSTROPHIA FIBROSA = OSTEITIS FIBROSA DISSEMINATA

= benign developmental anomaly of mesenchymal precursor of bone → slowly progressive replacement of normal bone marrow by immature fibroosseous tissue centered in medullary canal

Prevalence: 7% of benign bone tumors; 2.5% of all bone tumors; 1% of primary bone tumors at biopsy

Cause: probable gene mutation during embryogenesis manifested as defect in osteoblastic differentiation and maturation

Age: 1st–2nd decade (highest incidence between 3 and 15 years), 75% before age 30; progresses until growth ceases; M÷F = 1÷1 (range, 1÷1.2 to 2÷1)

Histo: spongiosa of medullary cavity replaced by

(a) abnormal fibrous tissue = variable degree of immature collagen and myxoid component, and
(b) osseous tissue containing poorly calcified + dysplastic + non–stress oriented + disorganized trabeculae of woven bone varying from solid round areas to curved / serpentine / curlicue shapes (= "Chinese characters" / alphabet soup); NO osteoblastic rimming of trabeculae (DDx from ossifying fibroma); cartilaginous islands present in 10% (DDx to chondrosarcoma)

Clinical Types:

1. Monostotic fibrous dysplasia (70–80%)
2. Polyostotic fibrous dysplasia (20–30%)

3. Craniofacial fibrous dysplasia = leontiasis ossea
   Variants: McCune-Albright syndrome (10%), Jaffé-Lichtenstein Disease (10%)
4. Cherubism (special variant)*1*

May be associated with:

(a) endocrine disorders:
- › precocious puberty in girls
- › hyperthyroidism
- › hyperparathyroidism: renal stones, calcinosis
- › acromegaly
- › diabetes mellitus
- › Cushing syndrome: osteoporosis, acne
- › growth retardation

(b) intramuscular soft-tissue myxoma (rare)
= **Mazabraud syndrome**:
[André Mazabraud (1921–2006), French rheumatologist and pathologist at Curie Institute, Paris]
- √ typically <u>multiple</u> intramuscular myxomas in vicinity of most severely affected bone
- √ polyostotic fibrous dysplasia (in 81%); M÷F = 1÷2
- • renal phosphate wasting

(c) aneurysmal bone cyst
- • swelling + tenderness; limp, pain (± pathologic fracture)
- • increased alkaline phosphatase
- • advanced skeletal + somatic maturation (early)

Common location: rib cage (30%), craniofacial bones [calvarium, mandible] (25%), femoral neck + tibia (25%), pelvis

Site: metaphysis is primary site with extension into diaphysis
= expands along longitudinal axis of bone (rarely over entire length)

Radiography:
- √ lesions in medullary cavity: characteristic "ground-glass" / radiolucent appearance / increased density:
  - √ expansile remodeling:
    - √ HALLMARK endosteal scalloping with thinned / lost cortex (rib, long bone) and intervening normal cortex
    - √ expansion of cortices (rib, skull, long bone) with "blown-out" appearance (DDx from ossifying fibroma which is focally more altered)
  - √ trabeculated appearance ← reinforced subperiosteal bone ridges in wall of lesion
  - √ ill-defined wide zone of transition (DDx to ossifying fibroma)
- √ well-defined thick sclerotic margin of reactive bone = rind
- √ lesion may undergo calcification + enchondral bone formation = fibrocartilaginous dysplasia
- √ no periosteal reaction unless fractured

CT (best technique for characterization):
- ◊ Most cases of monostotic fibrous dysplasia are incidental findings on (a cranial / other) CT examination!
- √ attenuation of typically 70–130 HU + intermixed areas of sclerosis with higher values:

√ **pagetoid** / ground glass appearance (53%) ← equal mixture of dense woven trabecular bone + radiolucent areas of fibrous tissue
√ homogeneously dense opaque **sclerotic** bone (23%) ← predominance of osseous elements
√ radiolucent **cystic** bone (21%) = spherical / ovoid density surrounded by dense bony shell ← abundance of fibrous elements
DDx: central ossifying fibroma, central giant cell granuloma, aneurysmal bone cyst, osteomyelitis, early fibro-osseous lesion
√ expansion of bone
√ fibrous dysplasia enhances ← inherent vascularity

MR:
◊ MRI should not be used to differentiate fibrous dysplasia from other entities due to extreme variability in appearance of bone lesions (depending on ratio of fibrous tissue to mineralized matrix)!
√ homogeneous / mildly heterogeneous marrow lesions:
√ low to intermediate SI on T1WI, typically hypointense to muscle
√ hyperintense to fat (63%) / low SI (18–38%) / intermediate SI (18%) on T2WI
√ intense heterogeneous enhancement:
(a) centrally (73%) ← numerous small vessels
(b) peripherally (27%) ← large sinusoids

NUC:
√ uptake on bone scan (lesions remain metabolically active into adulthood):
(a) intense activity on blood flow + blood pool images
(b) most intense activity on static delayed images

PET:
√ marked radiotracer avidity (SUV of 3–19)

@ Skull & facial bones
√ "blistering / bubbling" cystic calvarial lesions (CHARACTERISTIC), commonly crossing sutures:
√ widened diploic space displacing outer table + sparing inner table (DDx: Paget disease, inner table involved)
√ diffuse sclerosis of skull base obscuring ground-glass appearance:
√ sclerosis of orbital plate (DDx: Paget disease, meningioma en plaque)
√ occipital thickening
√ hypoplasia / obliteration of sphenoid + frontal sinuses ← encroachment by fibrous dysplastic bone
√ narrow neural foramina → visual + hearing loss
√ inferolateral displacement of small orbit
√ mandibular cystic lesion (very common) = osteocementoma, ossifying fibroma

@ Ribs
√ bubbly cystic multiseptated lesion (extremely common)
√ fusiform enlargement of rib + loss of normal trabecular pattern + thin preserved cortex (in up to 30%)

◊ Fibrous dysplasia is the most common cause of a benign expansile lesion of a rib!

◊ A rib is the most common site of monostotic (6–20%) + polyostotic (55%) fibrous dysplasia!

@ Pelvis

√ protrusio acetabuli

@ Extremities

• short stature as adult / dwarfism

√ premature fusion of ossification centers

√ epiphysis rarely affected before closure of growth plate

√ bowing deformities + discrepant limb length (tibia, femur) ← stress of normal weight bearing

√ "shepherd's crook" deformity of femoral neck = coxa vara

√ pseudarthrosis in infancy = osteofibrous dysplasia (DDx: neurofibromatosis)

√ premature onset of arthritis

@ Spine

• frequently asymptomatic / pain / fracture

√ mildly expansile lesion with "blown-out" cortical shell

√ lytic lesion with a sclerotic rim

√ common "ground-glass" matrix (characteristic)

Cx: (1) Dedifferentiation into osteo- / fibro- / (rarely) chondrosarcoma or malignant fibrous histiocytoma (0.4–1%; more often in polyostotic form)

• increasing pain

√ enlarging soft-tissue mass

√ previously mineralized lesion turns lytic

(2) Pathologic fractures: transformation of woven into lamellar bone may be seen, subperiosteal healing without endosteal healing

DDx: (1) Paget disease (older age group, mosaic pattern histologically, radiographically similar to monostotic cranial lesion, outer table involved, usually sparing of facial bones)

(2) Ossifying fibroma (narrow zone of transition, displacement of teeth)

(3) HPT (polyostotic, no bone expansion, chemical changes, generalized deossification, subperiosteal resorption)

(4) Osteofibrous dysplasia (almost exclusively in tibia of children < 10 years + anterior bowing, monostotic, lesion begins in cortex, spontaneous regression)

(5) Neurofibromatosis (rarely osseous lesions, vertebral column is primary target, ribbon ribs, cystic intraosseous neurofibroma rare, café-au-lait spots smooth, familial disease)

(6) Nonossifying fibroma = fibroxanthoma

(7) Simple bone cyst (more lucent than fibrous dysplasia, not affecting growth plate, straw-colored fluid on aspiration)

(8) Giant cell tumor (no well-defined sclerotic margin)

(9) Enchondroma (often calcified chondroid matrix)

(10) Eosinophilic granuloma = LCH

(11) Osteoblastoma

(12) Hemangioma

(13) Meningioma

(14) Low-grade osteosarcoma (invasion of surrounding soft tissues, osteolysis, cortical destruction)

Prognosis: bone lesions usually do not progress beyond puberty

Craniofacial Fibrous Dysplasia

= Leontiasis ossea [*leon*, Greek = lion]

Frequency: monostotic in 10–27%; polyostotic form in 50%

◊ Most common site of malignant degeneration!

• cranial asymmetry, facial deformity; nasal stuffiness

• hypertelorism, proptosis, exophthalmos, diplopia

• visual impairment, extraocular muscle palsy

Location: frontal > sphenoid > ethmoid maxilla > zygoma > parietal > occipital > temporal area; orbit (20–39%); hemicranial involvement (DDx: Paget disease is bilateral)

√ unilateral overgrowth of facial bones + calvarium:

√ NO extracranial lesions

√ outward expansion of outer table maintaining convexity

√ expanded diploic space + thin rim of cortical bone

DDx: Paget disease with destruction of inner + outer table

√ encroachment on orbits, sinuses, vascular + neural channels

√ prominence of external occipital protuberance

√ teeth nondisplaced (DDx from ossifying fibroma)

√ feline facial appearance ("leontiasis ossea"):

√ slowly progressive protrusion of malar surface

√ loss of the nasomaxillary angle

Cx: neurologic deficit of cranial nerves (eg, blindness) ← narrowed cranial foramina

DDx: juvenile ossifying fibroma, cherubism (limited to jaw), renal osteodystrophy

Familial / Hereditary Fibrous Dysplasia

= CHERUBISM [*kerubh*, Hebrew = winged angel]

= autosomal dominant disorder of variable penetrance; probably form of giant cell reparative granuloma rather than fibrous dysplasia

Age: childhood; more severe in males

• bilateral jaw fullness

• slight upward turning of eyes directed heavenward

Location: bilateral symmetric involvement of mandible + maxilla

√ bilateral mandibular swelling ← expansile multiloculated cystic masses

√ upward bulging of orbital floor ← maxillary expansion

Cx: problems with dentition after perforation of cortex

Prognosis: rapid progression until age of 7 years followed by regression after adolescence

McCune-Albright Syndrome (10%)

[Donovan James McCune (1902–1976), American pediatrician at Columbia University,

New York]
[Fuller Albright (1900–1969), American endocrinologist at Massachusetts General Hospital in Boston]
= nonhereditary phakomatosis
Genetics: gain-of-function mutation in GNAS1 gene → constitutive stimulation of cyclic AMP protein signaling pathway
Age: childhood
Sex: almost exclusively in girls
(1) Polyostotic fibrous dysplasia (mostly unilateral)
Location: skull + face (50%), pelvis, femur, tibia
√ medullary ground-glass lytic areas + thin cortices + endosteal scalloping
√ areas of sclerotic / cystic change
√ "shepherd's crook" deformity of femur ← multiple cortical microfractures
Cx: osteosarcoma (in 4%)
(2) Café-au-lait macules (35%)
= few large segmental yellowish to brownish dark tan patches of cutaneous pigmentation with jagged irregular / serrated border = **coast of Maine** patches (DDx: more numerous and lighter "coast of California" spots in neurofibromatosis)
Site: lumbosacral area (30–50%), buttocks, neck, shoulders without crossing the midline; often ipsilateral to bone lesions
(3) Endocrinopathy = increased endocrine function:
(a) peripheral sexual precocity (in females in 65–79%, in males in 15%)
• menarche in infancy (in 20%)
√ bilateral >> unilateral testicular enlargement
√ testicular microlithiasis
(b) hyperthyroidism ← hypothalamic dysfunction
• pituitary gigantism
• Cushing syndrome, galactorrhea
• hepatobiliary dysfunction
• renal phosphate wasting
√ adrenal + thyroid nodules

Jaffé-Lichtenstein Disease *(10%)*
[Henry Lewis Jaffe (1896–1979), American pathologist and director of laboratories at the Hospital for Joint Diseases, Langone Medical Center in New York]
[Louis Lichtenstein (1906–1977), American pathologist in New York, Los Angeles and San Francisco]
Location: craniofacial + noncraniofacial bones
• cutaneous café-au-lait spots
• rare endocrinopathies

Monostotic Fibrous Dysplasia (70–80%)
Age: 10–70 years
• usually asymptomatic until 2nd–3rd decade
• incidental discovery: obvious deformity / dull aching pain

• pain ← pathologic fracture

Location: ribs (6–28%), proximal femur (23%), tibia, craniofacial bones (10–25%)[frontal, sphenoid, maxillary, ethmoid], humerus

Rules: (1) No conversion to polyostotic form
(2) No increase in size over time
(3) Disease becomes inactive at puberty

Polyostotic Fibrous Dysplasia (20–30%)

Mean age: 8 years

• ⅔ symptomatic by age 10; coast of Maine café-au-lait spots
• leg pain, limp, pathologic fracture (75%)
• abnormal vaginal bleeding (25%)
• short stature ← bowing of extremities + premature fusion of growth plates + scoliosis

Associated with: endocrinopathy (in 2–3%)
◊ 2–3% of patients with polyostotic fibrous dysplasia have McCune-Albright syndrome

Location: usually unilateral + asymmetric; femur (91%), tibia (81%), pelvis (78%), foot (73%), ribs (55%), skull + facial bones (50%), upper extremities, lumbar spine (14%), clavicle (10%), cervical spine (7%)

Site: metadiaphysis

Rules: (1) Often unilateral + sometimes monomelic
(2) Tendency to involve larger segments of bone
(3) Frequently associated with severe deformities and fractures
(4) No spread / proliferation over time
(5) Disease becomes quiescent at puberty

√ leg length discrepancy (70%)
√ "shepherd's crook" deformity (35%) = coxa vara angulation of proximal femur
√ "saber shin" deformity = anterior bowing of tibia
√ facial asymmetry
√ tibial bowing
√ rib deformity
√ monomelic "ray" pattern = involvement of all phalanges and metacarpal bone in a single digit

FIBROUS HISTIOCYTOMA

Benign Fibrous Histiocytoma

Frequency: 0.1% of all bone tumors

Histo: interlacing bundles of fibrous tissue in storiform pattern (whorled / woven) interspersed with mono- / multinucleated cells resembling histiocytes, benign giant cells, and lipid-laden macrophages; resembles nonossifying fibroma / fibroxanthoma

Age: 23–60 years

• localized intermittently painful soft-tissue swelling

Location: long bone, pelvis, vertebra (rare)

Site: typically in epiphysis / epiphyseal equivalent
√ well-defined radiolucent lesion with septa / soap-bubble appearance / no definable matrix
√ may have reactive sclerotic rim
√ narrow transition zone (= nonaggressive lesion)
√ no periosteal reaction
Rx: curettage
DDx: nonossifying fibroma (childhood / adolescence, asymptomatic, eccentric metaphyseal location)

Atypical Benign Fibrous Histiocytoma

Histo: "atypical aggressive" features = mitotic figures present
√ lytic defect with irregular edges
Prognosis: may metastasize

Malignant Fibrous Histiocytoma

= MFH = UNDIFFERENTIATED PLEOMORPHIC SARCOMA
= MALIGNANT FIBROUS XANTHOMA
= XANTHOSARCOMA = MALIGNANT HISTIOCYTOMA
= FIBROSARCOMA VARIANT
Histo: spindle-cell neoplasm of a mixture of fibroblasts + giant cells resembling histiocytes with nuclear atypia and pleomorphism in pinwheel arrangement; closely resembles high-grade fibrosarcoma (= fibroblastic cells arranged in uniform pattern separated by collagen fibers)
(a) pleomorphic-storiform subtype (50–60%)
(b) myxoid subtype (25%)
(c) giant cell subtype (5–10%)
(d) inflammatory subtype (5–10%)
(e) angiomatoid subtype (< 5%)
Mean age: 50 (range, 10–90) years; peak prevalence in 5th decade; more frequent in Caucasians; M÷F = 3÷2
Location: potential to arise in any organ (ubiquitous mesenchymal tissue); soft tissues >> bone

Soft-tissue MFH

Frequency: 20–24–30% of all soft-tissue sarcomas; most common primary malignant soft-tissue tumor of late adult life
◊ Any deep-seated invasive intramuscular mass in a patient > 50 years of age is most likely MFH!
• large painless lobulated soft-tissue mass with progressive enlargement over several months
Location: extremities (75%), [lower extremity (50%), upper extremity (25%)], retroperitoneum (15%), head + neck (5%); subcutis (7–10%)
Site: within large muscle groups
Size: usually 5–10 cm → increasing over months / years
√ poorly defined curvilinear / punctate peripheral calcifications / ossifications (in 5–20%)

√ commonly cortical erosion of adjacent bone (HIGHLY SUGGESTIVE FEATURE)

CT:

√ well-defined large lobulated soft-tissue mass with attenuation similar to that of muscle

√ central hypodense area = myxoid MFH (DDx: hemorrhage, necrosis, leiomyosarcoma with necrosis, myxoid lipo- / chondrosarcoma)

√ enhancement of solid components

√ invasion of adjacent organs

MR:

√ inhomogeneous poorly defined lesion:

√ low to intermediate SI similar to muscle on T1WI

√ heterogeneously intermediate to high SI on T2WI

√ contrast enhancement more pronounced in periphery than at center ← central location of hemorrhage + necrosis + myxoid tumor component:

√ myxoid tumor component similar to fluid

√ nodular + peripheral enhancement of nonmyxomatous cellular region

Prognosis: larger + more deeply located tumors have a worse prognosis; 2-year survival rate of 60%; 5-year survival rate of 50%; local recurrence rate of 19–31%; metastatic rate of 31–35% (lung [90%], bone [8%], liver [1%], lymph nodes [4–17%])

DDx: (1) Liposarcoma (younger patient, presence of fat in > 40%, calcifications rare)

(2) Rhabdomyosarcoma

(3) Synovial sarcoma (cortical erosion)

Osseous MFH

Prevalence: 5% of all primary malignant bone tumors

- painful, tender, rapidly enlarging mass
- pathologic fracture (20%)

Associated with:

prior radiation therapy, bone infarcts, Paget disease, fibrous dysplasia, osteonecrosis, fibroxanthoma (= nonossifying fibroma), enchondroma, chronic osteomyelitis

◊ 20% of osseous MFH arise in areas of abnormal bone!

Location: femur (45%), tibia (20%), 50% about knee; humerus (10%); ilium (10%); spine; sternum; clavicle; rarely small bones of hand + feet

Site: central metaphysis of long bones (90%); eccentric in diaphysis of long bones (10%)

Size: 2.5–10 cm in diameter

√ radiolucent defect with ill-defined margins

√ extensive mineralization / small areas of focal metaplastic calcification

√ permeation + cortical destruction

√ expansion in smaller bones (ribs, sternum, fibula, clavicle)

√ occasionally lamellated periosteal reaction (especially in presence of pathologic fracture)

√ soft-tissue extension

Cx: pathologic fracture (30–50%)

DDx: (1) Metastasis
(2) Fibrosarcoma (often with sequestrum)
(3) Reticulum cell sarcoma
(4) Osteosarcoma
(5) Giant cell tumor
(6) Plasmacytoma

Pulmonary MFH (extremely rare)
√ solitary pulmonary nodule without calcification
√ diffuse infiltrate
NUC:
√ increased uptake of ^{99m}Tc-MDP (mechanism not understood)
√ increased uptake of ^{67}Ga-citrate
US:
√ well-defined mass with hyperechoic + hypoechoic (necrotic) areas
CT:
√ mass of muscle density with hypodense areas (necrosis)
√ invasion of abdominal musculature, but not IVC / renal veins (DDx to renal cell carcinoma)
Angio:
√ hypervascularity + early venous return

FLORID REACTIVE PERIOSTITIS

• progressive painful inflammatory swelling
Age: 20–30 years
Location: small bones of hands + feet with predilection for proximal phalanx
Site: index > middle > little > any other finger
√ calcified paraosseous mass (paraosseous = radiolucent band between mass and cortex of adjacent bone)
√ lamellar / compact periosteal reaction → maturing on follow-up without bone destruction

FOCAL FIBROCARTILAGINOUS DYSPLASIA OF TIBIA

Associated with: tibia vara
Age: 9–28 months
Histo: dense hypocellular fibrous tissue resembling tendon with lacuna formation
• slight shortening of affected leg
Location: insertion of pes anserinus (= tendinous insertion of gracilis, sartorius, semitendinosus muscles) distal to proximal tibial physis; unilateral involvement
√ unilateral tibia vara
√ well-defined elliptic obliquely oriented lucent defect in medial tibial metadiaphyseal cortex
√ sclerosis along lateral border of lesion
√ absence of bone margin superomedially
Prognosis: resolution in 1–4 years
DDx: (1) Unilateral Blount disease (typically bilateral in infants, varus angulation of upper

tibia, decreased height of medial tibial metaphysis, irregular physis)

(2) Chondromyxoid fibroma, eosinophilic granuloma, osteoid osteoma, osteoma, fibroma, chondroma (not associated with tibia vara, soft-tissue mass)

FRACTURE

= soft-tissue injury with break in continuity of bone or cartilage

General description:

(1) OPEN / CLOSED

open Fx = communication between fractured bone + skin

(2) COMPLETE / INCOMPLETE

complete Fx = all cortical surfaces disrupted

incomplete Fx = partial separation of bone

Incomplete pediatric fractures:

(a) longitudinal compressive force:
buckle / torus Fx

bowing Fx = plastic deformity of thin long bone (ulna > clavicle, fibula)

(b) force perpendicular to long axis of bone **greenstick Fx**

(c) combination fracture

lead-pipe Fx = combination of greenstick + torus Fx

(3) SIMPLE / COMMINUTED

simple Fx = noncomminuted

comminuted Fx = > 2 fragments

segmental Fx = isolated segment of shaft

butterfly fragment = V-shaped fragment not completely circumscribed by cortex

(4) DIRECTION OF FRACTURE LINE relative to long axis of bone:
transverse, oblique, oblique-transverse, spiral

Special terminology:

avulsion Fx = fragment pulled off by tendon / joint capsule / ligament from parent bone

transchondral Fx = cartilaginous surface involved

chondral Fx = cartilage alone involved

osteochondral Fx = cartilage + subjacent bone involved

Description of anatomic positional changes:

= change in position of distal fracture fragment in relation to proximal fracture fragment

LENGTH = longitudinal change of fragments

distraction = increase from original anatomic length

shortening = decrease from original anatomic length

› impacted = fragments driven into each other

› overriding = also includes latitudinal changes

› overlapping = bayonet apposition

DISPLACEMENT = latitudinal change of anatomic axis

› undisplaced

› anterior, posterior, medial / ulnar, lateral / radial

ANGULATION / TILT

= long axes of fragments intersect at the fracture apex:

› medial / lateral, ventral / dorsal
› varus = angular deviation of distal fragment toward midline on frontal projection
› valgus = angular deviation of distal fragment away from midline on frontal projection
eg, "ventral angulation of fracture apex"
eg, "in anatomic / near anatomic alignment"

ROTATION
◊ Difficult to detect radiographically!
√ differences in diameters of apposing fragments
√ mismatch of fracture line geometry
› internal / external rotation

NUC:

Typical time course:

1. Acute phase (3–4 weeks) abnormal in 80% < 24 hours, in 95% < 72 hours
   ◊ Elderly patients show delayed appearance of positive scan
   √ broad area of increased tracer uptake (wider than fracture line)
2. Subacute phase (2–3 months) = time of most intense tracer accumulation
   √ more focal increased tracer uptake corresponding to fracture line
3. Chronic phase (1–2 years)
   √ slow decline in tracer accumulation
   √ in 65% normal after 1 year; > 95% normal after 3 years

Return to normal:

◊ Non–weight-bearing bone returns to normal more quickly than weight-bearing bone
→ rib fractures return to normal most rapidly
◊ Complicated fractures with orthopedic fixation devices take longest to return to normal

1. Simple fractures: 90% normal by 2 years
2. Open reduction / fixation: < 50% normal by 3 years
3. Delayed union: slower than normal for type of fracture
4. Nonunion: persistent intense uptake in 80%
5. Complicated union (true pseudarthrosis, soft-tissue interposition, impaired blood supply, presence of infection)
   √ intense uptake at fracture ends
   √ decreased uptake at fracture site
6. Vertebral compression fractures: 60% normal by 1 year; 90% by 2 years; 97% by 3 years

Pathologic Fracture

= fracture at site of preexisting osseous abnormality

Cause: tumor, osteoporosis, infection, metabolic disorder

Stress Injury (Fracture)

= fracture produced as a result of repetitive prolonged muscular action on bone exceeding its capability for self-repair

Insufficiency Fracture

= normal physiologic stress applied to bone with abnormal elastic resistance / deficient

mineralization

Cause:

1. Osteoporosis
2. Renal osteodystrophy

Types of Fractures		
Type	*Bone Quality*	*Load*
Traumatic	normal	single large
Fatigue (stress)	normal	repetitive
Insufficiency (stress)	abnormal (metabolic)	minimal
Pathologic	abnormal (tumor)	minimal

3. Osteomalacia / rickets
4. Hyperparathyroidism
5. Radiation therapy
6. Rheumatoid arthritis
7. Paget disease
8. Fibrous dysplasia
9. Osteogenesis imperfecta
10. Osteopetrosis
11. Prolonged corticosteroid treatment
12. Tumor treatment with ifosfamide, methotrexate

Location: thoracic vertebra, sacrum, pubic bone, ilium, lower extremity (calcaneus, tibia, fibula)

Fracture orientation: perpendicular to long axis of bone

Plain film / CT (1–2 weeks after onset of fracture):

√ often normal in early stage of fracture
√ cortical linear lucency ← disruption (= fracture line)
√ localized cortical thickening
√ periosteal new bone formation
√ medullary sclerosis (endosteal callus formation)

MR:

√ zone of low SI on T1WI + variable intensity on T2WI (= discrete fracture line)
√ surrounded by diffuse marrow edema (hypointense on T1WI + hyperintense on T2WI) = stress reaction
√ circumferential periosteal reaction + early callus + surrounding edema adjacent to bone hyperintense on T2WI + enhancement after IV Gd-chelate (DDx: osteomyelitis with more eccentric involvement)

NUC (bone scan):

√ increased abnormal uptake

Pelvic Insufficiency Stress Fracture

- severe pain in lower back + sacroiliac joints; radiates to buttocks, hips, groin, legs; worsens with weight bearing
- walking ability impaired

Prevalence: 1.8–5% of women > 55 years
Predisposed: postmenopausal women
Location: sacral ala, parasymphyseal region of os pubis, pubic rami, supraacetabular region, iliac blades, superomedial portion of ilium
Types:
(a) occult fracture:
Site: sacrum > supraacetabulum, ilium
√ sclerotic band, cortical disruption, fracture line
◊ Often obscured by overlying bowel gas + osteopenia!
(b) aggressive fracture:
Site: parasymphysis, pubic rami
√ exuberant callus formation, osteolysis + fragments ← prolonged / delayed healing / chronic nonunion
CAVE: fracture may be misdiagnosed as neoplasm; interpretation also histologically difficult
NUC:
√ butterfly / H-shaped ("Honda" sign) / asymmetric incomplete H-shaped pattern of sacral uptake
√ pelvic outlet view for parasymphyseal fx
CT and MR (most accurate modalities):
√ sclerotic band, linear fracture line, cortical disruption, fragmentation, displacement
√ bone marrow edema
◊ Excludes bone destruction + soft-tissue masses!
Prognosis: healing in 12–30 months

FEMORAL INSUFFICIENCY FRACTURE

Site: subcapital
√ subtle femoral neck angulation
√ trabecular angulation
√ subcapital impaction line

Fatigue (Stress) Fracture

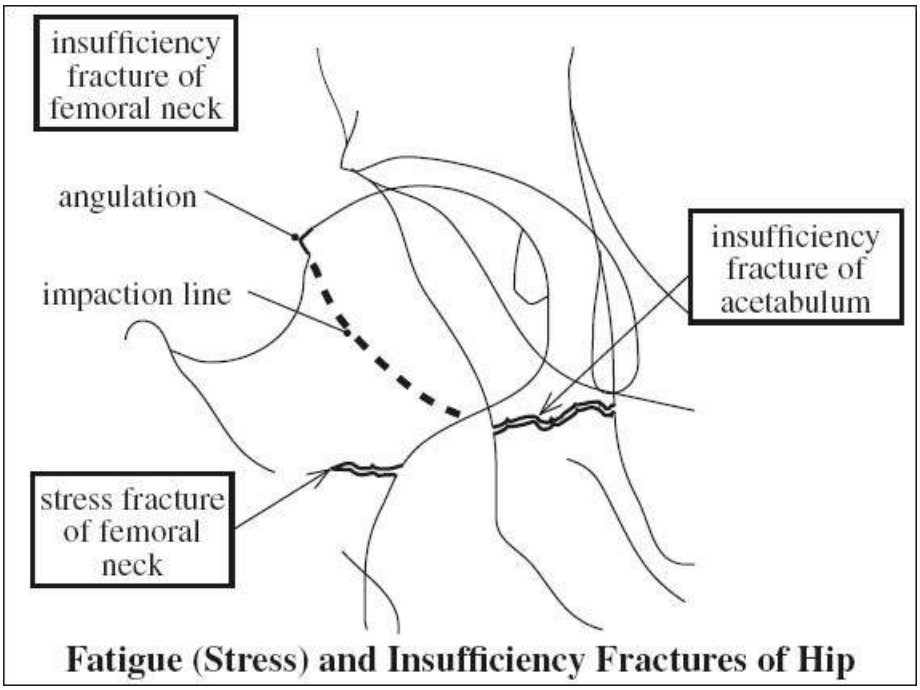
= normal bone subjected to repetitive stresses (none of which is singularly capable of producing a fracture) → leading to mechanical failure over time
Risk factors: new / different / rigorous repetitive activity; female sex; increased age; Caucasian race; low bone mineral density; low calcium intake; fluoride treatment for osteoporosis; condition resulting in altered gait
• activity-related pain abating with rest
• constant pain with continued activity
√ infraction in the center of an area of cortical thickening
√ extensive bidirectional cortical thickening from endosteum to periosteum
√ focal cortical ridge
NUC:
√ linear intense uptake of tracer
DDx: Osteoid osteoma (round nidus, no cortical ridge, "double-density" sign on bone

scan)

@ Spine
1. Clay shoveler's fracture: spinous process of lower cervical / upper thoracic spine
2. Spondylolysis = pars interarticularis of lumbar vertebra: ballet, gymnastics, diving
3. Ribs: carrying heavy pack, golf, coughing

@ Pelvis
1. Obturator ring of pelvis: stooping, bowling, gymnastics
   Site: superior / inferior pubic ramus
2. Sacrum (< 2%): long-distance runner, military recruits
   Site: unilateral ? ← leg length discrepancy

@ Upper extremity
1. Clavicle: postoperative (radical neck dissection)
2. Coracoid process of scapula: trap shooting



Fatigue (Stress) and Insufficiency Fractures of Hip

3. Coronoid process of ulna: pitching ball, throwing javelin, pitchfork work, propelling wheelchairs
4. Distal shaft of humerus: throwing ball (basketball, baseball, softball, javelin)
5. Hook of hamate: swinging golf club / tennis racquet / baseball bat
6. Other wrist bones: capitate > lunate > scaphoid

@ Lower extremity
1. Femur
   › neck: ballet, long-distance running
   Site: inferior surface of medial femoral neck
   √ subtle lucency / sclerosis (= acute fracture)
   √ lucent line surrounded by sclerosis (= subacute fracture)
   › shaft: ballet, marching, long-distance running, gymnastics

› distal metaphysis: endurance athlete (runner, soccer player, triathlete)

3. Patella: hurdling
4. Tibial shaft:
   › proximal diaphysis: running
   › middle + distal diaphysis: football, soccer, tennis, ballet, jogging
   ◊ Shin splint = early stress response
5. Fibula (distal diaphysis): long-distance running, jumping, parachuting

@ Foot (in order of frequency):

1. $2^{nd} > 3^{rd} + 4^{th}$ metatarsal: marching, stomping on ground, prolonged standing, ballet, long-distance running, postoperative bunionectomy
2. Calcaneus: jumping, parachuting, prolonged standing, long standing, recent immobilization
   √ vertical / oblique fracture orientation anterior to tuberosity
3. Tarsal navicular: stomping on ground, marching, long-distance running, prolonged standing, ballet
   √ vertically oriented fracture in midbody
   ◊ Midfoot fractures are difficult to diagnose by conventional radiography; CT + MRI are often helpful
4. Sesamoids of metatarsal: prolonged standing, gymnastics, long jumping

X-RAY (15% sensitive in acute fractures, increasing to 50% on follow-up):

› cancellous (trabecular) bone (notoriously difficult to detect)
  √ subtle blurring of trabecular margins
  √ faint sclerotic radiopaque area of peritrabecular callus (50% change in bone density needed)
  √ sclerotic band (← trabecular compression + callus formation) usually perpendicular to cortex
› compact (cortical) bone
  √ "gray cortex" sign = subtle ill definition of cortex
  √ intracortical radiolucent striations (early)
  √ solid thick lamellar periosteal new bone formation
  √ endosteal thickening (later)

◊ Follow-up radiography after 2–3 weeks of conservative therapy

NUC (no longer "gold standard" compared with MR):

◊ Highly sensitive with low specificity + ineffective in early cortical stress injuries
√ abnormal uptake within 6–72 hours of injury (prior to radiographic abnormality)
√ "stress reaction" = focus of subtly increased uptake
√ focal fusiform area of intense cortical uptake
√ abnormal uptake persists for months

MR (very sensitive modality; fat saturation technique most sensitive as it detects an increase in water content of medullary edema / hemorrhage):

√ increased marrow SI on T2WI + STIR (extensive micro- fractures cause edema + hemorrhage, which may obscure the fracture line); resolves within 6 months in 90%
√ low-intensity band contiguous with cortex on T2WI = fracture line of more advanced lesion
√ diminished marrow SI on T1WI of fracture line (less helpful)

√ periosteal edema = hyperintense line along periosteal surface on T2WI

CT (best modality for cortical abnormalities):

helpful in: longitudinal stress fracture of tibia; in confusing pediatric stress fracture (to detect endosteal bone formation)

√ cortical abnormalities:

√ osteopenia = increased hypoattenuation

√ resorption cavities = round / oval hypoattenuating intracortical defect

√ striations = subtle hypoattenuating intracortical lines

DDx: (1) Shin splints (activity not increased in angiographic / blood-pool phase)
√ long linear uptake on posteromedial (soleus muscle) / anterolateral (tibialis anterior muscle) tibial cortex on delayed images (from stress to periosteum at muscle insertion site)

(2) Osteoid osteoma (eccentric, nidus, solid periosteal reaction, night pain)

(3) Chronic sclerosing osteomyelitis (dense, sclerotic, involving entire circumference, little change on serial radiographs)

(4) Osteomalacia (bowed long bones, looser zones, gross fractures, demineralization)

(5) Osteogenic sarcoma (metaphyseal, aggressive periosteal reaction)

(6) Ewing tumor (lytic destructive appearance with soft-tissue component, little change on serial radiographs)

Apophyseal Injury = Avulsion Fracture

Mechanism: excessive avulsive force

◊ Physis under secondary ossification center is weakest part!

At risk: young athletes: hurdlers, sprinters, cheerleaders (repetitive to and fro adduction / abduction + flexion / extension)

Age: children > adults

◊ Avulsion injury of lesser trochanter in adults suggests underlying malignant disease

• pain, point tenderness, swelling

√ physeal widening

√ irregularity at site of avulsion

√ displaced pieces of bone of variable size:

√ crescentic ossific opacity if viewed on tangent

√ very subtle disk-shaped opacity if seen en face

√ abnormal foci of heterotopic ossification (later)

√ prominent bone formation in chronic avulsion injury from overuse with repeated microtraumas

DDx of healing acute injury: osteomyelitis, Ewing sarcoma

Overuse Injury to Physis

Little League Shoulder

= overuse injury to proximal humeral physis

Mechanism: excessive overhead throwing

Apophyseal Avulsion Injuries	
Location	*Muscle Origin / Insertion*
Iliac crest	abdominal musculature
Anterior superior iliac spine	sartorius muscle + tensor fasciae latae m.
Anterior inferior iliac spine	rectus femoris muscle
Symphysis pubis + inferior pubic ramus	long + short adductors, gracili
Ischial tuberosity	hamstrings
Lesser trochanter	iliopsoas muscle
Greater trochanter	gluteus medius + minimus, internal obturator, gemellus, piriformis
Inferior pole of patella	patellar tendon
Tibial tuberosity	patellar tendon

√ widening + irregularity of proximal humeral physis

Little League Elbow

= traction injury of medial humeral epicondyle

Mechanism: pitching → valgus stress of cocking and acceleration

√ localized bone marrow edema

√ widening of physis

Gymnast Wrist

Mechanism: repetitive weight bearing on wrist

√ physeal stress changes of distal radius ± ulna

√ positive ulnar variance ← abnormal distal radial growth

Cx: strain / tear of triangular fibrocartilage complex

Epiphyseal Plate Injury

Prevalence: 6–18–30% of bone injuries in children < 16 years

Peak age: 12 years

Location: distal radius (28%), phalanges of hand (26%), distal tibia (10%), distal phalanges of foot (7%), distal humerus (7%), distal ulna (4%), proximal radius (4%), metacarpals (4%), distal fibula (3%)

Mechanism: 80% shearing force; 20% compression

Resistance to trauma: ligament > bone > physis (hypertrophic zone most vulnerable)

MR:

√ focal dark linear area (= line of cleavage) within bright physis on gradient echo images (GRE)

Cx: (1) progressive angular deformity from segmental arrest of germinal zone growth with formation of a bone bridge across physis = "bone bar"

(2) limb length discrepancy from total cessation of growth

(3) articular incongruity from disruption of articular surface

(4) Bone infarction in metaphysis / epiphysis

Salter-Harris Classification:
(considering probability of growth disturbance)
[Robert Bruce Salter (1924–) and W. Robert Harris (1922–), orthopedic surgeons in Toronto, Canada]
◊ Prognosis is worse in lower extremities (ankle + knee) irrespective of Salter-Harris type!
mnemonic: SALTR

Slip of physis	=	type 1
Above physis	=	type 2 (distal)
Lower than physis	=	type 3 (proximal)
Through physis	=	type 4
Rammed physis	=	type 5

Salter Type 1 (6–8.5%)
= slip of epiphysis (← shearing force separates epiphysis from physis)
Line of cleavage: confined to physis
Location: most commonly in phalanges, distal radius (includes: apophyseal avulsion, slipped capital femoral epiphysis)
√ widening of growth plate
√ displacement of epiphyseal ossification center
Prognosis: favorable irrespective of location

Salter Type 2 (73–75%)
= shearing force splits growth plate
Line of fracture: through physis + extending through margin of metaphysis separating a triangular metaphyseal fragment (= "corner" sign)
Location: distal radius (33–50%), distal tibia + fibula, phalanges
Prognosis: good, may result in minimal shortening

Salter Type 3 (6.5–8%)
= intraarticular fracture, often occurring after partial closure of physis
Line of fracture: vertically / obliquely through epiphysis + extending horizontally to periphery of physis
Location: distal tibia, distal phalanx, rarely distal femur
√ epiphysis split vertically
Prognosis: fair (imprecise reduction leads to alteration in linearity of articular plane)

Salter Type 4 (10–12%)
Location: lateral condyle of humerus, distal tibia
√ fracture involves metaphysis + physis + epiphysis
Prognosis: guarded (may result in deformity + angulation)

TRIPLANE FRACTURE (6%)
Location: distal tibia, lateral condyle of distal humerus
√ vertical fracture of epiphysis + horizontal cleavage plane within physis + oblique

fracture of adjacent metaphysis

Salter Type 5 (< 1%)

= crush injury with injury to vascular supply
Location: distal femur, proximal tibia, distal tibia
Often associated with: fracture of adjacent shaft
√ no immediate radiographic finding
√ shortening of bone + cone epiphysis / angular deformity on follow-up
Prognosis: poor (impairment of growth in 100%)

Scapula Fracture

Most scapular fractures are minimally displaced extraarticular fractures of the scapular body, acromion, or coracoid process. Fractures of the glenoid neck or articular surface are more likely to require surgical repair.

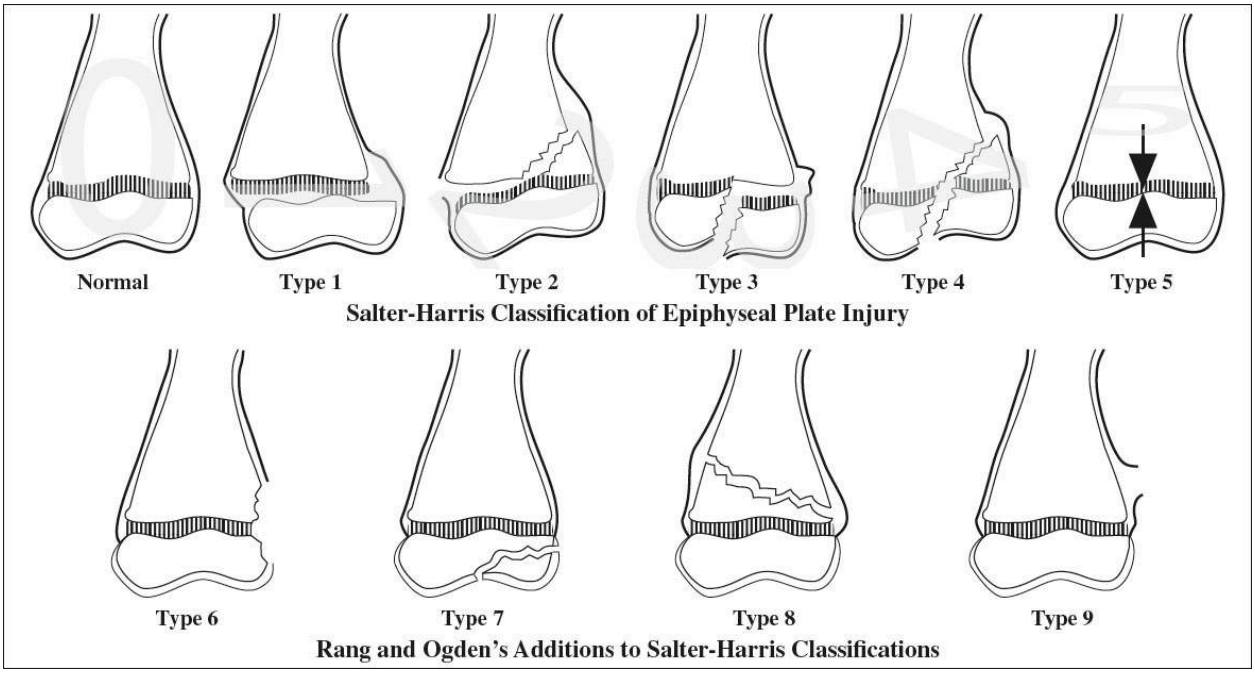
= rare < 1% of all extremity fractures
Mechanism: high-energy chest trauma
In 90% associated with: injury to chest, spine, pelvis, internal organs, brachial plexus, axillary vessels

Proximal Humerus Fracture

= may consist of up to 4 parts (fragment displaced by ≥ 1 cm / angled by ≥ 45°)
(1) anatomic head
(2) metaphyseal fragment with lesser tuberosity
(3) metaphyseal fragment with greater tuberosity
(4) humeral shaft

Prognosis: anatomic neck fractures are associated with an increased risk of avascular necrosis. The PPV is 97% if combined with a medial metaphyseal fragment < 8 mm short and > 2 mm displaced.

Neer classification (1970):
› 1-part fracture (85%) = no displacement / angulation
› 2- / 3- / 4-part fracture (15%)



Elbow Fracture

Pediatric Elbow Fracture

Age: common at 2–14 years

@ Soft-tissue

√ displacement of anterior + posterior fat pads (= elbow joint effusion with supracondylar / lateral condylar / proximal ulnar fractures)

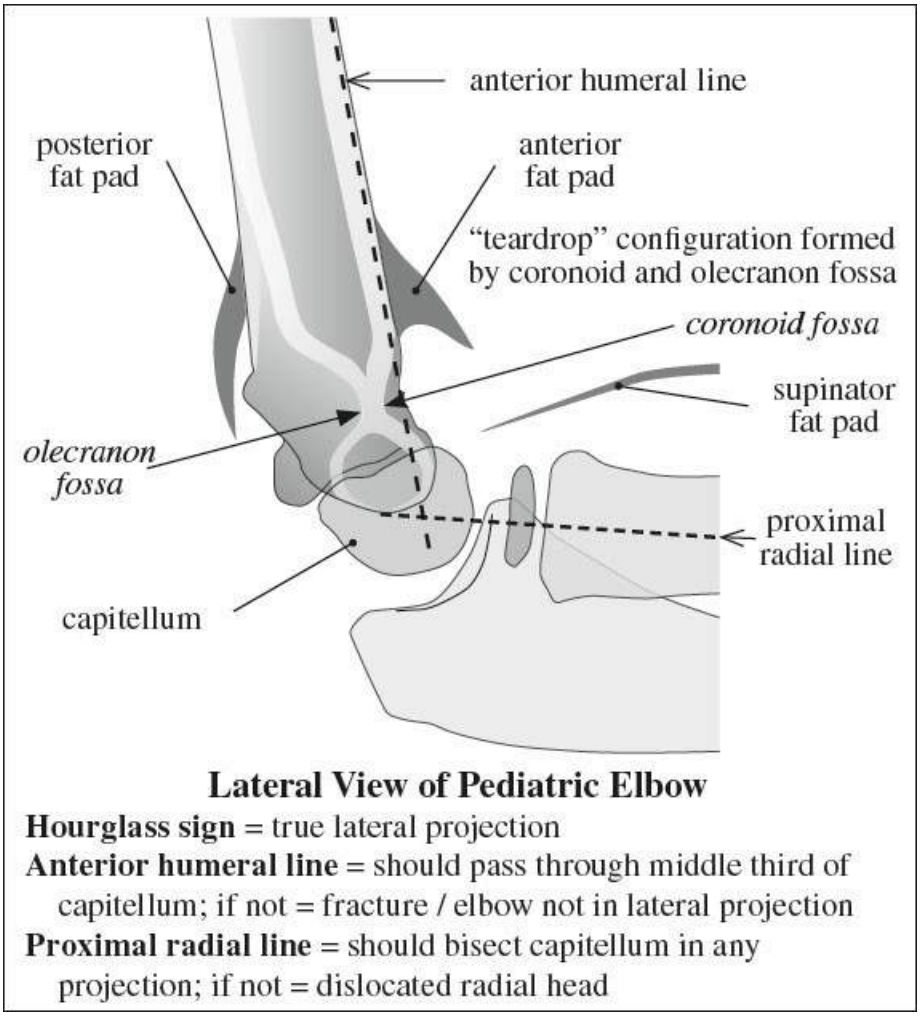
√ displaced supinator fat pad (= fracture of proximal radius)

√ focal edema medially (= medial epicondyle fx) / laterally (= lateral condyle fx)

@ Humerus (80%)

Supracondylar fracture (55%)

Mechanism: hyperextension with vertical stress



Lateral View of Pediatric Elbow

Hourglass sign = true lateral projection
Anterior humeral line = should pass through middle third of capitellum; if not = fracture / elbow not in lateral projection
Proximal radial line = should bisect capitellum in any projection; if not = dislocated radial head

√ transverse fracture line
√ distal fragment posteriorly displaced / tilted
√ anterior humeral line intersecting anterior to posterior third of capitellum (on lateral x-ray)

Lateral condylar fracture (20%)

Mechanism: hyperextension with varus stress

√ fracture line between lateral condyle + trochlea / through capitellum

Medial epicondylar fracture (5%)

Mechanism: hyperextension with valgus stress

√ avulsion of medial epicondyle (by flexor muscles of forearm)
√ may become trapped in joint space (after reduction of concomitant elbow dislocation)

@ Radius (10%)

Mechanism: hyperextension with valgus stress

√ Salter-Harris type II / IV fracture
√ transverse metaphyseal / radial neck fracture

Mechanism: hyperextension with varus stress

√ dislocation as part of Monteggia fracture (from rupture of annular ligament)

@ Ulna (10%)

√ longitudinal linear fracture through proximal shaft
Mechanism: hyperextension with vertical stress

√ transverse fracture through olecranon
Mechanism: hyperextension with valgus / varus stress; blow to posterior elbow in flexed position

√ coronoid process avulsion
Mechanism: hyperextension-rotation associated with forceful contraction of brachial m.

Elbow Dislocation

2nd most common joint dislocation in adult after shoulder

(a) Posterior elbow dislocation

(b) Anterior dislocation (rare): most often in child as a result of rebound following posterior dislocation

Associated soft-tissue injury (in sequence): lateral → medial

1. Lateral collateral ligament complex
2. Joint capsule + other lateral structures
3. MCL complex

Associated osseous injury:

Fracture of radial head + coronoid process (= terrible triad); medial epicondyle fracture; Essex-Lopresti fracture (rare)

Forearm Fracture

Pediatric Distal Forearm Fracture

BUCKLE / TORUS FRACTURE

= break in soft fibrous cortex with frequently intact periosteal sleeve

Cause: longitudinal compressive force

Location: distal radial + ulnar metaphyses

√ buckle in cortex on compression side of fracture

√ intact cortex on tension side

Prognosis: excellent stability; healing without complications after cast / splint immobilization

GREENSTICK FRACTURE

= break of bone cortex on tension side + intact periosteum

Cause: force perpendicular to long axis of bone

√ cortical disruption on tension (convex) side of fracture

√ intact cortex on compression side

Prognosis: unstable fracture → continued displacement for first 2 weeks

Barton Fracture

[John Rhea Barton (1794–1871), orthopedic surgeon at Pennsylvania Hospital,

Philadelphia]

Mechanism: fall on outstretched hand

√ intraarticular oblique fracture of ventral / dorsal lip of distal radius

√ carpus dislocates with distal fragment up + back on radius

Chauffeur Fracture

= HUTCHINSON FRACTURE = BACKFIRE FRACTURE = LORRY DRIVER FRACTURE

[Jonathan Hutchinson (1828–1913), British surgeon]

= name derived from direct trauma to radial side of wrist sustained from recoil of crank used in era of hand cranking to start automobiles

Mechanism: acute dorsiflexion + abduction of hand

√ triangular fracture of radial styloid process

Colles Fracture

[Abraham Colles (1773–1843), surgeon in Dublin, Ireland]

= POUTEAU FRACTURE (term used in France)

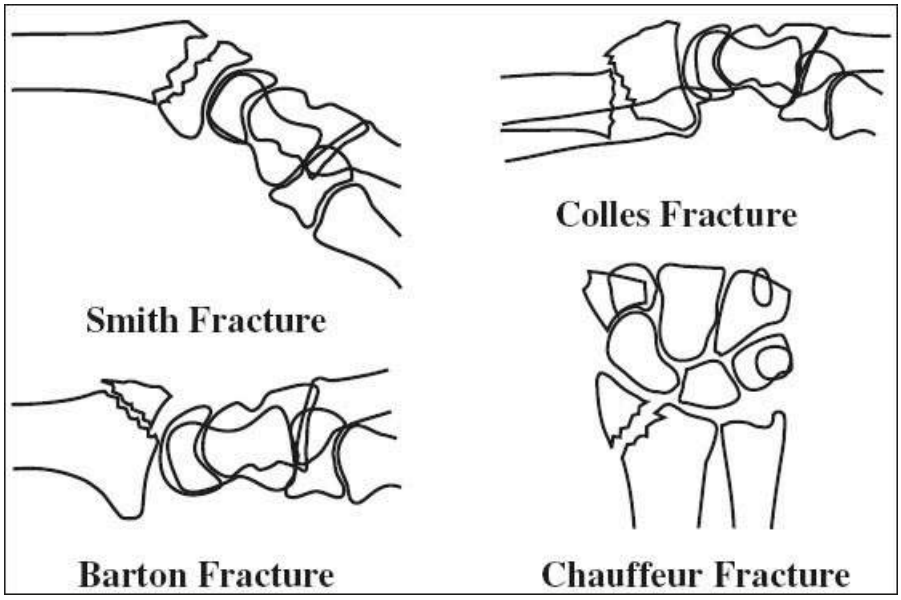
[Claude Pouteau (1725–1775), surgeon in Lyon, France]

◊ Most common fracture of forearm!

Mechanism: fall on outstretched hand

√ nonarticular radial fracture in distal 2 cm

√ dorsal displacement of distal fragment + volar angulation of fracture apex



√ ± ulnar styloid fracture

√ "silver-fork" deformity

Cx: posttraumatic arthritis

Rx: anatomic reduction important

Significant postreduction deformity:

1. Residual positive ulnar variance > 5 mm indicates unsatisfactory outcome in 40%

2. Dorsal angulation of palmar tilt > 15° decreases grip strength + endurance in > 50%

Essex-Lopresti Fracture

[Peter Gordon Essex-Lopresti (1918–1951), surgeon at Birmingham Accident Center, England]

Mechanism: FOOSH-type injury

• wrist pain / tenderness

√ "floating radius":

√ comminuted displaced radial head fracture

√ dislocation of distal radioulnar joint = discrepancy of radioulnar distance > 5 mm compared to contralateral uninjured wrist (on lateral radiograph)

√ disruption of interosseous membrane

Rx: nearly always surgical intervention

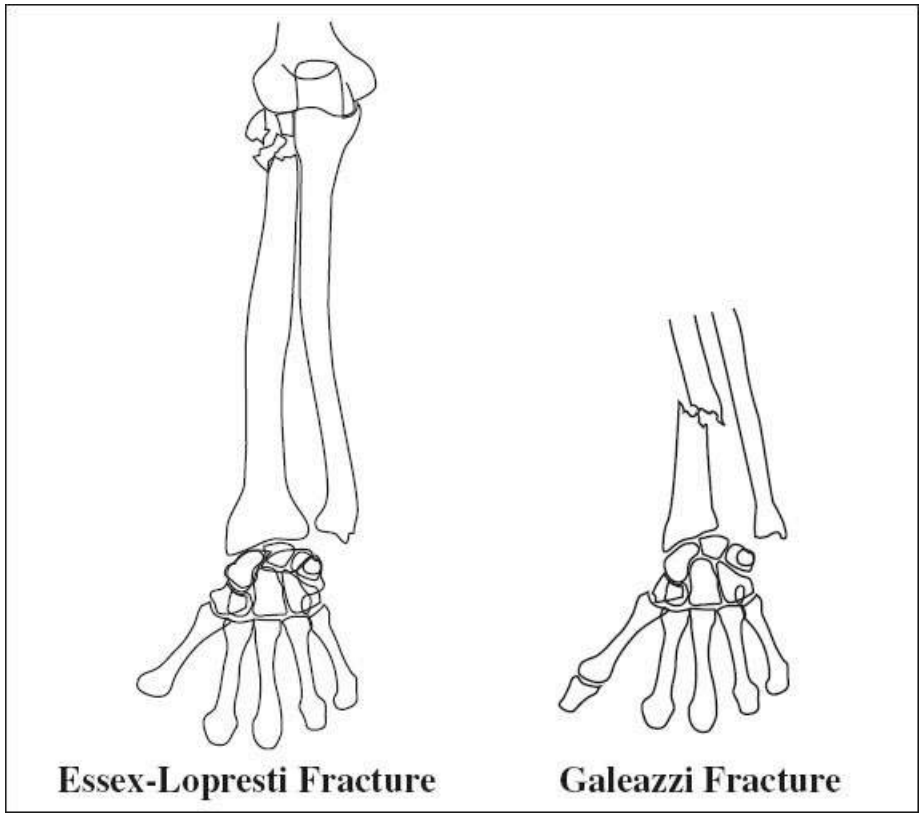
Galeazzi Fracture

[Ricardo Galeazzi (1866–1952), orthopedic surgeon in Italy]

= PIEDMONT FRACTURE

Mechanism: fall on outstretched hand with elbow flexed

√ radial shaft fracture (most commonly) at junction of distal to middle third with dorsal angulation



√ subluxation / dislocation of distal radioulnar joint

√ ulnar plus variance (= radial shortening) of > 10 mm implies complete disruption of

interosseous membrane = complete instability of radioulnar joint

Cx: (1) High incidence of nonunion, delayed union, malunion (unstable fracture)
(2) Limitation of pronation / supination

GALEAZZI-EQUIVALENT FRACTURE

= exclusively in skeletally immature children

Mechanism: hyperpronation / hypersupination

√ radial shaft fracture (4 primary types)

√ dislocation / epiphyseolysis of distal ulna

Monteggia-type Fracture

= ulnar shaft fracture + (often missed) radiocapitellar dislocation

Bado Classification:

[Jose Luis Bado (1903–1977), orthopedic surgeon in Uruguay]

Type I = classic fracture

[Giovanni Battista Monteggia (1762–1815), professor of anatomy and surgery at Istituzioni Chirurgiche at University of Pavia]

Mechanism: direct blow to the forearm

√ anteriorly angulated proximal ulnar fracture

√ anterior dislocation of radial head

√ may have associated wrist injury

Cx: nonunion, limitation of motion at elbow, nerve abnormalities

Type II = reverse Monteggia fracture

√ radial head displaced posteriorly / posterolaterally

√ dorsally angulated proximal ulnar fracture

Type III

√ lateral dislocation of radial head

√ ulnar metaphyseal fracture

Type IV

√ anterior displacement of radial head

√ fracture of proximal third of radius + ulna at the same level

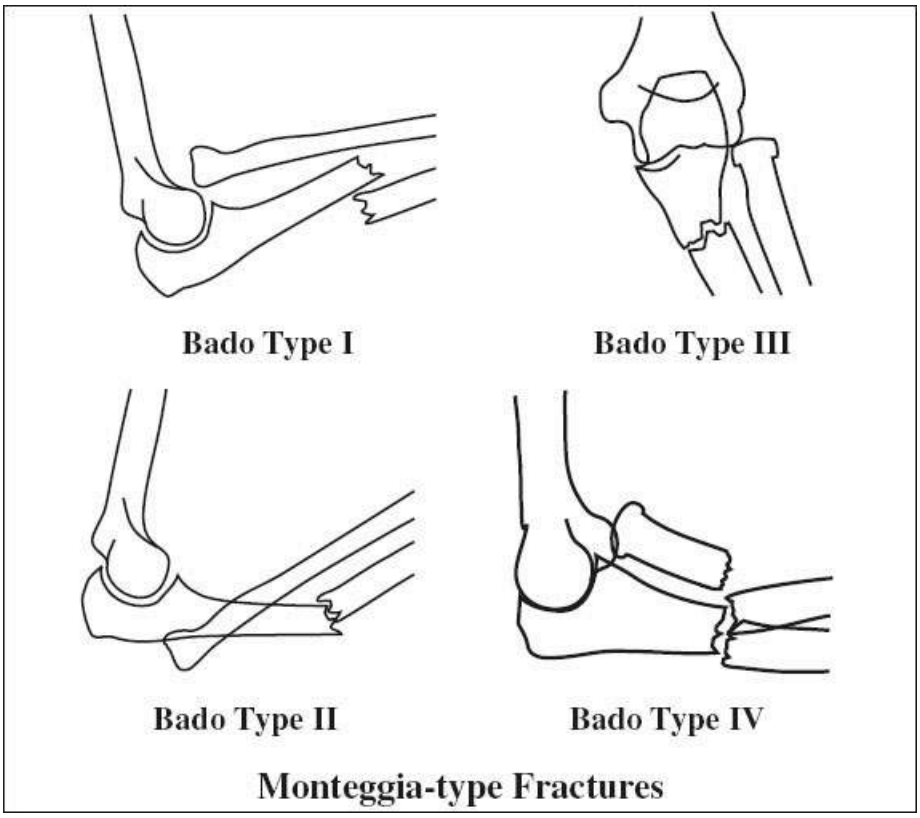
Smith Fracture

= REVERSE COLLES FRACTURE = REVERSE BARTON FRACTURE = GOYRAND FRACTURE (term used in France)

[Robert William Smith (1807–1873), succeeding Colles as professor of surgery at Trinity College in Dublin, Ireland]

Mechanism: hyperflexion with fall on back of hand

√ nonarticular distal radial fracture



Monteggia-type Fractures

√ ventral displacement of fragment
√ radial deviation of hand
√ "garden spade" deformity
Cx: altered function of carpus

Carpal Injury

Hamate Fracture

Prevalence: 1.7% of all carpal fractures
Mechanism: handle of racket / bat / club presses against protruding hook; axial loading force on body with clenched fist; fall on outstretched hand
May be associated with: perilunate dislocation
Location:
(a) hamate hook at palmar nonarticular surface
(b) body

• grip weakness; pain with resistance to flexion of 5th finger
√ hamulus not depicted on standard PA view
√ cortical density of hamulus lower than normal
Cx: 5th finger flexor tendon rupture; ulnar nerve palsy; hook nonunion
DDx: os hamuli proprium (ovoid / pyramidal bone with peripheral cortical bone)
Rx: open reduction with internal fixation for fractures displaced > 1 mm

Lunate Fracture

Prevalence: 4% of all carpal fractures
Mechanism: direct axial compression from head of capitate driven into lunate
Location: volar pole; dorsal pole; body
Fracture orientation: transverse, sagittal
Cx: nonunion → Kienböck disease

Pisiform Fracture

Prevalence: 1.3% of all carpal fractures (only 50% are diagnosed on PA radiograph)
Mechanism: fall on outstretched hand with direct impact on pisiform bone
May be associated with: carpal dislocation, distal radial fracture
Fracture type: linear, comminuted, chip
Cx: ulnar nerve injury
Rx: excision of pisiform bone

Scaphoid Fracture

= NAVICULAR FRACTURE
◊ Most frequent (90%) of all carpal bones fractures!
Age: active men during 2nd + 3rd decade
Mechanism: fall on dorsiflexed outstretched hand (hyperextension injury)
Location: waist (80%) > proximal pole
Fracture orientation: horizontal oblique, vertical oblique, transverse
• pain + tenderness at anatomic snuff box
Radiographic misses: 25–33–65%
N.B.: If initial radiograph negative, reexamine in 2 + 6 weeks after treatment with thumb-spica cast or proceed to CT / MRI!
CT: 89–97% sensitive; 85–100% specific; 97–99% NPV; 6–12 seconds examination time
MR: high sensitivity; 30–40 minutes examination time
Bone scan: up to 100% sensitive, 93% PPV after 2–3 days
Prognosis: dependent on following factors
√ fracture displacement with > 1 mm offset / angulation / rotation of fragments (less favorable)
√ location of blood supply:
› distal ⅓ (10%) = usually fragments reunite
› middle ⅓ (70%) = failure to reunite in 30%
› proximal ⅓ (20%) = failure to reunite in 90%
√ orientation of fracture
› transverse / horizontal oblique = relatively stable
› vertical oblique (less common) = unstable
◊ Good prognosis with distal fracture + no displacement + no ligamentous injury!
◊ Less favorable prognosis with displaced / comminuted fracture + proximal pole fracture!
Cx: (1) Malunion; delayed union; nonunion (5–15%)
(2) Progressive fragment displacement
(3) Avascular necrosis of proximal fragment (13–50%); higher prevalence if proximal pole fractured ← distal location of main nutrient a.

Trapezium Fracture

Prevalence: 3–5% of all carpal fractures
Mechanism: direct blow to volar surface / avulsion
Location: trapezial ridge (= vertical prominence on volar aspect); body
Associated with: carpometacarpal joint involvement; fracture through base of 1st metacarpal / scaphoid

Triquetral Fracture

Prevalence: 18% of all carpal fractures
Mechanism: wrist hyperextension with ulnar deviation → impingement of ulnar styloid process against dorsal surface of triquetrum
Location:
(a) dorsal ridge fracture
(b) triquetral body fracture (in combination with perilunate dislocation)
√ fragment along dorsal edge of triquetrum (LAT view in slight pronation)

Hand Fracture

Bennett Fracture

[Edward Halloran Bennett (1837–1907), surgeon in Dublin, Ireland]
Mechanism: forced abduction of thumb
√ intraarticular fracture-dislocation of base of 1st metacarpal
√ small fragment of 1st metacarpal continues to articulate with trapezium
√ lateral retraction of 1st metacarpal shaft by abductor pollicis longus
Rx: anatomic reduction important, difficult to keep in anatomic alignment
Cx: pseudarthrosis

Boxer's Fracture

Mechanism: direct blow with clenched fist
√ transverse fracture of distal metacarpal (usually 5th)

Gamekeeper's Thumb

= SKIER'S THUMB (originally described as chronic lesion in hunters strangling rabbits)
Frequency: 6% of all skiing injuries; 50% of skiing injuries to the hand
Mechanism: violent abduction of thumb with injury to ulnar collateral ligament (UCL) in 1st MCP (faulty handling of ski pole)
√ disruption of ulnar collateral ligament of 1st MCP joint, usually occurring distally near insertion on proximal phalanx
√ avulsed bone fragment (in 12% of lesions)
√ radial stress examination results in abduction angle > 35–45° or > 10° greater than on opposite side
◊ Controversial maneuver to document ligamentous disruption as it may complete incomplete tear
√ displacement of UCL superficial to aponeurosis of adductor pollicis (= **Stener lesion**) [torn end of UCL may be marked by avulsed bone fragment]

Rolando Fracture

[Silvio Rolando (?–1931?), surgeon in Genoa, Italy]

√ comminuted Y- / T-shaped intraarticular fracture-dislocation through base of thumb metacarpal

Prognosis: worse than Bennett fracture (difficult to reduce)

Chest Wall Fracture

Rib Fracture

◊ Most common skeletal injury in blunt chest trauma (in 50%)

Associated with: pneumothorax, hemothorax, lung contusion / laceration

CT is the most sensitive technique for imaging rib fractures by determining the site and number of fractures and providing information about any associated injuries.

@ 1st–3rd rib

◊ Indicates high-energy trauma ← protected location

Cause: acute trauma / fatigue fracture (from carrying a heavy back pack)

Associated with: aortic / great vessel + subclavian vascular injury; brachial plexus injury; thoracic vertebral fracture; scapular fracture

@ Lower ribs

Associated with: injury to liver, spleen, kidney, diaphragm

Cx: atelectasis + subsequent pneumonia ← limited respiratory movement

FLAIL CHEST

= segmental fracture of > 3 contiguous ribs in > 2 places

In > 50% associated with: significant intrathoracic injury that requires surgical Rx

- paradoxic motion of fractured chest wall with respiration on clinical examination
- respiratory failure

Rx: mechanical ventilation for prolonged periods

COUGH FRACTURE

Location: 4th–9th rib in anterior axillary line

Scapula Fracture

Prevalence: 3–5% of all shoulder girdle fractures

◊ In 3.7% of patients with multiple injuries

Cause: motor vehicle accident, fall from great height

Associated with: pneumothorax, hemothorax, lung injury, spinal injury (in 35–98%)

Prognosis: displaced glenoid intraarticular fracture + displaced juxtaarticular fracture require surgical management

Sternal Fracture

Cause: deceleration, direct blow

Associated with: anterior mediastinal hemorrhage

Sternal fractures are best demonstrated on multiplanar reformatted CT images, especially on sagittal views.

Pelvic Fracture

Unstable pelvic fractures:

(a) anterior compression
   1. Bilateral vertical pubic rami fractures
   2. Symphysis + sacroiliac joint diastasis

(b) lateral compression
   1. Malgaigne (ipsilateral anterior + posterior fx)
   2. Bucket-handle (contralateral anterior + posterior fx)

(c) vertical shear
   1. Superior displacement of pelvis

Acetabular Fracture

Anatomy & Function:

most important portion of acetabulum is roof / dome;
weight-bearing surface for entire lower limb is derived + supported by 2 columns which are oriented in an inverted "Y" and join above the acetabular roof at an angle of 60°:

(a) anterior iliopubic column of acetabulum
(b) posterior ilioischial column of acetabulum

Classification (Judet and Letournel):

A. Elementary 5 fractures
   Posterior wall* 27% Anterior column 5%
   Transverse* 9% Posterior column 4%
   Anterior wall 2%

B. Associated 5 fractures (= combinations / partial combinations of elementary fractures)
   Transverse + posterior wall* 27%
   Both columns* 19%
   T-shaped* 6%
   Anterior wall + posterior hemitransverse 5%
   Posterior column + posterior wall 3%

*= account for 80%of all acetabular fractures (3 most common types underlined)

POSTERIOR WALL (LIP / RIM) FRACTURE (27%)

Mechanism: indirect force transmitted through length of femur with flexed hip joint (knee strikes dashboard)

Associated with: posterior dislocation of femur

A posterior wall fracture involves only the posterior articular surface and is not seen on the medial acetabular surface.

TRANSVERSE FRACTURE (9%)

N.B.: most difficult to diagnose + comprehend

√ transects both the iliopubic + ilioischial columns with fracture line in an anteroposterior direction

On subsequent axial CT images, a transverse acetabular fracture is represented by a sagittal fracture line simulating anterior and posterior wall fractures, a pitfall easily avoided with 3-D

reconstructions.

ANTERIOR COLUMN FRACTURE (5%)

Mechanism: blow to greater trochanter with hip externally rotated

Associated with: posterior column / transverse fracture

√ fracture begins between anterior iliac spines + traverses the acetabular fossa + ends in the ischiopubic ramus

POSTERIOR COLUMN FRACTURE (4%)

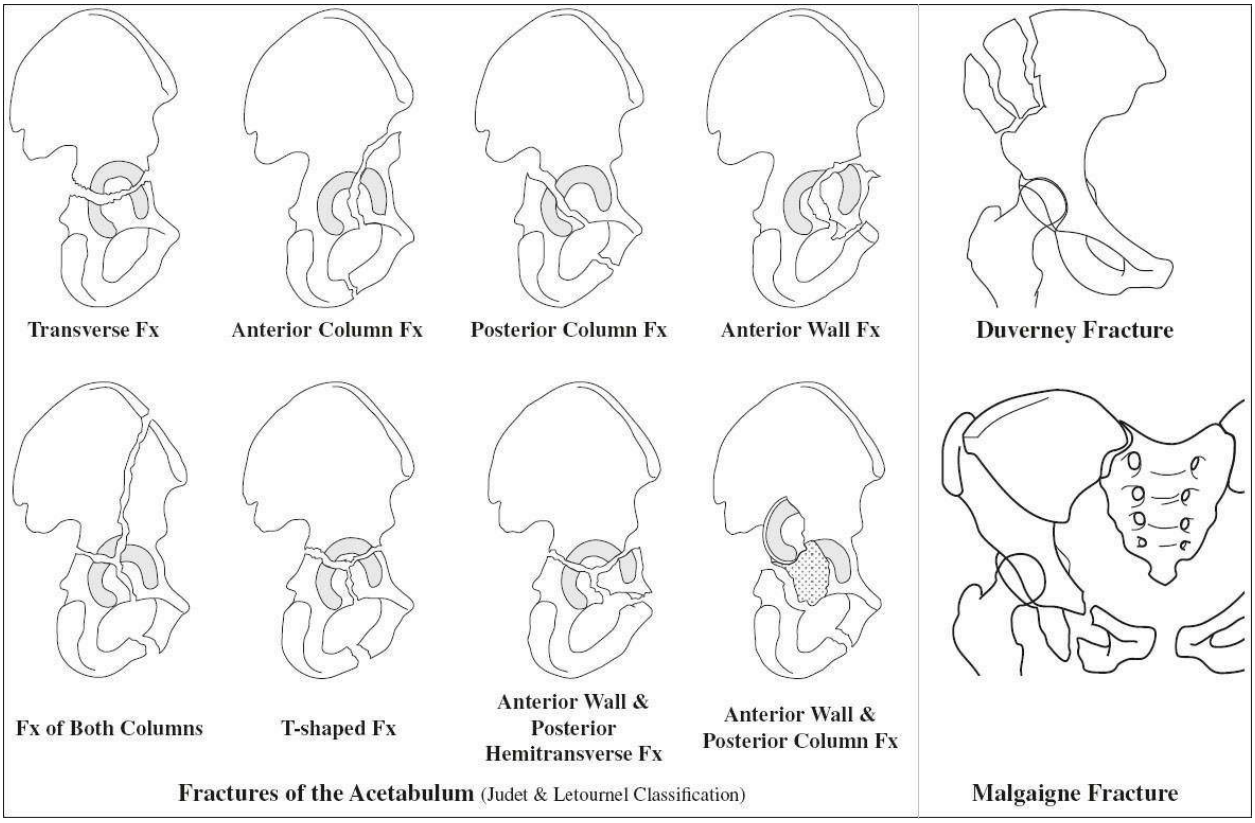
Mechanism: indirect force transmitted through length of femur with hip abducted

Associated with: posterior dislocation of femur + sciatic nerve injury

√ fracture begins at greater sciatic notch + traverses the posterior aspect of acetabular fossa + ends in the ischiopubic ramus

ANTERIOR WALL FRACTURE (2%)

Mechanism: force transmitted through greater trochanter



Fractures of the Acetabulum (Judet & Letournel Classification)

Associated with: posterior dislocation of femur + sciatic nerve injury

√ fracture begins on anterior rim of acetabulum + emerges on lateral aspect of superior pubic ramus

ASSOCIATED BOTH COLUMN FRACTURE (19%)

= separation of both columns from each other with 2 dominant fractures nearly perpendicular to each other

Associated with: additional fracture lines + medial displacement of femoral head
√ "spur sign" = shard of bone superior to femoral neck (on obturator view)

With both-column fractures the entire weight-bearing portion of the acetabulum is disconnected from the sciatic buttress.

Bucket Handle Fracture

√ double vertical fracture through superior and inferior pubic rami + sacroiliac joint dislocation on contralateral side

Duverney Fracture

[Joseph Guichard Duverney (1648–1730), French surgeon]
√ isolated fracture of iliac wing

Malgaigne Fracture

[Joseph François Malgaigne (1806–1865), French surgical historian, published first comprehensive book on fractures]
= fracture-dislocation of one side of the pelvis with anterior + posterior disruption of pelvic ring
Mechanism: direct trauma
• shortening of involved extremity
√ vertical fractures through one side of pelvic ring
(1) superior to acetabulum (ilium)
(2) inferior to acetabulum (pubic rami)
(3) ± sacroiliac dislocation / fracture
√ lateral unstable fragment contains acetabulum

Proximal Femur Fracture

Intracapsular Femur Fracture

A. Complete Femoral Head Fracture *(uncommon)*
Often associated with: posterior hip dislocation
Pipkin classification:

Type 1	below fovea centralis
Type 2	above fovea centralis with ligamentum teres often attached to fracture fragment
Type 3	type 1/2 + femoral neck fracture
Type 4	type 1/2 + acetabular fracture

The lateral margin of the femoral head-neck junction is crucial as it is the most common penetration point of the lateral epiphyseal vessels. Fractures involving this area create a high risk of critical vascular injury resulting in nonunion / AVN, with decreasing risk as fractures occur more distally along the femoral neck.

B. Osteochondral Impaction Fracture of Femoral Head

Often associated with: anterior hip dislocation
√ radiographically relatively occult:
√ subtle flattening / focal compression defect of head
√ subchondral fracture line + marrow edema at MRI

C. Femoral Neck Fracture
Location: subcapital, transcervical, basicervical
√ valgus-impacted / nondisplaced

N.B.: frequently missed on initial radiographs ← subtlety of cortical distortion at femoral head-neck junction + only mild fracture angulation

√ varus-impacted ("mushroom cap" = medially rotated head) / displaced → high risk for AVN

D. Femoral Neck Stress Fracture
√ often initially radiographically occult
@ Inferomedial cortex = fatigue fracture
Age: young athletic patient
√ cortical thickening + incomplete fracture line
√ extensive marrow edema
@ Superolateral cortex = insufficiency / fatigue fracture
Age: osteoporotic elderly
√ frequently displaced ← side of high tension

Extracapsular Fracture

A. Intertrochanteric Fracture
Cause: frequently osteoporosis in the elderly woman

N.B.: Isolated fractures of the lesser trochanter in adults should be considered pathognomonic for tumor infiltration.

B. Subtrochanteric Fracture
√ comminuted / spiral morphology

Knee Fracture

Anterior Cruciate Ligament Avulsion Fracture

Age: children > adults
Mechanism:
(a) children: forced flexion of knee + internal rotation
(b) adults: severe hyperextension
May be associated with: kissing bone contusion + tear of medial collateral lig. + PCL
• aching flexed knee; signs of anterior instability
√ avulsion of ACL from its distal insertion site just medial and anterior to tibial eminence

Arcuate Complex Avulsion Fracture

Mechanism: direct blow to anteromedial tibia with knee in extension / varus force to externally rotated tibia / sudden hyperextension
May be associated with:
disruption of ACL and PCL, lateral capsular lig., iliotibial band, popliteal muscle,

menisci, damage to peroneal nerve

- subtle physical finding
- mild swelling + tenderness

√ "arcuate" sign = avulsed elliptic bone fragment at fibular styloid process with its long axis horizontally oriented (AP view)

√ bone marrow edema in head of fibula + adjacent soft-tissue swelling

Biceps Femoris Tendon Avulsion Fracture

May be associated with:
disruption of lateral collateral lig., Segond fracture, damage to popliteal musculotendinous unit

√ irregular bone fragment off lateral fibular head in posterolateral aspect of knee joint (DDx: "arcuate sign" = horizontally oriented elliptic fragment off fibular styloid process)

√ avulsion + retraction of biceps femoris tendon

Iliotibial Band Avulsion Fracture

= primary stabilizing structure of anterolateral knee

Mechanism: pure varus force (rare)

May be associated with: ACL injury

√ avulsion + retraction of iliotibial band from its distal insertion on Gerdy tubercle

Posterior Cruciate Ligament Avulsion Fracture

Location: at tibial insertion site (40–55%)

Mechanism: direct blow to anterior tibia with flexed knee (dashboard injury); severe hyperextension

May be associated with:
disruption of medial / lateral collateral ligament complexes; medial / lateral meniscal tear; bone contusion of anterior tibia + lateral femoral condyle

√ focal discontinuity of posterior articular surface (LAT view)

Quadriceps Tendon Avulsion Fracture

Cause: strong deceleration in young athletes

Mechanism: sudden contraction of quadriceps muscle during jumping / kicking

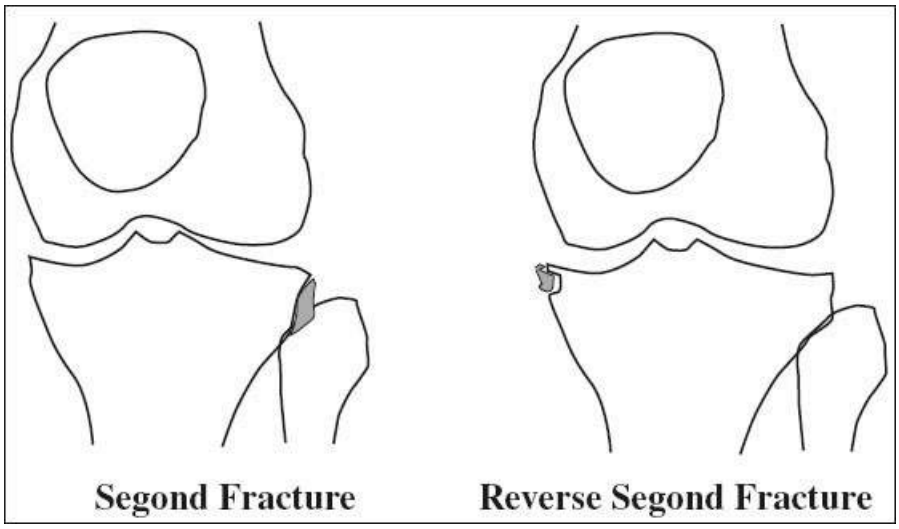
√ comminuted bone fragments off superior aspect of patella (LAT view)

√ patella baja deformity = abnormally low position of patella with respect to femur

√ marrow edema in upper pole of patella

√ suprapatellar joint effusion

DDx: rupture of quadriceps tendon (at musculotendinous junction; repetitive microtrauma / systemic diseases like HPT, diabetes, collagen vascular disease, gout)



Reverse Segond Fracture

= cortical avulsion of tibial insertion of deep capsular component of medial collateral ligament

Mechanism: external rotation + valgus stress

May be associated with:

midsubstance tear of posterior cruciate ligament; avulsion of PCL from posterior tibial plateau; tear of medial meniscus

√ elliptic bone fragment arising from medial aspect of proximal tibia

Segond Fracture

[Paul Ferdinand Segond (1851–1912), surgeon in chief at Salpêtrière in Paris, France]

= cortical avulsion of the tibial insertion of middle third of lateral capsular ligament ± avulsion of iliotibial tract ± anterior oblique band

Mechanism: internal rotation + varus stress

May be associated with:

lesion of anterior cruciate ligament (75–100%), meniscal tear (67%), avulsion of fibular attachment of long head of biceps femoris tendon + fibular collateral ligament

• pain at lateral joint line

• anterolateral rotational instability of the knee

√ "lateral capsular" sign = small elliptic fragment of proximal lateral tibial rim just distal to lateral plateau parallel to tibia (AP view)

√ marrow edema on MRI

Semimembranosus Tendon Avulsion Fracture

Mechanism: external rotation + abduction of flexed knee; varus force applied to flexed knee; valgus force applied to tibia

May be associated with:

ACL tear; tear of posterior horn of medial meniscus; posterior meniscocapsular separation

√ tiny avulsed bone fragment off tibia displaced posterosuperiorly (difficult to see on LAT view)

Tibial Plateau Fracture (Schatzker classification)

Type I = wedge-shaped pure cleavage fracture 6%
√ < 4 mm depression / displacement
√ ± distraction injury to MCL / ACL

Type II = combined cleavage + lateral plateau compression fracture 25%
√ distraction injury of MCL / medial meniscus in 20%

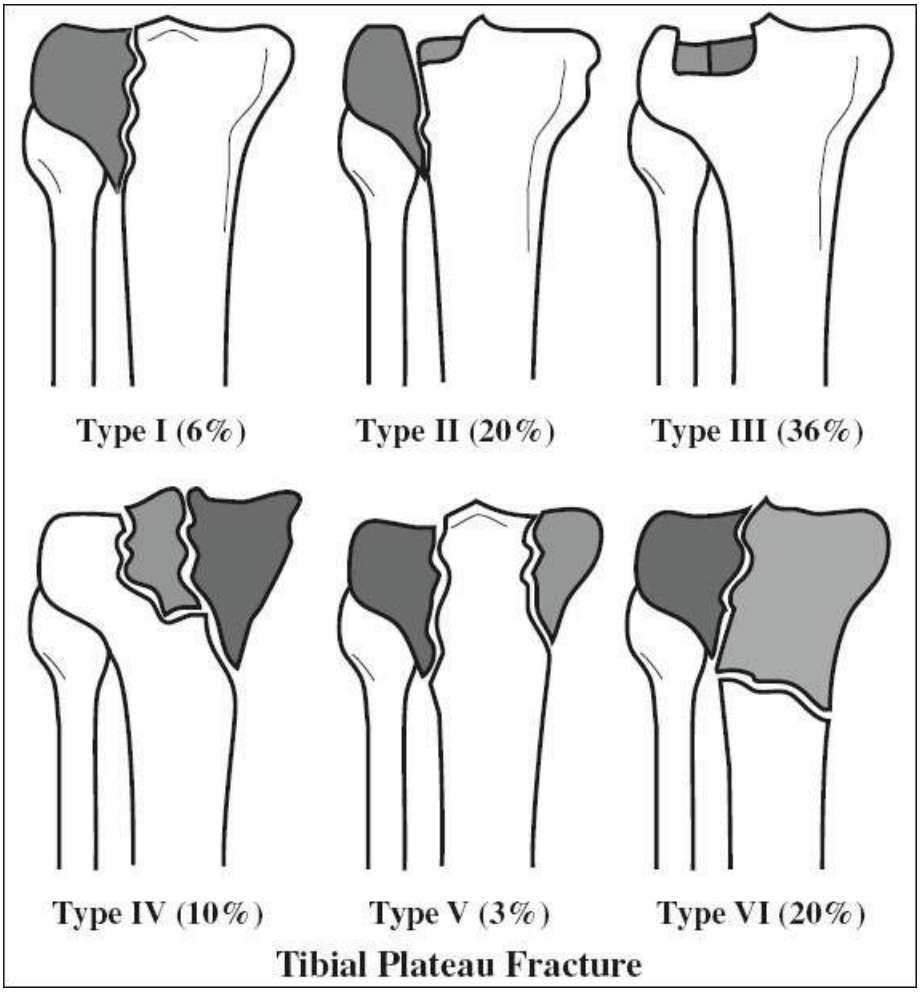
Type III = pure compression fracture of lateral tibial plateau 36%
√ depression of articular surface:
√ lateral depression (type IIIA)
√ central depression (type IIIB)

Type IV = medial plateau fracture with a split / depressed comminution 10%
√ ± distraction injury of lateral knee with LCL tear / posterolateral corner injury
√ ± fracture / dislocation of proximal fibula
Cx: injury to peroneal nerve / popliteal vessels

Type V = wedge fracture of medial + lateral plateau in 3%
√ often inverted Y appearance
√ articular depression typically of lateral tibial plateau
√ ± fracture of intercondylar eminence (= unstable 4-part fracture)
√ peripheral meniscal detachment (50%)
√ ACL avulsion injury (33%)

Type VI = transverse / oblique fracture with dissociation of metaphysis from diaphysis 20%
√ open fracture in (33%)

◊ Lateral plateau fractures (type I–III) are most common!



◊ Fractures of medial plateau are associated with greater violence and higher percentage of associated injuries!

Mechanism:

(a) for type I + II + III = valgus force combined with axial loading ("bumper / fender fracture" from lateral force of automobile against a pedestrian's fixed knee) / compression force often on extended knee

(b) for type IV = varus force combined with axial loading on hyperflexed knee

(c) type V + VI = combination of valgus + varus stresses combined with axial loading

Tibial Tubercle Fracture

Ogden classification:

Type 1: involvement of distal portion of tubercle
- 1A: without displacement
- 2A: with displacement

Type 2: involvement of entire ossification center
- 2A: separation of tubercle from proximal tibia
- 2B: comminuted fracture

Type 3: involvement of proximal tibial epiphysis into joint space

3A: without displacement
3B: with displacement

Toddler's Fracture

= CHILDHOOD ACCIDENTAL SPIRAL TIBIAL FRACTURE (CAST)
= lower extremity fracture associated with onset of ambulation
Cause: low-energy trauma ± rotational component
Age: toddler (9 months–3 years), young child (< 8 years)
• refusal to bear weight without recognized trauma
Location: distal third to distal half of tibia; fibula, tarsus (posterior calcaneus > base of cuboid > talus)
√ (typically) nondisplaced oblique spiral fracture of distal tibia
√ undisplaced spiral fracture

Foot Fracture

Ankle Fracture

Frequency: ankle injuries account for 10% of all emergency room visits; 85% of all ankle sprains involve lateral ligaments

LATERAL MALLEOLAR FRACTURES

Weber Type A

[Bernhard Georg Weber (1929–), orthopedic surgeon in St. Gall, Switzerland]
= SUPINATION-ADDUCTION INJURY = INVERSION-ADDUCTION INJURY
Mechanism:
(1) avulsive forces affect lateral ankle structures
(2) impactive forces ← talar shift stresses medial structures
√ sprain / rupture of lateral collateral ligament
◊ Anterior tibiofibular ligament ruptures alone in 66%
◊ Injury of all 3 lateral ligaments in 20%
Prognosis: chronic lateral ankle instability in 10–20%
√ transverse avulsion of malleolus sparing tibiofibular ligaments
√ ± oblique fracture of medial malleolus
√ ± posterior tibial lip fracture

Weber Type B

= SUPINATION-ABDUCTION INJURY = EVERSION-EXTERNAL ROTATION
Mechanism:
(1) avulsive forces on medial structures
(2) impacting forces on lateral structures (talar impact)
√ oblique / spiral fracture of lateral malleolus starting at level of joint space extending proximally
√ lateral subluxation of talus
√ partial disruption of tibiofibular ligament
√ ± sprain / rupture / avulsion of deltoid ligament

√ ± transverse fracture of medial malleolus

(a) **Dupuytren Fracture**

[Guillaume Dupuytren (1777–1835), French surgeon]

√ fracture of distal fibula above a disrupted tibiofibular ligament + disruption of deltoid lig.

(b) **Le Fort Fracture of Ankle**

[Léon Clément Le Fort (1829–1893), French surgeon]

√ vertical fracture of anterior medial portion of distal fibula

√ avulsion of anterior tibiofibular ligament

Weber Type C

= PRONATION-EXTERNAL ROTATION = EVERSION + EXTERNAL ROTATION

√ fibular fracture higher than ankle joint (Maisonneuve fracture if around knee)

√ ± deltoid ligament tear

√ ± medial malleolar fracture

√ tear of tibiofibular ligament / avulsion of anterior tubercle (Tillaux-Chaput) / avulsion of posterior tubercle (Volkmann)

√ tear of interosseous membrane = lateral instability

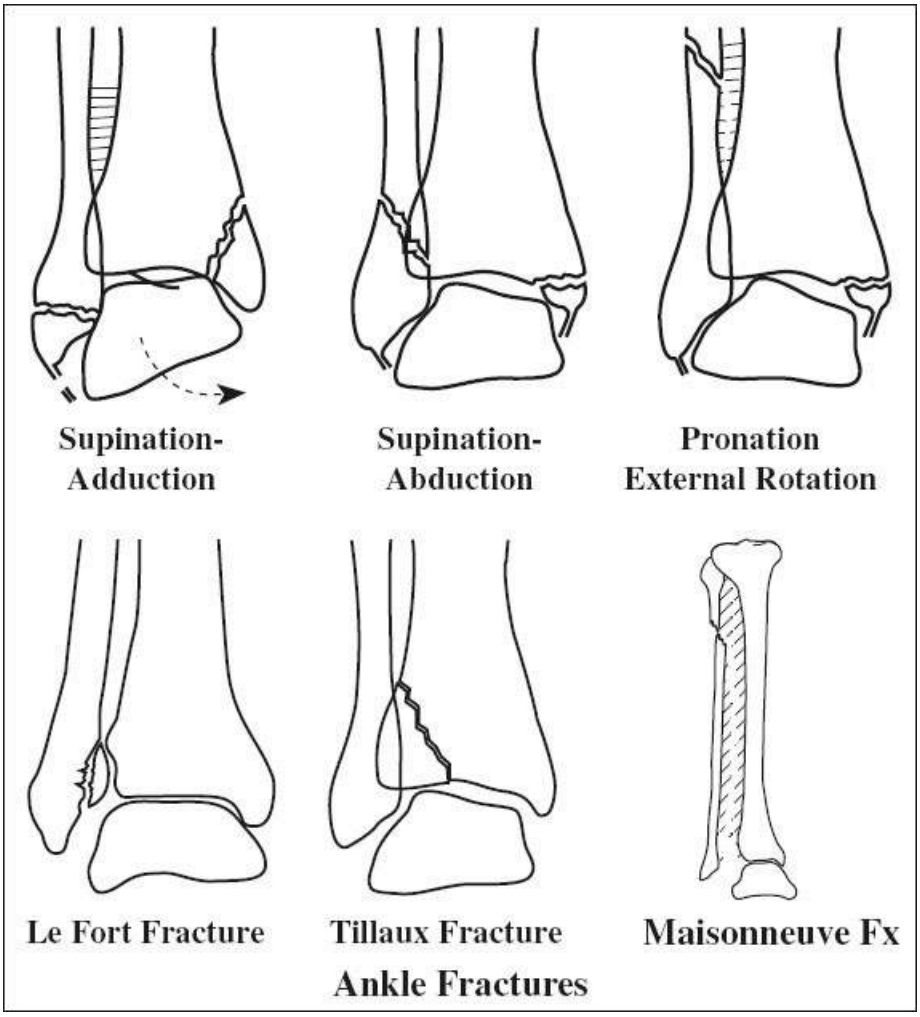
(a) **Tillaux Fracture**

[Paul Jules Tillaux (1834–1904), French surgeon and anatomist]

√ avulsion injury of anterior tibial tubercle at attachment of distal anterior tibiofibular ligament

√ type 3 epiphyseal plate injury in children

√ CT more sensitive in identification of fracture displacement > 2 mm (cutoff that requires reduction)



(b) **Maisonneuve Fracture**
[Jacques Gilles Maisonneuve (1809–1897), student of Dupuytren]
√ tear of distal tibiofibular syndesmosis + interosseous membrane
√ spiral fracture of upper third of fibula
√ associated fracture of medial malleolus / rupture of deep deltoid ligament

Calcaneal Fracture

Frequency: most commonly fractured tarsal bone; 60% of all tarsal fractures; 2% of all fractures in the body; commonly bilateral
Mechanism: fall from heights (axial overload)
In 10% associated with: thoracolumbar compression fracture
Age: 95% in adults, 5% in children
› adulthood: intraarticular (75%), extraarticular (25%)
› childhood: extraarticular (63–92%)
Classification:
(a) extraarticular fracture (25%) = no involvement of posterior talar facet:
› anterior process fracture
› fracture of mid calcaneus (body, sustentaculum tali, peroneal tubercle, lateral

calcaneal process)
› fracture of posterior calcaneus (tuberosity, medial calcaneal tubercle)

(b) intraarticular fracture (75%)
› subtalar joint involvement: undisplaced, displaced, comminuted
› calcaneocuboid joint involvement

Sanders Classification of intraarticular fractures (correlates with prognosis):

Technique: CT with image reformation parallel + per-pendicular to posterior facet of subtalar joint

Type I	nondisplaced (< 2 mm) fracture
Type II	2 articular fragments
Type IIA	laterally located fracture line
Type IIB	centrally located fracture line
Type IIC	medially located fracture line
Type III	3 articular fragments
Type IIIAB	lateral+ central fracture line
Type IIIAC	lateral + medial fracture line
Type IIIBC	central + medial fracture line
Type IV	> 3 intraarticular fracture lines

√ apex of lateral talar process does not point to "crucial angle" of Gissane
√ Böhler angle decreased below 28°–40°

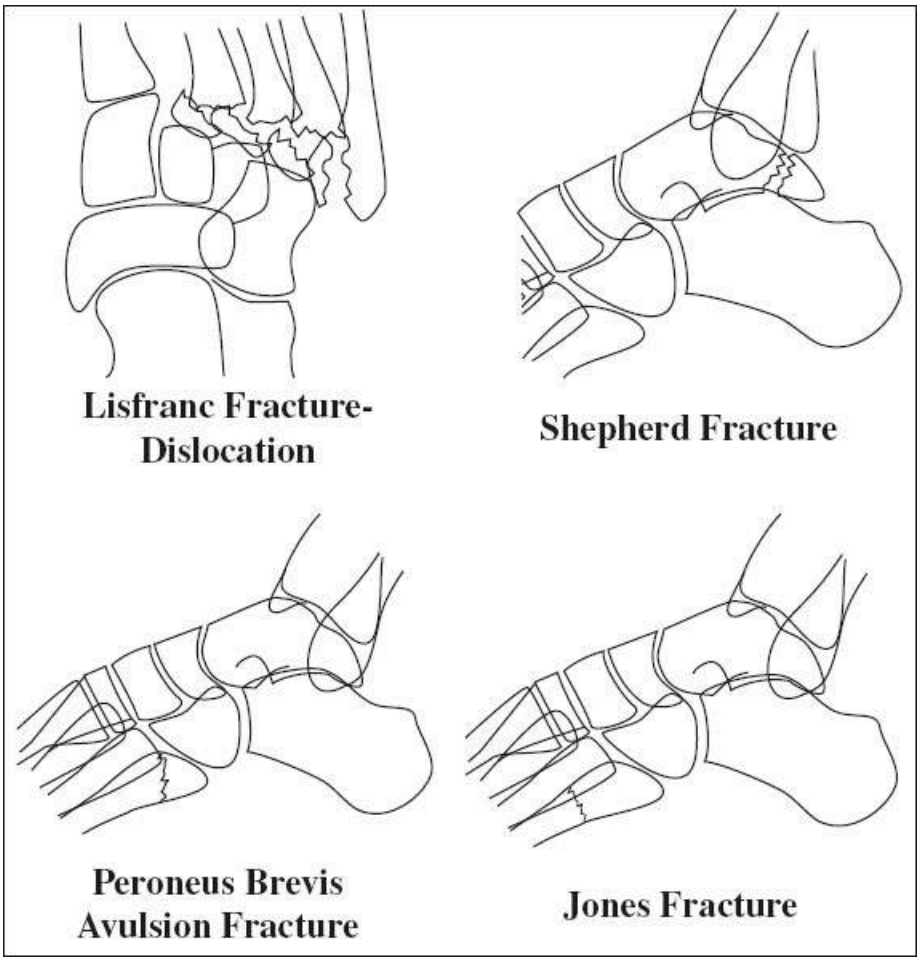
Chopart Fracture

[François Chopart (1743–1795), surgeon in Paris, France]
√ fracture-dislocation through midtarsal / Chopart (calcaneocuboid + talonavicular) joint
√ commonly associated with fractures of the bones abutting the joint

Jones Fracture

[Robert Jones (1857–1933), British orthopedic surgeon and pioneer in radiology described fracture in Ann Surg 1902]

Mechanism: adduction of forefoot with ankle in plantar flexion
√ transverse fracture at base of 5th metatarsal bone at junction of diaphysis and metaphysis (> 1.5 cm distal to proximal tip of metatarsal tuberosity)
Cx: delayed union / nonunion (poor blood supply)



Lisfranc Fracture

[Jacques Lisfranc de Saint Martin (1787–1847), field surgeon in Napoleon's army]

Mechanism: metatarsal heads fixed and hindfoot forced plantarward and into rotation

√ fracture-dislocation / fracture-subluxation of tarsometatarsal joints (typically 2 through 5)

√ lateral displacement of metatarsals

Peroneus Brevis Avulsion Fracture

= METATARSAL 5 TUBEROSITY FRACTURE

◊ Most common fracture of the proximal 5th metatarsal bone

Mechanism: plantar flexion + inversion (stepping off a curb)

√ transverse avulsion fracture of base of 5th metatarsal bone

Location: proximal to metatarsal tuberosity (insertion of peroneus brevis tendon); usually extraarticular

DDx: Jones fracture (slightly different location)

Shepherd Fracture

[Francis J. Shepherd (1851–1929), demonstrator in anatomy at McGill University in Montreal, Canada]

√ fracture of lateral tubercle of posterior process of talus

DDx: os trigonum

FROSTBITE

Cause: (1) cellular injury + necrosis from freezing process
(2) cessation of circulation ← cellular aggregates and thrombi forming as a result of exposure to low temperatures below –13° C (usually cold air)

• firm white numb areas in cutis (separation of epidermal-dermal interface)

Location: feet, hands (thumb commonly spared ← protection by clenched fist)

Early changes:

√ soft-tissue swelling + loss of tissue at tips of digits

CHILD

√ fragmentation / premature fusion / destruction of distal phalangeal epiphyses
√ secondary infection, articular cartilage injury, joint space narrowing, sclerosis, osteophytosis of DIP
√ shortening + deviation / deformity of fingers

ADULT

√ osteoporosis (4–10 weeks after injury)
√ periostitis
√ acromutilation ← osteomyelitis + surgical removal + tuftal resorption ← soft-tissue loss
√ small round punched-out areas near edge of joint
√ interphalangeal joint abnormalities (simulating osteoarthritis)
√ calcification / ossification of pinna

Angio:

√ vasospasm, stenosis, occlusion
√ proliferation of arterial + venous collaterals (in recovery phase)

Bone scintigraphy:

√ persistent absence of uptake (= lack of vascular perfusion) indicates nonviable tissue

Rx: selective angiography with intraarterial reserpine

GANGLION

Origin: coalescence of smaller cysts formed by myxomatous degeneration of periarticular connective tissue

Path: capsule of dense fibrous connective tissue

Histo: no synovial lining (frequent lack of communication with joint, infrequent association with joint / tendon sheath effusion)

Cause: repetitive stress

Location: joint capsule, tendon sheath, ligament, bursa, intraarticular, subchondral intraosseous, periosteal

Prognosis: symptomatic; bone erosion; spontaneous resolution frequent in pediatric cases

DDx: Synovial cyst (differentiation from ganglion cyst radiologically not possible)

Soft-tissue Ganglion

= cystic tumorlike lesion usually attached to a tendon sheath

Frequency: 50% of adult wrists

• asymptomatic / pain
• uni- / multilocular swelling
Location: periarticular hand, wrist, foot (over dorsum)
Site: arise from tendon, muscle, semilunar cartilage
√ soft-tissue mass with surface bone resorption
√ periosteal new-bone formation
√ arthrography may demonstrate communication with joint / tendon sheath
√ internal septations
√ lobulated configuration with peripheral fluid-filled pseudopodia ("bunch of grapes")
√ hypointense relative to muscle / hyperintense cyst content (high mucinous content, hemorrhage) on T1WI
√ hyperintense relative to fat on T2WI
√ no enhancement
Prognosis: may resolve spontaneously
Rx: steroid injection may improve symptomatology

Intraosseous Ganglion

= benign subchondral radiolucent lesion WITHOUT degenerative arthritis
• mild localized pain (in 4% of unexplained wrist pain)
Age: middle age
Origin: (1) mucoid degeneration of intraosseous connective tissue (perhaps due to trauma / ischemia)
(2) penetration of juxtaosseous soft-tissue ganglion (= synovial herniation) into underlying bone (occasionally)
Path: uni- / multilocular cyst surrounded by fibrous lining, containing gelatinous material
Location:
(a) epiphysis of long bone
1. proximal tibia (at attachment of cruciate ligaments)
2. medial malleolus
3. femoral head
4. carpal bones

(b) subarticular flat bone (acetabulum)
√ well-demarcated solitary 0.6–6 cm lytic lesion
√ sclerotic margin
√ NO communication with joint
√ increased radiotracer uptake on bone scintigraphy (in 10%)
DDx: posttraumatic / degenerative cyst

Periosteal Ganglion

= cystic structure with viscid / mucinous contents
Prevalence: 11 cases in literature
Age: 39–50 years; M > F
• swelling, mild tenderness
Location: long tubular bones of lower extremity
√ cortical erosion / scalloping / reactive bone formation

√ NO intraosseous component (endosteal surface intact)

CT:

√ well-defined soft-tissue mass adjacent to bone cortex with fluid contents

MR:

√ homogeneously isointense compared to muscle on T1WI

√ homogeneously hyperintense compared to fat on T2WI

√ NO internal septations (DDx to soft-tissue ganglion)

DDx: periosteal chondroma without matrix calcification, cortical desmoid, subperiosteal aneurysmal bone cyst, acute subperiosteal hematoma (history of trauma / blood dyscrasia), subperiosteal abscess (involvement of adjacent bone marrow)

Rx: surgical excision (local recurrence possible)

GAUCHER DISEASE

[Philippe Charles Ernest Gaucher (1854–1918), French dermatologist]

= rare autosomal recessive / dominant (in a few) lipid storage disorder; the most common lysosomal storage disorder;

Prevalence: 1÷50,000–100,000 (general population); 1÷500–1,000 (in Ashkenazi Jews); M = F

Etiology: deficiency of lysosomal hydrolase acid β-glycosidase (= b-glucocerebrosidase) → accumulation of glucosylceramide (glucocerebroside) within macrophages of RES (liver, spleen, bone marrow, lung, lymph nodes)

Histo: bone-marrow aspirate shows Gaucher cells (kerasin-laden histiocytes) of 20–100 μm in diameter with a foamy wrinkled-paper appearance

Clinical types:

(1) Adult / chronic nonneuropathic form = type 1 (most common form in USA)

Age of onset: 3rd–4th decade

• no clinical signs (most)

Prognosis: longest time of survival; pulmonary involve-ment / hepatic failure may lead to early death

(2) Rapidly fatal infantile / acute neuropathic form = type 2

Age of onset: 1–3–12 months

• early onset of significant hepatosplenomegaly

• severe progressive neurologic symptoms: seizures, mental retardation, strabismus, spasticity

√ skeletal manifestations are rare

Prognosis: fatal during first 2 years of life

(3) Juvenile / subacute neuropathic form = type 3 (rarest type)

Age of onset: 2–6 years

• variable hepatosplenomegaly

• mild neurologic involvement: seizures

√ delayed onset of skeletal manifestations

Prognosis: survival into adolescence

• hepatosplenomegaly, impairment of liver function, ascites

• elevated serum acid phosphatase

- pancytopenia, anemia (chronic fatigue), leukopenia, thrombocytopenia (easy bruising, hypersplenism)
- hemochromatosis (yellowish brown pigmentation of conjunctiva + skin)
- dull bone pain (bone involvement in 75%)

Location: predominantly long tubular bones (distal femur), axial skeleton, hip, shoulder, pelvis; bilateral

√ generalized osteopenia (decrease in trabecular bone density):
  √ striking cortical thinning + bone widening
  √ endosteal scalloping ← marrow packing
√ numerous sharply circumscribed lytic lesions resembling metastases / multiple myeloma (marrow replacement)
√ periosteal reaction = cloaking
√ Erlenmeyer flask deformity of distal femur + proximal tibia ← marrow infiltration (MOST CHARACTERISTIC)
√ weakening of subchondral bone:
  √ osteonecrosis (common, frequently of femoral head)
  √ degenerative arthritis
√ bone infarcts in long-bone metaphyses (most common in femoral + humeral heads):
  √ focal / serpentine areas of sclerosis
  √ bone-within-bone appearance
√ H-shaped / "step-off" / biconcave "fish-mouth" vertebrae (DDx: sickle cell disease)

MR:
  √ focal / diffuse replacement of adipocytes in bone marrow by Gaucher cells results in decreased marrow signal on T1WI + T2WI (marrow involvement follows the distribution of hematopoietic marrow in spine, pelvis, proximal femoral metaphysis; from proximal to distal in appendicular skeleton):
    √ epiphyses generally not involved
  √ myelofibrotic marrow of low SI on T1WI + T2WI (in long-standing disease)

@ Liver
  √ hepatomegaly
  √ nonspecific fatty + cirrhotic changes
  √ focal lesions hypointense on T1WI + hyper- to isointense on T2WI

@ Spleen
  √ splenomegaly + lymphadenopathy
  √ multiple nodular lesions (= clusters of RES cells laden with glucosylceramide):
    √ hypodense without enhancement on CT
    √ hypoechoic / hyperechoic on US
    √ slightly hypo- to isointense on T1WI
    √ hypointense (Gaucher cells / fibrosis) or hyperintense (dilated sinusoids filled with blood around Gaucher cell infiltrates) on T2WI
  √ splenic infarcts leading to fibrosis, especially in massively enlarged spleen

@ Lung
  √ normal
  √ nonspecific diffuse reticulonodular / miliary infiltrates at lung bases (= infiltration with Gaucher cells)

Dx: elevated serum activity of β-glucocerebrosidase; genotyping

Cx: ◊ > 90% have orthopedic complications at some time

(1) Pathologic fractures + compression fractures of vertebrae
(2) Avascular necrosis of femoral head, humeral head, wrist, ankle (common)
(3) Osteomyelitis (increased incidence)
(4) Myelosclerosis in long-standing disease
(5) Repeated pulmonary infections
(6) Cancer of hematopoietic origin (14.7-fold risk)

Prognosis: highly variable clinical course; strong relationship between splenic volume and disease severity

Rx: no cure; bone marrow transplantation; enzyme replacement therapy with Cerezyme®

DDx: metastatic disease, multiple myeloma, leukemia, sickle-cell disease, fibrous dysplasia

GIANT CELL REPARATIVE GRANULOMA

= GIANT CELL REACTION = GIANT CELL GRANULOMA

Cause: ? reactive inflammatory process to trauma / infection (not a true neoplasm)

Histo: numerous giant cells in exuberant fibrous matrix arranged in clusters around foci of hemorrhage + commonly exhibiting osteoid formation (unusual in giant cell tumor); indistinguishable from brown tumor of HPT; cystic degeneration + ABC components distinctly uncommon

Peak age: 2nd + 3rd decade (range, childhood to 76 years); 74% < 30 years of age; M÷F = 1÷1

May be associated with: enchondromatosis, Goltz syndrome, fibrous dysplasia, Paget disease

Location:

@ Gnathic (1–7% of all benign oral tumors): gingiva + alveolar mucosa of mandible, maxilla
(a) central type = in bone
(b) peripheral type = in gingival soft tissue
M÷F = 1÷2
• nonspecific pain + swelling (increasing during pregnancy)
√ expansile bone remodeling with multilocular appearance
√ thinned usually intact cortex
DDx: indistinguishable from odontogenic cyst, ABC, ameloblastoma, odontogenic myxoma, odontogenic fibroma

@ Small bones of hand + feet (less common): phalanges of hand > metacarpals > metatarsals > carpal bones > tarsal bones > phalanges of foot
M÷F = 1÷1
• nonspecific pain + swelling for months to years
Site: metaphysis ± extension into diaphysis; extension into epiphysis is UNCOMMON
√ expansile lytic defect of 2–2.5 cm in diameter with internal trabeculations
√ thinning of overlying cortex
√ matrix mineralization may be seen (DDx to GCT)
√ periosteal reaction is unusual (as in GCT)
√ extension beyond cortex is unusual

@ Other locations (rare):
ethmoid sinus, sphenoid sinus, temporal bone, skull, spine, clavicle, tibia, humerus, ribs,

femur

Cx: pathologic fracture

Prognosis: may recur; no malignant transformation

Rx: curettage (22–50% recurrence rate) / local excision

DDx: (1) Enchondroma (same location, matrix calcification)

(2) Aneurysmal bone cyst (rare in small bones of hand + feet, typically prior to epiphyseal closure)

(3) Giant cell tumor (more aggressive appearance)

(4) Infection (clinical)

(5) Brown tumor of HPT (periosteal bone resorption, abnormal Ca + P levels)

GIANT CELL TUMOR

= OSTEOCLASTOMA = OSTEOBLASTOCLASTOMA = TUMOR OF MYELOPLEXUS

= nonmineralized eccentric lytic meta-epiphyseal lesion involving a long bone with extension to subarticular bone in the skeletally mature patient (= with closed physis)

Origin: probably arises from zone of intense osteoclastic activity (of endochondral ossification) in skeletally immature patients

Frequency: 5% of all primary bone tumors; 20% of benign skeletal tumors; unusually high prevalence in China + southern India

Path: friable vascular stroma of numerous thin-walled capillaries with necrosis + hemorrhage + cyst formation (DDx: aneurysmal bone cyst without solid areas)

Histo: large number of multinucleated osteoclastic giant cells in a diffuse distribution in a background of ovoid mononuclear cells intermixed throughout a spindle cell stroma (DDx: giant cells characteristic of all reactive bone disease as in pigmented villonodular synovitis, benign chondroblastoma, nonosteogenic fibroma, chondromyxoid fibroma, fibrous dysplasia)

Peak age: 3rd (range, 2nd–4th) decade; < 3% below age 14; 80% between 20 and 50 years; 13% > age 50; M÷F = 1÷1.1 to 1÷1.5 (in spine 1÷2.5)

May be associated with: Paget disease located in skull + facial bones (50–60%), pelvis, spine

Hormonal stimulation: occasionally dramatic increase in size during pregnancy

Staging:

Stage 1 indolent radiographic + histologic appearance (10–15%)

Stage 2 more aggressive radiographic appearance with expansile remodeling (70–80%):

√ wide zone of transition
√ cortical thinning
√ expansile remodeling
√ cortical bone destruction

Stage 3 extension into adjacent soft tissues with histologically benign appearance (10–15%)

- pain at affected site (most common – in 10% pathologic fracture)
- local swelling + tenderness
- weakness + sensory deficits (if in spine)

Location:

@ long bones (75–90%)

› lower extremity:

(a) about knee (50%–65%):
» distal end of femur (23–30%)
» proximal end of tibia (20–25%)
(b) away from knee: proximal femur (4%) > distal tibia (2–5%) > proximal fibula (3–4%) > foot (1–2%)
rare: patella (the largest sesamoid bone), greater trochanter (epiphyseal equivalent)

› upper extremity (away from elbow): distal end of radius (10–12%) > proximal end of humerus (4–8%) > hand & wrist with predilection for metacarpal bones (1–5%)

@ flat bones (15%)
› pelvis: upper sacrum near SIJ (4%), iliac bone (3%) ← Paget disease
◊ 2nd most common primary sacral neoplasm after chordoma!
› rib (anterior / posterior end)
› skull (sphenoid bone) ← Paget disease
› scapula (< 1%)

@ spine (3–7%): lumbar > thoracic > cervical spine (2nd most frequent tumor after chordoma); vertebral body and pedicles (21%); frequent involvement of posterior arch

Site:
(a) eccentric metaepiphyseal (42–93%) = in metaphysis of long bones adjacent to ossified epiphyseal line
(b) extension to within 1 cm of subarticular bone (85–99%) after fusion of epiphyseal plate (MOST TYPICAL)
(c) intraarticular extension possible / transarticular spread (rare)

◊ The open epiphyseal plate acts as a barrier to tumor growth!

X-Ray:
√ well-circumscribed expansile solitary lytic bone lesion:
√ nonsclerotic margin ← aggressive rapid growth
√ narrow (80–90%) / (less well-defined) wide zone of transition
√ large lesions more centrally located
√ "soap bubble" appearance (47–60%) = expansile remodeling of multiloculated appearance:
√ NO internal mineralization of tumor matrix
√ prominent trabeculation (33–57%):
(a) reactive with appositional bone growth
(b) pseudotrabeculation of osseous ridges in endosteal scalloping
√ periosteal reaction (10–30%)
√ cortical penetration / disruption (33–50%):
√ cortical thinning
√ soft-tissue invasion (25%)
√ complete / incomplete pathologic fracture (11–12–37%)
√ may cross joint space in long bones (exceedingly rare)
@ Spine & sacrum (< 3%)
√ destruction of vertebral body with secondary invasion of posterior elements (DDx: ABC, osteoblastoma):

- √ purely osteolytic / with cortical expansion
- √ absence of mineralization
- √ lack of a sclerotic rim at tumor margins

√ frequently vertebral collapse
√ may involve adjacent vertebral disks + vertebrae
√ commonly involving both sides of the midline
√ joint transgression is unusual except for sacroiliac joint (38%) with sacral lesion
√ extraosseous involvement of soft tissues (79%)

NUC:
√ diffusely increased uptake on delayed bone scintigraphy
√ "doughnut" sign (57%) of central photopenia ← osteolysis / central necrosis
√ increased uptake across an articulation + in adjacent joints (62%) ← increased blood flow + disuse osteoporosis and NOT secondary to tumor extension

Angio:
√ hypervascular (60–65%) / hypovascular (20%) / avascular (10%) lesion

CT:
√ tumor of soft-tissue attenuation similar to muscle with foci of low attenuation (hemorrhage / necrosis):
- √ NO matrix mineralization

√ well-defined margins ± thin rim of sclerosis (in up to 20%)
√ soft-tissue extension (33–44%) usually at metaphyseal end of tumor
√ secondary ABC (aneurysmal bone cyst) components of low density with fluid-fluid levels (in up to 14%)
√ significant enhancement

MR: (nonspecific!)
√ low to intermediate SI on T1WI ± areas of hyperintensity ← recent hemorrhage
√ relatively well-defined heterogeneous lesion with low to intermediate SI on T2WI (63–96%) ← increased cellularity + high collagen content + hemosiderin
- ◊ HELPFUL feature to distinguish from other subarticular lesions (solitary subchondral cyst, intraosseous ganglion, Brodie abscess, clear cell chondrosarcoma with hyperintense matrix on T2WI)

√ focal aneurysmal bone cyst components with fluid-fluid level (in 14%) in tumor center with marked hyperintensity on T2WI
- ◊ Direct biopsy toward peripheral solid-tissue component to prevent misdiagnosis!

√ ± low-signal-intensity margin ← pseudocapsule
√ significant enhancement of solid-tissue component

Cx: in < 1% malignant transformation into high-grade sarcoma within first 9 years (M÷F = 3÷1) after radiation treatment / spontaneously after 19 years

Prognosis: ± locally aggressive; 10–20–90% recurrence rate within first 3 years after initial treatment

Dx: core needle / open bone biopsy

Rx: arterial embolization before surgery / for palliation; curettage + bone grafting (40–60% recurrence); curettage with filling of void with high-speed burr and polymethylmethacrylate (15–25% recurrence); wide resection (7% recurrence) + reconstruction with allografts / metal prosthesis; radiation therapy for inoperable GCT

(39–63% recurrence); denosumab

DDx: (1) Aneurysmal bone cyst (contains only cystic regions without enhancing soft-tissue component; in posterior elements of spine)

(2) Brown tumor of HPT (lab values, multicentric)

(3) Expansile lytic bone metastasis (primary renal / thyroid carcinoma)

(4) Plasmacytoma / multiple myeloma

(5) Chondroblastoma (extensive surrounding soft-tissue + marrow edema, sclerotic margin, central "rings-and-arcs" matrix)

(6) Clear cell chondrosarcoma

(7) Osteosarcoma subtypes: telangiectatic, giant cell-rich, fibroblastic

(8) Osteoblastoma

(9) Nonossifying fibroma

(10) Bone abscess

(11) Hemangioma

(12) Fibrous dysplasia

(13) Giant cell reparative granuloma

Benign Metastasizing Giant Cell Tumor (1–6%)

Cause: locally aggressive lesion / local recurrence / lesion of distal radius

√ lung metastasis

Multifocal Giant Cell Tumor

= additional GCTs (up to a maximum of 20) developing synchronously / metachronously for up to 20 years without increased risk of pulmonary metastases

Frequency: < 1% of all GCT cases

Age: 25 years (range, 11–62 years); M< F

May be associated with:

Paget disease, usually polyostotic (GCT develops at a mean age of 61 years + after an average time lapse of 12 years) with involvement of skull + facial bones

Location: increased prevalence for hands + feet

Malignant Giant Cell Tumor

= group of giant cell–containing lesions capable of malignant behavior + pulmonary metastases

Prevalence: 5–10% of all GCTs

Age: older than patients with benign GCTs

Types:

(1) Benign metastasizing GCT

Prevalence: 1–5%

√ pulmonary metastases may remain stable / regress spontaneously

√ pulmonary nodules may show peripheral ossification

Prognosis: death in 13%

(2) Primary malignant transformation of GCT

= malignant tumor of bone composed of sarcomatous growth juxtaposed to zones of typical benign GCT without a history of radiation therapy / repeated curettage / resection

Prognosis: median survival time of 4 years

(3) Secondary malignant GCT (86%)

= sarcomatous growth that occurs at a site of previously documented GCT usually after radiation therapy (80%) / repeated resections

Prognosis: median survival time of 1 year

(4) Osteoclastic (giant cell) sarcoma

= highly malignant tumor composed of anaplastic osteoclast-like giant cells without tumor osteoid / bone / cartilage

GOLTZ-GORLIN SYNDROME

= FOCAL DERMAL HYPOPLASIA

= X-linked dominant connective tissue genodermatosis

Genetics: defect in PORCN gene encoding a key protein involved in developmental Wnt signaling pathway

• soft red-yellow nodules in linear arrangement = fat herniating through hypoplastic dermis; short stature

Location: antecubital + popliteal fossa

• CHARACTERISTIC asymmetric erythematous / hyperpigmented / hypopigmented atrophic linear streaks:

• ± telangiectasia (often) ± superficially erosions + ulcers

Age: present at birth

√ scoliosis

√ generalized osteopenia

√ osteopathia striata = bilateral symmetric vertical metaphyseal striations of long bones with sparing of vertebrae and ilia

√ skeletal defects:

Location: hand, foot (60%)

√ "lobster claw" deformity = split hands and feet

√ clinodactyly, oligodactyly, polydactyly, syndactyly

√ regional asymmetric underdevelopment

√ spina bifida

√ rib and clavicular abnormalities

GLOMUS TUMOR

= rare small benign hamartoma of digits

Origin: cells derived from neuromyoarterial apparatus (responsible for thermoregulation in skin)

Glomus body = encapsulated oval organ of 300 µm length; located in reticular dermis (= deepest layer of skin); concentrated in tips of digits (93–501/cm²)

Components: afferent arteriole, tortuous arteriovenous anastomosis with an anastomotic vessel (= Sucquet-Hoyer canal lined by endothelium + surrounded by smooth

muscle fibers), system of collecting veins, intraglomerular neurovascular reticulum + capsule

Histo: endothelium-lined vascular spaces surrounded by masses of round epitheloid cells with tendency toward spindle form

Subtypes: (a) vascular (b) myxoid (c) solid form

Prevalence: 1–5% of soft-tissue tumors of hand

Age: mostly in 4th–5th decade; M÷F = 1÷1

Location: highly concentrated in digits (75% of glomus tumors)

◊ Account for 1.0–4.5% of all hand tumors

Site: subungual space (65%); multiple tumors in 2.3%

- intense joint tenderness + excruciating pain provoked by temperature sensitivity + mild trauma (on average 4–7 years duration prior to diagnosis); ± nail ridging + discoloration
- Love test = eliciting pain by applying precise pressure with a pencil tip
- Hildreth sign = disappearance of pain after application of a tourniquet proximally on arm (PATHOGNOMONIC)

@ SUBUNGUAL GLOMUS TUMOR

√ increased distance between dorsum of phalanx + underside of nail (25%)

√ extrinsic pressure erosion of adjacent bone (14–25–65%), often with sclerotic border

US:

√ small hypoechoic solid tumor (> 3 mm detectable)

√ ±erosion of underlying phalangeal bone

√ specific hypervascularity on color Doppler

MR:

√ lesion of intermediate / low SI on T1WI

√ homogeneously T2-hyperintense lesion (detectable if > 2 mm in diameter)

√ strong enhancement during arterial phase

√ tumor blush during delayed phase on CEMR images

@ GLOMUS TUMOR OF BONE occasionally within bone

√ resembles enchondroma

DDx: (1) Mucoid cyst (painless, in proximal nail fold, communicating with DIP joint, associated with osteoarthritis)

(2) Angioma (more superficially located)

GOUT

= metabolic disorder characterized by derangement of purine metabolism manifested by:

(1) Hyperuricemia ← ↑ production / ↓ excretion of uric acid exceeding physiologic saturation threshold of urate (around 380 μmol/L)

Kelley-Seegmiller syndrome = partial hypoxanthine-guanine phosphoribosyltransferase (HPRT) deficiency with onset of gout in late childhood

DDx: Lesch-Nyhan syndrome (complete HPRT deficiency)

(2) Deposition of positively birefringent monosodium urate monohydrate (MSU) crystals in synovial fluid

(3) Gross deposits of sodium urate in periarticular soft tissues (synovial membranes, articular cartilage, ligaments, bursae)

(4) Recurrent episodes of arthritis

Age: males > 40 years; gout may occur after menopause

Cause:

A. Primary Gout (90%)

Prevalence: 1–2% of population; M÷F = 20÷1; 5% in postmenopausal women

◊ Most prevalent form of metabolic arthritis in older men

Disturbance:

- overproduction of uric acid ← inborn error of metabolism
- inherited defect in renal urate excretion

(a) Idiopathic (99%)

- normal urinary excretion (80–90%)
- increased urinary excretion (10–20%)

(b) Specific enzyme / metabolic defect (1%)

(1) increased activity of PP-ribose-P synthetase

(2) partial deficiency of hypoxanthine-guanine phosphoribosyltransferase

B. Secondary Gout (10%)

◊ Rarely cause for radiographically apparent disease

(a) increased turnover of nucleic acids:

(1) Myeloproliferative disorders + sequelae of their treatment: polycythemia vera, leukemia, lymphoma, multiple myeloma

(2) Blood dyscrasias: chronic hemolysis

(b) increase in purine synthesis de novo ← enzyme defects:

(1) Glycogen storage disease Type I (von Gierke = glucose-6-phosphatase deficiency)

(2) Lesch-Nyhan syndrome (choreoathetosis, spasticity, mental retardation, self-mutilation of lips + fingertips) ← absence of hypo-xanthine-guanine phosphoribosyltransferase

(c) acquired defect in renal excretion of urates ← reduction in renal function:

(1) Chronic renal failure

(2) Drugs, toxins: lead poisoning

(3) Endocrinologic: myxedema, hypo- / hyperparathyroidism

(4) Vascular: myocardial infarction, hypertension

Histo: tophus (PATHOGNOMONIC LESION) composed of crystalline / amorphous urates surrounded by highly vascularized inflammatory tissue rich in histiocytes, lymphocytes, fibroblasts, foreign-body giant cells (similar to a foreign-body granuloma)

Clinical stages (phases) in chronologic order:

(1) Asymptomatic hyperuricemia: cumulative crystal deposition is frequently clinically silent

(2) **Acute gouty arthritis**

◊ 10% of hyperuricemic individuals develop clinical gout

◊ Gout accounts for 5% of all cases of arthritis

Precipitated by: trauma, surgery, alcohol, dietary indiscretion, systemic infection

Distribution:

(a) monoarticular (90%): lower limb joints 1st MTP joint (= podagra), tarsal joints, ankles, knees → progression to elbows + hands

(b) polyarticular (10%): any joint may be affected

• pain, swelling, erythema of affected joint

Prognosis:

(1) usually self-limited episodes (pain resolving within a few hours / days) without treatment

(2) recurrent longer attacks of acute arthritis → chronic arthropathy+ tophus deposition + renal disease

(3) **Chronic tophaceous gout** (30% within 5 years)

= multiple large aggregates of urate crystals + proteinaceous matrix surrounded by intense inflammatory reaction

Prevalence: < 50% of patients experience acute attacks

Histo: cartilage degeneration + destruction, synovial proliferation + pannus, destruction of subarticular bone + proliferation of marginal bone

Age: 5th–7th decades; M÷F = 20÷1

Distribution: symmetric polyarticular disease (resembling rheumatoid arthritis), asymmetric polyarticular disease, monoarticular disease

Site: intraarticular, extraarticular, intraosseous

Target areas: Achilles tendon, knee extensor mechanism, popliteal tendon

• more severe prolonged attacks

• may ulcerate expressing whitish chalky material

Cx: tendon rupture, nerve compression / paralysis

(4) **Gouty nephropathy** / nephrolithiasis

(a) Acute urate nephropathy

(b) Uric acid urolithiasis

◊ May precede arthritis in up to 20% of cases!

• renal hypertension

• isosthenuria (inability to concentrate urine)

• proteinuria

• pyelonephritis

Cx: increased incidence of calcium oxalate stones (urate crystals serve as a nidus)

Location:

(a) joints: hand + foot (1st MTP joint most commonly affected = **podagra**) > ankle > heel > wrist (carpometacarpal compartment especially common and severe) > finger > elbow; knee; shoulder; sacroiliac joint (15%, unilateral)

[pod = *Greek*, foot; agra = *Greek*, seizing]

◊ Involvement of hip + spine is rare

(b) bones, tendon, bursa

(c) external ear; pressure points over elbow, forearm, knee, foot

◊ Radiologic features present in 45% of afflicted patients but usually not seen until 6–12 years after initial attack!

@ Soft tissues

√ eccentric juxtaarticular lobulated soft-tissue masses (hand, foot, ankle, elbow, knee)

Site: tendency for extensor tendons, eg, quadriceps, triceps, Achilles tendon

√ calcific deposits in periphery of gouty tophi in 50%

(sodium urate crystals are not radiopaque, tophi radio-graphically visible only after

calcium deposition which requires an underlying abnormality of calcium metabolism)
√ bilateral effusion of bursae olecrani (PATHOGNOMONIC), prepatellar bursa
√ aural calcification

@ Joints
√ joint effusion (earliest sign)
√ periarticular soft-tissue nodules
√ preservation of joint space until late in disease
(IMPORTANT CLUE):
√ cartilage destruction (late in course of disease)
√ ABSENCE of periarticular demineralization ← short duration of attacks; important DDx for rheumatoid arthritis)
√ eccentric erosions with thin sclerotic margins:
√ scalloped erosion of bases of ulnar metacarpals
√ chondrocalcinosis (5%):
Location: menisci (fibrocartilage only)
◊ Patients with gout have a predisposition for calcium pyrophosphate dihydrate deposition disease (CPPD)
Cx: secondary osteoarthritis
√ round / oval well-marginated subarticular cysts (pseudotumor) up to 3 cm (containing tophus / urate crystal-rich fluid)
DDx: rheumatoid arthritis (marginal erosions without sclerotic rim, periarticular demineralization)

@ Bone
√ "punched-out" lytic bone lesion ± sclerosis of margin = "mouse / rat bite" erosion ← long-standing soft-tissue tophus
√ "overhanging margin" (40%) = elevated osseous spicule separating tophaceous nodule from adjacent erosion (in intra- and extraarticular locations) (HALLMARK)
√ proliferative bone changes:
√ club-shaped metatarsals, metacarpals, phalanges
√ enlargement of ulnar styloid process
√ diaphyseal thickening
√ ischemic necrosis of femoral / humeral heads
√ intraosseous calcification:
√ punctate / circular calcifications of subchondral / subligamentous regions (DDx: enchondroma)
√ bone infarction ← deposits at vascular basement membrane (DDx: bone island)

@ Kidney
√ renal stones (in up to 20%):
› pure uric acid stones (84%): radiolucent on radiographs, hyperdense on CT
› uric acid + calcium oxalate (4%)
› pure calcium oxalate / calcium phosphate (12%)

US:
√ distended joint capsule
√ intra-articular echogenic material with snowstorm appearance of multiple dotted bright foci ← urate acid crystals movable with transducer pressure

√ sharply defined erosion
√ positive color Doppler signals ← synovitis
√ lobulated echogenic mass(es) ← tophaceous gout

MR:
√ tophus (most frequently) isointense to muscle on T1WI
√ low to intermediate signal intensity on T2WI
√ homogeneous intense enhancement

Dx: needle-shaped negatively birefringent monosodium urate crystals in aspirated joint fluid / tophus

Rx: colchicine, allopurinol (effective treatment usually does not improve roentgenograms)

DDx:
(1) CPPD (pseudogout symptomatology, polyarticular chondrocalcinosis involving hyaline and fibrocartilage + degenerative arthropathy with joint space narrowing)
(2) Psoriasis (progressive joint space destruction, paravertebral ossification, sacroiliac joint involvement)
(3) Rheumatoid arthritis (nonproliferative marginal bone erosions, fusiform soft-tissue swelling, symmetric distribution, early joint-space narrowing, osteopenia)
(4) Septic arthritis (rapid destruction of joint space, loss of articular cortex over a continuous segment)
(5) Amyloidosis (bilateral symmetric involvement, periarticular osteopenia)
(6) Xanthomatosis (laboratory work-up)
(7) Osteoarthritis (symmetric distribution, elderly women)

GRANULOCYTIC SARCOMA

= CHLOROMA = MYELOID SARCOMA = MYELOBLASTOMA
= uncommon extramedullary solid tumor consisting of primitive precursors of the granulocytic series of WBCs (myeloblasts, promyelocytes, myelocytes)

Peak age: 7–8 years; child > adult; M=F

Myeloid sarcoma is a rare extramedullary proliferation of immature myeloid cells occurring in 3–5% of AML patients.

Clinical setting:
(1) patient with acute myelogenous leukemia (in 3–8%)
(2) harbinger of AML in nonleukemic patient: usually developing within 1 year (rare)
(3) indicator of impending blast crisis in CML (in 1%) / leukemic transformation in myelodysplastic syndromes (polycythemia rubra vera, myelofibrosis with myeloid metaplasia, hypereosinophilic syndrome)
(4) during remission of hematologic malignancy (up to 20%)
(5) isolated event

Associated with: chronic myeloid leukemia, myelodysplastic syndrome, essential thrombocythemia, polycythemia vera

• 60% are of green color (chloroma) ← high levels of **myeloperoxidase** (30% are white / gray / brown depending on preponderance of cell type + oxidative state of myeloperoxidase)

Location: often multifocal
(a) common: bone (skull, orbit, paranasal sinus, periosteum); lymph nodes; soft tissues; skin;

breast
(b) less common: GU tract, GI system, head & neck, chest

Site: propensity for bone marrow (arises from bone marrow traversing haversian canal + reaching the periosteum), perineural + epidural tissue

Radiography:
√ osteolysis with ill-defined margins

CT:
√ soft-tissue mass infrequently with bone erosion / demineralization / periosteal reaction
√ generally homogeneously isoattenuating to slightly hyperattenuating relative to muscle / brain
√ homogeneous enhancement on CT / MR (DDx to hematoma / abscess)

MR:
√ iso- to hypointense relative to gray matter / bone marrow / muscle on T1WI
√ heterogeneously iso- to slightly hyperintense on T2WI

Prognosis: poor outcome; resolution under chemotherapy ± radiation therapy; recurrence rate of 23%

DDx: osteomyelitis, histiocytosis X, neuroblastoma, lymphoma, multiple myeloma

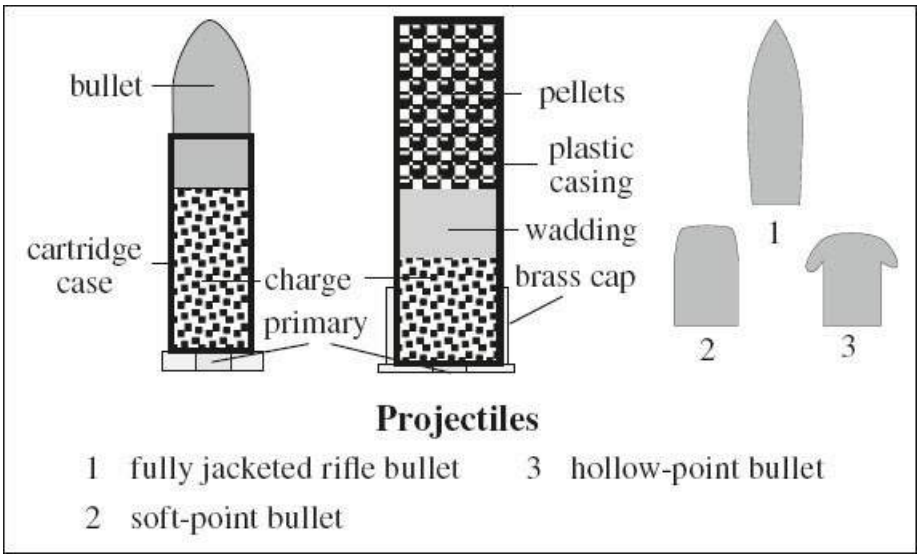
GUNSHOT INJURY

Prevalence: 200,000 gun-related injuries per year; 31,224 firearm-related deaths in USA (2007)

Firearms: handgun, rifle (great energy), shotgun

Projectiles:
(a) bullet:
› jacketed bullet with mantle of copper
› semi jacketed bullet = exposed lead at tip
› non jacketed bullet
(b) pellets of steel / lead:
› birdshot = small pellets
› buckshot =large pellets

Assessment of type of projectile:
√ fully jacketed bullets show no trail of lead fragments
√ semi- / non jacketed bullets distribute lead fragments along bullet track
√ hollow-point bullets transform into mushroom shape
√ "lead snowstorm" of high-velocity soft-point rifle bullets:
√ conical distribution with apex pointing toward entry site
√ steel pellets remain round, lead pellets become deformed + fragmented



Assessment of trajectory:
- √ bullet tips points to entry wound (after tumbling through 180°):
  - √ impact deformation of bullet modifies tumbling
- √ bullet + bone fragments deposited along track
- √ bone fracture beveled toward the direction of travel

Location: liver > small bowel > colon > spleen > kidney > pancreas

Pathophysiology of gunshot: complex interaction of mass, velocity, path, type of organ
- (a) projectile: bullet imparts kinetic energy to surrounding tissue → tissue displacement radially away from path of bullet → temporary cavity much larger than bullet diameter (depending on mass, material, design, velocity of projectile)
- (b) tissue: damage depends on specific gravity (density) and elasticity of type of soft tissue ↓ density + ↑ elasticity: skin, lung (less damage) ↑ density + ↓ elasticity: liver, spleen, muscle
- (c) fluid: pressure wave → bursting of fluid-filled organ
- (d) bone: bone fragments = numerous secondary missiles

Cx: pellet embolization, magnetization in MRI

HEMANGIOENDOTHELIAL SARCOMA

= HEMANGIOENDOTHELIOMA = HEMANGIOEPITHELIOMA

= neoplasm of vascular endothelial cells of intermediate aggressiveness with either benign or malignant behavior

Histo: irregular anastomosing vascular channels lined by one / several layers of atypical anaplastic endothelial cells

Age: 4th–5th decade; M÷F = 2÷1

- history of trauma / irradiation

Kaposiform Hemangioendothelioma

= locally aggressive vascular tumor of infancy

Path: infiltrative growth pattern with predominant Kaposi sarcoma–like content consisting of

fascicles of spindle cells (DDx: hemangioma of infancy)
Histo: fibrinogenic thrombi in capillaries, hemorrhage, foci resembling lymphangiomatosis (⅔)
Age: 1st year of life; present at birth (½)
√ cutaneous thickening, stranding of subcutaneous fat, hemorrhage
√ ill-defined margins ← involvement of multiple tissue planes
√ destructive changes and remodeling of adjacent bone
MR:
√ signal intensity similar to muscle on T1WI
√ heterogeneously hyperintense relative to muscle on T2WI
√ apparent infiltration of subcutaneous tissues
√ signal voids on GRE ← accumulation of blood products
√ diffuse heterogeneous enhancement

Soft-tissue Hemangioendothelioma (common)
Location: deep tissues of extremities
Site: in 50% closely related to a vessel (often a vein)

Osseous Hemangioendothelioma (rare)
= EPITHELIOID HEMANGIOENDOTHELIOMA OF BONE
= rare endothelial intermediate-grade malignant vascular neoplasm
Path: well-circumscribed tumor with irregular borders
Histo: solid nests + anastomosing cords of round polygonal / spindle-shaped cells with eosinophilic cytoplasm; intracytoplasmic vacuolization (= primitive vascular channels); few mitoses, only mild pleomorphism
Average age: 2nd–3rd decade; M÷F = 2÷1
Location: calvarium, spine, pelvis, tibia (23%), femur (18%), humerus (13%); visceral involvement of lung, liver, spleen
◊ Multifocal (> 50%) often with regional distribution (less aggressive)
N.B.: A thorough evaluation requires CT of chest and abdomen + bone scintigraphy + skeletal survey!
Site: metaphyseal / diaphyseal > epiphyseal
• pain + swelling of affected area
X-RAY:
√ eccentric lytic lesion without matrix mineralization
√ osteolytic aggressively destructive area with indistinct margins (high grade)
√ well-demarcated margins with scattered bony trabeculae (low grade)
√ osteoblastic area in vertebrae, contiguous through several vertebrae
√ ± osseous expansile remodeling
CT:
√ cortical disruption with extension into soft tissues
√ joint invasion (common)
√ homogeneous enhancement
MR:
√ low to intermediate signal intensity on T1WI

√ high signal intensity on T2WI
√ homogeneous enhancement
√ no serpentine vascular structures

Metastases to: lung (early)

Prognosis: variable course; poor prognosis with visceral involvement; local recurrence (18%); regional / distant metastasis (31%)

DDx: aneurysmal bone cyst, poorly differentiated fibrosarcoma, alveolar rhabdomyosarcoma, cystic angiomatosis, Langerhans cell histiocytosis, angiosarcoma, osteomyelitis, multiple myeloma, highly vascular metastasis, lymphoma

HEMANGIOMA

= benign nonreactive process involving an increase in number reminiscent of embryonic capillaries or veins

◊ Most common benign soft-tissue tumor of vascular origin!

Prevalence: 1–2% of population (higher in premature infants); in up to 10% of whites

Histo: increased number of thin-walled vessels containing RBCs / transudate lined by flat monolayered endothelial cells; frequently with variable amounts of nonvascular elements (fat, smooth muscle, fibrous tissue, bone, hemosiderin, thrombus)

◊ Fat overgrowth may be so extensive that some lesion may be misdiagnosed as a lipoma!

Age: most common tumor of infancy; present at birth in 30–40% M÷F = 1÷3

Location: lower extremity (common), head & neck (mid cheek, upper lip, upper eyelid)

Site: any soft tissue (eg, muscle), tendon, connective tissue, fatty tissue, synovium, bone

Distribution: focal + localized / diffuse + segmental

• painless mass; red (superficial); flesh colored / blue (deep)

√ multiple variable-sized phleboliths (frequent)

US:

√ partially defined hypoechoic hypervascular solid mass
√ mixed echogenicity ← reactive fat overgrowth
√ intratumoral bright foci of variable size + posterior acoustic shadowing = phleboliths
√ prominent vascular channels
√ abnormal arterial signal of low resistance with continuous forward flow during systole + diastole

MR:

√ mass of intermediate signal intensity on T1WI:
  √ serpentine / lattice-like enhancement
√ mass of extremely high signal intensity on T2WI:
  √ heterogeneous hyperintensity ← reactive fatty tissue around neoplastic vessels / vessels filled with blood
  √ serpentine pattern + flow voids (DDx to rhabdomyosarcoma)
√ well-defined / infiltrative margin
√ foci of low SI on T1WI + T2WI ← phleboliths / calcifications / fibrosis

Prognosis: cellular proliferation + enlargement during 1st year of life

A. CAPILLARY HEMANGIOMA (most common)

= small-caliber vessels lined by flattened epithelium
Site: skin, subcutaneous tissue; vertebral body
Classification:
(a) Juvenile capillary hemangioma
(b) Verrucous capillary hemangioma
(c) Senile capillary hemangioma
√ enlarged arteries + arteriovenous shunting
√ pooling of contrast material

B. CAVERNOUS HEMANGIOMA
= dilated blood-filled spaces lined by flattened endothelium
Site: deeper soft tissues, frequently intramuscular; calvarium
Age: childhood
√ phleboliths = dystrophic calcification in organizing thrombus (in nearly 50%)
√ large cystic spaces
√ enlarged arteries + arteriovenous shunting
√ pooling of contrast material
Prognosis: NO involution

C. ARTERIOVENOUS HEMANGIOMA
= persistence of fetal capillary bed with abnormal communications of an increased number of normal / abnormal arteries and veins
Etiology: (?) congenital arteriovenous malformation
Age: young patients
Site: soft tissues
(a) superficial lesion without arteriovenous shunting
(b) deep lesion with arteriovenous shunting
- limb enlargement, bruit
- distended veins, overlying skin warmth
- Branham sign = reflex bradycardia after compression

√ large tortuous serpentine feeding vessels
√ fast blood flow + dense staining
√ early draining veins

D. VENOUS HEMANGIOMA
= thick-walled vessels containing muscle
Site: deep soft tissues of retroperitoneum, mesentery, muscles of lower extremities
Age: adulthood
√ ± phleboliths
√ serpentine vessels with slow blood flow
√ vessels oriented along long axis of extremity (in 78%) + neurovascular bundle (in 64%)
√ multifocal involvement (in 37%)
√ muscle atrophy with increased subcutaneous fat
√ may be normal on arterial angiography

Osseous Hemangioma

Frequency: 10%
Histo: mostly cavernous; capillary type is rare

Age: 4th–5th decade; M÷F = 2÷1
• usually asymptomatic
@ Vertebra (28% of all skeletal hemangiomas)
Prevalence: in 5–11% of all autopsies; multiple in ⅓
Histo: capillary hemangioma interspersed in fatty matrix
◊ The larger the degree of fat overgrowth, the less likely the lesion will be symptomatic!
Age: any age; young adult; female
Location: in lower thoracic / upper lumbar spine
Site: vertebral body; may extend into posterior elements
• mostly asymptomatic
√ "accordion" / "corduroy" / "honeycomb" vertebra
= coarse vertical trabeculae with osseous reinforcement adjacent to bone rarefaction ← resorption caused by vascular channels (also in multiple myeloma, lymphoma, metastasis)
√ bulge of posterior cortex
√ extraosseous extension beyond bony lesion into spinal canal (with cord compression) / neural foramina
√ paravertebral soft-tissue extension
√ lesion enhancement ← hypervascularity
CT:
√ polka-dot appearance = small punctate areas of sclerosis (= thickened vertical trabeculae)
MR:
√ high signal intensity on T1WI + T2WI ← amount of adipocytes / vessels / interstitial edema (CHARACTERISTIC)
√ thick vertical struts of low SI
√ rarely low / intermediate SI on T1WI (= less fat indicating a more vascular / more aggressive lesion)
NUC:
√ photopenia / moderate increase in radiotracer uptake
Cx: vertebral collapse (unusual), spinal cord compression
@ Calvarium (20% of all hemangiomas)
Location: frontal / parietal region
Site: diploe
√ < 4 cm round osteolytic lesion with sunburst / weblike / spoke-wheel appearance of trabecular thickening
√ expansion of outer table to a greater extent than inner table producing a palpable lump
@ Flat bones & long bones (rare)
› ribs, clavicle, mandible, zygoma, nasal bones, metaphyseal ends of long bones (tibia, femur, humerus)
√ radiating trabecular thickening
√ bubbly bone lysis creating honeycomb / latticelike / "hole-within-hole" appearance
MR:
√ serpentine vascular channels with low SI on T1WI + high SI on T2WI (= slow blood flow) / low SI on all sequences (= high blood flow)

NUC (bone / RBC-labeled scintigraphy):
√ photopenia / moderate increased activity

Intracortical Hemangioma

Histo: expanded haversian canals containing dilated cavernous vessels
Location: tibia > femur, ulna, mandible
√ intracortical osteolytic lesion with vertically aligned intralesional calcifications
√ cortical thickening / periostitis
CT:
√ hypoattenuating intracortical lesion with spotty internal calcification = "wire-netting" appearance
MR:
√ hyperintense lesion with hypointense septa on T2WI
DDx: osteoid osteoma

Soft-tissue Hemangioma

Frequency: 7% of all benign soft-tissue tumors; most frequent tumor of infancy + childhood
Age: primarily in neonates
May be associated with: Maffucci syndrome (= multiple cavernous hemangiomas + enchondromas)
• intermittent change in size; painful
• bluish discoloration of overlying skin (rare)
• may dramatically increase in size during pregnancy
Location: usually intramuscular; synovium (< 1% of all hemangiomas)
√ nonspecific soft-tissue mass
√ infiltrating lesion of serpentine vessels interdigitating with fibroadipose tissue (in cavernous hemangioma)
√ may extend into bone creating subtle rounded / linear areas of hyperlucency (rare)
√ ± longitudinal / axial bone overgrowth ← chronic hyperemia
√ may contain phleboliths (30% of lesions, SPECIFIC)
√ nonspecific curvilinear / amorphous calcifications
√ may contain large amounts of fat → indistinguishable from lipoma
CT:
√ poorly defined mass with attenuation similar to muscle
√ areas of decreased attenuation approximating subcutaneous fat (= fat overgrowth) most prominent in periphery of lesion
MR:
√ poorly marginated mass hypo- / isointense to muscle on T1WI
√ interspersed areas of increased SI on T1WI in periphery of lesion ← fat extending into tumor septa
√ well-marginated markedly hyperintense ("cystic") mass on T2WI (← increased free water content in stagnant blood) with striated / septated configuration
√ tubular structures with blood flow characteristics (flow void / inflow enhancement; avid contrast enhancement)
√ foci of signal voids ← high-flow vascular channels / phleboliths / thrombi

√ high-signal-intensity areas on T1WI + T2WI (= hemorrhage + fat deposition)
√ internal fluid-fluid levels ← high proteinaceous / hemorrhagic content

US:
√ complex mass
√ low-resistance arterial signal (occasionally)

Juvenile Capillary Hemangioma

= STRAWBERRY NEVUS
Prevalence: 1÷200 births; in 20% multiple
Age: usually neonate within 1st week; apparent at birth in only 20%; M÷F = 1÷3 to 1÷5
Histo: neoplastic features of endothelial proliferation
Location: head and neck (60%) > trunk (25%) > extremity (15%)
• "strawberry marks" (= bright red protuberant compressible lesions) of face, scalp, back, anterior chest wall
Prognosis: rapid proliferation from 2–10 months; followed by variable period of stability; slow involution in 75–90% by age 7 years
Indication for imaging:
deep hemangioma, compromise of airway, impaired vision, heart failure, thrombocytopenic coagulopathy
√ flow voids (DDx to rhabdomyosarcoma)
√ T1 shortening during involuting phase ← fatty replacement of nidus
Cx: necrosis of overlying skin / Kasabach-Merritt syndrome (during proliferative phase)
Rx: expectant observation, assurance to parents, steroids, transcatheter embolization

Synovial Hemangioma

= rare benign vascular malformation
Age: child, young adult
• joint pain, swelling ← repetitive bleeding into joint
Location: knee (60%), elbow (30%)
√ phleboliths (not uncommon)
MR:
√ lobulated intraarticular mass
√ intermediate SI on T1WI
√ marked hyperintensity on T2WI ← pooling of blood within vascular spaces
√ linear hypointense structures on T2WI ← fibrous septa / vascular channels
DDx: hemophilic arthropathy (polyarticular)

Lobular Capillary Hemangioma

= PYOGENIC GRANULOMA
= relatively common acquired benign vascular neoplasm of skin + mucous membranes
Cause: presumed neoplastic process; not a reaction to trauma / infection
Path: well-circumscribed lesion with central vessel as branching point for capillary lobules
Histo: lobules of capillaries in an edematous fibromyxoid stroma containing elongated spindle cells with numerous mitotic figures
Average age: 38 (range, 15–60) years; M < F

Location: head, neck, upper extremity (esp. fingers)
- solitary rapidly growing bright red cutaneous mass
- commonly ulcerating + bleeding

US:
√ well-defined mildly to moderately echogenic mass containing small hypoechoic foci
√ prominent tumor vascularity with arterial waveform

MR:
√ lesion isointense on T1WI + hyperintense on T2WI
√ marked enhancement

DDx: true hemangioma, glomus tumor

HEMANGIOPERICYTOMA

= borderline tumor with benign / locally aggressive / malignant behavior (counterpart of glomus tumor)

◊ Clinical behavior + histopathologic features are similar to solitary fibrous tumor

Age: 4th–5th decade; M÷F = 1÷1

Path: large vessels predominantly in tumor periphery

Histo: cells packed around vascular channels containing cystic + necrotic areas closely resembling cellular areas of solitary fibrous tumor; arising from contractile cells that surround the walls of vessels (= Zimmermann pericytes)

May be associated with: hypoglycemia (← overproduction of insulinlike growth factor), arthralgia, osteoarthropathy, digital clubbing

- slow-growing mass ± local mass effect

MR:
√ well-circumscribed solid mass
√ low to intermediate SI on T1WI + T2WI
√ heterogeneously high SI on T2WI ← myxoid / cystic degeneration
√ low signal-intensity rim around lesion (= pseudocapsule) on T2WI

@ Soft tissue
= deep-seated well-circumscribed lesion arising in muscle
Location: lower extremity in 35% (thigh), pelvic cavity, retroperitoneum, head & neck (unlikely), meninges
- painless slowly growing mass up to 20 cm

√ large lobulated well-circumscribed hypervascular mass
√ foci of calcification + areas of necrosis
√ displacement of kidney

@ Breast (extremely rare)

@ Bone (rare)
Location: lower extremity, vertebrae, pelvis, skull (dura similar to meningioma)
√ osteolytic lesion in metaphysis of long / flat bone
√ subperiosteal large blowout lesion (similar to aneurysmal bone cyst)

Angio:
√ displacement of main artery
√ pedicle of tumor feeder arteries

√ spider-shaped arrangement of vessels encircling tumor
√ small corkscrew arteries
√ dense tumor stain

Prognosis: 47–86% 10-year survival rate

DDx: hemangioendothelioma, angiosarcoma

HEMOCHROMATOSIS

= excess iron deposition in tissues (hemosiderosis) resulting in tissue injury

Primary / Idiopathic Hemochromatosis

= autosomal recessive genetic disorder (abnormal iron-loading gene on short arm of chromosome 6) in thalassemia, sideroblastic anemia

Defect: increased absorption + parenchymal accumulation of dietary iron

Organs: liver, pancreas, heart (parenchymal iron overload)

Homozygous frequency: 1÷200; M÷F = 1÷1

Age: > 30 years (M), usually after menopause (F);
◊ Females protected by menstruation

- cirrhosis (frequently present at time of diagnosis)
- "bronzed diabetes" (50%) = insulin-dependent diabetes ← excess intracellular iron reduces function of beta islet cells while reserve capacity of exocrine function is not exceeded by toxic effects of iron; skin pigmentation
- congestive cardiomyopathy ← myocardial muscle accumulates toxic levels of intracellular iron
- hypogonadism + decreased libido ← pituitary dysfunction
- slowly progressive arthritic symptoms (30%)
- increased serum iron + ferritin level (nonspecific)
- transferrin saturation + serum ferritin assay (specific)

@ Skeleton

Distribution: most commonly in hands (metacarpal heads, particularly 2nd + 3rd MCP joints), carpal (30–50%) + proximal interphalangeal joints, knees, hips, elbows

√ generalized osteoporosis
√ small subchondral cystlike rarefactions with fine rim of sclerosis (metacarpal heads)
√ arthropathy in 50% (iron deposition in synovium)
√ uniform symmetric joint space narrowing (unusual for degenerative joint disease)
√ enlargement of metacarpal heads:
√ hook-like osteophytes on radial aspect of metacarpal heads (CHARACTERISTIC)
√ chondrocalcinosis in > 60%, knees most commonly affected
(a) calcium pyrophosphate deposition ← inhibition of pyrophosphatase enzyme within cartilage which hydrolyzes pyrophosphate to soluble orthophosphate
(b) calcification of triangular cartilage of wrist, menisci, annulus fibrosus, ligamentum flavum, symphysis pubis, Achilles tendon, plantar fascia

@ Brain

√ marked loss in SI of anterior lobe of pituitary gland ← iron deposition

@ Abdomen

√ decreased T2 signal intensity in liver, pancreas
√ normal SI of spleen on T2WI + T2*WI

Dx: liver biopsy with hepatic iron index > 2 (= iron concentration in μmol/g of dry weight divided by patient's age in years)

Cx: hepatoma in 14% (iron stimulates growth of neoplasms)

Prognosis: death from CHF (30%), death from hepatic failure (25%), death from HCC (in up to 33%)

Rx: (1) Phlebotomy (returns life expectancy to normal if instituted prior to complications)

(2) Screening of family members (gene can be located by human leukocyte antigen typing)

DDx: (1) Pseudogout (no arthropathy)

(2) Psoriatic arthritis (skin + nail changes)

(3) Osteoarthritis (predominantly distal joints in hands)

(4) Rheumatoid arthritis

(5) Gout (may also have chondrocalcinosis)

Secondary Hemochromatosis

= nongenetic iron overload

(1) ineffective erythropoiesis: thalassemia major increases demand for iron resulting in increased absorption + retention of dietary iron

Cx: increase in parenchymal iron

(2) Bantu siderosis = parenchymal + RES iron overload ← extensive use of iron pots for cooking

Transfusional Siderosis

[**siderosis** = exposure to excess iron]

= iron overload of RES (NOT a form of secondary hemochromatosis); iron less toxic

Pathophysiology: large number of damaged erythrocytes from blood transfusions are incorporated into RES cells + undergo lysis with liberation of iron from hemoglobin (extravascular hemolysis)

Organs of RES: Kupffer cells, spleen, bone marrow

√ decreased signal intensity of liver + spleen on T2WI

Iron storage capacity of RES: 10 g (equivalent to 40 units of packed RBCs)

HEMOLYTIC ANEMIA

Cause:

A. Anemia:
   1. Sickle cell disease
   2. Thalassemia
   3. Hereditary spherocytosis
   4. Paroxysmal nocturnal hemoglobulinuria
B. Chronic / severe blood loss
C. Marrow replacement by neoplastic cells

D. Treatment with GCSF (= granulocyte-macrophage colony-stimulating factor)

Reconversion = recruitment of yellow marrow for hematopoiesis once hematopoietic capacity of existing red marrow stores is exceeded

Order of reconversion: spine > flat bones > skull > long bones (proximal > distal metaphysis > diaphysis > epi- / apophyses)

MR:

√ SI of hyperplastic marrow similar to muscle on T1WI + T2WI + STIR

√ red marrow hypointense relative to fat on T2WI

√ low SI of renal cortex on T1WI + T2WI ← hemosiderin deposition (after intravascular hemolysis)

Cx:

(1) **Hemosiderosis** (histologic term of iron deposition in tissue) = excess iron in cells of RES ← repeated blood transfusions

√ magnetic susceptibility effects of hemosiderin produce hypointense marrow on T2WI (+ T1WI if hemosiderosis severe)

(2) Medullary infarction (common in sickle cell disease)

DDx: leukemia (hyperintense on STIR)

HEMOPHILIA

= X-linked deficiency / functional abnormality of coagulation factor VIII (= hemophilia A) in > 80% / factor IX (= hemophilia B = Christmas disease)

Prevalence: 1÷10,000 males

Hemophilic Arthropathy (most common)

Cause: repeated bleeding into synovial joint

Path: pannus formation erodes cartilage with loss of sub-chondral bone plate and formation of subarticular cysts

Histo: synovial hyperplasia, chronic inflammatory changes, fibrosis, siderosis of synovial membrane

Age: 1st and 2nd decade

• tense red warm joint with decreased range of motion ← muscle spasm; fever, elevated WBC (DDx: septic arthritis)

Location: knee > ankle > elbow > shoulder; commonly bilateral although bleeding episodes tend to recur within same joint

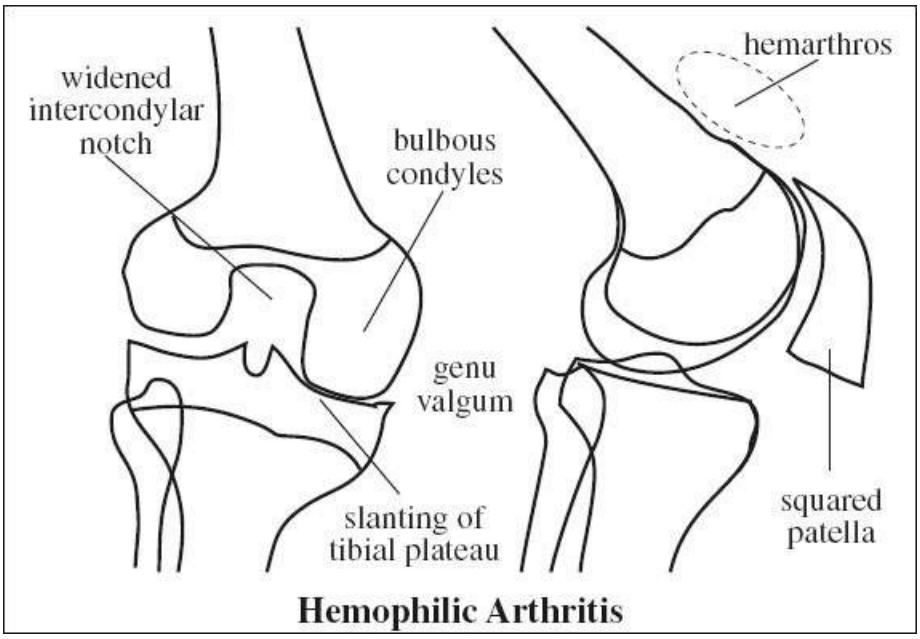
√ joint effusion (= hemarthrosis)

√ enlargement of epiphysis ← synovial inflammation with hyperemia)

√ juxtaarticular osteoporosis ← synovial inflammation with hyperemia

√ joint space narrowing (particularly patella) ← cartilaginous denudation

√ erosion of articular surface with multiple subchondral cysts



Hemophilic Arthritis

√ sclerosis + osteophytosis ← superimposed degenerative joint disease

@ Knee

√ "squared" patella

√ widening of intercondylar notch

√ flattening of condylar surface

√ medial "slanting" of tibiotalar joint

MR:

√ low SI of hypertrophied synovial membrane on all pulse sequences ← magnetic susceptibility effect of hemosiderin

√ varying intensity of subarticular defects (depending on substrate: fluid / soft tissue / hemosiderin)

Hemophilic Pseudotumor (1–2%)

= posthemorrhagic cystic swelling within muscle + bone characterized by pressure necrosis + destruction

(a) juvenile form = usually multiple intramedullary expansile lesions without soft-tissue mass in small bones of hand / feet (before epiphyseal closure)

(b) adult form = usually single intramedullary expansile lesion with large soft-tissue mass in ilium / femur

(c) soft-tissue involvement of retroperitoneum (psoas muscle), bowel wall, renal collecting system

√ mixed cystic expansile lesion

√ bone erosion + pathologic fracture

CT:

√ sometimes encapsulated mass containing areas of low attenuation + calcifications

MR:

√ hemorrhage of varying age

Cx: joint contracture (after repeated bleeding into muscle)
N.B.: Needle aspiration / biopsy / excision may cause fistulae / infection / uncontrolled bleeding!
Rx: palliative radiation therapy (destroys vessels prone to bleed) + transfusion of procoagulation factor concentrate

HEREDITARY HYPERPHOSPHATASIA

= "JUVENILE PAGET DISEASE"
= rare autosomal recessive disease with sustained elevation of serum alkaline phosphatase, especially in individuals of Puerto Rican descent
Histo: rapid turnover of lamellar bone without formation of cortical bone; immature woven bone is rapidly laid down, but simultaneous rapid destruction prevents normal maturation
Age: 1st–3rd year; usually stillborn
• rapid enlargement of calvarium + long bones; dwarfism
• cranial nerve deficit (blind, deaf); hypertension
• frequent respiratory infections; pseudoxanthoma elasticum
• elevated alkaline phosphatase
√ deossification = decreased density of long bones with coarse trabecular pattern
√ metaphyseal growth deficiency
√ wide irregular epiphyseal lines (resembling rickets in childhood), persistent metaphyseal defects (40% of adults)
√ bowing of long bones + fractures with irregular callus
√ widened medullary canal with cortical thinning (cortex modeled from trabecular bone)
√ skull greatly thickened with wide tables, cotton wool appearance
√ vertebra plana
OB-US:
√ diagnosis suspected in utero in 20%
Cx: pathologic fractures; vertebra plana universalis
DDx: (1) Osteogenesis imperfecta
(2) Polyostotic fibrous dysplasia
(3) Paget disease (> age 20, not generalized)
(4) Pyle disease (spares midshaft)
(5) van Buchem syndrome (only diaphyses > age 20, no long-bone bowing)
(6) Engelmann syndrome (lower limbs)

HEREDITARY MULTIPLE DIAPHYSEAL SCLEROSIS

= RIBBING DISEASE
= autosomal recessive disorder of intramembranous ossification similar to progressive diaphyseal dysplasia
Age: after puberty, typically in middle-aged adults
• mild neuromuscular symptoms
Location: typically tibia / femur

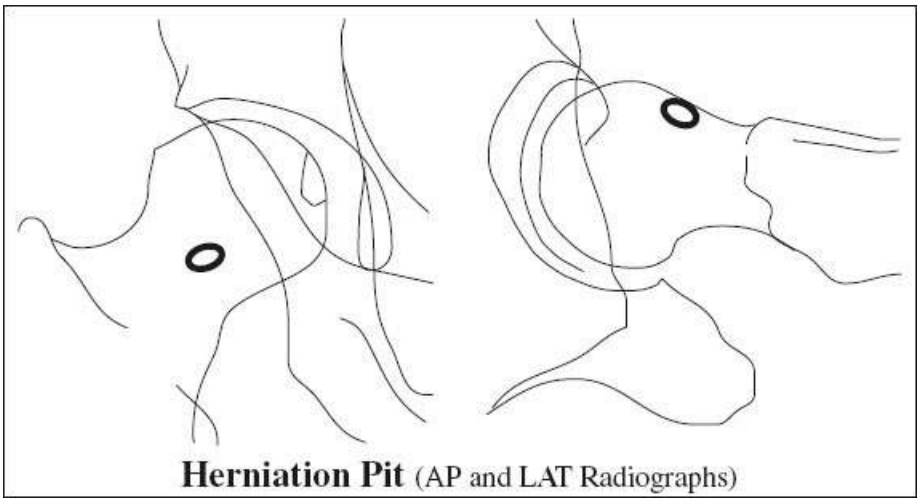
Site: diaphyseal portion of long bones only
Distribution: either unilateral / asymmetric + asynchronous bilateral involvement of long bones
√ cortical thickening of periosteal + endosteal surfaces
√ epiphyses characteristically spared
√ ± narrowing of medullary canal
√ disease may progress slowly and then stabilize
DDx: progressive diaphyseal dysplasia (begins in childhood, severe neuromuscular symptoms, symmetric bilateral sclerosis of long bones, skull involved)

HEREDITARY SPHEROCYTOSIS

= autosomal dominant congenital hemolytic anemia
Age: anemia begins in early infancy to late adulthood
• rarely severe anemia; jaundice; spherocytes in peripheral smear
√ bone changes rare (← mild anemia); long bones rarely affected
√ widening of diploe with displacement + thinning of outer table
√ hair-on-end appearance
Rx: splenectomy corrects anemia even though spherocytemia persists
√ improvement in skeletal changes following splenectomy

HERNIATION PIT

= SYNOVIAL HERNIATION PIT = CONVERSION DEFECT
= ingrowth of fibrous + cartilaginous elements from adjacent joint through perforation in cortex
Histo: fibroalveolar tissue
Age: usually in older individuals
• may be symptomatic; no clinical significance
Location: anterior superolateral aspect of proximal femoral neck; uni- or bilateral
Site: subcortical
Size: usually < 1 cm in diameter; may enlarge over time
√ well-circumscribed round lucency
√ reactive thin sclerotic border
√ hyperintense area on T2WI (= fluid signal intensity)
√ bone scan may be positive



Herniation Pit (AP and LAT Radiographs)

HIBERNOMA

[hibernus, *Latin* = winter]

= rare benign slow-growing soft-tissue tumor composed of brown fat arising in regions in which vestiges of fetal brown fat persist

Histo: admixture of multivacuolar adipocytes (containing multiple granular fine cytoplasmatic vacuoles) + brown fat cells interspersed with univacuolar adipocytes

Age: 20–40 years: M < F

Location: thigh, buttock, scapular region, trunk, neck, mediastinum, chest wall, perirenal, breast, scalp, periureteric region

• painless firm slow-growing mass

• warm overlying skin ← metabolic mitochondrial activity with relatively increased vascularity

Mean size: 9.4 (range, 1–24) cm

√ well-demarcated mass with attenuation and signal intensity between that of subcutaneous fat and muscle

√ varying degrees of internal contrast enhancement

√ no calcifications

US:

√ echogenic mass with well- / ill-defined border

√ increased flow in large surface vessels

CT:

√ well-defined hypoattenuating lesion with intratumoral septa

√ enhancement of septa ± entire mass

MR:

√ usually slightly hypointense relative to subcutaneous fat on T1WI

√ variable intensity on T2WI

√ hyperintense to subcutaneous fat on STIR

√ variable contrast enhancement of septations

√ rarely isointense to subcutaneous fat on all sequences (if multivacuolated adipocytes constitute < 70% of mass)

PET:

√ very high standardized uptake values (SUV): 1.9 – 26.7

HOLT-ORAM SYNDROME

Autosomal dominant; M < F

Associated with CHD: secundum type ASD (most common), VSD, persistent left SVC, tetralogy, CoA

- intermittent cardiac arrhythmia; bradycardia (50–60/min)

Location: upper extremity only involved; symmetry of lesions is the rule; left side may be more severely affected

√ aplasia / hypoplasia of radial structures: thumb, 1st metacarpal, carpal bones, radius
√ absent / "fingerized" hypoplastic / triphalangeal thumb
√ slender elongated hypoplastic carpals + metacarpals
√ hypoplastic radius; absent radial styloid
√ shallow glenoid fossa → voluntary dislocation of shoulder (common)
√ hypoplastic clavicula
√ high arched palate
√ cervical scoliosis
√ pectus excavatum

HOMOCYSTINURIA

Autosomal recessive disorder

Etiology: cystathionine B synthetase deficiency results in defective methionine metabolism with accumulation of homocystine + homocysteine in blood and urine; causes defect in collagen / elastin structure

- thromboembolic phenomena due to stickiness of platelets
- ligamentous laxity
- downward + inward dislocation of lens (DDx: upward + outward dislocation in Marfan syndrome)

Differences between Homocystinuria and Marfan

	Homocystinuria	*Marfan Syndrome*
Inheritance	autosomal recessive	autosomal dominant
Biochemical defect	cystathionine synthetase	not known
Osteoporosis	yes	no
Spine	biconcave vertebrae	scoliosis
Lens dislocation	downward	upward
Arachnodactyly	33%	100%

- mild / moderate mental retardation; malar flush
- crowding of maxillary teeth and protrusion of incisors

√ arachnodactyly in ⅓ (DDx: Marfan syndrome)
√ microcephaly
√ enlarged paranasal sinuses
√ osteoporosis of vertebrae (biconcave / flattened / widened vertebrae)
√ scoliosis

√ pectus excavatum / carinatum (75%)
√ osteoporosis of long bones (75%) with bowing + fracture
√ children: metaphyseal cupping (50%); enlargement of ossification centers in 50% (knee, carpal bones); epiphyseal calcifications (esp. in wrist, resembling phenylketonuria); delayed ossification
√ Harris lines = multiple growth lines
√ genu valgum, coxa valga, coxa magna, pes cavus
√ premature vascular calcifications

Prognosis: death from occlusive vascular disease / minor vascular trauma

HYPEROSTOSIS CORTICALIS GENERALISATA

= GENERALIZED CORTICAL HYPEROSTOSIS = ENDOSTEAL HYPEROSTOSIS
= extremely uncommon homozygous disorder of intramembranous ossification part of craniotubular hyperostoses; may be related to hyperphosphatasemia

Classification:

(1) **Van Buchem disease** (autosomal recessive)
[Franciscus Stephanus Petrus (Frans) van Buchem (1897–1979), Dutch internist]
• facial nerve palsy

(2) Truswell-Hansen disease = sclerosteosis (autosomal recessive)
• progressive facial nerve palsy
• syndactyly of 2nd + 3rd digits with nail dysplasia, tall stature

(3) Worth disease (autosomal dominant)
• flattened forehead
• elongated mandible, decreased gonial angle

(4) Nakamura disease (autosomal dominant)
• enlargement of mandible + maxilla with sparing of mandibular rami

Genetics: mutations in Wnt signaling pathway of osteoblasts on chromosome 17q12-q21 → inhibition of formation of a complex composed of 4 proteins (axin, adenomatous polyposis coli, glycogen synthase kinase 3, b-catenin) → proliferation and differentiation of osteoblasts → increased bone formation

• facial distortion; paralysis of facial nerve
• recurring headaches + dizziness ← reduced intracranial space + increased intracranial pressure
• auditory + ocular disturbances (in late teens ← foraminal encroachment)
• increased alkaline phosphatase (in 50%)

Location: skull, mandible, clavicles, ribs, long-bone diaphyses

@ Long bones
√ symmetrical dense homogeneous endosteal cortical thickening of diaphyses of long bones
√ narrowed medullary canals

@ Skull
√ thickening of skull, facial bones, mandible
√ obliteration of diploe

@ Spine
√ increased density of the axial skeleton

√ spinous processes thickened + sclerotic

MR:

√ herniation of cerebellar tonsils

√ subtotal depletion of subarachnoid space

√ distention of subarachnoid space along optic nerve sheaths

DDx: (1) Osteopetrosis (sclerosis of all bones, not confined to diaphyses)

(2) Generalized hyperostosis with pachydermia (involves entire long bones, considerable pain, skin changes)

(3) Hyperphosphatasia (infancy, widened bones but decreased cortical density)

(4) Camurati-Engelmann disease (rarely generalized, involves lower limbs)

(5) Pyle disease (does not involve middiaphyses)

(6) Polyostotic fibrous dysplasia (rarely symmetrically generalized, paranasal sinuses abnormal, skull involvement)

HYPERPARATHYROIDISM

= uncontrolled production of parathyroid hormone

Age: 3rd–5th decade; M÷F = 1÷3

Histo: decreased bone mass ← increased number of osteoclasts + increased osteoid volume (defect in mineralization) + slightly increased number of osteoblasts

- increase in parathyroid hormone (100%)
- increase in serum alkaline phosphatase (50%)
- elevation of serum calcium ← accelerated bone turnover and ↑ calcium absorption + ↓ in serum phosphate (30%)
- hypotonicity of muscles, weakness, constipation, difficulty in swallowing, duodenal / gastric peptic ulcer disease ← hypercalcemia
- polyuria, polydipsia (hypercalciuria + hyperphosphaturia)
- renal colic + renal insufficiency (nephrocalculosis + nephrocalcinosis)
- rheumatic bone pain + tenderness (particularly at site of brown tumor → pathologic fracture)

A. BONE RESORPTION

(a) subperiosteal (most constant + specific finding; virtually PATHOGNOMONIC of hyperparathyroidism):

√ lacelike irregularity of cortical margin; may progress to scalloping / spiculation (pseudoperiostitis)

Site: phalangeal tufts (earliest involvement), radial aspect of middle phalanx of 2nd + 3rd finger beginning in proximal metaphyseal region (early involvement), bandlike zone of resorption in middle / base of terminal tuft, distal end of clavicles, medial tibia plateau, medial humeral neck, medial femoral neck, distal ulna, superior + inferior margins of ribs in midclavicular line, lamina dura of skull and teeth

DDx: acroosteolysis

(b) subchondral:

√ pseudowidening of joint space

√ collapse of cortical bone + overlying cartilage with development of erosion, cyst, joint narrowing (similar to rheumatoid arthritis)

Site: DIP joint (most commonly 4th + 5th digit), MCP joint, PIP joint, distal clavicle, acromioclavicular joint (clavicular side), "pseudowidening" of sacroiliac joint (iliac side), sternoclavicular joint, temporomandibular joint, symphysis pubis, "scalloping" of posterior surface of patella, Schmorl nodes; typically polyarticular

(c) cortical (← osteoclastic activity within haversian canal):
- √ intracortical tunneling
- √ scalloping along inner cortical surface (= endosteal resorption)

(d) trabecular:
- √ spotty deossification with indistinct + coarse trabecular pattern
- √ granular salt and pepper skull
- √ loss of distinction between inner and outer table
- √ ground-glass appearance

(e) subligamentous / subtendinous:
- √ bone resorption with smooth scalloped / irregular ill-defined margins

Site: inferior surface of calcaneus (long plantar tendons + aponeurosis), Achilles tendon, inferior aspect of distal clavicle (coracoclavicular ligament), greater trochanter (hip abductors), lesser trochanter (iliopsoas), anterior inferior iliac spine (rectus femoris), humeral tuberosity (rotator cuff), ischial tuberosity (hamstrings), proximal extensor surface of ulna (anconeus), posterior olecranon (triceps)

B. BONE SOFTENING
- √ basilar impression of skull
- √ wedged vertebrae, kyphoscoliosis, biconcave vertebral deformities
- √ bowing of long bones
- √ slipped capital femoral epiphysis

C. BROWN TUMOR

= OSTEOCLASTOMA = CENTRAL GIANT CELL LESION

= focal osteolytic area with bone swelling

Cause: PTH-stimulated osteoclastic activity (more frequent in 1° HPT; in 1.5% of 2° HPT)

Path: localized replacement of bone by hypervascularized reactive fibrous stroma containing proliferating osteoclasts, osteoblasts and multinucleated giant cells; may become cystic following hemorrhage + necrosis + liquefaction (= osteitis fibrosa cystica)

Histo: differentiation from giant cell tumor not possible

- in patients with long-standing HPT
- hypercalcemia, hypophosphatemia
- elevated levels of parathyroid hormone

Location: rib, metaphysis of long bones (femur), facial bones, jaw, pelvis, axial skeleton

Site: often eccentric / cortical; frequently solitary

- √ expansile lytic cystlike lesion with variably defined margin (DDx: giant cell tumor)
- √ cortical expansion + endosteal scalloping
- √ generalized demineralization of medullary bones of jaw
- √ loss of lamina dura around roots of teeth
- √ no adjacent reactive bone formation

√ destruction of midportions of distal phalanges with telescoping
√ osteolytic vertebra + tumor growth within spinal canal
√ remineralization after parathyroidectomy

D. OSTEOSCLEROSIS

More frequent in 2° HPT

Cause: ? PTH-stimulated osteoblastic activity, ? role of calcitonin (poorly understood)

Site: strong predilection for axial skeleton, pelvis, ribs, clavicles, metaphysis + epiphysis of appendicular skeleton

√ "rugger jersey spine"

E. SOFT-TISSUE CALCIFICATION

More frequent in 2° HPT

• metastatic calcification when Ca x P product > 70 mg/dL

(a) cornea, viscera (lung, stomach, kidney)
(b) periarticular in hip, knee, shoulder, wrist
(c) arterial tunica media (resembling diabetes mellitus)
(d) chondrocalcinosis (15–18%) = calcification of hyaline / fibrous cartilage in menisci, wrist, shoulder, hip, elbow
(e) bilateral basal ganglia, dentate nuclei, peripheral subcortical white matter

Calciphylaxis = calcific uremic arteriolopathy
= systemic medial calcification of arterioles
• subcutaneous necrosis ← ischemia
• ± chronic hemodialysis / recent renal transplantation
√ calcium deposits in kidney, stomach, heart, lung

Prognosis: high mortality

F. EROSIVE ARTHROPATHY

• asymptomatic
√ simulates rheumatoid arthritis with preserved joint spaces

G. PERIOSTEAL NEW-BONE FORMATION

Cause: PTH-stimulation of osteoblasts

Site: pubic ramus along iliopectineal line (most frequent), humerus, femur, tibia, radius, ulna, metacarpals, metatarsals, phalanges

√ linear new bone paralleling cortical surface; may be laminated; often separated from cortex by radiolucent zone
√ increase in cortical thickness (if periosteal reaction becomes incorporated into adjacent bone)

Sequelae:

1. Renal stones / nephrocalcinosis (70%)
2. Increased osteoblastic activity (25%)
   • increased alkaline phosphatase
   (a) osteitis fibrosa cystica
      √ subperiosteal bone resorption + cortical tunneling
      √ brown tumors (primary HPT)
   (b) bone softening
      √ fractures
3. Peptic ulcer disease ← increased gastric secretion from gastrinoma

4. Calcific pancreatitis
5. Soft-tissue calcifications (2° HPT)
6. Marginal joint erosions + subarticular collapse (DIP, PIP, MCP)

Primary Hyperparathyroidism

= pHPT = 1° HPT = hypercalcemia due to autonomous hypersecretion of parathormone by one / more hyperfunctioning parathyroid glands featuring
(1) brown tumor
(2) chondrocalcinosis (20–30%)

◊ requires surgical Rx

Prevalence: 2–3 ÷ 1000 (female) and 1 ÷ 1000 (male)

Incidence: 25 ÷ 100,000 per year; 25–40% incidence of bone lesions in HPT

Etiology: sporadic / familial
(1) Parathyroid adenoma (94%): solitary (90%); double adenomas (4%)
(2) Parathyroid hyperplasia of multiple glands(6%): chief cell (4%); clear cell (2%)
◊ Hereditary disorders often involve multiple-gland hyperplasia
(3) Parathyroid carcinoma (< 1%)

Age: 3rd–5th decade; M÷F = 1÷3

Associated with:
(a) Familial hyperparathyroidism
(b) Multiple endocrine neoplasia syndrome
1. Wermer syndrome = MEA 1 (+ pituitary adenoma + pancreatic islet cell tumor)
2. Sipple syndrome = MEA 2A (+ medullary thyroid carcinoma + pheochromocytoma)

(c) Hyperparathyroidism–jaw tumor syndrome

- asymptomatic (75–80%): more common due to earlier detection ← widespread availability of laboratory screening for hypercalcemia
- symptomatic (20–25%):
  - weakness, easy fatigability, mild depression, anorexia
  - dementia, depression, constipation
  - peptic ulcer disease, pancreatitis, renal calculi
  - diffuse bone + joint pain ← osteitis fibrosa cystica

X-RAY (skeletal involvement in 10–20%):
√ generalized osteopenia
√ thin cortices with lacy cortical pattern ← subperiosteal bone resorption
√ brown tumor (particularly in jaw + long bones)
√ osteitis cystica fibrosa (= intertrabecular fibrous connective tissue)

NUC:
√ bone scan: normal in 80%
√ foci of abnormal uptake: calvarium (especially periphery), mandible, sternum, acromioclavicular joint, lateral humeral epicondyles, hands
√ increased uptake in brown tumors
√ extraskeletal uptake: cornea, cartilage, joint capsules, tendons, periarticular areas, lungs, stomach
√ normal renal excretion [except in stone disease / calcium nephropathy (10%)]
√ ^{99m}Tc-sestamibi parathyroid scintigraphy

Rx: pathologic glands identified by experienced surgeons in 90–95% on initial neck exploration (ectopic + supernumerary glands often overlooked at operation; recurrent hypercalcemia in 3–10%)

Indications for surgery:

(1) serum calcium level 1.0 mg/dL above upper limit of normal
(2) 24-hour urinary calcium level > 400 mg
(3) creatinine clearance reduced by 30%
(4) bone mineral density T-score of < −2.5 SD
(5) age < 50 years
(6) undesirability / impossibility of surveillance

Surgical risk for repeat surgery:

6.6% recurrent laryngeal nerve injury
20.0% permanent hypoparathyroidism
< 1.0% perioperative mortality

DDx of hypercalcemia:

(1) Malignancy (2nd most common cause): low / suppressed parathyroid hormone levels
(2) Benign familial hypocalciuric hypercalcemia:
= autosomal dominant disorder characterized by hypercalcemia + relative hypocalciuria distinguished by calcium-creatinine clearance ratio < 0.01

Secondary Hyperparathyroidism

= sHPT = 2° HPT = stimulation of all four parathyroid glands as a response to
(1) hypocalcemia → diffuse / adenomatous hyperplasia
(2) apparent insensitivity of parathyroid glands to ↑ serum calcium ← dysregulation of normal negative feedback loop (= pseudohyperparathyroidism)

◊ requires medical Rx

Etiology:

(a) endstage renal disease (most common cause) → decreased renal production of $1,25(OH)_2$-vitamin D
(b) calcium deprivation, hypovitaminosis D, maternal hypoparathyroidism, pregnancy
(c) rise in serum phosphate → decrease in calcium by feedback mechanism

- dementia, depression; peptic ulcer disease, constipation
- diffuse joint pain
- low (hypocalcemia) to normal calcium levels
- phosphate retention (hyperphosphatemia) = $Ca_3(PO_4)_2$ solubility product often exceeded
- vitamin D deficiency = ⇓ vitamin D serum levels → compensatory ⇑ in PTH production

√ soft-tissue calcifications
√ "rugger jersey" spine = striped osteosclerotic appearance
√ periostitis
√ brown tumor

NUC:

√ "superscan" in 2° HPT:
√ "absent kidney" sign
√ increased ratio of bone-to-soft tissue uptake

√ increased uptake in calvarium, mandible, acromioclavicular region, sternum, vertebrae, distal third of long bones, ribs

√ diffuse ^{99m}Tc-MDP uptake in lungs (60%)

Tertiary Hyperparathyroidism

= tHPT = 3° HPT = development of autonomously functioning parathyroid glands despite correction of initial cause → hypersecretion of PTH in spite of normal calcium levels in patients with chronically overstimulated hyperplastic parathyroid glands

Cause: secondary HPT ← renal insufficiency + renal dialysis with prolonged hypocalcemia and hyperphosphatemia

◊ requires surgical Rx

Clue: (a) intractable hypercalcemia

(b) inability to control osteomalacia by vitamin D administration

Ectopic Parathormone Production

= pseudohyperparathyroidism as paraneoplastic syndrome in bronchogenic carcinoma + renal cell carcinoma

HYPERTROPHIC OSTEOARTHROPATHY

= HYPERTROPHIC PULMONARY OSTEOARTHROPATHY (HPO) = MARIE-BAMBERGER DISEASE

= paraneoplastic syndrome

Etiology:

(1) Release of vasodilators which are not metabolized by lung
(2) Increased flow through AV shunts
(3) Reflex peripheral vasodilation (vagal impulses)
(4) Hormones: estrogen, growth hormone, prostaglandin

Histo: round cell infiltration of the outer fibrous layer of periosteum followed by new bone proliferation

A. THORACIC CAUSES

(a) malignant tumor (0.7–12%): bronchogenic carcinoma (88%), mesothelioma, lymphoma, pulmonary metastasis from osteogenic sarcoma, melanoma, renal cell carcinoma, breast cancer

◊ 4–17% of patients with bronchogenic carcinoma may develop HPO!

(b) benign tumor: benign pleural fibroma, tumor of ribs, thymoma, esophageal leiomyoma, pulmonary hemangioma, pulmonary congenital cyst

(c) chronic infection / inflammation: pulmonary abscess, bronchiectasis, blastomycosis, TB (very rare); cystic fibrosis, interstitial fibrosis

(d) cyanotic congenital heart disease with R-to-L shunt

B. EXTRATHORACIC CAUSES (less common)

(a) GI tract: ulcerative colitis, amebic + bacillary dysentery, intestinal TB, Whipple disease, Crohn disease, gastric ulcer, bowel lymphoma, gastric carcinoma

(b) liver disease: biliary + alcoholic cirrhosis, posthepatic cirrhosis, chronic active hepatitis, bile duct carcinoma, benign bile duct stricture, amyloidosis, liver abscess

(c) undifferentiated nasopharyngeal carcinoma, pancreatic carcinoma, chronic myelogenous leukemia

- burning pain, painful swelling of limbs, and stiffness of joints: ankles (88%), wrists (83%), knees (75%), elbows (17%), shoulders (10%), fingers (7%)
- peripheral neurovascular disorders: local cyanosis, areas of increased sweating, paresthesia, chronic erythema, flushing + blanching of skin
- hippocratic fingers + toes (clubbing)
- hypertrophy of extremities (soft-tissue swelling)

Location: tibia + fibula (75%), radius + ulna (80%), proximal phalanges (60%), femur (50%), metacarpus and metatarsus (40%), humerus + distal phalanges (25%), pelvis (5%); unilateral (rare)
◊ Spine, pelvis, ribs usually spared!

Site: in diametaphyseal regions

√ cortical thickening

√ lamellar periosteal proliferation of new bone, at first smooth then undulating + rough
Site: most conspicuous on concavity of long bones (dorsal + medial aspects)

√ soft-tissue swelling ("clubbing") of distal phalanges

Bone scan (reveals changes early with greater sensitivity + clarity):
√ "parallel track" / "double stripe" / "tramline" sign = patchy linear diffusely increased symmetric uptake along cortical margins of metaphysis + diaphysis of tubular bones ← periostitis
√ increased periarticular uptake ← synovitis
√ scapular involvement in $^{2}/_{3}$
√ mandible ± maxilla abnormal in 40%

Prognosis: treatment of underlying condition leads to remission of symptoms often within 24 hours + regression of radiographic findings in months

DDx: (1) Pachydermoperiostosis (self-limited, adolescence, autosomal dominant, M > F)
(2) Metastases (axial skeleton, focal asymmetric distribution)
(3) Chronic vascular insufficiency
(4) Thyroid acropachy
(5) Hypervitaminosis A

Differences between 1° and 2° HPT

Skeletal Findings	*1° HPT*	*2° HPT*
Osteopenia, diffuse	present	present
Osteosclerosis, regional / diffuse	rare	common
Bone resorption	common	common
Brown tumor	common	less common
Soft-tissue calcification	not infrequent	common
Chondrocalcinosis	not infrequent	rare

HYPERVITAMINOSIS A

Age: usually infants + children

Cause: overdosing vitamin A, 13-cis-retinoic acid (treatment for neuroblastoma)

- anorexia, irritability; jaundice, enlargement of liver
- loss of hair, dry skin, pruritus, fissures of lips

√ separation of cranial sutures (coronal > lambdoid) ← hydrocephalus in children < 10 years of age, may appear within a few days

√ symmetrical solid periosteal new-bone formation along shafts of long + short bones (ulna, clavicle)

√ premature epiphyseal closure + thinning of epiphyseal plates

√ accelerated growth

√ tendinous, ligamentous, pericapsular calcifications

√ changes usually disappear after cessation of vitamin A ingestion

DDx: infantile cortical hyperostosis (mandible involved)

HYPERVITAMINOSIS D

= excessive ingestion of vitamin D (large doses act like parathormone)

- loss of appetite, diarrhea, drowsiness, headaches
- polyuria, polydipsia, renal damage; convulsions
- excessive phosphaturia (parathormone decreases tubular absorption); hypercalcemia + hypercalciuria; anemia

√ deossification

√ widening of provisional zone of calcification

√ cortical + trabecular thickening

√ alternating bands of increased + decreased density near / in epiphysis (zone of provisional calcification)

√ vertebra outlined by dense band of bone + adjacent radiolucent line within

√ dense calvarium

√ metastatic calcinosis in

(a) arterial walls (between age 20 and 30 years)
(b) kidneys = nephrocalcinosis
(c) periarticular tissue (puttylike)
(d) premature calcification of falx cerebri (most consistent sign!)

HYPOPARATHYROIDISM

- tetany = hypocalcemic neuromuscular excitability (numbness, cramps, carpopedal spasm, laryngeal stridor, generalized convulsions)
- hypocalcemia + hyperphosphatemia
- normal / low serum alkaline phosphatase

√ premature closure of epiphyses

√ hypoplasia of tooth enamel + dentine; blunting of roots

√ generalized increase in bone density in 9%:

√ localized thickening of skull

√ sacroiliac sclerosis
√ bandlike density in metaphysis of long bones (25%), iliac crest, vertebral bodies
√ thickened lamina dura (inner table) + widened diploe
√ deformed hips with thickening + sclerosis of femoral head + acetabulum
@ Soft tissue
√ intracranial calcifications in basal ganglia, choroid plexus, occasionally in cerebellum
√ calcification of spinal and other ligaments
√ subcutaneous calcifications
√ ossification of muscle insertions
√ ectopic bone formation

Differences between Various Types of Hypoparathyroidism

	HypoPT	*Pseudo HypoPT*	*Pseudopseudo HypoPT*
Serum Ca	↓	↓	↔
Serum P	↑	↑	↔
AlkaPhos	↓ or ↔	↓ or ↔	↔
Response to PTH-Injection			
Urine cAMP	↑	↔	
Urine P	↑	↔	
Plasma AMP	↑	↔	

Differential Signs between PHypoPT and PPHypoPT

Radiographic Signs	*PHypoPT*	*PPHypoPT*
√ calcification of basal ganglia	44%	8%
√ soft-tissue calcifications	55%	40%
√ metacarpal shortening (4 + 5 always involved)	75%	90%
√ metatarsal shortening (3 + 4 involved)	70%	99%

Idiopathic Hypoparathyroidism

= rare condition of unknown cause
• round face, short dwarflike, obese; mental retardation
• cataracts; dry scaly skin, atrophy of nails
• dental hypoplasia (delayed tooth eruption, impaction of teeth, supernumerary teeth)

Secondary Hypoparathyroidism

= accidental removal / damage to parathyroid glands in thyroid surgery / radical neck dissection (5%); ^{131}I therapy (rare); external beam radiation; hemorrhage; infection; thyroid carcinoma; hemochromatosis (iron deposition)

Pseudohypoparathyroidism

= PHypoPT = congenital X-linked dominant abnormality with renal + skeletal resistance to

PTH due to
(1) Endorgan resistance
(2) Presence of antienzymes
(3) Defective hormone

May be associated with: hyperparathyroidism ← hypocalcemia; F > M

- short obese stature, round face, mental retardation
- abnormal dentition (hypoplasia, delayed eruption, excessive caries); corneal + lenticular opacity
- hypocalcemia + hyperphosphatemia (resistant to PTH injection); normal levels of PTH

√ brachydactyly in bones in which epiphysis appears latest: metacarpal, metatarsal bones I, IV, V (75%)
√ accelerated epiphyseal maturation resulting in dwarfism + coxa vara / valga
√ multiple diaphyseal exostoses (occasionally)
√ calcification of basal ganglia + dentate nucleus
√ calcification / ossification of skin + subcutaneous tissue

Pseudopseudohypoparathyroidism

= PPHypoPT = different expression of same familial disturbance with identical clinical + radiographic features as pseudohypoparathyroidism but normocalcemic

Cause: end-organ resistance to PTH

- short stature, round facies
- NO blood chemical changes = normal calcium + phosphorus
- normal response to injection of PTH

√ brachydactyly

HYPOPHOSPHATASIA

= autosomal recessive congenital disease with low activity of serum-, bone-, liver-alkaline phosphatase resulting in poor mineralization (= deficient generation of bone crystals)

Prevalence: 1÷100,000

Histo: indistinguishable from rickets

- phosphoethanolamine in urine as precursor of alkaline phosphatase; normal serum calcium + phosphorus

A. GROUP I = neonatal = congenital lethal form
√ marked demineralization of calvarium ("caput membranaceum" = soft skull)
√ lack of calcification of metaphyseal end of long bones
√ streaky irregular spotty margins of calcification
√ cupping of metaphysis
√ angulated shaft fractures with abundant callus formation
√ short poorly ossified ribs
√ poorly ossified vertebrae (especially neural arches)
√ small pelvic bones
OB-US:
√ high incidence of intrauterine fetal demise
√ increased echogenicity of falx (enhanced sound transmission ← poorly mineralized calvarium)

√ poorly mineralized short bowed tubular bones + multiple fractures
√ poorly mineralized spine
√ short poorly ossified ribs
√ polyhydramnios

Prognosis: death within 6 months

B. GROUP II = juvenile severe form
onset of symptoms within weeks to months
• moderate / severe dwarfism
• delayed weight bearing
√ resembles rickets
√ separated cranial sutures; craniostenosis in 2nd year

Prognosis: 50% mortality

C. GROUP III = adult mild form
recognized later in childhood / adolescence / adulthood
• dwarfism
√ clubfoot, genu valgum
√ demineralization of ossification centers (at birth / 3–4 months of age):
√ widened metaphyses
√ wormian bones

Prognosis: excellent; after 1 year no further progression

D. GROUP IV = latent form of heterozygous state
• normal / borderline levels of alkaline phosphatase
• patients are small for age
• disturbance of primary dentition
√ bone fragility + healed fractures
√ enlarged chondral ends of ribs
√ metaphyseal notching of long bones
√ Erlenmeyer flask deformity of femur

HYPOTHYROIDISM

Hypothyroidism during Childhood = Cretinism

Frequency: 1÷4,000 live births have congenital hypothyroidism

Cause: sporadic hypoplasia / ectopia of thyroid

√ delayed skeletal maturation (= delayed appearance + growth of ossification centers, delayed epiphyseal closure)
√ fragmented stippled epiphyses
√ wide sutures / fontanels with delayed closure
√ delayed dentition
√ delayed / decreased pneumatization of sinuses + mastoids
√ hypertelorism
√ dense vertebral margins
√ demineralization
√ hypoplastic phalanges of 5th finger

MR:

√ reduced myelination of brain (usually beginning during midgestation)

OB-US:

√ fetal goiter (especially in hyperthyroid mothers treated with methimazole / propylthiouracil / ^{131}I)

Hypothyroidism during Adulthood

√ calvarial thickening / sclerosis
√ wedging of dorsolumbar vertebral bodies
√ coxa vara with flattened femoral head
√ premature atherosclerosis
◊ No skeletal changes with adult onset!

INFANTILE CORTICAL HYPEROSTOSIS

= CAFFEY DISEASE
= uncommon self-limiting proliferative bone disease of infancy; remission + exacerbations are common

[John Patrick Caffey (1895–1978), pediatrician and professor of radiology at Columbia University, New York]

Cause: ? infectious; ? autosomal dominant with variable expression + incomplete penetrance / sporadic occurrence (rare)

Age: < 6 months, reported in utero; M÷F = 1÷1

Histo: inflammation of periosteal membrane, proliferation of osteoblasts + connective tissue cells, deposition of immature bony trabeculae

• sudden, hard, extremely tender soft-tissue swellings over bone
• irritability, fever; leukocytosis, anemia
• ± elevated ESR, increased alkaline phosphatase

Location: mandible (80%) > clavicle > ulna + others (except phalanges + vertebrae + round bones of wrists and ankles)

Site: hyperostosis affects diaphysis of tubular bones asymmetrically, epiphyses spared

√ massive periosteal new-bone formation + perifocal soft-tissue swelling
√ "double-exposed" ribs
√ narrowing of medullary space (= proliferation of endosteum)
√ bone expansion with remodeling of old cortex

Prognosis: usually complete recovery by 30 months

Rx: mild analgesics, steroids

Chronic Infantile Hyperostosis

• disease may persist or recur intermittently for years
• delayed muscular development, crippling deformities
√ bowing deformities, osseous bridging, diaphyseal expansion

DDx: (1) Hypervitaminosis A (rarely < 1 year of age)
(2) Periostitis of prematurity
(3) Healing rickets
(4) Scurvy (uncommon < 4 months of age)

(5) Syphilis (focal destruction)
(6) Child abuse
(7) Prostaglandin administration (usually following 4–6 weeks of therapy)
(8) Osteomyelitis
(9) Leukemia
(10) Neuroblastoma
(11) Kinky hair syndrome
(12) Hereditary hyperphosphatasia

INFECTIOUS MYOSITIS

= acute / subacute / chronic infection of skeletal muscle

Organism: viruses, bacteria (including mycobacteria), fungi, parasites; S. aureus (77%)

Pyomyositis / Bacterial Myositis

Risk factors: underlying HIV infection (17%), strenuous activity, rhabdomyolysis, muscle trauma (hematoma as nidus for infection)

Others: skin infection, infected insect bite, injection of illicit drug, underlying diabetes mellitus

Location: usually single muscle; multiple in 11–43%; quadriceps m. > gluteal m. > iliopsoas m. > upper extremity

Iliopsoas abscess: TB of spine (formerly), GI / GU infection (currently)

Stages:

(a) invasive: muscle edema → pain
(b) suppurative: fever → abscess
(c) late stage: toxicity → life-threatening sepsis

CT:

√ enlarged hypoattenuating muscle
√ effacement of surrounding fat planes
√ intramuscular fluid collection
√ nonenhancement of necrotic tissue
√ rim-enhancement of abscess

Cx: (1) Compartment syndrome
(2) Osteomyelitis
(3) Septic arthritis
(4) Muscle scarring, weakness, dysfunction

DDx: cellulitis (involvement of SQ tissue > muscle group)

INTRAMEDULLARY OSTEOSCLEROSIS

= rare condition increased bone formation within medullary cavity of long bones of lower extremity similar to progressive diaphyseal dysplasia / hereditary multiple diaphyseal sclerosis

Age: adulthood; F > M

• chronic leg pain that increases with physical activity

Location: uni- / bilateral in ≥ 1 long bone of lower extremity; most frequently in tibia
Site: middiaphyseal region
√ osteosclerosis limited to medullary cavity with minimal / no cortical thickening
Dx: after exclusion of other causes of osteosclerosis (eg, stress fractures, osteomyelitis, metabolic / endocrine disorders, malignancy)

IRON DEFICIENCY ANEMIA

Age: infant
Cause:
(1) inadequate iron stores at birth
(2) deficient iron in diet
(3) impaired gastrointestinal absorption of iron
(4) excessive iron demands from blood loss
(5) polycythemia vera
(6) cyanotic CHD
√ widening of diploe + thinning of tables with sparing of occiput (no red marrow)
√ hair-on-end appearance of skull
√ osteoporosis in long bones (most prominent in hands)
√ absence of facial bone involvement

JACCOUD ARTHROPATHY

[Sigismond Jaccoud (1830–1913), Swiss physician and professor of internal pathology at several hospitals in Paris]
= irreversible nonerosive deforming arthropathy after subsidence of frequent severe attacks of rheumatic fever / SLE
◊ Rheumatoid arthritis + SLE may occur simultaneously!
Path: pericapsular soft-tissue edema (= synovitis around small joints); periarticular fascial + tendon fibrosis
• rheumatic valve disease
Location: primarily involvement of hands; occasionally in great toe
√ periarticular swelling of small joints of hands + feet
√ ulnar deviation + flexion of MCP joints most marked in 4th + 5th finger
√ > 3 mm distance between scaphoid and lunate / other carpal bones = **carpal instability** (in 15% of SLE)
√ swan neck + boutonniere deformity
√ NO joint narrowing / erosion
√ juxtaarticular osteoporosis
√ muscular atrophy

JUVENILE XANTHOGRANULOMA

= relatively benign non-LCH dendritic cell disorder of early childhood
Age: < 1 year (majority)
@ Skin
• small yellow-reddish papule / plaque / nodule (early) with usually spontaneous

regression within a few years
Location: head, neck, upper trunk
@ Soft tissue
Location: subcutaneous to deep
√ heterogeneously hypoechoic hypovascular nodule
√ infiltrative nonenhancing mass of intermediate T1 signal
@ Bone
√ well-defined medullary lytic lesion with sclerotic margins
@ Liver, spleen, lung, bones, lymph nodes, GI tract
Dx: based on typical dermal findings

KELOID

= benign fibroblastic proliferation arising from dermis
Age: 15–45 years
Predisposed: persons of African / Chinese descent
Associated with: trauma, infection, connective tissue disease (at sites of increased skin tension)
Histo: hypocellular densely collagenous lesions
Location: face, shoulder, forearm, hand
• mass effect, pruritus, paresthesia, cosmetic deformity
MR:
√ short T2 relaxation
Rx: surgical excision combined with surgical injection of corticosteroids / postsurgical radiation therapy

KERATOACANTHOMA

[*acantha*, Greek =thorn, sharp spiny structure]
= rare benign neoplasm characterized by localized proliferation of squamous epithelium and central keratinized crater
Cause: exposure to sunlight, coal tar, other chemical carcinogens, trauma, immunocompromised state, vaccination, arterial puncture, burns
Path: keratin fills a central tumor crater; surrounding overhanging edges of normal epidermis
Histo: marked acanthosis (= diffuse thickening of stratum spinosum) + hyperkeratosis; proliferation of large squamous cells with glassy cytoplasm
Maybe associated with: eczema, psoriasis, atopic dermatitis, xeroderma pigmentosum
Peak age: 5th decade; M > F
• painful
√ crescent-shaped soft-tissue mass
√ osteolytic defect of underlying bone ← pressure erosion
√ no periosteal reaction / bone sclerosis
MR:
√ intermediate SI on T1WI + mixed SI on T2WI
√ thin peripheral rim enhancement
Prognosis: spontaneous involution within 12 months leaving a small pitted scar
Cx: malignant transformation to squamous cell carcinoma

Subungual Keratoacanthoma

= rare usually painful destructive variant of keratoacanthoma

• rapidly growing painful mass beneath nail

Location: nail bed

US:

√ well-circumscribed mass of mixed echogenicity

√ posterior acoustic enhancement + cortical erosion

Prognosis: spontaneous involution uncommon

DDx: squamous cell carcinoma (radiologically indistinguishable, older patient, slow growing, histologically aggressive, ulceration, numerous mitoses, marked pleomorphism, anaplasia)

KLINEFELTER SYNDROME

[Harry Fitch Klinefelter, Jr. (1912–1990), American rheumatologist and endocrinologist at Johns Hopkins Medical School]

47,XXY (rarely XXYY) chromosomal abnormality

Frequency: 1÷750 live births (probably commonest chromosomal aberration)

• testicular atrophy (hyalinization of seminiferous tubules) = small / absent testes, sterility (azoospermia)

• eunuchoid constitution: gynecomastia; paucity of hair on face + chest; female pubic escutcheon; mild mental retardation

• high level of urinary gonadotropins + low level of 17-ketosteroids after puberty

◊ NO distinctive radiological findings!

√ may have delayed bone maturation

√ failure of frontal sinus to develop

√ small bridged sella turcica

√ ± scoliosis, kyphosis

√ ± coxa valga

√ ± "metacarpal" sign (short 4th metacarpal)

√ accessory epiphyses of 2nd metacarpal bilaterally

Cx: breast cancer (3% risk + 20-fold increase in incidence due to elevated estrogen÷androgen ratio)

47,XXX = Superfemale Syndrome

• usually over 6 feet tall; subnormal intelligence; frequently antisocial behavior

KLIPPEL-TRÉNAUNAY SYNDROME

[Maurice Klippel (1858–1942), neurologist and psychiatrist, general medicine chief at Hôpital Tenon in Paris, France]

[Paul Trénaunay (1875–????), neurologist in Paris, France]

= rare sporadic (nonhereditary) combined capillary-venous malformation of trunk + extremities in association with limb overgrowth characterized by a triad of:

(1) Port-wine nevus = unilateral large flat infiltrative cutaneous capillary malformation often in dermatomal distribution of affected limb; may fade in 2nd–3rd decade

(2) Congenital varicose veins / venous malformation affecting superficial + deep venous system = megaveins on lateral aspect of affected limb; usually ipsilateral to capillary malformation
(a) superficial venous system: ectasia of small veins, persistent embryologic veins, large venous malformations
(b) deep venous system:" aneurysmal dilatation, aplasia, hypoplasia, duplications, venous incompetence
(3) Gigantism = overgrowth of distal digits / entire extremity (especially during adolescent growth spurt) involving soft-tissue + bone (most variable of the 3 classic features)

VARIANT: **Klippel-Trénaunay-Weber syndrome** = associated with (4) arteriovenous fistula

Incidence: > 1,000 cases reported

Pathogenesis:
failure of regression of large caliber superficial lateral venous channel at 6 weeks GA (= fetal lateral limb bud vein) → varicosity → impaired venous return → tissue overgrowth

Age: usually manifest at birth; M÷F = 1÷1

Associated with:
› polydactyly, syndactyly, clinodactyly, oligodactyly, ectrodactyly, congenital dislocation of hip
› vascular malformation of colon, rectum, bladder (1–10%)
› spinal hemangiomas + AVMs
› hemangiomas in liver / spleen
› lymphangiomas of limb

Location: one lower limb in 75–95% (10–15 x more common than upper extremity); bilateral in < 5%; lower limb ± upper limb; extension into trunk may occur

• pain in usually thicker + longer extremity
• spontaneous cutaneous hemorrhage
• chronic venous insufficiency
• cutaneous lymphatic vesicles, lymphorrhea

√ elongation of bones:
√ leg-length discrepancy
√ increased metatarsal / metacarpal + phalangeal size
√ cortical thickening
√ circumferential soft-tissue hypertrophy (at birth / later in life)
√ phleboliths in pelvis (bowel wall, anterior wall of urinary bladder) ← prior hemorrhage / thrombus
√ pulmonary vein varicosities
√ cystic lung lesions

CT / MR:
√ slow uptake of contrast material in visceral vascular malformations during delayed phase

Venogram:
√ extensive dilation of superficial veins
√ enlarged perforating veins
√ aplasia / hypoplasia of lower extremity veins (18–40%): ? selective flow of contrast material up the lateral venous channel may fail to opacify the deep venous system
√ incompetent valveless collateral venous channels (? persistent lateral limb bud vein =

Klippel-Trénaunay vein) arises near the ankle + extends a variable distance up the extremity and drains into deep femoral vein / iliac veins (in > 66%)

Color Doppler US:

√ deep venous malformations of femoral vein (common)

Lymphangiography:

√ hypoplasia of lymphatic system

Cx: stasis dermatitis, thrombophlebitis, cellulitis, deep venous thrombosis, pulmonary embolism, infected lymphangitis ± sepsis, bloody stool, hematuria, epistaxis, Kasabach-Merritt syndrome (= consumptive coagulopathy)

Rx: (1) conservative: application of graded compressive stockings, pneumatic compression devices, percutaneous sclerosis of localized venous malformations / superficial varicosities

(2) surgical: epiphysiodesis, excision of soft-tissue hypertrophy, vein stripping, life-threatening bleeding

DDx: (1) Parkes-Weber syndrome congenital persistence of multiple microscopic AV fistulas + spectrum of Klippel-Trénaunay-Weber syndrome (pulsatility, thrill, bruit)

(2) Neurofibromatosis (café-au-lait spots, axillary freckling, cutaneous neurofibromas, macrodactyly ← plexiform neurofibromas, wavy cortical reaction, early fusion of growth plate, limb hypertrophy not as extensive / bilateral)

(3) Beckwith-Wiedemann syndrome (aniridia, macroglossia, cryptorchidism, Wilms tumor, broad metaphyses, thickened long-bone cortex, advanced bone age, periosteal new-bone formation, hemihypertrophy)

(4) Macrodystrophia lipomatosis (hyperlucency of fat, distal phalanges most commonly affected, overgrowth ceases with puberty, usually limited to digits)

(5) Maffucci syndrome (cavernous hemangiomas, soft tissue hypertrophy, phleboliths, multiple enchondromas)

(6) Cutis marmorata telangiectatica congenita

(7) Servelle-Martorell syndrome

LABRAL TEARS OF SHOULDER

Anterior Labral Tear

Location: anteroinferior labrum > entire anterior labrum > isolated tear of anterosuperior labrum

Subtypes of anteroinferior labral tears:

(1) Bankart lesion

(2) Anterior labroligamentous periosteal sleeve avulsion

(3) Perthes lesion

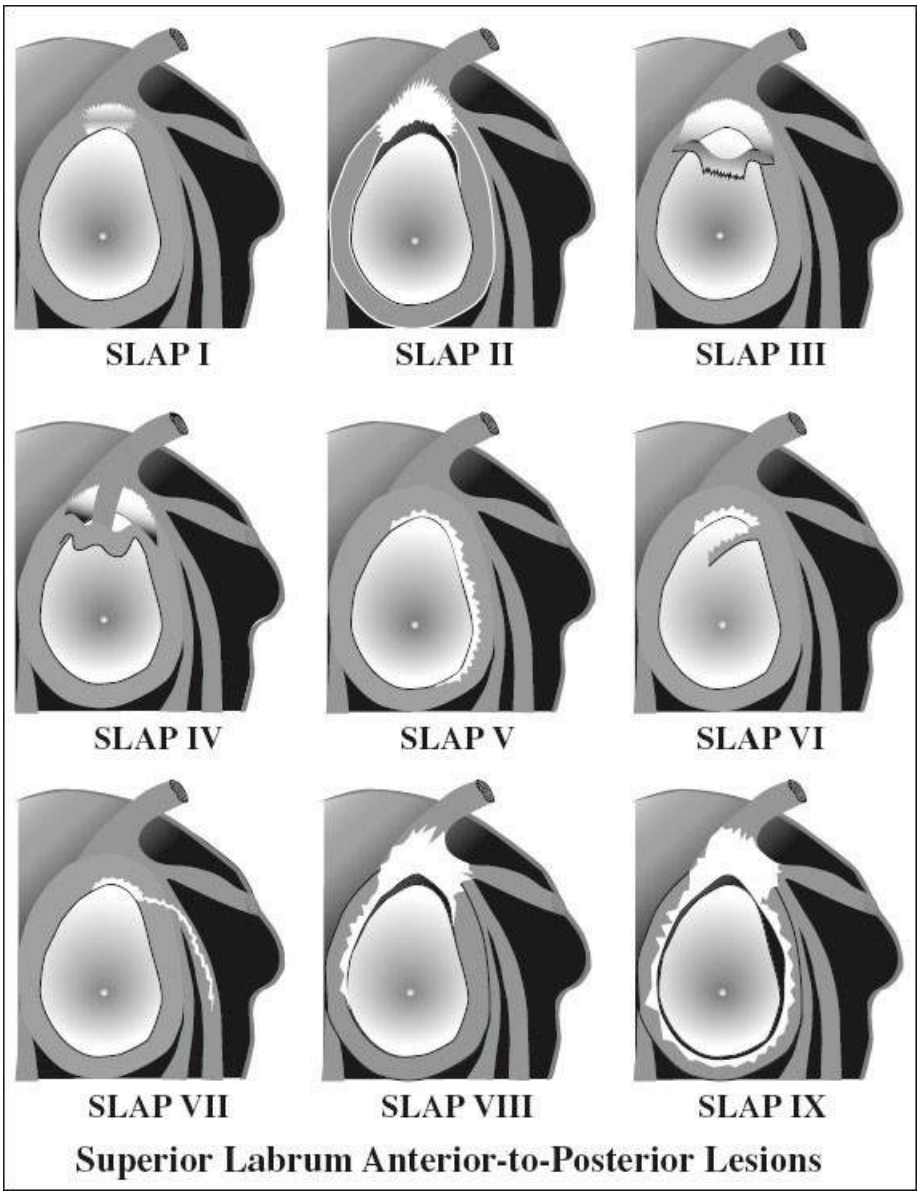
√ absence / detachment of labrum

√ frayed labrum with irregular margin

DDx: (1) Middle + inferior glenohumeral ligaments closely apposed to anterior labrum

(2) Recess between anterior labrum + glenoid rim

(3) Recess between middle + inferior ligaments



SLAP Lesion

= anterior-to-posterior lesion of the superior labrum centered at biceps tendon attachment

Mechanism: fall on an outstretched hand (most common), anterior shoulder dislocation, sports activity with overhead arm motion

- pain, clicking sensation
- after fall on outstretched hand (31%) patient usually presents with SLAP III, IV, V lesion

SLAP I = fraying of free edge of superior labrum; common in elderly as a degenerative tear

SLAP II = detachment of superior biceps-labral complex from glenoid rim

DDx: superior sublabral recess (less distance between labrum + glenoid, no irregular appearance, no lateral extension of defect)

SLAP III = bucket-handle tear of superior labrum leaving biceps tendon attached to

glenoid

SLAP IV = bucket-handle tear of superior labrum with tear extending into biceps tendon

SLAP V = Bankart lesion dissecting upward to involve the biceps tendon

SLAP VI = unstable radial / flap tear with separation of biceps anchor

SLAP VII = superior labral tear extending into middle glenohumeral ligament

SLAP VIII = SLAP II + entire posterior labral tear; anterior inferior labrum not involved

SLAP IX = circumferential labral tear

LANGERHANS CELL HISTIOCYTOSIS

= LCH = HISTIOCYTOSIS X (former name)

[Paul Langerhans (1847–1888), German pathologist, physiologist, and microscopist in Berlin, close friend of Virchow, discoverer of dendritic cells in the skin and islet cells of the pancreas]

= poorly understood group of disorders characterized by abnormal nonmalignant proliferation of monoclonal Langerhans cells within one / multiple organ systems

◊ Leading (most common) dendritic cell disorder apart from

(1) Erdheim-Chester disease
(2) Juvenile xanthogranuloma
(3) Rosai-Dorfman disease
(4) Hemophagocytic lymphohistiocytosis

Histo:

granuloma contains Langerhans cells (= large histiocyte of bone marrow origin), foamy histiocytes, lymphocytes, plasma cells, eosinophils

Langerhans cell:

› dendritic cell found in basal layer of skin + in liver (Kupffer cell), lymph nodes, spleen, bone marrow, lung (detects + phagocytizes pathogenic organisms and presents their surface antigens to T and B lymphocytes)

› contains unique mostly pentalaminar rods / "tennis racket"-shaped cytoplasmatic inclusion bodies known as **Birbeck granules** (identifiable by electron microscopy)

› stains positive for S100, CD1a, CD207

› proliferation triggers release of chemokines + proteases + enzymatic reactions → production of damaging free radicals → destruction of lung architecture → airway fibrosis + failed wound healing

Cause: uncertain (? primary proliferative disorder possibly due to defect in immunoregulation; neoplasm; virus)

Prevalence: 1÷2,000,000 children per year

Path: influx of eosinophilic leukocytes simulating inflammation; reticulum cells accumulate cholesterol + lipids (= foam cells); sheets or nodules of histiocytes may fuse to form giant cells, cytoplasm contains (? viral) Langerhans bodies

Age: any age, mostly presenting at 1–4 years; adults affected in < 30%; < 30 years in 80%; M÷F = 1÷1

Location: bone + bone marrow, lymph nodes, thymus, ear, liver and spleen, gallbladder, GI tract, endocrine system; multifocal (10–20%)

DDx: osteomyelitis, Ewing sarcoma, leukemia, lymphoma, metastatic neuroblastoma

Clinical manifestations:

A. Localized LCH (70%) = eosinophilic granuloma
B. Disseminated LCH (30%)
   1. Chronic disseminated LCH (20%) = Hand-Schüller-Christian disease
   2. Fulminant disseminated LCH (10%) = Letterer-Siwe disease

formerly: Histiocytosis X = eosinophilic granuloma / Letterer-Siwe disease / Hand-Schüller-Christian syndrome
- ◊ Names should be disregarded as they were thought of formerly as different diseases!

@ Bone (80%)

√ bone lesions: in 80% (most common radiographic manifestation)
Location: predilection for flat bones (skull > mandible > rib > pelvis > spine) especially in adults

› Skull:
- asymptomatic/ focal pain
- soft-tissue swelling in scalp

√ well-defined lytic "punched-out" lesion of skull
√ characteristic beveled edge = asymmetric destruction of inner + outer cortices
√ geographic skull = skull lesions may grow in size and coalesce

N.B.: calvarial disease lacks periosteal reaction

DDx for single lesion: epidermoid / dermoid cyst, osteomyelitis

DDx for multiple lesions: lymphoma, leukemia, multiple myeloma, metastases

» Mastoid bone
- swelling, dizziness, vertigo, otorrhea

√ soft-tissue component : T1-isointense + T2-hyperintense + enhancement; isoechoic on US

» Mandible
- gingival bleeding + facial swelling

√ "floating teeth" = destruction of alveolar ridge

› Vertebral body
- pain, substantial neurologic defects

√ lytic lesion in early disease
√ vertebra plana = symmetric uniform vertebral collapse + preservation of intervertebral disk spaces

DDx: leukemia, metastatic neuroblastoma, aneurysmal bone cyst, Ewing sarcoma

› Long bone: most commonly femur, humerus, tibia
- asymptomatic / focal pain + swelling

Site: intramedullary lesion of diaphysis / metaphysis

√ lytic expansile aggressive lesion (in early disease)
√ cortical thickening, smooth periosteal reaction
√ extramedullary soft-tissue component with decreased T1 + increased T2 signal intensity
√ increased radiotracer uptake on bone scan; may be falsely negative (not uncommon)
√ lesion resolution turning sclerotic ← periosteal new bone + sharply defined sclerotic

margin (in chronic mature lesion)

DDx: chondromyxoid fibroma, plasmacytoma, metastasis, unicameral cyst, aneurysmal bone cyst

@ Liver (15%)

- hepatic dysfunction

√ hepatomegaly + focal solid / cystlike lesions

√ hypoattenuating, hypoechoic, hypointense T1 and T2 signal along biliary tracts + portal triads= periportal fibrosis

Cx: progressive sclerosing cholangitis

◊ Involvement indicates a worse prognosis

@ Spleen (< 15%)

√ splenomegaly → hypersplenism → cytopenias

◊ Involvement indicates a worse prognosis

@ Lymph Nodes (20%)

Location: predominantly in neck

√ hard / soft matted groups of nodes → lymphedema

@ CNS (~16%)

- ataxia, cognitive dysfunction ← neurodegeneration (with T2-hyperintense lesions in cerebellum + basal ganglia)
- growth hormone deficiency (later in life)
- diabetes insipidus (most common) ← decreased secretion of antidiuretic hormone ← infiltration of posterior pituitary gland

√ loss of normal posterior pituitary bright spot

√ thickening of pituitary stalk (~70%) on CEMR

DDx: germinoma, craniopharyngioma, tuberculosis, sarcoidosis, lymphocytic hypophysitis

√ leukoencephalopathy-like white matter changes

√ lesions in meninges + choroid plexus

@ Lung (~10%)

Age: more common in adults + almost always associated with smoking

- shortness of breath, nonproductive cough
- fever / weight loss (sometimes)

√ centrilobular micronodules

Distribution: bilateral symmetric upper- to mid-lung with sparing of costophrenic angles

DDx: metastases, miliary tuberculosis, sarcoidosis, silicosis

√ usually < 1 cm cysts ± confluence to bulla formation → recurrent spontaneous pneumothorax

√ pleural effusion + enlarged hilar lymph nodes (rare)

DDx: lymphangioleiomyomatosis, lymphocytic interstitial pneumonia, bullous emphysema

Localized Langerhans Cell Histiocytosis (70%)

= EOSINOPHILIC GRANULOMA

= localized often solitary bone lesion as the most benign variety of LCH

Age: 5–10 years (highest frequency); range 2–30 years; < 20 years (in 75%); M÷F = 3÷2
Path: bone lesion arises within medullary canal (RES)
Histo: considerable number of eosinophils in addition to the dominant Langerhans cell constituent

- painful tender bone lesion + soft-tissue swelling (may be misdiagnosed as local trauma / seborrhoic skin lesion)
- fever, leukocytosis, elevated sedimentation rate
- eosinophilia in blood + CSF

Location: limited to single / few bones (in children); may involve lung (in adults)
Sites: monostotic involvement in 50–75%;
(a) flat bones: calvarium > mandible > ribs > pelvis > vertebrae (rarely posterior elements)
(b) long bones: diaphyseal (58%) + metaphyseal (28%) + metadiaphyseal (12%) + epiphyseal (2%) in humerus, femur, tibia

X-ray:
√ osteolytic bone lesions 1–15 cm in diameter:
√ geographic / permeative / moth-eaten configuration
√ well- / poorly defined borders
√ ± sclerosis
DDx: neuroblastoma metastasis, leukemia, lymphoma

CT:
√ moderately to markedly enhancing soft-tissue mass with bone erosion

MR:
√ low to intermediate SI on T1WI + hyperintense T2WI
√ diffuse avid contrast enhancement (fat suppression!)
√ depicts intracranial extension of LCH

@ Skull (40–50%)
Site: diploic space of parietal bone > temporal bone (petrous ridge, mastoid)
√ round / ovoid punched-out lytic lesion:
DDx: venous lake, arachnoid granulation, parietal foramen, epidermoid cyst, hemangioma
√ beveled edge / "hole-within-hole" appearance ← asymmetric destruction of inner + outer tables
√ sharply marginated without sclerotic rim (DDx: epidermoid with bone sclerosis)
√ sclerotic margin during healing phase (50%)
√ "button sequestrum" = remnants of bone as a central bone density within a lytic lesion ← erosive accumulation of histiocytes
√ soft-tissue mass overlying the lytic process in calvarium (often palpable)

@ CNS involvement (4%)
Site: predilection for hypothalamic pituitary axis
- diabetes insipidus (in 5 –50%)

√ thickening of the infundibular stalk > 3 mm
√ isodense markedly homogeneously enhancing mass in superior aspect of stalk / hypothalamus
√ absence of posterior pituitary "bright spot" on T1WI

√ partially / completely empty sella
√ threadlike narrowing of infundibulum (< 1 mm)

@ Orbit
• ptosis, palpebral and periocular erythema, enlargement of associated palpebral fissure
Site: superior / superolateral orbital region
√ osseous destruction + soft-tissue mass extending into orbit / temporal fossa / forehead / face / epidural space

@ Mastoid process
• intractable otitis media with chronically draining ear (in temporal bone involvement)
√ destructive lesion near mastoid antrum
DDx: otomastoiditis, cholesteatoma, metastasis
Cx: extension into middle ear may destroy ossicles leading to deafness

@ Jaw
• gingival + contiguous soft-tissue swelling
√ "floating" teeth = destruction of alveolar bone
√ mandibular fracture

@ Axial skeleton (8–25%)
• pain, rapidly subsiding after bed rest
• mild hyperpyrexia, mild ↑ ESR, slight eosinophilia, slight leukocytosis
• rarely mild neurologic complications
Site: vertebral body > posterior elements
√ "vertebra plana" = "coin on edge" = Calvé disease (6%) = collapse of vertebra (most commonly thoracic):

◊ Most common cause of vertebra plana in children!

√ pertinent negatives:
√ increased opacity in collapsed vertebral body
√ absence of osteolysis
√ preserved disk space + pedicles
√ rare involvement of posterior elements
√ no kyphosis
√ absence of adjacent paravertebral soft-tissue

√ lytic lesion in supraacetabular region
Prognosis: reconstitution of vertebral height is usual

@ Rib (9–15%)
√ rib lesions with fractures (common)
√ ± perilesional edema, especially in early phase

@ Proximal long bones (15–33%)
Site: mostly diaphyseal; epiphyseal lesions are uncommon
√ expansile lytic lesion with ill-defined / sclerotic edges
√ endosteal scalloping, widening of medullary cavity
√ cortical thinning, intracortical tunneling
√ erosion of cortex + soft-tissue mass
√ laminated periosteal reaction (frequent), may show interruptions
√ may appear rapidly within 3 weeks

√ lesions respect joint space + growth plate

@ Lung involvement (20%)

@ GI tract

Location: terminal ileum (most commonly)

• diarrhea, protein-losing enteropathy, malabsorption

√ diffuse concentric bowel wall thickening

@ Skin involvement (up 50%)

• erythematous papules + plaques → become eroded + develop serous / hemorrhagic crust

Frequently accompanied by: petechiae / purpura

Location: scalp, perinasal + preauricular areas of face, flexural areas

NUC:

√ negative bone scans in 35% (radiographs more sensitive)

√ bone lesions generally not ^{67}Ga avid

√ ^{67}Ga may be helpful for detecting nonosseous lesions

Prognosis: excellent with spontaneous resolution of bone lesions in 6–18 months

Chronic Disseminated LCH (20%)

= Hand-Schüller-Christian Disease

[Alfred Hand (1868–1949), American pediatrician at University of Pennsylvania, Philadelphia]

[Artur Schüller (1874–1957), neurologist, psychiatrist and neuroradiologist in Vienna, Austria and Melbourne, Australia]

[Henry Asbury Christian (1876–1951), American pathologist and first physician in chief at Peter Bent Brigham Hospital, Boston]

= chronic disseminated form of LCH characterized by CLASSIC triad (in 10–15%) of

(1) Exophthalmos (mass effect on orbital bone)

(2) Diabetes insipidus (basilar skull disease / direct infiltration of posterior pituitary gland)

(3) Destructive bone lesions (often of calvaria)

Path: proliferation of histiocytes, may simulate Ewing sarcoma

Age at onset: < 5 years (range from birth to 40 years); M÷F = 1÷1

• diabetes insipidus (30–50%) often with large lytic lesion in sphenoid bone / panhypopituitarism

• otitis media with mastoid + inner ear invasion

• exophthalmos (33%), sometimes with orbital wall destruction

• generalized eczematoid skin lesions (30%)

• ulcers of mucous membranes (gingiva, palate)

Sites: bone, liver, spleen, lymph nodes, skin

@ Bone

√ osteolytic skull lesions with overlying soft-tissue nodules

√ "geographic skull" = ovoid / serpiginous destruction of large area

√ "floating teeth" with mandibular involvement

√ destruction of petrous ridge + mastoids + sella turcica

@ Orbit

√ diffuse orbital disease with multiple osteolytic bone lesions

@ Liver
- √ hepatosplenomegaly (rare)
- √ scattered echogenic / hypoattenuating liver granuloma
- √ lymphadenopathy (may be massive)
- √ gallbladder wall thickening (from infiltration)

@ Lung
- √ cyst + bleb formation → spontaneous pneumothorax (25%)
- √ ill-defined diffuse nodular infiltration often progressing to fibrosis + honeycomb lung

@ Thymus
- √ enlarged thymus + punctate calcifications

Prognosis: spontaneous remissions + exacerbations; fatal in 15%

Fulminant Disseminated LCH (10%)

= LETTERER-SIWE DISEASE

= acute disseminated fulminant form of LCH characterized by wasting, pancytopenia (from bone marrow dysfunction), generalized lymphadenopathy, hepatosplenomegaly

Frequency: 1÷ 2,000,000

Age: several weeks after birth to 2 years

Path: generalized involvement of reticulum cells; may be confused with leukemia

- hemorrhage, purpura ← coagulopathy
- severe progressive anemia / pancytopenia
- intermittent fever
- failure to grow / malabsorption + hypoalbuminemia
- skin rash: scaly erythematous seborrhea-like brown to red papules

Location: especially pronounced behind ears, in axillary, inguinal, and perineal areas

Sites: liver, spleen, bone marrow, lymph nodes, skin

√ hepatosplenomegaly + lymphadenopathy (most often cervical)

√ obstructive jaundice

@ Bone involvement (50%):
- √ widespread multiple lytic lesions; "raindrop" pattern in calvarium

Prognosis: rapidly progressive with 70% mortality rate

LATERAL EPICONDYLITIS

= TENNIS ELBOW = TENDINITIS (epicondylitis is a misnomer)

= chronic overuse syndrome involving origin of extensor carpi radialis brevis tendon

Age: 35–50 years

Cause: tennis, throwing sports, swimming, carpentry, plumbing (repetitive forearm pronation + supination with wrist extension)

- pain + tenderness in region of lateral epicondyle radiating into forearm

Histo: tendon microtears followed by formation of angiofibrotic hyperplasia (= noninflammatory reactive tissue)

MR (oblique coronal images):

√ focally hyperintense signal compared with muscle + less intense than fluid on all sequences

Rx: (1) conservative management: avoidance of painful activity, application of ice, NSAID
(2) splints, steroid injection
(3) excision of abnormal tissue + decortication of epicondyle + reattachment of tendon

DDx of painful elbow: injury to radial collateral ligament / extensor carpi radialis longus tendon, cartilage defect

LAURENCE-MOON-BIEDL SYNDROME

• retardation; obesity; hypogonadism
√ craniosynostosis
√ polysyndactyly

LEPROSY

= HANSEN DISEASE

Organism: Mycobacterium leprae

Types:

(1) lepromatous: in cutis, mucous membranes, viscera
(2) neural: enlarged indurated nodular nerve trunks; anesthesia, muscular atrophy, neurotrophic changes
(3) mixed form

@ Osseous changes (in 15–54% of patients)
√ specific osseous signs of leprosy:
Location: center of distal end of phalanges / eccentric
√ ill-defined areas of decalcification, reticulated trabecular pattern, small rounded osteolytic lesions, cortical erosions
√ joint spaces preserved
√ healing phase: complete resolution / bone defect with sclerotic rim + endosteal thickening
√ nasal spine absorption + destruction of maxilla, nasal bone, alveolar ridge
√ enlarged nutrient foramina in clawlike hand
√ erosive changes of ungual tufts
√ nonspecific osseous signs of leprosy:
√ soft-tissue swelling; calcification of nerves
√ contractures / deep ulcerations
√ neurotrophic joints (distal phalanges in hands, MTP in feet, Charcot joints in tarsus)

LEUKEMIA OF BONE

A. CHILDHOOD

Most common malignancy of childhood:
⅓ of all pediatric malignancies

Histo:

1. Acute Lymphocytic Leukemia (ALL in 75%)
most often in children < 5 years of age
√ lymph node enlargement rare
2. Acute Myelogenous Leukemia (AML)

tends to affect older children + adolescents
√ lymph node enlargement common

- migratory paraarticular arthralgias (25–50%) ← adjacent metaphyseal lesions (may be confused with acute rheumatic fever / rheumatoid arthritis)
- low-grade fever, bruising, fatigue
- bone pain ← increased intraosseous pressure from proliferation of malignant cells
- elevated erythrocyte sedimentation rate, anemia
- hepatosplenomegaly, occasionally lymphadenopathy

◊ Peripheral blood smears may be negative in aleukemic form!

Skeletal manifestations in 50–90%:

Location: proximal + distal metaphyses of long bones, flat bones, spine

(a) Diffuse osteopenia (most common pattern)
√ diffuse demineralization of spine + long bones ← leukemic infiltration of bone marrow + catabolic protein / mineral metabolism
√ coarse trabeculation of spongiosa ← destruction of finer trabeculae
√ multiple biconcave / partially collapsed vertebrae (14%)

(b) "Leukemic lines" (40–53% in ALL):
√ transverse radiolucent metaphyseal bands, uniform + regular across the width of metaphysis (= leukemic infiltration of bone marrow / osteoporosis at sites of rapid growth)
Location: large joints (proximal tibia, distal femur, proximal humerus, distal radius + ulna)
√ horizontal / curvilinear bands in vertebral bodies + edges of iliac crest
√ dense metaphyseal lines after treatment

(c) Focal destruction of flat / tubular bones:
√ multiple small clearly defined ovoid / spheroid osteolytic lesions (destruction of spongiosa, later cortex) in 30–60%
√ moth-eaten appearance, sutural widening, prominent convolutional markings of skull

◊ Lytic lesions distal to knee / elbow in children are suggestive of leukemia (rather than metastases)!

(d) Isolated periostitis of long bones (infrequent):
√ smooth / lamellated / sunburst pattern of periosteal reaction (= cortical penetration by sheets of leukemic cells into subperiosteum) in 12–25%

(e) Metaphyseal osteosclerosis + focal osteoblastic lesion (very rare)
√ osteosclerotic lesions ← reactive osteoblastic proliferation (late in disease)
√ mixed (lytic + bone-forming) lesions in 18%

Dx: sternal marrow / peripheral blood smear

Cx: proliferation of leukemic cells in marrow leads to extraskeletal hematopoiesis

DDx: metastatic neuroblastoma, Langerhans cell histiocytosis

B. ADULTHOOD

◊ Death usually occurs before skeletal abnormalities manifest
√ osteoporosis
√ solitary radiolucent foci (vertebral collapse)

√ permeating radiolucent mottling (proximal humerus)

MR:

√ diffuse decrease in SI compared with normal marrow on T1WI

√ isointense / mildly hyperintense compared with normal marrow on T2WI ← high water content of leukemic cells + displacement of fat

√ abnormally hyperintense relative to normal marrow on STIR

LIPOBLASTOMA

= rare rapidly growing benign tumor in children < 3 years of age (= postnatal proliferation) composed of mesenchymal cells ranging from prelipoblasts (spindle cells) to mature adipocytes

Origin: derived from fetal adipose tissue

Frequency: 30% of adipocytic tumors in children

Path: encapsulated immature adipose tissue (embryonal fat) separated by septa into multiple lobules

Histo: uni- and multivacuolated lipoblasts interspersed between spindle / stellate mesenchymal cells + suspended in myxoid stroma

Molecular features: translocation involving 8q11–13 with rearrangement of Plag1 gene

Median age: 12–18 months of age (range, newborn to 16 years); < 3 years of age (in > 90%); M÷F = 2÷1

Types:

(a) lipoblastoma proper = circumscribed encapsulated form in superficial adipose tissue (⅔)

(b) lipoblastomatosis = diffuse nonencapsulated infiltrative form in deep adipose tissue (⅓)

Location: subcutaneous tissue of extremities (70%), head and neck, trunk, mediastinum, mesentery, perineum, retroperitoneum

Size: 3–5 cm

• gradually increasing painless soft-tissue mass

√ no enhancement for tumors composed purely of lipocytes

√ marked heterogeneous enhancement for tumors composed predominantly of lipoblasts

US:

√ homogeneous finely textured echogenic (relative to liver / adjacent muscle) mass

√ may contain occasionally cystic / focal hypoechoic ares

CT:

√ tumor of fat density separated by fibrous septa

√ intratumoral fat stranding

MR (preferred preoperative evaluation):

√ high (mature adipocytes) / intermediate SI (immature adipocytes) on T1WI + T2WI with a predominance of lipocytes

√ heterogeneous texture with T1-hypointense + T2-hyperintense areas ← excessive amount of immature fat (lipoblasts) / myxocollagenous stromal tissue / intratumoral infarction / extensive mucoid + cystic degeneration

√ CHARACTERISTIC areas of high signal intensity on fat-suppressed images ← predominance of myxocollagen (NEVER in lipoma!)

Prognosis: may evolve into mature lipoma; capable of invading surrounding tissue (=

lipoblastomatosis); NO metastatic potential

Rx: wide surgical resection; recurrence in 10–25% for lipoblastomatosis

DDx: (1) Teratoma (calcifications)
(2) Lipoma (very rare in children)
(3) Well-differentiated liposarcoma (no distinguishing imaging features, patient age < 3 years allows reliable differentiation)
(4) Dermoid cyst

LIPOFIBROMATOSIS

= INFANTILE FIBROMATOSIS OF NONDESMOID TYPE
= rare fibrofatty tumor of childhood

Histo: mass with abundant adipose tissue traversed by bundles of spindle-shaped fibroblasts

Location: hand + foot > head & neck, chest wall, abdominal wall, jaw

Median age: 1 year (range, 11 days to 12 years); present at birth in 18%; M÷F = 2÷1

• slow-growing painless subcutaneous mass

Median size: 2 (range, 1–10) cm

MR (modality of choice):
√ mass isointense to fat interspersed by low- to intermediate SI (= fibrous component) on all sequences:
√ infiltrative toward subcutaneous + deeper soft tissues
√ ± enhancement of fibrous component

LIPOMA OF BONE

= INTRAOSSEOUS LIPOMA

Frequency: < 0.1% of primary bone tumors

Age: any (4^{th}–5^{th} decade); M÷F = 1.6÷1

May be associated with: hyperlipoproteinemia

• asymptomatic / localized bone pain (in up to 66%)

Milgram classification:

Stage I viable large fat cells organized into lobules replacing bone marrow + encasing trabeculae
√ trabecular resorption + thin sclerotic rim
√ lucent lesion (–60 to 100 HU)
√ isointense to subcutaneous fat

Stage II areas of partial fat necrosis accompanied by foamy macrophages + fibrosis associated with calcifications + reactive bone formation
√ regions of increased density (calcifications)
√ variable SI on T1WI + hyperintense on T2WI for fat necrosis
√ thick rim of reactive sclerosis

Stage III almost complete involution of lipoma with cyst formation (= myxomatous degeneration) + thick radiodense border
√ expansile remodeling (DDx: osseous infarct)
√ regions of cyst formation (cystic degeneration)

Location in order of frequency:

extremities (proximal femur > proximal tibia, fibula, humerus, radius), calcaneus, ilium, ribs, skull, mandible, maxilla, sacrum, coccyx, vertebrae; multiple locations = **intraosseous lipomatosis**

Site: metaphysis > diaphysis of long bones; epiphysis unusual

√ expansile nonaggressive radiolucent lesion

√ loculated / septated appearance (trabeculae)

√ thin well-defined sclerotic border

√ ± thinned cortex (NO cortical destruction)

√ NO periosteal reaction

√ may contain clumps of calcification centrally (= dystrophic calcification from fat necrosis)

◊ VIRTUALLY DIAGNOSTIC in:

@ Proximal femur

Site: intertrochanteric / subtrochanteric

√ marked ossification of margins of lesion

@ Calcaneus

Site: in triangular region between major trabecular groups (on LAT projection)

√ calcified / ossified nidus

@ Ileum

Site: adjacent to sacroiliac joint

◊ Radiographic appearance similar to unicameral bone cyst (infarcted lipoma = unicameral bone cyst ?)

MR:

√ similar to fat on all sequences (T1-hyperintense lesion)

Cx: rarely malignant transformation

DDx: fibrous dysplasia, simple bone cyst, posttraumatic cyst, giant cell tumor, desmoplastic fibroma, chondromyxoid fibroma, osteoblastoma

LIPOMA OF SOFT TISSUE

Lipoma composed of mature adipose tissue is the most common mesenchymal tumor (16% of soft tissue tumors).

Histo: mature fat cells (adipocytes) of uniform size and shape with a small portion of surrounding / intervening connective tissue stroma; fat unavailable for systemic metabolism

Variants: fibrolipoma, osteolipoma, chondrolipoma, intramuscular lipoma, angiolipoma, chondroid lipoma, spindle cell lipoma, pleomorphic lipoma, sialolipoma

Molecular features: translocation of 12q13–15; absence of MDM2 + CDK4 amplification (= liposarcoma)

• stable size after initial period of discernible growth

Age: 5th–6th decade; M > F

Location:

(a) superficial = subcutaneous lipoma (more common) in posterior trunk, head & neck (25%), proximal extremities

(b) deep lipoma in retroperitoneum, mediastinum, chest wall, deep soft tissue of hands + feet;

multiple in 5–7% (up to several hundred tumors)

◊ The deeper + more centrally located a fatty mass resides the more likely it is malignant!

√ well-defined encapsulated mass of fat opacity / density / intensity identical to subcutaneous fat
√ no enhancement
√ cortical thickening (with adjacent parosteal lipoma)

CT:
√ well-defined + homogeneous tumor with low attenuation coefficient (–65 to –120 HU)
√ no enhancement following IV contrast material

MR:
√ well-defined + homogeneous, often with septations
√ SI characteristics similar to subcutaneous fat: hyperintense on T1WI + moderately intense on T2WI
√ thin septations of low SI (not uncommon) correspond to fibrous connective tissue
√ differentiation from other lesions by fat suppression technique

Atypical features:
√ septa > 2 mm thick + septal nodularity
√ soft tissue component with attenuation / SI of muscle / fibrous tissue / hemorrhage / calcification ± contrast enhancement

Rx: resection with < 5% recurrence rate

DDx: normal fatty deposit (no internal architecture, no mass effect on adjacent structures and their metabolic behavior)

Angiolipoma

= lesion composed of fat separated by small branching vessels

Age: 2nd + 3rd decade; 5% familial incidence

• tender

Location: upper extremity, trunk

√ signal characteristics of fat + mixed with varying numbers of large / small vessels
√ mostly encapsulated lesion, may infiltrate

Benign Mesenchymoma

= long-standing lipoma with chondroid + osseous metaplasia

Infiltrating Lipoma

= INTRAMUSCULAR LIPOMA
= relatively common benign lipomatous tumor extending between muscle fibers that become variably atrophic

Peak age: 5th–6th decade; M > F

Location: thigh (50%), shoulder, upper arm

Lipoma Arborescens

= DIFFUSE SYNOVIAL LIPOMA
= rare idiopathic intraarticular lesion characterized by replacement of subsynovial tissue by mature fat cells with villous synovial proliferation

Cause: nonspecific proliferative synovial reaction to chronic irritation from inflammation / trauma

Frequently associated with:
degenerative joint disease, chronic rheumatoid arthritis, prior trauma

Mean age: 59 years (range, 5th–7th decade); M÷F = 1÷1

Path: frondlike appearance resembling a tree in leaf [*arborescens*, Latin = treeforming / treelike]

Histo: fatty proliferation with hypertrophic synovial villi distended by fat + dense focally nodular lymphocytic and plasmacellular infiltrate

Location: knee >> other joints; monoarticular (94%)

Site: suprapatellar pouch of knee

- long-standing painless slowly progressive swelling
- recurrent joint effusions; joint pain + swelling (47%)

X-ray:
√ joint fullness with radiolucent areas
√ (frequently) osteoarthritic changes

US:
√ hyperechoic frondlike mass bending and waving in real time with joint manipulation

MR:
√ frondlike synovial mass isointense to fat on all sequences (PATHOGNOMONIC)
√ joint effusion
√ lack of magnetic susceptibility artifact

Rx: synovectomy

Neural Fibrolipoma

= FIBROLIPOMATOUS HAMARTOMA OF NERVE
= rare tumorlike condition characterized by sausage-shaped / fusiform enlargement of a nerve by fibrofatty tissue

Age: early adulthood < 30 years / at birth

Histo: infiltration of epineurium + perineurium by fibrofatty tissue with separation of nerve bundles

- soft slowly enlarging mass
- pain, tenderness, decreased sensation, paresthesia

Location: volar aspect of hand, wrist, forearm

Site: median n. (most frequently), ulnar n., radial n., brachial plexus

May be associated with:
macrodactyly (in 2/3) = macrodystrophia lipomatosa

√ may not be visible radiographically

MR:
√ longitudinally oriented, cylindrical, linear / serpiginous structures of signal void about 3 mm in diameter (= nerve fascicles with epi- and perineural fibrosis) separated by areas of fat SI (= mature fat infiltrating the interfascicular connective tissue)

US:
√ "cablelike appearance" = alternating hyper- and hypoechoic bands on US

DDx: cyst, ganglion, lipoma, traumatic neuroma, plexiform neurofibroma, vascular

malformation

LIPOSARCOMA

= malignant tumor of mesenchymal origin rarely arising from lipoma

Frequency: 10–16–35% of all soft-tissue sarcomas; 2nd most common soft-tissue sarcoma in adults (after malignant fibrous histiocytoma)

Prevalence: 4.1÷1,000,000 in USA (2001)

Age: 5th–6th decade; M÷F = 1÷1

Path: wide spectrum of pathologic appearances varying from circumscribed lesions consisting predominantly of adipose tissue to circumscribed / infiltrating masses without any macroscopically visible adipose elements

Histo: < 50% of liposarcomas contain lipid material; nonadipose components include fibrosis, inflammation, areas of myxoid change, fat necrosis ± calcification

Categories:

(1) well-differentiated = lipogenic subtype (50%)
(2) dedifferentiated round cell subtype (10%)
(3) myxoid subtype (20–50%)
(4) pleomorphic subtype (5–15%)
(5) mixed subtype (5–12%)

Molecular features: ring chromosome derived from chromosome 12; MDM2 + CDK4 amplification

Location: lower extremity (45%), abdominal cavity and retroperitoneum (14%), trunk (14%), upper extremity (7.6%), head & neck (4–6.5%), miscellaneous (13.5 %)

Spread: hematogenous to lung, visceral organs; myxoid liposarcoma shows tendency for serosal + pleural surfaces, subcutaneous tissue, bone; regional nodal metastases (in < 10%)

• typically painless, slow-growing (months – years) soft-tissue mass; pain + tenderness (10–15%)

√ unifying radiologic feature = adipose tissue (vast majority) of nodular / finely reticulated / amorphous appearance

√ associated nonlipomatous components and lesion location often allow specific diagnosis of subtype

Criteria favoring liposarcoma over lipoma:

• male patient age > 60 years
√ size of lesion > 10 cm
√ < 75% fat component
√ associated nonadipose mass
√ presence of thick septa > 2 mm of nodular / globular appearance with contrast enhancement
√ deep lesions in mediastinum / retroperitoneum

Rx: wide surgical excision ± radiation therapy ± adjunct chemotherapy

Well-differentiated Liposarcoma (50%)

= ATYPICAL LIPOMATOUS TUMOR

= locally aggressive tumor of intermediate malignant potential with < 25% of tissue volume consisting of fat

Peak age: 6th–7th decade; M÷F = 1÷1
Path: large multilobulated well-circumscribed mass
Histo: malignant lipoblasts with large amounts of lipid + scanty myxoid matrix; 5 variants (lipoma-like, sclerosing, inflammatory, spindle cell, liposarcoma with meningothelial whorls)
Location:
(a) deep soft tissues of extremities (65–75%): thigh
(b) retroperitoneum (20–33%): presenting quite large with > 20 cm in diameter
(c) upper extremity (14%)
(d) head & neck (5%)
Site: intramuscular > intermuscular / subcutaneous
√ round / lobulated mass of fat density displacing surrounding structures
X-Ray:
√ soft-tissue mass of >10 cm in diameter:
√ fat detectable in extremities, not in retroperitoneum
√ calcification / metaplastic ossification (10–32%)
US:
√ heterogeneous multi-lobulated well-defined mass
√ hyperechoic / variably echogenic fat
CT / MR:
√ adipose mass with low proportion of fat content (< 25% of tumor volume)
√ presence of nonadipose focal globular masslike areas and enhancing septa > 2 mm ± nodularity:
√ high attenuation on CT
√ hypo- / isointense relative to skeletal muscle on T1WI
√ hyperintense relative to skeletal muscle on T2WI
CEMR:
√ moderate (¼) / marked (¾) septal enhancement
Prognosis: no metastatic potential; risk of local recurrence (43% in extremity, 70% in groin, 91% in retroperitoneum)

Dedifferentiated Liposarcoma (10%)
Path: high-grade fibrosarcoma / malignant fibrous histiocytoma (90%) mixed with well-differentiated areas
Histo: supernumerary ring / giant chromosomes derived from 12q13–15 regions
Age: 7th decade; M÷F = 1÷1
Location: deep (retroperitoneum÷extremity = 3÷1); head & neck + trunk + spermatic cord (< 20%); subcutis (< 1%)
Development: 7–8 years from well-differentiated liposarcoma
√ large components identical to well-differentiated liposarcoma
√ additionally focal nodular nonlipomatous regions > 1 cm in size of low to intermediate SI on T1WI + high SI on T2WI:
√ fibrous collagenized tissue
√ metaplastic mineralization
√ fat necrosis

Prognosis: more aggressive than well-differentiated liposarcoma with local recurrence in 41% + distant metastasis (lung, liver, bone) in 21%

Myxoid Liposarcoma

= tumor of intermediate differentiation with varying degrees of mucin + fibrous tissue + relatively little lipid (< 10%)

Path: fat content often < 10–25% obscuring typical features of lipomatous tumors

Histo: plexiform vascular network + mixture of stellate spindle-shaped mesenchymal cells + lipoblasts in a basophilic myxoid ground substance

Genetics: reciprocal translocation of t(12;16)(q13;p11)

Peak age: 4th–5th decade (most common subtype to affect children); M÷F= 1÷1

Location: intermuscular fascial plane (70–80%) in deep-seated area

Site: (a) lower extremity (75–80%): medial thigh, popliteal region, groin, buttock, calf
(b) retroperitoneum (8%)
(c) upper extremity (5%)

√ well-defined multilobulated intermuscular mass:
- √ density between water + muscle on CT mimicking a cyst
- √ T1 prolongation with a cystic appearance (in 5–10%)
- √ very long relaxation times of large component of myxoid matrix (22%)
- √ pathognomonic lacy / linear amorphous foci of fat intensity (in 90–95%) of approx. 10% of entire lesion
- √ peripheral nodular (61%) / central nodular (44%) / diffuse (17%) enhancement

US:
- √ anechoic mass ± thin septa (disproving fluid content)

Dx: biopsy of adipose area

Prognosis: frequent recurrence; metastasis in unusual locations (opposite extremity, retroperitoneum, chest wall, pelvis); 5-year mortality of 47–77%

DDx: (1) Myxoma (intramuscular, only thin rind of perilesional fat on T1WI, surrounding muscle atrophy + edema)
(2) Synovial cyst / ganglion (typical location, thick wall and surrounding edema, clinical history of liquefied hematoma / abscess)

Pleomorphic Liposarcoma

Histo: marked cellular pleomorphism, paucity of lipid + mucin = highly undifferentiated

√ well-defined mass ± infiltrative margins:
- √ intensity of muscle (no distinguishing imaging features from other soft-tissue sarcomas) in 84%
- √ small lacy / linear / amorphous foci containing < 1% fat in 62–75% (fat suppression technique!)
- √ prominent heterogeneity with tumor necrosis in 81%

Dx: biopsy of adipose foci

Prognosis: aggressive high-grade sarcoma with marked propensity for tumor recurrence + metastases (lung); 5-year survival of 21–63%

LYME ARTHRITIS

= heterogeneous zoonosis with geographical variation in animal reservoir + tick species + spirochete subspecies

Agent: spirochete Borrelia burgdorferi transmitted by tick bite Ixodes dammini; in Europe Borrelia garinii

Histo: inflammatory synovial fluid, hypertrophic synovia with vascular proliferation + cellular infiltration

- endemic areas: Lyme and Old Lyme, Connecticut (first recognized location); now throughout USA, Europe, Australia
- recurrent attacks of arthralgias within days to 2 years after tick bite (80%); history of erythema chronicum migrans

Location: mono- / oligoarthritis of large joints (especially knee)

√ erosion of cartilage / bone (4%)

√ no neuroimaging manifestations (frequent)

√ painful meningoradiculitis (= Bannwarth syndrome)

√ abnormal smooth leptomeningeal enhancement with cranial or spinal nerve involvement

√ enhancing periventricular + callososeptal + infratentorial white matter lesions ← perivascular extension of lymphocytic inflammation (DDx: multiple sclerosis)

Rx: antibiotics

Posttreatment Lyme disease (10–20%) = syndrome due to autoimmune effects of molecular mimicry and antigen cross-reactivity

DDx: (1) Rheumatic fever
(2) Rheumatoid arthritis
(3) Gonococcal arthritis
(4) Reiter syndrome

LYMPHANGIOMA

= sequestered noncommunicating lymphoid tissue lined by lymphatic endothelium

Cause: congenital obstruction of lymphatic drainage

Subtypes:

(1) Capillary lymphangioma (rare)
Location: subcutaneous tissue

(2) Cavernous lymphangioma
Location: about the mouth + tongue

(3) Cystic lymphangioma (most common)
= cystic hygroma
Associated with: hydrops fetalis, Turner syndrome
Location: head, neck (75%), axilla (20%), extension into mediastinum (3–10%)
- soft fluctuant mass

◊ Lymphangiomas are frequently a mixture of subtypes!

Age: found at birth (50–65%); within first 2 years of life (90%)

Location: soft tissue; bone (rare)

√ multilocular cystic lesion with fibrous septations

√ occasionally serpentine vascular channels

√ opacification during lymphangiography / direct puncture
√ clear / milky fluid on aspiration
DDx: hemangioma (blood on aspiration)

LYMPHANGIOMATOSIS OF BONE

= MASSIVE OSTEOLYSIS = GORHAM-STOUT DISEASE
= VANISHING BONE DISEASE = PHANTOM BONE DISEASE
[Lemuel Whittington Gorham (1885–1968), internist, New York]
[Arthur Purdy Stout (1885–1967), surgeon and pathologist at College of Physicians & Surgeons of Columbia University, New York]
= infrequent disorder of bone + soft tissues characterized by aggressive nonneoplastic proliferation of lymphangiomatous tissue → massive local osteolysis
Cause: persistence of dilated lymphatics from 14th–20th week EGA
Prevalence: > 200 cases confirmed
Histo: proliferation of dilated lymph channels communicating with blood vessels in bone
Age: infant + child + adolescent, M=F
◊ Consider Gorham-Stout disease for any osteolytic lesion of unknown cause!
Associated with: cystic hygroma (neck, axilla, chest wall, mediastinum), splenic cysts, chylothorax, soft-tissue hemangiomas without calcifications
• frequently history of severe trauma (50%)
• little / no pain in affected body part
Location: any bone (frequently multiple locations); most commonly major long bones (humerus, shoulder, mandible), pelvis, spine, thorax, short tubular bones of hand + feet (unusual)
√ progressive relentless osteolytic resorption / destruction of bone with monocentric spread:
√ patchy osteopenia (early)
√ expanding intramedullary lytic lesion (later)
√ complete resorption of entire bone segments (late) of one bone / group of bones
√ no regard for joint boundaries
√ lack of reaction (no periosteal reaction, minimal sclerosis)
√ advancing edge of destruction not sharply delineated
√ tapering margins of bone ends at sites of osteolysis with conelike spicule of bone (early changes)
√ no soft-tissue calcifications / phleboliths
√ serous / chylous pleural effusions → significant mortality
MR:
√ varying SI depending on disease activity
√ hypointense soft tissue around osteolytic area on T1WI
√ hyperintense soft tissue around osteolytic area on T2WI
√ minimal contrast enhancement
Rx: no known validated treatment; interferon; steroids
DDx: Langerhans cell histiocytosis, fibrous dysplasia, brown tumor of hyperparathyroidism, infection, trauma, tumor, gout, scleroderma

LYMPHOMA OF BONE

Primary Lymphoma of Bone

= RETICULUM CELL SARCOMA = OSTEOLYMPHOMA

= singular bone lesion without evidence of distal nodal /disseminated disease for at least 6 months after diagnosis (= stage E in Ann Arbor classification)

N.B.: presence of locoregional lymphadenopathy is not a criterion of exclusion

Prevalence: < 5% of all primary bone tumors; < 1% of all NHL; 5% of extranodal lymphomas; 2–6% of all primary malignant bone tumors in children

Histo: (a) NHL (94%): mostly diffuse large B-cell (80%) / T-cell category; sheets of reticulum cells, larger than those in Ewing sarcoma (DDx: myeloma, inflammation, granulocytic osteosarcoma, eosinophilic granuloma)

(b) Hodgkin disease in 6%

Median age: 36–52 (range, 1.5–86) years; bimodal distribution with peaks in 2nd–3rd and 5th–7th decades; 50% < 40 years; 35% < 30 years; M÷F = 6÷1

- intermittent chronic dull pain; local swelling, palpable mass
- systemic symptoms such as weight loss and fever
- striking contrast between lesion size + patient's well-being

Location: lower femur (25%), upper tibia (40% about knee), humerus, pelvis, head & neck, vertebra (25%), scapula, ribs

Site: meta- / diaphysis

Radiography:

√ lytic process at end of a long bone with aggressive periosteal reaction (almost pathognomonic)

√ lytic-destructive pattern (70%):

√ "permeative" pattern = numerous small elongated rarefactions parallel to long bone axis

√ "moth-eaten" pattern = many medium to large areas of radiolucency in poorly marginated area of bone

√ lamellated / layered "onion-peel" / broken periosteal reaction (60%):

√ disrupted periosteal bone (poorer prognosis)

√ sunburst periosteal response (rare and less than in Ewing sarcoma)

√ blastic-sclerotic pattern (rare):

√ mixed lytic lesion with sclerotic areas

√ may develop after therapy

√ near absence of detectable abnormalities on plain X-ray

CT:

√ cortical destruction (late)

√ sequestrum within lytic lesion

MR:

√ bone marrow replacement:

√ areas of low signal intensity within marrow on T1WI

√ high SI on T2WI for tumor + peritumoral edema + reactive marrow changes

√ areas of enhancement within lesion

√ soft-tissue involvement ← spread of tumor cells from marrow through small vascular channels through cortex into surrounding soft tissue:
√ soft-tissue mass without calcification (70%)
N.B.: relatively minimal cortical destruction with extensive soft-tissue + marrow involvement
√ synovitis of knee joint common
√ cortical erosion (earliest detection by MR)

Cx: pathologic fracture (25% = most common among malignant bone tumors)

Rx: combination of radiation therapy + chemotherapy

Prognosis: 83% 5-year survival

DDx: (1) Osteosarcoma (less medullary extension, younger patient)
(2) Ewing tumor (systemic symptoms, debility, younger patient)
(3) Metastatic malignancy / secondary lymphoma (multiple bones involved, more destructive, recognized by whole-body surveillance)

Secondary Lymphoma of Bone

= disseminated malignant lymphoma (stage IV)

MACRODYSTROPHIA LIPOMATOSA

= rare nonhereditary congenital form of localized gigantism = neural fibrolipoma with macrodactyly

Path: striking increase in adipose tissue in a fine fibrous network involving periosteum, bone marrow, nerve sheath, muscle, subcutaneous tissue

May be associated with: syn-, clino-, polydactyly

• painless

Location: 2nd or 3rd digit of hand / foot; unilateral; one / few adjacent digits may be involved in the distribution of the median / plantar nerves

√ long + broad splayed phalanges with endosteal + periosteal bone deposition
√ overgrowth of soft tissue, greatest at volar + distal aspects
√ slanting of articular surfaces
√ lucent areas of fat (DIAGNOSTIC)

Prognosis: accelerated maturation possible; growth stops at puberty

DDx: fibrolipomatous hamartoma associated with macrodystrophia lipomatosa (indistinguishable), Klippel-Trénaunay-Weber syndrome, lymphangiomatosis, hemangiomatosis, neurofibromatosis, chronic vascular stimulation, Proteus syndrome

MARFAN SYNDROME

[Antoine Bernard-Jean Marfan (1858–1942), Chef de clinique medicale de l'Université de Paris and Hôpital des Enfants Malades]

= Arachnodactyly

= autosomal dominant (in 75%) multisystemic connective tissue disorder with high penetrance but extremely variable expression; new sporadic mutations in 25–30%

Genetics: > 135 mutations in fibrillin-1 gene (FBN1) on chromosome 15 which encodes a large glycoprotein (= component of extracellular microfibrils → connects elastic lamina to

adjacent endothelial cells + smooth muscle cells for structural integrity and coordination of contractile + elastic tension of vessel walls

Prevalence: 2–3÷10,000; M÷F = 1÷1

Path: disintegration and elastolysis of connective tissue with abnormal cross-linking of collagen fibers → aneurysm formation and dissection

Most common cause of death: aortic dissection, CHF, cardiac valvular disease

A. MUSCULOSKELETAL MANIFESTATIONS

- tall thin stature with long limbs, arm span greater than height (commonly basketball + volleyball players)
- muscular hypoplasia + hypotonicity
- scarcity of subcutaneous fat (= emaciated look)

√ generalized osteopenia

@ Skull

- elongated face

√ dolichocephaly

√ prominent jaw

√ high arched palate

@ Hand

√ **arachnodactyly** = elongation of phalanges + metacarpals:

- Steinberg sign = protrusion of thumb beyond confines of clenched fist (found in 1.1% of normal population)
- metacarpal index (averaging the 4 ratios of length of 2nd–5th metacarpals divided by their respective middiaphyseal width) > 8.8 (male) or 9.4 (female)

√ flexion deformity of 5th finger

@ Foot

√ pes planus (25%) / planovalgus ← increased ligamentous laxity

√ clubfoot

√ hallux valgus

√ hammer toes

√ disproportionate elongation of 1st digit of foot

@ Chest wall deformity (66%)

Cause: longitudinal overgrowth of ribs during periods of rapid growth (adolescence)

- reduction in lung capacity + forced vital capacity + forced expiratory volume in 1 second

√ **pectus excavatum** = retraction of lower sternum:

√ displacement of heart + lungs + diaphragm

Rx: surgery (Ravitch / Nuss procedure) for pectus index > 3.25 (dividing width of chest wall at its widest point by distance between posterior surface of sternum and anterior surface of spine) after maturation of skeleton

√ **pectus carinatum** = anterior protrusion of upper portion of sternum

Rx: surgery for cosmetic reasons

@ Spine

- ratio of measurements between symphysis and floor + crown and floor > 0.45

√ severe rigid progressive **scoliosis** (45–62%) / kyphosis (16%) / kyphoscoliosis

◊ Most frequent + potentially severe manifestation of Marfan syndrome → restriction

of lung volume
Age: young patient; M÷F = 1÷1
Rx: bracing for curvature < 25°; surgical correction for curvature > 40°
√ atlantoaxial translation (54%)
√ increased incidence of Schmorl nodes (Scheuermann disease) and spondylolisthesis
√ straight back syndrome
√ winged scapulae
√ **dural ectasia** (56–65%) of lumbosacral spine:
= ballooning / widening of dural sac ± nerve root sleeves
• usually asymptomatic
• occasionally back pain, headache, neurologic deficit
Location: lumbosacral spine
May be associated with: bone erosion, meningocele, arachnoid cyst
√ widening of interpediculate distance
√ posterior scalloping of vertebral body
√ dilatation of nerve root sleeve
√ expansion of sacral spinal canal
√ presacral + lateral sacral meningoceles
√ enlargement of sacral foramina

@ Joints
• ligamentous laxity + hypermobility + instability
√ premature osteoarthritis
√ patella alta
√ genu recurvatum
√ recurrent dislocations of patella, hip, clavicle, mandible
√ slipped capital femoral epiphysis
√ progressive protrusio acetabuli (16–27%) = invasion of acetabulum + femoral head into pelvic cavity
Location: bilateral > unilateral; F > M
• limited internal rotation + abduction of hip
√ increased center-edge angle of Wiberg > 40°
√ "teardrop" crossed by ilioischial line / obscured by femoral head

B. OCULAR MANIFESTATIONS
• bilateral ectopia lentis, usually upward + outward ← poor zonular attachments
• glaucoma, macrophthalmia
• hypoplasia of iris + ciliary body
• miosis (= contracted pupils) ← absence of dilatory effect of hypoplastic ciliary muscle
• myopia (= increased axial length of globe)
• retinal detachment
• strabismus, ptosis
• blue sclera
• megalocornea = flat thickened cornea

C. CARDIOVASCULAR MANIFESTATIONS (60–98%)
affecting mitral valve, ascending aorta, pulmonary artery, splenic + mesenteric arteries (occasionally)

◊ Dominant cause of death in 93%!
• chest pain, palpitations, shortness of breath, fatigue
• mid-to-late systolic murmur + one / more clicks
In ¹/³ associated with: congenital heart defect (ASD, incomplete coarctation)
@ Aorta (cause of death in 55%)
Histo: degeneration of elastic tissue in aortic media + cystic medial necrosis of smooth muscle cells

1. **Annuloaortic ectasia** (in 60–80% of adults
= uniform dilatation of all 3 sinuses of Valsalva with distal progression to sinotubular junction (= obliteration of normal sinotubular ridge) and aortic annulus
Histo: cystic medial necrosis
• leading cause of aortic valve insufficiency
√ "tulip bulb aorta" = symmetrical dilatation of aortic sinuses of Valsalva slightly extending into ascending aorta (58%)
√ triangular coaptation defect of valve cusps (during middiastolic closure at 70% of R-R interval of gated CT) = radiographic sign of aortic insufficiency
√ tethered valve cusps at midsystolic opening (= at 10% of R-R interval of a gated CT) ← dilatation of the sinus of Valsalva
Cx: aortic regurgitation (in 81% if root diameter > 5 cm; in 100% if root diameter > 6 cm), aortic root dissection, aortic root rupture
Prognosis: average age of death at 35 (75) years in untreated (treated) patients
Rx: prophylactic surgery at a sinus diameter of 55 mm in adulthood + 45–50 mm in childhood / aneurysm expansion of > 0.5–1 mm per year

The classic phenotypic appearance of the aorta in Marfan syndrome is annuloaortic ectasia with dilatation of aortic annulus and sinuses of Valsalva, and effacement of the sinotubular junction, resulting in a tulip-shaped configuration of the aortic root.

2. **Aortic aneurysm** (without annuloaortic ectasia)
√ fusiform dilatation of ascending aorta, rarely beyond innominate artery (rapid enlargement, young patient)
√ more rapid enlargement than atherosclerotic aneurysm
√ rarely intimal calcifications of the aortic wall
DDx: atherosclerotic aneurysm (older patient, less rapid enlargement, frequent thrombosis, intimal calcifications common)
3. **Aortic dissection**
CXR:
√ progressive aortic enlargement at serial imaging
√ enlarged aortic arch
√ double contour of aortic arch
√ displacement of intimal calcifications > 6 mm
√ new pericardial / pleural effusion
CT:
√ intimal flap + false lumen (in 70%) PATHOGNOMONIC
√ increased attenuation of thrombosed false lumen
√ internal displacement of intimal calcification

√ mediastinal / pericardial hematoma
√ infarction of organs supplied by branch vessels from the false lumen

Prognosis: recurrence common

Rx: composite graft to replace aortic root (Bentall procedure); antihypertensive medication

@ Mitral valve

Histo: myxomatous degeneration of valve leads to redundancy + laxness

• mid-to-late systolic murmur + one / more clicks

√ "floppy valve syndrome" (95%) = redundant chordae tendineae with mitral valve prolapse + regurgitation

Cx: (1) Mitral regurgitation

(2) Rupture of chordae tendineae (rare)

@ Coarctation (mostly not severe)

@ Pulmonary artery aneurysm and dilatation of pulmonary artery:
> 35 mm at root (in 43%) and > 28 mm at bifurcation

@ Cor pulmonale ← chest deformity

Criteria for Diagnosis of Marfan Syndrome (*Ghent Classification*)		
System Affected	*Major Criteria*	*Minor Criteria*
Cardio-vascular	√ dilatation of ascending aorta ± aortic regurgitation involving > 1 sinus of Valsalva √ dissection of descending aorta	√ dilatation / dissection of descending aorta < 50 years of age
Musculo-skeletal	√ scoliosis with curvature > 20° / spondylolisthesis √ pectus carinatum √ pectus excavatum requiring surgery √ acetabular protrusion √ reduced upper-to-lower segment ratio / arm span-to-height ratio > 1.05 √ wrist and thumb signs √ reduced extension of elbow < 170° √ medial displacement of medial malleolus causing pes planus	√ pectus excavatum of moderate severity √ joint hypermobility √ highly arched palate with crowding of teeth √ abnormal facial appearance (dolichocephaly, malar hypoplasia, enophthalmos, retrognathism, downslanting palpebral fissures)
CNS	√ lumbosacral dural ectasia	
Lung		√ spontaneous pneumothorax √ apical blebs
Eye	√ ectopia lentis	√ abnormal flat cornea √ increased axial length of globe √ hypoplastic iris / ciliary muscle causing decreased miosis
Skin		√ striae atrophicae √ recurrent / incisional hernia

D. PULMONARY MANIFESTATIONS (rare)

- √ lung cysts, bullae, blebs + diffuse apical bullous emphysema
- √ congenital malformation of bronchus + bronchiectasis
- √ recurrent spontaneous pneumothoraces (4–15%; 10 x times more common than in general population)
- √ interstitial parenchymal disease ± honeycombing

E. ABDOMINAL MANIFESTATION
√ recurrent biliary obstruction
F. INTEGUMENTUM
• striae atrophicae
√ recurrent incisional hernia

Prognosis: life expectancy close to normal; death (in 90% from aortic dissection, CHF, valvular disease)

DDx: (1) Homocystinuria (osteoporosis)
(2) Ehlers-Danlos syndrome
(3) Congenital contractural arachnodactyly (ear deformities, NO ocular / cardiac abnormalities)
(4) MEN 3 (medullary thyroid carcinoma, mucosal neuromas, pheochromocytoma, marfanoid habitus)

MELORHEOSTOSIS

= LÉRI DISEASE [melos, *Greek* = limb; rhein, *Greek* = flow]
[André Léri (1875–1930), pupil of Joseph Babinski and Pierre Marie, president of French Ophthalmological Society]
= rare sporadic mixed sclerosing bone dysplasia with disturbances in endochondral + intramembranous ossification characteristically appearing as flowing hyperostosis

Age: usually occult until adulthood; slow chronic progressive course in adults; rapid progression in children

Cause: developmental error of intramembranous bone formation related to mutation in LEMD3 on chromosome 12q, which codes for an inner nuclear membrane protein responsible for inhibition of transforming growth factor b + bone morphogenic protein

Path: overproduction of bone matrix + increased angiogenesis

Associated with: osteopoikilosis, osteopathia striata, tumors / malformations of blood vessels (hemangioma, vascular nevi, glomus tumor, AVM, aneurysm, lymphedema, lymphangiectasia)

• often asymptomatic incidental finding
• severe pain + limited joint motion (bone may encroach on nerves, blood vessels, or joints) → ± joint contracture
• thickening + fibrosis of overlying skin (resembling scleroderma); muscle atrophy (frequent)
• Dermatofibrosis lenticularis disseminata (**Buschke-Ollendorff syndrome)** = asymptomatic small flesh-colored to yellow dermal papules / coalescent plaques (in 25%) on buttocks, trunk, arms, skin folds
Age: usually in childhood; often during 1st year of life
Histo: connective tissue nevi with predominantly abnormal elastin / abnormal collagen

Location:
› common: in diaphysis of appendicular skeleton (lower > upper extremity); usually monomelic with at least two bones involved in dermatomal distribution (following spinal sensory nerve sclerotomes) / monostotic / polyostotic
› rare: in axial skeleton (skull, spine, ribs)

Site: entire cortex / limited to one side of cortex

Patterns: (1) osteoma-like, (2) myositis ossificans-like, (3) osteopathia striata-like, (4) classic dripping candle (5) mixed (overlap syndrome)

√ cortical + medullary hyperostosis of single / multiple adjacent bones:
  √ "dripping / flowing candle wax" sign = continuous / interrupted streaks / blotches of irregular cortical hyperostosis along tubular bone beginning at proximal end extending distally with slow progression
√ may cross joint with joint fusion
√ small opacities in scapula + hemipelvis (similar to osteopoikilosis)
√ discrepant limb length
√ flexion contractures of hip + knee
√ genu valgum / varus
√ dislocated patella
√ ossified soft-tissue masses (27%)

DDx: (1) Osteopoikilosis (generalized)
(2) Fibrous dysplasia (normal bone structure not lost, not as dense)
(3) Engelmann disease
(4) Hyperostosis of neurofibromatosis, tuberous sclerosis, hemangiomas
(5) Osteoarthropathy

MENISCAL TEAR

Cause: acute injury; degeneration related to aging; tear contributes to degenerative joint disease
Prevalence: increases with age
Type of cross-sectional tear pattern:
(a) vertical tear with longitudinal / radial / oblique surface pattern
(b) horizontal tear with longitudinal / oblique / cleavage surface pattern
(c) mixed pattern
Site of injury:
(a) medial meniscus (MM) in 45%:
  › no isolated tears of body
  › isolated tear of anterior horn in 2%
(b) lateral meniscus (LM) in 22%:
  › tear of posterior horn in 80% of all LM tears
  ◊ more common in acute injury of young individuals
  ◊ with ACL tear → increased prevalence of peripheral tears → decreased sensitivity for tear detection in LM
  › isolated tear of anterior horn in 16%
(c) both menisci involved in 33%
  › posterior horn of both menisci: constrained MM > LM
Associated with: ligamentous injury
• asymptomatic in up to 20% of older individuals
MR:
(a) DIRECT SIGNS (in the absence of prior surgery):
  √ increased signal extending to articular surface:
    √ "two-slice-touch" rule = ≥ 2 images with signals contacting the surface (94% PPV in

MM, 96% PPV in LM)
√ 1 image with signal contacting surface (43% PPV in MM, 18% PPV in LM) reported as **possible tear**

◊ Diagnosis of tear hinges on surface involvement!

◊ Truncation artifact + magic angle artifact may cause increased intrameniscal signal!

√ distortion of meniscal shape

(b) INDIRECT SIGNS

√ **meniscal cyst** (meniscal tear in 98–100%)
= synovial fluid accumulation in degenerated tissue
Location: intrameniscal, meniscocapsular margin, parameniscal
√ cyst in continuity with horizontal cleavage / complex meniscal tear

√ **meniscal extrusion**
= peripheral margin of meniscus extends ≥ 3 mm beyond edge of tibial plateau
N.B.: Exclude hypertrophic osteophyte for determination of outer margin!
Pathophysiology: disruption of circumferentially oriented collagen bundles → loss of meniscal hoop strength
Cause: root tear, complex tear, large radial tear, severe meniscal degeneration
◊ 76% of medial root tears have extrusion
◊ 39% of extrusions have medial root tears

√ **subchondral bone marrow edema**
= superficial edema adjacent to meniscal attachment site paralleling articular surface < 5 mm deep
@ medial meniscus (in 60%): 64–70% sensitive, 94–100% specific
√ posterior lip medial tibial plateau bone bruise (64% PPV for tear in posterior horn of MM)
@ lateral meniscus (in 90%): 88–89% sensitive, 98–100% specific

√ torn popliteomeniscal fascicle (79% PPV)

MR sensitivity, specificity, and accuracy:

Tear of	*Sensitivity*	*Specificity*	*Accuracy*
Medial meniscus	93%	88%	59–92%
Lateral meniscus	79%	96%	87–92%
Anterior cruciate lig.			91–96%
Posterior cruciate lig.			up to 99%

◊ MR has a high negative predictive value!
◊ 60–97% accuracy for arthrography
◊ 84–99% accuracy for arthroscopy (poor at posterior horn of medial meniscus)

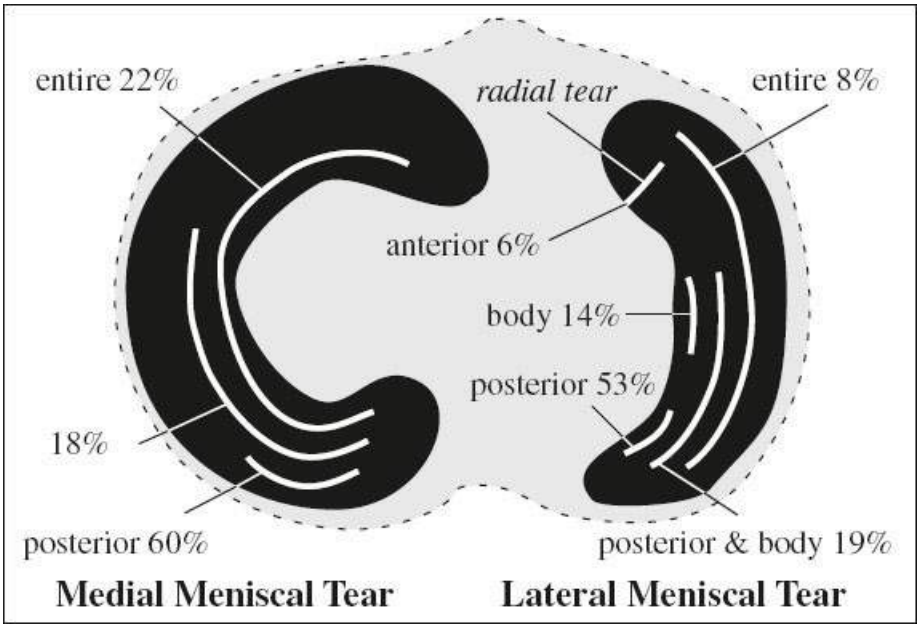
Interpretative / Diagnostic Error

(12% for experienced radiologist)
(a) anatomic error
FN: tear mistaken for normal anatomic structure
FP: normal anatomic structure mistaken for a tear
(b) technique-related error obscuring a tear

1. Arterial pulsation
2. Healed tear = retained abnormal increased SI
3. Magic-angle effect = collagen fibers oriented at 55° relative to magnetic field
   √ often seen in upslope medial segment of LM posterior horn

Lateral meniscus: 5.0% FN (middle + posterior horn)
1.5% FP (posterior horn)

Medial meniscus: 2.5% FN (posterior horn)
2.5% FP (posterior horn)



Pitfalls in Diagnosing Meniscal Tears

A. Normal variants simulating tears
   1. Superior recess on posterior horn of MM
   2. Popliteal hiatus
   3. Transverse ligament
   4. Meniscofemoral ligaments
   5. Oblique meniscomeniscal ligament (1–4%)
   6. Soft tissue between capsule + medial meniscus

B. Diskoid meniscus

C. Healed meniscus
   √ persistent grade 3 signal at least up to 6 months
   √ S/P meniscectomy (false-positive type IV finding)

D. Globular / linear increase in SI (grade 1 /2 signal)
   Cause:
   (a) internal mucinous degeneration in adults
   (b) normal vascularity in children + young adults
   (c) acute contusion in trauma

E. Tears difficult to detect on SAG images ← volume averaging
   (a) better depiction on COR images for

1. Small radial tear
2. Horizontal tear of body
3. Bucket-handle tear

(b) AXIAL images helpful for detection of
1. Small radial tear
2. Displaced tear
3. Peripheral tear of posterior horn of LM

Easily Missed Meniscal Injury
1. Radial tears
2. Displaced flap tears
3. Meniscocapsular separation

Horizontal Meniscal Tear
= CLEAVAGE TEAR
= tear oriented parallel to tibial plateau
› involving either articular surface / central free edge
› dividing meniscus into superior + inferior halves

Cause: degenerative in patients > 40 years

Associated with: parameniscal cyst formation ← direct communication with joint fluid

√ horizontally oriented line of high signal intensity contacting meniscal surface / free edge

Rx: débridement of smaller unstable meniscal leaf + decompression of associated parameniscal cyst

Longitudinal Meniscal Tear
= tear oriented parallel to long axis / outer margin of meniscus + perpendicular to tibial plateau dividing meniscus into central + peripheral halves

Cause: significant knee trauma in younger patient

MR Classification of Meniscal Signal Intensity vs. Injury

Grade	*Type*	*MR Finding*	*PPV for Tear*
0	0	normal meniscus	1%
1	I	globular / punctate intrameniscal signal	2%
2	II	linear signal not extending to surface	5%
	III	short tapered apex of meniscus	23%
	IV	truncated / blunted apex of meniscus	71%
3	V	signal extending to only one surface	85%
3	VI	signal extending to both surfaces	95%
3	VII	comminuted reticulated signal pattern	82%

Site: propensity to involve peripheral $^{1}/_{3}$ of meniscus + posterior horn (difficult diagnosis for LM because of complex attachment anatomy)

√ vertically oriented line of high SI contacting one / both articular surfaces (full / partial-thickness tear)

√ no involvement of free edge of meniscus
√ disruption of posterosuperior popliteomeniscal fascicle = high PPV for tear of LM posterior horn
Close association with: ACL tear (in 90% for MM, in 83% for LM)
Rx: may be amenable to repair if
(a) in vascularized (peripheral) outer 3–5 mm
(b) between 7 and 40 mm long

Radial Tear (6%)
= TRANSVERSE TEAR
= tear perpendicular to tibial plateau + long axis / free edge of meniscus → disruption of meniscal hoop strength → dramatic loss of function + possible meniscal extrusion
• tears < 3 mm may be asymptomatic
Site: posterior horn of medial meniscus, junction of anterior horn + body of lateral meniscus
√ cleft oriented perpendicular to free edge on AXIAL image:
√ "truncated triangle" sign / "ghost meniscus" sign" ← tear through horn on COR view
√ "cleft" sign ← tear through body on SAG view
√ "marching cleft" sign
√ blunting of the inner margin of meniscus (if image plane parallel to tear)
√ poorly defined meniscus with diffusely increased SI (if tear extends to outer margin)
√ usually seen on only 1 image = normal meniscus in adjacent sections
√ discrete vertical focus of increased SI (if image plane perpendicular to tear)
Cx: lack of resistance to hoop stresses
Rx: frequently not repaired because of its location within avascular "white zone" → low likelihood of healing / regaining significant function

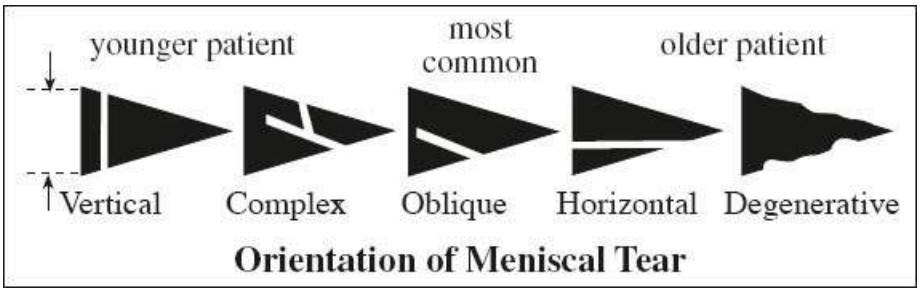
Meniscal Root Tear
= radial-type tear
High association with: meniscal extrusion, particularly in MM
Incidence: increased if ACL tear present
√ root should course over its respective tibial plateau on at least one COR image
√ posterior root of MM should be detected just medial to PCL on SAG image (otherwise suspect root tear)

Complex Meniscal Tear
= combination of radial, horizontal, longitudinal components → frequent fragmentation of meniscus

Parrot Beak Tear
= free edge tear with vertical + horizontal component

Truncation Sign & Ghost Sign *(on SAG Views)*

Marching Cleft Sign *(on SAG View)*
marching from free edge into substance



Orientation of Meniscal Tear

Cause: usually degenerative
Site: in body of lateral meniscus near the junction of body + posterior horn

Displaced Meniscal Tear

Free Meniscal Fragment

Flap Tear
= composite of radial tear that curves into longitudinal tear
Cause: traumatic, at times degenerative
Frequency: most common type of tear
N.B.: Search for displaced fragment in the absence of prior surgery / radial-type tear / severe underlying chondrosis if a foreshortened meniscus is present
Origin of flap: medial÷lateral meniscus = 7÷1
Site: common in midportion of medial meniscus
Location of displaced fragment:
@ Medial meniscus
› posteriorly near / posterior to PCL (²/³)
› intercondylar notch / superior recess (¹/³)
@ Lateral meniscus
› posterior joint line (½)
› lateral recess (½)
• persistent pain, potential knee locking
√ both horizontal and vertical components
√ commonly extending to inferior surface of meniscus

Rx: partial meniscectomy

Bucket-handle Tear

= longitudinal vertical tear with attached unstable central migration of inner "handle" fragment

MR sensitivity: 60–88%

Cause: traumatic

Age: frequently in young individuals

Prevalence: 9–19% of symptomatic patients; 10% of all meniscal tears

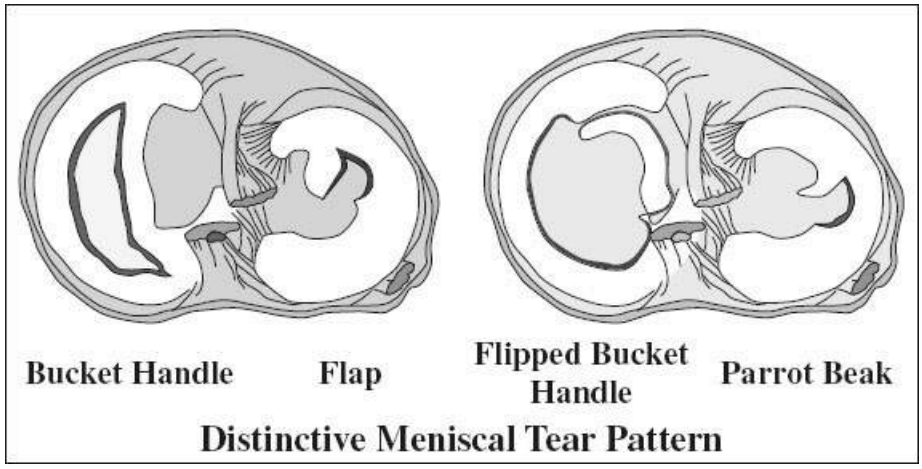
Origin of handle flap: medial÷lateral meniscus = 7÷1

• locked knee, lack of full knee extension

√ "absent bow-tie" sign (SAG image) = peripheral image fails to demonstrate normal bow-tie configuration on > 2 consecutive images (71–98% sensitive, 63% specific)

DDx: radial tear of body, macerated meniscus, prior partial meniscectomy (in small / pediatric patient)

√ "fragment-in-notch" sign (COR image) = displaced fragment in intercondylar notch



√ "double PCL" sign (SAG image) = medial meniscal fragment displaced into notch between PCL + medial tibial eminence oriented parallel to PCL (> 98% specific, 27–53% sensitive, 93% PPV) ← intact ACL acts as barrier against further lateral displacement

DDx: ligament of Humphry (smaller and thinner, very close to PCL); oblique meniscomeniscal ligament, intercondylar osseous bodies

√ double anterior horn

√ "flipped meniscus" sign

√ disproportionately small posterior horn = hypoplastic / truncated anterior + posterior horns on sagittal image

√ "double ACL" sign (LM) = fragment posterior to ACL

Rx: arthroscopic / surgical repair (reattachment / excision)

Meniscal Fraying

= surface irregularity along meniscal free edge without discrete tear

√ loss of sharp tapered central edge
√ subtle ill-defined horizontally oriented increased intrameniscal signal intensity contacting articular surface in posterior root
DDx: shallow partial-thickness tear / fraying / surrounding synovitis

Meniscocapsular Separation

= Peripheral Tear
= tearing of peripheral attachments of meniscus
√ linear region of fluid separating meniscus from capsule
√ uncovering of a portion of tibial plateau owing to inward movement of separated meniscus

MESOMELIC DWARFISM

= heritable bone dysplasia with shortening of intermediate segments (radius + ulna or tibia + fibula)

A. Langer type autosomal recessive
• mental impairment
√ mesomelic shortening of limbs
√ hypoplasia of ulna + fibula
√ hypoplasia of mandible with short condyles

B. Nievergelt type autosomal dominant
√ severe mesomelic shortening of lower limbs
√ marked thickening of tibia + fibula in central portion
√ clubfoot (frequent)

C. Reinhardt type: autosomal dominant

D. Robinow type: autosomal dominant

E. Werner type: autosomal dominant

F. Lamy-Bienenfeld type autosomal dominant
• ligamentous laxity
√ shortening of radius + ulna + tibia
√ absent fibula
√ normal femur + humerus

√ shortening of all long bones at birth, most marked in tibia + radius
√ modeling deformity with widening of diaphysis
√ mild to moderate bowing
√ hypoplasia of fibula with absent lateral malleolus
√ short + thick ulna with hypoplastic distal end
√ Madelung deformity of wrist
√ hypoplasia of a vertebral body may be present

METAPHYSEAL CHONDRODYSPLASIA

= severe short-limbed dwarfism
√ metaphyseal flaring (Erlenmeyer flask deformity) extending into diaphysis

A. Schmid type (most common)
autosomal dominant

- waddling gate

Distribution: more marked in lower limbs; mild involvement of hands + wrists

√ shortened bowed long bones
√ widened epiphyseal growth plates
√ irregular widened cupped metaphyses
√ coxa vara
√ genu varum

DDx: vitamin D–refractory rickets

B. McKusick type

autosomal recessive (eg, in Amish)

- sparse brittle hair, deficient pigmentation
- normal intelligence

√ shortening of long bones with normal width
√ cupped + widened metaphyses with lucent defects
√ short middle phalanges + narrow distal phalanges becoming triangular and bullet-shaped (more frequent in hands than feet)
√ widened costochondral junctions + cystic lucencies

C. Jansen type (less common)

sporadic occurrence with wide spectrum

- intelligence normal / retarded
- serum calcium levels often elevated

Distribution: symmetrical involvement of all long + short tubular bones

√ widened epiphyseal plates
√ expanded irregular + fragmented metaphyses (unossified cartilage extending into diaphyses)

DDx: rickets

D. Pyle disease = Metaphyseal dysplasia

- often tall
- often asymptomatic

Distribution: major long bones, tubular bones of hands, medial end of clavicle, sternal end of ribs, innominate bone

√ splaying of proximal + distal ends of long bones with thinned cortex
√ relative constriction of central portion of shafts
√ craniofacial hyperostosis
√ genu valgum

METASTASES TO BONE

◊ 15–100 times more common than primary skeletal neoplasms!

If primary known		If primary unknown	
Breast	35%	Prostate	25%
Prostate	30%	Lymphoma	15%
Lung	10%	Breast	10%
Kidney	5%	Lung	10%
Uterus	2%	Thyroid	2%
Stomach	2%	Colon	1%
Others	13%		

SOLITARY BONE LESION

◊ Of all causes only 7% are due to metastasis

◊ In patients with known malignancy solitary bone lesions are due to metastasis (55%), due to trauma (25%), due to infection (10%)

Location: axial skeleton (64–68%), ribs (45%), extremities (24%), skull (12%)

mnemonic: **S**everal **K**inds **O**f **H**orribly **N**asty **T**umors **L**eap **P**romptly **T**o **B**one
Sarcoma, **S**quamous cell carcinoma
Kidney tumor
Ovarian cancer
Hodgkin disease
Neuroblastoma
Testicular cancer
Lung cancer
Prostate cancer
Thyroid cancer
Breast cancer

Breast cancer: extensive osteolytic lesions; involvement of entire skeleton; pathologic fractures common

Thyroid / kidney: often solitary; rapid progression with bone expansion (bubbly); frequently associated with soft-tissue mass (distinctive)

Rectum / colon: may resemble osteosarcoma with sunburst pattern + osteoblastic reaction

Hodgkin tumor: upper lumbar + lower thoracic spine, pelvis, ribs; osteolytic / occasionally osteoblastic lesions

Osteosarcoma: 2% with distant metastases, adjuvant therapy has changed the natural history of the disease in that bone metastases occur in 10% of osteosarcomas without metastases to the lung

Ewing sarcoma: extensive osteolytic / osteoblastic reaction (13% with distant metastases)

Neuroblastoma: extensive destruction, resembles leukemia (metaphyseal band of rarefaction), mottled skull destruction + increased intracranial pressure, perpendicular spicules of bone

Mode of spread: through bloodstream / lymphatics / direct extension

Location: predilection for marrow-containing skeleton (skull, spine, ribs, pelvis, humeri, femora)

√ single / multiple lesions of variable size

√ usually nonexpansile

√ joint spaces + intervertebral spaces preserved (cartilage resistant to invasion)

Osteolytic Bone Metastases

Most common primary:

1. Lung
2. Breast
3. Thyroid
4. Kidney
5. Colon
6. Neuroblastoma (in childhood)

√ may begin in spongy bone (associated with soft tissue mass in ribs)
√ vertebral pedicles often involved (not in multiple myeloma)

Osteoblastic Bone Metastases

= evidence of slow-growing neoplasm

Most common primary:

1. Prostate carcinoma (elderly man)
2. Breast cancer (woman)
3. Lymphoma
4. Carcinoid tumor
5. Mucinous adenocarcinoma of GI tract
6. Pancreatic adenocarcinoma
7. Transitional cell (bladder) carcinoma
8. Neuroblastoma
9. Medulloblastoma (in childhood)

mnemonic: 6 **B**ees **L**ick **P**ollen

Brain (medulloblastoma)
Breast
Bronchus (especially carcinoid)
Bone (osteogenic carcinoma)
Bowel (mucinous)
Bladder
Lymphoma
Prostate

√ frequent in vertebrae + pelvis
√ may be indistinguishable from Paget disease

Mixed Bone Metastases

breast, prostate, lymphoma

Expansile / Bubbly Bone Metastases

kidney, thyroid

Permeative Bone Metastases

Burkitt lymphoma, mycosis fungoides

Bone Metastases with "Sunburst" Periosteal Reaction

= infrequent presentation in prostatic carcinoma, retinoblastoma, neuroblastoma (skull), GI tract cancer

Bone Metastases with Soft-tissue Mass

thyroid, kidney

Calcifying Bone Metastases

mnemonic: BOTTOM

Breast
Osteosarcoma
Testicular
Thyroid
Ovary
Mucinous adenocarcinoma of GI tract

Skeletal Metastases in Children

1. Neuroblastoma (most often): diffuse / focal
2. Lymphoma
3. Rhabdomyosarcoma
4. Ewing sarcoma
5. Retinoblastoma
6. Hepatoma

Skeletal Metastases in Adult

mnemonic: **C**ommon **B**one **L**esions **C**an **K**ill **T**he **P**atient

Colon
Breast
Lung
Carcinoid
Kidney
Thyroid
Prostate

Role of Bone Scintigraphy in Bone Metastases

Pathophysiology: accumulation of tracer at sites of reactive bone formation
False-negative scan: very aggressive metastases
False-positive scan: degeneration, healing fractures, metabolic disorders
Baseline bone scan:

(a) high sensitivity for many metastatic tumors to bone (particularly carcinoma of breast, lung, prostate); 5% of metastases have normal scan; 5–40% occur in appendicular skeleton
(b) substantially less sensitive than radiographs in infiltrative marrow lesions (multiple myeloma, neuroblastoma, histiocytosis)
(c) screening of asymptomatic patients
› useful in: prostate cancer, breast cancer

› not useful in: non–small-cell bronchogenic carcinoma, gynecologic malignancy, head and neck cancer

√ multiple asymmetric areas of increased uptake

√ axial > appendicular skeleton (dependent on distribution of bone marrow); vertebrae, ribs, pelvis involved in 80%

√ superscan in diffuse bony metastases

Follow-up bone scan:

√ stable scan = suggestive of relatively good prognosis

√ increased activity in:

(a) enlargement of bone lesions / appearance of new lesions indicate disease progression

(b) "healing flare" phenomenon (in 20–61%) = transient increase in lesion activity ← healing under antineoplastic treatment concomitant with increased sclerosis, detected at 3.2 ± 1.4 months after initiation of hormonal / chemotherapy, of no additional favorable prognostic value

(c) avascular necrosis particularly in hips, knees, shoulders caused by steroid therapy

(d) osteoradionecrosis / radiation-induced osteosarcoma

√ decreased activity in:

(a) predominately osteolytic destruction

(b) metastases under radiotherapy; as early as 2–4 months with minimum of 2000 rads

DDx: pulmonary metastasis (SPECT helpful in distinguishing nonosseous lung from overlying rib uptake)

Role of Bone Scintigraphy in Breast Cancer

Routine preoperative bone scan not justified:

Stage I : unsuspected metastases in 2%, mostly single lesion

Stage II : unsuspected metastases in 6%

Stage III : unsuspected metastases in 14%

Follow-up bone scan:

At 12 months no new cases; at 28 months in 5% new metastases; at 30 months in 29% new metastases

Conversion from normal:

Stage I : in 7%

Stage II : in 25%

Stage III : in 58%

◊ With axillary lymph node involvement conversion rate 2.5 x that of those without!

◊ Serial follow-up examinations are important to assess therapeutic efficacy + prognosis!

Role of Bone Scintigraphy in Prostate Cancer

Stage B: 5% with skeletal metastases

Stage C: 10% with skeletal metastases

Stage D: 20% with skeletal metastases

Test sensitivities for detection of osseous metastases:

(a) scintigraphy 1.00
(b) radiographic survey 0.68
(c) alkaline phosphatase 0.50
(d) acid phosphatase 0.50

Role of Magnetic Resonance in Bone Metastases

= ideal for bone marrow imaging ← high contrast between bone marrow fat + water-containing metastatic deposits

◊ Metastases are most often found in sites of dominant hematopoietic marrow because of its rich vascular supply!

in children: proximal + distal metaphyses of long bones, flat bones, spine

in adults: calvarium, spine, flat bones, proximal humeral + femoral metaphyses

(1) Focal lytic lesion (usual):
- √ hypointense on T1WI (more conspicuous when surroundings contain large number of fat cells)
- √ hyperintense on T2WI / STIR ← increased water content of hypercellular tumor tissue
- √ occasionally surrounded by mild edema

(2) Focal sclerotic lesion (eg, medulloblastoma, retinoblastoma):
- √ hypointense on T1WI + T2WI ← bone production

(3) Diffuse heterogeneous lesions (eg, neuroblastoma):
- √ inhomogeneously hypointense on T1WI + hyperintense on T2WI

(4) Diffuse homogeneous lesions:
- √ homogeneously hypointense on T1WI + hyperintense on T2WI

METATROPIC DYSPLASIA

= HYPERPLASTIC ACHONDROPLASIA = METATROPIC DWARFISM

metatropic = "changeable" (change in proportions of trunk to limbs over time ← developing kyphoscoliosis in childhood)

• longitudinal double skin fold overlying coccyx

√ long bones short with dumbbell-like / trumpet-shaped configuration (= exaggerated metaphyseal flaring)

√ "hourglass" phalanges (= short phalanges with widened ends)

√ wide separation of major joint spaces (thick articular cartilage)

√ delayed ossification of flat irregular epiphyses

@ Chest
- √ cylindrical narrowed elongated thorax
- √ short + wide ribs
- √ pectus carinatum

@ Vertebrae
- √ odontoid hypoplasia with atlantoaxial instability
- √ progressive kyphoscoliosis
- √ platyspondyly + very wide intervertebral spaces
- √ wedge- / keel-shaped vertebral bodies

@ Pelvis
- √ coccygeal appendage similar to a tail (rare but CHARACTERISTIC)

√ short squared iliac bones + irregular acetabula
√ narrowed greater sciatic notch

Prognosis: compatible with life; increasing disability from kyphoscoliosis

DDx: achondroplasia, mucopolysaccharidoses

MORTON NEUROMA

= INTERDIGITAL NEUROMA (neuroma is a misnomer)

= benign nonneoplastic lesion due to fibrosis + degeneration around a plantar digital nerve

Age: highest prevalence in 5th + 6th decade; M÷F = 1÷4

Path: perineural fibrosis entrapping a plantar digital nerve

Often associated with: intermetatarsal bursitis

Histo: dense collagenous + fibrous tissue

- numbness; burning / tingling electric forefoot pain increasing with activity + wearing of narrow shoes
- Mulder sign = painful palpable click when metatarsal heads are squeezed together with one hand + involved metatarsal space simultaneously compressed between thumb and index finger of the other hand

Location: plantar side of deep transverse intermetatarsal ligament beyond MTP joint

Site: typically 2nd / 3rd intermetatarsal space (rarely 1st / 4th)

√ splaying of metatarsal heads in large lesion

MR (87% sensitive, 100% specific):

◊ Best depicted prone (positional changes)

√ small well-demarcated teardrop-shaped mass isointense to muscle on T1WI + hypointense to fat on T2WI

√ variably hyperintense on gadolinium-enhanced fat-suppressed T1WI (easier to see)

√ ± fluid in intermetatarsal bursa (vertically oriented between metatarsal heads)

Rx: conservative treatment; surgical excision for neuromas > 5 mm in transverse diameter (more commonly symptomatic)

MUCOPOLYSACCHARIDOSES

= inherited lysosomal storage disorder from deficiency of specific lysosomal enzymes involved in degradation of mucopoly-saccharides (= inability to break down glycosaminoglycan)

Types:

Type I = Hurler
Type II = Hunter
Type III = Sanfilippo
Type IV = Morquio (most common)
Type V = Scheie
Type VI = Maroteaux-Lamy
Type VII = Sly

◊ All autosomal recessive except for Hunter (X-linked)!

Associated with: valvular heart disease

- corneal clouding; elevation of glycosaminoglycan in urine

• mental retardation (prominent in types I, II, III, VII)
• skeletal involvement dominates in types IV and VI
√ scaphocephaly, macrocephaly; thick calvarium; hypertelorism
√ platyspondyly with kyphosis + dwarfism
√ irregularity at anterior aspect of vertebral bodies
√ atlantoaxial subluxation + instability ← laxity of transverse ligament / hypoplasia or absence of odontoid
√ limb contractures
√ broad hands + brachydactyly
√ hepatosplenomegaly
@ Brain
√ brain atrophy
√ varying degrees of hydrocephalus
√ dilated Virchow-Robin spaces (from accumulation of glycosaminoglycan) resulting in cribriform appearance of white matter, corpus callosum and basal ganglia
√ increased SI of white matter surrounding Virchow-Robin spaces on T2WI + FLAIR ← edema, gliosis, de- / dysmyelination
√ ± arachnoid cyst ← meningeal glycosaminoglycan deposition
Cx: cord compression at atlantoaxial joint (types IV + VI)
Dx: combination of clinical features, radiographic abnormalities correlated with genetic + biochemical studies
Prenatal Dx: occasionally successful analysis of fibroblasts cultured from amniotic fluid
DDx: Gaucher disease, Niemann-Pick disease

Hurler Syndrome

[Gertrud Hurler (1889–1965), pediatrician in München-Neuhausen, Germany]
= GARGOYLISM = PFAUNDLER-HURLER DISEASE = MPS I-H
[Meinhard von Pfaundler (1872–1947), Austrian pediatrician and director of the university children's hospital in München]
= autosomal recessive disease
Cause: homozygous for MPS III gene with excess chondroitin sulfate B ← deficient X-L iduronidase (= Hurler corrective factor)
Prevalence: 1÷10,000 births
Age: usually appears > 1st year
• dwarfism; progressive mental deterioration after 1–3 years
• large head; sunken bridge of nose; hypertelorism
• early corneal clouding progressing to blindness
• "gargoyle" features = everted lips + protruding tongue
• teeth widely separated + poorly formed
• progressive narrowing of nasopharyngeal airway
• protuberant abdomen ← dorsolumbar kyphosis + hepatosplenomegaly
• urinary excretion of chondroitin sulfate B (dermatan sulfate) + heparan sulfate
• Reilly bodies (metachromic granules) in white blood cells or bone marrow cells
@ Skull (earliest changes > 6 months of age)
√ frontal bossing

- √ calvarial thickening
- √ premature fusion of sagittal + lambdoid sutures
- √ deepening of optic chiasm
- √ enlarged J-shaped sella (undermining of anterior clinoid process)
- √ small facial bones
- √ wide mandibular angle + underdevelopment of condyles
- √ communicating hydrocephalus

@ Extremities
- √ thick periosteal cloaking of long-bone diaphyses (early changes)
- √ swelling / enlargement of diaphyses + cortical thinning (← dilatation of medullary canal) + tapering of either end: distal humerus, radius, ulna, proximal ends of metacarpals
- √ deossification with heterogeneous bone density + course trabeculation ← deposition of accumulated precursor metabolites in bone marrow
- √ flexion deformities of knees + hips
- √ trident hands; clawing (occasionally)
- √ delayed maturation of irregular carpal bones

@ Spine
- √ thoracolumbar kyphosis with lumbar gibbus
- √ oval centra with normal / increased height + anterior beak at T12/L1/L2
- √ long slender pedicles
- √ proximally long slender ribs at level of neck and wide distally = spatulate rib configuration

@ Pelvis
- √ widely flared iliac wings with inferior tapering
- √ constriction of iliac bones
- √ coxa valga

Prognosis: death by age 10–15 years

Morquio Syndrome

= KERATOSULFATURIA = MPS IV (most common type)
= autosomal recessive; excess keratosulfate
Prevalence: 1÷40,000 births
Etiology: N-acetyl-galactosamine-6-sulfatase deficiency resulting in defective degradation of keratin sulfate (mainly in cartilage, nucleus pulposus, cornea)
Age: normal at birth; skeletal changes manifest within first 18 months; M÷F = 1÷1

- excessive urinary excretion of keratan sulfate
- normal intelligence; muscular weakness + hypotonia
- ligamentous laxity, but joint stiffness; progressive deafness
- short-trunk dwarfism (< 4 feet tall)
- semicrouching stance + knock knees ← flexion deformities of knees + hips
- head thrust forward + sunken between high shoulders
- corneal clouding evident around age 10
- coarse face with short nose, broad mouth, widely spaced teeth with thin enamel

@ Skull

√ mild dolichocephaly
√ hypertelorism
√ poor mastoid air cell development
√ short nose + depression of bridge of nose
√ prominent maxilla

@ Chest
√ increased AP diameter + marked pectus carinatum (horizontal protuberant sternum)
√ slight lordosis with wide short ribs
√ bulbous costochondral junctions
√ failure of fusion of sternal segments

@ Spine
√ hypoplasia / absence of odontoid process of C2
√ C1-C2 instability with anterior (life-threatening) atlanto-axial subluxation + progressive disabling myelopathy
√ thick C2-body with narrowing of vertebral canal
√ atlas close to occiput / posterior arch of C1 within foramen magnum
√ platyspondyly = universal vertebra plana esp. affecting lumbar spine by age 2–3 years (DDx: normal height in Hurler syndrome)
√ ovoid vertebral bodies with central anterior beak / tongue at lower thoracic / upper lumbar vertebrae
√ mild gibbus at thoracolumbar transition = low dorsal kyphosis
√ exaggerated lumbar lordosis
√ widened intervertebral disk spaces

Mucopolysaccharidoses

Type	*Eponym*	*Inheritance*	*Enzyme Deficiency*	*Urinary Glycosaminoglycan*	*Neurologic Signs*
I-H	Hurler	autosomal recessive	alpha-L-iduronidase	dermatan sulfate	marked
II	Hunter	X-linked recessive	iduronate sulfatase	dermatan / heparan sulfate	mild to moderate
III	Sanfilippo	autosomal recessive		heparan sulfate	mental deterioration
	A		heparan sulfate sulfatase		
	B		N-acetyl-alpha-D-glucosaminidase		
	C		alpha-glucosamine-N-acetyl-transferase		
	D		N-acetylglucosamine-6-sulfate sulfatase		
IV	Morquio	autosomal recessive	N-acetylgalactosamine-6-sulfate sulfatase	keratan sulfate	none
	A–D		beta-galactosidase		
I-S(V)	Scheie	autosomal recessive	alpha-L-iduronidase	heparan sulfate	none
VI	Maroteaux-Lamy	autosomal recessive	arylsulfatase B	dermatan sulfate	none
VII	Sly	autosomal recessive	beta-glucuronidase	dermatan / heparan sulfate	variable

@ Pelvis
√ “goblet-shaped” / “wineglass” pelvis = constricted iliac bodies + elongated pelvic inlet + broad flat “flared” iliac wings
√ oblique hypoplastic acetabular roofs

@ Femur
√ initially well-formed femoral head epiphysis, then involution + fragmentation by age 3–6 years
√ lateral subluxation of femoral heads; later hip dislocation

√ wide femoral neck + coxa valga deformity

@ Tibia

√ delayed ossification of lateral proximal tibial epiphysis

√ sloping of superior margin of tibial plateau laterally + severe genu valgum

@ Hand & foot

√ short bones of forearm with widening of proximal ends

√ delayed appearance + irregularity of carpal centers

√ small irregular carpal bones

√ proximally pointed short metacarpals 2–5

√ enlarged joints; hand + foot deformities (flat feet)

√ ulnar deviation of hand

Cx: cervical myelopathy (traumatic quadriplegia / leg pains / subtle neurologic abnormality) most common cause of death ← C2 abnormality; frequent respiratory infections (from respiratory paralysis)

Rx: early fusion of C1–C2

Prognosis: may live to adulthood (3rd–4th decade)

DDx: (1) Hurler syndrome (normal / increased vertebral height; vertebral beak inferior)

(2) Spondyloepiphyseal dysplasia (autosomal dominant, present at birth, absent flared ilia / deficient acetabular ossification, small acetabular angle, deficient ossification of pubic bones, varus deformity of femoral neck, minimal involvement of hand + foot, myopia)

MULTIPLE EPIPHYSEAL DYSPLASIA

= FAIRBANK DISEASE

[Harold Arthur Thomas Fairbank (1876–1961), English orthopedic surgeon at King's College Hospital, London]

= ? tarda form of chondrodystrophia calcificans congenita

√ mild limb shortening

√ irregular mottled calcifications of epiphyses (in childhood + adolescence)

√ epiphyseal irregularities + premature degenerative joint disease, especially of hips (in adulthood)

√ short phalanges

DDx: Legg-Perthes disease, hypothyroidism

MULTIPLE MYELOMA

= hematologic malignancy characterized by monoclonal proliferation of mature plasma cells

Precursor: premalignant asymptomatic monoclonal gammopathy of undetermined significance (MGUS) with cumulative risk for progression to multiple myeloma of 1% per year / Waldenström macroglobulinemia / lymphoma / primary amyloidosis / chronic lymphocytic leukemia

Frequency: 10% of all hematologic malignancies

◊ Most common primary malignant neoplasm in adults!

◊ Most frequent primary neoplasm of bone marrow!

◊ Most common primary osseous malignancy in elderly

◊ 2nd most common hematologic malignancy after NHL

Incidence: 22,350 new patients + 10,710 deaths in USA (2013)

Histo: normal / pleomorphic plasma cells (not PATHOGNOMONIC), may be mistaken for lymphocytes (lymphosarcoma, reticulum cell sarcoma, Ewing tumor, neuroblastoma)

(a) diffuse infiltration: myeloma cells intimately admixed with hematopoietic cells

(b) tumor nodules: displacement of hematopoietic cells by masses entirely composed of myeloma cells

Median age: 66 years (range, 5th–8th decade); 98% > 40 years; rare < 30 years; M÷F = 2÷1

Genetics: deletion of chromosome 13q14 (del13q14), amplification of chromosome 1q21 (amp1q21), deletion of chromosome 17p13 (del17p13)

Forms: (a) DISSEMINATED FORM: > 40 years of age (98%); M÷F = 3÷2

(b) SOLITARY FORM: mean age 50 years

Clinical manifestation:

(1) Plasma cell leukemia = aggressive form with a proportion of circulating plasma cells of > 20%

(2) Nonsecretory multiple myeloma (3%) = positive bone marrow biopsy without elevated level of M protein

- Symptomatic multiple myeloma:
  mnemonic: CRAB
  - **C**alcium elevation = hypercalcemia (30–50%)
  - **R**enal insufficiency (55%)
  - **A**nemia = normochromic normocytic anemia (62–73%)
  - **B**one abnormalities (lysis, osteopenia), bone pain (68%)
- fatigue, weight loss
- cutaneous / subcutaneous nodules (in < 5%)
- RBC rouleaux formation
- proteinuria (88%), Bence-Jones proteinuria (50%):
  - ↑ globulin production (= monoclonal gammopathy) of heavy chain (typically IgG or IgA) and light chain (typically κ)

Location:

A. DISSEMINATED FORM:
scattered; axial skeleton predominant site; vertebrae (50%) > ribs > skull > pelvis > long bones (distribution correlates with normal sites of red marrow)

B. SOLITARY PLASMACYTOMA OF BONE (< 5%):
vertebrae > pelvis > skull > sternum > ribs
→ progression to multiple myeloma within 3 years

C. SPINAL PLASMA CELL MYELOMA
√ sparing of posterior elements (no red marrow) (DDx: metastatic disease)
√ paraspinal soft-tissue mass with extradural extension
√ scalloping of anterior margin of vertebral bodies (osseous pressure from adjacent enlarged lymph nodes)

Extraosseous manifestations of multiple myeloma are radiologically detectable in 10–16%, most commonly involving lymph nodes, pleura, and liver.

Staging (Durie & Salmon Plus System):

◊ Detection of bone lesions at conventional radiography best correlates with measured myeloma cell mass

Stage	*Serum creatinine*	*End organ damage*	*Imaging*
IA	< 2.0 mg/dL	-	normal / limited disease / plasmacytoma
IB	> 2.0 mg/dL	+	mild diffuse disease < 5 focal lesions
IIA, B		+	moderate diffuse disease 5–20 focal lesions
IIIA, B		+	severe diffuse disease > 20 focal lesions
≥ 10% plasma cells for all stages; end organ damage = elevated blood calcium level / renal insufficiency / anemia / bone abnormalities			

Spread: to extramedullary sites (in 70%)

√ generalized osteopenia only (15%) with accentuation of trabecular pattern, especially in spine (early)
√ widespread punched-out osteolytic lesions (skull, long bones) with endosteal scalloping and of uniform size
√ diffuse osteolysis (pelvis, sacrum)
√ expansile osteolytic lesions (ballooning) in ribs, pelvis, long bones
√ soft-tissue mass adjacent to bone destruction (= extrapleural + paraspinal mass adjacent to ribs / vertebral column)
√ periosteal new-bone formation exceedingly rare
√ involvement of mandible (rarely affected by metastatic disease)
√ sclerosis may occur after chemotherapy, radiotherapy, fluoride administration
√ sclerotic form of multiple myeloma (1–3%)
(a) solitary sclerotic lesion: frequently in spine
(b) diffuse sclerosis

Associated with: **POEMS syndrome**

Polyneuropathy
- distal symmetric sensorimotor neuropathy (50%) affecting sensory + motor + autonomic neurons → severe disabling numbness, tingling, weakness in feet, legs, hands

Organomegaly
- hepatosplenomegaly, Castleman disease

Endocrine abnormalities
- amenorrhoea, gynecomastia, erectile dysfunction, testicular atrophy, type 2 diabetes, hypothyroidism, adrenal insufficiency

Monoclonal paraprotein (IgA / IgG in 75%)
√ osteosclerotic lesions mimicking metastatic prostate carcinoma

Skin lesions
- hypertrichosis, hirsutism, sclerodermatous thickening, hyperpigmentation, hemangiomas

- papilledema, pseudotumor cerebri (66%)

- edema: peripheral, pulmonary, pleural effusion, ascites, anasarca

MR (recognition dependent on knowledge of normal range of bone marrow appearance for age):

√ pattern of multiple myeloma infiltration:
- √ normal marrow
- √ micronodular pattern = variegated / salt-and-pepper
- √ focal pattern
- √ diffuse pattern
  - ◊ Diffuse infiltration apparent only if at least 20–30% of bone marrow infiltrated
  - ◊ Whole-body MRI detects additional lesions in 10%

√ hypointense multiple focal areas on T1WI (25%)
√ hyperintense multiple focal areas on T2WI (53%)
√ absence of fatty infiltration (nonspecific)

PET/CT (for staging, prognosis, monitoring treatment after suspension of corticosteroids for > 5 days):

√ metabolic activity of bone lesions
√ extraosseous manifestations of disease
√ quantification of marrow metabolic activity (SUV)

SENSITIVITY OF BONE SCANS VS. RADIOGRAPHS

Radiographs : in 90% of patients and 80% of sites
Bone scan : in 75% of patients and 24–54% of sites
Gallium scan : in 55% of patients and 40% of sites

◊ 30% of lesions only detected on radiographs
◊ 10% of lesions only detected on bone scans

Cx: (1) Renal involvement frequent
(2) Predilection for recurrent pneumonias ← leukopenia
(3) Secondary amyloidosis in 6–15%
(4) Pathologic fractures occur often

Prognosis: 43% 5-year survival; death from renal insufficiency, bacterial infection, thromboembolism

Rx: thalidomide, lenalidomide, bortezomib, autologous stem cell transplantation (ASCT), monoclonal antibodies

DDx:

› with osteopenia:
(1) Postmenopausal osteoporosis
(2) Hyperparathyroidism
(3) Steroid use

› with lytic lesion:
(1) Metastatic disease
(2) Amyloidosis
(3) Myeloid metaplasia

› with sclerotic lesion:
(1) Osteopoikilosis
(2) Lymphoma

(3) Osteoblastic metastasis
(4) Mastocytosis
(5) Myelosclerosis
(6) Fluorosis
(7) Renal osteodystrophy

10–20% of patients with multiple myeloma have normal findings at conventional radiography and differentiation of osteopenia from osteoporosis, steroid use, or excessive alcohol intake is difficult.

Myelomatosis

√ generalized deossification without discrete tumors
√ vertebral flattening

Solitary Plasmacytoma of Bone

= focal proliferation of malignant plasma cells without diffuse bone marrow involvement = early stage of multiple myeloma, precedes multiple myeloma by 1–20 years

Age: 5th–7th decade; > 60 years (in 70%)

• negative marrow aspiration; no IgG spike in serum / urine
• monoclonal immunoglobulin at low serum level (in 40%)

A. SOLITARY MYELOMA OF BONE (3–7%)

Site: thoracic / lumbar spine (most common) > pelvis > ribs > sternum, skull, femur, humerus

√ solitary "bubbly" osteolytic grossly expansile lesion replacing cancellous bone
√ poorly defined margins, Swiss-cheese pattern
√ hollow vertebral body / pedicle = partly preserved / sclerotic cortical bone
√ frequently pathologic fracture (collapse of vertebra)

MR:

√ low signal intensity on T1WI + high SI on T2WI
√ homogeneous marked enhancement

DDx: giant cell tumor, aneurysmal bone cyst, osteoblastoma, solitary metastasis from renal cell / thyroid carcinoma

B. EXTRAMEDULLARY PLASMACYTOMA

Location: majority in head + neck; 80% in nasal cavity, paranasal sinuses, upper airways of trachea, lung parenchyma

MUSCULOTENDINOUS INJURY

Muscle Contusion

Cause: direct trauma, usually by blunt object
Site: deep within muscle belly
• injury at point of impact
√ NO architectural changes
√ feathery appearance of diffuse muscle edema
√ increased muscle girth
√ deep intramuscular hematoma (with severe trauma resulting in disruption of muscle fibers):
  √ high SI on T1WI (= T1 shortening of methemoglobin)
  √ low SI on T2WI (= T2 shortening of hemosiderin)
  √ blooming with gradient-echo sequence

Myotendinous Strain

Cause: single traumatic event from excessive stretching
Susceptibility factors:
(1) muscle composed of (fast contracting) type II fibers
(2) fusiform shape of muscle
(3) extension across two joints
(4) superficial location of muscle
(5) eccentric muscle action
Site: myotendinous junction (= weakest point of musculotendinous unit)
Classification:
1° degree = stretch injury (some fiber disruptions)
• no loss of muscle function
Path: interstitial edema + hemorrhage at myotendinous junction with extension into adjacent muscle fibers
√ feathery appearance of muscle
2° degree = partial tear without retraction
• mild loss of muscle function
√ hematoma at myotendinous junction
√ perifascial fluid collection
3° degree = complete rupture
• complete loss of muscle function
√ retracted muscle tendon
√ hematoma at myotendinous junction

Acute Avulsion Injury

Cause: forceful unbalanced often eccentric muscle contraction
Path: periosteal stripping with hematoma at tendon attachment site
Site: at tendon insertion
• loss of function, severe tenderness
√ waviness + retraction of the torn end of tendon with fragment of bone / cartilage

MYELOFIBROSIS

= MYELOSCLEROSIS = AGNOGENIC MYELOID METAPLASIA = MYELO-PROLIFERATIVE SYNDROME = PSEUDOLEUKEMIA

= hematologic disorder of unknown etiology with gradual replacement of bone marrow elements by fibrotic tissue

Characterized by:

(1) extramedullary hematopoiesis
(2) progressive splenomegaly
(3) anemia
(4) variable changes in number of granulocytes + platelets; often predated by polycythemia vera

Cause:

(a) primary: rare in children
(b) secondary: radiation therapy / chemotherapy for leukemia or lymphoma or metastatic disease; Gaucher disease

Age: usually > 50 years

Path: fibrous / bony replacement of bone marrow; extramedullary hematopoiesis

Associated with: metastatic carcinoma, chemical poisoning, chronic infection (TB), acute myelogenous leukemia, polycythemia vera, McCune-Albright syndrome, histiocytosis

- dyspnea, weakness, fatigue, weight loss, hemorrhage
- normochromic normocytic anemia; polycythemia may precede myelosclerosis in 59%
- dry marrow aspirate

Location: red-marrow–containing bones in 40% (thoracic cage, pelvis, femora, humeral shafts, lumbar spine, skull, peripheral bones)

√ hepatosplenomegaly ← hematologic proliferation

√ widespread diffuse increase in bone density (ground-glass sclerosis) predominantly affecting medullary cavity:
  √ "jail-bar" ribs
  √ sandwich / rugger jersey spine

√ generalized increase in bone density in skull + obliteration of diploic space; scattered small rounded radiolucent lesions; or combination of both

MR:
  √ hypointense marrow on T1WI + T2WI
  √ signal intensity slightly higher than muscle on STIR

NUC:
  √ diffuse increased uptake of bone tracer in affected skeleton, possibly "superscan"
  √ increased uptake at ends of long bones

DDx: (1) With splenomegaly: chronic leukemia, lymphoma, mastocytosis
(2) Without splenomegaly: osteoblastic metastases, fluorine poisoning, osteopetrosis, chronic renal disease

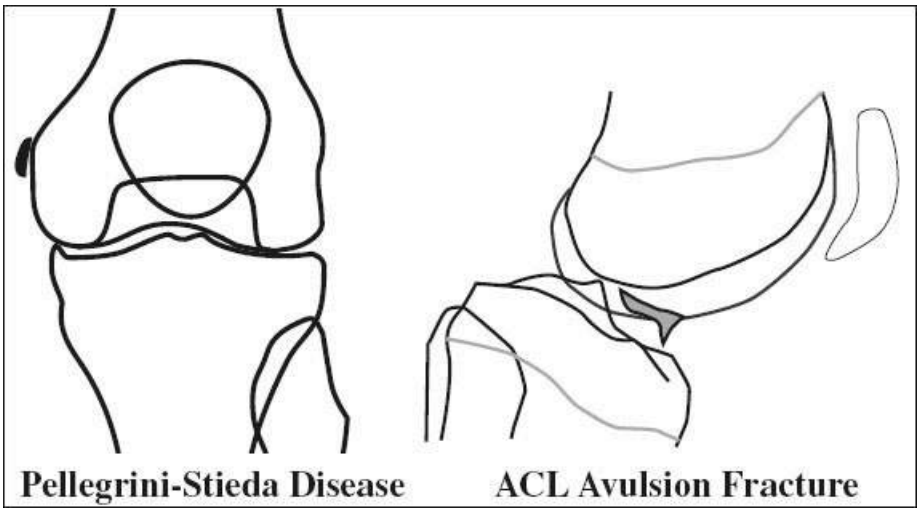
MYELOID DEPLETION

= APLASTIC ANEMIA

Cause: idiopathic; ? sequelae of viral infection, medication, toxin, chemo- / radiation therapy
Path: normal marrow replaced by fat cells
MR:
√ high signal intensity on T1WI
√ low signal intensity on fat-suppressed T2WI
◊ Best seen in areas with high percentage of hematopoietic marrow: proximal femoral metaphyses, spine

MYOSITIS OSSIFICANS

= PSEUDOMALIGNANT OSSEOUS TUMOR OF SOFT TISSUE = EXTRAOSSEOUS LOCALIZED NONNEOPLASTIC BONE AND CARTILAGE FORMATION = MYOSITIS OSSIFICANS CIRCUMSCRIPTA = HETEROTOPIC OSSIFICATION
= benign solitary self-limiting ossifying soft-tissue mass typically occurring within skeletal muscle as a mesenchymal response to soft tissue injury
◊ Myositis is a misnomer for lack of muscle inflammation!
Cause: direct trauma (75%), paralysis, burn, tetanus, intramuscular hematoma, spontaneous
Age: 2nd–3rd decades; M > F
Path: lesion rimmed by compressed fibrous connective tissue + surrounded by atrophic skeletal muscle
Histo: hypercellular fibrous tissue with mature bone formation usually within 6–8 weeks after onset of symptoms
(a) early stage: focal hemorrhage + degeneration + necrosis of damaged muscle → histiocytic invasion; central nonossified core of proliferating benign fibroblasts + myofibroblasts; mesenchymal cells enclosed in ground substance assume characteristics of osteoblasts → subsequent mineralization + peripheral bone formation
(b) intermediate stage (3–8 weeks): "zoning phenomenon":
› *central:* cellular osteoid with atypical mitotic figures (impossible to differentiate from soft-tissue sarcoma)
› *middle:* immature osteoid
› *outer:* well-formed lamellar mature trabeculated bone
(c) mature stage: shrinkage of mass → resolution in 30%
• pain, tenderness, soft-tissue mass
Location: large muscles of extremities (80%)



(a) within muscle: head & neck (temporalis, masseter, buccinator, sternocleidomastoid); anterolateral aspect of thigh + arm; small muscles of hands; gluteal muscle; "rider's bone" (adductor longus); "fencer's bone" (brachialis); "dancer's bone" (soleus); breast, elbow, knee

(b) periosteal at tendon insertion: **Pellegrini-Stieda disease** (in / near medial (tibial) collateral ligament of knee) as a result of Stieda fracture (= avulsion injury from medial femoral condyle at origin of tibial collateral ligament)
[Augusto Pellegrini (1877–1958), surgeon in Florence, Italy]
[Alfred Stieda (1869–1945), surgeon in Königsberg, Germany]

√ gradual ossification from periphery toward center (!) of mass:
- √ faint calcifications develop in 2–6 weeks after onset of symptoms
- √ well-defined partially ossified soft-tissue mass apparent by 6–8 weeks, becoming smaller + mature by 5–6 months
- √ radiolucent zone separating lesion from bone (DDx: periosteal sarcoma on stalk)
- √ ± periosteal reaction

CT:

Early phase:
- √ well-defined geometric hypodense mass with peripheral calcification after 4–6 weeks + less distinct lucent center

Mature phase:
- √ diffuse dense ossification in mature lesion

MR:
- √ initially heterogeneous muscle edema
- √ progression to masslike region of high SI on T2WI (during first days to weeks after injury simulating malignancy)

Early phase:
- √ mass with poorly defined margins + surrounding edema
- √ inhomogeneously hyperintense to fat on T2WI
- √ isointense to muscle on T1WI
- √ contrast enhancement

Intermediate phase:

√ isointense / slightly hyperintense core on T1WI, increasing in intensity on T2WI
√ diagnostic curvilinear hypointense rim surrounding the lesion (= peripheral mineralization / ossification)
√ increased peritumoral SI on T2WI (= edema of diffuse myositis)
√ focal signal abnormality within bone marrow (= marrow edema)

Mature phase: signal intensity characteristics of bone
√ well-defined hypointense rim and trabeculae, dense fibrosis and central adipose tissue
√ decreased SI inside and around lesion (dense ossification + fibrosis, hemosiderin from previous hemorrhage)

NUC:
√ intense tracer accumulation on bone scan (directly related to deposition of calcium in damaged muscle)
√ in phase of mature ossification activity becomes reduced + surgery may be performed with little risk of recurrence

Angio:
√ diffuse tumor blush + fine neovascularity in early active phase
√ avascular mass in mature healing phase

Prognosis: ? resorption in 1 year

DDx:
◊ In early stages difficult to differentiate histologically + radiologically from soft-tissue sarcomas!
(1) Osteosarcoma (densest calcification in center, least radiopaque bone at ill-defined periphery, no surrounding edema)
(2) Synovial sarcoma
(3) Fibrosarcoma
(4) Chondrosarcoma
(5) Rhabdomyosarcoma
(6) Parosteal sarcoma (usually metaphyseal with thick densely mineralized attachment to bone)
(7) Posttraumatic periostitis (ossification of subperiosteal hematoma with broad-based attachment to bone)
(8) Acute osteomyelitis (substantial soft-tissue edema + early periosteal reaction)
(9) Tumoral calcinosis (periarticular calcific masses of lobular pattern with interspersed lucent soft-tissue septa)
(10) Osteochondroma (stalk contiguous with normal adjacent cortex + medullary space)

Myositis Ossificans Variants

Panniculitis Ossificans

Location: subcutis of mostly upper extremities
√ less prominent zoning phenomenon

Fasciitis Ossificans

Location: fascia

Fibro-osseous Pseudotumor of Digits

= FLORID REACTIVE PERIOSTITIS
= nonneoplastic solitary self-limiting process of unknown pathogenesis, probably related to trauma
Mean age: 32 (range, 4–64) years; M÷F = 1÷2
• fusiform soft-tissue swelling / mass
Location: predominantly tubular bones of hand + foot: fingers ($2^{nd} > 3^{rd} > 5^{th}$)
Site: proximal > distal > middle phalanx
√ radiopaque soft-tissue mass with radiolucent band between mass + cortex
√ visible calcifications (50%)
√ focal periosteal thickening (50%)
√ cortical erosion (occasionally)
Rx: local excision
DDx: parosteal / periosteal osteogenic sarcoma, peripheral chondrosarcoma, periosteal chondroma, soft-tissue chondroma

MYXOMA

= true mesenchymal benign neoplasm
Histo: bland spindle shaped cells embedded in hypovascular abundantly myxoid stroma ± hypercellular areas with increased vascularity
Age: 4^{th}–6^{th} decade; M<F
Location: head & neck (scalene muscle, masticator space and posterior paraspinal muscles)
Site: intramuscular myxoma (82%), intermuscular, subfascial
Associated with: Mazabraud syndrome McCune-Albright syndrome
CT:
√ well-defined ovoid mass with attenuation similar to water
MR:
√ well-defined ovoid lesion with SI characteristic of fluid ← high mucin + low collagen content
√ thin peritumoral rim of perilesional fat on T1WI (70%):
√ T2 hyperintense ← fatty atrophy of muscle
√ fine inner linear stranding on T2WI ← fibrous septa
√ internal enhancement: (a) peripheral ← pseudocapsule (b) peripheral + internal linear stranding (c) peripheral + internal central focal patchy areas
Dx: core-needle / surgical biopsy
DDx: myxoid peripheral nerve sheath tumor, myxofibrosarcoma, myxoid liposarcoma, extraskeletal myxoid chondrosarcoma, undifferentiated pleiomorphic sarcoma

MYXOFIBROSARCOMA

= Myxoid malignant fibrous histiocytoma
= among the most common sarcomas in elderly
Histo: resembles myxoid liposarcoma with infiltrative growth along fascial planes
MR: similar to myxoma + myxoid liposarcoma
√ low to intermediate SI on T1WI + high SI on T2WI
√ septa of low SI

√ no fatty component
√ hyperintense cystlike myxoid component
√ heterogeneous nodular + peripheral enhancement of solid components

Prognosis: multiple recurrences ← infiltrative growth

DDx: other adult pleomorphic sarcomas (difficult DDx)

NAIL-PATELLA SYNDROME

= FONG DISEASE = ILIAC HORNS = FAMILIAL / HEREDITARY OSTEO-ONYCHODYSPLASIA = OSTEO-ONYCHODYSOSTOSIS = HOOD SYNDROME = ELBOW-PATELLA SYNDROME

= rare autosomal-dominant disorder characterized by symmetrical meso- and ectodermal anomalies

Etiology: ? enzymatic defect in collagen metabolism

Genetics: mutation of LMX1B gene encoding a transcription factor important to development of kidneys + limbs, particularly embryologically dorsal limb structures including nail + patella

Age: evident in 2nd + 3rd decades

◊ Diagnosed only late in life (if at all)!

- bilateral spooning / splitting / ridging of fingernails
- abnormal gait; abnormal pigmentation of iris
- renal dysfunction ← abnormal glomerular basement membrane: proteinuria, hematuria, failure later in life

√ 4 key features:

(1) Nail abnormality (98%):

Site: 1st–5th digit (in decreasing order of frequency)

- absent / hypoplastic / split nails
- hypoplasia of both thumbnails
- PATHOGNOMONIC triangular lunula
- lack of skin creases over dorsum of DIP joints

(2) Patella abnormality (74%):

√ fragmentation / hypoplasia / absence of patella
√ recurrent lateral dislocations (frequent)
- "squared" appearance of knees upon genuflection ← lateral subluxation

Cx: knee joint instability, restriction, pain, arthritis

(3) pathognomonic bilateral posterior iliac horns (= conical exostosis) in 68–80%

√ occasionally capped by an epiphysis

Site: at attachment of gluteus medius to posterior iliac wing

(4) Elbow abnormality (33%):

- pterygia = skin webs → restricted range of motion / dislocation

√ radial head / capitellum hypoplasia with subluxation / dislocation of radial head dorsally and increased carrying angle of elbow (DDx: congenital dislocation of radial head)

√ flared iliac crest with protuberant anterior iliac spines
√ flexion contractures of hip, knee, elbow, fingers, foot with inability of full extension

√ deltoid, triceps, quadriceps hypoplasia
√ mandibular cysts (occasionally)
√ scoliosis
@ Hand
√ clinodactyly of 5th finger
√ short 5th metacarpal
@ Knee
√ genu valgum ← asymmetrical development of femoral condyles
√ prominent tibial tubercles
@ Kidney
• accelerated age-related decline in renal function
• mild proteinuria (nephrotic-range in 5–10%)
√ renal osteodystrophy
Cx: renal failure and death
@ Eye
• open-angle glaucoma

DDx: (1) Seckel syndrome = bird-headed dwarfism
(2) Popliteal pterygium syndrome (absence of patella, toenail dysplasia)

NECROTIZING FASCIITIS

= progressive rapidly spreading infection of deep fascia → secondary necrosis of SQ tissue
N.B.: life-threatening surgical emergency!
Prevalence: 500 cases in literature
Age: 58 ± 14 years; M> F
Cause: deep internal infection / malignancy (perforated duodenal ulcer / retroperitoneal appendix, retroperitoneal / perirectal infection, infiltrating rectal / sigmoid carcinoma
Predisposed: immunocompromised patients (with diabetes, cancer, alcohol / drug abuse, vascular insufficiency, organ transplant), poor nutrition, foreign body in surgical wound
Organism: often gas-forming anaerobic bacteria in combination with aerobic gram-negative organisms: Staphylococcus, E. coli, Bacteroides, Streptococcus, Peptostreptococcus, Klebsiella, Proteus, C. perfringens (5–15%); multiple organisms in 75%
Histo: necrotic superficial fascia, leukocytic infiltration of deep fascial layers; fibrinoid thrombosis of arterioles + venules with vessel wall necrosis; microbial infiltration of destroyed fascia
• indolent: 1–21 days delay before diagnosis
• nonspecific symptoms: severe pain, fever, leukocytosis, shock, altered mental status
• crepitus (50%), overlying skin may be completely intact
Location: lower extremity, arm, neck, back, male perineum / scrotum (= Fournier gangrene)
√ image findings similar to cellulitis but more severe with involvement of deeper structures
√ asymmetric fascial thickening with fat stranding (80%) ← fluid
√ fluid collections along deep fascial sheaths
√ gas in soft-tissues dissecting along fascial planes ← gas-forming organisms (in 55%)
√ associated deep abscess (35%)

√ ± secondary muscle involvement:
  √ extension of edema into intermuscular septa and muscles
  √ no demonstrable enhancement of fascia ← necrosis

Prognosis: poor with delay in diagnosis ← progresses rapidly; morbidity and mortality rate of 70–80%

Rx: extensive surgical débridement + antibiotics

DDx: (1) Myonecrosis (= infection originating in muscle)
(2) Fasciitis-panniculitis syndromes (chronic swelling of skin + underlying soft tissues + fascial planes in arm + calf)
(3) Soft-tissue edema of CHF / cirrhosis (symmetrical diffuse fat stranding)
(4) cellulitis (less severe, without involvement of deeper structures)

NEUROPATHIC OSTEOARTHROPATHY

= NEUROTROPHIC JOINT = CHARCOT JOINT = "OSTEOARTHRITIS WITH A VENGEANCE"

[Jean-Martin Charcot (1825–1893), first professor of neurology at the Salpêtrière hospital in Paris]

= progressive degenerative + destructive joint disorder in patients with abnormal pain sensation + proprioception

Cause:

A. Congenital
  1. Myelomeningocele
  2. Congenital indifference to pain = asymbolia
  3. Familial dysautonomia (Riley-Day syndrome)
  4. Hereditary sensory and motor neuropathy (Charcot-Marie-Tooth disease)

B. Acquired
  (a) central neuropathy
    1. Injury to brain / spinal cord
    2. Syringomyelia (in ⅓ of patients): shoulder, elbow
    3. Neurosyphilis = tabes dorsalis (in 15–20% of patients): hip, knee, ankle, tarsals
    4. Spinal cord tumors / infection
    5. Extrinsic compression of spinal cord
    6. Multiple sclerosis
    7. Alcoholism
  (b) peripheral neuropathy
    1. Diabetes mellitus (most common cause, although incidence low): midfoot, tarsometatarsal joints (middle cuneiform + base of 2nd metatarsal bone first affected), intertarsal joints, subtalar joints, metatarsophalangeal joints, ankle
    2. Peripheral nerve injury
    3. Peripheral nerve tumor
    4. Leprosy (Hansen disease)
    5. Poliomyelitis
  (c) others
    1. Scleroderma, Raynaud disease, Ehlers-Danlos syndrome

2. Rheumatoid arthritis, psoriasis
3. Amyloid infiltration of nerves, adrenal hypercorticism
4. Uremia
5. Pernicious anemia

C. Iatrogenic
1. Prolonged use of pain-relieving drugs
2. Intraarticular / systemic steroid injections

mnemonic: DS6
Diabetes
Syphilis
Steroids
Spinal cord injury
Spina bifida
Syringomyelia
Scleroderma

Pathophysiology:
loss of proprioception with sensory deficits arising in the spinal cord / peripheral nerves
(1) Neurotraumatic theory
= repetitive trauma with absence of normal protective sensory feedback
(2) Neurovascular theory
= absence of neural stimuli → loss of sympathetic tone resulting in vasodilatation and hyperemia, which promotes bone resorption + weakening of subchondral bone

Pathology:
(a) atrophic pattern (most common):
joint destruction, resorption of fragments (osteoclasts + macrophages remove bone + cartilage debris), dissolution / "amputation" of periarticular bones, joint effusion
• notable absence of osteosclerosis + osteophyte formation
Associated with: syringomyelia, peripheral nerve lesion, also in diabetes
Location: non-weight-bearing joints of upper extremity
DDx: surgical amputation, septic arthritis
(b) hypertrophic pattern (only sensory nerves affected):
joint destruction, fragmentation of bone, periarticular bony debris
• osteosclerosis + osteophyte formation (early, attaining enormous size)
DDx: severe osteoarthritis
(c) mixed pattern
(d) common to both: joint disorganization, large persistent bloody joint effusion

• no history of trauma
• swollen + warm joint with normal WBC count + ESR (infection may coexist)
• usually painless joint; pain at presentation (in ⅓) with decreased response to deep pain + proprioception
• joint changes frequently precede neurologic deficit
• synovial fluid: frequently xanthochromic / bloody, lipid crystals (from bone marrow)
√ persistent joint effusion (first sign)
√ narrowing of joint space
√ speckled calcification in soft tissue (= calcification of synovial membrane)

√ fragmentation of eburnated subchondral bone
√ NO juxtaarticular osteoporosis (unless infected)
√ "bag-of-bones" appearance in late stage (= marked deformities around joint)
mnemonic: 6 Ds
√ **D**ense subchondral bone (= sclerosis)
√ **D**egeneration (= attempted repair by osteophytes)
√ **D**estruction of articular cortex (with sharp margins resembling those of surgical amputation)
√ **D**eformity ("pencil point" deformity of metatarsal heads)
√ **D**ebris (loose bodies)
√ **D**islocation (nontraumatic)
√ subluxation of joints (laxity of periarticular soft tissues)
√ progressive rapid bone resorption
√ joint distension (by fluid, hypertrophic synovitis, osteophytes, subluxation)
√ fracture: healing with exuberant bizarre callus formation
MR:
√ decreased SI in bone marrow on T1WI + T2WI ← osteosclerotic changes
@ Shoulder
Cause: syringomyelia, cord trauma with paraplegia
• shoulder mass (due to fluid distension)
√ amputated appearance of proximal humerus
√ dislocation
√ large joint effusion
√ fragmented osseous debris in joint capsule + subacromial-subdeltoid bursa
DDx: chondrosarcoma
@ **Neuropathic spine** = **Charcot spine** (involved in 6–21%)
Cause: diabetes mellitus > traumatic spinal cord injury, syringomyelia, inadequately treated syphilis, amyloidosis, congenital insensitivity to pain
Site: lower thoracic spine, lumbar spine > cervical spine, upper thoracic spine, sacrum
• mild pain and spinal deformity
√ intervertebral disk space narrowing
√ disk vacuum phenomenon
√ osteolysis / sclerosis of vertebrae:
√ extensive osseous fragmentation extending beyond confines of vertebral body margins into paraspinous musculature + into spinal canal
√ large hypertrophic beaking endplate osteophytes
√ paraspinous soft-tissue calcification:
√ mineralized paraspinal fluid collections containing osseous debris
√ facet joint erosion + subluxation (early findings) → spondylolisthesis
√ scoliosis + abrupt curvature
√ rimlike enhancement of disk + signal intensity changes of bone marrow
DDx: infectious spondylitis (NO involvement of facet joints, diffuse enhancement of disk + endplates), metastasis, granulomatous infection, severe degenerative disk disease
@ Hands + feet
Cause: leprosy (due to trauma + secondary bacterial infection)

√ claw hand / claw toes
√ "licked candy cane" appearance of metatarsal bone / tapered phalanx ← concentric bone atrophy with decrease in bone length + width
DDx: diabetes mellitus, frostbite, pernicious anemia, scleroderma, syringomyelia, tabes dorsalis, familial sensory neuropathy

@ Foot + ankle
Cause: long-term poorly controlled diabetes mellitus, syphilis
• soft-tissue swelling, warmth, erythema
Site: often begins in midfoot
√ vascular calcifications
√ subluxation (starting at 2nd tarsometatarsal joint)

NODULAR FASCIITIS

= mass-forming fibrous proliferation
Age: 2nd–4th decades (most common)
Pathogenesis: unknown: ? reactive / inflammatory process
Histo: immature fibroblasts + variable amount of mature birefringent collagen
Types:
(a) subcutaneous [3–10 x more common than (b) or (c)]
√ well-defined margins
(b) intramuscular
√ typically larger + deeper in location
√ ill-defined margins with extension along fascial planes
(c) intermuscular (fascial)
Location: head & neck (15–20%)
Size: 0.5–10 cm
CT:
√ homogeneous mass with attenuation similar to fluid
√ ± erosion of underlying bone
MR:
√ heterogeneous mass usually slightly hyperintense relative to muscle on T1WI
√ hyperintense relative to muscle on T2WI
√ ± marked enhancement

NONOSSIFYING FIBROMA

= FIBROXANTHOMA = NONOSTEOGENIC FIBROMA = XANTHOMA = XANTHOGRANULOMA OF BONE = FIBROUS METAPHYSEAL-DIAPHYSEAL DEFECT = FIBROUS MEDULLARY DEFECT
Frequency: up to 40% of all children > 2 years of age
Etiology: lesion resulting from proliferative activity of a fibrous cortical defect that has expanded into medullary cavity
Histo: interlacing whorled bundles of spindle-shaped fibroblasts + scattered multinucleated giant cells + foamy xanthomatous cells, variable degree of hemosiderin; usually cellular with only small amounts of collagen

Age: 8–20 years; 75% in 2nd decade of life
• usually asymptomatic; pain if large
Location: shaft of long bone; mostly in bones of lower extremity, esp. about knee (posteromedial surface of distal femur (55%) + proximal tibia); distal tibia; fibula
Site: eccentric / cortical to subcortical metaphyseal region, several cm shaftward from epiphysis, mostly intramedullary, rarely purely diaphyseal
√ well-circumscribed multiloculated bubbly oval osteolytic area
√ alignment along long axis of bone, > 2 cm in length
√ scalloped sclerotic margin toward medulla; V- or U-shaped at one end
√ mild expansile remodeling = endosteal scalloping + thinning ± overlying bulge
√ no periosteal reaction
√ migrates toward center of diaphysis
√ resolves with age
NUC:
√ minimal / mild uptake on bone scan
MR:
√ 80% hypointense on T1WI + T2WI ← extensive hypocellular fibrous tissue, hemosiderin pigment
√ 20% hypointense on T1WI + hyperintense on T2WI ← massive aggregation of foamy histiocytes
√ peripheral hypointense rim + internal septation ← marginal reactive sclerosis + trabeculation
√ adjacent marrow edema generally absent
√ intense contrast enhancement (in 80%) / marginal septal enhancement (in 20%) on T1WI
CAVE: lesions > 33 mm long involving > 50% of the transverse bone diameter need observation
Prognosis: spontaneous healing in most cases
Cx: (1) Pathologic fracture (not uncommon)
(2) Hypophosphatemic vitamin D–resistant rickets + osteomalacia (tumor may secrete substance that increases renal tubular resorption of phosphorus)
DDx: (1) Fibrous cortical defect (< 2 cm in greatest diameter)
(2) Adamantinoma (midshaft of tibia)
(3) Chondromyxoid fibroma (bulging of cortex more striking, hyperintense on T2WI)
(4) Fibrous dysplasia (internal septations rare)
(5) Aneurysmal bone cyst (heterogeneously hyperintense with fluid-fluid levels)
(6) Intraosseous ganglion (hyperintense on T2WI)

Multiple Fibroxanthomas (in 8–10%)
Associated with: neurofibromatosis, fibrous dysplasia, Jaffé-Campanacci syndrome

Jaffé-Campanacci Syndrome
= nonossifying fibroma with extraskeletal manifestations in children
• mental retardation; hypogonadism; ocular defect
• cardiovascular congenital defect; café-au-lait spots

NOONAN SYNDROME

= PSEUDO–TURNER = MALE TURNER SYNDROME
= phenotype similar to Turner syndrome but with normal karyotype (occurs in both males + females)
Genetics: striking familial incidence
• short / may have normal height
• webbed neck; agonadism / normal gonads
• delayed puberty; mental retardation
√ osteoporosis
√ retarded bone age
√ cubitus valgus
@ Skull
  √ mandibular hypoplasia with dental malocclusion
  √ hypertelorism
  √ biparietal foramina
  √ dolichocephaly, microcephaly / cranial enlargement
  √ webbed neck
@ Chest
  √ sternal deformity: pectus excavatum / carinatum
  √ right-sided CHD (valvar pulmonic stenosis, ASD, eccentric hypertrophy of left ventricle, PDA, VSD)
  √ coronal clefts of spine
  √ may have pulmonary lymphangiectasis
@ Gastrointestinal tract
  √ intestinal lymphangiectasia
  √ eventration of diaphragm
  √ renal malrotation, renal duplication, hydronephrosis, large redundant extrarenal pelvis
DDx: Turner syndrome (mental retardation rare, renal anomalies frequent)

OCHRONOSIS

= ALKAPTONURIA
[ochros, *Greek* = pale, light yellow brown color]
[alkapton from al-qaly, *Arabic* = potash + kapto, *Greek* = to suck up]
= rare inborn error of metabolism
Pathophysiology:
inherited absence of enzyme homogentisate 1,2-deoxygenase → inability to normally degrade aromatic amino acids tyrosine + phenylalanine → accumulation of their alternate degradation product homogentisic acid within bloodstream → excretion in urine + deposition in connective tissue (including cartilage, synovium, and bone)
Prevalence: 1÷250,00 to 1÷1,000,000 births; M÷F = 2÷1
Histo: black-pigmented cartilage subject to deterioration → calcification + denudation of cartilaginous tissue
• ochronosis =dark pigment in soft tissues (in 2nd decade): yellowish skin; gray pigmentation of sclera; bluish tinge of auricular + nasal cartilage

• alkaptonuria with black staining of diapers (homogentisic acid in urine is oxidized to benzoquinones which form melanin-like polymers responsible for discoloration)
• heart failure, renal failure (pigment deposition)

@ Spine

Age: 3rd–4th decade

Site: lumbar region with progressive ascension (cervical spine typically spared)

• progressive kyphosis with loss of height
• decreased lumbar flexion
√ CHARACTERISTIC laminated calcifications of multiple intervertebral disks (primarily of annulus fibrosus)
√ severe narrowing of intervertebral disk space + eventual obliteration
√ multiple "vacuum" phenomena (common)
√ osteopenia of adjoining vertebrae
√ loss of normal lumbar lordosis
√ massive vertebral osteophytosis (resembling syndesmophytes of ankylosing spondylitis) + ankylosis of spine (in older patient)
√ spotty calcifications in tissue anterior to vertebral bodies

@ Joints = **ochronotic arthropathy**

= manifestation of long-standing alkaptonuria in axial + peripheral skeleton similar to osteoarthritis
• long-standing joint pain + limited range of motion
√ hypertrophic changes in humeral head
√ severe progressive premature osteoarthritis (knee > shoulder > hip):
√ joint narrowing + subchondral sclerosis
√ prominence of intraarticular osteochondral fragments
√ relative lack of prominent osteophyte formation
√ small calcifications in paraarticular soft tissues + tendon insertions

DDx: ankylosing spondylitis (erosions and ankylosis of SI joints, severe facet joint involvement)

ORODIGITOFACIAL SYNDROME

= OROFACIODIGITAL SYNDROME
= heterogeneous group of defects, probably representing varying expressivity, involving face, oral cavity, and digits

Prevalence: 1÷50,000 live births
Etiology: autosomal trisomy of chromosome No. 1 with 47 chromosomes; X-linked dominant
Sex: nuclear chromatin pattern female (lethal in male)
Associated with: renal polycystic disease

• mental retardation; hypertelorism
• cleft lip + tongue, lingual hamartoma; bifid nasal tip
√ cleft in palate + jaw bone
√ hypoplasia of mandible (micrognathia) + occiput of skull
√ hypodontia
√ clinodactyly, syndactyly, brachydactyly (metacarpals may be elongated), polysyndactyly,

duplication of hallux

OSGOOD-SCHLATTER DISEASE

[Robert B. Osgood (1873–1956), orthopedic surgeon in Boston, USA]
[Carl Schlatter (1864–1934), surgeon in Zurich, Switzerland]
= chronic avulsion injury of the attachment of the patellar ligament to the tibial tuberosity (= traction osteochondritis, NOT osteonecrosis); bilateral in 25–50%
Age: 10–15 years; M > F
Anatomy: tibial tubercle develops as an anterior extension of proximal tibial physis; closes at 13–15 years (in girls) and 15–19 years (in boys)
Cause: repetitive microtrauma (common in sports that involve jumping, kicking, squatting)
• local pain + tenderness on pressure
• painful visible swelling of overlying soft tissue
√ soft-tissue swelling in front of tuberosity ← edema of skin + subcutaneous tissue
√ thickening + calcification of distal portion of patellar tendon
√ indistinct margin of patellar tendon
√ obliteration of inferior angle of infrapatellar fat pad
√ separation of several small ossicles from the developing ossification center of tibial tuberosity (= reactive secondary heterotopic bone formation)
√ single / multiple ossifications in avulsed fragment
√ comparison with other side (irregular development normal)
MR:
√ patellar tendon enlargement
√ increased SI at tibial insertion site of patellar tendon on T1WI + T2WI
√ distension of deep infrapatellar bursa
√ bone marrow edema adjacent to tibial tuberosity + tibial apophysis (rare)
√ thickened cartilage anterior to tibial tubercle
Cx: tibial tubercle fracture with nonunion of bone fragments, patellar subluxation, chondromalacia, avulsion of patellar tendon, genu recurvatum
Rx: immobilization / steroid injection
DDx: (1) Normal irregular ossification pattern of tibial tuberosity between ages 8–14 (asymptomatic)
(2) Osteitis: tuberculous / syphilitic
(3) Soft-tissue sarcoma with calcifications

OSSIFYING FIBROMA

= encapsulated circumscribed benign neoplasm closely related to fibrous dysplasia + adamantinoma
Incidence: peaks in 3rd–4th decade
Age: 2nd–4th decade; M < F
Histo: highly cellular fibrous connective tissue composed of spindle cells with osteoblastic activity producing varying amounts of osteoid in a pattern of uniform small round lamellated "psammoma-like" ossicles; irregular spicules / trabeculae of lamellar bone rimmed by osteoblasts (DDx from fibrous dysplasia)

Subtypes:
(a) cementifying fibroma
(b) cemento-ossifying fibroma
(c) juvenile ossifying fibroma: aggressive destructive, most common in boys < 15 years of age

Location: frequently in face / posterior mandible
• asymptomatic
• tooth displacement; facial asymmetry ← bone expansion
√ intense focal uptake on bone scan
@ Tibia
√ eccentric ground-glass lesion (resembling fibrous dysplasia)
√ initially lucent (= nonmineralized osteoid) + later often opaque lesion (depending on degree of calcification) similar to fibrous dysplasia
√ surrounded by thin line of lucency (= fibrous capsule) + thin outer rim of sclerotic (reactive) bone
√ ± soft-tissue enhancement
@ Mandible, maxilla
Site: premolar / molar region
• painless swelling of tooth-bearing portion of jaw
√ 1–5 cm well-circumscribed round / oval tumor
√ moderate unilocular expansion of intact cortex
√ homogeneous tumor matrix
√ dislodgment of teeth
√ NO halo of low attenuation; sclerotic border (occasionally)
Cx: significant potential for centrifugal growth perpendicular to long axis of bone; frequent recurrences
DDx: (1) Fibrous dysplasia (longitudinal growth pattern, nondisplaced teeth, crossing of sutures, osteoblastic rimming, no radiolucent boundary)
(2) Odontoma
(3) Sequestrum
(4) Vascular lesion

Juvenile Ossifying Fibroma
= PSAMMOMATOID OSSIFYING FIBROMA
= nonmetastasizing benign tumor that arises in sinonasal region of young patients often involving orbit with tendency for locally aggressive behavior
Age: children and adolescents; M÷F = 1÷1
Location: facial bones (85%), esp. paranasal sinuses; more than one sinus in ½
Site: ethmoid region / superior orbital plate of frontal bone
• proptosis, headache, sinusitis
• facial swelling, nasal obstruction
• visual / ocular motility disturbance
√ intracranial extension
Radiography:
√ monostotic round / ovoid well-demarcated expansile lesion of mixed lytic + sclerotic

density
√ ballooned / bowed appearance of sclerotic margin

CT:
√ predominantly soft-tissue attenuation with multiple foci of calcifications
√ ± multiloculated internal composition with sclerotic septa / enhancing septa of soft-tissue attenuation
√ lower-attenuation areas ← cystic changes
√ usually surrounded by a possibly partially disrupted sclerotic rim / shell
√ enhancement of shell + solid tumor portions

MR:
√ lesion isointense relative to muscle on T1WI
√ hypointense relative to muscle on T2WI
√ foci of high T2-signal intensity ← fluid-filled cystic spaces

DDx: fibrous dysplasia, cementifying fibroma (arises from periodontal ligament in molar teeth), aneurysmal bone cyst (infrequently in sinonasal region, fluid levels throughout its cystic component)

OSTEITIS CONDENSANS ILII

Prevalence: 2% of population
Cause: chronic stress ← instability of pubic symphysis
Age: young multiparous women
• associated with low back pain when instability of pubic symphysis present
√ triangular area of sclerosis along inferior anterior aspect of ileum adjacent to SI joint (joint space uninvolved)
√ similar triangle of reparative bone on sacral side
√ usually bilateral + symmetric; occasionally unilateral
√ sclerosis dissolves in 3–20 years following stabilization of pubic symphysis
DDx: (1) Ankylosing spondylitis (affects ilium + sacrum, joint space narrowing, involvement of other bones)
(2) Rheumatoid arthritis (asymmetric, joint destruction)
(3) Paget disease (thickened trabecular pattern)

OSTEOARTHRITIS

= DEGENERATIVE JOINT DISEASE = ARTHROSIS
= predominantly noninflammatory degeneration of cartilage in synovial joints
◊ Most common arthropathy ← repetitive articular cartilage damage
Age: prevalence increasing with age
Cause: (1) abnormal forces acting on a normal joint (eg, slipped capital femoral epiphysis)
(2) normal forces acting on abnormal joint due to
(a) cartilage abnormality
(b) subchondral bone abnormality
Path: ↓ chondroitin sulfate with age creates unsupported collagen fibrils → irreversible hyaline cartilage degeneration (= inability for regeneration)
√ joint space narrowing (stage III) = inaccurate indicator of cartilage integrity

√ subchondral sclerosis / eburnation in areas of stress
√ subchondral cyst formation (geodes)
√ increased joint fluid
√ synovial inflammation (in severe osteoarthritis)
√ osteophytosis at articular margin / nonstressed area

US:

√ step-up prominences of cortex = peripheral marginal osteophytes ← new bone formation
√ joint space narrowing, noted if marginal and severe
√ joint effusion ± hyperemia of synovitis (on color Doppler)

MR:

@ Cartilage

Stages of damage to cartilage:

I cartilage swelling + softening (from damage to collagen matrix → decreased proteoglycan content + increase in water content)
II increased cartilage thickness (from proliferation of chondrocytes)
III cartilage loss → fibrillation + erosion + cracking of articular cartilage ← decrease in cellular proliferation of chondrocytes

√ increased SI of abnormal cartilage on T2WI (= increased amount of free water)
√ morphologic defects on surface of cartilage (best seen on fat-suppressed spoiled gradient-echo MR)

Cartilage damage score on MR:

0 normal
1 increased T2 signal intensity
2 partial-thickness defect < 50%
3 partial-thickness defect > 50%
4 full-thickness defect

@ Bone

√ hyperintense subchondral bone marrow edema-like lesion on fat-suppressed T2WI / STIR ← increased fatty acid consumption
√ subchondral pseudocysts in weight-bearing areas (= contusional bone necrosis / intrusion of synovial fluid across damaged cartilage)
√ subchondral sclerosis (= stress-induced new bone deposition + trabecular microfractures + callus formation) hypointense on all sequences
√ osteophytes at joint margins ← stimulation of enchondral ossification in areas of low stress
√ flattening or depression of the articular cortex (= bone attrition)

@ Synovium

√ synovial thickening with positive correlation between pain and degree synovitis
√ joint effusion
√ popliteal bursal fluid (common)
√ joint bodies

Origin: chondral fragments, detached osteophytes, meniscal fragments, synovial osteochondromatosis

@ Hand + foot
Target area: 1st MCP; trapezioscaphoid; DIP > PIP; 1st MTP
√ loss of joint space, subchondral eburnation, marginal osteophytes, small ossicles in DIP + PIP:
√ Bouchard node = osteophytosis at PIP joint
√ Heberden node = osteophytosis at DIP joint: M÷F = 1÷10
√ radial subluxation of 1st metacarpal base
√ joint space narrowing + eburnation of trapezioscaphoid area
@ Shoulder
√ elevation of humeral head + lack of significant glenohumeral joint involvement (DDx to rheumatoid arthritis)
@ Hip
Predisposed: hip dysplasia, slipped capital femoral epiphysis, Legg-Calvé-Perthes disease, malunited femoral neck fracture, femoroacetabular impingement
√ femoral + acetabular osteophytes, sclerosis, subchondral cyst formation
√ thickening / buttressing of medial femoral cortex / calcar
√ migration of femoral head:
√ superolateral subluxation of femoral head
√ medial / axial subluxation ± protrusio acetabuli (in 20%)
√ primary hereditary protrusio = Otto pelvis (M < F)
@ Knee
Location: medial > lateral femorotibial > patellofemoral compartment
√ varus deformity (M>> F)
Associated with:
medial (66%), lateral (24%), bilateral (10%) meniscal tears (in 60% for asymptomatic + symptomatic patients alike), commonly associated with extrusion of meniscus from the joint line
@ Spine
√ sclerosis + narrowing of intervertebral apophyseal joints
√ osteophytosis usually associated with diskogenic disease
@ Sacroiliac joint
◊ Most common disorder of sacroiliac joints
Location: bi- / unilateral (contralateral SIJ with bad hip)
√ diffuse joint space loss
√ vacuum phenomenon
√ well-defined line of sclerosis, esp. on iliac side of articulation
√ prominent bridging osteophyte at superior + inferior limits of joint
DDx: osteoblastic metastasis

Erosive Osteoarthritis

= inflammatory form of osteoarthrosis
Predisposed: postmenopausal females
Site: distribution identical to noninflammatory osteoarthritis: DIP > PIP > MCP joints of hands; radial aspect of wrist; bilateral + symmetric
√ "bird-wing" / "sea-gull" joint configuration = central erosions + osteophytosis

√ may lead to bony ankylosis
DDx: Rheumatoid arthritis, Wilson disease, chronic liver disease, hemochromatosis

Early Osteoarthritis

mnemonic: **E**arly **O**steo**A**rthritis
Epiphyseal dysplasia, multiple
Ochronosis
Acromegaly

Milwaukee Shoulder

= association of
(1) Complete rotator cuff tear
(2) Osteoarthritic changes
(3) Noninflammatory joint effusion containing calcium hydroxyapatite and calcium pyrophosphate dihydrate (CPPD) crystals
(4) Hyperplasia of synovium
(5) Destruction of cartilage + subchondral bone
(6) Multiple osteochondral loose bodies
Age: older woman
• frequent history of trauma
• rapidly progressive arthritis of shoulder
Radiograph:
√ joint space narrowing
√ subchondral sclerosis + cyst formation
√ destruction of subchondral bone
√ soft-tissue swelling
√ capsular calcifications
√ intraarticular loose bodies
MR:
√ large effusion
√ complete rotator cuff tear
√ narrowing of glenohumeral joint

Rapidly Destructive Articular Disease

= unusual form of osteoarthritis typically involving the hip (almost always unilateral)
Age: elderly women
Associated with: conventional osteoarthritis in hands, wrists, knees, opposite hip
• hip pain
√ progressive loss of joint space
√ loss of subchondral bone in femoral head + acetabulum resulting in "hatchet" deformity of femoral head
√ superolateral subluxation of femoral head / intrusion deformity within ilium
√ no / small osteophytes
Prognosis: rapid destruction of hip within 14 months after onset of symptoms
Rx: total joint replacement

DDx: osteonecrosis, septic arthritis, neuroarthropathy, crystal-induced arthropathy

OSTEOBLASTOMA

= GIANT OSTEOID OSTEOMA = OSTEOGENIC FIBROMA OF BONE = OSSIFYING FIBROMA

= rare benign locally aggressive tumor with unlimited growth potential + capability of malignant transformation

Frequency: < 1% of all primary bone tumors; 3% of all benign bone tumors

Mean age: 6–19 years; 6–30 years (90%); 2nd decade (55%); 3rd decade (20%); M÷F = 2÷1

Size: lesion > 1.5 cm

N.B.: smaller lesions are classified as osteoid osteoma

Histo: numerous multinucleated giant cells (osteoclasts), irregularly arranged osteoid + bone; very vascular connective tissue stroma with interconnecting trabecular bone; trabeculae broader + longer than in osteoid osteoma

- dull localized pain of insidious onset (84%), worse at night in 7–13%; asymptomatic in < 2%
- response to salicylates in 7%
- localized swelling, tenderness, decreased range of motion (29%)
- painful scoliosis in 50% (with spinal / rib location) ← muscle spasm, may be convex toward side of tumor
- paresthesias, mild muscle weakness, paraparesis, paraplegia (← cord compression)
- occasional systemic toxicity (high WBC, fever)

Location: (rarely multifocal)

(a) spine (32–46%): 62–94% in neural arch, secondary extension into vertebral body (28–42%); cervical spine (31%), thoracic spine (34%), lumbar spine (31%), sacrum (3%)

(b) long bones (26–32%): femur (50%), tibia (19%), humerus (19%), radius (8%), fibula (4%); unusual in neck of femur

(c) small bones of hand + feet (15–26%): dorsal talus neck (62%), calcaneus (4%), scaphoid (8%), metacarpals (8%), metatarsals (8%)

(d) calvarium + mandible (= cementoblastoma)

Site: diaphyseal (58%), metaphyseal (42%); eccentric (46%), intracortical (42%), centric (12%), may be periosteal

√ similar to osteoid osteoma:
- √ radiolucent nidus > 2 (range, 2–12) cm in size
- √ well demarcated (83%)
- √ ± stippled / ringlike small flecks of matrix calcification
- √ reactive sclerosis (22–91%) / no sclerosis (9–56%)

√ progressive expansile lesion that may rapidly increase in size (25%):
- √ cortical expansion (75–94%) / destruction (20–22%)
- √ tumor matrix radiolucent (25–64%) / ossified (36–72%)
- √ sharply defined soft-tissue component
- √ thin shell of periosteal new bone (58–77%) / no periosteal reaction

√ scoliosis (35%)

√ talar osteoporosis ← disuse + hyperemia

√ rapid calcification after radiotherapy

√ marked enhancement
CT:
√ multifocal matrix mineralization + sclerosis
√ expansile bone remodeling, thin osseous shell
NUC:
√ intense focal accumulation of bone agent (100%)
Angio:
√ tumor blush in capillary phase (50%)
MR (of limited value in characterization & staging):
√ mainly lytic lesion by CT:
√ low to intermediate signal intensity on T1WI
√ mixed intermediate to high intensity on T2WI
√ lesion with some mineralization by CT:
√ mixed low and high signal intensity on T2WI
√ mainly of low signal intensity on T2WI
√ surrounding edema

Prognosis: 10–15% recurrence after excision; incomplete curettage can effect cure due to cartilage production + trapping of host lamellar bone

DDx: (1) Osteo- / chondrosarcoma (periosteal new bone)
(2) Osteoid osteoma (dense calcification + halo of bone sclerosis, stable lesion size < 2 cm due to limited growth potential)
(3) Cartilaginous tumors (lumpy matrix calcification
(4) Giant cell tumor (no calcification, epiphyseal involvement)
(5) Aneurysmal bone cyst
(6) Osteomyelitis
(7) Hemangioma
(8) Lipoma
(9) Epidermoid
(10) Fibrous dysplasia
(11) Metastasis
(12) Ewing sarcoma

OSTEOCHONDROMA

= OSTEOCARTILAGINOUS EXOSTOSIS
= developmental hyperplastic / dysplastic bone outgrowth composed of cortical + medullary bone with overlying cartilaginous cap; growth ends when nearest epiphyseal plate fuses
◊ Most common benign growth of the skeleton!
◊ Most common benign cartilage-containing tumor!

Prevalence: 20–50% of all benign bone tumors; 10% of all bone tumors

Etiology: separation of a fragment of physeal cartilage herniating through periosteal bone cuff that surrounds the growth plate (encoche of Ranvier); the fragment continues to grow and undergoes enchondral ossification

(a) developmental

(b) microtrauma / Salter-Harris injury with in vivo transplantation of physeal tissue
(c) radiation therapy (in 6–24%) with latency period of 3–17 years in patients between 8 months and 11 years of age receiving 1,500–5,500 cGy (frequently for treatment of neuroblastoma / Wilms tumor); at periphery of radiation field
◊ Most common benign radiation-induced tumor

Path: continuity of lesion with marrow + cortex of host bone (HALLMARK)

Histo: hyaline cartilage cap containing a basal surface with enchondral ossification (thin cortex + trabecular bone + marrow space) resembling growth plate

Location: 10% in small bones of the hands and feet; 1–4% in spine (50% in posterior elements of cervical spine)

• progressive painless deformity around a joint

Radiographic types:

√ sessile broad based exostosis
√ pedunculated with slender stalk / pedicle:
√ growth pointing away from nearest joint + toward center of shaft:
√ at right angle on diaphyseal side of stalk
√ slope on epiphyseal side
√ continuity of bone cortex with host bone cortex
√ <u>continuity (!) of medullary marrow space</u> with host bone
√ hyaline cartilaginous cap:
√ arcs / rings / flocculent calcifications on radiographs

CT:

√ optimal depiction of cortical + marrow continuity with host bone (PATHOGNOMONIC) by CT
√ nonmineralized cartilage cap hypodense to muscle (in 75–80%):
√ 6–8 mm thick in skeletally mature patients
√ up to 30 mm thick in skeletally immature patients

MR (best modality):

√ cortical + medullary continuity:
√ peripheral rim of low signal intensity = cortical bone
√ hyaline cartilage cap very hyperintense on T2WI + of low to intermediate intensity on T1WI ← high water content:
√ central area of fat signal intensity = cancellous bone
√ smooth continuous appearance with relatively thin cap
√ hypointense mineralized areas of cartilage
√ hypointense periphery = perichondrium
√ slight septal + peripheral enhancement
√ cartilage tends to thin and disappear at numerous points on surface of osteochondroma

US:

√ hypoechoic nonmineralized cartilaginous cap easily distinguished from muscle and fat
√ posterior acoustic shadowing for mineralized portion

NUC:

√ active lesion (predominantly in young patient)
√ quiescent lesion in older patient

Prognosis: exostosis begins in childhood; stops growing when nearest epiphyseal center fuses

after skeletal maturity

Rx: surgical excision (2% recurrence rate, 13% complication rate [neuropraxia, arterial laceration, compartment syndrome, fracture])

Cx:

(1) Osseous and cosmetic deformity (most frequent)
- mechanical limitation of joint movement
- snapping tendon / ligament
- hematuria (irritating pubic osteochondroma)

√ saucerization / scalloping of cortex of adjacent bone due to extrinsic pressure erosion (of paired tubular bones)

√ premature osteoarthritis

√ pleural effusion / spontaneous hemothorax ← irritating rib lesion

(2) Fracture through stalk of osteochondroma

(3) Vascular compromise

› venous / arterial stenosis

› arterial occlusion / venous thrombosis

› pseudoaneurysm formation:

Cause: repetitive trauma to vessel wall

Age: near end of normal skeletal growth

Location: popliteal a., brachial a., superficial femoral a., posterior tibial a.

(4) Neurologic compromise

› peripheral nerve compression with entrapment neuropathy: foot drop with peroneal nerve involvement (most frequent)

› central nerve compression: cranial nerve deficit, radiculopathy, cauda equina syndrome, cord compression with myelomalacia

√ often very narrow stalk of attachment

√ difficult imaging diagnosis owing to complex anatomy of skull base (21% TP)

√ spinal canal osteochondroma (15% FN)

(5) Reactive bursa formation (in 1.5%)
- enlarging mass overlying an osteochondroma simulating malignant transformation

Location: scapula (> 50%), lesser trochanter, shoulder

√ fluid-filled mass ± chondral filling defects:

√ mineralization of intrabursal chondral bodies may mimic a thick cartilage cap with growth

Cx: inflammation, infection, hemorrhage into bursa, secondary synovial chondromatosis

(6) Malignant transformation into secondary / peripheral chondrosarcoma / osteosarcoma

Frequency: 1% in solitary osteochondroma; 3–5% in hereditary multiple osteochondromatosis

Location: iliac bone commonest site

Of concern: interval growth, indistinct cortical margins, erosion of lesion + adjacent parent bone, large soft-tissue component

◊ Any cartilage cap > 1.0–1.5 cm thick / continued growth after skeletal maturation is suspect of malignant transformation!

mnemonic: GLAD PAST

Growth after physeal closure
Lucency (new radiolucency)
Additional scintigraphic activity
Destruction (cortical)
Pain after puberty
And
Soft-tissue mass
Thickened cartilaginous cap > 1.5 cm

DDx: parosteal osteosarcoma (no corticomedullary continuity)

Osteochondromatous Variants

1. Dysplasia epiphysealis hemimelica
2. Subungual exostosis
3. Turret exostosis
4. Traction exostosis (at tendinous attachments)
5. Bizarre parosteal osteochondromatous proliferation = Nora lesion
6. Florid reactive periostitis

Solitary Osteochondroma

Frequency: 1–2%; 20–50% of benign bone tumors; 10–15% of all bone tumors

Average age: 33 years (range, 1st–3rd decade); M÷F = 1.3÷1 to 4.1÷1

- incidental nontender painless mass near joints
- symptomatic (in 75% before the age of 20 years)

Site: metaphysis of long bones; rarely diaphysis

Location: in any bone that develops by enchondromal calcification; femur (30%), tibia (15–20%), about knee (40%), humerus (10–20%), hands and feet (10%), pelvis (5%), scapula (4%), rib (3%), spine (2%, cervical [esp. C2] > thoracic [T8 > T4] > lumbar)

Type: (a) pedunculated osteochondroma = narrow stalk
(b) sessile osteochondroma = broad base

Hereditary Multiple Exostoses

= DIAPHYSEAL ACLASIS (ACLASIA) = MULTIPLE OSTEOCHONDROMAS = FAMILIAL OSTEOCHONDROMATOSIS

= most common of osteochondrodysplasias characterized by formation of multiple exostoses

Prevalence: 1÷50,000 to 1÷100,000; 1÷1,000 on Guam / Mariana Islands

Genetics: autosomal dominant (incomplete penetrance in females); 3 distinct loci on chromosomes 8, 11, 19
◊ 2/3 of affected individuals have a positive family history

Age: forms shortly after birth; virtually all patients discovered by 12 years of age; M÷F = 1.9÷1.0

- short stature (40%) ← development of exostoses at the expense of longitudinal bone growth

Location: multiple + usually bilateral; knee (70–98%), humerus (50–98%), scapula + rib (40%), elbow (35–40%), hip (30–90%), wrist (30–60%), ankle (25–54%), hand (20–30%), foot (10–25%), pelvis (5–15%), vertebra (7–9%)

Site: metaphyses of long bones near epiphyseal plate (distance to epiphyseal line increases with growth)

√ disproportionate shortening of an extremity (50%)

@ Upper extremity

√ pseudo-Madelung deformity:

Classification of Acute Osteochondral Injury *(Outerbridge)*	
Type	*MRI Description*
1	thickening of articular cartilage with abnormal SI
2	superficial loss of cartilage thickness / fissuring
3	deep loss of cartilage thickness / fissuring
4	full-thickness injury + abnormal SI of subchondral bone
5	free osteochondral fragment

√ ulnar shortening + longer bowed radius

√ ulnar tilt of distal radial articular surface

√ ulnar deviation of hand

√ dislocation of radial head

√ radioulnar synostosis

√ shortening of 4th + 5th metacarpals

√ supernumerary fingers / toes

@ Lower extremity

√ coxa valga (25%)

√ genu valgus (20–40%)

√ valgus deformity of ankle = tibiotalar tilt (45–54%)

√ undertubulation with widened metadiaphyseal junction:

√ Erlenmeyer flask deformity of distal femur

CT:

√ "wavy pelvis" sign = small sessile lesion create undulating cortical contour

Cx: malignant degeneration in 3–5%

OSTEOCHONDROSIS DISSECANS

= OSTEOCHONDRITIS DISSECANS = OSTEOCHONDRAL FRACTURE

= fragmentation + possible separation of a portion of the articular surface

Etiology:

(1) subchondral fatigue fracture as a result of shearing, rotatory / tangentially aligned impaction forces / repetitive microtrauma

(2) ? autosomal dominant trait associated with short stature, endocrine dysfunction, Scheuermann disease, Osgood-Schlatter disease, tibia vara, carpal tunnel syndrome

Age: adolescence; M > F

- asymptomatic / vague complaints
- clicking, locking, limitation of motion
- swelling, pain aggravated by movement

Location:

(a) knee: medial (in 10% lateral) femoral condyle close to fossa intercondylaris; bilateral in

20–30%
(b) humeral head
(c) capitellum of elbow
(d) talus

√ purely cartilaginous fragment unrecognized on plain film
√ fracture line parallels joint surface
√ mouse = osteochondrotic fragment
Location: posterior region of knee joint, olecranon fossa, axillary / subscapular recess of glenohumeral joint
√ mouse bed = sclerosed pit in articular surface
√ soft-tissue swelling, joint effusion

MR:
√ focus of abnormal signal in subarticular marrow
√ defect in overlying cartilage
√ loose bodies of heterogeneous low-SI in coronoid and olecranon fossa outlined by hyperintense joint fluid on T2WI

DDx: spontaneous osteonecrosis, neuroarthropathy, degenerative joint disease, synovial osteochondromatosis

Juvenile Osteochondritis Dissecans of Knee

= disease manifestation before physeal closure
Etiology: repetitive trauma
Age: 10–15 years; M÷F= 3÷1 to 4÷1
• pain, clicking / catching of joint, loss of function ← intra-articular loose bodies
Site: (a) medial femoral condyle: posterolateral aspect (51%), weight-bearing portion (19%)
(b) lateral femoral condyle: medial aspect (7%)
√ signs of lesion instability (= high-grade lesion):
√ line of fluid signal intensity on T2WI between fragment + parent bone surrounded by low-intensity rim
√ multiple / > 5 mm cysts near lesion
√ fracture in articular cartilage
√ fluid-filled osteochondritis dissecans lesion

Osteochondritis Dissecans of Capitellum

Age: adolescent boys 13–16 years of age
Cause: overhead throwing activity / gymnastics
• dull poorly localized pain in elbow
• limited extension + locking of elbow
√ lucent defect within capitellum
√ flattening of anterior border of capitellum

OSTEOFIBROUS DYSPLASIA

= entity previously mistaken for fibrous dysplasia

Age: newborn up to 5 years
Histo: fibrous tissue surrounding trabeculae in a whorled storiform pattern
Location: normally confined to tibia (middiaphysis in 50%), lesion begins in anterior cortex; ipsilateral fibula affected in 20%
√ enlargement of tibia with anterior bowing
√ cortex thin / invisible
√ periosteal expansion
√ sclerotic margin (DDx: nonosteogenic fibroma, chondromyxoid fibroma)
√ spontaneous regression in ⅓
Cx: pathologic fracture in 25%, fractures will heal with immobilization; infrequently complicated by pseudarthrosis
DDx: fibrous dysplasia, Paget disease

OSTEOGENESIS IMPERFECTA

= PSATHYROSIS = FRAGILITAS OSSIUM = brittle bone disease = LOBSTEIN DISEASE
= heterogeneous group of a rare generalized connective tissue disorder leading to micromelic dwarfism characterized by bone fragility, blue sclerae, and dentinogenesis imperfecta
Incidence: 1÷15,000 live births per year; M÷F = 1÷1
Genetics: in 80% mutation of COL1A1 gene on chromosome 17 and COL1A2 gene on chromosome 7 that encode type I collagen
Pathophysiology: decreased / defective synthesis of type I collagen → immature collagen matrix → increased bone fragility
• hyperlaxity of joints; blue sclerae; otosclerosis; thin loose skin
@ Cranium
• soft skull (caput membranaceum)
• triangular shape of face + frontal bossing
• poor dentition
• malocclusion (← mandibular malformation)
√ multiple Wormian bones may persist into adulthood
√ retarded calvarial bone formation = abnormally thick / thin calvaria
√ brachycephaly = premature fusion of coronal suture → restricted anteroposterior skull growth → compensatory overgrowth of sagittal suture laterally + lambdoid sutures caudally
√ frontal fontanel is wider and remains open longer than normal
√ sinus + mastoid cell enlargement
√ mandibular prognathism ← vertical underdevelopment of dentoalveolar structures + condylar process
@ Ear
√ otosclerosis = otospongiosis (= thickened undermineralized otic capsule ← markedly delayed + deficient ossification of all 3 layers)
√ microfractures + deformities of middle ear ossicles (crus of stapes + handle of malleolus)
@ Brain
√ generalized cerebral atrophy ← ? impaired outflow of CSF
√ hydrocephalus
√ widened basilar cistern

Cx: intracranial hemorrhage ← moyamoya disease / vertebral artery damage / vascular fragility / spontaneous intracranial hypotension / friction between multiple bone fragments of skull

@ Craniocervical junction

√platybasia
√ basilar impression
√basilar invagination

@ Spine

√ diffuse osteopenia
√ defective cortical bone formation
√ sclerosis of vertebral endplates
√biconcave vertebral bodies + Schmorl nodes

√ collapsed vertebral bodies:
√ severe kyphoscoliosis
√ platyspondyly = loss of vertebral body height
√ biconvex / ellipsoid intervertebral disk spaces of increased height
√ spondylolisthesis (5%)

@ Thorax

√ rib thinning / notching / fractures

@ Tubular bones

√ generalized osteoporosis = diffuse demineralization, deficient trabecular structure, cortical thinning
√ defective cortical bone: increase in diameter of proximal ends of humeri + femora; slender fragile bone; multiple cystlike areas
√ multiple fractures + pseudarthrosis with bowing deformity
√ normal / exuberant callus formation
√ bowing deformities after child begins to walk

OB-US:

√ fetal movement may be reduced
√ weight of US probe may deform head quite easily

Rx: IV pamidronate administered once every 4–6 months for several years → reduced incidence of fractures and increased bone density, vertebral body height, and cortical bone thickness.

Cx: (1) Impaired hearing / deafness from otosclerosis (20–60%)
(2) Death from intracranial hemorrhage ← abnormal platelet function

Dx: chorionic villous sampling

Classification of Osteogenesis Imperfecta *(Sillence, 1979)* *based on overlapping clinical + radiologic manifestations*					
Type	*Severity*	*Sclerae*	*Fractures*	*Stature*	*Hearing*
I	mild	blue	childhood	slightly short	30%
II	lethal	dark blue	multiple in utero	death in utero / at birth	none
III	severe	white	at birth	markedly short	normal
IV	moderate	white	fragile bones	moderate growth failure	yes

Osteogenesis Imperfecta Type I

= OSTEOGENESIS IMPERFECTA TARDA
◊ Most common form of nondeforming mild disease
Transmission: autosomal dominant with varying expression; compatible with life
Prevalence: 3-4÷100,000 live births
Age at presentation: 2–6 years
• blue sclerae (50%); presenile hearing loss (50%)
• normal / abnormal dentinogenesis
√ infants of normal weight + length
√ osteoporosis; bone density may be normal in adults
√ fractures in neonate (occurring during delivery)
◊ Fractures rare after puberty as ossification is complete!

OB-US:
√ marked bowing of long bones
√ NO IUGR

Osteogenesis Imperfecta Type II

= Congenital lethal osteogenesis imperfecta
= least common perinatal (obstetrical) lethal form
Transmission: sporadic new dominant mutations / autosomal recessive
Prevalence: 1÷54,000 births
• disease manifest at birth (in utero); NO hearing loss
• blue sclerae; ligamentous laxity + loose skin
√ shortened broad crumpled long bones
√ bone angulations, bowing, demineralization
√ localized bone thickening from callus formation
√ thin beaded ribs ± fractures → bell-shaped / narrow chest
√ thin poorly ossified skull
√ wormian bones (present in most cases)
√ spinal osteopenia
√ platyspondyly

OB-US:
◊ A normal sonogram after 17 weeks MA excludes the diagnosis!
√ increased through-transmission of skull ← extremely poor mineralization:

√ unusually good visualization of brain surface + orbits
√ increased visualization of intracranial arterial pulsations
√ abnormal compressibility of skull vault with transducer
√ decreased visualization of skeleton
√ multiple fetal fractures + deformities of long bones + ribs:
√ wrinkled appearance of bone ← more than one fracture in single bone
√ beaded ribs ← callus formation around fractures
√ abnormally short limbs
√ small thorax ← collapse of chest cage
√ decreased fetal movement
√ infants small for gestational age (frequent)
√ polyhydramnios + nonimmune hydrops

Prognosis: stillborn / death shortly after birth ← pulmonary hypoplasia / cerebral hemorrhage

DDx: congenital hypophosphatasia; achondrogenesis type I; camptomelic dysplasia

Osteogenesis Imperfecta Type III

= SEVERE PROGRESSIVELY DEFORMING OI

Transmission: autosomal recessive; progressively deforming disorder compatible with life

Prevalence: 1-2÷100,000 live births

• bluish sclerae during infancy that turn pale with time
• joint hyperlaxity (50%); small nose, soft skull
• NO hearing loss
√ micrognathia
√ decreased ossification of skull
√ normal vertebrae + pelvis
√ shortened + bowed long bones
√ progressive deformities of limbs + spine into adulthood
√ ± rib fractures
√ multiple fractures present at birth in ²/₃ of cases
√ fractures heal well

OB-US:
√ short + bowed long bones
√ fractures
√ humerus almost normal in shape
√ normal thoracic circumference

Prognosis: progressive limb + spine deformities during childhood / adolescence

Osteogenesis Imperfecta Type IV

= less severely deforming than type III

Transmission: autosomal dominant

Prevalence: 3-4÷100,000 live births

• normal scleral color; hearing loss
√ tubular bones of normal length; mild femoral bowing may occur
√ osteoporosis

OB-US:
√ bowing of long bones

OSTEOID OSTEOMA

= benign osteoblastic neoplasm characterized by intracortical nidus of osteoid tissue / woven mineralized immature bone, often surrounded by dense sclerotic reactive bone

Size: < 1.5 cm in diameter (per definition);
N.B.: lesion > 1.5 cm = osteoblastoma

Frequency: 12% of benign bone tumors

Etiology: ? inflammatory response

Histo: small nidus of osteoid-laden interconnected trabeculae with background of highly vascularized fibrous connective tissue surrounded by zone of reactive bone sclerosis; osteoblastic rimming; indistinguishable from osteoblastoma [*nidus*, Latin = nest]

Mean age: 7–25 years (range, 19 months–56 years); 2nd + 3rd decade (73%); 5–25 years (90%); uncommon < 5 and > 40 years of age; uncommon in Blacks; M÷F = 2÷1 to 3÷1

- tender to touch + pressure
- local pain (95–98%), weeks to years in duration, worse at night, decreased by activity:
  - salicylates give relief in 20–30 minutes in 75–90%
- prostaglandin E2 elevated 100–1000 x normal within nidus (probable cause of pain and vasodilatation)

Location:

(a) meta- / diaphysis of long bones (73%): upper end of femur (43%), hands (8%), feet (4%); frequent in proximal tibia + femoral neck, fibula, humerus; no bone exempt

(b) spine (10–14%): predominantly in neural arch (50% in pedicle + lamina + spinous process); 20% in articular process) of lumbar (59%), cervical (27%), thoracic (12%), sacral (2%) segments
  - painful scoliosis, focal / radicular pain
  - gait disturbance, limb atrophy

(c) skull, scapula, rib, pelvis, mandible, patella

√ round / oval radiolucent nidus (75%) of < 1.5 cm in size
√ variable surrounding sclerosis ± central calcification
√ painful scoliosis concave toward lesion / kyphoscoliosis / hyperlordosis / torticollis with spinal location ← spasm
√ may show extensive synovitis + effusion + premature loss of cartilage with intraarticular site (lymphofollicular synovitis)
√ osteoarthritis (50%) with intraarticular site 1.5–22 years after onset of symptomatology
√ regional osteoporosis ← probably disuse
◊ Radiographically difficult areas: vertebral column, femoral neck, small bones of hand + feet

NUC (bone scintigraphy is the most sensitive method!):
√ intensely increased radiotracer uptake (increased blood flow + new-bone formation)
√ "double density" sign = small area of focal activity (nidus) superimposed on larger area of increased tracer uptake

CT (for characterization + precise localization of nidus):

√ small well-defined round / oval nidus of low attenuation:
√ surrounded by variable amount of sclerosis
√ nidus with variable amount of mineralization (50%): punctate / amorphous / ringlike / dense
√ nidus enhances on dynamic scan

MR (diminished conspicuity of lesion compared with CT):
√ heterogeneous nidus ← depending on tumor vascularity and presence of calcifications:
√ mostly hypo- to isointense to muscle on T1WI
√ variable signal intensity on T2WI; SI may increase to between that of muscle + fat / remains low on T2WI
√ perinidal edema / inflammation in adjacent bone marrow + soft tissues (47%)
√ synovitis + joint effusion with intraarticular site

Angio:
√ highly vascularized nidus with intense circumscribed blush appearing in early arterial phase + persisting late into venous phase

Prognosis: no growth progression, infrequently regression

Rx: (1) complete surgical excision of nidus (reactive bone regresses subsequently)
(2) percutaneous CT-guided removal
(3) percutaneous ablation with radio-frequency electrode / laser / alcohol

DDx: (1) Stress fracture (focal cortical ridge, decreasing size, linear intense uptake of bone tracer)
(2) Intracortical abscess (irregular inner margin, eccentric sequestrum, no central enhancement)
(3) Intracortical hemangioma (vertically aligned intralesional calcifications, hyperintense lesion with hypointense septa)
(4) Small chondroblastoma (epiphyseal intramedullary location, punctate calcification)
(5) Osteoblastoma (less painful, no response to salicylate, more expansile + larger than 2 cm, progressive growth)
(6) Compensatory hypertrophy of pedicle (contralateral spondylolysis, lack of nidus)

Intracortical Osteoid Osteoma (most common)

= nidus within cortex accompanied by cortical thickening + reactive sclerosis

Location: shaft of long bone

√ solid / laminated periosteal reaction
√ fusiform sclerotic cortical thickening
√ round / oval radiolucent area < 2 cm in diameter within center of osteosclerosis

DDx: Brodie abscess, sclerosing osteomyelitis, syphilis, bone island, stress fracture, osteosarcoma, Ewing sarcoma, osteoblastic metastasis, lymphoma, subperiosteal aneurysmal bone cyst, osteoblastoma

Cancellous Osteoid Osteoma (intermediate frequency)

= intramedullary

◊ Intraarticular lesion difficult to identify with delay in diagnosis of 4 months–5 years!

Site: juxta- / intraarticular at femoral neck, vertebral posterior elements, small bones of hands + feet

√ little osteosclerosis / sclerotic cortex distant to nidus ← functional difference of intraarticular periosteum

√ joint space widened ← effusion, synovitis

Subperiosteal Osteoid Osteoma (rare)

= round soft-tissue mass adjacent to bone

Site: juxta- / intraarticular at medial aspect of femoral neck, hands, feet (neck of talus)

√ juxtacortical mass excavating the cortex with almost no reactive sclerosis ← bony pressure atrophy

Intraarticular Osteoid Osteoma (rare)

= nidus within / near a joint

Location: hip

• joint tenderness, not necessarily worse at night

√ prominent joint effusion ± synovial hypertrophy

√ minimal / absent reactive cortical thickening ← lack of cambium (= inner layer of periosteum)

DDx: inflammatory / septic / tuberculous / rheumatoid arthritis, nonspecific synovitis / Legg-Calvé-Perthes disease

OSTEOMA

= benign tumor of membranous bone (= hamartoma)

Histo: mature compact / cancellous bone

Age: adult life

Associated with: Gardner syndrome (multiple osteomas + colonic polyposis)

Location: craniofacial bones

(1) inner / outer table of calvarium (usually from external table)

(2) paranasal sinuses (frontal / ethmoid sinuses)

(3) mandible (posterior body / condyle)

√ non–tooth-related circumscribed sclerotic mass

DDx: idiopathic osteosclerosis WITHOUT bone expansion cannot be differentiated from osteoma.

(4) nasal bones

√ well-circumscribed round extremely dense structureless lesion usually < 2 cm in size

√ ± bone expansion / exophytic growth

√ NO perilesional halo

Fibrous Osteoma

Probably a form of fibrous dysplasia

Age: childhood

√ less dense than osteoma / radiolucent

√ expanding external table without affecting internal table

DDx: endostoma, bone island, bone infarct (located in medulla)

OSTEOMYELITIS

= inflammation of bone and marrow caused by bacteria (most commonly pyogenic bacteria + mycobacteria), fungi, parasites, viruses

Predisposed: immunosuppression, diabetes mellitus, sickle cell disease, intravenous drug abuse, alcoholism

Source of infection:

(a) direct inoculation: open fracture / direct trauma (commonly in young adults)
- prominent local signs and symptoms

(b) hematogenous: bacteremia (commonly in elderly / child)
- slow insidious progression of symptoms
- positive blood culture (in 50%)

(c) extension from adjacent soft-tissue infection

Location: tibia, wrist, femur, rib, thoracolumbar spine

Dx: requires 2 out of 4 of the following criteria

(1) purulent material draining from site of osteomyelitis
(2) positive findings at bone tissue / blood culture
(3) localized classic physical findings of bone tenderness
(4) positive radiologic findings

Acute Pyogenic Osteomyelitis

Age: most commonly affects children

Organism:

(a) newborns: S. aureus, group B streptococcus, E. coli
(b) children: S. aureus (blood cultures in 50% positive)
(c) adults: S. aureus (60%), enteric species (29%), Streptococcus (8%)
(d) drug addicts: Pseudomonas (86%), Klebsiella, Enterobacteriae; (57 days average delay in diagnosis)
(e) sickle cell disease: S. aureus, Salmonella
(f) diabetics: often multiple organisms like S. aureus, Streptococcus, E. coli, Klebsiella, Clostridia, Pseudomonas (in soil + sole of shoes)
(g) HIV-infected patients: TB, atypical mycobacteria

Cause:

(1) genitourinary tract infection (72%)
(2) lung infection (14%)
(3) dermal infection (14%): direct contamination from a soft-tissue lesion in diabetic patient

Pathophysiology:

bacterial growth in bone → entrapped bone becomes necrotic within 48 hours → spread to shaft ± periosteum (large subperiosteal abscess in children) → lifted periosteum impedes blood supply → sequestrum (= dead bone) → rupture of periosteum → draining sinus + soft-tissue abscess; host response causes reactive sleeve of new bone deposition (= involucrum) [involucrum, *Latin* = covering / sheath]
[sequestrum, *Latin* = deposit], [cloaca, *Latin* = sewer, canal]

Location:

@ Lower extremity (75%) over pressure points in diabetic foot

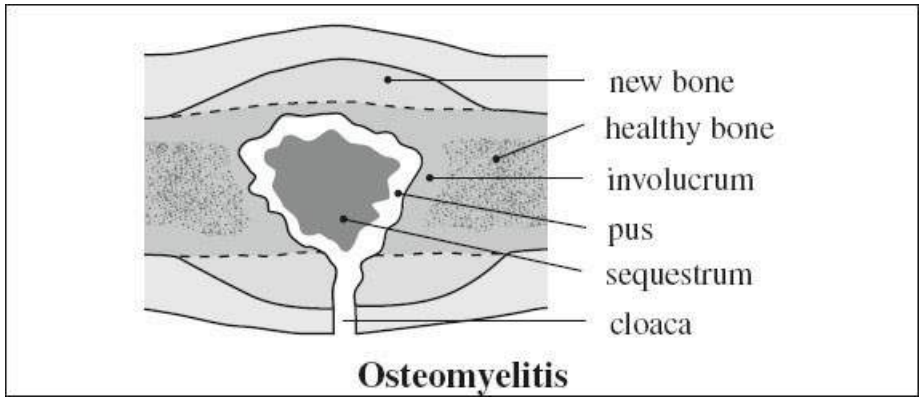
@ Vertebra (53%) = infectious spondylitis:
lumbar (75%) > thoracic > cervical
@ Radial styloid (24%)
@ Sacroiliac joint (18%)

• leukocytosis + fever (66%)

Conventional radiographs (insensitive):

√ radiographs normal in 95% at presentation (notoriously poor in early phase of infection for as long as 10–21 days)
DDx: infarction (similar radiographic findings)

√ some abnormality in 90% 28 days after onset of infection:
√ localized soft-tissue swelling adjacent to metaphysis with obliteration of usual fat planes (after 3–10 days)
√ permeative metaphyseal osteolysis (lags 7–14 days behind pathologic changes)
√ endosteal erosion
√ intracortical fissuring
√ involucrum = cloak of laminated / spiculated periosteal reaction (develops after 20 days)



Osteomyelitis

√ button sequestrum = detached necrotic cortical bone (develops after 30 days)
√ cloaca formation = space in which dead bone resides

US:

√ soft-tissue changes, fluid collection, periosteal reaction

CT:

√ overlying soft-tissue swelling
√ periosteal reaction
√ hypoattenuating marrow = density difference of > 20 HU compared to healthy side indicates marrow infection
√ trabecular coarsening
√ focal cortical erosion
√ extramedullary fat-fluid level ← cortical breach

MR (82% sensitive, 80% specific in diabetics):

◊ demonstrates extent of infection
◊ normal marrow / low SI on T2WI excludes osteomyelitis!
√ bone marrow hypointense on T1WI in geographic confluent pattern ← infiltration by

inflammatory cells + purulent material

√ hyperintense relative to normal fatty marrow on T2WI / STIR (= water-rich inflammatory tissue + edema fluid)

◊ Periarticular bone marrow edema can be seen adjacent to joints involved by noninfectious inflammatory arthropathy / osteoarthritis and does not reliably indicate osteomyelitis!

DDx: noninfectious inflammatory arthropathy (Charcot joint), osteoarthritis, cellulitis, normal hematopoietic marrow in children

√ variable enhancement after IV administration of Gd-chelate

√ focal / linear cortical involvement hyperintense on T2WI

√ subperiosteal infection = hyperintense halo surrounding cortex on T2WI

√ sinus tract (= communication of medullary fluid collection with soft-tissue fluid collection through cortical disruption) = hyperintense line on T2WI extending from bone to skin surface + enhancement of its borders

√ sequestrum = central hypointense area on T2WI

Abscess characteristics at MRI:

√ hyperintense enhancing rim (= hyperemic zone) around a central focus of low intensity (= necrotic / devitalized tissue) on contrast-enhanced T1WI

√ hyperintense fluid collection surrounded by hypointense pseudocapsule on T2WI + contrast enhancement of granulation tissue

√ adjacent hyperintense soft tissues on T2WI

√ fat-suppressed contrast-enhanced imaging (88% sensitive + 93% specific compared with 79% + 53% for nonenhanced MR imaging)

DDx: bone tumor ("no penumbra" sign = higher-SI layer of granulation tissue lining abscess cavity on T1WI)

NUC (~ 90% accurate):

Advantage: imaging of whole skeleton!

(1) ^{67}Ga scan: 100% sensitivity; increased uptake 1 day earlier than for ^{99m}Tc-MDP

◊ Gallium also helpful for chronic osteomyelitis!

(2) Static ^{99m}Tc-diphosphonate: 83% sensitive with 5–60% false-negative rate in neonates + children because of

(a) masking effect of epiphyseal plates

(b) early diminished blood flow with infection

(c) spectrum of uptake pattern from hot to cold

(3) **Triple-phase skeletal scintigraphy**:

92% sensitive + 87% specific

◊ Positive within 1–2 days after onset of symptoms!

Phase 1: Radionuclide angiography = increased perfusion phase of regional blood flow

Phase 2: "blood pool" images ← hyperemia = tissue phase

Phase 3: "bone uptake" ← increased osteoblastic activity = delayed phase

√ increased activity in all 3 phases (HALLMARK)

√ photopenia (rare) = "cold" osteomyelitis (due to vascular thrombosis + bone infarct) → may become "hot" at subsequent imaging (esp. TB)

◊ No uptake during delayed phase = no osteomyelitis!

◊ Obtain SPECT whenever possible!

Limitations: diagnostic difficulties in children (motion), in posttraumatic / postoperative state, diabetic neuropathy (poor blood supply), neoplasia, septic arthritis, Paget disease, healed osteomyelitis, noninfectious inflammatory process

(4) WBC-scan:

(a) ^{111}In-labeled leukocytes: best agent for acute infections

(b) ^{99m}Tc-hexamethylpropyleneamine oxime labeled leukocytes: preferred over ^{111}In-leukocyte imaging especially in extremities

◊ WBC scans have largely replaced gallium imaging for acute osteomyelitis ← faster imaging + greater resolution ← improved photon flux and improved dosimetry (higher dose allowed relative to ^{111}In)

(5) Bone marrow imaging (^{99m}Tc-sulfur colloid) in combination with WBC-scan

√ "cold" area in early osteomyelitis subsequently becoming "hot" if localized to long bones / pelvis (not seen in vertebral bodies)

√ local increase in radiopharmaceutical uptake (positive within 24–72 hours)

Scintigraphy is more useful than MR imaging in a child when the suspected site of osteomyelitis is not clinically evident (+ bacteremia / limping / refusing to bear weight)

Cx: (1) Abscess of soft-tissue / bone

(2) Fistula formation

(3) Pathologic fracture

(4) Septic arthritis (← extension into joint)

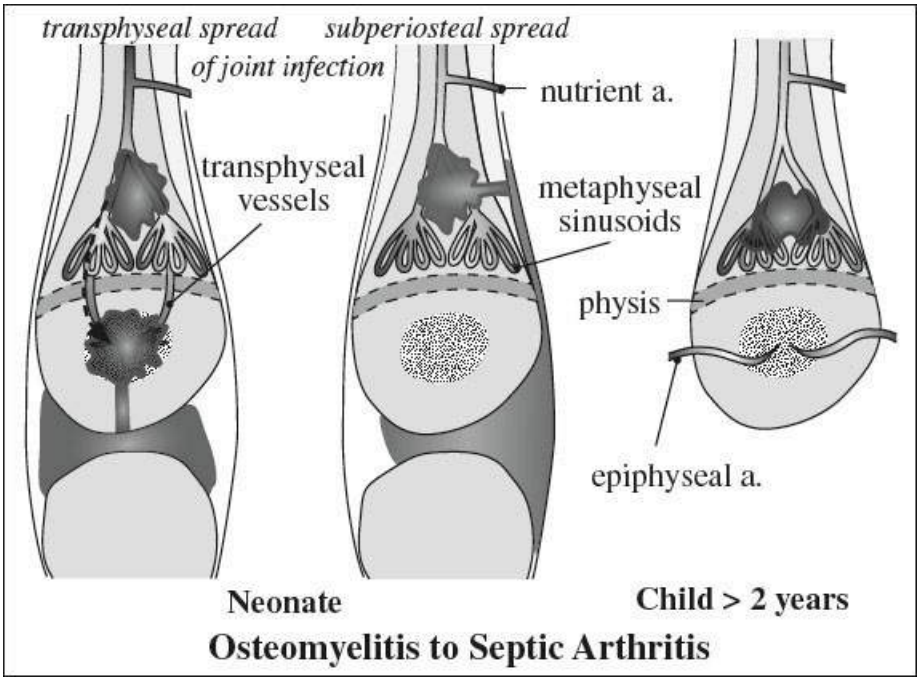
(5) Growth disturbance due to epiphyseal involvement

(6) Neoplasm

(7) Amyloidosis

(8) Severe deformity with delayed treatment

Acute Pyogenic Neonatal Osteomyelitis



Age: onset < 30 days of age
Prevalence: 1–3 ÷1000 admissions to nursery
Risk factors: prematurity, low birth weight, complicated delivery, antecedent illness, umbilical artery catheterization, invasive procedure
Anatomy: metaphyseal vessels penetrate growth plate (= physis) crossing into epiphysis
Site: metaphysis + epiphysis of long bones

• little / no systemic disturbance
√ multicentric involvement more common
√ often joint involvement (transphyseal / subperiosteal route)
√ bone scan falsely negative / equivocal in 70%

Acute Pyogenic Osteomyelitis in Infancy

Age: < 18 months of age
Anatomy: metaphyseal vessels penetrate growth plate (= physis) crossing into epiphysis
Pathomechanism: spread from metaphysis to epiphysis
√ striking soft-tissue component
√ subperiosteal abscess with extensive periosteal new bone
Cx: frequent infection of epiphysis + joint ← transphyseal blood flow

◊ osteomyelitis of proximal femur is usually associated with septic arthritis in children < 1 year of age.

Prognosis: rapid healing

Acute Pyogenic Osteomyelitis in Childhood

Cause: hematogenous spread ← bacteremia
Organism: Staphylococcus aureus, β-hemolytic Streptococcus, Streptococcus pneumoniae, Escherichia coli, Pseudomonas aeruginosa; increasing incidence

of methicillin-resistant S. aureus (MRSA) and Kingella kingae

Age: 2–16 years of age

Anatomy: transphyseal vessels closed; metaphyseal vessels adjacent to growth plate loop back toward metaphysis

Site: primary focus of infection located in metaphysis via nutrient artery; abscess formation in medulla with spread to cortex

Pathophysiology: metaphyseal capillaries lack phagocytic lining cells → uninhibited growth of microorganisms

Location: femur, tibia

√ sequestration frequent

√ periosteal elevation → disruption of periosteal blood supply

√ small single / multiple osteolytic areas in metaphysis

√ extensive periosteal reaction parallel to shaft (after 3–6 weeks); may be "lamellar nodular" (DDx: osteoblastoma, eosinophilic granuloma)

√ shortening of bone ← destruction of epiphyseal cartilage

√ growth stimulation ← hyperemia + premature maturation of adjacent epiphysis

√ midshaft osteomyelitis less frequent site

√ serpiginous tract with small sclerotic rim (PATHOGNOMONIC)

CAVE:

(1) Increased uptake in contralateral limb in patient with a limp

(2) Diffuse hyperemia in normal bones of an extremity involved with focal osteomyelitis should not be mistaken for multifocal osteomyelitis / septic arthritis.

Acute Pyogenic Osteomyelitis in Adulthood

Associated with: soft-tissue abscess, pathological fracture

Risk factors: IV drug use, previous trauma, immunosuppressed state, diabetes

Site: epiphysis + subchondral region (after growth plate closure)

√ delicate periosteal new bone

√ joint involvement common

Chronic Osteomyelitis

◊ ^{67}Ga citrate more useful than ^{111}In-labeled leukocytes ← lymphocytes are predominant cell type

◊ CT considered superior to MR for chronic osteomyelitis

√ cortical destruction and gas

√ thick irregular sclerotic bone with radiolucencies, elevated periosteum, chronic draining sinus

Sclerosing Osteomyelitis of Garré

= STERILE OSTEOMYELITIS

= low-grade nonnecrotic nonpurulent infection

Location: mandible (most commonly)

√ focal bulge of thickened cortex ← sclerosing periosteal reaction)

DDx: osteoid osteoma, stress fracture

Chronic Recurrent Multifocal Osteomyelitis

= benign self-limited disease of genetic etiology

◊ May be identical to chronic sclerosing osteomyelitis of Garré; childhood equivalent to SAPHO syndrome

Age: children + adolescents; M÷F = 1÷2

Histo: nonspecific subacute / chronic osteomyelitis

- pain, tenderness soft-tissue swelling
- limited range of motion
- elevated ESR + C-reactive protein; normal WBC

Associated with: psoriasis, palmoplantar pustulosis, inflammatory bowel disease

Location: tibia > femur > clavicle > fibula

◊ Whole-body imaging (^{99m}Tc bone scintigraphy, MRI) usually shows additional unsuspected locations

Site: metaphyses of long bones (75%); often symmetric

√ No abscess formation, fistula, sequestra

Early:

√ small areas of bone lysis, often confluent

√ progressive sclerosis surrounding osteolytic foci

MRI:

√ bone marrow edema, periostitis, soft-tissue inflammation, transphyseal disease

√ joint effusion (30%), synovial thickening, cartilage destruction, destruction of subchondral bone

Late:

√ sclerosis + hyperostosis

Prognosis: delayed spontaneous resolution

DDx: subacute + chronic infectious osteomyelitis; histiocytosis; hypophosphatasia; malignancy (leukemia, lymphoma, Ewing sarcoma)

Brodie Abscess

= small intraosseous abscess involving cortex surrounded by reactive bone (in smoldering indolent infection of subacute pyogenic osteomyelitis / inadequate treatment of acute osteomyelitis)

Organism: S. aureus (most common); cultures often negative

Histo: granulation tissue + eburnation

Age: more common in children; M > F

Location: predilection for ends of tubular bones (proximal / distal tibial metaphysis most common); carpal + tarsal bones

Site: metaphysis, rarely traversing the open growth plate; epiphysis (in children + infants)

√ lytic lesion often in an oval configuration that is oriented along the long axis of the bone

√ surrounded by thick dense rim of reactive sclerosis that fades imperceptibly into surrounding bone

√ lucent tortuous channel extending toward growth plate prior to physeal closure (PATHOGNOMONIC)

√ periosteal new-bone formation

√ ± adjacent soft-tissue swelling

√ may persist for many months
MR:
√ "double line" effect = high SI of granulation tissue surrounded by low SI of bone sclerosis on T2WI
√ well-defined lesion of low- to intermediate SI outlined by low-signal rim on T1WI
√ generally surrounded by marrow edema
√ no / rim enhancement after IV Gd-chelate
DDx: Osteoid osteoma

Epidermoid Carcinoma

Etiology: complication of chronic osteomyelitis (0.2–1.7%)
Histo: squamous cell carcinoma (90%); occasionally: basal cell carcinoma, adenocarcinoma, fibro-sarcoma, angiosarcoma, reticulum cell sarcoma, spindle cell sarcoma, rhabdomyosarcoma, parosteal osteosarcoma, plasmacytoma
Age: 30–80 (mean 55) years; M >> F
Latent period: 20–30 (range of 1.5–72) years
• history of childhood osteomyelitis
• exacerbation of symptoms with increasing pain, enlarging mass
• change in character / amount of sinus drainage
Location: at site of chronically / intermittently draining sinus; tibia (50%), femur (21%)
√ lytic lesion superimposed on changes of chronic osteomyelitis
√ soft-tissue mass
√ pathologic fracture
Prognosis:
(1) Early metastases in 14–20–40% (within 18 months)
(2) No recurrence in 80%

OSTEOPATHIA STRIATA

= VOORHOEVE DISEASE
= disorder of secondary spongiosa of X-linked dominant inheritance / sporadic occurrence
• usually asymptomatic (similar to osteopoikilosis)
• no known associated physical / laboratory abnormality → incidental radiographic discovery
Genetics: unknown
Location: all long bones symmetrically affected
Site: the only bone sclerosis primarily involving metaphysis (with extension into epi- and diaphysis)
√ dense linear longitudinal striations in diaphyses + metaphysis of long tubular bones: typically in areas of rapid growth
√ radiating fan-shaped densities of "sunburst" appearance from acetabulum into ileum

OSTEOPETROSIS

= rare hereditary disorder
Path: normal / increased number of osteoclasts → defective acidification function of osteoclast required to dissolve bone matrix → failure of proper reabsorption and

remodeling of primary spongiosa → bone sclerotic + thick but structurally weak + brittle

Cx: (1) Usually transverse fractures (common because of brittle bones) with abundant callus + normal healing
(2) Crowding of marrow (myelophthisic anemia + extramedullary hematopoiesis)
(3) Frequently terminates in acute leukemia

Rx: bone marrow transplant

DDx: (1) Heavy metal poisoning
(2) Melorheostosis (limited to one extremity)
(3) Hypervitaminosis D
(4) Pyknodysostosis
(5) Fibrous dysplasia of skull / face

Infantile Autosomal Recessive Osteopetrosis

= congenital more severe form / malignant subtype

Cause: defect on chromosome 11q13

Genetics:
(a) inactivation mutation of T-cell immune regulator 1 encoding α3 subunit of vacuolar proton pump ATP6i, responsible for proton transport in resorption lacunae
(b) homozygous mutations in chloride 7 channel
(c) defect in gray-lethal / osteopetrosis-associated transmembrane protein gene

- failure to thrive; lymphadenopathy
- premature senile appearance of facies; severe dental caries
- pancytopenia (= anemia, leukocytopenia, thrombocytopenia) ← severe marrow depression
- cranial nerve compression → optic atrophy, deafness
- hepatosplenomegaly ← extramedullary hematopoiesis
- subarachnoid hemorrhage ← thrombocytopenia

May be associated with: renal tubular acidosis + cerebral calcification

√ dense skeleton

√ splayed metaphyses + costochondral junctions

√ fractures from minor trauma ← brittle bones

Prognosis: stillbirth / early demise, survival beyond middle life uncommon (death due to recurrent infection, massive hemorrhage, terminal leukemia)

DDx: chronic renal failure, oxalosis, pyknodysostosis, physiologic sclerosis

Benign Adult Autosomal Dominant Osteopetrosis

= Osteopetrosis type 2 = = ALBERS-SCHÖNBERG DISEASE = MARBLE BONE DISEASE

[Heinrich Ernst Albers-Schönberg (1865–1921), radiologist, founder of the journal Fortschritte auf dem Gebiete der Röntgenstrahlen]

Cause: defect on chromosome 1p21

Genetics:
(a) deactivation of one allele of chloride 7 channel gene → some loss of function of the chloride 7 channel

(b) mutations in carbonic anhydrase II, T-cell immune regulator 1, osteopetrosis-associated transmembrane, and pleckstrin homology domain–containing family M member 1 (PLEKHM1)

Onset: in adolescence / adulthood with variable penetrance

- 50% asymptomatic; recurrent fractures
- mild anemia ← narrowed medullary canals
- occasionally cranial nerve palsy

√ increased density of medullary portion of bone with relative sparing of cortices (hallmark)

Phenotype I:

Distribution: long bones, skull, spine

√ diffuse osteosclerosis = generalized dense amorphous structureless bones with obliteration of normal trabecular pattern; mandible least commonly involved

√ Erlenmeyer flask deformity = clublike long bones with cortical thickening and medullary encroachment ← lack of tubulization + flaring of ends

Phenotype II:

Distribution: pelvis, spine

√ bone-within-bone appearance (= endobones)

√ "sandwich" vertebrae / rugger-jersey spine = dense endplate sclerosis with sharp margins

√ longitudinal metaphyseal striations:

√ alternating sclerotic + radiolucent transverse metaphyseal lines (phalanges, ilium) = indicators of fluctuating course of disease

√ sclerosis predominantly involving base of skull; calvaria often spared:

√ obliteration of mastoid cells, paranasal sinuses, basal foramina by osteosclerosis

Prognosis: normal life expectancy

OSTEOPOIKILOSIS

[*poikilos*, Greek = mottled]

= OSTEOPATHIA CONDENSANS DISSEMINATA

= rare autosomal dominant sclerosing bone dysplasia ← disorder of endochondral ossification involving the secondary spongiosa characterized by multiple bone islands / enostoses

Age: no age predilection (may not develop until after childhood); M = F

Histo: hamartomatous foci of lamellar cortical bone within dense trabeculae of spongy bone / inner bone cortex = compact bone islands

Genetics: inactivating mutation in LEM domain–containing protein 3 gene (LEMD = protein that antagonizes transforming growth factor (TGF)–b and bone morphogenic protein signaling focal deposits of compact lamellar bone in spongiosa

Associated with:

@ Dermatologic disorders:

1. Dermatofibrosis lenticularis disseminata (**Buschke-Ollendorff syndrome)** = asymptomatic small flesh-colored to yellow dermal papules / coalescent plaques (in 25%) on buttocks, trunk, arms, skin folds

Age: usually in childhood; often in 1st year of life

Histo: connective tissue nevi with predominantly abnormal elastin / abnormal

collagen
2. Scleroderma
3. Keloid formation

@ Bone abnormalities:
1. Melorheostosis
2. Osteopathia striata
3. Synovial chondromatosis
4. Rheumatoid arthritis

• commonly asymptomatic
• mild articular pain + joint effusion (15–20%)

Site: metaphyses + epiphyses (rarely extending into midshaft)

Location: long tubular bone epiphysis / metaphysis; hand (carpal + metacarpal), foot (tarsal + metatarsal), ankle, pelvis (glenoid + acetabulum), scapula; rare in skull, ribs, vertebral centra, mandible

√ multiple round / ovoid / lenticular bone islands (2–10 mm) in an often symmetric distribution:
√ long axis of lesions parallel to long axis of bone
√ may increase / decrease in size and number
√ may disappear

√ bone scintigraphic activity usually normal / mildly increased (similar to bone island / enostosis)

√ MR signal characteristics equal to cortical bone

Prognosis: not progressive, no change after cessation of growth

DDx: (1) Epiphyseal dysplasia (metaphyses normal)
(2) Melorheostosis (diaphyseal involvement)
(3) Mastocytosis
(4) Tuberous sclerosis
(5) Osteoblastic metastases

OSTEOSARCOMA

= malignant tumor of connective tissue producing osteoid matrix + variable amounts of cartilage matrix + fibrous tissue

Most common malignant primary bone tumor in adolescents + children; 2nd most common primary malignant bone tumor after multiple myeloma

Prevalence: 4–5÷1,000,000 annually; 15% of all primary bone tumors confirmed at biopsy; < 1% of all cancers in USA

Types & Frequency: *<u>underlined</u> are types recognized by WHO*

A. <u>Conventional</u> osteosarcoma:
› high-grade intramedullary 75%
› <u>telangiectatic</u> 4.5–11%
› <u>low-grade intraosseous</u> 4–5%
› <u>small cell</u> 1–4%
› osteosarcomatosis 3–4%
› gnathic 6–9%

B. Surface / juxtacortical osteosarcoma: 4–10%

associated with periosteum + variable medullary canal involvement
› parosteal 65%
› periosteal 25%
› high-grade surface 10%
› intracortical rare

C. Extraskeletal 4%

D. Secondary osteosarcoma 5–7%

Work-up: local staging by MR before biopsy; distant staging with bone scan + chest CT

Prognosis: dependent on age, sex, tumor size, site, classification; best predictor is degree of tissue necrosis in postresection specimen following chemotherapy (91% survival with tumor necrosis > 90%, 14% survival with < 90% tumor necrosis)

Extraskeletal Osteosarcoma

= extremely uncommon high-grade malignant tumor that occurs in older age group than osteosarcoma of bone

Frequency: 1.2% of soft-tissue sarcomas

Histo: variable amounts of neoplastic osteoid + bone + cartilage; frequently associated with fibrosarcoma, malignant fibrous histiocytoma, malignant peripheral nerve sheath tumor

Mean age: 50 years; 94% > 30 years of age; M > F

Location: lower extremity (thigh in 42–47%); upper extremity (12–23%); retroperitoneum (8–17%); buttock, back, orbit, submental, axilla, abdomen, neck, cheek, parotid gland, scalp, soft tissues adjacent to mandible, kidney, breast

Site: in soft tissue without attachment to bone / periosteum

- slowly growing firm soft-tissue mass; painful + tender (in 25–50%)
- history of trauma (12–31%): in preexisting myositis ossificans / site of intramuscular injection
- history of irradiation (5–10%)
- elevated levels of alkaline phosphatase (prognostic)

Size: average diameter of 9 cm

√ well circumscribed often deep-seated and fixed tumor

√ focal / massive area of characteristically amorphous mineralization (> 50%) most prominent at center of lesion

√ faint moderate inhomogeneous enhancement

√ increased radionuclide uptake on bone scan

Prognosis:

(1) multiple local recurrences (in 80–90%) after interval of 2 months to 10 years
(2) metastases after interval of 1 month to 4 years: lungs (81–100%), lymph nodes (25%), bone, subcutis, liver
(3) death within 2–3 years (> 50%) with tumor size as major predictor

DDx: myositis ossificans (calcifications most prominent at periphery of lesion)

High-grade Intramedullary Osteosarcoma

= CENTRAL / CONVENTIONAL OSTEOSARCOMA

Histo: arising from undifferentiated mesenchymal tissue; forming fibrous / cartilaginous / osseous matrix (mostly mixed) that produces osteoid / immature bone

(a) osteoblastic (50–80%)
(b) chondroblastic (5–25%)
(c) fibroblastic-fibrohistiocytic (7–25%)

Age: bimodal distribution 10–25 years and > 60 years; 21% < 10 years; 68% < 15 years; 70% between 10 and 30 years; M÷F = 3÷2 to 2÷1;
> 35 years: related to preexisting condition

- painful swelling (1–2 months' duration); fever (frequent)
- slight elevation of alkaline phosphatase
- diabetes mellitus (paraneoplastic syndrome) in 25%

Location: long bones (70–80%), femur (40–45%), tibia (16–20%); 50–55% about knee; proximal humerus (10–15%); facial bones (8%); cylindrical bone < 30 years; flat bone (ilium) > 50 years; spine (0.6–3.2%)

Site: origin in metaphysis (90–95%) / diaphysis (2–11%) /epiphysis (< 1%); growth through open physis with extension into epiphysis (75–88%)

Doubling time: 20–30 days

√ usually large bone lesion of > 5–6 cm when first detected
√ cloudlike density (90%) / almost normal density / osteolytic (fibroblastic type)
√ aggressive periosteal reaction: sunburst / hair-on-end / onion-peel = laminated / Codman triangle
√ moth-eaten bone destruction + cortical disruption
√ soft-tissue mass with tumor new bone (osseous / cartilaginous type)
√ transphyseal spread before plate closure (75–88%); physis does NOT act as a barrier to tumor spread
√ spontaneous pneumothorax ← subpleural metastases

NUC (bone scintigraphy):
√ intensely increased activity on blood flow, blood pool, delayed images (hypervascularity, new-bone formation)
√ soft-tissue extension demonstrated, especially with SPECT
√ bone scan establishes local extent (extent of involvement easily overestimated due to intensity of uptake), skip lesions, metastases to bone + soft tissues

CT:
√ very high attenuation (mineralized matrix) in 80%
√ soft-tissue attenuation (nonmineralized portion) replacing fatty bone marrow
√ low attenuation (higher water content of chondroblastic component / hemorrhage / necrosis)

MR (preferred modality):
√ tumor of intermediate SI on T1WI + high SI on T2WI
√ clearly defines marrow extent (best on T1WI), vascular involvement, soft-tissue component (best on T2WI)

Evaluate for:
(1) extent of marrow + soft-tissue involvement
(2) invasion of epiphysis
(3) joint (19–24%) + neurovascular involvement
(4) viable tumor + mineralized matrix for biopsy

Metastases (in 2% at presentation):

(a) hematogenous lung metastases (15%): calcifying; spontaneous pneumothorax ← subpleural cavitating nodules rupturing into pleural space
(b) lymph nodes, liver, brain (may be calcified)
(c) skeletal metastases uncommon (unlike Ewing sarcoma); skip lesions = discontinuous tumor foci in marrow cavity in 1–25%

Cx: (1) pathologic fracture (15–20%)
(2) radiation-induced osteosarcoma (30 years delay)

Rx: chemotherapy followed by wide surgical resection

Prognosis: 60–80% 5-year survival
(1) Amputation: 20% 5-year survival; 15% develop skeletal metastases; 75% dead within < 2 years
(2) Multidrug chemotherapy: 55% 4-year survival more proximal lesions carry higher mortality (0% 2-year survival for axial primary)

Predictors of poor outcome:
metastasis at presentation, soft-tissue mass > 20 cm, pathologic fracture, skip lesions in marrow

Predictors of poor response to chemotherapy:
no change / increase in size of soft-tissue mass, increase in bone destruction

DDx: Osteoid osteoma, sclerosing osteomyelitis, Charcot joint

High-grade Surface Osteosarcoma

Frequency: 0.4% of all osteosarcomas; least common of juxtacortical osteosarcomas
Histo: entirely high-grade mitotic activity
Origin: surface of bone
Age: 2nd + 3rd decades
Location: femur > humerus, fibula
Site: diaphysis + metaphysis of long bone
Size: usually 4.5–22 cm large tumor
√ dense ossification + periosteal reaction similar to periosteal osteosarcoma with bulk of lesion external to bone
√ cortical erosion + thickening (frequent)
√ often involves entire circumference of bone
√ invasion of medullary canal (in 8–48%)
Prognosis: 5-year survival rate of 46% (slightly better than conventional osteosarcoma)

DDx: (1) Parosteal osteosarcoma (ill-defined fluffy bone formation)
(2) Periosteal osteosarcoma (diaphysis, cortical destruction, periosteal reaction)
(3) Conventional osteosarcoma

Intracortical Osteosarcoma

Rarest form of osteosarcoma
Histo: sclerosing variant of osteosarcoma which may contain small foci of chondro- or fibrosarcoma
Location: femur, tibia
√ tumor < 4 cm in diameter

√ intracortical geographic bone lysis
√ tumor margin may be well defined with thickening of surrounding cortex
√ metastases in 29%

Low-grade Intraosseous Osteosarcoma

= LOW-GRADE CENTRAL OSTEOSARCOMA = WELL-DIFFERENTIATED / SCLEROSING OSTEOSARCOMA

Frequency: < 1% of all osteosarcomas

Path: penetration among bony trabeculae; fibrous stroma sometimes lacking nuclear atypia + pleomorphism; permeative extension of tumor cells between mature bone trabeculae

Histo: microtrabecular osseous matrix in bland stroma with highly variable amount of tumor osteoid production (similar to fibro-osseous lesions) = equivalent to low-grade parosteal osteosarcoma

Age: most frequently 3rd + 4th decade; M÷F = 1÷1

• protracted clinical course with nonspecific symptoms

Location: about the knee; femur involved in 50%

Site: medullary canal of metaphysis; often with extension into epiphysis

√ variable radiographic features:
  √ expansile lytic bone destruction with coarsely thick / thin trabeculations (61%)
  √ diffuse dense sclerosis (< 30%)
√ remodeling of bone
√ may have well-defined margins + sclerotic rim
√ subtle signs of aggressiveness: bone lysis, focally indistinct margin, cortical destruction, soft-tissue mass, variable periosteal reaction (22–50%)

N.B.: the relatively benign appearance has resulted in misdiagnosis as a benign entity!

Cx: transformation into high-grade osteosarcoma

Rx: surgical resection alone

Prognosis: 80–90% 5-year survival rate, similar to parosteal osteosarcoma; local recurrence in 10% (due to inadequate resection)

DDx: benign fibro-osseous lesions (fibrous dysplasia, nonossifying fibroma, desmoplastic fibroma, chondromyxoid fibroma); chondrosarcoma

Osteosarcoma of Jaw

= GNATHIC OSTEOSARCOMA

Average age: 34 years (10–15 years older than in conventional osteosarcoma)

Histo: chondroblastic predominance (~50%), osteoblastic predominance (~25%); better differentiated (grade 2 or 3) than conventional osteosarcoma (grade 3 or 4)

• simulating periodontal disease: rapidly enlarging mass, lump, swelling
• paresthesia (if inferior alveolar nerve involved)
• painful / loose teeth, bleeding gum

Location: body of mandible (lytic), alveolar ridge of maxilla (sclerotic), maxillary antrum

√ osteolytic / osteoblastic / mixed pattern
√ osteoid matrix (60–80%)
√ aggressive periosteal reaction for mandibular lesion
√ soft-tissue mass (100%)

√ opacification of maxillary sinus (frequent in maxillary lesions)
Prognosis: 40% 5-year survival rate (lower probability of metastases, lower grade)
DDx: metastatic disease (lung, breast, kidney), multiple myeloma, direct invasion by contiguous tumor from oral cavity, Ewing sarcoma, primary lymphoma of bone, chondrosarcoma, fibrosarcoma, acute osteomyelitis, ameloblastoma, Langerhans cell histiocytosis, giant cell reparative granuloma, "brown tumor" of HPT

Osteosarcomatosis

= MULTIFOCAL OSTEOSARCOMA = MULTIPLE SCLEROTIC OSTEOSARCOMA
Frequency: 2.7–4.2% of osteosarcomas
Etiology:
(a) multicentric type of osteosarcoma
(b) multiple metastatic bone lesions
Classification (Amstutz):

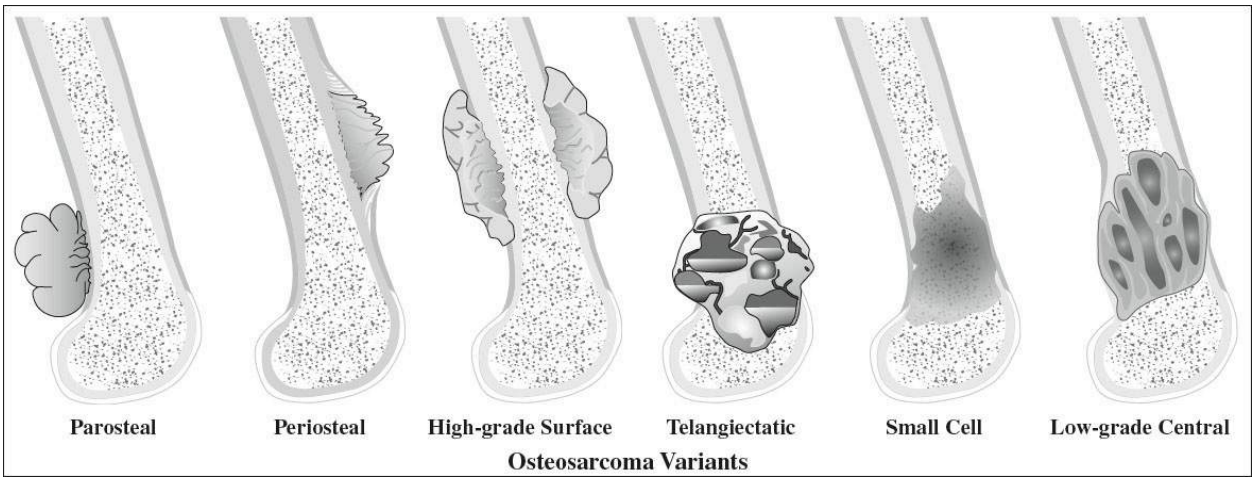
Type I	multiple synchronous bone lesions occurring within 5 months of diagnosis + patient ≤ 18 years of age
Type II	multiple synchronous bone lesions occurring within 5 months of presentation + patient > 18 years of age
Type IIIa	early metachronous metastatic osteosarcoma occurring 5 to 24 months after diagnosis
Type IIIb	late metachronous metastatic osteosarcoma occurring > 24 months after diagnosis

Mean age: Amstutz type I = 11 (range, 4–18) years
Amstutz type II = 30 (range, 19–63) years
Site: metaphysis of long bones; may extend into epiphyseal plate / begin in epiphysis
√ multicentric simultaneously appearing lesions with a radiologically dominant tumor (97%)
√ smaller lesions are densely opaque (osteoblastic)
√ lesions bilateral + symmetrical
√ early: bone islands
√ late: entire metaphysis fills with sclerotic lesions breaking through cortex
√ lesions are of same size
√ lung metastases (62%)
Prognosis: uniformly poor with mean survival of 12 (range, 6–37) months
DDx: heavy metal poisoning, sclerosing osteitis, progressive diaphyseal dysplasia, melorheostosis, osteopoikilosis, bone infarction, osteopetrosis

Parosteal Osteosarcoma

Frequency: 4–5% of all osteosarcomas; 65% of all juxtacortical osteosarcomas
Origin: outer fibrous layer of periosteum; slowly growing lesion with fulminating course if tumor reaches medullary canal
Histo: low-grade lesion with higher-grade regions (22–64%), invasion of medullary canal (8–59%); fibroblastic stroma + extensive osteoid with small foci of cartilage
Age: peak age 38 years (range of 12–58 years); 50% > age 30 (for central osteosarcoma 75% < age 30); M÷F = 2÷3

Location: posterior aspect of distal femur (50–65%), either end of tibia, proximal humerus, fibula, rare in other long bones



Site: metaphysis of long bones (80–90%)

• palpable mass

√ large lobulated "cauliflower-like" homogeneously ossified exophytic mass extending away from cortex

√ "string" sign = initially fine radiolucent cleavage plane separating tumor mass from cortex (30–40%)

√ tumor stalk (= attachment to cortex) grows with tumor obliterating the radiolucent cleavage plane

√ cortical thickening without aggressive periosteal reaction

√ tumor periphery less dense than center (DDx: myositis ossificans with periphery more dense than center + without attachment to cortex)

√ large soft-tissue component with osseous + cartilaginous elements

MR:

√ predominantly low SI on T1WI + T2WI = ossified tumor

√ unmineralized soft-tissue mass > 1 cm^3 / predominantly high T2-SI suggests high-grade tumor component

Prognosis: 86–91% 5-year survival rate (best prognosis of all osteosarcomas) compared to 53–61% for conventional osteosarcoma; dedifferentiation from low to high grade (in 16–43%)

DDx: (1) Osteochondroma (corticomedullary continuity)

(2) Myositis ossificans, periosteal chondroma, juxtacortical hematoma, fibrous malignancy, periosteal chondrosarcoma, other subtypes of juxtacortical osteosarcomas

Periosteal Osteosarcoma

Frequency: 1.5% of all osteosarcomas; 2nd most common of juxtacortical osteosarcomas

Origin: deep inner germinative layer of periosteum

Histo: intermediate-grade lesion; highly chondroblastic lesion with smaller areas of osteoid formation

Average age: 20 (range, 3–70) years); M÷F = 1.7÷1

Location: tibia (40%), femur (38%), ulna + humerus (5–10%)
Site: anteromedial diaphysis of proximal tibia + middle / distal femur; limited to periphery of cortex with normal endosteal margin + medullary canal (resembles parosteal sarcoma)
√ broad-based soft-tissue mass attached to cortex over entire extent of tumor (100%):
  √ tumor 7–12 cm in length, 2–4 cm in width
  √ involving 50–55% of osseous circumference
√ cortical thickening (82%): solid nonaggressive (51%)
√ cortical erosion
√ extrinsic scalloping of cortex (92%):
  √ affecting only thickened cortex (68%)
  √ involving native cortex (32%)
√ periosteal reaction (95%):
  √ short spicules of new bone perpendicular to shaft extending into soft-tissue mass (51%)
  √ aggressive periosteal reaction of laminated appearance / Codman triangle (11%)
  √ both patterns (38%)
√ cortical destruction / medullary cavity invasion (rare):
  √ marrow signal abnormality on MR usually due to reactive changes – unless continuous with surface component (2%)
√ additional areas of matrix calcification by CT (91%)
√ chondroblastic areas (80%) with inherent high water content of hyaline cartilage:
  √ hypodense on CT compared to muscle (91%)
  √ very high signal intensity on T2WI (83%)
  ◊ Biopsy may lead to erroneous diagnosis of chondrosarcoma!
NUC (bone scintigraphy):
  √ eccentric uptake (100%)
Prognosis: 83% 5-year survival rate (better than for conventional osteosarcoma but worse than for parosteal osteosarcoma)
DDx: (1) Juxtacortical chondrosarcoma (4^{th}–5^{th} decade, extensive osteoid + chondroid mineralization, no perpendicular periosteal reaction)
(2) Ewing sarcoma (rarely periosteal, no perpendicular periosteal reaction, soft-tissue component not mineralized + not low in attenuation + not of very high intensity)
(3) Parosteal osteosarcoma (densely ossified juxtacortical mass, 3^{rd} + 4^{th} decade, posterior distal metaphysis of femur, attached to bone by narrow stalk, no perpendicular periosteal reaction)
(4) High-grade surface osteosarcoma (surrounds > 50% of bone circumference, frequent invasion of medullary cavity, no high water content of soft-tissue mass)
(5) Periosteal chondroid tumor (well-defined border, typically metaphyseal location, curvilinear peripheral calcifications)

Secondary Osteosarcoma

= lesion arising from a preexisting abnormality
◊ Most osteosarcomas in patients > age 60 are secondary!

Cause: malignant transformation of benign process
(1) Paget disease (67–90%)
◊ 0.2–7.5% of patients with Paget disease develop osteosarcoma dependent on extent of disease
(2) Sequelae of irradiation (6–22%) 2–40 years ago (malignant fibrous histiocytoma most common; fibrosarcoma 3rd most common)
◊ 0.02–4% of patients with radiation therapy develop osteosarcoma related to exposure dose (usually > 1,000 cGy)
(3) Osteonecrosis, fibrous dysplasia, metallic implants, osteogenesis imperfecta, chronic osteomyelitis, retinoblastoma (familial bilateral type)
Path: high-grade anaplastic tissue with little / no mineralization
Age: middle-aged / late adulthood
Location: thoracic + lumbar spine > sacrum > cervical spine
Site: posterior elements (79%), 2 vertebral levels (17%)
√ aggressive bone destruction in area of preexisting condition associated with large soft-tissue mass
Prognosis: < 5% 5-year survival rate

Small-cell Osteosarcoma

Frequency: 1% of all osteosarcomas
Age: 2nd + 3rd decade; M÷F = 1÷1
Histo: small round blue cells (similar to Ewing sarcoma / primitive neuroectodermal tumor) lacking cellular uniformity and consistently producing fine reticular osteoid
Location: distal femur
Site: metaphysis with frequent extension into epiphysis; diaphysis (in 15%)
√ permeative lytic medullary lesion in all cases
√ cortical breakthrough
√ aggressive periosteal reaction (> 50%)
√ associated soft-tissue mass
Prognosis: 53–61% 5-year survival rate
DDx: (1) Ewing sarcoma (rare calcifications, cortical thickening + saucerization)
(2) Lymphoma (spread outside bone without osseous destruction, calcification uncommon)
(3) Conventional osteosarcoma

Telangiectatic Osteosarcoma

= MALIGNANT BONE ANEURYSM
Frequency: 1.2–12% of all osteosarcomas
Mean age: 20 (range, 3–67) years; M÷F = 3÷2
Path: malignant destructive osteoid-forming sarcoma of bone with > 90% of tumor volume consisting of large hemorrhagic + necrotic cavities mimicking an ABC
Histo: blood-filled cavernous vessels lined with osteoclastic giant cells; nuclear pleomorphism + high mitotic rate
Location: (a) about knee (62%): distal femur (48%), proximal tibia (14%)

(b) proximal humerus (16%), proximal femur, fibula, midfemur, midhumerus, mandible

Site: medullary cavity of metaphysis (90%); extension into epiphysis (87%)

√ radiolucent appearance of tumor ← scant bone matrix subtly visible radiographically in 58%

√ minimal peripheral sclerosis

√ geographic bone destruction with a wide zone of transition

√ marked aneurysmal expansion of bone (19%)

√ endosteal scalloping

√ extensive invasion of surrounding soft tissues

MR:

√ heterogeneous signal intensity with fluid levels (74%):

√ high T1 + variable T2 signal = hemorrhage (96%)

√ enhancing thickened nodular tumor periphery + septa

CT:

√ soft-tissue mass with attenuation lower than muscle

√ fluid levels (49%)

√ nodular calcific foci of osteoid matrix mineralization (85%) at periphery / within septa = SPECIFIC ← viable neoplastic tissue

√ thick peripheral + nodular septal enhancement ← viable high-grade sarcomatous tissue

NUC:

√ "doughnut" sign = peripherally increased uptake with central photopenia on bone scan = TYPICAL

Cx:

√ pathologic fracture (43–61%)

Prognosis: 67% 5-year survival rate

DDx: (1) Aneurysmal bone cyst (expansile remodeling with well-defined encapsulated margin, thin septa without nodularity, enhancing thin peripheral rim, no soft-tissue involvement)

(2) Giant cell tumor (epiphyseal location, solid mass, isointense to muscle on T1WI)

(3) Lytic metastasis(no fluid levels)

(4) Chondroblastic conventional osteosarcoma

(5) Ewing sarcoma, chondrosarcoma, lymphoma

OXALOSIS

Rare inborn error of metabolism

Etiology: excessive amounts of oxalic acid combine with calcium and deposit throughout body (kidneys, soft tissue, bone)

• hyperoxaluria = urinary excretion of oxalic acid > 50 mg/ day

• progressive renal failure

√ osteoporosis = cystic rarefaction + sclerotic margins in tubular bones on metaphyseal side, may extend throughout diaphysis

√ erosions on concave side of metaphysis near epiphysis (DDx: hyperparathyroidism)

√ bone-within-bone appearance of spine

√ nephrocalcinosis (2° HPT: subperiosteal resorption, rugger jersey spine, sclerotic metaphyseal bands)
Cx: pathologic fractures

PACHYDERMOPERIOSTOSIS

= OSTEODERMOPATHIA HYPERTROPHICANS (TOURAINE-SOLENTE-GOLE) = PRIMARY HYPERTROPHIC OSTEOARTHROPATHY
Autosomal dominant
Age: 3–38 years with progression into late 20s / 30s; M >> F
• large skin folds of face + scalp
Location: epiphyses + diametaphyseal region of tubular bones; distal third of bones of legs + forearms (early); distal phalanges rarely involved
√ enlargement of paranasal sinuses
√ irregular periosteal proliferation of phalanges + distal long bones (hand + feet) beginning in epiphyseal region at tendon / ligament insertions
√ thick cortex, BUT NO narrowing of medulla
√ clubbing
√ may have acroosteolysis
Prognosis: self-limiting = progression ceases after several years
DDx: hypertrophic pulmonary osteoarthropathy, thyroid acropachy

PAGET DISEASE

= OSTEITIS DEFORMANS
[Sir James Paget, 1st. Baronet (1814–1899), professor of anatomy & surgery at the Royal College of Surgeons at St. Bartholomew Hospital, London]
= multifocal chronic skeletal disease characterized by disordered and exaggerated bone remodeling
Etiology: ? chronic paramyxoviral infection
Prevalence: 3% of individuals > 40 years; 10% of persons > 80 years; higher prevalence in northern latitudes; 2nd most common disease (after osteoporosis) affecting older individuals
Age: Caucasian of Northern European descent > 55 years (in 3%); > 85 years (in 10%); unusual < 40 years; M÷F = 2÷1
Histo: increased resorption + increased bone formation; newly formed bone is abnormally soft with disorganized trabecular pattern ("mosaic pattern") causing deformity

A. ACTIVE PHASE = OSTEOLYTIC PHASE
= intense osteoclastic activity = aggressive bone resorption with lytic lesions
Path: replacement of hematopoietic bone marrow by fibrous connective tissue with numerous large vascular channels
√ osteoporosis circumscripta of skull
√ flame-shaped radiolucency extending from end of long bone into diaphysis

B. MIDDLE / MIXED / BLASTIC PHASE (common)
= decreased osteoclastic activity + increased osteoblastic activity
Location: polyostotic in axial skeleton: skull, pelvis, spine

√ coexistence of lytic + sclerotic phases
√ osseous sclerosis → coarse trabecular + cortical thickening + bone enlargement

C. INACTIVE / LATE PHASE = QUIESCENT PHASE
= diminished osteoblastic activity with decreased bone turnover
Path: loss of excessive vascularity
√ osteosclerosis + cortical accretion (eg, ivory vertebral body)

- asymptomatic (1/**5**–¾)
- fatigue; enlarged hat size; peripheral nerve compression
- neurologic disorders from compression of brainstem (basilar invagination)
- hearing loss, blindness, facial palsy ← narrowing of neural foramina (rare)
- pain from (a) primary disease process – rare
  (b) pathologic fracture
  (c) malignant transformation
  (d) degenerative joint disease / rheumatic disorder aggravated by skeletal deformity
- local hyperthermia of overlying skin
- high-output congestive heart failure from markedly increased perfusion (rare)
- increased alkaline phosphatase ← increased bone formation
- hydroxyproline increased ← increased bone resorption
- normal serum calcium + phosphorus

Sites: usually polyostotic + asymmetric; pelvis (75%) > lumbar spine > thoracic spine > proximal femur > calvarium > scapula > distal femur > proximal tibia > proximal humerus

Sensitivity: scintigraphy + radiography (60%) scintigraphy only (27–94%) radiography only (13–74%)

√ osseous expansion
√ trabecular coarsening
√ cortical thickening
√ cystlike areas (fat-filled marrow cavity / blood-filled sinusoids / liquefactive degeneration + necrosis of proliferating fibrous tissue)

@ Skull (involvement in 29–65%)
√ inner + outer table involved
√ diploic widening
√ osteoporosis circumscripta = well-defined lysis, most commonly in calvarium anteriorly, occasionally in long bones (destructive active stage)
√ "cotton wool" appearance = mixed lytic + blastic pattern of thickened calvarium (late stage)
√ basilar impression with encroachment on foramen magnum
√ deossification + sclerosis in maxilla
√ sclerosis of base of skull

@ Long bones (almost invariable at end of bone; rarely in diaphysis)
√ "candle flame" / "blade of grass" lysis = advancing tip of V-shaped lytic defect in diaphysis of long bone originating in subarticular site (CHARACTERISTIC)
√ lateral curvature of femur, anterior curvature of tibia (commonly resulting in fracture)

@ Ribs (involvement in 1–4%)

@ Small / flat bones
√ bubbly destruction + periosteal successive layering
@ Pelvis
√ thickened trabeculae in sacrum, ilium; rarefaction in central portion of ilium
√ thickening of iliopectineal line
√ acetabular protrusion (DDx: metastatic disease not deforming) + secondary degenerative joint disease
@ Spine (upper cervical, low dorsal, midlumbar)
√ expansion of vertebra
√ lytic / coarse trabeculations at periphery of bone
√ "picture-frame vertebra" = bone-within-bone appearance = enlarged square vertebral body with reinforced peripheral trabeculae + central osteopenia, typically in lumbar spine
√ "ivory vertebra" = blastic vertebra with increased density
√ isolated posterior arch involvement
√ ossification of spinal ligaments, paravertebral soft tissue, disk spaces

Bone scan (94% sensitive):
√ usually markedly increased uptake (symptomatic lesions strikingly positive ← increased blood flow + osteoblastic activity)
√ normal scan in some sclerotic burned-out lesions
√ marginal uptake in lytic lesions
√ enlargement + deformity of bones

Bone marrow scan:
√ sulfur colloid bone marrow uptake is decreased ← marrow replacement by cellular fibrovascular tissue

MR:
Indications: imaging of complications (spinal stenosis, basilar impression, sarcoma staging)
√ areas of decreased SI within marrow on T1WI + increased intensity on T2WI (= fibrovascular tissue resembling granulation tissue)
√ hypointense area / area of signal void on T1WI + T2WI (cortical thickening, coarse trabeculation)
√ reduction in size + SI of medullary cavity (= replacement of high-SI fatty marrow by ↑ medullary bone formation)
√ focal areas of higher SI than fatty marrow (= cystlike fat-filled marrow spaces)
√ widening of bone

Cx: (1) Associated neoplasia (0.7–1–20%)
(a) sarcomatous transformation into osteosarcoma (22–90%), fibrosarcoma / malignant fibrous histiocytoma (29–51%), chondrosarcoma (1–15%)
√ osteolysis in pelvis, femur, humerus
Prognosis: < 10% 5-year survival
(b) multicentric giant cell tumor (3–10%)
√ lytic expansile lesion in skull, facial bones
(c) lymphoma, plasma cell myeloma
(2) Insufficiency fracture

(a) "banana fracture" = tiny horizontal cortical infractions on convex surfaces of lower extremity long bones (lateral bowing of femur, anterior bowing of tibia)
(b) compression fracture of vertebra (soft bone despite increased density)

(3) Neurologic entrapment
(a) basilar impression with obstructive hydrocephalus + brainstem compression + syringomyelia
(b) spinal stenosis with extradural spinal block (osseous expansion / osteosarcoma / vertebral retropulsion ← compression fracture)

(4) Early-onset osteoarthritis
Pathogenesis: altered biomechanics across affected articulations

Cx: sarcomatous degeneration: most commonly osteo- / chondrosarcoma / malignant fibrous histiocytoma

Rx: calcitonin, biphosphonates, mithramycin

Detection of recurrence:
(a) in ⅓ detected by bone scan
(b) in ⅓ detected by biomarkers (alkaline phosphatase, urine hydroxyproline)
(c) in ⅓ by bone scan + biomarkers simultaneously
√ diffuse (most common) / focal increase in tracer uptake
√ extension of uptake beyond boundaries of initial lesion

DDx: osteosclerotic metastasis, osteolytic metastasis, Hodgkin disease, vertebral hemangioma

PARAOSTEOARTHROPATHY

= HETEROTOPIC BONE FORMATION = ECTOPIC OSSIFICATION = MYOSITIS OSSIFICANS

Common complication following surgical manipulation, total hip replacement (62%) and chronic immobilization (spinal cord injury / neuromuscular disorders)

Mechanism: pluripotent mesenchymal cell lays down matrix for formation of heterotopic bone similar to endosteal bone

Causes: para- / quadriplegia (40–50%), myelomeningocele, poliomyelitis, severe head injury, cerebrovascular disease, CNS infections (tetanus, rabies), surgery (commonly following total hip replacement)

Evolution: calcifications seen 4–10 weeks following insult; progression for 6–14 months; trabeculations by 2–3 months; stable lamellar bone ankylosis in 5% by 12–18 months

√ largest quantity of calcifications around joints, especially hip, along fascial planes
√ disuse osteoporosis of lower extremities
√ renal calculi (elevation of serum calcium levels)

Radiographic grading system (Brooker):

0 no soft-tissue ossification
I separate small foci of ossification
II > 1 cm gap between opposing bone surfaces of heterotopic ossifications
III < 1 cm gap between opposing bone surfaces
IV bridging ossification

Bone scan:
√ tracer accumulation in ectopic bone

√ assessment of maturity for optimal time of surgical resection (indicated by same amount of uptake as normal bone)

Cx: ankylosis in 5%

Rx: 1000–2000 rad within 4 days following surgical removal

PARKES WEBER SYNDROME

= KLIPPEL-TRÉNAUNAY-WEBER SYNDROME

[Frederick Parkes Weber (1863–1962), dermatologist, London]

= characterized by cutaneous capillary malformation and limb overgrowth in combination with high-flow malformations (small arteriovenous fistulas and shunts) and congenital varicose veins

• pseudo-Kaposi sarcoma = pseudo-capillary malformation = feeling of warmth over affected skin ← high oxygen partial pressure

• high-output cardiac failure (occasionally)

√ hemihypertrophy = outgrowth of soft tissues + overgrowth of bone in affected limb

√ arteriovenous fistula-like stains in periarticular region

DDx: Klippel-Trénaunay syndrome (low-flow vascular malformations)

PATELLAR TENDON RUPTURE

Cause: (a) acute trauma (b) repetitive microtrauma

Mechanism: eccentric contraction of quadriceps while foot planted + knee flexed

Predisposed: diabetes, systemic lupus erythematosus, chronic soft-tissue swelling

√ patella alta = high-riding patella

PFEIFFER SYNDROME

= ACROCEPHALOSYNDACTYLY TYPE 2

√ broad thumbs + toes

√ mild soft-tissue syndactyly

PHENYLKETONURIA

High incidence of x-ray changes in phenylalanine-restricted infants:

√ metaphyseal cupping of long bones (30–50%), especially wrist

√ calcific spicules extending vertically from metaphysis into epiphyseal cartilage (DDx to rickets)

√ sclerotic metaphyseal margins

√ osteoporosis

√ delayed skeletal maturation

DDx: homocystinuria

PHOSPHORUS POISONING

Etiology:

(1) ingestion of metallic phosphorus (yellow phosphorus)

(2) treatment of rachitis or TB with phosphorized cod liver oil

Location: long tubular bones, ilium

√ multiple transverse lines (intermittent treatment with phosphorus)
√ lines disappear after some years

PIERRE ROBIN SYNDROME

May be associated with: CHD, defects of eye and ear, hydrocephalus, microcephaly
• glossoptosis
√ micrognathia = hypoplastic receding mandible
√ arched ± cleft palate
√ rib pseudarthrosis
Cx: airway obstruction (relatively large tongue), aspiration

PIGMENTED VILLONODULAR SYNOVITIS

= PVNS
= benign hypertrophic neoplastic process characterized by villous + nodular + villonodular proliferation and pigmentation from hemosiderin
Classification:
(a) localized disease (77%)
› extraarticular: in bursa / tendon sheath (71%)
› intraarticular synovium (6%)
(b) diffuse intraarticular disease (23%)
Genetics: rearrangement in chromosome 1p11-13, a site for CSF-1 gene, commonly fusing to COL6a3 on chromosome 2q35; trisomy of chromosomes 5 and 7
Histo: mononuclear histiocytoid cells with reniform nuclei and plump eccentric eosinophilic cytoplasm, admixed with multinucleated giant cells + xanthoma cells; hemosiderin deposition

Diffuse Intraarticular PVNS 23%

= DIFFUSE-TYPE GIANT CELL TUMOR
= benign locally destructive proliferation of mononuclear cells that resemble those in the synovium, admixed with multinuclear giant cells and inflammatory cells
Incidence: 1.8÷1,000,000 population per year; 0.9% of all benign soft-tissue masses
Path: infiltrative mass involving synovium of entire joint with thickening + irregular papillary / villous projections + larger nodular / villonodular protrusions
Histo: diffuse villonodular infiltrative sheetlike growth of synovial membrane with hyperplasia of undifferentiated connective tissue + multinucleated large cells ingesting hemosiderin / lipoid (foam / giant cells) ± fibrosis
Age: mainly 3rd–4th decade (range, 12–68 years); 50% < 40 years; M÷F=1÷1
• history of antecedent trauma (44–53%)
• mean duration of symptoms: 15 (range 1–120) months
• hemorrhagic "chocolate" / serosanguinous / xanthochromic joint effusion without trauma
• insidious onset (93%) with intermittent fluctuating symptoms + slow progression:
  • pain (79–90%), swelling (72–79%)
  • soft-tissue mass (6–19%)
  • joint dysfunction (26–28%):

- stiffness with decreased range of motion, joint locking

Location: knee (66–80%), hip (4–16%) > ankle > shoulder > elbow > tarsal + carpal joints; predominantly monoarticular

Radiography:
- √ normal (in up to 21%)
- √ soft-tissue swelling ← effusion + synovial proliferation:
  - √ dense soft tissues ← hemosiderin deposits
- √ joint effusion in knee, but not relevant in other joints
- √ extrinsic pressure erosion with rim of sclerosis involving both sides of joint: hip (93%), shoulder (75%), elbow (63%), ankle (56%), knee (30%)
- √ multiple sites of irregular cystlike subchondral radiolucent defects ← invasion of bone by synovium
- √ normal bone mineralization, preservation of joint space, NO calcifications until late in the disease:
  - √ joint space narrowing (7%)
  - √ degenerative disease (4%)
  - √ intraarticular osteochondral bodies (7%)
  - √ osteopenia (7%)

US:
- √ joint effusion
- √ complex heterogeneous echogenic masses
- √ markedly thickened hypoechoic synovium ± nodular / villous projections with increased blood flow

CT:
- √ joint effusion of low-attenuation
- √ diffuse synovial thickening
- √ hyperattenuating to muscle (29%) ← hemosiderin
- √ small radiographically invisible extrinsic erosions
- √ subchondral cyst formation
- √ juxtaarticular soft-tissue mass ← involvement of synovium in joint recesses + bursae

MR (optimal modality):
- √ heterogeneous diffuse plaquelike synovial thickening ± nodularity of intermediate to low SI on T1WI + T2WI
- √ lobulated intraarticular masses of synovial tissue with joint effusion
- √ nearly pathognomonic “blooming” artifact of low SI on gradient-echo pulse sequences ← magnetic susceptibility artifact of hemosiderin
- √ high-SI areas ← fat, effusion, edema, inflammation
- √ bone erosion / subchondral cyst (62%), septations (67%)
- √ edema in adjacent bone / soft tissue (23%)
- √ articular cartilaginous defects (31%)
- √ scalloping / truncation of prefemoral fat pad

NUC:
- √ diffusely increased radionuclide activity on blood flow and blood pool > delayed images

PET:
- √ hypermetabolic activity with maximum SUV values of up to 11.3

Arthrography:
√ bloody (23%) / yellow (70%) / brownish (9%) effusion
√ extensive synovial thickening with villous / nodular projections extending into joint
Angiography:
√ prominent neovascularity with tumor blush
√ mild arteriovenous shunting
Rx: synovectomy (50% recurrence rate), arthrodesis, arthroplasty, radiation
DDx: (1) Degenerative / traumatic arthritis
(2) Synovial sarcoma (solitary calcified mass outside joint)
(3) Sclerosing hemangioma
(4) Benign xanthoma
(5) Xanthogranuloma

Intraarticular Localized Nodular Synovitis 6%

= synovial lining without hemosiderin
= 1.6%–3.9% of all benign soft-tissue masses
Location: knee
Site: infrapatellar (67%), suprapatellar (24%), posterior intercondylar (10%)
Size: mean lesion diameter of 2.7 cm
√ mostly normal x-rays
√ localized soft-tissue opacity replacing normal region of adipose tissue in Hoffa fat pad
MR:
√ joint effusion (38%)
√ extrinsic erosion of bone (20%)
√ moderate contrast enhancement (48%)
√ soft-tissue mass of low to intermediate SI on T2WI
√ focal circular areas of low SI on T2WI (76%) ← hemosiderin deposition
√ linear / cleftlike areas of high signal intensity within mass (33%) ← entrapped joint fluid

Tenosynovial Giant Cell Tumor 71%

= GIANT CELL TUMOR OF TENDON SHEATH
= localized extraarticular form of PVNS solely involving tendon sheath
Incidence: 9.2÷1,000,000 annually; M ÷F = 1 ÷1.5 to 1 ÷2.1
Path: circumscribed lobulated cauliflower-like nodular soft-tissue mass attached to tendon sheath / residing within known bursa
• mean duration of symptoms: 19 (range 1–120) months
• Chronic onset (88%) of:
  • soft-tissue mass (83–99%), pain (22–71%)
  • joint dysfunction / swelling (0–4%)
Size: 0.5–4.0 cm in greatest dimension
Location:
(a) tendon sheath:
› hand & wrist (65–89%) specifically index and long fingers; volar÷dorsal aspect = 2÷1

◊ 2nd most common soft-tissue mass of hand & wrist (after ganglia)

› foot & ankle (5–15%)
› rare: knee, hip, elbow, shoulder

(b) bursa: hip / knee

Radiography:
√ no abnormality (in up to 20%)
√ soft-tissue mass (50–70%)
√ extrinsic erosion of underlying bone with well-defined sclerotic margin (9–25%) simulating marrow invasion
√ periosteal reaction (8%), calcifications (6%)

US:
√ hypoechoic solid mass with well-defined margins intimately related to involved tendon
√ mean length of 5.7 cm and mean circumference of 136°
√ mass does not move with tendon during dynamic sonography

PILOMATRICOMA

= PILOMATRIXOMA (former name) = CALCIFYING EPITHELIOMA OF MALHERBE
= benign calcifying subcutaneous tumor arising from primitive cells of skin appendage that normally differentiate into hair matrix cells

Frequency: < 1% of all skin tumors;
◊ Most common solid cutaneous tumor in patients < 20 years

Histo: epithelial cells with basophilic cytoplasm arranged in arclike fashion at periphery (basaloid cells) → centrally transformed into shadow cells (= ghost cells); eosinophilic cells without nuclei + filled with keratin

Age: two peaks of < 20 years and 50–65 years

• slowly growing tumor confined to subcutis

Location: head & neck (68%), trunk (29%), extremities (17%)

√ typically centrally calcified (in 85%)

MR:
√ homogeneous intermediate signal intensity on T1WI
√ heterogeneous intermediate signal intensity on T2WI
√ peritumoral edema / inflammation
√ enhancement of connective tissue capsule but not center

DDx: calcified lymph node, ossifying hematoma, hemangioma with phlebolith, granuloma annulare, dermatofibrosarcoma protuberans

POLIOMYELITIS

√ osteoporosis
√ soft-tissue calcification / ossification
√ intervertebral disk calcification
√ rib erosion commonly on superior margin of 3rd + 4th rib ← pressure from scapula
√ "bamboo" spine (resembling ankylosing spondylitis)
√ sacroiliac joint narrowing

PROGERIA

= HUTCHINSON-GILFORD SYNDROME
= autosomal recessive inheritance; most commonly in populations with consanguineous marriages (Japanese, Jewish)
Age: shortly after adolescence; M÷F = 1÷1
• characteristic habitus + stature:
  • symmetric retardation of growth
  • absent adolescent growth spurt
  • dwarf with short stature + light body weight
  • spindly extremities with stocky trunk
  • beak-shaped nose + shallow orbits
• premature senescence:
  • birdlike appearance; graying of hair + premature baldness
  • hyperpigmentation; voice alteration; bilateral cataracts
  • diffuse arteriosclerosis; osteoporosis
• scleroderma-like skin changes:
  • atrophic skin + muscles; circumscribed hyperkeratosis
  • telangiectasia; tight skin; cutaneous ulcerations
  • localized soft-tissue calcifications
• endocrine abnormalities:
  • diabetes; hypogonadism
√ generalized osteoporosis
@ Skull
  √ thin cranial vault
  √ delayed sutural closure + wormian bones
  √ hypoplastic facial bones (maxilla + mandible)
@ Chest
  √ narrow thorax + slender ribs
  √ progressive resorption with fibrous replacement of outer portions of thinned clavicles (HALLMARK)
  √ coronary artery + heart valve calcifications with cardiac enlargement
@ Extremities & joints
  √ short + slender long bones
  √ coxa valga
  √ valgus of humeral head
  √ acroosteolysis of terminal phalanges (occasionally)
  √ flexion + extension deformities of toes (hallux valgus, pes planus)
  √ excessive degenerative joint disease of major + peripheral joints
  √ neurotrophic joint lesions (feet)
  √ widespread osteomyelitis + septic arthritis (hands, feet, limbs)
@ Soft tissue
  √ soft-tissue atrophy of extremities
  √ soft-tissue calcifications around bony prominences (ankle, wrist, elbow, knee)
  √ peripheral vascular calcifications = premature atherosclerosis

Prognosis: most patients die in their 30s / 40s from complications of arteriosclerosis (myocardial infarction, stroke) or neoplasm (sarcoma, meningioma, thyroid carcinoma)

DDx: Cockayne syndrome (mental retardation, retinal atrophy, deafness, family history)

PROGRESSIVE DIAPHYSEAL DYSPLASIA

= ENGELMANN-CAMURATI DISEASE = CAMURATI-ENGELMANN DISEASE

= autosomal dominant disorder of intramembranous ossification

Genetics: mutation in gene encoding transforming growth factor TGF-β1 (= latency-associated peptide causing premature activation of TGF-β1) on chromosome 19q13.1 → hyperostosis along periosteal + endosteal surfaces

Age: 5–25 years (primarily in childhood); M > F

- neuromuscular dystrophy = delayed walking (18–24 months) with broad-based waddling gait; often misdiagnosed as muscular dystrophy / poliomyelitis
- bone pain + tenderness usually in midshaft of long bones
- muscle pain + weakness with easy fatigability in legs:
  - underdevelopment of muscles ← malnutrition
- NORMAL laboratory values

Location: usually symmetric involvement of diaphyses of long bones, calvaria, mandible, facial bones, midsegment of clavicle; NO involvement of hands, feet, ribs, scapulae

@ Skull (initially affected)

√ amorphous sclerosis of skull base → cranial nerve palsy

√ encroachment of frontal + sphenoid sinus; sparing of maxillary sinus

√ mandible rarely affected

@ Long bones

Site: tibia > femur > fibula > humerus > ulna > radius

√ bilateral symmetric cortical thickening involving periosteal + endosteal surfaces of long bones:

√ fusiform enlargement of diaphysis

√ abrupt demarcation of lesions ← sparing of metaphyses + epiphyses ← formed by endochondral ossification

√ cortical thickening (= endosteal + periosteal accretion of mottled new bone) → progressive obliteration of medullary cavity

√ progression of lesions along long axis of bone toward either end

√ relative elongation of extremities

Rx: low-dose corticosteroids

DDx: (1) Chronic osteomyelitis (single bone)

(2) Hyperphosphatasemia (high alkaline phosphatase levels)

(3) Paget disease (age, new-bone formation, increased alkaline phosphatase)

(4) Infantile cortical hyperostosis (fever; mandible, rib, clavicles; regresses, < 1 year of age)

(5) Fibrous dysplasia (predominantly unilateral, subperiosteal new bone)

(6) Osteopetrosis (very little bony enlargement)

(7) Vitamin A poisoning

PROTEUS SYNDROME

[Proteus = Greek god who could change his shape, "Elephant Man"]

= cutaneous + visceral combined lymphatic-venous malformations with multiple subcutaneous hamartomas, pigmented nevi, hemihypertrophy, hand or foot overgrowth, bone exostoses, lipomatosis

Incidence: > 200 cases

Cause: mutation in Akt-1 kinase

• mild symptoms at birth with rapid aggravation at puberty

Diagnostic criteria:

group A › connective tissue nevi

group B
- › linear epithelial nevi
- › asymmetric overgrowth (limbs, spine, skull, internal organs)
- › bilateral ovarian cystadenomas / parotid monomorphic adenoma before 2nd decade of life

group C
- › lipomas / localized absence of fat
- › low-flow vascular malformations
- › lung cysts
- › facial malformations

Dx: A + 2 criteria of group B or 3 criteria of group C

√ asymmetric overgrowth of bones + soft tissues
√ hypertrophy of fat
√ skull enlargement
√ wall thickening of digestive tract
√ cystic emphysematous changes of lung

PSEUDOFRACTURES

= LOOSER LINES = LOOSER ZONES = OSTEOID SEAMS = MILKMAN SYNDROME

= insufficiency stress fractures + nonunion (incomplete healing ← mineral deficiency)

Path: area of unmineralized woven bone occurring at sites of mechanical stress / nutrient vessel entry

Associated with:

(1) Osteomalacia / rickets
(2) Paget disease ("banana fracture")
(3) Osteogenesis imperfecta tarda
(4) Fibrous dysplasia
(5) Organic renal disease in 1%
(6) Renal tubular dysfunction
(7) Congenital hypophosphatasia
(8) Congenital hyperphosphatasia ("juvenile Paget disease")

(9) Vitamin D malabsorption / deficiency
(10) Neurofibromatosis

mnemonic: "POOF"
Paget disease
Osteomalacia
Osteogenesis imperfecta
Fibrous dysplasia

Common locations:
scapulae (axillary margin, lateral + superior margin), medial femoral neck + shaft, pubic + ischial rami, ribs, lesser trochanter, ischial tuberosity, proximal ⅓ of ulna, distal ⅓ of radius, phalanges, metatarsals, metacarpals, clavicle

√ typically bilateral + symmetric at right angles to bone margin
√ paralleled by marginal sclerosis in later stages
√ healing fracture with little / no callus response
√ 2–3-mm stripe of lucency at right angle to cortex (= osteoid seam formed within stress-induced infractions (PATHOGNOMONIC) + nonunion (= incomplete healing due to mineral deficiency)

PSEUDOXANTHOMA ELASTICUM

= recessive hereditary systemic disorder characterized by degeneration of elastic tissue

@ Skin
- redundant skin folds, particularly in flexor regions
- yellowish xanthomatous papules

√ large amorphous calcific deposits in soft tissue about joints

@ Eyes
- diminished visual acuity due to alteration of chorioretinal structure
- angioid streaks = reddish brown serrated lines extending from optic disk in a spoke-wheel fashion

@ Arteries
- claudication + decreased pulses

Histo: tissue degeneration of internal elastic lamina + medial thickening
√ lobulated appearance of arteries (similar to fibromuscular hyperplasia)
√ aneurysm formation
√ vessel calcification at early age

Cx: GI tract hemorrhage

PSORIATIC ARTHRITIS

= uncommon autoimmune disease involving synovium + ligamentous attachments (= enthesopathy)with propensity for sacroiliitis / spondylitis classified as seronegative spondyloarthropathy 6/c

Frequency: 20% of patients with psoriasis (peripheral arthritis in 5%, sacroiliitis in 29%, peripheral arthritis + sacroiliitis in 10%)

Path: synovial inflammation (less prominent than in rheumatoid arthritis) with early fibrosis of proliferative synovium; bony proliferation at joint margins / tendon insertions /

subperiosteum

Age of onset: 30–50 years; rare under the age of 13 years; M = F

Types:

(1) true psoriatic arthritis (31%)
(2) psoriatic arthritis resembling rheumatoid arthritis (38%)
(3) concomitant rheumatoid + psoriatic arthritis (31%)

- plaque psoriasis = sharply demarcated erythematous plaques with thick white, laminated ("micaceous") scale
  - ◊ Skin rash precedes / develops simultaneously with onset of arthritis in 85%!
  - ◊ Arthritis may antedate dermatological changes by an interval of up to 20 years!
- pitting, discoloration, hyperkeratosis, subungual separation, ridging of nails (in 80%)
- positive HLA-B27 in 80%
- negative rheumatoid factor (= seronegative spondyloarthropathy)

Location: usually asymmetric + oligoarticular; upper > lower extremities, sacroiliac joints, spine

Distribution: widely variable terminal interphalangeal joints, ray distribution, unilateral polyarticular

√ NO / minimal juxtaarticular osteoporosis (early stage); frequent osteoporosis (later stages)
√ marginal erosions in joints
√ periarticular new bone formation (frequent)
√ intraarticular osseous excrescences
√ enthesitis (especially of calcaneus)

@ Hand + foot

Target area: DIP, PIP, MCP

√ CLASSIC "sausage digit" (40%) = nodular / irregular soft-tissue swelling of tendon sheath of entire digit ← dactylitis
Path: flexor tendon tenosynovitis

√ increased tenosynovial fluid
√ solid hyperemic nodules at color Doppler
√ destruction of interphalangeal joint of 1st toe with exuberant periosteal reaction + bony proliferation at distal phalangeal base (PATHOGNOMONIC)
√ destruction of distal interphalangeal joints (erosive polyarthritis) + osseous resorption
√ "pencil-in-cup" deformity = erosions with ill-defined margins + adjacent proliferation of periosteal new bone (CHARACTERISTIC)
√ **bony ankylosis** (10%)
√ **ivory phalanx** = sclerosis of terminal phalanx (28%)
√ poorly defined diffuse new bone formation at attachment of Achilles tendon + plantar aponeurosis
√ erosions at superior / posterior margin of calcaneus (20%)
√ acroosteolysis (occasionally)

@ Axial skeleton

√ "floating" osteophyte = large bulky vertically oriented paravertebral soft-tissue ossification (AP view):
√ ill-defined excrescence sweeping across the diskovertebral junction from midportion

of one vertebra to the next

Location: lower cervical, thoracic, upper lumbar spine; asymmetric / unilateral

√ squaring of vertebrae in lumbar region

√ sacroiliitis (40%) = (most commonly) bilateral + asymmetric sacroiliac joint widening, increased density, fusion

√ apophyseal joint narrowing + sclerosis

√ atlantoaxial subluxation + odontoid abnormalities

DDx: (1) Reiter syndrome (affects mostly lower extremity)

(2) Ankylosing spondylitis

(3) Rheumatoid arthritis (bilaterally symmetric well-defined erosions, juxtaarticular osteoporosis, no new bone formation)

PYKNODYSOSTOSIS

= MAROTEAUX-LAMY DISEASE

= autosomal recessive inherited disorder of primary spongiosa; probably variant of cleidocranial dysostosis

Genetics: mutation in cathepsin-K gene (= lysosomal cysteine proteinase expressed in osteoclasts and required for degradation of collagen)

Age: often diagnosed in infancy / early childhood; M÷F = 2÷1

• dwarfism; mental retardation (10%)

• no concurrent anemia ← preserved medullary cavities

√ generalized osteosclerosis of long bones with thickened cortices (resembling osteopetrosis but with preservation of medullary canal)

√ multiple spontaneous fractures ← brittle bones

@ Skull

• yellowish discoloration of teeth

• characteristic dysmorphic facies: beaked nose, receding jaw

√ brachycephaly + platybasia

√ wide cranial sutures, wormian bones

√ thick skull base

√ hypoplasia of mandible + obtuse mandibular angle

√ hypoplasia + nonpneumatization of paranasal sinuses

@ Hands

• widened hands + feet; dystrophic nails

√ hypoplastic tapered terminal tufts (= acroosteolysis)

@ Spine

√ nonsegmentation of C1/C2 and L5/S1

√ kyphoscoliosis with increased lumbar lordosis

√ dense vertebral bodies with characteristic sparing of transverse processes

@ Chest

√ pectus excavatum

√ clavicular dysplasia

DDx: (1) Osteopetrosis (no dwarfism, no mandibular / skull abnormality, no phalangeal hypoplasia, no transverse metaphyseal bands, anemia, Erlenmeyer flask deformity;

"bone-within-bone" appearance)

(2) Cleidocranial dysostosis (no dense bones / terminal phalangeal hypoplasia, short stature)

QUADRILATERAL SPACE SYNDROME

= neurovascular compression syndrome involving the posterior humeral circumflex artery ± axillary nerve

Quadrilateral space:

compartment formed by teres major m. (inferiorly) + long head of triceps m. (medially) + teres minor m. (posteriorly) + subscapularis m. (anteriorly) + surgical neck of humerus (laterally)

Cause: posttraumatic fibrotic bands, muscle hypertrophy in throwing athletes

Age: 20–35 years

- point tenderness over quadrilateral space aggravated by abduction + external rotation of arm
- burning pain over lateral aspect of shoulder and arm
- weakness of deltoid m. + teres minor m.

√ compression of posterior circumflex a.

√ atrophy of deltoid m. + teres minor m.

√ occlusion of posterior humeral circumflex a.

Rx: analgesics, physiotherapy

RADIATION INJURY TO BONE

Pathogenesis: vascular compromise with obliterative endarteritis + periarteritis → hypovascularity + hypoxia → damage to osteoblasts + osteoclasts → hypocellularity + fibrosis → decreased matrix production (growing bone + periosteal new bone most sensitive)

Dose effects:

depend on age of patient, absorbed dose, size of radiation field, beam energy, fractionation

> 300 rad:	microscopic changes
> 400 rad:	growth retardation
< 600–1200 rad:	histological recovery retained
> 1200 rad:	pronounced cellular damage to chondrocytes; bone marrow atrophy + cartilage degeneration after > 6 months; vascular fibrosis

A. FOCAL MARROW DEPLETION

Pathophysiology: marrow edema, vascular congestion, suppressed hematopoiesis; replacement of marrow elements by fibrosis + fat (complete by 3 months)

√ homogeneous high-intensity signal within radiation port on T1WI

√ occasionally bandlike appearance characterized by peripheral zone of low SI (red marrow) and a central zone of high SI (fatty marrow) on T1WI

B. BONE GROWTH DISTURBANCE

@ Appendicular skeleton

√ joint space widening ← cartilage hypertrophy (after 8–10 months)

√ growth plate widening in 1–2 months, often returning to normal by 6 months

√ permanent alteration in bone length / size ← premature fusion of physis
√ metaphyseal bowing
√ sclerotic metaphyseal bands
√ metaphyseal irregularity + fraying resembling rickets
√ longitudinal striations
√ overtubulation (= abnormal narrowing of the diaphyseal shaft)
Cx: slippage of femoral / humeral epiphysis ± ischemic necrosis (after doses of > 25 Gy)

@ Axial skeleton (dose of < 15 Gy)
√ "bone-within-bone" appearance after 9–12 months
√ irreversible scalloping + irregularity of vertebral endplate with decreased height of vertebra
(= failure of vertical growth)
√ scoliosis concave toward side of irradiation ← asymmetric vertebral growth + muscular fibrosis
√ hypoplasia of ilium + ribs
√ acetabular dysplasia, coxa vara / valga

C. RADIATION OSTEITIS = OSTEORADIONECROSIS
= RADIATION NECROSIS
= bone mottling due to osteopenia + coarse trabeculation and focally increased bone density ← attempts of osseous repair with deposition of new bone on ischemic trabeculae
Dose: > 6,000 cGy in adults; > 2,000 cGy in children
Time of onset: 1–3 years following radiation therapy
Location: mandible, ribs, clavicle, humerus, spine, pelvis, femur
√ focal lytic area with abnormal bone matrix:
√ radiolucency confined to radiation field with narrow zone of transition
√ periostitis
√ increased fragility with sclerosis (= pathologic insufficiency fracture)
√ ± cortical thinning from chronic infection
MR:
√ increased intensity of spinal bone marrow on T1WI + T2WI corresponding to radiation port (fatty infiltration)
NUC:
√ bone scan with decreased uptake in radiation field
Cx: increased susceptibility of irradiated bone to infection
DDx: recurrent malignancy, radiation-induced sarcoma (soft-tissue mass), infection

D. BENIGN NEOPLASM
Most likely in patients < 2 years of age at treatment; with doses of 1600–6425 rads
Latent period: 1.5–5–14 years
1. Osteochondroma = exostosis (exclusively in children under 2 years of age during treatment)
2. Osteoblastoma

E. MALIGNANT NEOPLASM
= RADIATION-INDUCED SARCOMA
Latency period: 3–55 (average of 11–14) years

Minimum dose: 1,660–3,000 rad

Criteria: (a) malignancy occurring within irradiated field
(b) latency period of > 5 years
(c) histologic proof of sarcoma
(d) microscopic evidence of altered histology of the original lesion

Histo: 1. Osteosarcoma (90%) = 4–11% of all osteogenic sarcomas
2. Fibrosarcoma > chondrosarcoma > malignant fibrous histiocytoma

• pain, soft-tissue mass, rapid progression of lesion

REACTIVE ARTHRITIS

= REITER SYNDROME
[Hans Conrad Julius Reiter (1881–1969), German bacteriologist and hygienist in institute of hygiene in Königsberg and Berlin-Dahlem convicted of war crimes at the Nürnberg trials for his medical experiments in the concentration camp at Buchenwald]

= noninfectious, asymmetric inflammatory oligoarthropathy characterized by the triad of
(1) Postinfectious peripheral arthritis
(2) Uveitis / conjunctivitis
(3) Urethritis / cervicitis
with characteristic skin lesions

M÷F = 98÷2

Types:
(1) endemic (venereal): Chlamydia + Ureaplasma (males)
(2) epidemic (postdysenteric): Shigella, Salmonella, Yersinia, Campylobacter (males + females)

Trigger: within a few weeks after infection of GU / GI tract; skeletal manifestations typically appear after urethral and ocular inflammation have subsided

• history of sexual exposure / diarrhea 3–11 days before onset of urethritis
• mucocutaneous lesions of coalescing pustules, vesicles, erosions (in up to 50%):
» **balanitis circinata sicca** (male)
» **ulcerative vulvitis** (females)
• **keratosis blennorrhagicum** = well-demarcated scaly hyperkeratotic + pustular papules coalescing to plaques
Location: palm, sole
• seronegative spondyloarthritis
• positive HLA-B27 in 76% → greater propensity for chronicity

Location: asymmetric mono- / pauciarticular with predilection for lower extremity (small joints of foot, calcaneus, ankle)

Spectrum: enthesitis, joint effusion, synovitis, bursitis, erosive + proliferative bone changes, diffuse soft-tissue edema with tenosynovitis of finger + toe

√ polyarthritis
√ articular soft-tissue swelling + joint space narrowing in 50% (particularly knee, ankle, foot)
√ widening + inflammation of Achilles + plantar fascial tendons → heel swelling + retrocalcaneal bursitis (frequent)
√ "fluffy" periosteal reaction (DISTINCTIVE) at metatarsal necks, proximal phalanges,

calcaneal spur, tibia + fibula at ankle and knee
√ juxtaarticular osteoporosis (rare in acute stage)
Chronic changes:
• recurrent joint attacks in a few cases
√ calcaneal spur at insertion of plantar fascia + Achilles tendon
√ periarticular deossification
√ marginal erosions, loss of joint space
√ bilateral sacroiliac changes indistinguishable from ankylosing / psoriatic spondylitis (in 10–40%)
√ paravertebral ossification = isolated "floating osteophyte" usually in thoracolumbar area
Cx: gastric ulcer + hemorrhage; aortic incompetence; heart block; amyloidosis
DDx: Psoriasis (radiographically indistinguishable; no predilection for lower extremities, asymmetric involvement, clinical findings)

REFLEX SYMPATHETIC DYSTROPHY

= CAUSALGIA = SHOULDER-HAND SYNDROME = POSTTRAUMATIC OSTEOPOROSIS = SUDECK DYSTROPHY
= serious + potentially disabling condition with poorly understood origin + cause
Etiology:
(1) Trauma in > 50% (fracture, frostbite; may be trivial)
◊ Affects 0.01% of all trauma patients
(2) Idiopathic in 27% (immobilization, infection)
(3) Myocardial ischemia in 6%
(4) CNS disorders in 6%
◊ Affects 12–21% of patients with hemiplegia
(5) Diskogenic disease in 5%
• burning pain, tenderness, allodynia, hyperpathia
• soft-tissue swelling ± pitting edema out of proportion to degree of injury; dystrophic skin + nail changes
• sudomotor changes: hyperhidrosis + hypertrichosis
• vasomotor instability (Raynaud phenomenon, local vasoconstriction / vasodilatation)
• end-stage (after 6–12 months): contractures, atrophy of skin + soft tissues
Location: hands and feet distal to injury
√ periarticular soft-tissue swelling
√ patchy osteopenia (50%) as early as 2–3 weeks after onset of symptoms (DDx: disuse osteopenia)
√ generalized osteopenia = ground-glass appearance with endosteal + intracortical excavation:
√ subperiosteal bone resorption
√ lysis of juxtaarticular + subchondral bone
√ preservation of joint space (DDx: rheumatoid / septic arthritis)
NUC (3-phase bone scan):
√ ↑ flow + ↑ blood pool + ↑ in periarticular uptake on delayed images in affected part (60%)
√ ↓ flow / delayed uptake (15–20%)

Rx: sympathetic block, α- / β-adrenergic blocking agents, nonsteroidal antiinflammatory drugs, radiation therapy, hypnosis, acupuncture, acupressure, transcutaneous nerve stimulation, physiotherapy, calcitonin, corticosteroids, early mobilization

RELAPSING POLYCHONDRITIS

= rare debilitating multisystem inflammatory + autoimmune disorder characterized by recurrent episodes of inflammation + destruction of cartilage in joints, ears, nose, larynx, airways

Etiology: acquired metabolic disorder (? abnormal acid mucopolysaccharide metabolism) / hypersensitivity / autoimmune process (antibodies directed against type II collagen)

Histo: loss of cytoplasm in chondrocytes; plasma cell and lymphocyte infiltration

Age: 40–60 years (no age predilection)

- nasal chondritis = saddle-nose deformity
- bilateral auricular chondritis = swollen + tender ears, cauliflower ears; ocular inflammation
- hearing loss ← obstruction of external auditory meatus / audiovestibular damage)
- cough, hoarseness, dyspnea ← collapse of trachea
- nonerosive seronegative inflammatory polyarthritis = arthralgia

@ Head
- √ calcification of pinna of ear

@ Chest
- √ manubriosternal / costochondral arthropathy (30%)

@ Respiratory tract (in up to 70%)
- √ ectasia + collapsibility (← cartilaginous destruction) of trachea and mainstem bronchi with focal thickening (← mucosal edema) + luminal narrowing (← fibrosis)
- √ bronchiectasis
- √ generalized + localized emphysema

@ Cardiovascular (in 15–46%)

Site: elastic elements of cardiac valves + aorta

Histo: cystic degeneration of collagen, destruction of elastic fibers, lymphocytic infiltration, decreased content of acid mucopolysaccharides

- √ aortic aneurysm (4–10%), mostly in ascending aorta, may be multiple / dissecting
- √ aortic / mitral valve insufficiency (8%)
- √ aortitis + systemic vasculitis (13%)
- √ obliterating vasculitis in medium-sized + large arteries

@ Bone
- √ periarticular osteoporosis
- √ erosive changes in carpal bones resembling rheumatoid arthritis
- √ soft-tissue swelling around joints + styloid process of ulna
- √ erosive irregularities in sacroiliac joints
- √ disk space erosion + increased density of articular plates

Rx: corticosteroids, immunosuppression

Prognosis: 74% 5-year survival rate; 55% 10-year survival rate; median survival time of 11 years; airway complications account for > 50% of deaths

RENAL OSTEODYSTROPHY

= constellation of musculoskeletal abnormalities that occur with chronic renal failure as a combination of

(a) osteomalacia (adults) / rickets (children)
(b) 2° HPT with osteitis cystica fibrosa + soft-tissue calcifications
(c) osteosclerosis
(d) soft-tissue + vascular calcifications

Classification:

A. Glomerular form = acquired renal disease: chronic glomerulonephritis (common)
B. Tubular form = congenital renal osteodystrophy:
   1. Vitamin D–resistant rickets = hypophosphatemic rickets
   2. Fanconi syndrome = impaired resorption of glucose, phosphate, amino acids, bicarbonate, uric acid, sodium, water
   3. Renal tubular acidosis

Pathogenesis:

(1) Renal insufficiency → decrease in vitamin D conversion into the active $1,25(OH)_2D_3$ (done by 25-OH D-1-α hydroxylase, which is exclusive to renal tissue mitochondria); <u>vitamin D deficiency</u> slows intestinal calcium absorption; <u>vitamin D resistance</u> predominates and calcium levels stay low (Ca x P product remains almost normal ← hyperphosphatemia); low calcium levels lead to OSTEOMALACIA; additional factors responsible for osteomalacia are (a) inhibitors to calcification produced in the uremic state, (b) aluminum toxicity, (c) dysfunction of hepatic enzyme system

(2) Renal insufficiency with diminished filtration → <u>phosphate retention</u>; maintenance of Ca x P product lowers serum calcium directly, which in turn increases PTH production (2° HPT); <u>2° HPT</u> predominates associated with mild vitamin D resistance → <u>increase in Ca x P product</u> with SOFT-TISSUE CALCIFICATION in kidney, lung, joints, bursae, blood vessels, heart as well as increase in osteoclastic activity = OSTEITIS FIBROSA

(3) Mixture of (a) and (b): increased serum phosphate inhibits vitamin D activation via feedback regulation

• phosphate retention; hypocalcemia

A. OSTEOPENIA (in 0–25–83%)

= diminution in number of trabeculae + thickening of stressed trabeculae = increased trabecular pattern

Cause: combined effect of

(1) Osteomalacia (= reduced bone mineralization ← acquired insensitivity to vitamin D / antivitamin D factor)
(2) Osteitis fibrosa cystica ← increase in bone resorption
(3) Osteoporosis ← decrease in bone quantity

Contributing factors:

chronic metabolic acidosis, poor nutritional status, pre- and posttransplantation azotemia, use of steroids, hyperparathyroidism, low vitamin D levels

Cx: fracture predisposition ← lessened structural strength with minor trauma / spontaneously; fracture prevalence increases with duration of hemodialysis + remains unchanged after renal transplantation

Site: vertebral body (3–25%), pubic ramus, rib (5–25%)

√ Milkman fracture / Looser zones (in 1%)
√ metaphyseal fractures
Prognosis: osteopenia may remain unchanged / worsen after renal transplantation + during hemodialysis

B. RICKETS (children)
Cause: in CRF normal vessels fail to develop in an orderly way along cartilage columns in zone of provisional calcification; this results in disorganized proliferation of the zone of maturing + hypertrophying cartilage and disturbed endochondral calcification
Location: most apparent in areas of rapid growth such as knee joints
√ diffuse bone demineralization
√ widening of growth plate
√ irregular zone of provisional calcification
√ metaphyseal cupping + fraying
√ bowing of long bones, scoliosis
√ diffuse concave impression at multiple vertebral end plates
√ basilar invagination
√ slipped epiphysis (10%): capital femoral, proximal humerus, distal femur, distal radius, heads of metacarpals + metatarsals
√ general delay in bone age

C. SECONDARY HPT (in 6–66%)
Cause: inability of kidneys to adequately excrete phosphate leads to hyperplasia of parathyroid chief cells (2° HPT); excess PTH affects the development of osteoclasts, osteoblasts, osteocytes
• hyperphosphatemia; hypocalcemia; ↑ PTH levels
√ subperiosteal, cortical, subchondral, trabecular, endosteal, subligamentous bone resorption:
√ replacement of trabeculation by ground-glass attenuation (early phase)
√ loss of definition of cortex, lamina dura, wall of inferior alveolar nerve canal
√ osteitis fibrosa (advanced pattern) = mixture of osteolysis + sclerosis + heterogeneous pattern of bone resorption with osteoid production and increased bone remodeling
√ osteoclastoma = brown tumor = osteitis fibrosa cystica in 1.5–1.7% ← PTH-stimulated osteoclastic activity (more common in 1° HPT)
√ periosteal new-bone formation (8–25%)
√ chondrocalcinosis (more common in 1° HPT)
@ Face
√ macrognathia + cortical thickening
√ protrusion + splaying of teeth

D. OSTEOSCLEROSIS (9–34%)
◊ One of the most common radiologic manifestations; most commonly with chronic glomerulonephritis; may be the sole manifestation of renal osteodystrophy
√ diffuse chalky density: thoracolumbar spine in 60% (rugger jersey spine); also in pelvis, ribs, long bones, facial bones, base of skull (children)
Prognosis: may increase / regress after renal transplantation

E. SOFT-TISSUE CALCIFICATIONS

= Uremic tumoral calcinosis = secondary tumoral calcinosis = pseudotumor calcinosis

◊ Most frequent cause of a periarticular calcified mass!

Cause: ?

(a) metastatic ← hyperphosphatemia (= solubility product for calcium + phosphate [Ca^{2+} • PO_4^{-2}] exceeds 60–75 mg/dL in extracellular fluid), hypercalcemia, alkalosis with precipitation of calcium salts

(b) dystrophic ← local tissue injury

Location:

› arterial (27–83%): in medial + intimal elastic tissue

Site: dorsalis pedis a., forearm, hand, wrist, leg

√ pipestem appearance without prominent luminal involvement

› periarticular (0.5–1.2%): multifocal, frequently symmetric, may extend into adjacent joint

• chalky fluid / pastelike material

• inflammatory response in surrounding tenosynovial tissue

√ discrete cloudlike dense areas

√ fluid-fluid level in tumoral calcinosis

Prognosis: often regresses with treatment

› visceral (79%): heart, lung, stomach, kidney

√ fluffy amorphous "tumoral" calcification

Rx: (1) Decrease of phosphorus absorption in bowel (in hyperphosphatemia)

(2) Vitamin D3 administration (if vitamin D resistance predominates)

(3) Parathyroidectomy for 3° HPT (= autonomous HPT)

Dialysis-associated Disorders

1. Osteomyelitis
2. Pyogenic spondylodiskitis
3. Osteonecrosis
4. Destructive spondyloarthropathy
5. Crystal deposition
6. Dialysis cysts
7. Amyloidosis

Congenital Renal Osteodystrophy

Vitamin D–Resistant Rickets

= PHOSPHATE DIABETES = PRIMARY HYPOPHOSPHATEMIA = FAMILIAL HYPOPHOSPHATEMIC RICKETS

= rare X-linked dominant disorder of renal tubular reabsorption characterized by

(a) impaired resorption of phosphate in proximal renal tubule ← defect in renal brush-border membrane

(b) inappropriately low synthesis of 1,25-dihydroxy-vitamin D3 [$1,25(OH)_2D_3$] in renal tubules → decreased intestinal resorption of calcium + phosphate

Age: < 1 year

- hypophosphatemia + hyperphosphaturia
- elevated serum alkaline phosphatase
- normal plasma + urine calcium
- normal / low serum $1,25(OH)_2D_3$

√ classic rachitic changes
√ skeletal deformity, particularly bowed legs
√ retarded bone age; dwarfism if untreated
√ osteosclerosis / bone thickening ← overabundance of incompletely calcified matrix

Rx: phosphate infusion + large doses of vitamin D

DDx: vitamin-D–deficient and –dependent rickets (absence of muscle weakness + seizures + tetany)

Fanconi Syndrome

Triad of
(1) Hyperphosphaturia
(2) Aminoaciduria
(3) Renal glucosuria (normal blood glucose)

Etiology: renal tubular defect

√ rickets, osteomalacia, osteitis fibrosa, osteosclerosis

Prognosis: functional renal impairment likely when bone changes occur

Rx: large doses of vitamin D + alkalinization

Renal Tubular Acidosis

- systemic acidosis, bone lesions

√ rickets, osteomalacia, pseudofractures, nephrocalcinosis, osteitis fibrosa (rare)

(a) **Lightwood syndrome** = salt-losing nephritis (transient self-limited form)
- NO nephrocalcinosis

(b) **Butler-Albright syndrome** (severe form)
- nephrocalcinosis

RHEUMATOID ARTHRITIS

= chronic systemic connective tissue disease
= type III (delayed) hypersensitivity
= immune complex disease (= formation of antigen-antibody complexes with complement fixation) with T-cell–mediated autoreactivity against synovium

Prevalence: 1–2% of world's population

Cause: genetic predisposition; ? reaction to antigen from Epstein-Barr virus / certain strains of E. coli

Peak age: 45–65 years; M÷F = 1÷3 if < 40 years; M÷F = 1÷1 if > 40 years

Pathogenesis:

injury to synovial endothelial cells → proliferative hyperplastic hypervascular synovitis (= pannus) mediated by TNF-α (tumor necrosis factor α) and IL-1 (interleukin 1) leads to invasion by local macrophages, fibroblasts, and activated lymphocytes; invasion of articular cartilage + bone ← secretion of degrading enzymes (metalloproteinases)

Diagnostic criteria of American Rheumatism Association (at least 4 criteria should be present):

(1) morning stiffness for ≥ 1 hour before improvement
(2) swelling of ≥ 3 joints, particularly of wrist / metacarpo-phalangeal / proximal interphalangeal joints for > 6 weeks
(3) symmetric swelling
(4) typical radiographic changes on PA views of hand & wrist
(5) subcutaneous rheumatoid nodules
(6) positive test for rheumatoid factor

- morning stiffness; fatigue, weight loss, anemia
- carpal tunnel syndrome
- rheumatoid factor (positive in 85–94%) = IgM-antibody
  = agglutination of sensitized sheep RBCs closely correlating with disease severity
  False positive: normal (5%), asbestos workers with fibrosing alveolitis (25%), viral / bacterial / parasitic infection, other inflammatory diseases
- human leukocyte antigen (HLA)–DR4 (positive in 70%)
- antinuclear antibodies (positive in many)
- LE cells (positive in some); positive latex flocculation test
- hormonal influence:
  (a) decrease in activity during pregnancy
  (b) men with RA have low testosterone levels

Location: bilateral symmetric involvement of > 3 diarthrodial joints (polyarthritis), commonly of hand, wrist, foot
◊ Symmetric arthritis of multiple small hand joints in > 60% of patients at initial presentation

Early signs:

MR and high-resolution US (methods of choice): ← greater sensitivity for detection of *synovitis* and articular erosions than either clinical examination / conventional radiography.

√ **synovitis** = abnormal hypo- / anechoic / (rarely) iso- / hyperechoic (relative to subdermal fat) <u>nondisplaceable poorly compressible</u> intra-articular material ± Doppler signals:
  √ positive Doppler signals = synovial hyperemia (in acute disease + exacerbation of chronic disease)
  √ synovial swelling (edema + cellular infiltrates)
  √ intermediate to low SI of **pannus** on T1WI + T2WI (= synovial hyperplasia = tumorlike focal proliferation of inflammatory tissue with destruction of cartilage and bone)

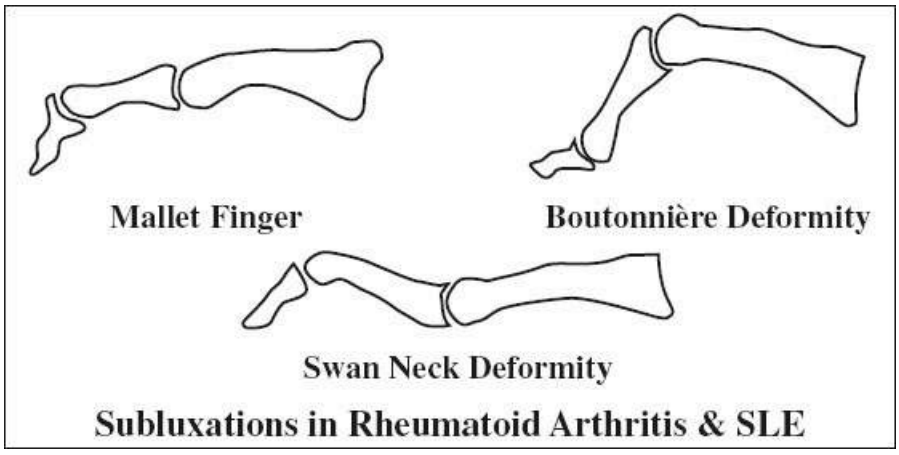
Synovitis occurs early in RA and is considered a strong predictor of developing bone erosion.

√ **tenosynovitis** = abnormal an- / hypoechoic (relative to tendon fibers) tendon sheath widening / distention ← abnormal tenosynovial fluid ± synovial hypertrophy
√ **joint effusion** = abnormal hypo- / anechoic / (rarely) iso- / hyperechoic (relative to subdermal fat) <u>displaceable compressible</u> intra-articular material without Doppler signals
√ **bursal effusion**
√ marginal **bone erosion** = intra-articular discontinuity of bone surface at *"bare area"* (= site of attachment of internal synovial layer of joint capsule to bone) ← lack of protective

cartilage layer:
√ pre-erosive subcortical cysts
√ bone marrow edema at site of erosion (by MRI only)
Time of onset: within first 6 symptomatic months
Prognosis: poor prognostic indicator in early disease

Radiography (indirect & nonspecific):
√ fusiform periarticular swelling ← joint effusion
√ periarticular osteoporosis ← inactivity due to pain + local inflammatory hyperthermia
√ translucent subchondral end plate
√ widened joint space ← synovial swelling + joint fluid
√ effacement of fat pads
√ subcortical synovial cyst
√ marginal erosion (up to 47% within 1st year after onset) initially at *"bare area"*
◊ Radiographically detectable 1–2 years after US / MR

Late signs:
√ concentric joint space narrowing ← destruction of cartilage, formation of scar tissue, fibrosis
√ subluxation ← laxity of capsule + ligaments ← inflammatory destruction + capsular shrinkage ← fibrosis + scar formation:
√ mallet finger = droopy distal phalanx due to disrupted extensor tendon insertion site
√ swan-neck deformity = hyperextension at PIP + flexion at DIP
√ boutonnière deformity = flexion at PIP + hyperextension at DIP
√ hitchhiker deformity = flexion at MCP + hyperextension at DIP
√ dislocation
√ marked destruction + fractures of bone ends:
√ intraarticular loose bodies
√ (polished) rice bodies = subset of loose bodies
√ soft-tissue rheumatoid nodule of heterogeneous echogenicity



@ Hand & wrist (typical)
Target areas:
all five MCP, PIP, interphalangeal joint of thumb, all wrist compartments (especially

radiocarpal, inferior radioulnar, pisiform-triquetral joints); earliest changes seen in MCP 2 + 3, PIP 3

√ marginal + central bone erosions (less common in large joints); site of first erosion is classically base of proximal phalanx of 4th finger

√ changes in ulnar styloid + distal radioulnar joint (early sign)

√ flexion + extension contractures with ulnar subluxation + dislocation

@ Cervical spine

√ erosions of odontoid process (1) between anterior arch of atlas + dens, (2) between transverse ligament of atlas + dens, (3) at tip of odontoid process

√ anterior atlantoaxial subluxation (in > 6%): > 2.5 mm in adults, > 4.5 mm in children during neck flexion

√ "cranial settling" = odontoid process projects into skull base ← significant disease of atlanto-occipital and atlantoaxial joints

√ lateral head tilt = lateral subluxation = asymmetry between odontoid process + lateral masses of atlas

√ "stepladder appearance" of cervical spine ← subaxial subluxations + absence of osteophytosis:

√ destruction + narrowing of disk spaces

√ irregular vertebral body outlines

√ erosion + destruction of zygapophyseal joints

√ resorption of spinous processes

√ osteoporosis

Cx: spinal cord compression

@ Cricoarytenoid arthritis (54–72%)

• hoarseness, sense of pharyngeal fullness in throat (26%)

• dyspnea, stridor, dysphagia, odynophagia

• pain radiating into ears, pain with speech

√ cricoarytenoid erosion, luxation, prominence / mass at CT

√ abnormal position of the true vocal cord

@ Ribs

√ erosion of superior margins of posterior portions of ribs 3–5

@ Shoulder

√ symmetric loss of glenohumeral joint space:

√ marginal erosions at superolateral aspect of humeral head

√ osteoporosis

√ elevation of humeral heads = narrowing of acromiohumeral distance ← tear / atrophy of rotator cuff

√ widened acromioclavicular joint:

√ erosions at acromial + clavicular end

√ tapered margins of distal clavicle

√ scalloped erosion on undersurface of distal clavicle opposite coracoid process (= attachment of coracoclavicular ligament)

@ Sacroiliac joint (rarely affected)

√ typically asymmetric unilateral distribution

√ shallow erosions + mild sclerosis

√ rare ankylosis

@ Hip (rarely affected)

√ often appears normal during early disease process

√ pannus formation (MR imaging)

√ symmetric loss of joint space with axial migration of femoral head

√ marginal + central erosions, cysts, localized sclerosis

√ decompression of joint effusion into iliopsoas bursa through weak anterior capsule displacing muscle + vasculature

√ rupture of gluteal tendon

√ protrusio acetabuli (from osteoporosis)

@ Knee

Location: medial + lateral femorotibial compartments; bilateral symmetric

√ diffuse loss of joint space

√ osteoporosis

√ superficial + deep marginal + central erosions

√ subchondral sclerosis (especially in tibia)

√ synovial herniation + cysts (eg, popliteal cyst)

√ varus / valgus angulation ← crumbling of osteoporotic bone of tibia + ligamentous abnormalities

@ Foot (typical)

Target areas:

medial aspect of MT heads (2,3,4), medial + lateral aspect of MT5 (earliest sign); interphalangeal joints of foot (esp. great toe); midfoot joints; talonavicular, subtalar, tarsometatarsal joints; bilateral + symmetric

• sinus tarsi syndrome = compression of tibial nerve

√ calcaneal plantar spur

√ retrocalcaneal bursitis

DDx: (1) Acute viral polyarthritis: Parvovirus B19, Rubella, Hepatitis B

(2) Seronegative spondyloarthropathies: psoriasis, reactive arthritis, inflammatory bowel disease, ankylosing spondylitis

(3) Connective tissue disease: SLE, primary Sjögren syndrome, mixed connective tissue disease, scleroderma, dermatomyositis-polymyositis

(4) Crystal disease: gout, CPPD, osteoarthritis

EXTRA-ARTICULAR MANIFESTATIONS (50–76%)

(a) **Felty syndrome** (< 1%)

= rheumatoid arthritis (present for > 10 years) + splenomegaly + neutropenia

Age: 40–70 years; F > M; rare in Blacks

• rapid weight loss; therapy refractory leg ulcers

• brown pigmentation over exposed surfaces of extremities

(b) Sjögren syndrome (15%)

= keratoconjunctivitis + xerostomia + rheumatoid arthritis

(c) Rheumatoid lung

(d) **Subcutaneous nodules**

(in 5–35% with active arthritis) over extensor surfaces of forearm + other pressure points

(eg, olecranon) without calcifications (DDx to gout)

(e) Cardiovascular involvement
1. Pericarditis (20–50%)
2. Myocarditis: arrhythmia, heart block
3. Aortitis (5%) of ascending aorta → aneurysm (2%)
4. Leaflet thickening of aortic valve → regurgitation

(f) **Rheumatoid vasculitis**
= leukocytoclastic lesion of small venules mimicking periarteritis nodosa
• polyneuropathy, cutaneous ulceration, gangrene, polymyopathy, myocardial / visceral infarction

(g) Neurologic sequelae
1. Distal neuropathy (related to vasculitis)
2. Nerve entrapment: atlantoaxial subluxation, carpal tunnel syndrome, Baker cyst

(h) Lymphadenopathy (up to 25%)
√ splenomegaly (1–5%)

Cystic Rheumatoid Arthritis

= intraosseous cystic lesions as dominant feature

Pathogenesis: increased pressure in synovial space from joint effusion → decompresses through microfractures of weakened marginal cortex into subarticular bone

◊ Increase in size + extent of cysts correlates with increased level of activity + absence of synovial cysts

Age: as above; M÷F = 1÷1

• seronegative in 50%

√ juxtaarticular subcortical lytic lesions with well-defined sclerotic margins

√ relative lack of cartilage loss, osteoporosis, joint disruption

DDx: gout (presence of urate crystals), pigmented villonodular synovitis (monoarticular)

Juvenile Rheumatoid Arthritis

= rheumatoid arthritis in patients < 16 years of age; M < F

• morning stiffness, arthralgia; subcutaneous nodules (10%)

• skin rash (50%); fever, lymphadenopathy

Location: early involvement of large joints (hips, knees, ankles, wrists, elbows); later of hands + feet

√ radiologic signs similar to rheumatoid arthritis (except for involvement of large joints first, late onset of bony changes, more ankylosis, wide metaphyses)

√ periarticular soft-tissue swelling

√ thinning of joint cartilage

√ large cystlike lesions removed from articular surface (invasion of bone by inflammatory pannus); rare in children

√ articular erosions at ligamentous + tendinous insertion sites

√ joint destruction may resemble neuropathic joints

√ juxtaarticular osteoporosis

√ "balloon epiphyses" + "gracile bones" (epiphyseal overgrowth + early fusion with bone shortening ← hyperemia

@ Hand / foot
√ "rectangular" phalanges (periostitis + cortical thickening)
√ ankylosis in carpal joints
@ Axial skeleton
Location: predominantly upper cervical spine
√ ankylosis of cervical spine (apophyseal joints), sacroiliac joints
√ decreased size of vertebral bodies + atrophic intervertebral disks
√ subluxation of atlantoaxial joint (66%)
√ thoracic spinal compression fractures
@ Chest
√ ribbon ribs
√ pleural + pericardial effusions
√ interstitial pulmonary lesions (simulating scleroderma, dermatomyositis)
√ solitary pulmonary nodules, may cavitate
Prognosis: complete recovery (30%); secondary amyloidosis
Clinical classification:
(1) Juvenile-onset adult type (10%)
• IgM RA factor positive; age 8–9; poor prognosis
√ erosive changes; profuse periosteal reaction; hip disease with protrusio
(2) Polyarthritis of the ankylosing spondylitic type
• iridocyclitis; boys age 9–11 years
√ peripheral arthritis; fusion of greater trochanter; complete fusion of both hips; heel spur
(3) **Still disease**
(a) systemic
(b) polyarticular
(c) pauciarticular + iridocyclitis (30%)
• fever, rash, lymphadenopathy, hepatosplenomegaly; pericarditis, dwarfism
• fatal kidney disease in 20%
Age: 2–4 and 8–11 years of age; M < F
Location: involvement of carpometacarpal joints ("squashed carpi" in adulthood), hind foot, hip (40–50%)
√ periosteal reaction of phalanges; broadening of bones; accelerated bone maturation + early fusion (stunting of growth)

RICKETS

= osteomalacia during enchondral bone growth
Age: 4–18 months
Histo: zone of maturation has an increase in the number of maturing cartilage cells with loss of normal columnar arrangement; zone of preparatory calcification does not form; failure of osteoid mineralization also in shafts so that osteoid production elevates periosteum
• irritability, bone pain, tenderness
• craniotabes; delayed dentition
• bowed legs; swelling of wrists + ankles; rachitic rosary

Location: metaphyses of long bones subjected to stress are particularly involved (wrists, ankles, knees); costochondral junction of ribs

√ poorly mineralized irregular epiphyseal centers with delayed appearance

√ axial widening of growth plate = ↑ distance between end of shaft and epiphyseal center ← ↑ osteoid production (earliest changes)

√ cupping + fraying of metaphysis with threadlike shadows into epiphyseal cartilage (weight-bearing bones)

√ cortical spurs projecting at right angles to metaphysis

√ coarse trabeculation (NO ground-glass pattern as in scurvy)

√ periosteal reaction may be present

√ deformities common (bowing of soft diaphysis, molding of epiphysis, fractures)

√ bowing of long bones

√ frontal bossing

mnemonic: "RICKETS"

Reaction of periosteum may occur
Indistinct cortex
Coarse trabeculation
Knees + wrists + ankles mainly affected
Epiphyseal plates widened + irregular
Tremendous metaphysis (fraying, splaying, cupping)
Spur (metaphyseal)

Cx: stress fracture, bowing deformity

Causes of Rickets

I. ABNORMALITY IN VITAMIN D METABOLISM associated with reactive hyperparathyroidism
   A. Vitamin D deficiency (most common cause)
      (a) dietary lack of vitamin D = famine osteomalacia = nutritional lack of vitamin precursors (vegetarian diet, prolonged total breast feeding without vitamin D supplementation)
      (b) lack of sunshine exposure eg, residence in high latitudes, clothing covering skin, sunshine avoidance for religious / cultural reasons, heavy skin pigmentation
      (c) malabsorption of vitamin D
         = gastroenterogenous rickets due to
         1. Pancreatitis + biliary tract disease
         2. Steatorrhea, celiac disease, postgastrectomy
         3. Inflammatory bowel disease
   B. Defective conversion of vitamin D to 25-OH-cholecalciferol (vitamin D3) in liver
      1. Liver disease
      2. Anticonvulsant drug therapy (= induction of hepatic enzymes that accelerate degradation of biologically active vitamin D metabolites)
   C. Defective conversion of prehormone calcifediol [$25(OH)D_3$] to cholecalciferol [$1,25(OH)_2D_3$] in kidney
      1. Chronic renal failure = renal osteodystrophy
      2. Vitamin D–dependent rickets = autosomal recessive enzyme defect of 25(OH)D-

1α-hydroxylase

II. ABNORMALITY IN PHOSPHATE METABOLISM not associated with hyperparathyroidism ← normal serum calcium
   A. Phosphate deficiency
      1. Intestinal malabsorption of phosphates
      2. Ingestion of aluminum salts [$Al(OH)_3$] forming insoluble complexes with phosphate
      3. Low phosphate feeding in prematurely born infants
      4. Severe malabsorption state
      5. Parenteral hyperalimentation
   B. Disorders of renal tubular reabsorption of phosphate
      1. Renal tubular acidosis (renal loss of alkali)
      2. **deToni-Debré-Fanconi** syndrome = hypophosphatemia, glucosuria, aminoaciduria
      3. Vitamin D–resistant rickets
      4. Cystinosis
      5. Tyrosinosis
      6. Lowe syndrome
      7. Ifosfamide nephrotoxicity (for the treatment of rhabdomyosarcoma, Wilms tumor)
   C. Hypophosphatemia with nonendocrine tumors
      = **Oncogenic rickets** = elaboration of humeral substance which inhibits tubular reabsorption of phosphates (paraneoplastic phenomenon)
      1. Nonossifying fibroma
      2. Sclerosing hemangioma
      3. Hemangiopericytoma
      4. Ossifying mesenchymal tumor
   D. Hypophosphatasia

III. CALCIUM DEFICIENCY
   1. Dietary rickets = milk-free diet (extremely rare)
   2. Malabsorption
   3. Consumption of substances forming chelates with calcium

Classification of Rickets

I. Primary vitamin D–deficiency rickets

II. Gastrointestinal malabsorption
   A. Partial gastrectomy
   B. Small intestinal disease: gluten-sensitive enteropathy / regional enteritis
   C. Hepatobiliary disease: biliary atresia / chronic biliary obstruction / biliary cirrhosis resulting in failure of the emulsifying action of bile salts (fat-soluble vitamin) or failure of conversion
   D. Pancreatic disease: chronic pancreatitis

III. Primary hypophosphatemia; vitamin D–deficiency rickets

IV. Renal disease
   A. Chronic renal failure

B. Renal tubular disorders: renal tubular acidosis

C. Multiple renal defects

V. Hypophosphatasia + pseudohypophosphatasia

VI. Fibrogenesis imperfecta osseum

VII. Axial osteomalacia

VIII. Miscellaneous:

Hypoparathyroidism, hyperparathyroidism, thyrotoxicosis, osteoporosis, Paget disease, fluoride ingestion, ureterosigmoidostomy, neurofibromatosis, osteopetrosis, macroglobulinemia, malignancy

ROSAI-DORFMAN DISEASE

= sinus histiocytosis with massive lymphadenopathy

= rare dendritic cell disorder characterized by macrophage proliferation

Age: children and young adults; M > F; predilection for individuals of African descent

Histo: ***emperipolesis*** (= phagocytosis of lymphocytes, plasma cells, erythrocytes, PMNs) by histiocytes that show S100 positivity; negative for CD1a + Birbeck granules [*em*, Greek= inside, *peri* = around, *polemai* = to wander about]

@ Lymphadenopathy

√ uptake of gallium and FDG by lymphadenopathy

• fever, elevated ESR, mild anemia

√ nonspecific imaging appearance of painless lymphadenopathy

Location: cervical > retroperitoneal, mediastinal, axillary, inguinal

@ Extranodal disease (50%) in nearly every organ system

› Head

√ intracranial lesions primarily in the epidural or subdural compartments

√ orbital extraconal soft-tissue mass

› Neck

√ enhancing polypoid masses / mucosal thickening of occasionally aggressive appearance

√ salivary gland lymphoid hyperplasia

› Bone: commonly in skull, tibia, femur

√ medullary multicentric lytic lesions ± sclerotic margin

› Lung mass

Prognosis: overall good with indolent clinical course ± spontaneous resolution

ROTATOR CUFF LESIONS

Pathogenesis: (controversial)

(1) Extrinsic theory (Neer):

(a) hypertrophic changes of acromion

(b) osteophytes from acromioclavicular joint

(c) Type 3 hooked acromion

→ impingement of subacromial-subdeltoid bursa and rotator cuff

(2) Intrinsic (intratendinous) theory: tendon degeneration → partial-thickness tear → superior

migration of humeral head → abrasion of rotator cuff against undersurface of acromion → full-thickness tear

Subacromial Pain Syndrome

(1) Impingement syndrome
(2) Rotator cuff tendinitis
(3) Degeneration without impingement
(4) Shoulder instability with secondary impingement
(5) Instability without impingement

Impingement Syndrome

= clinical NOT radiographic diagnosis consisting of lateral shoulder pain with abduction and forward flexion

Cause: inadequate space for the normal motion of rotator cuff

Age: lifelong process; 1st stage < 25 years; 2nd stage 25–40 years; complete rotator cuff tear > 40 years

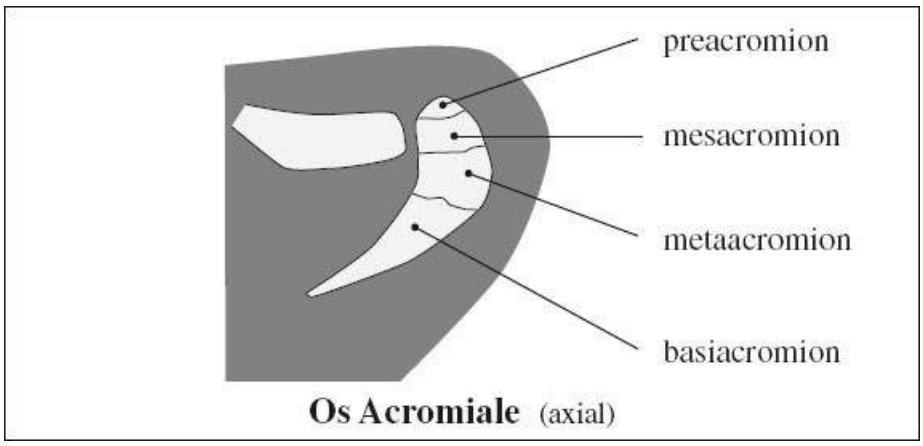
Pathophysiology:

movement of humerus impinges rotator cuff tendons against coracoacromial arch resulting in microtrauma, which causes inflammation of subacromial bursa (= fibrous thickening of subacromial bursa) / rotator cuff (*critical zone of rotator cuff* = supraspinatus tendon 2 cm from its attachment to humerus)

Impingement anatomy:

narrowing of subacromial space secondary to

(1) Acquired
  (a) degenerative subacromial enthesophyte / osteophyte
    › traction enthesophyte at coracoacromial ligament (= subacromial spur)
    › osteophytes ← acromioclavicular joint hypertrophy in osteoarthrosis
  (b) hypertrophy of coracoacromial ligament
  (c) primary bursitis in rheumatoid arthritis
  (d) swollen supraspinatus tendon ± calcific tendinosis impinging upon coracoacromial arch
(2) Congenital
  (a) curvature of acromion in anterior third (SAG)
    › flat (type 1)
    › curved downward (type 2)
    › hooked downward (type 3)
    › curved upward (type 4)
    ◊ Type 3 and possibly type 2 acromion processes have a higher prevalence of bursal-side rotator cuff tears!
  (b) lateral acromial angle (COR)



√ downsloping of acromion in lateral direction

(c) os acromiale = unfused acromial apophysis (8% of population)

◊ Impingement syndrome may exist without impingement anatomy and may be secondary to primary instability!

- night pain
- passive elevation of arm to 170° followed by passive internal + external rotation while arm adducted against ear → increased pain with rotation = test positive
- "arc of pain" sign = pain during active descent of abducted arm in abduction plane → minimal pain at full elevation with maximal pain between 70° and 120° = test positive

X-ray (AP view):

√ inferolateral tilt of acromion (on AP view)

X-ray (supraspinatus outlet [modified Y] view + caudal tilt view):

√ type III acromion = anterior aspect of acromion hooked inferiorly

√ anterior tilt / low position of acromion

√ anterior subacromial spur on undersurface of AC joint (= enthesophyte) at insertion site of coracoacromial lig.

MR (can identify the anatomy predisposing to impingement):

√ unstable os acriomale pulled downward by deltoid muscle during abduction

√ thickening of coracoacromial ligament

√ acromioclavicular joint osteoarthritis ± bone spurs

US:

√ bunching of subdeltoid bursa during abduction of arm

◊ US can direct steroid injection into bursa

Cx: (1) partial / complete tear (may be precipitated by acute traumatic event on preexisting degenerative changes; common cause of rotator cuff tears)

(2) cuff tendinitis / degenerative tendinosis

Dx: Lidocaine impingement test (= subacromial lidocaine injection relieves pain)

Rx: acromioplasty (= removal of a portion of the acromion), removal of subacromial osteophytes, removal / lysis / débridement of coracoacromial ligament, resection of distal clavicle, removal of acromioclavicular joint osteophytes

Internal Impingement

√ humeral head cysts / defects
√ undersurface degeneration + tearing of posterior supraspinatus and anterior infraspinatus tendons
√ posterosuperior labral tear
√ posterosuperior glenoid chondral lesion + cyst

Anterosuperior Impingement

= intraarticular impingement = pulley lesions (Habermeyer classification)
(1) Group 1 lesion
= isolated superior GHL lesions
(2) Group 2 lesion
= superior GHL lesion + partial articular-side supraspinatus tendon tear
(3) Group 3 lesion
= superior GHL lesion + partial articular-side subscapularis tendon tear
(4) Group 4 lesion
= superior GHL lesions + partial articular-side tears of supraspinatus and subscapularis tendons

Glenohumeral Instability

Glenohumeral stability is dependent on a functional anatomic unit (= anterior capsular mechanism) formed by: glenoid labrum, joint capsule, superior + middle + inferior (anterior + posterior parts) glenohumeral ligaments, coracohumeral ligament, subscapularis tendon, rotator cuff

Age: < 35 years
Frequency: acute, recurrent, fixed
Cause: traumatic, microtraumatic, atraumatic
Direction: anterior > multidirectional > inferior > posterior
Type of lesions: labral abnormalities (compression, avulsion, shearing), capsular / ligamentous tear / avulsion
Associated osseous lesions:
Hill-Sachs defect, glenoid rim fracture, trough line fracture
Associated soft-tissue lesions:
Bankart lesion, GLAD, Perthes, ALPSA, HAGL, labral cyst
◊ Normal clefts may exist within labrum!
False positive for labral separation:
(1) Articular cartilage deep to labrum
(2) Glenohumeral ligaments passing adjacent to labrum

Rotator Cuff Tear

Etiology:
(1) Attritional change ← repetitive microtrauma = overuse of shoulder from professional / athletic activities
(2) Subacromial impingement between humeral head + coracoacromial arch
(3) Tendon degeneration ← hypovascularity ← aging
(4) Acute trauma (rare)

Prevalence in asymptomatic patients:
in 40% of patients > 50 years (full-thickness tear); in > 60% of patients > 60 years (partial & full thickness)
Age: most commonly > 50 years; young athletic patient may have "rim-rent" tear (= avulsion of attachment at greater tuberosity
Location:
Supraspinatus tendon tear:
› "critical zone" of anterior supraspinatus tendon 1 cm medial to attachment (= area of relative hypovascularity)
Infraspinatus tendon tear (30–40%):
› precludes arthroscopic repair
› worst postoperative prognosis
› isolated tear more common in throwing sports
Teres minor tendon tear (rare):
› also affected by posterior instability
Subscapularis tendon tear:
› more common in superior articular surface
› associated with supraspinatus tendon tear + rotator interval lesion + biceps tendon pathology
› cysts of lesser tuberosity + edema (common)
• clinical assessment (during US):
› test of supraspinatus m.
(a) supraspinatus weakness
• straight hanging and 20° abducted arm pushed against applied force = assessment of strength
(b) impingement: 97% sensitive + 67% PPV
• "arc of pain": 98% sensitive + 67% PPV
(c) weakness of abduction: 64% sensitive + 78% PPV
• drop-arm test = active abduction of arm to 90° then slowly lowering arm: if arm drops abruptly test is positive (98% specific, 10% sensitive)
• combination of (a) + (b) + (c) = 98% chance of rotator cuff tear
› test of infraspinatus m. + teres minor m.
(d) weakness of external rotation: 76% sensitive + 79% PPV
• resist inward force with elbow flexed 90° + shoulder internally rotated
› test of subscapularis m.
• passive positioning of arm behind back with palm facing outward: failure to hold forearm + hand off the back = positive test
› patient age
• night pain: 88% sensitive + 70% PPV
Assessment:
(1) Depth of tear
(a) incomplete rupture = **partial-thickness tear** involves either bursal or synovial surface or remains intratendinous
◊ Articular-surface partial-thickness tear >> bursal-surface partial thickness tear
› PASTA = partial thickness articular supraspinatus tendon avulsion (at attachment

of tendon to greater tuberosity = footprint)
› PAINT = partial articular tear with intratendinous extension
√ fluid-filled defect not extending across the entire tendon width
√ disruption of superior / inferior tendon fibers only

(b) complete rupture = **full-thickness tear** from subacromial bursal surface to articular surface of glenohumeral joint
› pure transverse tear
› pure vertical / longitudinal tear
› tear with retraction of tendon edges
› global tear = massive tear / avulsion of cuff involving more than one of the tendons

(2) Size of tear

Depth of partial tear (normal thickness = 12 mm):

(a) small = grade 1 (< 25%) = < 3 mm
(b) medium = grade 2 (25–50%) = 3–6 mm
(c) large = grade 3 (> 50%) = > 6 mm

Greatest dimension of full-thickness tear:

(a) small = < 1 cm
(b) medium = 1–3 cm
(c) large = 3–5 cm
(d) massive = > 5 cm

(3) Geometry of tear (as viewed from tendon surface)
(a) crescentic = minimal retraction of tendon
(b) U-shaped = massive tear that may extend to level of glenoid fossa
(c) L-shaped = massive tear with longitudinal component

(4) Injury extension (to adjacent structures)
(a) in anterior direction: supraspinatus tendon → medial aspect of coracohumeral ligament (rotator interval) → superior subscapularis tendon fibers
(b) in posterior direction: supraspinatus tendon → infraspinatus tendon → teres minor tendon
(c) involvement of long head of biceps brachii tendon
◊ Injury / disruption of LHBB tendon in up to 77%
◊ Subluxation / dislocation in up to 44%

(5) Muscle atrophy (decreased bulk, fatty infiltration) as strongest prognosticator of surgical outcome
◊ Muscle cross-sectional area measurement correlates with muscle strength!
√ on SAG OBL plane at level of medial coracoid process:
√ "tangent" sign = supraspinatus muscle does not cross a line drawn through superior border of scapular spine + superior margin of coracoid process
√ scapular ratio of < 50% = occupation ratio of cross-sectional area of supraspinatus m. to area of supraspinatus fossa

(6) Impingement anatomy

X-ray (AP view):
√ usually normal in acute rotator cuff tear
√ acromiohumeral distance ≤ 2 mm (with active abduction to 90°) ← absence / retraction

of supraspinatus tendon
√ flattened / ill-defined superior soft-tissue contour with heterogeneous decreased density → fatty replacement (on supraspinatus outlet [modified Y] view)

X-ray (late findings):
√ superior migration of humeral head = acromiohumeral distance < 7 mm
√ cuff arthropathy = sclerosis, subchondral cysts, osteolysis, notching / pitting of greater tuberosity ← repetitive contact between humeral head + acromion
√ remodeling of acromial undersurface with matching sclerosis, faceting, concavity of inferolateral aspect of acromion

US (scans in hyperextended position, 75–100% sensitive, 43–97% specific, 65–95% NPV, 55–75% PPV):
Sequence of examination:
biceps, subscapularis, supraspinatus, infraspinatus, teres minor, posterior glenohumeral joint
√ direct primary signs of tendon tear
√ focal absence of rotator cuff= partial thickness:
√ well-defined hypo- / anechoic defect in tendon replaced by fluid → with extension either to bursal /or articular surface
√ abrupt + sharply demarcated focal thinning
√ small comma-shaped area of hyperechogenicity (= small tear filled with granulation tissue / hypertrophied synovium)
√ nonvisualization of retracted tendon in massive supraspinatus tear (most reliable sign):
√ discontinuity of rotator cuff filled with joint fluid
√ defect filled with hypoechoic thickened bursa + peribursal fat
√ "naked tuberosity" sign = retracted tendon leaves a bare area of bone
√ deltoid muscle directly on top of humeral head
√ hypervascularity of defect on color Doppler
√ <u>indirect primary signs of tendon tear</u>
√ "double cortex" / "cartilage interface" sign = 2 hyperechoic lines representing cartilage + cortex ← fluid-enhanced increase in through-transmission
√ compressibility = loss of normal convex contour of peribursal fat ← displacement of fluid with compression by transducer over hypoechoic defect
√ "sagging peribursal fat" sign = depression of hyperechoic peribursal fat into area of torn tendon
√ increased echogenicity + decreased bulk of muscle = muscle atrophy (in 77% of rotator cuff tears)
√ secondary signs of tendon tear:
√ cortical irregularity of greater tuberosity
√ shoulder joint effusion = anechoic fluid in axillary pouch, posterior recess, biceps tendon sheath
False negative: longitudinal tear, partial tear
False positive: intraarticular biceps tendon, soft-tissue calcification, small scar / fibrous tissue

Arthrography (71–100% sensitive, 71–100% specific for combined full + partial thickness

tears):
√ opacification of subacromial-subdeltoid bursa
√ contrast enters substance of rotator cuff tendons
MR (41–100% sensitive and 79–100% specific for combined full + partial thickness tears):
√ discontinuity of cuff with retraction of musculotendinous junction
√ focal / generalized intense / markedly increased SI on T2WI (= fluid within cuff defect) in < 50%
√ fluid within subacromial-subdeltoid bursa (most sensitive)
√ low / moderate SI on T2WI (= severely degenerated tendon, intact bursal / synovial surface, granulation / scar tissue filling the region of torn tendinous fibers)
√ cuff defect with contour irregularity
√ abrupt change in signal character at boundary of lesion
√ supraspinatus muscle atrophy (MOST SPECIFIC)
Pitfalls:
√ hyperintense focus in distal supraspinatus tendon
√ gray signal isointense to muscle on all pulse sequences:
(a) partial volume averaging with superior + lateral infraspinatus tendon
(b) vascular "watershed" area
(c) magic angle effect = orientation of collagen fibers at 55° relative to main magnetic field
√ hyperintense focus within rotator cuff on T2WI:
(a) partial volume averaging with fluid in biceps tendon sheath / subscapularis bursa
(b) partial volume averaging with fat of peribursal fat
(c) motion artifacts: respiration, vascular pulsation, patient movement
√ fatty atrophy of muscle
(a) impingement of axillary / suprascapular nn. = quadrilateral space syndrome

DDx: (1) Partial-thickness tear with diffuse less-than-fluid intensity on T2WI
(2) Tendon degeneration (tendinopathy)
(3) Tendinitis
(4) Full-thickness tear containing granulation tissue

Subacromial-Subdeltoid Bursitis

common finding in rotator cuff tears
√ peribursal fat totally / partially obliterated + replaced by low-signal-intensity tissue on all pulse sequences
√ fluid accumulation within bursa

Supraspinatus Tendinopathy / Tendinosis

= chronic tendon degeneration with disorganized repair
Cause: impingement, acute / chronic stress
Histo: mucinous + myxoid degeneration
√ increase in tendon SI on proton-density images without disruption of tendon
√ tendinous enlargement + inhomogeneous signal pattern

√ fibers on superior + inferior tendon surface remain visible and contiguous
Cx: main risk factor for subsequent rotator cuff tear (not impingement)
DDx: supraspinatus tear (tendon has fluid intensity)

RUBELLA

= CONGENITAL RUBELLA = GERMAN MEASLES
Prevalence: endemic rate of 0.1%
Age: infants (in utero transmission)
• neonatal dwarfism ← intrauterine growth retardation
• retinopathy, cataracts, glaucoma, microphthalmia
• deafness; mental deficiency with encephalitis + microcephaly
• thrombocytopenic purpura, petechiae, anemia; failure to thrive
√ "celery-stalk" sign (50%) = irregular metaphyseal margins + coarsened trabeculae extending longitudinally from epiphysis; distal end of femur > proximal end of tibia, humerus
√ no periosteal reaction
√ hepatosplenomegaly + adenopathy
√ pneumonitis
@ Cardiovascular:
√ congenital heart disease (PDA, VSD)
√ peripheral pulmonary artery stenosis
√ necrosis of myocardium
@ CNS
√ punctate / nodular calcifications
√ porencephalic cysts
√ occasionally microcephaly
Prognosis: osseous manifestations disappear in 1–3 months; severe congenital defects from infection during first trimester
DDx: (1) CMV
(2) Congenital syphilis (diaphysitis + epiphysitis)
(3) Toxoplasmosis

RUBINSTEIN-TAYBI SYNDROME

= BROAD THUMB SYNDROME
= rare sporadic syndrome without known chromosomal / biochemical markers; M÷F = 1÷1
• small stature; mental, motor, language retardation
@ Characteristic facies
• beaked / straight nose ± low nasal septum
• antimongoloid slant of palpebral fissures
• epicanthic folds; broad fleshy nasal bridge
• high-arched palate; dental abnormalities
@ Ophthalmologic findings
• strabismus, ptosis, refractive errors
@ Cutaneous findings
• keloids, hirsutism, simian crease

• flat capillary hemangioma on forehead / neck

@ Musculoskeletal findings
√ short broad "spatulate" terminal phalanges of thumb and great toe ± angulation deformity (MOST CONSISTENT + CHARACTERISTIC FINDING)
√ radial angulation of distal phalanx (50%) caused by trapezoid / delta shape of proximal phalanx
√ tufted "mushroom-shaped" fingers + webbing
√ thin tubular bones of hand + feet
√ club feet
√ retarded skeletal maturation
√ dysplastic ribs
√ spina bifida occulta
√ scoliosis
√ flat acetabular angle + flaring of ilia

@ Genitourinary tract anomalies
√ bilateral renal duplication
√ renal agenesis
√ bifid ureter
√ incomplete / delayed descent of testes

@ Cardiovascular abnormalities
√ atrial septal defect
√ patent ductus arteriosus
√ coarctation of aorta
√ valvular aortic stenosis
√ pulmonic stenosis

OB-US:
√ decreased head circumference
√ small for gestational age

Cx in infancy: obstipation, feeding problems, recurrent upper respiratory infection

SAPHO SYNDROME

= **S**ynovitis, **A**cne, **P**almoplantar pustulosis, **H**yperostosis, **O**steitis
= PUSTULOTIC ARTHROSTEITIS = STERNOCLAVICULAR HYPEROSTOSIS
= association of sterile osteoarticular inflammation with skin abnormalities (palmoplantar pustulosis + severe acne)
◊ Delay of several years can separate osseous from cutaneous lesions! Many patients have endured years of consultations and unnecessary invasive procedures before receiving the correct diagnosis!

Etiology: ? variant of psoriasis, exaggerated immune response in genetically susceptible individuals to Propionibacterium acnes

Age: young to middle-aged adults; M÷F = 1÷1

Histo: osteolytic portion of bone lesion contains plasma cells

• palmoplantar pustulosis (52%) = chronic eruption of yellowish intradermal sterile 2–4 mm monomorphic pustules limited to palms + soles

• acute severe acne (15%) = acne fulminans, acne conglobata, hidradenitis suppurativa → sudden eruption of highly inflammatory tender ulcerative nodules + plaques with hemorrhagic crust on face, back, chest
Organism: Propionibacterium acnes (= anaerobe typically found in acne lesions)
• blood + bone cultures usually negative
• chronic relapsing-remitting course with pain, soft-tissue swelling, limitation of motion at skeletal site of involvement (most often in anterior chest wall) ± fever
± elevated erythrocyte sedimentation rate + C-reactive protein
• rheumatoid factor negative + human leukocyte antigen (HLA)–B27 positive = seronegative spondyloarthropathy
√ bone sclerosis combined with variable degree of osteolysis and periostitis:
√ medullary trabecular changes = osteitis
√ cortical hyperostosis in long-standing disease
√ accompanied by adjacent inflammatory arthritis ± enthesitis + ankylosis
Bone scintigraphy:
√ often reveals asymptomatic skeletal lesions
@ Sternoclavicular joint (70–90%)
Age: adulthood + childhood
Site: manubrium sterni, insertion of costoclavicular ligament, clavicles with mediolateral progression
√ osteolysis at beginning of disease
√ hyperostosis + osteosclerosis later in disease
√ ankylosis of sternoclavicular joint
√ diagnostic costoclavicular enthesopathy + small hyperostotic foci at sternal end of 1st ribs
NUC (bone scintigraphy):
√ "bull's head" sign = increased radiotracer uptake in manubrium + both sternoclavicular joints (HIGHLY SPECIFIC)
@ Axial skeleton (33%)
Age: adulthood
√ homogeneous osteosclerosis / osteolysis of one / more vertebral bodies (usually monovertebral) → collapse
√ disk space narrowing + endplate erosion (mimicking infectious spondylodiskitis)
√ sclerosis + expansion (mimicking Paget disease)
√ asymmetric bulky paravertebral ossification + sacroiliitis (mimicking psoriatic arthritis):
√ paravertebral ossifications (mimicking marginal / nonmarginal syndesmophytes / massive bridging)
√ unilateral sacroiliitis + associated osteosclerosis of adjacent iliac bone
MR:
√ focal / diffuse marrow signal abnormality with enhancement (= edema / osteitis)
√ hyperintense paravertebral soft-tissue swelling
√ endplate irregularities + CHARACTERISTIC anterior vertebral body corner erosion at multiple levels
√ increased disk signal intensity on T2WI
√ disk enhancement after contrast administration
DDx: infectious spondylitis (abscess, epidural involvement, single level of involvement)

@ Appendicular skeleton (30%)
Age: childhood
• chronic recurrent multifocal osteomyelitis (misnomer)
Location: distal femur, proximal tibia, fibula, humerus, radius, ulna, rib
Site: metaphysis
√ osteosclerosis / osteolysis + periosteal new bone formation + bone expansion with aggressive appearance
@ Joints
Location: knee, hip, ankle, DIP of hand
√ synovial inflammation with juxtaarticular osteoporosis (early)
√ joint narrowing, marginal erosion, hyperostosis, enthesopathy (later)
Prognosis: chronic course with unpredictable exacerbations + remissions
Dx: sterile culture of osseous lesion
Rx: nonsteroidal antiinflammatory drugs, corticosteroids, methotrexate, tumor necrosis factor α inhibitor, analgesics, cyclosporine
DDx: infectious osteomyelitis / spondylitis, chronic recurrent multifocal osteomyelitis, osteosarcoma, Ewing sarcoma, metastasis, Paget disease, aseptic necrosis of clavicle

SCLEROSTEOSIS

= autosomal recessive inheritance
Cause: mutation in gene-encoding sclerostin on chromosome 17q12-q21 leading to osteoblast hyperactivity
Age: manifestation in infancy
• early cranial nerve paralysis
• increased intracranial pressure (in 80%)
√ massive square prognathic chin
√ frontal bossing
√ sclerosis of calvaria
@ Hand
√ radial deviation
√ syndactyly
Cx: sudden death ← increase in intracranial pressure ← impaction of brain stem in narrowed foramen
DDx: Van Buchem disease

SCURVY

= BARLOW DISEASE = HYPOVITAMINOSIS C
= vitamin C (= ascorbic acid) deficiency with defective osteogenesis from abnormal osteoblast function

Infantile Scurvy

Age: 6–9 months (maternal vitamin C protects for first 6 months)
Predisposed: feeding with pasteurized / boiled milk
Pathogenesis: abnormal collagen formation

- irritability
- tenderness + weakness of lower limbs
- scorbutic rosary of ribs
- bleeding of gums ← teething
- legs drawn up + widely spread = pseudoparalysis

Location: distal femur (esp. medial side), proximal and distal tibia + fibula, distal radius + ulna, proximal humerus, sternal end of ribs

√ "ground-glass" osteoporosis (CHARACTERISTIC)

√ cortical thinning

√ soft-tissue edema (rare)

@ Metaphysis

√ white line = metaphyseal zone of preparatory calcification (DDx: lead / phosphorus poisoning, bismuth treatment, healing rickets)

√ Trümmerfeld zone = radiolucent zone on shaft side of Fränkel white line (site of subepiphyseal infraction)

√ Pelkan spurs = metaphyseal spurs projecting at right angles to shaft axis
[Karl Francis Pel(i)kan (1890–????), University of California]

√ Park corner sign = subepiphyseal infraction / comminution resulting in mushrooming / cupping of epiphysis (DDx: syphilis, rickets)
[E. Park, 1935, pathologist]

@ Epiphysis

√ Wimberger ring = sclerotic ring around low-density epiphysis ← osteopenia of epiphysis

@ Diaphysis

√ subperiosteal hematoma with calcification of elevated periosteum (sure sign of healing)

@ Teeth

√ cyst formation + hemorrhage in enamel

DDx: TORCH infections, leukemia, neuroblastoma

Adult Scurvy

Frequency: rare

√ hemarthrosis + bleeding at synchondrosis

SEPTIC ARTHRITIS

N.B.: MEDICAL EMERGENCY = treatment necessary within 48 hours to prevent irreversible permanent joint damage!

Risk factors: advanced age, immunocompromised state, rheumatoid arthritis, intraarticular injection, prosthetic joint

Transmission: inoculation ← trauma / recent instrumentation; bacteremia → hematogenous seeding to large joints of shoulder, hip, knee

Organism:

› Staphylococcus aureus (with 31% most common)

› Gonorrhea (multifocal septic arthritis in young adults; indistinguishable from tuberculous

arthritis, but more rapid)
› Brucellar arthritis (indistinguishable from tuberculosis, slow infection)
› Salmonella (commonly associated with sickle cell disease / Gaucher disease)
(a) neonates, infants: group D streptococcus
(b) < 4 years of age: Haemophilus influenzae, Streptococcus pyogenes, S. aureus
(c) > 4 years of age: S. aureus
(d) > 10 years of age: S. aureus, Neisseria gonorrhoeae
(e) adults: S. aureus

Pathophysiology:
(1) lytic enzymes in purulent articular fluid → destruction of articular + epiphyseal cartilages
(2) pus in joint → increased intraarticular pressure → compromised blood flow → osteonecrosis

Age: most commonly encountered in neonates

Location: shoulder, hip, knee, elbow, ankle; multifocal involvement common in the very young

• painful joint, fever

Character of aspirated synovial fluid:
• frankly purulent / turbid fluid
• WBC > 20,000 / mm^3 with > 90% PMNs
• positive result on Gram stain; positive culture for bacteria

√ joint effusion

CT:
√ bone erosions around joint
√ fat-fluid level in the absence of trauma (specific)

MR:
√ intense enhancement of hypertrophied synovium
√ perisynovial edema of adjacent soft tissue
√ subtle bone marrow signal alterations adjacent to articular surface: decreased on T1WI + increased on T2WI + enhancement ← reactive marrow edema (DDx: osteomyelitis with more obvious SI alterations)

Cx: (1) Bone growth disturbance (lengthening, shortening, angulation)
(2) Osteonecrosis = avascular necrosis
(3) Chronic degenerative arthritis
(4) Ankylosis

DDx: (1) Transient synovitis (no MR-signal alterations in subarticular bone marrow)

SHIN SPLINTS

= SHIN SORENESS = MEDIAL TIBIAL STRESS SYNDROME = SOLEUS SYNDROME
= nonspecific term describing exertional lower leg pain

Frequency: 75% of exertional leg pain

Cause: ? atypical stress fracture, traction periostitis, compartment syndrome

• diffuse tenderness along posteromedial tibia in its middle to distal aspect

Location: posterior / posteromedial tibial cortex

Plain radiographs:
√ normal / longitudinal periosteal new bone

Bone scintigraphy:
√ normal radionuclide angiogram + blood-pool phase (DDx to stress fracture)
√ linear longitudinal uptake on delayed images
MR:
√ marrow edema / hemorrhage
√ periosteal fluid

SHORT-RIB POLYDACTYLY SYNDROME

= group of autosomal recessive disorders characterized by short limb dysplasia, constricted thorax, postaxial polydactyly (on ulnar / fibular side)

Type I = SALDINO-NOONAN SYNDROME
Type II = MAJEWSKI TYPE
Type III = NAUMOFF TYPE
Type IV = BEEMER

√ severe micromelia
√ pointed femurs at both ends (type I); widened metaphyses (type III)
√ narrow thorax
√ extremely short horizontally oriented ribs
√ distorted underossified vertebral bodies + incomplete coronal clefts
√ polydactyly
√ cleft lip / palate

Prognosis: uniformly lethal

SICKLE CELL DISEASE

= common inherited autosomal recessive hemoglobinopathy with 2 abnormal β-globin genes (homozygous / heterozygous in combination with other abnormal hemoglobins) characterized by sickle-shaped RBCs cleared by RES

Normal adult hemoglobin:

Hb A = 2 α globin chains on chromosome 16p13.3 (duplicated on each chromosome = 4 gene loci) + 2 β globin chains on chromosome 11p15.5 (one copy on each chromosome = 2 gene loci)
- makes up 96–98% of hemoglobin component

Genetics: mutation in both alleles of β-globulin gene

Hb S = DNA point mutation at the 6th codon in β-globin gene located on short arm of chromosome 11 → glutamic acid in position 6 on β-chain is substituted with valine (α2βS2)

Hb C = DNA point mutation substitutes glutamic acid in position 6 on β-chain with lysine (α2βC2)

Definition:

Sickle cell anemia = any formation of Hb S in combination with one other abnormal hemoglobin:

(a) <u>homozygous</u> (with another sickle cell chain Hb S)
1. Hb SS = sickle cell disease

(b) <u>heterozygous</u> (with other abnormal chain, not Hb S)

2. Hb SC disease
3. Hb S-thal

- lessens the severity of infection with falciparum malaria

Prevalence: 8–13% of African Americans carry sickling factor (gene for Hb S); 1÷600 African Americans in USA are homozygous (Hb SS) and have sickle cell disease; 1÷40 with sickling trait will manifest sickle cell disease; 1÷120 with sickling trait will manifest Hb SC disease; affects people from Middle East + eastern Mediterranean region

Pathogenesis:

low oxygen tension → deoxygenation of Hb S → aggregation of abnormal Hb molecules into long chains (= polymerization into twisted ropelike Hb molecule strands with binding between chains) →

(a) increase in blood viscosity with stasis in microvasculature ("log jam" occlusion of small blood vessels) → tissue ischemia → infarction, necrosis, superinfection

(b) altered plasticity + distortion of RBCs into sickle shape → intravascular hemolysis → endothelial injury → coagulopathy + vasomotor in stability + proliferative vasculopathy → pulmonary hypertension

Location: damage of intima occurs most frequently in vessels with high flow rates (terminal ICA); sickling occurs in areas of

(a) slow flow (spleen, liver, renal medulla)
(b) rapid metabolism (brain, muscle, placenta)

- Vaso-occlusion (earliest + most common manifestation):
  - stroke; retinal hemorrhages; sensorineural hearing loss
  - abdominal crisis; chronic leg ulcers (over bony prominences)
  - priapism; rheumatism-like joint pain
  - bone pain (vasoocclusive crisis÷osteomyelitis = 50÷1)
  - functional asplenia ← splenic autoinfarction
- Chronic normocytic hemolytic anemia (= intravascular hemolysis of sickled RBCs + reduction in sickled RBC life span to 1/10 its normal duration by sequestration in spleen)
  - increased cardiac output + high blood flow velocity
  - jaundice; splenomegaly (in children + infants)
- Infection (↑ susceptibility to encapsulated bacteria like Haemophilus influenzae type b, Streptococcus pneumoniae, Streptococcus group b, Neisseria meningitides, Klebsiella, Salmonella): osteomyelitis; cellulitis

Cx: high incidence of infections (lung, bone, brain)

Prognosis: death < 40 years (decrease of average life expectancy by 25–30 years)

Osseous Manifestation of Sickle Cell Disease

(1) DEOSSIFICATION DUE TO MARROW HYPERPLASIA

Cause: chronic anemia → constant marrow stimulation and medullary expansion → trabecular thickening + cortical thinning → bone softening → pathologic fractures

Pathogenesis: arrested conversion of red to yellow marrow → persistence of appendicular red marrow in ankles + wrists + shafts of long bones

√ granular appearance of skull ← porous decrease in bone density of skull (25%)
√ widening of diploe with thinning of inner and outer tables (22%)

√ vertical hair-on-end striations projecting from outer skull vault (5%) ← prominent trabeculae + new bone
√ coarse trabeculae of mandible
√ osteopenia with thinning of trabeculae
√ biconcave "fish-mouth" vertebrae = compression fracture of vertebral endplates ← invagination of intervertebral disks ← bone softening (in 70%)
Cx: kyphosis from vertebral collapse
√ widening of medullary space + thinning of cortices
Cx: pathologic fracture
√ coarsening of trabecular pattern in long + flat bones
√ rib notching

(2) EXTRAMEDULLARY HEMATOPOIESIS more common in other hemolytic anemias
Location: liver, spleen, paravertebral region, kidney, adrenal gland, skin, paranasal sinus
√ intermediate signal intensities on T1WI + T2WI
√ uptake by ^{99m}Tc-sulfur colloid

(3) THROMBOSIS AND INFARCTION OF BONE
Cause: abnormal RBCs → vaso-occlusive disease
(a) bone infarcts + avascular necrosis within epiphyses and medullary cavities
(b) infarcts of muscles + soft tissue → myonecrosis and ulcers
Location: in diaphysis of small tubular bones (children); in metaphysis + subchondrium of long bones (adults)
√ sickle cell dactylitis = hand-foot syndrome (in 50%):
Age: 6 months – 2 years; rare > 6 years ← regression of red marrow
Cause: cold-induced vasoconstriction
• tender swollen hand / foot with reduction in movement; fever
√ patchy areas of lucency + periosteal reaction
√ ± bone destruction → deformity
√ osteolysis (in ACUTE infarction)
√ bone sclerosis (= dystrophic medullary calcification) in pelvis, ribs, spine
√ bone-within-bone appearance = periosteal reaction / layered new bone deposits along inner surface of infarcted cortex
√ juxtacortical sclerosis
√ Lincoln log = Reynold sign = H-vertebrae = steplike endplate depression
√ articular disintegration
√ epiphyseal infarction (in 50% by age 35 years)
= avascular necrosis = frequently bilateral collapse of femoral head (DDx: Legg-Calvé-Perthes disease)
• joint pain + limited movement

NUC (bone agent):
√ decreased / normal radiotracer uptake (first few days)
√ increased uptake (with revascularization)
√ return to normal (after a few months in old infarcts with adequate blood supply)
√ photopenic foci (in avascular bone of old infarcts)

MR:
√ high signal intensity of bone marrow edema on STIR

√ "serpiginous double line" sign on T2WI = hyperintense inner border (← inflammatory response with granulation tissue) + hypointense periphery (← reactive bone interface)
√ heterogeneous rimlike enhancement
√ ± subperiosteal hemorrhage + fluid collection

(4) SECONDARY OSTEOMYELITIS (18%)

Pathogenesis: hyposplenism → impaired phagocytosis, complement dysfunction → increased susceptibility to osteomyelitis + septic arthritis

Organism: Salmonella in unusual frequency (S. typhimurium, S. enteritidis, S. choleraesuis, S. paratyphi B) > Staphylococcus aureus (10%) > gram-negative enteric bacilli

Location: long bones (mostly), vertebrae

• positive blood culture (50%)

(5) GROWTH EFFECTS ← diminished blood supply

Location: particularly in metacarpus / phalanx

√ bone shortening = premature fusion of infarcted physis
√ epiphyseal deformity with cupped metaphysis
√ tibiotalar slant
√ protrusio acetabuli (20%)
√ cup / peg-in-hole defect of distal femur
√ diminution in vertebral height (shortening of stature + kyphoscoliosis)
√ H-shaped vertebra with central growth plate infarction
√ tower vertebrae = compensatory lengthening of vertebrae adjacent to H-shaped vertebra

Bone marrow scintigraphy:

√ usually symmetric marked expansion of hematopoietic marrow beyond age 20 involving entire femur, calvarium, small bones of hand + feet (normally only in axial skeleton + proximal femur and humerus)
√ bone marrow defects indicative of acute / old infarction

^{99m}Tc-diphosphonate scan:

√ increased overall skeletal uptake (high bone-to-soft tissue ratio)
√ prominent activities at knees, ankles, proximal humerus (delayed epiphyseal closure / increased blood flow to bone marrow)
√ bone marrow expansion (calvarial thickening with relative decrease in activity along falx insertion)
√ decreased / normal uptake on bone scan within 24 hr in acute infarction / posthealing phase following infarction (cyst formation)
√ increased uptake on bone scan after 2–10 days persistent for several weeks in healing infarction
√ increased uptake on bone scan within 24–48 hours in osteomyelitis
√ increased blood-pool activity + normal delayed image on bone scan in cellulitis
√ renal enlargement with marked retention of tracer in renal parenchyma (medullary ischemia + failure of countercurrent system) in 50%
√ persistent splenic uptake ← degeneration, atrophy, fibrosis, calcifications

CNS Manifestations of Sickle Cell Disease

Pathophysiology:

chronic anemia produces cerebral hyperemia, hypervolemia, impaired autoregulation

(a) cerebral blood flow cannot be increased leading to infarction in time of crisis

(b) increased cerebral blood flow → produces epithelial hyperplasia of large intracranial vessels (terminal ICA / proximal MCA) resulting in thrombus formation

• stroke (5–17%): ischemic infarction (70%), ischemia of deep white matter (25%), hemorrhage (20%), embolic infarct

√ arterial tortuosity (= adaptive response to chronic anemia):

√ ectasia of arterial segment

√ abnormal increase in length of an arterial segment → obvious bowing of an arterial segment

Angio (in 87% abnormal):

√ arterial stenosis / occlusion of supraclinoid portion of ICA + proximal segments of ACA and MCA

√ moyamoya syndrome (35%)

√ distal branch occlusion ← thrombosis / embolism

√ aneurysm (rare)

CT:

√ cerebral infarction (mean age of 7.7 years)

√ subarachnoid hemorrhage (mean age of 27 years)

Splenic Manifestations of Sickle Cell Disease

√ splenomegaly < age 10 (in patients with heterozygous sickle cell disease)

Cx: splenic rupture

√ splenic infarction

√ hemosiderosis

Functional Asplenia

= anatomically present nonfunctional spleen

• Howell-Jolly bodies, siderocytes, anisocytosis, irreversibly sickled cells

√ normal-sized / enlarged spleen on CT

√ absence of tracer uptake on sulfur colloid scan

Autosplenectomy

= autoinfarction of spleen in homozygous sickle cell disease (function lost by age 5)

Histo: extensive perivascular fibrosis with deposition of hemosiderin + calcium

√ small (as small as 5–10 mm) densely calcified spleen

Acute Splenic Sequestration Crisis

= sudden trapping of large amount of blood in spleen

Cause: obstruction of small intrasplenic veins / sinusoids; unknown trigger event

Age: (a) homozygous: infancy / childhood

(b) heterozygous: any age

• LUQ pain ← sudden massive splenic enlargement

• rapid drop in hemoglobin, hematocrit, platelets ← spleen traps large volumes of blood
• rise in reticulocytes
√ enlarged spleen
√ multiple lesions at periphery of spleen: hypoechoic by US, of low attenuation by CT
√ hyperdense areas ← acute hemorrhage
√ hyperintense areas on T1WI + T2WI ← subacute hemorrhage
√ main splenic vessels patent by Doppler US
Prognosis: in 50% death < 2 years of age ← hypovolemic shock

Other Manifestations of Sickle Cell Disease

@ Chest
√ cardiomegaly + CHF
@ Gallbladder
√ cholelithiasis
@ Kidney
• hematuria ← multiple infarctions
• hyposthenuria
• nephrotic syndrome
• renal tubular acidosis (distal)
• hyperuricemia ← increased cell turnover
• progressive renal insufficiency
√ normal urogram (70%)
√ papillary necrosis (20%)
√ focal renal scarring (20%)
√ smooth large kidney (4%)
US:
√ increased cortical echogenicity ← glomerular hypertrophy + interstitial fibrosis
√ increased medullary echogenicity ← vascular congestion (in older child)
MR:
√ decreased cortical signal on T2-weighted images ← renal cortical iron deposition
@ **Fat embolism syndrome**
= rare potentially lethal complication of sickle cell disease with diagnosis based on clinical manifestations
Cause: bone marrow infarcts + necrosis → embolization of fat to multiple organs
Pathomechanism:
bone marrow necrosis → fat globules enter venous channels + circulation → R-to-L shunt / traversing pulmonary capillary bed → systemic fat emboli
(a) occlusion of end-organ capillaries → local ischemia + inflammation → release of vasoactive amines
(b) hydrolysis of free fatty acids → toxic intermediates → damage of capillary endothelium
Primary criteria:
• cutaneous petechiae (= microscopic hemorrhagic infarcts) ← vessel wall rupture from embolus / extravasation of blood surrounding area of necrosis
• progressive respiratory distress: dyspnea, severe hypoxemia, ARDS

- cerebral involvement: altered level of consciousness, seizures, focal neurologic deficits, coma

Secondary criteria:

- tachycardia
- fever
- anemia + thrombocytopenia

CT: typically negative

MR:

Location: diffuse widespread + unusual sites (splenium, internal capsule)

√ starfield pattern = innumerable bright punctate foci on DWI

√ numerous "blooming" black dots of susceptibility artifacts on T2* (= microhemorrhages)

√ diffuse hyperintense foci on FLAIR + T2WI ← edema

Sickle Cell Trait= Sickling Trait

= mild disease with few episodes of crisis + infection; sickling provoked only under extreme stress (unpressurized aircraft, anoxia with CHD, prolonged anesthesia, marathon running)

Prevalence: 8–10% of American Blacks

Composition: Hb AS formation (55% Hb A + 45% Hb S)

- asymptomatic; recurrent gross hematuria
- may have normal laboratory tests = NO anemia

√ splenic infarction

SC Disease

Prevalence: 3% of American Blacks (more common but less severe form than sickle cell disease)

- less frequent + less severe symptoms of sickle cell disease
- occasionally normal Hb levels
- retinal hemorrhages
- gross hematuria ← multiple infarctions

√ aseptic necrosis of femoral head

Rx: similar to sickle cell disease

Sickle-Thal Disease = β-Thalassemia (rare)

[*thalassa*, Greek = sea]

= underproduction of the β chain ← mutations in the HBB gene on chromosome 11

Composition: Hb SA (65–90% Hb S + 5–25% Hb A + elevated Hb A_2 and Hb F)

- clinically resembling Hb SS patients
- anemia (no normal adult hemoglobin)

√ persistent splenomegaly

SINDING-LARSEN-JOHANSSON DISEASE

[Christian Magnus Falsen Sinding-Larsen (1866–1930), director of Rikshospitalet in Kristiania (now Oslo), Norway]

[Sven Christian Johansson (1880–1959), surgeon and head physician in Gothenburg, Sweden]

= osteochondrosis of inferior pole of patella, often bilateral (NOT osteonecrosis / epiphysitis / osteochondritis)
Cause: traction tendinitis / traumatic avulsion of bone; repeated subluxation ± dislocation of patella
Mechanism: forceful contraction of quadriceps against resistence
Age: adolescents (often 10–14 years)
Predisposed: cerebrospastic children
• tenderness + soft-tissue swelling over lower pole of patella
√ peripatellar soft-tissue swelling
√ calcification / ossification of patellar tendon
√ patella alta deformity = abnormally elevated position of patella with respect to femur (LAT view)
√ small bone fragments at lower pole of patella (LAT view)
MR:
√ hypointense area on T1WI + hyperintense on T2WI in inferior pole of patella + proximal portion of patellar tendon + surrounding soft tissues
DDx:
1. Jumper's knee
= pain syndrome involving proximal / distal insertion of patellar tendon, commonly seen in young athletes
Cause: chronic stress + inflammation
√ thickening of patellar tendon without tear / avulsion
2. Patellar sleeve avulsion
= cartilage of inferior patellar pole pulled off patella often in combination with small avulsed bone fragment (= cartilaginous injury)
Mechanism: vigorous contraction of quadriceps applied to flexed knee
Age: 8–12 years (unique to pediatric population)
√ small bone fragment inferior to lower pole of patella
√ patella alta
√ joint effusion
√ bone marrow edema of patella (MRI!)

SMALLPOX

5% of infants
Location: elbow bilateral; metaphysis of long bones
√ rapid bone destruction spreading along shaft
√ periosteal reaction
√ endosteal + cortical sclerosis frequent
√ premature epiphyseal fusion with severe deformity
√ ankylosis is frequent

SOFT-TISSUE CHONDROMA

= EXTRASKELETAL CHONDROMA = CHONDROMA OF SOFT PARTS
= rare benign cartilage-forming tumor in extraarticular soft tissue consisting of small nodule of

cartilage without connection to underlying bone

Origin: ? embryonal remnants in areas of preexistent fetal cartilage / pluripotential mesenchyme; not from mature cartilaginous / osseous tissue

Frequency: 1.5% of all benign soft-tissue tumors

Age: 30–60 (range, 1–85) years; M÷F = 1.2÷1

Histo: lobules of adult-type hyaline cartilage with areas of calcification + ossification; myxoid change; regions of increased cellularity + cytologic atypia

- asymptomatic (usually), slow-growing soft-tissue mass
- occasionally pain + tenderness

Location: hand (54–80%) + foot (20–28%); head & neck (rare): tongue, auricle, cheek, parotid gland, parapharyngeal space, masticator space

√ lobulated well-defined extraskeletal mass < 2 cm in size

√ may contain calcifications (33–70%) with ringlike appearance / ossifications

√ scalloping of adjacent bone with sclerotic reaction

CT:

√ circumscribed heterogeneously enhancing mass

√ typically punctate / curvilinear / ringlike chondroid calcifications (in 33–70%)

US:

√ well-defined heterogeneously hypoechoic mass

√ salient vascularity in subungual area

MR:

√ multilobulated mass of high signal intensity on T2WI

√ low to intermediate SI relative to muscle on T1WI

√ conspicuous peripheral / septal contrast enhancement

Rx: local excision

Prognosis: 15–25% recurrence rate

DDx: (1) Extraskeletal myxoid chondrosarcoma (deep-seated in large muscles of upper + lower extremities, pelvic + shoulder girdles)

(2) Periosteal chondroma

Periosteal (Juxtacortical) Chondroma

= benign hyaline cartilage tumor akin to enchondroma

Origin: deep layer of periosteum

Location: metaphyseal surface of long bones

√ radiolucent lesion with variable degrees of chondroid matrix calcifications

√ cortical excavation of tissue forming shallow shelving depression = **saucerization** ← local periosteal destruction by tumor + surrounding periosteal reaction

√ well-formed periosteal reaction

MR:

√ round mass with hyperintense T2 signal ← high water content of chondroid matrix

√ adjacent marrow edema (uncommon)

DDx: periosteal chondrosarcoma (size usually > 4 cm); periosteal osteosarcoma

SOFT-TISSUE OSTEOMA

= OSTEOMA OF SOFT PARTS (extremely rare)

Histo: mature lamellar bone with well-defined haversian system; bone marrow, myxoid, vascular, fibrous connective tissue between bone trabeculae; collagenous capsule blending into benign hyaline cartilage

Location: head (usually posterior part of tongue), thigh

√ ossified mass

NUC:

√ intense tracer accumulation, greater than adjacent bone

SOLITARY BONE CYST

= UNICAMERAL / SIMPLE BONE CYST

Frequency: up to 5% of primary bone lesions

Etiology: ? trauma (synovial entrapment at capsular reflection), ? vascular anomaly (blockage of interstitial drainage)

Histo: cyst filled with clear yellowish fluid often under pressure, wall lined with fibrous tissue + hemosiderin, giant cells may be present

Age: 3–19 years (80%); occurs during active phase of bone growth; M÷F = 3÷1

• asymptomatic, unless fractured

Location: proximal femur + proximal humerus (60–75%); fibula; at base of calcaneal neck (4%, > 12 years of age); talus; rare in ribs, ilium, small bones of hand + feet; NOT in spine / calvarium; solitary lesion

Site: intramedullary centric metaphyseal, adjacent to epiphyseal cartilage (during active phase) / migrating into diaphysis with growth (during latent phase), does not cross epiphyseal plate

√ 2–3 cm oval radiolucency with long axis parallel to long axis of host bone

√ fine sclerotic boundary

√ scalloping + erosion of internal aspect of underlying cortex

√ photopenic area on bone scan (if not fractured)

√ "fallen fragment" sign if fractured (20%) = centrally dislodged fragment falls into a dependent position

Prognosis: mostly spontaneous regression

Cx: pathologic fracture (65%)

DDx: (1) Enchondroma (calcific stipplings)
(2) Fibrous dysplasia (more irregular lucency)
(3) Eosinophilic granuloma
(4) Chondroblastoma (epiphyseal)
(5) Chondromyxoid fibroma (more eccentric + expansile)
(6) Giant cell tumor
(7) Aneurysmal bone cyst (eccentric)
(8) Hemorrhagic cyst
(9) Brown tumor

SOLITARY FIBROUS TUMOR

= mesenchymal tumor of fibroblastic / myofibroblastic origin and intermediate malignant potential
◊ Clinical behavior + histopathologic features are similar to hemangiopericytoma
◊ Most solitary fibrous tumors are benign!
Histo: patternless architecture characterized by alternating hypo- and hypercellular areas separated by thick bands of hyalinized collagen and branching vessels
Age: middle-aged adults
Location: anywhere; extrapleural > pleural site
@ head & neck: nasal cavity, paranasal sinus, nasopharynx, parapharyngeal space, larynx
@ meninges
May be associated with: hypoglycemia (← overproduction of insulinlike growth factor), arthralgia, osteoarthropathy, digital clubbing
• slow-growing mass ± local mass effect
CT:
√ solitary well-circumscribed lobulated mass
√ soft-tissue attenuation
√ intense contrast enhancement
√ heterogeneous texture if large ← hemorrhage, necrosis, cysts
MR:
√ well-circumscribed solid mass
√ low to intermediate SI on T1WI + T2WI
√ heterogeneously high SI on T2WI ← myxoid / cystic degeneration
√ low signal-intensity rim around lesion (= pseudocapsule) on T2WI
√ hypervascularity with prominent enhancement + flow voids
DDx: hemangiopericytoma (overlapping histology)

SPONDYLOEPIPHYSEAL DYSPLASIA

Spondyloepiphyseal Dysplasia Congenita

Autosomal dominant / sporadic (most)
• disproportionate dwarfism with spine + hips more involved than extremities
• waddling gait + muscular weakness
• flat facies; short neck; deafness
√ cleft palate
@ Axial skeleton
√ ovoid vertebral bodies + severe platyspondyly (incomplete fusion of ossification centers + flattening of vertebral bodies)
√ hypoplasia of odontoid process (Cx: cervical myelopathy)
√ progressive kyphoscoliosis (short trunk) involving thoracic + lumbar spine
√ narrowing of disk spaces → short trunk
√ broad iliac bases + deficient ossification of pubis
√ flat acetabular roof
@ Chest
√ bell-shaped thorax

√ pectus carinatum

@ Extremities

√ normal / slightly shortened limbs

√ severe coxa vara + genu valgum

√ multiple accessory epiphyses in hands + feet

√ talipes equinovarus

Cx: (1) Retinal detachment, myopia (50%)

(2) Secondary arthritis in weight-bearing joints

Spondyloepiphyseal Dysplasia Tarda

= sex-linked recessive form with milder manifestation + later clinical onset

Age: apparent by 10 years; exclusive to males

√ hyperostotic new bone along posterior ²/₃ of vertebral end plate (PATHOGNOMONIC)

√ platyspondyly with depression of anterior ⅓ of vertebral body

√ narrowing with calcification of disk spaces + spondylitic bridging

√ short trunk

√ dysplastic joints (eg, flattened femoral heads)

√ premature osteoarthritis

DDx: Ochronosis

SPRENGEL DEFORMITY

[Otto Gerhard Karl Sprengel (1852–1915), president of the Surgical Society of Germany and medical privy counsellor of Braunschweig]

= failure of descent of scapula ← fibrous / osseous omovertebral connection

Associated with: Klippel-Feil syndrome, renal anomalies

• webbed neck; shoulder immobility

√ elevation + medial rotation of scapula

SUBUNGUAL EXOSTOSIS

= DUPUYTREN EXOSTOSIS

= uncommon solitary benign bone lesion arising from distal phalanx beneath the nail producing a bony stalk under a fibrocartilaginous cap

Cause: repetitive trauma (14–25%); ? infection

Age: 2nd–3rd decade (range, 7–58 years); M÷F = 1÷2

Histo: inflammatory growth of proliferating fibroblasts and cartilage undergoing enchondral ossification at the base

Location: toes (86–90%, big toe in 77–80%), thumb + index finger (10–14%, dominant hand in 75%)

Site: dorsal / dorsomedial aspect of distal phalanx under / adjacent to nail bed

• rapidly growing mass ± pain + overlying skin ulceration

√ radiographic appearance similar to osteochondroma:

√ broad sessile / narrow pedunculated base of bone spur

√ indistinct / well-demarcated cartilage cap larger than base

√ NO continuity to cortex / medulla of host bone (DDx to osteochondroma)

√ ossific mass with trabecular bony overgrowth distal to physeal scar: ± defined cortex
US:
√ heterogeneously hyperechoic lesion
√ well-defined margins + calcifications
√ hypoechoic fibrocartilaginous cap of < 20 mm in diameter
√ no / mild vascularity
MR:
√ subungual exostosis hypointense on all sequences
Rx: complete surgical excision
Prognosis: 11–53% recurrence rate
DDx: osteochondroma (exostosis continuous with cortex and medulla of host bone, hyaline cartilage of high SI on T2WI)

SUPERFICIAL FIBROMATOSES

= benign disease with somewhat aggressive biologic behavior between that of fibrous proliferation and fibrosarcoma arising from fascia or aponeurosis
Histo: spindle-shaped myofibroplastic cells in dense deposits of intercellular collagen fibers with variable amounts of extracellular myxoid matrix + compressed elongated vessels

Infantile Digital Fibromatosis

= INCLUSION BODY FIBROMATOSIS = REYE TUMOR = INFANTILE DIGITAL FIBROMA / MYOFIBROMATOSIS / MYOFIBROBLASTOMA / FIBROMATOSIS = INFANTILE DERMAL FIBROMATOSIS /FIBROMA = DIGITAL FIBROUS TUMOR OF INFANCY AND CHILDHOOD
= single / multiple nodular dermal protrusion of fibrous tissue on extensor surface of digits
Age: 1st year of life (80%); 33% congenital; M < F
Histo: intracytoplasmic perinuclear inclusion bodies
Location: fingers (60%), toes (40%)
Site: lateral aspect of distal / middle phalanx
√ nonspecific soft-tissue mass involving a digit
√ infrequently bone involvement
Prognosis: spontaneous regression (in 8%); 60% recurrence rate after excision

Juvenile Aponeurotic Fibroma

= CALCIFYING APONEUROTIC FIBROMA
= rare locally aggressive benign fibrous tumor in childhood
Prevalence: 0.4% of all benign soft-tissue tumors
Histo: cellular dense fibrous tissue with focal often calcified chondral elements infiltrating adjacent structures (= cartilaginous tumor)
Peak age: 8–14 years; M÷F = 2÷1
• slow-growing asymptomatic soft-tissue mass
Location: palm of hand (67–75%); sole of foot; neck, thigh, forearm, popliteal fossa, lumbosacral region
Site: deep volar (palmar) fascia + tendon + aponeurosis
√ nonspecific soft-tissue mass overlying inflamed bursa (often mistaken for calcified bursitis)

√ stippled calcifications (frequent)
√ interosseous soft-tissue mass of forearm + wrist
√ erosion / scalloping of bone may occur
Prognosis: recurrence rate of > 50% after resection
Dx: biopsy (to differentiate from synovial sarcoma)
DDx: synovial sarcoma (commonly calcifies, bone erosion), chondroma, fibrosarcoma, osteosarcoma, myositis ossificans

Palmar Fibromatosis

= DUPUYTREN DISEASE / CONTRACTURE
◊ Most common type of superficial fibromatosis
Prevalence: 1–2%
Ethnicity: Caucasians esp. of Northern European ancestry; northern Scotland, Iceland, Norway, Australia
Age: > 65 years(in 20%); M÷F = 4÷1
Path: < 1 cm small often coalescent nodules attached to palmar aponeurosis and adherent to overlying skin; 2–10 mm in diameter, 10–55 mm in length; terminate in branching configuration at level of distal metacarpals
Histo: uniform fibromyoblastic proliferation of spindle-shaped cells with variably prominent vascularity
Associated with: plantar fibromatosis (5–20%), Peyronie disease, knuckle pads; diabetes (20%), epilepsy, alcoholism, keloids
• painless subcutaneous nodules on palmar surface of distal crease of hand progressing to cords and bands causing skin puckering / dimpling
• flexion contractures of digits ← fibrous attachment to flexor tendons
Location: 4th + 5th (most commonly) > 2nd + 3rd digit; bilateral in 40–60%
Site: volar aponeurosis = flexor tendons
√ hypervascular hypoechoic nodules
√ nodular thickening iso- to hyperattenuating to muscle
(a) early stage hypercellular mitotically active lesion → higher rate of recurrence after local excision
√ high to intermediate signal intensity on T2WI
(b) mature lesion with high collagen content
√ low signal intensity on T2WI
Rx: surgical excision (of mature lesion)
Prognosis: 70% recurrence rate for early stage disease

Plantar Fibromatosis

= PLANTAR FASCIITIS = LEDDERHOSE DISEASE
Prevalence: 0.23%
Cause: trauma; likely multifactorial
Age: 30–50 years; < 30 years (44%); M÷F = 2÷1
Path: abnormal fibrous tissue replacing the plantar aponeurosis and infiltrating subcutaneous tissue + skin
Histo: nonencapsulated proliferation of fibroblasts separated by variable amounts of

collagen

At risk: runners, obese patients

Associated with: Dupuytren contracture (10–65%), knuckle pads (42%), Peyronie disease; diabetes, epilepsy, keloids, alcoholism

- heel pain (one of the most common causes)
- one / multiple firm fixed subcutaneous nodules

Location: proximal / central portion of plantar aponeurosis; bilateral in 20–50%, typically metachronous with a 2–7-year interval

Site: middle to medial aspect of plantar arch; may involve skin + deep structures of the foot

√ hypervascular (92%) hypoechoic / mixed echogenic nodules in subcutaneous tissues superficial to often thickened plantar aponeurosis, medially (60%) / centrally (40%)

√ calcaneal spur

MR:

√ single or multiple nodules / poorly defined infiltrative heterogeneous (92%) mass iso- / hypointense compared to plantar muscles on T1WI + T2WI

√ marked contrast enhancement in 64%

√ ± subcutaneous edema

Rx: local excision with wide margins (for painful or disabling lesion); intralesional steroid injection; postoperative radiation therapy

SYNOVIAL CYST

◊ Often used interchangeably with ganglion (lined by flat spindle cells)

Histo: lined by synovial cells

Cause: herniation of synovial membrane through joint capsule

DDx: fluid distention of paraarticular bursa, synovial cyst (differentiation from ganglion cyst radiologically not possible)

Popliteal Cyst

= BAKER CYST

[William Morrant Baker (1839–1896), surgeon and governor at St. Bartholomew's Hospital, London]

= synovial cyst in the posterior aspect of knee joint communicating with posterior joint capsule

Prevalence: 19% in general orthopedic patients; 61% in patients with rheumatoid arthritis

Pathophysiology:

formed by escape of synovial effusion into one of the bursae; fluid trapped by one-way valvular mechanism

(a) Bunsen-type valve = expanding cyst compresses the communicating channel

(b) ball-type valve = ball composed of fibrin + cellular debris plugs the communication channel

Etiology:

(1) Arthritis: degenerative, rheumatoid, pyogenic

(2) Internal derangement: meniscal / anterior cruciate ligament tears

(3) Pigmented villonodular synovitis

- pseudothrombophlebitis syndrome (= pain + swelling in calf)
- cellulitis (after leakage / rupture)

Location:

(a) gastrocnemius-semimembranosus bursa = posterior to gastrocnemius muscle at level of medial condyle

(b) supralateral bursa = between lateral head of gastrocnemius muscle + distal end of biceps muscle superior to lateral condyle (uncommon)

(c) popliteal bursa = beneath lateral meniscus + anterior to popliteal muscle (uncommon)

√ communication with bursa (documented on arthrogram)

√ well-outlined hypointense collection on T1WI + hyperintense on T2WI

√ septa in 50%

Types:

1. Intact cyst
   - √ smooth contour
2. Dissected cyst
   - √ smooth contour extending along fascial planes (usually between gastrocnemius + soleus)
3. Ruptured cyst
   - √ leakage into calf tissues

DDx of other synovial cysts about the knee:

(1) Meniscal cyst (at lateral / medial side of joint line; associated with horizontal cleavage tears)

(2) Tibiofibular cyst (at proximal tibiofibular joint, which communicates with knee joint in 10%)

(3) Cruciate cyst (surrounding anterior / posterior cruciate ligaments following ligamentous injury)

SYNOVIAL OSTEOCHONDROMATOSIS

= SYNOVIAL CHONDROMATOSIS = JOINT CHONDROMA

Primary Synovial Osteochondromatosis

= benign self-limiting monoarticular disorder characterized by proliferation + metaplastic transformation of synovium with formation of multiple intrasynovial cartilaginous / osteocartilaginous nodules with tendency for detachment and migration within joint space

Cause: hyperplastic synovium with cartilage metaplasia (foci < 2–3 cm); loose body may remain free floating / form conglomerate with other loose bodies into large mass / reattach to synovium with either reabsorption or continued growth

Histo: foci of hyaline cartilage with mineralized chondroid matrix beneath synovial surface + within subsynovial connective tissue; hypercellularity + nuclear atypia may be confused with malignancy

Composition of cartilaginous bodies:

cartilage alone / cartilage + bone / mature bone + fatty bone marrow

Age: 3rd–5th decade; M÷F = 2÷1 – 4÷1

Phase:

(a) early phase = synovial proliferation → formation of intrasynovial cartilaginous

nodules
(b) late phase = inactive synovial disease with persistent nodules that may break off into joint cavity

- slow-growing soft-tissue mass within joint
- progressive joint pain for several years
- limitation of motion / locking ± hemorrhagic joint effusion

Location: knee (most common in > 50%, in 10% bilateral) elbow > hip > shoulder > ankle > wrist; usually monoarticular, occasionally bilateral

Sites: joint / tendon sheath / ganglion / bursa / periarticular

√ pathognomonic multiple calcified / ossified loose bodies in a single joint (bony shell of remodeled lamellar bone is rare) in a rings-and-arcs morphology

√ varying degrees of bone mineralization (25–30% of chondromas show no radiopacity)

√ characteristically uniform size of nodules that may vary between a few mm and several cm

√ marginal pressure erosion of adjacent bone in joints with tight capsule (eg, hip)

√ widening of joint space (from accumulation of loose bodies)

√ joint effusion uncommon

√ NO osteoporosis

CT:

√ multiple calcified / ossified intraarticular bodies

√ intraarticular soft-tissue mass of near-water attenuation containing multiple small calcifications

MR:

√ homogeneous lobulated intraarticular mass isointense to muscle on T1WI + hyperintense to muscle on T2WI ± osteochondral bodies

DDx: large effusion, soft-tissue tumor

√ osteochondral bodies:

√ multiple foci of low signal intensity ← calcifications

√ peripheral contrast enhancement of chondral lesions

√ intraarticular bodies with central area of high SI on T1WI = with fatty marrow

Cx: (1) Long-standing disease → secondary degenerative arthritis ← chronic mechanical irritation + destruction of articular cartilage by loose bodies

(2) Malignant dedifferentiation to synovial chondrosarcoma (in < 5%)

Rx: surgical synovectomy with removal of loose bodies (recurrence is common)

DDx: (1) Synovial sarcoma, chondrosarcoma

(2) Osteochondral fracture (history of trauma), osteochondritis dissecans, osteonecrosis

(3) Secondary osteochondromatosis

(4) Pigmented villonodular synovitis, synovial hemangioma, lipoma arborescens

Secondary Synovial Osteochondromatosis

= joint surface disintegration

Cause: trauma, osteonecrosis, rheumatoid arthritis, neuropathic arthropathy, tuberculous arthritis, degenerative joint disease

√ intraarticular bodies tend to be larger, less numerous, more varied in size compared to

primary synovial osteochondromatosis
√ prominent osteoarthritis

SYNOVIAL SARCOMA

= (MALIGNANT) SYNOVIOMA = TENDOSYNOVIAL SARCOMA = SYNOVIOBLASTIC SARCOMA = SYNOVIAL ENDOTHELIOMA
= [misnomer related to appearance of cells not their origin] slow-growing expansile malignant tumor originating from mesenchymal tissue (not synovium, named for its histologic resemblance of synovium) with extensive metastatic potential
Origin: pluripotential mesenchymal cell of variable epithelial differentiation; it has been proposed to rename tumor carcinosarcoma / spindle cell sarcoma of soft tissue
Frequency: 4th most common soft-tissue sarcoma (after malignant fibrous histiocytoma, liposarcoma, rhabdomyosarcoma); 7–10% of all primary soft-tissue sarcomas
Histo: in 90% positive staining for keratin (epithelial marker) pankeratin, EMA, CK7 (absent in malignant peripheral nerve sheath tumor + Ewing sarcoma)
(a) biphasic (20–30%): mesenchymal spindle cell + epithelial component usually forming glands
(b) monophasic (50–60%): spindle cell component with fascicular interlacing growth pattern predominates
(c) poorly differentiated (15–25%): generally epitheloid with high mitotic activity + geographic necrosis
Cytogenetics: t(X;18) translocation + SYT-SSX gene fusion products (identified by FISH / RT-PCR studies)
Median age: 30–38 (84% between 15 and 50) years; M÷F = 1.2÷1.0
• slow-growing occasionally painful palpable soft-tissue mass (2–4 years average duration of symptoms) often mistaken for benign indolent process
Site: in synovial lining / bursa / tendon sheath adjacent to joint (40–50%) / within 5 cm of joint (60–75%); uncommonly intraarticular (in 5–10%)
Location: 80–95% in extremities; pelvis (8%); trunk (7%); head & neck (5%, pharynx); retroperitoneum (0.3%); rare in: chest wall, mediastinum, heart, lung, pleura; usually solitary
(a) lower extremity (2/3): thigh, popliteal fossa (most common), hip, foot & ankle (18%)
(b) upper extremity (1/3): elbow, wrist, hands, feet
√ large spheroid well-defined soft-tissue mass:
√ homogeneous / heterogeneous dependent on degree of hemorrhage / necrosis
√ amorphous punctate calcifications / ossification (30–40%), often eccentric or at periphery of tumor
◊ Calcifications in other soft-tissue connective tissue sarcomas are uncommon!
√ lesion about 1 cm removed from joint cartilage
√ often indolent nonaggressive appearance of involvement of adjacent bone (11–20%):
√ periosteal reaction
√ bone remodeling (pressure from tumor)
√ invasion of cortex with wide zone of transition

√ infiltration of adjacent soft tissue (infrequent)
√ juxtaarticular osteoporosis

CT:
√ heterogeneous deep-seated multinodular soft-tissue mass with attenuation slightly less than muscle ← necrosis / hemorrhage (in 50%)
√ multinodular morphology with well-defined (53%) / irregular (47%) margins
√ areas of lower attenuation represent necrosis / hemorrhage
√ predominantly areas of low attenuation mimicking hematoma / cystic mass (in 6%)
√ calcifications (in 27–41%)
√ bone erosion / marrow invasion (25%)
√ heterogeneous enhancement (89–100%)

MR:
√ predominantly well-defined mass of homogeneous texture for lesions < 5 cm (rare) mimicking a benign process
√ prominently heterogeneous soft-tissue mass with SI similar to / slightly higher than muscle on T1WI
√ heterogeneously increased SI on T2
√ "triple signal intensity" sign on T2WI (in 35–57%) = marked heterogeneity with a mixture of areas of
(1) hypointensity ← calcified / fibrotic collagenized tissue,
(2) isointensity ← solid cellular elements, and
(3) hyperintensity ← hemorrhage / necrosis (in 40%)
√ "bowl of grapes" sign = large multilocular multilobulated cystic spaces + prominent hemorrhagic foci separated by septa (67–75%) on T2WI
√ fluid-fluid levels (10–25%) ← previous hemorrhage
√ bone marrow invasion / cortical erosion (in up to 21%)
√ neurovascular encasement (17–24%)

CEMR:
√ prominent heterogeneous (83%) / homogeneous (17%) enhancement
√ peripheral / nodular enhancement for necrotic tumor
√ serpentine vascular channels (1/3)
√ initially rapid progressive linear increase in SI followed by washout (60%) / late sustained increase (40%)

US:
√ focal nodular round / lobulated hypoechoic solid soft-tissue mass (66%)
√ heterogeneous texture with irregular margins

Angio:
√ hypervascular tumor displacing native vessels
√ arteriovenous shunting (in 24%)

NUC:
√ prominently increased uptake on blood flow + blood pool images of bone scan ← increased tumor vascularity
√ heterogeneous mild uptake (← mixture of viable + necrotic tissue) perhaps associated with calcifications

PET:

√ markedly increased activity with high SUV

Spread: distant metastases develop in 41% within 2–5 years; lung (94%) > lymph nodes (4–18%) > bone (8–11%)

◊ Metastasis present in 16–25% at presentation

Rx: local excision / amputation + radiation + chemotherapy

Prognosis: local recurrence in 30–50% within 2 years after Rx; 36–76% 5-year survival rate; 20–63% 10-year survival rate

Poor prognosticators: tumor size > 5 cm, trunk > peripheral location, poorly differentiated areas

SYPHILIS OF BONE

[*syphlos*, Greek = crippled]

= "The Great Imitator" of neoplastic / autoimmune conditions

Organism: spirochete Treponema pallidum = spiral-shaped extracellular microorganisms with internal flagella resulting in twisting locomotion; evades immune system through antigenic variation

Transmission: sexually / placentally

• local mucocutaneous infection → gradual progression to chronic systemic disease

Congenital Syphilis

◊ Transplacental transmission cannot occur < 16 weeks gestational age

• positive rapid plasma reagin (measures quantity of antibodies to assess new infection / efficacy of Rx)

• positive microhemagglutination test for Treponema pallidum (remains reactive for life)

√ pneumonia alba

√ hepatomegaly

Location: symmetrical bilateral osteomyelitis involving multiple bones (HALLMARK)

A. Early phase

◊ Skeletal radiography abnormal in 19% of infected newborns without overt disease!

1. Metaphysitis
   - √ lucent metaphyseal band adjacent to thin / widened zone of provisional calcification ← disturbance in enchondral bone growth
   - √ frayed edge of metaphyseal-physeal junction (osteochondritis) = erosions + lytic defects
2. Diaphyseal periostitis = "luetic diaphysitis"
   - √ solid / lamellated periosteal new-bone growth = bone-within-bone appearance
3. Spontaneous epiphyseal fractures causing Parrot pseudopalsy (DDx: battered child syndrome)
4. Bone destruction
   - √ marginal destruction of spongiosa + cortex along side of shaft with widening of medullary canal (in short tubular bones)
   - √ patchy rarefaction in diaphysis
5. Wimberger sign
   - √ symmetrical focal bone destruction of medial portion of proximal tibial metaphysis (ALMOST PATHOGNOMONIC)

B. Late phase
- Hutchinson triad = dental abnormality, interstitial keratitis, 8th nerve deafness
  √ frontal bossing of Parrot = diffuse thickening of outer table
  √ saddle nose + high palate (syphilitic chondritis + rhinitis)
  √ short maxilla (maxillary osteitis)
  √ thickening at sternal end of clavicle
  √ "saber-shin" deformity = anteriorly convex bowing in upper ²/₃ of tibia with bone thickening

Acquired Syphilis

= TERTIARY SYPHILIS resembles chronic osteomyelitis
√ dense bone sclerosis of long bones
√ irregular periosteal proliferation + endosteal thickening with narrow medulla
√ extensive calvarial bone proliferation with mottled pattern (anterior half + lateral skull) in outer table (DDx: fibrous dysplasia, Paget disease)
√ ill-defined lytic destruction in skull, spine, long bones (= gumma formation)
√ enlargement of clavicle ← cortical + endosteal new bone
√ Charcot arthropathy of lower extremities + spine

Primary Syphilis
- HALLMARK painless cutaneous ulcer (chancre)

Meningovascular Neurosyphilis
Cause: direct spirochete invasion of vascular endothelial cells → vasculitis
- stroke in young adult (MCA > basilar artery territory)

TARSAL COALITION

= abnormal fibrous / cartilaginous / osseous fusion of two or more tarsal ossification bones
◊ Clinically most important congenital problem of calcaneus
Prevalence: 1–2% of population
Cause: abnormal segmentation of primitive mesenchyme with lack of joint formation
Age: fibrous coalition at birth, ossification during 2nd decade of life with onset of symptoms; M÷F = 1÷1
- asymptomatic: often first noted after antecedent trauma / weight gain / increase in athletic activity
- peroneal spastic / rigid pes planus (= flatfoot) in adjustment for calcaneus valgus (= heel valgus)
- hindfoot / tarsal pain or stiffness

√ both feet affected in 20–50%
√ osseous bars between bones of hindfoot / bones in close proximity with irregular surfaces
MR (of joint space):
√ bone marrow contiguity (osseous coalition)
√ fluid- / cartilage-intensity (cartilaginous coalition)
√ intermediate- to low-signal intensity (fibrous coalition)
√ reactive periarticular bone changes

√ bone marrow edema along fused joint (STIR images)

Types:

(1) CALCANEONAVICULAR COALITION (45%)

Age: 8–12 years ← earlier ossification

• rigid flat foot ± pain in 2nd decade of life

Radiographs:

√ narrowed calcaneonavicular joint with indistinct articular margins (bones that usually do not articulate)

√ widening / flattening of anteromedial calcaneus

√ "anteater's nose" = elongation of anterior dorsal calcaneus on lateral radiograph

√ hypoplastic talar head

CT (axial scan):

√ broadening of medial aspect of anterodorsal calcaneus in apposition to navicular

√ narrowing of space between calcaneus and navicular + minimal marginal reactive sclerosis

Dx: mostly diagnosed on 45° internal oblique films

(2) Talocalcaneal coalition (45%)

Age: 12–16 years

• painful peroneal spastic flat foot, relieved by rest

Site: middle facet at level of sustentaculum tali (most frequently)

Secondary radiographic signs ← alteration in hindfoot biomechanics:

√ prominent talar beak (66%) arising from dorsal aspect of head / neck of talus ← impaired subtalar joint motion

√ rounding of the lateral talar process

√ narrowing of posterior subtalar joint

√ lack of depiction of middle facets

√ asymmetric anterior talocalcaneal joint

√ "ball-in-socket" ankle mortise in severe cases

√ "C" sign = C-shaped outline of the medial talar dome + posteroinferior sustentaculum on lateral radiograph (from bone bridge between talar dome + sustentaculum)

CT (coronal scan):

√ bony bar bridging the middle facet of subtalar joint

√ narrowed middle facet with reactive cystic + hypertrophic changes

√ downward or horizontal slope of sustentaculum, instead of upward

Dx: requires cross-sectional imaging for diagnosis

(3) TALONAVICULAR COALITION

(4) CALCANEOCUBOID COALITION

(5) CUBONAVICULAR COALITION

Rx: orthotics, casting, NSAID, steroid injections, physical therapy, resection, arthrodesis

DDx: acquired intertarsal ankylosis (infection, trauma, arthritis, surgery)

TARSAL TUNNEL SYNDROME

= entrapment / compression neuropathy (analogous to carpal tunnel syndrome) of

(a) posterior tibial nerve (most common)
(b) its terminal branches (= medial and lateral plantar nn., medial calcaneal n.)

Tarsal tunnel = fibro-osseous passageway from level of medial malleolus to navicular bone distally

Medial floor: tibia, talus, sustentaculum tali, medial wall of calcaneus

Lateral roof: deep fascia of leg, flexor retinaculum = lacinate lig., abductor hallucis

Contents: medial ankle tendons (tibialis posterior, flexor hallucis longus, flexor digitorum longus) + posterior tibial nerve and artery and veins

Cause:

(a) intrinsic (mass effect): ganglion cyst, neural sheath tumor, lipoma, tenosynovitis of flexor hallucis longus, marked varicosities, accessory muscle, fracture, fibrosis of chronic ankle sprain, rheumatoid arthritis, diabetes
(b) extrinsic (tension): tarsal coalition, excessive pronation, valgus / varus heel, repetitive stress (jogger's foot)

- burning pain, tingling, numbness, nocturnal paresthesia along plantar surface of heel, foot and toes
- radiation of paresthesia to medial aspect of calf (Valleix phenomenon)
- positive Tinel sign = percussion of posterior tibial n. posteroinferiorly from medial malleolus causes paresthesia

√ mass in tarsal tunnel (ganglion, neurilemmoma, lipoma, thickened flexor retinaculum, muscle)
√ muscle edema from denervation in abductor hallucis (supplied by medial plantar nerve) / abductor digiti minimi (supplied by lateral plantar nerve)
√ fracture of sustentaculum tali / medial tubercle of posterior talar process
√ serpiginous varicosities

Rx: orthotics, release

THALASSEMIA SYNDROMES

= inherited disorders of hemoglobin synthesis typically seen in individuals of Mediterranean descent

Physiologic hemoglobins:

(a) in adulthood:
Hb A (98% = 2 α- and 2 β-chains);
Hb A_2 (2% = 2 α- and 2 δ-chains)
(b) in fetal life:
Hb F (= 2 α- and 2 γ-chains)
rapidly decreasing up to 3 months of newborn period

A. ALPHA-THALASSEMIA
= decreased synthesis of α-chains → excess of β-chains and γ-chains (Hb H = 4 β-chains; Hb Bart = 4 γ-chains)
- disease begins in intrauterine life as no fetal hemoglobin is produced
- homozygosity is lethal (lack of oxygen transport)

B. BETA-THALASSEMIA
= decreased synthesis of β-chains leading to excess of α-chains + γ-chains (= fetal hemoglobin)

• disease manifest in early infancy
(a) homozygous defect = thalassemia major = Cooley anemia
(b) heterozygous defect = thalassemia minor

Thalassemia Major

= COOLEY ANEMIA = MEDITERRANEAN ANEMIA
= HEREDITARY LEPTOCYTOSIS = β-THALASSEMIA
= most severe form with trait inherited from both parents (= homozygous form)
Prevalence: 1% for American Blacks; 7.4% for Greek population; 10% for certain Italian populations
Age: develops after newborn period within first 2 years of life
• retarded growth
• elevated serum bilirubin
• hyperpigmentation of skin
• hyperuricemia
• secondary sexual characteristics retarded, normal menstruation rare ← primary gonadotropin insufficiency ← iron overload in pituitary gland
• hypochromic microcytic anemia (Hb 2–3 g/dL), nucleated RBC, target cells, reticulocytosis, decrease in RBC survival, leukocytosis
• susceptible to infection ← leukopenia ← splenomegaly
• bleeding diathesis ← thrombocytopenia
@ Skull:
• mongoloid facies
√ marrow expansion of diploe:
√ widening of diploic space with coarsened trabeculations and displacement ← marrow hyperplasia (= extramedullary hematopoiesis)
√ thinning of outer table
√ frontal bossing
√ severe hair-on-end appearance (frontal bone, NOT inferior to internal occipital protuberance)
√ marrow expansion in paranasal sinuses:
√ impaired pneumatization of maxillary antra + mastoid sinuses
√ narrowing of nasal cavity
√ rodent facies = ventral displacement of incisors ← marrow overgrowth in maxillary bone with dental malocclusion
√ lateral displacement of orbits
@ Peripheral skeleton:
• earliest changes in small bones of hands + feet (> 6 months of age)
√ diffuse osteopenia:
√ atrophy + coarsening of trabeculae ← marrow hyperplasia
√ prominence of nutrient foramina
√ widened medullary spaces with thinning of cortices
√ Erlenmeyer flask deformity = bulging of normally concave outline of metaphyses
√ premature fusion of epiphyses (10%), usually at proximal humerus + distal femur
√ arthropathy ← hemochromatosis + CPPD + acute gouty arthritis

√ regression of peripheral skeletal changes (as red marrow becomes yellow)

@ Chest:

√ cardiac enlargement + congestive heart failure ← anemia

√ paravertebral masses (= extramedullary hematopoiesis)

@ Ribs

√ costal osteomas = bulbous widening of posterior aspect of ribs with thinned cortices

√ undertubulated broad ribs

√ heterogeneous rib ossification:

√ localized lucencies

√ cortical erosion

√ rib-within-rib appearance

@ Abdomen:

√ hepatosplenomegaly

√ gallstones

Cx: (1) Pathologic fractures

(2) Iron overload + hemosiderosis ← frequent blood transfusion therapy (absent puberty, diabetes mellitus, adrenal insufficiency, myocardial insufficiency)

Prognosis: usually death within 1st decade

Rx: systematic transfusion has lessened the severity of skeletal abnormalities

DDx: chronic anemia, storage diseases, fibrous dysplasia

Thalassemia Intermedia

= subgroup of homozygous form

• milder clinical presentation

• not requiring hypertransfusion to maintain an adequate hematocrit

Prognosis: longer life expectancy

Thalassemia Minor

= beta-thalassemia trait inherited from one parent (heterozygous)

• usually asymptomatic except for periods of stress (pregnancy, infection)

• microcytic hypochromic anemia (Hb 9–11 g/dL)

• occasionally jaundice + splenomegaly

THANATOPHORIC DYSPLASIA

[*thanatos*, Greek = death; *phoric*, Greek = bearing]

= sporadic lethal skeletal dysplasia characterized by severe rhizomelia (micromelic dwarfism)

Prevalence: 6.9÷100,000 births; 1÷6,400–16,700 births;

◊ Most common lethal bone dysplasia after osteogenesis imperfecta type II

Genetics: autosomal dominant mutation of gene-encoding fibroblast growth factor receptor 3 (FGFR3)

• severe respiratory distress (early in life)

• hypotonic infants; protuberant abdomen

• extended arms + abducted externally rotated thighs

@ Head

√ disproportionately large head with short base of skull + prominent forehead
√ occasionally trilobed cloverleaf skull = "Kleeblattschädel"
√ depressed nasal bridge + protruding eyes

@ Chest radiograph (PATHOGNOMONIC)
√ narrow chest with normal trunk length
√ short horizontal ribs:
  √ not extending beyond anterior axillary line
  √ cupped anterior ends
√ short curved "telephone handle" humeri
√ H- / U-shaped vertebra plana
√ small scapula + normal clavicles

@ Spine
√ normal length of trunk
√ reduction of interpediculate space of last few lumbar vertebrae
√ extreme generalized platyspondyly = severe H- / U-shaped vertebra plana
√ excessive intervertebral space height

@ Pelvis (hypoplastic iliac bones)
√ iliac wings small + square (vertical shortening but wide horizontally)
√ flat acetabulum
√ narrow sacrosciatic notch
√ short pubic bones

@ Extremities
√ severe micromelia:
  √ bowing of extremities (type 1) / straight (type 2)
√ metaphyseal flaring = "telephone handle" appearance of long bones
√ thornlike projections in metaphyseal area
√ polydactyly

OB-US (findings may be seen very early in pregnancy):
√ polyhydramnios (50–71%)
√ short-limbed dwarfism with extremely short + bowed "telephone receiver"-like femurs
√ extremely small hypoplastic thorax with short ribs + narrowed in anteroposterior dimension
√ protuberant abdomen
√ macrocrania with frontal bossing ± hydrocephalus (increased HC÷AC ratio)
√ "cloverleaf skull" (in 14%) (DDx: encephalocele)
√ diffuse platyspondyly
√ redundant soft tissues

Prognosis: often stillborn; uniformly fatal within a few hours / days after birth ← respiratory failure

DDx: (1) Ellis-van Creveld syndrome (extra digit, acromesomelic short limbs)
(2) Asphyxiating thoracic dysplasia (less marked bone shortening, vertebrae spared)
(3) Short-rib polydactyly syndrome
(4) Homozygous achondroplasia
(5) Achondrogenesis

THROMBOCYTOPENIA-ABSENT RADIUS SYNDROME

= TAR SYNDROME
= rare autosomal recessive disorder
May be associated with: CHD (33%): ASD, tetralogy
• platelet count < 100,000/mm^3 (decreased production by bone marrow)
√ usually bilateral radial aplasia / hypoplasia
√ uni- / bilaterally hypoplastic / absent ulna / humerus
√ defects of hands, feet, legs
Prognosis: death in 50% in early infancy ← hemorrhage

THYROID ACROPACHY

Onset: after > 18 months following surgical / radioactive ablation of thyroid gland for hyperthyroidism (does not occur with antithyroid medication)
Frequency: 0.5–1% of patients with thyrotoxicosis
• clubbing, soft-tissue swelling, NO pain
• eu- / hypo- / hyperthyroid state
Location: metacarpals + phalanges of hand; less commonly feet, lower legs, forearms
√ thick spiculated lacy "feathery" periosteal reaction in an asymmetric distribution; mostly on radial aspect of bone
DDx: (1) Pulmonary osteoarthropathy (painful)
(2) Pachydermoperiostosis
(3) Fluorosis (ligamentous calcifications)

TRANSIENT REGIONAL OSTEOPOROSIS

= TRANSIENT BONE MARROW EDEMA
Cause: unknown; ? overactivity of sympathetic nervous system + local hyperemia similar to reflex sympathetic dystrophy syndrome, trauma, synovitis, transient ischemia

Regional Migratory Osteoporosis

= rapid onset of self-limiting episodes of severe localized osteoporosis and pain but repetitive occurrence of same symptoms in other regions of same / opposite lower extremity
• rapid onset of local pain
• diffuse erythema, swelling, increased heat
• significant disability ← severe pain on weight bearing
Age: middle-aged males
Location: usually lower extremity (ie, ankle, knee, hip, foot)
√ rapid localized osteoporosis within 4–8 weeks after onset migrating from one joint to another; may affect trabecular / cortical bone
√ linear / wavy periosteal reaction
√ preservation of subchondral cortical bone
√ no joint space narrowing / bone erosion
MR:
√ affected area has low SI on T1WI, high SI on T2WI (= bone marrow edema)

NUC:
√ increased activity
Prognosis: persists for 6–9 months in one area; cycle of symptoms may last for several years
Rx: variable response to analgesics / corticosteroids

Partial Transient Osteoporosis
= variant of regional migratory osteoporosis with more focal pattern of osteoporosis, which may eventually become more generalized
(a) zonal form = portion of bone involved, ie, one femoral condyle / one quadrant of femoral head
(b) radial form = only one / two rays of hand / foot involved

Transient Osteoporosis of Hip

= self-limiting disease of unknown etiology
Age: typically in middle-aged males / in 3rd trimester of pregnancy in females involving left hip; M > F
• spontaneous onset of hip and groin pain, usually progressive over several weeks
• painful swelling of joint followed by progressive demineralization
• rapid development of disability, limp, ↓ range of motion
Site: hip most commonly affected; generally only one joint at a time
√ progressive marked osteoporosis of femoral head, neck, acetabulum (3–8 weeks after onset of illness)
√ virtually PATHOGNOMONIC striking loss of subchondral cortex of femoral head + neck region
√ NO joint space narrowing / subchondral bone collapse
NUC:
√ markedly increased uptake on bone scan without cold spots / inhomogeneities (positive before radiograph)
MR:
√ diffuse bone marrow edema involving femoral head + neck + sometimes intertrochanteric region
√ small joint effusion
Cx: pathologic fracture common
Prognosis: spontaneous recovery within 2–6 months; recurrence in another joint within 2 years possible
DDx: (1) AVN (cystic + sclerotic changes, early subchondral undermining)
(2) Septic / tuberculous arthritis (joint aspiration!)
(3) Monoarticular rheumatoid arthritis
(4) Metastasis
(5) Reflex sympathetic dystrophy
(6) Disuse atrophy
(7) Synovial chondromatosis
(8) Villonodular synovitis

TRANSIENT SYNOVITIS OF HIP

= OBSERVATION HIP = TRANSITORY SYNOVITIS = TOXIC SYNOVITIS = COXITIS FUGAX
= nonspecific inflammatory reaction

◊ Most common nontraumatic cause of acute limp in a child!

Etiology: unknown; no organism on joint aspiration
Average age: 6 (range, 5–10) years; M÷F = 2÷1
• history of recent viral illness (65%)
• mild fever (25%), mildly elevated ESR (50%)
• developing limp over 1–2 days; pain in hip, thigh, knee
• serosanguinous joint fluid
√ radiographs usually normal
√ joint effusion:
  √ displacement of femur from acetabulum
  √ displacement of psoas line
  √ lateral displacement of gluteal line (least sensitive + least reliable)
√ regional osteoporosis (? hyperemia, disuse)
US:
  √ fluid in anterior recess between capsule + femoral neck
MR:
  √ joint effusion
  √ intense enhancement of hypertrophied synovium (DDx: septic arthritis)
NUC:
  √ normal / slight increase in activity → excluding osteomyelitis + avascular necrosis
Prognosis: complete recovery within a few weeks
Dx: per exclusion
Rx: non–weight-bearing treatment
DDx: (1) Septic arthritis
(2) Trauma
(3) Legg-Perthes disease
(4) Acute rheumatoid arthritis
(5) Acute rheumatic fever
(6) Tuberculosis
(7) Malignancy

TREACHER-COLLINS SYNDROME

[Edward Treacher Collins (1862–1932), English surgeon and ophthalmologist at Moorfields Eye Hospital, London]
= MANDIBULOFACIAL DYSOSTOSIS
= autosomal dominant disease (with new mutations in 60%) characterized by bilateral malformations of eyes, malar bones, mandible, and ears resulting in birdlike face
Prevalence: 1÷50,000 births
Cause: defect in growth of 1st + 3rd branchial arches before the 7th–8th week of gestation

◊ NO limb anomalies (important DDx!)
• extension of scalp hair growth onto cheek; microstomia
√ craniosynostosis
√ narrowing of retropharyngeal space (apnea, speech difficulties)
@ Eyes
• antimongoloid eye slant (drooping lateral lower eyelids ← hypoplasia of lateral canthal tendon of orbicular muscle
• sparse / absent eye lashes / coloboma in lower lids
√ egg-shaped orbits = drooping of outer inferior orbital rim
√ hypoplasia of lateral wall of orbits + shallow / incomplete orbital floor
@ Nose
• broad / protruded nose
√ choanal shortening
@ Malar bone
√ sunken cheek ← marked hypoplasia / agenesis of zygomatic arches (= malar hypoplasia)
@ Maxilla
√ hypoplasia of maxilla + maxillary sinus
√ narrow / overprojected maxilla
√ high-arched / narrow palate
@ Mandible
• retruded chin, retrognathism; dental malocclusion
√ pronounced micrognathia = mandibular hypoplasia with broad concave curve on lower border of body
@ Ear
• dysplastic low-set auricles; preauricular skin tags / fistulas
• conductive hearing loss (common)
√ microtia with small middle ear cavity
√ deformed / fused / absent auditory ossicles
√ atresia / stenosis of external auditory canal
OB-US:
√ polyhydramnios ← swallowing difficulty
Prognosis: early respiratory problems (tongue relatively too large for hypoplastic mandible)
Rx: surgical correction
DDx: (1) Goldenhar-Gorlin syndrome (unilateral microtia + midface anomalies, hemivertebrae, block vertebrae, vertebral hypoplasia, microphthalmia, coloboma of upper lid)
(2) Acrofacial dysplasia (limb malformations)
(3) Crouzon disease (maxillary hypoplasia with protrusion of mandible, hypertelorism, exophthalmos, craniosynostosis)

TRISOMY D SYNDROME

= TRISOMY 13–15 GROUP SYNDROME
Etiology: additional chromosome in D group; high maternal age
• severe mental retardation

• hypertonic infant
• cleft lip + palate

Associated with: capillary hemangioma of face + upper trunk
• hypotelorism; coloboma, cataract, microphthalmia
• malformed ear with hypoplastic external auditory canal
• hyperconvex nails

√ postaxial polydactyly

@ Skull
- √ deficient ossification of skull
- √ cleft / absent midline structures of facial bones
- √ poorly formed orbits
- √ slanting of frontal bones
- √ microcephaly
- √ arrhinencephaly
- √ holoprosencephaly

@ Chest
- √ thin malformed ribs
- √ diaphragmatic hernia (frequent)
- √ congenital heart disease

Prognosis: death within 6 months of age

TRISOMY E SYNDROME

= TRISOMY 16–18 GROUP SYNDROME

Etiology: additional chromosome at 18 or E group location

Sex: usually female

◊ Marked phenotypic variability!

- hypertonic spastic infant; mental + psychomotor retardation
- typical facies: micrognathia, high narrow palate with small buccal cavity, low-set deformed ears
- flexed ulnar-deviated fingers + short adducted thumb
- 2nd finger overlapping 3rd (CHARACTERISTIC)

Associated with: congenital heart disease in 100% (PDA, VSD); hernias; renal anomalies; eventration of diaphragm

√ stippled epiphyses

@ Skull
- √ thin calvarium
- √ persistent metopic suture
- √ dolichocephaly with prominent occiput
- √ micrognathia ← hypoplastic mandible (most constant feature) + maxilla

@ Chest
- √ increase in AP diameter of thorax
- √ "shield deformity" ← hypoplastic short sternum
- √ hypoplastic clavicles (DDx: cleidocranial dysostosis)
- √ 11 rib pairs with slender hypoplastic + tapered ribs
- √ diaphragmatic eventration (common)

@ Pelvis
- √ small pelvis with forward rotation of iliac wings
- √ increased obliquity of acetabulum
- √ acute iliac angle (DIAGNOSTIC)

@ Hand & foot
- √ adducted thumb = short 1st metacarpal + phalanges (DIAGNOSTIC)
- √ 2nd finger overlapping 3rd (DIAGNOSTIC)
- √ flexed ulnar-deviated fingers
- √ short 1st toe
- √ varus deformities of forefoot + dorsiflexion of toes
- √ rocker bottom foot / extreme pes planus (frequent)

OB-US:
- √ hydrocephalus
- √ cystic hygroma
- √ diaphragmatic hernia
- √ clubfoot
- √ overlapping index finger
- √ choroid plexus cyst (30%)

Prognosis: child rarely survives beyond 6 months of age

DDx: osteogenesis imperfecta, trisomy 13 syndrome, Cockayne syndrome, Werdnig-Hoffmann disease

TUBERCULOSIS OF BONE

Frequency: 1–3–5% of tuberculous patients
Age: any; rare in 1st year of life; M÷F = 1÷1
- negative skin test excludes diagnosis; 14% FN rate
- history of active pulmonary disease (in 30–50%)

Location: spinal column, pelvis, hip, knee, wrist, elbow
Pathogenesis:
1. Hematogenous spread from
   (a) primary infection of lung (particularly in children)
   (b) quiescent primary pulmonary site / extraosseous focus
   (c) lymphatic focus in synovium
2. Direct spread from adjacent focus of osteomyelitis (rare)
3. Reactivation: especially in hip

Average delay in Dx: 16–19 months

Tuberculous Arthritis

= joint involvement usually ← direct spread from adjacent osteomyelitis / hematogenous dissemination
Prevalence: 84% of skeletal tuberculosis (about 50% as tuberculous spondylitis)
Pathophysiology: synovitis with pannus formation leads to chondronecrosis
Age: middle-aged / elderly
- chronic pain, weakness, muscle wasting
- soft-tissue swelling, draining sinus
- joint fluid: high WBC count, low glucose level, poor mucin clot formation (similar to rheumatoid arthritis)

Location: hip, knee (large weight-bearing joints) >> elbow, wrist, sacroiliac joint, glenohumeral, articulation of hand + foot
◊ TYPICALLY monoarticular!

Nonspecific imaging findings similar to other arthritides:
√ osteopenia
√ synovitis + other soft-tissue swelling
√ marginal erosions
√ varying degrees of cartilage destruction

√ Phemister triad:
1. Gradual narrowing of joint space ← slow cartilage destruction (DDx: much quicker cartilage destruction in pyogenic arthritis)
   Associated with: hyperemia + epiphyseal overgrowth in young patients
2. Peripherally located (= marginal) bone erosions
3. Juxtaarticular osteoporosis

(DDx: fungal disease, rheumatoid arthritis)

Imaging findings favoring tuberculous arthritis:

√ insidious onset
√ minimal sclerosis
√ relative absence of periosteal reaction + bone proliferation
√ relative preservation of joint space in early stages

Early radiographs:
√ joint effusion (hip in 0%, knee in 60%, ankle in 80%)
√ extensive periarticular osteopenia (deossification) adjacent to primarily weight-bearing joints
√ soft tissues usually normal

Late radiographs:
√ small cystlike marginal erosions in non–weight-bearing line opposing one another
DDx: pyogenic arthritis (erodes articular cartilage)
√ no joint space narrowing for months (CLASSIC!) ← preservation of articular cartilage until late in disease
√ articular cortical bone destruction earlier in joints with little unopposed surfaces (hip, shoulder)
√ "kissing sequestra" = wedge-shaped areas of necrosis on both sides of the joint ← infection of subchondral bone
√ increased density with extensive soft-tissue calcifications in healing phase
√ rice bodies
√ sinus formation

Cx: fibrous (rarely osseous) ankylosis; leg shortening
Dx: joint aspiration (microscopic analysis), synovial biopsy (in 90% positive), culture of synovial fluid (in 80% positive)
DDx: pyogenic / fungal arthritis (central erosion of articular cartilage, early joint space narrowing, bony ankylosis)

Tuberculous Osteomyelitis

◊ Isolated tuberculous osteomyelitis in the absence of tuberculous arthritis is RARE !

Frequency: 16% of skeletal tuberculosis
Age: children < 5 years (0.5–14%); rare in adults
Predisposed: HIV-infected individuals
• painless swelling of hand / foot
Location: femur, tibia, small bones of hand + foot (most common); any bone may be involved
Site:
(a) metaphysis (TYPICALLY) with transphyseal spread (in child) (DDx: pyogenic infections usually do not extend across physis)
(b) epiphysis with spread to joint / spread from adjacent affected joint
(c) diaphysis (< 1%)

√ initially round / oval poorly defined lytic lesion with minimal / no surrounding sclerosis
√ varying amounts of eburnation + periostitis:
√ no periosteal reaction (in adult)
√ advanced epiphyseal maturity / overgrowth ← hyperemia

√ ± limb shortening from premature physeal fusion
√ **cystic tuberculosis** = well-marginated round / oval radiolucent lesions with variable amount of sclerosis
(a) in children (frequent): in peripheral skeleton, ± symmetric distribution, no sclerosis
(b) in adults (rare): in skull / shoulder / pelvis / spine, with sclerosis
(*DDx:* eosinophilic granuloma, sarcoidosis, cystic angiomatosis, plasma cell myeloma, chordoma, fungal infection, metastasis)
√ **tuberculous dactylitis** = digit with exuberant lamellated / solid periosteal new-bone formation and fusiform soft-tissue swelling (children >> adults):
√ spina ventosa ("wind-filled sail") = ballooning dactylitis forming an enlarging cystlike cavity with erosion of endosteal cortex (end-stage disease)
√ formation of sinus tracts

DDx: (1) Pyogenic osteomyelitis (no transphyseal spread)
(2) Syphilitic dactylitis (bilateral symmetric involvement, less soft-tissue swelling and sequestration)
(3) Sarcoidosis, hemoglobinopathies, hyperparathyroidism, leukemia

TUMORAL CALCINOSIS

= LIPOCALCINOGRANULOMATOSIS = TEUTSCHLäNDER DISEASE
= rare familial metabolic disorder characterized by solitary or multiple painless, periarticular masses
= disease with progressive large nodular juxtaarticular calcified soft-tissue masses in patients with normal serum calcium and phosphorus + no evidence of renal, metabolic, or collagen-vascular disease

Etiology: autosomal dominant ($^{1}/_{3}$) with variable clinical expressivity; unknown biochemical defect of phosphorus metabolism → abnormal phosphate reabsorption + 1,25-dihydroxy-vitamin D formation

Path: multilocular cystic lesions with creamy white fluid (calcium hydroxyapatite crystals with amorphous calcium carbonate and calcium phosphate) + many giant cells (granulomatous foreign body reaction) surrounded by fibrous capsule

Associated with: hyperostosis, diaphysitis, pseudoxanthoma elasticum

Age: onset mostly within 1st / 2nd decade (range of 1–79 years); M÷F = 1÷1; predominantly in Blacks

- progressive painful / painless soft-tissue mass with overlying skin ulceration + sinus tract draining chalky milklike fluid
- prominent dental abnormalities
- swelling; limitation of motion
- <u>hyperphosphatemia</u> + ↓ fractional phosphate excretion
- hypervitaminosis D (↑ 1,25-dihydroxy–vitamin D formation)
- <u>normal</u> serum calcium, alkaline phosphatase, renal function, parathyroid hormone

@ Soft tissue

Location: hip (greater trochanteric bursa) > elbow > shoulder > foot, rib, ischial spine, wrist; single / multiple joints; ALMOST NEVER knees

Distribution: periarticular; usually along <u>extensor surface</u> of joints (? initially a calcific

bursitis)

X-ray:

√ amorphous cystic multilobulated homogeneously calcified soft-tissue mass of 1–20 cm in size

√ underlying bones NORMAL without erosion / osseous destruction

√ periosteal reaction ← bone marrow involvement

CT:

√ patchy areas of increased attenuation

√ cystic appearance with radiolucent septa (= connective tissue)

√ "sedimentation" sign = fluid-fluid levels with milk-of-calcium consistency

NUC:

√ ↑ tracer uptake of soft-tissue mass on bone scan

MR:

√ inhomogeneous high SI on T2WI (in spite of large amount of calcium) of 2 distinctive patterns:

√ diffuse lower-signal-intensity pattern

√ bright nodular pattern with alternating areas of high signal intensity and signal void

√ inhomogeneous lesion with low SI on T1WI

@ Bone

√ diaphyseal periosteal reaction (diaphysitis)

√ patchy areas of calcification in medullary cavity (= calcific myelitis)

√ increased uptake on bone scintigraphy

@ Teeth

√ bulbous root enlargement

√ pulp stones = intrapulp calcifications

@ Pseudoxanthoma elasticum-like features

√ calcinosis cutis = skin calcifications

√ vascular calcifications

√ angioid streaks of retina

@ Eye

• angioid streaks / corneal calcification deposits

Prognosis: tendency for recurrence after incomplete excision

Rx: phosphate depletion

DDx: Chronic renal failure on hemodialysis, calcinosis universalis, calcinosis circumscripta, calcific tendonitis, CPPD, paraosteoarthropathy, hyperparathyroidism

TURNER SYNDROME

[Henry Hubert Turner (1892–1970), chair of medicine at the University of Oklahoma, secretary and president of the Endocrine Society]

= nondisjunction of sex chromosomes as

(1) Complete monosomy (45,XO)

(2) Partial monosomy (structurally altered 2nd X chromosome)

(3) Mosaicism (XO + another sex karyotype)

Prevalence: 1÷3,000–5,000 livebirths

Associated with: coarctation (20–36% affected), aortic stenosis, horseshoe kidney (most common)

- sexual infantilism (spontaneous puberty in 5–15%):
  - primary amenorrhea
  - absent secondary sex characteristics
- short stature; absence of prepubertal growth spurt
- webbed neck; low irregular nuchal hair line
- shield-shaped chest + widely spaced nipples
- mental deficiency (occasionally); high palate; thyromegaly
- multiple pigmented nevi; keloid formation
- idiopathic hypertension; elevated urinary gonadotropins

@ Cardiovascular
- √ dilatation of ascending aorta (40%)
- √ juxtaductal coarctation / pseudocoarctation of aortic arch (10%); aortic stenosis; bicuspid aortic valve; elongation of aortic arch; partial anomalous pulmonary venous return

@ General
- √ normal skeletal maturation with growth arrest at skeletal age of 15 years
- √ delayed fusion of epiphyses > age 20 years
- √ osteoporosis during / after 2nd decade ← gonadal hormone deficiency
- √ coarctation of aorta (10%); aortic stenosis
- √ renal ectopia / horseshoe kidney
- √ lymphedema

@ Skull
- √ basilar impression; basal angle > 140°
- √ parietal thinning
- √ small bridged sella
- √ hypertelorism

@ Axial skeleton
- √ hypoplasia of odontoid process + C1
- √ osteochondrosis of vertebral plates
- √ squared lumbar vertebrae; kyphoscoliosis
- √ deossification of vertebrae
- √ small iliac wings; late fusion of iliac crests
- √ android pelvic inlet with narrowed pubic arch + small sacrosciatic notches

@ Chest
- √ thinning of lateral aspects of clavicles
- √ thinned + narrowed ribs with pseudonotching

@ Hand + arm
- √ "positive metacarpal" sign = relative shortening of 3rd and 4th metacarpal
- √ "positive carpal" sign = narrowing of scaphoid-lunate-triquetrum angle < 117°
- √ phalangeal preponderance = length of proximal + distal phalanx exceeds length of 4th metacarpal by > 3 mm
- √ shortening of 2nd + 5th middle phalanx (also in Down syndrome)
- √ "drumstick" distal phalanges = slender shaft + large distal head
- √ "insetting" of epiphyses into bases of adjacent metaphyses (phalanges + metacarpals)

√ Madelung deformity = shortening of ulna / absence of ulnar styloid process
√ cubitus valgus = bilateral radial tilt of articular surface of trochlea
√ deossification of carpal bones

@ Knee
√ tibia vara = enlarged medial femoral condyle + depression of medial tibial plateau (DDx: Blount disease)
√ small exostosis-like projection from medial border of proximal tibial metaphysis

@ Foot
√ deossification of tarsal bones
√ shortening of 1st, 4th, and 5th metatarsals
√ pes cavus

US:
√ prepubertal uterus
√ nonvisualized / streaky ovaries (in complete monosomy); normal ovaries (in mosaic karyotype)

OB-US:
√ large nuchal cystic hygroma
√ lymphangiectasia with generalized hydrops
√ symmetrical edema of dorsum of feet
√ CHD (20%): coarctation of aorta (70%), left heart lesions
√ horseshoe kidney

Bonnevie-Ullrich Syndrome

= infantile form of Turner syndrome
(1) Congenital webbed neck
(2) Widely separated nipples
(3) Lymphedema of hands + feet

TURRET EXOSTOSIS

Cause: trauma with formation of subperiosteal hematoma
• immobile, occasionally painful lump on dorsum of finger
• reduced ability to flex finger (= ossified hematoma diminishes excursion of extensor tendon)
Location: dorsum of proximal / middle phalanx of hand
√ smooth dome-shaped extracortical mass

ULNAR COLLATERAL LIGAMENT TEAR

Cause: chronic overuse in throwing / other overhead motion (eg, tennis serving) generating increased valgus stress
• acute onset of sharp / gradual onset of increasing pain in medial elbow
• ulnar nerve dysfunction (40%): pain, paresthesia of forearm + in 4th and 5th digits
√ ossification within ulnar collateral ligament (UCL)
√ loose bodies
√ osteoarthritis of ulnohumeral articulation
√ osteochondritis dissecans of capitellum

√ excessive medial joint opening on stress radiographs
MR (coronal plane):
√ laxity / discontinuity of UCL
√ increased signal intensity of UCL + surrounding tissues
√ poor definition of ligament margins
Rx: rest, application of ice, NSAID, exercise, steroid injections; reconstruction of ligament

ULNAR NEUROPATHY

= GUYON CANAL SYNDROME
= ulnar nerve entrapment / injury at wrist (2nd most common site after elbow)
Cause:
(1) Repetitive continuous pressure on ulnar nerve in sports: cycling (esp. mountain biking), martial arts, racket sport
(2) Exposure to frequent vibration: work in foundry / with pneumatic drills
(3) Adjacent mass: ganglion cyst, lipoma, ulnar artery aneurysm, dislocation of pisiform bone, fracture of hamulus, os hamuli proprium, osteoarthritis of pisotriquetral joint, anomalous muscle (abductor digit minimi, flexor digiti minimi brevis), abnormal tendon (flexor carpi ulnaris)
- tenderness over Guyon canal
- Tinel sign = tingling radiating to 4th + 5th fingers
- reduced strength of grip
- loss of motor function (= zone 2 injury): handlebar palsy
- sensory loss (= zone 3 injury) to hypothenar eminence + 4th finger + part of 5th finger
- combination of motor + sensory function (zone 1 injury): injury proximal to bifurcation of ulnar n.

WILLIAMS SYNDROME

[J. C. P. Williams (1900–????), New Zealand cardiologist]
= IDIOPATHIC HYPERCALCEMIA OF INFANCY
- peculiar elfinlike facies, dysplastic dentition
- neonatal hypercalcemia (not in all patients)
- mental + physical retardation

@ Skeletal manifestations
√ osteosclerosis ← trabecular thickening
√ dense broad zone of provisional calcification
√ radiolucent metaphyseal bands
√ dense vertebral end plates + acetabular roofs
√ bone islands in spongiosa
√ metastatic calcification
√ craniostenosis

@ Cardiovascular manifestations
√ supravalvular aortic stenosis (33%), aortic hypoplasia
√ valvular + peripheral pulmonary artery stenosis
√ ASD, VSD

√ stenoses of major vessels (innominate, carotids, renal aa.)

@ GI and GU tract:

√ colonic diverticula

√ bladder diverticula

Prognosis: spontaneous resolution after 1 year in most

Rx: withhold vitamin D + calcium

DDx: Hypervitaminosis D

CENTRAL NERVOUS SYSTEM

DIFFERENTIAL DIAGNOSIS OF SKULL AND SPINE DISORDERS

BIRTH TRAUMA

1. **Caput succedaneum**
   = localized edema in presenting portion of scalp
   Frequently associated with: microscopic hemorrhage and subcutaneous hyperemia
   Cause: trauma of vaginal delivery
   Location: commonly at vertex
   • soft superficial pitting edema
   √ crosses suture lines
2. **Subgaleal hemorrhage**
   = hemorrhage between *galea aponeurotica* (= central fascia formed by occipitofrontal + temporoparietal muscles) and periosteum of outer table
   • may become symptomatic ← significant blood loss in children
   • firm fluctuant mass increasing in size after birth
   • may dissect into subcutaneous tissue of neck
   • usually resolves over 2–3 weeks
   ◊ Occasionally due to spontaneous decompression of intracranial (epidural) hematoma
3. **Cephalohematoma**
   = traumatic hematoma beneath outer layer of periosteum confined by cranial sutures
   Cause: incorrect application of obstetric forceps / skull fracture during birth
   Prevalence: 1–2% in spontaneous vaginal deliveries; 3–4% in forceps- / vacuum-assisted deliveries
   Location: most commonly parietal
   • firm tense mass; usually increase in size after birth
   • resolution in few weeks to months
   √ crescent-shaped lesion adjacent to outer table of skull
   √ will not cross cranial suture line
   √ usually resolved by a few weeks to 3–4 months
   √ may calcify / ossify causing thickening of diploe ← prolonged resorption (= chronic cephalohematoma)
   MR:
   √ T1- and T2-hyperintense lesion ← subacute hemorrhage
   Cx: infection
4. Skull fracture
   Frequency: 1% of all deliveries
   √ CT shows associated intracranial hemorrhage
5. Subdural hemorrhage
   (a) convexity hematoma

(b) interhemispheric hematoma
(c) posterior fossa hematoma

6. **Benign subdural effusion**
= benign condition that resolves spontaneously
• clear / xanthochromic fluid with elevated protein level
√ extracerebral fluid collection accompanied by ventricular dilatation (= communicating hydrocephalus caused by impaired CSF absorption of these subdural fluid collections)

LOW BACK PAIN

Low Back Pain in Adults

◊ 80% of population experiences lower back pain at some time in their lives
◊ A specific cause is accurately determined in 5–10% of patients with acute symptoms + in 50% with chronic symptoms

Cause: viscerogenic, vascular, psychogenic, neurogenic

(a) spondylogenic / degenerative disease (most prevalent)
Age: 50% at 40 years; > 85% at 80 years
1. Disk herniation
2. Facet disease
3. Acquired stenosis
4. Spondylolisthesis

(b) infectious
1. Diskitis
2. Osteomyelitis

(c) inflammatory
1. Rheumatoid arthritis
2. Ankylosing spondylitis
3. Sacroiliitis

(d) trauma, iatrogenic
(e) congenital: congenital stenosis
(f) metabolic: osteoporosis
(g) neoplastic: primary, metastatic

Low Back Pain in Childhood

Frequency: in 40% of pediatric + adolescent population; structural causes in 12–26%

^{99m}Tc methylene diphosphonate (MDP) SPECT bone scintigraphy with coregistered CT is an important tool in imaging workup of pediatric low back pain, because of its utility in assessment of spondylolysis.

1. Spondylolysis (60–83%)
2. Spondylolisthesis
3. Osteomyelitis, diskitis
4. Leukemia
5. Histiocytosis X
6. Osteoid osteoma, osteoblastoma

7. Facet arthropathy / fracture

Abnormalities of Posterior Elements

1. Spondylolysis
2. Lumbar interspinous bursitis = Baastrup disease
3. Spinous process avulsion / transverse process fracture
4. Facet hypertrophy
5. Osteochondroma

Endplate and Disk Abnormalities

(a) endplate-apophyseal injury
   1. Schmorl node = central disk herniation
   2. Limbus vertebrae

(b) degenerative disk disease

(c) endplate compression fractures

Sacroiliac Abnormalities

1. Bertolotti syndrome
2. Sacroiliac joint syndrome
3. Sacral stress fracture

Lumbosacral Postsurgical Syndrome

= FAILED BACK SURGERY SYNDROME

= signs of dysfunction and disability + pain and paresthesia following surgery

◊ Interpretation in immediate postoperative period difficult, stabilization of findings occurs in 2–6 months

Frequency: failure of improvement in 5–15%

A. OSSEOUS CAUSE

(a) mechanical instability
   1. Spondylolisthesis
   2. Pseudarthrosis

(b) osseous stenosis
   1. Central stenosis
   2. Foraminal stenosis

B. SOFT-TISSUE CAUSES

1. Perioperative intraspinal hemorrhage (onset < 1 week)
2. Residual disk herniation (onset < 1 week)
3. Recurrent disk herniation (onset 1 week – 1 month)
   √ no enhancement on early T1WI (appears enhanced ≥ 30 min post injection)
4. Spinal / meningeal / neural inflammation / infection (onset 1 week – 1 month) = **Postoperative diskitis**
   • elevated ESR + frequently normal WBC count
   √ deceased marrow signal intensity on T1WI
   √ contrast enhancement of disk + adjacent vertebral bodies
5. Intraspinal scar formation (onset > 1 month)
   (a) **Epidural fibrosis** (scarring)

√ enhancing epidural plaque / mass
√ heterogeneous enhancement on early T1WI (maximum at about 5 min post injection) most pronounced within 9 months of surgery

(b) **Fibrosing arachnoiditis** = adhesive arachnoiditis
√ thickened irregular clumped nerve roots
√ adhesion of roots to wall of thecal sac
√ abnormal enhancement of thickened meninges + matted nerve roots

C. SURGICAL ERRORS
1. Wrong level / side of surgery
2. Direct nerve injury

D. Remote phenomena unrelated to spine

mnemonic: ABCDEF
Arachnoiditis
Bleeding
Contamination (infection)
Disk (residual / recurrent / new level)
Error (wrong disk excised)
Fibrosis (scar)

Cauda Equina Syndrome

= constellation of signs + symptoms resulting from compressive lesion in lower lumbar spinal canal

Cause:
(1) Displaced disk fragment
(2) Intra- / extramedullary tumor
(3) Osseous: Paget disease, osteomyelitis, osteoarthrosis of facet joints, complication of ankylosing spondylitis

- diminished sensation in lower lumbar + sacral dermatomes
- wasting + weakness of muscles; decreased ankle reflexes
- impotence; decreased sphincter tone
- disturbed sphincter function + overflow incontinence

SKULL

Lumps & Bumps of Pediatric Skull

A. Congenital Lesions
1. Encephalocele
2. Nasal glioma
3. Dermoid
4. Epidermoid cyst
5. Hemangioma
6. Vascular malformation: venous, lymphatic, sinus pericranii
7. PHACE syndrome

B. Acquired Lesions
1. Rhabdomyosarcoma

2. Fibrosarcoma
2. Langerhans cell histiocytosis
3. Metastatic neuroblastoma
4. Infection: Pott puffy tumor
5. Trauma: cephalohematoma

Sutural Abnormalities

Wide Sutures

= > 10 mm at birth, > 3 mm at 2 years, > 2 mm at 3 years of age; (sutures are splittable up to age 12–15; complete closure by age 30)

A. NORMAL VARIANT
in neonate + prematurity; growth spurts occur at 2–3 years and 5–7 years

B. CONGENITAL UNDEROSSIFICATION
osteogenesis imperfecta, hypophosphatasia, rickets, hypothyroidism, pyknodysostosis, cleidocranial dysplasia

C. METABOLIC DISEASE
hypoparathyroidism; lead intoxication; hypo- / hypervitaminosis A

D. RAISED INTRACRANIAL PRESSURE
Cause:
(1) Intracerebral tumor
(2) Subdural hematoma
(3) Hydrocephalus
Age: seen only if < 10 years of age
Location: coronal > sagittal > lambdoid > squamosal suture

E. INFILTRATION OF SUTURES
Cause: metastases to meninges from
(1) Neuroblastoma
(2) Leukemia
(3) Lymphoma
√ poorly defined margins

F. RECOVERY from
(1) Deprivational dwarfism
(2) Chronic illness
(3) Prematurity
(4) Hypothyroidism

Craniosynostosis

= CRANIOSTENOSIS = premature closure of sutures (closing normally at about 30 years of age)

Age: often present at birth; M÷F = 4÷1

Etiology:

A. PRIMARY CRANIOSYNOSTOSIS

B. SECONDARY CRANIOSYNOSTOSIS
(a) hematologic: sickle cell anemia, thalassemia

(b) metabolic: rickets, hypercalcemia, hyperthyroidism, hypervitaminosis D
(c) bone dysplasia: hypophosphatasia, achondroplasia, metaphyseal dysplasia, mongolism, Hurler disease, skull hyperostosis, Rubinstein-Taybi syndrome
(d) syndromes: Crouzon, Apert, Carpenter, Treacher-Collins, cloverleaf skull, craniotelencephalic dysplasia, arrhinencephaly
(e) microcephaly: brain atrophy / dysgenesis
(f) after shunting procedures

Types:

Sagittal suture most commonly affected followed by coronal suture

1. **Scaphocephaly** = Dolichocephaly (55%): premature closure of sagittal suture (long skull)
2. **Brachycephaly** = Turricephaly (10%): premature closure of coronal / lambdoid sutures (short tall skull)
3. **Plagiocephaly** (7%): unilateral early fusion of coronal + lambdoidal suture (lopsided skull)
4. **Trigonocephaly**: premature closure of metopic suture (forward pointing skull)
5. **Oxycephaly= Acrocephaly**: premature closure of coronal, sagittal, lambdoid sutures (conical skull); most severe form of craniosynostosis
6. **Cloverleaf skull** = Kleeblattschädel: intrauterine premature closure of sagittal, coronal, lambdoid sutures (3-fold bulging skull)

May be associated with: thanatophoric dysplasia

√ sharply defined thickened sclerotic suture margins
√ delayed growth of BPD in early pregnancy

Wormian Bones

[Ole Worm (1558–1654), Professor of Anatomy, Copenhagen]
= intrasutural ossicles in posterior sutures (lambdoid, posterior sagittal, temporosquamosal), normal up to 6 months of age (most frequently)

With > 10 wormian bones an underlying pathologic process should be considered.

mnemonic: PORK CHOPS I

Pyknodysostosis
Osteogenesis imperfecta
Rickets in healing phase
Kinky hair syndrome
Cleidocranial dysostosis
Hypothyroidism / Hypophosphatasia
Otopalatodigital syndrome
Primary acroosteolysis (Hajdu-Cheney) / **P**achydermoperiostosis / **P**rogeria
Syndrome of Down
Idiopathic (normal variant)

Increased Skull Thickness

A. GENERALIZED
1. Chronic severe anemia (eg, thalassemia, sickle cell dz)

2. Cerebral atrophy following shunting of hydrocephalus
3. Engelmann disease: mainly skull base
4. Hyperparathyroidism
5. Acromegaly
6. Osteopetrosis

B. FOCAL
1. Meningioma
2. Fibrous dysplasia
3. Paget disease
4. Dyke-Davidoff-Mason syndrome
5. **Hyperostosis frontalis interna** = dense hyperostosis of inner table of frontal bone; M < F

mnemonic: HIPFAM
Hyperostosis frontalis interna
Idiopathic
Paget disease
Fibrous dysplasia
Anemia (sickle cell disease, iron deficiency, thalassemia, spherocytosis)
Metastases

Hair-on-end Skull

mnemonic: HI NEST
Hereditary spherocytosis
Iron deficiency anemia
Neuroblastoma
Enzyme deficiency: glucose-6-phosphate dehydrogenase deficiency → hemolytic anemia
Sickle cell disease
Thalassemia major

Leontiasis Ossea

= overgrowth of facial bones causing leonine (lionlike) facies
1. Fibrous dysplasia
2. Paget disease
3. Craniometaphyseal dysplasia
4. Hyperphosphatasia

Abnormally Thin Skull

A. GENERALIZED
1. Obstructive hydrocephalus
2. Cleidocranial dysostosis
3. Progeria
4. Rickets
5. Osteogenesis imperfecta
6. Craniolacunia

B. FOCAL
   1. Neurofibromatosis
   2. Chronic subdural hematoma
   3. Arachnoid cyst

Inadequate Calvarial Calcification

1. Achondroplasia
2. Osteogenesis imperfecta
3. Hypophosphatasia

Osteolytic Lesion of Skull

A. NORMAL VARIANT
   1. **Emissary vein**
      connecting venous systems inside + outside of skull
      √ bony channel < 2 mm in width
   2. **Venous lake**
      = outpouching of diploic vein
      √ extremely variable in size, shape, and number
      √ irregular well-demarcated contour
   3. **Fossae lacunae** = pacchionian granulations
      = agglomeration of hypertrophic arachnoid villi communicating with dural sinus
      Age: > 18 months; usually adulthood
      √ usually multiple "punched-out" lesions with irregular contour in parasagittal location
      Location: within 3 cm of superior sagittal sinus, anterior > posterior frontal bone
      Site: inner table > diploe > outer table
   4. **Parietal foramina**
      nonossification of embryonal rests in parietal fissure; bilateral at superior posterior angles of parietal bone; hereditary transmission

B. TRAUMA
   1. Surgical burr hole
   2. Leptomeningeal cyst

C. INFECTION
   1. Osteomyelitis
   2. Hydatid disease
   3. Syphilis
   4. Tuberculosis

D. CONGENITAL
   1. Epidermoid / dermoid
   2. Neurofibromatosis (asterion defect)
   3. Meningoencephalocele
   4. Fibrous dysplasia
   5. Osteoporosis circumscripta of Paget disease

E. BENIGN TUMOR
   1. Hemangioma

2. Enchondroma
3. Brown tumor
4. Eosinophilic granuloma

F. MALIGNANT TUMOR
1. Solitary / multiple metastases
2. Multiple myeloma
3. Leukemia
4. Neuroblastoma

Solitary Lytic Lesion in Skull

mnemonic: HELP MFT HOLE

Hemangioma
Epidermoid / dermoid
Leptomeningeal cyst
Postop, **P**aget disease
Metastasis, **M**yeloma
Fibrous dysplasia
Tuberculosis
Hyperparathyroidism
Osteomyelitis
Lambdoid defect (neurofibromatosis)
Eosinophilic granuloma

Multiple Lytic Lesions in Skull

mnemonic: BAMMAH

Brown tumor
AVM
Myeloma
Metastases
Amyloidosis
Histiocytosis

Lytic Area in Bone Flap

mnemonic: "RATI"

Radiation necrosis
Avascular necrosis
Tumor
Infection

Button Sequestrum

mnemonic: TORE ME

Tuberculosis
Osteomyelitis
Radiation
Eosinophilic granuloma
Metastasis

Epidermoid

Absent Greater Sphenoid Wing

mnemonic: M FOR MARINE

Meningioma
Fibrous dysplasia
Optic glioma
Relapsing hematoma
Metastasis
Aneurysm
Retinoblastoma
Idiopathic
Neurofibromatosis
Eosinophilic granuloma

Absence of Innominate Line

= OBLIQUE CAROTID LINE
= vertical line projecting into orbit (on PA skull film) produced by orbital process of sphenoid

A. CONGENITAL
   1. Fibrous dysplasia
   2. Neurofibromatosis
B. INFECTION
C. TUMOR

Widened Superior Orbital Fissure

mnemonic: A FAN

Aneurysm (internal carotid artery)
Fistula (cavernous sinus)
Adenoma (pituitary)
Neurofibroma

Tumors of Central Skull Base

A. DEVELOPMENTAL
   1. Encephalocele
B. INFECTION / INFLAMMATION
   1. Extension from paranasal sinus / mastoid infection
   2. Complication of trauma
   3. Fungal disease: mucormycosis in diabetic, aspergillosis in immunosuppressed patient
   4. Sinus + nasopharyngeal sarcoidosis
   5. Radiation necrosis
C. BENIGN
   1. Juvenile angiofibroma
   2. Meningioma
   3. Chordoma

4. Pituitary tumor
5. Paget disease
6. Fibrous dysplasia

D. MALIGNANT
1. Metastasis: prostate, lung, breast
2. Chondrosarcoma
3. Nasopharyngeal carcinoma
4. Rhabdomyosarcoma
5. Perineural tumor spread: head + neck neoplasm

Craniofacial Syndromes

= developmental malformations of the face + skull associated with CNS malformations

1. Midfacial clefts
2. Goldenhar syndrome
3. Apert syndrome
4. Crouzon syndrome
5. Treacher-Collins syndrome

MAXILLA AND MANDIBLE

Attenuation (lytic / sclerotic / mixed / ground-glass attenuation), margination (narrow / wide transition zone), and relationship to adjacent teeth determine the radiologic diagnosis of jaw lesions.

Maxillary Hypoplasia

1. Down syndrome
2. Drugs (alcohol, dilantin, valproate)
3. Apert / Crouzon syndrome
4. Achondroplasia
5. Cleft lip / palate

Mandibular Hypoplasia = Micrognathia

A. WITH ABNORMAL EARS
1. Treacher-Collins syndrome
2. Goldenhar syndrome (hemifacial microsomia) = facioauriculovertebral spectrum (x-rays of vertebrae!)
3. Langer-Giedion syndrome (IUGR, protruding ears)

B. ABNORMALITIES OF EARS + OTHER ORGANS
1. Miller syndrome (severe postaxial hand anomalies)
2. Velocardiofacial syndrome (hand + cardiac lesions)
3. Otopalatodigital syndrome - type II (hand abnormalities)
4. Stickler syndrome (ear anomalies not severe)
5. Pierre-Robin syndrome (large fleshy ears)

C. NO EAR ANOMALIES
1. Pyknodysostosis

D. OTHERS

1. Seckel syndrome (bird-headed dwarfism)
2. Multiple pterygium syndrome
3. Pena-Shokeir syndrome
4. Beckwith-Wiedemann syndrome
5. Arthrogryposis
6. Skeletal dysplasias
7. Trisomy 13, 18, 9 (abnormal karyotype in 25%)

Destruction of Temporomandibular Joint

mnemonic: HIRT

Hyperparathyroidism
Infection
Rheumatoid arthritis
Trauma

Mandibular Lesion by Location

A. Anterior mandible
   1. Adenomatoid odontogenic tumor
   2. Periapical cemental dysplasia
   3. Florid cemento-osseous dysplasia
   4. Central giant cell granuloma
   5. Odontoma
B. Posterior mandible
   1. Follicular (dentigerous) cyst
   2. Odontogenic keratocyst
   3. Solitary bone cyst
   4. Ameloblastoma
   5. Cementoblastoma
   6. Ossifying fibroma
   7. Ameloblastic carcinoma
   8. Stafne cyst
   9. Metastasis
C. Nonspecific location
   1. Periapical (radicular) cyst

Odontogenic Lesion Of Impacted 3rd Molar Tooth

1. Dentigerous cyst (93%)
2. Odontogenic keratocyst (7%)
3. Ameloblastoma (0.41%)

Solid Benign Lesion of Jaw

Primary Odontogenic Tumor of Jaw

1. Odontoma
2. Ameloblastoma = Adamantinoma of Jaw
3. Odontogenic Myxoma

4. Calcifying Epithelial Odontogenic Tumor
5. Cementoblastoma
6. Ameloblastic fibroma
7. Adenomatoid odontogenic tumor

Primary Nonodontogenic Tumor of Jaw

1. Ossifying fibroma
2. Cemento-osseous dysplasia

Prevalence of Solid Benign Mandibular Lesions

A. Most common
   1. Odontoma
B. Fairly common
   1. Ameloblastoma
   2. Periapical cemento-osseous dysplasia
   3. Florid cemento-osseous dysplasia
   4. Ossifying fibroma
C. Less common
   1. Calcifying epithelial odontogenic (Pindborg) tumor
   2. Ameloblastic fibroma
   3. Odontogenic myxoma
   4. Cementoblastoma
D. Rare
   1. Adenomatoid odontogenic tumor
   2. Juvenile ossifying fibroma
   3. Clear cell odontogenic tumor
   4. Squamous odontogenic tumor
   5. Calcifying odontogenic cyst

Vascular Lesion of Jaw

1. Central giant cell granuloma
2. Brown tumor of hyperparathyroidism
3. Arteriovenous Malformation of jaw

Solid Malignant Lesion of Jaw

1. Odontogenic Carcinoma
   = rare aggressive intraosseous lesion
   Histo: poorly differentiated epithelial + clear cells
   √ diffuse honeycomb-like radiolucent lesion
   √ surrounding cortical destruction
   Prognosis: high rate of recurrence
2. Ameloblastic Carcinoma
   = malignant ameloblastoma
   √ aggressive features of cortical destruction, extraosseous extension, extensive solid components
3. Sarcoma

Histo: osteo~, chondro~, fibro~, leiomyosarcoma
√ symmetrically widened periodontal membrane in a single tooth (earliest sign of osteogenic sarcoma of mandible)

4. Mucoepidermoid Carcinoma
   ◊ typically originate from minor salivary glands of buccal mucosa
5. Lymphoma / leukemia
6. Multiple Myeloma
   • may present with chin numbness ← involvement of inferior alveolar nerve

Prevalence of Solid Malignant Mandibular Lesions

A. Most common
   1. Squamous cell carcinoma arising from adjacent mucosa
B. Fairly common
   1. Multiple myeloma, plasmacytoma
   2. Lymphoma, leukemia
   3. Metastasis
   4. Mucoepidermoid carcinoma arising from adjacent mucosa
   5. Adenoid cystic carcinoma arising from adjacent mucosa
C. Rare
   1. Nonodontogenic sarcoma
   2. Odontogenic carcinoma
   3. Odontogenic sarcoma
   4. Odontogenic carcinosarcoma

Sclerotic Lesion of Jaw

Sclerotic Tooth-Related Jaw Lesion

1. Cementoblastoma
2. Cemento-osseous dysplasia
3. Condensing osteitis
4. Odontoma
5. Idiopathic osteosclerosis
6. **Hypercementosis**
   = bulbous enlargement of a root
   (a) idiopathic
   (b) associated with Paget disease

Sclerotic Non–Tooth-Related Jaw lesion

1. Osteoma
2. Torus = exostosis
3. Benign fibro-osseous lesions
   (a) Ossifying fibroma: young adult; mandible > maxilla
   (b) Monostotic fibrous dysplasia: M < F; younger patient
   √ near apex of nonvital tooth
4. Paget disease
   involvement of jaw in 20%; maxilla > mandible

Location: bilateral, symmetric involvement
√ widened alveolar ridges
√ flat palate
√ loosening of teeth
√ hypercementosis
√ may cause destruction of lamina dura

5. Sclerosing metastasis / multiple myeloma

Jaw Lesion with Ground-glass Attenuation

(a) diffuse
1. Renal osteodystrophy
2. Fibrous dysplasia

(b) multifocal
1. Florid cemento-osseous dysplasia
2. Multiple ossifying fibromas
3. Brown tumor of HPT

(c) unifocal jaw lesion with ground-glass attenuation
(1) Ossifying fibroma
Path: osteoblastic rim
√ narrow zone of transition
(2) Monostotic fibrous dysplasia
√ wide zone of transition
√ longitudinal growth pattern
√ nondisplaced teeth

PERIAPICAL SCLEROTIC LESION WITH PERIAPICAL HALO

1. Cementoblastoma
2. Cemento-osseous dysplasia

Mixed Lytic and Sclerotic Jaw Lesion

1. Osteoradionecrosis
Vulnerability: mandible > maxilla buccal > lingual cortex
◊ Chin + angle of mandible spared ← muscle insertions
√ area of marked osteosclerosis
√ loss of trabeculation in spongiosa
√ cortical interruptions + fragmentation
√ poorly marginated areas of soft-tissue attenuation + fluid collections + gas attenuation
√ sequestration
2. Biphosphonate-related osteonecrosis of jaw (BRONJ)
3. Mandibular osteomyelitis
Cause: caries, extractions, fracture, osteoradionecrosis
√ cortical interruption
√ sclerotic sequestra in low-attenuation zones
√ periosteal new bone formation
√ areas of gas attenuation
4. Primary chronic osteomyelitis

Age peak: childhood and > 50 years
- insidious jaw swelling, normal mucosa, vital teeth
- absence of fever + leukocytosis

√ poorly marginated lesion with progressive sclerosis
√ scattered osteolysis + bone expansion
√ "onion skin" periosteal reaction

Radiolucent Lesion of Mandible

Sharply Marginated Radiolucent Lesion of Mandible

A. around apex of tooth
   1. Radicular cyst
   2. Cementoma

B. around unerupted tooth
   1. Dentigerous cyst
   2. Ameloblastoma

C. unrelated to tooth
   1. Simple bone cyst
   2. Fong disease
   3. Basal cell nevus syndrome

DDx: (1) Early cemento-osseous dysplasia
(2) Early ossifying fibroma

Poorly Marginated Radiolucent Lesion of Mandible

√ "floating teeth": suggestive of primary / secondary malignancy
√ resorption of tooth root: hallmark of benign process

A. INFECTION

Cause: mostly dental caries → irreversible pulpitis → periapical cyst → granuloma → abscess

1. Apical periodontitis
   √ thickened periodontal ligament space (earliest sign of the cystic form)
   √ contrast-enhancing rim around abscess
2. Osteomyelitis
   = infection of bone and marrow
   √ focal / diffuse radiolucent / radiopaque lesion

B. RADIOTHERAPY

1. Osteoradionecrosis
   √ scattered sclerotic + lytic lesion
   √ enlarged trabecular spaces
   √ sequestered bone

C. MALIGNANT NEOPLASM

1. Osteosarcoma (⅓ lytic, ⅓ sclerotic, ⅓ mixed)
2. Local invasion from gingival / buccal neoplasms (more common)
3. Metastasis from breast, lung, kidney in 1% (in 70% adenocarcinoma)
   Location: posterior body and angle ← increased marrow vascularity

D. OTHER
1. Eosinophilic granuloma: "floating tooth"
2. Fibrous dysplasia
3. Osteocementoma
4. Ossifying fibroma (very common)

Cystic Lesion of Jaw

1. **Periapical cyst = Radicular cyst**

◊ Most common cyst of the jaw

Cause: periapical inflammatory lesion ← pulpal necrosis in deep carious lesion / deep filling / trauma

Age: 30–50 years

Pathogenesis: secondary apical periodontitis → granuloma → abscess → cyst

Site: intimately associated with apex of nonvital tooth

√ round / pear-shaped unilocular well-defined periapical lucent lesion, usually < 1 cm in diameter

√ bordered by thin sclerotic rim of cortical bone

√ ± displacement of adjacent teeth

√ ± mild root resorption

Cx: root canal therapy, tooth extraction, surgery (creation of mucoperiosteal flap over tooth apex)

DDx: periapical granuloma, periapical abscess

2. **Dentigerous cyst = follicular cyst**

◊ Most common type of noninflammatory developmental odontogenic cyst

Path: epithelial-lined cyst from odontogenic epithelium developing around crown of an unerupted tooth

Histo: fluid collection between follicular epithelium and crown of tooth

Age: 30–40 years

• typically painfree

Location: mandible, maxilla (may expand into maxillary sinus)

Site: around crown of unerupted tooth (usually 3rd molar)

√ expansile cystic pericoronal lesion containing the crown of an impacted tooth projecting into cystic cavity (PATHOGNOMONIC)

√ roots of tooth often outside lesion

√ well-defined round / ovoid corticated lucent lesion ± mandibular remodeling rather than expansion

Cx: may degenerate into mural ameloblastoma (rare)

DDx: unilocular odontogenic keratocyst

3. **Odontogenic keratocyst** (OKC)

Origin: dental lamina + other sources of odontogenic epithelium

Prevalence: 5–15% of all jaw cysts

Age: 2nd–4th decade

Associated with: basal cell nevus (Gorlin-Goltz) syndrome if OKC multiple

Path: daughter cysts + nests of cystic epithelia in vicinity (high rate of recurrence)

Histo: parakeratinized lining epithelium + "cheesy" material in lumen of lesion

Location: body + ramus of mandible (most often); may be anywhere in mandible / maxilla
√ unilocular lucent lesion with smooth corticated border
√ often associated with impacted tooth
√ ± undulating borders / multilocular appearance (daughter cysts)
√ ± cortical thinning / erosion, tooth displacement, root resorption
Prognosis: high recurrence rate after resection
DDx: indistinguishable from dentigerous cyst (no cortical erosion or expansion) / ameloblastoma

4. **Primordial cyst**
arising from follicle of tooth that never developed
Cause: dental follicle undergoes cystic degeneration
√ well-defined radiolucent nonexpansile lesion

5. **Stafne Cyst**
= Static bone cavity = LINGUAL SALIVARY GLAND INCLUSION DEFECT
= well-defined depression in lingual surface of mandible
Path: cavity filled with fat ± aberrant submandibular gland tissue
• asymptomatic
Location: posterior mandible, usually near mandibular angle
Site: just above inferior border of mandible, anterior to angle of jaw, inferior to mandibular canal, posterior to 3rd molar
√ oval / round / rectangular well-defined radiolucent lesion within cortical defect
√ typically < 2 cm
√ border surrounded by an opaque line
√ may extend to buccal cortex
DDx: arteriovenous malformation

6. **Solitary bone cyst**
= TRAUMATIC BONE CYST = SIMPLE BONE CYST = HEMORRHAGIC BONE CYST
= not a true cyst for lack of epithelial lining
Pathogenesis: trauma → intramedullary hemorrhage → resorption
Age: 2nd decade
• asymptomatic
Location: marrow space of posterior mandible
√ unilocular sharply marginated lucent defect
√ CHARACTERISTIC scalloped superior margin with fingerlike projections extending between roots of adjacent teeth
√ ± thinning of mandibular cortex ± osseous expansion
DDx: vascular lesion, central giant cell granuloma, ossifying fibroma

7. Residual cyst
= any cyst that remains after surgical intervention

Periapical Lucency

1. Periapical cyst
2. Periapical cemento-osseous dysplasia
3. Hyperparathyroidism

4. Langerhans cell histiocytosis
5. Odontogenic keratocyst
6. Leukemia / lymphoma

Prevalence of Cystic Mandibular Lesion of Jaw

A. Most common
   1. Periapical (radicular) cyst
   2. Follicular (dentigerous) cyst)
B. Fairly Common
   1. Odontogenic keratocyst
   2. Stafne cyst
   3. Solitary bone cyst
C. Rare
   1. Aneurysmal bone cyst
   2. Calcifying odontogenic cyst
D. Lesions radiolucent ONLY early in their development

> Periapical inflammatory lesions are entirely radiolucent. So are early ossifying fibromas or early cemento-osseous dysplasia (the latter associated with a vital tooth + intact lamina dura ± central calcifications)

   1. Cemento-osseous dysplasia
   2. Ossifying fibroma (= pure osteoid matrix)

UNILOCULAR CYSTIC LESION OF JAW

1. Radicular cyst: surrounding apex of infected tooth
2. Dentigerous cyst: adjacent to unerupted tooth

CRANIOVERTEBRAL JUNCTION

Craniovertebral Junction Anomaly

mnemonic: PF ROACH

Paget disease
Fibrous dysplasia
Rheumatoid arthritis, **R**ickets
Osteogenesis imperfecta, **O**steomalacia
Achondroplasia
Cleidocranial dysostosis, **C**hiari malformation
Hyperparathyroidism

Cx: compression of brainstem
(a) → aqueductal stenosis → hydrocephalus
(b) → cord edema, syrinx

Rx: surgical decompression of posterior cranial fossa / foramen magnum (posterior approach); resection of odontoid (anterior approach)

Basilar Invagination

= congenital primary developmental anomaly with abnormally high position of vertebral

column prolapsing into skull base ← bone softening

Associated with: Chiari malformation, syringohydromyelia in 25–35%

Cause: mnemonic: MACKO

Mucopolysaccharidosis
Achondroplasia
Cleidocranial dysostosis
Klippel-Feil syndrome
Osteogenesis imperfecta

• limitation in range of motion of CVJ

√ abnormal craniometry:

1. Condylus tertius = ossicle at distal end of clivus
   √ pseudojoint with odontoid process / anterior arch of C1
2. Condylar hypoplasia
   √ lateral masses of atlas may be fused to condyles
   √ violation of Chamberlain line
   √ widening of atlanto-occipital joint axis angle
   √ tip of odontoid > 10 mm above bimastoid line
3. Basiocciput hypoplasia
   √ shortening of clivus
   √ violation of Chamberlain line
   √ clivus-canal angle typically decreased
4. Atlanto-occipital assimilation
   = complete / partial failure of segmentation between skull + 1st cervical vertebra
   √ violation of Chamberlain line
   √ clivus-canal angle decreased
   May be associated with: fusion of C2 + C3
   Cx: atlantoaxial subluxation (50%); sudden death

√ C-spine + foramen magnum bulge into cranial cavity

√ elevation of posterior arch of C1

Basilar Impression

= acquired form of basilar invagination with bulging of C-spine and foramen magnum into cranial cavity with normal bone

√ tip of odontoid process protrudes upward through foramen magnum into cranium = projects > 5 mm above Chamberlain line (= line between hard palate + opisthion)

Cause: mnemonic: HORRIFic P

Hyperparathyroidism
Osteomalacia
Rickets
Rheumatoid arthritis
Infection of skull base
Fibrous dysplasia
Paget disease

Platybasia

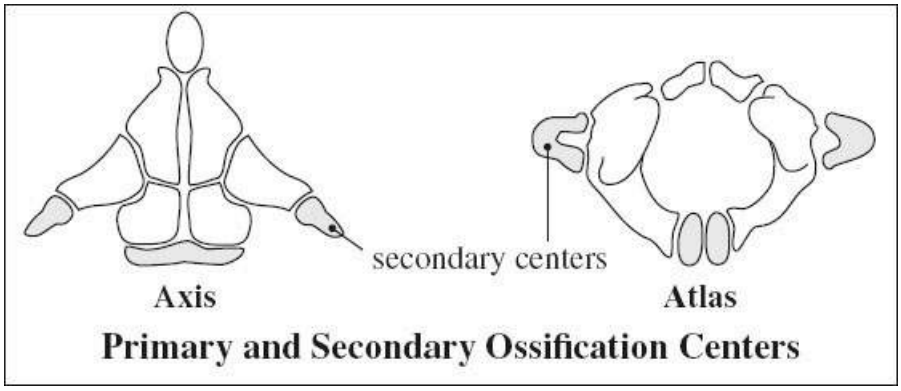
= anthropometric term referring to flattening of skull base
May be associated with: basilar invagination
• cord symptoms
√ craniovertebral = clivus-canal angle becomes acute (< 150°)
√ Welcher basal angle = sphenoid angle > 140–145°
√ bowstring deformity of cervicomedullary junction

ATLAS AND AXIS

Atlas Anomalies

A. POSTERIOR ARCH ANOMALIES
1. Posterior atlas arch rachischisis (4%)
Location: midline (97%); lateral through sulcus of vertebral artery (3%)
√ absence of arch-canal line (LAT view)
√ superimposed on odontoid process / axis body simulating a fracture (open-mouth odontoid view)
2. Total aplasia of posterior atlas arch
3. Keller-type aplasia with persistence of posterior tubercle
4. Aplasia with uni- / bilateral remnant + midline rachischisis
5. Partial / total hemiaplasia of posterior arch

B. ANTERIOR ARCH ANOMALIES
1. Isolated anterior arch rachischisis (0.1%)
2. Split atlas = anterior + posterior arch rachischisis
√ plump rounded anterior arch overlapping the odontoid process making identification of predental space impossible (LAT view)
√ duplicated anterior margins (LAT view)



Primary and Secondary Ossification Centers

Axis Anomalies

1. Persistent ossiculum terminale = Bergman ossicle
√ unfused odontoid process > 12 years of age
DDx: type 1 odontoid fracture
2. Odontoid aplasia (extremely rare)
3. Os odontoideum
= independent os cephalad to axis body in location of odontoid process

√ absence of odontoid process
√ anterior arch of atlas hypertrophic + situated too far posterior in relation to axis body
Cx: atlantoaxial instability
DDx: type 2 odontoid fracture (uncorticated margin)

Odontoid Erosion

mnemonic: P LARD
Psoriasis
Lupus erythematosus
Ankylosing spondylitis
Rheumatoid arthritis
Down syndrome

Atlantoaxial Subluxation

= displacement of atlas with respect to axis
(1) Posterior atlantoaxial subluxation (rare)
(2) Anterior atlantoaxial subluxation (common)
= distance between dens + anterior arch of C1 (measurement along midplane of atlas on lateral view):
(a) predental space: > 2.5 mm > 4.5 mm (in children)
(b) retrodental space: < 18 mm

Causes of subluxation:

A. Congenital
1. Occipitalization of atlas
0.75% of population; fusion of basion + anterior arch of atlas
2. Congenital insufficiency of transverse ligament
3. Os odontoideum / aplasia of dens
4. Down syndrome (20%)
5. Morquio syndrome
6. Bone dysplasia

B. Arthritis
due to laxity of transverse ligament or erosion of dens
1. Rheumatoid arthritis
2. Psoriatic arthritis
3. Reiter syndrome
4. Ankylosing spondylitis
5. SLE
rare: in gout + CPPD

C. Inflammatory process
pharyngeal infection in childhood, retropharyngeal abscess, coryza, otitis media, mastoiditis, cervical adenitis, parotitis, alveolar abscess
√ dislocation 8–10 days after onset of symptoms

D. Trauma (very rare without odontoid fracture)

E. Marfan disease

mnemonic: JAP LARD

Juvenile rheumatoid arthritis
Ankylosing spondylitis
Psoriatic arthritis
Lupus erythematosus
Accident (trauma)
Retropharyngeal abscess, **R**heumatoid arthritis
Down syndrome

Pseudosubluxation of Cervical Spine

= ligamentous laxity in infants allows for movement of the vertebral bodies on each other, esp. C2 on C3

SPINAL DYSRAPHISM

= abnormal / incomplete fusion of midline embryologic mesenchymal, neurologic, bony structures

External signs (in 50%):

- subcutaneous lipoma
- hypertrichosis
- pigmented nevi
- pathologic plantar response
- bladder + bowel dysfunction
- spastic gait disturbance
- foot deformities
- absent tendon reflexes
- sinus tract
- skin dimple

Spina Bifida

= incomplete closure of bony elements of the spine (lamina + spinous processes) posteriorly

Spina Bifida Occulta

= OCCULT SPINAL DYSRAPHISM

= cleft / tethered cord WITH skin cover

Frequency: 15% of spinal dysraphism

- rarely leads to neurologic deficit in itself

Associated with:

(a) vertebral defect (85 – 90%)

(b) lumbosacral dermal lesion (80%):

- hairy tuft (= hypertrichosis), dimple, sinus tract, nevus, hyperpigmentation, hemangioma, subcutaneous mass

1. Diastematomyelia
2. Lipomeningocele
3. Tethered cord syndrome
4. Filum terminale lipoma
5. Intraspinal dermoid

6. Epidermoid cyst
7. Myelocystocele
8. Split notochord syndrome
9. Meningocele
10. Dorsal dermal sinus
11. Tight filum terminale syndrome

Spina Bifida Aperta

= SPINA BIFIDA CYSTICA

= posterior protrusion of all / parts of the contents of the spinal canal through a bony spinal defect

Frequency: 85% of spinal dysraphism

Associated with: hydrocephalus, Arnold-Chiari II malformation

◊ Most severe form of midline fusion defect

• neural placode WITHOUT skin cover

Associated with: neurologic deficit in > 90%

1. Simple meningocele
   = herniation of CSF-filled sac without neural elements
2. Myelocele
   = midline plaque of neural tissue lying exposed at the skin surface
3. Myelomeningocele
   = a myelocele elevated above skin surface by expansion of subarachnoid space ventral to neural plaque
4. Myeloschisis
   = surface presentation of neural elements completely uncovered by meninges

Caudal Spinal Anomalies

= malformation of distal spine and cord

Associated with: hindgut, renal, genitourinary anomalies

1. Terminal myelocystocele
2. Lateral meningocele
3. Caudal regression

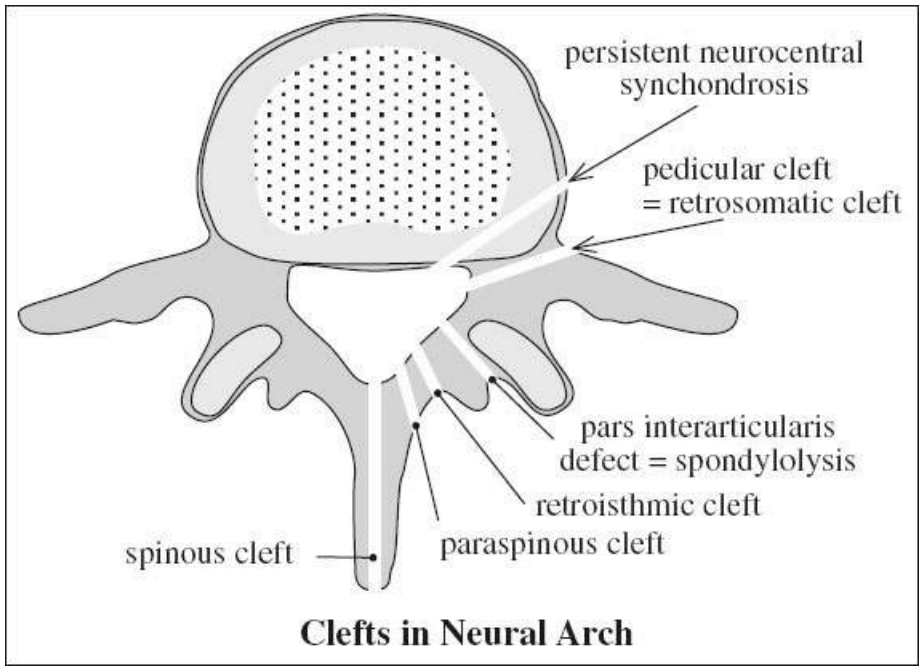
Segmentation Anomalies of Vertebral Bodies

during 9th–12th week of gestation two ossification centers form for the ventral + dorsal half of vertebral body

1. **Asomia** = agenesis of vertebral body
   √ complete absence of vertebral body
   √ hypoplastic posterior elements may be present
2. **Hemivertebra**
   (a) Unilateral wedge vertebra
   √ right / left hemivertebra
   √ scoliosis at birth
   (b) Dorsal hemivertebra
   √ rapidly progressive kyphoscoliosis

(c) Ventral hemivertebra (extremely rare)

3. **Coronal cleft**
   = failure of fusion of anterior + posterior ossification centers
   May be associated with: premature male infant, Chondrodystrophia calcificans congenita
   Location: usually in lower thoracic + lumbar spine
   √ vertical radiolucent band just behind midportion of vertebral body; disappears mostly by 6 months of life
4. **Butterfly vertebra**
   = failure of fusion of lateral halves ← persistence of notochordal tissue
   May be associated with: anterior spina bifida ± anterior meningocele
   √ widened vertebral body with butterfly configuration (AP view)
   √ adaptation of vertebral endplates of adjacent vertebral bodies
5. **Block vertebra**



Clefts in Neural Arch

   = congenital vertebral fusion
   Location: lumbar / cervical
   √ height of fused vertebral bodies equals the sum of heights of involved bodies + intervertebral disk
   √ "waist" at level of intervertebral disk space
6. Hypoplastic vertebra
7. Klippel-Feil syndrome

VERTEBRAL BODY

Increased T1 Signal Intensity of Spinal Bone Marrow

= mostly benign

A. FOCAL

1. Hemangioma (11%)
2. Modic type 2 endplate changes
3. Lipoma
4. Paget disease (later stage)
5. Hemorrhage (with fracture)
6. Melanoma

B. DIFFUSE / multifocal
1. Normal variant
2. S/P radiation treatment
3. Osteoporosis
4. Multiple hemangiomas
5. Spondyloarthritis
6. Anorexia nervosa

Decreased T1 Signal Intensity of Spinal Bone Marrow

= equal to / lower than SI of muscle

A. CENTERED ON ENDPLATE
1. Modic type 1 + 3 endplate changes
2. Osteomyelitis
3. Amyloid

B. CENTERED IN VERTEBRAL BODY
1. Malignancy (metastasis, lymphoma, plasma cell dyscrasia, solitary plasmacytoma, multiple myeloma)
2. Fracture
3. Hemangioma (rare presentation)
4. Fibrous dysplasia

C. CENTERED IN POSTERIOR ELEMENTS METASTASES, MYELOMA, LYMPHOMA, FRACTURE, PRIMARY BONE TUMOR

D. DIFFUSE / MULTIFOCAL
1. Hematopoietic hyperplasia
   (a) chronic anemia: sickle cell disease, thalassemia, hereditary spherocytosis
   (b) chronic illness: HIV
   (c) heavy smoking
   (d) obesity
   (e) drugs: granulocyte-colony-stimulating factor, erythropoietin
2. Neoplasm
   √ avid enhancement
3. Renal osteodystrophy
4. Systemic inflammation: sarcoidosis, gout, spondyloarthropathy
4. Hematologic malignancy: myelofibrosis. mastocytosis

Destruction of Vertebral Body

A. NEOPLASM
1. Metastasis
2. Primary neoplasm: chordoma, chondrosarcoma, lymphoma, multiple myeloma

B. INFECTION
1. Pyogenic vertebral osteomyelitis
2. Tuberculous spondylitis
3. Brucellosis
4. Fungal disease
5. Echinococcosis
6. Sarcoidosis

Granulomatous Spondylitis
1. TB
2. Brucellosis
3. Sarcoidosis

Gas in Vertebral Body
1. Osteonecrosis = Kümmell disease
   √ linear collection
2. Osteomyelitis
   √ small gas bubbles ± extension into adjacent soft-tissues
3. Intraosseous displacement of cartilaginous / Schmorl node
   √ branching gas pattern
4. Malignancy

Small Vertebral Body
1. Radiation therapy
   during early childhood in excess of 1,000 rad
2. Juvenile rheumatoid arthritis
   Location: cervical spine
   √ atlantoaxial subluxation may be present
   √ vertebral fusion may occur
3. Eosinophilic granuloma
   Location: lumbar / lower thoracic spine
   √ compression deformity / vertebra plana
4. Gaucher disease
   = deposits of glucocerebrosides within RES
   √ compression deformity
5. **Platyspondyly generalisata**
   = flattened vertebral bodies associated with many hereditary systemic disorders: achondroplasia, spondyloepiphyseal dysplasia tarda, mucopolysaccharidosis, osteopetrosis, neurofibromatosis, osteogenesis imperfecta, thanatophoric dwarfism
   √ disk spaces of normal height

Vertebra Plana
mnemonic: FETISH
Fracture (trauma, osteogenesis imperfecta)
Eosinophilic granuloma (Langerhans cell histiocytosis)
Tumor (metastatic neuroblastoma, myeloma, leukemia, aneurysmal bone cyst, Ewing

sarcoma)
Infection
Steroids (avascular necrosis)
Hemangioma

mnemonic: MELT
Metastasis / **M**yeloma
Eosinophilic granuloma
Lymphoma
Trauma / **T**B

SIGNS OF ACUTE VERTEBRAL COLLAPSE ON MR

1. Osteoporosis
   √ retropulsion of posterior bone fragment
2. Malignancy
   √ epidural soft-tissue mass
   √ no residual normal marrow signal intensity
   √ abnormal enhancement

Enlarged Vertebral Body

1. Paget disease
   √ "picture framing"; bone sclerosis
2. Gigantism
   √ increase in height of body + disk
3. Myositis ossificans progressiva
   √ bodies greater in height than width
   √ osteoporosis
   √ ossification of ligamentum nuchae

Enlarged Intervertebral Foramen

= NEUROFORAMINAL WIDENING = DUMBBELL-SHAPED / HOURGLASS LESION

A. SOLID BENIGN
   1. Benign peripheral nerve sheath tumor (PNST):
      › Neurofibroma
      › Neurilemmoma = schwannoma
   2. Meningioma
   3. Extradural cavernous hemangioma
   4. Congenital absence / hypoplasia of pedicle

B. SOLID MALIGNANT
   1. Metastatic destruction of pedicle: neuroblastoma
   2. Malignant PNST
   3. Ewing sarcoma / primitive neuroectodermal tumor
   4. Solitary bone plasmacytoma
   5. Chondrosarcoma

C. CYSTIC
   1. Dural ectasia (Marfan syndrome, Ehlers-Danlos syndrome)

2. Synovial cyst
3. Traumatic pseudomeningocele
4. Arachnoid cyst
5. Hydatid cyst

Cervical Spine Fusion

mnemonic: SPAR BIT

Senile hypertrophic ankylosis (DISH)
Psoriasis, **P**rogressive myositis ossificans
Ankylosing spondylitis
Reiter disease, **R**heumatoid arthritis (juvenile)
Block vertebra (Klippel-Feil)
Infection (TB)
Trauma

Vertebral Border Abnormality

Straightening of Anterior Border

1. Ankylosing spondylitis
2. Paget disease
3. Psoriatic arthritis
4. Reiter disease
5. Rheumatoid arthritis
6. Normal variant

Anterior Scalloping of Vertebrae

1. Aortic aneurysm
2. Lymphadenopathy
3. Tuberculosis
4. Multiple myeloma (paravertebral soft-tissue mass)

Posterior Scalloping of Vertebrae

in conditions associated with dural ectasia

A. INCREASED INTRASPINAL PRESSURE
    1. Communicating hydrocephalus
    2. Ependymoma
B. MESENCHYMAL TISSUE LAXITY (**dural ectasia**)
    1. Neurofibromatosis
    2. Marfan syndrome
    3. Ehlers-Danlos syndrome
    4. Posterior meningocele
C. BONE SOFTENING
    1. Mucopolysaccharidoses: Hurler, Morquio, Sanfilippo
    2. Achondroplasia
    3. Acromegaly (lumbar vertebrae)
    4. Ankylosing spondylitis (lax dura acting on osteoporotic vertebrae)

mnemonic: SALMON
Spinal cord tumor
Achondro**P**lasia
Mucopolysaccharidosis
Osteogenesis imperfecta
Neurofibromatosis

mnemonic: DAMN MALE SHAME
Dermoid
Ankylosing spondylitis
Meningioma
Neurofibromatosis
Marfan syndrome
Acromegaly
Lipoma
Ependymoma
Syringohydromyelia
Hydrocephalus
Achondroplasia
Mucopolysaccharidoses
Ehlers-Danlos syndrome

Bony Outgrowths from Vertebra

A. CHILDHOOD
1. Hurler syndrome = gargoylism
   √ rounded appearance of vertebral bodies
   √ mild kyphotic curve with smaller vertebral body at apex of kyphosis displaying tonguelike beak at anterior half (usually at T12 / L1)
   √ "step-off" deformities along anterior margins
2. Hunter syndrome
   less severe changes than in Hurler syndrome
3. Morquio disease
   √ flattened + widened vertebral bodies
   √ anterior "tonguelike" elongation of central portion of vertebral bodies
4. Hypothyroidism = cretinism
   √ small flat vertebral bodies
   √ anterior "tonguelike" deformity (in children only)
   √ widened disk spaces + irregular endplates

B. ADULTS
1. Spondylosis deformans
   √ osteophytosis along anterior + lateral aspects of endplates with horizontal + vertical course ← shearing of outer annular fibers (Sharpey fibers connecting annulus fibrosus to adjacent vertebral body)
2. Diffuse idiopathic skeletal hyperostosis (DISH)
   √ flowing calcifications + ossifications along anterolateral aspect of > 4 contiguous thoracic vertebral bodies ± osteophytosis

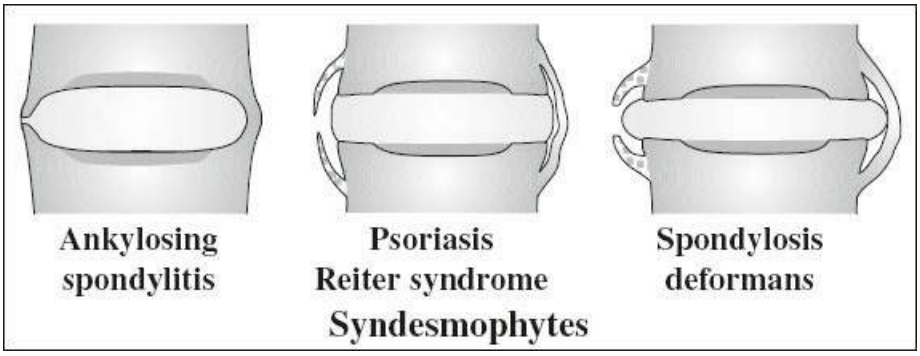
3. Ankylosing spondylitis
   √ bilateral symmetric syndesmophytes (= ossification of annulus fibrosus)
   √ "bamboo spine"
   √ "diskal ballooning" = biconvex intervertebral disks ← osteoporotic deformity of endplates
   √ straightening of anterior margins of vertebral bodies ← erosions
   √ ossification of paraspinal ligaments
4. Fluorosis
   √ vertebral osteophytosis + hyperostosis
   √ sclerotic vertebral bodies + kyphoscoliosis
   √ calcification of paraspinal ligaments
5. Acromegaly
   √ increase in anteroposterior diameter of vertebrae + concavity on posterior portion
   √ enlargement of intervertebral disk
6. Hypoparathyroidism
7. Neuropathic arthropathy
8. Sternoclavicular hyperostosis

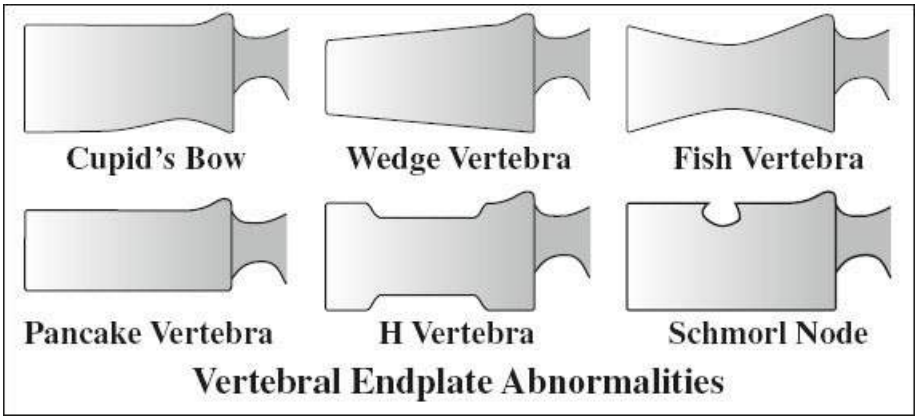
Spine Ossification

1. Syndesmophyte = ossification of annulus fibrosus
   √ thin slender vertical outgrowth extending from margin of one vertebral body to next
   Associated with: ankylosing spondylitis, ochronosis
2. Osteophyte
   = ossification of anterior longitudinal ligament
   √ initially triangular outgrowth several millimeters from edge of vertebral body
   Associated with: osteoarthritis
3. Flowing anterior ossification
   = ossification of disk, anterior longitudinal ligament, paravertebral soft tissues
   Associated with: DISH
4. Paravertebral ossification
   √ initially irregular / poorly defined paravertebral ossification eventually merging with vertebral body
   Associated with: psoriatic arthritis, Reiter syndrome

Vertebral Endplate Abnormality

1. Cupid's bow vertebra
   Cause: ? (normal variant)
   Location: 3rd–5th lumbar vertebra
   √ two parasagittal posterior concavities on inferior aspect of vertebral body (best viewed on AP)
2. Osteoporosis (senile / steroid-induced)
   (a) "fish vertebra / fish-mouth vertebra"





Cause: osteoporosis, osteomalacia, Paget disease, osteogenesis imperfecta, multiple myeloma, hyperparathyroidism, Gaucher disease

√ biconcave vertebra

√ bone sclerosis along endplates

(b) wedge-shaped vertebra

√ anterior border height reduced by > 4 mm compared to posterior border height

(c) "pancake" vertebra

√ overall flattening of vertebra

3. "H-vertebra"
   = compression of central portions ← subchondral infarcts
   Cause: sickle cell + other anemias, Gaucher disease
4. Schmorl / cartilaginous node
   = intraosseous herniation of nucleus pulposus at center of weakened endplate
   Cause: Scheuermann disease, trauma, hyperparathyroidism, osteochondrosis
5. Butterfly vertebra
   Cause: congenital defect
6. Limbus vertebrae
   = intraosseous herniation of disk material at junction of vertebral bony rim of centra + endplate (anterosuperior corner)
7. "Rugger-jersey spine"
   Cause: hyperparathyroidism, myelofibrosis
   √ horizontal sclerosis subjacent to vertebral endplates with intervening normal osseous density (resembling the stripes on rugby jerseys)

8. "Sandwich" / "Hamburger" vertebra
   Cause: osteopetrosis, myelofibrosis
   √ sclerotic endplates alternate with radiolucent midportions of vertebral bodies
9. "Ring" epiphysis

Ring Epiphysis

= normal small steplike recess at corner of anterior edge of developing vertebral body that calcifies ~ 6 years of age, ossifies ~ 13 years of age, and fuses with vertebral body ~ 17 years of age

1. Severe osteoporosis
2. Healing rickets
3. Scurvy

Bullet-shaped Vertebral Body

mnemonic: HAM

Hypothyroidism
Achondroplasia
Morquio syndrome

Bone-within-bone Vertebra

= "ghost vertebra" following stressful event during vertebral growth phase in childhood

1. Stress line of unknown cause
2. Leukemia
3. Heavy metal poisoning
4. Thorotrast injection, TB
5. Rickets
6. Scurvy
7. Hypothyroidism
8. Hypoparathyroidism

Ivory Vertebra

= increase in opacity of vertebral body retaining its size and contours

Cause: stimulation of osteoblasts, coarsening of trabeculae, reactive bone formation

(a) in adults:	metastasis (prostate, breast), lymphoma (Hodgkin disease), Paget disease, osteosarcoma, carcinoid
(b) in children:	Hodgkin disease >> osteosarcoma, metastatic neuroblastoma, medulloblastoma, osteoblastoma

mnemonic: LOST FROM CHOMP

Lymphoma
Osteopetrosis
Sickle cell disease
Trauma, **T**uberculous spondylitis
Fluorosis
Renal osteodystrophy
Osteoblastic metastasis

Myelosclerosis
Chronic sclerosing osteomyelitis, **C**hordoma
Hemangioma
Osteosarcoma
Myeloma
Paget disease

Sclerotic Pedicle

1. Osteoid osteoma
2. Unilateral spondylolysis
3. Contralateral congenitally absent pedicle

TUMOR OF VERTEBRA

Expansile Lesion of Vertebra

A. INVOLVEMENT OF MULTIPLE VERTEBRAE
Metastases, multiple myeloma / plasmacytoma, lymphoma, hemangioma, Paget disease, angiosarcoma, eosinophilic granuloma

B. INVOLVEMENT OF ≥ 2 CONTIGUOUS VERTEBRAE
Osteochondroma, chordoma, aneurysmal bone cyst, myeloma

C. BENIGN LESION

1. Osteochondroma (1–5% of solitary osteochondromas, 7–9% in hereditary multiple exostoses) commonly arising from posterior elements, esp. C2
2. Osteoblastoma (30–40% in spine)
M÷F = 2÷1; equal distribution in spine; posterior elements (lamina, pedicle), may involve body if large; expansile lesion with sclerotic / shell-like rim, foci of calcified tumor matrix in 50%; younger patient
3. Giant cell tumor (5–7% in spine)
commonly sacrum, expansile lytic lesion of vertebral body with well-defined borders; secondary invasion of posterior elements; malignant degeneration in 5–20% after radiation therapy
4. Osteoid osteoma (10–25% in spine)
commonly lower thoracic / upper lumbar spine, posterior elements (pedicle, lamina, spinous process)
   - younger patient
   - painful scoliosis with concavity toward lesion

   √ involvement of pedicle + lamina (in 63%)
   √ extending anteriorly affecting ⅓ to ⅔ of posterolateral vertebral body
   √ sparing of intervertebral disk space
   √ edema in neural arch at adjacent level possible
5. Aneurysmal bone cyst (12–30% in spine)
thoracic > lumbar > cervical spine, posterior elements with frequent extension into vertebral bodies, well-defined margins, may arise from primary bone lesion (giant cell tumor, fibrous dysplasia) in 50%, may involve two contiguous vertebrae
6. Hemangioma (30% in spine)

10% incidence in general population; commonly lower thoracic / upper lumbar spine, vertebral body, "accordion" / "corduroy" appearance

7. Hydatid cyst (1% in spine)
   slow-growing destructive lesion, well-defined sclerotic borders, endemic areas
8. Paget disease
   vertebral body ± posterior elements, enlargement of bone, "picture framing"; bone sclerosis
9. Eosinophilic granuloma (6% in spine)
   most often cervical / lumbar spine; multiple involvement common
   √ vertebra plana / incomplete collapse of vertebra
   √ absence of osteolytic area
   √ preservation of posterior elements + pedicles
10. Fibrous dysplasia (1% in spine)
    vertebral body, nonhomogeneous trabecular "ground-glass" appearance
11. Enostosis (1–14% in spine)
    Location: T1–T7 > L2–L3

D. MALIGNANT LESION

1. Chordoma (15% in spine)
   ◊ Most common nonlymphoproliferative primary malignant tumor of the spine in adults
   Location: particularly C2, within vertebral body; violates disk space
2. Chondrosarcoma (3–12% in spine)
   ◊ 2nd most common nonlymphoproliferative primary malignant tumor of the spine in adults
   Mean age: 45 years; M > F
   Location: thoracic spine (mostly)
   Site: vertebral body (15%), posterior elements (40%), both (45%)
   • pain (95%); palpable mass (28–82%)
   • neurologic symptoms (45%)
   √ large calcified mass with bone destruction
   √ involvement of adjacent vertebra by extension through disk (35%)
3. Metastasis: osteolytic, osteoblastic
4. Multiple myeloma / plasmacytoma

   Clue: vertebral pedicles usually spared

   √ single vertebral collapse as usual manifestation
   √ "minibrain" appearance on axial CT = hollow vertebral body / pedicle + cortical thickening

   Characteristics suggestive of multiple myeloma:
   √ sharply demarcated scalloped lytic lesions
   √ marked osteoporosis
   √ "cold" lesions on bone scans
   √ lack of a primary neoplasm
5. Angiosarcoma
   10% involve spine, most commonly lumbar

6. Ewing sarcoma and PNET
   ◊ Most common nonlymphoproliferative primary malignant tumor of the spine in children; metastases more common than primary
   Site: vertebral body with extension to posterior elements
   √ diffuse sclerosis + osteonecrosis (69%)
7. Osteosarcoma (4% in spine)
   Average age: 4th decade; M > F
   Histo: mostly osteoblastic
   Location: thoracic + lumbar segments
   Site: vertebral body, posterior elements (79%)
   • neurologic symptoms
   √ may present as "ivory vertebra"
8. Lymphoma
   Peak age: 5th–7th decade; M÷F = 8÷1
   Location: paraspinal, vertebral, epidural
   Site: tumor spread from medullary cavity along small vascular channels
   √ lytic in NHL
   √ sclerotic "ivory vertebra" or mixed pattern in HD
   √ ↑ radionuclide uptake on bone scintigraphy

Bone Tumors Favoring Vertebral Bodies

(a) benign
   1. Hemangioma
   2. Eosinophilic granuloma
   3. Giant cell tumor

(b) malignant
   1. Metastasis
   2. Myeloma
   3. Plasmacytoma
   4. Lymphoma
   5. Chordoma

mnemonic: CALL HOME

Classification of Primary Spinal Tumors by Tissue Origin		
Tissue Origin	*Benign*	*Malignant*
Osteogenic	Enostosis (bone island) Osteoid osteoma Osteoblastoma	Osteosarcoma
Chondrogenic	Osteochondroma Chondroblastoma	Chondrosarcoma
Fibrogenic	Fibrous dysplasia Benign fibrous histiocytoma	Malignant fibrous histiocytoma
Vascular	Hemangioma Hemangiopericytoma	Epithelioid hemangio-endothelioma
Hematopoietic, reticulo-endothelial, lymphatic	Eosinophilic granuloma	Schüller-Christian syndrome, Letterer-Siwe disease Lymphoma / leukemia Plasmacytoma / multiple myeloma Ewing sarcoma
Notochordal		Chordoma
Unknown	Aneurysmal bone cyst Giant cell tumor	

Chordoma
Aneurysmal bone cyst
Leukemia
Lymphoma
Hemangioma
Osteoid osteoma, **O**steoblastoma
Myeloma, **M**etastasis
Eosinophilic granuloma

Primary Vertebral Tumors in Children

[in order of frequency:]

1. Osteoid osteoma
2. Benign osteoblastoma
3. Aneurysmal bone cyst
4. Ewing sarcoma

Primary Tumor of Posterior Elements

A. BENIGN

1. Osteoid osteoma
2. Osteoblastoma
3. Osteochondroma
4. Aneurysmal bone cyst

B. MALIGNANT
1. Chondrosarcoma
2. Osteosarcoma
3. Ewing sarcoma

mnemonic: A HOG
Aneurysmal bone cyst
Hydatid cyst, **H**emangioma
Osteoblastoma, **O**steoid osteoma
Giant cell tumor

Blowout Lesion of Posterior Elements

mnemonic: GO APE
Giant cell tumor
Osteoblastoma
Aneurysmal bone cyst
Plasmacytoma
Eosinophilic granuloma

Multiple Bone Lesions of Spine

A. BENIGN
1. Enostosis
2. Hemangioma

B. MALIGNANT
1. Metastasis
2. Myeloma
3. Lymphoma
4. Eosinophilic granuloma

Spine Lesions Involving Adjacent Levels

A. BENIGN
1. Chordoma
2. Aneurysmal bone cyst
3. Giant cell tumor

B. MALIGNANT
1. Osteosarcoma
2. Chondrosarcoma
3. Myeloma / plasmacytoma
4. Lymphoma
5. Ewing sarcoma

Osteoblastic Tumor of Spine

A. BENIGN
   1. Bone island
   2. Reactive bone sclerosis adjacent to osteoid osteoma and osteoblastoma
B. malignant
   1. Metastasis
   2. Lymphoma
   3. Osteosarcoma

Tumor of Spine with Fluid-fluid Level

1. Aneurysmal bone cyst
2. Telangiectatic osteosarcoma

Fat-containing Tumor of Spine

1. Vertebral hemangioma
2. Fibrous dysplasia
3. Paget disease
4. Schmorl node

Benign Tumor of Spine with Soft-tissue Extension

1. Aneurysmal bone cyst
2. Aggressive hemangioma
3. Eosinophilic granuloma

PARAVERTEBRAL MASSES

A. NONTUMOROUS
   1. Extramedullary hematopoiesis
      • hemolytic anemia / myelofibrosis
   2. Pott abscess
      √ calcification in a large paraspinal abscess WITHOUT new bone formation / sclerosis favors tuberculosis
   3. Castleman disease
      √ intense homogeneous enhancement
      √ frequent calcifications
B. TUMOROUS
   1. Lymphoma
      √ faint homogeneous enhancement
   2. Neurogenic tumor: neurofibroma, schwannoma, ganglion tumor
      √ commonly erosions / scalloping of vertebrae ± ribs
      √ moderate homogeneous enhancement
   3. Pleuropulmonary synovial sarcoma
   4. Extraadrenal neuroblastoma
   5. Extraskeletal Ewing sarcoma

Neurogenic Tumor

A. Nerve sheath

1. Schwannoma
2. Neurofibroma
3. Malignant nerve sheath tumor

B. Ganglionic cell
1. Ganglioneuroma
2. Ganglioneuroblastoma
3. Neuroblastoma

C. Paraganglionic cell
1. Paraganglioma
2. Pheochromocytoma

SACRUM

Pediatric Presacral Mass

A. Congenital & developmental mass
1. Sacrococcygeal teratoma
2. Anterior sacral meningocele
3. Dermoid cyst
4. Enteric cyst
5. Cystic lymphatic malformation

B. Neurogenic mass
1. Neuroblastoma
2. Ganglioneuroma
3. Schwannoma
4. Neurofibroma

C. Mesenchymal mass
1. Rhabdomyosarcoma
2. Undifferentiated sarcoma
3. Lymphoma
4. Vascular malformation

D. Sacral mass with presacral extension
(a) benign primary sacral tumor
1. Giant cell tumor
2. Aneurysmal bone cyst

(b) malignant primary sacral tumor
1. Chordoma
2. Ewing sarcoma

E. Inflammatory mass
1. Pelvic abscess
2. Pelvic hematoma

Sacroiliitis

√ findings predominate on the iliac side (thinner cartilage)

A. BILATERAL SYMMETRIC
1. Ankylosing spondylitis

√ small regular erosion = loss of definition of white cortical line on iliac side (initially)
√ subchondral sclerosis + subsequent ankylosis
√ ossification of interosseous ligaments

2. Enteropathic arthropathy
   √ same signs as in ankylosing spondylitis
3. Rheumatoid arthritis (in late stages)
   √ joint space narrowing without reparation
   √ osteoporosis
   √ ankylosis may occur
4. Deposition arthropathy: gout, CPPD, ochronosis, acromegaly
   √ slow loss of cartilage
   √ subchondral reparative bone + osteophytes
5. Osteitis condensans ilii

DDx: Hyperparathyroidism (subchondral bone resorption on iliac side resembling erosion + widening of joint)

B. BILATERAL ASYMMETRIC
1. Psoriatic arthritis
   √ large extensive erosion
   √ subchondral sclerosis + occasional ankylosis
2. Reiter syndrome
3. Juvenile rheumatoid arthritis

C. UNILATERAL
1. Infection
2. Osteoarthritis from abnormal mechanical stress

Differential Diagnosis of Sacroiliac Joint Disease

	Osteoarthritis	*Ankylosing spondylitis ilii*	*Osteitis condensans*
Age	older	younger	younger
Sex	M, F	M > F	F > M
Distribution	bi- / unilateral symmetric	bilateral symmetric	bilateral
Sclerosis	iliac mild focal	iliac ± extensive	iliac triangular
Erosions	absent	common	absent
Intraarticular ankylosis	rare	common	absent
Ligamentous ossification	less common	common	absent

√ no erosions
√ irregular narrowing of joint space with subchondral sclerosis
√ osteophytes at anterosuperior / -inferior aspect of joint (may resemble ankylosis)

DDx: psoriatic arthritis, Reiter syndrome, trauma, gout, pigmented villonodular synovitis, osteitis condensans ilii

Sacroiliac Joint Widening

mnemonic: CRAP TRAP

Colitis
Rheumatoid arthritis
Abscess (infection)
Parathyroid disease
Trauma
Reiter syndrome
Ankylosing spondylitis
Psoriasis

Sacroiliac Joint Fusion

mnemonic: CARPI

Colitic spondylitis

Psoriatic arthritis
Infection (TB)

Widened Symphysis Pubis

mnemonic: EPOCH

Exstrophy of the bladder
Prune belly syndrome
Osteogenesis imperfecta
Cleidocranial dysostosis
Hypothyroidism

Destructive Sacral Lesion

mnemonic: SPACEMONG

Sarcoma: chondrosarcoma
Plasmacytoma
Aneurysmal bone cyst
Chordoma
Ependymoma, myxopapillary
Metastasis
Osteomyelitis
Neuroblastoma
Giant cell tumor

Sacral Tumor

Sacral Bone Tumor

A. BENIGN
   1. Giant cell tumor (2nd most common primary)
   2. Aneurysmal bone cyst (rare)
   3. Cavernous hemangioma (very rare)

4. Osteoid osteoma / osteoblastoma (very rare)

B. MALIGNANT
   1. Metastases (most common sacral neoplasm):
      › hematogenous: lung, breast, kidney, prostate
      › contiguous: rectum, uterus, bladder
   2. Plasmacytoma, multiple myeloma
   3. Lymphoma, leukemia
   4. Chordoma (most common primary)
   5. Sacrococcygeal teratoma
   6. Ewing sarcoma (rare)

Sacral Canal Tumor *(less common)*

A. BENIGN
   1. Neurofibroma: multiple suggestive of NF
   2. Schwannoma (rare)
   3. Meningioma (very rare)

B. MALIGNANT
   1. Ependymoma
   2. Drop metastases
   3. Carcinoid tumor

INTERVERTEBRAL DISK

Loss of Disk Space

1. Degenerative disk disease
2. Neuropathic osteoarthropathy
3. Dialysis spondyloarthropathy with amyloidosis
4. Ochronosis
5. Ankylosing spondylitis with pseudarthrosis
6. Sarcoidosis

Spinal Vacuum Phenomena

Pathophysiology:

= gaslike density due to

(a) <u>acute</u> / true vacuum phenomenon ← rapid increase in volume of joint space
   √ acute protraction of shoulder in children

(b) subacute / <u>chronic</u> vacuum phenomenon
   √ common in degenerative disk of spine

Cause: reduction of barometric pressure up to 1/20th of atmosphere

Location: joint under traction, spine

(a) nucleus pulposus	Osteochondrosis
(b) annulus fibrosus	Spondylosis deformans
(c) disk within vertebral body	Cartilaginous node
(d) disk within spinal canal	Intraspinal disk herniation

(e) apophyseal facet joint — Osteoarthritis ± ~listhesis
(f) vertebral body — Ischemic necrosis

Vacuum Phenomenon in Intervertebral Disk Space

= liberation of nitrogen gas from surrounding tissues into clefts with an abnormal nucleus or annulus attachment

Composition: N_2 (90-92%) + O_2 + CO_2 + traces of other gases

Prevalence: in 1–3% of all spinal radiographs; in up to 20% of plain radiographs; in up to 50% of spinal CT in patients > age 40

Cause:

1. Primary / secondary degeneration of nucleus pulposus
2. Intraosseous herniation of disk (= Schmorl node)
3. Spondylosis deformans (gas in annulus fibrosus)
4. Adjacent vertebral metastatic disease with vertebral collapse
5. Infection (extremely rare)

√ accentuated on supine X-ray during spine extension
√ obscured on upright radiograph during spine flexion

Site:

(a) marginal = traumatic / degenerative crack in peripheral fibers of annulus fibrosus
  √ spondylosis deformans = associated with marginal single anterior osteophyte
(b) central = intradiskal cleft due to
  › primary disk degeneration
  › secondary ← injury, interference with nutrition (CPPD, alkaptonuria, trauma, Scheuermann disease, osteoporotic vertebral collapse)

Intravertebral Gas

Cause:

1. Schmorl node = accumulation of gas from fissuring intravertebral disk
   √ rounded intravertebral gas with sclerotic rim
2. Limbus vertebrae
   √ intradiskal gas extends into vertebral cleft beneath superior / inferior ring apophysis
3. Pneumatocyst
   Incidence: 9% (on CT)
   Location: iliac bone, sacrum, humeral head, clavicle
   • asymptomatic
   √ cystlike lesion of gas attenuation ± sclerotic rim ± communication with adjacent joint
   √ erosive defect in osteocartilaginous endplates → direct extension of gas into vertebra
4. Intravertebral vacuum cleft
5. Intraspinal gaseous cyst
   (a) gas-containing intraspinal disk herniation
   (b) gas expulsion through rent in annulus fibrosus

Intervertebral Disk Calcification

mnemonic: A DISC SO WHITE

Amyloidosis, **A**cromegaly
Degenerative disk disease
Infection
Spinal fusion
CPPD
Spondylitis ankylosing
Ochronosis
Wilson disease
Hemochromatosis, **H**yperparathyroidism, **H**omocystinuria
Idiopathic skeletal hyperostosis
Traumatic
Etceteras: Gout and other causes of chondrocalcinosis

Intervertebral Disk Ossification

Associated with: fusion of vertebral bodies

1. Ankylosing spondylitis
2. Ochronosis
3. Sequelae of trauma
4. Sequelae of disk-space infection
5. Degenerative disk disease

SPINAL CORD

◊ Most spinal cord neoplasms are malignant!
◊ 90–95% are classified as gliomas

Intramedullary Lesion

Prevalence: 4–10% of all CNS tumors; 20% of all intraspinal tumors in adults (35% in children)

A. TUMOR
√ expansion of cord
√ heterogeneous signal on T2WI
√ cysts + necrosis
√ variable degrees of enhancement (vast majority with some enhancement)
(a) primary:
1. Ependymoma 60%
◊ Most common glial tumor in adults
2. Astrocytoma 25%
◊ Most common intramedullary tumor in children
3. Hemangioblastoma 5%
4. Oligodendroglioma 3%
5. Epidermoid, dermoid, teratoma 1–2%
6. Ganglioglioma 1%
7. Lipoma 1%

Location:

- › cervical region: astrocytoma
- › thoracic region: teratoma-dermoid, astrocytoma
- › lumbar region: ependymoma, dermoid

(b) metastatic: eg, malignant melanoma, breast, lung

B. CYSTIC LESION

√ fluid isointense to CSF
√ smooth well-defined internal margins
√ thinned adjacent parenchyma
√ cord atrophy
√ no contrast enhancement

(a) peritumoral cyst = syringomyelia

1. Syringomyelia
2. Hydromyelia
3. Reactive cyst

(b) tumoral cyst

√ shows peripheral enhancement

1. Ganglioglioma (in 46%)
2. Astrocytoma (in 20%)
3. Ependymoma (in 3%)
4. Hemangioblastoma (2–4%)

C. VASCULAR

1. Cord concussion = reversible local edema
2. Hemorrhagic contusion
3. Cord transection
4. AVM

D. chronic inflammation

1. Sarcoid
2. Transverse myelitis
3. Multiple sclerosis

mnemonic: I'M ASHAMED

Inflammation (multiple sclerosis, sarcoidosis, myelitis)
Medulloblastoma
Astrocytoma
Syringomyelia / hydromyelia
Hematoma, Hemangioblastoma
Arteriovenous malformation
Metastasis
Ependymoma
Dermoid

Intramedullary Neoplastic Lesion

A. GLIAL NEOPLASM (90–95%)

1. Ependymoma 60%
2. Astrocytoma 33%
3. Ganglioglioma 1%

B. NONGLIAL NEOPLASM
   (a) highly vascular lesions
      1. Hemangioblastoma
      2. Paraganglioma
   (b) rare lesions
      3. Metastasis
      4. Lymphoma
      5. Primitive neuroectodermal tumor

C. USUALLY EXTRAMEDULLARY NEOPLASM
   1. Intramedullary meningioma
   2. Intramedullary schwannoma

Intramedullary Nonneoplastic Mass

1. Epidermoid
2. Congenital lipoma
3. Posttraumatic pseudocyst
4. Wegener granuloma
5. Cavernous malformation
6. Abscess

Intramedullary Nonneoplastic Lesion

Prevalence: 4%

√ no cord expansion

1. Demyelinating disease
2. Sarcoidosis
3. Amyloid angiopathy
4. Pseudotumor
5. Dural arteriovenous fistula
6. Cord infarction
7. Chronic arachnoiditis
8. Cystic myelomalacia

Cord Lesions

A. INFLAMMATION
   1. Multiple sclerosis
   2. Acute disseminated encephalomyelitis
   3. Acute transverse myelitis
      √ involves half the cross-sectional area of cord
   4. Lyme disease
   5. Devic syndrome

B. INFECTION
   1. Cytomegalovirus
   2. Progressive multifocal leukoencephalopathy

3. HIV

C. VASCULAR
   1. Anterior spinal artery infarct
      √ affects central gray matter first
      √ extends to anterior two-thirds of cord
   2. Venous infarct / ischemia
      √ starts centrally progressing centripetally

D. NEOPLASM

Intradural Extramedullary Mass

1. Nerve sheath tumor (35%)
2. Meningioma (25%)
3. Lipoma
4. Dermoid
   commonly conus / cauda equina; associated with spinal dysraphism (⅓)
5. Ependymoma commonly filum terminale; NO spinal dysraphism
6. Metastasis
   (a) "Drop metastases" from CNS tumors
   (b) Metastases from outside CNS
8. Arachnoid cyst
9. Neurenteric cyst
10. Hemangioblastoma
11. Paraganglioma

mnemonic: MAMA N
Metastasis
Arachnoiditis
Meningioma
AVM, **A**rachnoid cyst
Neurofibroma

CSF-isointense Focal Spinal Cord Displacement

= space-occupying CSF-isointense intradural / intraspinal extramedullary lesion with widened CSF space

• nonspecific symptoms: back pain, weakness, numbness, Brown-Séquard syndrome

1. Epidermoid cyst
2. Intradural arachnoid cyst
3. Synovial cyst
4. Cystic schwannoma
5. Teratoma
6. Meningocele
7. Epidural abscess of spine
8. Epidural hematoma
9. Idiopathic spinal cord herniation

Epidural Extramedullary Lesion

= EXTRADURAL LESIONS OF SPINE
arise from bone, fat, vessels, lymph nodes, extramedullary neural elements
Prevalence: 30% of all spinal tumors

A. TUMOR
   (a) benign
      1. Dermoid, epidermoid
      2. Lipoma: over several segments
      3. Fibroma
      4. Neurinoma (with intradural component)
      5. Meningioma (with intradural component)
      6. Ganglioneuroblastoma, ganglioneuroma
   (b) malignant
      1. Hodgkin disease
      2. Lymphoma: most commonly in dorsal space
      3. Metastasis: breast, lung – most commonly from involved vertebrae without extension through dura
      4. Paravertebral neuroblastoma

B. DISK DISEASE
   1. Bulging disk
   2. Herniated nucleus pulposus
   3. Sequestered nucleus pulposus

C. BONE
   1. Tumor of vertebra
   2. Spinal stenosis
   3. Spondylosis

D. INFECTION: epidural abscess / phlegmon

E. BLOOD: hematoma

F. OTHERS: synovial cyst, arachnoid cyst, extradural lipomatosis, extramedullary hematopoiesis

mnemonic: MANDELIN
Metastasis (drop mets from CNS tumor), Meningioma
Arachnoiditis, Arachnoid cyst
Neurofibroma
Dermoid / epidermoid
Ependymoma
Lipoma
Infection (TB, cysticercosis)

Normal but tortuous roots

Anterior Epidural Space Abnormality

A. Neoplasm
   Histo: metastases spread from marrow via venous foramina into spinal canal preserving cortex
   √ solid enhancement

√ may have central necrosis
√ commonly uni- / bilobed appearance (= preservation of tethered appearance of posterior longitudinal ligament [PLL])

B. Infection
√ frequently central convex appearance (= disruption of posterior vertebral cortex by osteomyelitis)
1. Epidural abscess
√ peripheral enhancement
2. Epidural phlegmon
√ solid enhancement

C. Hemorrhage
√ frequently central convex appearance (= disruption of posterior vertebral cortex by fracture)
√ no enhancement

D. Disk herniation
√ sequestered / extruded disk rarely crosses midline

Cord Atrophy

1. Multiple sclerosis
2. Amyotrophic lateral sclerosis
3. Cervical spondylosis
4. Sequelae of trauma
5. Ischemia
6. Radiation therapy
7. AVM of cord

Delayed Uptake of Water-Soluble Contrast in Cord Lesion

1. Syringohydromyelia
2. Cystic tumor of cord
3. Osteomalacia

exceedingly rare:

4. Demyelinating disease
5. Infection
6. Infarction

Extraarachnoid Myelography

A. SUBDURAL INJECTION
√ spinal cord, nerve roots, blood vessels not outlined
√ irregular filling defects
√ slow flow of contrast material
√ CSF pulsations diminished
√ contrast material pools at injection site within anterior / posterior compartments

B. EPIDURAL INJECTION
√ contrast extravasation along nerve roots
√ contrast material lies near periphery of spinal canal

√ intraspinal structures are not well outlined

MUSCULOSKELETAL NEUROGENIC TUMORS

A. BENIGN NEUROGENIC TUMOR
   1. Traumatic neuroma
   2. Morton neuroma
   3. Neural fibrolipoma
   4. Nerve sheath ganglion
   5. Benign peripheral nerve sheath tumor (PNST)
      (a) Schwannoma = Neurilemmoma
      (b) Neurofibroma: localized, diffuse
      (c) Plexiform neurofibroma

B. MALIGNANT NEUROGENIC NEOPLASM
   = malignant peripheral nerve sheath tumor (MPNST)

SURGICAL LUMBAR PROCEDURES

Posterior Lumbar Surgical Procedures

= posterior decompression + fusion

1. Posterior lumbar interbody fusion
   › bilateral caudad + cephalad partial laminectomies
   › diskectomy
   › bone graft into disk space + interbody spacer
   › posterior stabilization (until bone fusion occurs)
2. Transforaminal lumbar interbody fusion
   = lateral approach leaving midline bone structures intact
   › total facetectomy for access to lateral disk space
   › transforaminal interbody spacers
3. Posterolateral fusion
   = alternative to posterior lumbar interbody fusion ← severe loss of disk space height
   › bone graft material placed laterally between transverse processes
   › supplemented by posterior instrumentation

Anterior Lumbar Surgical Procedures

= anterior fusion for predominantly diskogenic pain without need for posterior decompression

1. Anterior lumbar interbody fusion
   › lower abdominal incision / retroperitoneal flank approach
   › removal of degenerate disk
   › spacers for anterior osseous fusion replacing disk height
2. Stand-alone lumbar interbody fusion
   › cage fixed to the adjacent vertebral bodies by screws

SPINAL FIXATION DEVICES

Function:

(1) to restore anatomic alignment in fractures (fracture reduction)
(2) to stabilize degenerative disease
(3) to correct congenital deformities (scoliosis)
(4) to replace diseased / abnormal vertebrae (infection, tumor)

Posterior Fixation Devices

using paired / unpaired rods attached with

1. Sublaminar wiring
   = passing a wire around lamina + rod
2. Interspinous wiring
   = passing a wire through a hole in the spinous process; a Drummond button prevents the wire from pulling through the bone
3. Subpars wiring
   = passing a wire around the pars interarticularis
4. Laminar / sublaminar hooks
   used on rods for compression / distraction forces to be applied to pedicles / laminae
   (a) upgoing hook curves under lamina
   (b) downgoing hook curves over lamina
5. Pedicle / transpedical screws
   √ connected by plates / rods spanning single / multiple segments
   √ crossbars (for additional strength)
6. Rods
   (a) Luque rod = straight / L-shaped smooth rod 6–8 mm in diameter
   (b) O-ring fixator, rhomboid-shaped bar, Luque rectangle, segmental rectangle = preshaped loop to form a flat rectangle
   (c) Harrington distraction rod
   (d) Harrington compression rod
   (e) Knodt rod = threaded distraction rod with a central fixed nut (turnbuckle) and opposing thread pattern
   (f) Cotrel-Dubousset rods = a pair of rods with a serrated surface connected by a cross-link with ≥ 4 laminar hooks / pedicle screws
7. Plates
   (a) Roy-Camille plate
   = simple straight plates with round holes
   (b) Luque plate
   = long oval holes with clips encircling the plate
   (c) Steffee plate = straight plates with long slots
8. Translaminar / facet screw
   = cancellous screws for single level fusion when posterior elements are left intact
9. Percutaneous pinning
   = (hollow) interference screws placed across disk level

Anterior Fixation Devices

1. Dwyer device

= screws threaded into vertebral body over staples embedded into vertebral body connected by braided titanium wire; placed on convex side of spine

2. Zielke device
   = modified Dwyer system replacing cable with solid rod
3. Kaneda device
   = 2 curved vertebral plates with staples attached to vertebral bodies with screws, plates connected by 2 threaded rods attached to screw heads
4. Dunn device
   (similar to Kaneda device, discontinued)

Reconstruction after Diskectomy / Corpectomy

1. Auto- / allograft bone block
2. Allograft strut (eg, fibula, humerus)
3. Interbody spacers: titanium / radiolucent material (eg, polyetheretherketone)
   (a) ramp
   (b) bone graft cage: open structure filled with bone graft material
   √ 2 radiopaque markers for assessment of spacer position: posterior marker should be ≥ 2 mm anterior to posterior vertebral body margin
4. Vertebral body replacement device
   (a) expandable hollow cylinder packed with bone graft / cement (Synex cage)
   (b) mesh (Moss cage)
   (c) stackable carbon-fiber-reinforced polymer cages held together by metallic rods
5. Disk replacement device
   Indication: pain from disk degeneration only
   Contraindication: facet joint degeneration, < 4 mm residual disk height, significant endplate degeneration

Complications of Spinal Instrumentation

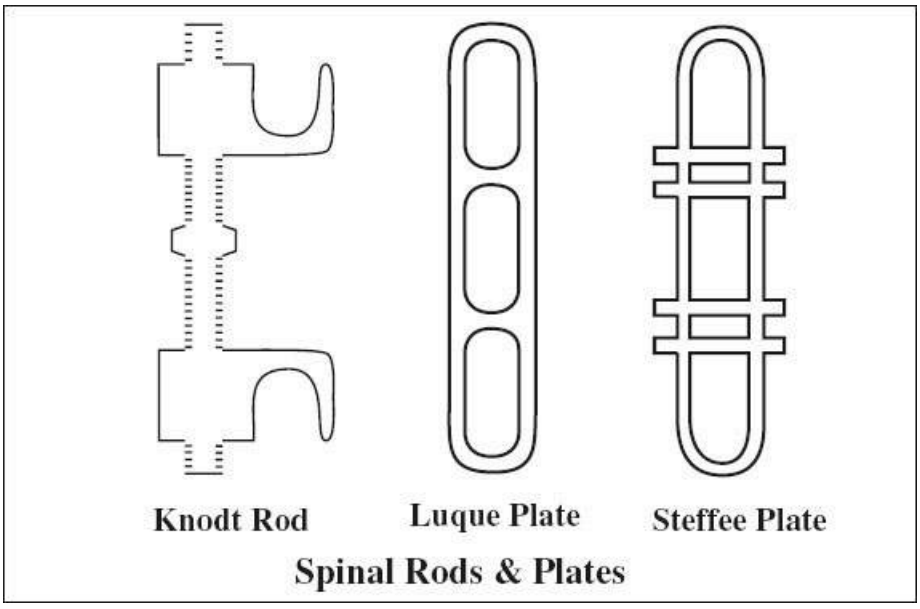
1. Pseudarthrosis
   √ corticated linear lucency across graft material
   √ focally increased signal on T2WI
   √ increased tracer activity on bone scintigraphy
2. Malpositioned pedicle screws (2.4% complication rate)
   • nerve root irritation (medial angulation of screw)
   √ disruption of cortical bone
   (a) medial deviation
   (b) lateral deviation
   (c) penetration of anterior cortex (exception are sacral screws which may be anchored in anterior cortex of the sacrum for additional stability)
   √ lucent rim around screw threads ← loosening
3. Malpositioned anterior cervical plate
   √ penetration into adjacent disk space / foramen transversarium / spinal cord / nerve roots
4. Herniation of graft material
   √ anteriorly / posteriorly displaced graft

5. Postoperative hematoma
6. Surgery at wrong level
7. Accelerated degenerative changes / ligamentous instability / fracture at adjacent levels
8. Superficial / deep infection (diskitis, osteomyelitis)
9. Arachnoiditis

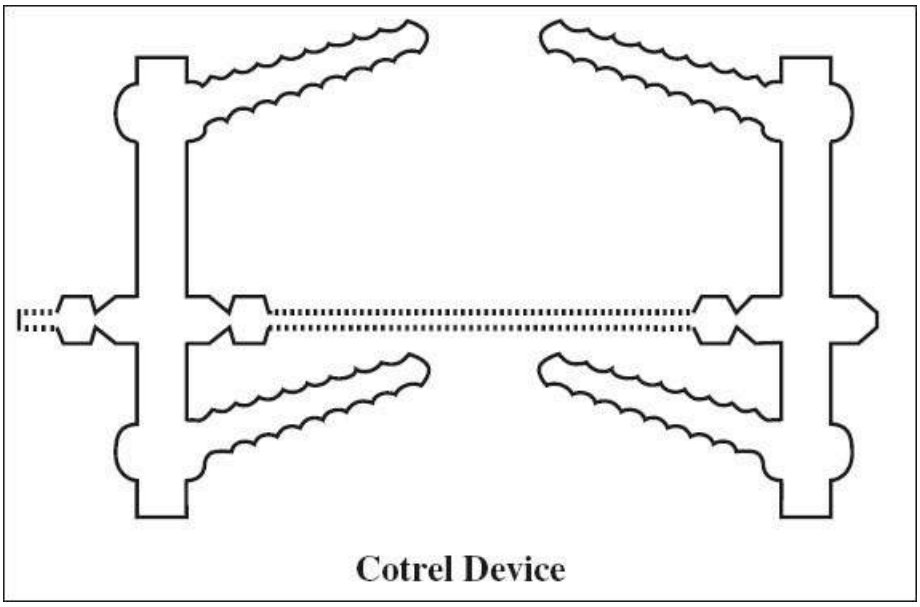
Assessment of Bridging Spinal Fusion

Time from surgery: 6–9 months

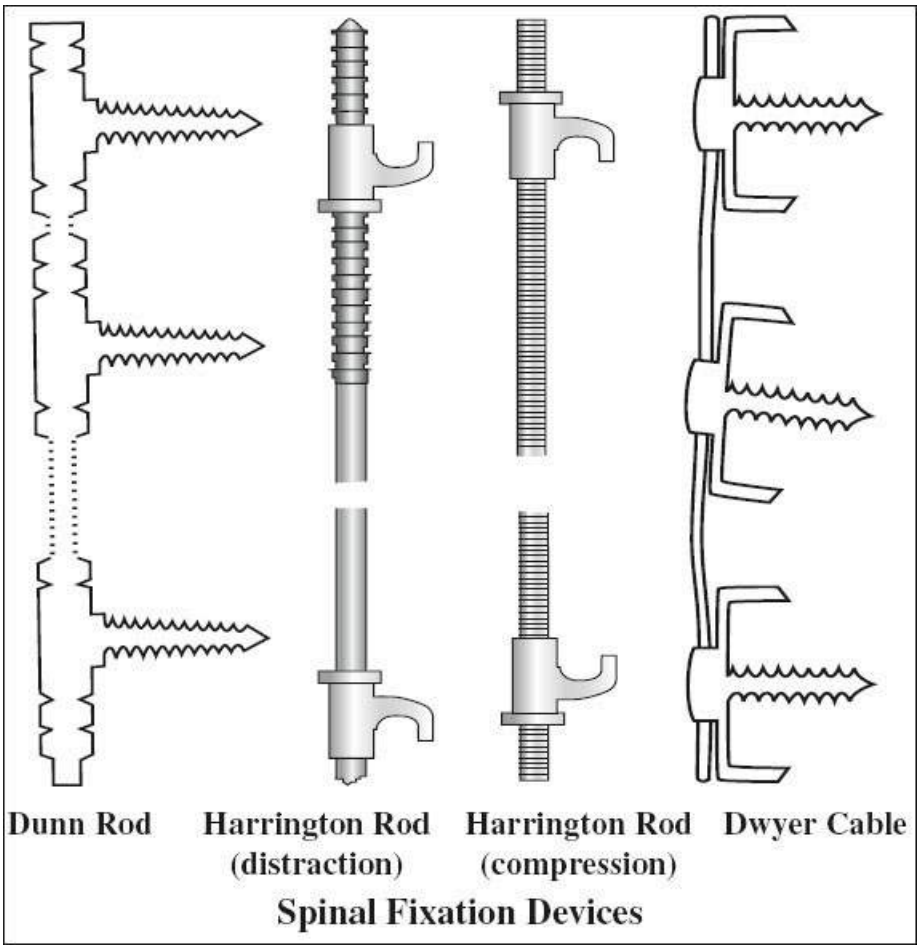
√ < 3° of intersegmental positional change on lateral flexion + extension views
√ visible bone formation in / about graft material
√ minimal loss of disk height
√ absence of lucency around implant
√ absence of fracture of device / graft / vertebra



Spinal Rods & Plates



Cotrel Device



Spinal Fixation Devices

ANATOMY OF SKULL AND SPINE

SCALP

◊ Outer 3 layers are often torn off as a unit in accidents; wounds do not gape if epicranius (occipitofrontal) m. not involved

Area: from supraorbital ridge to superior nuchal line, laterally to zygomatic arch and external auditory meatus 3 primary muscle groups: frontalis, occipitalis, temporalis

1. SKIN
   √ linear hyperattenuating structure
2. SUBCUTIS
   = fibroadipose tissue closely adherent to skin and underlying epicranius
   √ thick layer of fat attenuation
3. GALEA APONEUROTICA
   = layer of thick fibrous tissue continuous with epicranius (occipitofrontal) muscle consisting of
   (a) frontal muscle belly + auricularis m. anteriorly
   (b) occipital muscle belly posteriorly
   forming centrally the large epicranial aponeurosis
   √ thin line of increased attenuation ← temporalis fascia
4. SUBGALEAL SPACE
   = subaponeurotic areolar tissue between periosteum of outer table and galea aponeurotica
   Histo: analogous to loose areolar tissue containing fat
   • allows the 3 superficial layers of scalp to move as a unit on the cranium → enabling the scalp to wrinkle
   √ allows fluid to accumulate and spread across the cranium analogous to intracranial subdural fluid collections
5. PERICRANIUM = periosteum of outer table
   • firmly adheres to margins of underlying skull bones at suture lines
   √ usually not visible by CT without subperiosteal hematoma
6. SUBPERIOSTEAL SPACE
   = potential space created when periosteum of outer table becomes detached from calvaria (= cephalohematoma); analogous to intracranial extradural hematoma

SKULL VAULT / CALVARIA

[*calvaria*, Latin = top part of skull, from *calvus* = bald]

1. OUTER TABLE = outer layer of cortical bone
   √ well defined and of very high attenuation
   √ very low signal intensity
2. DIPLOË = layer of cancellous bone
   [*diploë* from *diploos*, Latin = double]
   √ slightly lower attenuation than outer table

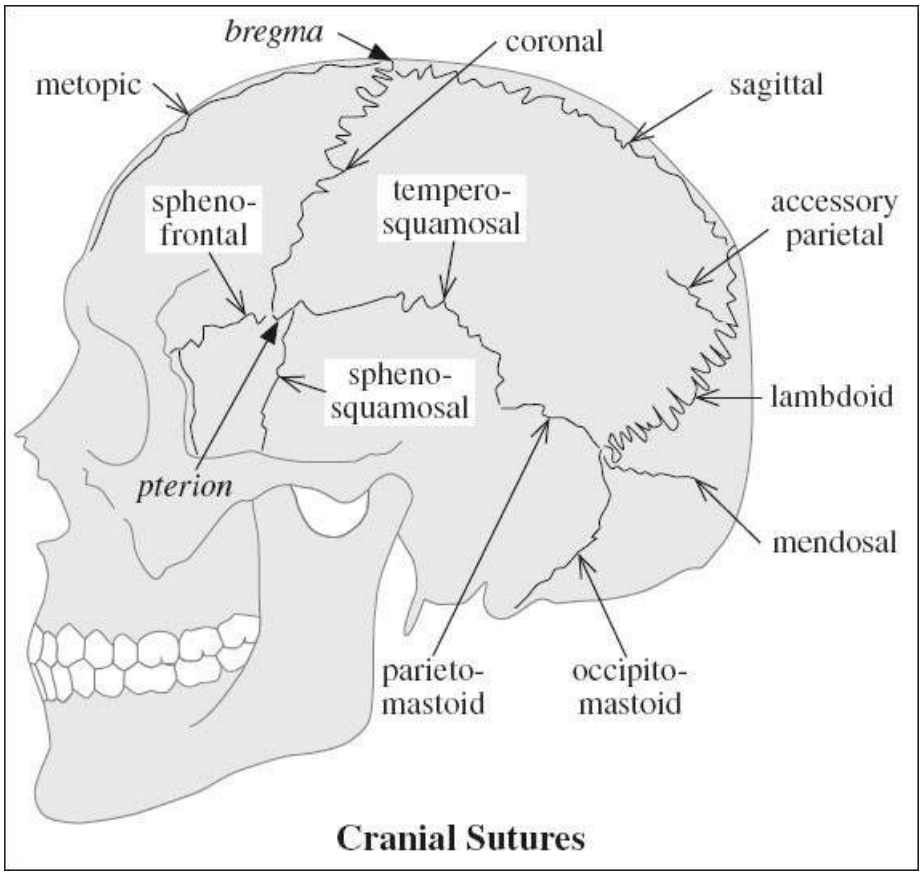
√ low signal intensity on T1WI during first 2 decades
√ high signal intensity later ← fatty marrow conversion

3. INNER TABLE = inner layer of cortical bone
   √ well defined and of very high attenuation
   √ very low signal intensity
4. DURA MATER = double-layered membrane composed of
   (a) outer layer = periosteum of inner table
   (b) inner layer = dura mater proper

   The usually continuous double-layered membrane separates to form:
   › dural venous sinuses
   › tentorium cerebelli, falx cerebri, falx cerebelli
   › diaphragm sellae
   √ short low-signal-intensity segments with enhancement (no blood-brain barrier) most prominent over convexities

SUTURES

A. METOPIC / FRONTAL SUTURE



Cranial Sutures

= from nasion to anterior angle of bregma
[*bregma*, Greek = top of head]

Closure: by 3 months – 6 years of age; in up to 10% open until adulthood

Sutura frontalis persistens = metopism
= no closure of incomplete / complete metopic suture
DDx: anterior vertical fracture

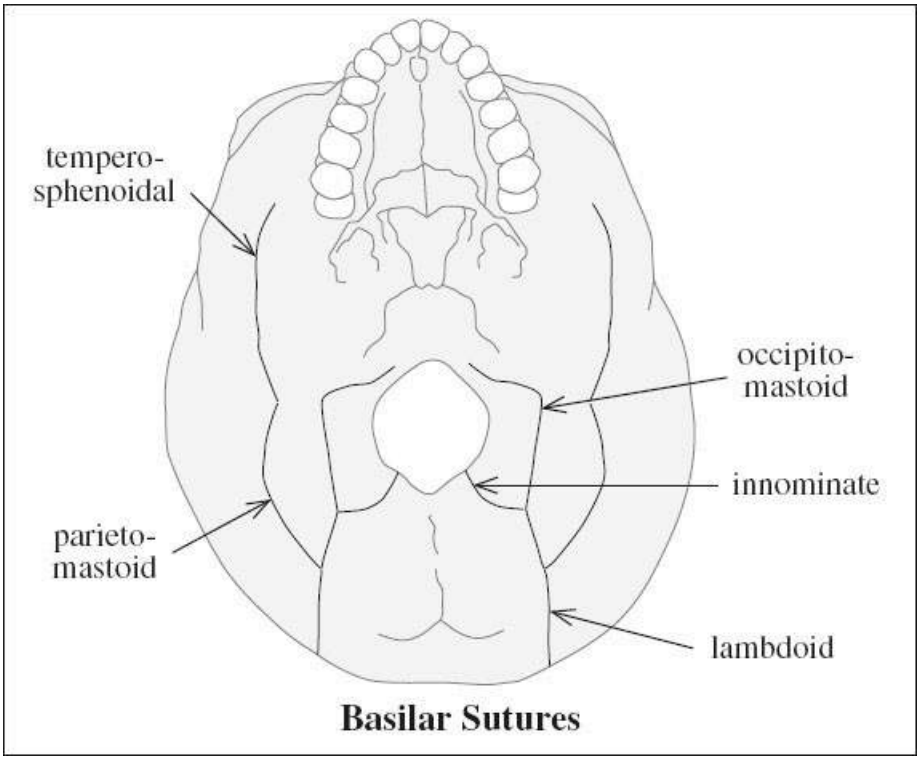
B. SAGITTAL SUTURE
[*sagitta*, Latin = arrow]
= fibrous connective tissue joint between two parietal bones
Average width: 5.0 ± 0.2 mm (at birth), 2.4 ± 0.1 mm (1 month of age); narrowing further over time
Closure: 21–30 years of age; fusing anteriorly beginning at intersection with lambdoid suture

C. CORONAL SUTURE
= separates frontal from parietal bones
Average width: 2.5 ± 0.1 mm (at birth), 1.3 ± 0.1 mm (1 month of age)
Closure: 24 years of age

D. SQUAMOSAL SUTURE
(a) temporosquamosal suture
= connects temporal bone squama with lower border of parietal bone; arches posteriorly from pterion (= contact point between frontal, parietal, temporal, sphenoid)
[*pteron*, Greek = wing]
√ often visualized at two points at CT with lambdoid suture acting as a useful posterior reference point
= continuous posteriorly with parietomastoid suture uniting mastoid process of temporal bone with region of mastoid angle of parietal bone
(b) sphenosquamosal suture
= courses inferiorly from pterion separating sphenoid bone from squama of temporal bone
N.B.: often mistaken for skull base fracture

E. LAMBDOID SUTURE
[upper case *Greek* letter lambda = L]
= connects parietal with occipital bone
Closure: 26 years of age
N.B.: the most common site of wormian bones

F. OCCIPITOMASTOID SUTURE



Basilar Sutures

= inferior continuation of lambdoid suture at the point where lambdoid suture intersects with temporosquamosal suture

G. PARIETOMASTOID SUTURE

= links temporosquamosal and lambdoid sutures

√ often not seen on axial CT images

H. OCCIPITOMASTOID SUTURE

= between occipital bone + mastoid process of temporal bone as a continuation of the lambdoid suture toward skull base

N.B.: not infrequently mistaken for a skull base fracture

I. SPHENOFRONTAL SUTURE

= transverse suture between anterior margin of lesser sphenoid wing + posterior margin of horizontal orbital plate

√ lesser sphenoid wing (posterior to suture) is a useful landmark for suture localization

J. ACCESSORY PARIETAL SUTURE (RARE)

= the most common of all usually bilateral and symmetric accessory sutures

Location: parietal and occipital bone → multiple ossification centers

K MENDOSAL / ACCESSORY OCCIPITAL SUTURE

Frequency: 3% in an Indian subcontinent population

Closure: in utero / first few days of life; may persist up to 6 years of age

Os incae = large single centrally located intrasutural bone at junction of lambdoid and sagittal sutures; often forms in a persistent mendosal suture

K SKULL BASE SUTURES

Ossification: 50% (84%) of anterior base by 6 (24) months

(a) innominate / intraoccipital

Closure: 4 years of age

(b) lambdoid
(c) occipitomastoid
(d) parietomastoid
(e) temporosphenoidal

Symmetry and knowledge of the anatomic appearances of basal sutures are important for avoiding misdiagnosis.
A persistent hypoattenuating area of any length extending from foramen magnum beyond 4 years of age indicates a fracture.

FORAMINA OF BASE OF SKULL

on inner aspect of middle cranial fossa 3 foramina are oriented along an oblique line in the greater sphenoidal wing from anteromedial behind the superior orbital fissure to posterolateral

mnemonic: "rotos"
foramen **rot**undum
foramen **o**vale
foramen **s**pinosum

Foramen Rotundum

= canal within greater sphenoid wing connecting middle cranial fossa + pterygopalatine fossa

Location: inferior and lateral to superior orbital fissure

Course: extends obliquely forward + slightly inferiorly in a sagittal direction parallel to superior orbital fissure

Contents: (a) nerves: V_2 (maxillary nerve)
(b) vessels: (1) artery of foramen rotundum
(2) emissary vv.

√ best visualized by coronal CT

Foramen Ovale

= canal connecting middle cranial fossa + infratemporal fossa

Location: medial aspect of sphenoid body, situated posterolateral to foramen rotundum (endocranial aspect) + at base of lateral pterygoid plate (exocranial aspect)

Contents: (a) nerves: (1) V_3 (mandibular nerve)
(2) lesser petrosal nerve (occasionally)
(b) vessels: (1) accessory meningeal artery
(2) emissary veins

Foramen Spinosum

Location: on greater sphenoid wing posterolateral to foramen ovale (endocranial aspect) + lateral to eustachian tube (exocranial aspect)

Contents: (a) nerves: (1) recurrent meningeal branch of mandibular nerve
(2) lesser superficial petrosal nerve
(b) vessels: (1) middle meningeal artery

(2) middle meningeal vein

Foramen Lacerum

covered (occasionally) by fibrocartilage, carotid artery rests on endocranial aspect of fibrocartilage

Location: at base of medial pterygoid plate

Contents: (inconstant)

(a) nerve: pterygoid canal n. (actually pierces cartilage)

(b) vessel: meningeal branch of ascending pharyngeal a.

Foramen Magnum

basion = anterior lip of foramen

opisthion = posterior lip of foramen

Contents: (a) nerves: (1) medulla oblongata
(2) CN XI (spinal accessory nerve)

(b) vessels: (1) vertebral artery
(2) anterior spinal artery
(3) posterior spinal artery

Pterygoid Canal

= VIDIAN CANAL

= within sphenoid body connecting pterygopalatine fossa anteriorly to foramen lacerum posteriorly

Location: at base of pterygoid plate below foramen rotundum

Contents: (a) nerves: vidian nerve = nerve of pterygoid canal = continuation of greater superficial petrosal nerve (from cranial nerve VII) after its union with deep petrosal nerve

(b) vessel: vidian artery = artery of pterygoid canal = branch of terminal portion of internal maxillary a. arising in pterygopalatine fossa → passing through foramen lacerum posterior to vidian n.

Hypoglossal Canal

= ANTERIOR CONDYLAR CANAL

Location: in posterior cranial fossa anteriorly above condyle starting above anterolateral part of foramen magnum, continuing in an anterolateral direction + exiting medial to jugular foramen

Contents: (a) nerves: cranial nerve XII (hypoglossal n.

(b) vessels: (1) pharyngeal artery
(2) branches of meningeal artery

Jugular Foramen

Location: at posterior end of petrooccipital suture directly posterior to carotid orifice

(a) anterior part:

(1) inferior petrosal sinus

(2) meningeal branches of pharyngeal artery + occipital a.

(b) intermediate part:

(1) cranial nerve IX (glossopharyngeal nerve)

(2) cranial nerve X (vagus nerve)

(3) cranial nerve XI (spinal accessory nerve)

(c) posterior part: internal jugular vein

CRANIOVERTEBRAL JUNCTION (CVJ)

CRANIOCERVICAL JUNCTION: C1 (atlas) + C2 (axis) + occiput

Variants of CVJ: precondylar tubercles, third occipital condyle, ossification of ligament of odontoid process

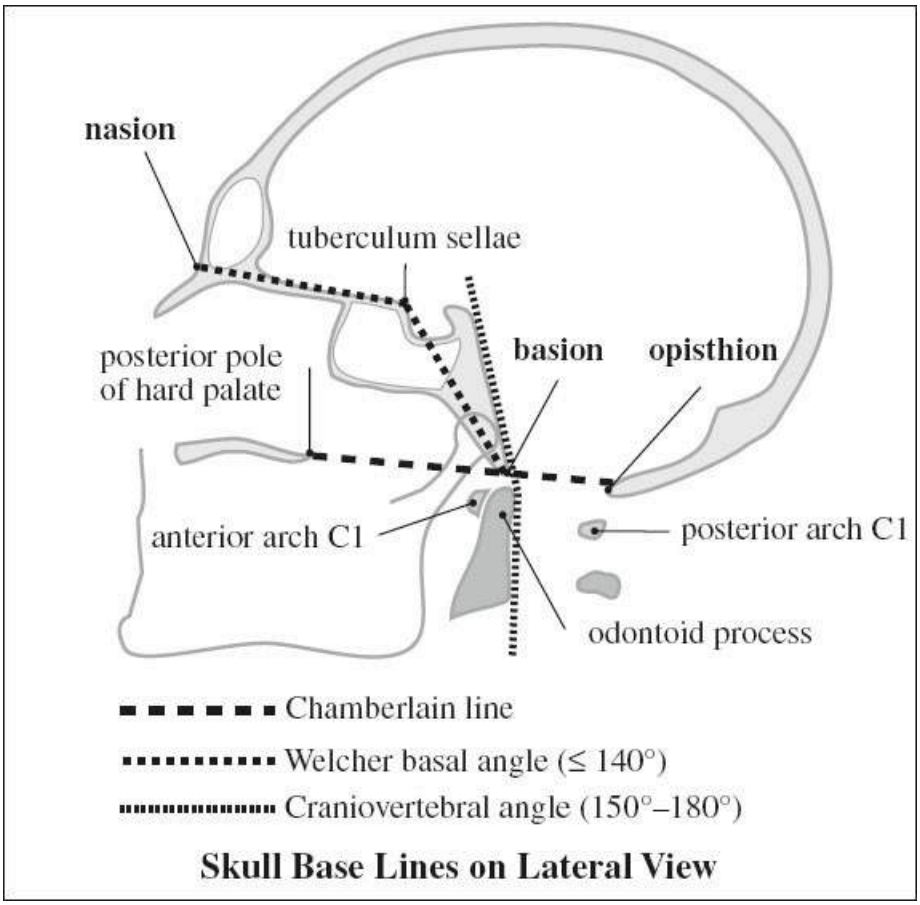
Craniometry:

› LATERAL VIEW

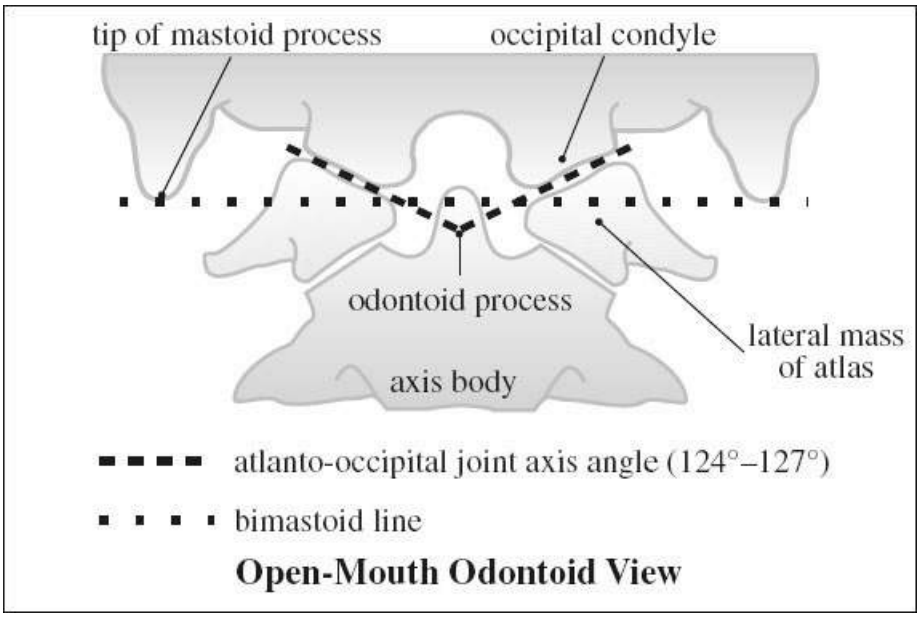
1. **Chamberlain line**
   = line between posterior edge of hard palate + posterior margin of foramen magnum (= opisthion)
   √ tip of odontoid process usually lies below / tangent to Chamberlain line by > 3 mm
   √ tip of odontoid process may lie up to 1 ± 6.6 mm above the Chamberlain line
2. **McGregor line**
   = line between posterior edge of hard palate + most caudal portion of occipital squamosal surface
   ◊ Substitute to Chamberlain line if opisthion not visible
   √ tip of odontoid < 4.5–5.0 mm above this line
3. **Wackenheim clivus baseline**
   = BASILAR LINE = CLIVAL LINE = line along clivus
   √ usually falls tangent to posterior aspect of tip of odontoid process
4. **Craniovertebral angle** = clivus-canal angle
   = angle formed by line along posterior surface of axis body and odontoid process + basilar line
   √ ranges from 150° in flexion to 180° in extension
   √ ventral spinal cord compression may occur at < 150°
5. **Welcher basal angle**
   = intersection of nasion-tuberculum line and of tuberculum-basion line (along clivus)
   √ angle averages 132° (should be < 140–145°)
6. **McRae line**
   = line between anterior lip (= basion) to posterior lip (= opisthion) of foramen magnum
   √ tip of odontoid below this line = NO basilar invagination; if poorly seen → Chamberlain line

› ANTEROPOSTERIOR VIEW (= "open-mouth" / odontoid view)

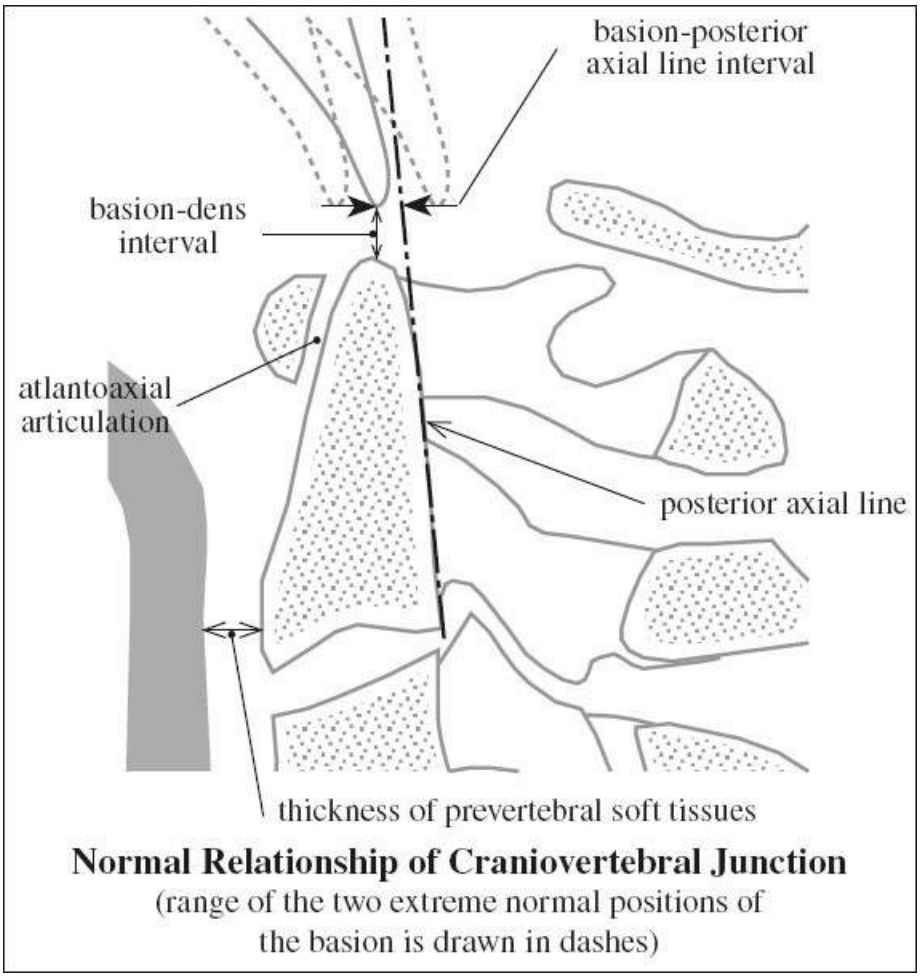
7. **Atlanto-occipital joint axis angle**
   = formed by lines drawn parallel to atlantooccipital joints
   √ lines intersect at center of odontoid process
   √ average angle of 125° (range, 124° to 127°)



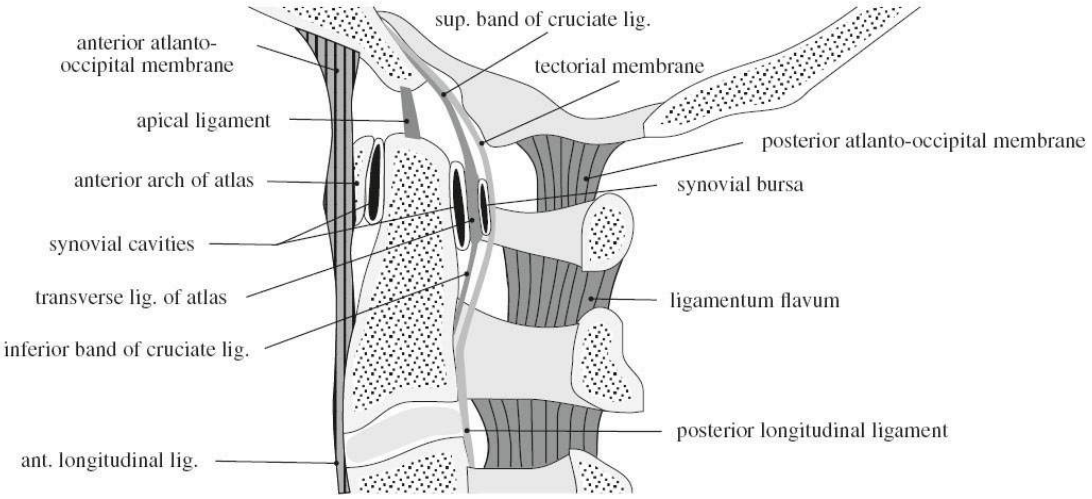
Skull Base Lines on Lateral View



Open-Mouth Odontoid View



Normal Relationship of Craniovertebral Junction
(range of the two extreme normal positions of the basion is drawn in dashes)



Joints and Ligaments of Occipitoatlantoaxial Region

8. **Digastric line**
   = line between incisurae mastoideae (origin of digastric muscles)
   √ tip of odontoid below this line

9. **Bimastoid line**
   = line connecting the tips of both mastoid processes
   √ tip of odontoid < 10 mm above this line

Normal dimensions for adults:

[posterior axial line = vertical line drawn along posterior aspect of the subdental body of C2]

Basion-dens interval (in 95%) < 12 mm

Basion-posterior axial line interval (in 98%)
  posterior to dens < 12 mm
  anterior to dens < 4 mm

Prevertebral soft tissues at C2 < 6 mm

Anterior atlanto-dens interval < 2 mm

Lateral atlanto-dens interval (side-to-side) < 3 mm

Atlanto-occipital articulation < 2 mm

Atlantoaxial articulation < 3 mm
  (for children < 5 mm)

Atlas (C1)

= ring-shaped vertebra

Composition:

(1) bilateral paired lateral masses
  › superior articulation with occipital condyles = **atlanto-occipital joints**
  › inferior articulation with C2 = **atlantoaxial joints**
  › groove for vertebral artery on superior aspect

(2) anterior arch
  › articular surface for odontoid process on dorsal aspect = **atlantoaxial joint**

(3) posterior arch
  › attachment of posterior atlanto-occipital membrane

◊ The only vertebra without a body / intervertebral disc!

Axis (C2)

Composition:

(1) Paired superior articular processes
(2) Paired inferior articular processes
(3) Superior projection = odontoid process / dens

ATLANTOAXIAL (C1-C2) JOINT

Motion mechanics: flexion, extension, minimal rotation

Physiologic range of rotation: 25°–53°

Major joint stabilizers (thickest + strongest ligaments):

› transverse lig. → allowing axial rotation
› alar ligg. → restrictors of lateral flexion, limiting excessive rotation
› joint capsules

A. INTRINSIC LIGAMENTS (= 3 layers anterior to dura mater)

(1) **Odontoid ligament**

(a) ***Apical ligament***
Function: secondary stabilizer preventing anterior shift
Course: from middle aspect of tip of odontoid process → anterior margin of foramen magnum

(b) ***Alar ligaments*** (paired)
Function: secondary stabilizer preventing anterior shift
Course: from lateral aspect of tip of dens → medial aspect of occipital condyles

(2) **Cruciate (cross-shaped) ligament**

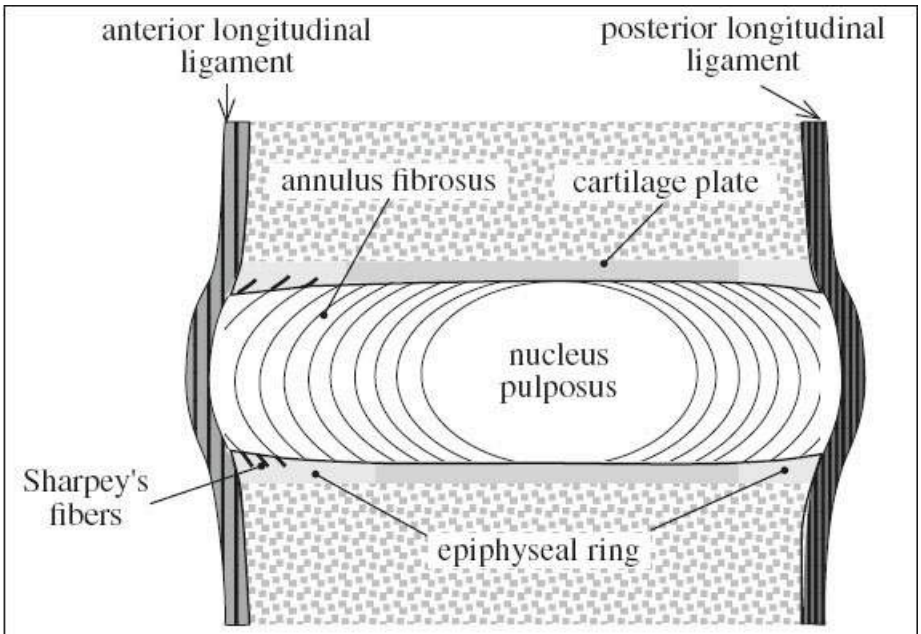
(a) ***Transverse ligament*** of atlas
Function: primary stabilizer of joint preventing excessive anterior motion of atlas on axis
Course: between medial portions of lateral masses: horizontal course behind dens

(b) ***Crus superioris***
Location: superior extension from transverse lig.
Attachment: lower margin of occipital bone

(c) ***Crus inferioris***
Location: inferior extension from transverse lig.
Attachment: posterior surface of body of axis

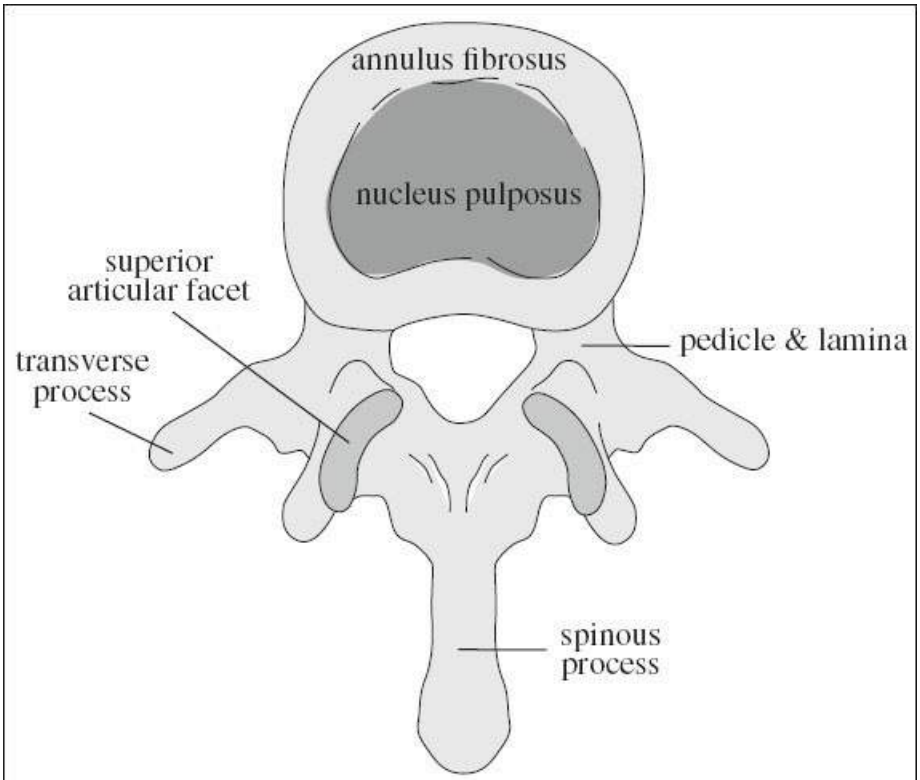
(3) **Tectorial membrane**
= rostral continuation of posterior longitudinal lig.
Course: from body of C2 → anterior margin of foramen magnum
Function: restricts extension

B. EXTRINSIC LIGAMENTS
= fibroelastic membranes as rostral continuations of
(1) Anterior longitudinal lig.
(2) Ligamentum flavum
(3) Nuchal ligament
= continuation of inter- and supraspinous ligaments

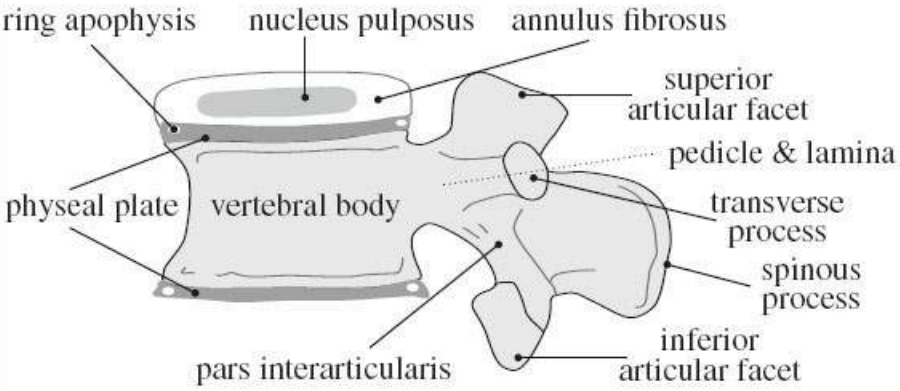


Anatomy of Diskovertebral Junction

anterior longitudinal ligament attaches to anterior surface of vertebral body; it is less adherent to intervertebral disk; posterior longitudinal ligament is applied to back of intervertebral disk and vertebral bodies

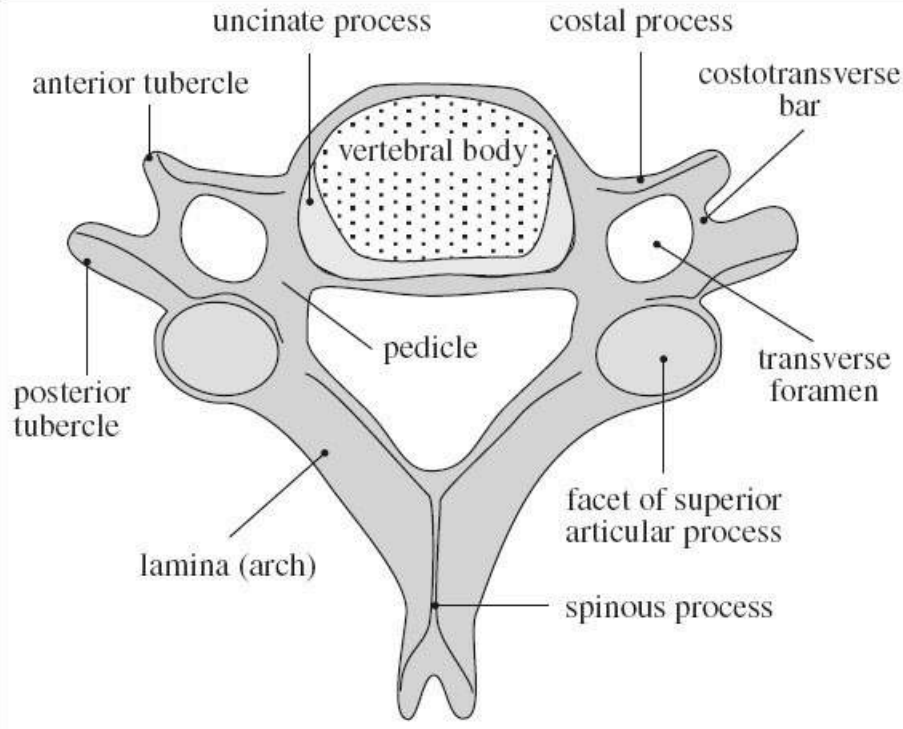


Normal Axial Lumbar Pediatric Vertebral Anatomy

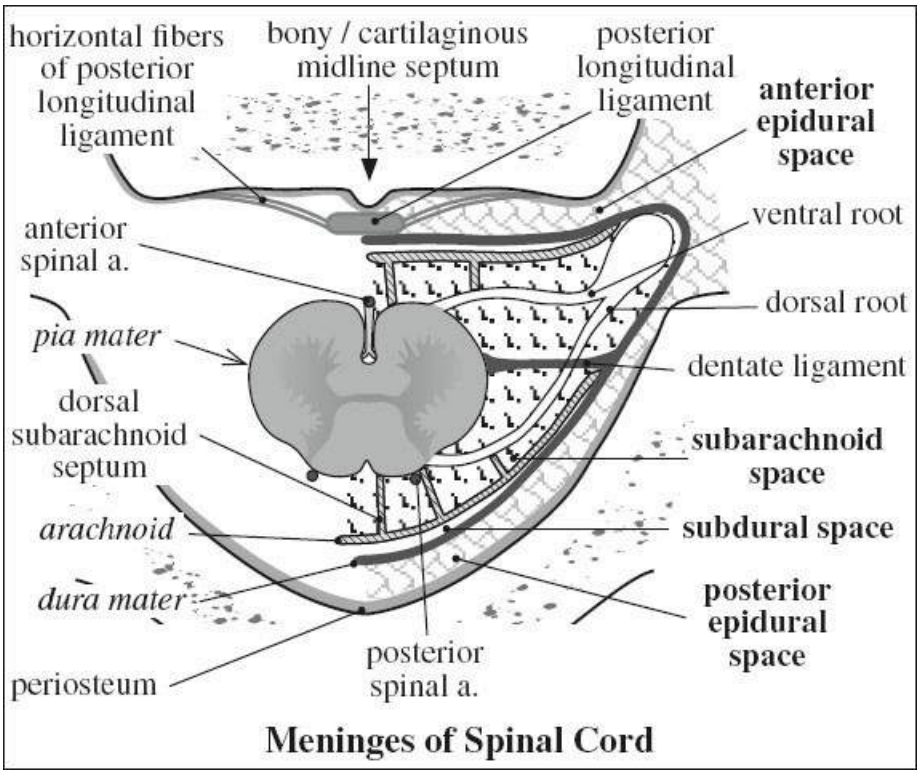


Normal Sagittal Lumbar Pediatric Vertebral Anatomy

3 ossification centers: fusion of 1 vertebral body + 2 posterior elements usually complete by 6 years of age;
physeal plates provide longitudinal growth through enchondral ossification;
ring apophysis calcifies around 6 years of age, ossifies around 13 years of age, and fuses with vertebral body around 17 years of age



Typical Cervical Vertebra (cranial aspect)



Course: 7th cervical vertebra → external occipital protuberance
Function: restriction of hyperflexion

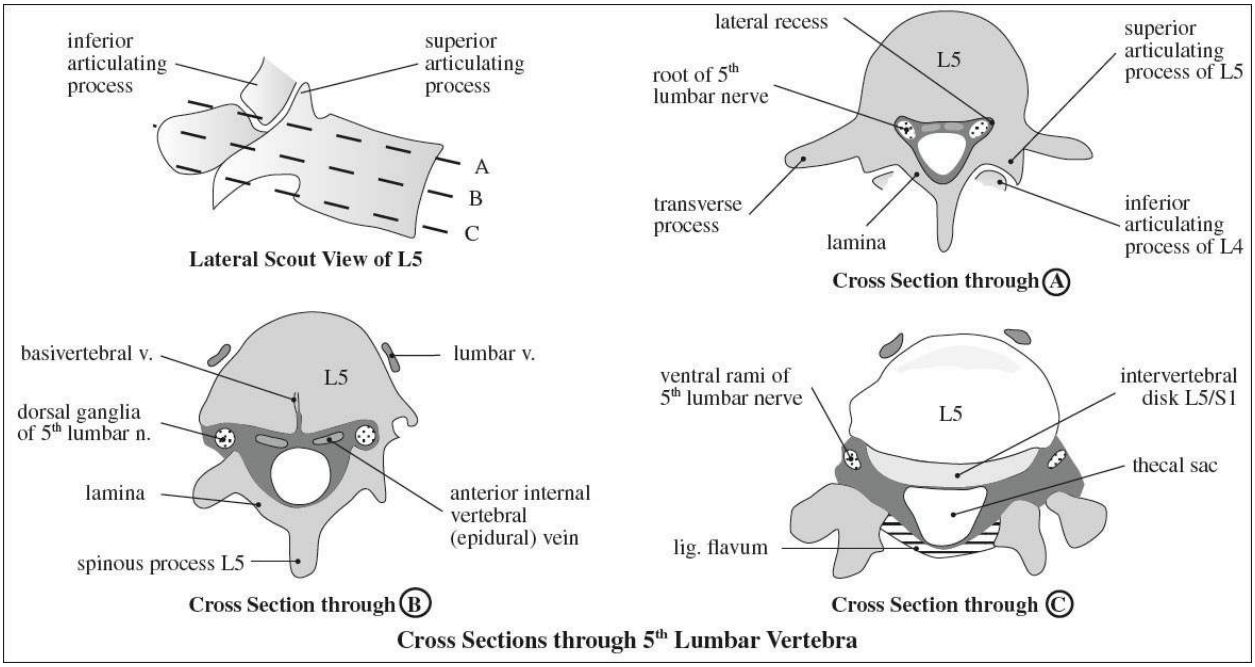
(4) Posterior atlanto-occipital membrane
= cephalic projection of ligamentum flavum
Course: posterior arch of atlas → posterior margin of foramen magnum

MENINGES OF SPINAL CORD

A. PERIOSTEUM
= continuation of outer layer of cerebral dura mater

B. EPIDURAL SPACE
= space between dura mater + bone containing rich plexus of epidural veins, lymphatic channels, connective tissue, fat
(a) cervical + thoracic spine: spacious posteriorly, potential space anteriorly
√ normal thickness of epidural fat 3–6 mm at T7
(b) lower lumbar + sacral spine: may occupy more than half of cross-sectional area

C. DURA
= continuation of meningeal / inner layer of cerebral dura mater; ends at 2nd sacral vertebra + forms coccygeal ligament around filum terminale; sends tubular extensions around spinal nerves; continuous with epineurium of peripheral nerves



Attachment: at circumference of foramen magnum, bodies of 2nd + 3rd cervical vertebrae, posterior longitudinal ligament (by connective tissue strands)

D. SUBARACHNOID SPACE

= space between arachnoid and pia mater containing CSF, reaching as far lateral as spinal ganglia

dentate ligament partially divides CSF space into an anterior + posterior compartment extending from foramen magnum to 1st lumbar vertebra, is continuous with pia mater of cord medially + dura mater laterally (between exiting nerves)

dorsal subarachnoid septum connects the arachnoid to the pia mater (cribriform septum)

E. PIA MATER

= firm vascular membrane intimately adherent to spinal cord, blends with dura mater in intervertebral foramina around spinal ganglia, forms filum terminale, fuses with periosteum of 1st coccygeal segment

Artery of Adamkiewicz

[Albert Wojciech Adamkiewicz (1850–1921) Polish physician and chair of General and Experimental Pathology of Jagiellonian University in Kraków, Poland]

= GREAT ANTERIOR RADICULOMEDULLARY ARTERY

= most important feeder artery of thoracolumbar spinal cord

Diameter: 0.8–1.3 mm

Supply: lower ⅓ of spinal cord

Origin: left intercostal / lumbar artery (68–73%)

Level: 9–12th intercostal artery (62–75%)

Anatomy:

descending aorta →

<u>intercostal / lumbar</u> artery → division into

(a) anterior branch

(b) posterior branch → subdivision into
› muscular branch
› dorsal somatic branch
› radiculomedullary artery → subdivision into
» posterior radiculomedullary artery
» anterior radiculomedullary artery

Hairpin turn: at junction of artery of Adamkiewicz and anterior spinal artery ← increasing disparity between spinal segmental and vertebral levels during growth of spine

Visualization of hairpin: by MR angiography in 93%
by CT angiography in 83%
by selective angiography in 86%

Rx: paraplegia ← conventional selective angiography

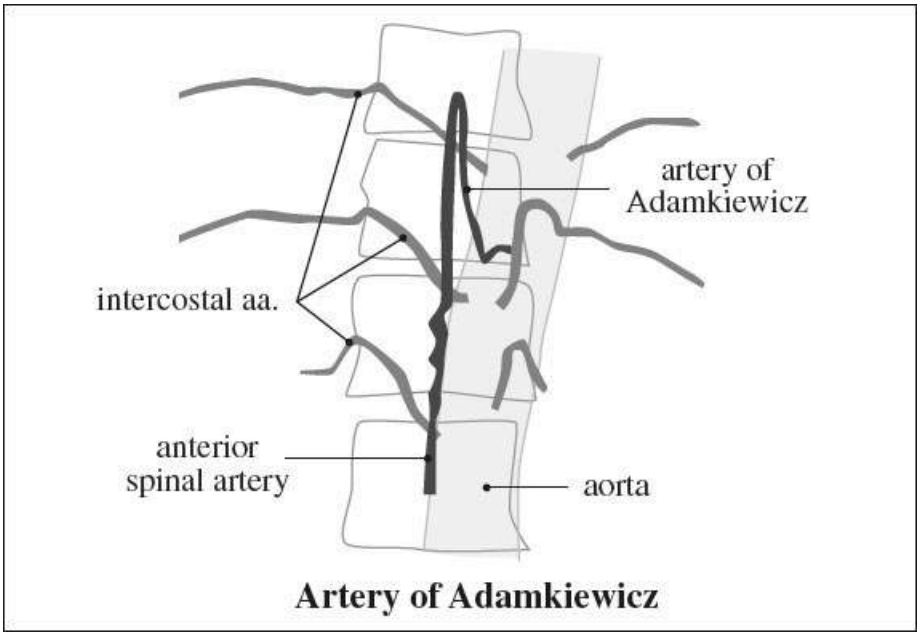
DDx: anterior radiculomedullary vein (very similar shape and course as artery of Adamkiewicz)

BIOMECHANICS OF SPINAL COLUMN

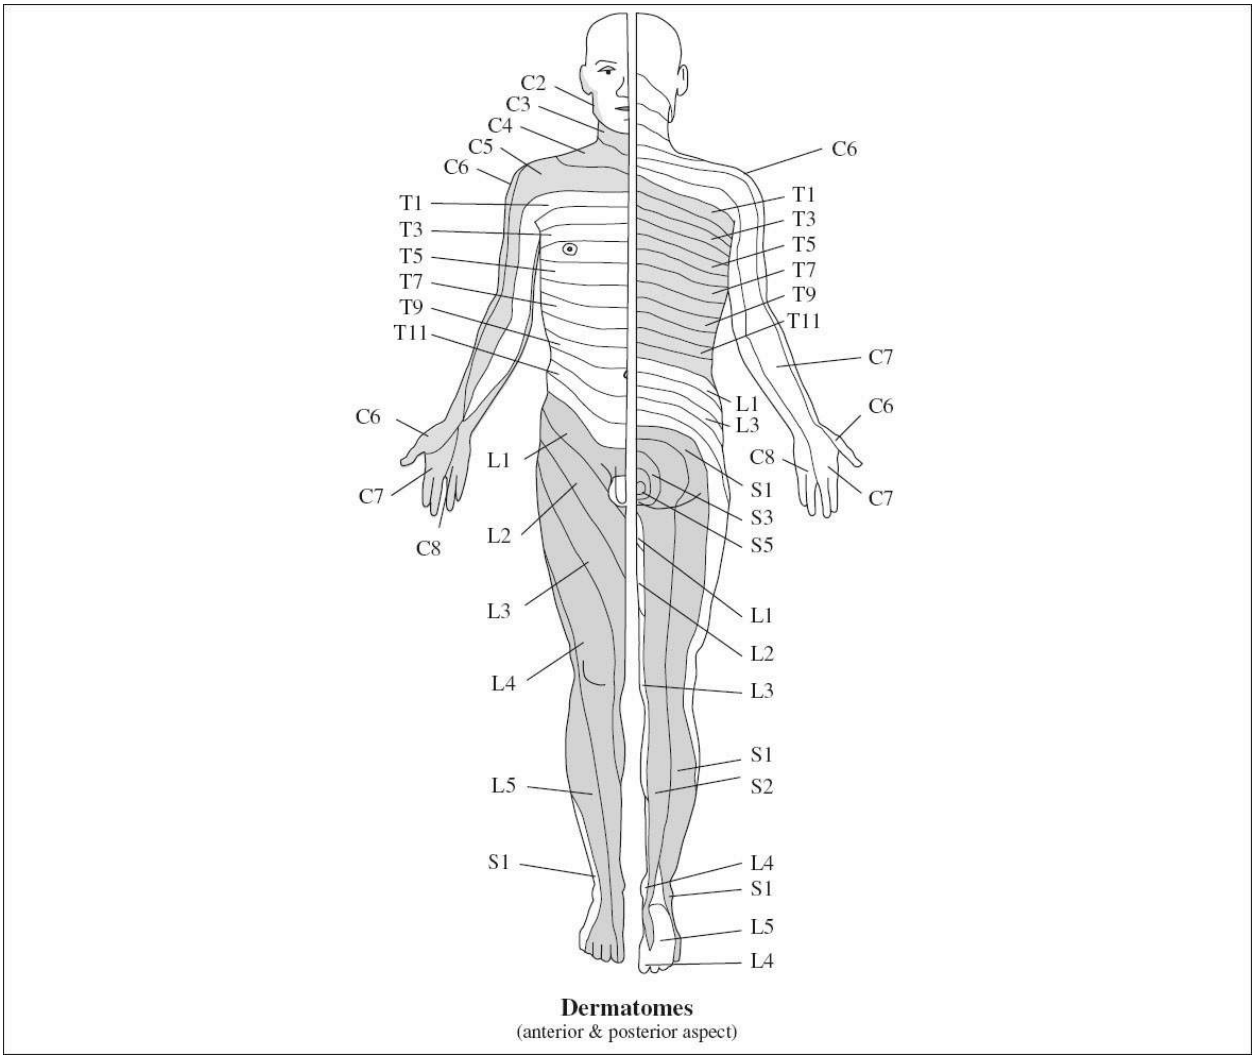
= primary structural support of human body (Francis Denis, 1983)
(a) transmitting axial load of most of the body's weight
(b) restraining motion during flexion, extension, rotation, lateral bending

A. **Anterior column**
= anterior longitudinal ligament, anterior annulus fibrosus, anterior ⅔ of vertebral body
Function: bearing axial load, resisting extension

B. **Middle column**
= posterior ⅓ of vertebral body, nucleus pulposus, posterior annulus fibrosus, posterior longitudinal ligament



Artery of Adamkiewicz



Dermatomes
(anterior & posterior aspect)

Function: bearing some axial load, resisting flexion

◊ Integrity of the middle column is synonymous with stability!

C. **Posterior column**

= posterior elements (pedicles, facets, laminae) + ligaments (lig. flavum, interspinous ligament, supraspinous ligament)

Function: resisting flexion, stabilizing rotation + lateral bending

Posterior Ligamentous Complex (PLC)

Function: "tension band" of spinal column resisting compressive forces on vertebral bodies

1. Supraspinous ligament
   = strong cordlike ligament connecting tips of spinous processes from C7 to sacrum
2. Interspinous ligament
3. Articular facet capsules
4. Ligamentum flavum
   = thick broad structure connecting laminae of adjacent vertebrae

Posterior Longitudinal Ligament

Function: contributes to stability of spinal column

Attachment: tethered to vertebral body via a central septum creating a left + right anterior epidural space

(a) superficial dorsal layer: 8–10 mm wide at disk space level separable from dura at dissection

(b) deep layer: 2–3 mm wide at disk space level

Thoracic Spine

› 12 load-bearing vertebrae

› posterior arch (= pedicles, laminae, facets, transverse processes) handles tensional forces

› vertebral bodies:

(a) height of vertebrae anteriorly 2–3 mm less than posteriorly → mild kyphotic curvature

(b) AP diameter: gradual increase from T1 to T12

(c) transverse diameter: gradual increase from T3 to T12

Thoracolumbar Spine (T12–L1)

Functional unit: 2 vertebrae + interconnecting soft tissues

(a) anterior portion = 2 aligned vertebral bodies + intervertebral disk + anterior and posterior longitudinal ligaments

(b) posterior portion = vertebral arches + facet joints + posterior ligamentous complex

Transitional Vertebra

= vertebra retaining partial features of segments below and above; total number of vertebrae in 92% unchanged with 24 (= 7 + 12 + 5) segments

Incidence: 3–21% of population

- **Bertolotti syndrome** = back pain from transitional 5th lumbar vertebra resulting in partial sacralization
- incidental finding

Location: thoracolumbar (4%) + lumbosacral (15%) junction

Variability of distribution (see table):

(a) variation from 12 thoracic + 5 lumbar segments maintaining together 17 presacral segments, eg, 11 thoracic + 6 lumbar OR 13 thoracic + 4 lumbar

(b) anomalous number of vertebrae (= 23 / 25 presacral segments)

(c) thoracolumbar / lumbosacral transitional vertebra

Thoracolumbar Transitional Vertebra

√ one side with a rib (= laterally downsloping osseous structure with articulation to vertebra)

√ other side with a transverse process (= horizontal osseous structure without central articulation to vertebra)

Lumbosacral Transitional Vertebra

◊ The first non–rib-bearing vertebra = L1

√ "sacralized L5" = L5 incorporated into sacrum

√ "lumbarized S1" = S1 incorporated into lumbar spine

√ uni- / bilateral dysplastic / enlarged transverse processes of lumbosacral transitional vertebra ± uni- / bilateral contact / pseudarthrosis / fusion to adjacent sacral ala
√ "squared" morphology of transitional vertebra
√ decreased height of intervertebral lumbosacral disk
√ none / small residual / well-formed S1-2 disk
√ alteration of lumbosacral intervertebral disk angle

Cx: confusion over labeling / assignment of vertebral levels during treatment planning
◊ Counting cephalad from presumed lumbosacral angle can lead to errors!

Numbering Vertebral Levels at Lumbar MR

Nota bene:

(1) The **iliolumbar ligament** (= low SI structure extending from transverse process to posteromedial iliac crest) identifies the lumbosacral junction (99%), but does NOT ALWAYS denote level of L5
(2) The magnitude of the **lumbosacral intervertebral disk angle** is not useful
(3) A **thoracolumbar transitional vertebra** is NOT associated with an anomalous number of presacral segments

Distribution of Presacral Segments			
Segments			*thoracic + lumbar seg.*
23	5%	3.5%	*11 + 5
		1.5%	*12 + 4
24	92%	89.0%	*12 + 5
		2.2%	*13 + 4
		0.8%	*11 + 6
25	3%	2.4%	*12 + 6
		0.6%	*13 + 5
*The cervical spine is morphologically stable with 7 vertebrae			

(4) A **lumbosacral transitional vertebra** is associated with an anomalous number of presacral segments:
◊ Avoid wrong-level spine surgery and obtain whole-spine localizer image!

MR Report:

"This report assumes that there are five lumbar-type vertebrae, with the lowest lumbar vertebra identified by the iliolumbar ligament."
"A lumbosacral transitional vertebra is present characterized by …. The lowest well-formed intervertebral disk is at …."

NORMAL POSITION OF CONUS MEDULLARIS

◊ Vertebral bodies grow more quickly than spinal cord during fetal period of < 19 weeks MA!
◊ No significant difference regardless of age!

Inferior-most aspect of conus:

L1–L2 level: normal (range T12 to L3)
L2–L3 or higher: in 97.8%

L3 level: indeterminate (in 1.8%)
L3–L4 / lower: abnormal
by 3 month: above inferior endplate of L2 (in 98%)

N.B.: If conus is at / below L3 level, a search should be made for tethering mass, bony spur, thick filum!

SACROILIAC JOINT

A. Upper dorsal part = syndesmosis
   = bone surfaces united by interosseous sacral ligaments
   Location: superior ⅔ to ½ of joint
   √ irregular syndesmotic margins
B. Lower ventral part = synovial joint
   = anatomic characteristics of cartilaginous articulation (hyaline cartilage firmly attached to adjacent bone by fibrous tissue with inner capsule of synovial cells)
   Location: inferior ⅓ to ½ of joint
   √ smooth parallel joint margins
   √ normal joint space width of 2.49 ± 0.66 mm in people < 40 years of age
   (a) 3–5 mm thick cartilage on sacral side
   (b) 1 mm thick cartilage on iliac side
   √ loss of joint space width in people > 40 years of age to 1.47 ± 0.21 mm ± asymmetry of joint width
   √ focal joint space narrowing + nonuniform ill-defined subchondral iliac sclerosis frequent > 30 years of age
C. Ligamentous stabilizers of SI joint
   1. Interosseous ligament
   2. Ventral + dorsal sacroiliac ligaments
   3. Sacrospinous ligament
   4. Sacrotuberous ligament
   5. Iliolumbar ligament

Positioning: oblique view + modified Ferguson view = AP projection with 23° cephalad angulation

Anatomic Variants of SI Joint

1. Accessory sacroiliac joint (most common)
   Site: posterosuperior portion
2. Iliosacral complex
   = iliac projection inserted into a complementary sacral recess
   Site: transition between ligamentous + synovial portion
3. Bipartite iliac bone plate
   Site: posteroinferior portion

23	11	Cuspid (canine / eye tooth)
24	12	1st Bicuspid (1st premolar)
25	13	2nd Bicuspid (2nd premolar)
26	14	1st Molar (6-year molar)
27	15	2nd Molar (12-year molar)
28	16	3rd Molar (wisdom tooth)

Int	A	
38	17	3rd Molar (wisdom tooth)
37	18	2nd Molar (12-year molar)
36	19	1st Molar (6-year molar)
35	20	2nd Bicuspid (2nd premolar)
34	21	1st Bicuspid (1st premolar)
33	22	Cuspid (canine / eye tooth)
32	23	Lateral incisor
31	24	Central incisor

Tooth Numbering System for Permanent Arch
(according to American Dental Association [A] & Fédération Dentaire Internationale [Int])
Tooth surfaces: (a) anterior / *buccal* (vestibular) for maxilla + mandible (b) posterior / *palatine* for maxilla (c) *lingual* for mandible
Relationship of dental structures to mental foramen: *mesial* = anterior to mental foramen; *distal* = posterior to mental foramen

TEETH

Primary (deciduous) Dentition (20 teeth)

= 5 teeth in each quadrant: NO premolars + only 2 molars

Permanent Dentition (32 teeth)

= 8 teeth in each quadrant

Development:

from occlusal surface toward root apex within maxilla and mandible; resorption of root of primary tooth during migration toward oral cavity; eruption continues until tooth occludes with tooth from opposite jaw

Anomalous Tooth Development

Hypodontia = < 32 teeth

Hyperdontia = > 32 teeth

Frequency: molar (44%), premolar (33%), incisor (23%)

May be associated with: Gardner syndrome, cleidocranial dysplasia

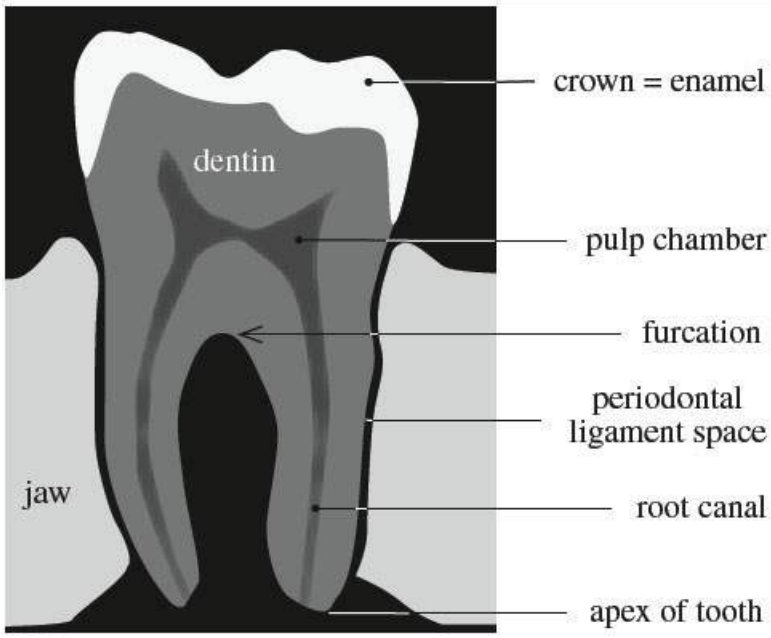
mesiodens: in maxillary midline adjacent to incisors

distodens: posterior to 3rd molar, often impacted causing dental inflammation / infection

Cx of supernumerary teeth:

crowding / abnormal eruption / noneruption / damage of normal teeth

DDx: odontoma, hamartoma of odontogenic origin



Drawing of CT Image of Mandibular Molar
(sagittal oblique view)

lamina dura = lining of tooth socket;
periodontal ligament = thin radiolucent layer between surface of root + lamina dura

Tooth surface: outward = **facial** (**buccal / labial**); inward = **lingual** (for mandible) / **palatal** (for maxilla);
anterior = **mesial**; posterior = **distal**;
premolar / molar biting surface = **occlusal**

ADENOMATOID ODONTOGENIC TUMOR

= rare tumor
Age: 2nd decade; M << F
Location: 70% in maxilla
√ well-demarcated radiolucent lesion + punctate calcifications
DDx: dentigerous cyst (less apical in location)

AMELOBLASTIC FIBROMA

Histo: epithelium representing enamel + embryonic connective tissue
Associated with: impacted tooth
Location: posterior mandible
√ well-defined pericoronal radiolucent lesion
√ mostly multiloculated

AMELOBLASTOMA OF JAW

= ADAMANTINOMA OF JAW
= benign locally aggressive infiltrative epithelial neoplasm
Prevalence: most common (10%) of odontogenic tumors
Origin: enamel-forming odontogenic epithelium of dental follicle that failed to regress during embryonic development; 30–50% arise from epithelium of dentigerous cyst (= mural ameloblastoma)
Classification (WHO 2006):
(a) intraosseous: arises in jaw as unicystic / desmoplastic / mixed cystic + solid (most aggressive) lesion
(b) extraosseous (peripheral): sessile / pedunculated mass confined to gingiva / alveolar mucosa
Age: 20–40 years; M÷F = 1÷1
• slow-growing painless mass
Location: ramus + posterior body of mandible (75%), maxilla (25%)
Site: in region of bicuspids + molars, typically 3rd molar (angle of mandible commonly affected)
√ well-defined well-corticated unilocular lucent lesion (DDx: odontogenic keratocyst, dentigerous cyst)
√ uni- / multilocular lesion with internal septations (honeycomb / soap bubble appearance)
√ typically expansile with scalloped margin
√ may perforate lingual cortex + infiltrate adjacent soft tissues
√ erosion of roots of adjacent teeth (UNIQUE)
√ often associated with crown of an impacted / unerupted tooth
CT:

√ cystic areas of low attenuation + isoattenuating enhancing solid component
√ ± resorption of roots of adjacent teeth

Prognosis: frequently local recurrence even more aggressive after excision; rarely metastasize to lung

Cx: may undergo carcinomatous change

Rx: wide surgical resection ± radiation therapy

ANKYLOSING SPONDYLITIS

= autoimmune disease of unknown etiology characterized by inflammation of multiple articular + paraarticular structures frequently resulting in bone ankylosis primarily affecting axial skeleton

Prevalence: 0.1–0.2% of general population

Peak age: 15–35 years; M÷F = 3÷1 to 10÷1; Caucasian÷Blacks = 3÷1

Associated with: (1) Ulcerative colitis, regional enteritis
(2) Iritis in 25%
(3) Aortic insufficiency + atrioventricular conduction defect

• HLA-B27 antigen positive in 96%
• insidious onset of low back pain + stiffness

Path: involves synovial + cartilaginous joints and sites of ligamentous attachment

Location:
(a) axial skeleton: sacroiliac joints, thoracolumbar + lumbosacral junctions
◊ HALLMARK is sacroiliac joint involvement!
(b) peripheral skeleton (10–20%): sternal joint, symphysis pubis, hip, glenohumeral joint
(c) tendinous insertions in pelvis + proximal femur

Temporal course: initial abnormalities of sacroiliac joints + thoracolumbar + lumbosacral junctions with gradual involvement of remaining spine

@ Skull
√ temporomandibular joint space narrowing, erosions, osteophytosis

@ Hand (30%)
√ exuberant osseous proliferation
√ osteoporosis, joint space narrowing, osseous erosions (deformities less striking than in rheumatoid arthritis)

@ Sacroiliac joint / symphysis pubis
√ initially sclerosis of joint margins primarily on iliac side (bilateral + symmetric late in disease, may be unilateral + asymmetric early in disease)
√ later irregularities + widening of joint (= cartilage destruction)
√ bony fusion

@ Pelvis
√ periostitic "whiskering": ischial tuberosity, iliac crest, ischiopubic rami, greater femoral trochanter, external occipital protuberance, calcaneus

@ Spine
√ squaring = straightened / convex anterior vertebral margins = erosive osteitis of anterior corners
√ "shiny corners" = reactive sclerosis of corners of vertebral body

√ diskitis = erosive abnormalities of diskovertebral junction
√ "diskal ballooning" = biconvex shape of intervertebral disk related to osteoporotic deformity + diskal calcification
√ marginal syndesmophyte formation (in 15%) = thin vertical radiodense spicules bridging the vertebral bodies = ossification of outer fibers of annulus fibrosus (NOT anterior longitudinal ligament):
  √ "bamboo spine" on AP view = undulating contour due to syndesmophytosis
    Cx: prone to insufficiency fracture → pseudarthrosis
√ ankylosis of vertebral edges / center (with bony extension through disk)
√ asymmetric erosions of laminar + spinous processes of lumbar spine
√ ossification of supraspinous + interspinous ligaments:
  √ "dagger" sign = single radiodense line on AP view
  √ "trolley-track" sign on AP view = central line of ossification with two lateral lines of ossification (= apophyseal joint capsules)
√ apophyseal + costovertebral joint ankylosis (on oblique views)
√ dorsal arachnoid diverticula in lumbar spine with erosion of posterior elements (Cx: cauda equina syndrome)
√ atlantoaxial subluxation

MR:
  √ anterior / posterior / marginal spondylitis
  √ spondylodiskitis
  √ transdiskal / transvertebral insufficiency fracture
  √ arthritis of zygapophyseal (facet), costovertebral, costotransverse joints (best seen on axial images)
  √ bone marrow edema
  √ joint effusion, synovitis, erosions
  √ ankylosis in late stage → impairing chest excursion
  √ enthesitis of interspinous ligaments ± osteitis of subjacent spinous processes
  √ syndesmophytes + ankylosis of diskovertebral unit

@ Chest

Frequency: 1% of patients with ankylosing spondylitis, usually at an advanced stage of disease

Histo: interstitial + pleural fibrosis with foci of dense collagen deposition, NO granulomas

• bone manifestation obvious + severe

Location: apices / upper lung fields

√ sternomanubrial joint irregularities + sclerosis
√ uni- / bilateral coarse upper lobe pulmonary fibrosis with upward retraction of hila (DDx: tuberculosis)
√ reticulonodular progressively confluent opacities in lung apices
√ apical bullae, cysts + cavitation (mimicking TB)

HRCT:
  √ peripheral interstitial lung disease
  √ bronchiectasis
  √ paraseptal emphysema
  √ tracheobronchomegaly

√ apical fibrosis

Cx: superinfection, especially with aspergillus (mycetoma formation) in 19–60% / atypical mycobacteria
- hemoptysis

DDx: other causes of pulmonary apical fibrosis (primary infection by fungi / mycobacteria; cancer)

@ Cardiovascular (up to 80% paralleling duration of disease)

Location: ascending aorta, aortic valve

√ aortic wall thickening (60%)

√ aortic valve thickening + nodularity → aortic valve insufficiency

Prognosis: 20% progress to significant disability; occasionally death from cervical spine fracture / aortitis

Rx: regular lifelong exercises + NSAID; tumor-necrosis factor (TNF)–α inhibitors

DDx: (1) Reiter syndrome (unilateral asymmetric SI joint involvement, paravertebral ossifications)

(2) Psoriatic arthritis (unilateral asymmetric SI joint involvement, paravertebral ossification)

(3) Inflammatory bowel disease

(4) Sternoclavicular hyperostosis (pustulosis palmaris et plantaris)

ARACHNOIDITIS

Etiology: idiopathic; trauma, back surgery (spinal fusion, laminectomy), meningitis, subarachnoid hemorrhage (spinal tap, epidural steroid injections, difficult epidural blood patch); Pantopaque® myelography (pre 1986) ← inflammatory effect potentiated by presence of blood

M > F ← spinal / epidural anesthesia for delivery

Associated with: syrinx
- chronic low back pain ± radicular symptoms
- par- and hypesthesia, gait disturbance, incontinence, myelopathic symptoms

Location: most easily seen in lumbar region (= cauda equina)

√ residual oil-soluble contrast media in dural sac

√ intrathecal calcification

Myelo:

√ blunting of nerve root sleeves

√ blocked nerve roots without cord displacement (⅔)

√ streaking + clumping of contrast

CT:

√ fusion / clumping (= abnormal distribution) of nerve roots

√ intradural pseudomass

√ intradural cysts

√ "empty thecal sac" = featureless empty-looking sac with individual nerve roots adherent to wall (final stage)

MR:

√ conglomeration of adherent roots centrally within thecal sac:

√ thickened nerve roots
√ pseudotethering
√ "empty-sac" sign = roots adherent to wall of dural sac:
√ deformed / narrowed dural sac ← extra- / intradural scarring
√ intrathecal pseudocysts
√ soft-tissue mass replacing subarachnoid space
√ enhancement of nerve roots (= edema during first 3 months)
Cx: syringomyelia

ARACHNOID CYST OF SPINE

= subset of meningeal cysts
Cause: posttraumatic, postinfectious, congenital diverticulum, idiopathic (arachnoid herniation through dural defect /abnormal distribution of arachnoid trabeculations)
Histo: lined with fibrous tissue + scattered meningothelial cells
Age: 15–45 years (in 77%); range of several months to 80 years; M=F
Relationship to CSF:
(a) encapsulated completely separate from CSF
(b) communication with subarachnoid space via a neck ± one-way valve
• pain (waxing + waning), sensory changes, urinary dysfunction, weakness
• progressive spastic / flaccid paresis improving in supine position + worsening during Valsalva maneuver
• symptomatic with compression of spinal cord / nerve root ← arachnoid cyst expansion (osmotic gradient, ball-valve mechanism, active secretions from cyst lining)
√ oval sharply demarcated extramedullary mass
√ filling with intrathecal contrast material depending upon size of opening between cyst + subarachnoid space:
initially in 50%, nearly 100% with delayed imaging
DDx: epidermoid cyst (asymmetric filling defect)
√ local displacement + compression of spinal cord
√ higher SI than CSF (from relative lack of CSF pulsations)
√ NO enhancement
MR:
√ iso- to hyperintense to CSF on T1WI + T2WI
√ variability in signal intensity ← pulsatility of CSF / higher protein content
√ isointense to CSF on FLAIR MR images
√ NO restricted diffusion at DWI
Types:

I	extradural arachnoid cyst without nerve root fibers
	Ia extradural arachnoid cyst
	Ib sacral meningocele
II	extradural meningeal cyst containing neural tissue (= Tarlov cyst)
III	intradural arachnoid cyst

Pitfalls of CT myelography / MRI:

(1) Nonopacification of noncommunicating arachnoid cyst → misidentification as a different type of lesion
(2) Absence of mass effect on cord → failure to detect additional cysts / small CSF-isointense arachnoid cyst

DDx: traumatic / lateral thoracic meningoceles
Cx: spinal cord myelopathy, nerve root radiculopathy

Extradural Arachnoid Cyst

Cause: congenital / acquired dural defect
Age: 2nd decade of life; M>F
Location: thoracic (80%) > cervical (15%) > lumbar (5%)spine; extending over 3.7 vertebral bodies
Site: posteriorly / posterolaterally to cord
√ scalloping of vertebral body
√ thinning / erosion of pedicles
√ widening of interpeduncular distance

Intradural Arachnoid Cyst

Cause: congenital deficiency within arachnoid (= true arachnoid cyst) / adhesion from prior infection or trauma (= arachnoid loculation)
√ focal displacement and compression of spinal cord
√ widened dorsal subarachnoid space with diminished CSF flow artifact

ARACHNOID DIVERTICULUM

= widening of root sheath with arachnoid space occupying > 50% of total transverse diameter of root + sheath together
Cause: ? congenital / traumatic, arachnoiditis, infection
Pathogenesis: hydrostatic pressure of CSF
√ scalloping of posterior margins of vertebral bodies
√ myelographic contrast material fills diverticula

ARTERIOVENOUS MALFORMATION OF SPINAL CORD

Classification:
1. True intramedullary AVM
   = nidus of abnormal intermediary arteriovenous structure with multiple shunts
   Age: 2nd–3rd decade
   Cx: subarachnoid hemorrhage, paraplegia
   Prognosis: poor (especially in midthoracic location)
2. Intradural arteriovenous fistula
   = single shunt between one / several medullary arteries + single perimedullary vein
3. Dural arteriovenous fistula
   = single shunt between meningeal arteries + intradural vein
4. Metameric angiomatosis

ARTERIOVENOUS MALFORMATION OF JAW

• occasionally pulsatile soft-tissue swelling

Location: ramus + posterior body of mandible

√ cystlike due to bone resorption ± calcifications

√ ± multilocular ± bone expansion

√ ± erosive margins

√ angiogram confirms diagnosis

Cx: Tooth extraction can result in lethal exsanguination!

DDx: traumatic bone cyst, central giant cell granuloma, ossifying fibroma

ATLANTOAXIAL ROTARY FIXATION

= AARF = ATLANTOAXIAL ROTATORY SUBLUXATION (AARS)
= ATLANTOAXIAL ROTATORY FIXATION (AARF)
= SPONTANEOUS HYPEREMIC DISLOCATION
= ATLANTOAXIAL ROTATORY / ROTARY DISLOCATION
= DISTENTION LUXATION = NASOPHARYNGEAL TORTICOLLIS

= nontraumatic subluxation / rotational disorder of atlantoaxial joint leading to limited rotation / fixation of neck comprising many different entities

Cause: idiopathic spontaneous

(a) increased ligamentous laxity: rheumatoid arthritis, Marfan syndrome, Down syndrome, Morquio syndrome

(b) congenital abnormality: incomplete odontoid process, incomplete transverse ligament

(c) infection: sinusitis, otomastoiditis, otitis media, pharyngitis, adenotonsillitis, cervical / retropharyngeal / tonsillar abscess = **Grisel syndrome**
(= not associated with trauma or bone disease primarily in children) ← hyperemia + pathologic ligamentous relaxation

Predisposed: cervical dystonia, post surgery

May be associated with: ipsilateral contracted SCMM

• history of insignificant cervical spine trauma / upper respiratory tract infection

• limited painful neck motion = painful torticollis

• head held in "cock-robin" position = rotation + flexion + tilt of head contralateral to direction of rotation with inability to turn head that does not resolve within 5–7 days after injury

X-ray (Dx difficult to make):

√ atlanto-odontoid asymmetry (open mouth odontoid view):

√ decrease in atlanto-odontoid space + widening of lateral mass on side ipsilateral to rotation

√ increase in atlanto-odontoid space + narrowing of lateral mass on side contralateral to rotation

√ atlantoaxial asymmetry remains constant with head turned into neutral position

√ posterior arch of C1 not identified in true lateral projection

√ obscuration of craniovertebral junction in true lateral view

CT (dynamic with 3D reconstruction [a] with head in resting position [b] with maximal contralateral rotation):

√ facet displacement in neutral head position

√ asymmetrically fixed C1-C2 rotation

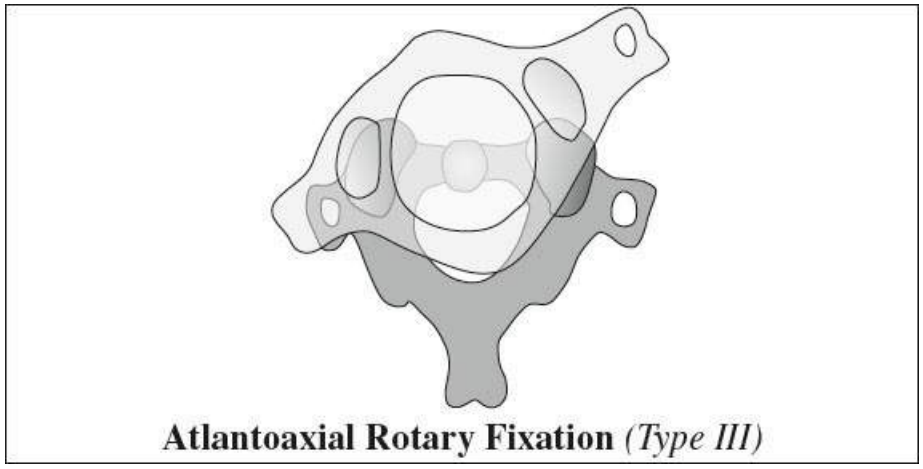
Rotation up to an average of 79° in adult volunteers, loss of contact of articular facets of C1 and C2 during rotation as high as 74–85% in physiologic conditions. Therefore, a diagnosis of subluxation of the atlanto-occipital joint should not be made based solely on the CT appearance of this joint.

MR:
√ disruption of alar + transverse ligg.
√ spinal cord compression (rare)

Types:

I < 3 mm anterior displacement of atlas on axis = rotatory fixation within normal range of movement (most common)
Injury: intact alar + transverse ligaments
√ pivot around dens, NO anterior displacement of atlas

II 3–5 mm anterior displacement of atlas + unilateral displacement of lateral mass of atlas ← restraint by alar lig.
Injury: transverse ligament



Atlantoaxial Rotary Fixation *(Type III)*

√ center of rotation shifted to one of lateral masses

III > 5 mm anterior displacement of atlas + anterior displacement of both lateral masses
Injury: deficiency of both (alar + transverse) ligaments

IV posterior displacement of atlas on axis (rare)
Injury: deficiency of both (alar + transverse) ligaments

DDx: torticollis (atlantoaxial symmetry reverts to normal with head turned into neutral position)

Traumatic Rotatory Subluxation

Cause: injury of alar ligaments ← flexion + rotation forces
Age: more prevalent in children than in adults ← mostly flat articular facets allow ample movement in multiple directions

BRACHIAL PLEXUS INJURY

= most severe nerve injury of extremities
Cause: severe traction force on upper limb at birth / in traffic accident (motorcycle)

1. **Erb-Duchenne palsy**: adduction injury affecting C5-6 ← downward displacement of shoulder
   - paralysis of shoulder muscles + biceps
2. **Klumpke palsy**: abduction injury at C7, C8, T1 ← arm stretched over head
   - paralysis of forearm flexors + intrinsic hand muscles

CT myelography (preferred method):

◊ Shoulder artifacts may be problematic at C8–T1 level

√ displacement of spinal cord to contralateral side ← absence of normal nerve root traction on cord

√ pouchlike nerve root sleeve at site of avulsion

√ asymmetric slightly deformed root sleeve + nerve roots

√ obliteration of tip of root sleeve

√ traumatic meningocele

√ contrast extravasation collecting in axilla

√ metrizamide in neural foramina

MR:

◊ Conventional MR only in 50% accurate!

Pitfalls: partial root avulsion, intradural fibrosis, traumatic meningocele, movement artifacts (respiration, swallowing, blood flow)

√ focal T2-hyperintense cord changes ← edema of acute phase / myelomalacia in chronic phase

√ focal T2-hypointense cord changes ← hemosiderin

√ enhancement of morphologically normal intradural nerve root / root stump ← functional impairment (mostly preganglionic)

√ abnormal enhancement of paraspinal (multifidus) muscle ← muscle denervation = indirect sign of root avulsion

√ thickening of postganglionic brachial plexus ← edema + fibrosis

CAUDAL REGRESSION SYNDROME

= SACRAL AGENESIS = CAUDAL DYSPLASIA SEQUENCE

= midline closure defect of neural tube with a spectrum of anomalies including complete / partial agenesis of sacrum + lumbar vertebrae and pelvic deformity

Etiology: disturbance of caudal mesoderm < 4th week of gestation from toxic / infectious / ischemic insult

Prevalence: 1÷60,000 births; 0.005–0.01% of population; in 0.1–1% of pregnancies in diabetic women; M÷F = 2.7÷1

Predisposed: infants of diabetic mothers; risk increases 200–400 times in women dependent on insulin

◊ 16–22% of children with sacral agenesis have mothers with diabetes mellitus

◊ NOT associated with VATER syndrome!

A. Musculoskeletal anomalies

@ Lower extremity

- symptoms from minor muscle weakness to complete sensorimotor paralysis of both lower extremities

√ hip dislocation
√ hypoplasia of lower extremities
√ flexion contractures of lower extremities
√ foot deformities

@ Lumbosacral spine = SACRAL AGENESIS

Spectrum:

Type 1 = unilateral partial agenesis localized to sacrum / coccyx
Type 2 = bilateral partial symmetric defects of sacrum + iliosacral articulation
Type 3 = total sacral agenesis + iliolumbar articulation
Type 4 = total sacral agenesis + ilioilial fusion posteriorly

√ nonossification of lower spine
√ fusion of caudal-most 2 or 3 vertebrae
√ spina bifida (lipomyelomeningocele often not in combination with Arnold-Chiari malformation)
√ narrowing of spinal canal rostral to last intact vertebra
√ hypoplastic iliac wings

B. Spinal cord anomalies
√ characteristic club- / wedge-shaped configuration of conus medullaris (= hypoplasia of distal spinal cord)
√ ± tethered spinal cord
√ ± dural sac stenosis with high termination
√ ± spinal cord lipoma, teratoma, cauda equina cyst
√ ± syrinx

C. Genitourinary anomalies
• neurogenic bladder (if > 2 segments are missing)
• malformed external genitalia
√ ± bilateral renal aplasia with pulmonary hypoplasia and Potter facies

D. Hindgut anomalies
• lack of bowel control
√ anal atresia

OB-US:
• normal / imperforate anus
√ short CRL in 1st trimester ← diabetic embryopathy
√ normal / mildly dilated urinary system
√ normal / increased amniotic fluid
√ 2 umbilical arteries
√ 2 hypoplastic nonfused lower extremities in a CHARACTERISTIC froglike position
√ fusion of pelvic bones
√ sacral agenesis, absent vertebrae from lower thoracic / upper lumbar spine caudally

N.B.: brain, proximal spine, and spinal cord are notably spared!

Sirenomelia

= fused lower extremities resembling a mermaid (siren)

Cause: aberrant vessel that shunts blood from the high abdominal aorta to the umbilical cord (steal phenomenon) → severe ischemia of caudal portion of fetus

◊ NOT associated with maternal diabetes mellitus!

• pulmonary hypoplasia + Potter facies

• absence of anus; absent genitalia

√ bilateral renal agenesis / dysgenesis (lethal)

√ marked oligohydramnios

√ single aberrant umbilical artery

√ two-vessel umbilical cord

√ single / fused lower extremity often with fewer leg bones than normal

√ sacral agenesis, absent pelvis, lumbosacral "tail", lumbar rachischisis

Prognosis: incompatible with life

CEMENTOBLASTOMA

= rare benign periapical lesion

Origin: true neoplasm of cementum

Prevalence: <1% of all odontogenic tumors

Age: < 20 years (50%); < 30 years (75%)

Associated with: erupted permanent tooth (common); near impacted / unerupted tooth (rare)

Location: mandible (>75%): 90% molar / premolar region

Site: fusion with root of tooth(s); invasion of root canal / pulp chamber (occasionally)

√ periapical sclerotic sharply marginated round opaque sunburst lesion

√ surrounded by thin halo of low attenuation

Rx: complete removal of tooth to avoid recurrence

DDx: condensing osteitis (periodontal ligament space not obscured)

CEMENTO-OSSEOUS DYSPLASIA

= CEMENTOMA = FIBROOSTEOMA

= nonneoplastic benign hamartoma associated with tooth apex

Histo: proliferation of connective tissue within periodontal membrane

Age: 4th–5th decade; in woman: black / Asian descent

• asymptomatic / dull ache

Associated with: vital nonrestored tooth + intact lamina dura

Location: mandible >> maxilla

Site: usually apex of vital tooth

√ one / more, closely apposed / confluent, round / ovoid lucent lesion with varying amounts of opacity:

√ initially lytic lesion

√ later mixed lysis + sclerosis with varying amounts of opacity; little expansion

√ calcifies centrally with time

√ periapical sclerotic sharply marginated area NOT fused to tooth

√ ± low-attenuation halo

√ adjacent lesions may coalesce

Cementoblastoma and cemento-osseous dysplasia are both periapical sclerotic sharply marginated

lesions with low-attenuation halo.
DDx: (1) Cementoblastoma (in child + young adult, fuses directly to tooth root)
(2) Cemento-osseous dysplasia (common in black woman + woman of Asian descent during 4th / 5th decade of life, does not fuse to tooth root)

Periapical Cemento-osseous Dysplasia

Site: anterior mandible between mandibular canine teeth involving one / a few teeth
√ often multicentric
DDx: ossifying fibroma, fibrous dysplasia, Paget disease

Focal Cemento-osseous Dysplasia

Site: posterior mandible involving molar teeth
√ no extension into adjacent bone
√ no cortical expansion
DDx: periapical periodontitis, ossifying fibroma

Florid Cemento-osseous Dysplasia

= diffuse form of periapical cemento-osseous dysplasia
Location: involving ≥ 2 jaw quadrants / entire mandible
May be complicated by: osteomyelitis with drainage of necrotic bone debris into oral cavity

CENTRAL GIANT CELL GRANULOMA (COMMON)

= single lesion of altered vascular + reactive response within bone
Age: < 30 years (75%); in girls + young women
• painless swelling, tenderness on palpation
Location: mandible÷maxilla = 2÷1
Site: anterior to 1st molar (= deciduous teeth); propensity for crossing midline (especially in maxilla)
√ small unilocular area of lucency (early)
√ multilocular honeycomb with wispy internal septa (later)
√ expansion of bone + erosion / remodeling of cortex
√ displacement of teeth + root resorption
√ usually well-defined border
DDx: brown tumor of HPT (histologically similar)

CHONDROSARCOMA OF SPINE

= 2nd most common nonlymphoproliferative primary malignant tumor of spine in adults
Peak age: 30 and 70 years; M÷F = 2÷1 to 4÷1
Location: thoracic + lumbar spine > sacrum
Site: posterior element (40%), vertebral body (15%), both (45%)
√ large calcified mass with bone destruction
√ ± true ossification ← residual osteochondroma
CT:
√ low attenuation of nonmineralized portion of tumor

√ chondroid matrix mineralization

MR:

√ nonmineralized portion of tumor = high water content:

√ low to intermediate SI on T1WI

√ very high signal intensity on T2WI

√ rings and arcs enhancement pattern ← lobulated growth

√ extension through intervertebral disk (in 35%)

Rx: en bloc resection

CHORDOMA

Prevalence: 1÷2,000,000; 2–4% of all primary malignant bone tumors; 1% of all CNS tumors

◊ 2nd most common primary malignant tumor of spine in adults after lymphoproliferative neoplasms! Highly malignant in children.

Etiology: originates from embryonic remnants of notochord / ectopic cordal foci between Rathke pouch + coccyx (notochord appears between 4th and 7th week of embryonic life and forms nucleus pulposus)

Mean age: 50 (range, 30–70) years; peak in 5th decade; M÷F = 2÷1

Path: lobulated tumor with fluid, gelatinous mucoid substance, recent + old hemorrhage, necrotic areas, occasionally calcifications + sequestered bone fragments contained within pseudocapsule

Histo: [*physallis*, Greek = bladder, bubble; *phoros* = bearing]

(1) typical chordoma: cords + clusters of **physaliferous cells** (PAS-positive stain) in a lobular arrangement with a large bubblelike multivacuolated cytoplasm containing intracytoplasmic mucous droplets; abundant extracellular mucus deposition + areas of hemorrhage

(2) chondroid chordoma: cartilage instead of mucinous differentiation of extracellular matrix

Location: (a) 50–60% in sacrum (sacrococcygeal chordoma)

(b) 30–35% in clivus (sphenooccipital chordoma)

(c) 15% in vertebrae (vertebral chordoma): cervical > thoracic / lumbar spine; vertebral body with sparing of posterior elements

(d) other sites (5%) in mandible, maxilla, scapula

Site: midline / paramedian

√ amorphous calcification (50–75%)

√ heterogeneous enhancement

CT:

√ low-attenuation within soft-tissue mass ← myxoid-type tissue

√ higher attenuation fibrous pseudocapsule

MR (modality of choice):

√ low to intermediate intensity on T1WI, occasionally hyperintense ← high protein content:

√ heterogeneous internal texture ← calcification, necrosis, gelatinous mucoid collections

√ very high SI on T2WI ← physaliferous cells similar to nucleus pulposus with high water content

Angio:

√ prominent vascular stain

NUC:
√ cold lesion on bone scan
√ no uptake on gallium scan
Metastases (in 5–43%) to: liver, lung, regional lymph nodes, peritoneum, skin (late), heart
Prognosis: poor in spite of low grade + slow growth; almost 100% recurrence rate despite radical surgery
DDx: giant notochordal rest (nonprogressive indistinct lesion, normal bone / variable degree of sclerosis, no soft-tissue involvement)

Intracranial Chordoma (35%)
= locally invasive + destructive lesion of clivus
Location: infrasellar midline
√ mass of usually T1 hypointensity + T2 signal hyperintensity
√ hypointense intratumoral septations
√ foci of T1 signal hyperintensity within tumor / periphery ← residual ossified fragments / tumor calcifications, / small collections of proteinaceous fluid / hemorrhage
√ posterior extension indenting pons
DDx: cartilaginous tumor (more lateral location, at petrooccipital synchondrosis, curvilinear calcifications)

Sacrococcygeal Chordoma (50–70%)
= large destructive sacral mass with 2ndary soft-tissue extension
◊ Most common primary sacral tumor after giant cell tumor!
Peak age: 40–60 years; M÷F = 2–3÷1
Path: slow-growing tumor → large size at presentation
• clinically indolent and subtle; rectal bleeding (42%)
• low back pain (70%); sciatica + weakness in hip / lower limbs ← sacral root compression
• constipation, frequency, urgency, straining on micturition ← compression by tumor
• autonomic dysfunction → urinary / fecal incontinence
• palpable sacral mass on digital examination (17%)
Location: predominantly in 4th + 5th sacral segment
√ presacral mass with average size of 10 cm extending superiorly + inferiorly; rarely posterior location
√ displacement of rectum + bladder
√ solid tumor with cystic areas (in 50%)
√ amorphous peripheral calcifications (15–89%)
√ secondary bone sclerosis in tumor periphery (50%)
√ honeycomb pattern with trabeculations (10–15%)
√ may cross sacroiliac joint
X-ray:
√ osteolytic midline mass in sacrum + coccyx associated with soft-tissue mass and calcifications
CT (useful for defining extent of bone involvement):
√ bone destruction associated with lobulated midline soft-tissue mass
√ areas of low attenuation within mass ← high water content of myxoid properties

MR:
√ hypo- / isointense mass relative to muscle on T1WI:
√ intrinsic hyperintense areas on T1WI ← hemorrhage or myxoid / mucinous collections
√ hyperintense mass similar to nucleus pulposus on T2WI ← high water content:
√ dividing septa + hemosiderin of low signal intensity
√ heterogeneous often moderate enhancement

The combination of high T2 signal intensity in a lobulated sacral mass that contains areas of hemorrhage and calcification is strongly suggestive of a chordoma!

Prognosis: 7–10 years average survival; 50–74% 5-year survival rate (in adulthood); 52–64% 10-year survival; 52% 20-year survival
Dx: fine-needle aspiration biopsy
Rx: radical surgical excision (most critical); radiation therapy; 70% rate of local recurrence after excision

DDx:
› Primary neural tumor: schwannoma, neurofibroma, meningioma, myxopapillary ependymoma (from within spinal canal, more intense enhancement)
› Primary bone tumor:
(1) Giant cell tumor (2nd most common primary, upper sacrum, may be eccentric, ± extension across SI joint, low-to-intermediate T2 intensity ± fluid-fluid levels)
(2) Chondrosarcoma (off midline from sacroiliac joint space cartilage, heterogeneous T2 SI, no hemorrhage)
(3) Aneurysmal bone cyst
(4) Osteoblastoma
(5) Lymphoma
› Metastasis, plasmacytoma
› Soft-tissue neoplasm: atypical hemangioma, prostatic carcinoma, osteosarcoma, osteomyelitis

Sphenooccipital Chordoma (15–35%)

Age: younger patient (peak age of 20–40 years); M÷F - 1÷1
• orbitofrontal headache
• visual disturbances, ptosis
• 6th nerve palsy / paraplegia
Location: clivus, sphenooccipital synchondrosis
√ bone destruction (in 90%): clivus > sella > petrous bone > orbit > floor of middle cranial fossa > jugular fossa > atlas > foramen magnum
√ reactive bone sclerosis (rare)
√ calcifications / residual bone trabeculae (20–70%)
√ soft-tissue extension into nasopharynx (common), into sphenoid + ethmoid sinuses (occasionally), may reach nasal cavity + maxillary antrum
√ variable degree of enhancement
MR:
√ large intraosseous mass extending into prepontine cistern, sphenoid sinus, middle cranial

fossa, nasopharynx
√ posterior displacement of brainstem
√ usually hypo- / isointense to brain / occasionally inhomogeneously hyperintense on T1WI
√ hyperintense on T2WI
√ ± CHARACTERISTIC honeycomb enhancement pattern
Prognosis: 4–5 years average survival
DDx: meningioma, metastasis, plasmacytoma, giant cell tumor, sphenoid sinus cyst, nasopharyngeal carcinoma, chondrosarcoma

Vertebral / Spinal Chordoma (15–20%)
◊ More aggressive than sacral / cranial chordomas
Age: younger patient; M÷F = 2÷1
• low back pain + radiculopathy + retention of urine
Location: cervical (8% – particularly C2), thoracic spine (4%), lumbar spine (3%)
Site: midline centra sparing posterior elements; arising in perivertebral musculature (uncommon)
√ destructive expansile lesion of vertebral body:
√ + epidural soft-tissue mass of collar button / mushroom / dumbbell shape over several segments
√ often incomplete sparing of disk spaces to involve adjacent bodies (10–14%) simulating infection
√ exophytic anterior soft-tissue mass
√ expansion into neural foramen mimicking nerve sheath tumor
√ solitary midline spinal mass
√ sclerosis / "ivory vertebra" in 43–62%
√ total destruction of vertebra, initially without collapse
√ amorphous peripheral calcifications in 40%
Cx: complete spinal block
Prognosis: 4–5 years average survival
DDx: metastasis, primary bone tumor, primary soft-tissue tumor, neuroma, meningioma

CONDENSING OSTEITIS OF JAW
= reactive osteitis surrounding apex of tooth with pulpitis / pulpal necrosis
Associated with: carious tooth
√ periapical inflammatory lesion: granuloma / cyst / abscess
√ periapical poorly marginated nonexpansile sclerosis

CSF FISTULA
= characterized by egress of CSF from intracranial cavity through abnormal communication between subarachnoid space and pneumatized structure within skull base (= osteodural defect)
Cause:
A. CONGENITAL: ENCEPHALOCELE
B. ACQUIRED

(a) traumatic (80–90% of all cases)
◊ 2% of all head injuries develop CSF fistula
(b) nontraumatic:
› infection
› tumor (esp. those arising from pituitary gland)
(c) spontaneous: idiopathic intracranial hypertension

• rhinorrhea / otorrhea (may be exacerbated by Valsalva maneuver)
• "serous otitis media" with conductive / sensory hearing loss
• presence of β-2 transferrin (= polypeptide specific for CSF) / β-trace protein

Technique:

(a) invasive techniques (time-consuming, poorly tolerated)
1. Radionuclide cisternography
2. CT cisternography
◊ Contraindicated in active meningitis / elevated intracranial pressure!

Disadvantage:
› requires poorly tolerated lumbar puncture
› time-consuming
› slight risk of complications (low-tension headache, infection, bleeding at puncture site)
› hypersensitivity reaction to contrast
› high dose of radiation
› requires active CSF leak

(b) noninvasive techniques (best used in combination)
1. Multidetector CT (92% sensitive, 100% specific)
√ bone defect / dehiscence at skull base
√ adjacent prominent arachnoid granulations
√ air-fluid level / opacification of contiguous sinus / middle ear / mastoid
√ pneumocephalus
√ lobular / nondependent area of soft-tissue opacification (meningocele, meningoencephalocele)
DDx: mucosal reaction, cholesteatoma, granulation tissue, cholesterin granuloma
2. MR cisternography (87–100% sensitive, 57–100% specific, 78–89% accurate)
√ hyperintense CSF fistulous tract
√ CSF collection = meningocele
DDx: inflammatory paranasal secretions
√ extradural brain = meningoencephalocele
√ secondary gliosis of herniated brain
√ dural enhancement in stalk of meningoencephalocele

Spontaneous CSF Fistula

Location: cribriform plate along course of anterior ethmoid artery (most common), lateral lamella, perisellar region (sphenoid roof > floor of sella > posterior wall), lateral recess of sphenoid, tegmen tympani, tegmen mastoideum, skull base foramina

Traumatic CSF Fistula

- traumatic leak: usually unilateral; onset within 48 hours after trauma, usually scanty; resolves in 1 week
- nontraumatic leak: profuse flow; may persist for years
- anosmia (in 78% of trauma cases)

Location: fractures through frontoethmoidal complex + middle cranial fossa (most commonly)

Cx: (1) meningitis / encephalitis / brain abscess (in 25–50% of untreated cases)
(2) pneumocephalus

CURRARINO TRIAD

= triad of **a**norectal malformation + **s**acrococcygeal osseous defect + **p**resacral mass (= ASP triad)

= rare syndrome characterized by autosomal dominant genetic inheritance (in > 50%)

Path: presacral mass consists of teratoma, anterior sacral meningocele > dermoid cyst, hamartoma, enteric duplication cyst

Age: < 16 years at diagnosis (in 80%)

- constipation

DEGENERATIVE DISK DISEASE

◊ Therapeutic decision-making should be based on clinical assessment alone!

◊ There are no prognostic indicators on images in patients with acute lumbar radiculopathy!

◊ 35% of individuals without back trouble have abnormal findings (HNP, disk bulging, facet degeneration, spinal stenosis)

◊ Imaging is only justified in patients for whom surgery is considered!

Pathophysiology:

loss of disk height leads to stress on facet joints + uncovertebral joints (= uncinate process), exaggerated joint motion with misalignment (= rostrocaudal subluxation) of facet joints, spine instability with arthritis, capsular hypertrophy, hypertrophy of posterior ligaments, facet fracture

Plain film:

√ **intervertebral osteochondrosis** = disease of nucleus pulposus (= desiccation = loss of disk water):
- √ narrowing of disk space
- √ vacuum disk phenomenon
- √ disk calcification
- √ bone sclerosis of adjacent vertebral bodies

√ **spondylosis deformans** = degeneration of the outer fibers of the annulus fibrosus:
- √ endplate osteophytosis growing initially horizontally and then vertically several millimeters from diskovertebral junction ← displacement of nucleus pulposus in anterior + anterolateral direction producing traction on osseous attachment of annulus fibrosus [= fibers of Sharpey])
- √ enlargement of uncinate processes

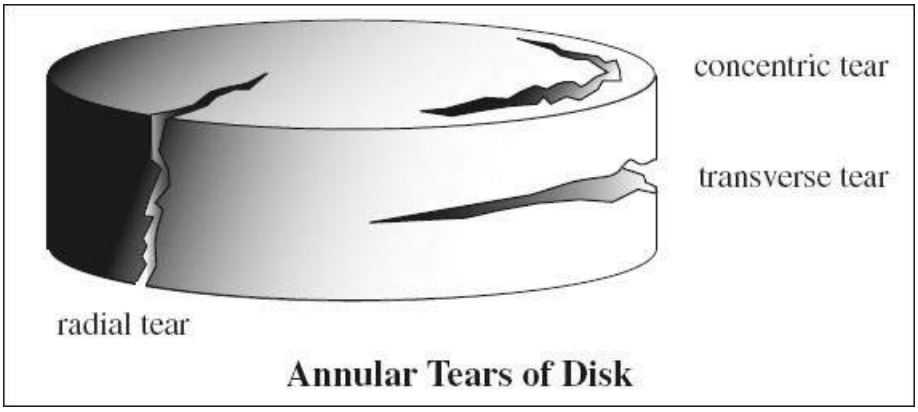
√ **osteoarthritis** = degenerative disease of synovium-lined apophyseal / costovertebral joints:

√ degenerative spondylolisthesis
√ cartilaginous node = intraosseous disk herniation

Myelography:
√ delineation of thecal sac, spinal cord, exiting nerve roots

CT (accuracy > 90%):
√ facet joint disease (marginal sclerosis, joint narrowing, cyst formation, bony overgrowth)
√ uncovertebral joint disease of cervical spine (osteophytes project into lateral spinal canal + neuroforamen)

MR:
√ **scalloping of cord** (T2WI FSE / GRE images):
√ anterior encroachment by disk / spondylosis
√ posterior encroachment by ligamentum flavum hypertrophy
√ **loss of disk signal** ← desiccation ←decrease in water-binding proteoglycans + increase in collagen within nucleus pulposus) on T2WI
√ **annular tear:**
(1) concentric tear - separation of annular lamellae
(2) transverse tear
(3) radial tear - crossing multiple annular lamellae with greater vertical dimension + more limited horizontal extent
• diskogenic pain
◊ does NOT imply disk herniation
√ gap near middle of annulus



Annular Tears of Disk

Modified Dallas Diskogram Classification	
Grade	*Description*
0	contrast confined within nucleus pulposus
1	contrast extends to inner third of annulus
2	contrast extends to middle third of annulus
3	outer third of annulus + < 30° of circumference
4	outer third of annulus + > 30° of circumference
5	extension of contrast beyond annulus

√ cleft of high SI in a normally hypointense outer annulus on T2WI

√ contrast enhancement ← granulation tissue / hyperemia / inflammation

√ **reduction in disk height** (late):

√ Schmorl's node

√ moderate linear uniform enhancement on T1WI

√ vacuum phenomenon with low signal on T1WI

√ **endplate + marrow changes** (Modic & DeRoos):

= linear signal alterations paralleling adjacent endplates

(a) Type 1 (4%) = *edema pattern*

Cause: replacement of bone marrow with hyperemic fibrovascular tissue + edema ← acute disk degeneration

√ hypointense on T1WI + hyperintense on T2WI

√ contrast-enhancement of marrow

(b) Type 2 (16%) = *fatty marrow pattern*

Cause: replacement of bone marrow with fat ← chronic disk degeneration

√ hyperintense marrow signal on T1WI

√ iso- to mildly hyperintense on T2WI

√ hypointense on STIR

(c) Type 3 = *bony sclerosis pattern*

Cause: replacement of bone marrow with sclerotic bone ← chronic disk degeneration after a few years

√ hypointense marrow signal on T1WI + T2WI

√ juxtaarticular **synovial cyst** in posterolateral spinal canal (most frequently at L4-5):

√ smooth well-defined extradural mass adjacent to facet joint

√ variable signal pattern ← serous, mucinous, gelatinous fluid components, air, hemorrhage

√ contrast-enhancing hypointense perimeter ← fibrous capsule with calcium + hemosiderin

NUC:

SPECT imaging of vertebrae can aid in localizing increased uptake to vertebral bodies, posterior elements, etc.

√ eccentrically placed increased uptake on either side of an intervertebral space (osteophytes, diskogenic sclerosis)

Sequelae:

(1) Disk bulging

(2) Disk herniation

(3) Spinal stenosis

(4) Facet joint disease

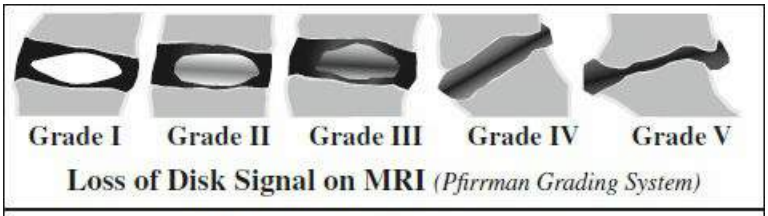
(5) Instability

√ dynamic slip > 3 mm on flexion-extension

√ static slip > 4.5 mm

√ traction spurs

√ vacuum phenomenon



Loss of Disk Signal on MRI *(Pfirrman Grading System)*

MRI Grades of Disk Degeneration

Grade	*T2 signal*	*Structure of Nucleus*	*Distinction to Annulus*	*Height*
I	⇑	white, homogeneous	clear	normal
II	↑	heterogeneous, horizontal bands	clear	normal
III	↔	gray, heterogeneous	unclear	↓
IV	↔/↓	gray to black, hetero	none	⇓
V	⇓	black, heterogeneous	none	collapsed

DDx: **Idiopathic segmental sclerosis of vertebral body** (middle-aged / young patient, hemispherical sclerosis in anteroinferior aspect of lower lumbar vertebrae with small osteolytic focus, only slight narrowing of intervertebral disk; unknown cause)

Bulging Disk = Disk Bulge

= concentric smooth expansion of softened disk material beyond the confines of endplates with disk extension outward involving > 50% of disk circumference

Cause: weakened and lengthened but intact annulus fibrosus + posterior longitudinal ligament

Age: common finding in individuals > 40 years of age

Location: L4-5, L5-S1, C5-6, C6-7

√ rounded symmetric defect localized to disk space level

√ smooth concave indentation of anterior thecal sac

√ encroachment on inferior portion of neuroforamen

√ accentuated by upright myelography

MR:

√ nucleus pulposus hypointense on T1WI + hyperintense on T2WI ← desiccation (= water loss through degeneration + fibrosis)

Herniation of Nucleus Pulposus

= HNP = protrusion of disk material > 3 mm beyond margins of adjacent vertebral endplates involving < 50% of disk circumference

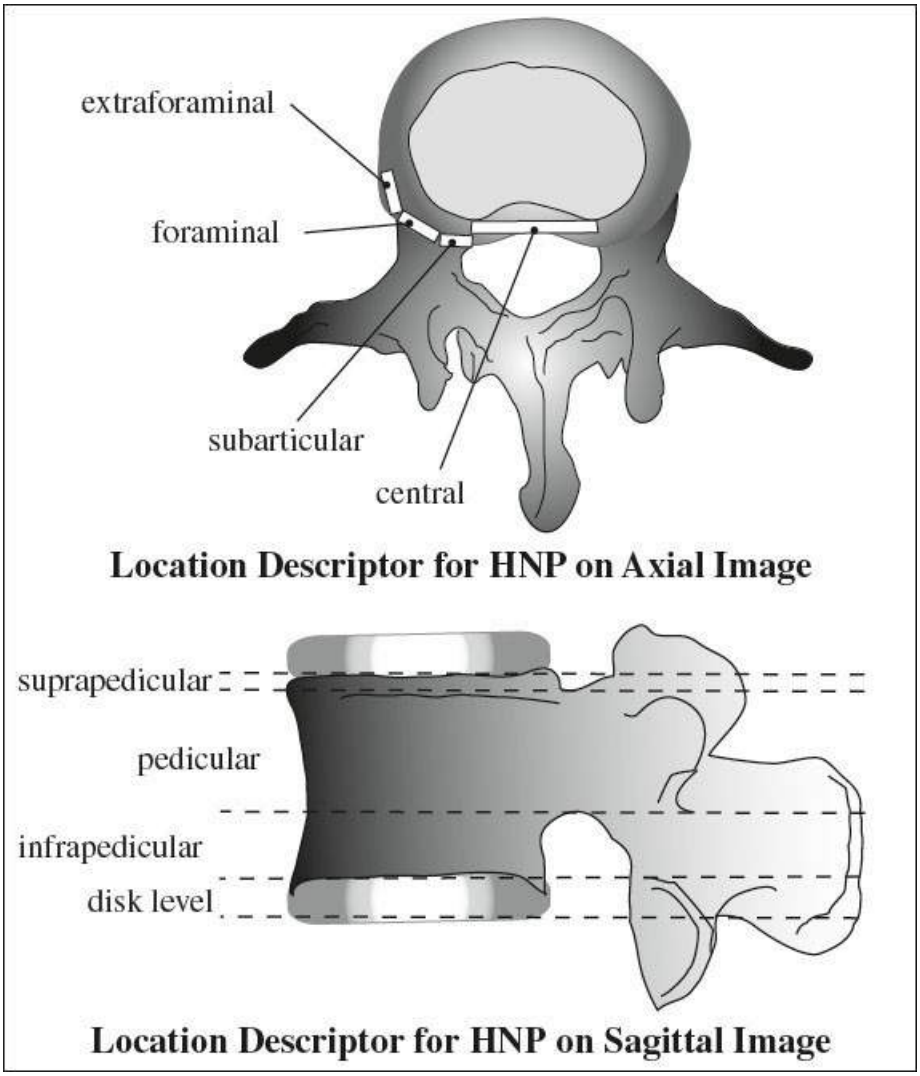
Cause: rupture of annulus fibrosus with disk material confined within posterior longitudinal ligament

◊ 21% of an asymptomatic population has a herniated disk!

- local somatic spinal pain = sharp / aching, deep, localized
- centrifugal radiating pain = sharp, well-circumscribed, superficial, "electric," confined to dermatome
- centrifugal referred pain = dull, ill-defined, deep or superficial, aching or boring, confined to somatome (= dermatome + myotome + sclerotome)

Site:

(a) posterolateral (49%) = weakest point along posterolateral margin of disk at lateral recess of spinal canal



◊ The posterior longitudinal ligament is tightly adherent to posterior central margins of disk!

(b) posterocentral (8%)
(c) bilateral (to both sides of posterior ligament)
(d) lateral / foraminal (< 10%)
(e) extraforaminal = anterior (commonly overlooked) (29%)
(f) intraosseous / vertical = Schmorl node (14%)

Myelography:

√ sharply angular indentation on lateral aspect of thecal sac with extension above / below level of disk space (ipsilateral oblique projection best view)
√ asymmetry of posterior disk margin
√ double contour ← superimposed normal + abnormal side (horizontal beam lateral view)

√ narrowing of intervertebral disk space (most commonly a sign of disk degeneration)
√ deviation of nerve root / root sleeve
√ enlargement of nerve root ("trumpet" sign) ← edema
√ amputated / truncated nerve root (= nonfilling of root sleeve)

MR:

√ herniated disk material of low SI displaces the posterior longitudinal ligament and epidural fat of relative high SI on T1WI
√ "squeezed toothpaste" effect = hourglass appearance of herniated disk at posterior disk margin on sagittal image
√ asymmetry of posterior disk margin on axial image

Cx: (1) spinal stenosis mild = < ⅓
moderate = ⅓ to ⅔
severe = > ⅔
(2) neuroforaminal stenosis

Prognosis:

conservative therapy reduces size of herniation by
0–50% in 11% of patients,
50–75% in 36% of patients,
75–100% in 46% of patients
(secondary to growth of granulation tissue)

Broad-based Disk Protrusion

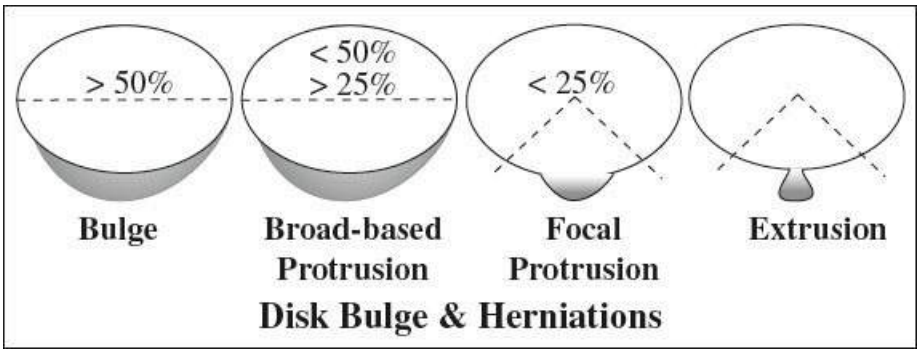
√ triangular shape of herniation with a base wider than the radius of its depth
√ 25–50% of disk circumference

Focal Disk Protrusion

√ triangular shape of herniation with a base wider than the radius of its depth
√ < 25% of disk circumference

Disk Extrusion

= prominent focal extension of disk material through the annulus with only an isthmus of connection to parent disk through intact / ruptured posterior longitudinal ligament
√ mushroom-shaped herniation with base narrower than the radius of its depth
√ "toothpaste" sign



Disk Sequestration

= FREE FRAGMENT HERNIATION
= complete separation of disk material from parent disk with rupture through posterior longitudinal ligament into epidural space
◊ Missed free fragments are a common cause of failed back surgery!
√ migration superiorly / inferiorly away from disk space with compression of nerve root above / below level of disk herniation
√ disk material > 9 mm away from intervertebral disk space = NO continuity
√ soft-tissue density with higher value than thecal sac
DDx: (1) Postoperative scarring (retraction of thecal sac to side of surgery)
(2) Epidural tumor
(3) Tarlov cyst (dilated nerve root sleeve)
(4) **Conjoined nerve root** (2 nerve roots arising from thecal sac simultaneously representing mass in ventrolateral aspect of spinal canal; normal variant in 1–3% of population)

Free Fragment Migration

= separated disk material travels above / below intervertebral disk space
√ ± continuity

Cervical Disk Herniation

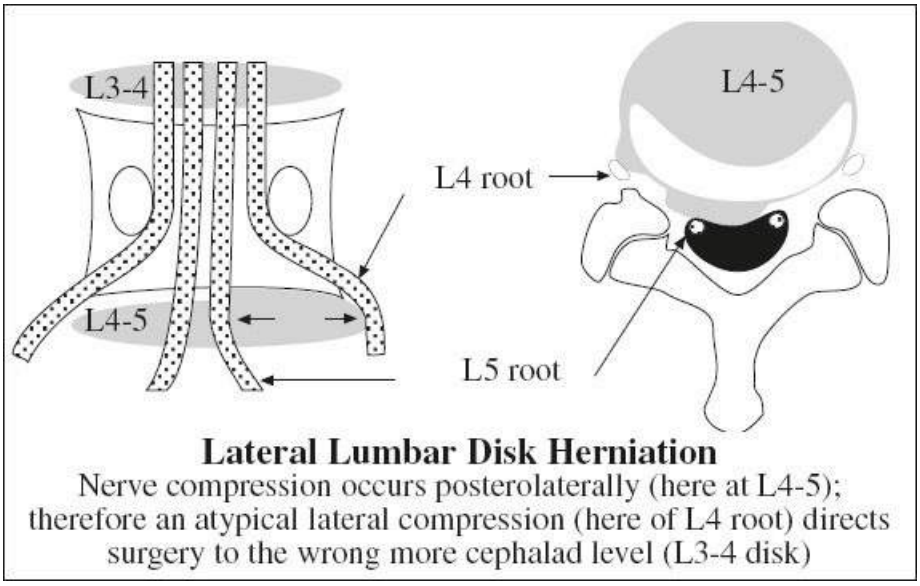
Peak age: 3rd–4th decade
• neck stiffness, muscle splinting; dermatomic sensory loss
• weakness + muscle atrophy; reflex loss
Sites: C6-7 (69%); C5-6 (19%); C7-T1 (10%); C4-5 (2%)
Sequelae:
(1) compression of exiting nerve roots with pain radiating to shoulder, arm, hand
(2) cord compression (spinal stenosis + massive disk rupture)

Thoracic Disk Herniation

Prevalence: 1% of all disk herniations
Sites: T11-12
√ calcification of disk fragments + parent disk (frequent)

Lumbar Disk Herniation

• **sciatica** =
(1) Stiffness in back
(2) Pain radiating down to thigh / calf / foot
(3) Paresthesia / weakness / reflex changes
• pain exaggerated by coughing, sneezing, physical activity + worse while sitting / straightening of leg
Sites: L4-5 (35%) > L5/S1 (27%) > L3-4 (19%) > L2-3 (14%) > L1-2 (5%)



Lateral Lumbar Disk Herniation
Nerve compression occurs posterolaterally (here at L4-5); therefore an atypical lateral compression (here of L4 root) directs surgery to the wrong more cephalad level (L3-4 disk)

DIASTEMATOMYELIA

= SPLIT CORD = MYELOSCHISIS [*diastema*, Greek = slit, cleft]
= sagittal division of spinal cord into two hemicords, each containing a central canal, one dorsal horn + one ventral horn

Etiology: congenital malformation as a result of adhesions between ectoderm and endoderm; M÷F = 1÷3

Path:

(a) 2 hemicords each covered by layer of pia within single subarachnoid space + dural sac (60%); not accompanied by bony spur / fibrous band
(b) 2 hemicords each with its own pial, subarachnoidal + dural sheath (40%); accompanied by fibrous band (in 25%), cartilaginous / bony spurs (in 75%)

Associated with: myelomeningocele

- hypertrichosis, nevus, lipoma, dimple, hemangioma overlying the spine (26–81%)
- muscle wasting, ankle weakness in one leg; clubfoot (50%)

Location: lower thoracic / upper lumbar > upper thoracic > cervical spine

√ sagittal cleft in spinal cord resulting in 2 asymmetric hemicords which usually reunite caudal to cleft
√ occasionally 2 coni medullaris
√ eccentric central canal within both hemicords
√ bony spur through center of spinal canal arising from posterior aspect of centra (< 50%)
√ thickened filum terminale > 2 mm (> 50%)
√ tethered cord (> 50%)
√ low conus medullaris below L2 level (> 75%)
√ defect in thecal sac on myelogram
@ Vertebrae
  √ congenital scoliosis (50–75%)
    ◊ 5% of patients with congenital scoliosis have diastematomyelia
  √ spina bifida over multiple levels

√ anteroposterior narrowing of vertebral bodies
√ widening of interpediculate distance
√ narrowed disk space with hemivertebra, butterfly vertebra, block vertebra
√ fusion + thickening of adjacent laminae (90%)
(a) fusion to ipsilateral lamina at adjacent levels
(b) diagonal fusion to contralateral adjacent lamina = intersegmental laminar fusion

Cx: progressive spinal cord dysfunction

DISKITIS

◊ Most common pediatric spine problem!

Etiology:

(1) Bloodborne bacterial invasion of vertebrae infecting disk via communicating vessels through endplate
◊ Vertebral osteomyelitis + diskitis may be the same entity!
(2) Invasive procedure / trauma: surgery, diskography, myelography, chemonucleolysis
(3) Extension of adjacent infection

Organism:

(a) pyogenic: Staphylococcus aureus (> 50%), gram-negative rods (in IV drug abusers / immunocompromised patients)
(b) nonpyogenic: tuberculosis, coccidioidomycosis
◊ TB has a propensity to extend beneath longitudinal ligaments with involvement of multiple vertebral levels

Pathogenesis: infection starts in disk (still vascularized in children) / in anterior inferior corner of vertebral body (in adults) with spread across disk to adjacent vertebral endplate

Age peaks: 6 months to 4 years; 10–14 years; 6th–7th decade

- over 2–4 weeks gradually progressing irritability, malaise, low-grade fever; refusal to bear weight; myelopathy
- neck / back / referred hip pain, limp, focal tenderness
- elevated sedimentation rate, WBC count often normal
- positive blood culture (in 58%)

Location: L3-4, L4-5, unusual above T9

Distribution: 2 adjacent vertebrae + intervening disk

Plain film (positive 2–4 weeks after onset of symptoms):

√ decrease in disk space height (earliest sign) = intraosseous herniation of nucleus pulposus into vertebral body through weakened endplate
√ indistinctness of adjacent endplates with destruction
√ endplate sclerosis (during healing phase beginning anywhere from 8 weeks to 8 months after onset)
√ bone fusion (after 6 months to 2 years)

CT (SAG / COR reformatted images more sensitive!):

√ early loss of disk height
√ endplate irregularities ← destruction
√ vertebral body collapse

√ paravertebral inflammatory mass / abscess
√ epidural soft-tissue extension with deformity of thecal sac

MR (preferred modality; 93% sensitive, 97% specific, 95% accurate):
◊ Very sensitive modality early on in disease process!
√ ↓ marrow intensity on T1WI in 2 contiguous vertebrae
√ signal intensity of disk decreased on T1WI + increased on T2WI compared to skeletal muscle
◊ Fluid-sensitive sequence with fat suppression!
√ progressive destruction of vertebral body
√ in early stage preserved disk height with variable intensity on T2WI (often increased)
√ in later stages loss of disk height with increased intensity on T2WI (= intradiskal fluid)

CEMR:
√ focal enhancement of involved disk + adjacent vertebral endplates ± bone marrow

NUC (41% sensitive, 93% specific, 68% accurate on ^{99m}Tc-MDP + ^{99m}Tc WBC scans):
√ positive before radiographs
√ increased uptake in vertebral endplate adjacent to disk
√ bone scan usually positive in adjacent vertebrae (until age 20) ← vascular supply via endplates; may be negative after age 20

Dx: needle biopsy (77% positive) before IV antibiotics
Cx: (1) epidural / paravertebral abscess ← extension of infection
(2) kyphosis
Rx: immobilization in body cast for ~ 4 weeks
DDx: neoplastic disease (no breach of endplate, disk space often intact)

Postoperative Diskitis

Frequency: 0.75–2.8%
Organism: Staphylococcus aureus; many times no organism recovered
- severe recurrent back pain 7–28 days after surgery accompanied by decreased back motion, muscle spasm, positive straight leg raising test
- fever (33%), wound infection (8%)
- persistently elevated / increasing ESR

MR:
√ decreased SI within disk + adjacent vertebral body marrow on T1WI
√ increased SI in disk + adjacent marrow on T2WI often with obliteration of intranuclear cleft
√ contrast-enhancement of vertebral bone marrow ± disk space

DDx: degenerative disk disease type I (no gadolinium-enhancement of disk)

Pyogenic Spondylodiskitis

= INFECTIOUS SPONDYLODISKITIS
Pathophysiology: infection of anterior vertebral body (2° to rich blood supply) → extension into disk → extension into neighboring vertebra
Predisposed: diabetes mellitus, immunocompromised, IV drug abuse
Location: lumbar > thoracic > cervical spine
- insidious back pain, fever, chills, night sweats

• elevated ESR, elevated C-reactive protein, ±leukocytosis

DDx: (1) Dialysis-associated spondyloarthropathy (intradiskal fluid + enhancement uncommon, NO epidural / paraspinal abscess)

(2) Degenerative disk disease (hypointense T1 and hyperintense T2 endplate changes flanking a degenerated disk ± enhancement, NO fluidlike disk signal intensity, disk vacuum phenomenon)

DISLOCATION OF CERVICAL SPINE

= CRANIOCERVICAL DISSOCIATION

Atlantooccipital Dislocation

= ATLANTOOCCIPITAL DISTRACTION INJURY = ATLANTO-OCCIPITAL DISSOCIATION (AOD)

= disruption of tectorial membrane + paired alar ligaments resulting in grossly unstable injury

◊ Diagnosis difficult to make and easy to overlook at whole-body CT!

Cause: rapid deceleration with either hyperextension or hyperflexion → in up to ⅓ of high-velocity injuries

Age: in adults much less common than in children ← larger size of head relative to body, increased laxity of ligaments, shallow horizontally oriented occipitoatlantoaxial joint, hypoplastic occipital condyles

May be associated with: occipital condyle fracture

• neurologic symptoms: range from respiratory arrest with quadriplegia to normal neurologic exam

• discomfort, stiffness

Direction of dislocation / subluxation: anteriorly, posteriorly, superiorly (vertical = life-threatening)

Lateral radiograph:

√ **Powers ratio** (assessment for anterior subluxation) = BC÷OA ratio > 1 = ratio of distance between basion + spinolaminar line of C1 and distance between posterior cortex of anterior tubercle of C1 + opisthion (74% sensitive)

√ **basion-dens interval** (BD) > 12 mm on X-ray / 9.5 mm on CT without traction placed on head / neck

√ **basion-axial interval** > 12 mm anterior / > 4 mm posterior to posterior axial line (PAL)

√ **atlanto-dental interval** > 3 mm (man) / > 2.5 mm (woman):

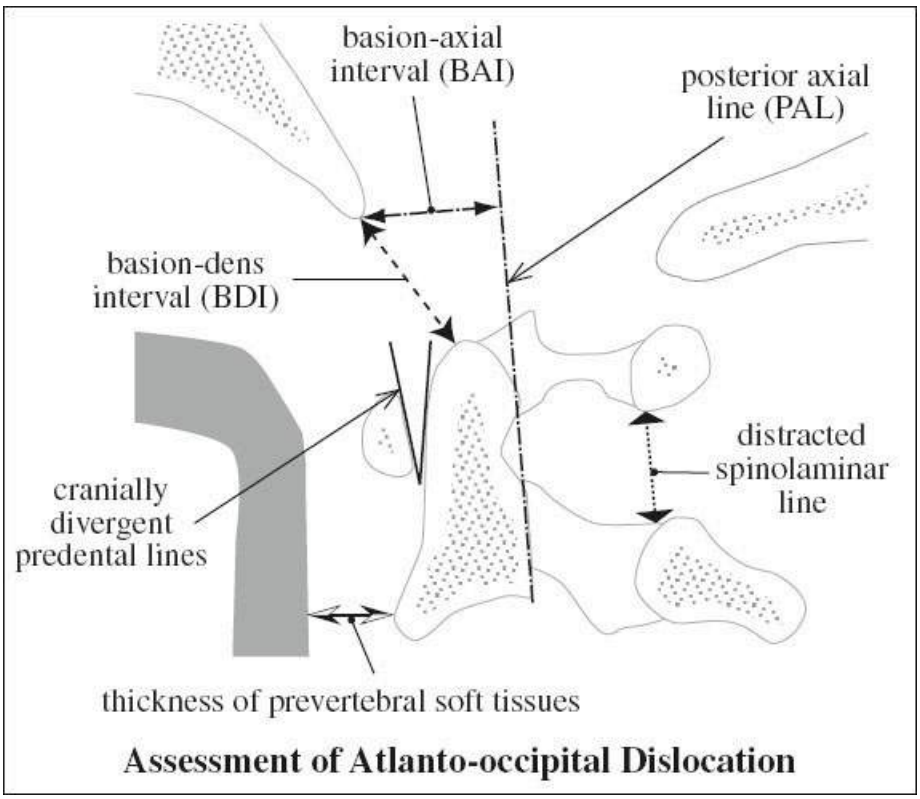
√ "V sign" = cranially divergent predental lines ← transverse ligament injury

√ atlanto-occipital interval > 4 mm

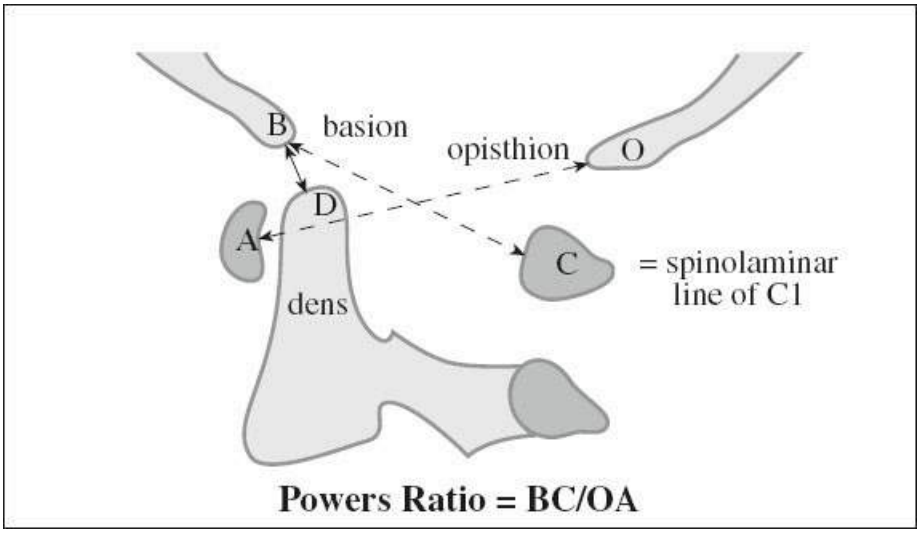
√ atlanto-axial interval > 2.6–4 mm

√ > 10 mm soft-tissue swelling anterior to C2 + pathologic convexity of soft tissues (80%)

CT (≤ 1.25 mm thick sections, superior to radiographs):



Assessment of Atlanto-occipital Dislocation



Powers Ratio = BC/OA

A basion-dens distance > 10 mm is highly suggestive of dissociation. The alar ligaments + tectorial membrane are the most important stabilizing ligaments given the little inherent osseous stability.

√ blood in region of tectorial membrane + alar ligaments
√ condylar fracture ± fracture extension through hypoglossal canal (for cranial nerve XII)
√ widening / incongruity of articulation between occipital condyles + lateral masses of C1

MR:

Indications for MRI:

(1) Detection of soft-tissue injury + spinal cord injury

(2) Treatment planning of unstable cervical spine
(3) Patients with neurologic deficits
(4) Suspected ligamentous injury
(5) Patients who cannot be clinically evaluated for > 48 hours ← altered level of consciousness

√ fluid in articular capsules, nuchal ligament, interspinous ligament

Cx: (1) Injury to caudal cranial nn. + upper 3 cervical nerves
(2) Epidural hematoma with brainstem compression + upper spinal cord injury
(3) Vasospasm / dissection of internal carotid and vertebral arteries

Prognosis: usually fatal; more survivable in skeletally immature pediatric trauma patients

Atlantoaxial Distraction

= traumatic widening of atlantoaxial interval

Cause: injury to transverse atlantal ligament, alar ligaments, tectorial membrane between C1 and C2, disruption of articular capsules

May be associated with: type 1 dens fracture

√ prevertebral soft-tissue swelling

√ subluxation with enlargement of predental space to
> 5 mm in children < 9 years of age
> 3 mm in adults

√ widening of C1-C2 facets

MR:
√ prevertebral, interspinous, nuchal ligament edema
√ facet widening / fluid
√ increased signal intensity of spinal cord
√ ± epidural hematoma

DORSAL DERMAL SINUS

= epithelium-lined dural tube extending from skin surface to intracanalicular space + frequently communicating with CNS / its coverings

Cause: focal point of incomplete separation of cutaneous ectoderm from neural ectoderm during neurulation

Age: early childhood to 3rd decade; M÷F = 1÷1

• small midline dimple / pinpoint ostium
• hyperpigmented patch / hairy nevus / capillary angioma

Location: lumbosacral (60%), occipital (25%), thoracic (10%), cervical (2%), sacrococcygeal (1%), ventral (8%)

Course: in a craniad direction from skin level toward cord ← ascension of cord relative to spinal canal during embryogenesis

Associated with: epidermoid / dermoid tumors in up to 20%
◊ 50% of dorsal dermal sinuses end in dermoid / epidermoid cysts!
◊ 20–30% of dermoid cysts / dermoid tumors are associated with dermal sinus tracts!

CT myelography (best modality to define intraspinal anatomy):
√ groove in upper surface of spinous process + lamina of vertebra
√ hypoplastic spinous process
√ single bifid spinous process

√ focal multilevel spina bifida
√ laminar defect
√ dorsal tenting of dura + arachnoid
√ sinus may terminate in conus medullaris / filum terminale / nerve root / fibrous nodule on dorsal aspect of cord / dermoid / epidermoid
√ nerve roots bound down to capsule of dermoid / epidermoid cyst
√ displacement / compression of cord by extramedullary dermoids / epidermoids
√ expansion of cord by intramedullary dermoids / epidermoids
√ clumping of nerve roots from adhesive arachnoiditis

Cx: (1) Meningitis (bacterial / chemical)
(2) Subcutaneous / epidural / subdural / subarachnoid / subpial abscess (bacterial ascent)
◊ Dermal sinus accounts for up to 3% of spinal cord abscesses!
(3) Compression of neural structures

DDx: pilonidal sinus / simple sacral dimple (no extension to neural structures)

EPIDURAL ABSCESS OF SPINE

Incidence: ~ 1.8÷100,000 annually; 0.2–2.8÷10,000 hospital admissions annually

Organism: Staphylococcus aureus including methicillin-resistant S aureus (²/₃ of cases); rarely fungus / parasite / mycobacterium

Cause:
(a) hematogenous (50%):
› urinary tract infection (Escherichia coli)
› pneumonia (Streptococcus pneumoniae)
› prior soft-tissue / skin infection (S epidermidis)
› IV drug abuse (Pseudomonas aeruginosa)
(b) contiguous infection from adjacent structures (33%):
› vertebral osteomyelitis, diskitis
› psoas abscess
(c) iatrogenic / penetrating trauma to spine:
» invasive procedure on spine + nearby structures (Staphylococcus epidermidis)

At risk: acquired immunosuppressive / immunodeficiency disorder, drug addiction, cancer, alcoholism, systemic inflammation / infection, liver disease, diabetes, trauma, surgical procedure involving spine / surrounding structures

Age: > 20 years (range, 10 days to 87 years); M÷F = 1.7÷1

• classic triad:
  • localized severe back pain (70%) → radicular pain
  • fever, leukocytosis (60%)
  • neurologic disease (30%): fecal / urinary incontinence with motor / sensory deficit → eventual rapid irreversible neurologic deterioration

Location: thoracic spine (50%)

Site: dorsolateral spanning multiple vertebral levels

Category: (a) focal ≤ 5 vertebrae (b) diffuse > 5 vertebrae

May be associated with: (1) Osteomyelitis

(2) Diskitis
(3) Paravertebral abscess

N.B.: NO myelography! → may seed infection into subarachnoid space

MR:
- √ ± effacement of epidural fat + subarachnoid space
- √ thickening of epidural tissues (early stage):
  - √ isointense on T1WI
  - √ moderately hyperintense on T2WI
- √ liquefied abscess cavity oval-shaped on axial images:
  - √ hypointense on T1WI + hyperintense on T2WI

DDx: CSF

- √ hyperintense at DWI + reduced apparent diffusion coefficient (ADC) ← restricted diffusion

CEMR:
- √ diffuse heterogeneous / homogeneous enhancement (= phlegmonous infection with microabscesses)
- √ peripheral enhancement of varying thickness around a central pus collection

- √ cellulitis surrounding abscess ← inflamed hypervascular tissue (best seen on fat-suppressed CEMR)
- √ linear enhancement along compressed dura mater (in only 75% of diffuse spinal epidural abscess)
- √ engorgement of epidural / basivertebral veins (best seen on sagittal images)

EPIDURAL HEMATOMA OF SPINE

Cause: (1) Trauma (71%)
(a) vertebral fracture / dislocation
(b) traumatic lumbar puncture
(c) spine surgery (0.1–3%)
(2) Hypertension
(3) Pregnancy
(4) AVM
(5) Vertebral hemangioma
(6) Bleeding diathesis / anticoagulation / hemophilia
(7) Idiopathic (45%)

Pathophysiology: tearing of epidural veins

Mean age: 41–52 years

• acute radicular pain; rapid onset of paraplegia

Location: cervical > thoracic > lumbar spine

Site: anterior / posterior to cord

√ spinal cord compression

√ high attenuation lesion on CT

MR:
- √ iso- / hyperintense on T1WI + hyperintense on T2WI compared to spinal cord (intensities quite variable)

√ strikingly low SI on gradient-echo sequences ← deoxyhemoglobin

Rx: conservative management

FRACTURES OF SKULL

1. Linear fracture (most common type)
   √ deeply black sharply defined line
   DDx:
   (1) Vascular groove, esp. temporal artery (gray line, slightly sclerotic margin, branching like a tree, typical location (temporal artery projects behind dorsum sellae)
   (2) Suture
2. Depressed fracture
   • often palpable
   √ bone-on-bone density
   Rx: surgery indicated if depression > 3–5 mm ← arachnoid tear / brain injury
   N.B.: CT / MR mandatory to assess extent of underlying brain injury
3. Skull-base fracture = **basilar skull fracture**
   • rhinorrhea (CSF); otorrhea (CSF / hemotympanum)
   • raccoon eyes = periorbital ecchymosis
   √ basic rules for skull fractures:
   √ overlying soft-tissue injury / hematoma
   √ sharp nonsclerotic border, often crossing sutures
   √ may bifurcate
   √ increase in diameter as fracture approaches suture
   √ diastasis of suture
   √ pneumocephalus
   √ air in sulci
   √ air-fluid level in sinuses
   Cx: infection, acute / delayed cranial nerve deficit, vascular laceration / dissection / occlusion / infarction
   DDx: suture (same diameter, interdigitating "zigzag" pattern)
4. **Healing skull fracture**
   @ infants: in 3–6 months without a trace
   @ children (5–12 years): in 12 months
   @ adults: in 2–3 years
   √ persistent lucency mimicking vascular groove
   Cx: leptomeningeal cyst (= growing fracture)

Le Fort Fracture

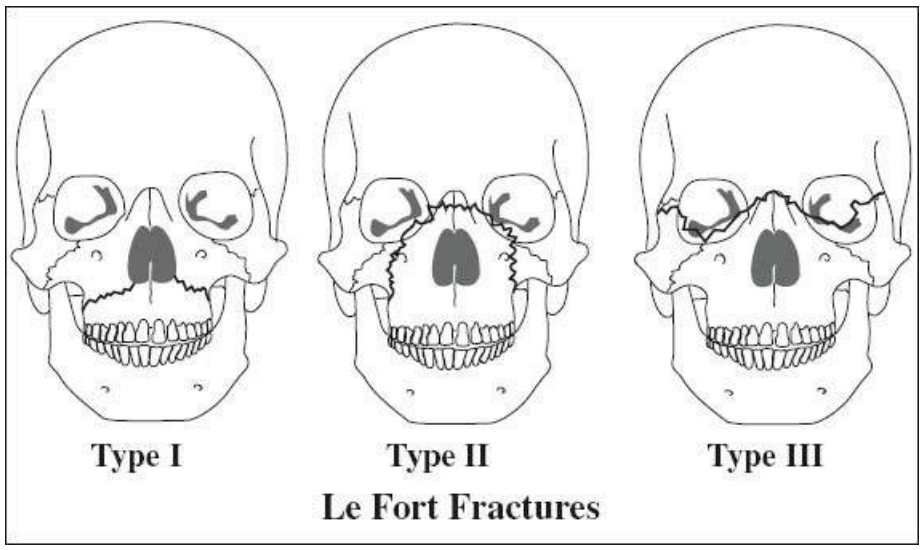
[René Le Fort (1869–1951), French surgeon]

◊ All Le Fort fractures involve the pterygoid process!

A. Le Fort I = transverse (horizontal) maxillary fracture caused by blow to premaxilla
   Fracture line: (a) alveolar ridge
   (b) lateral aperture of nose
   (c) inferior wall of maxillary sinus

√ detachment of alveolar process of maxilla
√ teeth contained in detached fragment

B. Le Fort II = "pyramidal fracture"
◊ May be unilateral



Le Fort Fractures

Fracture line: arch through
(a) posterior alveolar ridge
(b) medial orbital rim
(c) across nasal bones

√ separation of midportion of face
√ floor of orbit + hard palate + nasal cavity involved

C. Le Fort III = **"craniofacial disjunction"**

Fracture line: horizontal course through
(a) nasofrontal suture
(b) maxillofrontal suture
(c) orbital wall
(d) zygomatic arch

√ separation of entire face from base of skull

Sphenoid Bone Fracture

Prevalence: involved in 15% of skull-base fractures

- CSF rhinorrhea / otorrhea; hemotympanum
- "battle" sign = mastoid region ecchymosis
- raccoon eyes = periorbital ecchymosis; 7th / 8th nerve palsy
- muscular dysfunction: problems with ocular motility, mastication, speech, swallowing, eustachian tube function

√ air-fluid level in sinuses + mastoid
√ axial thin-slice high-resolution CT for best delineation of fractures
√ water-soluble intrathecal contrast material for CSF fistula

Temporal Bone Fracture

Frequency: 14–22% of skull fractures

Mechanism: motor vehicle crash (45–47%), fall (31–33%), assault (11–12%)

Cause of conductive hearing loss of temporal bone fracture:

(1) Hemotympanum
(2) Disruption of tympanic membrane
(3) Disruption of the ossicular chain:
  › commonly incus injury:
    (a) incudostapedial joint subluxation
    (b) malleoincudal subluxation
    (c) incus dislocation
    (d) dislocation of the malleoincudal complex
  › less commonly: stapedial and mallear fracture

A common complication of temporal bone fractures is hearing loss, either sensorineural, conductive, or mixed.

Longitudinal Fracture of Temporal Bone *(75%)*

= fracture parallel to long axis of petrous pyramid typically traversing middle ear cavity with frequent disruption of ossicles → conductive hearing loss

Line of force:

usually extralabyrinthine from lateral to medial terminating in foramen lacerum; commonly involving EAC (external auditory canal), tegmen tympani, squamosa of temporal bone

Subtypes:

(a) anterior to labyrinthine structures toward eustachian tube + middle cranial fossa (common)
  Cx: epidural hematoma in middle cranial fossa ← vascular injury to middle meningeal artery
(b) posterior to labyrinth, toward jugular foramen and posterior cranial fossa (less common)

Commonly associated with: fracture of temporal squamosa + parietal bone

- bleeding from EAC ← disruption of tympanic membrane
- otorrhea ← CSF leak with ruptured tympanic membrane (rare)
- conductive hearing loss ← dislocation of auditory ossicles (most commonly incus as the least anchored ossicle)
  - NO neurosensory hearing loss
- facial nerve palsy (7–20%) ← edema / fracture of facial canal near first genu / anterior tympanic segment of facial nerve; frequent spontaneous recovery

√ pneumocephalus
√ herniation of temporal lobe
√ incudostapedial joint dislocation (weakest joint):
  √ "ice cream" (malleus) has fallen off the "cone" (incus) on direct coronal CT scan
  √ fracture of "molar tooth" on direct sagittal CT scan
√ mastoid air cells opaque / with air-fluid level

Plain film views: Stenvers / Owens projection

Cx: ossicular injury, tympanic membrane rupture, hemotympanum → conductive hearing loss, (rarely) facial n. injury

Transverse Fracture of Temporal Bone *(25%)*

= fracture perpendicular to long axis of petrous pyramid

Line of force:

anterior to posterior originating in occipital bone (near jugular foramen / foramen magnum) extending anteriorly across the base of skull + across the petrous pyramid into middle cranial fossa; commonly passing through / near vestibular aqueduct with variable involvement of otic capsule

Subtypes:

(a) medial relative to arcuate eminence

Course: traversing fundus of IAC

- ± complete SNHL ← transection of cochlear n.

(b) lateral relative to arcuate eminence

Course: traversing bony labyrinth

Associated with: ± perilymphatic fistula ← injury of stapes footplate

- ± complete SNHL

- irreversible sensorineural hearing loss ← fracture line across apex of IAC / labyrinthine capsule with injury to both parts of cranial nerve VIII)
- persistent vertigo (benign paroxysmal positional vertigo resolves in 6–12 months, perilymphatic fistula, cupulolithiasis = otolith detachment, trauma to semicircular canals)
- facial (cranial nerve VII) nerve palsy in 50% (injury in IAC); less frequent spontaneous recovery because of disruption of nerve fibers

Site: labyrinthine segment, geniculate ganglion

- rhinorrhea ← CSF leak with intact tympanic membrane
- bleeding into middle ear

Plain film views: posteroanterior (transorbital) + Towne projection

Mixed Temporal Bone Fracture

Temporal bone fractures may be complex with mixed features of both longitudinal + transverse fractures.

= combination of longitudinal + transverse fractures

- sensorineural hearing loss ← disruption of otic capsule
- conductive hearing loss ← ossicular injury

◊ Quite common!

Ossicular Injury

- persistent conductive hearing deficit after healing of tympanic membrane / resorption of middle ear debris

A. Ossicular dislocation: incudostapedial separation > complete separation of incus including incudomalleolar separation > dislocation of malleoincudal complex > stapediovestibular dislocation

A. Ossicular fracture: long process of incus > crura of stapes > neck of malleus

Zygomaticomaxillary Fracture

= "TRIPOD" FRACTURE = MALAR / ZYGOMATIC COMPLEX FRACTURE

Cause: direct blow to malar eminence

- loss of sensibility of face below orbit
- deficient mastication
- double vision / ophthalmoplegia
- facial deformity

Fracture line:
(a) lateral wall of maxillary sinus
(b) orbital rim close to infraorbital foramen
(c) floor of orbit
(d) zygomaticofrontal suture / zygomatic arch

Blowout Fracture

= isolated fracture of orbital floor

Cause: sudden direct blow to globe (ball or fist) with increase in intraorbital pressure transmitted to weak orbital floor

- diplopia on upward gaze (entrapment of inferior rectus + inferior oblique muscles)
- enophthalmos
- facial anesthesia

Associated with: fracture of the thin lamina papyracea (= medial orbital wall) in 20–50%

√ soft-tissue mass extending into maxillary sinus ← herniation of orbital fat
√ complete opacification of maxillary sinus ← edema + hemorrhage
√ depression of orbital floor (= orbital process of maxilla)
√ posttraumatic atrophy of orbital fat → enophthalmos
√ opacification of adjacent ethmoid air cells
√ disruption of lacrimal duct

Occipital Condyle Fracture

Anderson & Montesano Types (I–III):

I = stable <u>comminution-impaction</u> with minimal / no fracture displacement ← axial loading injury

II = linear <u>skull base fracture</u> extending into occipital condyle ← direct blow to head

III = unstable <u>avulsion fracture</u> (75%) of occipital condyle ← avulsion injury of alar ligaments ← forced rotation + lateral bending

Tuli Types (1, 2A, 2B)

1 = nondisplaced fracture

2A = displaced fracture WITHOUT ligamentous instability
Rx: rigid collar

2B = displaced fractures WITH ligamentous instability
Rx: surgical intervention

FRACTURES OF CERVICAL SPINE

◊ Clearing of the cervical spine on clinical grounds has become the standard of care in alert adult patients.

Factors associated with higher risk of fracture:

(1) Glasgow Coma Score < 14
(2) Neck tenderness
(3) Loss of consciousness
(4) Neurologic deficit
(5) Drug ingestion
(6) Specific mechanism of injury: motor vehicle accident, fall from a height > 3 m

Indications for screening CT of cervical spine:

high-risk adult patients (= > 5% pretest probability of injury) defined by:

(1) High-speed (> 35 mph) motor vehicle accident
(2) Crash resulting in death at scene of accident
(3) Fall from height > 3 m (10 feet)
(4) Significant closed head injury (intracranial hemorrhage seen on CT)
(5) Neurologic signs / symptoms referred to C-spine
(6) Pelvic / multiple extremity fractures

Frequency: 1–3% of all trauma cases;
C2, C6 > C5, C7 > C3, C4 > C1
◊ Cervical spine trauma accounts for ⅔ of all spinal cord injuries!

• neurologic / spinal cord damage (39–50%)

Location:

(a) upper cervical spine = C1/2 (19–25%): atlas (4%), odontoid (6%)
(b) lower cervical spine = C3–7 (75–81%)
(c) cervicothoracic junction (9–18%)
(d) multiple noncontiguous spine fractures (15–20%)

Site: vertebral arch (50%), vertebral body (30%), intervertebral disk (25%), posterior ligaments (16%), dens (14%), locked facets (12%), anterior ligament (2%)

Associated with injury to:

head (70%), thoracic spine (15%), lumbar spine (10%), thorax (35%), pelvis (15%), upper extremity (10%), lower extremity (30%)

N.B.: 5–8% of patients with fractures may have normal radiographs!
◊ Most missed fractures involve C2 (34%), C6-7 (14%), C4 (12%), C1 (8%), occipital condyles
◊ C7–T1 space not visualized in at least 26% of all trauma patients

Normal range of motion: 10–20° during flexion and extension; 4–12° of lateral tilting

Cx: neurologic deterioration with delay in diagnosis

A. HYPERFLEXION INJURY (46–79%)

1. Odontoid fracture
2. Simple wedge fracture (stable)
3. **Flexion teardrop fracture** = avulsion of anteroinferior corner by anterior ligament (unstable)
◊ Most severe + unstable injury of C-spine
Location: C5, C6, C7

√ triangular fragment in soft tissues anterior to vertebral body
√ retrolisthesis
√ widening of facets
√ narrowing of spinal canal
√ mild kyphosis
Associated with: ligamentous tears, spinal cord compression

Subaxial Injury Classification and Scoring
*(CT Severity Score for Entire Spine, 2007)**

Injury Category	*Point Value*
Injury Morphology	
Compression	1
Burst	2
Distraction	3
Translation / rotation	4
Discoligamentous complex	
Intact	0
Indeterminate	2
Disrupted	3
Neurologic status	
Intact	0
Root injury	1
Spinal cord injury	
incomplete	2
complete	3
Cord injury + ongoing compression	4
Total Score: ≤ 3 manageable without surgery	
4 indeterminate;	
≥ 5 need for surgical intervention	

* a separate score is given to each injured level

◊ Triangular teardrop fracture without posterior element distraction / vertebral body translation should be characterized as (1) compression or (2) burst injury.

4. Anterior subluxation
5. **Bilateral facet lock** = interlocking of articular surfaces (unstable)
   √ anterolisthesis of affected vertebra by ½ vertebral body width
   √ mild focal kyphosis
   √ soft-tissue swelling
   √ no rotation
6. Anterior disk space narrowing
7. Spinous process fracture = **clay shoveler's fracture**
   = sudden load on flexed spine with avulsion fracture of C6 / C7 / T1 (stable)
8. **Flexion instability** = isolated rupture of posterior ligaments
   ◊ Dx may be missed without delayed flexion views
   √ no fracture

√ interspinous widening
√ loss of facet parallelism
√ widening of posterior portion of disk
√ anterolisthesis > 3 mm
√ focal kyphosis

B. HYPEREXTENSION INJURY (20–38%)

Mechanism: impact on forehead / face, whiplash

◊ High risk for neurologic deficit!
◊ Radiographs may be completely normal!

1. Hyperextension dislocation
   followed by immediate realignment
   • upper extremity paresthesia to complete quadriplegia
   √ disruption of anterior longitudinal ligament, annulus, intervertebral disk, lig. flavum
   √ prevertebral swelling ← hemorrhage + edema
   √ stripping of posterior longitudinal ligament
   √ tears of paraspinal muscles
   √ widening of disk space anteriorly
   √ avulsion of anteroinferior endplate
   √ transverse dimension of anteroinferior avulsion fragment greater than vertical dimension
2. **Extension teardrop fracture**
   = avulsion of intact fibers of anterior longitudinal ligament off anteroinferior endplate
   Location: C2, C3
   • acute central cord syndrome (in up to 80%)
   √ vertical dimension of triangular fragment greater than transverse dimension
3. Neural arch fracture of C1 (stable fracture = anterior ring + transverse ligament intact)
   √ vertically oriented fracture of posterior arch (stable if isolated / part of Jefferson burst fracture)
4. Anterior arch fracture of C1
   • biomechanically stable
   √ transverse fracture through inferior pole / midportion at attachment of atlantodental lig. / longus colli m.
5. Uni- / bilateral laminar fracture commonly part of a burst fracture / pedicolaminar fracture-separation / flexion teardrop fracture
   √ extension into adjacent spinous process (frequent)
6. Subluxation (anterior / posterior)
7. Hangman's fracture

C. FLEXION-ROTATION INJURY (12%)

1. **Unilateral facet lock** (oblique views!, stable fracture)
   √ anterolisthesis < ¼ vertebral body width
   √ "bow-tie" sign = the 4 rotated facets on LAT view
   √ decrease in spinolaminar space
   √ rotation of spinous process (on AP view)
   √ "naked facet" (on CT)

D. VERTICAL COMPRESSION (4%)

= axial loading

1. Jefferson fracture
2. **Burst fracture** = intervertebral disk driven into vertebral body below (fracture may be stable / unstable)
   √ loss of posterior vertebral body height with several fragments:
   √ sagittal fracture component extending to inferior endplate
   √ retropulsed fragment from posterior superior margin in spinal canal
   √ interpedicular widening
   √ posterior element fracture
   Associated with: widening of apophyseal joints, fracture of posterior vertebral arches

E. LATERAL FLEXION / SHEARING (4–6%)

1. Uncinate fracture
2. Isolated pillar fracture
3. Transverse process fracture
4. Lateral vertebral compression

Normal Variants as Pitfalls in Cervical Trauma

1. Congenital absence of posterior arch(es)
2. Congenital cleft (smooth well-corticated)
3. Os odontoideum
4. Os terminale
5. Partial ossification of atlanto-occipital membrane
6. Ponticulus posticus = bone excrescence partially covering horizontally oriented vertebral artery
7. Arcuate foramen = bone excrescence completely surrounding vertebral artery

Signs of Significant Cervical Vertebral Trauma

(a) most reliable + specific:
   √ widening of interspinous space (43%)
   √ widening of facet joint (39%)
   √ displacement of prevertebral fat stripe (18%)

(b) reliable but nonspecific:
   √ wide retropharyngeal space > 7 mm (31%)
   DDx: mediastinal hemorrhage of other cause, crying in children, S/P difficult intubation)

(c) nonspecific:
   √ loss of lordosis (63%)
   √ anterolisthesis / retrolisthesis (36%)
   √ kyphotic angulation (21%)
   √ tracheal deviation (13%)
   √ disk space: narrow (24%), wide (8%)

Atlas Fracture

Prevalence: 4% of cervical spine injuries, 25% of craniocervical injuries
Associated with: axis fracture (44%), fractures of C7 (25%), C2 pedicle (15%), extraspinal fractures (58%)

N.B.: A ring tends to fracture in more than one place!

Types:

I Isolated fracture of posterior arch ← hyperextension

II Isolated fracture of anterior arch (rare)

III Bilateral posterior arch fractures + uni- / bilateral anterior arch fracture ← axial loading

1. **Jefferson fracture**

   [Sir Geoffrey Jefferson (1886–1961), neurosurgeon in Manchester, England]

   √ comminuted burst fracture of ring of C1 (unstable) with 4 uni- / bilateral ipsilateral anterior + posterior fractures

   √ lateral displacement of lateral masses (self-decompressing) on AP view

   DDx: **Pseudo-Jefferson fracture** = lateral offset of lateral masses of atlas without fracture = fusion anomaly of anterior / posterior arches of C1 (in children as lateral masses of atlas ossify earlier than C2)

IV fracture of lateral mass ← excessive lateral flexion

V Transversely oriented anterior arch fracture ← avulsion of longus colli / atlantoaxial ligament

Burst and lateral mass fractures are unstable and can be associated with tears of the transverse ligament, which may compromise the atlantodental relationship → dorsal displace-ment of dens → compression of thecal sac and its contents.

Axis Fracture

Prevalence: 17–20% of cervical spine fractures

Associated with: fractures of C1 in 8%

Odontoid / Dens Fracture *(59%)*

Prevalence: 59% of C2 fractures

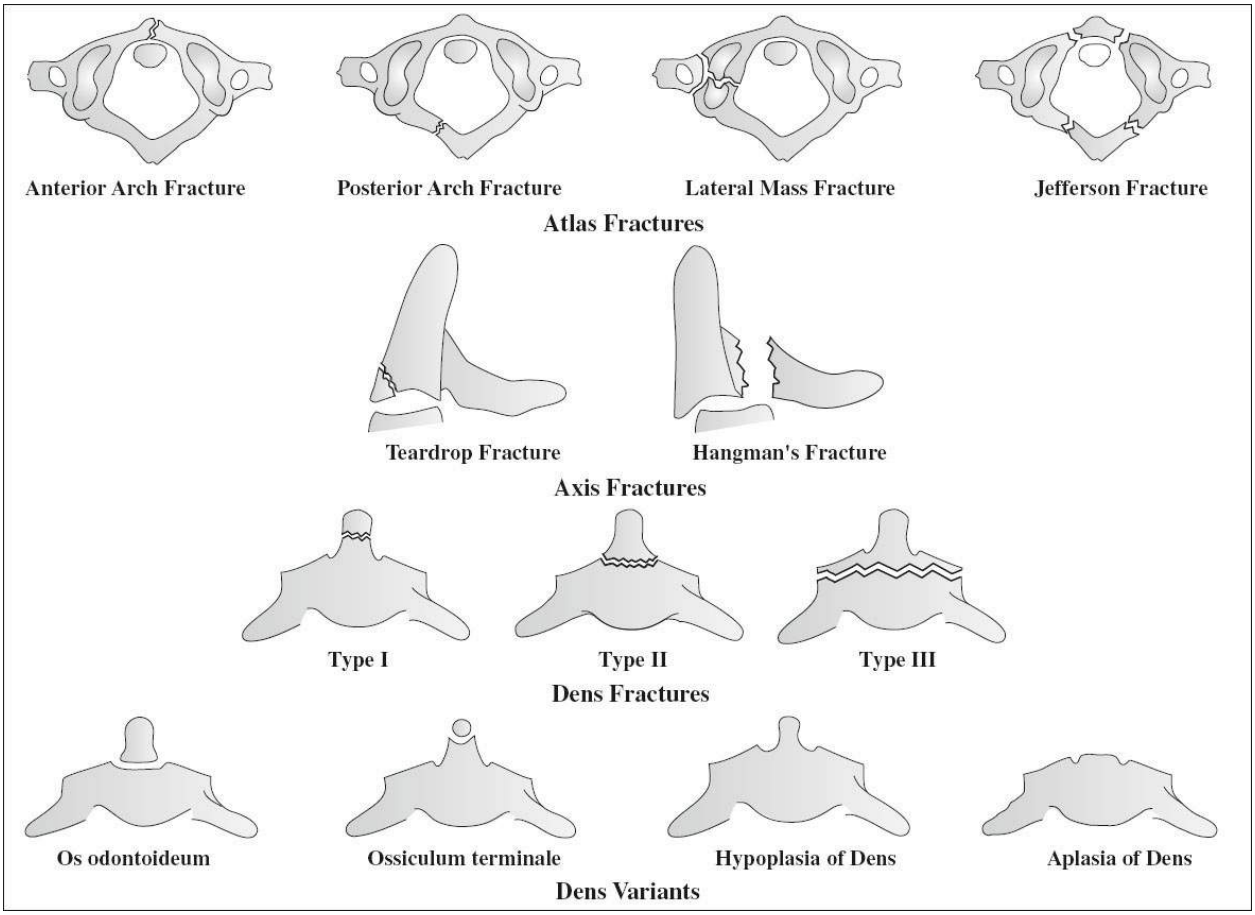
Type I avulsion fracture through odontoid tip (1–8%) at attachment of alar ligaments

√ obliquely oriented fracture through tip of odontoid that is difficult to detect

Prognosis: bone fusion in almost 100% with collar / halo immobilization

Type II fracture through base of dens (54–60%)

Cx: nonunion (in 26% of nonsurgical treatment, with fracture gap ≥ 6-mm increased to 67%)



◊ Axial CT alone misses > 50%!

Type III horizontal subdental fracture (39–42%) through cancellous portion of body

Prognosis: heals in 88% with immobilization

DDx: os odontoideum, ossiculum terminale, hypoplasia of dens, aplasia of dens

Hangman's Fracture *(23%)*

= TRAUMATIC SPONDYLOLISTHESIS

Prevalence: 23% of C2 fractures, 4% of cervical fractures

◊ 2nd most common C2 fracture; unstable

Mechanism: direct impact to face ← compressive hyperextension / distractive hyperflexion

Associated with: neurologic sequelae in only 26%, atlas fracture in 6–26%, other cervical fractures in 8–32%

Types:

I minimally displaced with < 2-mm translation, no angulation / posterior intervertebral disk space widening (stable)

II anterior angulation >11° + anterior translation ← distractive flexion / compressive hyperextension

III (7–10% of hangman fractures) ← severe distractive flexion + bilateral facet dislocation / fracture-dislocation

√ bilateral vertical pars interarticularis fracture of C2 → separation of body from posterior arch → decompression of spinal canal
√ fracture through posterior body of C2
√ prevertebral soft-tissue swelling > 5 mm at anterior-inferior margin of C2
√ ± widening of C2-C3 disk space
√ ± bilateral interfacetal dislocation
√ anterior subluxation of C2 on C3:
  √ disruption of C1–C2 spinolaminar line
  √ disruption of C2–C3 posterior vertebral body line
√ avulsion of anteroinferior corner of C2 (= rupture of anterior longitudinal ligament) = **teardrop fracture**

FRACTURES OF THORACOLUMBAR SPINE

◊ 40% of all vertebral fractures that cause neurologic deficit; mostly complex (body + posterior elements involved)

Location: ⅔ at thoracolumbar junction

Morphology:

1. Compression
   = loss of vertebral body height / disruption of vertebral endplate
   √ vertebral height loss (approximate percentage!)
   √ degree of kyphosis
2. Burst
   = compression of posterior vertebral body + varying degrees of retropulsion
   √ "burst" fragments at superior surface of body
   √ retropulsion of body fragments into spinal canal:
     = distance of line drawn between posterior margins of adjacent vertebral bodies + most posterior margin of bone fragment
   √ narrowing of spinal canal (approximate percentage!)
3. Translation / rotation
   = horizontal displacement or rotation of one vertebral body with respect to another
   √ rotation of spinous processes
   √ uni- / bilateral facet fracture-dislocation
   √ vertebral subluxation
4. Distraction
   = dissociation along vertical axis ← disruption of anterior and posterior ligaments + osseous elements
   √ diastasis of apophyseal joints:
   √ widening of facet joints
   √ empty "naked" facet joints
   √ perched / dislocated facet joints
   √ widening of interspinous space
   √ avulsion fracture of superior / inferior aspects of contiguous spinous processes
   √ vertebral body translation / rotation
   Cx: kyphotic progression → subsequent vertebral collapse

Injury of Posterior Ligament Complex

MRI (only modality for direct assessment!):

- √ disruption of hypointense black stripe on sagittal T1WI / T2WI = tear of supraspinous ligament / ligamentum flavum / interspinous ligament
- √ fluid in facet capsules
- √ interruption of disk
- √ tear of anterior / posterior longitudinal ligaments
- √ edema in interspinous region = capsular / interspinous ligament injury

CT:

- √ widening of facet joints
- √ widening of interspinous distance
- √ spinous process avulsion fracture
- √ significant vertebral body subluxation / dislocation /translation
- √ UNRELIABLE: loss of vertebral body height, kyphosis

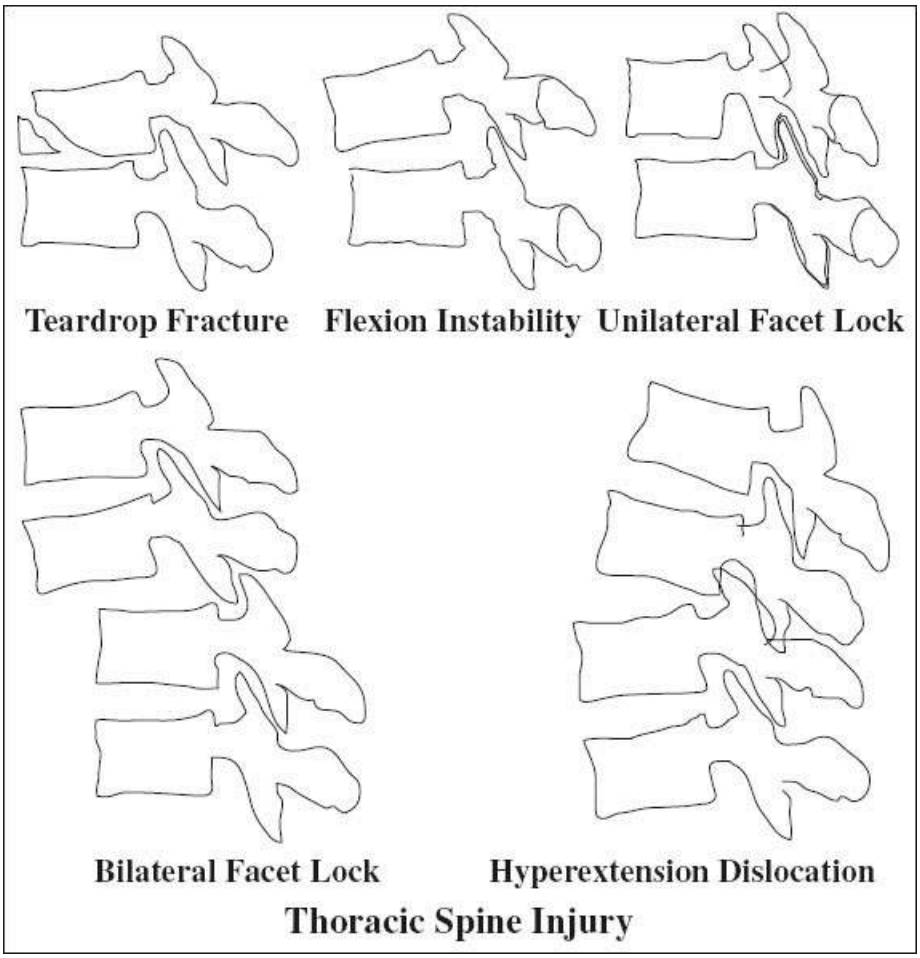
N.B.: inverse relationship between osseous destruction and ligamentous injury!

Fracture of Upper Thoracic Spine (T1 to T10)

Frequency: in 3% of all blunt chest trauma

Types:

1. Compression / axial loading fracture (most common)
   - √ wedging of vertebral body
   - √ retropulsion of bone fragments
   - √ posttraumatic disk herniation



2. Burst fracture (more severe compression fracture)
   √ associated fracture of posterior neural arch
   √ comminuted retropulsed bone fragments
3. Sagittal slice fracture
   √ vertebra above telescopes into vertebra below, displacing it laterally
4. Anterior / posterior dislocation
   √ torn anterior / posterior longitudinal ligament
   √ facet dislocation

◊ Relatively stable fractures due to rib cage + strong costovertebral ligaments + more horizontal orientation of facet joints!

◊ Only 51% detected on initial CXR!

Often associated with: fracture of sternum

√ widening of paraspinal lines
√ mediastinal widening
√ loss of height of vertebral body
√ obscuration of pedicle
√ left apical cap
√ deviation of nasogastric tube

Signs of Spinal Instability:

= inability to maintain normal associations between vertebral segments while under physiologic load

√ displaced vertebra

√ widening of interspinous / interlaminar distance

√ facet dislocation

√ disruption of posterior vertebral body line

Fracture of Thoracolumbar Junction (T11 to L2)

= area of transition between a stiff + mobile segment of spine

• neurologic deficit (in up to 40%)

Classification based on injury to the middle column:

(1) **Hyperflexion injury** (most common)

= compression of anterior column + distraction of posterior spinal elements

(a) hyperflexion-compression fracture

√ loss of height of vertebral body anteriorly + laterally

√ focal kyphosis / scoliosis

√ fracture of anterosuperior endplate

(b) flexion-rotation injury (unusual)

◊ Very unstable!

• catastrophic neurologic sequelae: paraplegia

√ subluxation / dislocation

√ widening of interspinous distance

√ fractures of lamina, transverse process, facets, adjacent ribs

(c) shearing fracture-dislocation

= damage of all 3 columns ← horizontally impacting force

(d) flexion-distraction injury: Chance fracture

2. **Hyperextension injury** (extremely uncommon)

√ widened disk space anteriorly

√ posterior subluxation

√ vertebral anterior superior corner avulsion

√ posterior arch fracture

3. **Axial compression fracture**

◊ Unstable!

√ burst fracture with herniation of intervertebral disk through endplates + comminution of vertebral body

√ marked anterior vertebral body wedging

√ retropulsed bone fragment

√ increase in interpediculate distance

√ ± vertical fracture through vertebral body, pedicle, lamina

Chance Fracture

= SEATBELT FRACTURE

[George Quentin Chance, British radiologist in Manchester, England]

Mechanism: shearing flexion-distraction injury (lap-type seatbelt injury in back-seat

passengers)

• neurologic deficit infrequent (20%)

Location: L2 or L3

√ horizontal splitting of spinous process, pedicles, laminae + superior portion of vertebral body

√ disruption of ligaments

√ distraction of intervertebral disk + facet joints

◊ Fracture often unstable!

Often associated with:

(1) other bone injury
rib fractures along the course of diagonal strap; sternal fractures; clavicular fractures

(2) soft-tissue injury
transverse tear of rectus abdominis muscle; anterior peritoneal tear; diaphragmatic rupture

(3) vascular injury
mesenteric vascular tear; transection of common carotid artery; injury to internal carotid artery, subclavian artery, superior vena cava; thoracic aortic tear; abdominal aortic transection

(4) visceral injury
perforation of jejunum + ileum > large intestine > duodenum (free intraperitoneal fluid in 100%, mesenteric infiltration in 88%, thickened bowel wall in 75%, extraluminal air in 56%); laceration / rupture of liver, spleen, kidneys, pancreas, distended urinary bladder; uterine injury

Chance Equivalent

= purely ligamentous disruption leading to lumbar subluxation / dislocation

√ mild widening of posterior aspect of affected disk space

√ widened facet joints

√ splaying of spinous processes = "empty hole" sign on AP view

Holdsworth Fracture

[Sir Frank Wild Holdsworth (1904–1969), British pioneering orthopedist in rehabilitation of spinal injuries]

Location: thoracolumbar junction

√ unstable spinal column fracture-dislocation with fracture through vertebral body + articular processes

√ rupture of posterior spinal ligaments

Seatbelt Injury

= injury caused by three-point restraint type (combined lap and shoulder belt device)

• bruise in subcutaneous tissue + fat of anterior chest wall

• skin abrasions are associated with significant internal injuries (in 30%)

@ Skeleton
sternum, ribs (along diagonal course of shoulder harness), clavicle, transverse processes of C7 or T1

@ Cardiovascular
aortic transection, cardiac contusion, ventricular rupture, subclavian artery, SVC
@ Airways
tracheal / laryngeal tear, diaphragmatic rupture

Transverse Process Fracture of Lumbar Spine

Cause: direct trauma, violent lateral flexion-extension forces, avulsion of psoas muscle, Malgaigne fracture
Frequency: 7%
In 21–51% associated injury:
genitourinary injury, hepatic + splenic laceration
Location: L3 > L2 > L1 > L4 > L5; L÷R = 2÷1; multiple÷single = 2÷1; unilateral÷bilateral = 20÷1
√ vertical÷horizontal (94%÷6%) fractures
√ associated lumbar burst / compression fracture
◊ Detection by conventional radiography in 40% only!
Prognosis: minor and stable injury; 10% mortality

Sacral Fracture

Zone 1 = fracture lateral to sacral foramina
• significant neurologic deficit (uncommon)
Zone 2 = fracture through ≥ 1 foramina
• unilateral lumbar / sacral radiculopathy (rare)
Zone 3 = fracture through central canal
• significant bilateral neurologic damage (frequent): bowel / bladder incontinence
Cx: chronic disability (in up to 50%)

Acute Atraumatic Compression Fractures of Spine

Osteoporotic Compression Fracture of Vertebra

√ low-signal-intensity band on T1WI and T2WI (93% sensitive)
√ spared normal bone marrow SI of the vertebral body (85% sensitive)
√ retropulsion of a posterior bone fragment into spinal canal (60% sensitive)
√ "fluid" sign = circumscribed fluidlike SI on T2WI + STIR subjacent to fractured end plate
√ multiple compression fractures
√ rimlike enhancement around low-signal-intensity bands
√ "wafer-like" distribution of radionuclide activity along endplate

Metastatic Compression Fracture of Vertebra

√ convex posterior border of vertebral body (74% sensitive)
√ abnormal SI of the pedicle or posterior element on enhanced fat-suppressed T1WI
√ epidural mass
√ encasing epidural mass
√ focal paraspinal soft-tissue mass (41% sensitive)
√ other sites of spinal metastases without compression fractures (63% sensitive)

√ enhancement of metastatic foci
√ completely replaced bone marrow of vertebral body (by tumor cells before trabeculae critically weakened)
Cx: spinal cord compression

GLIOMA OF SPINAL CORD

Astrocytoma of Spinal Cord

◊ Most common intramedullary neoplasm in children!
◊ 2nd most common intramedullary neoplasm in adults
Frequency: 30% of spinal cord tumors; 2nd in prevalence to ependymoma in adults
Mean age: 29 years; M÷F = 58÷42
Path: ill-defined fusiform cord enlargement without cleavage plane / capsule
Histo: hypercellularity with infiltrative growth along scaffold of normal astrocytes, oligodendrocytes and axons

Grade I	pilocytic astrocytoma (75%), usually most common in cerebellum
Grade II	low-grade fibrillary type
Grade III	anaplastic astrocytoma with necrosis (up to 25%)
Grade IV	glioblastoma multiforme with endothelial proliferation (0.2–1.5%)

Location: thoracic cord (67%), cervical cord (49%), conus medullaris (3%); on average over 4–7 vertebral segments involved; holocord presentation (in up to 60% in children); often extending into lower brainstem
Site: eccentric within spinal cord (57%)
• pain + sensory deficit (54%); torticollis (27%)
• motor dysfunction (41%), gait abnormalities (27%)
√ eccentric irregular tumor cysts + polar cysts + syrinx (common):
√ water-soluble myelographic contrast enters cystic space on delayed CT images
Radiographs:
√ scoliosis (24%)
√ widened interpedicular distance
√ bone erosion
MR:
√ usually extensive ill-defined homogeneous cord tumor with expansion of spinal cord:
√ iso- to hypointense to cord on T1WI
√ hyperintense on T2WI
√ poorly defined margins
√ dilated veins on surface of cord
√ patchy irregular enhancement
√ leptomeningeal spread (in 60% of glioblastoma multiforme)
Rx: tumor debulking + radiation therapy
Prognosis: 95% 5-year survival in low-grade tumors; higher mortality rate than for ependymoma
DDx: ependymoma ("cap" sign, central location, well defined, hemorrhage common, focal

intense enhancement, predilection for conus)

Ependymoma of Spinal Cord

◊ Most common intramedullary spinal neoplasm in adults!

Frequency: 40–60% of primary spinal cord tumors; 90% of primary tumors in filum terminale

Mean age: 39 years; M÷F = 57÷43

Origin: ependymal cells lining the central canal (62–76%)

Path: symmetric cord expansion with displacement of neural tissue yielding a cleavage plane

Histo: perivascular pseudorosettes; cystic degeneration (50%); hemorrhage at superior + inferior tumor margins

Subtypes: cellular (most common, cervical cord), myxopapillary (along filum terminale), papillary, clear cell, tanycytic, melanotic

Location: cervical cord alone (44%) / with extension into thoracic cord (23%); thoracic cord alone (26%); conus medullaris (7%); extends over several vertebral segments (on average 3.6 segments involved)

ectopic: sacrococcygeal region, broad ligament of ovary (associated with spina bifida occulta [33%])

Site: central within spinal cord

- long antecedent history (mean duration of 37 months) ← slow tumor growth:
  - back / neck pain (67%) = compression / interruption of central spinothalamic tracts first
  - sensory deficits (52%), motor weakness (46%)
  - bowel / bladder dysfunction (15%)

Metastases to: lung, retroperitoneum, lymph nodes

√ well-demarcated / diffusely infiltrating cord tumor

√ associated with at least one cyst (in 78–84%):

- √ polar cyst (62%) at cranial and caudal aspect of tumor, which do not contain malignant cells
- √ tumoral cyst (4–50%), which may contain tumor
- √ syringohydromyelia (9–50%)

Radiographs:

- √ scoliosis (16%)
- √ widening of spinal canal (11%):
  - √ scalloping of vertebral body
  - √ pedicle erosion, laminar thinning

Myelography:

- √ enlarged cord with complete / partial block to flow of contrast material

CT:

- √ iso- / slightly hyperattenuating cord mass
- √ intense enhancement

MR:

- √ iso- / hypointense (rarely hyperintense from hemorrhage) mass relative to spinal cord on T1WI
- √ hyper- / isointense on T2WI

√ **"cap" sign** = extremely hypointense rim at the tumor poles on T2WI (in 20–33%) due to hemosiderin deposits from prior hemorrhage
√ cord edema (60%)
√ mostly intense homogeneous enhancement (84%) with well-defined margins (89%)
Prognosis: 82% 5-year survival rate
DDx: astrocytoma (pediatric tumor, eccentric location, ill defined, hemorrhage uncommon, patchy irregular enhancement)

Myxopapillary Ependymoma of Spinal Cord
= special variant of ependymoma of lower spinal cord
Prevalence: 13% of all spinal ependymomas; most common neoplasm of conus medullaris (83%)
Mean age: 35 years; M> F
Origin: ependymal glia of filum terminale
Path: heterogeneous tumor with generous mucin production
• lower back / leg / sacral pain
• weakness / sphincter dysfunction
Location: conus medullaris, filum terminale; occasionally multiple (14–43%)
√ isointense on T1WI + hyperintense on T2WI
√ occasionally hyperintense on T1WI + T2WI ← mucin content / hemorrhage
√ almost always contrast enhancing
√ occasionally large lytic area of bone destruction

Subependymoma of Spinal Cord
= variant of CNS ependymoma
Origin: tanycytes that bridge pial + ependymal layers [*tanyos*, Greek = stretch]
Mean age: 42 years; M÷F = 74÷26
Histo: sparsely dispersed ependymal cells among predominant fibrillar astrocytes
• 52 months mean duration of symptoms:
  • pain, sensory + motor dysfunction
  • atrophy of one / both distal upper extremities (83%)
Location: ventricular system of brain, some in cervical cord
√ fusiform dilatation of spinal cord:
  √ enhancing lesion with well-defined borders (50%)
  √ nonenhancing lesion with diffuse symmetric cord enlargement
√ eccentrically located mass
√ ± edema

Ganglioglioma of Spinal Cord
= GANGLIOGLIONEUROMA = GANGLIONIC NEUROMA = NEUROASTROCYTOMA = NEUROGANGLIOMA = GANGLIONIC GLIOMA = = NEUROGLIOMA = NEUROMA GANGLIOCELLULARE
Prevalence: 0.4–6.2% of all CNS tumors; 1.1% of all spinal neoplasms
Mean age: 12 years; children > adults; M÷F = 1÷1
Histo: mixture of irregularly oriented neoplastic mature neuronal elements (neurons /

ganglion cells) + glial elements (neoplastic astrocytes), arranged in clusters = grade I or II lesions

Location: cervical cord (48%), thoracic cord (22%), conus, holocord (average length of 8 vertebral segments); usually supratentorial (temporal lobe)

• duration of symptoms between 1 month and 5 years

√ scoliosis (44%), spinal remodeling (93%) ← relatively slow growth (rare in astrocytoma / ependymoma)

√ eccentric

√ small tumoral cysts (in 46%)

√ calcifications (rare compared with intracranial tumor)

MR:

√ mixed tumor signal intensities on T1WI (in 84%)

√ tumor homogeneously hyperintense on T2WI

√ surrounding edema (less common than in ependymoma / astrocytoma)

√ patchy (65%) / no (15%) tumor enhancement

√ enhancement of pial surface (58%)

Cx: malignant transformation (10%)

Prognosis: slow growth; 89% 5-year and 83% 10-year survival rate; 27% recurrence rate

HEMANGIOBLASTOMA OF SPINE

= ANGIOBLASTOMA = ANGIORETICULOMA

Prevalence: 1–7.2% of all spinal cord tumors; mostly sporadic

Associated with: Von Hippel-Lindau disease (in ⅓)

Recommendation: screening MR imaging of brain + spine in patients with Von Hippel-Lindau syndrome

Age: middle age; M÷F = 1÷1

Path: nonglial highly vascular discrete nodular masses abutting leptomeninges with prominent dilated + tortuous vessels on posterior cord surface

Histo: large pale stromal cells of unknown origin packed between blood vessels of varying sizes

Location: intramedullary (75%), radicular (20%), intradural extramedullary (5%); thoracic cord (50%), cervical cord (40%); solitary in > 80%, multiple lesions indicate Von Hippel-Lindau syndrome + require screening of entire spine

Site: subpial aspect of dorsal spine; may extend exophytically into subarachnoid / extradural space

• mean duration of symptoms is 38 months:

• sensory changes (39%): impaired proprioception

• motor dysfunction (31%), pain (31%)

√ increased interpediculate distance (mass effect)

Angio:

√ highly vascular mass with dense prolonged blush

√ large draining veins form sinuous mass along posterior aspect of cord

MR:

√ iso- (50%) / hyperintense (25%) diffuse cord expansion on T1WI

√ hyperintense lesion with intermixed focal flow voids on T2WI:
  √ curvilinear areas of signal voids
√ cyst formation / syringohydromyelia (in up to 100%):
  √ intratumoral cystic component (50–60%)
  √ occasionally cystic mass with enhancing mural nodule (CLASSIC for cerebellar hemangioblastoma)
  √ densely staining tumor nodule
√ ± surrounding edema and "cap" sign
√ well-demarcated Gd-enhancing mass
Cx: intramedullary hemorrhage, hematomyelia, subarachnoid hemorrhage (rare)
DDx: arteriovenous fistula (not well circumscribed, heterogeneous signal intensity)

IDIOPATHIC OSTEOSCLEROSIS OF JAW

Age: late 1st / early 2nd decade
• asymptomatic
Location: mandible (90%)
Site: periapical near 1st molar / 2nd molar / premolar
√ small focal round / oval solitary sclerotic lesion
√ sharply marginated ± peripheral spiculations
√ nonexpansile WITHOUT rim of low attenuation

IDIOPATHIC SPINAL CORD HERNIATION

= spinal cord displacement through anterior / lateral dura mater defect → uncommon cause of thoracic myelopathy
Cause: ? occult minor trauma / remote traumatic event (herniated / calcified disk may cause thinning / erosion / rupture of dura)
Mean age: 51 (range, 21–78) years; M÷F = 2÷3
• symptomatic for 1–20 years: Brown-Séquard syndrome (66%), chronic progressive paraparesis (30%), isolated sensory deficit (3%), ataxia, pain, spastic monoparesis

Idiopathic spinal cord herniation often present with symptoms of Brown-Séquard syndrome, including ipsilateral upper motor neuron paralysis, loss of proprioception and contralateral loss of pain and temperature sensation

Location: T3–T7 ← anterior position of spinal cord with physiologic kyphosis; usually solitary lesion
Site: level of intervertebral disk >> vertebral body; spanning (usually) 1–2 / multiple vertebrae (rare)
√ variable degree of cord deformity / kinking:
Type K: obvious **k**inking toward the ventral region
Type D: **d**isappearance of spinal cord completely
Type P: **p**rotrusion of ventral aspect of spinal cord with full effacement of anterior subarachnoid space + little posterior cord kinking
Type C: **c**entral hiatus
Type L: **l**ateral hiatus
Myelography:

√ acute anterior kink of thoracic spinal cord with enlargement of dorsal subarachnoid space
√ free flow of contrast material (cannot completely exclude space-occupying lesion as in wide-necked communicating arachnoid cyst)

N.B.: arachnoid cyst must be excluded!

CT myelography:

√ "nuclear trail" sign = linear high-attenuation lesion in inferior endplate of adjacent vertebra ← posterior interosseous disk herniation
√ soft tissue extending from apex of cord displacement through dural defect into epidural space
√ ± concomitant scalloping of vertebral body

MR:

√ obliteration of CSF space ventral to cord
√ widened dorsal CSF space
√ absence of solid / cystic mass posterior to cord
√ small amount of extradural soft tissue extending from ventral apex of displaced cord into epidural space (occasionally)
√ NO enhancement
√ ± cord atrophy and high T2 signal intensity

Errors in diagnosis (common):

intradural arachnoid cyst, extradural mass with cord compression, disk herniation with cord tethering

Rx: postoperatively improved neurologic symptoms (88%)

DDx: traumatic / iatrogenic cord herniation; CSF flow artifact

INCLUSION CYST OF SPINE

Cause:

(a) congenital dermal rest / focal expansion of dermal sinus ← inclusion / aberrant implantation of ectodermal cells at time of neural groove closure (3rd–5th week of GA)
(b) acquired from implantation of viable epidermal / dermal tissue (lumbar puncture by spinal needle without trocar)

Similarities: both composed of

(a) outer wall formed by collagenous tissue
(b) inner lining formed by ectodermal tissue only (= stratified squamous epithelium)

Histologic differentiation:

1. Epidermoid cyst
   › thin squamous lining
   • cyst content = waxy white **"pearly tumor"** composed of desquamated epithelial cells (= keratin, triglycerides, fatty acids, cholesterol crystals)
2. Dermoid cyst (may arise earlier in embryonic process)
   › thicker lining including calcifications, sebaceous secretions, sweat glands, hair follicles, hair
   › forming fat-fluid levels
   • cyst content = composed of (1) desquamated epithelium and (2) secretions of sebaceous glands

- nonspecific symptoms: weakness, back pain
- slowly progressive myelopathy ← space-occupying lesion causing irritation / compression of adjacent structures:
  - motor + sensory disturbance (paresthesia)
  - urinary / fecal incontinence
- acute onset of chemical / aseptic meningitis / arachnoiditis ← spread of cholesterol crystals via CSF ← cyst rupture:
  - headache, nausea, vomiting, vertigo, visual problems
  - meningism, mental change, hemiplegia, coma

Dermoid Cyst of Spine

= uni- / multilocular benign cystic tumor lined by stratified squamous epithelium containing skin (dermal) appendages

Path: (a) wall ± calcifications (in 31%) and papillary projections along inner surface
(b) cystic contents of fluid-like mucoid (in virtually 100%) and lipid fatty (67–75%) components
- thick foul-smelling yellow material ← secretion of sebaceous glands + desquamated epithelium

Prevalence: 1–2% of intraspinal tumors; 0.7–1.8% of all CNS tumors

Age at presentation: 2nd–3rd decade; M÷F = 1÷1

May be associated with:
myelomeningocele, dermal sinus tract (in 20%), hypertrichosis; **Currarino triad** (= anorectal malformation + sacral dysplasia + presacral mass → severe constipation since birth)

Location: lumbosacral (60%), cauda equina (20%)

Site: extramedullary (60%), intramedullary (40%)

CT:
√ almost always complete spinal block on myelography
√ CT myelography facilitates detection
√ well-demarcated isoattenuating mass ± hypoattenuating fat
√ ± wall calcifications + papillary projections

MR:
√ uni- / multilocular cystic lesion with variable SI:
  √ hyperintense on T1WI + hypointense on Gd-enhanced fat-suppressed T1WI (fatty component)
  √ occasionally hypointense on T1WI + hyperintense on T2WI (fluid secretions from sweat glands within tumor)
  √ ± fat-fluid level
√ NO contrast enhancement (except for small soft-tissue component)
√ dissemination of lipid droplets scattered throughout CSF and intra-axially throughout spinal cord

Cx: spontaneous / intraoperative / traumatic dermoid cyst rupture → lipid droplets transported along CSF pathway

Prognosis: high risk of morbidity + mortality (with rupture)

Rx: dependent on symptoms

DDx: (1) Epidermoid cyst (without dermal appendages, T1 hypointense + T2 hyperintense)
(2) Lipoma (homogeneous midline T1-hyperintense lesion with smooth well-defined border)
(3) Teratoma (heterogeneous enhancement)
(4) Intraaxial tumor: ependymoma, astrocytoma, hemangioblastoma

Epidermoid of Spine

= cystic tumor lined by a membrane composed of epidermal elements of skin
Prevalence: 0.2%–1% of intracranial tumors; < 1% of spinal cord tumors
Mean age: 34 (range, 3–71) years; M÷F = 1.35÷1.00
May be associated with:
(a) skin lesion: hairy nevus, dyschromia, angioma, scar
(b) spinal dysraphism: dermal sinus, spina bifida, hemivertebra, syringomyelia, tethered cord syndrome, dorsal meningocele, diastematomyelia
Mean delay in Dx: 6 years (range, 2 days to 53 years)
Location: upper thoracic (17%), lower thoracic (26%), lumbosacral (22%), cauda equina (35%)
Site: intradural extramedullary (60%), intramedullary (40%)
Growth rate: similar to that of normal skin
√ displacement of spinal cord / nerve roots
√ NO internal enhancement + faint to NO rim enhancement
Myelography (CT facilitates detection):
√ asymmetric filling defect / complete spinal block
DDx: communicating arachnoid cyst typically opacifies
MR:
√ circumscribed mass WITHOUT peripheral edema
√ variable signal intensity ← differing concentrations of cyst content of keratin + water + cholesterol:
√ T1 isointense (especially when tumor small) to slightly hyperintense relative to CSF
√ iso- to slightly hyperintense relative to CSF on T2WI
√ T1 hyperintense + T2 hypointense "**white epidermoid**" (rare) ← high protein concentration
√ hyperintense to CSF on FLAIR and D WI ← restricted diffusion (DD x: arachnoid cyst (isointense to CSF on FLAIR and D WI)
Cx: malignant transformation (extremely rare)

KLIPPEL-FEIL SYNDROME

= BREVICOLLIS
= synostosis of two / more cervical segments
[André Feil (1884–?), neurologist in Paris]
May be associated with:
platybasia, syringomyelia, encephalocele, facial + cranial asymmetry, Sprengel deformity (25–40%), syndactyly, clubbed foot, hypoplastic lumbar vertebrae; renal anomalies in 50% (agenesis, dysgenesis, malrotation, duplication, renal ectopia); congenital heart disease in 5%

(atrial septal defect, coarctation)
- clinical triad of
  (1) short neck
  (2) restriction of cervical motion
  (3) low posterior hairline
- deafness (30%)
- torticollis; webbed neck

Location: cervical spine
√ wide and flat vertebral bodies
√ ± cervicothoracic / cervical / occipitoatlantal fusion:
  √ fusion of vertebral bodies and posterior elements
√ ± hemivertebrae
√ scoliosis
√ rib fusion
√ Sprengel deformity (25–40%)
√ ear anomalies: absent auditory canal, microtia, deformed ossicles, underdevelopment of bony labyrinth

KüMMELL DISEASE

[Hermann Kümmell (1852–1937), professor of surgery at the University of Hamburg, published Chirurgische Operationslehre]
= INTRAVERTEBRAL VACUUM PHENOMENON
= delayed posttraumatic collapse of vertebral body
Incidence: < 1% (on X-ray), 12% (on CT); in 15–30% of osteoporotic fractures
Cause: ischemic necrosis weeks to months following acute fracture
Pathophysiology: compression fracture → subsequent partial distraction by paraspinal muscles in supine position → vertebral cavity / cleft → low pressure within cleft allows accumulation of gas (principally nitrogen) in the absence of bleeding = "ischemic vertebral collapse"
Age: > 50 years
Location: thoracolumbar junction: T12 & L1
√ collapsed vertebral body
√ transverse linear / semilunar radiolucency located centrally within / adjacent to endplate
√ gas collection increases with extension + traction, decreases with flexion
√ contiguous intradiskal vacuum phenomenon (in 83%)
√ gas may become replaced by fluid
N.B.: presence of gas virtually excludes tumoral + infectious etiology (rare exceptions: myeloma, E. coli, clostridia, TB, brucellosis, peptococcus, streptococcus, staphylococcus)

LEPTOMENINGEAL CYST

= **"Growing" fracture** = loculation of CSF into / through skull
Prevalence: 1% of all pediatric skull fractures
Pathogenesis: skull fracture with dural tear leads to arachnoid herniation into dural defect;

CSF pulsations produce fracture diastasis + erosion of bone margins (apparent 2–3 months after injury)

√ skull defect with indistinct scalloped margins

√ CSF-density cyst adjacent to / in skull, may contain cerebral tissue

MR:

√ cyst isointense with CSF + communicating with subarachnoid space

√ area of encephalomalacia underlying fracture (frequent)

√ intracranial tissue extending between edges of bone

LIPOMA OF SPINE

= partially encapsulated mass of fat + connective tissue in continuity with leptomeninges / spinal cord

• skin-coated subcutaneous back mass, occasionally associated with hemangiomatous / hairy lesion

• sensory deficiency, paresis, neurogenic bladder

Types:

(a) lipomyelomeningocele (84%)

(b) fibrolipoma of filum terminale (12%)

(c) intradural lipoma (4%)

Location: lumbosacral region

◊ Intradural lipomas + lipomyelomeningoceles represent 35% of skin-covered lumbosacral masses + 20–50% of occult spinal dysraphism!

Intradural Lipoma

= subpial juxtamedullary mass totally enclosed in intact dural sac

Prevalence: < 1% of primary intraspinal tumors

Etiology: abnormal embryonic neurulation

Age peaks: first 5 years of life (24%), 2nd + 3rd decade (55%), 5th decade (16%)

• slow ascending mono- / paraparesis, spasticity, cutaneous sensory loss, defective deep sensation (with cervical + thoracic intradural lipoma)

• flaccid paralysis of legs, sphincter dysfunction (with lumbosacral intradural lipoma)

• overlying skin most often normal

• elevation of protein in CSF (30%)

Location: thoracic (30%) / cervicothoracic (24%) / cervical (12%)

Site: dorsal aspect of cord (75%), lateral / anterolateral (25%)

√ spinal cord open in midline dorsally

√ lipoma in opening between lips of placode

√ exophytic component at upper / lower pole of lipoma

√ syringohydromyelia (2%)

√ focal enlargement of spinal canal ± adjacent neural foramina

√ narrow localized spina bifida

Lipomyelomeningocele

= lipoma tightly attached to exposed dorsal surface of neural placode blending with subcutaneous fat

Prevalence: 20% of skin-covered lumbosacral masses; in up to 50% of occult spinal dysraphism
Age: typically < 6 months of age; M < F
• semifluctuant lumbosacral mass with overlying skin intact
• sensory loss in sacral dermatomes, motor loss, bladder dysfunction; foot deformities, leg pain
Location: lumbosacral; longitudinal extension over entire length of spinal canal (in 7%)
Site:
› lipoma dorsally continuous with subcutaneous fat
› lipoma may extend upward within spinal canal external to dura (= "epidural lipoma")
› lipoma may enter central canal and extend rostrally (= "intradural intramedullary lipoma")
√ deformed undulating spinal cord with dorsal cleft
√ tethered cord
√ ventral + dorsal nerve roots leave neural placode ventrally
√ dilated subarachnoid space
US:
√ echogenic intraspinal mass adjacent to deformed spinal cord + continuous with slightly hypoechoic subcutaneous fat
@ Vertebral changes
√ large spinal canal
√ erosion of vertebral body + pedicles
√ posterior scalloping of vertebral bodies (50%)
√ focal spina bifida
√ segmental anomalies / butterfly vertebra (up to 43%)
√ confluent sacral foramina / partial sacral agenesis (up to 50%)

Fibrolipoma of Filum Terminale

Prevalence: 6% of autopsies
• asymptomatic
Location: intradural filum, extradural filum, involvement of both portions
√ thin linear fat-containing mass of filum terminale
Prognosis: potential for development of symptoms of tethered cord

LÜCKENSCHÄDEL

= CRANIOLACUNIA = LACUNAR SKULL
= mesenchymal dysplasia of calvarial ossification (developmental disturbance)
Age: present at birth
Associated with:
(1) Meningocele / myelomeningocele / encephalocele
(2) Spina bifida
(3) Cleft palate
(4) Arnold-Chiari II malformation
• normal intracranial pressure
Location: particularly upper parietal area

√ honeycombed appearance about 2 cm in diameter (thinning of diploic space)
√ premature closure of sutures (turricephaly / scaphocephaly)
Prognosis: spontaneous regression within first 6 months of life
DDx: (1) Convolutional impressions = "digital" markings (visible at 2 years, maximally apparent at 4 years, disappear by 8 years of age)
(2) "Hammered silver" appearance of increased intracranial pressure

LYMPHOMA OF SPINAL CORD

Prevalence: 3.3% of CNS lymphoma, 1% of all lymphomas
Mean age: 47 years; M< F
Histo: monotonous collection of lymphocytes packed tightly into perivascular space; predominantly B-cell lymphocyte population; no necrosis
• weakness, numbness, progressive difficulty in ambulation
Location: cervical > thoracic > lumbar cord
Site: in extradural compartment (most commonly)
MR:
√ mostly solitary, rarely multicentric
√ isointense relative to cord on T1WI
√ hypointense with cord on T2WI (related to high nuclear-to-cytoplasmic ratio)
√ extensive cord edema
√ hetero- / robust homogeneous enhancement
√ restricted diffusion ← high cellularity + reduced extracellular matrix
Cx: compression of cord due to narrowing of spinal canal
Rx: initial response to steroids; radiation therapy results in rapid reduction in size + compressive effects

MENINGEAL CYST

= abnormal dilatation of meninges within sacral canal / foramina ± presacral component
Prevalence: 5%
Cause: diverticulum of spinal meningeal sac / nerve root sheath / arachnoid
√ unilocular / multilocular cyst
√ remodeling erosion of sacral canal / foramen ← CSF pulsations
√ thinned cortical margins
DDx of presacral cyst: cystic sacrococcygeal teratoma; anal duct cyst; degenerative neurogenic tumor; adnexal cyst

Perineural Sacral Cyst / Tarlov Cyst

[Isadore Max Tarlov (1905–1977), professor of neurology and neurosurgery at New York Medical College]
= dilated nerve-root sleeve as normal variant
Cause: ? congenital, traumatic
Location: posterior rootlets (S2 + S3 most common)
• neurologic symptoms if large (in 22%)
√ cyst communicates freely with subarachnoid space

√ cyst wall continuous with arachnoid + dura
√ cyst cavity occupies space between peri- and endoneurium
√ bone remodeling + enlargement of neural foramen
Rx: surgical decompression, sacral laminectomy, percutaneous drainage

Sacral Meningeal / Arachnoid Cyst (less common)
= OCCULT INTRASACRAL MENINGOCELE
• usually asymptomatic
√ cyst does not communicate with subarachnoid space

MENINGIOMA OF SPINE

Prevalence: 25–45% of all spine tumors; 2–3% of pediatric spinal tumors; 12% of all meningiomas
Age: > 40 years + female (80%)
Location: thoracic region (82%); cervical spine on anterior cord surface near foramen magnum (2nd most common location); 90% on lateral aspect
Site: intradural extramedullary (50%); entirely epidural; intradural + epidural
• spinal cord / nerve root compression
√ bone erosion in < 10%
√ scalloping of posterior aspect of vertebral body
√ widening of interpedicular distance
√ enlargement of intervertebral foramen
√ may calcify (not as readily as intracranial meningioma)
CT:
√ solid smoothly marginated mass isodense with skeletal muscle
√ marked enhancement
MR:
√ isointense with spinal cord on T1WI + T2WI
√ ± dural tail reflecting tumor spread / reactive changes
√ rapid + intense enhancement after Gd-DTPA
DDx: nerve sheath tumor

METASTASIS TO VERTEBRA

◊ Most common vertebral tumor!
Prevalence: 5–10% of cancer patients
Age: usually > 50 years of age
Source:
(a) Metastatic tumor: lung, breast, prostate (15–20%) > kidney, lymphoma, malignant melanoma
(b) Primary tumor: multiple myeloma
Spread:
(a) hematogenous spread to vertebral body (bones with greatest vascularity) + epidural space
(b) contiguous spread from paraspinal region: lymphoma, sarcoma, lung carcinoma
• back pain; motor deficits; sensory abnormality

• autonomic dysfunction (bladder, bowel)

Location: thoracic > lumbosacral > cervical spine

Clues: √ multiple lesions of variable size
√ pedicles often destroyed
√ vertebral compression fracture
√ associated epidural tumor
√ cortical disruption (= osteolysis)

Radiograph:
√ osteolytic >> osteoblastic > mixed metastases

MR (93% sensitive, 97% specific, 97% accurate):
√ patchy multifocal relatively well-defined lesions
√ diminished signal on T1WI on background of high-signal appearance of marrow fat
√ increased signal on T2WI (except for blastic metastases with diminished T1 + T2 signals)
√ contrast enhancement on T1WI (majority)
√ pathologic compression fracture:
√ fracture only after all vertebral body fat replaced
√ hyperintense on diffusion-weighted images (DDx: hypointense benign osteoporotic fracture)
◊ Whole-spine MRI to search for multifocal involvement!

Risk: malignant **spinal cord compression** (5–10%)

◊ Metastatic extension into spinal canal can result in neurologic symptoms and paralysis.

DDx: (1) Infection (centered around disk space)
(2) Primary vertebral tumor (rare in older patients, almost always benign in patients < 21 years of age)

METASTASIS TO SPINAL CORD

Frequency: 90% of all spinal cord + vertebral neoplasms

Intramedullary Metastasis

Prevalence: 0.9–2.1% of CNS metastases (autoptic)

Origin: lung (40–85%), breast (11%), melanoma (5%), renal cell (4%), colorectal (3%), lymphoma (3%), cerebellar medulloblastoma; 5% of unknown origin

Spread:
(a) common: hematogenous (via arterial supply) / direct extension from leptomeninges
(b) rare: dissemination along central canal / extension along Batson venous plexus from retroperitoneal primary tumor / extension along perineural lymphatic ducts

• symptomatic for < 1 month (in 75%):
• motor weakness, bowel / bladder dysfunction (60%)
• pain (70%), paresthesia (50%)

Location: cervical (45%), thoracic (35%), lumbar cord (8%)

Myelography (up to 40% undetected)

MR:
√ mild cord expansion over several segments (average length of 2–3 vertebral segments)

√ central area of low SI (mimicking syrinx) on T1WI
√ high SI on T2WI ← edema / tumor infiltration
√ intense homogeneous enhancement
√ disproportionately large amount of surrounding edema
Prognosis: 66% die within 6 months
Rx: radiation therapy, corticosteroids

Extradural / Epidural Metastasis

Origin: breast (22%), lung (15%), lymphoma (10%), prostate (10%), kidney (7%), gastrointestinal (5%), melanoma (4%)
DDx: schwannoma, neurofibroma, cysts

Intradural Metastasis

= MENINGEAL CARCINOMATOSIS OF SPINE
√ round multifocal masses varying substantially in size from a few mm to > 10 mm
√ enlarged cord (from diffuse tumor coating of spinal cord) simulating an intramedullary lesion
√ thickening of meninges (especially in lymphoma, breast cancer, prostate cancer)
√ thickened + nodular matted nerve roots
√ nodular + irregularly narrowed thecal sac
√ Gd-DTPA enhancement (difficult to detect due to adjacent fat + enhancing epidural venous plexus)
Dx: CSF analysis (more sensitive than imaging)
DDx: moderate to severe meningitis, benign postoperative arachnoiditis, neurofibromatosis

Metastases from Outside CNS

(a) with subarachnoid hemorrhage:
bronchogenic carcinoma, malignant melanoma, choriocarcinoma, hypernephroma
(b) others: breast (most common), lymphoma
√ predominantly dorsal location

Drop Metastases

= CSF SEEDING OF INTRACRANIAL NEOPLASMS
Age: occurs more frequently in pediatric age group than in adults
Location: lumbosacral + dorsal thoracic spine ← CSF flow / gravitation)
Site: on spinal arachnoid / pia mater
CNS tumors causing drop metastases:

1. Primitive neuroectodermal tumor
2. Medulloblastoma: up to 33%
3. Anaplastic glioma
4. Ependymoma: after local recurrence, more common in infra- than supratentorial ependymomas
5. Germinoma
6. Pineoblastoma, pineocytoma

Less common: choroid plexus carcinoma, teratoma, angioblastic meningioma
mnemonic: MEGO TP

Medulloblastoma
Ependymoma
Glioblastoma multiforme
Oligodendroglioma
Teratoma
Pineoblastoma, **P**NET

MYELOCYSTOCELE

= SYRINGOCELE
= hydromyelic spinal cord + arachnoid herniated through posterior spina bifida; least common form of spinal dysraphism
May be associated with: GI tract anomalies, GU tract anomalies
• cystic skin-covered mass over spine
• cloacal exstrophy (frequent)
Location: lower spine > cervical > thoracic spine
√ direct continuity of meningocele with subarachnoid space
√ cyst communicating with widened central canal of spinal cord typically posteriorly + inferiorly to meningocele
√ lordosis, scoliosis, partial sacral agenesis (common)

MYELOMENINGOCELE

= sac covered by leptomeninges containing CSF + variable amount of neural tissue; herniated through a defect in the posterior / anterior elements of spine
Prevalence: 1÷1,000–2,000 births (in Great Britain 1÷200 births); twice as common in infants of mothers > 35 years of age; Caucasians > Blacks > Orientals; most common congenital anomaly of CNS
Etiology: localized defect of closure of caudal neuropore (usually closed by 28 days); persistence of neural placode causes derangement in the development of mesenchymal + ectodermal structures
• positive family history in 10%
• neural placode = reddish neural tissue in the middle of back made up of open spinal cord
• normal skin / cutaneous abnormality: pigmented nevus, abnormal distribution of hair, skin dimple, angioma, lipoma
• MS-AFP (≥ 2.5 S.D. over mean) permits detection in 80% (2–5% PPV) if defect not covered by full skin thickness
Recurrence rate: 3–7% chance of NTD with previously affected sibling / in fetus of affected parent
Associated with:
(1) Hydrocephalus (70–90%): requiring ventriculoperitoneal shunt in 90%
◊ 25% of patients with hydrocephalus have spina bifida!
(2) Chiari II malformation (99%)
(3) Congenital / acquired kyphoscoliosis (90%)
(4) Vertebral anomalies: vertebral body fusion, hemivertebrae, cleft vertebrae, butterfly vertebrae

(5) Diastematomyelia (20–46%): spinal cord split above (31%), below (25%), at the same level (22%) as the myelomeningocele
(6) Duplication of central canal (5%) cephalic to + at level of placode
(7) **Hemimyelocele** (10%) = two hemicords in separate dural tubes separated by fibrous / bony spur: one hemicord with myelomeningocele on one side of midline, one hemicord normal / with smaller myelomeningocele at a lower level
• impaired neurological function on side of hemimyelocele
(8) Hydromyelia (29–77%) cranial to placode ← disturbed CSF circulation
(9) Chromosomal anomalies (10–17%): trisomy 18, trisomy 13, triploidy, unbalanced translocation
◊ In 20% no detectable associated anomalies!
(10) Tethering of spinal cord (70–90%)
(11) Arachnoid cyst (2%) ← developmental deficiency during formation of arachnoid / dura mater with a subdural location

Distribution: thoracic (2%), thoracolumbar (32%), lumbar (22%), lumbosacral (44%)

Location:
(a) cranial meningocele = encephalocele
(b) dorsal / posterior meningocele
(c) anterior sacral meningocele
(d) lateral thoracic / lumbar meningocele

OB-US:
detection rate of 85–90%; sensitivity dependent on GA (fetal spine may be adequately visualized after 16–20 weeks GA); false-negative rate of 24%
√ spinal level estimated by counting up from last sacral ossification center = S4 in 2nd trimester + S5 in 3rd trimester (79% accuracy for ± spinal level)
√ may have clubfoot / rocker-bottom foot
√ polyhydramnios
@ Spine:
√ loss of dorsal epidermal integrity
√ soft-tissue mass protruding posteriorly + visualization of sac
√ widening of lumbar spine with fusiform enlargement of spinal canal:
√ splaying (= divergent position) of ossification centers of laminae with cup- / wedge-shaped pattern (in transverse plane = most important section for Dx)
√ absence of posterior line = posterior vertebral elements (in sagittal plane)
√ gross irregularity in parallelism of lines representing laminae of vertebrae (in coronal plane)
√ anomalies of segmentation / hemivertebrae (33%) with short-radius kyphoscoliosis
√ tethered cord + lumbar / lumbosacral myelomeningocele
@ Head:
√ "lemon" sign = concave / linear frontal contour abnormality located at coronal suture strongly associated with spina bifida
√ "banana" sign
Prevalence: in 96% of fetuses ≤ 24 weeks; in 91% of fetuses > 24 weeks
√ "nonvisualization" of cerebellum
√ effaced cisterna magna (100% sensitivity)

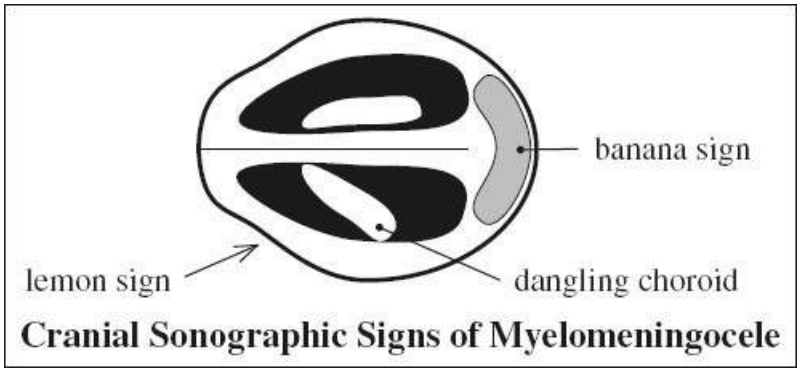
◊ A normal cisterna magna is 3–10 mm deep and usually visualized in 97% at 15–25 weeks GA

√ BPD < 5th percentile during 2nd trimester (70% sensitive)

√ HC < 5th percentile (35% sensitivity)

√ ventriculomegaly (40–90%) with choroid plexus incompletely filling the ventricles (54–63% sensitivity) = "dangling" choroid on dependent side

Prevalence: in 44% of myelomeningoceles < 24 weeks GA; in 94% of myelomeningoceles during 3rd trimester



Cranial Sonographic Signs of Myelomeningocele

Plain films:

√ bony defect in neural arch

√ deformity + failure of fusion of lamina

√ absent spinous process

√ widened interpedicular distance

√ widened spinal canal

Rx: (1) Possibly elective cesarean section at 36–38 weeks GA (may decrease risk of contaminating / rupturing the meningomyelocele sac)

(2) Repair within 48 hr

Postoperative complications:

(1) Postoperative tethering of spinal cord by placode / scar

(2) Constricting dural ring

(3) Cord compression by lipoma / dermoid / epidermoid cyst

(4) Ischemia from vascular compromise

(5) Syringohydromyelia

Prognosis:

(1) Mortality 15% by age 10 years

(2) Intelligence: IQ < 80 (27%); IQ > 100 (27%); learning disability (50%)

(3) Urinary incontinence: 85% achieve social continence (scheduled intermittent catheterization)

(4) Motor function: some deficit (100%); improvement after repair (37%)

(5) Hindbrain dysfunction associated with Chiari II malformation (32%)

(6) ventriculitis: 7% in initial repair within 48 hours, more common in delayed repair > 48 hours

Dorsal / Posterior Meningocele

› lumbosacral (70% below L2): may be associated with tethered cord, partial sacral agenesis
› suboccipital

Anterior Sacral Meningocele

= prolapse through sacral foramen / anterior bony defect
May be associated with:
neurofibromatosis type 1, Marfan syndrome, partial sacral agenesis, imperforate anus, anal stenosis, tethered spinal cord, GU tract / colonic anomalies; Currarino triad
Prevalence: 1÷40,000
Age: 1st decade of life (in 80%); M÷F = 1÷4
• usually asymptomatic in older children
• constipation, dysmenorrhea, urinary incontinence ← mass effect
• back pain, numbness in lower limbs, headache ← neurologic compromise / meningitis / rupture
√ vertebral body scalloping, hypoplasia, aplasia
√ scimitar sacrum = sickle-shaped sacrum

Lateral Thoracic Meningocele

= outpouching of leptomeninges through enlarged intervertebral foramen into extrapleural aspect of thorax
Location: right > left side, in 10% bilateral
Often associated with: neurofibromatosis (75–85%) with sharply angled scoliosis convex to meningocele
√ expanded spinal canal
√ erosion of posterior surface of vertebral body
√ thinning of neural arch
√ enlarged neural foramen
√ spinal abnormalities: kyphoscoliosis, scalloping of dorsal vertebrae, enlargement of intervertebral foramen, pedicle erosion, thinning of ribs

Lateral Lumbar Meningocele

Site: through enlarged neural foramina into subcutaneous tissue / retroperitoneum
Often associated with: Marfan / Ehlers-Danlos syndrome / neurofibromatosis
√ expanded spinal canal
√ erosion of posterior surface of vertebral body
√ thinning of neural arch
√ enlarged neural foramen

Traumatic Meningocele

= avulsion of spinal nerve roots ← tear in meningeal root sheath
Location: (most commonly) in C-spine after brachial plexus injury
√ small irregular arachnoid diverticulum with extension outside the spinal canal

NEURENTERIC CYST

= incomplete separation of foregut and notochord with persistence of canal of Kovalevski between yolk sac and notochord; cyst connected to meninges through midline defect

Frequency: rarest of bronchopulmonary foregut malformations (like pulmonary sequestration, bronchogenic cyst, enteric cyst)

Associated with: neurofibromatosis; meningocele; spinal malformation (stalk connects cyst and neural canal; usually no stalk between cyst and esophagus)

Location: anterior to spinal canal on mesenteric side of gut

√ posterior mediastinal mass

√ air-fluid level (if communicating with GI tract through diaphragmatic defect)

√ spinal dysraphism at the same level:

- √ midline cleft in centra (accommodates stalk)
- √ anterior / posterior spina bifida
- √ vertebral body anomalies: absent vertebra, butterfly vertebra, hemivertebra, scoliosis
- √ diastematomyelia
- √ thoracic myelomeningocele

Tailgut Cyst

= RETRORECTAL CYSTIC HAMARTOMA = RECTAL DUPLICATION CYST = MUCIN-SECRETING CYST = TAILGUT VESTIGES = MYOEPITHELIAL HAMARTOMA OF RECTUM

= rare congenital abnormality in presacral space ← persistent remnant of embryonic gut

Age: manifested in childhood / adulthood

Histo: NO smooth muscle layer

√ uni- / multilocular cyst

√ high signal intensity on T1WI ← mucoid content

ODONTOGENIC MYXOMA

= clinically + radiographically indistinguishable from ameloblastoma

Prevalence: 3–6% of odontogenic tumors

Origin: mesenchymal odontogenic tissue

Age: 10–30 years; M < F

• usually painless

Location: maxilla > mandible

√ well-demarcated / ill-defined lytic lesion of varying size

√ often multilocular + honeycomb-like internal osseous trabeculae

√ foci of irregular calcifications (frequent)

Cx: can be locally aggressive causing considerable destruction of adjacent bone + soft-tissue infiltration

DDx: malignancy, traumatic bone cyst, central giant cell granuloma, calcifying epithelial odontogenic tumor

ODONTOMA

= odontogenic developmental hamartomatous malformation → obstruction of tooth eruption
Prevalence: most common odontogenic tumor (67%)
Age: 2nd decade; before or after tooth eruption
Histo: various tooth components including dentin + enamel
Associated with: impacted tooth (in 50%); dentigerous / calcifying odontogenic cyst (occasionally)
Location: between roots of teeth
Site: pericoronal
√ sharply marginated lesion
√ initially purely radiolucent ± small calcifications
√ later radiopaque mass with a lucent halo
√ 1–3 cm in diameter
√ may be surrounded by lucent follicle
Types:
(a) simple
√ supernumerary tooth
(b) compound odontoma (more common)
√ multiple small toothlike structures (abortive teeth = denticles)
Site: anterior maxilla
(b) complex odontoma
= conglomerate mass of enamel + dentin
Site: molar region (most common)
√ well-defined lesion with amorphous calcifications
√ low-attenuation halo surrounds odontoma
DDx: osteoma (NO halo)
Cx: impaction, malpositioning, resorption of adjacent teeth
DDx: focal cemento-osseous dysplasia, osteoma, ameloblastic fibroodontoma, adenomatoid odontogenic tumor

OSSIFYING FIBROMA

Peak incidence: first 2 decades of life
Histo: areas of osseous tissue intermixed with highly cellular fibrous tissue
Site: maxilla > frontal > ethmoid bone > mandible; rarely seen elsewhere
√ areas of increased + decreased attenuation
√ intact inner + outer table
√ slow-growing expansile lesion
√ usually unilateral + monostotic
DDx: may be impossible to differentiate from fibrous dysplasia

OSTEOMYELITIS OF VERTEBRA

Prevalence: 2–10% of all cases of osteomyelitis
Cause:
(1) Direct penetrating trauma (most common) following surgical removal of nucleus pulposus
(2) Hematogenous: associated with urinary tract infections / following genitourinary surgery /

instrumentation; diabetes mellitus; drug abuse

Pathophysiology: infection begins in low-flow end-vascular arcades adjacent to subchondral plate

Organism: Staphylococcus aureus, Salmonella

Peak age: 5th–7th decade

- pain in back, neck, chest, abdomen, flank, hip
- neurologic deficit; positive blood / urine culture
- fever (most common presenting symptom), leukocytosis
- increased erythrocyte sedimentation rate

Location: vertebral body, intervertebral disk, posterior elements (20%)

√ disk space narrowing (earliest radiographic sign)

√ demineralization of adjacent vertebral endplates

√ bulging of paraspinal lines

MR (90% accuracy = method of choice):

√ hypointense decreased marrow signal on T1WI

√ iso- / hyperintense marrow signal on T2WI

√ hyperintense signal on STIR sequence

CEMR:

√ enhancing foci in bone marrow + disk space

NUC (time-intensive combined bone-gallium scan):

√ tracer uptake in adjacent portions of two vertebral bodies

√ PET-CT (comparable to gallium imaging)

Cx: secondary infection of intervertebral disk (frequent)

Rx: > 4 weeks course of IV antibiotics

DDx: diskitis

PARAGANGLIOMA OF SPINAL CORD

Mean age: 46 years; M > F

Path: soft encapsulated (75%) slightly hemorrhagic mass supplied by numerous feeding arteries

Histo: chief cells + sustentacular cells surrounded by fibrovascular stroma; nests of chief cells in classic "Zellballen" configuration

- lower back pain, sciatica (mean duration for 4 years)

Location: cauda equina, filum terminale

Site: intradural extramedullary compartment

Mean size: 3.3 (range, 1.5–10.0) cm

CT:

√ bone erosion of spine

MR:

√ well-circumscribed mass isointense to cord on T1WI

√ iso- to hyperintense on T2WI:

√ "cap" sign = low-signal–intensity rim on T2WI from hemorrhage

√ ± "salt-and-pepper" appearance

√ intense enhancement

√ serpentine flow voids along surface + within tumor nodule
√ ± syringohydromyelia

Angio:
√ intense early blush persisting well into late arterial + early venous phase

PERIPHERAL NERVE SHEATH TUMOR (PNST)

Dx: distinctive features suggesting peripheral nerve sheath tumor:
(1) Location in region of a major nerve
(2) Depiction of nerve entering / exiting mass
(3) Presence of split fat sign, fascicular sign, target sign

MR:
√ "split-fat" sign = lesion surrounded by a rim of fat ← displacement of fat surrounding neurovascular bundle suggesting a tumor origin in intermuscular space
√ "fascicular" sign = multiple small ringlike structures with peripherally higher SI on T2WI ← fascicular bundles within nerves
√ "target" sign= fibrocollagenous tissue centrally and myxomatous tissue peripherally:
√ tumor periphery of high SI ← myxoid degeneration
√ center of tumor of low SI ← fibrocollagenous tissue of condensed Schwann cells

Angio:
√ displacement of major vascular structures
√ corkscrew-type vessels at upper / lower pole of tumor (= hypertrophy of nutrient nerve vasculature)

Benign Peripheral Nerve Sheath Tumor

= (BENIGN PNST) = BENIGN TUMOR OF NERVE SHEATH = NEURINOMA
Frequency: 10% of benign soft-tissue tumors

Schwannoma = Neurilemmoma

[neuron, *Greek* = nerve, sinew; eilema, *Greek* = covering, coil]
= usually solitary well-encapsulated slow-growing benign proliferation of Schwann cells in a collagenous matrix → eccentric displacement of nerve fibers
Schwann cell = cell that surrounds cranial, spinal, and peripheral nerves producing myelin sheath around axons thus providing mechanical protection and serving as a tract for nerve regeneration
◊ NOTE that myelin sheaths within brain substance are made by oligodendrocytes!
[Theodor Schwann (1810–1882), German physiologist at Belgian Universities Löwen/Leuven/Louvain and Lüttich/Liège]
◊ Nerve root NOT incorporated
Prevalence: 5% of all benign soft-tissue tumors
Age: 40–60 years; M=F
Uncommonly associated with: neurofibromatosis type 1
Path: › fusiform mass entering + exiting the nerve
› mass exophytic / eccentric to nerve of origin
› surrounded by a true capsule of epineurium
› nerve flattened against periphery of tumor

Histo: positive for S-100 protein + vimentin + CD56

(a) cellular component (**Antoni type A** tissue):
more organized area composed of densely packed cellular spindle cells with carrot-shaped or wavy nuclei arranged in short cordlike bundles / interlacing fascicles forming Verocay bodies (= palisading arrangements of elongated cells)
[Nils RE Antoni (1887-1968), professor of neurology at Karolinska Institutet in Stockholm, Sweden]
Location: posterior mediastinum, retroperitoneum, 25% of extremity lesions
√ hypointense on T2WI
√ smaller lesion with uptake of contrast material

(b) myxoid component (**Antoni type B** tissue):
less organized loosely arranged stellate cells in a mucoid stroma (= hypocellular myxoid tissue with high water content)
√ larger lesion hyperintense on T2WI

(c) ancient / cystic schwannoma (see below)

◊ Antoni type A & B often coexist in a single tumor!

- painless, fairly mobile mass
- ± motor and sensory nerve disturbance

Location: in typical peripheral nerve distribution (94%)

(a) intracranial: mostly from sensory nerves
@ Vestibulocochlear (CN VIII) nerve (most common) > trigeminal (V) cranial nerve (2nd most common) > VII
◊ Usually sporadic tumor, but 5–20% of patients with solitary intracranial schwannomas have NF2!

(b) extracranial:
@ Orbit (rare): branches of trigeminal (V) nerve (most common) > oculomotor > trochlear > abducens > parasympathetic > sympathetic fibers > ciliary ganglia
@ Neck, flexor surfaces of upper + lower extremities
Site: ulnar n., peroneal n.
◊ Usually solitary, but in 5% associated with neurofibromatosis type 1 (= > 2 schwannomas / one plexiform neurofibroma)
@ Spine
Location: spinal and sympathetic nerve roots; most common in lower thoracic and lumbar spine > presacral
Site: intradural (70–75%), extradural (15%), both intra- and extradural (15%), intramedullary (< 1%)
@ Posterior mediastinum + retroperitoneum (commonly paravertebral, adjacent to kidneys)
Frequency: 6% of retroperitoneal neoplasms
@ Abdominal wall

Size: 0.1–2.5 cm at time of surgery

Plain film:
√ fusiform mass delineated by surrounding fat
√ soft-tissue and osseous overgrowth
√ bone involvement + mineralization (osteoid / chondroid / amorphous) only in larger

lesions

US:

√ hypoechoic well-circumscribed mass ± cystic spaces

CT:

√ solitary fusiform well-encapsulated round tumor:

√ entering + exiting nerve (intradural / extradural)

√ dumbbell shape with extension into enlarged neural foramen (intra- and extradural)

√ low attenuation (as low as 5–25 HU) due to

(a) high lipid content of myelin from Schwann cells

(b) entrapped fat

(c) endoneural myxoid tissue with high water content (Antoni B areas)

√ well-defined hyperdense margins

√ marked uniform enhancement (most helpful for intradural lesions)

√ slow growth

√ homo- / heterogeneous (33%) enhancement: homogeneous (heterogeneous) if small (large)

√ muscle atrophy with striated increased fat content (in 23%)

√ punctate / mottled / curvilinear calcifications

MR:

√ well-delineated mass of hypo– to isointense signal relative to skeletal muscle on T1WI

√ moderate to markedly increased slightly heterogeneous signal intensity on T2WI:

√ T2 hypointense foci centrally ← dense cellularity / collagen / hemorrhage

√ markedly T2 hyperintense focal areas ← zones of fluid signal = cystic degeneration

√ frequently low-signal-intensity rim ← capsule

√ peritumoral edema in 33%

Cx: malignant transformation (rare)

Rx: excision (affected nerve usually separable from neoplasm after incision of epineurium)

DDx: may appear similar to meningioma

ANCIENT / CYSTIC SCHWANNOMA

= rare variant of schwannoma characterized by marked degenerative changes (old hemorrhage, calcification, cystic change) + decreased cellularity

Age: elderly

Histo: significantly decreased Antoni type A (hypercellular) area with Antoni type B areas occupying majority of tumor

Location: head & neck (orbit, intraventricular, olfactory groove, cavernous sinus), mediastinum, retroperitoneum, pelvis

√ heterogeneously enhancing mass with cystic areas ← myxoid + hemorrhagic change

√ fluid-fluid levels ← hemorrhage

√ ± calcifications / ossification

DDx: serous / mucinous cystadenocarcinoma, abscess, necrotic metastatic lymphadenopathy, arachnoid cyst, dermoid cyst

Ganglioneuroma

Origin: ganglion cell

Mean age: 7 years; M<F

Histo: mature gangliocytes and stroma

◊ Neuroblastoma + ganglioneuroblastoma may mature into ganglioneuroma!

Location: sympathetic ganglia (commonly in mediastinum and retroperitoneum)

• rarely symptoms of catecholamine excess (= vanillylmandelic acid / homovanillic acid)

Average size: 8 cm

Histo: stroma composed of Schwann cells + variable amounts of mature ganglion cells; stains with neuron-specific enolase, neurofilament protein, synaptophysin

US:

√ well-defined homogeneously hypoechoic mass

√ ± punctate echogenic foci ← calcifications

CT:

√ speckled / coarse calcifications within solid homogeneously hypoattenuating mass

√ mild to moderate homogeneous / heterogeneous enhancement

MR:

√ low T1 SI + heterogeneous high T2 signal intensity

√ heterogeneous progressive enhancement

NUC:

√ ± metaiodobenzylguanidine (MIBG) uptake

Rx: complete surgical resection

Neurofibroma

= benign slow-growing peripheral nerve sheath tumor → fusiform enlargement of nerve by separating nerve fibers

Prevalence: 5% of all benign soft-tissue tumors

Path: › round / ovoid mass arising from nerve fascicle

› centrally located mass intrinsic to host nerve

› often infiltrative + rarely encapsulated

› inseparable from parent nerve with tendency to insinuate between tissue planes

Histo: swirls of neuronal elements containing fibroblasts, Schwann cells, nerve fibers; spindle-shaped cells arranged in ribbons and cords among a background of loose myxoid stroma; tumor expresses S100

Typical Demographic and Radiologic Features of Nerve Sheath Tumors			
Feature	*Schwannoma*	*Neurofibroma*	*Malignant Nerve Sheath Tumor*
Demographics			
Prevalence	5% of all benign soft-tissue tumors	5% of all benign soft-tissue tumors	6% of all sarcomas
Age [years]	25–65	20–55	20–65
M÷F ratio	1.3÷1	1.2÷1	1÷1
Multiplicity	rarely multiple	typically solitary	solitary
Associated with NF1	in 18% (with multiple lesions)	in 63% (with multiple lesions)	~ 50%
Malignant change	extremely rare	extremely rare (except for NF1)	in < 5% of NF1
Location	lower extremity > torso > upper extremity > retroperitoneum	head & neck, lower extremity, torso > upper extremity	major nerve trunk of proximal extremity, torso
Radiology			
Mass vs. nerve	eccentric to but inseparable from nerve	central to nerve, intimately intertwined	central to nerve + infiltrating
Capsule	in 70%	in 30%	rare
Target sign	in 0–50%	in 50–70%	absent
Fascicular sign	25%	63%	occasional
Intratumoral cyst	common	rare	N/A
Margin	well-circumscribed	well-circumscribed	more often well-circumscribed than irregular
Central enhancement	3%	63%	

Types: localized (90%), diffuse, plexiform

Age: 20–30 years; M÷F = 1÷1

In 10% associated with: neurofibromatosis type 1 (HALLMARK lesion of NF1)

◊ Neurofibroma is the hallmark lesion of NF1!

◊ Schwannoma is more characteristic of NF2!

Location: skin, soft tissues, viscera; any level, but particularly cervical

(a) peripheral nerves

√ nonencapsulated well-circumscribed fusiform mass of peripheral nerves

(b) intradural extramedullary mass

◊ The spinal neurofibroma is rarely sporadic and usually a sign of type 1 neurofibromatosis!

√ well-defined mass of dumbbell configuration (= intradural + extradural component extending through neural foramen)

√ widening of intervertebral foramen + erosion of pedicles

√ scalloping of vertebral bodies

US:

√ nonspecific solid round / oval mass

√ well-defined homogeneously hypoechoic lesion

√ may demonstrate posterior acoustic enhancement

√ "target" appearance = more hypoechoic periphery (= homogeneous myxoid material) and hyperechoic central zone (= fibrocollagenous core)

CT:

√ well-defined round / oval homogeneously hypodense (CHARACTERISTIC) mass of 20–25 HU (= mucinous matrix + lipid-rich Schwann cells + adipocytes + entrapment of adjacent fat + cystic degeneration)

√ fusiform shape ← entering + exiting nerve = best imaging feature

CECT:
√ typically homogeneous enhancement (30–50 HU)
√ occasionally targetlike enhancement
MR:
√ homogeneous mass hypo- to isointense to cord / muscle on T1WI
√ T2 hyperintense with some heterogeneity
√ "target sign" = central T2-hypointense area (← central core of collagenous + fibrillary tissue) surrounded by high peripheral T2 signal (← fat and myxoid matrix / cystic degeneration, hemorrhage, calcifications)
√ "whorled" appearance with T2 hypointense curvilinear areas ←bundles of collagen and Schwann cells
CEMR:
√ ringlike enhancement of areas of low T2 signal (= myxoid stroma / complex fascicular arrangement)
√ ± muscular atrophy
Cx: malignant transformation (7–13% lifetime risk) → rapid growth, necrosis, hemorrhage, calcification, loss of "target sign", invasion of adjacent structures associated with edema
Rx: surgical resection with sacrifice of nerve (tumor not separable from normal nerve)
DDx: conjoined nerve root sleeve

AMPUTATION NEUROMA *(extremely rare)*
= TRAUMATIC NEUROMA
= nonneoplastic proliferation of the proximal end of a severed / partially transected injured nerve
Histo: nonencapsulated tangled multidirectional regenerating axonal masses + Schwann cells + endo- and perineural cells in dense collagenous matrix with surrounding fibroblasts
Types:
(a) spindle neuroma = internal focal fusiform swelling
Cause: chronic friction / irritation of nondisrupted injured but intact nerve trunk
(b) lateral / terminal neuroma
Cause: severe trauma with partial avulsion / disruption / total transection of nerve
Time of onset: 1–12 months after injury
• history of prior surgery
• Tinel sign = palpation / tapping on lesion reproduces pain
Location: lower extremity (after amputation), head and neck (after tooth extraction), radial nerve, brachial plexus
√ fusiform mass / focal enlargement with entering and exiting nerve (spindle type)
√ bulbous mass in continuity with normal nerve proximally (lateral / terminal type)
MR:
√ isointense to muscle on T1WI
√ heterogeneous intermediate to high SI on T2WI
√ "fascicular" sign = heterogeneous ringlike T2 pattern

Rx: acupuncture, cortisone injection, transcutaneous / direct nerve stimulation, physical therapy, surgical resection

LOCALIZED SOLITARY NEUROFIBROMA *(90%)*

Prevalence: 90% of all neurofibromas
Path: fusiform tumor, often remaining within epineurium as a true capsule
Histo: interlacing fascicles of wavy elongated cells containing abundant amounts of collagen
• painless fusiform mass
Location: affecting primarily superficial cutaneous nerves, occasionally deep-seated larger nerves
√ mostly solitary slow-growing lesion < 5 cm in size
◊ Solitary lesion associated with NF1 in ~ 12%!
US:
√ homo- or heterogeneous hypoechoic mass
MR:
√ "string" sign = visualization of entering + exiting nerve roots at both ends of vertically oriented fusiform mass
√ characteristically low signal intensity on T1WI
√ heterogeneously high on T2WI:
√ high SI on T2WI ← areas of cystic degeneration / myxoid matrix
√ areas of low T2 signal show enhancement ← collagen + fibrous tissue
DDx: schwannoma (encapsulated, difficult DDx)
@ Orbit
Location: superior extraconal orbit
• hypoglobus = downward displacement of globe

DIFFUSE NEUROFIBROMA

Age: children + young adults
Path: poorly defined lesion within subcutaneous fat, infiltrating along connective tissue septa, inseparable from normal nerve tissue
Histo: very uniform prominent fibrillary collagen
Location: most frequently in subcutaneous tissues of head + neck
• plaquelike elevation of skin with thickening of entire subcutis
◊ Isolated lesion (in 90%) unassociated with NF1!
√ always indistinct infiltrative margins ← subcutaneous spread along connective tissue septa
√ hypointense on T2WI

PLEXIFORM NEUROFIBROMA

= involvement of a long segment of nerve + branches extending into adjacent muscle, fat, subcutaneous tissue
Histo: heterogeneous mixture of Schwann cells, perineural cells and fibroblasts
Age: earlier age than other neurofibromas
Location: nerve plexus / multiple fascicles in a medium- to large-sized nerve like lumbosacral plexus; usually bilateral + symmetric

◊ In combination with multiple localized neurofibromas PATHOGNOMONIC of neurofibromatosis type 1

• reticulated linear branching pattern within subcutaneous tissue; often large disfiguring mass

√ serpentine "bag of worms" appearance = tortuous tangles / fusiform enlargement of a branching peripheral nerve

√ ropelike mass involving nonbranching nerve

√ infiltrative mass without respect for fascial boundaries (= transspatial involvement)

√ heterogeneous uptake of contrast material

US:

√ homo- or heterogeneously hypoechoic well-defined masses

CT:

√ iso- or hypoattenuating infiltrative mass ← lipid-rich Schwann cells + adipocytes + myxoid change

√ "targetlike" with benign neurogenic tumor (in 52%)

√ hypovascular / intensely enhancing soft-tissue mass

MR:

√ innumerable ringlike structures corresponding to cross sectioning of ropelike masses

√ T1 + T2 prolongation:

√ heterogeneous intensity on T1WI

√ marked T2-hyperintensity with multiple linear hypointense areas

√ diffuse intense contrast enhancement

√ typically "targetlike" pattern on T2WI:

√ peripheral high SI (← myxoid stroma)

√ central low SI (← fibrous-collagenous tissue)

@ Orbit (1st division of CN V in orbital apex):

Path: tumor may cross tissue planes + involve large portions of face

√ enlargement of affected orbit + neural foramina and erosion of orbital walls + skull base (esp. sphenoid)

Cx: potential for malignant transformation to malignant peripheral nerve sheath tumor (5%)

DDx: lymphatic malformation (fluid-fluid levels)

Malignant Peripheral Nerve Sheath Tumor

= (MPNST) MALIGNANT TUMOR OF NERVE SHEATH = NEUROFIBROSARCOMA = MALIGNANT SCHWANNOMA = NEUROGENIC (SPINDLE CELL) SARCOMA

Prevalence: 5–6–10% of all soft-tissue sarcomas

Lifetime risk in NF1: 4–5%

Age: 20–50 years (mean, 26 years); M÷F = 1÷1

Associated with: neurofibromatosis type 1 (in 10–50–70%), radiation therapy (in 11% of all malignant PNSTs after a latent period of 10–20 years)

Path: fusiform mass with areas of necrosis (in 60%)

Histo: tumor cells arranged in fascicles in a herring-bone pattern resembling fibrosarcoma;

additional heterotopic foci with mature cartilage and bone, rhabdomyosarcoma elements, glandular and epithelial components (in 10–15%)

- progressive enlargement
- pain, motor weakness, sensory deficits in extremity
- clinically silent tumors in abdomen + retroperitoneum

Location: major nerve trunks (commonly in proximal extremities + paraspinal region of torso (sciatic n., sacral plexus, brachial plexus); head & neck

Size: frequently > 5 cm in diameter

Metastases: lung, bone, pleura, retroperitoneum (60%); regional lymph nodes (9%)

√ fusiform mass with entering + exiting nerve typically larger than benign PNST

√ frequently indistinct irregular + infiltrative margins = aggressive biology

√ sudden increase in size of a previously stable neurofibroma

√ heterogeneous tumor with heterogeneous enhancement ← areas of hemorrhage + necrosis

√ invasion of adjacent organs → destruction of adjacent vertebrae / pelvic bones (NO difference to benign PNST)

NUC:

√ ^{67}Ga-citrate uptake in majority of MPNST (DDx: benign tumors show no uptake)

N.B.: only helpful in ^{67}Ga-positive tumors (← false negative rate unknown for MPNST)

Rx: resection + adjuvant chemo- and radiation therapy with local recurrence in 40%

Prognosis: highly aggressive tumor with a 44% 5-year survival rate

PRIMITIVE NEUROECTODERMAL TUMOR OF SPINAL CORD

Prevalence: 20 cases reported in literature

Location: spinal cord, intradural-extramedullary compartment, extradural compartment

Age: more common in adults than children; M÷F = 6÷4

Histo: small round blue cells with hyperchromatic nuclei + scanty cytoplasm, frequent mitoses

- weakness, paresthesia, gait disturbance, pain

Spread: throughout CSF space into cranium, lung, bone, lymph node

√ T1 and T2 prolongation

Prognosis: in > 50% death within 2 years

SACROCOCCYGEAL TERATOMA

Prevalence: 1÷40,000 live births

◊ Most common presacral germ cell tumor in children!

◊ Most common congenital solid tumor in newborn!

Pathogenesis:

(1) growth of residual primitive pluripotential cells derived from the primitive streak + knot (Hensen node) of very early embryonic development

(2) attempt at twinning

- increased prevalence of twins in family

Histo:

(1) **Mature teratoma** (55–75%) with elements from glia, bowel, pancreas, bronchial mucosa, skin appendages, striated + smooth muscle, bowel loops, bone components (metacarpal bones + digits), well-formed teeth, choroid plexus structures (→ production

of CSF)

◊ MATURE TERATOMA = benign tumor composed of tissues foreign to anatomic site in which they arise, usually contains tissue from at least 2 germ cell layers

(2) **Immature teratoma** (11–28%): admixed with primitive neuroepithelial / renal tissue

◊ IMMATURE TERATOMA = benign teratoma with embryonic elements

(3) **Malignant germ cell tumor**

(a) mixed malignant teratoma (7–17%): elements of endodermal sinus tumor (= yolk sac tumor) + either form of teratoma

(b) pure endodermal sinus tumor (rare)

(c) seminoma (dysgerminoma), embryonal carcinoma, choriocarcinoma (extremely rare)

Metastases to: lung, bone, lymph nodes (inguinal, retroperitoneal), liver, brain

Age: 50–70% during first few days of life; 80% by 6 months of age; < 10% > 2 years of age; rare in adulthood (only 100 cases reported); M÷F = 1÷4

◊ Older age means increased prevalence of malignancy (in 50–90% > 2–4 months of age)!

Classification (Altman):

Type I predominantly external lesion covered by skin with only minimal presacral component (47%)

Type II predominantly external tumor with significant presacral component (35%)

Type III predominantly sacral / abdominal component + external extension (8%)

Type IV presacral tumor with no external component (10%)

◊ Internal component suggests malignant transformation!

Associated with: other congenital anomalies (in 18%):

(1) Musculoskeletal (5–16%): spinal dysraphism, sacral agenesis, hip dislocation, clubbed feet

(2) Renal anomalies: hydronephrosis, renal cystic dysplasia, Potter syndrome, urethral atresia, urinary ascites

(3) GI tract: imperforate anus, rectal atresia / stenosis, gastroschisis

(4) Hydrocolpos, undescended testes

(5) Fetal hydrops ← high-output cardiac failure

(6) Placentomegaly ← fetal hydrops

(7) Curvilinear sacrococcygeal defect (rare autosomal dominant inheritance with equal sex incidence, low malignant potential, absence of calcifications) + anorectal stenosis / atresia, vesicoureteral reflux

- ↑ AFP elevated with mixed malignant teratoma + endodermal sinus tumor (CAVE: fetal + newborn serum contains AFP, which does not reach adult levels until about 8 months of age)
- premature labor ← polyhydramnios + large mass
- uterus large for dates
- radicular pain, constipation, urinary frequency / incontinence
- asymptomatic / mass + pressure symptoms like constipation
- recurrent pilonidal infections

Average size: 8 (range, 1–30) cm in diameter

Plain film:

√ amorphous, punctate, spiculated calcifications, possibly resembling bone (36–50%); suggestive of benign tumor

√ soft-tissue mass in pelvis protruding anteriorly + inferiorly

BE:

√ anterosuperior displacement of rectum

√ luminal constriction

IVP:

√ displacement of bladder anterosuperiorly

√ development of bladder neck obstruction

Myelography:

√ intraspinal component may be present

Angio:

√ neovascularity (arterial supply by middle + lateral sacral + gluteal branches of internal iliac artery, branches of profunda femoris artery)

√ enlargement of feeding vessels

√ arterial encasement

√ arteriovenous shunting

√ early venous filling with serpiginous dilated tumor veins

US / CT:

√ solid (25%) / mixed (60%) / cystic (15%) sacral mass

√ polyhydramnios (⅔)

√ poor prognostic factors : oligohydramnios, fetal hydrops with ascites, fetal hydronephrosis, pleural effusions, skin edema, placentomegaly

OB-US:

Age: as early as 14 weeks GA

√ increased size of uterus ← mass / polyhydramnios

√ rapid growth reaching enormous volumes:

√ assessment of tumor volume, amniotic fluid index, placental thickness, diameter of IVC, cardiothoracic ratio, pulmonary hypoplasia

√ oligohydramnios ← obstruction of urinary tract

√ arteriovenous shunting (Doppler US)

Cx (in 18%): preterm labor, preeclampsia, HELLP syndrome, premature delivery, dystocia, intratumoral hemorrhage, tumor avulsion → fetal exsanguination

Rx: US-guided drainage of cystic component, fetal surgery + Cesarean section for solid tumor

MR (preferred modality for initial Dx + surveillance):

√ lobulated + sharply demarcated tumor extremely heterogeneous on T1WI ← high signal from fat, intermediate signal from soft tissue, signal void from Ca2+

√ best modality to detect spinal canal invasion

Prognosis: likely benign: predominantly fatty / cystic tumor

likely malignant: hemorrhagic / necrotic tumor, sacral destruction, patient > 2 months of age

Mortality: 5% for infant; 50% for fetus (worse < 30 weeks GA)

Cx: (1) Dystocia in 6–13%

(2) Massive intratumoral hemorrhage

(3) Fetal death in utero / stillbirth

Rx: 1. Complete tumor resection + coccygectomy + reconstruction of pelvic floor: up to 37% recurrence rate, esp. without coccygectomy
2. Multiagent chemotherapy (in malignancy) with long-term survival rate of 50%

DDx: (1) Myelomeningocele (superior to sacrococcygeal region, not septated, axial bone changes)
(2) Rectal duplication, anterior meningocele (purely cystic)
(3) Hemangioma, lymphangioma, lipomeningocele, lipoma, epidermal cyst, chordoma, sarcoma, ependymoma, neuroblastoma

SACROILIITIS

Radiography:

◊ Conventional radiographic diagnosis insensitive
(= delay in diagnosis by 8–11 years)

Benefit: helpful if positive

Disadvantage: low intra- and interobserver agreement

√ uniform narrowing of joint space
√ erosions
√ intraarticular ankylosis
√ osteophytes
√ pneumocysts
√ articular "vacuum" sign

Grading: 0 normal
1 incipient sclerosis + ↓ focal joint width
2 minimally abnormal with loss of definition of articular margins, subchondral osteoporosis, areas of reactive sclerosis
3 unequivocally abnormal with subchondral sclerosis of sacral + iliac articular margins, erosions, reduced width, widening of joint space, incipient ankylosis
4 complete ankylosis + residual sclerosis

CT: (more sensitive than conventional radiography)

Grading: IA SI joint space > 4 mm
IB SI joint space < 2 mm
IIA joint contour irregularities
IIB erosions on iliac > sacral side
IIIA significant subchondral sclerosis
IIIB spur formation
IVA transarticular bone bridge
IVB total ankylosis

MR: (cardinal tool + biomarker for disease activity)

√ bone marrow edema (first to appear)
√ subchondral sclerosis = low SI bands extending > 5 mm from joint space (DDx: physiologic sclerosis)
√ erosions = T1-hypointense + T2-hyperintense bone defect at margins of cartilaginous

compartment
√ periarticular fat deposits (= previous inflammation)
√ ankylosis (= fusion of bone buds)

CEMR:
√ vasoactive bone marrow edema
√ synovitis = enhancement of synovium
√ capsulitis = enhancing anterior + posterior joint capsule
√ enthesitis = enhancing ligamentous attachments

DDx: (1) Osteoarthritis (anterior osteophytes)
(2) Septic sacroiliitis (joint effusion, bone marrow edema, intramuscular abscess)
(3) Sacral insufficiency fracture
(4) Osteitis condensans ilii (middle-aged woman, mainly iliac bone sclerosis, normal joint space)
(5) Bone tumor

SCHEUERMANN DISEASE

= SPINAL OSTEOCHONDROSIS = KYPHOSIS DORSALIS JUVENILIS = VERTEBRAL EPIPHYSITIS

[Holger Werfel Scheuermann(1877–1960), Danish orthopedic surgeon and radiologist, head physician to the navy]

= disorder consisting of vertebral wedging + endplate irregularity + narrowing of intervertebral disk space

Prevalence: in 31% (21%) of males (females) with back pain

Age: onset at puberty

Location: lower thoracic / upper lumbar vertebrae; in mild cases limited to 3–4 vertebral bodies

√ anterior wedging of vertebral body of > 5°
√ increased anteroposterior diameter of vertebral body
√ slight narrowing of disk space
√ kyphosis of > 40°/ loss of lordosis; scoliosis
√ Schmorl nodes = intravertebral herniation of nucleus pulposus = depression in contour of endplate in posterior half of vertebral body; found in up to 30% of adolescents + young adults
√ flattened area in superior surface of epiphyseal ring anteriorly = avulsion fracture of ring apophysis due to migration of nucleus pulposus through weak point between ring apophysis + vertebral endplate (fusion of ring apophysis usually occurs at about 18 years of age)
√ detached epiphyseal ring anteriorly

DDx: (1) Developmental notching of anterior vertebrae (NO wedging or Schmorl nodes)
(2) Osteochondrodystrophy (earlier in life, extremities show same changes)

SCHMORL NODE

= CARTILAGINOUS NODE

= superior / inferior intravertebral herniation / prolapse of disk material through weakened area of vertebral endplate

[Christian Georg Schmorl (1861–1932), pathologist at city hospital in Dresden, Germany]

Pathogenesis: disruption of cartilaginous plate of vertebral body left during regression of chorda dorsalis, ossification gaps, previous vascular channels

Cause:

(a) osseous: osteoporosis, osteomalacia, Paget disease, hyperparathyroidism, infection, neoplasm

(b) cartilaginous: intervertebral osteochondrosis, disk infection, juvenile kyphosis

Location: predominantly in thoracolumbar spine

• acute Schmorl nodes may be painful

√ concave defects at upper and lower vertebral endplates with sharp margins

MR:

√ node of similar signal intensity as disk

√ low signal intensity of rim

√ associated with narrowed disk space

DDx: inflammatory disease

mnemonic of DDx: SHOOT

Scheuermann disease

Hyperparathyroidism

Osteoporosis

Osteomalacia

Trauma

SCOLIOSIS

= presence of ≥ 1 lateral curves of the vertebral column in the coronal plane with a Cobb angle of ≥ 10°

◊ A curve of < 10° represents *spinal asymmetry* and NOT scoliosis, is asymptomatic and nonprogressive!

Mechanism: rotation of vertebrae in axial plane → discrepant axial loading between ventral + dorsal portions

Etiology:

A. Primary = idiopathic (80%)

1. Infantile (0–3 yrs.): M÷F=3.5÷1; levoscoliosis; self-limited
2. Juvenile (4–10 yrs.): progression in 70–95%
3. Adolescent (11–18 yrs.): M÷F=1÷4; dextroscoliosis; progression in 5%

B. Secondary

(a) congenital (10%) with progression in 75%

1. Osteogenic: wedge-shaped vertebra, hemivertebra, fused vertebra, unilateral bar
2. Neuropathic: tethered cord, syringomyelia, Chiari malformation, (myelo)meningocele, diastematomyelia

(b) developmental

1. Skeletal dysplasia: achondroplasia
2. Skeletal dysostosis: neurofibromatosis, osteogenesis imperfecta
3. Degenerative scoliosis
4. Traumatic scoliosis

(c) neuromuscular

1. Neuropathic (acquired): cerebral palsy, spinocerebellar degeneration, poliomyelitis
2. Myopathic: muscular dystrophy

(d) tumor-associated

1. Osseous: osteoid osteoma, osteoblastoma
2. Extraosseous: extramedullary (eg, neurofibroma) / intramedullary (eg, astrocytoma) tumor

A focal short-segment scoliosis or painful scoliosis should raise suspicion for an underlying lesion.

Nomenclature:

apex = vertebra / disk with the greatest rotation / farthest deviation from center of vertebral column

end vertebra = vertebra with maximum tilt toward apex of curvature; used to measure Cobb angle

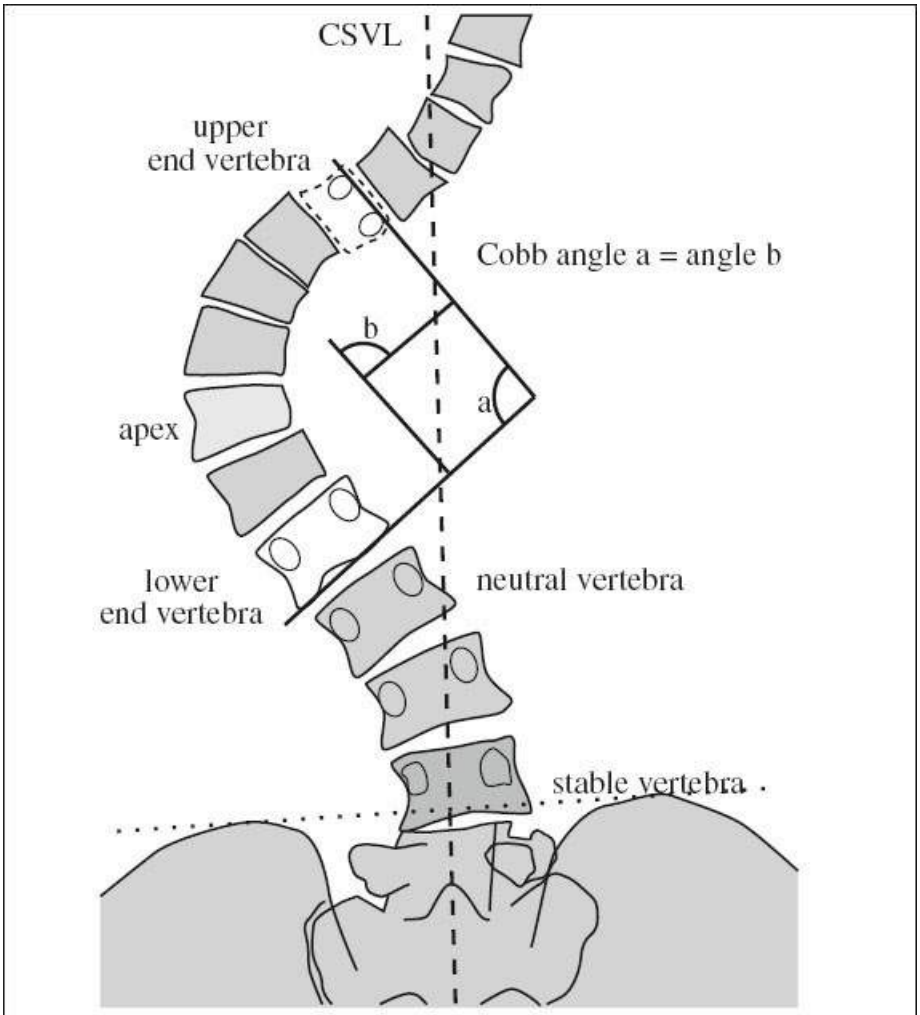
neutral vertebra = vertebra without rotation (= symmetric pedicles) on standing frontal radiograph

stable vertebra = vertebra farthest cephalad roughly bisected by CSVL below end vertebra of distal curve

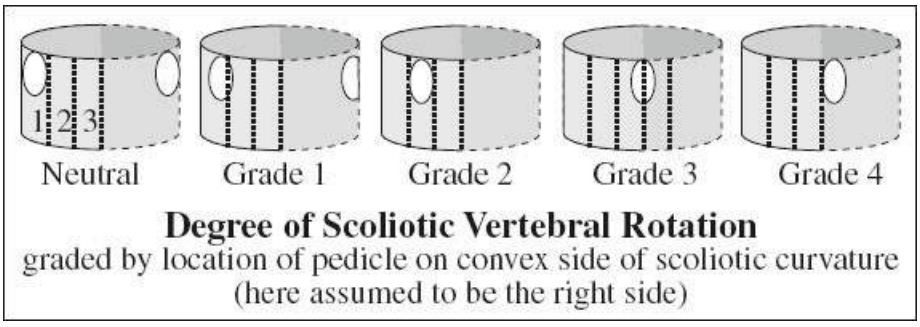
CSVL = central sacral vertical line = line drawn perpendicular to tangential line across iliac crests bisecting sacrum

Primary and Secondary Curves

Major curve = primary structural curve with a Cobb angle of > 25° on ipsilateral bending; largest abnormal curve that develops first; not correctable with ipsilateral bending



Significant Vertebrae in Scoliosis with Cobb Angle
if endplates are not reliably visualized
the borders of the pedicles are used to draw the Cobb angle a



Degree of Scoliotic Vertebral Rotation
graded by location of pedicle on convex side of scoliotic curvature
(here assumed to be the right side)

Minor curve = secondary nonstructural compensatory smaller curve that develops later by repositioning the head and trunk over pelvis to maintain balance; correctable with ipsilateral bending

Vertebral Balance

Plumb line = vertical line drawn downward from center of C7 parallel to lateral edge of radiograph

Coronal imbalance = distance between CSVL + plumb line > 2 cm on frontal x-ray; plumb line to right (left) of CSVL = positive (negative) imbalance

Sagittal imbalance = distance between posterosuperior aspect of S1 + plumb line > 2 cm on lateral x-ray; plumb line anterior (posterior) to S1 = positive (negative) imbalance

Vertebral Rotation (Nash-Moe method)

Cobb angle: angle formed by intersection of 2 lines parallel to endplates of superior + inferior end vertebrae or intersection of the 2 lines drawn perpendicular to the endplate lines

Accuracy: ± 5°

Progressive curve: angle increase of ≥ 5°

Limitation: 2-D radiograph describing a 3D deformity with vertebral rotation

Pitfalls: diurnal variation of 5° (worse in afternoon); 2–7° measurement error; 5–10° interobserver error; actual angle may be 20% greater than plotted depending on accuracy + reproducibility of patient positioning on frontal x-ray

Progression: parallels spinal growth; after skeletal maturity at < 30° no progression, at 30–50° increase by 10–15° per year, at 50–75° increase by 1° per year

Prognosis: with Cobb angle > 50° higher rate of back pain + mortality associated with cardiopulmonary Cx

SERONEGATIVE SPONDYLOARTHRITIS

= SPONDYLOARTHROPATHY

= group of chronic inflammatory rheumatic diseases not associated with rheumatoid factor / rheumatoid nodules

Prevalence: 0.5–1.9%

Subgroups:

1. Ankylosing spondylitis 0.86%
2. Undifferentiated spondyloarthritis 0.67%
   √ NO definite signs of sacroiliitis
3. Psoriatic arthritis 0.29%
   √ parasyndesmophytes
   • psoriatic skin lesions
4. Reactive arthritis (eg, Reiter disease)
   • urogenital tract infection
5. Arthritis associated with inflammatory bowel disease (eg, Crohn disease, ulcerative colitis)

• pain and stiffness; seronegative for rheumatoid factor
• often associated with human lymphocyte antigen (HLA)–B27

Stage of Spondyloarthropathy by MR characteristics			
Stage	*Vertebra*	*Disk*	*Interpretation*
0	↔ T1 + ↓ T2	↓ T1+ ↑ T2	normal
1	↓ T1 + ↑ T2	↓ T1+ ↑ T2	florid inflammation
2	↑ T1 + ↓ T2	↓ T1 + ↑ T2	fatty marrow degeneration
3	↔ T1 + ↓ T2	↔ T1 + ↓ T2	ankylosis

◊ 20-fold greater risk to develop spondyloarthritis in patients with positive HLA–B27 antigen

Location: predominantly axial skeleton (sacroiliac joints frequently first involved)

Site: vertebra, intervertebral disk, synovial joints of spine, tendon, ligamentous attachment (enthesis)

√ sacroiliitis

Extraaxial involvement:

• uveitis

√ calcaneal enthesitis

√ peripheral arthritis

Prognosis: syndesmophytes + ankylosing spondylitis with longstanding disease

Rx: NSAID, TNF (tumor necrosis factor)–α inhibitors, intensive physical therapy

DDx: rheumatoid arthritis, degenerative disk disease, diffuse idiopathic skeletal hyperostosis, pyogenic spondylodiskitis, vertebral fracture, Paget disease

Spondylitis

= ROMANUS LESION (ENTHESITIS)

= inflammation of attachment of annulus fibrosus to vertebral endplate (rim of endplate)

Site: edge of endplates

› **anterior spondylitis** @ anterior endplate

› **posterior spondylitis** @ posterior endplate

› **marginal spondylitis** = both

√ irregularities / erosions involving edges of vertebral endplates (epiphyseal ring)

√ "shiny corners" = sclerotic changes of edges of vertebral endplates during chronic phase

MR:

√ hypointense on T1WI + hyperintense on STIR (← bone marrow edema / osteitis during acute phase)

√ hyperintense on T1WI (← postinflammatory fatty bone marrow degeneration during chronic phase)

Spondylodiskitis

= ANDERSON LESION = RHEUMATIC SPONDYLODISKITIS

= noninfectious inflammation of intervertebral disk by spondyloarthritis

Prevalence: 8% of radiographs in ankylosing spondylitis

Site: diskovertebral unit (= intervertebral disk and adjacent halves of superior and inferior vertebrae)

√ irregularities / erosions of central portion of vertebral endplates (during late phase)

MR:

√ T1-hypointense + STIR-hyperintense disk signals involving one / both halves of adjacent vertebral bodies (in acute edematous phase)

Dialysis-associated Spondyloarthropathy

= spondyloarthropathy in patients on long-term hemodialysis of > 3 years duration
Frequency: 20% of patients on long-term hemodialysis
Cause: amyloid (β2-microglobulin) deposition in synovium and intervertebral disks
Location: lower cervical spine > craniocervical junction > thoracolumbar spine
Associated with: amyloid arthropathy of hands + wrists
Site: usually multiple levels of involvement
• frequently asymptomatic / mild pain + stiffness
• radiculopathy + myelopathy are unusual
• normal ESR, normal WBC count
• elevated levels of β2-microglobulin
√ intervertebral disk space loss ± disc vacuum phenomenon
√ extensive marginated erosions of vertebral endplates and facet joints + cyst formation
√ NO / minimal osteophytosis
√ frequently subluxation + spondylolisthesis
MR:
√ mostly hypointense disk space on T2WI
DDx: (1) Infectious spondylodiskitis (T2-hyperintense disk space, fever)
(2) Ankylosing spondylitis
(3) Degenerative disk disease (no endplate erosions, marked osteophytosis)

SINUS PERICRANII

= venous anomaly (? subperiosteal venous angioma)
= collection of abnormal nonmuscular scalp veins adherent to skull (= dilated subperiosteal epicranial venous structure) connected to intracranial venous system (sinus / cortical vein) by anomalous diploic veins through a well-defined calvarial defect
Etiology: congenital; ? traumatic
Age: childhood; M = F
• focal soft painless scalp mass that reduces under compression
• headache, scalp pressure, pain (rare)
Location: frontal + parietal bone
√ calvarial thinning + defect
√ mild ↓ / mild ↑ / no change in size over time
CT:
√ sessile sharply marginated homogeneous densely enhancing mass adjacent to outer table of skull
√ transcalvarial perforating channels
√ connection to adjacent dural venous sinus
√ possible drainage into extracranial scalp veins
Angio:
√ extracalvarial sinus may not opacify ← slow flow
Rx: ligation of communicating veins + removal of sinus; endovascular embolization

DDx: cephalocele, hemangioma, dermoid cyst, calvarial metastasis

SPINAL STENOSIS

= encroachment on central spinal canal, lateral recess, or neuroforamen by bone / soft tissue

Cause:

A. Congenitally short pedicles
   (a) idiopathic
   (b) developmental: Down syndrome, achondroplasia, hypochondroplasia, Morquio disease

B. Acquired:
   1. Hypertrophy of ligamentum flavum = buckling of ligament ← joint slippage in facet joint osteoarthritis (most common)
   2. Facet joint hypertrophy
   3. Degenerated bulging / herniated disk
   4. Spondylosis, spondylolisthesis
   5. Surgical fusion
   6. Fracture
   7. Ossification of posterior longitudinal ligament
   8. Paget disease
   9. Epidural lipomatosis

Age: middle-aged for congenital cause / elderly during 6th–8th decade for acquired cause; M > F

Location: generally involves lumbar spinal canal; cervical spinal canal may be similarly affected

√ obliteration of epidural fat
√ interpedicular distance < 25 mm
◊ Measurements are NOT a valid indicator of disease!

Cervical Spinal Stenosis

Location: multiple levels in mid- and lower cervical spine
√ sagittal diameter of cervical spinal canal < 13 mm
√ hourglass narrowing of thecal sac with scalloping of the dorsal + ventral margins of the cord
√ greater degree of stenosis in hyperextended position ← buckling of ligamenta flava:
  √ ± spinal block in hyperextended neck on AP views

Lumbar Spinal Stenosis

Cause:

1. Achondroplasia:
   √ narrowed interpediculate distance progressive toward lumbar spine
2. Paget disease: bony overgrowth
3. Spondylolisthesis
4. Operative posterior spinal fusion
5. Herniated disk
6. Metastasis to vertebrae

7. Developmental / congenital

Age: presentation between 30 and 50 years of age

- often asymptomatic until middle age (until development of secondary degenerative changes); low back pain
- "neurogenic / spinal claudication" = bilateral lower extremity pain, numbness, weakness worse during walking / standing + relieved in supine position and flexion
- cauda equina syndrome: paraparesis, incontinence, sensory findings in saddlelike pattern, areflexia

√ sagittal diameter of spinal canal < 16 mm (normal range in adults: 15–23 mm)
√ diminished amount of CSF + crowding of nerve roots
√ unusual small quantity of contrast material to fill thecal sac
√ constricted anteroposterior + interpediculate diameter of spinal canal
√ dural sac area < 100 mm^2
√ hourglass configuration of thecal sac (SAG view)
√ triangular / trefoil shape of thecal sac (AXIAL view)
√ redundant serpiginous nerve roots above + below stenosis
√ thickened articular process, pedicles, laminae, ligaments
√ bulging disks

SPLIT NOTOCHORD SYNDROME

= spectrum of anomalies with persistent connection between gut + dorsal ectoderm

Etiology: failure of complete separation of ectoderm from endoderm with subsequent splitting of notochord and mesoderm around the adhesion about 3rd week of EGA

√ fistula / isolated diverticula / duplication / cyst / fibrous cord / sinus along the tract

Types:

1. **Dorsal enteric fistula**
   = fistula between intestinal cavity + dorsal midline skin traversing prevertebral soft tissue, vertebral body, spinal canal, posterior elements of spine
   - bowel ostium / exposed pad of mucous membrane in dorsal midline in newborn
   - opening passes meconium + feces

   √ dorsal bowel hernia into a skin- / membrane-covered dorsal sac after passing through a combined anterior + posterior spina bifida
2. **Dorsal enteric sinus**
   = blind remnant of posterior part of tract with midline opening to dorsal external skin surface
3. **Dorsal enteric enterogenous cyst**
   = prevertebral / postvertebral / intraspinal enteric-lined cyst derived from intermediate part of tract

   Intraspinal enteric cyst

   Age at presentation: 20–40 years
   - intermittent local / radicular pain worsened by elevation of intraspinal pressure

   Location: intraspinal in lower cervical / upper thoracic region

   √ enlarged spinal canal at site of cyst
   √ hemivertebrae, segmentation defect, partial fusion, scoliosis in region of cyst

4. **Dorsal enteric diverticulum**
   = tubular / spherical diverticulum arising from dorsal mesenteric border of bowel as a persistent portion of tract between gut + vertebral column
5. **Dorsal enteric cyst**
   = involution of portion of diverticulum near gut
   • mass in abdomen / mediastinum ← bowel rotation

SPONDYLOLISTHESIS

= anterior displacement of one vertebra over another

Direction: anterolisthesis, retrolisthesis, lateral translation

Prevalence: 4% of general population

Causes (Newman classification):

I congenital / dysplastic
II isthmic / spondylytic
III degenerative (disk disease)
IV traumatic (fracture)
V pathologic (bone tumor)
VI postsurgical (removal of > 50% of facet joint)

Grades I–IV (Meyerding method): each grade equals ¼ anterior subluxation of upper on lower vertebral body

Isthmic Spondylolisthesis = open-arch type

= pars interarticularis defect between superior + inferior articulating processes as weakest portion of spinal unit → separation of anterior part (vertebral body, pedicles, transverse processes, superior articular facet) slipping forward from posterior part (inferior facet, laminae, dorsal spinous process)

Cause: usually bilateral spondylolysis

Age: often < 45 years

Location: L5-S1 (most common) or L4-5

• symptomatic if intervertebral disk + posterosuperior aspect of vertebral body encroaches on superior portion of neuroforamen causing nerve root compression:
  • backache ± leg pain; sciatica ± backache

√ elongation of spinal canal in anteroposterior diameter
√ bilobed configuration of neuroforamen
√ ratio of maximum anteroposterior diameter of spinal canal at any level divided by diameter at L1 > 1.25
√ inverted "Napoleon's hat" sign (on AP view) = severely subluxed L5 body (= dome of hat) that projects end-on overlapping the sacrum with transverse processes forming the hat's tapered brim

Napoleon's Hat Sign

Degenerative Spondylolisthesis = closed-arch type

= PSEUDOSPONDYLOLISTHESIS

Cause: degenerative / inflammatory joint disease (eg, rheumatoid arthritis)

Pathophysiology: excess motion of facet joints allowing forward / posterior movement

Age: usually > 60 years; M < F (at L4-5)

• commonly symptomatic ← spinal stenosis + narrowing of neuroforamen

√ narrowing of spinal canal

√ hypertrophy of facet joints

√ ratio of maximum anteroposterior diameter of spinal canal at any level divided by diameter at L1 < 1.25

SPONDYLOLYSIS

= break in the interarticular portion of a vertebra

pars interarticularis = junction of vertebral pedicle, lamina, superior + inferior articular facets

> Pars interarticularis abnormalities are a spectrum of nonunion, spondylolysis and stress without spondylolysis.

Prevalence: 3–7% of population; in 30–70% other family members afflicted

Age: early childhood; M÷F = 3÷1; Whites÷Blacks = 3÷1

Cause:

A. Chronic low-grade trauma: stress (fatigue) fracture of pars interarticularis from repetitive minor trauma (in most); during teenage growth spurt; common in gymnastics (30%), ballet, scrubbing floors, lifting heavy objects, diving, contact sports (college football player (20%), wrestler (28%), soccer, hockey, lacrosse)

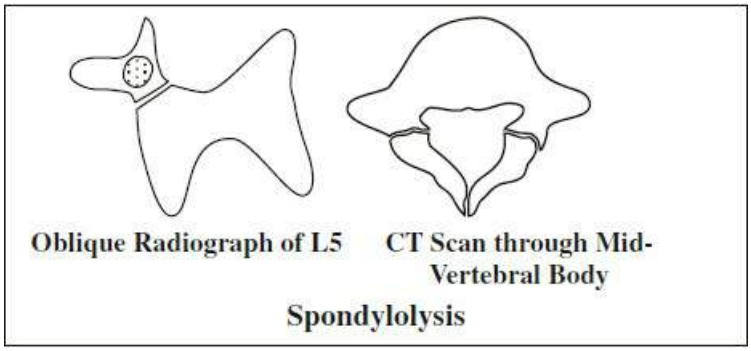
B. Developmental deficiency:
   (a) hereditary hypoplasia of pars → insufficiency fracture; eg, pars defect in 34% of Eskimos
   (b) congenital malformation: frequently associated with spina bifida occulta of S1, dorsally wedge-shaped body of L5, hypoplasia of L5; HOWEVER: no pars defects have been identified in fetal cadavers

C. Secondary spondylolysis: neoplasm, osteomyelitis, Paget disease, osteomalacia, osteogenesis imperfecta

• activity-related low back pain + hamstring tightness in 50% (if associated with degenerative

disk disease / spondylolisthesis)

Location: L5 (67–95%); L4 (15–30%); L3 (1–2%); in 75% bilateral



Plain film (57% PPV):

√ radiolucent band ± sclerotic margin resembling the collar of a "Scottish dog" (on oblique view)

√ may be associated with spondylolisthesis

√ subluxation of involved vertebra (if pars defect bilateral)

√ **Wilkinson syndrome** = reactive sclerosis + bony hypertrophy of contralateral pedicle + lamina ← stress changes related to weakening of neural arch in unilateral pars defect

CT:

√ pars defect located 10–15 mm above disk space

√ inner contour of spinal canal interrupted

NUC bone scintigraphy:

Sensitivity: SPECT/CT > SPECT > planar imaging

Spectrum: uni- / bilateral stress or break

√ stress (50%) = uni- / bilateral focal radiotracer uptake of pars interarticularis WITHOUT break BUT osteosclerosis

√ active spondylysis = uni- / bilateral focal radiotracer uptake + osteolysis (CLASSIC)

√ nonunion (pseudarthrosis) = NO radiotracer uptake + break in pars interarticularis and sclerosis along margins of defect

Cx: (1) Spondylolisthesis (uncommon; most likely before 16 years of age)

(2) Vertebral pedicle fracture (rare; typically unilateral fracture with contralateral spondylolysis; best seen on SAG reformatted CT)

Spondylolysis of Cervical Spine

= progressive degeneration of intervertebral disks leading to proliferative changes of bone + meninges; more common than disk herniation as a cause for cervical radiculopathy

Prevalence: 5–10% at age 20–30; > 50% at age 45; > 90% by age 60

- spastic gait disorder
- neck pain

Location: C4-5, C5-6, C6-7 (greater normal cervical motion at these levels)

Sequelae:

(a) direct compression of spinal cord

(b) neural foraminal stenosis

(c) ischemia due to vascular compromise
(d) repeated trauma from normal flexion / extension

DDx of myelopathy:
rheumatoid arthritis, congenital anomalies of craniocervical junction, intradural extramedullary tumor, spine metastases, cervical spinal cord tumor, arteriovenous malformation, amyotrophic lateral sclerosis, multiple sclerosis, neurosyphilis

SYRINGOHYDROMYELIA

= SYRINGOMYELIA = SYRINX (used in a general manner reflecting difficulty in classification)
= longitudinally oriented CSF-filled cavities + gliosis within spinal cord frequently involving both parenchyma + central canal
Age: primarily childhood / early adult life
Cause: Chiari I malformation (41%), trauma (28%), neoplasm (15%), idiopathic (15%)
• loss of sensation to pain + temperature ← interruption of spinothalamic tracts
• trophic changes = (skin lesions; Charcot joints in 25% affecting shoulder, elbow, wrist)
• muscle weakness ← anterior horn cell involvement
• spasticity, hyperreflexia ← upper motor neuron involvement
• abnormal plantar reflexes ← pyramidal tract involvement
Location: predominantly lower end of cervical cord; extension into brainstem (= syringobulbia)

CT:
√ distinct area of decreased attenuation in spinal cord (100%)
√ swollen / normal-sized / atrophic cord
√ NO contrast enhancement
√ change in shape + size of cord with change in position (rare)
√ flattened vertebral border (rare) with increased transverse diameter of cord
√ filling of syringohydromyelia with intrathecal contrast
(a) <u>early</u> filling ← direct communication with subarachnoid space
(b) <u>late</u> filling after 4–8 hours (80–90%) ← permeation of contrast material

Myelography:
√ enlarged cord (DDx: intramedullary tumor)
√ "collapsing cord" sign = collapsing of cord with gas myelography as fluid content moves caudad in the erect position (rare)

MR:
√ cord enlargement
√ cystic area → low SI on T1WI + increased SI on T2WI
√ presence of CSF flow-void (= low SI on T2WI) within cavity ← pulsations
√ beaded cavity ← multiple incomplete septations
DDx: **pseudosyrinx** = truncation artifact consisting of linear abnormal signal within cord on sagittal images in phase-encoding direction ← limited number of frequencies for fast Fourier transform

Hydromyelia

= PRIMARY / CONGENITAL SYRINGOHYDROMYELIA

= dilatation of persistent central canal of spinal cord (normally obliterated in 70–80%) which communicates with 4th ventricle (= **communicating syringomyelia**)

Histo: lined by ependymal tissue

Associated with:

(1) Chiari malformation in 20–70%
  √ metameric haustrations within syrinx on sagittal T1WI
(2) Spinal dysraphism
(3) Myelocele
(4) Dandy-Walker syndrome
(5) Diastematomyelia
(6) Scoliosis in 48–87%
(7) Klippel-Feil syndrome
(8) Spinal segmentation defects
(9) Tethered cord (in up to 25%)

DDx: transient dilatation of the central canal (transient finding in newborns during the first weeks in life)

Syringomyelia

= ACQUIRED / SECONDARY SYRINGOHYDROMYELIA

= any cavity within substance of spinal cord that may communicate with the central canal, usually extending over several vertebral segments

Histo: not lined by ependymal tissue

Pathophysiology: interrupted flow of CSF through the perivascular spaces of cord between subarachnoid space + central canal

Cause:

1. **Posttraumatic syringomyelia**
   Prevalence: in 3.2% after spinal cord injury
   Location: 68% in thoracic cord
   Average length: 6.0 (range, 0.5–40.0) cm
   √ syrinx may be septated (parallel areas of cavitation) on transverse T1WI
   √ loss of sharp cord-CSF interface (obliteration of arachnoid space by adhesions)
   √ in 44% associated with arachnoid loculations (extra-medullary arachnoid cysts) at upper aspect of syrinx
2. **Postinflammatory syringomyelia**
   subarachnoid hemorrhage, arachnoid adhesions, S/P surgery, infection (tuberculosis, syphilis)
3. **Tumor-associated syringomyelia** = peritumoral cyst of spinal cord tumor / herniated disk ← circulatory disturbance + thoracic spinal cord atrophy
   Prevalence: in 60% of all intramedullary tumors
   √ polar / satellite cysts = rostral / caudal cysts ← reactive dilatation of central canal
   ◊ A higher location within spinal canal raises the likelihood of syrinx development
4. Vascular insufficiency

Reactive Cyst

= POSTTRAUMATIC SPINAL CORD CYST

= CSF-filled cyst adjacent to level of trauma; usually single (75%)
• late deterioration in patients with spinal cord injury (NOT related to severity of original injury)
Rx: shunting leads to clinical improvement

TERATOMA OF SPINE

= neoplasm containing tissue belonging to all 3 germinal layers at sites where these tissues do not normally occur
Prevalence: 0.15% (excluding sacrococcygeal teratoma)
Age: all ages; M÷F = 1÷1
Path: solid thin- / thick-walled partially / wholly cystic space with clear / milky / dark cyst fluid; uni- / multilocular; presence of bone / cartilage
Location: intra- / extramedullary
√ complete block at myelography
√ syringomyelia above level of teratoma
√ spinal canal may be focally widened

TERMINAL MYELOCYSTOCELE

= combination of posterior spina bifida + meningocele + tethered cord + hydromyelia + cystic dilatation of distal central canal
Cause: disturbed CSF circulation resulting in dilatation of ventriculus terminalis + disruption of dorsal mesenchyme
Associated with: anorectal + genitourinary + vertebral anomalies: anal atresia, cloacal exstrophy, scoliosis, sacral agenesis
• skin-covered mass in lumbosacral region
√ spinal cord surrounded dorsally + ventrally by dilated subarachnoid space of the meningocele
√ nerve root exit ventrally
√ bifid spinal cord
√ hydromyelia

TETHERED CORD

= TIGHT FILUM TERMINALE SYNDROME = LOW CONUS MEDULLARIS
= abnormally short + thickened filum terminale with position of conus medullaris below L2-3
Normal location of tip of conus medullaris: L4/5 at 16 weeks of gestation, L2/3 at birth, L1-2 > 3 months of age
◊ RULE OF THREES: above L3 by age 3 months!
Etiology: incomplete involution of distal spinal cord with failure of ascent of conus
Pathophysiology: stretching of cord → vascular insufficiency at level of conus
Age at presentation: 5–15 years (in years of growth spurt); M÷F = 2÷3
Associated with: filar lipoma in 29–78%, filar cyst, diastematomyelia, imperforate anus
• dorsal nevus, dermal sinus tract, hair patch (50%)
• bowel + bladder dysfunction in childhood
• spastic gait with muscle stiffness; radiculopathy (adults)
• lower extremity weakness + muscle atrophy

- asymmetric hyporeflexia + fasciculations
- orthopedic anomalies: scoliosis, pes cavus, tight Achilles tendon
- hypalgesia, dysesthesia; paraplegia, paraparesis
- hyperactive deep tendon reflexes; extensor plantar responses
- anal / perineal pain (in adults)
- back pain (particularly with exertion)

@ Tight filum
- √ diameter of filum terminale > 2 mm (normal range, 0.5–2.0 mm) at L5/S1 level (55%)
- √ small fibrolipoma within thickened filum (23%)
- √ small filar cyst (3%)
- √ spinal cord ending in a small lipoma (13%)

@ Tethered cord (100%)
- √ conus medullaris below level of L3 at birth + below L2 by age 12 (86%)
- √ abnormal dorsal fixation of cord adjacent to vertebral arches (in prone position)
- √ reduced / absent pulsatile movement of the cord + nerve roots (on M-mode scanning)
- √ widened triangular thecal sac tented posteriorly (thecal sac pulled posteriorly by filum)
- √ abnormal lateral course of nerve roots (> 15° angle relative to spinal cord)

@ Vertebrae
- √ lumbar spina bifida occulta with interpedicular widening
- √ scoliosis (20%)

MR:
- √ prolonged T1 relaxation in center of spinal cord on T1WI in 25% (? myelomalacia / mild hydromyelia)

Rx: decompressive laminectomy / partial removal of lipoma ± freeing of cord

Dx: tip of conus medullaris below L2-3

TORUS

= oral exostosis

Age: adulthood (most commonly)

Types and location:
(1) Torus mandibularis: above mylohyoid line along lingual surface of mandible in region of bicuspids
(2) Torus palatinus: at midline of hard palate
(3) Torus maxillaris: lingual surface of posterior maxilla / buccal cortex of maxilla

√ exophytic lesion ± small amount of marrow

√ slowly growing with spontaneous growth arrest

TUBERCULOSIS OF SPINE

Tuberculous Meningitis

- √ CSF loculation
- √ obliteration of subarachnoid space
- √ loss of outline of spinal cord (cervicothoracic spine)
- √ matting of nerve roots (lumbar spine)

√ nodular thick linear intradural enhancement
Cx: syringomyelia

Tuberculous Spondylitis

= POTT DISEASE
[Percivall Pott (1714–1788), full surgeon at St. Bartholomew's Hospital, London, author of the Chirurgical works and discoverer of coal tar-induced cancer of the scrotum in chimney sweeps]
= destruction of vertebral body + intervertebral disk by tuberculous mycobacterium
Frequency: 5% of patients with tuberculosis; 25–50–60% of all skeletal tuberculosis
Associated with: pulmonary TB in 10%
Age: children / adults of 50 years; M > F
• insidious onset of back pain, stiffness
• local tenderness
• NO pulmonary lesions in 50%
Location: upper lumbar + lower thoracic spine (L1 most common); TYPICALLY more than one (up to 5–10) vertebrae + intervening disks affected
Site: vertebral body (82%) with predilection for anterior part adjacent to superior / inferior subchondral bone plate >> posterior elements (18%)
◊ RARELY affects posterior elements + pedicles!
Spread:
(a) contiguous into adjacent disk by penetrating subchondral endplate + cartilaginous endplate
(b) subligamentous spread beneath anterior / posterior longitudinal ligaments to adjacent vertebral bodies → sparing of adjacent disks
(c) hematogenous spread via paravertebral venous plexus of **Batson:** separate foci in 1–4%
(d) skip lesions = SPECIFIC but rare sign of TB
√ TYPICALLY little / NO reactive sclerosis / local periosteal reaction (DDx: pyogenic infection)
√ demineralization = vertebral osteopenia (= resorption of dense margin) of vertebral endplates (earliest change):
√ "gouge defect" = mild contour irregularity of anterior and lateral aspect of vertebral body (= erosion from subligamentous extension of tuberculous abscess)
√ collapse of vertebral body:
√ vertebra plana in children
√ angular kyphotic deformity (= gibbus deformity) ← preferential anterior involvement in adults
√ vertebra within a vertebra (= growth recovery lines)
√ ivory vertebra (= reossification as healing response to osteonecrosis)
√ slight narrowing + collapse of intervertebral disk space
N.B.: vertebral disk space maintained longer than in pyogenic arthritis (disk preserved, but fragmented)
√ <u>paraspinal infection</u>:
√ lateral bowing of psoas shadow (on abdominal film)

√ anterior scalloping of vertebral bodies (DDx: lymphoma, abdominal aortic aneurysm)
√ large cold fusiform abscess in paravertebral gutters / psoas (= Pott abscess), commonly bilateral ± anterolateral scalloping of vertebral bodies
√ nearly PATHOGNOMONIC amorphous / teardrop-shaped calcification in paraspinal area between L1 + L5 (DDx: nontuberculous abscess rarely calcifies)
√ abscess may extend into groin / thigh / internal viscus

MR:
√ centrosomatic rounded well-limited abscess
√ surrounded by bone marrow edema
√ normal disk spaces

NUC: 35% (up to 70%) FN rate for bone (gallium) scan

Cx: (1) Kyphoscoliosis
(2) Ankylosis of vertebrae with obliteration of intervening disk space ← with healing
(3) Osteonecrosis
(4) Paralysis ← spinal cord compression from abscess, granulation tissue, bone fragments, arachnoiditis)

Prognosis: 26–30% mortality rate

Imaging features favoring tuberculous spondylitis:
√ involvement of > 1 segment
√ delay in destruction of intervertebral disks
√ large calcified paravertebral mass
√ absence of sclerosis

DDx: (1) Pyogenic spondylitis (rapid destruction, multiple abscess cavities, no thickening / calcification of abscess rim, little new-bone formation, posterior elements not involved)
(2) Brucellosis (gas within disk, minimal paraspinal mass, no kyphosis, predilection for lower lumbar spine)
(3) Sarcoidosis
(4) Fungal spondylitis
(5) Neoplasia / metastasis (multiple noncontiguous lesions, no disk destruction, little soft-tissue involvement, posterior elements involved)

Tuberculous Spondylitis without Diskitis

increasingly more common type of TB
Predilection: foreign-born (sub-Saharan Africa)
Age: 40 years (10 years younger)
√ absence of disk destruction
√ initial multifocal vertebral involvement in 42%
√ extraspinal skeletal involvement (frequent)

VENTRICULUS TERMINALIS

= small ependyma-lined oval cyst at the transition from tip of conus medullaris to origin of filum terminale

Origin: result of canalization and regressive differentiation of the caudal end of the developing spinal cord during embryogenesis

Size: 8–10 mm long, 2–4 mm in diameter
◊ Regresses during the first weeks after birth

DIFFERENTIAL DIAGNOSIS OF NERVOUS SYSTEM DISORDERS

INCREASED INTRACRANIAL PRESSURE

1. Intracranial mass
2. Hydrocephalus
3. Malignant hypertension
4. Diffuse cerebral edema
5. Increased venous pressure
6. Elevated CSF protein
7. Pseudotumor cerebri

• papilledema

√ enlargement of perioptic nerve subarachnoid space

PROLACTIN ELEVATION

Normal level: up to 25 ng/mL

Cause:

1. Interference with hypothalamic-pituitary axis:
   (a) hypothalamic tumor
   (b) parasellar tumor
   (c) pituitary adenoma
   (d) sarcoidosis
   (e) histiocytosis
   (f) traumatic infundibular transection
2. Pharmacologic agents
   alpha-methyldopa, reserpine, phenothiazine, butyrophenone, tricyclic antidepressants, oral contraceptives
3. Hypothyroidism (TRH also stimulates prolactin)
4. Renal failure
5. Cirrhosis
6. Stress / recent surgery
7. Breast examination
8. Pregnancy
9. Lactation

STROKE

= sudden intracranial insult that leaves a permanent neurological residual

Incidence:

3rd leading cause of death in USA (after heart disease + cancer);
2nd leading cause of death due to cardiovascular disease in USA;
2nd leading cause of death in patients > 75 years of age;
~ 800,000 new cases per year (USA 2006);

leading cause of death in Orient

Age: > 55 years (12% occur in young adults); M÷F = 2÷1

Risk factors: heredity, hypertension (50%), smoking, diabetes (15%), obesity, familial hypercholesterolemia, myocardial infarction, atrial fibrillation, congestive heart failure, alcoholic excess, substance abuse, oral contraceptives, pregnancy, high anxiety + stress

Etiology:

A. NONVASCULAR (5%): eg, tumor, hypoxia
B. VASCULAR (95%)
   1. Brain infarction = ischemic stroke (80%)
      (a) Occlusive atheromatous disease of extracranial (35%) / intracranial (10%) arteries = large vessel disease between aorta + penetrating arterioles
         › critical stenosis, thrombosis,
         › plaque hemorrhage / ulceration / embolism
      (b) Small vessel disease of penetrating arteries (25%) = lacunar infarct
      (c) Cardiogenic emboli (6–15–23%)
         › Ischemic heart disease with mural thrombus
         » acute myocardial infarction (3% risk/year)
         » cardiac arrhythmia
         › Valvular heart disease
         » postinflammatory (rheumatic) valvulitis
         » infective endocarditis (20% risk/year)
         » nonbacterial thrombotic endocarditis (30% risk/year)
         » mitral valve prolapse (low risk)
         » mitral stenosis (20% risk/year)
         » prosthetic valves (1–4% risk/year)
         › Nonvalvular atrial fibrillation (6% risk/year)
         › Left atrial myxoma (27–55% risk/year)
      (d) Nonatheromatous disease (5%)
         › arterial elongation, coil, kinks (up to 20%)
         › fibromuscular dysplasia (typically spares origin + proximal segment of ICA)
         › aneurysm (rare) may occur in cervical / petrous portion / intracranially
         › dissection: traumatic / spontaneous (2%); up to 15% of strokes in young adults
         › cerebral arteritis (Takayasu, collagen disease, lymphoid granulomatosis, temporal arteritis, Behçet disease, chronic meningitis, syphilis)
         › postendarterectomy thrombosis / embolism / restenosis
      (e) Overactive coagulation (5%)
   2. Hemorrhagic stroke (20%)
      (a) Primary intracerebral hemorrhage (15%)
         › Hypertensive hemorrhage 45%
         › Amyloid angiopathy 7–17%
         › Anticoagulants 10%
         › Tumor 5–10%
         › Drug use 6%
         › Vascular malformation, aneurysm 5%

› Bleeding diathesis (eg, hemophilia) < 1%
› Severe migraine
› Surgery (carotid endarterectomy, heart)

(b) Vasospasm due to nontraumatic SAH (4%)
› Ruptured aneurysm 75–80%
› Vascular malformation 10–15%
› "Nonaneurysmal" SAH 5–15%

(c) Venoocclusive disease (1%): sinus thrombosis

- May be preceded by TIA:

◊ 10–14% of all strokes are preceded by TIA!
◊ 60% of all strokes ascribed to carotid disease are preceded by TIA!

Prognosis:

(1) Death during hospitalization (25%): alteration in consciousness, gaze preference, dense hemiplegia have a 40% mortality rate
◊ Hypodensity involving > 50% of MCA territory has a fatal outcome in 85%!
(2) Survival with varying degrees of neurologic deficit (75%)
(3) Good functional recovery (40%)

Role of imaging:

1. Confirm clinical diagnosis
◊ Clinical diagnosis is inaccurate in 13%!
2. Identify primary intracerebral hemorrhage
3. Detect structural lesions mimicking stroke:
tumor, vascular malformation, subdural hematoma
4. Detect early complications of stroke:
cerebral herniation, hemorrhagic transformation

Indications for cerebrovascular testing:

1. **TIA** = transient ischemic attack
2. Progression of carotid disease to 95–98% stenosis
3. Cardiogenic cerebral emboli

Temporal classification:

1. **TIA** = transient ischemic attack
• lasts 5 to 30 minutes + clears within 24 hours
2. **RIND** = reversible ischemic neurologic deficit
= fully reversible prolonged ischemic event resulting in minor neurologic dysfunction
• > 24 hours and < 8 weeks with eventual total recovery
Incidence: 16÷100,000 population / year
3. **Progressing stroke / intermittent progressive stroke**
= stepwise / gradually progressing accumulative neurologic deficit evolving over hours / days
4. **Slow stroke**
= rare clinical syndrome presenting as developing neuronal fatigue with weakness in lower / proximal upper extremity after exercise; occurs in patients with occluded ICA
5. **Completed stroke**
= severe + persistent stable neurologic deficit = cerebral infarction (death of neuronal

tissue) as end stage of prolonged ischemia > 21 days
- level of consciousness correlates well with size of infarct

Prognosis: 6–11% recurrent stroke rate

TRANSIENT ISCHEMIC ATTACK

= brief episode of transient focal neurological deficit ← ischemia of < 24 hours duration with return to pre-attack status

Incidence: 31÷100,000 population per year; increasing with age; 105,000 new cases per year in USA; M > F

Cause:

(a) embolic: usually from ulcerated plaque at carotid bifurcation
(b) hemodynamic: fall in perfusion pressure distal to a high-grade stenosis / occlusion

Risk factors:

(1) Hypertension → linear increase in probability of stroke with increase in diastolic blood pressure
(2) Cardiac disorders: prior myocardial infarction, angina pectoris, valvular heart disease, dysrhythmia, CHF
(3) Diabetes mellitus
(4) Cigarette smoking (weak risk factor)

Prognosis: 5.3% stroke rate per year for 5 years after first TIA; per year 12% increase of stroke / myocardial infarction / death; completed stroke in 5% (33%) within (1 month) 5 years

Rx:
1. Carotid endarterectomy (1% mortality, 5% stroke)
   › prophylactic carotid endarterectomy + chronic low-dose aspirin therapy in patients with recently symptomatic TIA / minor stroke + > 70% carotid artery stenosis
2. Anticoagulation
3. Antiplatelet agent: aspirin, ticlopidine (Ticlid®)

Carotid Transitory Ischemic Attack *(~ 66%)*

- carotid attacks < 6 hours in 90%
- transient weakness / sensory dysfunction CLASSICALLY in
  (a) hand / face with embolic event
  (b) proximal arm + lower extremity with hemodynamic event (located to watershed area)
  › motor dysfunction = weakness, paralysis, clumsiness of one / both limbs on same side
  › sensory alteration = numbness, loss of sensation, paresthesia of one / both limbs on same side
  › speech / language disturbance = difficulty in speaking (dys- / aphasia) / writing, in comprehension of language / reading / performing calculations
  › visual disturbance = loss of vision in one eye, homonymous hemianopia, amaurosis fugax
- paresis (mono-, hemiparesis) in 61%
- paresthesia (mono-, hemiparesthesia) in 57%
- amaurosis fugax (= transient premonitory attack of impaired vision due to retinal ischemia) in 12% ← transient hypotension or emboli of platelets / cholesterol crystals, (which may be

revealed by funduscopy)
- facial paresthesia in 30%

Vertebrobasilar Transient Ischemic Attack *(~ 33%)*

- vertebrobasilar events < 2 hours in 90%
  - › motor dysfunction = as with carotid TIA but sometimes changing from side to side including quadriplegia, diplopia, dysarthria, dysphagia
  - › sensory alteration = as with carotid TIA usually involving one / both sides of face / mouth / tongue
  - › visual loss = as with carotid TIA including uni- / bilateral homonymous hemianopia
  - › disequilibrium of gait / postural disturbance, ataxia, imbalance / unsteadiness
  - › drop attack = sudden fall to the ground without loss of consciousness
- binocular visual disturbance in 57%; vertigo in 50%
- paresthesia in 40%; diplopia in 38%; ataxia in 33%
- paresis in 33%; headaches in 25%; seizures in 1.5%

Accelerating / Crescendo TIA

= repeated periodic events of neurologic dysfunction with complete recovery to normal in interphase

DEMENTIA

= acquired progressive global impairment of intellectual functioning

Prevalence: 35 million worldwide; rising due to increase in life expectancy; in USA 14% of population > 65 years of age and > 50% of individuals > 85 years

Dx: multiple cognitive deficits representing a decrease from baseline + interfering with social / professional function including impairment of (1) memory (2) motor activity (3) recognition (4) executive function

Etiology: may be caused by more than 80 diseases

A. CORTICAL
   1. Alzheimer disease
   2. Pick disease = frontotemporal dementia
   3. Mild cognitive impairment
   4. Creutzfeldt-Jakob disease

B. SUBCORTICAL
   1. Vascular dementia: multi-infarct, Binswanger, CADASIL = cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy)
   2. Dementia with Lewy bodies
   3. Huntington disease
   4. Parkinson disease
   5. Wernicke-Korsakoff syndrome
   6. Wilson disease
   7. Multiple sclerosis
   8. Infectious etiology (HIV, Lyme disease, syphilis
   9. Dementia syndrome of depression

C. OTHERS

1. MELAS
2. Cortical venous thrombosis
3. Normal pressure hydrocephalus
4. Subdural hematoma
5. Brain mass (CNS lymphoma + other neoplasms)

In order of frequency:

1. Alzheimer disease 60–70%
2. Dementia with Lewy bodies 25%
3. Frontotemporal dementia 5–10%
4. Vascular dementia ?% (declining)
5. Mixed etiology 6%
6. Normal pressure hydrocephalus 1%
7. Depression 1%
8. Tumor 1%

PET in Dementia

◊ PET is replacing SPECT ← (1) better spatial resolution, (2) greater sensitivity for hypometabolism compared to perfusion and (3) ability to quantify changes!

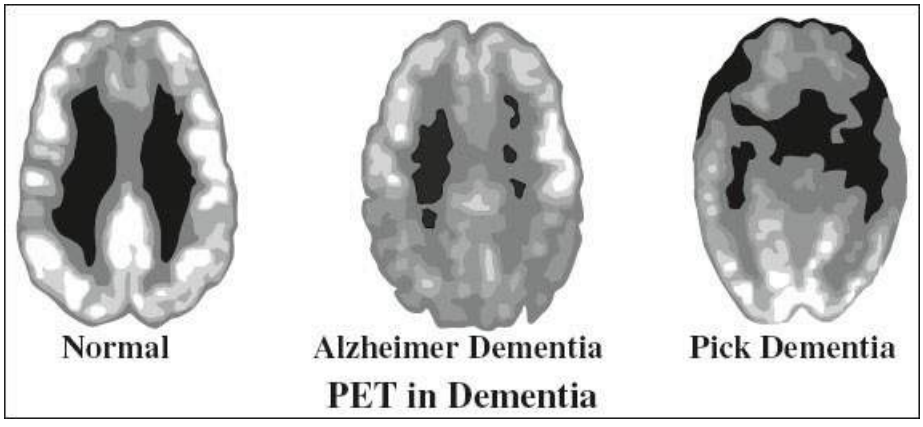
Rationale: dementia diminishes the usually high metabolic rate of active neurons in a typical pattern of distribution

Indication: distinguish between Alzheimer disease and frontotemporal (Pick) dementia

Requirements for PET imaging:

(1) > 6 months of progressive dementia
(2) Comprehensive neurological exam
(3) Diagnostic criteria for dementia have been met

√ sparing of sensorimotor cortex



TRIGEMINAL NEUROPATHY

- facial pain, numbness, weakness of masticatory muscles, trismus
- diminished / absent corneal reflex
- abnormal jaw reflex; atrophy of masticatory muscles
- decreased pain / touch / temperature sensation
- **tic douloureux** = paroxysmal facial pain (usually confined to V_2 and V_3) mainly ←

neurovascular compression (tortuous elongated superior cerebellar artery / anterior inferior cerebellar artery / vertebrobasilar dolichoectasia / venous compression)

A. BRAINSTEM LESION
   1. Vascular: infarct, AVM
   2. Neoplastic: glioma, metastasis
   3. Inflammatory: multiple sclerosis (1–8%), herpes rhombencephalitis
   4. Other: syringobulbia

B. CISTERNAL CAUSES
   1. Vascular: aneurysm, AVM, vascular compression
   2. Neoplastic: acoustic schwannoma, meningioma, trigeminal schwannoma, epidermoid cyst, lipoma, metastasis
   3. Inflammatory: neuritis

C. MECKEL CAVE + CAVERNOUS SINUS
   1. Vascular: carotid aneurysm
   2. Neoplastic: meningioma, trigeminal schwannoma, epidermoid cyst, lipoma, pituitary adenoma, base of skull neoplasm, metastasis, perineural tumor spread
   3. Inflammatory: Tolosa-Hunt syndrome

D. EXTRACRANIAL
   1. Neoplastic: neurogenic tumor, squamous cell carcinoma, adenocarcinoma, lymphoma, adenoid cystic carcinoma, mucoepidermoid carcinoma, melanoma, metastasis, perineural tumor spread
   2. Inflammatory: sinusitis
   3. Other: masticator space abscess, trauma

HORNER SYNDROME

= syndrome ← interruption of oculosympathetic pathway:
- ipsilateral blepharoptosis; pupillary miosis; facial anhidrosis

Oculosympathetic pathway:

(a) 1st order neuron: posterolateral hypothalamus → brainstem → intermediolateral column of spinal cord → exit at C8, T1, T2

(b) 2nd order preganglionic neuron: ventral spinal root → arch over apex of lung → cervical sympathetic chain → superior cervical ganglion

(c) 3rd order postganglionic neuron: with carotid artery → cavernous sinus → ophthalmic branch of cranial nerve V

A. CENTRAL HORNER (uncommon)

Location: hypothalamus, thalamus, brainstem, cervical cord

Cause: infarction of PICA / distal vertebral artery
- hypothalamic / brainstem / spinal cord signs

B. PREGANGLIONIC HORNER

Location: cervicothoracic cord, brachial plexus, anterior neck, mediastinum

Cause: trauma, lung (Pancoast) / mediastinal tumor, lesion in cervical spinal cord / brachial plexus

C. POSTGANGLIONIC HORNER

Location: superior cervical ganglion, internal carotid artery, cavernous sinus, orbital apex

Cause: ICA dissection / aneurysm, carotid-cavernous fistula / thrombophlebitis, inflammation (Tolosa-Hunt syndrome), skull base tumor

CLASSIFICATION OF CNS ANOMALIES

A. DORSAL INDUCTION ANOMALY
   = defects of neural tube closure
   1. Anencephaly
   2. Cephalocele at 4 weeks
   3. Chiari malformation at 4 weeks
   4. Spinal dysraphism
   5. Hydromyelia

B. VENTRAL INDUCTION ANOMALY
   = defects in formation of brain vesicles + face
   1. Holoprosencephaly: 5–6 weeks
   2. Septo-optic dysplasia: 6–7 weeks
   3. Dandy-Walker malformation: 7–10 weeks
   4. Agenesis of septum pellucidum

C. NEURONAL PROLIFERATION & HISTOGENESIS
   1. Neurofibromatosis: 5 weeks–6 months
   2. Tuberous sclerosis: 5 weeks–6 months
   3. Primary hydranencephaly: > 3 months
   4. Neoplasia
   5. Vascular malformation (vein of Galen, AVM, hemangioma)

D. NEURONAL MIGRATION ANOMALY
   due to infection, ischemia, metabolic disorders
   1. Schizencephaly: 2 months
   2. Agyria + pachygyria: 3 months
   3. Gray matter heterotopia: 5 months
   4. Dysgenesis of corpus callosum: 2–5 months
   5. Lissencephaly
   6. Polymicrogyria
   7. Unilateral megalencephaly

E. DESTRUCTIVE LESION
   1. Hydranencephaly
   2. Porencephaly
   3. Hypoxia: periventricular leukomalacia, germinal matrix hemorrhage
   4. Toxicosis
   5. Infections (TORCH)
      (a) **T**oxoplasmosis
      (b) **O**ther: syphilis, hepatitis, zoster
      (c) **R**ubella
         √ punctate / nodular calcifications
         √ porencephalic cysts
         √ occasionally microcephaly

(d) **C**ytomegalovirus inclusion disease
√ typically punctate / stippled / curvilinear periventricular calcifications
√ often hydrocephalus
(e) **H**erpes simplex

Absence of Septum Pellucidum

1. Holoprosencephaly
2. Callosal agenesis
3. Septo-optic dysplasia
4. Schizencephaly
5. Severe chronic hydrocephalus
6. Destructive porencephaly

Phakomatoses

[*phako* , Greek = lens / lentil-shaped object]
= NEUROCUTANEOUS SYNDROMES = NEUROECTODERMAL DYSPLASIAS
= development of benign tumors / malformations in organs of ectodermal origin (CNS, eye, skin)

(a) autosomal dominant:
1. Neurofibromatosis (von Recklinghausen)
2. Tuberous sclerosis (Bourneville)
3. Retinocerebellar hemangioblastoma (Von Hippel-Lindau)
4. Neurocutaneous melanosis

(b) not autosomal dominant:
5. Encephalotrigeminal angiomatosis (Sturge-Weber-Dimitri)
6. Ataxia-telangiectasia

DEGENERATIVE DISEASES OF HEMISPHERES

= progressive fatal disease characterized by destruction / alteration of gray and white matter

Etiology: genetic; viral infection; nutritional disorders (eg, anorexia nervosa, Cushing syndrome); immune system disorders (eg, AIDS); exposure to toxins (eg, CO); exposure to drugs (eg, alcohol, methotrexate + radiation)

Myelinoclastic / Demyelinating Disease

= disease that destroys normally formed myelin
◊ Usually affects older children / adults

(a) infectious
1. Progressive multifocal leukoencephalopathy
2. Subacute sclerosing panencephalitis (SSPE)
3. Acute disseminated encephalomyelitis (ADEM)

(b) noninfectious
1. Radiation
2. Anoxia
3. Hypertensive encephalopathy
4. Disseminated necrotizing leukoencephalopathy (from methotrexate therapy)

(c) others
1. Multiple sclerosis (most frequent of primary demyelinating disease)
2. Alzheimer disease (most common of diffuse gray matter degenerative diseases)
3. Parkinson disease (most common of subcortical degenerative disease)
4. Creutzfeldt-Jakob disease
5. Menkes disease (sex-linked recessive disorder of copper metabolism)
6. Globoid cell leukodystrophy
7. Spongiform degeneration
8. Cockayne syndrome
9. Spongiform leukoencephalopathy
10. Myelinoclastic diffuse sclerosis (= Schilder disease)

Dysmyelinating Disease

= metabolic disorder (= enzyme deficiency) resulting in deficient / absent myelin sheaths
◊ Usually presents in first 2 years / 1st decade of life!
◊ Associated with white matter atrophy

(a) macrencephalic:
1. Alexander disease (frontal areas affected first)
2. Canavan disease (white matter diffusely affected)

(b) hyperdense thalami, caudate nuclei, corona radiata
1. Krabbe disease

(c) family history (X-linked recessive)
1. X-linked adrenoleukodystrophy
2. Pelizaeus-Merzbacher disease

(d) others
1. Metachromatic leukodystrophy (most common hereditary leukodystrophy)
2. Binswanger disease (SAE)
3. Multi-infarct dementia (MID)
4. Pick disease
5. Huntington disease
6. Wilson disease
7. Reye syndrome
8. Mineralizing microangiopathy
9. Diffuse sclerosis

VASCULAR DISEASE OF BRAIN

Classification of Vascular CNS Anomalies

A. VASCULAR MALFORMATION

(a) arterial = arteriovenous malformation (AVM)
1. Classic brain AVM
2. Cerebral proliferative angiopathy
3. Cerebrofacial arteriovenous metameric syndrome
2. Vein of Galen malformation

(b) capillary = capillary telangiectasia

1. Capillary telangiectasia
2. Facial port-wine stain

(c) venous = venous malformation
1. Developmental venous anomaly
2. Sinus pericranii

(d) lymphatic
1. Cystic hygroma

(e) combinations
1. Sturge-Weber disease
2. Rendu-Osler-Weber disease

B. VASCULAR TUMOR
1. Hemangioma
(a) capillary hemangioma: seen in children, involution by 7 years of age in 95%
(b) cavernous hemangioma: seen in adults, no involution
2. Hemangiopericytoma
3. Hemangioendothelioma
4. Angiosarcoma

Blunt Cerebrovascular Injury

= carotid (CA) + vertebral artery (VA) injuries during generalized multitrauma / direct craniocervical trauma

Prevalence: 1.1–1.6% of all blunt trauma

Mechanism: partial / complete failure of arterial mural integrity ← longitudinal stretching of artery, direct blow to artery, piercing by bone fragment

Prognosis: 25–38% mortality if injury untreated

Cx: (1) Infarction ← intimal disruption / flap / hematoma
→ thromboembolism of platelet aggregates
→ critical luminal stenosis + occlusion
(2) Brain ischemia ← steal phenomenon by AV fistula
(3) Fatal exsanguination

Type of Arterial Injury

1. Minimal intimal injury
√ nonstenotic luminal irregularity
DDx: arterial spasm
2. Raised intimal flap
√ linear intraluminal filling defect emanating from arterial wall
3. Dissection with intramural hematoma
√ eccentric / circumferential mural thickening:
√ narrowed arterial lumen
√ increased arterial diameter
4. Arterial occlusion
√ lack of intraluminal enhancement
5. Pseudoaneurysm
√ eccentric outpouching from native arterial lumen:

√ minimal contour abnormality
√ large irregular saccular outpouching
√ focal ballooning of arterial lumen

6. Transection with active hemorrhage
   √ irregular collection of extravascular contrast material surrounding parent vessel
7. Arteriovenous fistula
   √ early venous enhancement during the arterial phase
   √ enlargement of draining vein

DDx: (1) Atherosclerosis (presence of calcification, characteristic location, increasing age)
Location: vessel origin, carotid bulb, cavernous carotid segment
(2) Coiled / looped cervical ICA segment (5–15%)
(3) Congenitally absent / small ICA (small / absent carotid canal)

Shunt Lesions of Cerebral Vasculature

1. AV malformation
2. AV fistula: pia, dura, carotid-cavernous sinus
3. Vein of Galen malformation

Congenital Venous Lesions

1. Developmental venous anomaly
2. Cerebral cavernous malformation
3. Sinus pericranii

Occlusive Vascular Disease

(a) Embolic state:
√ single vascular territory
(b) Hypoperfusive state:
√ multiple vascular territories

Cause:

1. Vasospasm from subarachnoid hemorrhage
2. **Embolic infarction** (50%)
   (a) thrombus (atrial fibrillation, valvular disease, atheromatous plaques of extracerebral arteries, fibromuscular dysplasia, intracranial aneurysm, surgery, paradoxic emboli, sickle cell disease, atherosclerosis, thrombotic thrombocytopenic purpura)
   • fluctuating blood pressures; hypercoagulability
   √ cerebral petechial hemorrhage within cortical / basal gray matter during 2nd week (from fragments of embolus) in up to 40%; initial ischemia is followed by reperfusion (= HALLMARK of embolic infarction)
   √ "supernormal artery" on NECT = high-density material lodged in cerebral vessel near major bifurcations
   √ atheromatous narrowing of vessels
   (b) fat
   (c) nitrogen

3. Watershed / border zone infarct (10%)
4. Hypertension
   (a) Hypertensive encephalopathy
   √ diffuse white matter hypodensity (edema ← arterial spasm)
   (b) Hypertensive hemorrhage
   Location: basal ganglia (putamen, external capsule), thalamus, pons, cerebellum
   (c) Lacunar infarction
   (d) Subcortical arteriosclerotic encephalopathy
5. Amyloidosis involvement of small- + medium-sized arteries of meninges + cortex
   • normotensive patient > 65 years of age
   √ multiple simultaneous / recurrent cortical hemorrhages
6. Vasculitis
   (a) Bacterial meningitis, TB, syphilis, fungus, virus, rickettsia
   (b) Collagen-vascular disease: Wegener granulomatosis, polyarteritis nodosa, SLE, scleroderma, dermatomyositis
   (c) Granulomatous angiitis: giant cell arteritis, sarcoidosis, Takayasu disease, temporal arteritis
   (d) Inflammatory arteritis: rheumatoid arteritis, hypersensitivity arteritis, Behçet disease, lymphomatoid granulomatosis
   (e) Drug-induced: IV amphetamine, ergot preparations, oral contraceptives
   (f) Radiation arteritis = mineralizing microangiopathy
   (g) Moyamoya disease
7. Anoxic encephalopathy cardiorespiratory arrest, near-drowning, drug overdose, CO poisoning
8. Venous thrombosis

Multiple Infarctions

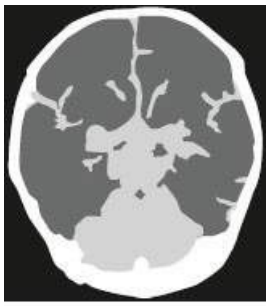
◊ Typical in extracranial occlusive disease, cardiac output problems, small vessel disease; in 6% from a shower of emboli

Location: usually bilateral + supratentorial (¾); supra- and infratentorial (¼)

Reversal Sign

= inversion of the normal attenuation relationship between gray and white matter (gray matter of lower attenuation than adjacent white matter of thalami, brainstem, cerebellum) on NECT of brain

Pathogenesis: not fully understood



Reversal Sign

Cause: global cerebral injury with anoxic insult ← head trauma, nonaccidental trauma, hypoxia, drowning, status epilepticus, hypothermia, bacterial meningitis, strangulation

Prognosis: poor ← irreversible brain damage; survivors with profound neurologic deficits + severe developmental delay

Diffusion Weighted Imaging (DWI)

Hyperintense Lesion on DWI

1. Cerebral infarction
2. Epidermoid inclusion cyst
3. Abscess with pus
4. Encephalitis of cortex
5. Creutzfeldt-Jakob disease
6. Trauma: axonal shearing injury
7. Neoplasm: medulloblastoma

INNUMERABLE PUNCTATE HYPERINTENSE LESIONS ON DWI

= Starfield pattern

1. Diffuse axonal injury (trauma)
2. Emboli: cardiogenic, septic, fat
3. Vasculitis
4. Minute hemorrhagic metastases

Hypointense Lesion on DWI

1. CSF
2. Tumor cyst: pilocytic, hemangioblastoma
3. Tumor nodules: hemangioblastoma

False Penumbra on Perfusion CT

True penumbra: successfully treatable with thrombolysis

√ mean transit time (MTT) ↑
√ cerebral blood flow (CBF) ↓
√ cerebral blood volume (CBV) ↔

False penumbra: area of abnormal perfusion as in ischemic penumbra NOT treatable with thrombolysis

A. Atherosclerosis at carotid bifurcation
   = upstream flow limitation WITHOUT significant intracranial collateral blood supply
   √ carotid bulb disease by CT angiography
B. Evolving ischemic condition / chronic infarct
   = delayed reperfusion + vascular collateralization of incomplete acute / chronic infarct
   √ hypoattenuation in the same region
   √ restricted diffusion on DWI + ADC map
C. Vascular dysregulation
   = hyperemia on symptomatic side with apparent perfusion abnormality on contralateral normal side
   • clinical history!
   Cause:
      1. Hypertensive encephalopathy (PRES)
         √ perfusion abnormality ← vasospasm
         √ hyperintensity on STIR sequence
         √ no restricted diffusion
      2. Seizure, subarachnoid hemorrhage, hemiplegic migraine
         • seizure activity
         √ no restricted diffusion
D. Head tilt / angulation
E. Variations in cerebrovascular anatomy
   = physiologic perfusion delay in circle of Willis variants, unequal blood supply between anterior + posterior circulation, congenitally absent ICA, etc.

CNS Vasculitis

A. LARGE-VESSEL VASCULITIS
   1. Takayasu arteritis
   2. Giant cell arteritis = Temporal arteritis
B. MEDIUM-SIZED–VESSEL VASCULITIS
   1. Polyarteritis nodosa
      √ aneurysm / stenosis / occlusion of intracranial carotid arteries
   2. Kawasaki disease
      √ nonspecific subdural effusion, cerebral infarction
      √ reversible hyperintense lesion in splenium
C. SMALL-VESSEL VASCULITIS
   1. IgA vasculitis = Henoch-Schönlein purpura
      √ hypertensive encephalopathy
      √ focal ischemic / hemorrhagic lesions
   2. Microscopic polyangiitis
      √ cerebral hemorrhage + infarction, pachymeningitis
      √ variable degree of small-vessel disease
   3. Granulomatosis with polyangiitis = Wegener granulomatosis
      √ leptomeningeal enhancement
   4. Eosinophilic granulomatosis with polyangiitis = Churg-Strauss syndrome
      √ macro- / microinfarctions + macro- / microhemorrhages

√ optic neuropathy

D. VARIABLE-SIZED VESSEL VASCULITIS
1. Behçet disease
2. Cogan syndrome
   √ nonspecific ischemic changes
   √ obliteration / narrowing of vestibular labyrinth

E. SINGLE-ORGAN VASCULITIS
1. Primary angiitis of CNS (PACNS)
   √ discrete / diffuse supra- and infratentorial lesions
   √ ± areas of infarction and hemorrhage

F. VASCULITIS OF SYSTEMIC DISEASE
1. Systemic lupus erythematosus (SLE)
   √ subcortical + periventricular white matter hyperintensity (60%)
   √ cerebral atrophy (30%), intracranial hemorrhage (3%)
2. Sjögren syndrome
   √ extensive white + gray matter lesions + microbleeds
3. Rheumatoid arthritis
   √ pachymeningitis with leptomeningeal enhancement
   √ cerebral vasculitis (rare)
4. APLA (antiphospholipid antibody) syndrome
   √ arterial / venous thrombosis, thrombocytopenia
5. Scleroderma
   √ nonspecific infarction, macro- and microhemorrhages

G. VASCULITIS WITH PROBABLE ETIOLOGY
1. Infection-induced vasculitis
2. Acute septic meningitis
   √ cerebral infarcts (5–15% in adults, 30% in neonates)
3. Mycobacterium tuberculosis
   √ vasculitis of smaller cerebral arteries → small infarcts in basal ganglia
4. Neurosyphilis
   √ predominantly MCA stroke in young adult
5. Viral (in childhood):
   › HIV-related vasculitis
     √ aneurysm, vessel occlusion, embolic disease, venous thrombosis
   › Varicella-zoster vasculopathy
     √ uni- / bilateral basal ganglia infarcts
6. Fungal: mucormycosis aspergillosis
7. Parasitic: cysticercosis
8. Malignancy-induced vasculitis
9. Drug-induced vasculitis
   › cocaine
     √ vasculitis, vasospasm, infarction, moyamoya-like
   › heroin
     √ spongiform leukoencephalopathy
10. Radiation-induced vasculitis

√ wall thickening + prominent wall enhancement in affected large arteries

11. **Reversible cerebral vasoconstriction syndrome**: Call-Fleming syndrome, postpartum angiopathy, migrainous vasospasm, benign angiopathy of CNS, vasoactive substances (cannabis, selective serotonin recapture inhibitors, nasal decongestants)

Imaging signs of cerebral vasculitis:

(a) direct
- √ vessel wall thickening
- √ vessel wall enhancement with contrast material

(b) indirect
- √ cerebral perfusion deficit
- √ ischemic brain lesion
- √ intracerebral / subarachnoid hemorrhage
- √ vascular stenosis

BRAIN ATROPHY

Cerebral Atrophy

= irreversible loss of brain substance + subsequent enlargement of intra- and extracerebral CSF-containing spaces (hydrocephalus ex vacuo = ventriculomegaly)

A. DIFFUSE BRAIN ATROPHY

Cause:

(a) Trauma, radiation therapy
(b) Drugs: dilantin, steroids, methotrexate, marijuana, hard drugs, chemotherapy, alcohol, hypoxia
(c) Demyelinating disease: multiple sclerosis, encephalitis
(d) Degenerative disease: eg, Alzheimer disease, Pick disease, Jakob-Creutzfeldt disease
(e) Cerebrovascular disease + multiple infarcts
(f) Advancing age, anorexia, renal failure

√ enlarged ventricles + sulci

B. FOCAL BRAIN ATROPHY

Cause: vascular / chemical / metabolic / traumatic / idiopathic (Dyke-Davidoff-Mason syndrome)

C. REVERSIBLE PROCESS SIMULATING ATROPHY (in younger people)

Cause: anorexia nervosa, alcoholism, catabolic steroid treatment, pediatric malignancy

√ prominent sulci
√ ipsilateral dilatation of basal cisterns + ventricles
√ ex vacuo dilatation of ventricles
√ thinning of gyri
√ focal areas of periventricular high signal intensity
√ increased iron deposition in putamen approaching the concentration in globus pallidus
√ dilatation of Virchow-Robin perivascular space

Cerebellar Atrophy

A. WITH CEREBRAL ATROPHY
   = generalized senile brain atrophy
B. WITHOUT CEREBRAL ATROPHY
   1. Olivopontocerebellar degeneration / Marie ataxia / Friedreich ataxia
      • onset of ataxia in young adulthood
   2. Ataxia-telangiectasia
   3. Ethanol toxicity: predominantly affecting midline (vermis)
   4. Phenytoin toxicity: predominantly affecting cerebellar hemispheres
   5. Idiopathic degeneration 2° to carcinoma (= paraneoplastic), usually oat cell carcinoma of lung
   6. Radiotherapy
   7. Focal cerebellar atrophy: (a) infarction
      (b) traumatic injury

Hippocampal Atrophy
1. Alzheimer Disease
2. Mesial temporal sclerosis
   • complex partial seizures
3. Normal in octogenarians

BRAIN HERNIATION

= shift of normal brain from high to low pressure through rigid structures of skull ← ⇑ intracranial pressure

Cause: mass effect by primary / metastatic tumor, trauma, infection (abscess) / inflammation, intracranial hemorrhage, subdural hematoma, ischemia / infarction, acute hydrocephalus, iatrogenic (after lumbar puncture / pneumocephalus following craniotomy)

Classification:

A. SUPRATENTORIAL HERNIATION
   1. Uncal (transtentorial)
   2. Central
   3. Cingulate (subfalcine)
   4. Transcalvarial
   5. Tectal (posterior)
B. INFRATENTORIAL HERNIATION
   1. Upward (upward cerebellar / upward transtentorial)
   2. Tonsillar (downward cerebellar)

Subfalcine / Cingulate Herniation (most common)

= contralateral shift of midline structures under falx cerebri
= herniation of cingulate gyrus across falx cerebri

Risk: compression of one of anterior cerebral arteries

May be associated with: transtentorial herniation

• weakness / paresis of contralateral leg ← compression of parafalcine cortex
• weakness ± sensory changes of contralateral leg ← infarction of paracentral lobule /

superior frontal gyrus ← compression of ACA / pericallosal artery
• somnolence ← raised intracranial pressure
√ <u>early signs:</u>
@ falx
√ shift of ipsilateral cingulate gyrus beneath falx
√ deviation of anterior falx with widened CSF space at contralateral side
N.B.: posterior falx remains relatively undisplaced due to greater height + rigidity
@ cingulate gyrus
√ compression of contralateral cingulate gyrus
@ corpus callosum
√ depression of ipsilateral corpus callosum
√ depression / elevation of contralateral corpus callosum
@ ventricle
√ compression / effacement of ipsilateral ventricle with amputation of ipsilateral frontal horn
√ <u>late signs:</u>
√ displacement of lateral ventricle to opposite side
√ obstruction of foramen of Monro → contralateral dilatation of the lateral ventricle + subependymal edema
√ infarction of cingulate gyrus
√ compression of anterior cerebral artery → infarction of ACA territory
Assessment: degree of greatest displacement of septum pellucidum / falx measured in mm relative to a straight line drawn through anterior and posterior falcine attachments on axial image
Prognosis: good with shift of < 5 mm; poor with shift > 15 mm
Cx: traumatic aneurysm of ACA / pericallosal artery

Transtentorial (Central) Herniation

= herniation of brain up / down across tentorium cerebelli
Tentorium cerebelli = inelastic reflection of dura
Connected to: occipital bone posteriorly, petrous temporal bone laterally, clinoid processes anteriorly
Content: transverse sinus, straight sinus
Tentorial hiatus / incisura
Content: cerebral peduncles + brainstem

Alert: NO lumbar puncture with effacement of basal cisterns + displacement of 4th ventricle!

Descending Transtentorial Herniation

= downward herniation of brain toward posterior fossa
• oculomotor nerve (cranial n. III) palsy:
• ipsilateral dilated pupil (= mydriasis) due to uncal herniation → compression of parasympathetic fibers traveling on outside of CN III → <u>unopposed sympathetic activity</u> to iris sphincter m.
• abnormal extraocular muscle function (except for superior oblique m., lateral rectus

m., levator palpebrae superioris m.)

- ipsilateral hemiparesis (on side of expanding lesion) (*false localizing sign* = **Kernohan notch** syndrome) due to severe lateral translation of midbrain against opposite tentorial edge → compression of opposite corticospinal tracts <u>above</u> decussation
- permanent anterograde amnesia ← infarction of uncal / parahippocampal gyrus ← arterial compression
- permanent visual field defect ← temporal / occipital lobe infarction ← compression of calcarine branch of PCA against tentorium

Location and degree of herniation:

(a) anterior / uncal herniation (see below)
(b) posterior: herniation of parahippocampal gyrus
(c) total: herniation of entire hippocampus

√ compression of ipsilateral cerebral peduncle
√ compression of contralateral cerebral peduncle → notching of midbrain (= Kernohan notch)
√ compression of aqueduct of Sylvius → early dilatation of temporal horn → obstructive hydrocephalus
√ widening of contralateral temporal horn
√ widening (obliteration) of ipsilateral (contralateral) basilar (ambient + quadrigeminal) cisterns

Cx:

(1) Occipital infarction ← compression of ipsilateral posterior cerebral artery against cerebral peduncle by uncus + parahippocampal gyrus
√ effacement / displacement of ipsilateral PCA
(2) **Duret hemorrhage** = hemorrhage in median / paramedian mesencephalon / tectum ← stretching of pontine perforators ← downward displacement of pons
(3) Respiratory arrest

UNCAL / ANTERIOR TRANSTENTORIAL HERNIATION

= herniation of uncus (most medial part of temporal lobe) across tentorium cerebelli into suprasellar cistern
◊ Most common subtype of transtentorial herniation caused by lesions in anterior half of brain
√ uncus displaced into suprasellar cistern → pressure on midbrain + brainstem
√ truncation of six-pointed star appearance of suprasellar cistern

Risk: (1) compression of midbrain (brainstem)
(3) Kernohan notch syndrome

Ascending Transtentorial / Cerebellar Herniation

= displacement of cerebellum through tentorial incisura superiorly = upward (superior vermian) displacement

Cause: slowly growing cerebellar / brainstem process, infarction

- nausea & vomiting → obtundation → coma

√ compression + anterior displacement of 4th ventricle
√ occlusion of aqueduct → obstructive hydrocephalus

√ narrowing / effacement of ambient + quadrigeminal cistern
√ compression of pons against clivus
√ upward displacement of cerebellar vermis
√ superior displacement of tectum
√ "spinning top" appearance of midbrain due to bilateral compression on posterolateral aspect of midbrain
√ downward displacement of cerebellar tonsils
Cx: (1) basilar artery compression ← displacement of midbrain / pons against clivus
(2) compression of vein of Galen / basal vein of Rosenthal → parenchymal congestion
(3) compression of posterior cerebral + superior cerebellar arteries ← superior displacement of cerebellum

Alar / Transalar / Retroalar / Sphenoid Herniation

= herniation of frontal lobe posteriorly across edge of sphenoid ridge
Associated with: transtentorial + subfalcine herniation
• paucity of clinical symptomatology, clinically occult
› posterior / descending: frontal lobe mass
√ frontal lobe displaced posteriorly
√ posterior displacement of sylvian fissure, temporal lobe + horizontal segment of MCA
› anterior / ascending: temporal lobe / insula lesion
√ temporal lobe displaced anteriorly

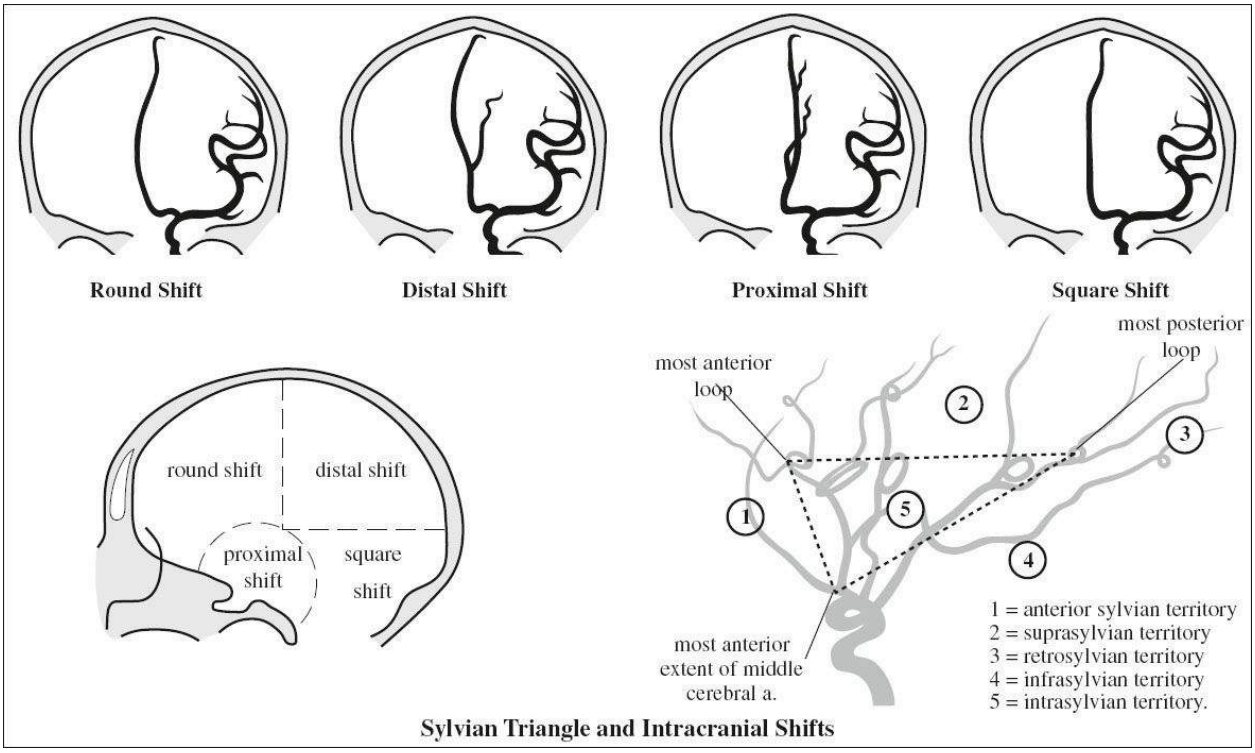
Transforaminal / Tonsillar Herniation

= herniation of inferior mesial portions of cerebellum (= inferior tonsils) downward through foramen magnum
Commonly associated with: ascending (⅔) or descending (⅓) transtentorial herniation
• neck pain, nystagmus, vomiting (in conscious patient)
• Cushing response (= irregular respiration, bradycardia, hypertension) as warning sign in unconscious patient
• decerebrate posturing
Risk: compression of medulla → respiratory arrest → cardiovascular collapse → coma → death
√ cerebellar tonsils at level of dens on axial images
√ cerebellar tonsils ≥ 5 mm below foramen magnum (= line connecting basion with opisthion) in adults; ≥ 7 mm in children on sagittal / coronal images
√ effacement of 4th ventricle / aqueduct → hydrocephalus of 3rd + lateral ventricles with transependymal CSF flow
√ ± concurrent upward displacement of vermis
Cx: compression of vulnerable PICA → cerebellar infarction

Alert: Known complication of lumbar puncture performed in context of elevated intracranial pressure!

Transcalvarial / External Herniation

= brain protrusion through fracture / surgical site of skull



Sylvian Triangle and Intracranial Shifts

Displacement of Vessels

A. ARTERIAL SHIFT

(a) Pericallosal arteries

1. Round shift = frontal lesion anterior to coronal suture
2. Square shift = lesion behind foramen of Monro in lower half of hemisphere
3. Distal shift = posterior to coronal suture in upper half of hemisphere
4. Proximal shift = basifrontal lesion / anterior middle cranial fossa including anterior temporal lobe

(b) Sylvian triangle

= branches of MCA within sylvian fissure on outer surface of insula form a loop upon reaching the upper margin of the insula; serves as angiographic landmark for localizing supratentorial masses

Location of lesion:

- anterior sylvian — frontal region
- suprasylvian — posterior frontal + parietal
- retrosylvian — occipital, parietooccipital
- infrasylvian — temporal lobe + extracerebral region
- intrasylvian — usually due to meningioma
- lateral sylvian — frontal, frontotemporal, parietotemporal
- central sylvian — deep posterior frontal, basal ganglia

B. CEREBRAL VEINS

= indicate the midline of the posterior part of the forebrain showing the exact location of the roof of the 3rd ventricle

BRAIN MASSES

Classification of Primary CNS Tumors

Incidence: 9% of all primary neoplasms (5th most common primary neoplasm); 5–10÷100,000 population per year; account for 1.2% of autopsied deaths

A. TUMORS OF BRAIN AND MENINGES
   (a) Gliomas
      ASTROCYTOMA (50%)
         1. Astrocytoma (astrocytoma grades I–II)
         2. Glioblastoma (astrocytoma grades III–IV)
      OLIGODENDROGLIOMA
      PARAGLIOMA
         1. Ependymoma
         2. Choroid plexus papilloma
      GANGLIOGLIOMA
      MEDULLOBLASTOMA
   (b) Pineal tumor
      1. Germinoma
      2. Teratoma
      3. Pineocytoma
      4. Pineoblastoma
   (c) Pituitary tumor
      1. Pituitary adenoma
      2. Pituitary carcinoma
   (d) Meningioma
   (e) Nerve sheath tumor
      1. Schwannoma
      2. Neurofibroma
   (f) Miscellaneous
      1. Sarcoma
      2. Lipoma
      3. Hemangioblastoma
B. TUMORS OF EMBRYONAL REMNANTS
   (a) Craniopharyngioma
   (b) Colloid cyst
   (c) Teratoid tumor
      1. Epidermoid (0.2–1.8%)
      2. Dermoid
      3. Teratoma

CNS Tumors Presenting at Birth

1. Hypothalamic astrocytoma
2. Choroid plexus papilloma / carcinoma
3. Teratoma

4. Primitive neuroectodermal tumor
5. Medulloblastoma
6. Ependymoma
7. Craniopharyngioma

CNS Tumors in Pediatric Age Group

Prevalence:

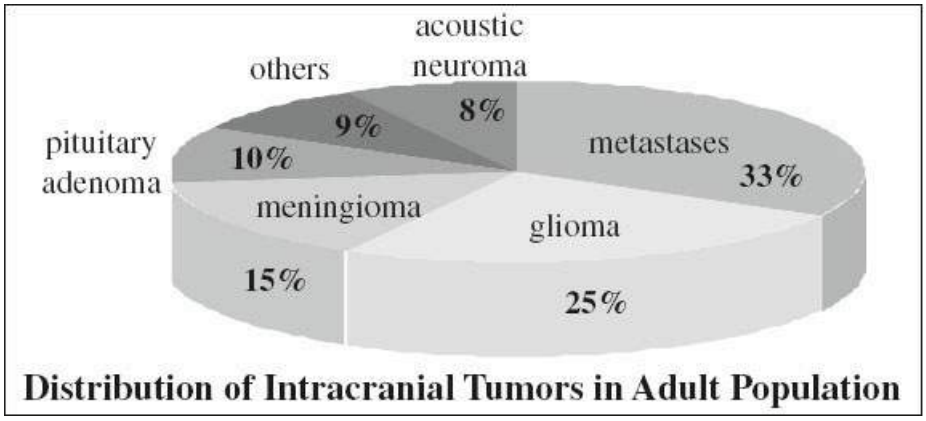
2.4÷100,000 (< 15 years of age); 2nd most common pediatric tumor (after leukemia); 15% of all pediatric neoplasms; 15–20% of all primary brain tumors; M > F

- increased intracranial pressure
- increasing head size

A. SUPRATENTORIAL (50%)

Age: first 2–3 years of life

Covering of brain	:	dural sarcoma, schwannoma, meningioma (3%)
Cerebral hemisphere	:	astrocytoma (37%), oligodendroglioma
Corpus callosum	:	astrocytoma
3rd ventricle	:	colloid cyst, ependymoma
Lateral ventricle	:	ependymoma (5%), choroid plexus papilloma (12%)
Optic chiasm	:	craniopharyngioma (12%), optic nerve glioma (13%), teratoma, pituitary adenoma
Hypothalamus	:	glioma (8%), hamartoma
Pineal region	:	germinoma, pinealoma, teratoma (8%)



Distribution of Intracranial Tumors in Adult Population

Incidence of Brain Tumors			
All Age Groups		*Pediatric Age Group*	
Glioma	34%	Astrocytoma	50%
Meningioma	17%	Medulloblastoma	15%
Metastasis	12%	Ependymoma	10%
Pituitary adenoma	6%	Craniopharyngioma	6%
Neurinoma	4%	Choroid plexus papilloma	2%
Sarcoma	3%		
Granuloma	3%		

Craniopharyngioma	2%	
Hemangioblastoma	2%	

Differences of Some Pediatric CNS Tumors			
	PNET	*Ependymoma*	*Astrocytoma*
CT	hyper	iso	hypo
T2WI	intermed.	intermed.	increased
Enhancement	moderate	minimal	nodule
Calcification	10–15%	40–50%	< 10%
Cyst formation	rare	common	typical
CSF seeding	15–40%	rare	rare
Foraminal spread	no	yes	no

B. INFRATENTORIAL (50%)

Age: 4–11 years

Cerebellum : astrocytoma (31–33%), PNET / medulloblastoma (26–31%)

Brainstem : glioma (16–21%)

4th ventricle : ependymoma (6–14%), choroid plexus papilloma

mnemonic: "BE MACHO"

Brainstem glioma
Ependymoma
Medulloblastoma
AVM
Cystic astrocytoma
Hemangioblastoma
Other

Supratentorial Tumor with Mural Nodule

1. Extraventricular ependymoma
2. Pleomorphic xanthoastrocytoma
3. Hemispheric pilocytic astrocytoma
4. Ganglioglioma
5. Dysembryoplastic neuroepithelial tumor (DNET)

Supratentorial Midline Tumors

1. Optic + hypothalamic glioma (39%)
2. Craniopharyngioma (20%)
3. Astrocytoma (9%)
4. Pineoblastoma (9%)
5. Germinoma (6%)
6. Lipoma (6%)
7. Teratoma (3.5%)
8. Pituitary adenoma (3.5%)
9. Meningioma (2%)

10. Choroid plexus papilloma (2%)

Classification by Histology

1. Astrocytic tumors (33.5%)
2. "Primitive" neuroectodermal tumor = PNET (21%)
   - › Medulloblastoma (16%)
   - › Ependymoblastoma (2.5%)
   - › PNET of cerebral hemisphere (2.5%)
3. Mixed gliomas (16%)
4. Malformative tumors (11.5%)
   - › Craniopharyngioma (5.5%)
   - › Lipoma (4.5%)
   - › Dermoid cyst (1%)
   - › Epidermal cyst (0.5%)
5. Choroid plexus tumors (4%)
6. Ependymal tumors (4%)
7. Tumors of meningeal tissues (3.5%)
   - › Meningioma (3%)
   - › Meningeal sarcoma (0.5%)
8. Germ cell tumors (2.5%)
   - › Germinoma (1.5%)
   - › Teratomatous tumor (1%)
9. Neuronal tumors
   - › Gangliocytoma (1.5%)
10. Tumors of neuroendocrine origin
    - › Pituitary adenoma (1%)
11. Oligodendroglial tumors (0.5%)
12. Tumors of blood vessel
    - › Hemangioma (1%)

Superficial Gliomas

= peripherally located cortical neoplasms serving as a seizure focus

1. Ganglioglioma
2. Desmoplastic infantile ganglioglioma
3. Gangliocytoma
4. Dysplastic cerebellar gangliocytoma
5. Pleomorphic xanthoastrocytoma
6. Dysembryoplastic neuroepithelial tumor

Multifocal CNS Tumors

A. METASTASES FROM PRIMARY CNS TUMOR
   (a) via commissural pathways: corpus callosum, internal capsule, massa intermedia
   (b) via CSF: ventricles / subarachnoid cisterns
   (c) satellite metastases
B. MULTICENTRIC CNS TUMOR

(a) true multicentric gliomas (4%)
(b) concurrent tumors of different histology (coincidental)

C. MULTICENTRIC MENINGIOMAS (3%) without neurofibromatosis
D. MULTICENTRIC PRIMARY CNS LYMPHOMA
E. PHAKOMATOSES
1. Generalized neurofibromatosis:
meningiomatosis, bilateral acoustic neuromas, bilateral optic nerve gliomas, cerebral gliomas, choroid plexus papillomas, multiple spine tumors, AVMs
2. Tuberous sclerosis:
subependymal tubers, intraventricular gliomas (giant cell astrocytoma), ependymomas
3. Von Hippel-Lindau disease:
retinal angiomatosis, hemangioblastomas, congenital cysts of pancreas + liver, benign renal tumors, cardiac rhabdomyomas

Multifocal Deep Hemispheric Masses

1. Primary CNS Lymphoma
2. Gliomatosis cerebri
√ nonenhancing tumor extension (common)

CNS Tumors Metastasizing Outside CNS

mnemonic: MEGO
Medulloblastoma
Ependymoma
Glioblastoma multiforme
Oligodendroglioma

Large Heterogeneous Intracerebral Mass

1. High-grade glioma
√ increased relative cerebral blood volume (rCBV) in zone of edema on perfusion-weighted images
2. Metastasis
√ reduced relative cerebral blood volume (rCBV) in zone of edema on perfusion-weighted images

Mass with Large Tumor Vessels and Edema

1. Glioblastoma multiforme
2. Meningioma

Avascular Mass of Brain

mnemonic: TEACH
Tumor: astrocytoma, metastasis, oligodendroglioma
Edema
Abscess
Cyst, **C**ontusion
Hematoma, **H**erpes

Calcified Intracranial Mass

1. Oligodendroglioma (frequent, although rare tumor)
2. Low-grade astrocytoma (in 10–20%)

mnemonic: Ca2+ COME

Craniopharyngioma
Astrocytoma, **A**neurysm
Choroid plexus papilloma
Oligodendroglioma
Meningioma
Ependymoma

HYPODENSE BRAIN LESIONS

Diffusely Swollen Hemispheres

A. METABOLIC
   1. Metabolic encephalopathy: eg, uremia, Reye syndrome, ketoacidosis
   2. Anoxia: cardiopulmonary arrest, near-drowning, smoke inhalation, ARDS

B. NEUROVASCULAR
   1. Hypertensive encephalopathy
   2. Superior sagittal sinus thrombosis
   3. Head trauma
   4. Pseudotumor cerebri

C. INFLAMMATION / INFECTION
   eg, herpes encephalitis, CMV, toxoplasmosis

Brain Edema

= increase in brain volume ← increased tissue-water content (80% for gray matter + 68% for white matter is normal)

Etiology:

(a) **Cytotoxic edema**
reversible increase in <u>intracellular</u> water content 2° to ischemia / anoxia (axonal pallor) → depletion of ATP → ion pump dysfunction across glial cell membrane → increase in intracellular Na+ and K+
- characteristically seen in cerebral infarction
- 30–60 min after onset of symptoms

√ decreased ADC value (dark)

(b) **Vasogenic edema** (most common form)
fluid leakage of water out of capillaries into extracellular interstitial space ← damage of capillary endothelium; increase in pinocytotic activity with passage of protein across vessel wall into intercellular space
- associated with primary brain neoplasm, metastases, hemorrhage, inflammation, infarction
- takes > 3–6 hours; requires residual / reestablished blood flow

√ lack of contrast enhancement means breakdown of blood-brain barrier is NOT the cause

√ increased ADC value (bright)
DDx: blood-brain barrier break-down after 8–10 days

Types:

1. Hydrostatic edema
   rapid increase / decrease in intracranial pressure
2. Interstitial edema
   increase in periventricular interstitial spaces ← transependymal flow of CSF with elevated intraventricular pressure
3. Hypo-osmotic edema
   produced by overhydration from IV fluid / inappropriate secretion of antidiuretic hormone
4. Congestive brain swelling
   rapid accumulation of extravascular water as a result of head trauma; may become irreversible (brain death) if intracranial pressure equals systolic blood pressure

√ decreased distinction between gray + white matter
√ compressed slitlike lateral ventricles
√ compression of cerebral sulci + perimesencephalic cisterns

CT:
√ areas of hypodensity
◊ Edema is always greatest in white matter!
√ mass effect: flattening of gyri, displacement + deformation of ventricles, midline shift
√ return to normal: from nonhemorrhagic edema / brain atrophy, from white matter shearing injury

MR:
√ decreased intensity on T1WI
√ increased intensity on T2WI
√ enhancement with gadolinium

US:
√ generalized / focal increase of parenchymal echogenicity with featureless appearance
√ decreased resistive indices

Midline Cyst

1. Cavum septi pellucidi
2. Cavum vergae
3. Cavum veli interpositi
4. Colloid cyst anterior + superior to cavum septi pellucidi
5. Arachnoid cyst in region of quadrigeminal plate cistern
   √ curvilinear margins

Intracranial Nonneoplastic Cyst

Characteristics:
√ no detectable wall / associated soft-tissue mass
√ homogeneous signal intensity identical to CSF
√ absence of surrounding edema / gliosis
√ NO contrast enhancement

1. Choroid plexus cyst (most common, abnormal DWI in ⅔)
2. Ependymal cyst
3. Neuroglial cyst
4. Enlarged perivascular spaces (typically multiple, clustered around basal ganglia)
5. Arachnoid cyst (typically extraaxial)
6. Porencephalic cyst (communication with lateral ventricle, surrounding gliosis)
7. Infectious cyst of neurocysticercosis (< 1 cm, partially enhancing)
8. Epidermoid cyst

Cyst with Mural Nodule

1. Ependymoma
2. Pilocytic astrocytoma (childhood)
3. Pleomorphic xanthoastrocytoma
4. Ganglioglioma
5. Glioblastoma multiforme
6. Hemangioblastoma (posterior fossa, spinal cord)

Multiple Tiny CNS Cysts

A. DIFFUSE DEGENERATIVE DISEASE
B. DIFFUSE INFLAMMATORY PROCESS
C. LOW-GRADE CYSTIC NEOPLASM
   1. Ganglioglioma
   2. Pyelocytic astrocytoma
   3. Pleomorphic xanthoastrocytoma

Anterior Temporal Cysts with Leukoencephalopathy

1. Congenital CMV infection
2. Leukoencephalopathy with subcortical temporal cysts and megalencephaly
3. Vanishing white matter disease

Cystic Lesions on Head Ultrasound

A. NORMAL VARIANTS
   1. Cavum septi pellucidi
   2. Cavum vergae
   3. Cavum veli interpositi
B. CYSTIC LESIONS OF POSTERIOR FOSSA
   Evaluate
   - size of 4th ventricle + communication with 4th ventricle
   - size of vermis + cerebellar hemispheres
   - mass effect on cerebellum

   1. Megacisterna magna
   2. Dandy-Walker continuum disorder
   3. Blake pouch cyst
   4. Arachnoid cyst
   5. Vein of Galen malformation

B. SUPRATENTORIAL PERIVENTRICULAR CYSTS
   1. **Connatal cyst**
      = coarctation of lateral ventricles + frontal horn cysts
      Location: at / just below superolateral angles of frontal horns / body of lateral ventricles anterior to foramen of Monro
      Cause: normal variant ← approximation of walls of frontal horns; NOT sequelae of ischemia
   2. Subependymal cyst
   3. Choroid plexus cyst
   4. Periventricular leukomalacia
   4. Pseudoporencephaly
C. SUPRATENTORIAL INTRA- / EXTRAAXIAL CYSTS
   1. Schizencephaly
   2. Ventriculomegaly: hydrocephalus, brain atrophy
   3. Holoprosencephaly
   4. Supratentorial arachnoid cyst
   5. Spontaneous intracranial hematoma
   6. Brain abscess (uncommon)

Cholesterol-containing CNS Lesions

1. Epidermoid inclusion cyst
2. Cholesterol granuloma
3. Acquired epidermoid of middle ear
4. Congenital cholesteatoma of middle ear
5. Craniopharyngioma

Mesencephalic Low-density Lesion

1. Normal: decussation of superior cerebellar peduncles at level of inferior colliculi
2. Syringobulbia found in conjunction with syringomyelia, Arnold-Chiari malformation, trauma
   √ CSF density centrally
   √ intrathecal contrast enters central cavity
3. Brainstem infarction
   √ abnormal contrast enhancement after 1 week
   √ well-defined low-attenuation region without enhancement after 2–4 weeks
4. Central pontine myelinolysis
5. Brainstem glioma
6. Metastasis
   √ well-defined contrast enhancement
7. Granuloma in TB / sarcoidosis (rare)

Intracranial Pneumocephalus

A. TRAUMA (74%):
   (a) blunt trauma
   in 3% of all skull fractures; in 8% of fractures involving paranasal sinuses (frontal >

ethmoid > sphenoid > mastoid) or base of skull
(b) penetrating injury

B. NEOPLASM INVADING SINUS (13%):
1. Osteoma of frontal / ethmoid sinus
2. Pituitary adenoma
3. Mucocele, epidermoid
4. Malignancy of paranasal sinuses

C. INFECTION WITH GAS-FORMING ORGANISM (9%) in mastoiditis, sinusitis

D. SURGERY (4%)
hypophysectomy, paranasal sinus surgery

E. SUPRATENTORIAL CRANIOTOMY
Location: in any compartment; most often in subdural space over frontal lobe
Duration after surgery: 2 days (100%), 7 days (75%), 2nd week (60%), 3rd week (26%), > 3 weeks (0%)

Mechanism of dural laceration:
(1) ball-valve mechanism during straining, coughing, sneezing
(2) vacuum phenomenon ← loss of CSF

Time of onset: on initial presentation (25%), usually seen within 4–5 days, delay up to 6 months (33%)

Mortality: 15%

Cx: (1) CSF rhinorrhea (50%)
(2) Meningitis / epidural / brain abscess (25%)
(3) Extracranial pneumocephalus = air collection in subaponeurotic space

HYPERDENSE INTRACRANIAL LESIONS

Intracranial Calcifications

mnemonic: PINEEAL
Physiologic
Infection
Neoplasm
Endocrine
Embryologic
Arteriovenous
Leftover Ls

A. PHYSIOLOGIC INTRACRANIAL CALCIFICATIONS

B. INFECTION
TORCH (toxoplasmosis, others [syphilis, hepatitis, zoster], CMV, rubella, herpes), healed abscess, hydatid cyst, granuloma (tuberculoma, actinomycosis, coccidioidomycosis, cryptococcosis, mucormycosis), cysticercosis, trichinosis, paragonimiasis
mnemonic:
CM**V** calcifications are circumventricular
Toxo**p**lasma calcifications are in**t**ra**p**arenchymal

C. NEOPLASM
Craniopharyngioma (40–80%), oligodendroglioma (50–70%), chordoma (25–40%),

choroid plexus papilloma (10%), meningioma (20%), pituitary adenoma (3–5%), pinealoma (10–20%), dermoid (20%), lipoma of corpus callosum, ependymoma (50%), astrocytoma (15%), after radiotherapy, metastases (1–2%, lung > breast > GI tract)
N.B.: Astrocytomas calcify less frequently but are the most common tumor!

D. ENDOCRINE Hyperparathyroidism, hypervitaminosis D, hypoparathyroidism, pseudohypoparathyroidism, CO poisoning, lead poisoning
E. EMBRYOLOGIC Neurocutaneous syndromes (tuberous sclerosis, Sturge-Weber, neurofibromatosis), Fahr disease, Cockayne syndrome, basal cell nevus syndrome
F. ARTERIOVENOUS Atherosclerosis, aneurysm, AVM, occult vascular malformation, hemangioma, subdural + epidural hematomas, intracerebral hemorrhage
G. LEFTOVER Ls
Lipoma, lipoid proteinosis, lissencephaly

Physiologic Intracranial Calcification

1. **Pineal calcification**
   Age: no calcification < 5 years of age, in 8–10% at 8–14 years of age, in 40% by 20 years of age; in ⅔ of adult population
   √ amorphous / ringlike calcification < 3 mm from midline usually < 10 mm in diameter
   √ ~ 30 mm above highest posterior elevation of pyramids

CAVE: pineal calcification > 14 mm suggests pineal neoplasm (teratoma / pinealoma)

2. **Habenula**
   Frequency: ~ in ⅓ of population
   Age: > 10 years of age
   √ posteriorly open C-shaped calcification 4–6 mm anterior to pineal gland
3. **Choroid plexus** may calcify in all ventricles: most commonly in glomus within atrium of lateral ventricles, near foramen of Monro, tela choroidea of 3rd ventricle, roof of 4th ventricle, along foramina of Luschka
   Age: > 3 years of age
   √ 20–30 mm behind + slightly below pineal on lateral projection, symmetrical on AP projection
   DDx: neurofibromatosis
4. **Dura, falx cerebri, falx cerebelli, tentorium**
   Frequency: 10% of population
   Age: > 3 years of age
   DDx: basal cell nevus syndrome (Gorlin syndrome), pseudoxanthoma elasticum, congenital myotonic dystrophy
5. **Petroclinoid ligament** (= reflection of tentorium between tip of dorsum sellae and apex of petrous bone)
   Age: > 5 years of age
6. **Interclinoid ligament** = interclinoid bridging
7. **Arteriosclerosis**: particularly intracavernous segment of ICA, basilar a., vertebral a.
8. **Basal ganglia**

Increased Density of Falx

1. Subarachnoid hemorrhage
2. Interhemispheric subdural hematoma
3. Diffuse cerebral edema (= increased density relative to low-density brain)
4. Dural calcifications (hypercalcemia from chronic renal failure, basal cell nevus syndrome, hyperparathyroidism)
5. Normal falx (can be normal in pediatric population)

Intraparenchymal Hemorrhage

mnemonic: "ITHACANS"

Infarction (hemorrhagic)
Trauma
Hypertensive hemorrhage
Arteriovenous malformation
Coagulopathy
Aneurysm, **A**myloid angiopathy
Neoplasm: metastasis / primary neoplasm
Sinus thrombosis

Dense Cerebral Mass

Substrate: calcification / hemorrhage / dense protein

A. VESSEL
   1. Aneurysm
   2. Arteriovenous malformation
   3. Hematoma (acute / subacute)

B. TUMOR
   1. Lymphoma
   2. Medulloblastoma
   3. Meningioma
   4. Metastasis
      (a) from mucinous-producing adenocarcinoma
      (b) hemorrhagic metastases: melanoma, choriocarcinoma, hypernephroma, bronchogenic carcinoma, breast carcinoma (rarely)

T1-HYPERINTENSE INTRACRANIAL LESIONS

A few naturally occurring substances reduce T1 relaxation times depending on the degree of substance concentration: methemoglobin, melanin, lipid, protein, and minerals.

A. METHEMOGLOBIN

Source: intracellular (early subacute phase = 3–7 days) + extracellular (late subacute phase = 8–31 days) methemoglobin

1. Hemorrhagic infarct
2. Intraparenchymal hematoma (eg, amyloid angiopathy)
3. Diffuse axonal injury
4. Subarachnoid hemorrhage
5. Epidural hematoma

6. Intraventricular hemorrhage
7. Thrombus: arterial / venous
8. Vascular malformation (eg, cavernous malformation)
9. Hemorrhagic neoplasm

B. MELANIN

Source: paramagnetic effect of stable free radicals + metal scavenging effect of melanin binding to chelated metal (= metallomelanin)

1. Metastatic melanoma
2. Primary diffuse meningeal melanomatosis
3. Melanocytoma
4. Neurocutaneous melanosis

C. LIPID

Source: short T1 relaxation time of H+ nuclei within lipid molecules

1. Intracranial lipoma
2. Teratoma
3. Dermoid cyst
4. Lipomatous ependymoma
5. Chemical meningitis from ruptured dermoid

D. PROTEIN

Source: high SI of protein + hydration layer effect

1. Colloid cyst
2. Rathke cleft cyst
3. Ectopic posterior pituitary gland

E. MINERAL DEPOSITION

1. Calcium concentration < 30%
2. Manganese, copper, iron
3. Cockayne syndrome
4. Neurodegeneration with iron accumulation (eg, Hallervorden-Spatz disease)
5. Hepatic encephalopathy
6. Wilson disease

F. OTHER

1. Type I neurofibromatosis
2. Cholesterol granuloma
3. Craniopharyngioma
4. Cortical laminar necrosis

Increased T1 Signal Intensity of Sellar Region

A. NORMAL CONDITION

1. Vasopressin storage

   Source: vasopressin–neurophysin II–copeptin macroprotein complex

   Site: posterior aspect of sella turcica immediately anterior to dorsum sellae

2. Anterior pituitary lobe hyperactivity

   Source: ↑ in intracellular protein concentration

   Cause: hypersecretion during first few weeks of life in newborn, pregnancy, postpartum period, lactation

T1-Hyperintense Intracranial Lesions by Location	
Location	*Lesion*
Deep gray matter nuclei	Cockayne syndrome: lentiform, dentate nuclei
	Pantothenate-kinase-associated neurodegeneration: bilateral globus pallidus + substantia nigra
	Hypertensive hemorrhage: putamen, external capsule, thalamus
	Hepatic encephalopathy: bilateral globus pallidus + substantia nigra
	Hypoxic-ischemic injury: lateral thalamus, posterior putamen + hippocampus
	Fabry disease: pulvinar
	Fahr disease: basal ganglia, thalamus, dentate, centrum semiovale
	Hypoparathyroidism, pseudo~, pseudopseudo~: similar to Fahr disease
	Lead, cyanide, methanol: bilateral putamen
	NF2: bilateral globus pallidus + internal capsule
	Wilson disease: basal ganglia + thalami
	Nonketotic hyperglycemia: bilateral caudate nucleus + globus pallidus
	HIV infection: caudate nucleus + putamen
	Neurodegenerative Langerhans cell histiocytosis: putamen
Cerebral hemi-sphere	Amyloid angiopathy, hemorrhagic metastasis / tumor, lipomatous ependymoma, vascular malformation, hemorrhagic contusion, hemorrhagic infarct, cortical laminar necrosis
Midline	Dermoid cyst, teratoma, lipoma, osteolipoma, hypothalamic hamartoma, pituitary microhemorrhage + apoplexy, deep cerebral vein thrombosis
Sellar / suprasellar	all above + craniopharyngioma, Rathke cleft cyst, ectopic posterior pituitary, thrombosed COW aneurysm, Langerhans cell histiocytosis
Ventricles	Intraventricular hemorrhage, 3rd ventricular colloid cyst, ruptured dermoid cyst
Dura mater	Lipomatous meningioma, hemorrhagic metastasis, melanoma, venous sinus thrombosis

3. Bone
   Source: marrow fat in elderly
   Site: nonpneumatized posterior sphenoid body, dorsum sellae, posterior clinoid process
4. Magnetic susceptibility artifact
   Source: abrupt transition between air-filled bone + dense cortical bone

Site: just above sellar floor

5. Flow artifact

B. LESION IN / NEAR SELLA TURCICA

(a) blood clot / hemorrhage

1. Pituitary apoplexy
2. Aneurysm

(b) lesion with high protein content

1. Rathke cleft cyst
2. Craniopharyngioma
3. Mucocele
4. Cholesterol granuloma

(c) lesion with high fat content

1. Lipoma of floor of 3rd ventricle, infundibulum, adjacent cranial nn.
2. Dermoid cyst
3. Lipoblastic meningioma

(c) intratumoral calcifications depending on degree of mineralization

1. Chordoma
2. Cartilaginous tumor (chondroma, chondrosarcoma)

(c) others

1. Pituitary abscess (very rare)
2. Excess manganese
   - parenteral nutrition / chronic liver deficiency

√ bilateral hyperintense T1 signal in adenohypophysis + globus pallidus

3. Melanoma

C. POSTTHERAPEUTIC CONDITION

(a) postoperative

1. Blood products
2. Surgical packing: fat, gelatin sponge
3. Metallic artifact
4. Mucocele

(b) medical therapy

1. Hemorrhage: bromocriptine
2. Hyperactive residual adenophysis

ENHANCING BRAIN LESIONS

Pachymeningeal Enhancement

= DURA-ARACHNOID ENHANCEMENT

Site: periosteum of inner table + meningeal layer

Location: dural reflections of falx cerebri + tentorium cerebelli + cavernous sinus; subcortical

√ inconspicuous enhancement against inner table on CT

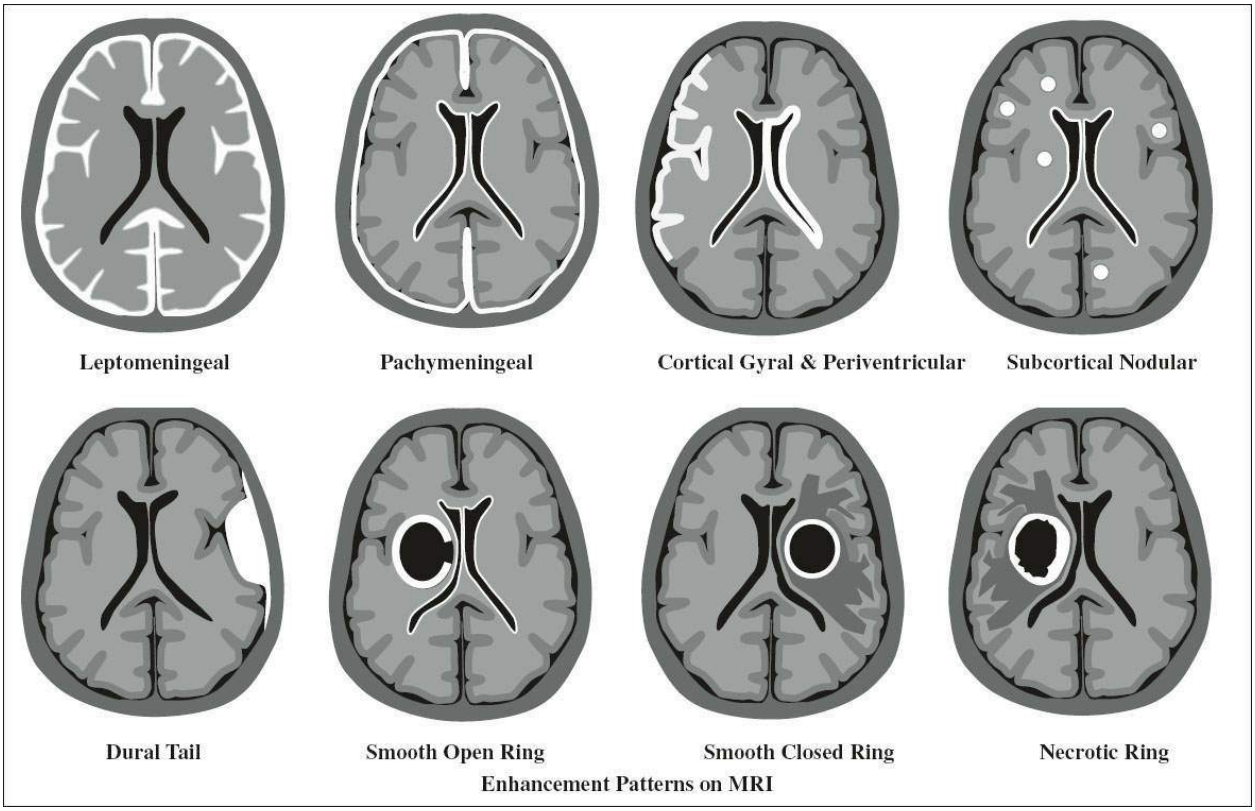
√ thin linear discontinuous enhancement on T1WI

Cause:

A. BENIGN

1. Transient postoperative enhancement
2. Intracranial hypotension
3. Granulomatous disease of basilar meninges (sarcoidosis, tuberculosis, Wegener granulomatosis, luetic gumma, rheumatoid nodules, fungal disease)
4. Uncomplicated lumbar puncture (in < 5%)

B. MALIGNANT
1. Meningioma
3. Secondary CNS lymphoma
2. Metastases: breast, prostate, melanoma, RCC



Enhancement Patterns on MRI

Leptomeningeal Enhancement

= PIA-ARACHNOID ENHANCEMENT

Site: pial surface of brain

Location: subarachnoid spaces of sulci + cisterns

√ gyriform / serpentine enhancement

Cause:

1. Infectious meningitis (bacterial, viral, fungal)
2. Carcinomatous meningitis
   (a) primary CNS tumor: medulloblastoma, ependymoma, glioblastoma, oligodendroglioma)
   (b) secondary tumor: lymphoma, breast cancer

Gyral Enhancement

√ serpentine enhancement

A. VASCULAR
- abrupt onset of symptoms

√ often in territory of single artery (MCA in 60%)

1. Reperfusion of ischemic brain
2. Vasodilative phase of migraine headaches
3. Posterior reversible encephalopathy syndrome
4. Vasodilation with seizures
5. Subarachnoid hemorrhage
   (enhancing fibroblastic proliferation)
6. Subacute / acute brain infarct: luxury perfusion
7. Dural sinus thrombosis: venous congestion

B. INFLAMMATORY
- nonspecific headache / lethargy

√ multiple territories

1. Herpes simplex encephalitis

C. NEOPLASTIC

(a) Meningeal carcinomatosis from systemic tumor, eg, breast carcinoma, small cell carcinoma of lung, malignant melanoma, lymphoma / leukemia

(b) Seeding primary CNS tumor:
1. Medulloblastoma
2. Pineoblastoma
3. Ependymoma

mnemonic: CAL MICE

Cerebritis
Arteriovenous malformation
Lymphoma
Meningitis
Infarct
Carcinomatosis
Encephalitis

Nodular Cortical / Subcortical Enhancement

Cause: hematogenous dissemination
1. Metastasis
2. Clot embolus

√ small < 2 cm circumscribed lesions near gray–white matter junction

Small Spherical Ring-enhancing Lesion at Corticomedullary Margin with Substantial Amount of Vasogenic Edema

1. Primary / secondary neoplasm
2. Abscess of brain

(a) bacterial / granulomatous: Streptococcus, Staphylococcus, Bacteroides, Mycobacteria, Nocardia, Actinomyces, Listeria

(b) fungal: Zygomycetes, Histoplasma, Coccidioides, Aspergillus, Cryptococcus

(b) parasitic: Toxoplasma, Taenia (cysticercosis), Entamoeba, Echinococcus

3. Subacute infarction
4. Resolving hematoma

Deep Ring-enhancing Lesion

Cause:

1. Glioma (40%): single lesion in 77%
2. Metastasis (30%): single lesion in 45%
3. Abscess (8%): multiple lesions in 75%
4. Demyelinating disease (6%): multiple lesions in 85%
5. Necrotic high-grade primary neoplasm (GBM)
   √ wavy undulating rim of > 10 mm in thickness
6. Fluid-secreting low-grade primary neoplasm (pilocytic astrocytoma, hemangioblastoma)
   √ enhancing mural nodule within cyst

Pathogenesis:

(1) hypervascular margin of lesion = granulation tissue / peripheral vascular channels / hypervascular tumor capsule

(2) breakdown of blood-brain barrier = leakage of contrast out of abnormally permeable vessels into extracellular fluid space

(3) hypodense center = avascular / hypovascular (requires time to fill) / cystic degeneration

Incidence of ring blush:

abscess (in 73%); glioblastoma (in 48%); metastasis (in 33%); grade II astrocytoma (in 26%) [NOT in grade I astrocytoma]

Multiple Ring-enhancing Lesions in Immunocompromised Patient

1. Lymphoma (necrotic)
   √ thick nodular ring enhancement
2. Metastatic disease
3. Multiple abscesses
   √ restricted diffusion (ADC values lower than lymphoma / metastatic disease / toxoplasmosis)

Solitary Ring-enhancing Lesion of Brain

A. NEOPLASM

1. Primary neoplasm: high-grade glioma, meningioma, lymphoma, leukemia, pituitary macroadenoma, acoustic neuroma, craniopharyngioma
2. Metastatic carcinoma + sarcoma

√ thick irregular peripheral enhancement

√ more nodular + irregular appearance compared with abscess

B. INFECTION / INFLAMMATION

Abscess / granuloma: bacterial, fungal, parasitic

√ thin ring iso- to hypointense relative to white matter using long repetition time

√ thin medial margin → propensity for intraventricular rupture

√ restricted diffusion of necrotic center

C. HEMORRHAGIC-ISCHEMIC LESION
1. Resolving infarction
2. Aging hematoma
3. Operative bed following resection
4. Thrombosed aneurysm

D. DEMYELINATING DISORDER
1. Radiation necrosis
2. Tumefactive demyelinating lesion ("singular sclerosis")
3. Necrotizing leukoencephalopathy after methotrexate
√ often incomplete ring enhancement with open portion of ring abutting gray matter
√ arc pattern with ongoing plaque activity at one margin = more classic asymmetric comma-shaped peripheral-enhancement pattern compared with abscess

mnemonic: MAGICAL DR
Metastasis
Abscess / cerebritis
Glioblastoma multiforme, **G**lioma
Infarct (resolving), **I**mpact
Contusion
AIDS toxoplasmosis
Lymphoma (often AIDS-related)
Demyelinating disease
Radiation necrosis, **R**esolving hematoma

Isolated Ring-enhancing Lesion of Brainstem

A. NEOPLASM
(a) primary
(b) secondary

B. INFECTION / INFLAMMATION
1. Abscess
2. Acute disseminated encephalomyelitis (ADEM)
3. Multiple sclerosis (1st episode)

Periventricular Enhancement

1. Primary CNS lymphoma
2. Primary glial tumor
3. Infectious ependymitis

Well-defined Superficial Enhancing Mass

A. EXTRAAXIAL DURA-BASED TUMOR
√ displacement of underlying cortex
√ adjacent dural thickening
√ reactive bone changes
√ supply by dural arteries
1. Meningioma

2. Metastasis (prostate, breast, melanoma, RCC)
3. Lymphoma

B. INTRAAXIAL
1. Glioblastoma multiforme

Dense & Enhancing Lesion

1. Aneurysm
2. Meningioma
3. CNS lymphoma
4. Medulloblastoma
5. Metastasis

Multifocal Enhancing Lesions

1. Multiple infarctions
2. Arteriovenous malformations
3. Multifocal primary / secondary neoplasms
4. Multifocal infectious processes
5. Demyelinating disease: eg, multiple sclerosis

Innumerable Small Enhancing Cerebral Nodules

A. METASTASES
B. PRIMARY CNS LYMPHOMA
C. DISSEMINATED INFECTION
1. Cysticercosis
2. Histoplasmosis
3. Tuberculosis

D. INFLAMMATION
1. Sarcoidosis
2. Multiple sclerosis

E. SUBACUTE MULTIFOCAL INFARCTION
from hypoperfusion, multiple emboli, cerebral vasculitis (SLE), meningitis, cortical vein thrombosis

BRAIN VENTRICLES

Ventriculomegaly

A. MACROCEPHALY
• increased intraventricular pressure
(a) Obstruction to CSF flow
1. Communicating hydrocephalus
2. Noncommunicating hydrocephalus

(b) Overproduction of CSF
= nonobstructive hydrocephalus

(c) Neoplasm

B. MICROCEPHALY

- normal intraventricular pressure

(a) Primary failure of brain growth
- › dysgenesis
  1. Holoprosencephaly
  2. Aneuploidy syndromes (trisomies)
  3. Migrational (< 6 layers)
- › environment: alcohol, drugs, toxins
- › infection: TORCH

(b) Loss of brain mantle
- › infection: TORCH
- › vascular accident
  1. Hydranencephaly
  2. Schizencephaly
  3. Porencephaly
- › hemorrhage
  1. Porencephaly
  2. Leukomalacia

C. NORMOCEPHALY

Colpocephaly

= dilatation of trigones + occipital horns + posterior temporal horns of lateral ventricles

1. Agenesis of corpus callosum
2. Arnold-Chiari malformation
3. Holoprosencephaly

Enhancing Ventricular Margins

(a) Subependymal spread of metastatic tumor
1. Bronchogenic carcinoma (esp. small cell carcinoma)
2. Melanoma
3. Breast carcinoma

(b) Subependymal seeding of CNS primary
1. Glioma
2. Ependymoma
3. Giant cell astrocytoma

(c) Ependymal seeding of CNS primary
1. Medulloblastoma
2. Germinoma

(d) Primary CNS lymphoma / systemic lymphoma

(e) Inflammatory ventriculitis

Intraventricular Tumor

Many intraventricular tumors have similar patterns of signal intensity + contrast enhancement. Lesion location + patient's age, gender, and underlying conditions help narrow the DDx.

Prevalence: 10% of all intracranial neoplasms

1. Ependymoma 20%
2. Astrocytoma 18%
3. Colloid cyst 12%
4. Meningioma 11%
5. Choroid plexus neoplasm 7%
6. Epidermoid / dermoid 6%
7. Craniopharyngioma 6%
8. Medulloblastoma 5%
9. Cysticercosis 5%
10. Arachnoid cyst 4%
11. Subependymoma 2%
12. AVM 2%
13. Teratoma 1%
14. Central neurocytoma 0.5%
15. Metastasis
16. Central neurocytoma
17. Oligodendroglioma

Supratentorial Intraventricular Tumors

(a) Lateral ventricle (¾)
   1. Choroid plexus neoplasm (44%)
   2. Giant cell astrocytoma (19%)
   3. Hemangioma in Sturge-Weber syndrome (12%)

(b) Third ventricle (¼)
   1. Astrocytoma (13%)
   2. Choroid plexus neoplasm (6%)
   3. Meningioma (6%)

UNIFORMLY ENHANCING TUMOR IN TRIGONE OF LATERAL VENTRICLE

1. Choroid plexus neoplasm
2. Ependymoma
3. Vascular malformation
4. Meningioma

DENSE LESION NEAR FORAMEN OF MONRO

A. INTRAVENTRICULAR LESION
   1. Colloid cyst
   2. Meningioma
   3. Choroid plexus neoplasm / granuloma
   4. AVM of septal, thalamostriate, internal cerebral v.

B. PERIVENTRICULAR MASS
   1. Primary CNS lymphoma
   2. Tuberous sclerosis
      (a) subependymal tuber
      (b) giant cell astrocytoma
   3. Metastasis from mucin-producing adenocarcinoma / hemorrhagic metastasis

(melanoma, choriocarcinoma, hypernephroma, bronchogenic carcinoma, breast carcinoma)

4. Glioblastoma of septum pellucidum

C. MASSES PROJECTING SUPERIORLY FROM SKULL BASE

1. Pituitary adenoma
2. Craniopharyngioma
3. Aneurysm
4. Dolichoectatic basilar artery

Mass in 3rd Ventricle

Purely intraventricular 3rd ventricle masses are rare:

(a) primary choroid plexus lesion: choroid plexus papilloma / carcinoma
(b) vascular malformation of choroid plexus
(c) lesion seeding to choroid plexus:
  › metastatic neoplasm
  › infection (eg, TB)

1. Colloid cyst
2. Glioma
3. Aneurysm
4. Craniopharyngioma
5. Ependymoma
6. Meningioma
7. Choroid plexus neoplasm
8. Central neurocytoma

CONGENITAL MALFORMATION OF THIRD VENTRICLE

1. Aqueductal stenosis
2. Persistent embryonic infundibular recess
3. Cavum veli interpositi cyst
4. **Congenital intraventricular cyst**

Origin: arachnoidal / endodermal / neuroepithelial
√ nonenhancing cyst of CSF density
√ hydrocephalus ← (possibly intermittent) obstruction of aqueduct / foramen of Monro
DDx: dilatation of 3rd ventricle

ACQUIRED MASS OF THIRD VENTRICLE

A. ANTERIOR MASS

Masses that distort / invade the 3rd ventricle most frequently arise in its anterior aspect and can be broadly grouped into

(a) sellar-suprasellar mass
(b) hypothalamic-chiasmatic mass

B. POSTERIOR MASS

(a) pineal mass: pineal germinoma, pineal cyst, pineocytoma, pineoblastoma, teratoma

(b) tectal mass
(c) inferior thalamic mass

C. INFERIOR / FLOOR MASS (uncommon)
1. Hypothalamic hamartoma
2. Basilar artery ectasia / aneurysm
3. Arachnoid cyst

D. MASS AT FORAMEN OF MONRO
1. Colloid cyst
2. Subependymal giant cell tumor (in TS complex)
3. Subependymoma

E. INTRAVENTRICULAR MASS

Mass in Anterior Portion of Third Ventricle

(a) pediatric patient
1. Germinoma
2. Pilocytic astrocytoma
3. Craniopharyngioma
4. Langerhans cell histiocytosis

(b) adult patient
1. Lymphoma
2. Pituitary macroadenoma
3. Craniopharyngioma
4. Metastasis
5. Granulomatous disease: eg, sarcoidosis
6. Sellar meningioma

Mass in 4th Ventricle

1. Choroid plexus papilloma
2. Ependymoma / glioma
3. Hemangioblastoma
4. Vermian metastasis
5. AVM
6. Epidermoid tumor (rare)
7. Inflammatory mass
8. Cyst

PERIVENTRICULAR REGION

Periventricular Calcifications in Childhood

1. Tuberous sclerosis
2. Congenital infection: CMV, toxoplasmosis

Periventricular Hypodensity

1. Encephalomalacia
   √ slightly denser than CSF

2. Porencephaly
   = cavity communicating with ventricle / cistern from intracerebral hemorrhage
   Associated with: dilated ventricle, sulci, fissures
   √ CSF density
3. Resolving hematoma
   • history of previously demonstrated hematoma
   √ may show ring enhancement + compression of adjacent structures
4. Cystic tumor
   √ mass effect + contrast enhancement

Periventricular T2-hyperintense Lesions

Leukoencephalopathy = disease of white matter
Leukodystrophy = degenerative diffuse sclerosis with symmetrical bilateral white matter lesions
Histo: reduced myelin, axonal loss, astrocytic gliosis
Associated with: dementia, gait abnormalities, late-onset depression

A. NORMAL (increasing with age)
   Frequency: 22% between 0 and 20 years; 22% between 21 and 40 years; 51% between 41 and 60 years; 92% over 60 years
   1. Enlarged perivascular spaces
   2. Ependymitis granularis
   3. Neuroepithelial cyst
B. DEMYELINATING DISEASE
   1. Multiple sclerosis
   2. Acute disseminated encephalomyelitis (ADEM) = postviral leukoencephalopathy
   3. Progressive multifocal leukoencephalopathy
   4. Lymphomatoid granulomatosis
C. VASCULAR DISEASE
   1. Arteriolosclerosis
   2. Lacunar infarcts
   3. **Migraine**: in 41% with classic migraine, in 57% with complicated migraine; presumed to represent vasculitis-induced small infarcts
   4. Vasculitis: Primary angiitis of CNS (PACNS), polyarteritis nodosa, Wegener granulomatosis, SLE, Behçet disease, syphilis, Sjögren syndrome, sickle cell disease
   5. Sarcoidosis
   6. Antiphospholipid antibodies (non-SLE)
   7. Susac syndrome
   8. Periventricular leukoencephalopathy / leukomalacia (= white matter injury of prematurity)
   9. Posterior reversible leukoencephalopathy syndrome (PRES) = hypertensive encephalopathy
D. INFECTION / INFLAMMATION
   1. HIV encephalitis:
      √ well-defined "patchy" / ill-defined "dirty white matter"
      √ central atrophy

2. Lyme encephalopathy
3. Neurocysticercosis
4. Fungal disease: cryptococcosis
5. Congenital CMV infection of CNS

E. TUMOR
1. Subependymal tumor
2. Multiple parenchymal metastases
3. Intravascular (angiocentric) lymphoma

F. TRAUMA
1. Diffuse axonal / shearing injury
2. Diffuse white matter injury = radiation-induced (mineralizing microangiopathy)
3. Diffuse necrotizing leukoencephalopathy = intrathecal methotrexate ± whole brain irradiation

G. METABOLIC
1. Vitamin B12 deficiency
2. Hydrocephalus = transependymal CSF flow
   √ smooth halo of even thickness
3. Pseudotumor cerebri
4. Mucopolysaccharidosis

H. GENETIC
1. Neurofibromatosis 1
2. CADASIL (= cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy)
3. Fabry disease
4. Globoid cell leukodystrophy = Krabbe disease
5. Metachromatic leukodystrophy
6. Spongiform leukoencephalopathy
7. Adrenoleukodystrophy
8. Fibrinoid leukodystrophy = Alexander disease

Multifocal Black Dots on T2 + T2* GRE

= "blooming" susceptibility artifacts on T2* GRE

1. Cerebral amyloid disease
2. Hypertensive microhemorrhages
3. Hemorrhagic lacunar infarcts
4. Multiple vascular malformations (capillary telangiectasia, cavernous malformation)
5. Traumatic diffuse axonal injury
6. Embolic microhemorrhages:
   (a) Hemorrhagic micrometastases
   (b) Metallic microemboli from artificial heart valves
   (c) Microhemorrhages from fat emboli
7. CADASIL (= cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy)

Corpus Callosum Lesion

A. TUMOR
   1. GBM
   2. Lymphoma
   3. Metastasis
B. TRAUMA
   1. Shearing injury
C. WHITE MATTER DISEASE
   1. Multiple sclerosis
   2. Progressive multifocal leukoencephalopathy
   3. Adrenoleukodystrophy
   4. Marchiafava-Bignami disease (often related to chronic alcoholism)
C. INFECTION
   1. Toxoplasmosis

Ring-enhancing Lesion Crossing Corpus Callosum

mnemonic: GAL

Glioblastoma multiforme (butterfly glioma)
Astrocytoma
Lymphoma

BASAL GANGLIA

Bilateral Basal Ganglia Lesions in Childhood

◊ Basal ganglia are susceptible to damage during childhood because of high energy requirements (ATP) mandating a rich blood supply + high concentration of trace metals (iron, copper, manganese)
• increased irritability, lethargy, dystonia
• seizure, behavioral changes
√ bilateral necrosis of basal ganglia

Acute Basal Ganglia Lesions

A. Compromise of vascular supply
   1. Hemolytic-uremic syndrome
      → microthrombosis of basal ganglia, thalami, hippocampi, cortex
   2. Arterial occlusion
   3. Deep cerebral venous thrombosis
B. Infection
   1. Encephalitis: Japanese encephalitis (Asia), West Nile fever (Middle East, North America), Murray Valley fever (Australia) by flavivirus infection
   2. Neurologic Behçet disease
   3. Toxoplasmosis
C. Compromise of nutrient supply
   1. Hypoxic ischemic encephalopathy
   2. Osmotic myelinolysis
   3. Hypoglycemia

√ hemorrhage rarely seen

In unexplained coma obtain blood sugar levels to differentiate this perhaps reversible condition from other causes!

D. Acute toxic poisoning
= impairment of mitochondrial cellular respiratory enzymes
• acute cognitive impairment, coma

1. **Carbon monoxide poisoning**
Action: inhibition of electron transport
Site: preferentially affects globus pallidus
(a) acute phase

√ foci of T2-hyperintensity
√ restricted diffusion
(b) delayed
√ delayed leukoencephalopathy in deep white matter
√ T1 shortening in globus pallidus

rare in children:

2. Hydrogen sulfide
3. **Cyanide poisoning**
Action: blockage of trivalent iron in respiratory chain
√ hemorrhagic necrosis in putamen
4. **Methanol poisoning**
• optic neuritis (initial symptom)
√ hemorrhagic necrosis in putamen
√ ± white matter edema
√ hypoattenuating areas in lentiform nuclei + corpus callosum + subcortical deep white matter in frontal and parietooccipital regions

Chronic Basal Ganglia Lesions

A. INBORN ERRORS OF METABOLISM
1. Leigh disease
2. Wilson disease

Basal Ganglia Lesion	
Thalamus involved	*Thalamus NOT involved*
Hypoxia	Toxic poisoning
Osmotic myelinolysis	Hypoglycemia
Wilson disease	Hyperglycemia
Leigh disease	Liver disease
Fahr disease	Huntington disease
Creutzfeldt-Jacob disease	Neurofibromatosis 1
Deep cerebral vein thrombosis	Neurodegeneration with Brain Iron Accumulation
Infection	
Primary CNS lymphoma	

3. **Mitochondrial encephalomyelopathies**
   = subset of lactic acidemias with structurally abnormal mitochondria
   • "ragged red" fibers in muscle biopsy
4. **Maple syrup urine disease**
   = inability to catabolize branched-chain amino acids (leucine, isoleucine, valine)
   • urine smells of maple syrup
5. **Methylmalonic acidemia**
   = group of genetically distinct autosomal recessive disorders of organic acid metabolism affecting conversion of methylmalonyl-CoA to succinyl-CoA
   • accumulation of methylmalonic acid in blood + urine

Symmetric diffuse abnormalities of the entire lentiform and caudate nuclei suggest systemic / metabolic causes!

B. DEGENERATIVE DISEASE
1. Huntington disease
2. Creutzfeldt-Jakob disease
3. Fahr disease
4. Neurodegeneration with brain iron accumulation (NBIA)

C. DYSMYELINATING DISEASE
N.B.: basal ganglia are a mixture of gray + white matter
1. Canavan disease
2. Metachromatic leukodystrophy

D. MALIGNANCY
1. Primary CNS lymphoma
2. Primary bilateral thalamic glioma

Asymmetric focal discrete lesions affecting only part of basal ganglia suggest involvement by infection / neoplasm

E. OTHERS
1. Neurofibromatosis type 1
   √ bilateral bright objects in globus pallidus, brainstem, cerebellum on T2WI (? hamartomas)
2. Hepatic cirrhosis
   √ bilateral T1-hyperintense areas in globus pallidus + substantia nigra ← deposition of manganese
3. Acute hyperammonemia
   √ bilateral symmetric swelling + T2 prolongation + restricted diffusion in basal ganglia + insular cortex + cingulate gyrus
4. Wernicke encephalopathy

Low-attenuation Lesion in Basal Ganglia

1. Poisoning: carbon monoxide, cyanide poisoning, methanol intoxication, barbiturate intoxication, hydrogen sulfide poisoning
2. Hypoxic ischemic encephalopathy
3. Hypoglycemia

4. Hypotension (lacunar infarcts)
5. Wilson disease

Hemorrhagic Basal Ganglia Lesions

1. Poisoning
2. CNS toxoplasmosis
3. Venous infarction
4. Flavivirus infection

Basal Ganglia Calcification

Prevalence in children: 1.1–1.6%

A. PHYSIOLOGIC WITH AGING
B. ENDOCRINE
   1. Hypoparathyroidism, pseudo-, pseudopseudo- (60%)
   2. Hyperparathyroidism
   3. Hypothyroidism
C. METABOLIC
   1. Leigh disease
   2. Mitochondrial cytopathy
      (a) **Kearns-Sayre syndrome** = ophthalmoplegia, retinal pigmentary degeneration, complete heart block, short stature, mental deterioration
      (b) **MELAS** = **M**itochondrial myopathy, **E**ncephalopathy, **L**actic acidosis, **A**nd **S**trokelike episodes
      (c) **MERRF** = **M**yoclonic **E**pilepsy with **R**agged **R**ed **F**ibers
   3. Fahr disease
D. CONGENITAL / DEVELOPMENTAL
   1. Familial idiopathic symmetric basal ganglia calcification
   2. Hastings-James syndrome
   3. Cockayne syndrome
   4. Lipoid proteinosis = hyalinosis cutis
   5. Neurofibromatosis
   6. Tuberous sclerosis
   7. Oculocraniosomatic disease
   8. Methemoglobinopathy
   9. Down syndrome
E. INFLAMMATION / INFECTION
   1. Toxoplasmosis, congenital rubella, CMV
   2. Measles, chicken pox
   3. Pertussis, Coxsackie B virus
   4. Cysticercosis
   5. Systemic lupus erythematosus
   6. AIDS
F. TRAUMA
   1. Childhood leukemia following methotrexate therapy
   2. S/P radiation therapy

3. Birth anoxia, hypoxia
4. Cardiovascular event

G. TOXIC
1. Carbon monoxide poisoning
2. Lead intoxication
3. Nephrotic syndrome

mnemonic: "BIRTH"
Birth anoxia
Idiopathic (most common), Infarct
Radiation therapy
Toxoplasmosis / CMV
Hypoparathyroidism / pseudoHPT

Multiple Small Enhancing Lesions in Deep Nuclei

1. Metastases
2. Primary CNS lymphoma
3. Disseminated infection
4. Noninfectious inflammatory process
5. Subacute multifocal infarction
6. Vasculitis

Linear Echogenic Foci in Thalamus + Basal Ganglia

A. IN UTERO INFECTION
= **mineralizing vasculopathy = lenticulostriate vasculopathy** = destruction of wall of lenticulostriate arteries + replacement by deposits of amorphous granular basophilic material
1. STORCH agents: **S**yphilis, **T**oxoplasma, **O**thers (hepatitis, zoster), **R**ubella virus, **C**ytomegalovirus, **H**erpes virus
2. Human immunodeficiency virus

B. CHROMOSOMAL ABNORMALITY
1. Down syndrome
2. Trisomy 13

C. OTHERS (anoxic injury?)
1. Perinatal asphyxia, respiratory distress syndrome, cyanotic congenital heart disease, necrotizing enterocolitis
2. Fetal alcohol syndrome
3. Nonimmune hydrops

Bithalamic T2-hyperintense Lesions

Only a few naturally occurring substances (methemoglobin, melanin, lipid, protein, minerals) are known to reduce T1 relaxation times, and the extent of that reduction depends on their occurrence in substantial concentrations.

1. Artery of Percheron infarction
2. Encephalitis

3. Acute disseminated encephalomyelitis (ADEM)
4. Creutzfeldt-Jakob disease
5. Wernicke encephalitis

Hypothalamic Lesions

- hormonal disorders; diencephalic syndrome (failure to thrive, vomiting, emaciation), precocious puberty, stunted growth, diabetes insipidus
- neurologic disorders: epilepsy (laughing fits)

A. DEVELOPMENTAL CYSTS
   1. Epidermoid cyst /dermoid
   2. Rathke cleft cyst
   3. Colloid cyst

B. DEVELOPMENTAL TUMORS
   1. Craniopharyngioma
   2. Germinoma
   3. Hamartoma
   4. Lipoma

C. INFLAMMATORY
   1. Langerhans cell histiocytosis
   2. Lymphocytic infundibuloneurohypophysitis
   3. Sarcoidosis

D. VASCULAR TUMORS
   1. Hemangioblastoma
   2. Cavernoma

E. PRIMARY CNS TUMORS
   1. Hypothalamic-chismatic glioma
   2. Ganglioglioma
   3. Choristoma

MENINGES

Diffuse Dural Thickening

1. Metastasis: prostate, melanoma, breast, rectum, lymphoma
2. Meningioma
3. Granuloma: TB, sarcoid, syphilis
4. Wegener granulomatosis
5. Granulomatous angiitis
6. Erdheim-Chester disease (lipid granulomatosis)
7. Rheumatoid arthritis
8. Neuroblastoma
9. Idiopathic hypertrophic pachymeningitis
10. Pachymeningitis interna hemorrhagica (breast mets)

Dural Calcifications

1. Normal variant (esp. if small)

2. Chronic renal failure
3. Tertiary hyperparathyroidism
4. Ankylosing spondylitis
5. **Arachnoiditis ossificans**
   Frequently associated with:
   significant often progressive neurologic deficit, trauma, surgery, subarachnoid hemorrhage, myelography (with oil-based contrast agents)

Mass Lesion of Dura

1. Meningioma
2. Hemangiopericytoma
3. Primary dural lymphoma
4. Metastasis: breast. lung, prostate
5. Rosai-Dorfman disease
6. Solitary fibrous tumor
7. EBV-associated leiomyoma and leiomyosarcoma
8. Melanocytic lesion: primary / metastatic
9. Melanocytoma
10. Erdheim-Chester disease
11. Sarcoid

Leiomyoma and leiomyosarcoma should be included in the DDx of dural-based masses in AIDS patients.

Dural Tail Sign

= curvilinear area of enhancement tapering off from the margin of the lesion along dural surface ← dural tumor infiltration / reactive inflammatory hypervascularity

1. Meningioma
2. Acoustic schwannoma

Other superficial masses

3. Chloroma
4. Primary CNS lymphoma
5. Sarcoidosis
6. Syphilitic gumma
7. Metastasis

Leptomeningeal Disease

A. INFLAMMATION
   1. Langerhans cell histiocytosis
   2. Sarcoidosis
   3. Wegener granulomatosis
   4. Chemical meningitis: rupture of epidermoid
B. INFECTION
   1. Bacterial meningitis
   2. Tuberculous meningitis
   3. Fungal meningitis

4. Neurosyphilis

C. TUMOR
   (a) Primary meningeal tumor
      1. Meningioma
      2. Glioma: primary leptomeningeal glioblastomatosis / gliosarcomatosis
      3. Melanoma / melanocytoma
      4. Sarcoma
      5. Lymphoma
   (b) CSF-spread from primary CNS tumor
      1. Medulloblastoma
      2. Germinoma
      3. Pineoblastoma
   (c) Metastasis
      1. Breast carcinoma
      2. Lymphoma / leukemia
      3. Lung carcinoma
      4. Malignant melanoma
      5. Gastrointestinal carcinoma
      6. Genitourinary carcinoma

D. TRAUMA
   1. Old subarachnoid hemorrhage
   2. Surgical scarring from craniotomy
   3. Lumbar puncture

EXTRAAXIAL LESIONS

Extraaxial Tumor

mnemonic: MABEL

Meningioma
Arachnoid cyst
Bony lesion
Epidermoid
Leukemic / lymphomatous infiltration

Low-attenuation Extraaxial Lesion

1. Acoustic schwannoma (occasionally low-density mass)
2. Epidermoid tumor
3. Arachnoid cyst

Pericerebral Fluid Collection in Childhood

A. ENLARGED SUBARACHNOID SPACE
   (a) due to macrocephaly
      1. Benign macrocephaly of infancy
   (b) due to brain atrophy

√ superficial cortical veins cross subarachnoid space to reach superior sagittal sinus

√ wide sulci, normal configuration of gyri
√ normal / prominent size of ventricles

B. SUBDURAL FLUID COLLECTION
(1) Subdural hygroma
(2) Subdural empyema / abscess ← meningitis
(3) Subdural hematoma
√ superficial cortical veins are prevented from crossing the subarachnoid space by the presence of arachnoid / neomembrane
√ wide interhemispheric fissure

Subdural Fluid Collection

A. Hyperdense = acute subdural hematoma
B. Isodense = subacute subdural hematoma
C. Hypodense
1. Chronic subdural hematoma
2. Subdural hygroma
3. Effusion from meningoencephalitis

Jugular Foramen Mass

A. NONNEOPLASTIC ENTITIES
1. Asymmetrically enlarged jugular foramen
2. High-riding jugular bulb
√ dome of bulb reaches above internal acoustic canal
√ thin osseous plate separates jugular bulb from middle ear cavity (thin-section CT!)
3. **Dehiscent jugular bulb**
• pulsatile tinnitus
• vascular tympanic membrane
√ middle ear soft-tissue mass contiguous with jugular foramen (= jugular bulb bulges into middle ear cavity)

Intra- versus Extraaxial Mass

	Intraaxial	*Extraaxial*
Relationship to dura	no attachment until advanced	contiguous
Local bony changes	uncommon	common
Cortex displaced	toward bone	away from bone, buckling of gray + white matter, displacement of vessels
Subarachnoid cistern	effaced	widened, CSF cleft
Feeding arteries	pial	dural

√ absence of bony plate separating jugular bulb from posteroinferior middle ear cavity

DDx: Jugular megabulb (rises above floor of EAC but with preservation of bony

plate)
4. Jugular vein thrombosis

B. NEOPLASM
1. Paraganglioma = glomus tumor
2. Nerve sheath tumor = neuroma
3. Meningioma
4. Vascular metastasis (renal / thyroid cancer)

C. PRIMARY BONE LESION
1. Multiple myeloma
2. Lymphoma
3. Langerhans cell histiocytosis

Cerebellopontine Angle Tumor

= extraaxial tumor arising in CSF-filled space bound by pons + cerebellar hemisphere + petrous bone

Frequency: 5–10% of all intracranial tumors

- cranial neuropathy: high frequency hearing loss (CN VIII), tinnitus, facial motor dysfunction (CN VII), facial sensory dysfunction (CN V), taste disturbance (chorda tympani)
- signs of posterior fossa mass effect: headache, nausea, vomiting, disequilibrium, ataxia
- hemifacial spasm, trigeminal neuralgia (tic douloureux)

√ may widen CSF space (cistern) in 25%
√ bone erosion / hyperostosis
√ sharp margination with brain

Types:

(a) benign condition
1. Vestibular schwannoma (60–90%)
2. Meningioma (10–18%)
3. Epidermoid cyst (5–9%)
4. Nonvestibular schwannoma:
   › trigeminal schwannoma
   › facial schwannoma
   › glossopharyngeal schwannoma
5. Arachnoid cyst(< 1%)
6. Lipoma (< 1%)
7. Dermoid
8. Choroid plexus papilloma
9. Ependymoma
10. Glomus jugulare tumor
11. Chordoma
12. Aneurysm of basilar / vertebral / posterior inferior cerebellar artery
13. Atherosclerotic dolichoectasia

(b) malignancy
1. Lymphoma
2. Melanoma
3. Metastasis (0.2–2%)

4. Chondrosarcoma
5. Exophytic brainstem glioma

mnemonic: **E**ver **G**rave **C**erebelloPontine **A**ngle **M**asses
Epidermoid
Glomus jugulare tumor
Chondroma, **C**hordoma, **C**holesteatoma
Pituitary tumor, **P**ontine glioma (exophytic)
Acoustic + trigeminal schwannoma, **A**neurysm of basilar / vertebral artery, **A**rachnoid cyst
Meningioma, **M**etastasis

POSTERIOR FOSSA

Congenital Anomalies of Posterior Fossa

Cerebellar vermis ± hemispheres may be hypo- / dysplastic.
Predominant involvement of cerebellar hemispheres is characteristic of pontocerebellar hypoplasia + disruptive cerebellar development in very premature newborns.
Posterior fossa malformations typically involve both cerebellar hemispheres equally.
Hypoplasia ± dysplasia of one cerebellar hemisphere is likely due to prenatal hemorrhage.

A. PREDOMINANTLY CEREBELLUM
   (a) predominantly vermian involvement
      1. Dandy-Walker malformation
      2. Blake pouch cyst
      3. Megacisterna magna
      4. Arachnoid cyst
      5. Isolated vermian hypoplasia
      6. Rhombencephalosynapsis
   (b) global cerebellar cortical maldevelopment
      1. Lissencephaly
      2. Polymicrogyria
      3. Periventricular nodular heterotopia
      4. Primary microcephaly
      5. Congenital CMV infection
   (c) unilateral cerebellar involvement
      1. PHACES syndrome
      2. Cerebellar cleft
B. CEREBELLUM + BRAINSTEM
   1. Pontocerebellar hypoplasia
   2. Joubert syndrome
C. PREDOMINANTLY BRAINSTEM
   1. Pontine tegmental cap dysplasia
D. PREDOMINANTLY MIDBRAIN
   1. Dysplasia of diencephalomesencephalic junction

Posterior Fossa Cystic Malformation

1. Dandy-Walker malformation
2. Dandy-Walker variant
3. Megacisterna magna
4. Arachnoid pouch

Cystic Mass in Cerebellar Hemisphere

1. Hemangioblastoma
2. Cerebellar astrocytoma
3. Metastasis
4. Lateral medulloblastoma (= "cerebellar sarcoma")
5. Choroid plexus papilloma with lateral extension

Differential Diagnosis of Predominantly Vermian Posterior Fossa Malformations

Entity	*Vermis*	*4th ventricle*	*Posterior fossa*	*Hydrocephalus*	*Scalloped occipital bone*
Dandy-Walker malformation	hypoplastic	⇑	⇑	(mostly) yes	no
Isolated vermian hypoplasia	inferior hypoplasia	⇑	↔	no	no
Blake pouch cyst	normal	⇑	normal	yes	no
Megacisterna magna	normal	normal	⇑ / ↔	no	±
Posterior fossa arachnoid cyst	10–15%	40–50%	< 10%	±	yes

Posterior Fossa Tumor In Adult

Extraaxial	*Intraaxial*
1. Acoustic neuroma	1. Metastasis (lung, breast)
2. Meningioma	2. Hemangioblastoma
3. Chordoma	3. Lymphoma
4. Choroid plexus papilloma	4. Lipoma
5. Epidermoid	5. Glioma

SELLA

Destruction of Sella

1. Pituitary adenoma
2. Suprasellar tumor
3. Carcinoma of sphenoid + posterior ethmoid sinus
   √ opacification of sinus + destruction of walls
   √ associated with nasopharyngeal mass (common)
4. Nasopharyngeal carcinoma
   (a) squamous cell carcinoma
   (b) lymphoepithelioma = Schmincke tumor = nonkeratinizing form of squamous cell carcinoma
   √ sclerosis of adjacent bone
5. Metastasis to sphenoid: from breast, kidney, thyroid, colon, prostate, lung, esophagus
6. Primary tumor of sphenoid bone (rare): osteogenic sarcoma, giant cell tumor, plasmacytoma
7. Chordoma
8. Mucocele of sphenoid sinus (uncommon)

9. Enlarged 3rd ventricle aqueductal stenosis ← infratentorial mass, maldevelopment

J-shaped Sella

mnemonic: "CONMAN"

Chronic hydrocephalus
Optic glioma, **O**steogenesis imperfecta
Neurofibromatosis
Mucopolysaccharidosis
Achondroplasia
Normal variant

Enlarged Sella

A. PRIMARY TUMOR
   1. Pituitary adenoma
   2. Craniopharyngioma
   3. Meningioma: hyperostosis
   4. Optic glioma: J-shaped sella
B. PITUITARY HYPERPLASIA
   1. Hypothyroidism
   2. Hypogonadism
   3. **Nelson syndrome**
      = rapid enlargement of pre-existing ACTH-secreting pituitary adenoma
      Frequency: in 7% of patients after removal of both adrenal glands
      Cause: absence of negative feedback of cortisol on production of ACTH
C. CSF SPACE
   1. Enlarged 3rd ventricle
   2. Hydrocephalus
   3. Empty sella
D. VESSEL
   1. Arterial aneurysm
   2. Ectatic internal carotid artery

mnemonic: CHAMPS

Craniopharyngioma
Hydrocephalus (empty sella)
AVM, **A**neurysm
Meningioma
Pituitary adenoma
Sarcoidosis, TB

Pituitary Gland Enlargement

1. Neoplasm: eg, pituitary gland adenoma
2. Hypertrophy: primary precocious puberty, primary hypothyroidism
3. Lymphocytic hypophysitis
4. Infection
5. Severe dural AV fistula

Complex Sellar / Parasellar Cyst

1. Cystic craniopharyngioma
2. Hemorrhagic pituitary adenoma
3. Hemorrhagic / proteinaceous Rathke cleft cyst

Intrasellar Mass

1. Pituitary adenoma / carcinoma (most common cause)
2. Craniopharyngioma (2nd most common cause)
3. Meningioma: from surface of diaphragm / tuberculum sellae
4. Chordoma
5. Metastasis: lung, breast, prostate, kidney, GI tract, spread from nasopharynx
6. Intracavernous ICA aneurysm: bilateral in 25%
7. Pituitary abscess: rapidly expanding mass associated with meningitis
8. Empty sella
9. Rathke cleft cyst: commonly at junction of anterior + posterior pituitary gland
10. Choristoma: benign neoplasm of posterior pituitary gland
11. Granuloma: sarcoidosis, giant cell granuloma, TB, syphilis, eosinophilic granuloma
12. Lymphoid adenohypophysitis
13. Pituitary hyperplasia, eg, in Nelson syndrome

Calcified Sellar Lesion

1. Aneurysm
2. Craniopharyngioma
3. Chordoma
4. Cartilaginous tumor

Decreased T2 Signal Intensity of Pituitary Gland

1. Hemochromatosis
2. Malignant melanoma
3. Pituitary hemorrhage
4. Flow void (aneurysm)
5. Rathke cleft cyst
6. Calcification (craniopharyngioma, chordoma)

Hypointense Lesion of Sella

1. Empty sella
2. Pituitary stone (= pituilith)
   = sequelae of autonecrosis of pituitary adenoma
3. Intrasellar aneurysm
4. Persistent trigeminal artery
5. Calcified meningioma
6. Pituitary hemochromatosis (anterior pituitary lobe only)

Thickened Pituitary Stalk

1. Langerhans cell histiocytosis
2. Germinoma

3. Craniopharyngioma
4. Tuberculosis
5. Sarcoidosis
6. Lymphocytic hypophysitis

Parasellar Mass

1. Meningioma: tentorium cerebelli
2. Neurinoma (III, IV, V_1, V_2, VI)
3. Metastasis: lung, breast, kidney, GI tract, spread from nasopharynx
4. Epidermoid
5. Aneurysm
6. Carotid-cavernous fistula

Suprasellar Mass

1. Meningioma
2. Craniopharyngioma: in 80% suprasellar
3. Chiasmal + optic nerve glioma in 38% of neurofibromatosis; adolescent girls
   DDx: chiasmal neuritis
4. Hypothalamic glioma
5. Hamartoma of tuber cinereum
6. Infundibular tumor: metastasis (esp. breast); glioma; lymphoma / leukemia; histiocytosis X; sarcoidosis; tuberculosis
   √ diameter of infundibulum > 4.5 mm immediately above level of dorsum; cone-shaped (on coronal scan)
7. Germinoma
   = malignant tumor similar to seminoma (= "ectopic pinealoma")
   √ frequently calcified (teratoma)
   √ CSF spread (germinoma + teratocarcinoma)
   √ enhancement on CECT (common)
8. Epidermoid / dermoid
   √ cystic lesion containing calcifications + fat
   √ minimal / no contrast enhancement
9. Arachnoid cyst
   • hydrocephalus (common), visual impairment
   • endocrine dysfunction
   Age: most common in infancy
10. Enlarged 3rd ventricle extending into pituitary fossa
11. Suprasellar aneurysm
    √ rim calcification + eccentric position

Suprasellar Mass in Adulthood

mnemonic: SATCHMO

Sarcoidosis, **S**ella neoplasm with superior extension
Aneurysm (ectatic carotid, carotid-cavernous sinus fistula), **A**rachnoid cyst, **A**denoma (pituitary)

Tuberculosis, **T**eratoma: dysgerminoma (usually), dermoid, epidermoid
Craniopharyngioma, **C**hordoma
Hypothalamic glioma, **H**istiocytoma, **H**amartoma
Meningioma, **M**etastatic disease, **M**ucocele
Optic nerve glioma, neuroma

Suprasellar Mass with Low Attenuation

1. Craniopharyngioma
2. Dermoid / epidermoid
3. Arachnoid cyst
4. Lipoma
5. Simple pituitary cyst
6. Glioma of hypothalamus

Suprasellar Low-density Lesion with Hydrocephalus

A. CYST
   1. Arachnoid cyst
   2. Ependymal cyst of 3rd ventricle
   3. Parasitic cyst of 3rd ventricle (cysticercosis)
   4. Dilated 3rd ventricle (in aqueductal stenosis)

B. CYSTIC MASS
   1. Epidermoid
   2. Hypothalamic pilocytic astrocytoma
   3. Cystic craniopharyngioma

N.B.: Cystic lesion may be inapparent within surrounding CSF; metrizamide cisternography is helpful in detection + to exclude aqueduct stenosis

Suprasellar Mass with Mixed Attenuation

A. IN CHILDREN
   1. Hypothalamic-chiasmatic glioma
   2. Craniopharyngioma
   3. Hamartoma of tuber cinereum
   4. Histiocytosis

B. IN ADULTS
   1. Suprasellar extension of pituitary adenoma
   2. Craniopharyngioma
   3. Epidermoid cyst
   4. Thrombosed aneurysm
   5. Low-grade hypothalamic / optic glioma
   6. Inflammatory lesion: sarcoidosis, TB, sphenoid mucocele

Suprasellar Mass with Calcification

A. CURVILINEAR
   1. Giant carotid aneurysm
   2. Craniopharyngioma

B. GRANULAR

1. Craniopharyngioma
2. Meningioma
3. Granuloma
4. Dermoid cyst / teratoma
5. Optic / hypothalamic glioma (rare)

Hyperintense Suprasellar Mass on T1WI

1. Craniopharyngioma
   √ viscous material in cystic region (protein concentration of 10-30%)
   √ intrasellar component in 70%
2. Germinoma
   √ hemorrhagic mass → methemoglobin
   • most common in adolescent girls
   • diabetes insipidus
3. Thrombosed aneurysm
   √ laminated internal architecture ← thrombus of differing age (best appreciated on T2WI)
4. Rathke cleft cyst
   √ containing thickly mucinous material
   √ no contrast enhancement
   √ intra- / suprasellar in location
5. Dermoid cyst
   √ with predominantly sebaceous material
   √ suppressed by fat saturation scan
6. Lipoma at floor of 3rd ventricle
   √ round + homogeneous
   √ suppressed by fat saturation scan
7. Ectopic neurohypophysis
   √ along floor of 3rd ventricle
   √ quite small
8. Cavernous angioma
   = collection of sinusoidal spaces
   • occasionally familial
   √ multinodular "popcorn" aggregate with central zones of T1 shortening surrounded by rind of T2 shortening
   √ frequently multiple
   √ angiographically occult /cryptic
9. Hemorrhagic metastasis

Suprasellar Mass with Uniform Enhancement

1. Pituitary adenoma
2. Pituitary Hyperplasia
   √ symmetrical masslike contour
   • appropriate clinical setting (hypothyroidism, pregnancy)
3. Meningioma

√ midline suprasellar lesion

4. Lymphocytic adenohypophysitis
   - usually in women during postpartum period
   - diabetes insipidus common

   √ suprasellar extension common
5. Chiasmatic / hypothalamic glioma
6. Unusual craniopharyngioma
7. Langerhans histiocytosis
8. Germinoma

Enhancing Supra- and Intrasellar Mass

1. Pituitary adenoma
2. Meningioma
3. Germinoma
4. Hypothalamic glioma
5. Craniopharyngioma

Perisellar Vascular Lesion

1. ICA aneurysm

   ◊ Giant aneurysms are those > 2.5 cm in diameter

   √ destruction of bony sella / superior orbital fissure

   √ calcified wall / thrombus

   √ CECT enhancement, nonuniform with thrombosis
2. Ectatic carotid artery

   √ curvilinear calcifications

   √ encroachment upon sella turcica
3. Carotid-cavernous sinus fistula

Lesion Expanding Cavernous Sinus

A. TUMOR
   1. Trigeminal schwannoma
   2. Pituitary adenoma
   3. Parasellar meningioma
   4. Parasellar metastasis
   5. Invasion by tumor of skull base

B. VESSEL
   1. Internal carotid artery aneurysm
   2. Carotid-cavernous fistula
   3. Cavernous sinus thrombosis

C. Tolosa-Hunt syndrome (← cavernous sinus inflammation)

PINEAL GLAND

Classification of Pineal Gland Tumors

Incidence of pineal mass:

< 1% of all intracranial tumors in adults; 3–8% of all intracranial masses in childhood; 9% of all intracranial masses in Asia

Symptoms of pineal region mass:

Cause: invasion / compression of tectal plate

- **Parinaud syndrome**:
  1. Failure of conjugate vertical eye movement (= paralysis of upward gaze)
  2. Failure of ocular convergence
  3. Mydriasis
  4. Blepharospasm (= eyelid contraction or twitch)
- precocious puberty = secretion of hCG by tumor (more common with germ cell tumor)
- pineal apoplexy = hemorrhage into pineal tumor / cyst:
  - sudden decrease in consciousness, headache

√ hydrocephalus ← obstruction of aqueduct of Sylvius:

- headache, nausea, vomiting

A. PRIMARY TUMOR

(a) Germ cell tumors (⅔)

Frequency: 0.4–3.4% of pediatric brain tumors in Western countries; up to 11% of those in Japan / other Asian countries

Age: 10–30 years; M÷F = 3÷1

› forming embryonic tissue

1. Germinoma (40–50%)
2. Teratoma (15%)
3. Embryonal carcinoma

› forming extraembryonic tissue

4. Choriocarcinoma (< 5%)
5. Endodermal sinus tumor = yolk sac tumor
6. Mixed germ cell tumor

(b) Pineal parenchymal cell origin (< 15%)

1. Pineocytoma
2. Pineoblastoma

Pineal parenchymal cell tumors expand and obliterate the pineal architecture → "exploding" normal pineal calcifications toward the periphery

(c) Other cell origin

1. Trilateral retinoblastoma
2. Astrocytoma (pineal + tectal glioma)
3. Meningioma
4. Lipoma
5. Ependymoma
6. Hemangiopericytoma
7. Cavernous hemangioma

(d) Cysts

1. Pineal cyst
2. Malignant teratoma
3. AVM, vein of Galen aneurysm

4. Arachnoid cyst
5. Congenital inclusion cysts (dermoid, epidermoid)

B. SECONDARY TUMOR

Metastasis: 0.4–3.8% in patients with solid tumors; lung > breast > kidney > esophagus > stomach > colon

DDx considerations:

female:	likely NOT germ cell tumor
hypodense matrix:	likely NOT pineal cell tumor
distinct tumor margins:	probably pineocytoma / teratoma / germinoma
calcification:	likely NOT teratocarcinoma, metastasis, germinoma
engulfed calcifications:	germinoma
CSF seeding:	NOT teratoma
intense enhancement:	likely NOT teratoma

Serum (oncoprotein) markers:

choriocarcinoma	β-hCG
embryonal cell carcinoma	α-FP and β-hCG
endodermal sinus tumor	α-FP
teratoma	β-hCG and α-FP
germinoma	placental alkaline phosphatase

Presence of oncoproteins / engulfment of pineal calcifications help narrow the differential diagnosis.

Intensely Enhancing Mass in Pineal Region

1. Germinoma
2. Pineocytoma / pineoblastoma
3. Pineal teratocarcinoma
4. Glioma of brainstem / thalamus
5. Subsplenial meningioma
6. Vein of Galen aneurysm

COMPLICATIONS OF BRAIN SURGERY

A. INFECTION (< 1%)

1. Bone flap infection (44% of all infections)
   At risk: postoperative CSF leakage, breach of paranasal sinuses, septic surgery performed for active infection, source of intracerebral contamination (compound skull fracture / penetrating injury)
2. Meningitis
3. Extradural abscess (0.43% of all craniotomies)
4. Subdural empyema (0.11% of all craniotomies)
5. Brain abscess

B. PERTAINING TO CRANIOTOMY / CRANIECTOMY

1. **Extracranial herniation** after decompressive craniectomy
   Cause: created craniectomy defect too small

Cx: compression of cortical veins → venous infarction; contusion of brain at craniectomy margins

2. **Subdural / subgaleal hygroma** (21–50%)
   Cause: disturbance of CSF circulation after craniectomy
   Location: fluid collection ipsilateral to craniectomy / contralateral / interhemispheric space
   Timing: appearance within days of surgery, resorption over weeks to months
3. **External brain tamponade**
   Cause: subgaleal fluid accumulates under pressure and pushes on the brain across craniectomy defect
   √ bulging skin flap + subgaleal fluid collection
4. **Trephine syndrome** (13%)
   = sinking skin flap syndrome = syndrome of the trephined
   Cause: atmospheric pressure + gravity overwhelm intracranial pressures → brain appears sunken
   Time after surgery: 28–188 days
   • headaches, seizures, dizziness, undue fatigability
   √ depressed skin flap at craniectomy site
   √ concave deformity of adjacent brain
5. Postsurgical brain herniation (see below)

C. HEMORRHAGE

1. "**Plunging**" = inadvertent breach of dura during drilling
   Cx: intracerebral hematoma (71%), cortical laceration (16%), extradural hematoma (5%), subdural hematoma (5%), intraventricular hemorrhage (3%)
2. Postoperative hemorrhage (6–7%)
   Location: intraparenchymal (43%), extradural (33%), subdural (5%), mixed (8%)
3. Extradural hematoma
   Location: regional (63%) = beneath bone flap; adjacent (31%) = at craniotomy margins: remote (6%) = distant to craniotomy site
4. Intraparenchymal hemorrhage (11%)
5. **Remote cerebellar hemorrhage**
   = CSF volume depletion → sagging of cerebellum → occlusion of superior bridging veins → hemorrhagic infarction
   √ "zebra" sign = streaky curvilinear areas of increased attenuation in cerebellar sulci + folia

Postsurgical Brain Herniation

Fungus Cerebri

= EXTRACRANIAL HERNIATION
= herniation of brain tissue through skull defect after trauma / therapeutic craniectomy
Cx: brain infarction

Paradoxical Brain Herniation

= SYNDROME OF THE TREPHINED

◊ Neurosurgical emergency!

• mesodiencephalic herniation syndrome: depressed level of consciousness, autonomic instability, signs of brainstem release, focal neurologic deficits

At risk: large craniectomy defect followed by CSF drainage procedure (lumbar puncture, external ventricular drainage, ventriculoperitoneal shunting)

Pathophysiology:

decrease in CSF pressure → reduction in intracranial pressure to below atmospheric pressure

√ sunken skin flap

√ subfalcine / transtentorial herniation of brain away from craniectomy defect:

- √ midline shift
- √ compression of midbrain
- √ effacement of basal cisterns

Rx: Trendelenburg position, clamping of ventricular shunt / drain, intravenous fluid, lumbar epidural blood patch, performing early cranioplasty to restore continuity of calvaria

Tension Pneumocephalus

◊ Rare life-threatening neurosurgical emergency!

= commonly following neurosurgical decompression of subdural hematoma / posterior fossa craniotomy

Cause: air enters via subdural defect → check-valve mechanism prevents escape of air → increasing intracranial pressure

• falling Glasgow coma scale

√ "peaking" sign = subdural air collections compress both frontal lobes

√ "Mount Fuji" sign = compression and separation of frontal lobes by air → widening of interhemispheric space

√ transtentorial ± tonsillar herniation

ANATOMY OF THE NERVOUS SYSTEM

EMBRYOLOGY

Neurulation

neural plate	=	CNS originates as a plate of thickened ectoderm on the dorsal aspect of the embryo
neural crest	=	elevation of the lateral margins of the neural plate; forms the peripheral nervous system
neural tube	=	invagination between the 2 neural crests; its wall forms the brain + spinal cord; its lumen forms the ventricles + spinal canal
4.6 weeks MA:		formation of neural tube
5.6 weeks MA:		rostral neuropore closes
5.9 weeks MA:		caudal neuropore closes
6.0 weeks MA:		3 primary brain vesicles develop (prosencephalon, mesencephalon, rhombencephalon) + development of cervical flexure
6.5 weeks MA:		prosencephalon cleaves into telencephalon anteriorly + diencephalon posteriorly
7.0 weeks MA:		2 additional primary brain vesicles form out of rhombencephalon (pontine flexure divides into myelencephalon, metencephalon)
15 weeks MA:		dorsal portion of alar plates bulging into 4th ventricle have fused in midline to form cerebellar vermis

Brain Growth

= increase in thickness of brain mantle with relative constant ventricular width

◊ Most rapid brain growth from 12 to 24 weeks MA!

Sulcal Development

10 weeks MA:	interhemispheric fissure ← longitudinal cleavage
14–19 weeks	sylvian fissure
16–22 weeks	calcarine, parieto-occipital, cingulate sulci
20–25 weeks	rolandic sulcus
23–26 weeks	superior temporal + intraparietal sulci
26–28 weeks	superior frontal, pre- and postcentral, middle temporal sulci
34 weeks	all primary + most secondary sulci present

Neuronal Migration

7th week	subependymal neuronal proliferation = germinal matrix depicted as low SI band along ventricular wall on T2WI

Germinal Matrix

= highly vascular gelatinous subependymal tissue adjacent to lateral ventricles in which the cells that compose the brain are generated; has its largest volume around 26 weeks GA; decreases in size with increasing fetal maturity; usually involutes by 32–34 weeks of gestation

Location: greatest portion of germinal matrix above caudate nucleus in floor of lateral ventricle, tapering as it sweeps from frontal horn posteriorly into temporal horn, roof of 3rd + 4th ventricle

Arterial supply: via Heubner artery from ACA, striate branches of MCA, anterior choroidal a., perforating branches from meningeal a.

Capillary network: persisting immature vascular rete = large irregular endothelial-lined channels devoid of connective tissue support (collagen and muscle)

Venous drainage: terminal vv., choroidal v., thalamostriate v. course anteriorly + feed into internal cerebral v. which has a posterior course

Myelination

Progression: caudal to rostral; posterior to anterior; center to periphery

MR: T1WI if < 7 months of age; T2WI if > 7 months of age

Milestones:

term birth: brainstem, cerebellum, posterior limb of internal capsule

2 months: anterior limb of internal capsule

3 months: splenium of corpus callosum

6 months: genu of corpus callosum

Occipital white matter:

√ central at 5 months (T1WI), 14 months (T2WI)

√ peripheral at 7 months (T1WI), 15 months (T2WI)

Frontal white matter:

√ central at 6 months (T1WI), 16 months (T2WI)

√ peripheral at 11 months (T1WI), 18 months (T2WI)

MENINGES OF BRAIN

A. CALVARIA = upper part of cranium enclosing the brain
   (a) outer table of resilient compact bone
   (b) diploë = trabecular bone containing red bone marrow
   (c) inner table of thin and brittle compact bone

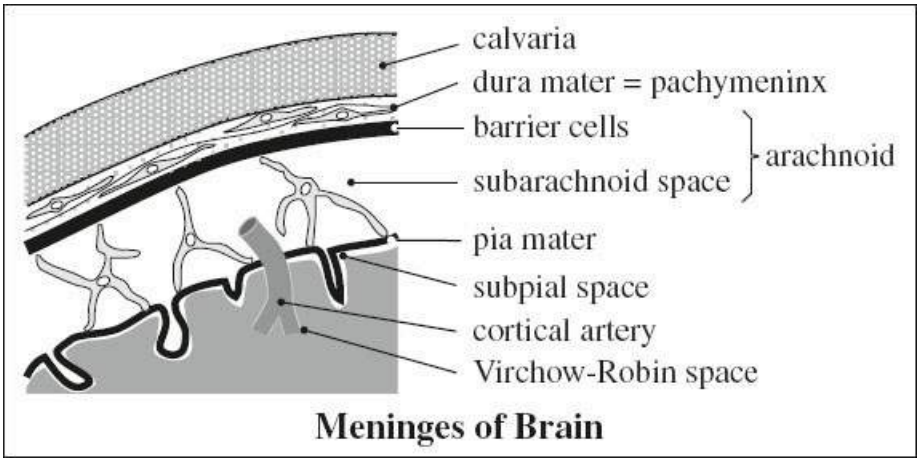
B. EPIDURAL SPACE
   = created when outer layer of dura (periosteum of inner table) becomes detached from calvaria

C. PACHYMENINGES = DURA MATER
   = thick inelastic membrane composed of 2 layers of fibrous + elastic connective tissue that are fused except for a separation allowing the passage of dural venous sinuses
   (a) outer endosteal dural layer
      = highly vascularized periosteum of inner table containing blood vessels that supply the bone

(b) space for venous sinuses
(c) inner meningeal dural layer
= protective meningeal layer lined on its inner brain surface by layer of mesothelium derived from meninx
→ extensions are reduplications of the meningeal layer projecting into skull cavity to form falx cerebri, tentorium cerebelli, falx cerebelli, diaphragma sellae

D. SUBDURAL SPACE
= cleft formed in pathologic states within inner layer of dura

E. LEPTOMENINGES
1. Arachnoid mater [*arakhnoeides*, Greek = like a cobweb]
= closely applied to inner surface of dura
2. Subarachnoid space



Meninges of Brain

Histo: fine connective tissue + cellular septa link pia and arachnoid
› contains CSF that drains through the valves of arachnoid granulations into venous sinuses
› forms basal cisterns

3. Pia mater [*pia* , Latin = tender]
= delicate innermost layer of meninges
Histo: thin fibrous tissue impermeable to fluid with perforations for blood vessels to pass through

F. SUBPIAL SPACE
= perivascular space = VR (Virchow-Robin) space
[Rudolf Virchow (1821–1902), pathologist in Berlin, Germany]
[Charles P. Robin (1821–1885), anatomist in Paris, France]
Histo: no communication with subarachnoid space; VR space around intracortical artery continues within subarachnoid space; VR space around cerebral vein is continuous with subpial space
Function: lymphatic drainage system of the brain
Sites: Type I = lenticulostriate arteries
Type II = medullary arteries over high convexities
Type III = collicular arteries in midbrain

√ smoothly demarcated typically < 5 mm fluid-filled cyst; often in clusters
√ SI visually similar to CSF (actually lower when measured as VR spaces are entrapments of interstitial fluid)
√ no restricted diffusion + no enhancement
√ inflow effects on flow-sensitive T1WI

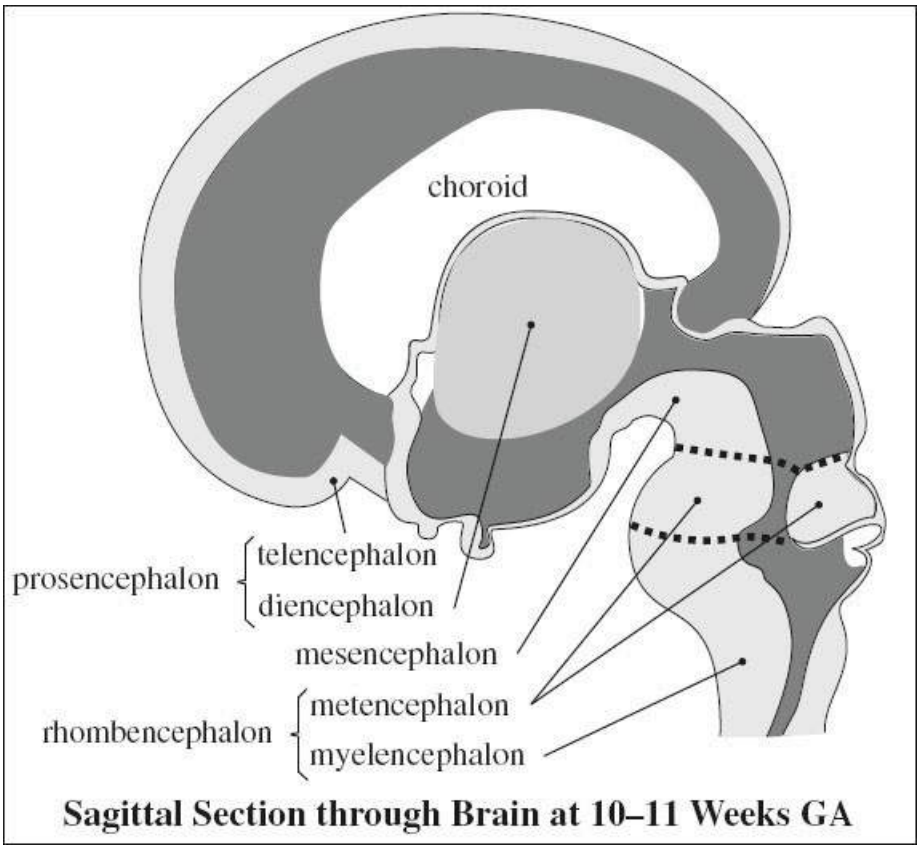
G. EPENDYMA
= thin epithelial-like lining of ventricular system + central canal of spinal cord composed of ciliated simple columnar ependymocytes
Origin: one of four types of neuroglia in CNS
Function: (1) Production + regulation of CSF, (2) Reservoir for neuroregeneration

Falx Cerebri [*falx*, Latin = curved blade or scythe]
= large crescent-shaped inelastic reflection of meningeal layer of dura mater that descends vertically in longitudinal fissure between cerebral hemispheres
Connected to:
(a) anteriorly: crista galli anteriorly in proximity to cribriform plate + frontal and ethmoid sinuses
(b) posteriorly: upper surface of the tentorium cerebelli
Margins:
(a) superior margin attached at midline to internal surface of skull as far back as internal occipital protuberance
› contains superior sagittal sinus overlying longitudinal cerebral fissure
(b) inferiorly adjacent to corpus callosum + cingulate gyrus + pericallosal arteries
› contains inferior sagittal sinus arching over corpus callosum deep in longitudinal cerebral fissure

Falx Cerebelli
= small sickle-shaped fold of dura mater projecting forward into posterior cerebellar notch + into cerebellar vallecula between cerebellar hemispheres
Base: attached to inferoposterior part of tentorium cerebelli
Posterior margin: attached to vertical crest of inner skull surface below internal occipital protuberance

CLASSIFICATION OF BRAIN ANATOMY

A. PROSENCEPHALON = forebrain
forms from process of ventral induction (ie, 3 closely interconnected sequential events of formation + cleavage + midline development)



√ cerebrum, lateral ventricles, choroid, thalami, cerebellum sonographically visible at 12 weeks MA

1. Telencephalon = cerebrum
   = cerebral hemispheres, putamen, caudate nucleus
2. Diencephalon
   = thalamus, hypothalamus, epithalamus (= pineal gland + habenula), globus pallidus, optic vesicles

B. MESENCEPHALON = midbrain
   = short segment of brainstem above pons; traverses the hiatus in tentorium cerebelli; contains cerebral peduncles, tectum, colliculi (corpora quadrigemina)

C. RHOMBENCEPHALON = hindbrain
   √ posterior cystic space of 4th ventricle sonographically detectable between 8 and 10 weeks MA
   1. Metencephalon = cerebellar hemispheres, vermis
   2. Myelencephalon = medulla oblongata, pons

D. BRAINSTEM = midbrain + pons + medulla contains
   (a) cranial nerve nuclei
   (b) sensory and motor tracts between thalamus, cerebral cortex, and spinal cord
   (c) reticular formation controlling respiration, blood pressure, gastrointestinal function, centers for arousal and wakefulness

THALAMUS

= midline structure situated between cerebral hemispheres + midbrain with paired symmetric portions

Location: on either side of 3rd ventricle

Function: relay of sensory + motor signals; regulation of consciousness, sleep, alertness

Blood supply: PCA + pCom

Hypothalamus [*hypo*, Greek = below; *thalamus*, Greek = bed]

= part of diencephalon below the thalamus

Origin: neuroectoderm

Boundaries:

(a) anterior = lamina terminalis extending from anterior commissure to optic chiasm
(b) posterior = line extending from mamillary bodies to posterior commissure
(c) lateral = medial thalamus
(d) inferior = tuber cinereum (posteriorly) + median eminence (middle) + infundibular stalk (anteriorly)

Function: homeostasis for blood pressure, body temperature, fluid + electrolyte balance, body weight

Regulatory mechanism:

(a) endocrine secretion:
› neuronal stimulation of posterior pituitary gland via infundibulum
› hypothalamic releasing factors to anterior pituitary gland via portal plexus as a vascular conduit
(b) autonomic function
(c) emotions

BASAL NUCLEI

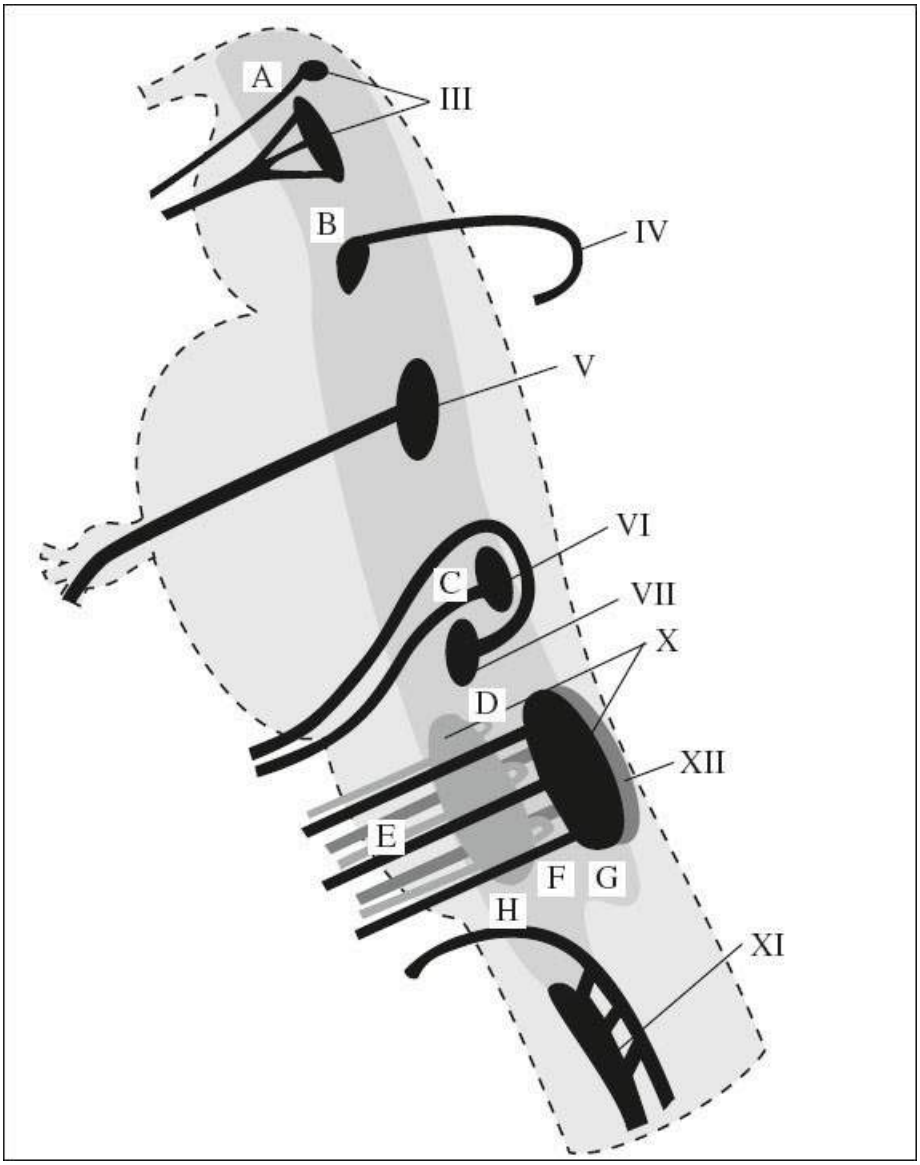
= BASAL GANGLIA (earlier incorrect designation)

Function: part of extrapyramidal motor system; involvement in memory, emotion, other cognitive function

Blood supply: ACA and MCA → medial + lateral lenticulostriate aa.

A. Amygdaloid body
B. Claustrum
C. Corpus striatum

Location: between lateral ventricle + insular cortex



Cranial Nuclei of Brainstem and Reticular Formation		
A	=	sleep, wakefulness, consciousness
B	=	visual spatial orientation, higher autonomic coordination of food intake
C	=	pneumotaxic center, coordination of breathing and circulation
D	=	swallowing
E	=	blood pressure, cardiac activity, vascular tone
F	=	expiration
G	=	area postrema = trigger zone for vomiting
H	=	inspiration

(1) Caudate nucleus
√ isointense to cortical gray matter on all pulse sequences
√ no enhancement
(2) Lentiform nucleus

√ may exhibit dilated Virchow-Robin perivascular spaces
√ may contain bilateral symmetric age-related calcifications
(a) pallidum = globus pallidus
√ slightly hypointense relative to putamen ← progressive iron deposition with age
(b) putamen
√ isointense to cortical gray matter on all pulse sequences
√ no enhancement

PITUITARY GLAND

= hypophysis cerebri within hypophyseal fossa of sphenoid, covered superiorly by sellar diaphragm (= dura mater) which has an aperture for the infundibulum centrally

Size: (adult size is achieved at puberty)
Height in adult females: 7 (range 4–10) mm
Height in adult males: 5 (range 3–7) mm
(normal height in men aged 40–49 = 4.89 ± 0.87 mm)

Shape:
√ flat / downwardly convex superior border
√ upwardly convex during puberty, pregnancy, in hypothyroidism (due to hyperplasia)

Anterior Lobe of Pituitary Gland

= larger anterior portion of adenohypophysis comprising 80% of pituitary gland volume

Origin: ectodermal derivative of stomadeum

Function:
(a) chromophil cells
1. acidophil cells = α cells
› growth hormone = somatotropin (STH)
› prolactin = lactogenic hormone (LTH)
2. basophil cells = β cells
› adrenocorticotropic hormone (ACTH)
› thyrotropin = thyroid-stimulating hormone (TSH)
› follicle-stimulating hormone (FSH)
› interstitial-cell-stimulating hormone (ICSH)
› luteinizing hormone (LH)
› melanocyte-stimulating hormone (MSH)

(b) chromophobe cells
50% of epithelial cell population, of unknown significance

MR:
√ larger homogeneous component isointense to white matter on T1WI + T2WI
√ prominent contrast enhancement (during first 3 minutes) ← lack of blood-brain barrier
√ hyperintense in newborn fading to normal adult signal by 2nd month of life

Pars Intermedia of Pituitary Gland

= posterior portion of adenohypophysis, separated from anterior lobe by hypophyseal cleft in fetal life

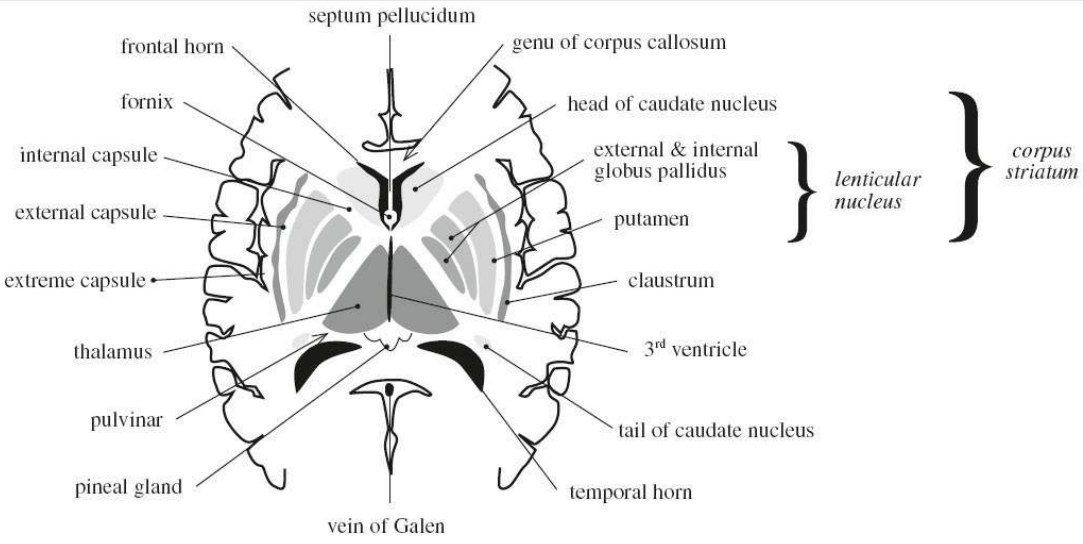
Origin: Rathke cleft / Rathke pouch within intermediate lobe of pituitary gland

Function: termination point of short hypothalamic axons elaborating tropic hormones (= releasing factors + prolactin inhibiting factor), which are carried to anterior lobe via the portal system

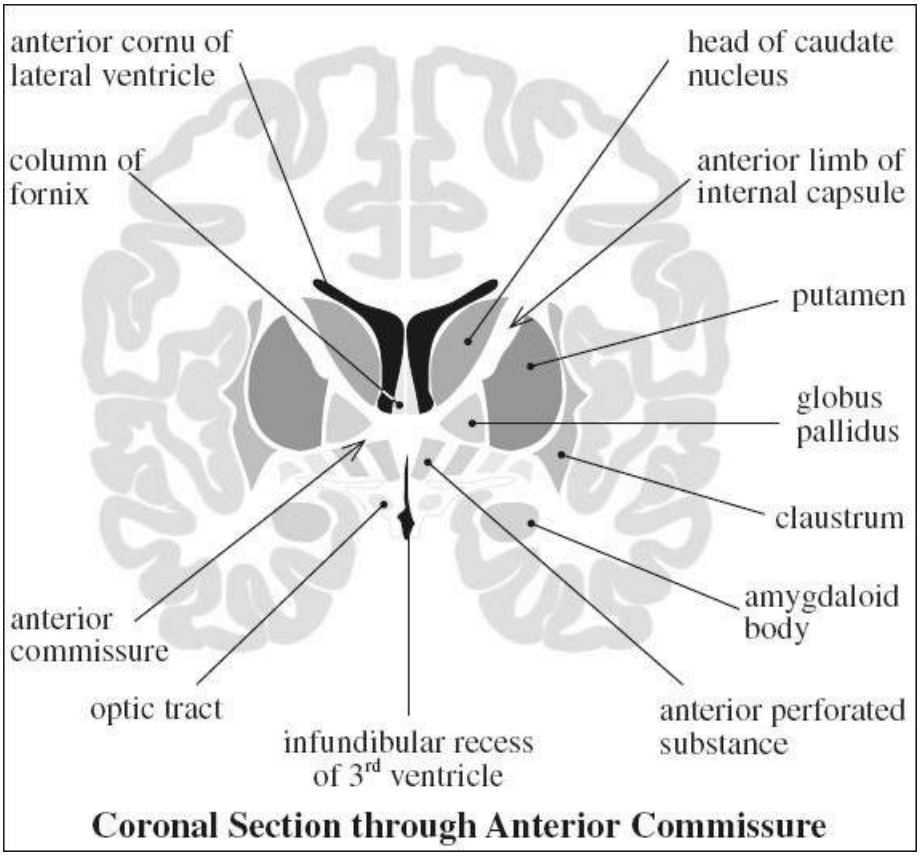
√ not visible with imaging techniques

Posterior Lobe of Pituitary Gland

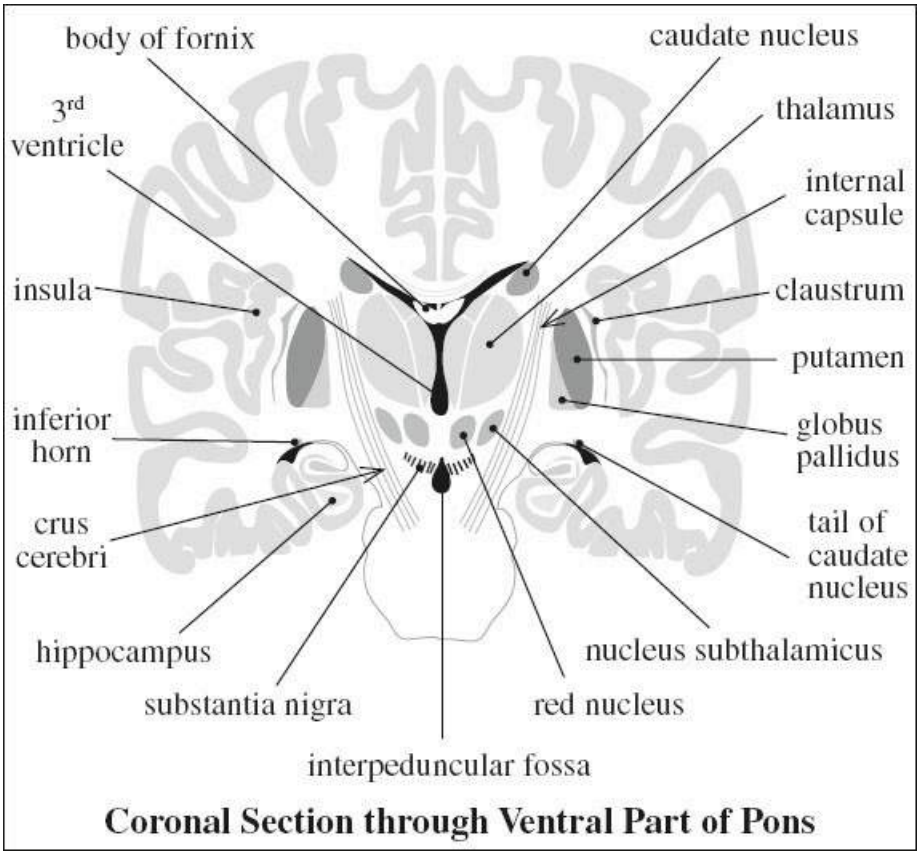
= major portion of neurohypophysis



Axial Section through Level of Third Ventricle



Coronal Section through Anterior Commissure



Coronal Section through Ventral Part of Pons

= termination point of neurosecretory axons from supraoptic and paraventricular nuclei of hypothalamus (= hypothalamohypophyseal tract)

Origin: diencephalic outgrowth

Function: storage site for transported
› vasopressin (= antidiuretic hormone [ADH])
› oxytocin

MR:
√ crescent of T1-hyperintensity + T2-isointensity compared with anterior pituitary lobe ← lipid in glial cell pituicytes + phospholipids of vasopressin
√ isointense in 10% of normal individuals

Pituitary Stalk / Infundibulum

Origin: arises from anterior aspect of floor of 3rd ventricle (infundibular recess)

Histo: formed from axons of cells lying in supraoptic + paraventricular nuclei of hypothalamus
√ joins posterior lobe at junction of anterior + posterior lobes
√ up to 3 mm thick superiorly, up to 2 mm thick inferiorly
√ usually in midline, may be slightly tilted to one side

MR:
√ prominent contrast enhancement

SEPTUM PELLUCIDUM

= 1.5–3.0 mm thin vertical membrane of triangular shape (when viewed from side)
› connecting corpus callosum to columns of fornix
› forming the medial wall of the lateral ventricles
› separating both anterior horns

Base of triangle: located anteriorly

Apex of triangle: located posteriorly

Five layers (leaves / laminae) of septum:
› CSF in anterior horn of RT lateral ventricle
› ependymal lining (gray matter) of RT lamina
› pial layer (white matter) of RT lamina
» potential space / slitlike cavity / cavum
› pial layer (white matter) of LT lamina
› ependymal lining (gray matter) of LT lamina
› CSF in anterior horn of LT lateral ventricle

Borders:
below: column + body of fornix
above: corpus callosum
ventral: continuous with precommissural septum + subcallosal gyrus
lateral: wall of lateral ventricles

Function: ?, part of limbic system moderating rage + arousal

Cavum Septi Pellucidi

= persistence / failure of fusion of potential space (= slitlike cavity = 5th ventricle) between the 2 laminae forming septum pellucidum

Frequency: in 80% of term infants; in 15% of adults
Location: posterior to genu of corpus callosum, inferior to body of corpus callosum, anterosuperior to anterior pillar of fornix
Marker for: cerebral dysfunction
√ extends to foramen of Monro
√ may dilate + cause obstructive hydrocephalus (rare)
Regression: from back to front as fetus approaches term / in first few weeks after birth

Cavum Vergae

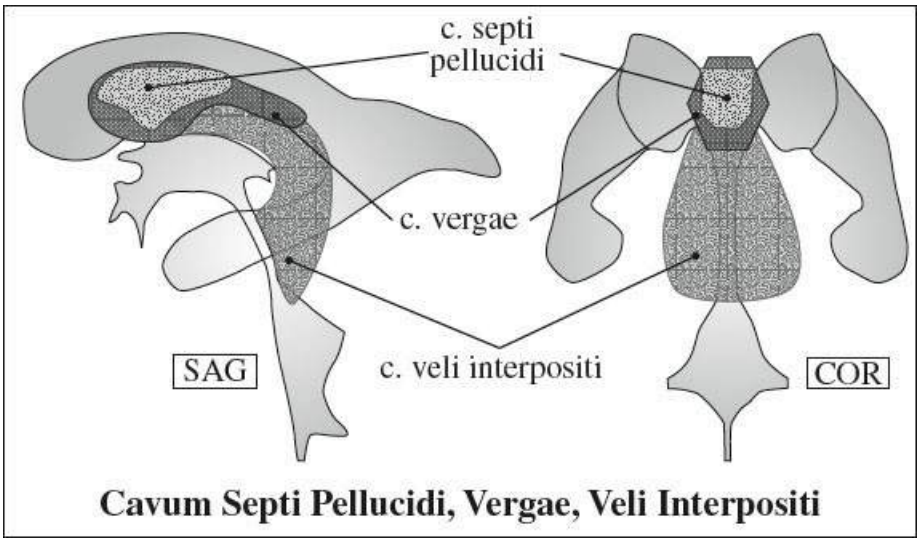
= "6th ventricle"
[Andrea Verga (1811–1895), clinical professor of psychiatry at Ospedale Maggiore in Milan, Italy]
= fluid-filled cavity located posterior to a vertical plane formed by columns of fornix
Frequency: in 30% of term infants; in 15% of adults
Location: posterior to fornix; anterior to splenium of corpus callosum inferior to body of corpus callosum superior to transverse fornix
√ posterior midline continuation of cavum septi pellucidi beyond foramen of Monro (= communicates with cavum septi pellucidi)
Regression: cavum vergae (1st) > cavum septi pellucidi (2nd); contracts after about 6th gestational month

VELUM INTERPOSITUM [*velum*, Latin = veil]

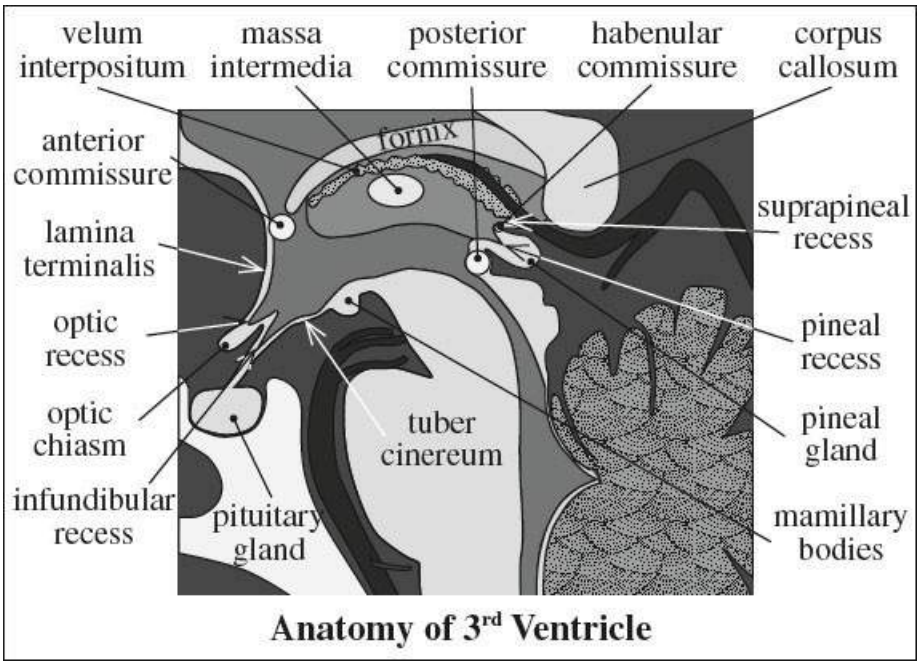
= small triangular (on axial view) membrane containing a closed space between the 2 layers of tela choroidea in the roof of the 3rd ventricle
Borders:
above: columns of fornices + hippocampal commissure
below: tela choroidea of 3rd ventricle, internal cerebral veins
lateral: thalamus
posterior: splenium of corpus callosum

Cavum Veli Interpositi

= anatomic variant characterized by dilated CSF space of the cistern of the velum interpositum / extension of quadrigeminal plate cistern above 3rd ventricle
Cause: abnormal separation of crura of fornices



Cavum Septi Pellucidi, Vergae, Veli Interpositi



Anatomy of 3rd Ventricle

√ triangular-shaped CSF space / cyst in pineal region
  › above tela choroidea of 3rd ventricle
  › below columns of fornices
√ separated from cavum vergae by crura of fornices

VENTRICLES

Third Ventricle

Position: in midline of diencephalon

Walls:

› inferiorly: curving floor of 3rd ventricle formed
  » anteriorly by median eminence and tuber cinereum

» posteriorly by mammillary bodies + midbrain posterior to tuber cinereum

› superiorly: curving roof with 5 layers:

(1) body of fornix

(2) superior layer of tela choroidea

(3) vascular layer = velum interpositum containing bathed in CSF:

(a) internal cerebral veins

(b) medial posterior choroidal arteries

(4) inferior layer of tela choroidea

(5) choroid plexus of 3rd ventricle

› superior lateral wall: formed by medial aspects of thalami

› inferior lateral wall: formed by hypothalamus anteriorly + subthalamus posteriorly

› massa intermedia = band of gray matter as a communication between 2 thalami across midline

› anteriorly: lamina terminalis

» anterosuperior border: anterior commissure

» anteroinferior border: optic chiasm

› posteriorly: pineal gland

Recesses: 2 anterior + 2 posterior recesses

(1) optic recess superiorly

(2) infundibular recess inferiorly = pars cava infundibuli formed by funnel-shaped proximal hypothalamic infundibulum (pituitary stalk)

» median eminence at base of infundibulum = raised portion of hypothalamic gray matter

(3) pineal recess in deep aspect of pineal gland

» posterior commissure in inferior wall of pineal recess

» habenular commissure in superior wall of pineal recess

(4) suprapineal recess above habenular commissure and below splenium of corpus callosum

Tela choroidea ventriculi tertii

= ependymal + glial layers forming choroid plexus (= richly vascularized tela) that projects into 3rd ventricle

(a) upper layer attached to lower surface of fornix

(b) lower layer attached anteriorly to stria medullaris thalami + posteriorly to superior surface of the pineal body

[*tela*, Latin = web], [*khorion*, Greek = membrane enclosing fetus, afterbirth] [chorioeides, Greek = membrane-like] [*plexus*, Latin = braid, network]

Interventricular Foramen of Monro

= Y-shaped communication between 2 lateral ventricles and 3rd ventricle

Location: posterior to anterior columns of fornix

Aqueduct of Sylvius

= opening at posterior aspect of 3rd ventricle below posterior commissure

MEGACISTERNA MAGNA

= GIANT CISTERNA MAGNA = ENLARGED CISTERNA MAGNA
= large retrocerebellar CSF space with normal vermis + cerebellar hemispheres
Prevalence: 1% of all brains
May be associated with: infarction, inflammation, infection (esp. CMV), chromosomal abnormalities (esp. trisomy 18)
Size of normal cisterna magna:
3–8 mm measured in midsagittal plane from posterior lip of foramen magnum to caudal margin of inferior vermis
√ intact vermis + normal 4th ventricle
√ paired linear echoes that join + descend toward base of posterior fossa = dural folds = inferior attachment of tentorium
√ NO enlarged posterior fossa, NO mass effect on cerebellum
DDx: arachnoid cyst

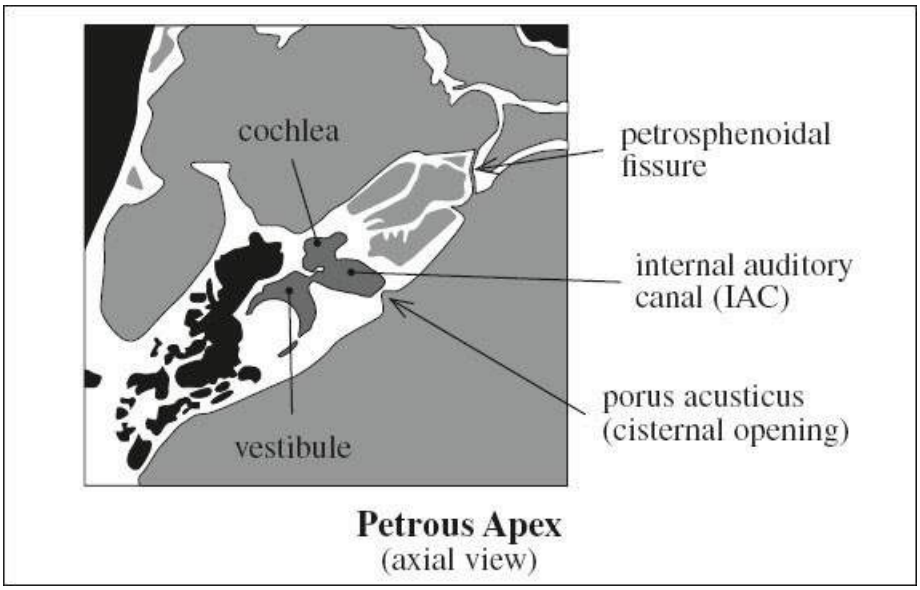
PINEAL GLAND

[*pinea* , Latin = pine cone]
= PINEAL BODY = EPIPHYSIS CEREBRI = "Third eye"
Development: diverticulum lined by ependyma at the most caudal portion of diencephalic roof of 3rd ventricle → area of ependymal thickening → evaginates into pinecone-shaped mass during 7th week GA
Function: secretion of melanin
1. Regulation of long-term biologic rhythm (eg, onset of puberty)
2. Regulation of short-term biologic rhythm (eg, diurnal / circadian) due to photoperiodic clues via accessory optic pathway

Histo:
(a) lobules of pineocytes with dendritic processes (= specialized neuronal cells related to retinal rods and cones) make up 95% of population
(b) astrocytes as neuroglial supporting cells = 5% of population
(c) fibrovascular stroma
(d) corpora arenacea = concentric calcifications appear in adolescence (in 40% of patients 17–29 years old)
[arenacea, *Latin* = sandy]

Location: midline
suspended from pineal stalk that is attached to upper aspect of posterior border of 3rd ventricle
(a) inferior to splenium + vein of Galen
(b) superior to tentorium + superior colliculi
(c) posterior to cistern of velum interpositum (= cistern of transverse fissure)
(d) surrounded by CSF of quadrigeminal cistern

Size: 10–14 mm
√ enhancement with contrast ← absence of blood-brain barrier



PETROUS APEX

= pyramid-shaped structure formed by medial portion of temporal bone

Borders:

lateral: inner ear
medial: petro-occipital fissure
anterior: petrosphenoidal fissure + internal auditory canal
posterior: posterior cranial fossa

Surfaces: superiorly: middle cranial fossa + Meckel cave + ICA
inferiorly: jugular bulb + inferior petrosal sinus

Division:

(a) large anterior portion (bone marrow):
- › filled with marrow (60%)
- › pneumatized (33%) with communication to mastoid and middle ear cavity; asymmetric (5–10%)

N.B.: with asymmetry high signal intensity fatty marrow may be mistaken for a cholesterol granuloma!

- › sclerotic (7%)

(b) small posterior portion (otic capsule)

N.B.: with asymmetry high–signal-intensity marrow in nonsclerotic apex can mimic a lesion!

Vascular & neural channels:

(1) **Petrous carotid canal** in anterior portion of petrous apex (= horizontal portion of petrous segment of ICA), passes over foramen lacerum
(2) **Internal auditory canal** (IAC) in midportion of petrous apex for vestibulocochlear + facial nn., anterolateral from cerebellopontine angle cistern
(3) **Dorello canal** extends through posteromedial portion of petrous apex, contains abducens n. (CN VI)

(4) **Subarcuate canal** = petromastoid canal between crura of superior semicircular canal, contains subarcuate a. (blood supply to bony labyrinth + facial canal + mastoid antrum)
(5) **Singular canal** extends from posterior margin of IAC to junction of ampulla of posterior semicircular canal and vestibule, contains singular n. (= division of inferior vestibular n. that innervates ampulla of posterior semicircular canal)
(6) **Meckel cave** = dura-lined diverticulum creating smooth depression along anterior aspect of petrous apex, contains trigeminal (gasserian / semilunar) ganglion + rootlets of trigeminal n. (CN V)

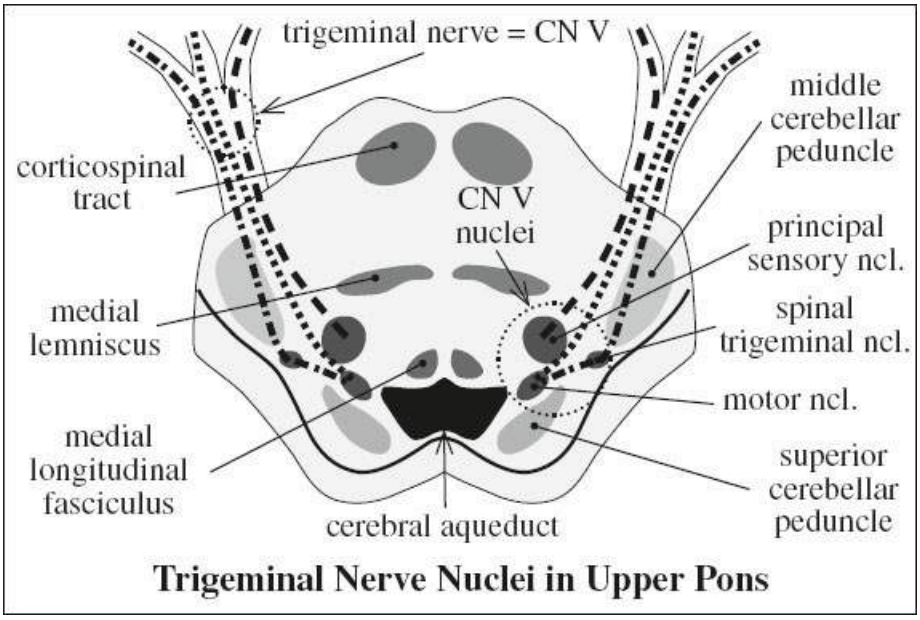
TRIGEMINAL NERVE (CN V)

Function: (1) sensation to face
(2) motor innervation to muscles of mastication

Nuclei: (3 sensory + 1 motor nucleus)
(1) mesencephalic nucleus: <u>proprioception</u> extends to level of inferior colliculus

Cranial Nerves

#	*Name*	*Nuclei*	*Function*
I	Olfactory	Anterior olfactory nucleus	Transmits sense of smell; Located in olfactory foramina of ethmoid
II	Optic	Lateral geniculate nucleus	Transmits visual information to brain; Located in optic canal
III	Oculomotor	Oculomotor nucleus, Edinger-Westphal nucleus	Innervates levator palpebrae superioris, superior rectus, medial rectus, inferior rectus, and inferior oblique; Located in superior orbital fissure
IV	Trochlear	Trochlear nucleus	Innervates superior oblique muscle; Located in superior orbital fissure
V	Trigeminal	Principal sensory trigeminal nucl., Spinal trigeminal nucleus, Mesencephalic trigeminal nucl., Trigeminal motor nucleus	Receives sensation from face and innervates muscles of mastication; Located in superior orbital fissure (ophthalmic branch), foramen rotundum (maxillary branch), and foramen ovale (mandibular branch)
VI	Abducens	Abducens nucleus	Innervates lateral rectus; Located in superior orbital fissure
VII	Facial	Facial nucleus, Solitary nucleus, Superior salivary nucleus	Provides motor innervation to muscles of facial expression and stapedius, receives special sense of taste from anterior ⅔ of tongue, and provides secretomotor innervation to salivary glands (except parotid) and lacrimal gland; Located and runs through internal acoustic canal to facial canal and exits at stylomastoid foramen
VIII	Vestibulocochlear (vestibular + statoacustic n .)	Vestibular nucleus, Cochlear nucleus.	Senses sound, rotation and gravity; Located in internal acoustic canal
IX	Glossopharyngeal	Nucleus ambiguus, Inferior salivary nucleus, Solitary nucleus	Receives taste from posterior ⅓ of tongue, provides secretomotor innervation to parotid gland, and provides motor innervation to stylopharyngeus (essential for tactile, pain, and thermal sensation). Sensation is relayed to opposite thalamus and some hypothalamic nuclei. Located in jugular foramen
X	Vagus	Nucleus ambiguus, Dorsal motor vagal nucleus, Solitary nucleus	Supplies branchiomotor innervation to most laryngeal and pharyngeal muscles; provides parasympathetic fibers to nearly all thoracic and abdominal viscera down to the splenic flexure; and receives special sense of taste from epiglottis. Major function: controls muscles for voice and resonance and soft palate. Located in jugular foramen
XI	Accessory	Nucleus ambiguus, Spinal accessory nucleus	Controls muscles of neck and overlaps with functions of vagus; Located in jugular foramen
XII	Hypoglossal	Hypoglossal nucleus	Provides motor innervation to muscles of tongue and other glossal muscles. Important for swallowing (bolus formation) and speech articulation. Located in hypoglossal canal
	mnemonic:	On Old Olympus Towering Tops A Finn And German Viewed Some Hops	



Trigeminal Nerve Nuclei in Upper Pons

(2) main sensory nucleus: tactile sensation
(3) motor nucleus: motor innervation
(4) spinal nucleus: pain + temperature sensation extends to level of 2nd cervical vertebra

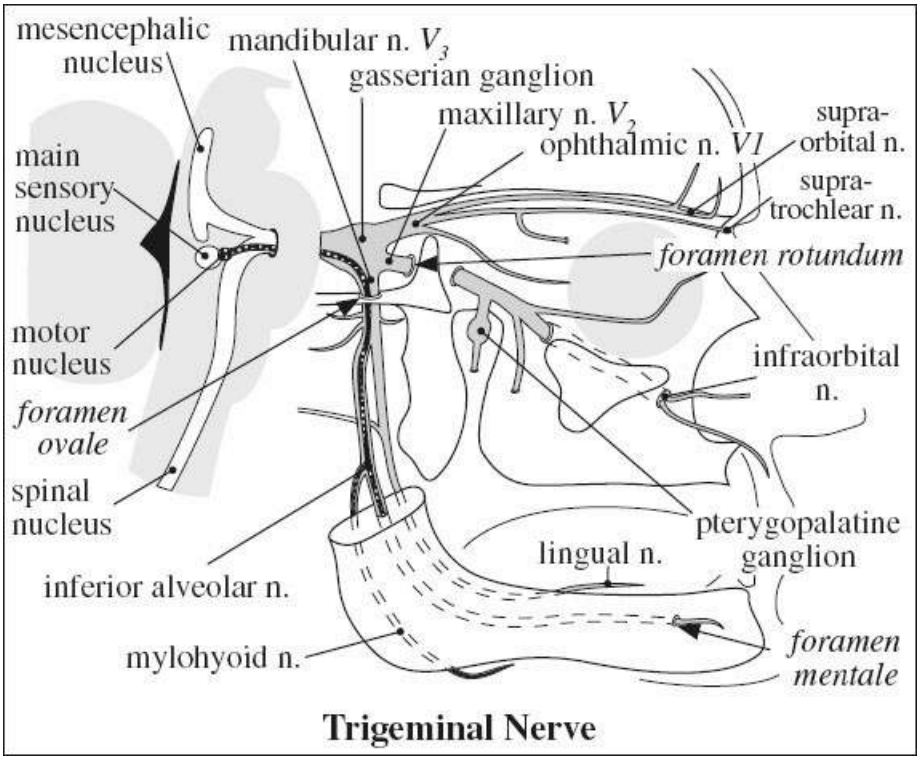
Location: tegmentum of lateral pons, along anterolateral aspect of 4th ventricle

Segments:

(1) cisternal portion exits lateral pons traversing prepontine cistern before passing underneath the tentorium to enter the middle cranial fossa at the petrous apex
(2) preganglionic portion passes through porus trigeminus (= opening in dura) into the Meckel cave (trigeminal cistern), where it synapses with trigeminal (= gasserian / semilunar) ganglion
Meckel cave: CSF-filled subarachnoid space formed by dura mater + leptomeninges at the most anteromedial portion of petrous pyramid
Gasserian ganglion: contains cell bodies of sensory fibers except those for proprioception
(3) postganglionic portion → trifurcation

Trifurcation into 3 principal branches:

(1) **Ophthalmic nerve** (V_1)
Course: travels within lateral cavernous sinus inferior to cranial nerve IV and superior to V_2
Exit: superior orbital fissure
Supply: sensory innervation of scalp, forehead, nose, globe
Division: lacrimal, frontal, nasociliary nn.
• mediates afferent aspect of corneal reflex



(2) **Maxillary nerve** (V_2)

Course: travels within lateral cavernous sinus inferior to V_1

Exit: through foramen rotundum into pterygopalatine fossa

Supply: sensory innervation of middle third of face, upper teeth

Main trunk: infraorbital nerve

(3) **Mandibular nerve** (V_3)

Course: NOT through cavernous sinus

Exit: from Meckel cave through foramen ovale into masticator space

Supply:

(a) sensory innervation of lower third of face, tongue, floor of mouth, jaw

(b) motor innervation of muscles of mastication (masseter, temporalis, medial + lateral pterygoid), mylohyoid m., anterior belly of digastric m., tensor tympani m., tensor veli palatini m.

Exits from Meckel cave:

mnemonic: **S**tanding **R**oom **O**nly

V_1 = **S**uperior orbital fissure

V_2 = Foramen **R**otundum

V_3 = Foramen **O**vale

FACIAL NERVE (CN VII)

Function: mixed nerve responsible for motor innervation of muscles of facial expression + taste of anterior ⅔ of tongue + parasympathetic innervation of lacrimal and submandibular glands

1. Lacrimation (via greater superficial petrosal nerve)
2. Stapedius reflex: sound damping
3. Taste of anterior ⅔ of tongue (via chorda tympani nerve to lingual nerve)
4. Facial expression (platysma + orbicularis oculi)
5. Secretion of lacrimal + submandibular + sublingual glands (via **nervus intermedius**)

Nuclei: one motor nucleus + two sensory nuclei located within ventrolateral pons

(1) Motor nucleus: ventrolateral deep in reticular formation of the caudal part of the pons
Innervation to: stapedius m., stylohyoid m., posterior belly of digastric m., occipitalis m., buccinator, muscles of facial expression, platysma

(2) Nucleus solitarius (sensory nucleus)
› **nervus intermedius**: sensation from anterior ⅔ of tongue, skin on + adjacent to ear

(3) Superior salivatory nucleus (parasympathetic secretomotor innervation)
› greater petrosal n.: secretion of lacrimal glands, nasal cavity, paranasal sinuses
› chorda tympani: submandibular + sublingual glands

Exit from brainstem: 2 separate nerve roots traversing cerebellopontine angle cistern
(1) motor root anteriorly
(2) sensory root posteriorly

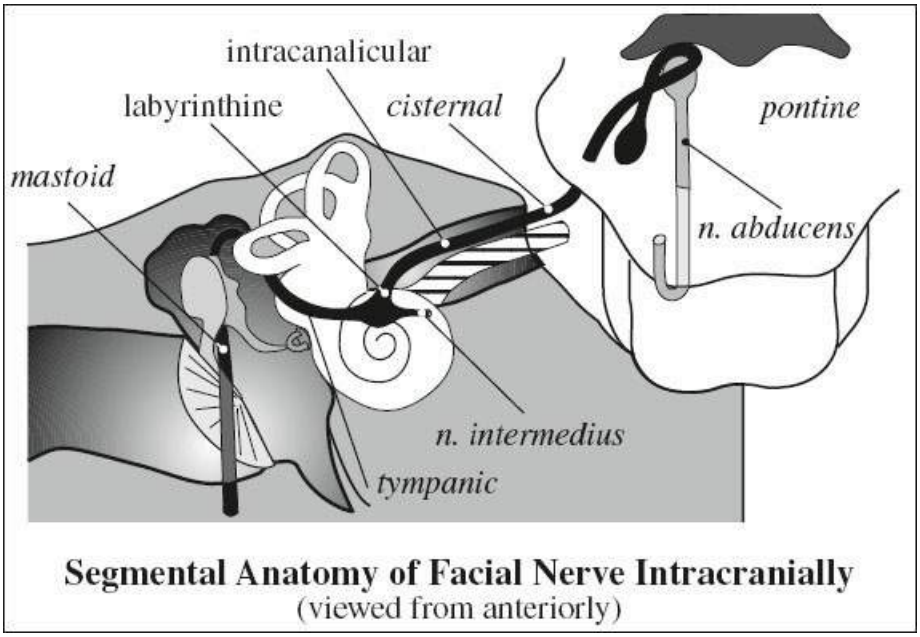
Segments: circuitous course

(a) intracranial segment from brainstem to porus acusticus internus:
› pontine segment:
» motor root fibers of facial n. run dorsomedially towards 4th ventricle
» curve anterolaterally to hook around upper pole of abducens nucleus (= **geniculum**)
» form **facial colliculus** (= elevation in floor of 4th ventricle)
» nerve descends anterolaterally through reticular formation + continues lateral from corticospinal tract
› cisternal segment:
» facial n. exits from lateral aspect of brainstem at pontomedullary junction
» courses anterolaterally in **cerebellopontine angle cistern** to internal auditory canal (IAC) above crista falciformis

(b) intracanalicular (IAC) segment

(c) labyrinthine segment emerges from anterosuperior aspect of IAC
› 3–4 mm short segment of facial n. traveling anterolaterally within its own bony canal (= **fallopian canal**) and curving anteromedially over top of cochlea
› terminates in anteromedial genu (**geniculate ganglion**) where greater superficial petrosal n. branches pass anteromedially to carry parasympathetic fibers to lacrimal gland

(d) tympanic segment
= 12 mm long segment from geniculate ganglion to posterior genu underneath lateral semicircular canal
› horizontal segment: facial n. at **first (anterior) genu** makes a 130° turn posteriorly + horizontally along medial wall of mesotympanum lateral to vestibule between lateral semicircular canal (above) and oval window (below) to reach sinus tympani
√ "snake eyes" on COR CT at level of cochlea corresponding to proximal portion of tympanic + distal portion of labyrinthine segments



Segmental Anatomy of Facial Nerve Intracranially
(viewed from anteriorly)

√ inferior to lateral semicircular canal + superolateral to oval window on COR CT at level of oval window

√ anterior genu superomedial to cochlear promontory

› pyramidal segment: at sinus tympani facial n. turns gently posteroinferiorly to form **second / posterior genu** in pyramidal eminence; gives off the nerve for the stapedius muscle

(e) mastoid segment (longest segment with 15–20 mm)

facial n. assumes a more vertical position + descends just behind the posterior wall of the tympanic cavity from posterior genu through anterior mastoid (= medial wall of aditus ad antrum) + gives off chorda tympani just prior to exit from skull base through **stylomastoid foramen**

(f) parotid / extracranial segment

facial n. travels forward between superficial + deep lobes of parotid gland lateral to styloid process + external carotid a. + retromandibular v.

Branches:

(1) **Greater superficial petrosal nerve** (parasympathetic + motor fibers) arises from geniculate ganglion, runs anteromedially, and exits at the facial hiatus on the anterior surface of the temporal bone + passes under Meckel cave near foramen lacerum

› forms **vidian nerve** after receiving sympathetic fibers from deep petrosal nerve, which surrounds the internal carotid artery

(2) **Stapedial nerve** (motor fibers) arises from proximal descending facial n.

(3) **Chorda tympani** (sensory + parasympathetic fibers) leaves facial n. about 5–6 mm above stylomastoid foramen from the lateral aspect of the mastoid segment of the facial nerve

› ascends in subtle curvature superoanteriorly in a bony canal (= canaliculus chorda tympani)

› perforates posterior wall of tympanic cavity

› proceeds anteriorly within tympanic cavity and crosses medial to handle of malleolus

underneath mucosa of tympanic cavity

› exits temporal bone through a minute canal (= anterior canaliculus) near petrotympanic fissure

› joins lingual nerve (= branch of V_2) containing sensory taste fibers from anterior ⅔ of tongue + secretomotor fibers for submandibular + sublingual glands

VESTIBULOCOCHLEAR NERVE (CN VIII)

Function: sensory nerve unified only within cisternal segment

Two main components:

(1) **Vestibular nerve** for balance

Course: arises from the Scarpa ganglion in IAC fundus

Division:

› central fibers coalesce to form **superior & inferior vestibular nerves**

Location: posterior aspect of IAC; components separated from each other by crista falciformis

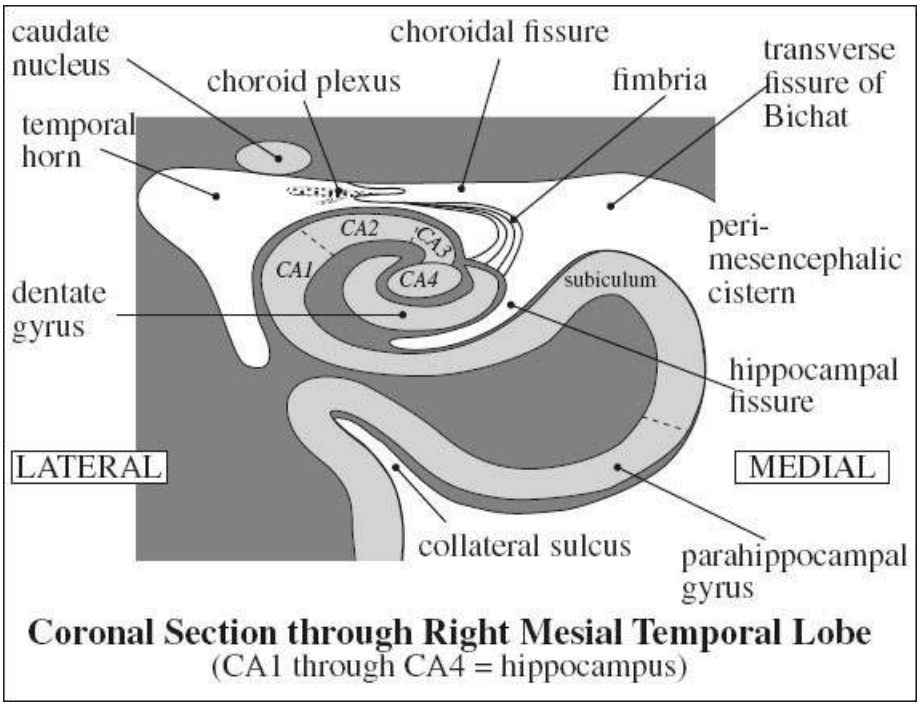
› peripheral fibers innervate sensory epithelium of utricle, saccule, and semicircular canals

(2) **Cochlear nerve** for hearing

Dysfunction:

damage from ***superficial siderosis*** ← hemosiderin ← slow / repeated episodes of subarachnoid hemorrhage exposing its long cisternal segment

√ deposition of hemosiderin within cerebellar folia + surrounding brainstem + along cisternal segment of CN VIII visible on gradient-echo T2*-weighted MR images



Coronal Section through Right Mesial Temporal Lobe
(CA1 through CA4 = hippocampus)

PERIHIPPOCAMPAL FISSURES

1. Transverse fissure of Bichat
   = lateral extension of perimesencephalic cistern separating thalamus superiorly from parahippocampal gyrus inferiorly
2. Choroidal fissure
   = superior lateral extension of transverse fissure extending superior to hippocampus
3. Hippocampal fissure
   = inferior lateral extension of transverse fissure extending between hippocampus and parahippocampal gyrus
4. Temporal horn of lateral ventricle
   = lateral margin of hippocampus; separated from transverse fissure by fimbria + choroid plexus
   ◊ Does not communicate with transverse fissure

Uncus [*uncus*, Latin = hook]
= medial protrusion near ventral surface of parahippocampal gyrus (= innermost gyrus) of temporal lobe
Function: part of primary olfactory area

CEREBROSPINAL FLUID

Total volume: 50 mL in newborn, 150 mL in adult
Composition: inorganic salts like those in plasma, traces of protein + glucose
Production: 0.3–0.4 mL/min resulting in 500 mL/day; secreted into ventricles by choroid plexuses (80–90%), 10–20% from parenchyma of cerebrum and spinal cord
Circulation:
from ventricles through foramina of Magendie + Luschka of 4th ventricle into cisterna magna + basilar cisterns; 80% of CSF flows initially into suprasellar cistern + cistern of lamina terminalis, ambient / superior cerebellar cisterns → eventually ascending over superolateral aspects of each hemisphere; 20% initially enters spinal subarachnoid space + eventually recirculates into cerebral subarachnoid space
Absorption: into venous system by
(a) arachnoid villi of superior sagittal sinus (villi behave as one-way valves with an opening pressure between 20–50 mm of CSF)
(b) cranial + spinal nerves with eventual absorption by lymphatics (50%)
(c) prelymphatic channels of capillaries within brain parenchyma
(d) vertebral venous plexuses, intervertebral veins, posterior intercostal + upper lumbar veins into azygos + hemiazygos veins
Opening pressure: 80–180 mm H_2O

Cerebral Aqueduct

pulsatile flow (← brain motion during cardiac cycle) + net outflow into 4th ventricle; diameter of 2.6–4.2 mm; peak outflow velocity of 6–51 mm/sec; inflow velocity of 3–28 mm/sec

CEREBRAL VESSELS

Common Carotid Artery

- 70% of blood flow is delivered to ICA

√ shares waveform characteristics of both internal + external carotid arteries

√ velocity increases toward the aorta (9 cm/sec for each cm of distance from the carotid bifurcation)

Carotid Bifurcation

= physiologic stenosis ← inertial forces of blood flow diverting main-flow stream from midvessel to a path along vessel margin at flow divider

Location: lateral to upper border of thyroid cartilage; at level of C3-4 intervertebral disk

Branches: ECA arises anterior + medial to ICA (95%)

External Carotid Artery Branches

mnemonic: **A**ll **S**ummer **L**ong **E**mily **O**gled **P**eter's **S**porty **I**suzu

Ascending pharyngeal artery
Superior thyroid artery
Lingual artery
External maxillary = facial artery
Occipital artery
Posterior auricular artery
Superficial temporal artery
Internal maxillary artery

Internal Carotid Artery

A. CERVICAL SEGMENT

ascends posterior and medial to ECA; enters carotid canal of petrous bone; NO branches

Carotid bulb = carotid sinus:

= dilated proximal part of ICA with thinner media + thicker adventitia containing many receptor endings of glossopharyngeal nerve

Function: baroreceptor responsive to changes in arterial blood pressure

- hypersensitive carotid sinus

= slight touch / head movement initiates

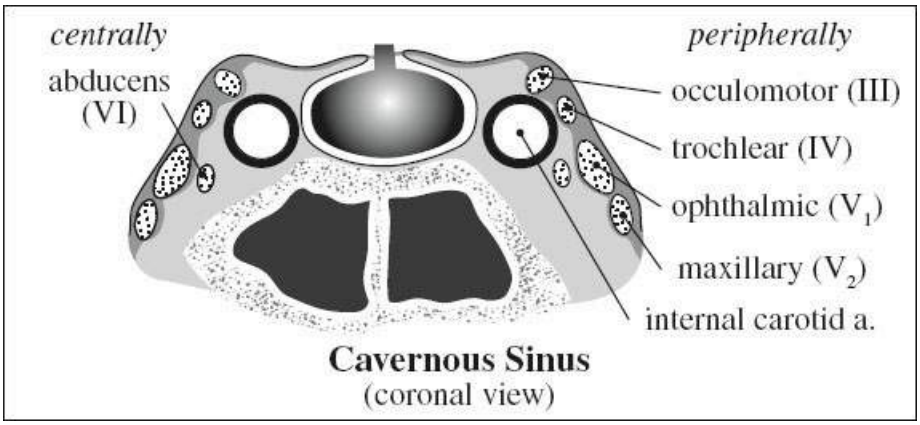
(a) vasodilatation with drop in blood pressure

(b) vagal stimulation with sinoatrial / atrioventricular cardiac block

√ stagnant eddy that rotates at outer vessel margin

B. PETROUS SEGMENT

ascends briefly in carotid canal → bends anteromedially in a horizontal course (anterior to tympanic cavity and cochlea); exits near petrous apex through posterior portion of foramen lacerum; ascends to juxtasellar location where it pierces dural layer of cavernous sinus



Branches:

1. **Caroticotympanic a.**: to tympanic cavity, anastomoses with anterior tympanic branch of maxillary a. + stylomastoid a.
2. **Pterygoid (vidian) a.**: through pterygoid canal; anastomoses with recurrent branch of greater palatine a.

C. CAVERNOUS SEGMENT

ascends to posterior clinoid process → then turns anteriorly + superomedially through cavernous sinus; exits medial to anterior clinoid process piercing dura

Branches:

1. **Meningohypophyseal trunk**
   (a) tentorial branch
   (b) dorsal meningeal branch
   (c) inferior hypophyseal branch
2. **Anterior meningeal a.**: supplies dura of anterior fossa; anastomoses with meningeal branch of posterior ethmoidal a.
3. Cavernous rami supply trigeminal ganglion, walls of cavernous + inferior petrosal sinuses

D. SUPRACLINOID SEGMENT

ascends posterior + lateral between oculomotor + optic nerve

Branches:

mnemonic: OPA

Ophthalmic a.
Posterior communicating a.
Anterior choroidal a.

1. **Ophthalmic a.** exits from ICA medial to anterior clinoid process, travels through optic canal inferolateral to optic nerve
   (a) recurrent meningeal branch: dura of anterior middle cranial fossa
   (b) posterior ethmoidal a.: supplies dura of planum sphenoidale
   (c) anterior ethmoidal a.
2. **Superior hypophyseal a.**: optic chiasm, anterior lobe of pituitary
3. **Posterior communicating a.** (pCom)
4. **Anterior choroidal a.**
5. **Middle + anterior cerebral arteries** (MCA, ACA)

Carotid Siphon

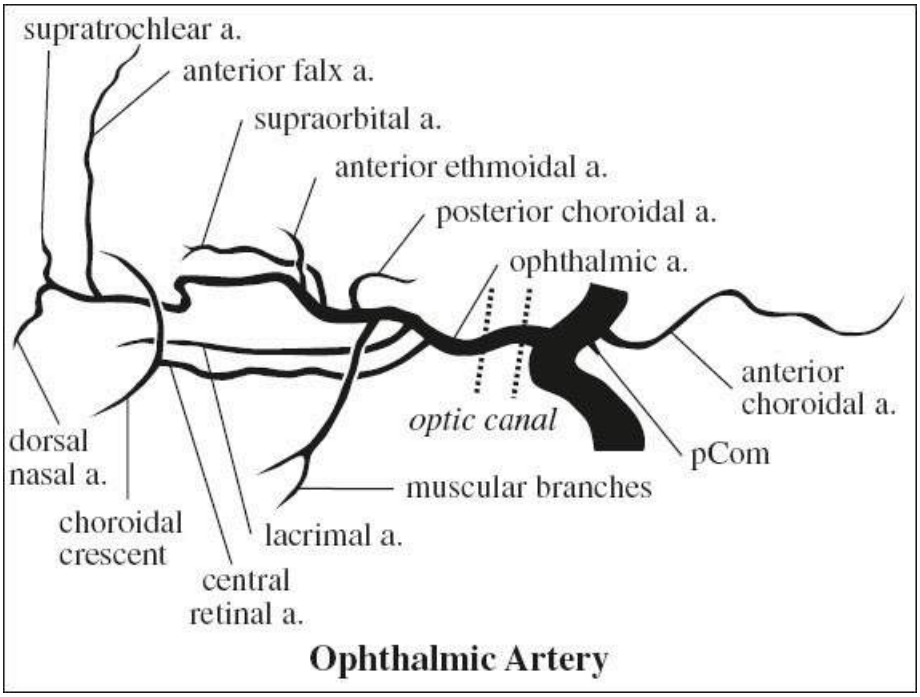
Flow direction: C4–C1

(a) C4 segment = before origin of ophthalmic a.

(b) C3 segment = genu of ICA

(c) C2 segment = supraclinoid segment after origin of ophthalmic a.

(d) C1 segment = terminal segment of ICA between pCom + ACA



Ophthalmic Artery

Duplex Identification of Carotid Arteries		
Criteria	*External Carotid Artery*	*Internal Carotid Artery*
Size	usually smaller than ICA	usually larger than ECA
Location	oriented medially + anteriorly toward face	oriented laterally + posteriorly toward mastoid process (*mnemonic:* IAC vis-à-vis ECA positioned like helix vis-à-vis tragus of your ear)
Branches	gives off arterial branches (superior thyroid artery as 1st branch)	NO arterial branches
Waveform	high-resistance flow pattern supplying capillary beds in skin + muscle: √ forward systolic component √ early diastolic flow reversal, occasionally followed by another component √ little / no flow in late diastole	low-resistance waveform pattern supplying capillary bed in brain: √ high-velocity forward systolic component √ sustained strong forward flow in diastole √ stagnant eddy with flow reversal opposite to flow divider in carotid bulb
Maneuver	oscillations on temporal tap maneuver	

Anterior Cerebral Artery (ACA)

A1 (horizontal) segment between origin and anterior communicating a. (aCom)

(a) inferior branches
supply superior surface of optic nerve + chiasm

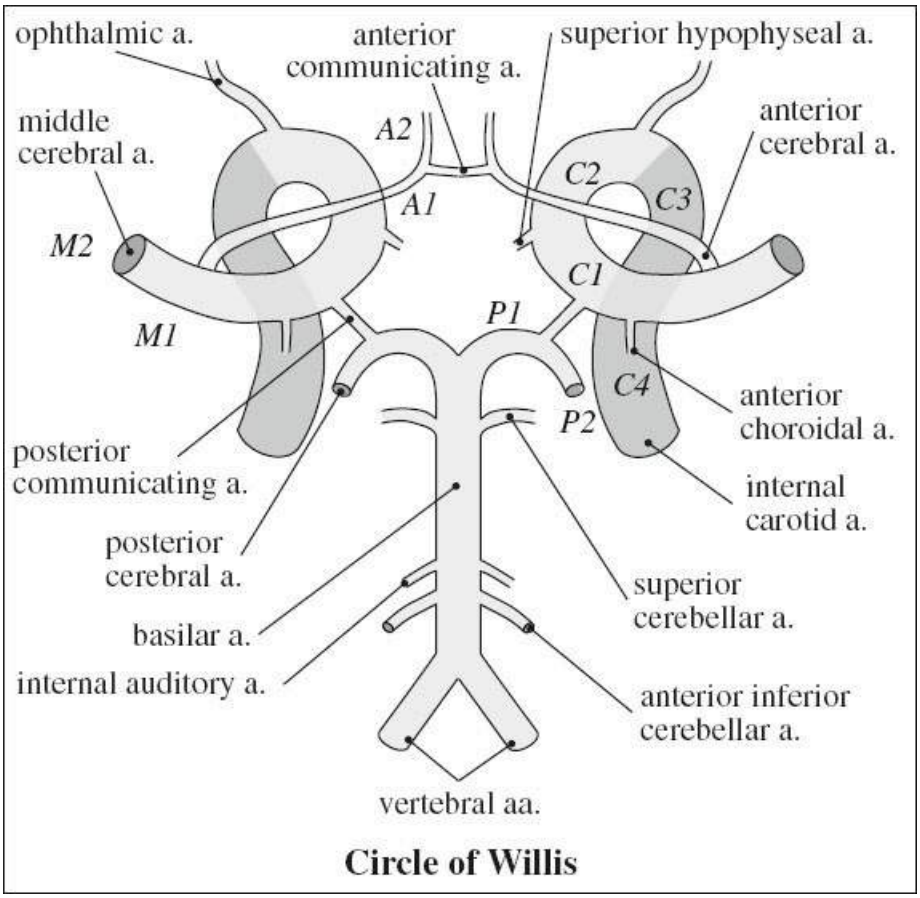
(b) superior branches penetrate brain to supply anterior hypothalamus, septum pellucidum, anterior commissure, fornix columns, anterior inferior portion of corpus

striatum

(c) medial lenticulostriate artery (largest striatal artery) = **recurrent artery of Heubner** for anteroinferior portion of head of caudate, putamen, anterior limb of internal capsule

A2 (interhemispheric) segment after origin of anterior communicating a. (aCom); ascends in cistern of lamina terminalis

Branches:



Circle of Willis

1. **Medial orbitofrontal a.:** along gyrus rectus
2. **Frontopolar a.**
3. **Callosomarginal a.**: within cingulus gyrus
4. **Pericallosal a.**: over corpus callosum within callosal cistern
   (a) Superior internal parietal a.: anterior portion of precuneus + convexity of superior parietal lobule
   (b) Inferior internal parietal a.
   (c) Posterior pericallosal a.

   from callosomarginal / pericallosal artery:
   - anterior + middle + posterior internal frontal aa.
   - paracentral a.: supplies pre- + postcentral gyri

Supply: anterior ⅔ of medial cerebral surface + 1 cm of superomedial brain over convexity

Middle Cerebral Artery

= largest branch of ICA arising lateral to optic chiasm

M1 (horizontal) segment = courses in lateral direction

Branches: lateral lenticulostriate aa.

Supply: part of head and body of caudate, globus pallidus, putamen, and posterior limb of internal capsule

M2 (sylvian) segment = enters sylvian fissure just ventral to anterior perforated substance; divides into superior and inferior divisions with 2 / 3 / 4 branches

Branches: temporal lobe and insular cortex (sensory language area of Wernicke), parietal lobe (sensory cortical areas), inferolateral frontal lobe

M3 (cortical) segment = distal branches lateral to insular cortex = candelabra [*candelabrum*, Latin = decorative candlestick / lamp with several arms or branches]

Branches:

1. **Anterior temporal artery**
2. **Ascending frontal artery** / prefrontal a.
3. **Precentral artery** = pre-Rolandic a.
4. **Central artery** = Rolandic a.
5. **Anterior parietal artery** = post-Rolandic a.
6. **Posterior parietal artery**
7. **Angular artery**
8. **Middle temporal artery**
9. **Posterior temporal artery**
10. **Temporooccipital artery**

Supply: lateral cerebrum, insula, anterior + lateral temporal lobe

Posterior Cerebral Artery

originates from bifurcation of basilar artery within interpeduncular cistern (in 15% as a direct continuation of posterior communicating artery); lies above oculomotor nerve and circles midbrain above the tentorium cerebelli

Branches:

1. Mesencephalic perforating branches: tectum + cerebral peduncles
2. Posterior thalamoperforating aa.: midline of thalamus + hypothalamus
3. Thalamogeniculate aa.: geniculate bodies + pulvinar
4. Posterior medial choroidal a.: circles midbrain parallel to PCA; enters lateral aspect of quadrigeminal cistern; passes laterally and above pineal gland and enters roof of 3rd ventricle; supplies quadrigeminal plate + pineal gland
5. Posterior lateral choroidal a.: courses laterally and enters choroidal fissure; anterior branch to temporal horn + posterior branch to choroid plexus of trigone and lateral ventricle + lateral geniculate body
6. Cortical branches:
   (a) Anterior inferior temporal artery
   (b) Posterior inferior temporal artery
   (c) Parietooccipital artery
   (d) Calcarine artery
   (e) Posterior pericallosal artery

Supply: medial + posterior temporal lobe, medial parietal lobe, occipital lobe

Thalamic Blood Supply

by multiple small vessels originating from Pcom + P1 and P2 segments of the PCAs

Territories:

(1) anterior: polar / thalamotuberal arteries ← Pcom
(2) paramedian: paramedian / thalamoperforating arteries ← P1 segment of PCA
(3) inferolateral: thalamogeniculate arteries ← P2 segment of PCA
(4) posterior: posterior choroidal arteries ← P2 segment

Anatomic variant (uncommon):

Artery of Percheron = single dominant thalamoperforating artery supplying both medial thalami (with variable contribution to rostral midbrain)

Occlusion:

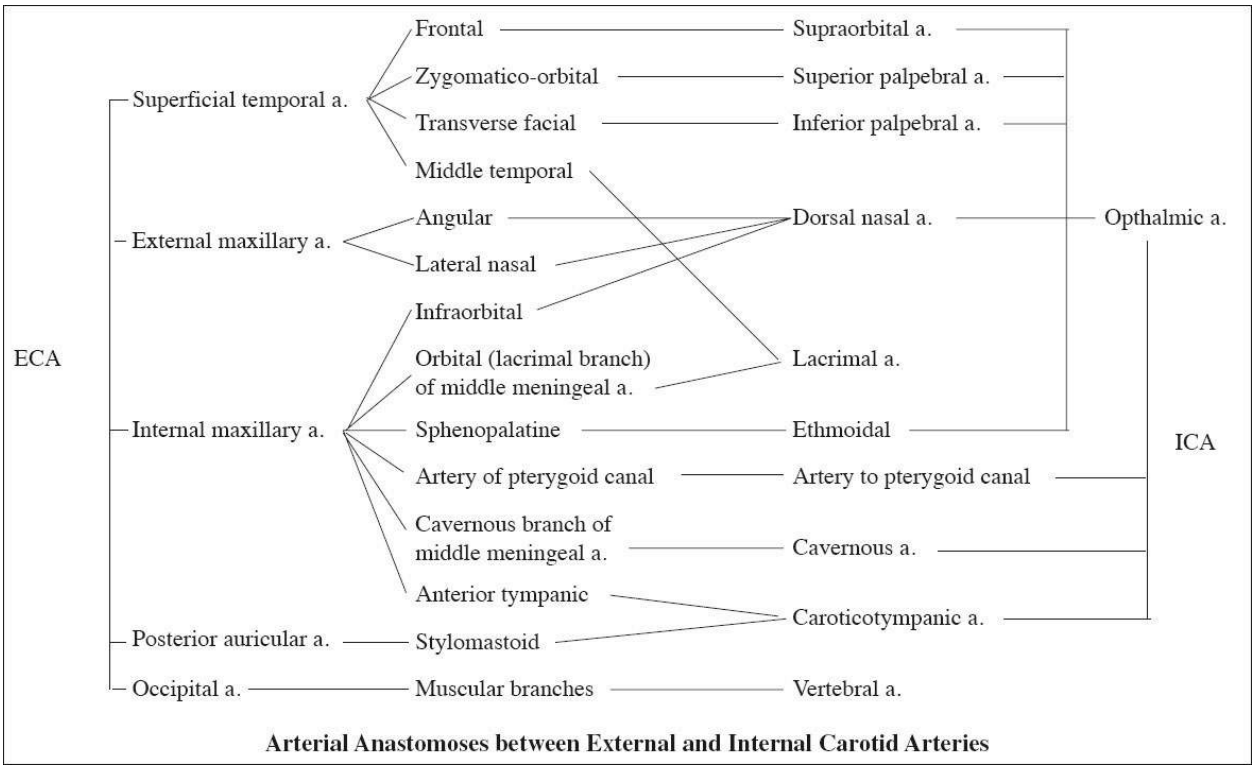
√ CHARACTERISTIC bilateral paramedian thalamic infarcts ± midbrain involvement

Arterial Anastomoses of the Brain

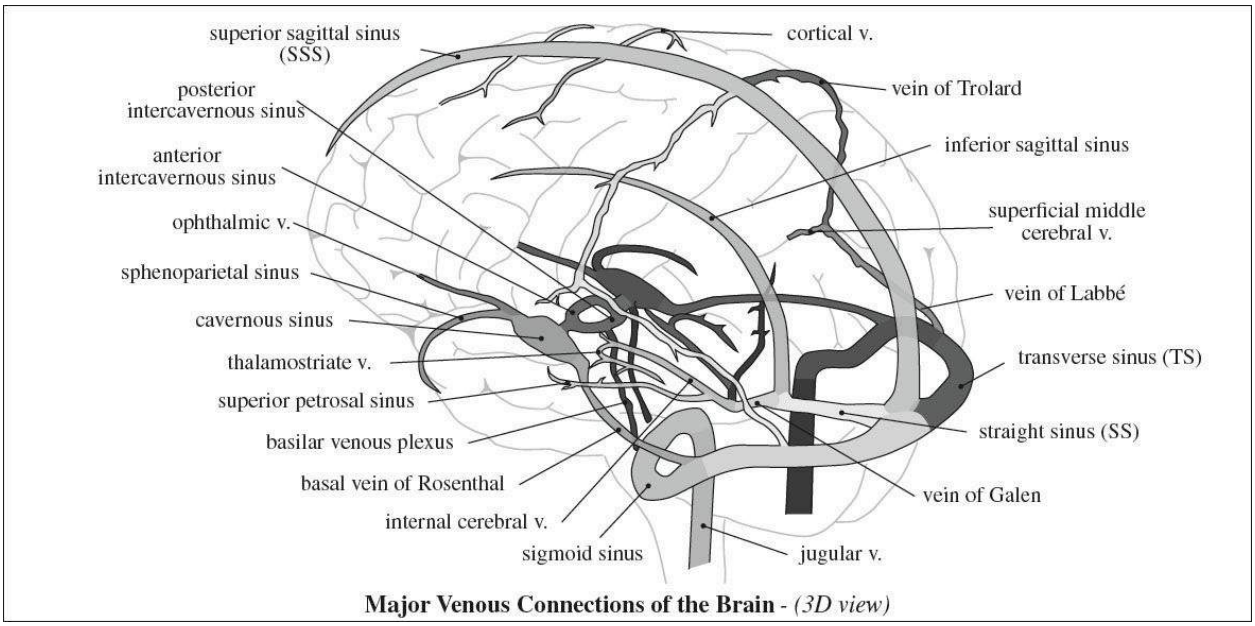
Anastomoses via Arteries at the Base of the Brain

A. Circle of Willis
   1. Right ICA ↔ right ACA ↔ aCom ↔ left ACA ↔ left ICA
   2. ICA ↔ pCom ↔ basilar a.
   3. ICA ↔ anterior choroidal a. ↔ posterior choroidal a. ↔ PCA ↔ basilar a.

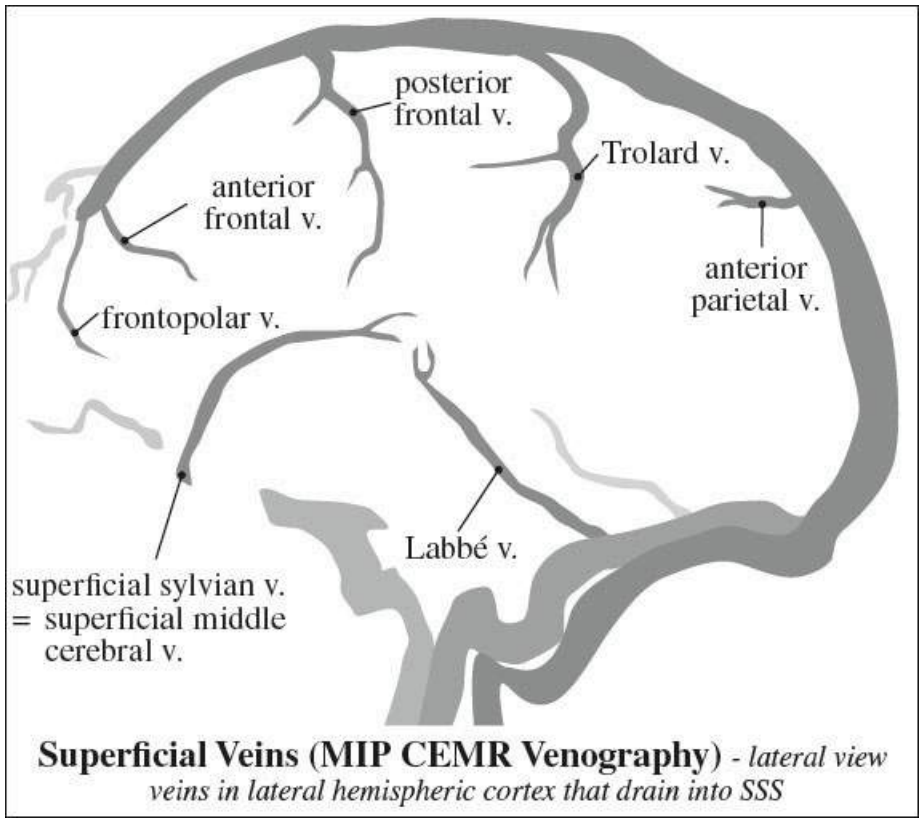
B. Developmental anomaly four transient embryonal carotid-basilar anastomoses named according to their corresponding cranial nerves that regress in the following sequence:
   1. **Primitive acoustic (otic) artery**
      = arterial connection between petrous portion of ICA within carotid canal + proximal basilar artery / posterior inferior cerebellar a.
      √ traverses internal auditory canal (with CN VIII)
   2. **Primitive hypoglossal artery**
      = arterial connection between the C1–C3 portion of ICA and proximal portion of basilar a.
      √ traverses hypoglossal canal (with CN XII)
   3. **Persistent primitive trigeminal artery**
      Frequency: ~ 1%
      √ short wide connection between the cavernous portion of ICA + basilar artery (between anterior inferior cerebellar a. and superior cerebellar a.)
      √ penetrates sella turcica (in 50%)



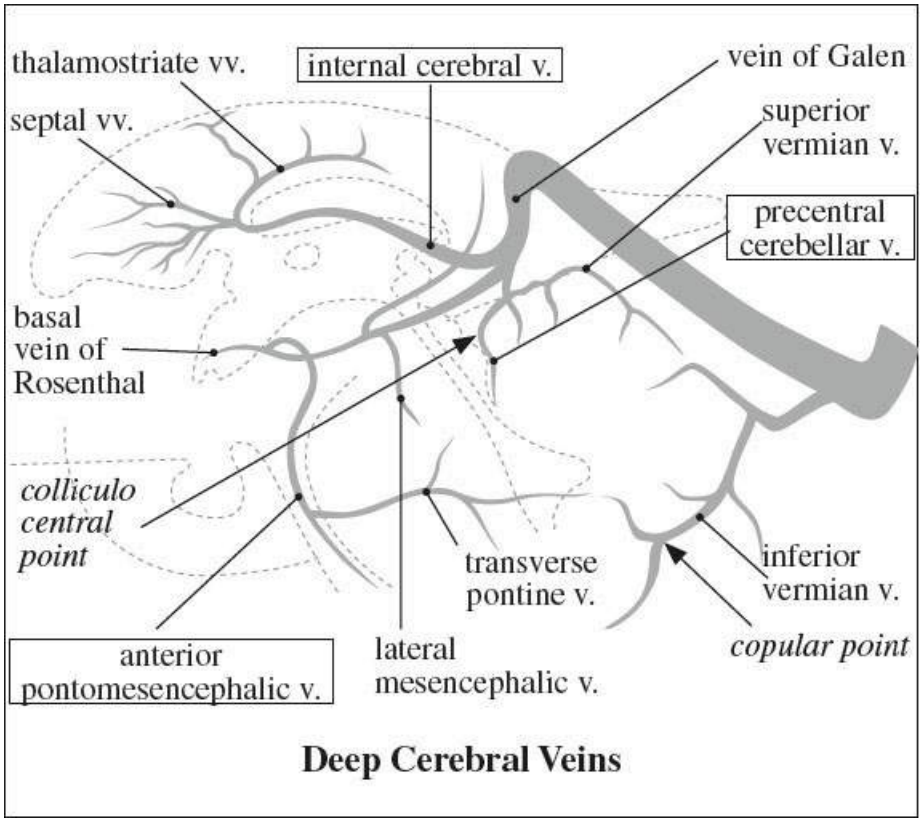
Arterial Anastomoses between External and Internal Carotid Arteries



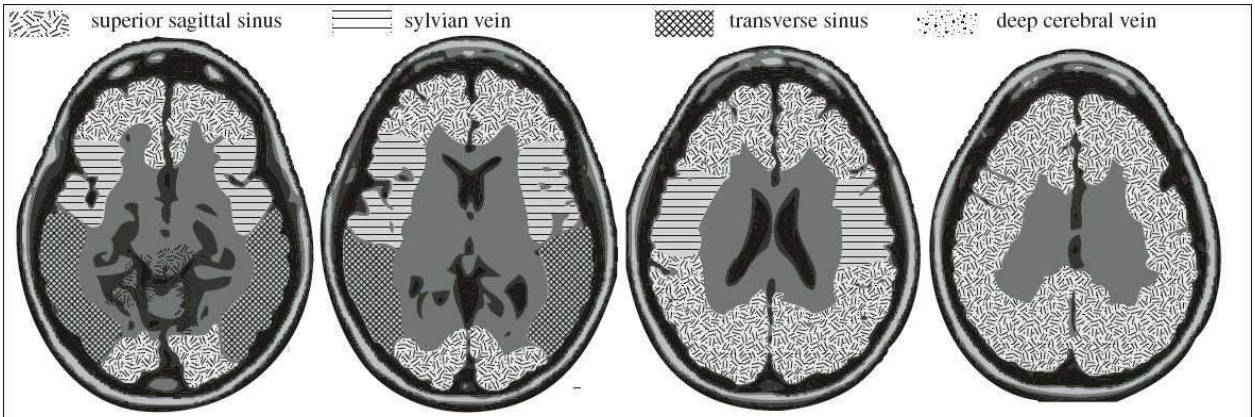
Major Venous Connections of the Brain - *(3D view)*



Superficial Veins (MIP CEMR Venography) - *lateral view*
veins in lateral hemispheric cortex that drain into SSS



Deep Cerebral Veins



Major Superficial Cortical Venous Drainage Territories of the Brain
(axial views from lower to higher levels)

√ enlargement of ipsilateral ICA
√ ectopic vessel crossing the pontine cistern to anastomose with basilar artery

4. **Proatlantal intersegmental artery**
   = arterial connection between CCA bifurcation / ECA (57%) / ICA at C2–C4 level (38%) and vertebral a. in suboccipital region
   √ traverses foramen magnum

Anastomoses via Surface Vessels

A. Leptomeningeal anastomoses of the cerebrum: ACA ↔ MCA ↔ PCA
B. Leptomeningeal anastomoses of the cerebellum: Superior cerebellar a. ↔ AICA ↔ PICA

Rete Mirabile

ECA ↔ middle meningeal a. / superficial temporal a. ↔ leptomeningeal aa. ↔ ACA / MCA

Cerebral Venous System

Histo: NO smooth muscle / venous valves → bidirectional flow

Dural Venous Sinuses

= major drainage pathway from cerebral veins into internal jugular veins; enclosed by leaves of dura

(a) Superior group draining majority of brain + skull

1. Superior sagittal sinus (SSS) collects superficial cerebral veins that drain cerebral convexities
   √ luminal surface of triangular shape
   √ traversed by septa → maintaining laminar flow + preventing venous reflux into cortical veins
2. Inferior sagittal sinus
3. Straight sinus (SS)
4. Occipital sinus small midline vein draining toward foramen magnum / into jugular fossa / suboccipital veins

Location: at attachment of falx cerebelli
√ may replace an aplastic transverse sinus

5. Transverse sinus (TS)
receives blood from the temporal, parietal, and occipital lobes
√ commonly asymmetric with right dominance
6. Sigmoid sinus
7. Confluence of sinuses (t**orcular herophili**) formed by union of the SSS +SS + TS
√ often asymmetric in appearance (see below)

(b) inferior group drains superficial cerebral veins + basal and medial parts of undersurface of the brain + orbits + sphenoparietal sinus + cavernous sinus

1. Cavernous sinus complex
2. Superior petrosal sinus
› arising from junction of transverse with sigmoid sinus
› extends along petrous ridge
3. Inferior petrosal sinus
› arising from distal portion of sigmoid sinus / jugular bulb
› extends along clivus

VARIANTS OF TORCULAR HEROPHILI

A. Codominant transverse sinuses (TS)
B. Dominant right TS
C. Dominant left TS
D. Segmental hypo- / aplasia of proximal left TS + inflow to distal segment of TS from vein of Labbé and tentorial tributaries
E. SSS drains into right TS + SS into left TS
F. high split of SSS + SS drains into both TS

Superficial Venous System

= SUPERFICIAL CORTICAL VEINS
= great variability in drainage territories
(a) ascending (= superiorly draining) veins named for cortical area that is drained
(b) descending (inferiorly draining) veins

1. Labbé vein
2. Sylvian (superficial middle cerebral) vein drains blood from peri-insular region into basal dural sinuses

◊ Relative luminal diameters of Trolard vein + Labbé vein + superficial sylvian vein are reciprocal

Location: subarachnoid space; traverse arachnoid mater + meningeal layer of dura mater to drain into dural venous sinus

Deep Venous System

= DEEP CEREBRAL VEINS
= centripetal drainage of hemispheric white matter and basal ganglia
(a) internal cerebral veins:

1. Internal cerebral vein ← thalamostriate v. ← corpus callosum drainage (from anterior to posterior)

(a) septal vein
(b) anterior caudate vein
(c) terminal vein

2. Basal vein of Rosenthal
3. Vein of Galen
4. Medullary + subependymal veins

(b) transcerebral veins:
draining cerebral white matter
√ typically not visualized due to small caliber

Infratentorial Venous System

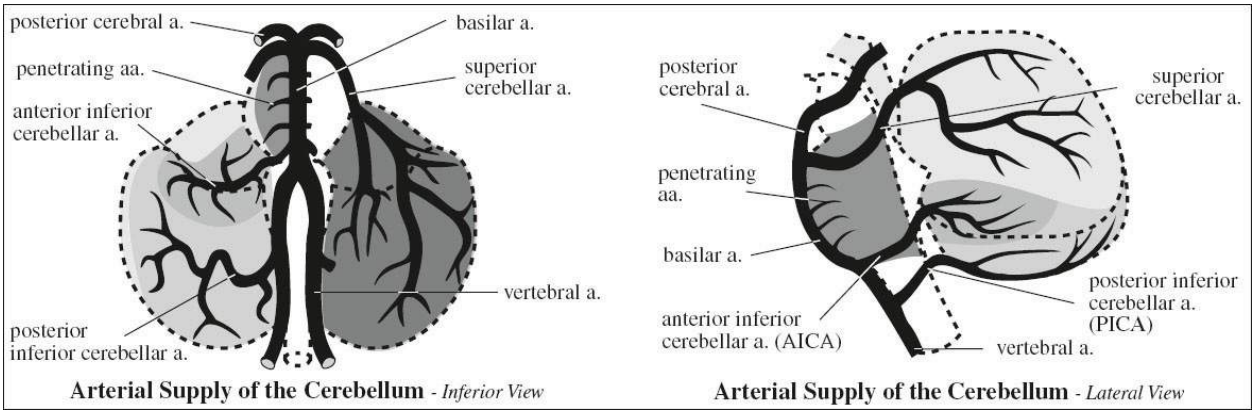
(a) superiorly into vein of Galen
(b) anteriorly into petrosal sinuses
(c) posteriorly into dural sinuses

Important vascular markers:

1. Pontomesencephalic v. = anterior border of brainstem
2. Precentral cerebellar v. = position of tectum
   ◊ Colliculocentral point = midpoint of Twining's line at knee of precentral cerebellar vein
3. Venous angle = acute angle at junction of thalamostriate with internal cerebral v. = posterior aspect of foramen of Monro
4. Internal cerebral vv. = demarcate caudad border of splenium of corpus callosum superiorly + pineal gland inferiorly
5. Copular point = junction of inferior + superior retrotonsillar tributaries draining cerebellar tonsils in region of copular pyramids of vermis

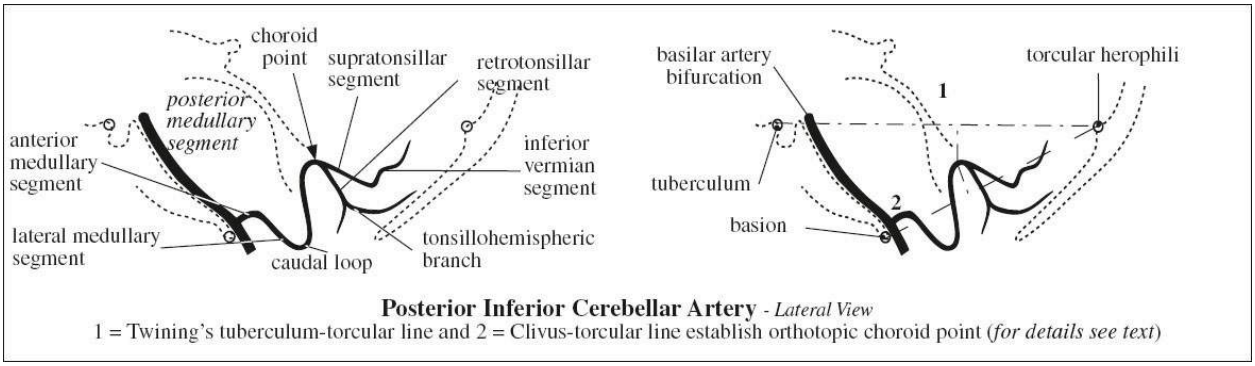
Arachnoid Granulations of Pacchioni

Prevalence: 66% (↑ in number + conspicuity with age)
Function: resorption of CSF
Location: within lacunae laterales of SSS
√ well-defined 2–9 mm focal filling defects within dural sinus
√ produce 13–15 mm calvarial impressions lateral to midline
√ iso- (⅓) / hypoattenuating (⅔) relative to parenchyma

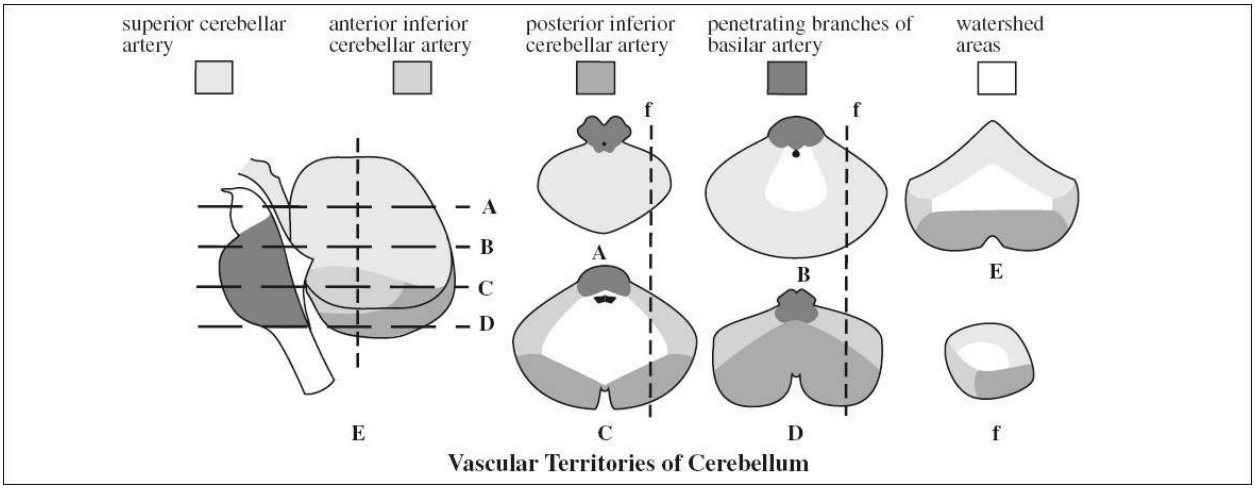


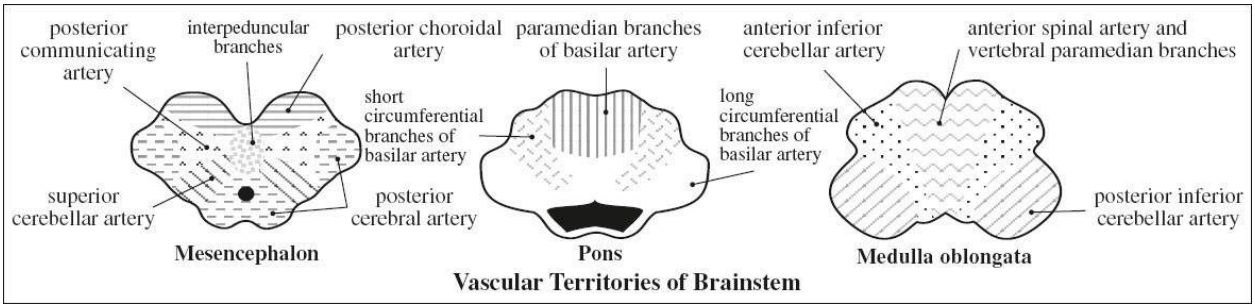
Arterial Supply of the Cerebellum - *Inferior View*

Arterial Supply of the Cerebellum - *Lateral View*



Posterior Inferior Cerebellar Artery - *Lateral View*
1 = Twining's tuberculum-torcular line and 2 = Clivus-torcular line establish orthotopic choroid point (*for details see text*)





CEREBELLAR VESSELS

Vertebral Artery

originates from subclavian a. proximal to thyrocervical trunk; left vertebral a. usually greater than right cerebral a.; left vertebral a. may originate directly from aorta (5%)

A. PREVERTEBRAL SEGMENT (V1)
ascends posterosuperiorly between longus colli + anterior scalene muscle; enters transverse foramen at C6
Branches: muscular branches

B. MIDCERVICAL SEGMENT (V2)
ascends through transverse foramina of C6 to C2 in close proximity to uncinate processes
Branches:

1. **Anterior meningeal a.**

C. ATLANTIC SEGMENT = Atlas loop (V3)
exits transverse foramen of atlas; passes posteriorly in a groove on superior surface of posterior arch of atlas; pierces atlanto-occipital membrane + dura mater to enter cranial cavity

Branches:

1. **Posterior meningeal branch** to posterior falx + tentorium

D. INTRACRANIAL SEGMENT (V4)
ascends anteriorly + laterally around medulla to reach midline at pontomedullary junction; anastomoses with contralateral side to form basilar artery at clivus

Branches:

1. Anterior + posterior spinal a.
2. Posterior inferior cerebellar a. (PICA)
3. Anterior inferior cerebellar a. (AICA)
4. Internal auditory a.
5. Superior cerebellar a.
6. Posterior cerebral a. (PCA)
7. Medullary + pontine perforating branches

◊ May terminate in common AICA-PICA trunk

Anterior Inferior Cerebellar Artery

= AICA = first branch of basilar artery

Supply: lateroinferior part of pons, middle cerebellar peduncle, floccular region, anterior petrosal surface of cerebellar hemisphere

◊ Quite variable course + vascular supply with reciprocal relation between vascular territories of AICA + PICA!

Posterior Inferior Cerebellar Artery

= PICA = last and largest branch of vertebral artery

Supply: inferoposterior surface of cerebellar hemisphere adjacent to occipital bone, ipsilateral part of inferior vermis, inferior portion of deep white matter only

Parts:

1. Premedullar segment = caudal loop around medulla, may descend below level of foramen magnum
2. Retromedullar segment = ascending portion up to the level of 4th ventricle and tonsils
3. Supratonsillar segment = the most cranial point is the choroidal point

P1 segment = horizontal segment between origin of PICA + pCom

P2 segment = segment downstream from pCom take-off

Variations: commonly asymmetric; hypoplastic / absent in 20% [vascular supply then provided by anterior inferior cerebellar artery (AICA)]

*Orthotopic **choroid point** established by:*

1. perpendicular line from choroid point onto Twining's line = TTT-line (Twining's Tuberculum-Torcular line) bisects TTT-line (length of anterior portion 52–60%)
2. perpendicular line from choroid point cuts CT-line (Clivus-Torcular line) < 1 mm

anterior / < 3 mm posterior to junction of anterior and middle thirds of CT-line

Superior Cerebellar Artery

= SCA = last but one branch of basilar artery

Supply: superior aspect of cerebellar hemisphere (tentorial surface), ipsilateral superior vermis, largest part of deep white matter including dentate nucleus, pons

ABSCESS OF BRAIN

Pyogenic Brain Abscess

= focal area of necrosis beginning in area of cerebritis with formation of surrounding membrane

Prevalence: 0.4–0.9÷100,000

Cause:

1. Extension from paranasal sinus infection (41%) / mastoiditis / otitis media (5%) / facial soft-tissue infection / dental abscess
2. Generalized septicemia (32%):
   (a) lung (most common): bronchiectasis, empyema, lung abscess, bronchopleural fistula, pneumonia
   (b) heart (less common): CHD with R-L shunt (in children > 60%), AVM, bacterial endocarditis
   (c) osteomyelitis
3. Penetrating trauma or surgery
4. Cryptogenic (25%)

Predisposed: diabetes mellitus, patients on steroids / immunosuppressive drugs, congenital / acquired immunologic deficiency

Organism: anaerobic streptococcus (most common), bacteroides, staphylococcus; in 20% multiple organisms; in 25% sterile contents

Pathophysiologic stages:

1 ***Early cerebritis*** = vascular congestion, petechial hemorrhage, edema ← neutrophilic response to invasive organism
√ ill-defined hypoattenuation on NECT
√ absent / variable enhancement on CECT

2 ***Late cerebritis*** = cerebral softening + necrosis ← marginal fibroblast accumulation (but NO collagen deposition) ← breakdown of blood-brain barrier
√ ringlike enhancement diffusing centrally on delayed images
√ suppressed enhancement after corticosteroid Rx

Capsule develops over 2–4 weeks = SIGNATURE imaging feature of an abscess!

3 ***Early capsule*** = fibroblasts create reticulin matrix ← blockage of necrotic material

4 ***Late capsule*** = matrix transitions to mature collagen

Histo: liquefaction + cavitation + capsule + pericapsular (progressively decreasing) edema

Capsule:
(a) inner layer of granulation tissue
(b) middle layer of collagen
(c) outer layer of astroglia

√ well-vascularized capsule tends not to persist on delayed scan
√ NO suppressed enhancement after corticosteroid Rx
√ capsule often thinner medially ← relatively poor vascularity + reduced fibroblast migration

Cx: (1) daughter abscesses
(2) intraventricular rupture

- headache, drowsiness, confusion, seizure
- focal neurologic deficit
- fever, leukocytosis (resolves with encapsulation)

Location: typically at corticomedullary junction; frontal and temporal lobes; supratentorial÷infratentorial = 2÷1

NECT:
√ well-defined hyperattenuated ring compared with central necrosis + peripheral edema:
√ zone of low density with mass effect (92%)
√ slightly increased rim density (4%) ← development of collagen layer takes 10–14 days
√ gas within lesion (4%) is diagnostic of gas-forming organism

CECT:
√ ring enhancement (90%) with peripheral zone of edema
√ continuous regular smooth 2–7-mm ring, nonspecific but HIGHLY CHARACTERISTIC of a pyogenic abscess!
√ homogeneous enhancement in lesions < 0.5 cm
√ edema + contrast enhancement suppressed by steroids
√ multiloculation + subjacent daughter abscess in white matter

MR: (most sensitive modality)
√ abscess centrally increased / variable intensity on T2WI
√ T1-hyperintense + T2-hypointense rim (= abscess capsule) ← paramagnetic effect of bactericidal free radicals generated by active macrophages
√ outside border of increased SI on T2WI (edema)
√ restricted diffusion in abscess core ← high cellularity and viscosity of pus impedes water mobility
√ (CHARACTERISTIC) hyperintensity on DWI
√ corresponding hypointensity on ADC maps

DWI is the best sequence for differentiation of ringenhancing pyogenic abscess from necrotic tumor.

MR spectroscopy:
√ ↑ amino acid level (0.9 ppm) = marker of proteolytic enzymes from neutrophils (in 80%)

Cx: (1) Development of daughter abscesses toward white matter
(2) Rupture into ventricular system / subarachnoid space (thinner capsule formation on medial wall of abscess related to relative hypovascularity) → ventriculitis ± meningitis

Dx helpful features:
› multiple lesions at gray-white matter border
› clinical history of altered immune status

› R-to-L shunt: eg, pulmonary AV fistula
› foreign travel
› high-risk behavior: eg, IV drug abuse

Rx: IV antibiotics (penetrate brain abscess to therapeutic levels) + needle aspiration for best clinical outcome

DDx: (1) Primary / metastatic neoplasm (restricted diffusion typically in tumor periphery ← high cellular density
(2) Subacute infarction
(3) Resolving hematoma

Granulomatous Brain Abscess

1. Tuberculoma
2. Sarcoid abscess
3. Fungal abscess: coccidioidomycosis, mucormycosis (in diabetics), aspergillosis, cryptococcus

Predisposed: immunocompromised host (candida, aspergillus)
√ enhancement of leptomeningeal surface
√ nodular / ring-enhancing parenchymal lesion
Cx: Communicating hydrocephalus ← thick exudate blocks basal cisterns

ACRANIA

= EXENCEPHALY
= developmental anomaly characterized by partial / complete absence of membranous neurocranium + complete but abnormal development of brain tissue
Incidence: 25 cases reported
Cause: impaired migration of mesenchyme to its normal location under calvarial ectoderm → failed development of dura mater + skull + musculature
Time: develops after closure of anterior neuropore during 4th week
May be associated with:
cleft lip, bilateral absence of orbital floors, metatarsus varus, talipes, cervicothoracic spina bifida
• ± elevation of maternal serum AFP
√ absence of calvarium
√ normal ossification of chondrocranium (face, skull base)
√ hemispheres surrounded by thin membrane
Prognosis: uniformly lethal; progression to anencephaly (brain destruction ← exposure to amniotic fluid and mechanical trauma)
DDx: encephalocele, anencephaly, osteogenesis imperfecta, hypophosphatasia

ADRENOLEUKODYSTROPHY

= BRONZED SCLEROSING ENCEPHALOMYELITIS
= inherited metabolic disorder characterized by progressive demyelination of cerebral white matter + adrenal insufficiency
Etiology: defective peroxisomal fatty acid oxidation ← impaired function of lignoceryl-

coenzyme A ligase with accumulation of saturated very long chain fatty acids (cholesterol esters) in white matter + adrenal cortex + testes

Dx: assay of plasma, red cells, cultured skin fibroblasts for the presence of increased amounts of very long chain fatty acids

Mode of inheritance:

(a) X-linked recessive in boys (common)

(b) autosomal recessive in neonates (uncommon)

Histo: PAS cytoplasmic inclusions in brain, adrenals, other tissues

Age: 3–10 years (X-linked recessive)

- loss of hearing (50%), ataxia
- deteriorating vision (27%), optic disk pallor
- adrenal gland insufficiency → abnormal increased pigmentation, elevated ACTH level
- altered behavior, attention disorder, mental deterioration, death

Location: disease process usually starts in central occipital white matter → advances anteriorly through internal and external capsules + centrum semiovale → centripetal progression to involve subcortical white matter → interhemispheric spread via corpus callosum particularly splenium → involvement of optic radiation ± auditory system ± pyramidal tract

CT:

√ large symmetric low-density lesions in occipitoparieto-temporal white matter (80%) advancing toward frontal lobes + cerebellum

√ thin curvilinear / serrated enhancing rims near edges of lesion

√ initial frontal lobe involvement (12%)

√ calcifications within hypodense areas (7%)

√ cerebral atrophy in late stage (progressive loss of cortical neurons)

MR:

√ hypointensity on T1WI in affected areas (= hypointense atrophic splenium of corpus callosum)

√ bilateral confluent hyperintense areas on T2WI

Prognosis: usually fatal within several years after onset of symptoms

Adrenomyeloneuropathy

= clinically milder form with later age of onset

- symptoms of spinal cord demyelination + peripheral neuropathy

AGENESIS OF CORPUS CALLOSUM

= COMPLETE DYSGENESIS OF CORPUS CALLOSUM

= failure of formation of corpus callosum originating at lamina terminalis at 7–13 weeks from where a phalanx of callosal tissue extends backward arching over the diencephalon; usually developed by 20 weeks EGA

Incidence: 0.7–5.3%

Cause: congenital / acquired (← infarction of ACA)

Histo: axons from cerebral hemispheres that would normally cross continue along medial walls of lateral ventricles as longitudinal callosal bundles of Probst that terminate randomly in occipital + temporal lobes

Associated with:

(a) CNS anomalies (85%):

1. Dandy-Walker cyst (11%)
2. Interhemispheric arachnoid cyst may be continuous with 3rd and lateral ventricles
3. Hydrocephalus (30%)
4. Midline intracerebral lipoma of corpus callosum often surrounded with ring of calcium (10%)
5. Arnold-Chiari II malformation (7%)
6. Midline encephalocele
7. Porencephaly
8. Holoprosencephaly
9. Hypertelorism median cleft syndrome
10. Polymicrogyria, gray-matter heterotopia

(b) Cardiovascular, gastrointestinal, genitourinary anomalies (62%)

(c) Abnormal karyotype (trisomy 13, 15, 18)

• normal brain function in isolated agenesis

• intellectual impairment; seizures

√ absence of septum pellucidum + corpus callosum + cavum septi pellucidi

√ longitudinal bundles of Probst create crescentic lateral ventricles:

- √ colpocephaly (= dilatation of trigones + occipital horns + posterior temporal horns in the absence of splenium
- √ "bat-wing" appearance of lateral ventricles (= wide separation of lateral ventricles with straight parallel parasagittal orientation with absent callosal body)
- √ laterally convex frontal horns in case of absent genu of corpus callosum

√ "high-riding third ventricle" = upward displacement of widened 3rd ventricle often to level of bodies of lateral ventricle

√ anterior interhemispheric fissure adjoins elevated 3rd ventricle ± communication (PATHOGNOMONIC)

√ "interhemispheric cyst" = interhemispheric CSF collection as an upward extension of 3rd ventricle

√ enlarged foramina of Monro

√ "sunburst gyral pattern" = dysgenesis of cingulate gyrus with characteristic radial orientation of cerebral sulci from the roof of the 3rd ventricle (on sagittal images)

√ failure of normal convergence of calcarine + parietooccipital sulci

√ persistent eversion of cingulate gyrus (rotated inferiorly + laterally) with absence on midsagittal images

√ incomplete formation of Ammon's horn in the hippocampus

OB-US (> 22 weeks GA):

- √ absence of septum pellucidum
- √ "teardrop" ventriculomegaly = disproportionate enlargement of occipital horns = colpocephaly
- √ dilated + elevated 3rd ventricle
- √ radial array pattern of medial cerebral sulci

Angio:

- √ wandering straight posterior course of pericallosal arteries (lateral view)

√ wide separation of pericallosal arteries ← intervening 3rd ventricle (anterior view)
√ separation of internal cerebral veins
√ loss of U-shape in vein of Galen

DDx: (1) Prominent cavum septi pellucidi + cavum vergae (should not be mistaken for 3rd ventricle)
(2) Arachnoid cyst in midline (suprasellar, collicular plate) raising and deforming the 3rd ventricle and causing hydrocephalus

Partial Agenesis of Corpus Callosum

= milder form of callosal dysgenesis (best seen on MR) depending on time of arrested growth (anteroposterior development of genu + body + splenium, however, rostrum forming last)

(a) genu only
(b) genu + part of the body
(c) genu + entire body
(d) genu + body + splenium (without rostrum)

AIDS

= late symptoms of DNA retrovirus infection attacking monocytes + macrophages → deficient cell-mediated immunity

Incidence: 1,200,000 HIV-seropositive persons (0.3% of population) in USA IN 2011; 14% undiagnosed; 50,000 new HIV infections per year

Histo: formation of microglial nodules instead of granulomas in 75–80% of autopsied brains

• neurologic symptoms as initial complaint in 7–10%, ultimately afflict up to 40–60%: personality + mental status changes, headache, memory loss, difficulty to concentrate, depression, confusion, dementia, new onset of seizures, focal deficit from mass lesion

◊ Any male with neurologic symptoms between age 20 and 50 has AIDS until proven otherwise

◊ Unusual presentations are clues to HIV infection: pansinusitis, mastoiditis, parotid cysts, cervical adenopathy, hypointense spine

Rx: azidothymidine (AZT)

A. ATROPHY:
(1) Malnutrition, dehydration, steroid therapy, chronic dialysis, normal aging
(2) **AIDS dementia complex** (ADC)
= SUBACUTE ENCEPHALITIS = HIV ENCEPHALITIS
= cognitive disturbances → progressing to dementia
Etiology: HIV-1 infection of CNS macrophages generating neurotoxic factors
Prevalence: 7–27% of AIDS patients
Histo: predominantly perivascular HIV encephalitis; HIV leukoencephalopathy characterized by diffuse myelin loss + infiltration by macrophages
√ cerebral atrophy
√ subtly increased signal intensities on T2 and FLAIR sequences without mass effect ← leaky capillaries with egress of water:
√ focal / diffuse
√ symmetric / asymmetric
√ reversible / nonreversible

B. INTRAAXIAL LESION WITHOUT MASS EFFECT

(1) Progressive multifocal leukoencephalopathy

C. MASS LESION
  (1) Toxoplasmosis
  (2) Primary CNS lymphoma (PCNSL)
  (3) Fungal, granulomatous, viral, bacterial infection
    (a) Cryptococcosis
    (b) Other opportunistic CNS infections:
      › tuberculosis
      › neurosyphilis

◊ With multiple CNS lesions toxoplasmic encephalitis is the more likely diagnosis!
◊ With a single CNS lesion the probability of lymphoma is at least equal to toxoplasmosis!

ALEXANDER DISEASE

= FIBRINOID LEUKODYSTROPHY
= rare autosomal dominant / sporadic CNS disease (< 500 cases)
Cause: mutation in gene for glial fibrillary acidic protein (GFAP) of chromosome 17q21
Age: as early as first few weeks of life to 2 years
• macrocephaly; failure to attain developmental milestones
• progressive spastic quadriparesis; intellectual failure
Location: frontal white matter gradually extending posteriorly into parietal region + internal capsule
CT:
  √ low-density white matter lesion
  √ contrast enhancement near tip of frontal horn
MR:
  √ prolonged T1 + T2 relaxation times
Prognosis: death in infancy / childhood usually within 10 years

ALZHEIMER DISEASE

= diffuse gray matter disease with large loss of cells from cerebral cortex + other areas
◊ Most common of dementing disorders in elderly!
Incidence: 10% of people > 65 years of age; 50% of people > 85 years of age
Histo: intraneuronal deposits of abnormally phosphorylated τ protein (neurofibrillary tangles) and extracellular β-amyloid (senile plaques)
• slowly progressive cognitive decline, memory impairment, adverse impact on activities of daily living (large overlap with other dementias of elderly)
Location: early neuronal loss + gliosis in mesiotemporal cortex
√ "cracked walnut" appearance of brain atrophy = symmetrically enlarged sulci in high-convexity area
√ focal atrophic change in medial temporal lobe (82% sensitive, 75% specific, 80% accurate):
  √ volume loss of hippocampus + parahippocampal gyrus
  √ enlargement of perihippocampal fissures
√ smooth periventricular halo of hyperintensity (50%)
PET (axial images with 3D stereotactic surface projection):

√ classic pattern of altered cortical metabolism:
√ hypometabolism in posterior cingulate gyrus, precuneus, posterior temporal + parietal lobes (earliest changes)
√ hypometabolism of prefrontal association cortices ± frontal lobe involvement
√ sparing of sensorimotor cortex, visual cortex, anterior cingulate cortex, basal ganglia, thalamus, posterior fossa

Prognosis: 4th leading cause of death in individuals > 65 years

AMYOTROPHIC LATERAL SCLEROSIS

= Lou Gehrig's disease (famous baseball player for NY Yankees)
= most common form of motor neuron disease (without autonomic / sensory / cognitive involvement)

Cause: free radical damage to neurons / autoimmune process / heavy metal toxicity
Age: middle – late adulthood; M > F
Path: atrophy of precentral gyrus
Histo: loss of pyramidal + Betz cells in motor cortex; loss of anterior horn cells in spinal cord; swelling of proximal axons of neuronal cells

• progressive neurodegenerative disorder
  • upper neuronal symptoms: hyperreflexia, spasticity
  • lower neuronal symptoms: fasciculation, atrophy

MR:
√ hyperintense corticospinal tracts (corona radiata, corpus callosum, posterior limb of internal capsule, ventral aspect of brain stem, anterolateral column of spinal cord) on T2WI
√ low SI in motor cortex on T2WI ← iron deposition

DDx: Friedreich ataxia, vitamin B12 deficiency (abnormal signal limited to internal capsule)

ANENCEPHALY

= lethal anomaly with failure of closure of the rostral end of the neural tube by 5.6 weeks MA
◊ Associated with highest AF-AFP and MS-AFP values; > 90% will be detected with MS-AFP ≥ 2.5 MoM

Incidence: 1÷1,000 births in USA (3.5÷1,000 in South Wales); M÷F = 1÷4; most common congenital defect of CNS; 50% of all neural tube defects
Recurrence rate: 3–4%
Etiology: multifactorial (genetic + environmental)
Path: absence of cerebral hemispheres + cranial vault; partial / complete absence of diencephalic + mesencephalic structures; hypophysis + rhombencephalic structures usually preserved
Risk factors: family history of neural tube defect; twin pregnancy
Associated anomalies:
spinal dysraphism (17–50%), cleft lip / palate (2%), clubfoot (2%), umbilical hernia, amniotic band syndrome
√ absence of bony calvarium cephalad to orbits
√ ± cranial soft-tissue mass (= angiomatous stroma)
√ bulging froglike eyes

√ short neck
√ polyhydramnios (40–50%) after 26 weeks GA (← failure of normal fetal swallowing) / oligohydramnios
Dx: in 100% > 14 weeks GA
Prognosis: uniformly fatal within hours to days of life; in 53% premature birth; in 68% stillbirth
DDx: acrania, encephalocele, amniotic band syndrome

ANEURYSM OF CNS

Etiology:
(a) congenital (97%) = "berry aneurysm" in 2% of population (in 20% multiple); associated with aortic coarctation and adult polycystic kidney disease
(b) infectious (3%) = mycotic aneurysm
(c) arteriosclerotic: fusiform shape
(d) traumatic
(e) neoplastic
(f) fibromuscular disease

Risk factors:
(1) Family history for aneurysms in 1st- / 2nd-degree relatives
(2) Female gender
(3) Oral contraceptives / pregnancy
(4) Advanced age > 50 years
(5) Hypertension
(6) Cigarette smoking
(7) Cerebral arteriovenous malformation
(8) Vasculitis
(9) Connective tissue disorder: Marfan syndrome, Ehlers-Danlos syndrome type IV, autosomal dominant polycystic renal disease, pseudoxanthoma elasticum, neurofibromatosis type 1
(10) Asymmetry of circle of Willis

Pathogenesis: arterial wall deficient in tunica media + external elastic lamina (natural occurrence with advancing age)

Aneurysm by shape:
A. Saccular
= berry- / bleb-like outpouching
Cause: hemodynamic stress + repeated endothelial damage ← turbulent blood flow
Site: circle of Willis (COW) in 90–95%, arterial bifurcation in 5–10%
Location: anterior circulation (90%), posterior circulation (10%), distal to COW (5%)
Size: 2–3 mm small to giant >2.5 cm
B. Fusiform
= circumferential involvement of wall
Cause: predominantly atherosclerotic degeneration
Location: posterior circulation
(a) Serpentine

= partly thrombosed containing tortuous vascular channels

Cause: recurrent cycles of thrombosis + recanalization within fusiform aneurysm

Location of aneurysm:

A. by autopsy:
   (a) circle of Willis (85%): aCom (25%), pCom (18%), MCA bifurcation (25%), distal ACA (5%), ICA at bifurcation (4%), ophthalmic a. (4%), anterior choroidal a. (4%)
   (b) posterior fossa (15%): basilar bifurcation (7%), basilar trunk (3%), vertebral-PICA (3%), PCA (2%)
B. by CT: detection rate of aneurysms at pCom (40%), aCom / MCA, basilar artery (80%)
C. by angiography (= symptomatic aneurysms): pCom (38%) > aCom (36%) > MCA bifurcation (21%) > ICA bifurcation > tip of basilar artery (2.8%)
D. by risk of bleeding: 1–2% per year aCom (70% bleed), pCom (2nd highest risk)

◊ Aneurysms at bifurcations / branching points are at greatest risk for rupture!

NECT:
- √ well-delineated round / lobulated slightly hyperdense extra-axial mass
- √ calcium deposit common in atherosclerotic fusiform aneurysm

CECT:
- √ enhancing lumen of partially thrombosed aneurysm
- √ rim-enhancement in completely thrombosed aneurysm

CTA: 95% positive detection rate

MR:
- √ mass:
  - √ iso- / hyperintense on T1WI
  - √ hypointense on T2WI (DDx to primary brain tumor)
- √ patent aneurysm with internal signal / flow void ← rapid internal blood flow:
  - √ flow void on T2WI = CLASSIC feature
  - √ flow void on T1WI in 50% (DDx: aerated anterior clinoid / supraorbital cell)
- √ partially / completely thrombosed aneurysm:
  - √ well-demarcated round para- / intrasellar lesion
  - √ internal T1-hyperintensity + CHARACTERISTIC heterogeneous T2-hypointensity ← blood clot
  - √ laminated layers of variable SI if thrombosed
- √ hypointense rim of hemosiderin
- √ high SI in sulci + cisterns on FLAIR = sign of rupture

CEMR (T1WI):
- √ enhancing slow flow in patent lumen
- √ increased phase artifact in patent aneurysm

MRA (3D TOF): detects aneurysm > 3 mm in diameter

Angio (all 4 cerebral vessels):
- √ contrast outpouching
- √ < 2 mm infundibuli typically occur at pCom / anterior choroidal a. origin
- √ mass effect in thrombosed aneurysm
- ◊ 2nd arteriogram within 1–2 weeks detects aneurysm in 10–20% following negative 1st

angiogram!

Purpose: confirm aneurysm and host vessel, detect multiple aneurysms, define neck, identify perforating arteries, assess potential for collateral circulation

Prognosis:

(1) Death in 10% within 24 hours from concomitant intracerebral hemorrhage, extensive brain herniation, massive infarcts + hemorrhage within brainstem
Mortality: 45% within 30 days (25% prior to admission)

(2) Complete recovery in 58% of survivors

(3) Cerebral ischemia + infarction

(4) Rebleeding rate: 12–20% within 2 weeks, 11–22% within 30 days, up to 50% within 6 months (increased mortality); thereafter 1–2–4% risk/year

Cx: subdural hematoma

Rx: clipping; endovascular coiling

Surgical mortality rate: 50% (1–3%) for ruptured (unruptured) aneurysm

Cavernous Sinus Aneurysm

Age: 20–70 years, peak 5th–6th decade; F >> M

Cause: sinus thrombophlebitis

- progressive visual impairment
- **cavernous sinus syndrome**: trigeminal nerve pain, oculomotor nerve paralysis

Site: extradural portion of cavernous sinus ICA

√ undercutting of anterior clinoid process
√ erosion of lateral half of sella
√ erosion of posterior clinoid process
√ invasion of middle cranial fossa
√ enlargement of superior orbital fissure
√ erosion of tip of petrous pyramid
√ rimlike calcification (33%)
√ displacement of thin bony margins without sclerosis

Rx: often inoperable; balloon embolization ± parent artery occlusion

Giant Aneurysm

= aneurysm > 25 mm in diameter, usually presenting with intracranial mass effect
◊ Risk of rupture increases proportionally with size!

Incidence: 5% of all intracranial aneurysms

Age: 5th–7th decade; M< F

- visual disturbance; cranial nerve palsy; seizure
- TIA / infarct ← thromboemboli from aneurysm

Type: saccular >> fusiform

Location: (arise from arteries at the base of the brain)

(a) middle fossa: cavernous segment of ICA (43%), supraclinoid segment of ICA, terminal bifurcation of ICA, middle cerebral artery

(b) posterior fossa: at tip of basilar artery, AICA, vertebral a.

Skull film:

√ predominantly peripheral curvilinear calcification (22%)

√ mass effect:
√ bone erosion (44%)
√ pressure changes on sella turcica (18%)

CT:
√ well-delineated, round / lobulated, slightly hyperattenuating extraaxial mass
√ often peripheral intramural / luminal calcified thrombus

CECT:
√ "target" sign = centrally opacified vessel lumen + ring of thrombus + enhancing fibrous outer wall
√ simple ring-blush (75%) of fibrous outer wall with total thrombosis
√ little / no surrounding edema

MR:
√ mixed heterogeneous signal intensity of laminated appearance (= combination of subacute + chronic hemorrhage, calcification)

Cx: 6% annual risk of rupture; subarachnoid hemorrhage in > 50%

Mortality for untreated giant aneurysm:
68% at 2 years, 80% at 5 years

DDx: partially thrombosed giant aneurysm may mimic slowly growing solid destructive tumor → MR / conventional angiography prior to biopsy!

Ruptured Berry Aneurysm

Incidence: 28,000 cases/year = 10 cases/10,000 persons/year

Age: 50–60 years of age; M÷F = 1÷2

Rupture size: 5–15 mm

- "worst headache of one's life" ± meningismus
- neck stiffness, nausea, vomiting
- history of warning leak / sentinel hemorrhage hours to days earlier; sudden loss of consciousness (in up to 45%)

Clues for which aneurysm is bleeding:
(a) the largest aneurysm (87%)
(b) anterior communicating artery (70%)
(c) contralateral side of all visualized aneurysms (60%), nonvisualization due to spasm

mnemonic: BISH
Biggest
Irregular contour
Spasm (adjacent)
Hematoma location

Location of blood suggesting accurately in 70% the site of the ruptured aneurysm:
(a) according to location of <u>subarachnoid hemorrhage</u>:

1. Anterior chiasmatic cistern:	aCom
2. Septum pellucidum:	aCom
3. Interhemispheric fissure:	aCom
4. Intraventricular:	aCom, ICA, MCA
5. Sylvian fissure:	MCA, ICA, pCom

6. Anterior pericallosal cistern: ACA, aCom
7. Prepontine cistern: basilar a.
8. Foramen magnum: PICA
9. Symmetric distribution in subarachnoid space: ACA + basilar a.

(b) according to location of cerebral hematoma:

1. Inferomedial frontal lobe: aCom
2. Temporal lobe: MCA
3. Corpus callosum: pericallosal a.

(c) intraventricular hemorrhage:
from aneurysms at aCom, MCA, pericallosal artery
CAVE: blood may have entered in retrograde manner from subarachnoid location

Multiple CNS Aneurysms

Cause: congenital in 20–30%, mycotic in 22%
mnemonic: FECAL P
Fibromuscular dysplasia
Ehlers-Danlos syndrome
Coarctation
Arteriovenous malformation
Lupus erythematosus
Polycystic kidney disease (adult)

◊ 35% of patients with one MCA aneurysm have one on the contralateral side (= mirror image aneurysms)!

◊ Simultaneous aneurysm + AVM in 4–15%

Mycotic Aneurysm

= 3% of all intracranial aneurysms; multiple in 20%
Source: subacute bacterial endocarditis (65%), acute bacterial endocarditis (9%), meningitis (9%), septic thrombophlebitis (9%), myxoma
Location: distal to first bifurcation of major vessel (64%); often located near surface of brain, especially over convexities
(a) suprasellar cistern = circle of Willis
(b) inferolateral sylvian fissure = MCA trifurcation
(c) genu of corpus callosum = origin of callosomarginal artery
(d) bottom of 3rd ventricle = pericallosal a.

NECT:
√ aneurysm rarely visualized; indirect evidence from focal hematoma after rupture
√ zone of increased density / calcification
√ increased density in subarachnoid, intraventricular, intracerebral spaces ← extravasated blood
√ focal / diffuse lucency of brain ← edema / infarction / vasospasm

CECT:
√ intense homogeneous enhancement within round / oval mass contiguous with vessel

√ incomplete opacification with mural thrombus

Cx: recurrent bleeding (more frequent than with congenital aneurysm)

Supraclinoid Carotid Aneurysm

= 38% of intracranial aneurysms

Site: (a) at origin of pCom (65%)
(b) at bifurcation of internal carotid artery (23%)
(c) at origin of ophthalmic artery (12%) medial to anterior clinoid process → most likely to become giant aneurysm

Presentation: bitemporal hemianopia ← extrinsic compression on chiasm

√ calcifications rare (DDx: frequent in atherosclerotic cavernous sinus aneurysm)

AQUEDUCTAL STENOSIS

= focal reduction in size of aqueduct at level of superior colliculi / intercollicular sulcus (normal range, 0.2–1.8 mm2)

Embryology:
aqueduct develops at 6th week GA + decreases in size until birth ← growth pressure from adjacent mesencephalic structures

Incidence: 0.5–1÷1,000 births; most frequent cause of congenital hydrocephalus (20–43%); 1–4.5% recurrence rate in siblings; M÷F = 2÷1

Manifestation: any time from fetal age to adulthood; age at presentation depends on severity of stenosis and hydrocephalus

Etiology:
(a) postinflammatory (50%): perinatal infection (toxoplasmosis, CMV, syphilis, mumps, influenza virus) OR intracranial hemorrhage → destruction of ependymal lining of aqueduct → marked adjacent fibrillary gliosis
(b) developmental: aqueductal forking (= marked branching of aqueduct into channels) / narrowing / transverse septum (X-linked recessive inheritance in 25% of males)
(c) neoplastic (extremely rare): pinealoma, meningioma, tectal astrocytoma (may be missed on routine CT scans, easily visualized by MR)

May be associated with: other congenital anomalies (16%): thumb deformities

Location: most often proximal aqueduct as congenital / acquired (= postinflammatory aqueductal gliosis) stenosis

√ enlargement of lateral + 3rd ventricles + normal-sized sulci and 4th ventricle (4th ventricle may be normal with communicating hydrocephalus)

◊ Adult hydrocephalus is in 10% due to aqueductal stenosis!

√ rounded anterior recesses extending into suprasellar cistern

√ 3rd ventricular floor displaced inferiorly into prepontine cistern

Prognosis: 11–30% mortality

Rx: 3rd ventriculostomy = creating a perforation in tuber cinereum → communication with prepontine cistern

N.B.: Alert surgeon prior to ventriculostomy of an anomalous floor contour of 3rd ventricle (long-standing hydrocephalus displaces floor downward)

ARACHNOID CYST

= CSF-containing intraarachnoid cyst without ventricular communication / brain maldevelopment

Incidence: 1% of all intracranial space-occupying lesions

Origin:

(1) congenital: arising from clefts / duplication / "splitting" of arachnoid membrane with expansion by CSF due to secretory activity of arachnoid cells = **true arachnoid cyst**

(2) acquired: following surgery / trauma / subarachnoid hemorrhage / infection in neonatal period / associated with extraaxial neoplasm = loculation of CSF surrounded by arachnoidal scarring with expansion by osmotic filtration / ball-valve mechanism = **leptomeningeal cyst** = **secondary arachnoid cyst** = **acquired arachnoid cyst**

Histo: cyst filled with clear fluid; thin wall composed of cleaved arachnoid membrane; lined by ependymal / meningothelial cells

Age: presentation at any time during life

- often asymptomatic
- symptomatic ← mass effect, hydrocephalus, seizures, headaches, hemiparesis, intracranial hypertension, craniomegaly, developmental delay, visual loss, precocious puberty, bobble-head doll syndrome

Location: in CSF cisterns between brain + dura

(a) floor of middle fossa near tip of temporal lobe (50%): common in sylvian fissure
- usually asymptomatic

(b) suprasellar / chiasmatic cistern (10%)
- propensity to become symptomatic in early childhood:
  - hydrocephalus (most common manifestation)
  - visual impairment
  - endocrinopathy: eg, precocious puberty

(c) posterior fossa (⅓–¼): cerebellopontine angle (11%), quadrigeminal plate cistern (10%), in relationship to vermis (9%), prepontine / interpeduncular cistern (3%)

Associated with: Aicardi syndrome, glutaric aciduria type I, unbalanced X,9 translocation

(d) interhemispheric fissure, cerebral convexity, anterior infratentorial midline

√ forward bowing of anterior wall of cranial fossa + elevation of sphenoid ridge
√ extraaxial unilocular thin-walled CSF-density cyst with well-defined smooth angular margins
√ compression of subarachnoid space + subjacent brain (minimal mass effect)
√ may erode inner table of calvarium
√ NO enhancement (intrathecal contrast penetrates into cyst on delayed scans)
√ NO calcifications

MR (best modality):

√ well-circumscribed extraaxial fluid collection / cyst isointense to CSF
√ lack of complete signal suppression (on fluid-attenuated inversion-recovery sequence) ← proteinaceous content
√ free water motion / facilitated diffusion similar to CSF on DWI
√ thin cyst wall not visualized on MR

Cx: (1) hydrocephalus (30–60%) + remodeling / thinning of overlying occipital bone ←

secondary obstruction of ventricular system ← mass effect on cerebellum + vermis ← enlargement during infancy

(2) concurrent subdural / intracystic hemorrhage

Prognosis: favorable if removed before onset of irreversible brain damage

Rx: resection, fenestration, endoscopic ventriculocystostomy, cystoperitoneal shunting

CT-DDx:

epidermoid cyst, dermoid, subdural hygroma, infarction, porencephaly

US-DDx:

choroid plexus cyst, porencephalic cyst (communicates with ventricle), cystic tumor (solid components), midline cyst associated with agenesis of corpus callosum, dorsal cyst associated with holoprosencephaly, Dandy-Walker cyst (extension of 4th ventricle, developmental delay), vein of Galen aneurysm

Posterior Fossa Arachnoid Cyst

Incidence: 10% of arachnoid cysts in children

- may be asymptomatic + discovered incidentally
- obstructed CSF flow possible → macrocephaly, signs of increased intracranial pressure, developmental delay

Location:

(a) retrocerebellar = inferior / posterior to vermis (in midsagittal location)

(b) supravermian = cranial to vermis in tentorial hiatus

(c) anterior / lateral to cerebellar hemispheres

(d) anterior to brainstem

√ NO communication with 4th ventricle / subarachnoid space

Differences between Epidermoid and Arachnoid Cyst

	Epidermoid	*Arachnoid Cyst*
CT density	± hyperdense to CSF	CSF-like
Margins	scalloped	smooth
Vessels	encased	displaced
Proton density	deviates from CSF	CSF-like
Diffusion	restricted	CSF-like

ARTERIOVENOUS FISTULA

= AVF

= abnormal communication between artery + vein resulting in tremendous amount of flow due to high pressure gradient → enlargement + elongation of draining veins; NO nidus

Cause:

(1) Vessel laceration (delay between trauma + clinical manifestation ← delayed lysis of hematoma surrounding arterial laceration)

(2) Angiodysplasia: fibromuscular disease, neurofibromatosis, Ehlers-Danlos syndrome

(3) Congenital arteriovenous fistula

Location:

(a) carotid-cavernous sinus fistula (most common)

(b) vertebral artery fistula
(c) external carotid artery fistula (rare)

Carotid-Cavernous Sinus Fistula

= abnormal communication between veins of cavernous sinus and ≥ 1 branches of internal / external carotid artery

(1) **Direct shunt** = direct communication between cavernous segment of ICA + cavernous sinus

Etiology:

(1) Trauma: laceration of ICA within cavernous sinus
  (a) usually due to basal skull fracture (cavernous ICA + small cavernous branches fixed to dura)
  (b) penetrating trauma
  (c) surgery
(2) Spontaneous: rupture of an intracavernous ICA aneurysm (in atherosclerosis, Ehlers-Danlos syndrome, osteogenesis imperfecta, pseudoxanthoma elasticum)
(3) Dural sinus thrombosis

Age: any

- classic triad:
  - pulsatile exophthalmos, conjunctival chemosis / edema
  - persistent auscultatory orbital bruit
- restricted extraocular movement
- decrease in vision ← increase in intraocular pressure (50%) / cranial nerve deficits = indication for EMERGENT TREATMENT

(2) **Indirect shunt** = communication between dural branch of ICA / ECA + cavernous sinus

Age: 40–60 years; M < F

Etiology: atherosclerosis

- proptosis, loss of vision

√ ± visualization of feeding dural branches of ECA / ICA

Route of drainage:

(a) superior ophthalmic vein (common)
(b) contralateral cavernous sinus
(c) petrosal sinus
(d) cortical veins (rare)

√ dilatation + tortuosity of ipsilateral superior ophthalmic vein, facial veins, internal jugular vein
√ enlargement of dural venous sinuses ← increased venous flow + pressure
√ enlarged edematous extraocular muscles
√ focal asymmetric / diffuse enlargement of cavernous sinus
√ occasionally sellar erosion / enlargement
√ enlargement of superior orbital fissure (in chronic phase)
√ stretching of optic nerve
√ proptosis
√ subchoroidal effusion

US:

√ arterial flow in cavernous sinus + superior ophthalmic vein

CECT:

√ early opacification of cavernous sinus

MR:

√ flow voids in cavernous sinus

Angio:

√ ipsilateral ICA contrast injection shows wall of ICA to be incomplete

√ contralateral ICA contrast injection + compression of involved ICA

√ early opacification of veins of cavernous sinus

√ retrograde flow through dilated superior ophthalmic vein

Rx: transvenous / transarterial coil ablation ± stent placement; latex / silicone balloon detached inside cavernous sinus to plug laceration (→ ocular signs resolve within 7–10 days with successful treatment)

DDx: cavernous sinus thrombosis, enhancing cavernous sinus mass (meningioma, metastasis)

Dural AV Fistula

Arterial supply: artery normally feeding meninges (meningeal artery) / bone / muscles

Draining vein: venules within wall of dural sinus / cortical vein

Cause: dural sinus thrombosis → collateral revascularization

Prevalence: 10–15% of intracranial AV shunts

Peak age: 20–40 years; M=F

- pulsatile tinnitus

Borden classification:

- benign fistula (Borden type 1) → no cortical venous reflux → no neurologic deficits
- malignant fistula (Borden type 2 & 3) → with cortical venous reflux
  - intracranial hemorrhage, seizure, dementia
  - focal neurologic symptoms due to venous congestion / rupture of venous pouches; altered consciousness

Location: cavernous sinus (20–40%), transverse / sigmoid sinus (20–60%), tentorium (12–14%), superior sagittal sinus (8%), anterior fossa (2–3%)

CECT:

√ multiple small vessels within wall of thrombosed / partially recanalized stenotic dural venous sinus

√ prominent feeding meningeal artery:

(a) ECA → dural / transosseous branch

(b) ICA / vertebral artery → tentorial / dural branch

√ enlarged draining veins

√ dilated transcalvarial channels ← transosseous feeding artery

MR:

√ dilated cortical veins (= pseudophlebitic pattern):

√ abnormal enhancing tubular structures

√ flow voids within cortical sulci

√NO true nidus within brain parenchyma

Rx: observation, embolization, surgical resection

DDx: dural venous sinus thrombosis with prominent collaterals, pial AV malformation, pial AV fistula

Pial AV Fistula

= often high-flow lesions with direct fistulous communication between a pial artery + a vein WITHOUT intervening nidus

Arterial supply: enlarged pial artery
Draining vein: enlarged draining vein / capillary bed
Prevalence: 5% of all brain AVMs
Associated with: hereditary hemorrhagic telangiectasia (frequent)
Location: brain surface
Cause: trauma, genetically dysregulated angiogenesis
√ dilated vessels of brain surface (from MCA, ACA, PCA)
√ asymmetric dilatation of pial feeder artery
√ dilated often (serpentine) varicose draining vein
√ ± dilated venous pouches outside brain parenchyma
√ NO nidus / classic intraparenchymal tangle of vessels
√ ± spontaneous intracranial hemorrhage
Rx: embolization of draining vein at fistula
DDx: AV malformation, dural AV fistula, vein of Galen malformation

ARTERIOVENOUS MALFORMATION

= congenital abnormality consisting of abnormal dilated closely packed pathologic vessels → shunting of blood from arterial to venous side without intermediary capillary bed

Risk of future hemorrhage:
(a) evidence of old hemorrhage (gradient-echo T2 sequence)
(b) angioarchitectural weak points:
› aneurysm: (1) intranidal (2) posterior fossa location
› venous caliber: (3) ectasia + (4) stenosis
› venous drainage: (5) deep + (6) single
◊ Imaging report should mention these risk factors!

Risk of nonhemorrhagic neurologic deficit:
high-flow shunt, venous congestion / outflow obstruction, long pial course of draining vein, perifocal / perinidal gliosis, mass effect / hydrocephalus, arterial steal

Classic Brain (Pial) AVM

◊ Most common type of symptomatic vascular malformation!

Diagnostic criteria:
(a) presence of a nidus = racemose tangle of abnormal dilated tortuous arteries + veins embedded within parenchyma
› glomerular / compact nidus = abnormal vessels without any interspersed normal brain tissue
› diffuse / proliferative nidus = interspersed normal brain parenchyma (2–4%)
(b) early venous drainage

Histo: affected arteries have thin walls (no elastica, small amount of muscularis)
Prevalence: 0.02–0.15% for sporadic AVM; 2% for syndromic AVM (hereditary hemorrhagic telangiectasia, cerebrofacial AV metameric syndrome)
Peak age: 20–40 years; 80% by end of 4th decade; 20% < 20 years of age; M=F
Associated with: aneurysm in feeding artery in 10%

- headaches, seizures (nonfocal in 40%), mental deterioration
- progressive hemispheric neurologic deficit (50%)
- ictus from acute intracranial hemorrhage (50%): multicompartmental in 31%, subarachnoid in 30%, parenchymal in 23%, intraventricular in 16%

Location: usually solitary; in 2% multiple
(a) supratentorial (90%): parietal > frontal > temporal lobe > paraventricular > intraventricular region > occipital lobe
(b) infratentorial (10%)

Site: (a) superficial / cortical:
› supply via pial arteries = branches of ACA, MCA, PCA;
› drainage via cortical veins
(b) deep / ventricular:
› supply via lenticulostriate, thalamoperforator branches, anterior / medial / lateral / posterior choroidal arteries
› drainage via deep venous system

Vascular supply:
(a) pial branches of ICA in 73% of supratentorial location, in 50% of posterior fossa location
(b) dural branches of ECA in 27% with infratentorial lesions
(c) mixed

√ NO mass effect (due to replacement of normal brain tissue) unless complicated by hemorrhage + edema:
√ intraparenchymal / intraventricular / subarachnoid hemorrhage
√ adjacent parenchymal atrophy ← vascular steal + ischemia

Skull film:
√ speckled / ringlike calcifications (15–30%)
√ thinning / thickening of skull at contact area with AVM
√ prominent vascular grooves on inner table of skull (= dilated feeding arteries + draining veins) in 27%

NECT:
√ irregular lesion with large feeding arteries + draining veins
√ mixed density (60%): dense large vessels + hemorrhage + calcifications
√ isodense lesion (15%): recognizable by mass effect
√ low density (15%): brain atrophy due to ischemia
√ not visualized (10%)

CECT:
√ tangle of intensely enhancing tubular structures = nidus ← tortuous dilated vessels (in 80%):
√ No avascular spaces within AVM
√ rapid shunting with veins seen during "arterial" phase

√ ± interspersed internal focal isoattenuating areas ← normal brain parenchyma (in diffuse subtype)

√ lack of mass effect / edema (unless thrombosed / bleeding)

√ No enhancement if thrombosed

√ thickened arachnoid covering

MR:

√ flow void ← rapid arteriovenous shunting (imaging with GRASS gradient echo + long TR sequences)

√ 3-D TOF demonstrates feeding arteries + nidus + draining veins

Pitfalls: (1) signal void in tortuous vessels

(2) nonvisualization of draining veins resulting from spin saturation

(3) difficulty differentiating blood flow from blood clot

Angio:

√ grossly dilated efferent + afferent vessels with a racemose tangle ("bag of worms")

√ arteriovenous shunting into at least one early draining vein

√ negative angiogram ← compression by hematoma / thrombosis

Cx: (1) Hemorrhage (common): bleeding on venous side ← increased pressure / ruptured aneurysm (5%)

(2) Infarction

Rx: embolization, stereotactic radiosurgery, microsurgery

Prognosis: 10% mortality; 30% morbidity

Risk of hemorrhage: lifelong; increasing yearly by 2–4%; increasing to 6% in year following 1st bleed + 25% in year following 2nd bleed

DDx: glioblastoma with AV shunting, dural AV fistula, cerebral proliferative angiopathy

Cerebral Proliferative Angiopathy

= diffuse nidus type AVM

Prevalence: 2–4%

Mean age: 20 years; M÷F = 1÷2

- progressive neurologic deficit
- transient ischemic attack, seizure, headaches

Histo: proliferative "nidus" composed of multiple arteries with intervening gliotic brain parenchyma between vessels

Pathophysiology: cortical ischemia → endothelial proliferation + angiogenesis

Location: often entire lobe / brain hemisphere

Vascular supply:

(a) arterial feeders of normal size / only moderately enlarged + associated stenoses

(b) extensive transdural supply through branches of ECA

(c) lack of clear early venous drainage

MR:

√ multiple flow voids

√ contrast-enhanced tubular structures

√ normal brain parenchyma interspersed between abnormal vessels

Angio:

√ relatively normal-sized arterial branches
√ lack of early venous drainage
√ extensive transdural supply via middle meningeal artery

Cerebrofacial Arteriovenous Metameric Syndrome

= CAMS = WYBURN-MASON SYNDROME = BONNET-DECHAUME-BLANC DISEASE

Cause: somatic mutation occurring in region of neural crest / adjacent cephalic mesoderm before migration of precursor cells to their final location = segmental neurovascular syndrome

Classification:

CAMS type 1: involves medial prosencephalon → AVMs in corpus callosum, hypothalamus (hypophysis), nose

CAMS type 2: involves lateral prosencephalon → AVMs in occipital lobe, optic tract including thalamus, retina, maxilla

CAMS type 3: involves rhombencephalon, → AVMs in cerebellum, pons, mandible

Clue: multiple AVMs in brain parenchyma + facial region in a segmental distribution

Age: childhood

- rarely manifest with hemorrhage
- symptoms related to facial AVMs:
  - progressive vision loss resulting in blindness
  - severe bleeding from teeth and gums
  - cosmetic problems like facial asymmetry

ASTROCYTOMA

Incidence: 70–75% of all primary intracranial tumors; most common brain tumor in children (40–50% of all primary pediatric intracranial neoplasms)

Distribution: proportional to amount of white matter

Location:

cerebral hemisphere (lobar), thalamus, pons, midbrain, may spread across corpus callosum; no particular lobar distribution

(a) in adults: central white matter of cerebrum (15–30% of all gliomas)
(b) in children: cerebellum (40%), brainstem (20%), supratentorial (30%)

Well-differentiated = Low-grade Astrocytoma

Incidence: 9% of all primary intracranial tumors; 10–15% of gliomas

Age: 20–40 years; M > F

Path: benign nonmetastasizing; poorly defined borders with infiltration of white matter + basal ganglia + cortex; NO significant tumor vascularity / necrosis / hemorrhage; blood-brain barrier may remain intact

WHO Classification of Astrocytomas		
Grade I	Circumscribed astrocytoma	generally benign well-circumscribed tumor, specific unique histologic features for each tumor, pilocytic astrocytoma (most common), subependymal giant cell astrocytoma; no tendency to progress to higher grade; low rate of recurrence
Grade II	Astrocytoma	diffusely infiltrating; well-differentiated; minimal pleomorphism or nuclear atypia; no vascular proliferation / necrosis
Grade III	Anaplastic astrocytoma	pleomorphism and nuclear atypia; increased cellularity; mitotic activity; vascular proliferation + necrosis absent
Grade IV	Glioblastoma multiforme	marked vascular proliferation and necrosis; increased cellularity; anaplasia + pleomorphism; variable mitotic activity; cell type may be poorly differentiated, fusiform, round or multinucleated

Histo: homogeneous relatively uniform appearance with proliferation of well-differentiated multipolar fibrillary / protoplasmic astrocytes; mild nuclear pleomorphism + mild hypercellularity; rare mitoses

Location: posterior fossa in children, supratentorial in adults (typically lobar)

√ may develop a cyst with high-protein content (rare)

CT:

√ usually hypodense lesion with minimal mass effect + minimal / NO peritumoral edema

√ well-defined tumor margins

√ central calcifications (15–20%)

√ minimal / no contrast enhancement (normal capillary endothelial cells)

MR:

√ well-defined hypointense lesion with little mass effect / vasogenic edema / heterogeneity on T1WI

√ hyperintense on T2WI

√ little / no enhancement on Gd-DTPA

√ cyst with content hyperintense to CSF ← protein

√ hyperintense area within tumor mass ← paramagnetic effect of methemoglobin

√ inhomogeneous gadolinium-DTPA enhancement of tumor nodule

Angio:

√ majority avascular

Prognosis: 3–10 years postoperative survival; may convert into more malignant form several years later

Anaplastic Astrocytoma

Incidence: 11% of all primary intracranial neoplasms; 25% of gliomas

Path: frequently vasogenic edema; NO necrosis / hemorrhage

Histo: less well differentiated with greater degree of hypercellularity + pleomorphism, multipolar fibrillary / protoplasmic astrocytes; mitoses + vascular endothelial proliferation common

Location: typically frontal + temporal lobes

MR:

√ moderate mass effect

√ well-defined slightly heterogeneous hypointense lesion on T1WI with prevalent vasogenic edema

√ hyperintense on T2WI

√ ± enhancement on Gd-DTPA

Prognosis: postoperative survival of 2 years

Cerebellar Astrocytoma

= CEREBELLAR PILOCYTIC ASTROCYTOMA

2nd most frequent tumor of posterior fossa in children

Incidence: 10–20% of pediatric brain tumors

Histo: mostly grade I

Age: children > adults; no specific age peak; M÷F = 1÷1

Path:

(1) cystic lesion with tumor nodule ("mural nodule") in cyst wall (50%); (midline astrocytomas cystic in 50%, hemispheric astrocytomas cystic in 80%)
(2) solid mass with cystic (= necrotic) center (40–45%)
(3) solid tumor without necrosis (< 10%)

- hydrocephalus, headache, vomiting, neck pain, 6th nerve palsy
- blurred vision, diplopia, papilledema, nystagmus
- cerebellar signs: truncal ataxia, dysdiadochokinesia appendicular dysmetria, gait disturbance

Location: originating in midline with extension into cerebellar hemisphere (29–53%), vermis (16–71%) > tonsils > brainstem (34%)

√ calcifications (20%): dense / faint / reticular / punctate / globular; mostly in solid variety

√ may develop extreme hydrocephalus (quite large when finally symptomatic)

CT:

√ round / oval cyst with density of cyst fluid > CSF
√ round / oval / plaquelike mural nodule with intense homogeneous enhancement
√ cyst wall slightly hyperdense + nonenhancing (= compressed cerebellar tissue)
√ uni- / multilocular cyst (= necrosis) with irregular enhancement of solid tumor portions
√ round / oval lobulated fairly well-defined iso- / hypodense solid tumor with hetero- / homogeneous enhancement

MR:

√ hypointense on T1WI + hyperintense on T2WI
√ enhancement of solid tumor portion

Angio:

√ avascular

Prognosis:

malignant transformation exceedingly rare
– 40% 25-year survival rate for solid cerebellar astrocytoma
– 90% 25-year survival rate for cystic juvenile pilocytic astrocytoma

DDx of solid astrocytoma:

(1) Medulloblastoma (hyperdense mass, noncalcified)
(2) Ependymoma (4th ventricle, 50% calcify)

DDx of cystic astrocytoma:

(1) Hemangioblastoma (lesion < 5 cm)
(2) Arachnoid cyst
(3) Trapped 4th ventricle

(4) Megacisterna magna
(5) Dandy-Walker cyst

Pilocytic Astrocytoma

= JUVENILE PILOCYTIC ASTROCYTOMA
= most benign histologic subtype of astrocytoma without progression to high-grade glioma
Incidence: 0.6–5.1% of all intracranial neoplasms
◊ Most common pediatric CNS glioma; 85% of all cerebellar + 10% of all cerebral astrocytomas in children
Age: predominantly in children + young adults; 75% in first 2 decades of life; peak age between birth and 9 years of age; M÷F = 1÷1
Histo: biphasic pattern of compact bipolar pilocytic (hairlike) astrocytes arranged mostly around vessels + loosely aggregated protoplasmic astrocytes undergoing microcystic degeneration
Associated with: neurofibromatosis type 1
Location: in / near midline
common: cerebellum, optic nerve / chiasm, hypothalamus (around 3rd ventricle)
less common: cerebral hemispheres (adults), cerebral ventricles, velum interpositum, spinal cord
Site: near ventricles (82%)
Imaging patterns:
(1) Cyst with intensely enhancing mural nodule (67%)
(a) nonenhancing cyst wall (21%)
(b) enhancing cyst wall (46%)
(2) Solid mass (33%)
(a) central nonenhancing necrotic zone (16%)
(b) minimal / no cystic component (17%)
CT:
√ well-demarcated smoothly marginated round / oval mass with cystic features
√ occasional calcifications
√ intense enhancement (94%)
√ multilobulated / dumbbell appearance along optic pathway
√ mural tumor nodule located in wall of cerebellar cyst
MR:
√ T1-isointense + T2-hyperintense to normal brain
√ small rim of vasogenic edema (low biologic activity)
√ increased heterogeneous signal intensity on early Gd-DTPA-enhanced T1WI; homogeneous enhancement on delayed images
Prognosis: relatively benign clinical course, almost never recurs after surgical excision; 94% (79%) postsurgical 10-year (20-year) survival; NO malignant transformation to anaplastic form
DDx: metastasis, hemangioblastoma, atypical medulloblastoma

Brainstem Pilocytic Astrocytoma

- nausea, vomiting, ataxia, torticollis

• papilledema, nystagmus, 6th & 7th nerve palsy
√ exophytic extension from dorsal surface of brainstem
√ obliteration of 4th ventricle
DDx: fibrillary astrocytoma (dismal prognosis)

Hypothalamic Pilocytic Astrocytoma
= HYPOTHALAMIC GLIOMA
• obesity, diabetes insipidus ← hypothalamic-pituitary dysfunction
• diencephalic syndrome (= emaciation despite normal / slightly decreased caloric intake, alert appearance, hyperkinesis, irritability, normal / accelerated growth)
• hemiparesis ← compression of corticospinal tracts
√ hydrocephalus
Prognosis: may regress spontaneously

Cerebral Pilocytic Astrocytoma
• headache, seizure activity, hemiparesis
• ataxia, nausea, vomiting
Location: temporal lobe

Optic Pathway Pilocytic Astrocytoma
= OPTIC NERVE GLIOMA
Location: optic nerve / chiasm
◊ Most common tumor in NF1 population (15–21%); NF1 diagnosed in ⅓ of all optic pathway gliomas; NF1 diagnosed in 40–70% of all tumors in this region; 1.5–3.5% of all orbital neoplasms; ²/₃ of all neoplasms of the optic nerve
Age: < 6 years; M÷F = 2÷1
• visual loss / visual-field deficit, optic disk pallor, optic nerve atrophy ← axonal damage + ischemia
• precocious puberty (39%) in NF1 patients

Pleomorphic Xanthoastrocytoma
= superficially located supratentorial tumor that involves leptomeninges
Prevalence: 1% of all brain neoplasms
Age: average age of 26 years (range, 5–82 years)
Path: circumscribed tumor attached to meninges with infiltration into surrounding brain
Histo: pleomorphic spindled tumor cells (reactive to glial fibrillary acidic protein) with intracytoplasmic lipid (xanthomatous) deposits in a dense intercellular reticulin network; giant cells; eosinophilic granular bodies; WHO grade II tumor
• long history of seizures (71%)
Location: supratentorial (98%): temporal (49%) / parietal (17%) / frontal (10%) / occipital (7%) lobe; thalamus; cerebellum; spinal cord
◊ Its PERIPHERAL LOCATION is the single most consistent imaging feature
√ cystic (48%) supratentorial mass with mural nodule
√ intense enhancement of solid portions
√ CHARACTERISTIC involvement of leptomeninges (71%)
√ peritumoral vasogenic edema / calcification / skull erosion are uncommon

CT:
√ hypo- / isoattenuating mass
MR:
√ hypo- to isointense mass relative to gray matter on T1WI
√ hyper- to isointense mass on T2WI
Rx: surgical resection (unresponsive to chemotherapy + radiation therapy)
Prognosis: 81% (70%) 5-year (10-year) survival rate; high rate of recurrence; malignant transformation in 20%
DDx: meningioma, glioblastoma multiforme, oligodendroglioma, metastatic disease, infection

ATAXIA-TELANGIECTASIA

= autosomal recessive disorder characterized by telangiectasias of skin + eye, cerebellar ataxia, sinus + pulmonary infections, immunodeficiencies, propensity to develop malignancies
Incidence: 1÷40,000 livebirths
Path: neuronal degradation + atrophy of cerebellar cortex (? from vascular anomalies)
• cerebellar ataxia at beginning of walking age
• progressive neurologic deterioration
• oculomotor abnormalities, dysarthric speech, choreoathetosis, myoclonic jerks
• mucocutaneous telangiectasias: bulbar conjunctiva, ears, face, neck, palate, dorsum of hands, antecubital + popliteal fossa
• recurrent bacterial + viral sinopulmonary infections
√ cerebellar cortical atrophy: diminished cerebellar size, dilatation of 4th ventricle, increased cerebellar sulcal prominence
√ cerebral hemorrhage ← rupture of telangiectatic vessels
√ cerebral infarct ← emboli shunted through vascular malformations in lung
Cx: (1) Bronchiectasis + pulmonary failure (most common cause of death)
(2) Malignancies (10–15%): lymphoma, leukemia, epithelial malignancies

BENIGN MACROCEPHALY OF INFANCY

= BENIGN ENLARGEMENT OF SUBARACHNOID SPACES = BENIGN EXTRAAXIAL COLLECTIONS OF INFANCY = EXTERNAL HYDROCEPHALUS
Cause: defective reabsorption of CSF at arachnoid villi; commonly familial with autosomal dominant inheritance
Age: presentation between 3 and 12 months
• infant with macrocephaly (head circumference > 90th percentile)
• delayed motor development, hypotonia (in up to 30%)
Location: bilateral frontoparietal area + interhemispheric fissure + sylvian fissure + basal cisterns
√ enlarged subarachnoid spaces
√ "floating" cortical veins
√ NO / mild ventricular enlargement
Cx: subdural hematoma in response to minor impacts
Prognosis: self-limiting transient development that usually resolves by 2–3 years

DDx: (1) Cerebral atrophy (diffuse sulcal prominence not localized to frontoparietal area)
(2) Spontaneous subdural hematoma (12%)

BINSWANGER DISEASE

= ENCEPHALOPATHIA SUBCORTICALIS PROGRESSIVA = LEUKOARIAOSIS = SUBCORTICAL ARTERIOSCLEROTIC ENCEPHALOPATHY (SAE)

Cause: arteriosclerosis affecting the poorly collateralized distal penetrating arteries (perforating medullary arteries, thalamoperforators, lenticulostriates, pontine perforators); positive correlation with hypertension + aging

Path: ischemic demyelination / infarction

Age: > 60 years

- psychiatric changes, intellectual impairment, slowly progressive dementia, transient neurologic deficits
- seizures, spasticity, syncope

Location: periventricular white matter, centrum semiovale, basal ganglia; sparing of subcortical white matter "U" fibers + corpus callosum

√ multifocal hypodense lesions (periventricular, centrum semiovale) with sparing of U fibers

√ lacunar infarcts in basal ganglia

√ sulcal enlargement + dilated lateral ventricles (brain atrophy)

MR:

√ focal areas of increased signal intensity on T2WI (= "unidentified bright objects")

DDx: leukodystrophy, progressive multifocal leukoencephalopathy, multiple sclerosis

BLAKE POUCH CYST

= embryonic midline outpouching of superior medullary velum extending inferior + posterior to vermis into cisterna magna

Blake pouch = rudimentary 4th ventricular tela choroidea membrane as a normal transient structure that regresses by 12 weeks GA to form the foramen of Magendie (communication between 4th ventricle + subarachnoid space)

Cause: failure of fenestration of foramen of Magendie

Age: neonate

√ retrocerebellar / infraretrocerebellar cyst = diverticulum of enlarged 4th ventricle

√ enhancing structure along anterosuperior aspect of cyst inferior to vermis = displaced choroid plexus (on SAG contrast-enhanced T1WI)

√ mild indentation of inferior vermis / caudomedial aspects of cerebellar hemispheres ← mass effect of cyst

√ tetraventricular hydrocephalus

Pertinent negatives:

√ NO supratentorial morphologic abnormalities aside from hydrocephalus

√ posterior fossa + cerebellum of normal size + shape

Prognosis: favorable (shunt-related complications possible)

DDx: megacisterna magna

BRAIN / CEREBRAL DEATH

Confirmatory tests of absent blood flow function:

1. Four-vessel contrast angiography (carotid and vertebral aa.)
2. Radionuclide cerebral blood flow angiography
3. CECT
4. Ultrasonic echoencephalography
5. Doppler ultrasound
6. Digital subtraction angiography (DSA)
7. MRI

◊ Administration of contrast may damage brain / kidney OR compromise tissue function

DDx by EEG:

Severe barbiturate intoxication (may produce a flat EEG response in the absence of brain death)

Radionuclide Angiography

= 1st-line test for cerebral perfusion; can be performed at the ICU bed site

Indication:

(1) Prior to organ harvest
(2) Hypothermia / drug intoxication interfering with clinical + EEG assessment of brain activity
(3) Brain death as a possible result of criminal activity

Pathophysiology: increased intracranial pressure above systemic arterial pressure results in markedly decreased cerebral perfusion → thrombosis → total cerebral infarction

Path: severe brain edema, diffuse liquefactive necrosis

Agent:

› nondiffusable hydrophilic ^{99m}Tc pentetic acid (^{99m}Tc-DTPA)
◊ Absence of effective cerebral perfusion at planar scintigraphy does NOT equate with brain death as blood flow to brainstem cannot be adequately assessed with ^{99m}Tc pentetic acid!
› diffusible brain imaging agents that cross the normal blood brain barrier
» lipophilic ^{99m}Tc bicisate (^{99m}Tc-ECD)
» lipophilic ^{99m}Tc exametazime (^{99m}Tc-HMPAO)

√ activity stops abruptly at the skull base = lack of activity in distribution of anterior and middle cerebral arteries + superior sagittal sinus (SSS) during 1st pass (= angiographic phase):
√ NO / faint activity in SSS on static image with ^{99m}Tc pentetic acid
√ absence of activity in cerebrum on delayed images with ^{99m}Tc bicisate / ^{99m}Tc exametazime
√ sagittal sinus not visualized

N.B.:

√ common carotid arteries must be clearly visualized on 1st pass which confirms a good technically adequate bolus
√ activity in face (“hot nose” sign) / scalp must not be mistaken as focal brain activity

False negative:

decrease in intracranial pressure may allow continuous flow through intracranial arteries

and has been observed in
(a) extensive liquefactive brain necrosis
(b) incompletely ossified skull in child
(c) open head injury in adults

CANAVAN DISEASE

= SPONGIFORM LEUKODYSTROPHY
= rare form of leukodystrophy as an autosomal recessive disorder, most common in Ashkenazi Jews
Incidence: < 100 reported cases
Cause: deficiency of aspartoacyclase leading to accumulation of N-acetylaspartic acid in brain, plasma, urine, CSF
Histo: spongy degeneration of white matter with astrocytic swelling + mitochondrial elongation
Age: 3–6 months
• marked hypotonia, spasticity, seizures
• progressive megalencephaly
• failure to attain motor milestones, intellectual failure
• optic atrophy with blindness, swallowing impairment
√ diffuse symmetric white matter abnormality
√ may involve basal ganglia
√ cortical atrophy
CT:
√ low-density white matter
MR:
√ white matter hypointense on T1WI + hyperintense on T2WI
Prognosis: death in 2nd–5th year of life
Dx: (1) elevation of N-acetylaspartic acid in urine
(2) deficiency of aspartoacyclase in cultured skin fibroblasts

CAPILLARY TELANGIECTASIA

= CAPILLARY ANGIOMA
= nest of dilated capillaries separated by normal neural tissue; commonly "cryptic"
May be associated with:
hereditary Rendu-Osler-Weber syndrome, ataxia-telangiectasia syndrome, irradiation (latency period of 5 months to 22 years)
Age: typically in elderly
• usually asymptomatic (incidental finding at necropsy)
Location: mostly in pons / midbrain > cerebral cortex > spinal cord; usually multiple / may be solitary
√ poorly defined area of dilated vessels (resembling petechiae)
√ best delineated with MR (due to hemorrhage) with focus of increased signal intensity on contrast-enhanced studies
Cx: punctate hemorrhage (uncommon); gliosis + calcifications (rare)

Prognosis: bleeding in pons (usually fatal)
DDx: cavernous angioma (identical image signature)

CAVUM VELI INTERPOSITI CYST

= cyst of ventricular roof in between two-layered tela choroidea
√ distortion of posterior superior contour of 3rd ventricle mimicking an obstructed 3rd ventricle
√ cyst of triangular contour on axial images
√ superior displacement of fornix
√ inferolateral displacement of internal cerebral veins

CENTRAL NEUROCYTOMA

= name reserved for neurocytoma that occurs in ventricles
Incidence: 0.25–0.5% of intracranial tumors
Origin: ? bipotential progenitor cells capable of both neuronal + glial differentiation
Histo: solid sheets / large lobules of small round to ovoid neoplastic cells with delicate vascular network + intervening irregular patches of fibrillary neuropils; pineocytomatous rosettes (not in oligodendroglioma)
Immunohisto: synaptophysin, neuron-specific enolase
Mean age: 29 years (range, 8 days to 67 years); M=F
• symptoms of increased intracranial pressure
Location: (a) lateral ventricle ± extension into 3rd ventricle
Site: septum pellucidum, ventricular wall
(b) extraventricular: parenchyma, cerebellum, spinal cord
√ well-circumscribed lobulated mass
√ frequently "bubbly" appearance ← presence of multiple cysts
√ calcifications (50%)
√ moderate to strong enhancement
CT:
√ hyperattenuating lesion
MR:
√ lesion T1-isointense + T2-hyperintense to gray matter
√ ± prominent flow voids
√ increased T2 signal intensity in adjacent periventricular white matter

MR spectroscopy:
√ presence of glycine (3.55 ppm)

Rx: usually curative resection
Cx: recurrence after resection, CSF dissemination

CEPHALOCELE

= mesodermal defect of calvarial suture + dura with extracranial extension (= herniation) of intracranial structures and persistent connection to subarachnoid space

Cranial meningocele: = herniation of meninges + CSF only

Encephalocele = herniation of meninges
(Meningoencephalocele) + CSF + neural tissue

Nomenclature: based on origin of their roof + floor
eg, frontonasal: frontal bone = roof, nasal bone = floor

Prevalence:
1–4÷10,000 live births; 5–6–20% of all craniospinal malformations; predominant neural axis anomaly in fetuses spontaneously aborted < 20 weeks GA; 3% of fetal anomalies detected with MS-AFP screening; 6% of all detected neural tube defects in fetuses

Cause:
failure of surface ectoderm to separate from neuroectoderm early in embryonic development (3rd week GA)

@ Skull base
(1) faulty closure of neural tube (without mesenchyme membranous cranial bone cannot develop)
(2) failure of basilar ossification centers to unite

@ Calvarium
(1) defective induction of bone
(2) pressure erosion of bone by intracranial mass / cyst

In 60% associated with:
1. Spina bifida (7–30%)
2. Corpus callosum dys- / agenesis
3. Chiari malformation
4. Dandy-Walker malformation
5. Cerebellar hypoplasia
6. Amniotic band syndrome: multiple irregular asymmetric off-midline encephaloceles
7. Migrational abnormalities
8. Chromosomal anomalies in 44% (trisomy 18)

• MS-AFP elevated in 3% (skin-covered in 60%)
• CSF rhinorrhea; meningitis

Prognosis: dependent on associated malformations + size and content of lesion; 21% liveborn; 50% survival of liveborns, 74% retarded
◊ The larger the brain volume the poorer the outcome

Risk of recurrence: 3% (25% with Meckel syndrome)

DDx: teratoma, cystic hygroma, iniencephaly, scalp edema, hemangioma, branchial cleft cyst, cloverleaf skull

Occipital Encephalocele (75%)
Most common encephalocele in Western Hemisphere

Associated with:
(1) Meckel-Gruber syndrome
= occipital encephalocele + microcephaly + cystic dysplastic kidneys + polydactyly
(2) Dandy-Walker malformation
(3) Chiari malformation
(4) Callosal + migrational anomalies

• external occipital mass

Location: supra- and infratentorial structures involved with equal frequency
√ skull defect (visualized in 80%)
√ flattening of basiocciput
√ ventriculomegaly
√ "lemon" sign = inward depression of frontal bones (33%)
√ cyst-within-a-cyst (ventriculocele = herniation of 4th ventricle into cephalocele)
√ acute angle between mass + skin line of neck and occiput
DDx: cystic hygroma

Sincipital Encephalocele (13–15%)
= FRONTOETHMOIDAL ENCEPHALOCELE
Most common variety in Southeast Asian population
Location: midface about dorsum of nose, orbits, and forehead
Cause: failure of anterior neuropore located near optic recess to close normally at 4th week GA
Types:
1. **Nasofrontal** (40–60%)
   = herniation of dura mater through foramen cecum + fonticulus frontalis
   Site: along nasal bridge between nasofrontal sutures into glabella
2. **Nasoethmoidal** (30%)
   = persistent herniation of dural diverticulum through foramen cecum into prenasal space
   Site: between nasal bone + nasal cartilage (beneath nasal bone + above nasal septum)
3. **Naso-orbital**
   Site: between maxilla + lacrimal bone (= along medial orbit at level of frontal process of maxilla and ethmoid-lacrimal bone junction)

Common root: foramen cecum (= small ostium anterior to crista galli formed by closure of frontal + ethmoid bones)
Associated with: midline craniofacial dysraphism (dysgenesis of corpus callosum, interhemispheric lipoma, anomalies of neural migration, facial cleft, schizencephaly)
• obvious nonprogressive pulsatile mass
• broad nasal root, hypertelorism, nasal stuffiness, rhinorrhea
• change in size during crying / Valsalva maneuver
• positive Fürstenberg test = change in size during jugular compression
√ soft-tissue mass extending to glabella / nasal cavity
√ pedunculated intranasal mass extending from superomedial nasal cavity downward
√ enlarged foramen cecum
OB-US:
√ widened interorbital distance
CT:
√ bifid / absent crista galli
√ absent cribriform plate / frontal bone
MR:
√ isointense relative to gray matter

√ may be hyperintense on T2WI (due to gliosis)

N.B.: biopsy is CONTRAINDICATED (→ potential for CSF leaks, seizures, meningitis)

Risk of recurrence: 6% of congenital CNS abnormalities for younger siblings

Rx: complete surgical resection with repair of dura mater (NO neurologic deficit due to abnormal function of herniated brain)

DDx: (1) Dacryocystocele / nasolacrimal mucocele
(2) Nasal glioma (no subarachnoid connection on cisternography)

Sphenoidal Encephalocele (10%)

= BASAL ENCEPHALOCELE

Age: present at end of 1st decade of life

- clinically occult ← internal protrusion
- mass in nasal cavity, nasopharynx, mouth, posterior portion of orbit increasing with Valsalva
- mouth breathing due to nasopharyngeal obstruction
- diminished visual acuity with hypoplasia of optic disks
- hypothalamic-pituitary dysfunction

Associated with: agenesis of corpus callosum (80%)

Types:

(a) transethmoidal = through midline cribriform plate
(b) sphenoethmoidal = through sphenoid + ethmoid
(c) trans-sphenoidal = through floor of sella may be associated with: cleft palate
√ displacement of cavernous sinus (laterally), pituitary gland, hypothalamus, optic nerves, chiasm
(d) frontosphenoidal
(e) sphenopharyngeal = through sphenoid body
(f) sphenoorbital = through superior orbital fissure
(g) sphenomaxillary = through maxillary sinus

Parietal Encephalocele (10–12%)

Associated with: dysgenesis of corpus callosum, large interhemispheric cyst

√ hole in sphenoid bone (seen on submentovertex film)
√ cranium bifidum = cranioschisis = "split cranium" (= skull defect) = smooth opening with well-defined sclerotic rim of cortical bone
√ hydrocephalus in 15–80% (from associated aqueductal stenosis, Arnold-Chiari malformation, Dandy-Walker cyst)
√ nonenhancing expansile homogeneous paracranial mass
√ mantle of cerebral tissue often difficult to image in encephalocele (except with MR)
√ intracranial communication often not visualized
√ metrizamide / radionuclide ventriculography DIAGNOSTIC
√ microcephaly (20%)
√ polyhydramnios

DDx: (1) sonographic refraction artifact at skull edge
(2) clover leaf skull (± temporal bone partially absent)

CEREBRAL AMYLOID ANGIOPATHY

= deposition of β-amyloid protein in media + adventitia of small + medium-sized vessels of cerebral cortex, subcortex and leptomeninges

Age: increasing with age: 33% in 60–70 years, 75% in > 90 years

Path: fibrinoid necrosis, focal vessel wall fragmentation, microaneurysm → vessel leakage + frank hemorrhage; luminal narrowing → ischemic change

Histo: yellow-green birefringent (under polarized light) deposits along vessel wall with Congo red stain

Types: sporadic form (common), hereditary form (rare)

- asymptomatic (in many): underrecognized with petechial microhemorrhages ≤ 5 mm
- headaches, emesis, focal neurologic deficit, seizure, coma with macrohemorrhage > 5 mm
- transient ischemic attack, dementia
- normotensive elderly without trauma

√ acute / chronic intracerebral hemorrhage (ICH)

◊ Cerebral amyloid angiopathy represents 2% of all ICH

Location: cortical / subcortical in any lobe; sparing of deep white matter + basal ganglia + brainstem

√ may be associated with subarachnoid / subdural hemorrhage

√ leukoencephalopathy ± involvement of U-fibers

√ cerebral atrophy

MR:

√ multiple foci of marked signal loss at GRE imaging (most sensitive sequence for hemosiderin)

DDx: hypertensive hemorrhage (basal ganglia, thalami, brainstem)

CEREBRAL CAVERNOUS MALFORMATION

= CAVERNOUS ANGIOMA OF BRAIN = CAVERNOUS HEMANGIOMA = CAVERNOMA

= benign vascular hamartoma of immature blood vessels + intralesional hemorrhage

Cause: sporadic + solitary (⅔); hereditary + multiple (⅓)

Prevalence: 0.2–0.4% of general population

Associated with: ? developmental venous anomaly

Path: well-circumscribed nodule of honeycomblike dilated endothelial lined spaces separated by fibrous collagenous bands WITHOUT intervening neural tissue

Age: any; 3rd–6th decade (most common); M = F

- asymptomatic (most)

◊ Most common asymptomatic vascular malformation!

- headache, seizures (commonly presenting symptom), neurologic deficit (15%)

Location: cerebrum (mainly superficial subcortical in close contact with subarachnoid space / ventricles) > pons > cerebellum; solitary > multiple

√ NO obvious mass effect / edema

√ usually contain blood degradation products of different stages

√ slow blood flow in vascular channels

NECT:

√ small round / lobulated hyperdense region (CLUE)

√ minimal surrounding edema
√ extensive calcifications = hemangioma calcificans (20%)

CECT:
√ none / minimal / intense enhancement
√ low-attenuation areas due to thrombosed portions

MR (DIAGNOSTIC):
√ typically popcorn appearance with bright lobulated center on T1WI + T2WI
√ well-defined area of mixed signal intensity centrally (= "mulberry"-shaped lesion) with a mixture of:
√ increased signal intensity (= extracellular methemoglobin / slow blood flow / thrombosis)
√ decreased intensity (= deoxyhemoglobin / intracellular methemoglobin / hemosiderin / calcification)
√ surrounded by hypointense rim (= hemosiderin) on T2WI

Angio:
√ negative = "cryptic / occult vascular malformation"

Cx: hemorrhage of varying age
Risk of hemorrhage: 0.4–3.1% (4.3–6.5%) per year for sporadic (familial) cases

Rx: none; microsurgery (if symptomatic)

DDx: (1) Hemorrhagic neoplasm (edema, mass effect)
(2) Hypertensive hemorrhage
(3) Small AVM (thrombosed / small feeding vessels, associated hemorrhage)
(4) Capillary telangiectasia / angioma (no difference)

CEREBRAL VENOUS THROMBOSIS

= DURAL SINUS THROMBOSIS = VENOUS SINUS / SUPERIOR SAGITTAL SINUS THROMBOSIS

◊ The radiologist may be the first to suggest the diagnosis!

Annual Incidence: 2–7÷1,000,000

Cause: > 100 causes suggested

A. IDIOPATHIC = spontaneous (10–30%)
B. LOCAL CAUSE (= intrinsic / mechanical conditions of veins / dural sinuses)
› Septic causes (esp. in childhood): sinusitis, otitis, mastoiditis, sub- / epidural empyema, meningitis, encephalitis, brain abscess, face + scalp cellulitis
› Aseptic causes:
(a) Tumor compressing sinus: meningioma
(b) Trauma: fracture through sinus wall, brain damage, cranial surgery, jugular vein catheterization
C. SYSTEMIC CAUSE (= conditions that promote thrombosis)
› Septic causes: septicemia
› Aseptic causes:
(a) Low-flow state: CHF, CHD, dehydration, shock, surgery, immobilization
(b) Hypercoagulability: antithrombin III deficiency, antiphospholipid syndrome, protein S + C deficiency, pregnancy, peripartum state, oral contraceptives,

malignancy, polycythemia vera, idiopathic thrombocytosis, thrombocytopenia, sickle cell disease, cryofibrinogenemia, disseminated intravascular coagulopathy

(c) Chemotherapy: eg, ARA-C, L-asparaginase

› Unusual causes: Behçet disease, AIDS, ulcerative colitis, SLE, nephrotic syndrome, sarcoidosis

Pathophysiology:

dural sinus thrombosis → thrombus propagation into cortical veins → venous congestion → cerebral venous infarction (in 50%) → vasogenic / cytotoxic edema → intracranial hemorrhage; occasionally hydrocephalus (→ decreased CSF absorption ← impaired function of arachnoid granulations)

Onset: acute = < 2 days (in 30%), subacute = 2–30 days (in 50%), chronic = > 30 days (20%)

- symptoms of intracranial hypertension (20–40%): headaches (75–95%), nausea, vomiting, visual blurring, papilledema
  often confused with: tension headaches, migraine
- drowsiness, confusion, coma, decreased mentation, lethargy, obtundation, seizures, fever
- focal neurologic deficits = stroke symptomatology (dysphasia, cranial nerve palsy, cerebellar incoordination) ← frequently parenchymal changes

Location: superior sagittal sinus (62%) > L transverse sinus (45%) > R transverse sinus (41%) > sigmoid sinus (15%) > straight sinus (18%) > cortical veins (17%) > deep venous system (11%) > jugular bulb (8%) > vein of Galen (7%) > cavernous sinus (1%) > cerebellar veins (0.3%)

√ bilateral parasagittal hemispheric lesions ← superior sagittal sinus thrombosis

√ ipsilateral temporo-occipital + cerebellar lobe lesions ← transverse sinus thrombosis

√ bilateral thalamic lesions ← deep cerebral venous thrombosis

NECT (usually subtle findings):

√ hyperattenuating intravascular material (← acute blood clot) in sagittal sinus = "**dense triangle" sign** / straight sinus / cerebral cortical vein = "**cord**" sign lasting for 1–2 weeks (seen in only 20% ← variability in degree of thrombus attenuation)

DDx to hyperattenuated thrombus:

dehydrated patient, elevated hematocrit level, polycythemia, nonmyelinated brain in neonates, subjacent subarachnoid / subdural hemorrhage

√ subdural collection

√ stroke (often hemorrhagic)

◊ Thrombosis of intracranial dural sinuses, cortical / deep cerebral veins, cavernous sinus is an easily recognizable condition that accounts for 1% of acute cerebral infarcts.

√ dense transcortical medullary vein ← collateral drainage

CECT venography (30–40 sec delay):

(a) direct

√ **"empty delta" sign** / "empty triangle" = filling defect in straight sinus / superior sagittal sinus surrounded by a triangular area of enhancing collateral dural venous channels + cavernous spaces (in 25–35–75%)

False positive: subdural hematoma / empyema, arachnoid granulations

False negative: partial volume averaging, small / recanalized organized thrombus

√ enlargement of thrombosed vein near obstruction

√ shaggy irregular contour of veins (= small collateral veins enhance near the obstructed vein)

(b) indirect (subtle early changes)

√ brain edema + swelling of gyri

√ low attenuation lesion of venous infarction

√ ± subcortical hemorrhage in venous distribution

Mimics of cerebral venous thrombosis on CECT:
1. Hypo- / aplastic transverse sinus
2. Variable bolus transit time with delayed filling
3. Arachnoid granulation
4. Sinus compression by adjacent mass
5. Extradural abscess

Advantage over MR: shorter exam time, NO contraindication to pacemaker, fewer equivocal findings, NO flow-related artifacts

Disadvantage over MR: difficult MIP reconstruction (due to adjacent bone), adverse reaction to contrast material, ionizing radiation

NEMR:

√ replacement of flow void by abnormal signal intensity

(a) acute thrombosis (first 5 days)

√ clot isointense to gray matter on T1WI (and therefore easily missed) + hypointense on T2WI (← deoxyhemoglobin in RBCs trapped in thrombus)

√ low SI rather than normal flow void on T1WI

√ blooming artifacts on GRE in thrombosed segment

√ hyperintense thrombosed sinus on DWI with diminished mean ADC value (in 41%)

(b) subacute thrombosis (6–15 days = in 55% of patients)

◊ most frequent stage at clinical presentation (55%) + easiest stage for thrombus detection

√ hyperintense thrombus within sinus on T1WI (← intra- and extracellular methemoglobin)

√ iso- / hyperintense thrombus on T2WI (← extracellular methemoglobin)

N.B.: hypointense thrombus on T2WI ← intracellular methemoglobin may mimic flow void of a patent dural sinus

(b) chronic thrombosis (> 15 days = 15% of patients) with incomplete recanalization

◊ Most difficult stage to diagnose!

√ isointense on T1WI + iso- / hyperintense T2WI

MR venography (TOF, CEMR):

√ excellent sensitivity to slow flow perpendicular to plane of acquisition for 2D-TOF

Pitfalls: nulling of venous signal in plane of acquisition; hyperintense thrombus on T1WI time-of-flight venography can simulate flow-related enhancement

√ filling defect in sinus on CEMR

Pitfall: marked contrast enhancement of organized revascularized thrombus in chronic thrombosis

◊ Sinus contrast enhancement does NOT DEFINITELY indicate patency!

√ wall-enhancement of thrombosed dural sinus

Angio (DSA):
√ nonfilling of thrombosed sinus
√ filling of collateral cortical veins, deep venous system, cavernous sinus

Prognosis: high mortality

Bad outcome: hemorrhage on admission CT, thrombosis of deep cerebral veins, CNS infection

Rx: heparin (full recovery in 70%), local thrombolysis (worsening in spite of adequate anticoagulation), reduction of intracranial pressure

Parenchymal Changes in Cerebral Venous Thrombosis
√ focal edema WITHOUT hemorrhage (CT in 8%, MR in 25%):
√ increased ADC value = vasogenic edema
√ decreased ADC value = cytotoxic edema (in 50%)
◊ The term "venous infarct" is discouraged as parenchymal abnormalities due to venous occlusion are reversible!
√ parenchymal swelling without SI abnormalities (in 42%):
√ sulcal effacement
√ diminished visibility of cisterns
√ reduction in ventricular size
√ parenchymal enhancement (in 1–29%):
√ gyral enhancement in periphery of infarction ± extension into white matter
√ increased tentorial enhancement ← dural venous collaterals (rare)
√ leptomeningeal enhancement
√ cortical venous enhancement ← venous congestion
√ parenchymal hemorrhage (in 33%):
√ flame-shaped irregular zones of hemorrhage in parasagittal frontal + parietal lobes (in superior sagittal sinus thrombosis)
√ temporal / occipital hemorrhage (in transverse sinus thrombosis)
√ cortical / subcortical hemorrhage ← retrograde extension of thrombus (in superficial venous thrombosis)
√ perfusion changes:
√ prolongation of mean transit time
√ normal / abnormal relative cerebral blood volume

Cavernous Sinus Thrombosis / Thrombophlebitis

Cause: vascular spread of infection from
(a) common: facial cellulitis, paranasal sinusitis, dental infection
(b) less frequent: orbit, middle ear, tonsils

Organism: Staphylococcus aureus, Streptococcus, gram-negative bacteria, anaerobes, mucormycosis

Spread: to contralateral side

- acute headache, periorbital pain + edema
- photophobia, ptosis, chemosis

• cranial nerve deficits III–VI: abducens nerve palsy (most common)
√ enlarged convex-shaped cavernous sinus + filling defect
√ enlarged superior ophthalmic vein
√ proptosis
Prognosis: visual impairment, permanent CN deficit, meningitis, sepsis, death
Rx: IV antibiotics, anticoagulation
DDx: neoplasm (meningioma, metastasis, lymphoma), sarcoidosis, cavernous-carotid fistula, Wegener granulomatosis, Tolosa-Hunt syndrome

Deep Cerebral Venous Thrombosis

Site: thrombus in straight sinus, vein of Galen, internal cerebral veins, vein of Rosenthal
√ T2 prolongation in thalamus, internal capsule, basal ganglia, deep white matter
√ hemorrhagic conversion (common)
√ thrombosed veins on MRV

With simultaneous involvement of both thalami and basal ganglia search for subtle signs of venous thrombosis!

CEREBRITIS

= focal area of inflammation within brain substance
CT:
√ area of decreased density ± mass effect
√ no contrast enhancement (initially) / central or patchy enhancement (later)
MR:
√ focal area of increased intensity on T2WI
Cx: brain abscess

CHIARI MALFORMATION

Chiari I Malformation (adulthood)

= CEREBELLAR TONSILLAR ECTOPIA
= herniation of cerebellar tonsils below a line connecting basion with opisthion (= level of foramen magnum)
◊ Frequently isolated hindbrain abnormality of little consequence without supratentorial anomalies!
Proposed causes:
(a) small posterior fossa
(b) disproportionate CSF absorption from subarachnoid spinal space
(c) cerebellar overgrowth
Associated with:
(1) syringohydromyelia (20–30%)
(2) hydrocephalus (25–44%)
(3) malformation of skull base and cervical spine:
(a) basilar impression (25%)
(b) craniovertebral fusion: eg, occipitalization of C1 (10%), incomplete ossification of

C1-ring (5%)
(c) Klippel-Feil anomaly (10%)
(d) platybasia
◊ NOT associated with myelomeningocele!
• benign cerebellar ectopia: < 3 mm of no clinical consequence; 3–5 mm of uncertain significance; > 5 mm clinical symptoms likely
• no symptoms in childhood (unless associated with hydrocephalus / syringomyelia)
• ± cranial nerve dysfunction / dissociated anesthesia of lower extremities in adulthood
√ downward displacement of cerebellar tonsils + medial part of inferior lobes of cerebellum > 5 mm below level of foramen magnum
√ inferior pointing peglike / triangular tonsils
√ obliteration of cisterna magna
√ elongation of 4th ventricle, which remains in normal position
√ slight anterior angulation of lower brainstem

Chiari II Malformation (childhood)
= ARNOLD-CHIARI MALFORMATION
= most common + serious complex of anomalies involving hindbrain, spine, mesoderm ← posterior fossa too small
HALLMARK is dysgenesis of hindbrain with
(a) caudally displaced 4th ventricle
(b) caudally displaced brainstem
(c) tonsillar + vermian herniation through foramen magnum
No association with: basilar impression / C1-assimilation / Klippel-Feil deformity
• newborn: respiratory distress, apneic spells, bradycardia, impaired swallowing, poor gag reflex, retrocollis, spasticity of upper extremities
• teenager: gradual loss of function + spasticity of lower extremities
Skull film:
√ Lückenschädel (most prominent near torcular herophili / vertex) in 85% = dysplasia of membranous skull disappearing by 6 months of age
√ scalloping of clivus + posterior aspect of petrous pyramids (from pressure of cerebellum) in 70–90% leading to shortening of IAC
√ small posterior fossa
√ enlarged foramen magnum + enlarged upper spinal canal secondary to molding (in 75%)
√ absent / hypoplastic posterior arch of C1 (in 70%)
@ Supratentorial
√ obstructive hydrocephalus (duct of Sylvius dysfunctional but probe patent); may not become evident until after repair of myelomeningocele (in 50–98%)
√ nonvisualization of aqueduct (in up to 70%)
√ colpocephaly (= enlargement of occipital horns + atria) ← maldeveloped occipital lobes
√ dysgenesis of corpus callosum (in 80–90%): hypoplasia / absence of splenium + rostrum
√ absence of septum pellucidum (40%)
√ interdigitation of medial cortical gyri ← hypoplasia + fenestration of falx (in up to

100%)

√ **"bat-wing"** configuration of frontal horns (on COR views) = frontal horns point inferiorly with blunt superolateral angle ← prominent impressions by enlarged caudate nucleus

√ "hourglass ventricle" = small biconcave 3rd ventricle ← large massa intermedia

√ wide prepontine + supracerebellar cisterns

√ **stenogyria** = multiple small closely spaced gyri separated by shallow sulci within cortex of normal thickness ← dysplasia (in up to 50%)
Location: medial occipital lobe (on SAG image)

@ Cerebellum

√ "cerebellar peg" = protrusion of vermis + hemispheres through foramen magnum (90%) → craniocaudal elongation of cerebellum

√ hypoplastic poorly differentiated cerebellum (poorly visualized folia on sagittal images) ← severe degeneration

√ elongated / obliterated vertically oriented thin-tubed 4th ventricle with narrowed AP diameter exiting below foramen magnum (40%)

√ obliteration of CPA cistern + cisterna magna by cerebellum growing around brainstem

√ dysplastic tentorium with wide U-shaped incisura inserting close to foramen magnum (95%)

√ "tectal beaking" = fusion of midbrain colliculi into a single beak pointing posteriorly and invaginating into cerebellum

√ V-shaped widened quadrigeminal plate cistern ← hypoplasia of cingulate gyri

√ "towering cerebellum" = "pseudomass" = cerebellar extension above incisura of tentorium

√ triple peak configuration = corners of cerebellum wrapped around brainstem pointing anteriorly+ laterally (on axial images)

√ flattened superior portion of cerebellum ← temporoparietal herniation

√ vertical orientation of shortened straight sinus

@ Spinal cord

√ medulla + pons displaced into cervical canal

√ "cervicomedullary kink" = herniation of medulla posterior to spinal cord (up to 70%) at level of dentate ligaments

√ widened anterior subarachnoid space at level of brainstem + upper cervical spine (40%)

√ AP diameter of pons narrowed

√ upper cervical nerve roots ascend toward their exit foramina

√ syringohydromyelia

√ lumbar myelomeningocele (> 95%)

√ low-lying often tethered conus medullaris below L2

OB-US:

√ hydrocephalus

√ "banana" sign = cerebellum wrapped around posterior brainstem + obliteration of cisterna magna ← small posterior fossa + downward traction of spinal cord

Chiari III Malformation

most severe rare abnormality; probably unrelated to type I and II Chiari malformation
√ low occipital / high cervical meningomyeloencephalocele
Prognosis: survival usually not beyond infancy

Chiari IV Malformation

extremely rare anomaly probably erroneously included as type of Chiari malformation
√ agenesis of cerebellum
√ hypoplasia of pons
√ small + funnel-shaped posterior fossa

CHORISTOMA

= INFUNDIBULOMA = GRANULAR CELL TUMOR
= benign slow-growing low-grade glioma = maldeveloped tissue in an abnormal site [*choristos* , Greek = separated, apart]
Incidence: rare tumor (70 cases reported in literature)
Origin: pituicyte (= modified astrocyte)
Age: 4th–5th decade; M÷F = 1÷2
Location: along neurohypophysis (sella, suprasellar cistern)
• visual field deficit, panhypopituitarism, diabetes insipidus (rare)
MR:
√ solid component iso- to mildly hypointense to brain on T1WI + T2WI
√ ± cystic component
√ heterogeneous enhancement
Prognosis: no invasion, no recurrence

CHOROID PLEXUS CYST

= cyst arising from folding of neuroepithelium with trapping of secretory products + desquamated choroid epithelium
Incidence: 0.9–3.6% in sonographic population; in up to 50% of autopsied brains
Histo: epithelial-lined cyst, filled with clear fluid ± debris
May be associated with: aneuploidy (76% in trisomy 18, 17% in trisomy 21, 7% in triploidy / Klinefelter syndrome)
◊ In the absence of other anomalies 1% of fetuses with choroid plexus cysts will have trisomy 18!
◊ In the presence of other anomalies 4% of fetuses with choroid plexus cysts will have trisomy 18!
◊ 40–71% of autopsied fetuses with trisomy 18 have choroid plexus cysts bilaterally > 10 mm in diameter
◊ The risk of chromosomal abnormalities is not linked to size, bilaterality, gestational age at appearance / disappearance of choroid plexus cysts!
• usually asymptomatic
Location: frequently at level of atrium; bi- / unilateral; 3rd ventricle (rare)
Site: body of plexus ± protrusion into ventricular cavity
Average size: 4.5 (range, 2–25) mm

US:
√ single / multiple round anechoic cysts
CT:
√ iso- to slightly hyperattenuating compared with CSF
MR:
√ iso- to hyperintense on T1WI compared with CSF
√ hyperintense on T2WI compared with CSF
√ incompletely hypointense (suppressed) on FLAIR
√ restricted diffusion = hyperintense on DWI (66%)
√ nodular / rim enhancement
Cx: hydrocephalus (if cyst large)
Prognosis: 90% disappear by 26th–28th week; may persist; in 95% of no significance
OB-management:
a choroid plexus cyst should stimulate a thorough sonographic examination at > 19 weeks; if no other sonographic abnormalities are identified, the yield of abnormal karyotype is low so that the risk of trisomy 18 (1÷450–500) is lower than risk of fetal loss due to amniocentesis (~ 1÷200–300)
Risk of karyotype abnormality:
increased by 10 times with 1 additional defect
increased by 600 times with ≥ 2 additional defects
DDx: (1) Choroid plexus pseudocyst in the inferolateral aspect of atrium (? corpus striatum) on oblique coronal plane, which elongates by turning transducer
(2) Ependymal cyst (no enhancement)
(3) Villous hyperplasia (very rare, uniform strong enhancement)

CHOROID PLEXUS NEOPLASM

Incidence: 0.5–0.6% of all primary intracranial tumors; 2–5% of pediatric brain tumors; 5% of all supratentorial tumors in children; 60–70% of all choroidal tumors
Age: up to 20% < 1 year of age; in 75% < 2 years of age; in 86% < 5 years of age; M >> F
Path: large aggregation of choroidal fronds producing great quantities of CSF; occasionally found incidentally on postmortem examination
Pathophysiology: abnormal rate of CSF production of 1.0 mL/min (normal rate = 0.2 mL/min)
Subdivision:
1. Choroid plexus **papilloma** (CPP) (WHO grade I)
2. **Atypical** choroid plexus papilloma (WHO grade II) ≥ 2 mitoses per 10 randomly selected high-power fields
3. Choroid plexus **carcinoma** (CPC) (WHO grade III) > 5 mitoses per high-power field

CPP÷CPC = 5÷1

Imaging does not allow distinction between subdivisions.
All subtypes may demonstrate CSF dissemination → imaging of the entire neuroaxis is recommended!

May be associated with: von Hippel-Lindau syndrome (papillomas in unusual locations), Aicardi syndrome, Li-Fraumeni syndrome
• signs of increased intracranial pressure
Location: anywhere within choroid plexus epithelium

(a) glomus of choroid plexus in atrium (trigone) of lateral ventricles (in 50% of adults, in 80% of children), L > R (in children); M=F
(b) 4th ventricle (40%) + cerebellopontine angle (in adults); M÷F = 3÷2
(c) 3rd ventricle (10%)
(d) multiple in 5–7%

√ large mass with papillary / smooth lobulated border (DDx from other intraventricular neoplasms)
√ small foci of calcifications (common)
√ ± cystic areas within tumor
√ engulfment of glomus of choroid plexus (DISTINCTIVE feature)
√ asymmetric diffuse ventricular dilatation = communicating hydrocephalus
Cause: (a) CSF overproduction by neoplasm
(b) obstruction of CSF absorption ← proteinaceous exudate / repeated occult hemorrhage
(c) direct obstruction of CSF pathway)
√ dilatation of temporal horn in atrial location (obstruction)
√ occasionally growth into surrounding white matter (more commonly a feature of choroid plexus carcinoma)
√ septa / cysts within ventricular system ← inflammatory reaction to tumor / tumoral hemorrhage

CT:
√ iso- / mildly hyperattenuating homogeneous mass
√ ± calcifications and foci of hemorrhage

CECT:
√ intense homogeneous enhancement ← very vascular lesion

MR:
√ iso- to slightly hypointense lesion on T1WI + iso- to hyperintense on T2WI relative to white matter
√ flow voids (common)
√ surrounded by hypointense signal on T1WI + hyperintense signal on T2WI (CSF)
√ intraventricular enhancing island of tumor on Gd-DTPA + retention of contrast within tumor interstitium

MR spectroscopy:
√ marked choline peak WITHOUT N-acetylaspartate / creatine peak; elevated lactate level for carcinomas

US:
√ echogenic mass adjacent to normal choroid plexus

Angio:
√ enlarged choroidal artery if neoplasm located in atrium ← supplied by anterior + posterior choroidal arteries

Cx: (1) Transformation into malignant choroid plexus papilloma = choroid plexus carcinoma (in 5%)
(2) Hydrocephalus (in children) ← increased intracranial pressure from CSF-overproduction
(3) Tumor infarction ← twist of pedicle

Rx: surgical removal (24% operative mortality) cures hydrocephalus
Prognosis: 97% 5-year survival rate for papilloma; 26–43% 5-year survival rate for carcinoma
DDx: intraventricular meningioma, ependymoma, metastasis, cavernous angioma, xanthogranuloma, astrocytoma

COCKAYNE SYNDROME

[Edward Alfred Cockayne (1880–1956), English pediatrician who published "Inherited Abnormalities of the Skin and its Appendages" in 1933, the first book on inherited skin disorders]
= autosomal recessive diffuse demyelinating disease
Age: beginning at age 1
• dwarfism; retinal atrophy + deafness
• progressive physical + mental deterioration
√ brain atrophy / microcephaly
√ calcifications in basal ganglia + cerebellum
√ skeletal changes superficially similar to progeria
DDx: Progeria

COLLOID CYST

Incidence: 2% of glial tumors of ependymal origin; 0.5–1% of CNS tumors
Origin: neuroepithelial / endodermal
Histo: single layer of ciliated + columnar mucin-secreting epithelium; squamous cells of ependymal origin; tough fibrous capsule; filled with thick viscous mucus consisting of blood products, macrophages, cholesterol crystals, numerous metallic ions
Age: 5th–6th decade; M > F
• positional headaches (← transient obstruction secondary to ball-valve mechanism at foramen of Monro)
• hypogonadism, galactorrhea (for intra- / suprasellar location)
• change in mental status ± dementia (related to increased intracranial pressure); gait apraxia
• papilledema (may become medical emergency with acute herniation)
Location: inferior aspect of septum pellucidum protruding into anterior superior portion of 3rd ventricle between columns of fornix; suprasellar cistern (rare)
Size: several mm to 3 cm
√ ± sellar erosion
√ 3rd ventricular enlargement (to accommodate cyst anteriorly)
√ asymmetric lateral ventricular enlargement (invariably)
√ occasionally widens septum pellucidum
√ may show enhancement of border ← draped choroid plexus / capsule
NECT:
√ spherical iso- / (often) hyperattenuating lesion with smooth surface contour without enhancement
√ fluid contents:
(a) in 20% similar to CSF (= isodense)

(b) in 80% mucinous fluid, proteinaceous debris, hemosiderin, desquamated cells (= hyperdense)

MR:

√ variable SI lesion (dependent on mucus composition):

√ hyperintense on T1WI + FLAIR ← large protein molecules / paramagnetic effect of magnesium, copper, iron in cyst

√ iso- to hypointense on T2WI (most common)

Prognosis: asymptomatic and stable in 90%; 10% enlarge / cause hydrocephalus; with rapid enlargement → coma and death

DDx: meningioma, ependymoma of 3rd ventricle (rare) with enhancement

CONGENITAL INCLUSION CYSTS OF CNS

Origin: defect in cleavage of neural tissue from cutaneous ectoderm during closure of neural tube in 5th week of fetal life (early inclusion results in midline lesion, later inclusion results in more lateral location)

Frequency: dermoid÷epidermoid = 1÷3 to 1÷10

Location: most commonly in midline (anterior fontanelle, glabella, nasion, vertex, subocciput) > frontotemporal > parietal location

Affected sutures: frontozygomatic, sphenofrontal, sphenosquamosal, squamosal, coronal, lambdoid, parietomastoid

• ± external skin ostia and deep sinus tracts

√ angiographically avascular

√ NO contrast enhancement internally (DDx to teratoma)

√ rare peripheral rim enhancement ← perilesional inflammation / infection

Cx: (1) Chemical / aseptic meningitis (rare)

(2) Squamous cell carcinoma (rare)

Dermoid Cyst of CNS

Path: ectoderm + skin elements = pilosebaceous mass of squamous epithelial cells + mesodermal cells (hair follicles, sweat glands and sebaceous glands)

Growth: desquamation of epithelial cells + glandular secretion → faster growth than epidermoids

Incidence: 1% of all intracranial tumors

Age: < 30 years (appears in adulthood due to slow growth); M < F

Location:

(a) spinal canal (most common): extra- / intramedullary in lumbosacral region

(b) posterior fossa within vermis / 4th ventricle (predilection for midline)

(c) posterior to superior orbital fissure, may be associated with bone defect

(d) sellar + parasellar region

(e) nasion ± sinus tract up to foramen cecum

Risk: CNS infection

• bouts of chemical / bacterial meningitis possible

√ thick-walled inhomogeneous mass with focal areas of fat

√ mural / central calcifications / bone (possible)

√ may have sinus tract to skin surface (dermal sinus) if located in midline at occipital / nasofrontal region
√ fat-fluid level if cyst ruptures into ventricles, fat droplets in subarachnoid space

CT:

√ variable appearance ± areas of low attenuation due to lipid component

MR:

Dermoid Cyst versus Teratoma	
Dermoid Cyst	*Teratoma*
Inclusion cyst	Germ cell neoplasm
√ unilocular	√ multilocular
√ rim enhancement	√ internal enhancement
√ rim calcification	√ internal calcification

√ variointense on T1WI (hyperintense with contents of liquefied cholesterol products)
√ curvilinear regions of low SI on T1WI + T2WI (= hair)
√ shortened T1 + T2 relaxation times (= fat)
√ suppressed fat signal on fat-suppressed images

Epidermoid Cyst of CNS

Path: ectoderm WITHOUT skin elements = "pearly tumor" = well-defined solid lesion with glistening irregular nodular surface; lamellar cyst contents consists of soft flaky desquamated keratinaceous debris rich in cholesterol + triglycerides = **primary / congenital cholesteatoma**

Incidence: 0.2–1.8% of all primary intracranial neoplasms; most common congenital intracranial tumor

Histo: tumor lined by simple stratified cuboidal squamous epithelium; surrounded by thin band of collagenous connective tissue

Growth: extremely slow linear growth resulting from desquamation of epithelial cells

Age: 10–60 years, peak age in 4th–5th decade (slow tumor expansion over decades thus becoming symptomatic in adulthood); M÷F = 1÷1

- facial pain
- cranial nerve palsies with CP angle epidermoid (50%)
- visual abnormality + endocrinologic disturbance (eg, diabetes insipidus) with suprasellar epidermoid
- hydrocephalus with suprasellar epidermoids
- chemical meningitis (← leakage of tumor contents into subarachnoid space) with middle cranial fossa epidermoids

Location:

(a) cerebellopontine angle (40%, account for 5% of CP angle tumors)
(b) suprasellar region, perimesencephalic cisterns (14%)
(c) in ventricles, brainstem, brain parenchyma
(d) pineal region (3–4%): peak age in 3rd decade
(e) skull vault

Site: midline / paramidline; intradural (90%) / extradural; transspatial growth (= extension

from one into another intracranial space)
√ soft lesion insinuating into adjacent brain parenchyma:
√ conforming to + molding itself around brain surfaces
√ intimately surrounding vessels + cranial nerves rather than displacing them (limited resectability)
√ little mass effect, no edema / hydrocephalus
√ may be associated with dermal sinus tract at occipital / nasofrontal region if midline in location
CT:
√ typically lobulated round homogeneous mass with density similar to CSF (between water and –20 HU)
√ occasionally hyperdense due to high protein content, saponification of keratinaceous debris, prior hemorrhage into cyst, ferrocalcium / iron-containing pigment, abundance of PMNs
√ bony erosion with sharply defined well-corticated margins
√ peripheral calcifications (in 25%)
MR:
√ lamellated onionskin appearance with septations (layer-on-layer accretion of desquamated material)
√ "**black epidermoid**" (majority) = SI similar to CSF:
√ heterogeneously hypointense lesion on T1WI
√ hyperintense on T2WI
Cause: cholesterol in solid crystalline state + keratin within tumor + CSF within tumor interstices
√ "**white epidermoid**" (rare) = SI similar to fat:
√ hyperintense on T1WI
√ iso- to hyperintense on T2WI
Cause: triglycerides + polyunsaturated fatty acids
√ SI similar to calcium = hypointense on T2WI (very rare) ← peripheral calcifications, low hydration, viscous secretion, paramagnetic iron-containing pigment
√ incomplete saturation on FLAIR = hyperintense relative to CSF (DDx: arachnoid cyst)
√ lesion very hyperintense on DWI
√ signal intensity suppression on fat-suppressed sequence (DDx: lipoma exhibits more suppression)
Cisternography:
√ papillary / frondlike surface with contrast material extending into tumor interstices
Rx: surgical resection (complicated by adherence to surrounding brain + cranial nerves, spillage of cyst contents with chemical meningitis, CSF seeding + implantation)
DDx: arachnoid cyst (smooth surface, earlier diffusion, equal to CSF), lipoma, cystic schwannoma, adenomatoid tumor, atypical meningioma, chondroma, chondrosarcoma, chordoma, calcified neurogenic tumor, teratoma, calcified astrocytoma, ganglioglioma

CORTICAL CONTUSION

= CEREBRAL CONTUSION = BRAIN CONTUSION

= traumatic injury to cortical surface of brain

Incidence: most common type of primary intraaxial lesion; in 21% of head trauma patients; children÷adults = 2÷1

Pathogenesis: capillary disruption leads to extravasation of whole blood, plasma (edema) and RBCs

Path: petechial hemorrhage (= admixture of blood with native tissue) followed by liquefaction + edema after 4–7 days, tissue necrosis

Mechanism: linear acceleration-deceleration forces / penetrating trauma

1. **Coup** (same side as impact)
   = small area of direct impact on stationary brain
   Associated with: skull fracture
2. **Contrecoup** (180° opposite to side of impact)
   = broad area of impact as a result of moving brain against stationary calvarium
   Associated with: fall

Location: multiple bilateral lesions;

– common: along anterior + lateral + inferior surfaces of <u>frontal lobe</u> (in orbitofrontal, inferior frontal, and rectal gyri above cribriform plate, planum sphenoidale, lesser sphenoid wing) and <u>temporal lobe</u> (just above petrous bone / posterior to greater sphenoid wing)
– less frequent: in parietal + occipital lobes, cerebellar hemispheres, vermis, cerebellar tonsils
– often bilateral / beneath an acute subdural hematoma

• confusion (mild initial impairment), focal cerebral dysfunction
• seizures, personality changes
• focal neurologic deficits (late changes)

CT (sensitive only to hemorrhage in acute phase):

◊ Look for scalp swelling to focus your attention on the location of the coup!
√ "salt and pepper lesion" = mottled / speckled densities as focal / multiple (29%) poorly defined areas of low attenuation with irregular contour (edema) intermixed with a few tiny areas of increased density (petechial hemorrhage)
√ diffuse cerebral hypodensity + swelling without hemorrhage in immediate posttraumatic period (common in children) ← hyperemia / ischemic edema
√ some degree of contrast enhancement ← leaking new capillaries
√ hemorrhage isodense after 2–3 weeks
√ true extent of lesions becomes more evident with progression of edema + cell necrosis + mass effect over ensuing weeks

MR (best modality for initial detection of contusional edema with accurate portrayal of extent of lesion):

√ hemorrhagic lesion (detected in 50% of all contusions):
  √ initially decreased intensity (← deoxyhemoglobin of acute hemorrhage) surrounded by hyperintense edema on T2WI
  √ hyperintense on T1WI + T2WI in subacute phase ← Met-Hb
  √ hyperintense gliosis + hypointense hemosiderin on T2WI in chronic phase
√ nonhemorrhagic lesion hypointense on T1WI + hyperintense on T2WI

Cx: (1) Progression to cerebral hematoma

(2) Encephalomalacia (= scarred brain)
(3) Porencephaly (= formation of cystic cavity lined with gliotic brain and communicating with ventricles / subarachnoid space)
(4) Hydrocephalus ← adhesions ← subarachnoid blood

CRANIOPHARYNGIOMA

Incidence: 3–4% of all intracranial neoplasms; 15% of supratentorial + 50% of suprasellar tumors in children; most common suprasellar mass
Origin: from epithelial rests along vestigial craniopharyngeal duct + primitive buccal epithelium (Rathke cleft cells within intermediate lobe of pituitary gland)
Path: cystic (rich in liquid cholesterol) / complex / solid
Age: from birth–7th decade; M > F; bimodal age distribution with age peaks in 1st–2nd decade (75%) and in 4th–6th decade (25%)
• diabetes insipidus ← compression of pituitary gland
• growth retardation ← compression of hypothalamus
• bitemporal hemianopia ← compression of optic nerve chiasm
• headaches from hydrocephalus ← compression of foramen of Monro / aqueduct of Sylvius
Location: anywhere along infundibular stalk from floor of 3rd ventricle to pituitary gland
(a) suprasellar (20%)
(b) intrasellar (10%)
(c) intra- and suprasellar (70%)
Ectopic craniopharyngioma:
(e) floor of anterior 3rd ventricle (more common in adults)
(f) sphenoid bone

Skull films:
√ normal sella (25%)
√ enlarged J-shaped sella with truncated dorsum
√ thickening + increased density of lamina dura in floor of sella (10%)
√ extensive sellar destruction (75%)
√ curvilinear / flocculent / stippled calcifications / lamellar ossification; calcifications seen in youth in 70–90%, in adults in 30–40%

CT:
√ multilobulated inhomogeneous suprasellar mass
√ solid (15%) / mixed (30%) / cystic lesion (54–75%) [cystic appearance ← cholesterol, keratin, necrotic debris with higher density than CSF]
√ enhancement of solid lesion, peripheral enhancement of cystic lesion
√ marginal hyperdense lesion (calcification / ossification) in 70–90% in childhood tumors + 30–50% of adult tumors
√ ± obstructive hydrocephalus
√ extension into middle > anterior > posterior cranial fossa (25%)

MR (relatively ineffective in demonstrating calcifications):
√ hyperintense (mostly), but also iso- / hypointense on T1WI (variability ← hemorrhage / cholesterol-containing proteinaceous fluid)
√ markedly hyperintense on T2WI

√ heterogeneous enhancement of solid components + cyst wall

Angio:

√ usually avascular

√ lateral displacement, elevation, narrowing of supraclinoid segment of ICA

√ posterior displacement of basilar artery

DDx: (1) Epidermoid (no contrast enhancement)

(2) Rathke cleft cyst (small intrasellar lesion)

(3) Hemorrhagic pituitary macroadenoma (fluid-fluid level)

CREUTZFELDT-JACOB DISEASE

[Hans Gerhard Creutzfeldt (1885–1964), German neuropathologist and director of the university psychiatric and neurological division in Kiel]

[Alfons Maria Jakob (1884–1931), German neurologist and head of the laboratory of anatomical pathology at the psychiatric State Hospital Hamburg-Friedrichsberg]

= rare subacutely progressive neurological disorder due to transmissible infectious disease developing over weeks

Cause: "**prion**" (self-replicating proteinaceous infectious particles) = protein devoid of functional nucleic acid converted to proteinaceous infectious scrapie particles that accumulate in + around neurons leading to cell death; kuru among aboriginal Fore people of New Guinea (ritualistic oral ingestion of body parts)

[scrapie = affected animals compulsively scrape off their fleece against rocks, trees or fences]

Iatrogenic causes: corneal transplantation, ingestion of prion-contaminated human growth hormone, transplantation of cadaveric dura mater

Age: older adults (57–73 years)

Histo: classified as spongiform encephalopathy "mad cow disease"

• rapidly progressive dementia, ataxia, generalized myoclonus

• synchronous discharges on EEG as generalized periodic sharp wave complexes (in 60%)

• CSF protein 14-3-3 (96% specific + 96% sensitive)

Subtypes: sporadic, familial, iatrogenic, variant

Location: cerebral cortex, basal ganglia (caudate nucleus), thalamus

CT:

√ usually normal

√ rapidly progressive atrophic changes

MR:

√ hyperintense T2 lesions in basal ganglia (head of caudate nucleus + putamen), occipital cortex, bilaterally (79% sensitive)

√ high-SI lesions on DWI (← vacuolization of neutrophil leading to gliosis + astrocytosis and restriction of water diffusion) + decreased ADC (94% sensitive, 92% specific):

Location: cerebral cortex, basal ganglia

√ restricted diffusion is more sensitive than T2-FLAIR, especially for cortical lesions ← spongiform neuronal degeneration

√ "pulvinar" sign / "hockey stick" sign = T2 prolongation + restricted diffusion in medial thalamus

√ NO gadolinium enhancement of lesions
√ NO white matter involvement
Dx: brain biopsy
Prognosis: usually fatal within 2 year of onset of symptoms (mean, 8.8 months)

CRYPTOCOCCOSIS OF BRAIN

= ubiquitous soil fungus Cryptococcus neoformans infects lungs followed by hematogenous spread
Organism: unicellular yeast
Transmission: inhalation of reproductive spores found in bird feces (eg, pigeon droppings)
◊ Most common cause of opportunistic fungal infection in immunocompromised + AIDS patients
◊ Most common fungal disease of CNS
Path: choroid plexitis, meningitis, encephalitis (lack of anticryptococcal factors in CSF)
Incidence: 5% of all patients with AIDS
• headache, malaise, fever, nausea, vomiting
Location: from base of brain extension along Virchow-Robin spaces
√ hydrocephalus + cortical / central atrophy (with inadequate immune response)
√ abnormal nodular leptomeningeal enhancement (with sufficient immune response), most pronounced at base of brain
√ enlargement of Virchow-Robin spaces = distension of perivascular spaces ← budding yeast + mucoid material from organism's capsule
√ gelatinous pseudocysts frequently in basal ganglia, thalami and midbrain
√ miliary (< 3 mm) / larger parenchymal cryptococcoma
CT:
√ frequently normal: edema + enhancement may be attenuated in immunodeficiency / corticosteroid therapy
√ pseudocystic perivascular lesions in region of basal ganglia
MR:
√ low T1 + high T2 signal intensities without enhancement in lenticulostriate region (= gelatinous pseudocyst = budding yeast + mucoid material from organism's capsule)
√ hyperintense lesions on FLAIR
√ restricted diffusion if contents of high viscosity
√ leptomeningeal enhancement
Dx: detection of cryptococcal antigen in CSF
Cx: hydrocephalus ← acute meningeal exudate / meningeal adhesions
Prognosis: mean survival of 2–3 months
DDx: enlarged Virchow-Robin spaces (hypointense on FLAIR)

CYSTICERCOSIS OF BRAIN

= NEUROCYSTICERCOSIS
Organism: Taenia solium = larva of pork tapeworm; frequently involving CNS, eyes, muscle, heart, fat tissue, skin
Incidence: most common parasitic infection involving CNS in developing countries (in up to 90%)

Endemic to: Mexico, South America, Africa, eastern Europe, Asia, Indonesia
Associated with: poverty
Route of infection:
(1) **Cysticercosis** = ingestion of ova by fecal-oral route via contaminated food / water or autoinfection; embryophore is dissolved by gastric acid and enzymes + oncosphere is liberated
(2) **Taeniasis** following ingestion of cysticercus by definitive host a tapeworm develops within intestinal tract

Life cycle:
embryos invade intestinal wall → cross mucosa and move into capillary system → enter circulation disseminating in brain, muscles, and various other parts of body; embryo develops into a cysticercus (= complex wall surrounding a cavity containing vesicular fluid + scolex) usually within < 3 months

Location: meninges (39%) esp. in basal cisterns, parenchyma (20%), intraventricular (17%), mixed (23%), intraspinal (1%)
Seeding: through subarachnoid space + ventricles

Site in brain: gray-white matter junction, basal ganglia, cerebellum, brainstem

A. STAGE OF LARVAL TISSUE INVASION
- asymptomatic
√ localized focus of edema on T2WI
√ nodular tissue enhancement

B. VESICULAR STAGE
= antigenetically inert, therefore without inflammatory reaction / circumferential edema; parasite protected by cyst wall rich in glycoproteins as an effective barrier toward surrounding tissue
- asymptomatic
√ single / multiple thin-walled nonenhancing 4–20 mm spherical cysts:
  √ center with clear fluid of CSF intensity
  √ "target" or "dot in a hole" appearance = 2–3 mm mural nodule (= scolex) of soft-tissue attenuation and signal intensity similar to brain parenchyma
√ NO surrounding edema

C. COLLOIDAL VESICULAR STAGE
= death of scolex from natural processes / from effects of therapy associated with disruption of cyst wall; unprotected decaying parasite and its metabolic breakdown (colloidal suspension) causes an intense inflammatory reaction → focal meningoencephalitis with breakdown of blood-brain barrier
- focal seizures (50–70%; in endemic countries most common cause of adult-onset epilepsy
√ markedly hyperintense lesion on FLAIR ← proteinaceous cyst fluid with gelatinous debris
√ center hypointense to white matter and hyperintense to CSF on T1WI
√ hypointense mural nodule on T2WI with strong homogeneous enhancement
√ surrounded by typically extensive white matter edema (DDx: metastasis without edema)
√ avidly ring-enhancing capsule on postcontrast T1WI

D. NODULAR-GRANULAR STAGE
= degeneration of cysticercus = cyst retraction + formation of granulomatous nodule →

surrounding gliosis and mineralization
√ gradually subsiding perilesional edema
√ shrinkage of cyst with thick retracted cyst wall becoming isointense with brain on T1WI + hypointense on T2WI
√ hypointense on all pulse sequences ← completely calcified
√ isoattenuating lesion with enhancement of thick nodular ring on CT

E. CALCIFIED (nonactive) STAGE
= complete involution of lesion with continued mineralization
• asymptomatic / posttreatment seizures
√ small focal calcifications; may appear within 8 months to 10 years after acute infection
√ "ricelike" muscle calcifications rarely visible
√ calcified scolex on GRE sequence

Radiographic types:

1. Parenchymal type
   √ multiple / solitary cystic lesions up to 6 cm in size:
   √ large cysts are usually multiloculated
   √ calcified granulomata (larvae not dead unless completely calcified)
   √ diffuse encephalitic form more common in young females, children, patients receiving antihelmintic therapy
   √ **progressive midbrain syndrome** = multiple areas of ischemic injury
   Cause: occlusion of vessels traversing cisterns
   Location: midbrain, thalamus
   Cx: arachnoiditis, meningitis, cranial nerve palsies, lacunar infarctions
2. **Subarachnoid / racemose neurocysticercosis**
   = infiltration of basal cisterns + sylvian fissures associated with local meningeal inflammation / fibrosis
   √ lucent cystic lesions up to several cm in basal cisterns (= racemose cysts) with variable enhancement, usually located in cerebellopontine angle / suprasellar cistern
   Cx: hydrocephalus; scattered infarctions ← vasculitis of basal perforating vessels
3. **Intraventricular neurocysticercosis**
   • symptoms related to hydrocephalus (30%)
   • papilledema, loss of consciousness (Bruns syndrome)
   √ obstructive hydrocephalus ← blockage within various portions of ventricular system from solitary / multiple cysts (OCCULT on CT!)
4. Mixed type (frequently different stages in same patient)

Rx: antihelmintic therapy (usually albendazole, praziquantel)

Taeniasis

= ingestion of raw / undercooked contaminated pork containing cysticerci (= T solium larvae); tapeworm develops in and is confined to intestinal lumen → release of eggs
• altered appetite, weight loss, abdominal pain, constipation
• vomiting, diarrhea, fever, eosinophilia, dyspnea
√ pleural effusion, ascites
√ rice grain–shaped calcifications in muscles ← calcified granulomas
Dx: stool analysis, serologic testing

CYTOMEGALOVIRUS INFECTION

= double-stranded DNA virus with replication inside cell nucleus causing a lytic productive / latent infection; member of Herpes viridae family (with varicella-zoster virus, Epstein-Barr virus, herpes simplex virus types 1 and 2)

◊ Most common intrauterine infection in USA!

Incidence: 0.4–2.4% of liveborn infants; 40,000 babies born each year with CMV infection in USA

Transmission:

(a) horizontally by contact with saliva / urine or sexually

(b) vertically from mother to fetus transplacentally; spreads hematogenously throughout fetus

◊ Outcome poorer if infected during first half of pregnancy at a younger gestational age!

Histo: necrotizing inflammatory process

Predilection: CMV has special affinity for metabolically active neuroblasts of germinal matrix

Prenatal screening:

antibodies in 30–60% of pregnant women;
primary CMV infection in 2.5% of pregnant women

Postnatal screening:

10% of neonates excrete virus;
1.6% of newborns shed CMV in urine / saliva

- asymptomatic + subclinical (90%)
- symptomatic at birth (10–15%):
  - sensorineural deafness, mental retardation, neurologic deficits, seizures
  - ocular abnormalities (15–50%): chorioretinitis, optic neuritis, optic atrophy, hypoplasia + coloboma of optic nerve, anterior uveitis, anophthalmia, microphthalmia, cataracts, cyclopia
  - jaundice, hemolytic anemia, thrombocytopenic purpura

  ◊ Leading cause of brain disease + hearing loss in children!
- symptomatic in adults (in up to 15%):
  - fever, pharyngitis, lymphadenopathy, polyarthritis

√ intrauterine growth retardation
√ hepatosplenomegaly (nontender)
√ ascites
√ hydrops
√ pneumonitis

Dx: polymerase chain reaction analysis of CSF / urine / saliva / blood to detect CMV DNA; positive viral culture within first 2 weeks of life

Rx: no effective treatment for maternal infection

DDx: toxoplasmosis, teratoma, tuberous sclerosis, Sturge-Weber syndrome, venous sinus thrombosis, microcephaly intracranial calcification syndrome

Acquired CMV Infection of CNS

Cause: HIV infection; immunosuppression; solid organ / bone marrow transplantation

- mental status change

Role of CT: rule out mass lesion / substantial cerebral edema before planned lumbar puncture

√ meningoencephalitis (most frequently):
  √ cortical + subcortical areas of hypointensity on T1WI + hyperintensity on T2WI
    Location: especially frontal + parietal lobes
  √ diffuse leptomeningeal enhancement
√ ventriculoencephalitis (with advanced HIV infection):
  √ cerebral volume loss
  √ ventriculomegaly
  √ periventricular enhancement
√ enhancing mass lesions (only with advanced AIDS)
  DDx: lymphoma / other neoplasm, pyogenic abscess
√ polyradiculopathy (in adults)

Congenital CMV Infection of CNS

√ intracranial calcifications (34–70%):
  ◊ Most common finding of congenital CMV infection!
  √ thick and chunky postinflammatory periventricular Ca2+
  √ faint punctate Ca2+ in basal ganglia + thalami + parenchyma
  Associated with: developmental delays
√ cerebral atrophy
  √ ventriculomegaly (in up to 45%)
    ◊ 2nd most common finding of congenital CMV infection!
    Cause: ventriculitis; obstruction by inflammatory exudate; brain atrophy
  √ microcephaly (in up to 27%)
    Cause: encephaloclastic effect of virus / disturbance of cell proliferation
  √ cerebral volume loss
  √ cerebellar volume loss (in up to 67%):
    √ widening of cerebellar folia
    √ expansion of CSF spaces in posterior fossa
    √ severe diffuse hypoplasia / dysplasia of cerebellum
√ neuronal migrational disorders (in up to 10%)
  √ lissencephaly = smooth surface with absence of sulcation of a thin / thickened cortical mantle

Congenital CMV Imaging Findings versus Time of Infection

Estimated Gestational Age:	*< 18 wks*	*18–24 wks*	*> 26 wks*
√ periventricular Ca^{2+}	+	+	++
√ ventriculomegaly	++	+	
√ lissencephaly + thin cortex	+		
√ cerebellar hypoplasia	+	+	
√ delayed myelination	+		+
√ polymicrogyria		+	
√ schizencephaly (rare)		+	
√ dysmyelination			+
√ leukoencephalopathy			+

√ pachygyria = broad gyri + partial sulcation
√ diffuse / focal polymicrogyria = nodular cortical surface + irregular scalloped gray-white matter junction + thickened cerebral cortex
rare: schizencephaly, cortical dysplasia, heterotopia

√ white matter disease (in up to 22%) = leukoencephalopathy = static nonprogressive focal patchy / confluent areas of hyperintensity on T2WI and FLAIR images in parietal / posterior regions

√ periventricular cysts = subependymal cysts (= focal areas of necrosis + glial reaction) commonly in anterior temporal lobes (initially vacuolization → cyst formation)
Location: anterior temporal lobe > occipital pole of lateral ventricles > frontoparietal white matter

√ ventricular adhesions = intraventricular septa = thin strands of tissue crossing the ventricle ← ventriculitis

√ lenticulostriate vasculopathy (in up to 27%) = uni- / bilateral curvilinear highly echogenic streaks within basal ganglia + thalami
Cause: mineralizing vasculopathy with deposition of amorphous basophilic material in arterial walls

Prognosis: poor neurologic outcome with microcephaly + calcifications

DANDY-WALKER MALFORMATION

= characterized CLASSICALLY by
(1) Vermian hypoplasia with cephalad rotation of remnant
(2) Cystlike dilatation of 4th ventricle → enlarged posterior fossa with abnormally high position of tentorium and torcular (lambdoid-torcular inversion)

Incidence: 12% of all congenital hydrocephaly
◊ Most common posterior fossa malformation

Genetics: sporadic occurrence; 1–5% risk of recurrence

Path: defect in vermis connecting an ependyma-lined retrocerebellar cyst with 4th ventricle (PATHOGNOMONIC)

Cause: dysmorphogenesis of roof of 4th ventricle with failure to incorporate the area membranacea into developing choroid plexus

Time of origin: high insertion of tentorium suggests development before end of embryonic period! Originally proposed as congenital atresia of foramina of **L**uschka (**l**ateral) + **M**agendie (**m**edian) – but proposal NOT likely since foramina are not patent until 4th month of GA

Associated anomalies:
› midline CNS anomalies (in > 60%)
(1) Dysgenesis of corpus callosum (20–25%), lipoma of corpus callosum
(2) Holoprosencephaly (25%)
(3) Malformation of cerebral gyri (dysplasia of cingulate gyrus) (25%)
(4) Cerebellar heterotopia + malformation of cerebellar folia (25%)
(5) Malformation of inferior olivary nucleus
(6) Hamartoma of tuber cinereum
(7) Syringomyelia

(8) Cleft palate
(9) Occipital encephalocele (< 5%)

› other CNS anomalies:
(1) Polymicrogyria / gray matter heterotopia (5–10%)
(2) Schizencephaly
(3) Lumbosacral meningocele

› non-CNS anomalies (25%)
(1) Polydactyly, syndactyly
(2) Klippel-Feil syndrome
(3) Cornelia de Lange syndrome
(4) Cleft palate
(5) Facial angioma
(6) Cardiac anomalies

Age: majority < 1 year

• macrocephaly (90%)

Skull film:

√ large skull ← hydrocephalus + dolichocephaly
√ diastatic lambdoid suture
√ disproportionately large expanded posterior fossa
√ torcular-lambdoid inversion = upward displacement of tentorium + torcular herophili + transverse and lateral dural sinuses high above lambdoid angle

CT / US / MR:

√ absence / <u>hypoplasia of cerebellar vermis</u>: total (25%), partial (75%)
√ superiorly displaced superior vermis cerebelli
√ small widely separated ± hypoplastic cerebellar hemispheres ← anterolateral displacement by cystic 4th ventricle
√ <u>large posterior fossa</u> cyst with extension through foramen magnum = diverticulum of roofless 4th ventricle
√ <u>elevated insertion of tentorium cerebelli</u>
√ cerebellar hemispheres in apposition without intervening vermis following shunt procedure
√ absence of falx cerebelli
√ scalloping of petrous pyramids
√ <u>ventriculomegaly</u> (in 72% open communication with 3rd ventricle; in 39% patent 4th ventricle; in 28% aqueductal stenosis; in 11% incisural obstruction); present prenatally in 30%, by 3 months of age in 75%
√ anterior displacement of pons

Angio:

√ high position of transverse sinus
√ elevated great vein of Galen
√ elevated posterior cerebral vessels
√ anterosuperiorly displaced superior cerebellar arteries above the posterior cerebral arteries
√ small / absent PICA with high tonsillar loop

Cx: trapping of cyst above tentorium = "keyhole configuration"

Prognosis: fetal demise in 66%; 22–50% mortality during 1st year of life
DDx: (1) Posterior fossa extra-axial cyst
(2) Arachnoid cyst (normal 4th ventricle, patent foramina, intact vermis)
(3) Isolated 4th ventricle
(4) Megacisterna magna
(5) Porencephaly

It is not recommended to use terms like Dandy-Walker variant, Dandy-Walker complex, Dandy-Walker spectrum because they lack specificity and add confusion.

Dandy-Walker Variant

characterized by
(1) Variable hypoplasia of posteroinferior portion of vermis → communication between 4th ventricle + cisterna magna
(2) NO / only mild enlargement of posterior fossa
(3) Cystic dilatation of 4th ventricle

◊ More common than Dandy-Walker malformation; accounts for ⅓ of all posterior fossa malformations
◊ Demarcation of classic from variant Dandy-Walker is vague!

Cause: focal insult to developing cerebellum
Associated CNS anomalies:
agenesis of corpus callosum (21%), cerebral gyral malformation (21%), heterotopia, holoprosencephaly (10%), diencephalic cyst (10%), posterior fossa meningoencephalocele (10%)
Other associated anomalies:
polydactyly; cardiac, renal, facial anomalies; abnormal karyotype (29%)

√ 4th ventricle smaller + better formed
√ retrocerebellar cyst smaller
√ communication between retrocerebellar cyst and subarachnoid space through a patent foramen of Magendie may be present
√ posterior fossa smaller than in usual Dandy-Walker syndrome

OB-US:
√ incomplete closure of vermis is normal until 18 weeks GA!

Dandy-Walker Continuum / Complex

= continuum of anomalies, including Dandy-Walker malformation + Dandy-Walker variant + megacisterna magna + Blake pouch cyst, characterized by partial / complete dysgenesis of vermis cerebelli

Cause: broad insult to alar plate from various abnormalities
Associated with:
A. Inherited genetic syndromes
› autosomal recessive:
1. Meckel-Gruber syndrome
2. Ellis-van Creveld syndrome
3. Walker-Warburg syndrome

› autosomal dominant:
1. X-linked cerebellar hypoplasia
2. Aicardi syndrome

B. Abnormal karyotype (33%)
1. Duplications of chromosomes 5p, 8p, 8q
2. Trisomies 9, 13, 18

C. Infection
1. Virus: CMV, rubella
2. Protozoan: toxoplasmosis

D. Teratogen: alcohol, sodium warfarin

E. Multifactorial

Pseudo-Dandy-Walker Malformation

= developing normal rhombencephalon during 1st trimester

√ fluid-filled space in posterior aspect of fetal head

DEMENTIA WITH LEWY BODIES

= 2nd most common neurodegenerative disorder in patients > 65 years

Histo: loss of dopaminergic neurons in substantia nigra

• classic clinical triad:
(1) Fluctuating levels of cognitive arousal
(2) Visual hallucinations
(3) Spontaneous parkinsonism

• clinical condition may worsen under neuroleptic medications

PET:

√ hypometabolism in both parietal + posterior temporal lobes and posterior cingulate gyrus (similar to Alzheimer's)

√ ± involvement of occipital lobes (spared in Alzheimer's)

DEVELOPMENTAL VENOUS ANOMALY

= VENOUS ANGIOMA

= intraparenchymal tangle / cluster of dilated medullary veins converging on a single enlarged draining vein; bleed rarely

◊ Most common cerebral vascular malformation (~ 60%)!

◊ Can be considered a normal variant!

Cause: (?) accidents during embryogenesis → occlusion / maldevelopment of superficial / deep veins → creation of compensatory pathway by recruiting and dilating preexisting transmedullary veins

Age: any; M = F

Histo: venous channels without internal elastic lamina, separated by gliotic neural tissue that may calcify; probably representing persistent fetal venous system; normal intervening brain parenchyma

Associated with: blue rubber bleb nevus syndrome with multiple angiomas; increased coexistence of cavernous angiomas which can bleed!

- asymptomatic (common)
- headache, seizure, hemorrhage (unusual)

Risk of hemorrhage: 0.15% (increased with thrombosed draining vein / coexistent cavernous malformation)

A DVA rarely bleeds and is unlikely the cause of an intraparenchymal hemorrhage → search for a cavernoma, which is best be seen with gradient-echo / blood oxygen level-dependent (BOLD) sequences (= heavily T2* weighted).

- soft + compressible without thrills / pulsations
- distension with Valsalva maneuver

Location: deep cerebral / cerebellar white matter; most commonly adjacent to frontal horn

√ "umbrella / spoked-wheel / medusa head" configuration = multiple small radially oriented transmedullary veins at periphery of lesion converging on venous collector

√ interspersed normal brain parenchyma

√ dense capillary stain in larger lesion

√ linear / curvilinear enhancing structure = venous collector draining into superficial dural sinus / deep venous system (ependymal vein)

√ NO enlarged arterial vessels

Cx (uncommon): hemorrhage, ischemia

DDx: vascular neoplasm, cavernous vascular malformation, venous varix, Sturge-Weber disease (diffuse pial angiomatosis with venous-type capillaries)

DIFFUSE AXONAL INJURY

= WHITE MATTER SHEARING INJURY

Incidence: most common type of primary traumatic injury in patients with severe head trauma (48%)

Cause: high-velocity trauma (MVA) resulting in indirect injury due to <u>rotational</u> / angular (especially coronal) acceleration / deceleration forces (direct impact to head or fracture not required)

Pathogenesis:

cortex and deep structures move at different speed causing shearing stress of

(a) axons resulting in axonal tears followed by wallerian degeneration

(b) small white-matter vessels resulting in small petechial hemorrhages

Path: much of the injury is microscopic

Histo: multiple axonal retraction balls (HALLMARK), numerous perivascular hemorrhages

- immediate severe impairment of consciousness at time of impact
- persistent vegetative state

Location (according to severity of trauma):

(a) lobar white matter at corticomedullary junction (67%): parasagittal region of frontal lobe + periventricular region of temporal lobe; occasionally in parietal + occipital lobes

(b) internal + external capsule / basal ganglia, corona radiata, cerebellar peduncles

(c) corpus callosum (21%):

¾ of lesions at undersurface of posterior body + splenium

√ often associated with intraventricular hemorrhage

(d) brainstem: posterolateral quadrants of midbrain + upper pons; superior cerebellar

peduncles especially vulnerable
√ sparing of cortex
√ 20% of lesions with small central areas of petechial hemorrhage
CT (negative in 30% of positive MR cases):
√ foci of decreased density (usually seen when > 1.5 cm in size)
MR (most sensitive modality):
√ multiple small oval / round foci of decreased signal intensity on T1WI + increased signal on T2WI
Prognosis:
(1) Poor due to sequelae (may go on to die without signs of high intracranial pressure)
(2) Brain atrophy with enlargement of sulci + ventricles

DIFFUSE (MYELINOCLASTIC) SCLEROSIS

= MYELINOCLASTIC DIFFUSE SCLEROSIS = SCHILDER DISEASE
= rare demyelinating disorder with episodic recurrence + remission
Age: children (5–14 years) > adults; M÷F = 1÷1
Histo: selective confluent demyelination with relative axonal sparing, perivascular inflammatory infiltrate, reactive astrocytosis (indistinguishable from multiple sclerosis)
• hemiplegia, aphasia, ataxia, blindness
• swallowing difficulties, progressive dementia
• increased intracranial pressure: headache, vomiting
• vision and speech impairment, deafness
• aphasia, seizures, personality changes, tremors, balance instability, incontinence, muscle weakness
Location: centrum semiovale in both hemispheres
√ large well defined bilateral low-attenuation white matter lesions with mass effect
√ enhancement with IV contrast material
Rx: usually responsive to corticosteroids
DDx: (1) Acute disseminated encephalomyelitis (history of recent viral illness, monophasic course, lesions less confluent, no mass effect / enhancement)
(2) Adrenoleukodystrophy (bilaterally symmetric, confluent lesions, parietal location)
(3) Tumor, abscess, infarct

DYKE-DAVIDOFF-MASON SYNDROME

= CEREBRAL HEMIATROPHY = INFANTILE / CONGENITAL HEMIPLEGIA = SYNDROME OF HEMICONVULSIONS, HEMIPLEGIA, AND EPILEPSY
= unilateral cerebral atrophy with ipsilateral small skull
Cause: insult to immature brain resulting in neuronal loss + impaired brain growth:
(a) prenatal: congenital malformation, infection, vascular insult
(b) perinatal: birth trauma, anoxia, hypoxia, intracranial hemorrhage
(c) postnatal: trauma, tumor, infection, prolonged febrile seizures
Age: presents in adolescence
• seizures, mental retardation
• hemiparesis (typically spastic hemiplegia)

√ unilateral thickening of skull
√ unilateral decrease in size of cranial fossa
√ unilateral overdevelopment of sinuses
√ contraction of a hemisphere / lobe
√ compensatory enlargement of adjacent ventricle + sulci with midline shift

DYSEMBRYOPLASTIC NEUROEPITHELIAL TUMOR

= benign tumor of neuroepithelial origin arising from cortical / deep gray matter
Origin: derived from secondary germinal layers; originally diagnosed as low-grade astrocytoma
Histo: specific glioneuronal element in a columnar pattern oriented perpendicular to cortical surface; admixture of astrocytes + oligodendroglial elements in association with "floating neurons" and mucinous degeneration; ± multinodular architecture
Age: usually < 20 years; M > F
• medically refractory partial seizures; neurologic deficits (rare)
Location: temporal (62%) / frontal (31%) lobe; caudate nucleus; cerebellum; pons
CT:
√ hypoattenuating mass ± calcifications
√ remodeling of inner table of skull
MR:
√ cortical mass without surrounding vasogenic edema:
√ hypointense on T1WI + hyperintense on T2WI
√ "soap bubble" / megagyrus appearance at cortical margin = enlargement of cortical surface
√ contrast enhancement (in 33%)
Prognosis: partial resection stops seizure activity; rarely recurs
DDx: diffuse astrocytoma, ganglioglioma, oligodendroglioma

EMPTY SELLA SYNDROME

= extension of subarachnoid space into sella turcica, which becomes exposed to CSF pulsations ← defect in diaphragma sellae; characterized by normal / molded pituitary gland + normal or enlarged sella (empty sella = misnomer)
Incidence: 24% in autopsy study
√ slowly progressive symmetrical / asymmetrical (double floor) enlargement of sella
√ remodeled lamina dura remains mineralized
√ small rim of pituitary tissue displaced posteriorly + inferiorly
√ "infundibulum" sign = infundibulum extends to floor of sella
DDx: cystic tumor, large herniated 3rd ventricle (displaced infundibulum)

Primary Empty Sella

Incidence: 10% of adult population; M÷F = 1÷4
Probable causes:
(1) pituitary enlargement followed by regression during pregnancy
(2) involution of a pituitary tumor

(3) congenital weakness of diaphragma sellae

◊ Occurs more frequently in patients with increased intracranial pressure

- usually asymptomatic
- increased risk for CSF rhinorrhea
- NO endocrine abnormalities

Secondary Empty Sella

= postsurgical after disruption of diaphragma sellae

- visual disturbance, headaches

EMPYEMA OF BRAIN

Cause: paranasal sinusitis, otitis media, calvarial osteomyelitis, infection after craniotomy or ventricular shunt placement, penetrating wound, contamination of meningitis-induced subdural effusion

√ rim-enhancing purulent collection

√ restricted diffusion on DWI (DDx: simple effusion of acute bacterial meningitis is WITHOUT diffusion restriction)

Subdural Empyema

20% of all intracranial bacterial infections

Location: frontal + inferior cranial space in close proximity to paranasal sinuses; 80% over convexity extending into interhemispheric fissure or posterior fossa

√ hypo- / isodense crescentic / lentiform zone adjacent to inner table

√ may show mass effect (sulcal effacement, ventricular compression, shift)

√ thin curvilinear rim of enhancement (7–10 days later) adjacent to brain

√ severe sinusitis / mastoiditis (may be most significant indicator)

Mortality: 30% (neurosurgical emergency)

Cx: venous thrombosis (= thrombophlebitis), infarction, seizures, hemiparesis, hemianopia, aphasia, cerebritis, brain abscess

◊ Subdural >> epidural empyema more likely to cause complications requiring urgent neurosurgery!

DDx: subacute / chronic subdural hematoma

Epidural Empyema

• NO neurologic deficits (dura minimizes pressure exerted on brain)

√ thick enhancing rim

ENCEPHALITIS

= term generally reserved for diffuse inflammatory process of viral etiology, most commonly arthropod-borne arboviruses (Eastern + Western equine encephalitis, California virus encephalitis, St. Louis encephalitis)

√ diffuse mild cerebral edema

√ small infarctions / hemorrhage (less frequent)

√ hyperintensity on T2WI in areas of cortical involvement

Granulomatous Amebic Encephalitis

= usually in immunocompromised patients

Organism: Acanthamoeba histolytica, Balamuthia species

Endemic: southern California, Texas, Georgia, Florida

Transmission:

(a) hematogenous: skin / lower respiratory tract for Acanthamoeba

(b) inhalation: airborne cysts in soil

(c) direct contamination: from skin lesion, organ transplantation, stagnant water

• headache, altered mental status, focal neurologic deficits

√ hypoattenuated / T1 hypointense lesions
√ heterogeneous hyperintensity on T2WI
√ variably restricted diffusion + enhancement
Dx: identification of trophozoites with "spiky" pseudopodia on wet mount / Giemsa stains of CSF; positive polymerase chain reaction test
Prognosis: death within 7–10 days after onset of illness
DDx: neoplasm; acute disseminated encephalomyelitis; neurocysticercosis; toxoplasmosis

Primary Amebic Meningoencephalitis
= extremely aggressive amebic infection
Organism: free-living thermophilic ameba Naegleria fowleri = "brain-eating ameba" with predilection for warm fresh water bodies and soil
Transmission: through nasal cavity during swimming / diving activity in nature or poorly chlorinated swimming pool water
◊ NOT by drinking contaminated water!
Path: amebic collections in olfactory grooves + extensive destruction of olfactory tracts
√ leptomeningeal enhancement, brain edema
√ cerebral infarction

Herpes Simplex Encephalitis (HSE)
= most common cause of nonepidemic necrotizing meningo-encephalitis in immunocompetent individuals in USA
◊ Neurologic emergency due to high morbidity + mortality
Organism: HSV type I (in adults); HSV type II (in neonates from transplacental infection)
• preceding viral syndrome, low-grade fever, headache, seizures
• mental status changes: confusion, disorientation, hallucination, personality change, aphasia
Location: inferomedial temporal > frontal > parietal lobes; propensity for limbic system (olfactory tract, temporal lobes, cingulate gyrus, insular cortex); initially predominantly unilateral
√ mild patchy peripheral / gyral / cisternal enhancement (50%), may persist for several months
CT:
√ may be negative in first 3 days
√ poorly defined bilateral areas of mildly decreased attenuation in one / both temporal lobes + insulae
√ spared putamen forms sharply defined concave / straight border (DDx: infarction, glioma)
√ mild mass effect with compression of lateral ventricles + loss of sylvian fissure (brain edema)
√ tendency for hemorrhage + rapid dissemination in brain
MR (study of choice, positive within 2 days):
√ increased signal intensity on T2WI + mild to moderate hypointensity on T1WI
√ increased signal on DWI ← cytotoxic edema
√ small foci of hemorrhage (common)
NUC:

Agents: standard brain imaging (eg, ^{99m}Tc-DTPA); newer brain agents (eg, ^{123}I-iodoamphetamine / ^{99m}Tc-HMPAO)
◊ SPECT imaging improves sensitivity
√ characteristic focal increase in activity in temporal lobes on brain scintigraphy ← breakdown of blood-brain barrier
Dx: (1) identification of virus within CSF (using polymerase chain reaction technique)
(2) fluorescein antibody staining / viral culture from brain biopsy
Mortality: 30–70%
Rx: adenine arabinoside
DDx: (1) Infarction (involves either medial or lateral temporal lobe, almost exclusively unilateral)
(2) Low-grade glioma
(3) Abscess

Human Immunodeficiency Virus Encephalitis (HIV)

often in combination with CMV encephalitis
Histo: microglial nodules + perivascular multinucleated giant cells accompanying gliosis of deep white + gray matter
√ predominantly central CNS atrophy
√ symmetric periventricular / diffuse white matter disease without mass effect:
√ hypodense on CT, hyperintense on T2WI

Postinfectious Encephalitis

following exanthematous viral illness (measles, mumps, rubella, smallpox, chickenpox, Epstein-Barr virus, varicella, pertussis) / vaccination

Acute Disseminated Encephalomyelitis (ADEM)

= POSTVIRAL LEUKOENCEPHALOPATHY
= autoimmune reaction against patient's white matter
• 7–14 days / several weeks following an exanthematous viral infection / vaccination
• confusion, headaches, fever
• seizures, focal neurologic deficits
Histo: diffuse perivenous inflammatory process resulting in areas of demyelination
Location: subcortical white matter of both hemispheres asymmetrically; may involve brainstem / posterior fossa
√ lesions may demonstrate contrast enhancement
CT:
√ multifocal hypodense white matter abnormalities
√ sparing of cortical gray matter, occasionally deep gray matter involvement
√ no additional lesions on follow-up exam
MR:
√ multifocal punctate / large confluent areas of hyperintensity on FLAIR / T2WI
Rx: corticosteroids result in dramatic improvement
Prognosis: complete resolution of neurologic deficits within 1 month (80–90%) / some permanent neurologic damage (10–20%)

DDx: multiple sclerosis (rarely recurrent episodes as in multiple sclerosis); autoimmune vasculitis; aging brain

Acute Hemorrhagic Leukoencephalitis

= fulminant myelinoclastic disease of CNS
= hyperacute form of acute disseminated encephalomyelitis
Cause: immunoreactive disease following prodromal illness (minor upper respiratory viral infection, ulcerative colitis)
Path: marked edema, brain softening
Histo: necrotizing angiitis of venules + capillaries within white matter with extravasation of PMNs and lymphocytes; fibrinoid necrosis of affected capillaries + surrounding tissues; confluent hemorrhages with ball-and-ring configuration due to diapedesis of RBCs

- progressive coma, motor disturbance, speech difficulty, seizures, pyrexia, leukocytosis
- pleocytosis (= ↑ WBC in spinal / other bodily fluid)
- elevated protein in spinal fluid

Location: unilateral disease; parietal + posterior frontal white matter at level of centrum semiovale (sparing subcortical U-fibers + cortex) > basal ganglia, cerebellum, brainstem, spinal cord
√ rapid development of profound mass effect resembling infarction
√ multiple punctate white matter hemorrhages
√ extensive hypoattenuation virtually confined to hemispheric white matter
Prognosis: usually results in death
DDx: (1) Herpes simplex encephalitis (cortical lesions in temporal + inferior frontal lobes + insular region, no imaging findings until 3–5 days after onset of significant symptoms)
(2) Tumefactive multiple sclerosis
(3) Osmotic demyelination
(4) Toxic encephalopathy: lipophilic solvent, methanol
(5) Hypertensive encephalopathy: eclampsia, thrombotic thrombocytopenic purpura

ENLARGED PERIVASCULAR SPACES

= ENLARGED / ATYPICAL VIRCHOW-ROBIN SPACES
= small invaginations of subarachnoid space following pia mater along perforating nutrient end vessels into brain substance
Location: inferior basal ganglia (lenticulostriate arteries); inferior third of putamen = état criblé (cribriform / sievelike); midbrain + deep white matter (perforating medullary arteries); subinsular cortex; thalamus, dentate nucleus; corpus callosum; cingulate gyrus; usually bilateral
√ no restricted diffusion
√ no enhancement
√ normal signal intensity of surrounding parenchyma
√ occasionally central high SI on T1WI ← inflow effect
√ small 1–2-mm round lesions isointense to CSF
√ moderate 2-5 mm round lesions isointense to CSF

√ clusters of variably sized bizarre cystic spaces bordering ventricles / subarachnoid space
Cx: hydrocephalus
DDx: multiple lacunar infarcts (adjacent parenchymal hyperintensity), cystic neoplasm (SI not like CSF), infectious / parasitic cysts (enhancing cyst wall); neuroepithelial cyst; mucopolysaccharidosis

État Criblé
= giant sievelike Virchow-Robin spaces
= clusters of variable sized cysts with bizarre cystic configuration and mass effect
√ ± hydrocephalus
√ ± surrounding reactive gliosis

EPENDYMAL CYST
= rare benign thin-walled cyst
Cause: sequestration of developing neuroectoderm during embryogenesis
Histo: thin-walled ependyma-lined cyst containing clear serous fluid
Location: lateral ventricle, juxtaventricular in temporoparietal region + frontal lobe; rare in subarachnoid space, brainstem, cerebellum
Site: along choroid fissure
√ thin-walled CSF-containing cyst
DDx: choroid plexus cyst (NOT of CSF signal intensity on all sequences, typically bilateral), arachnoid cyst (in arachnoid spaces), neurocysticercosis (hyperintense rim on FLAIR), asymmetric ventricles

EPENDYMOMA
= in majority benign slow-growing neoplasm of mature well-differentiated ependymal cells lining the ventricles
Incidence: most common in children; 5–9% of all primary CNS neoplasms; 15% of posterior fossa tumors in children; 63% of spinal intramedullary gliomas
Histo: benign aggregates of ependymocytes in form of perivascular pseudorosettes; may have papillary pattern (difficult DDx to choroid plexus papilloma)
Age: (a) supratentorial: at any age (atrium / foramen of Monro)
(b) posterior fossa: age peaks at 5 + 34 years; M÷F = 0.8÷1
Associated with: neurofibromatosis
• increased intracranial pressure (90%)
Location:
(a) infratentorial: floor of 4th ventricle (70% of all intracranial ependymomas)
(b) conus medullaris: 40–65% of all spinal intramedullary gliomas
(c) supratentorial: in frontal > parietal > temporoparietal juxtaventricular region (uncommonly intraventricular), lateral ventricle, 3rd ventricle
in children: infratentorial÷supratentorial = 7÷3
√ small cystic areas in 15–50% (central necrosis)
√ fine punctate multifocal calcifications (25–50%)
√ intratumoral hemorrhage (10%)

√ frequently grows into brain parenchyma with extension to cortical surface (particularly in frontal + parietal lobes)
√ may invaginate into ventricles
√ expansion frequently through foramen of Luschka into cerebellopontine angle (15%) or through foramen of Magendie into cisterna magna (up to 60%) (CHARACTERISTIC)
√ direct invasion of brainstem / cerebellum (30–40%)
√ insinuation around blood vessels + cranial nerves
√ communicating hydrocephalus (100%) ← protein exudate elaborated by tumor clogging resorption pathways

CT:
√ sharply marginated multilobulated iso- / slightly hyperdense 4th ventricular mass
√ thin well-defined low-attenuation halo (= distended effaced 4th ventricle)
√ heterogeneous / moderately uniform enhancement of solid portions (80%)

MR:
√ low to intermediate heterogeneous SI on T1WI
√ hypointense tumor margins on T1WI + T2WI in 64% (= hemosiderin deposits)
√ foci of high-signal intensity on T2WI (= necrotic areas / cysts) + low signal intensity (= calcification / hemorrhage)
√ fluid-fluid level within cysts
√ homogeneous Gd-DTPA enhancement of tumor

Cx: subarachnoid dissemination via CSF (rare) (DDx: malignant ependymoma, ependymoblastoma)

Rx: surgery (difficult to resect due to adherence to surrounding brain) + radiation (partially radiosensitive) + chemotherapy

DDx of cerebellar ependymoma:
(1) Astrocytoma (hypodense, displaces 4th ventricle from midline, cystic lucency, intramedullary)
(2) Medulloblastoma (hyperdense, calcifications in only 10%)
(3) Trapped 4th ventricle (no contrast enhancement)

EPIDURAL HEMATOMA OF BRAIN

= EXTRADURAL HEMATOMA
= hematoma within potential space between naked inner table of skull + calvarial periosteum (inner dura layer), which is bound down firmly to cranium at sutural margins (= subperiosteal hematoma of inner table)

Incidence: 2% of all serious head injuries; in < 1% of all children with cranial trauma; uncommon in infants

Cause: impact on skull causes linear fracture + laceration of periosteal layer of outer table; temporary inward displacement of fragments lacerates meningeal vessels and strips both dural layers from inner table while the inner layer (meningeal dura) remains intact; blood accumulates between naked inner table and dura

Age: more common in younger patients 20–40 years ← dura more easily stripped away from skull

Associated with:

(1) Skull fracture in 75–85–95%
√ best demonstrated on skull radiographs
◊ Skull fractures frequently not visible in children ("ping-pong fracture")!
(2) Subdural hemorrhage
(3) Contusion

Source of bleeding:

(a) laceration of (middle) meningeal artery (high pressure) / meningeal vein (low pressure) adjacent to inner table from calvarial fracture (91%)
(b) disruption of dural venous sinuses (transverse / superior sagittal sinus) with low pressure + high flow ← diastatic fracture of lambdoid / coronal suture (major cause in younger children)
(c) avulsion of diploic veins / marrow sinusoids at points of calvarial perforations

Time of presentation: within first few days of injury (80%), 4–21 days (20%)

- transient loss of consciousness(= brief period of unconsciousness from concussion of brainstem)
- "lucid interval" (in < 33%)
- delayed somnolence (24–96 hours after accident) due to accumulation of epidural hematoma:
  ◊ DANGEROUS because of focal mass effect + rapid onset (NEUROSURGICAL EMERGENCY unless small)!
- progressive deterioration of consciousness → coma
- focal neurologic signs: 3rd nerve palsy (as a sign of cerebral herniation), hemiparesis

◊ Only a minority of skull fractures across the middle meningeal artery groove result in an epidural hematoma!

Types:

I	acute epidural hematoma	(58%) from arterial bleeding
II	subacute hematoma	(31%)
III	chronic hematoma	(11%) from venous bleeding

Factors determining the rate of epidural expansion:

injury to artery or vein, spasm of artery, containment of bleed through pseudoaneurysm or tamponade, decompression of hematoma into meningeal + diploic veins or through fracture into scalp

Location:

◊ Most commonly clinically significant if located in temporoparietal region!
(a) in 66% temporoparietal (most often from laceration of middle meningeal artery)
(b) in 29% at frontal pole, parietooccipital region, between occipital lobes, posterior fossa (most often from laceration of dural sinuses by fracture)
◊ NO crossing of sutures unless diastatic fracture of suture present!

CT:

√ fracture line in area of epidural hematoma
√ expanding biconvex (lenticular = elliptical) extra-axial fluid collection (most frequent) = under high pressure:
√ usually does not cross suture lines
√ separation of venous sinuses / falx from inner table

◊ The ONLY intracranial hemorrhage displacing falx / venous sinuses away from inner table!

√ hematoma usually homogeneous:
√ fresh extravasated blood (30–50 HU) / coagulated blood (50–80 HU) in acute stage
√ rarely with hypoattenuated "swirl" ← admixture of fresh blood into clotted blood during active bleeding
√ mass effect ("compression cone effect") with effacement of gyri + sulci from:
› epidural hematoma (57%)
› hemorrhagic contusion (29%)
› cerebral edematous swelling (14%)
√ marked stretching of vessels
√ signs of arterial injury (rare): contrast extravasation, arteriovenous fistula, middle meningeal artery occlusion, formation of pseudoaneurysm

MR:
√ low intensity of fibrous dura mater allows differentiation of epidural from subdural blood in the late subacute phase (= extracellular methemoglobin) with hyperintensity on T1WI + T2WI

Angio:
√ meningeal arteries displaced away from inner table of skull
√ pseudoaneurysm = extravasation of contrast material
√ arteriovenous fistula at fracture line

Cx: herniation, coma, death (15–30%)

Rx: after surgical evacuation return of ventricular system to midline

◊ Epidural hematoma at another site may be unmasked following surgical decompression!

DDx: Chronic subdural hematoma (may have similar biconvex shape, crosses suture lines, stops at falx, no associated skull fracture, no displaced dura on MR)

FAHR DISEASE

= BILATERAL STRIOPALLIDODENTATE CALCINOSIS = FAMILIAL CEREBROVASCULAR FERROCALCINOSIS

= rare neurodegenerative disease characterized by bilateral symmetric deposition of calcium + other minerals in basal ganglia, thalamus, dentate nucleus, centrum semiovale

- slow onset of headaches, vertigo, movement disorder, syncope, seizures, paresis, spasticity, gait disturbance, speech disorder
- coma, dementia, Parkinsonism, chorea, tremor
- dystonia, myoclonia, orthostatic hypotension
- NO hypoparathyroidism

Affected area: basal ganglia, dentate nucleus, thalamus, cerebral subcortical white matter

√ bilaterally symmetric hyperdense + T1-hyperintense calcifications

DDx: hypoparathyroidism, pseudohypoparathyroidism, pseudopseudohypoparathyroidism

GANGLION CELL TUMOR

Gangliocytoma

= rare benign tumor composed of mature ganglion cells

Prevalence: 0.1–0.5% of all brain tumors

Age: children + young adults
Associated with: dysplastic + malformed brain
Cause: ? dysplastic brain
Histo: purely neuronal tumor composed of abnormal mature ganglion cells without neoplastic glial cells (= no immunoreactivity for glial fibrillary acidic protein)
Location: floor of 3rd ventricle > temporal lobe > cerebellum > parietooccipital region > frontal lobe > spinal cord
CT:
√ hyperattenuating mass with little mass effect
MR:
√ iso- to hypointense on T1WI + T2WI
√ bright on proton density images

Dysplastic Cerebellar Gangliocytoma
= LHERMITTE-DUCLOS DISEASE
= rare hamartomatous disorder
Average age: 34 years; occasionally pediatric patients
Associated with: polydactyly, partial gigantism, multiple hemangiomas, leontiasis ossea
Strong association with: Cowden syndrome
Path: disruption of normal cerebellar laminar structure
Histo: dysplastic hypertrophic ganglion cells expanding granule layer; increased myelination of molecular layer of cerebellar cortex; loss of Purkinje cells and white matter; marked reduction in myelination of central white matter of cerebellar folia
- asymptomatic / symptoms of increased intracranial pressure (headaches, blurred vision, vomiting)
- slowly progressive cerebellar syndrome (40%)
- megalencephaly (50%); mental retardation

X-ray:
√ thinning of skull in occipital region
CT:
√ hypo- / isoattenuating cerebellar mass
√ hydrocephalus ← compression of 4th ventricle + effacement of cerebellopontine angle cistern
√ calcification uncommon
√ NO enhancement
MR:
√ cerebellar mass with "striated cerebellum" sign = tiger-striped / corduroy laminated folial pattern of alternating intensity bands on T1WI + T2WI:
√ hyper- and isointense relative to gray matter on T2WI
√ iso- and hypointense relative to gray matter on T1WI
√ enhancement extremely uncommon
√ ± syringohydromyelia
Rx: decompression of ventricles + resection of mass
DDx: medulloblastoma

Ganglioglioma

= uncommon slow-growing relatively benign tumor composed of glial + nerve cells

Prevalence: 0.4–1.3% of all intracranial neoplasms; 1–4% of all pediatric CNS neoplasms

Peak age: 10–20 years; in 80% < 30 years of age; M > F

Histo: containS ganglion + glial elements: ganglion cells (neurons) arise from primitive neuroblasts and mature during growth; usually astrocytic glial cells predominate in various stages of neoplastic differentiation

• headaches; medically refractory seizures:

◊ Most common cause of chronic temporal lobe epilepsy!

Location: frequently above tentorium: in periphery of cerebral hemisphere [temporal (38%) / parietal (30%) / frontal (18%) lobes]; brainstem; cerebellum; pineal region; spinal cord; optic nerve; optic chiasm; ventricles; local involvement of subarachnoid space

√ circumscribed slow-growing mass:

√ solid (43%) / purely cystic (5%) / solid-cystic combination (52%)

√ calcifications (30%)

√ little associated mass effect / vasogenic edema

CT:

√ hypoattenuating (38%) / mixed attenuation (32%) / isoattenuating (15%) / hyperattenuating (15%) mass

√ ± remodeling of skull

√ contrast enhancement (16–80%)

◊ Occasionally completely undetectable by CT

MR:

√ variable (hypo- / isointense) nonspecific MR appearance on T1WI

√ commonly at least one hyperintense region on T2WI

√ cystic component may have higher signal intensity than CSF ← gelatinous material

√ nonenhancing / ringlike / homogeneously intense enhancement

Prognosis: favorable; malignant degeneration (6%)

Rx: gross total resection (with resolution of seizure activity in majority of patients)

Desmoplastic Infantile Ganglioglioma

= DESMOPLASTIC INFANTILE ASTROCYTOMA = SUPERFICIAL CEREBRAL ASTROCYTOMA ATTACHED TO DURA

= uncommon variety of ganglioglioma exclusively in infants

Age: < 18 months (vast majority); M÷F = 2÷1

Histo: spindle cell neoplasm with oval / elongated moderately pleomorphic nuclei + clusters of larger cells with large prominent eccentric nuclei and cytoplasm containing Nissl bodies

• rapidly increasing head circumference; seizure (uncommon)

Location: frontal + parietal > temporal > occipital lobes

√ exceptionally large heterogeneously mass:

√ slightly hyperattenuating solid portion typically located along cortical margin

√ cystic components

√ intense enhancement of solid component
√ CHARACTERISTIC extension of enhancement to leptomeningeal margin ← firm dural attachment
√ rare vasogenic edema
√ NO calcification
Prognosis: good
Rx: surgical resection

GERMINOMA

= malignant primitive germ cell neoplasm
Incidence: 1–2% of all cranial neoplasms
Age: < 20 years in 90%
Histo: lymphocytes + large polygonal primitive germ cells; absence of capsule facilitates invasion
◊ Identical to testicular seminoma + ovarian dysgerminoma with the same radiosensitivity.
Location: (a) pineal region (50–65%)
(b) suprasellar hypothalamic region (25–35%): infundibular stalk, floor of 3rd ventricle
(c) others: basal ganglia, thalamus
(d) synchronous locations in 10% of all intracranial germ cell tumors
√ hyperattenuated mass on CT + reduced perfusion on DWI ← to abundance of lymphocytes
Cx: frequent CSF seeding (CSF cytology more sensitive than imaging like contrast MR of entire neuroaxis)
Rx: combination of irradiation (very radiosensitive) and chemotherapy (doxorubicin, cisplatin, cyclophosphamide)
Prognosis: 90% 5-year survival

Suprasellar / Hypothalamic Germinoma

Age: childhood + young adulthood; M = F
• hypothalamic symptoms:
• diabetes insipidus, emaciation
• precocious puberty frequent in children < 10 years of age (tumor may be small / radiologically invisible)
√ homogeneous well-marginated round solid mass
√ prompt homogeneous contrast enhancement
MR:
√ iso- to hypointense to gray matter on T1WI
√ iso- to slightly hyperintense on T2WI ← diminished free water content
√ absence of hyperintense posterior pituitary lobe ← blockage of infundibulum by mass

Pineal Germinoma

= DYSGERMINOMA = ATYPICAL TERATOMA = PINEALOMA (former inaccurate names)
◊"pinealoma" = misnomer as it refers to any pineal mass

Incidence: 1–2% of all cranial neoplasms; most common pineal tumor (> 50% of all pineal tumors, 66% of pineal germ cell tumors)
Age: 10–25 years (90% < 20 years old); M÷F = 10÷1
May be associated with: ectopic pinealoma = secondary focus in inferior portion of 3rd ventricle

• Parinaud syndrome
√ ± hydrocephalus ← compression of aqueduct of Sylvius
√ well-defined lesion restricted to pineal gland
√ may infiltrate quadrigeminal plate / thalamus
CT:
√ sharply circumscribed hyperattenuating mass ← highly cellular lymphocyte component
√ mass engulfs pineal calcifications
√ moderate / marked uniform contrast enhancement
MR:
√ round / lobular well-circumscribed relatively homogeneous mass iso- to hyperintense to gray matter on T1WI and T2WI ± cystic components
√ reduced perfusion on DWI ← highly cellular lymphocyte component
√ avid homogeneous Gd-DTPA enhancement

Cx: common invasion of adjacent brain + dissemination by CSF requires imaging of the entire neuroaxis!
Prognosis: good ← lesions highly responsive to radiation therapy with ≥ 90% 5-year survival

DDx: primary pineal neoplasm

GLIOBLASTOMA MULTIFORME

= GBM
Most malignant form of all gliomas / astrocytomas; end stage of progressive severe anaplasia of preexisting Grade I / II astrocytoma (not from embryologic glioblasts)
Incidence: most common primary brain tumor; 50% of all intracranial tumors; 1–2% of all malignancies; 20,000 cases per year
Age: all ages; peak incidence at 65–75 years; M÷F = 3÷2; more frequently in whites
Genetics: Turcot syndrome, neurofibromatosis type 1, Li-Fraumeni syndrome (familial neoplasms in various organs based on abnormal p53 tumor-suppressor gene)
Path: multilobulated appearance; quite extensive vasogenic edema (transudation through structurally abnormal vascular tumor channels); deeply infiltrating neoplasm; hemorrhage; necrosis is essential for pathologic diagnosis (HALLMARK)
Histo: highly cellular, often bizarrely pleomorphic / undifferentiated multipolar astrocytes; common mitoses + prominent vascular endothelial proliferation; no capsule; pseudopalisading (= viable neoplastic cells form an irregular border around necrotic debris as the tumor outgrows its blood supply)
Subtypes:
(a) giant cell GBM = monstrocellular sarcoma
(b) small cell GBM = gliosarcoma = Feigin tumor
Location:
(a) hemispheric: white matter of centrum semiovale: frontal > temporal lobes; common in

pons, thalamus, quadrigeminal region; relative sparing of basal ganglia + gray matter
DDx: solitary metastasis, tumefactive demyelinating lesion ("singular sclerosis"), atypical abscess

(b) callosal: "butterfly glioma" may grow exophytically into ventricle
(c) posterior fossa: pilocytic astrocytoma, brainstem astrocytoma
(d) extraaxial: primary leptomeningeal glioblastomatosis
(e) multifocal: in 2–5%

Spread:

(a) direct extension along white matter tracts:
corpus callosum (36%), corona radiata, cerebral peduncles, anterior commissure, arcuate fibers
√ readily crosses midline = "*butterfly*" glioma (clue: invasion of septum pellucidum)
√ frontal + temporal gliomas tend to invade basal ganglia
√ may invade pia, arachnoid and dura (mimicking meningioma)
(b) subependymal carpet after reaching surface of ventricles
(c) via CSF (< 2%)
(d) hematogenous (extremely rare):
√ osteoblastic bone lesion

NECT:

√ inhomogeneous low-density mass with irregular shape + poorly defined margins (hypodense solid tumor / cavitary necrosis / tumor cyst / peritumoral "fingers of edema")
√ considerable mass effect → compression + displacement of ventricles, cisterns, brain parenchyma
√ iso- / hyperdense portions (= hemorrhage) in 5%
√ rarely calcifies (if coexistent with lower-grade glioma / after radio- or chemotherapy)

CECT:

Enhancement pattern: contrast enhancement ← breakdown of blood-brain barrier / neovascularity / areas of necrosis
(a) diffuse homogeneous enhancement
(b) heterogeneous enhancement
(c) ring pattern (occasionally enhancing mass within the ring)
(d) low-density lesion with contrast-fluid level ← leakage of contrast

√ almost always ring blush of variable thickness: multiscalloped ("garland"), round / ovoid; may be seen surrounding ventricles (= subependymal spread); tumor usually extends beyond margins of enhancement
√ sedimentation level ← cellular debris / hemorrhage / accumulated contrast material in tumoral cyst

MR:

√ poorly defined lesion with some mass effect / vasogenic edema / heterogeneity
√ hemosiderin deposits (gradient echo images)
√ hemorrhage (= hypointensity on T2WI and T2*WI)
√ T1WI + gadolinium-DTPA enhancement separates tumor nodules from surrounding edema, central necrosis and cyst formation

Angio:

√ wildly irregular neovascularity + early draining veins

√ avascular lesion

PET:

√ increase in glucose utilization rate

Rx: surgery + radiation therapy + chemotherapy

Prognosis: 16–18 months postoperative survival (frequent tumor recurrence ← during surgery uncertainty about tumor margins)

Multifocal GBM

(1) Spread of primary GBM
(2) Multiple areas of malignant degeneration in diffuse low-grade astrocytoma ("gliomatosis cerebri")
(3) Inherited / acquired genetic abnormality

GLIOMA

= malignant tumors of glial cells growing along white matter tracts with tendency to increase in grade with time; may be multifocal

Incidence: 30–40% of all primary intracranial tumors; 50% of solitary supratentorial masses

√ contrast enhancement:
→ increases in proportion to degree of anaplasia
→ intensity of enhancement diminishes with steroid therapy

CELL OF ORIGIN

1.	Astrocyte	Astrocytoma
2.	Oligodendrocyte	Oligodendroglioma
3.	Ependyma	Ependymoma
4.	Medulloblast	Medulloblastoma; (PNET = primitive neuroectodermal tumor)
5.	Choroid plexus	Choroid plexus papilloma

FREQUENCY OF INTRACRANIAL GLIOMAS

Glioblastoma multiforme	51%
Astrocytoma	25%
Ependymoma	6%
Oligodendroglioma	6%
Spongioblastoma polare	3%
Mixed gliomas	3%
Astroblastoma	2%

Age peak: middle adult life

Location: cerebral hemispheres; spinal cord; brainstem + cerebellum (in children)

Brainstem Glioma

Incidence: 1%; 12–15% of all pediatric brain tumors; 20–30% of infratentorial brain tumors in children

Histo: usually anaplastic astrocytoma / glioblastoma multiforme with infiltration along fiber tracts

Age: in children + young adults; peak age 3–13 years; M÷F = 1÷1

- become clinically apparent early before ventricular obstruction occurs
- ipsilateral progressive multiple cranial nerve palsies
- cerebellar dysfunction: ataxia, nystagmus
- contralateral hemiparesis, eventually respiratory insufficiency

Location: pons > midbrain > medulla; often unilateral at medullopontine junction
◊ Medullary + mesencephalic gliomas are more benign than pontine gliomas!

Growth pattern:
(a) diffuse infiltration of brainstem with symmetric expansion + rostrocaudal spread into medulla / thalamus + spread to cerebellum
(b) focally exophytic growth into adjacent cisterns (cerebellopontine, prepontine, cisterna magna)

√ asymmetrically expanded brainstem
√ flattening + posterior displacement of 4th ventricle + aqueduct of Sylvius
√ compression of prepontine + interpeduncular cistern (in upward transtentorial herniation)
√ paradoxical widening of CP angle cistern with tumor extension into CP angle
√ paradoxical anterior displacement of 4th ventricle with tumor extension into cisterna magna

CT:
√ isodense / hypodense mass with indistinct margins
√ hyperdense foci (= hemorrhage) uncommon
√ absent / vague (minimal / patchy) contrast enhancement (50%)
√ ring enhancement in necrotic / cystic tumors (= most aggressive tumors)
√ prominent enhancement in exophytic lesion
√ hydrocephalus uncommon (because of early symptomatology)

MR: (best evaluation in subtle cases)
√ hypointense on T1WI + hyperintense on T2WI
√ often only subtle enhancement
√ ± engulfment of basilar artery

Angio:
√ anterior displacement of basilar artery + anterior pontomesencephalic vein
√ posterior displacement of precentral cerebellar vein
√ posterior displacement of posterior medullary + supratonsillar segments of PICA
√ lateral displacement of lateral medullary segment of PICA

Prognosis: 10–30% 5-year survival rate
Rx: radiation therapy
DDx: focal encephalitis, resolving hematoma, vascular malformation, tuberculoma, infarct, multiple sclerosis, metastasis, lymphoma

Hypothalamic-Chiasmatic Glioma

Origin: often undeterminable: hypothalamic gliomas invade chiasm, chiasmatic gliomas invade hypothalamus
Incidence: 10–15% of supratentorial tumors in children
Age: 2–4 years; M÷F = 1÷1
Associated with: von Recklinghausen disease (20–50%)

- diminished visual acuity (50%) ← optic atrophy
- diencephalic syndrome (in up to 20%): marked emaciation, pallor, unusual alertness,

hyperactivity, euphoria
• short stature (in 20%) ← reduction in growth hormone
• obese child, sexual precocity, diabetes insipidus
√ suprasellar hypodense lobulated mass with dense inhomogeneous enhancement
√ heterogeneous lesion ← cyst formation, necrosis, calcifications
√ hypointense on T1WI + hyperintense on T2WI + FLAIR
√ obstructive hydrocephalus
DDx: hypothalamic hamartoma, ganglioglioma, choristoma

GLOBOID CELL LEUKODYSTROPHY

= KRABBE DISEASE
= autosomal recessive neurodegenerative disorder characterized by severe myelin loss + globoid cells in white matter
Cause: deficiency of galactosylceramide β-galactosidase → cerebroside accumulation + destruction of oligodendrocytes
Age: 3–6 months
• fever, hyperactive reflex, flaccidity, irritability, restlessness
• optic atrophy, hyperacusis
Lesion location: thalami, posterior limb of internal capsules, caudate nuclei, brainstem, cerebellar dentate nuclei, centrum semiovale
√ symmetric hyperintensity / hyperdensity in periventricular white matter, thalami, basal ganglia, dentate + caudate nuclei, corona radiata
√ decreased attenuation of white matter
√ brain atrophy with enlargement of ventricles
MR spectroscopy:
√ elevated choline + creatine + myo-inositol associated with moderate N-acetylaspartate
Dx: biochemical assay from white blood cells / skin fibroblasts
Prognosis: death within first few years of life

HALLERVORDEN-SPATZ DISEASE

= PANTOTHENATE KINASE-ASSOCIATED NEURODEGENERATION
= rare familial neurodegenerative metabolic disorder with abnormal iron retention in basal ganglia
Cause: mutation of PANK2 gene encoding pantothenate kinase → neurodegeneration with iron accumulation
Age: 2nd decade of life
Histo: hyperpigmentation and symmetrical destruction of globus pallidus + substantia nigra
Types:
(a) classic early-onset rapidly progressive disease
(b) atypical late-onset slowly progressive disease
• progressive gait impairment + rigidity of limbs
• slowing of voluntary movements, dysarthria
• choreoathetotic movement disorder, progressive dementia
CT:

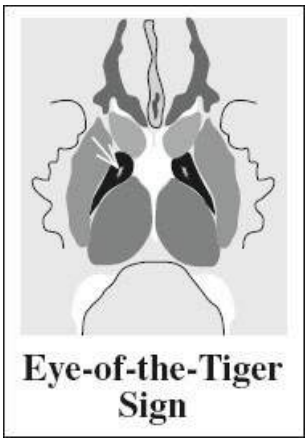
√ low- (= tissue destruction) / high-density (= dystrophic calcification) foci in globus pallidus

MR:

√ "eye-of-the-tiger" sign = high-signal-intensity center surrounded by the more typical hypointensity in globus pallidus:

√ initially bilateral hypointense globus pallidus on T2WI (= iron accumulation)

√ later central hyperintense foci on T2WI (= tissue destruction + gliosis)



HAMARTOMA OF CNS

rare tumor

(a) sporadic

(b) associated with tuberous sclerosis; may degenerate into giant cell astrocytoma

Age: 0–30 years

Location: temporal lobe, hamartoma of tuber cinereum, subependymal in tuberous sclerosis

√ cyst with little mass effect, possibly with focal calcifications

√ usually NO enhancement

Hypothalamic hamartoma

= HAMARTOMA OF TUBER CINEREUM

= rare developmental congenital malformation composed of normal neuronal tissue arising from posterior hypothalamus in region of tuber cinereum

Age: 1st–2nd decade; M > F

Histo: heterotopic collection of neurons, astrocytes, oligodendroglial cells (closely resembling histologic pattern of tuber cinereum)

• neurodevelopmental delay

• central precocious puberty, gelastic seizures

Location: mamillary bodies / tuber cinereum, hypothalamus

(a) **parahypothalamic** hamartoma (common)

• isosexual precocious puberty ← LHRH secretion

√ pedunculated mass attached to tuber cinereum / mamillary bodies by thin stalk

(b) **intrahypothalamic** hamartoma (rare)

• gelastic seizures, hyperactivity

√ sessile mass with broad attachment to hypothalamus
√ distortion of 3rd ventricle

Size: up to 4 cm in diameter

√ well-defined round / oval mass projecting from base of brain into suprasellar / interpeduncular cistern

√ stable in size over time

CT:

√ round homogeneous mass isodense with brain tissue

√ NO enhancement

MR:

√ well-defined round pedunculated mass suspended from tuber cinereum / mamillary bodies

√ imaging characteristics of gray matter:

√ iso- to mildly hypointense on T1WI

√ iso- to slightly hyperintense on T2WI

√ NO gadolinium enhancement

HEAD TRAUMA

= CNS TRAUMA

Incidence: 0.2–0.3% significant CNS trauma annually in USA; 550÷100,000 persons with peak age of 15–24 years; second peak > 50 years of age

Cause: motor vehicle accidents (51%), fall (21%), assault and violence (12%), sports and recreation (10%)

Classification:

A. Primary traumatic lesion

(a) primary neuronal injury

1. Cortical contusion
2. Diffuse axonal injury
3. Subcortical gray matter injury
   = injury to thalamus ± basal ganglia
4. Primary brainstem injury

(b) primary hemorrhages (from injury to a cerebral artery / vein / capillary)

1. Subdural hematoma
2. Epidural hematoma
3. Intracerebral hematoma
4. Diffuse hemorrhage (intraventricular, subarachnoid)

(c) primary vascular injuries

1. Carotid-cavernous fistula
2. Arterial pseudoaneurysm
   Location: branches of ACA + MCA, intracavernous portion of ICA, pCom
3. Arterial dissection / laceration / occlusion
4. Dural sinus laceration / occlusion

(d) traumatic pia-arachnoid injury

1. Posttraumatic arachnoid cyst

2. Subdural hygroma

(e) cranial nerve injury

B. Secondary traumatic lesion

• deterioration of consciousness / new neurologic signs some time after initial injury

1. Major territorial arterial infarction

Cause: prolonged transtentorial / subfalcine herniation pinching the artery against a rigid dural margin

Location: PCA, ACA territory

2. Boundary + terminal zone infarction
3. Diffuse hypoxic injury
4. Diffuse brain swelling / edema
5. Pressure necrosis from brain herniation

Cause: increased intracranial pressure

Location: cingulate, uncal, parahippocampal gyri, cerebellar tonsils

6. Secondary "delayed" hemorrhage
7. Secondary brainstem injury (mechanical compression, secondary (Duret) hemorrhage in tegmentum of rostral pons + midbrain, infarction of median / paramedian perforating arteries, necrosis)
8. Other (eg, fatty embolism, infection)

• **Duret hemorrhage**

= delayed 2ndary hemorrhage in ventral + paramedian aspects of upper brainstem (mesencephalon + pons) due to massive temporal lobe herniation causing stretching + laceration of pontine perforating branches of basilar artery

• **Kernohan phenomenon**

= contusion of contralateral brainstem caused by pressure of free edge of tentorium

Pathophysiology:

expanding supratentorial mass forces medial aspect of temporal lobe downward over tentorium compressing the neighboring oculomotor nerve (III); lateral pressure on midbrain compresses opposite crus cerebri against free edge of tentorium forming indentation in crus (*Kernohan notch*)

- ipsilateral pupillary dilatation
- ipsilateral oculomotor nerve palsy
- ipsilateral hemiparesis (false localizing sign)

Pathomechanism:

A. Direct impact on brain ← fracture / skull distortion

√ scalp / skull abnormal

√ superficial neural damage localized to immediate vicinity of calvarial injury

1. Cortical laceration ← depressed fracture fragment
2. Epidural hematoma

B. Indirect injury irrespective of skull deformation

√ scalp / skull normal

(a) compression-rarefaction strain = change in cell volume without change in shape (rare)

(b) shear strain = change in shape without change in volume

› rotational acceleration forces (more common)

√ bilateral multiple superficial / deep lesions possibly remote from the site of

impact

1. Cortical contusion (brain surface)
2. Diffuse axonal injury (white matter)
3. Brainstem + deep gray matter nuclei

› linear acceleration forces (less common)

1. Subdural hematoma

Glasgow Coma Scale			
Response	*Score*	*Response*	*Score*
Eye opening		**Verbal response**	
spontaneous	4	oriented	5
to voice	3	confused	4
to pain	2	inappropriate words	3
none	1	incomprehensible	2
		none	1
Motor response			
obeys commands	6	localizes pain	5
withdraws (pain)	4	flexion (pain)	3
extension (pain)	2	none	1

2. Small superficial contusion

Prognosis: 10% fatal, 5–10% with residual deficits

Centripetal approach in search of injury:

A. Scalp
   1. Scalp abrasion: not visible
   2. Scalp laceration: air inclusion
   3. Scalp contusion: salt-and-pepper densities
B. Subgaleal hematoma
   Location: between periosteum of outer table and galea (= underneath scalp fat)
C. Skull fracture:
   linear ~, stellate ~, depressed ~, basilar ~, eggshell fracture
D. Epidural hematoma
E. Subdural hematoma
F. Subarachnoid hemorrhage
G. Brain injury
   1. Contusion/ edema
   2. Brain hematoma
H. Ventricular hemorrhage

Indications for radiographic skull series:

Only in conjunction with positive CT scan findings!

1. Evaluation of difficult depressed skull fracture / fracture of base of skull

Indications for CT:

1. Loss of consciousness (more than transient)
2. Altered mental status during observation

3. Focal neurologic signs
4. Clinically suspected basilar fracture
5. Depressed skull fracture (= outer table of fragment below level of inner table of calvarium)
6. Penetrating wound (eg, bullet)
7. Suspected acute subarachnoid hemorrhage, epidural / subdural / parenchymal hematoma

CT report in CNS trauma must address:

√ midline shift
√ localized mass effect
√ distortion / effacement of basal, perimesencephalic, suprasellar, quadrigeminal cisterns
√ pressure on brainstem, brainstem abnormality
√ hemorrhage / contusion: extraaxial, intraaxial, subarachnoid, intraventricular
√ edema: generalized / localized
√ hydrocephalus
√ presence of foreign bodies, bullet, bone fragments, air
√ base of skull, face, orbit
√ scalp swelling

Indications for MR:

1. Postconcussive symptomatology
2. Diagnosis of small sub- / epidural hematoma
3. Suspected diffuse axonal (shearing) injury, cortical contusion, primary brainstem injury
4. Vascular damage (eg, pseudoaneurysm formation due to basilar skull fracture)

Sequelae of head injury:

1. Posttraumatic hydrocephalus (⅓)
   = obstruction of CSF pathways ← intracranial hemorrhage; develops within 3 months
2. Generalized cerebral atrophy (⅓)
   = result of ischemia + hypoxia
3. Encephalomalacia
   √ focal areas of decreased density, but usually higher density than CSF
4. Pseudoporencephaly
   = CSF-filled space communicating with ventricle / subarachnoid space from cystic degeneration
5. Subdural hygroma
6. Leptomeningeal cyst
   = progressive protrusion of leptomeninges through traumatic calvarial defect
7. Cerebrospinal fluid leak
   • rhinorrhea, otorrhea (indicating basilar fracture with meningeal tear)
8. Posttraumatic abscess
   due to (a) penetrating injury, (b) basilar skull fracture, (c) infection of traumatic hematoma
9. Parenchymal injury
   brain atrophy, residual hemoglobin degradation products, wallerian-type axonal degeneration, demyelination, cavitation, microglial scarring

Prognosis: up to 10% fatal;
5–10% with some degree of neurologic deficit

Mortality: 25÷100,000 per year (traffic-related in 20–50%, gunshot 20–40%; falls)

Extracerebral Hemorrhage

1. Subdural hematoma
   in adults: dura inseparable from skull
2. Epidural hematoma
   in children: dura easily stripped away from skull
3. Subarachnoid hemorrhage
   common accompaniment to severe cerebral trauma

Intracerebral Hemorrhage

1. Diffuse axonal injury
2. **Hematoma**
   = blood separating relatively normal neurons
   (a) shear-strain injury (most common)
   (b) blunt / penetrating trauma (bullet, ice pick, skull fracture fragment)
   Incidence: 2–16% of trauma victims
   Location: low frontal + anterior temporal white matter / basal ganglia (80–90%)
   • frequently no loss of consciousness
   • development may be delayed in 8% of head injuries
   √ well-defined homogeneously increased density
3. **Cortical contusion**
   = blood mixed with edematous brain
   √ poorly defined area of mixed high and low densities, may increase with time
4. **Intraventricular hemorrhage**
   = potential complication of any intracranial hemorrhage
   ◊ For earliest detection focus on occipital horns!

Other Posttraumatic Lesions

1. Pneumocephalus
2. Penetrating foreign body

HEMANGIOPERICYTOMA

= HPC = ANGIOBLASTIC MENINGIOMA
= rare neoplasm thought to arise from Zimmermann pericytes surrounding capillaries + postcapillary venules
Incidence: < 0.4% of all CNS tumors
Age: 38–42 years (younger age group than for meningiomas); M÷F = 1.4÷1
Path: part of spectrum with solitary fibrous tumor; WHO grade II / grade III lesion
Histo: closely packed randomly oriented cells with scant cytoplasm + interrupted by gaping capillary-caliber vessels with a branching "staghorn" pattern; CD34 positive; EMA negative
Location: supratentorial; almost always solitary
• headache, seizure, visual dysfunction, motor weakness
√ similar to meningioma
√ narrow base of attachment to dura

√ significant edema in subjacent brain parenchyma (frequent)

Angio:

√ hypervascular lesion with dual blood supply from ECA + ICA / vertebral artery

√ NO early draining veins

√ fluffy" stain (rather than "sunburst" stain of meningioma)

MR:

√ typically isointense to gray matter on both T1WI + T2WI

√ ± prominent flow voids

√ avid enhancement, sometimes heterogeneously

√ "mushrooming" into adjacent brain

√ lobulated / irregular borders

√ high myo-inositol peak at 3.56 ppm + lack of alanine

DDx: meningioma (broad base of dural attachment, sunburst" stain of tumor blush, low myo-inositol + positive alanine peak)

Hemangiopericytoma	*Meningioma*
√ erosion of adjacent bone	√ hyperostosis
√ NO intratumoral calcification	√ ± calcifications

Hemangioblastoma of CNS

= benign autosomal dominant tumor of vascular origin

Incidence: 1–2.5% of all intracranial neoplasms; most common primary infratentorial neoplasm in adults (10% of posterior fossa tumors)

Age: (a) adulthood (> 80%): 20–50 years, average age of 33 years; M > F
(b) childhood (< 20%): in von Hippel-Lindau disease (10–20%); girls

Associated with:

(a) von Hippel-Lindau disease (in 20%), may have multiple hemangioblastomas (only 20% of patients show other stigmata)

(b) pheochromocytoma (often familial)

(c) syringomyelia

(d) spinal cord hemangioblastomas

• headaches, ataxia, nausea, vomiting

• erythrocythemia in 20% (tumor elaborates stimulant)

Location: paravermian cerebellar hemisphere (85%) > spinal cord > cerebral hemisphere / brainstem; multiple lesions in 10%

√ solid (⅓) / cystic / cystic with mural nodule

√ solid portion often intensely hemorrhagic

√ almost never calcifies

CT:

√ cystic sharply marginated mass of CSF-density (⅔)

√ peripheral mural nodule with homogeneous enhancement (50%)

√ occasionally solid with intense homogeneous enhancement

MR:

√ well-demarcated tumor mass moderately hypointense on T1WI + T2WI

√ hyperintense areas on T1WI (= hemorrhage)

√ hypointense areas on T1WI + hyperintense areas on T2WI (= cyst formation)
√ intralesional vermiform areas of signal dropout (= high-velocity blood flow)
√ heterogeneous enhancement on Gd-DTPA with nonenhancing foci of cyst formation + calcification + rapidly flowing blood
√ perilesional Gd-DTPA enhancing areas of slow-flowing blood vessels feeding and draining the tumor
√ peripheral hyperintense rim on T2WI (= edema)

Angio:
√ densely stained tumor nidus within cyst ("contrast loading")
√ staining of entire rim of cyst
√ draining vein

Prognosis: > 85% postsurgical 5-year survival rate

DDx: (1) Cystic astrocytoma (> 5 cm in size, calcifications, larger nodule, thick-walled lesion, no angiographic contrast blush of mural nodule, no erythrocythemia)
(2) Arachnoid cyst (if mural nodule not visualized)
(3) Metastasis (more surrounding edema)

HEMATOMA OF BRAIN

= INTRACEREBRAL HEMATOMA

Etiology:

A. Very common
1. Chronic hypertension (50%)
Age: > 60 years
Location: external capsule and basal ganglia (putamen in 65%) / thalamus (25%), pons (5%), brainstem (10%), cerebellum (5%), cerebral hemisphere (5%)
2. Trauma
3. Aneurysm
4. Vascular malformation: AVM, cavernous hemangioma, venous angioma, capillary telangiectasia

B. Common
1. Hemorrhagic infarction = hemorrhagic transformation of stroke
2. Amyloid angiopathy (20%): elderly patients
3. Coagulopathy (5%): DIC, hemophilia, idiopathic thrombocytopenic purpura; aspirin, heparin, coumadin
4. Drug abuse (5%): amphetamines, cocaine, heroine
5. Bleeding into tumor
(a) primary: GBM, ependymoma, oligodendroglioma, pituitary adenoma
(b) metastatic: melanoma, choriocarcinoma, renal cancer, thyroid cancer, adenocarcinoma

C. Uncommon
1. Venous infarction
2. Eclampsia
3. Septic emboli
4. Vasculitis (especially fungal)

5. Encephalitis

Stages of Cerebral Hematomas

Progression: hematoma gradually "snowballs" in size, dissects along white matter tracts; may decompress into ventricular system / subarachnoid space

Resolution: resorption from outside toward the center; rate depends on size of hematoma (usually 1–6 weeks)

FALSE-NEGATIVE CT:

1. Impaired clotting
2. Anemia

√ iso- / hypodense stage

Hyperacute Cerebral Hemorrhage

Time period: 4–6 hr

Substrate: fresh oxygenated arterial blood contains 95% diamagnetic (= NO unpaired electrons) intracellular oxyhemoglobin (Fe2+) with higher water contents than white matter; oxyhemoglobin persists for 6–12 hr)

NECT:

√ homogeneous consolidated high-density lesion (50–70 HU) with irregular well-defined margins increasing in density during day 1–3 (hematoma attenuation dependent on hemoglobin concentration + rate of clot retraction)

√ usually surrounded by low attenuation appearing within 24–48 hours ← edema, contusion

(a) irregular shape in trauma

(b) spherical + solitary in spontaneous hemorrhage

√ less mass effect compared with neoplasms

MR (less sensitive than CT during first hours):

√ little difference to normal brain parenchyma = center of hematoma iso- to hypointense on T1WI + minimally hyperintense on T2WI

√ peripheral rim of hypointensity (= degraded blood products as clue for presence of hemorrhage)

Acute Cerebral Hematoma

Time period: 12–48 hours

Substrate: paramagnetic (= 4 unpaired electrons) intracellular deoxyhemoglobin (Fe2+); deoxyhemoglobin persists for 3 days

MR:

√ slightly hypo- / isointense on T1WI (= paramagnetic deoxyhemoglobin in intact hypoxic RBCs within blood clot does not cause T1 shortening)

√ very hypointense on T2WI ← progressive concentration of RBCs, blood clot retraction, and fibrin production shorten T2

√ surrounding tissue isointense on T1WI / hyperintense on T2WI ← edema

Early Subacute Cerebral Hematoma

Time period: 3–7 days

Substrate: intracellular strongly paramagnetic (= 5 unpaired electrons) methemoglobin

(Fe3+) inhomogeneously distributed within cells

NECT:

√ increase in size of hemorrhagic area over days / weeks

√ high-density lesion within 1st week; often with layering

MR:

√ very hyperintense on T1WI (= oxidation of deoxyhemo-globin to methemoglobin → marked shortening of T1)

(a) beginning peripherally in parenchymal hematomas

(b) beginning centrally in partially thrombosed aneurysm (oxygen tension higher in lumen)

DDx: melanin, high-protein concentration, flow-related enhancement, gadolinium-based contrast agent

√ very hypointense on T2WI (= intracellular methemoglobin causes T2 shortening)

Late Subacute Cerebral Hematoma

Time period: > 1 week

Substrate: extracellular strongly paramagnetic methemoglobin (homogeneously distributed)

NECT:

√ gradual decrease in density from periphery inward (1–2 HU per day) during 2nd + 3rd week

CECT:

√ peripheral rim enhancement at inner border of perilesional lucency (1–6 weeks after injury) in 80% ← blood-brain barrier breakdown / luxury perfusion / formation of hypervascular granulation tissue

√ ring blush may be diminished by administration of corticosteroids

MR:

√ hyperintense on T1WI (= RBC lysis allows free passage of water molecules across cell membrane)

√ hyperintense on T2WI (= compartmentalization of methemoglobin is lost ← RBC lysis)

√ surrounding edema isointense on T1WI + hyperintense on T2WI

Chronic Cerebral Hematoma

Time period: > 1 months

Substrate: superparamagnetic **ferritin** (= soluble and stored in intracellular compartment) and hemosiderin (= insoluble and stored in lysosomes) cause marked field inhomogeneities

NECT:

√ isodense hematoma from 3rd–10th week with perilesional ring of lucency

CT:

√ hypodense phase (4–6 weeks) ← fluid uptake by osmosis

√ decreased density (3–6 months) / invisible

√ after 10 weeks lucent hematoma (= encephalomalacia ← proteolysis and phagocytosis + surrounding atrophy) with ring blush (DDx: tumor)

MR:

√ rim slightly hypointense on T1WI and very hypointense on T2WI (= superparamagnetic hemosiderin + ferritin within macrophages); rim gradually increases over weeks in thickness, eventually fills in entire hematoma = HALLMARK

√ center hyperintense on T1WI + T2WI (= extracellular methemoglobin of lysed RBCs just inside the darker hemosiderin ring); present for months to 1 year

√ surrounding hyperintensity on T2WI (= edema + serum extruded from clot) with associated mass effect; should resorb within 4–6 weeks (DDx: malignant hemorrhage)

Prognosis:

(1) Herniation (if hematoma 3–4 cm in size)

(2) Death (if hematoma > 5 cm in size)

Basal Ganglia Hematoma

= rupture of small distal microaneurysms in lenticulostriate arteries in patients with poorly controlled systemic arterial hypertension

MR Appearance of Intracerebral Hematoma

Phase	*Age*	*Compartment*	*Hemoglobin*	*T1*	*T2*	*Comments*

T1 and T2 Signal Changes in Evolution of Intracerebral Hematoma

Cx: (1) Dissection into adjacent ventricles (⅔)
(2) Porencephaly
(3) Atrophy with ipsilateral ventricular dilatation

HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS

= macrophage-related disorder characterized by excess lymphocytes + activated macrophages, typically with hemophagocytosis

Histo: absence of CD1a

Location: bone marrow, spleen, liver, lymph nodes

Classification:

(1) primary / familial autosomal recessive form (~ 25%) in infants
(2) secondary form in older children + adults
Associated with: infection, prolonged immunosuppression

- serum ferritin levels > 10,000 μg/L (90% sensitive, 96% specific)
- seizures, altered consciousness, hemiparesis, ataxia
- nuchal rigidity

Chest X-ray:

√ interstitial opacities ± pleural effusion

MR:

√ subcortical white matter foci with ↑ T2 signal intensity
Location: frontal + parietal lobes, basal ganglia
√ leptomeningeal enhancement
√ cerebral volume loss → dilated ventricles + prominent extra-axial fluid

CT:

√ calcifications favoring gray-white matter junction
√ hepatosplenomegaly

US:
√ gallbladder wall thickening, ↑ periportal echogenicity
√ ascites, lymphadenopathy
√ nephromegaly, ↑ renal cortical echogenicity

Dx: at least 5 of 8 criteria: (1) fever (2) splenomegaly (3) cytopenia of at least two cell lineages (4) hypertriglyceridemia ± hyperfibrinogenemia (5) tissue hemophagocytosis (6) low and/or absent natural killer cell activity (7) hyperferritinemia (8) high-soluble interleukin-2 receptor levels

Prognosis: variably relapsing + remitting / rapidly progressive; fatal if untreated

HETEROTOPIC GRAY MATTER

= collection of cortical neurons in an abnormal location ← arrest of migrating neuroblasts from ventricular walls to brain surface between 7–24 weeks of GA

Frequency: 3% of healthy population

May be associated with: agenesis of corpus callosum, aqueductal stenosis, microcephaly, schizencephaly

• seizures

Location:
(1) nodular form: usually symmetric bilaterally in subependymal region / periventricular white matter with predilection for posterior + anterior horns
(2) laminar form: deep / subcortical regions within white matter (less common)

√ single / multiple bilateral subependymal nodules along lateral ventricles
√ isointense with gray matter on all sequences, NO surrounding edema, NO contrast enhancement

DDx: subependymal spread of neoplasm, subependymal hemorrhage, vascular malformation, tuberous sclerosis, intraventricular meningioma, neurofibromatosis

HOLOPROSENCEPHALY

= HPE = spectrum of congenital structural forebrain + midface anomalies characterized by failure of prosencephalon to divide (= cleavage disorder) → varying degrees of frontal lobe "fusion" (= noncleavage of cerebral hemispheres)

Etiology: multifactorial with environmental factors (maternal diabetes, ethyl alcohol, cigarette smoking, retinoic acid); chromosomal and genetic abnormalities; teratogen exposure; syndromic associations

Classic holoprosencephaly is a primary defect of ventral induction and patterning → total / partial failure of separation of prosencephalon into 2 separate hemispheres.

Pathogenesis:
arrested lateral ventricular growth in 6-week embryo → lack of cleavage / diverticulation of forebrain (= prosencephalon), laterally (cerebral hemispheres), transversely (telencephalon, diencephalon), horizontally (optic + olfactory structures) → cortical brain tissue develops to cover monoventricle and fuses in midline → posterior part of the monoventricle becomes enlarged and saclike

Associated with: agenesis of corpus callosum, septo-optic dysplasia, absence of cavum septi pellucidi

◊ Septum pellucidum ALWAYS absent!

Sequence of disorders in prosencephalic ventral induction:
aprosencephaly → atelencephaly → alobar HPE → semilobar HPE → syntelencephaly → lobar HPE

Prevalence: 1÷10,000 in live and stillbirths; M÷F = 1÷1
◊ High rate of spontaneous abortions (50÷10,000)!
◊ Most common malformation of brain + face in humans

Classification (DeMyer):
(a) alobar = no hemispheric development
(b) semilobar = some hemispheric development
(c) lobar = frontal and temporal lobation + small monoventricle

Associated with:
polyhydramnios (60%), genital defects (24%), postaxial polydactyly (8%), vertebral defects (5%), limb reduction defects (4%), transposition of great arteries (4%), renal and cardiac anomalies; chromosomal anomalies (predominantly trisomy 13 + 18 in 24–45%)

Associated borderline syndromes ← diencephalic malformation:
1. Anophthalmia
2. Microphthalmia
3. Aplasia of pituitary gland
4. Olfactogenital dysplasia
5. Septooptic dysplasia

Prognosis: not uniformly lethal depending on severity of brain and facial malformations, presence of chromosomal abnormalities, involvement of other organs, and presence of multiple anomaly syndrome

DDx:
(1) Severe hydrocephalus (roughly symmetrically thinned cortex)
(2) Dandy-Walker cyst (normal supratentorial ventricular system)
(3) Hydranencephaly (frontal + parietal cortex most severely affected)
(4) Agenesis of corpus callosum with midline cyst (lateral ventricles widely separated with pointed superolateral margin)

Alobar Holoprosencephaly

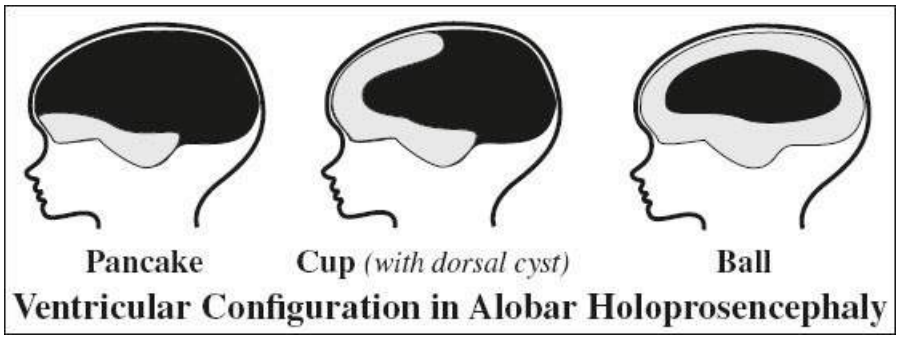
= extreme form in which the prosencephalon does not divide
- minimal motor activity, little sensory response (ineffective brain function); seizures
- severe facial anomalies ("the face predicts the brain"):
  1. Normal face in 17%
  2. **Cyclopia** (= midline single orbit); may have proboscis (= fleshy supraorbital prominence) + absent nose [*pro*, Greek = forward; *boscos*, Greek = feed; *proboskis*, latinized = forward feeder, eg, elephant trunk]
     Embryology: developmental interruption of single midline eye field into L + R eyes under signaling influence of prechordal plate
  3. **Ethmocephaly** = 2 hypoteloric orbits + proboscis between eyes and absence of nasal structures
  4. **Cebocephaly** = 2 hypoteloric orbits + single nostril with small flattened nose + absent

nasal septum
[*kebos*, Greek = monkey; *kephale*, Greek = head]

5. Median cleft lip + cleft palate + hypotelorism
   - absent philtrum
6. Others: micrognathia, trigonocephaly (early closure of metopic suture), microphthalmia, microcephaly

In alobar holoprosencephaly prosencephalic cleavage fails → single midline forebrain with primitive monoventricle often associated with a large dorsal cyst.

√ <u>crescent-shaped holoventricle</u> = single large ventricle without occipital or temporal horns:
  √ "horseshoe" / "boomerang" configuration of brain
    = peripheral rim of cerebral cortex displaced rostrally (coronal plane)
    (a) ball configuration (most common) = complete covering of monoventricle without dorsal cyst
    (b) cup configuration = more cortex visible posteriorly
    (c) pancake configuration = cortex covers monoventricle to edge of dorsal cyst



Ventricular Configuration in Alobar Holoprosencephaly

  √ cerebral mantle pachygyric
√ <u>absence of</u>: <u>anterior commissure</u>, <u>cavum septi pellucidi</u>, <u>falx cerebri</u>, <u>interhemispheric fissure</u>, <u>corpus callosum</u>, fornix, optic tracts, olfactory bulb (= arrhinencephaly), internal cerebral veins, superior + inferior straight sagittal sinus, vein of Galen, tentorium, sylvian fissure, opercular cortex
√ normal / fused / absent optic nerves
√ <u>fused thalami</u>:
  √ protrusion of anteriorly placed fused hypothalamic and thalamic nuclei + basal ganglia into monoventricle resulting in absence of 3rd ventricle
√ <u>large dorsal cyst</u> (in 92%) occupying most of calvarium widely communicating with single ventricle
  Cause: fused thalami obstruct CSF flow → posterior ballooning of 3rd ventricle through suprapineal recess (= point of least resistance)
√ <u>pancakelike cerebrum</u> in posterior cranium
√ ± single / azygos anterior cerebral artery:
  √ ± absence of middle + anterior cerebral arteries replaced by network of vessels arising from ICA + basilar vessels
√ midbrain, brainstem, cerebellum structurally normal
√ midline clefts in maxilla + palate

Prognosis: death within 1st year of life / stillborn
DDx: severe hydrocephalus, hydranencephaly (normal thalamic cleavage, partially visualized falx cerebri)

Semilobar Holoprosencephaly

= intermediate form with incomplete cleavage of prosencephalon (more midline differentiation + beginning of sagittal separation) with > 50%fusion of frontal lobes
• absent / mild facial anomalies: midline cleft lip + palate
• hypotelorism
• mental retardation
√ single ventricular chamber with partially formed occipital horns + rudimentary temporal horns
√ peripheral rim of brain tissue is several cm thick
√ partially fused thalami anteriorly situated + abnormally rotated resulting in small 3rd ventricle:
  √ dorsal cyst (in 28%) → macrocephaly (if cyst large)
√ absence of septum pellucidum + corpus callosum + olfactory bulb:
  √ part of corpus callosum may be present between posteriorly separated hemispheres
√ rudimentary falx cerebri + interhemispheric fissure form posteriorly + caudally with partial separation of occipital lobes
√ incomplete hippocampal formation
Prognosis: infants survive frequently into adulthood

Lobar Holoprosencephaly

= mildest form with formation of 3rd ventricle + some frontal horn + splenium and posterior body of corpus callosum
◊ May be part of septooptic dysplasia!
• usually not associated with facial anomalies except for hypotelorism, mild to severe mental retardation
• spasticity, athetoid movements
√ interhemispheric fissure present along nearly entire midline
√ separation into 2 cerebral hemispheres + 2 lateral ventricles
√ closely apposed bodies of mildly dilated lateral ventricles
√ distinct occipital + frontal horns
√ colpocephaly
√ dorsal cyst (in 9%)
√ rudimentary unseparated frontal horns of angular squared shape + flat roof (on coronal images) ← dysplastic frontal lobes
√ dysplastic anterior falx + interhemispheric fissure
√ absence of septum pellucidum + sylvian fissures
√ corpus callosum usually normal / incomplete
√ hippocampal formation nearly normal
√ basal ganglia + thalami completely / almost completely separated
√ pachygyria (= abnormally wide + plump gyri), lissencephaly (= smooth gyri)
Prognosis: survival into adulthood

HYDRANENCEPHALY

= liquefaction necrosis of cerebral hemispheres replaced by a thin membranous sac of leptomeninges in outer layer and remnants of cortex and white matter in inner layer, filled with CSF + necrotic debris

Incidence: 0.2% of infant autopsies

Etiology: absence of supraclinoid ICA system (? vascular occlusion / infection with toxoplasmosis or CMV) with intact posterior circulation
= extreme form of porencephaly

- seizures; respiratory failure; generalized flaccidity
- decerebrate state with vegetative existence

√ normal skull size / macrocrania / microcrania
√ complete filling of hemicranium with membranous sac
√ absence of cortical mantle (inferomedial aspect of temporal lobe, inferior aspect of frontal lobe, occipital lobe may be identified in some patients)
√ brainstem usually atrophic
√ cerebellum almost always intact
√ thalamic, hypothalamic, mesencephalic structures usually preserved projecting into cystic cavity
√ central brain tissue can be asymmetric
√ choroid plexus present
√ falx cerebri + tentorium cerebelli usually intact, may be deviated in asymmetric involvement, may be incomplete / absent

Prognosis: NOT compatible with prolonged extrauterine life (NO intellectual improvement from shunting!)

DDx: (1) Severe hydrocephalus (some identifiable cortex present)
(2) Alobar holoprosencephaly (facial midline anomalies)
(3) Schizencephaly (some spared cortical mantle)

HYDROCEPHALUS

= excess of CSF ← increased intraventricular pressure ← imbalance of CSF formation and absorption

Pathophysiology:

A. Overproduction (rare)
B. Impaired absorption
   1. Blockage of CSF flow within ventricular system, cisterna magna, basilar cisterns, cerebral convexities
   2. Blockage of arachnoid villi / lymphatic channels of cranial nerves, spinal nerves, adventitia of cerebral vessels

<u>Signs of raised intracranial pressure (skull film):</u>

(a) young infant / newborn
√ increase in craniofacial ratio
√ bulging of anterior fontanel
√ sutural diastasis
√ macrocephaly + frontal bossing

√ "beaten brass" = "hammered silver" appearance = prominent digital impressions (wide range of normals in 4–10 years of age)

(b) adolescent / adult → changes in sella turcica:
- √ atrophy of anterior wall of dorsum sellae
- √ shortening of the dorsum sellae producing pointed appearance
- √ erosion / thinning / discontinuity of floor of sella
- √ depression of floor of sella with bulging into sphenoid sinus
- √ enlargement of sella turcica

DDx: osteoporotic sella (aging, excessive steroid hormone)

Signs favoring hydrocephalus over white matter atrophy:
- √ commensurate dilatation of temporal horns of lateral ventricles (most reliable sign)
- √ narrowing of ventricular angle (= angle between anterior / superior margins of frontal horns at level of foramen of Monro) ← concentric enlargement:
  - √ Mickey Mouse ears on axial scan
- √ enlargement of frontal horn radius (= widest diameter of frontal horns taken at 90° angle to long axis of frontal horn):
  - √ rounding of frontal horn shape
- √ enlargement of ventricular system disproportionate to enlargement of cortical sulci (← compression of brain tissue against skull + consequent sulcal narrowing)
- √ interstitial edema from transependymal flow of CSF:
  - √ periventricular hypodensity
  - √ rim of prolonged T1 + T2 relaxation times surrounding lateral ventricles
- √ hydrocephalic distortion of ventricles + brain:
  - √ atrial diverticulum = herniation of ventricular wall through choroidal fissure of ventricular trigone into supracerebellar and quadrigeminal cisterns
  - √ dilatation of suprapineal recess expanding into posterior incisural space resulting in inferior displacement of pineal gland / shortening of tectum in rostral-caudal direction / elevation of vein of Galen
  - √ enlargement of anterior recess of 3rd ventricle extending into suprasellar cistern

Compensated Hydrocephalus

= new equilibrium established at higher intracranial pressure ← opening of alternate pathways (arachnoid membrane / stroma of choroid plexus / extracellular space of cortical mantle = transependymal flow of CSF)

Obstructive Hydrocephalus

= obstruction to normal CSF flow ← impaired absorption

NUC: radioisotope cisternography
- √ delay (up to 48 hours) for tracer to surround convexities + reach arachnoid villi
- √ positive "w" sign

Communicating Hydrocephalus

= EXTRAVENTRICULAR HYDROCEPHALUS

= elevated intraventricular pressure ← blockade beyond outlet of 4th ventricle within subarachnoid pathways

Incidence: 38% of congenital hydrocephaly

Pathophysiology: unimpeded CSF flow through ventricles; impeded CSF flow over convexities by adhesions / impeded reabsorption by arachnoid villi

Cause:

repetitive subarachnoid microhemorrhage (most common cause), immaturity of arachnoid villi, meningeal carcinomatosis (medulloblastoma, germinoma, leukemia, lymphoma, adenocarcinoma), purulent / tuberculous meningitis, subdural hematoma, craniosynostosis, achondroplasia, Hurler syndrome, venous obstruction (obliteration of superior sagittal sinus), absence of Pacchioni granulations

√ symmetric enlargement of lateral, 3rd + often 4th ventricles

√ dilatation of subarachnoid cisterns

√ normal / effaced cerebral sulci

√ symmetric low attenuation of periventricular white matter (transependymal CSF flow)

√ delayed ascent of radionuclide tracer over convexities

√ persistence of radionuclide tracer in lateral ventricles for up to 48 hours

Changes after successful shunting:

√ diminished size of ventricles + increased prominence of sulci

√ cranial vault may thicken

Cx: subdural hematoma ← precipitous decompression

Noncommunicating Hydrocephalus

= INTRAVENTRICULAR HYDROCEPHALUS

= <u>blockade</u> of CNS flow <u>within ventricular system</u> with dilatation of ventricles proximal to obstruction

Pathogenesis: increased CSF pressure causes ependymal flattening with breakdown of CSF-brain barrier → myelin destruction + compression of cerebral mantle (brain damage)

Location:

(a) Lateral ventricular obstruction

Cause: ependymoma, intraventricular glioma, meningioma

(b) Foramen of Monro obstruction

Cause: 3rd ventricular colloid cyst, tuber, papilloma, meningioma, septum pellucidum cyst / glioma, fibrous membrane (post infection), giant cell astrocytoma

(c) Third ventricular obstruction

Cause: large pituitary adenoma, teratoma, craniopharyngioma, glioma of 3rd ventricle, hypothalamic glioma

(d) Aqueductal obstruction

Cause: Congenital web / atresia (often associated with Chiari malformation), fenestrated aqueduct, tumor of mesencephalon / pineal gland, tentorial meningioma, S/P intraventricular hemorrhage or infection

(e) Fourth ventricular obstruction

Cause: Congenital obstruction, Chiari malformation, Dandy-Walker syndrome, inflammation (TB), tumor within 4th ventricle (ependymoma), extrinsic compression of 4th ventricle (astrocytoma, medulloblastoma, large CPA

tumor, posterior fossa mass), isolated / trapped 4th ventricle

√ enlarged lateral ventricles (enlargement of occipital horns precedes enlargement of frontal horns)
√ effaced cerebral sulci
√ periventricular edema with indistinct margins (especially frontal horns)
√ change in RI indicates increased intracranial pressure (ΔRI 47–132% versus 3–29% in normals)
√ radioisotope cisternography: no obstruction if tracer reaches ventricle

Nonobstructive Hydrocephalus

= rapid CSF production

Cause: Choroid plexus papilloma

√ ventricle near papilloma enlarges
√ intense radionuclide uptake in papilloma
√ enlarged anterior / posterior choroidal artery and blush

Congenital Hydrocephalus

= multifactorial CNS malformation during the 3rd / 4th week after conception

Etiology:

(1) Aqueductal stenosis (43%)
(2) Communicating hydrocephalus (38%)
(3) Dandy-Walker syndrome (13%)
(4) Other anatomic lesions (6%):
  (a) Genetic factors: spina bifida, aqueductal stenosis (X-linked recessive trait with a 50% recurrence rate for male fetuses), congenital atresia of foramina of Luschka and Magendie (Dandy-Walker syndrome; autosomal recessive trait with 25% recurrence rate), cerebellar agenesis, cloverleaf skull, trisomy 13–18
  (b) Nongenetic etiology: tumor compressing 3rd / 4th ventricle, obliteration of subarachnoid pathway due to infection (syphilis, CMV, rubella, toxoplasmosis), proliferation of fibrous tissue (Hurler syndrome), Chiari malformations, vein of Galen aneurysm, choroid plexus papilloma, vitamin A intoxication

Incidence: 0.3–1.8÷1,000 pregnancies

Associated with:

(a) intracranial anomalies (37%): hypoplasia of corpus callosum, encephalocele, arachnoid cyst, arteriovenous malformation
(b) extracranial anomalies (63%): spina bifida in 25–30% (with spina bifida hydrocephalus present in 80%), renal agenesis, multicystic dysplastic kidney, VSD, tetralogy of Fallot, anal agenesis, malrotation of bowel, cleft lip / palate, Meckel syndrome, gonadal dysgenesis, arthrogryposis, sirenomelia
(c) chromosomal anomalies (11%): trisomy 18 + 21, mosaicism, balanced translocation

• elevated amniotic α-fetoprotein level

OB-US (assessment difficult prior to 20 weeks GA as ventricles ordinarily constitute a large portion of cranial vault):

√ "dangling choroid plexus" sign:
  √ choroid plexus not touching medial + lateral walls of lateral ventricles

√ downside choroid plexus falling away from medial wall + hanging from tela choroidea
√ upside choroid falling away from lateral wall
√ lateral width of ventricular atrium ≥ 10 mm (size usually constant between 16 weeks MA and term)
◊ 88% of fetuses with sonographically detected neural axis anomalies have an atrial width > 10 mm
√ BPD > 95th percentile (usually not before 3rd trimester)
√ polyhydramnios (in 30%)

Recurrence rate: < 4%

Mortality: (1) Fetal death in 24%
(2) Neonatal death in 17%

Prognosis: poor with
(1) Associated anomalies
(2) Shift of midline (porencephaly)
(3) Head circumference > 50 cm
(4) Absence of cortex (hydranencephaly)
(5) Cortical thickness < 10 mm

Infantile Hydrocephalus

- ocular disturbances: paralysis of upward gaze, abducens nerve paresis, nystagmus, ptosis, diminished pupillary light response
- spasticity of lower extremities (from disproportionate stretching of paracentral corticospinal fibers)

Etiology:

mnemonic: **A VP-S**hunt **C**an **D**ecompress **T**he **H**ydrocephalic **C**hild

Aqueductal stenosis
Vein of Galen aneurysm
Postinfectious
Superior vena cava obstruction
Chiari II malformation
Dandy-Walker syndrome
Tumor
Hemorrhage
Choroid plexus papilloma

Doppler:
√ RI > 0.8 (sign of increased ICP) in neonate:
√ RI of 0.84 ± 13% decreasing to 0.72 ± 11% after shunting
√ RI > 0.65 (sign of increased ICP) in older children

Normal Pressure Hydrocephalus

= NPH = ADAM SYNDROME
= pressure gradient between ventricle + brain parenchyma in spite of normal CSF pressure

◊ Potentially treatable cause of dementia in elderly!

Cause: communicating hydrocephalus with incomplete arachnoidal obstruction from neonatal intraventricular hemorrhage, spontaneous subarachnoid hemorrhage, intracranial trauma, infection, surgery, carcinomatosis

mnemonic: PAM the HAM

Paget disease
Aneurysm
Meningitis
Hemorrhage (from trauma)
Achondroplasia
Mucopolysaccharidosis

Pathophysiology of CSF:

(?) brain pushed toward cranium from ventricular enlargement; brain unable to expand during systole thus compressing lateral + 3rd ventricles + expressing large CSF volume through aqueduct; reverse dynamic during diastole; "water-hammer" force of recurrent ventricular expansion damages periventricular tissues

Age: 50–70 years

- normal opening pressure at lumbar puncture
- dementia, gait apraxia, urinary incontinence

mnemonic: wacky, wobbly and wet

√ communicating hydrocephalus with prominent temporal horns
√ ventricles dilated out of proportion to any sulcal enlargement
√ upward bowing of corpus callosum
√ flattening of cortical gyri against inner table of calvarium (DDx: rounded gyri in generalized atrophy)

MR:

√ pronounced aqueductal flow void ← diminished compliance of normal pressure hydrocephalus
√ periventricular hyperintensity ← transependymal CSF flow

NUC: radioisotope cisternography

√ reversal of normal CSF flow dynamic = tracer moves from basal cisterns into 4th, 3rd and lateral ventricles
√ loss of "w" sign

Rx: CSF shunting (only in 50% improvement)

HYPOXIC-ISCHEMIC ENCEPHALOPATHY

= HIE = HYPOPERFUSION INJURY

Frequency: 2–9÷1,000 live births

Cause:

(a) <u>in utero</u> ← interruption of placental blood flow + gas exchange:

› fetal factors: fetomaternal hemorrhage, thrombosis, bradycardia, disrupted umbilical circulation (tight nuchal cord, cord prolapse)
› inadequate placental perfusion: maternal hypotension, preeclampsia, placental abruption, chronic vascular disease
› impaired maternal oxygenation: asthma, pulmonary embolism, pneumonia, CO

poisoning, severe anemia

(b) postnatally: severe hyaline membrane disease, pneumonia, meconium aspiration, CHD

(c) older child: cardiac arrest, near drowning, asphyxiation (strangling), barbiturate intoxication → circulatory / respiratory failure

Pathophysiology:

⇓ cerebral blood flow (= ischemia) and ⇓ blood oxygenation (= hypoxemia) → shift in metabolism from oxidative phosphorylation to inefficient anaerobic oxidation → rapid energy depletion, acidosis, release of inflammatory mediators and excitatory neurotransmitters (particularly glutamate), free radical formation, calcium accumulation, lipid peroxidation → necrosis → cell death

- low Apgar score (0–3) at birth, multiorgan dysfunction
- profound metabolic acidosis in cord blood
- seizures, coma, hypotonia, abnormal EEG

Prognosis: (a) full recovery

(b) neonatal death (20%)

(c) significant neurologic sequelae (25%): one of the most common causes of cerebral palsy (spastic quadriplegia, diplegia)

DDx: metabolic encephalopathy from inborn errors of metabolism (congenital lactic acidosis, urea cycle disorder, amino aciduria), congenital + neonatal CNS infections, congenital malformations, severe birth trauma

Temporal evolution and optimal imaging modality:

US:

√ increased parenchymal echogenicity in days 2–10

CT:

√ parenchyma of low attenuation in days 1–7

MR:

√ immediate ⇑ lactate (spectroscopy most useful within hours) → pseudonormalization ~ 24 hours after birth

√ restricted diffusion (DWI in days 1–5 most sensitive test) → pseudonormalization 5 days after birth

√ T1WI and T2WI (most useful after day 2):

√ T2 prolongation ← edema

√ T2 shortening ← mineral deposition

Hypoperfusion Injury in Older Child

Location:

(a) mild HIE: watershed zones

(b) severe HIE: gray matter of cerebral cortex, basal ganglia, hippocampi + sparing of brainstem and cerebral white matter

CT:

√ decreased attenuation of cortical gray matter (diffuse edema)

√ loss of normal gray matter–white matter differentiation

√ bilateral decreased attenuation of basal ganglia and thalami

√ "reversal" sign = higher attenuation of white matter

√ "white cerebellum" sign = lower attenuation of supratentorial brain with relative sparing of cerebellum + brainstem

MR:

√ increased signal intensity on DWI (after 2 hours)

√ subtle increased intensity + swelling of affected areas (after > 24 hours)

√ diffuse T2 prolongation in subcortical white matter (= delayed postanoxic leukoencephalopathy)

Hypoperfusion Injury in Preterm Infant

Gestational age: < 36 weeks

Frequency: 5% of infants born < 32 weeks EGA

Location:

› periventricular white matter (mild hypotension)

› thalami, brainstem, cerebellum = metabolically most active tissue (severe hypotension)

Consequence:

(1) Germinal matrix hemorrhage

(2) Periventricular leukomalacia

US:

√ globular hyperechoic change = PVL (early)

√ localized anechoic / hypoechoic lesions = cystic PVL (2–6 weeks later)

√ progressive periventricular necrosis + ventricular enlargement = end-stage PVL

MR:

√ hyperintense areas on T1WI within larger hyperintense area on T2WI (early)

√ ventricular enlargement with irregular margins of body + trigone of lateral ventricles (later):

√ loss of periventricular white matter with ↑ T2 signal

√ thinning of corpus callosum

Prognosis: germinal matrix hemorrhage upon reperfusion to ischemic tissues

Cx: cerebral palsy in up to 19% of infants < 28 weeks EGA

◊ 50% of cerebral palsy cases occur in infants born prematurely

Hypoperfusion Injury in Term Infant

Gestational age: ≥ 36 weeks

Location:

Mild to moderate hypoxic-ischemic injury causes lesions in watershed areas, parasagittal cortex, and subcortical white matter, while sparing brainstem, cerebellum, deep gray matter structures.

Severe hypoxic-ischemic injury involves the lateral + ventral thalamus, posterior putamen, perirolandic sensorimotor cortex, and corticospinal tracts.

Injury pattern:

(a) peripheral pattern (= parasagittal, watershed / borderzone) - more common

MR:

√ restricted diffusion in parasagittal cortex and underlying subcortical white matter

√ cortical thinning + diminution of underlying white matter

√ ex vacuo dilatation of adjacent lateral ventricles in trigones and occipital horns

(b) basal ganglia–thalamus pattern

MR:

√ bilateral abnormal T1 hyperintensity (days 3–7) in posterolateral putamen, ventrolateral thalamus, corticospinal tract

√ absent posterior limb sign = loss of normal mildly hyperintense T1 focus in posterior limb of internal capsule

√ indistinct / abnormally iso- or hyperintense T2 foci relative to adjacent gray matter instead of normal hypointense foci in posterolateral putamen, posterior limb of internal capsule, ventrolateral thalamus

Prognosis: 15–20% of neonatal mortality; significant developmental deficits in 25%

IDIOPATHIC INTRACRANIAL HYPERTENSION

= PSEUDOTUMOR CEREBRI = BENIGN INTRACRANIAL HYPERTENSION (BIH)

Pathophysiology:

(a) elevation in blood volume (85%)

(b) decrease in regional cerebral blood flow with delayed CSF absorption (10%)

Etiology:

1. Sinovenous occlusive disease, SVC occlusion, obstruction of dural sinus, obstruction of both internal jugular veins
2. Dural AVM
3. S/P brain biopsy with edema
4. Endocrinopathies
5. Hypervitaminosis A
6. Hypocalcemia
7. Menstrual dysfunction, pregnancy, menarche, birth control pills
8. Drug therapy

Predilection for: obese young to middle-aged women

- headache
- papilledema
- elevated opening pressures on lumbar puncture (normal range of 80–180 mm H_2O in horizontal lateral decubitus position)

√ normal ventricular size / pinched ventricles

√ increased volume of subarachnoid space

INFARCTION OF BRAIN

= brain cell death leading to coagulation necrosis

Cause: large vessel occlusion of ICA / MCA / PCA (50%) ← emboli from atherosclerotic stenosis, small-vessel lacunes (25%), cardiac cause (15%), blood disorder (5%), non-arteriosclerotic (5%), venous thrombosis (1%)

◊ 33% of TIAs will lead to infarction!

Pathophysiology:

distal microstasis occurs within 2 minutes after occlusion of cerebral artery; regional cerebral blood flow is acutely decreased in area of infarction + remains depressed for several days at center of infarct; arterial circulation time may be prolonged in entire

hemisphere; rapid development of vasodilatation due to hypoxia, hypercapnia, tissue acidosis; delayed filling + emptying of arterial channels in area of infarction (= arteriolar-capillary block) well into venous phase; by end of 1st week regional blood flow commonly increases to rates even above those required for metabolic needs (= hyperemic phase = luxury perfusion)

• stroke

Mimics: intracerebral hemorrhage, subdural hematoma, cerebritis, hemiplegic / hemisensory migraine, tumor, arteriovenous malformation

Detection rate by CT:

80% for cortex + mantle, 55% for basal ganglia, 54% for posterior fossa

◊ Positive correlation between degree of clinical deficit and CT sensitivity

CT sensitivity: on day of ictus 48%
1–2 days later 59%
7–10 days later 66%
10–11 days later 74%

Location: cerebrum÷cerebellum = 19÷1

(a) supratentorial
- cerebral mantle (70%) in territory of MCA (50%), PCA (10%), watershed between MCA + ACA (7%), ACA (4%)
- basal ganglia + internal capsule (20%)

(b) infratentorial (10%) upper cerebellum (5%), lower cerebellum (3%), pons + medulla (2%)

Hyperacute Ischemic Infarction

Time period: < 12 hr

NECT (100% specific):

Sensitivity: 57% (with standard 40/20 HU window width & level; increased to 71% with 8/32 HU)

√ normal (in 10–60%)

√ identifies hemorrhage

◊ Hemorrhage contraindicates thrombolytic therapy!

√ subtle <u>decrease in attenuation</u> within affected brain area due to cytotoxic edema:

√ "disappearing basal ganglia" sign = obscuration and loss of gray-white matter differentiation in basal ganglia:

√ lentiform nucleus becomes isodense to internal and external capsule within 2 hours after onset of stroke

√ "insular ribbon" sign = loss of gray-white matter differentiation of insular cortex (in 50–80% of MCA occlusions)

√ "<u>hyperdense vessel</u>" sign (HIGHLY SPECIFIC):

√ "hyperdense middle cerebral artery" sign = acute intraluminal thrombus of 80 HU (← extrusion of serum from thrombus) versus 40 HU of flowing blood in M1 segment; transient phenomenon

Incidence: 17–35–50% of acute MCA occlusions

Associated with: poor clinical outcome

DDx: high hematocrit, polycythemia, calcification of vessel wall (usually bilateral), arterial dolichoectasia

√ "MCA dot" sign = punctate focus of hyperattenuation in sylvian fissure (in M2/M3 segment of MCA) ← thromboembolus (38% sensitive, 100% specific)

√ calcified intraluminal embolus (rare)

√ hypoattenuating fat embolus (rare)

√ mass effect from brain swelling:

√ hemispheric cortical sulcal effacement / compression

√ narrowing of sylvian fissure (in MCA infarct)

CECT:

√ visualization of thrombus within intracranial arteries

√ assessment of carotid + vertebral arteries

Perfusion CT:

= monitoring first pass of a small iodinated contrast agent bolus through cerebral circulation with continuous cine imaging for 45 seconds of same slab of tissue

◊ Motion artifacts in ROI invalidate the study!

(1) *Time-attenuation curves* for arterial ROI in unaffected ACA / MCA + venous ROI in superior sagittal sinus / torcular Herophili and in each parenchymal pixel

(2) *Color-coded perfusion maps* for

(a) **mean transit time** (MTT)

= mathematical deconvolution on time-attenuation curve of each pixel with respect to arterial curve

◊ Most sensitive to disruption of cerebral perfusion

◊ MTT correlates directly with perfusion pressure

Increase in: ischemia (infarct core and penumbra), asymptomatic vessel stenosis, vasospasm

(b) **cerebral blood volume** (CBV)

= dividing areas under curve in parenchymal pixel by area under curve in arterial pixel

√ CBV higher in highly vascularized basal ganglia and cortical surface than in white matter

√ increased CBV in penumbra → functioning autoregulation → dilatation of vessels

√ decreased CBV in infarct core → loss of autoregulation → blood vessels no longer dilate

(c) **cerebral blood flow** (CBF = CBV÷MTT)

◊ Most important parameter!

Normal: > 50 mL / 100 g brain tissue

Ischemia threshold: 10–15 mL / 100 g

(3) *Summary map* of percentage *of mismatch*

= CBV area ÷ CBF area

√ ischemic area (= prolonged MTT) divided into:

(a) irreversibly infarcted nonsalvageable tissue ("**infarct core**")

√ markedly decreased CBF + markedly decreased CBV

(b) surrounded by stunned (nonfunctioning potentially salvageable) cells that

receive collateral blood supply ("**penumbra**")
√ decreased CBF + normal / mildly increased CBV ← autoregulatory mechanisms

Perfusion CT Analysis of Hyperacute Ischemic Stroke			
Entity	*Mean Transit Time*	*Cerebral Blood Flow*	*Cerebral Blood Volume*
Penumbra	↑ (> 145%)	↓ (> 34%)	↔ / ↑
Infarct core	↑	⇓	⇓ (< 2 mL/100 g)

MR (routinely positive by 4–6 hours post ictus):
√ parenchymal changes:
√ bright signal (← less signal loss) on DWI with ↓ ADC
Pathophysiology of homeostasis of tissue water:
excess intracellular water (= cytotoxic edema) + ↓ rate of water molecular diffusion (= restriction of normal brownian motion of water molecules)
Sensitivity & specificity: 88–100% & 86–100%

Rule of thumb: low signal intensity on ADC map means the stroke is < 1 week old!

√ hyperintense signal on T2WI + FLAIR involving cortical gray matter

In most ischemic strokes FLAIR images are positive 6–12 hours after onset of symptoms!

√ loss of gray-white matter differentiation on T2WI
√ subtle parenchymal swelling with sulcal effacement ← cytotoxic edema can be seen by 2 hours post ictus (best on T1WI)
√ abnormal blooming on T2*WI identifies hemorrhage

The diagnosis of ischemic stroke is unlikely if parenchymal enhancement persists > 8–12 weeks.

√ vessel signs:
√ loss of normal intravascular flow voids on T2WI
√ intravascular low SI on T2* + high SI on FLAIR (similar to "hyperdense MCA" sign)
√ stasis of contrast material within affected arteries ← stasis of flow distal to thrombus
√ ischemic penumbra = combination of perfusion + diffusion-weighted images allows identification of areas at risk for infarction

DWI & ADC Map in Acute Stroke		
Time Course	*DWI signal*	*ADC*
30 min – 5 days	bright (← restricted diffusion)	reduced
1 – 4 weeks	mildly bright (← T2 shine-through from infarcted tissue)	pseudonormal
weeks to months	variable	increased

NUC:
◊ Newer imaging agents (eg, ^{99m}Tc-HMPAO) may be positive within minutes of the event, while CT and MR are normal

√ hemispheric hypoperfusion throughout all phases
√ defect corresponding to nonperfused vascular territory
√ "flip-flop" sign in radionuclide angiogram (15%)
= decreased uptake during arterial + capillary phase followed by increased uptake during venous phase
√ "luxury perfusion syndrome" (14%) = increased perfusion

Rx: recombinant tissue plasminogen activator (tPA) if symptom onset < 6 hours ago
One-third rule: early ischemic changes on NECT in > ⅓ of MCA territory (in acute ischemic stroke within 6 hours of symptom onset) excludes patient for IV and intraarterial thrombolytic therapy → NO benefit with higher risk of symptomatic hemorrhage

Acute Ischemic Infarction

Histo: cortical cytotoxic edema (= accumulation of intracellular water due to cell membrane damage) followed by extracellular white matter vasogenic edema

√ bright lesion on DWI very conspicuous within 0–6 hours after onset of symptoms + up to 14 days after ictus (diffusion coefficient is a measure of proton mobility in tissue)
◊ false positive DWI:
diffusion coefficient of infarcts is influenced by T2 properties + b-value of gradient strength (T2 shine-through)
◊ 5% false negative DWI

√ hypointense signal on ADC map (negates T2 shine-through effect) within 24 hours (ADC map shows pure diffusion characteristics without T2 effect, but has low lesion conspicuity)
→ a low coefficient (acute infarct) gives a hyperintense signal
→ a high coefficient (CSF) gives a hypointense signal

Early Acute Ischemic Infarction

Time period: 12–24 hours

NECT:
√ low-density lesion (30–60% invisible)
√ loss of differentiation between cortical gray matter and subjacent white matter:
√ blurring of the clarity of internal capsule
√ "insular ribbon" sign = hypodense extreme capsule no longer distinguishable from insular cortex
√ subtle sulcal effacement (8%)

CECT:
√ no iodine accumulation in affected cortical region
√ meningeal gyriform enhancement

MR:
√ subtle narrowing of sulci
√ blurring of gray-white matter junction on T2- and proton-density images
√ increase in thickness of cortex (= gyral swelling)
√ subtle low signal intensity on T1WI, high signal intensity on T2WI (masking of gyral infarcts on heavily T2WI ← sulcal CSF intensity)

◊ 20–30% false negative T2WI during first 24 hours

MRA:

√ absence of flow for infarcts > 2 cm in diameter

Late Acute Ischemic Infarction

Time period: 1–3–7 days

NECT:

√ hypodense wedge-shaped lesion with base at cortex in a vascular distribution (in 70%) ← vasogenic + cytotoxic edema

√ mass effect (23–75%): sulcal effacement, transtentorial herniation, displaced subarachnoid cisterns + ventricles

√ "bland infarct" may be transformed into hemorrhagic infarct after 2–4 days ← leakage of blood from ischemically damaged capillary endothelium following lysis of intraluminal clot + arterial reperfusion

CECT:

√ ⇓ meningeal and ⇓ intravascular contrast enhancement

√ ⇑ parenchymal enhancement

MR:

√ ↑ SI on DWI during 1st week after onset of symptoms

√ "intravascular enhancement" sign (77%)

= Gd-pentetate enhancement of cortical arterial vessels in area of brain injury after 1–3 days ← slow arterial blood flow provided by collateral circulation via leptomeningeal anastomoses

√ "meningeal enhancement" sign (33%)

= Gd-pentetate enhancement of meninges adjacent to infarct after 2–6 days ← meningeal inflammation

Angio:

√ narrowed / occluded vessels supplying infarcted area

√ delayed filling + emptying of involved vessels

√ early draining vein

√ luxury perfusion of infarcted area (rare) = loss of small vessel autoregulation ← local increase in pH

Subacute Ischemic Infarction

Time period: 7–30 days = paradoxical phase with resolution of edema + onset of coagulation necrosis

NECT:

√ "fogging phenomenon" = less apparent low-density area

√ decrease of mass effect + ex vacuo dilatation of ventricles (in 57%)

√ ± transient calcification (especially in children)

CECT:

√ gyral blush + ring enhancement for 2–8 weeks (in 65–80% within first 4 weeks) ← breakdown of blood-brain barrier + luxury perfusion

√ NO enhancement in 20% of patients

MR:

Histo: vasogenic edema (= increased extracellular water) ← disruption of blood-brain barrier

√ ↑ SI on DWI ← T2 shine-through from infarcted tissue

√ hypointense on T1WI, hyperintense on T2WI

√ intravascular + meningeal enhancement signs resolve toward end of 1st week

√ gyriform parenchymal Gd-pentetate enhancement

◊ Gyriform parenchymal enhancement permits differentiation of subacute from chronic infarction!

√ infarction flip-flops from hyperintense lesion to iso- / hypointense lesion on ADC maps 5–10 days after ictus

Chronic Ischemic Infarction

Time period: months to years (> 30 days)

Histo: demyelination + gliosis complete

◊ Focal brain atrophy after 8 weeks!

√ cerebral atrophy + encephalomalacia + gliosis (HALLMARKS)

√ possible calcification (especially in children)

NECT:

√ cystic foci of CSF density (= encephalomalacia) in distribution of vascular territory

MR:

√ patchy region with increased intensity on T2WI

√ gliosis (hyperintense on T2WI) often surrounding encephalomalacic region

√ wallerian degeneration (= antegrade degeneration of axons ← neuronal injury) of corticospinal tracts in the wake of old large infarcts that involve the motor cortex

Hemorrhagic Infarction

Hemorrhagic transformation is rare during first 12 hours after stroke onset and usually occurs within 24–48 hours. It is almost always present 4–5 days after stroke.

Etiology: lysis of embolus / opening of collaterals / restoration of normal blood pressure following hypotension / hypertension / anticoagulation → extravasation in reperfused ischemic brain

Incidence: 6% of clinically diagnosed brain infarcts; 20% of autopsied brain infarcts

Path: petechial hemorrhages in various degrees of coalescence

Location: corticomedullary junction

CT:

√ hyperdensity (56–76 HU) appearing within a previously imaged hypodense area of acute ischemic infarction = hemorrhagic transformation (in 50–72%)

False negative: hematoma isoattenuating if hematocrit < 20%

MR:

√ hypointense area on T2WI within edema marking gyri = deoxyhemoglobin of acute hemorrhage

√ hyperintense area on T1WI = methemoglobin of subacute hematoma

◊ Early parenchymal enhancement within 6 hours of stroke has a higher risk for clinically significant hemorrhagic transformation.

Basal Ganglia Infarct

= occlusion of small penetrating arteries at base of brain (lenticulostriate / thalamoperforating arteries) = lacunar infarct (= infarct < 1 cm in size)

Cause:

(1) Embolism
(2) Hypoperfusion
(3) Carbon monoxide poisoning
(4) Drowning
(5) Vasculopathy (hypertension, microvasculopathy, aging)

√ dense homogeneous enhancement outlining caudate nucleus, putamen, globus pallidus, thalamus

√ dense round nodular enhancement / peripheral ring enhancement

Cortical Laminar Necrosis

= ischemic changes affecting deep layers of the cortex

◊ Layers 3, 5, 6 are very sensitive to oxygen deprivation

MR:

(a) acute stage
  √ linear cortical hyperintensity on T1WI
  √ contrast enhancement
  √ white matter edema on T2WI
(b) chronic stage
  √ thin hypointense cortex
  √ hyperintense white matter
  √ enlargement of CSF spaces

Lacunar Infarction

[*lacuna*, Latin = hole]

= small deep infarcts in the distal distribution of penetrating vessels (lenticulostriate, thalamoperforating, pontine perforating arteries, recurrent artery of Heubner)

Cause: occlusion of small penetrating end arteries arising from MCA, PCA, basilar, ACA and vertebral arteries at base of brain due to fibrinoid degeneration

Age: usually > 55 years; M÷F = 1÷1

Predisposed: hypertension, diabetes

Incidence: 15–20% of all strokes

Path: lacune = small hole of encephalomalacia traversed by cobweblike fibrous strands; if multiple = état lacunaire (lacunar state)

Histo: "microatheroma" = hyalinization + arteriolar sclerosis → thickening of vessel wall + luminal narrowing

- pure motor / pure sensory stroke
- ataxic hemiparesis, vascular dementia

Location: upper two-thirds of putamen > caudate > thalamus > pons > internal capsule

√ small discrete foci of hypodensity of 3–15 mm in size (most < 1 cm in diameter)

MR:

(a) acute lacunar infarction (between 12 hours and 7 days):

√ small high-signal–intensity region on T2WI + FLAIR
√ hypointense area on T1WI
√ high signal intensity on DWI + corresponding low signal intensity on ADC map

(b) chronic lacunar infarction:
√ high signal intensity on T2WI
√ low signal intensity on T1WI
√ hypointense center + hyperintense rim (= gliosis) on FLAIR
√ normal signal intensity on DWI

√ may enhance in late acute / early subacute stage (up to 8 weeks)
√ unilateral pontine infarcts are sharply marginated at midline

DDx: enlarged Virchow-Robin spaces, neurocysticercosis

TIA and RIND

√ hypodense small lesions located peripherally near / within cortex without enhancement
√ lesions detected in only 14%, contralateral lesion present in 14% (CT of marginal value)

Watershed / Border Zone Infarct

= infarct localized to border zone between 2 adjacent nonanastomosing vascular beds of major cerebral arteries

Cause: global hypoperfusion ← poor cardiac output / cervical carotid artery occlusion or severe stenosis / noncompetent circle of Willis / microembolism

Isolated cortical border zone infarcts may be embolic in nature and are less frequently associated with hemodynamic compromise.

Pathophysiology:

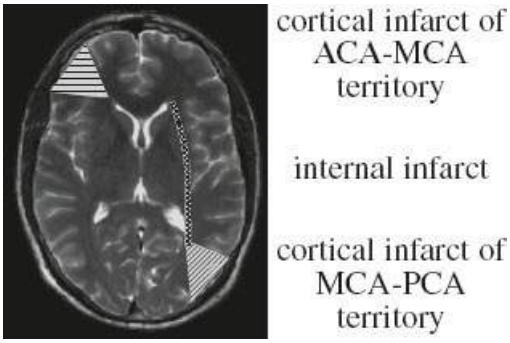
(a) repeated episodes of hypotension with severe arterial stenosis / occlusion → lower perfusion pressure → autoregulatory vasodilation → increased susceptibility to ischemia → infarction (esp. for external border zone infarcts)

› Stage I hemodynamic impairment:
√ ↑ cerebral blood volume + ↑ mean transit time

› Stage II hemodynamic impairment:
√ ↓ blood flow + ↑ oxygen extraction (measured with PET) = **misery perfusion**= chronic failure of cerebral autoregulation

Classification of Border Zone Infarcts
External (cortical) Infarct
Frontal cortex (between ACA + MCA)
Occipital cortex (between MCA + PCA)
Paramedian white matter (between ACA + MCA)
Internal (subcortical) Infarct
Between lenticulostriate + MCA
Between lenticulostriate + ACA
Between Heubner artery + ACA
Between anterior choroidal artery + MCA
Between anterior choroidal artery + PCA

(b) microemboli from heart / atherosclerotic plaques in major arteries → preferential propagation to cortical border zones secondary to lower perfusion pressure → limited ability to wash out emboli (esp for internal border zone infarcts)



Location:

(a) cortical (external) watershed

Cause: (a) Unilateral posterior external border zone infarcts ← emboli from heart / CCA
(b) Bilateral infarcts ← vascular stenosis

√ wedge-shaped / ovoid cortical "territorial" infarct
√ location of cortical border zones may vary ← development of leptomeningeal collaterals

(b) subcortical (internal) watershed

Cause: arterial stenosis / occlusion / hemodynamic compromise.

√ multiple 3-mm infarcts in rosarylike pattern arranged in linear fashion parallel to lateral ventricle in centrum semiovale / corona radiata

Small internal border zone infarcts typically represent the "tip of the iceberg" of decreased perfusion reserve and may be predictive of impending stroke.

◊ 6% of cerebral infarcts are hemorrhagic (red infarct)

- completed stroke, TIA, RIND
- amaurosis fugax = transient monocular blindness
- weakness / numbness in an extremity, aphasia, dizziness

• diplopia, dysarthria (vertebrobasilar ischemia)

INFECTION IN IMMUNOCOMPROMISED

Cause: underlying malignancy, collagen disease, cancer therapy, AIDS, immunosuppressive therapy in organ transplant

Organism: Toxoplasma, Nocardia, Aspergillus, Candida, Cryptococcus

√ poorly defined hypodense zones with rapid enlargement in size + number, particularly affecting basal ganglia + centrum semiovale (poorly localized + encapsulated infection with poor prognosis)

√ ring / nodular enhancement (sufficient immune defenses): Toxoplasma, Nocardia

√ enhancement may be blunted by steroid Rx

AIDS may be associated with:

thrombocytopenia, lymphoma, plasmacytoma, Kaposi sarcoma, progressive multifocal leukoencephalopathy

INIENCEPHALY

= complex developmental anomaly characterized by

(1) Exaggerated lordosis
(2) Rachischisis
(3) Imperfect formation of skull base at foramen magnum

M÷F = 1÷4

Associated with other anomalies in 84%:

anencephaly, encephalocele, hydrocephalus, cyclopia, absence of mandible, cleft lip / palate, diaphragmatic hernia, omphalocele, gastroschisis, single umbilical artery, CHD, polycystic kidney disease, arthrogryposis, clubfoot

√ dorsal flexion of head

√ abnormally short + deformed spine

Prognosis: almost uniformly fatal

DDx: (1) Anencephaly
(2) Klippel-Feil syndrome
(3) Cervical myelomeningocele

INTRACRANIAL HYPOTENSION

= rare cause of orthostatic headache worsening in upright position

Cause:

(a) persistent CSF leak:
diagnostic lumbar puncture, spinal anesthesia, myelography, craniotomy, spinal surgery, trauma

(b) spontaneously:
rupture of Tarlov cyst, dehydration, hyperpnea, uremia, diabetic coma

• low CSF opening pressure of < 80 mm H_2O

√ sagging of posterior fossa:

√ low-lying cerebellar tonsils

√ elongation of 4th ventricle

√ effacement of prepontine cistern
√ diffuse smooth linear pachymeningeal enhancement ← ↑ intracranial venous blood flow compensating for CSF loss
√ bilateral subdural effusions
√ enlarged pituitary gland
Rx: conservative therapy with bed rest; autologous epidural blood patch

INTRAVENTRICULAR NEUROCYTOMA

= INTRAVENTRICULAR NEUROBLASTOMA
= benign primary neoplasm of lateral + 3rd ventricles
Incidence: unknown; tumor frequently mistaken for intraventricular oligodendroglioma
Age: 20–40 years
Histo: uniform round cells with central round nucleus + fine chromatin stippling ± perivascular pseudorosettes, focal microcalcifications (closely resembling oligodendroglioma but with neuronal differentiation into synapselike junctions)
Location: body ± frontal horn of lateral ventricle, may extend into 3rd ventricle
√ entirely intraventricular well-circumscribed tumor, coarsely calcified (69%), containing cystic spaces (85%)
√ mild to moderate contrast enhancement
√ attachment to septum pellucidum CHARACTERISTIC
√ ± hemorrhage into tumor / ventricle
√ hydrocephalus
√ peritumoral edema extremely uncommon
MR:
√ isointense relative to cortical gray matter on T1WI + T2WI with heterogeneous areas due to calcifications, cystic spaces, vascular flow voids (62%)
Rx: complete surgical resection
DDx:
(1) Intraventricular oligodendroglioma (no hemorrhage)
(2) Astrocytoma (peritumoral edema in 20%)
(3) Meningioma (almost exclusively in trigone, > 30 years of age)
(4) Ependymoma (in + around 4th ventricle / trigone, in childhood)
(5) Subependymoma (in + around 4th ventricle, young adult)
(6) Choroid plexus papilloma (body + posterior horn of lateral ventricle, intense enhancement, younger patient)
(7) Colloid cyst (anterior 3rd ventricle / foramen of Monro, calcifications uncommon)
(8) Craniopharyngioma (extraventricular origin)
(9) Teratoma + dermoid cyst (fat attenuation)

ISOLATED VERMIAN HYPOPLASIA

= DANDY-WALKER VARIANT (nonpreferred term)
Genetics: usually no recurrence risk
• mild deficits in fine motor activity + receptive language
√ partial absence of inferior vermis (best on midsagittal image)

√ remainder of vermis + cerebellar hemispheres + 4th ventricle + posterior fossa of normal size and architecture

OB-US: diagnosis reliable > 18–20 weeks GA

Cave: high false-positive rate (~ 30%)

Prognosis: favorable outcome in 75%

JOUBERT SYNDROME

= rare genetic disorder affecting cerebellum

- hypotonia, ataxia
- neonatal breathing dysregulation: episodic hyperpnea
- ocular motor apraxia (abnormal eye movement)
- mental retardation (intellectual disability) of variable severity = global cognitive developmental delay

Genetics: autosomal recessive disorder with 25% recurrence risk; > 8 causative gene mutations

Systemic involvement:

√ nephronophthisis
√ congenital hepatic fibrosis
√ coloboma, retinal dystrophy
√ various forms of polydactyly

Related disorders:

COACH (**c**erebellar vermis hypoplasia / aplasia, **o**ligophrenia, **a**taxia, ocular **c**oloboma, **h**epatic fibrosis) syndrome
CORS (cerebello-oculo-renal syndrome)
OFD6 (oro-facial-digital syndrome type 6)

Path: (1) nearly total aplasia of cerebellar vermis
(2) dysplasia + heterotopia of cerebellar nuclei
(3) near total absence of pyramidal decussation
(4) anomalies in structure of inferior olivary nuclei, descending trigeminal tract, solitary fascicle, dorsal column nuclei

√ "molar tooth sign" on AXIAL image (virtually PATHOGNOMONIC):
√ elongated thickened horizontally oriented superior cerebellar peduncles
√ deep interpeduncular fossa
√ vermian hypoplasia / dysplasia

√ change in shape of 4th ventricle: triangle-shaped at mid-level + bat-wing–shaped superiorly
√ cerebellar hemispheres appose one another in midline
√ superior cerebellar peduncles surrounded by CSF
√ small isthmus + midbrain in AP diameter ← absence of decussation of superior cerebellar peduncles
√ brainstem abnormalities:
√ dysmorphic tectum + midbrain
√ thickened elongated midbrain + small pons
√ supratentorial abnormalities (30%):
√ callosal dysgenesis, cephaloceles, hippocampal malrotation, migrational disorders,

ventriculomegaly
Prognosis: renal + hepatic disease responsible for mortality
DDx: Dandy-Walker malformation

LEIGH DISEASE

= SUBACUTE NECROTIZING ENCEPHALOMYELOPATHY
= autosomal recessive disorder characterized by deficiencies in pyruvate carboxylase + pyruvate dehydrogenase complex + cytochrome c oxidase → anaerobic ATP production
• central hypotonia, ataxia, developmental regression / arrest
• ophthalmoplegia
• lactic acidosis = ↑ ratio of lactate to pyruvate in CSF + serum
Location: putamen (consistently), periaqueductal region, cerebral peduncles
√ T2 prolongation of affected areas
√ abnormally high lactate levels on MR spectroscopy

LIPOMA

= uncommon congenital malformation developing within subarachnoid space as a result of abnormal differentiation of the meninx primitiva (which differentiates into pia mater, arachnoid, inner meningeal layer of dura mater)
Incidence: < 1% of brain tumors
Age: presentation in childhood / adulthood
Associated with congenital anomalies:
(a) in anterior location: various degrees of agenesis of corpus callosum (in 50–80%)
(b) in posterior location (in < 33%)
• asymptomatic in 50%
Location: tendency to involve midline structures (usually in subarachnoid space): callosal cistern (25–50%), sylvian fissure, quadrigeminal cistern, chiasmatic cistern, interpeduncular cistern, CP angle cistern, cerebellomedullary cistern, tuber cinereum, choroid plexus of lateral ventricle
√ NO enhancement
CT:
√ well-circumscribed mass with CT density of –100 HU
√ occasionally calcified rim (esp. in corpus callosum)
MR:
√ hyperintense mass on T1WI + less hyperintense on T2WI (CHARACTERISTIC)
√ saturation on fat-suppressed sequences
Rx: insinuating mass around vessels + nerves → difficult to resect

Lipoma of Corpus Callosum

= congenital pericallosal tumor not actually involving corpus callosum ← faulty disjunction of neuroectoderm from cutaneous ectoderm during process of neurulation
Incidence: ~ 30% of intracranial lipomas
Associated with:
(1) anomalies of corpus callosum (30% with small posterior lipoma, 90% with large

anterior lipoma)
(2) frontal bone defect (frequent) = encephalocele
(3) cutaneous frontal lipoma

- in 50% symptomatic:
  - seizure disorder, mental retardation, dementia
  - emotional lability, headaches, hemiplegia

Plain film:
√ midline calcification with associated lucency of fat density

CT:
√ area of marked hypodensity immediately superior to lateral ventricles with possible extension inferiorly between ventricles / anteriorly into interhemispheric fissure
√ curvilinear peripheral / nodular central calcification within fibrous capsule (more common in anterior compared with posterior lipomas)

MR:
√ hyperintense midline mass superior + posterior to corpus callosum on T1WI
√ no callosal fibers dorsal to lipoma
√ branches of pericallosal artery frequently course through lipoma

DDx: dermoid (denser, extraaxial), teratoma

Hypothalamic Osteolipoma

Incidence: extremely rare (30 cases in literature)
Location: between mamillary bodies + infundibular stalk

- rarely symptomatic: variety of neurologic symptoms + endocrinologic disturbances

√ one / more masses directly behind infundibular stalk
√ central adipose (hyperintense on T1WI + T2WI with positive fat suppression) + peripheral osseous tissue (hypointense on T1WI + T2WI)
√ consistent size

LISSENCEPHALY

= AGYRIA-PACHYGYRIA COMPLEX
= "smooth brain" = most severe of neuronal migration anomalies; autosomal recessive disease with abnormal cortical stratification

agyria = absence of gyri on brain surface
pachygyria = focal / diffuse area of few broad flat gyri

A. COMPLETE LISSENCEPHALY = AGYRIA
most frequently parietooccipital in location

B. INCOMPLETE LISSENCEPHALY
= areas of both agyria + pachygyria, pachygyric areas most frequently in frontal + temporal regions

Histo: thick gray + thin white matter with only four cortical layers I, III, V, VI (instead of six layers)

Often associated with:
(1) CNS anomalies: microcephaly, hydrocephalus, agenesis of corpus callosum, hypoplastic thalami
(2) micromelia, clubfoot, polydactyly, camptodactyly, syndactyly, duodenal atresia,

micrognathia, omphalocele, hepatosplenomegaly, cardiac + renal anomalies
- microencephaly, severe mental retardation
- hypotonia + occasional myoclonic spasm
- early seizures refractory to medication

√ smooth thickened cortex with diminished white matter
√ figure-eight appearance of cerebrum on axial images ← shallow widened vertically oriented sylvian fissures
√ absent / shallow sulci and gyri (brain looks similar to that in fetuses of < 23 weeks GA)
√ middle cerebral arteries close to inner table of calvarium ← absence of sulci
√ small splenium + absent rostrum of corpus callosum
√ hypoplastic brainstem ← lack of formation of corticospinal + corticobulbar tracts
√ ventriculomegaly (affecting atrium + occipital horns)
√ midline round calcification in area of septum pellucidum (CHARACTERISTIC)
√ polyhydramnios (50%)

Prognosis: death by age 2
DDx: polymicrogyria (= formation of multiple small gyri mimicking pachygyria on CT + MR, most common around sylvian fissures, broad thickened gyri with frequent gliosis subjacent to polymicrogyric cortex as the most important differentiating feature)

LYMPHOID HYPOPHYSITIS

= rare inflammatory autoimmune disorder with lymphocytic infiltration of pituitary gland
Associated with: thyrotoxicosis + hypopituitarism
Age: almost exclusively in early postpartum women
- headaches, vision loss
- inability to lactate / to resume normal menses

√ enlarged homogeneously enhancing pituitary gland
Prognosis: spontaneous regression
Rx: steroids (reduction in pituitary size on follow-up)

LYMPHOMA OF BRAIN

Clues: (1) Multicentric involvement of deep hemispheres
(2) Association with immunosuppression
(3) Rapid regression with corticosteroids / radiation therapy = "ghost tumor"
Prevalence: 0.3–2% of all intracranial tumors; 7–15% of all primary brain tumors (equivalent to meningioma + low-grade astrocytoma); M > F
Peak age: 30–50 years; M÷F = 2÷1
Histo: atypical pleomorphic B-cells mixed with reactive T-cells infiltrate blood vessel walls + cluster within perivascular (Virchow-Robin) spaces simulating vasculitis
- symptoms of rapidly enlarging mass (60%)
- symptoms of encephalitis (< 25%), stroke (7%)
- cranial nerve palsy, demyelinating disease, motor dysfunction
- personality changes, headaches, seizures, cerebellar signs,
- CSF cytology positive in 4–25–43%: elevated protein, mononuclear / blast / other lymphoma cells

Location: supratentorial÷posterior fossa = 3–9÷1; paramedian structures preferentially affected; white matter + corpus callosum (55%), deep central gray matter of basal ganglia + thalamus + hypothalamus (17%), posterior fossa + cerebellum (11%), spinal cord (1%); multicentricity in 11–47%

Site: abuts ventricular ependyma + meninges (12–30%); **"butterfly lymphoma"** in frontal lobe involvement; dural involvement may mimic meningioma (rare)

Spread: typically infiltrating; may cross anatomic boundaries + midline (crosses corpus callosum); diffuse leptomeningeal spread; subependymal spread with ventricular encasement (= rim-lymphoma)

◊ Primary lymphoma is indistinguishable from secondary!

√ commonly large discrete solitary lesion (57%)
◊ A large lesion is suggestive of lymphoma!
√ small + symmetric multiple nodular lesions (43–81%)
√ diffusely infiltrating lesion with blurred margins
√ spontaneous regression (UNIQUE feature)

CT:
√ usually mildly hyperdense (33%) ← high nuclear-to-cytoplasmic ratio
√ occasionally isodense / low-density area (least common)
√ little mass effect with paucity of peritumoral edema

CECT:
√ homogeneously dense + well-defined / irregular + patchy periventricular contrast enhancement
√ commonly thick-walled ring enhancement in immuno-competent patient
◊ Steroids may inhibit contrast enhancement

MR (superior to CT):
√ well-demarcated round / oval / gyral-shaped (rare) mass
√ relatively little mass effect for size
√ isointense / slightly hypointense (← high cell density) relative to gray matter on T1WI
√ hypo- to isointense / hyperintense (less common) relative to gray matter on T2 / FLAIR (← high cellularity):
√ ring pattern (= central necrosis with densely cellular rim in hyperintense "sea of edema") typical in immunocompromised patients
√ intense ring-shaped contrast enhancement on T1WI
√ irregular sinuous / gyral-like contrast enhancement or homogeneous enhancement:
√ solid homogeneous enhancement in immunocompetent patient
√ irregular heterogeneous ringlike mass in immunocompromised patient
√ periventricular enhancement is highly SPECIFIC (DDx: CMV ependymitis)
√ elevated choline levels on MR spectroscopy

Angio:
√ avascular mass / tumor neovascularity
√ focal blush in late arterial-to-capillary phase persisting well into venous phase
√ arterial encasement
√ dilated deep medullary veins

NUC:

√ increased uptake of ^{201}Thallium on SPECT (100% sensitive, 93% specific)
√ increased uptake of 11C-methionine on PET

Prognosis: median survival of 45 days for AIDS patients; median survival of 3.3 months for immunocompetent patients; improved with radiation therapy (4.5–20 months) + chemotherapy

Rx: sensitive to radiation therapy

DDx:

A. Neoplastic disorders
   (1) Glioma (may be bilateral with involvement of basal ganglia + corpus callosum, may show dense homogeneous enhancement with vascularity)
   (2) Metastases (known primary, at gray-white matter junction)
   (3) Primitive neuroectodermal tumor
   (4) Meningioma
B. Infectious disease (multicentricity)
   (1) Abscess, especially toxoplasmosis (large edema)
   (2) Sarcoidosis
   (3) Tuberculosis
C. Demyelinating disease
   (1) Multiple sclerosis
   (2) Progressive multifocal leukoencephalopathy

Primary CNS Lymphoma (93%)

= PCNSL = RETICULUM CELL SARCOMA = HISTIOCYTIC LYMPHOMA = MICROGLIOMA
= high-grade B-cell NHL with strong association to Epstein-Barr virus infection

Prevalence: 2–10%
◊ Initial manifestation in 0.6% of AIDS patients
◊ 2nd most common cause of a CNS mass in AIDS

Risk: increased (350-fold) in immunocompromised patients: AIDS (2–10%), renal transplant, Wiskott-Aldrich syndrome, immunoglobulin deficiency A, rheumatoid arthritis, progressive multifocal leukoencephalopathy

Associated with: intraocular lymphoma

Location: anywhere; mostly periventricular; crosses corpus callosum (DDx: edema from infection will not)

√ uni- or multifocal lesions + variable mass effect
√ doubling in size within 2 weeks
√ paucity of edema

NECT:
√ often increased attenuation ← high nuclear-to-cytoplasmic ratio

MR:
√ iso- to hypointense on T1WI
√ variable intensity on T2 / FLAIR; may be hypointense ← high cell density
√ homogeneous enhancement; frequent ring enhancement in AIDS patients ← central necrosis

NUC (^{201}Tl SPECT - 100% sensitive, 93% specific):

√ uptake (DDx: toxoplasmosis not avid)
Dx: brain biopsy for unifocal lesion
Rx: sensitive to radiation therapy

Primary Dural Lymphoma
Incidence: < 1% of all CNS lymphomas
Histo: low-grade marginal zone lymphoma, follicular, Hodgkin, diffuse large B-cell subtypes; mucosa-associated lymphoid tissue (MALT) subgroup (in majority)
Age: middle-aged female
• headache, meningeal signs, cranial nerve involvement
√ ± blurred margin = indistinct brain-tumor interface
√ vasogenic edema in adjacent brain parenchyma
CT:
√ single / multiple hyperattenuating masses ← highly cellular lesion
MR:
√ iso- to hypointensity on T2WI
√ avid enhancement, sometimes heterogeneous
Prognosis: excellent
DDx: meningioma, subdural hematoma

Secondary Lymphoma of CNS (7%)
= SYSTEMIC LYMPHOMA
Type: NHL > Hodgkin disease
Location: tendency for dura mater + leptomeninges
• palsies of cranial nerves III, VI, VII
√ hydrocephalus

Spinal Epidural Lymphoma
(a) invasion of epidural space through intervertebral foramen from paravertebral lymph nodes
(b) destruction of bone with vertebral collapse (less common)
(c) direct involvement of CNS (rare)

Leukemia
CNS affected in 10% of patients with acute leukemia
√ enlargement of ventricles + sulci ← atrophy (31%)
√ sulcal / fissural / cisternal enhancement ← meningeal infiltration (in 5%)
Prognosis: 3–5 months survival if untreated

MEDULLOBLASTOMA
◊ Most malignant infratentorial neoplasm; most common neoplasm of posterior fossa in childhood (followed by cerebellar pilocytic astrocytoma)
Incidence: 15–20% of all pediatric intracranial tumors; 30–40% of all posterior fossa neoplasms in children; 2–10% of all intracranial gliomas
Origin: external granular layer of inferior medullary velum (= roof of 4th ventricle)
Histo: completely undifferentiated cells (50%), desmoplastic variety (25%), glial / neuronal

differentiation (25%)

Age: 40% within first 5 years of life; 75% in first decade; between ages 5 and 14 (⅔); between ages 15 and 35 (⅓); M÷F = 2–4÷1

• duration of symptoms < 1 month prior to diagnosis: nausea, vomiting, headache, increasing head size, ataxia

Site: (a) vermis cerebelli + roof of 4th ventricle (younger age group) in 91%
(b) cerebellar hemisphere (older age group)

Size: usually > 2 cm in diameter

√ well-defined vermian mass with widening of space between cerebellar tonsils
√ encroachment on 4th ventricle / aqueduct with hydrocephalus (85–95%)
√ shift / invagination of 4th ventricle
√ rapid growth with extension into cerebellar hemisphere / brainstem (more often in adults)
√ extension into cisterna magna + upper cervical cord, occasionally through foramina of Luschka into cerebellopontine angle cistern
√ mild / moderate surrounding edema (90%)

CT:

Classic tumor features in 53%:
√ slightly hyperdense (70%) / isodense (20%) / mixed (10%)
√ rapid intense homogeneous enhancement (97%) ← tumor usually solid

Atypical features:
√ cystic / necrotic areas (10–16%) with lack of enhancement
√ calcifications in 13%
√ hemorrhage in 3%
√ supratentorial extension

MR:
√ mixed / hypointense on T1WI
√ hypo- / iso- / hyperintense on T2WI
√ usually homogeneous Gd-DTPA enhancement with hypointense rim
√ cerebellar folia blurred

Cx: (1) Subarachnoid metastatic spread (30–100%) via CSF pathway to spinal cord + cauda equina ("drop metastases" in 40%), cerebral convexities, sylvian fissure, suprasellar cistern, retrograde into lateral + 3rd ventricle
√ continuous "frosting" of tumor on pia
(2) Metastases outside CNS (axial skeleton, lymph nodes, lung) after surgery

Rx: surgery + radiation therapy (extremely radiosensitive)

DDx of midline medulloblastoma:
ependymoma, astrocytoma (hypodense)

DDx of eccentric medulloblastoma:
astrocytoma, meningioma, acoustic neuroma

MEGACISTERNA MAGNA

= normal variant of focal enlargement of subarachnoid space in posteroinferior aspect of posterior fossa

Cause: ? delayed fenestration of Blake pouch

• incidental finding
√ cisterna magna ≥ 10 mm (on midsagittal image)
√ free communication with 4th ventricle + cervical subarachnoid space (confirmed with CSF flow study)

Pertinent negatives:
√ intact vermis + normal 4th ventricle
√ absence of hydrocephalus
√ occasionally enlarged posterior fossa

DDx: (1) Blake pouch cyst (hydrocephalus)
(2) Isolated inferior vermian hypoplasia

MELANOCYTOMA

= benign lesion arising from resident melanocytic cells found within leptomeninges

Age: any; 5th decade (majority); F > M

Path: darkly pigmented mass

Histo: tight cellular nests / whorls ± abundant melanin pigment within cytoplasm: NO mitotic activity, NO nuclear pleomorphism, NO hyperchromaticity; S-100 + melan-A + HMB-45 positivity (similar to melanoma)

• myelopathy, radiculopathy
• seizures, hydrocephalus, cranial nerve deficits

Location: posterior fossa, Meckel cave, spinal canal (cervical + thoracic spine)

√ avidly enhancing iso- to hyperattenuating mass
√ indolent growth pattern
√ typically iso- to hypointense on T2WI ± T1 hyperintensity ← melanin

Rx: surgical resection (in up to 22% recurrence within 3 years)

DDx: melanoma

MENINGIOMA

Incidence: most common extraaxial tumor: 15–18% of intracranial tumors in adults; 1–2% of primary brain tumors in children; 33% of all incidental intracranial neoplasms

Origin: derived from meningothelial cells concentrated in arachnoid villi (= "arachnoid cap cells"), which penetrate the dura (villi are numerous in large dural sinuses, in smaller veins, along root sleeves of exiting cranial + spinal nerves, choroid plexus)

Histologic classification:

› benign behavior pattern
(a) fibroblastic (fibrous) type = interwoven bands of spindle cells + collagen + reticulin fibers
(b) transitional (mixed) type
= features of meningothelial + fibroblastic forms

› aggressive imaging appearance
(c) meningothelial (syncytial) type = forming a syncytium of closely packed cells with indistinct borders
(d) angioblastic (malignant) type
= probably hemangiopericytoma / hemangioblastoma arising from vascular pericytes

Peak age: 45 (range, 35–70) years; rare < 20 years (in children > 50% malignant); M÷F = 1÷2 to 1÷4

In pediatric age group:
NO gender predilection
Higher risk of sarcomatous change
Consider association with neurofibromatosis type 2

Associated with: NF2 (multiple meningiomas, occurrence in childhood), basal cell nevus syndrome

◊ 10% of patients with multiple meningiomas have type 2 neurofibromatosis!

◊ Most common radiation-induced CNS tumor with latency period of 19–35 years varying with dosage!

Types:

(1) **Globular meningioma** (most common):
compact rounded mass with invagination of brain; flat at base; contact to falx / tentorium / basal dura / convexity dura

(2) **Meningioma en plaque**:
pronounced hyperostosis of adjacent bone, particularly along base of skull; difficult to distinguish hyperostosis from tumor cloaking the inner table (DDx: Paget disease, chronic osteomyelitis, fibrous dysplasia, metastasis)

(3) **Multicentric meningioma** (2–9%):
16% in autopsy series; tendency to localize to a single hemicranium; present clinically at earlier age; global / mixed; CSF seeding is exceptional; in 50% associated with neurofibromatosis type 2

Location:

A. Supratentorial (90%)
   (a) convexity = lateral hemisphere (20–34%)
   (b) parasagittal = medial hemisphere (18–22%):
   falcine meningioma (5%) below superior sagittal sinus, usually extending to both hemispheres
   (c) sphenoid ridge + middle cranial fossa (17–25%)
   (d) frontobasal at olfactory groove (10%)

B. Infratentorial (9–15%)
   (a) cerebellar convexity (5%)
   (b) tentorium cerebelli (2–4%)
   (c) cerebellopontine angle (2–4%)
   (d) clivus (< 1%)

C. Spine (12%)

Atypical location:

(a) cerebellopontine angle (< 5%)
(b) optic nerve sheath (< 2%)
(c) intraventricular (0.5–3.7%): 80% in atrium (L > R), 15% in 3rd, 5% in 4th ventricle ← infolding of meningeal tissue during formation of choroid plexus
   ◊ Most common trigonal intraventricular mass in adulthood!
(d) ectopic = extradural (< 1%): intradiploic space, outer table of skull, scalp, paranasal

sinus, parotid gland, parapharyngeal space, mediastinum, lung, adrenal gland

Plain film:

- √ hyperostosis at site close to / within bone (exostosis, enostosis, sclerosis):
  - ◊ Hyperostosis does NOT indicate tumor infiltration!
- √ blistering at paranasal sinuses (ethmoid, sphenoid) ± sclerosis (= pneumosinus dilatans)
- √ enlarged meningeal grooves (if location in vault)
- √ enlarged foramen spinosum
- √ calcification (= psammoma bodies)

CT:

- √ sharply demarcated well-circumscribed slowly growing mass
- √ hyperdense (70–75% ← highly cellular nature or psammomatous calcifications) / isodense lesion on NECT
- √ calcifications (15–20–25%) in circular / radial pattern (DDx: osteoma)
- √ "cortical buckling" of underlying brain
- √ "intraosseous meningioma" = permeation of bone with intra- and extracerebral soft-tissue component (DDx: fibrous dysplasia)
- √ hyperostosis of adjacent bone (18%)
- √ intense uniform enhancement on CECT ← absence of blood-brain barrier:
  - √ "dural tail" = wide attachment to adjacent dura mater
- √ minimal peritumoral edema (in up to 75%):
  - ◊ NO correlation between tumor size + amount of edema (DDx: intraaxial lesion)
- √ cystic component: major in 2%, minor in 15%

MR (100% detection rate with gadolinium DTPA):

- √ hypo- to isointense on T1WI + iso- to hyperintense on T2WI (intensity depends on amount of cellularity versus collagen elements):
  - √ tends to follow cortical signal intensity
  - √ homogeneous / heterogeneous texture (← tumor vascularity, cystic changes, calcifications)
- √ arcuate bowing of white matter + cortical effacement
- √ tumor-brain interface ← low-intensity vessels + high-intensity cerebrospinal cleft on T2WI
- √ contrast enhancement for 3–60 min on T1WI as high as 148% above enhancement of brain parenchyma
- √ "dural tail" sign (in 60–72%)
- √ encasement + narrowing of vessels
- √ elevated alanine peak (1.5 ppm) + glutamate–glutamic acid peak (2.1–2.5 ppm)

Differences between Meningioma and Schwannoma		
	Meningioma	*Schwannoma*
Angle with dura	obtuse	acute
Dural tail	frequent	rare
Calcification	20%	rare
Cystic/necrotic	rare	10%
IAC involvement	rare	80%
NECT	hyperdense	isodense
Enhancement	uniform	32% nonuniform

Angio:

√ "mother-in-law" phenomenon (contrast material shows up early and stays late into venous phase)

√ "sunburst" / "spoke-wheel" pattern of tumor vascularity with hypervascular cloudlike stain

√ early draining vein (rare: perhaps in angioblastic meningioma)

√ en plaque meningioma is poorly vascularized

Vascular supply:

A. External carotid artery (almost always):
   1. vault: middle meningeal artery
   2. sphenoid plane + tuberculum: recurrent meningeal branch of ophthalmic a.
   3. tentorium: meningeal branch of meningohypophyseal trunk of ICA
   4. clivus + posterior fossa: vertebral artery / ascending pharyngeal artery
   5. falx: partly middle meningeal artery + others

B. Internal carotid artery (rare):
   1. intraventricular: choroidal vessels

Cx: local invasion of venous sinuses

Atypical Meningioma (15%)

1. Low attenuation area of necrosis, old hemorrhage, cyst formation, fat (DDx: malignant glioma, metastasis)
   (a) **Cystic meningioma** (2–4%)
   Frequency: 55–65% in 1st year of life; 10% in children
   Type I = intratumoral central / eccentric cyst (ischemic necrosis, microcystic degeneration, breakdown of hemorrhagic products); often associated with meningothelial / microcystic / atypical / malignant histologic subtypes
   Type II = extratumoral intraparenchymal cyst (arachnoid cyst / reactive gliosis / liquefactive necrosis of adjacent brain)
   Type III = trapped CSF (DDx: cystic / necrotic glioma)
   (b) **Lipoblastic / xanthomatous meningioma** (5%) lipid-laden meningothelial cells (in 10–90%) with metaplasia of meningothelial cells into mature adipocytes
2. Heterogeneous / ring enhancement ← bland tumor infarction / necrosis in aggressive histologic variants / true cyst formation from benign fluid accumulation
3. "En plaque" morphology

4. "Comma shape" = combination of semilunar component bounded by dural interface + spherical component growing beyond dural margin
5. Sarcomatous transformation with spread over hemisphere + invasion of cerebral parenchyma (leptomeningeal supply)
6. **M eningeal hemangiopericytoma**
   √ multilobulated contour
   √ narrow dural base / "mushroom" shape
   √ large intratumoral vascular signals
   √ bone erosion
   √ prominent peritumoral edema
   √ multiple irregular feeding vessels on angiogram

Sphenoid Wing Meningioma

1. Hyperostotic meningioma en plaque
   • slowly progressive unilateral painless exophthalmos
   • numbness in distribution of cranial nerve $V_1 + V_2$
   • headaches, seizures
2. Meningioma arising from middle third of sphenoid ridge
   • headaches, seizures
   √ compression of regional frontal + temporal lobes
3. Meningioma arising from clinoid process
   √ encasement of carotid + middle cerebral arteries
   √ compression of optic nerve + chiasm
4. Meningioma of planum sphenoidale
   √ subfrontal growth + posterior growth into sella turcica and clivus
   √ hyperostotic blistering of planum sphenoidale

Suprasellar Meningioma

Incidence: 10% of all intracranial meningiomas

Origin: from arachnoid + dura along tuberculum sellae / clinoids / diaphragma sellae / cavernous sinus with secondary extension into sella; NOT from within pituitary fossa

• hypothalamic / pituitary dysfunction (rare)

√ irregular hyperostosis = blistering adjacent to sinus (HALLMARK of meningiomas at planum sphenoidale / tuberculum sellae)

√ pneumatosis sphenoidale = increased pneumatization of sphenoid in area of anterior clinoids + dorsum sellae (DDx: normal variant)

√ broad base of attachment

√ intense homogeneous enhancement (may be impossible to differentiate from supraclinoid carotid aneurysm on CT)

√ blood supply: posterior ethmoidal branches of ophthalmic artery, branches of meningohypophyseal trunk

MR:

√ large mass isointense to gray matter on T1WI + T2WI

√ hyperintense flattened pituitary gland within floor of sella

√ marked homogeneous enhancement on T1WI
DDx: metastasis, glioma, lymphoma

MENINGITIS

= infection of the pia mater + arachnoid + adjacent CSF

1. Pachymeningitis: infection of dura mater
2. Leptomeningitis: infection of pia matter / arachnoid (most common) + CSF

• headaches, stiff neck, confusion, disorientation
• positive CSF lab analysis

ROLE of CT and MR:

(1) to exclude parenchymal abscess, ventriculitis, localized empyema
(2) to evaluate paranasal sinuses / temporal bone as source of infection
(3) to monitor complications: hydrocephalus, subdural effusion, infarction

Chemical / Aseptic Meningitis

= rare complication of dermoid / epidermoid cyst ← cyst rupture into subarachnoid space

MR:

√ T1-hyperintense speckles in cortical sulci
√ fat-fluid level in ventricles

Purulent / Bacterial / Acute Septic Meningitis

Cause: otitis media / sinusitis

Organism:

(a) adults: Neisseria meningitidis, Diplococcus pneumoniae, Haemophilus influenzae, Meningococcus, Staphylococcus aureus
(b) children: group B Streptococcus (86%), S pneumonia (= Pneumococcus in 58%), Escherichia coli, Citrobacter

Incidence: 4100 cases annually in USA

• fever, headache, seizures, altered consciousness, neck stiffness

Neuroimaging most useful to:

› exclude herniation before lumbar puncture
› to detect complications

Cross-sectional imaging is neither sensitive nor specific for detection of meningitis.

NECT:

√ often normal / falsely negative due to subtlety of findings
√ sulcal effacement
√ slightly increased density in subarachnoid space ← increased vascularity, esp. in children
√ small ventricles ← diffuse cerebral edema

CECT:

√ marked curvilinear meningeal enhancement over cerebrum (frontal + parietal lobes) and interhemispheric + sylvian fissures
√ obliteration of basal cisterns with enhancement (common)

MR (most sensitive modality):

√ no abnormality (in most cases)
√ ± hyperintense obliterated basal cisterns on FLAIR ← increased protein content (NOT

specific for meningitis)
√ abnormal hyperintensity in cerebral sulci on DWI (NOT specific for meningitis) ← pyogenic (bacterial) >> lymphocytic (viral) / aseptic meningitis

CEMR (postcontrast FLAIR + delayed T1WI):
√ abnormal enhancement of pia mater + subarachnoid space (leptomeninges) ← inflammatory breakdown of blood-brain barrier (in only 50%):
√ thin linear enhancement in cerebral sulci = typical for acute pyogenic (bacterial) + lymphocytic (viral) meningitis
√ thick nodular enhancement in basal cisterns = typical of granulomatous / carcinomatous meningitis
√ leptomeningeal enhancement (in chronic infection)

Dx: CSF analysis

Cx:
(1) Cerebritis (parenchymal) / subdural infection, especially with streptococcus / staphylococcus
(2) Ventriculitis ← retrograde spread
(3) Brain atrophy
(4) Brain infarction ← arteritis, venous thrombosis (5–15% of adults, in up to 30% of neonates)
(5) Subdural effusion [sterile subdural effusion ← H. influenzae meningitis (in children) may turn into subdural empyema]
(6) Hydrocephalus ← cellular debris blocking foramen of Monro, aqueduct, 4th ventricular outlet / intraventricular septa / arachnoid adhesions
(7) Cranial nerve dysfunction

Prognosis:
◊ Cerebral infarction + edema predict poor outcome
◊ Enlargement of ventricles + subarachnoid spaces + subdural effusions have no predictive value

Mortality: 10% for H. influenza + meningococcus, 30% for Pneumococcus (5th commonest cause of death in children between 1 and 4 years of age)

DDx: meningeal carcinomatosis

Granulomatous Meningitis

Histo: thick exudate, perivascular inflammation, granulation tissue + reactive fibrosis

(1) **Tuberculous meningitis** = basilar meningitis
part of generalized miliary tuberculosis / primary tuberculous infection

(2) **Sarcoidosis** (in 5% of sarcoidosis cases)
Histo: granulomatous infiltration of leptomeninges
√ nodular pattern (DDx from bacterial causes)
√ thick meningeal plaques over convexities (mimicking meningioma)
√ marked enhancement
√ may be associated with single / multiple intracerebral mass(es)
Cx: cranial nerve palsy, hypothalamic-pituitary dysfunction, chronic meningitis

(3) **Fungal meningitis**: coccidioidomycosis (endemic), blastomycosis, mucormycosis (diabetics), nocardiosis, actinomycosis, aspergillosis (under chronic corticosteroid

therapy)

(a) yeast = unicellular eukaryotic microorganism that reproduce by asymmetric fission:
  › Cryptococcosis
  › Candidiasis

(b) mold = multicellular filaments (hyphae) that can form into macroscopic networks (mycelia); too large for meningeal microcirculation and more likely cause invasive parenchymal CNS disease in immunocompromised patients
  › Aspergillus
  › Mucormycosis

(c) dimorphic fungus = dimorphic fungus that grows as mold (yeast) at room (body) temperature; resides in soil in endemic regions and releases conidia (spores) into the air (unicellular eukaryotes at body temperature → initially misidentified as protozoa)
  › Blastomycosis
  › Coccidioidomycosis
  › Histoplasmosis

Fungal CNS diseases are usually opportunistic infections from hematogenous dissemination in susceptible hosts at extremes of age or with immunodeficiency.

• acute life-threatening process / chronic indolent disease

May be associated with: cerebritis, abscess formation

√ hydrocephalus

CT:

√ obliteration of basal cisterns, sylvian fissure, suprasellar cistern (isodense cisterns ← filling with debris)

√ intense contrast enhancement of gyri + involved subarachnoid spaces

√ calcification of meninges

√ decreased attenuation of white matter

MR:

√ high-signal intensity of basilar cisterns on T2WI

√ enhancement with gadopentetate dimeglumine

Cx: (1) Hydrocephalus ← obliteration of basal cisterns, blocking of CSF flow + blocking of CSF absorption

(2) Infarction ← arteritis

MESIAL TEMPORAL SCLEROSIS

Cause: long-standing temporal lobe epilepsy

Histo: marked neuronal loss + astrogliosis in hippocampal subfields CA1 + CA3 + CA4

Mechanism for excitotoxicity-induced neuronal death:

seizures → excessive neuronal depolarization → overproduction of excitory amino acid neurotransmitters → excessive activation of N-methyl-D-aspartate receptors → unregulated entry of $Ca2+$ → neuronal swelling with cytotoxic edema

Location: uni- / bilateral; symmetric / asymmetric

√ hippocampal atrophy + loss of internal architecture

√ increased signal intensity on T2WI

√ dilatation of temporal horn

Associated limbic system findings:
√ ipsilateral atrophy of fornix (55%)
√ ipsilateral atrophy of mamillary body (26%)
Associated extrahippocampal abnormalities:
√ increased SI of anterior temporal lobe cortex (38%)
√ cerebral hemiatrophy (1%)
Rx: amygdalohippocampectomy

METACHROMATIC LEUKODYSTROPHY

= MLD = most common hereditary (autosomal recessive) leukodystrophy (dysmyelinating disorder)
Cause: deficiency of arylsulfatase A resulting in severe deficiency of myelin lipid sulfatide within macrophages + Schwann cells
Age of presentation: before age 3 (⅔), in adolescence (⅓)
A. LATE INFANTILE FORM
Age: 2nd year of life
• gait disorder + strabismus, impairment of speech
• spasticity + tremor, intellectual deterioration
Prognosis: death within 4 years of onset
B. JUVENILE FORM
Age: 5–7 years
C. ADULT FORM
• organic mental syndrome
• progressive corticospinal, corticobulbar, cerebellar, extrapyramidal signs
√ progressive loss of hemispheric brain tissue
CT:
√ symmetric low density of white matter adjacent to ventricles (esp. centrum ovale and frontal horns)
√ progressive atrophy
√ no contrast enhancement
MR:
√ progressive symmetrical areas of hypointensity on T1WI
√ hyperintensity on T2WI (increased water)
√ early sparing of internal capsule + subcortical U-fibers
Prognosis: death within several years

METASTASIS TO BRAIN

Incidence: 14–37% of all intracranial tumors
◊ Most common intracranial neoplasm!
◊ Most common infratentorial mass in adulthood
Metastatic primary:
Six tumors account for 95% of all brain metastases:
1. Bronchial carcinoma (47%): rarely squamous cell ca.
2. Breast carcinoma (17%)

3. GI-tract tumors (15%): colon, rectum
4. Hypernephroma (10%)
5. Melanoma (8%)
6. Choriocarcinoma

In childhood:

1. Leukemia / lymphoma
2. Neuroblastoma

◊ Brain metastases from sarcomas are exceptionally rare!

Location:

(a) corticomedullary junction of brain (most characteristic)
(b) subarachnoid space = carcinomatous meningitis
(c) subependymal spread (frequent in breast carcinoma)
(d) skull (5%)

N.B.: CORTICAL METASTASES
√ minimal / no edema
√ may not be identified on T2WI
√ contrast-enhancement essential for detection

Presentation:

› multiple lesions (⅔), single lesion (⅓)
› cerebral hemispheres (57%), cerebellum (29%), brainstem (32%)
› nodular deposits to dura (common)

√ usually well-defined round masses:
√ multiple lesions of different sizes + locations
√ surrounding edema usually exceeds tumor volume
◊ Employ contrast enhancement to disclose additional lesions!

CT:

√ hypodense on NECT (unless hemorrhagic / hypercellular)
√ solid enhancement in small tumors / ringlike enhancement in large tumors

MR (combination of T2WI + contrast-enhanced T1WI offer greatest sensitivity):

√ hypointense on T1WI
√ hypointense mass relative to edema / variable intensity on T2WI ← hemorrhage, necrosis, cyst formation:
√ hypointensity more pronounced in melanoma + mucinous adenocarcinoma ← paramagnetic effect
√ homogeneous / ring / nodular mixed enhancement after Gd-DTPA; often more than one metastatic focus identified in region of colliding edema
√ asymmetric enhancement of dura with dural spread
√ leptomeningeal enhancement (eg, in metastatic ependymoma)

DDx: glioma (indistinct border, less well defined, lesser amount of vasogenic edema); multifocal inflammatory lesions

Carcinomatous Meningitis (8–15%)

= Meningeal Carcinomatosis
= metastatic involvement of leptomeninges

Source:

A. Primary CNS tumor: medulloblastoma, glioblastoma, pineal tumors
B. Secondary tumor: carcinoma of breast + lung, melanoma, NHL, leukemia

Histo: adenocarcinoma (75%)

Spread:
(a) hematogenous dissemination (most common)
(b) contiguous perineural spread
(c) lymphatic spread
(d) shedding of tumor cells from parenchymal metastases

Associated with: concurrent brain parenchymal metastases (in 20%)

◊ Simultaneous occurrence of symptoms localized to more than one area!

- headaches (50%), seizures (15%), cauda equina syndrome
- cranial nerve deficits (40%): visual disturbances, diplopia, hearing loss, facial numbness
- mental status changes: lethargy + confusion (20%)
- progressive asymmetric weakness of extremities

Dx: harvest of malignant cells ← lumbar puncture positive in 45–55% (1st puncture), 80% (after several taps)

N.B.: Perform MRI prior to lumbar puncture

◊ Lumbar puncture contraindicated if intracranial pressure increased!

Location: basal cisterns, lumbar spine (areas of CSF stasis)

√ communicating hydrocephalus ← tumor interferes with CSF reabsorption in pacchionian granulations near vertex

√ ischemic changes ← vasculitis (rare)

CEMR (abnormalities in up to ⅔):
√ linear / nodular enhancement of sulci, cisternal spaces, ventricles with associated effacement
√ diffuse / asymmetric nodular enhancement
√ hydrocephalus
√ cranial nerve enhancement

Patterns:

1. **Dural Meningeal Carcinomatosis**
   » rarely associated with positive cytology
   √ short discontinuous thin sections of enhancement localized / diffuse curvilinear underneath inner table in expected position of dura
2. **Leptomeningeal Carcinomatosis**
   » frequently associated with positive cytology
   √ thin rim of subarachnoid enhancement following convolutions of gyri "coating the surface of the brain"
   √ discrete leptomeningeal nodules
   √ invasion of underlying brain → mass effect + edema

DDx: bacterial / fungal meningitis, postoperative changes (fibrosis), previous subarachnoid hemorrhage, idiopathic cranial pachymeningitis, vasculitis, extramedullary hematopoiesis, primary leptomeningeal gliomatosis, amyloidosis, glioneural heterotopia, Castleman disease, Gaucher disease

Dural Metastasis

Origin: most common: breast, lung, prostate
others: melanoma, lymphoma, RCC, gastric cancer
√ often solitary linear dural thickening / nodular lesion: focal / diffuse involvement
√ ± dural tail
√ avid enhancement ← lack of blood-brain barrier:
√ dural enhancement adjacent to osseous involvement ← dural invasion / reactive dural response
◊ The lower the T2 signal the more hypercellular the lesion!

Dural metastases are frequently solitary, potentially leading to a misdiagnosis of meningioma and delay in care.

Hemorrhagic Metastases to Brain (in 3–4%)

1. Malignant melanoma
2. Breast cancer
3. Choriocarcinoma
4. Oat cell carcinoma of lung
5. Renal cell carcinoma
6. Thyroid carcinoma

√ hyperdense without contrast
√ hypervascular with contrast
mnemonic: MR CT BB
Melanoma
Renal cell carcinoma
Choriocarcinoma
Thyroid carcinoma
Bronchogenic carcinoma
Breast carcinoma

Cystic Metastasis to Brain

1. Squamous cell carcinoma of lung
2. Adenocarcinoma of lung

DDx: benign cyst, abscess

Calcified Metastasis to Brain

1. Mucin-producing neoplasm: GI, breast
2. Cartilage- / bone-forming sarcoma
3. Effective radio- and chemotherapy

Malignant Melanoma Metastatic to Brain

Prevalence: 39% at autopsy
Location: cerebrum > cerebellum; usually multiple lesions
• variable degree of pigmentation
√ tendency for hemorrhage
1. Melanotic pattern (in 24–54%)
√ paramagnetic property of melanin → T1-shortening effect:

√ hyperintense relative to cortex on T1WI
√ iso- / hypointense relative to cortex on T2WI

Cause: free radicals in melanin + blood products

◊ NO clear consensus on contribution of paramagnetic effect of blood products versus melanin!

2. Amelanotic pattern (38%)
   ◊ Pattern similar to other brain neoplasm
   √ hypo- / isointense on T1WI
   √ hyper- / isointense on T2WI
3. Other patterns
   √ isointense on T1WI
   √ hyperintense on T2WI

Prognosis: median survival of 113 days after discovery

DDx: primary malignant melanoma of CNS (1% of all melanoma cases; solitary lesion; leptomeningeal / choroid plexus location)

MICROCEPHALY

= clinical syndrome characterized by a head circumference below the normal range

Incidence: 1.6÷1,000 or 1÷6,200 to 1÷8,500 births

Etiology:

(1) Undiagnosed intrauterine infection (toxoplasmosis, rubella, CMV, herpes, syphilis), toxic agents, drugs, hypoxia, irradiation, maternal phenylketonuria
(2) Premature craniosynostosis
(3) Chromosomal abnormalities (trisomies 13, 18, 21)
(4) Meckel-Gruber syndrome

Often associated with:

microencephaly, macrogyria, pachygyria, atrophy of basal ganglia, decrease in dendritic arborization, holoprosencephaly

√ AC÷HC discrepancy
√ head circumference < 3 SD below the mean
√ apelike sloping of forehead
√ dilatation of lateral ventricles
√ poor growth of fetal cranium
√ intracranial contents may not be visible (rare)

Prognosis: normal to severe mental retardation (depending on degree of microcephaly)

MINERALIZING MICROANGIOPATHY

= RADIATION-INDUCED LEUKOENCEPHALOPATHY

= sequelae of radiotherapy combined with methotrexate therapy for leukemia

Incidence: in 25–30% after > 9 months after treatment

Age: childhood

Cause: deposition of calcium within small vessels of previously irradiated brain parenchyma

• 85% without neurologic deficits

CT:

√ thin reticular / serrated linear / punctate calcifications near corticomedullary junction, especially in basal ganglia + frontal and posterior parietal lobes
√ symmetric low-attenuation process in white matter near corticomedullary area

MR:

√ confluent diffuse periventricular distribution spreading peripherally with an irregular scalloped edge

Diffuse White Matter Injury

= radiation-induced demyelination of periventricular white matter

Cause: whole-brain irradiation

• subclinical

Diffuse Necrotizing Leukoencephalopathy

Cause: intrathecal methotrexate ± whole brain irradiation

• rapidly deteriorating clinical course

√ confluent pattern with scalloped margins in periventricular white matter extending out to subcortical U-fibers

MOYAMOYA DISEASE

[*moyamoya*, Japanese = puff of smoke]

= uncommon occlusive cerebral arteritis classically involving supraclinoid internal carotid arteries with relative sparing of the posterior fossa in early stages

Etiology: unknown; NO underlying cause identified

Age: bimodal distribution in 1st decade + 4th decade of life

Path: development of extensive tiny basal perforator and transdural collateral vessels (moyamoya vessels)

Histo: endothelial hyperplasia + fibrosis without associated inflammatory reaction

• headaches, behavioral disturbances

√ bilateral stenosis / occlusion of supraclinoid portion of ICA extending to proximal portions of MCA + ACA

√ large network of moyamoya vessels in basal ganglia + upper brainstem fed by basilar a. + ACA + MCA (dilatation of lenticulostriate + thalamoperforating arteries)

√ anastomoses between dural meningeal + leptomeningeal aa.

MR:

√ tiny flow voids commonly arising from basal cisterns extending into basal ganglia / thalamus

√ microbleeds (in 15–44%)

√ ischemia and infarction

√ NO nidus / dilated vessels

√ "ivy" sign = curvilinear high signal intensities along cortical sulci + brain surface = sulcal hyperintensity on FLAIR ← leptomeningeal collateral vessels

√ marked leptomeningeal enhancement along cortical sulci

◊ Angio needed for planning of revascularization procedure

Cx: in children: transient ischemic hemiparetic attacks, cerebral infarction

in ½ of adults: intracranial hemorrhage

Moyamoya Syndrome

= underlying cause for moyamoya image identified

Etiology: neurocutaneous syndromes (eg, neurofibromatosis), atherosclerosis, sickle cell anemia, periarteritis nodosa, coarctation of aorta, Down syndrome, Marfan syndrome, head trauma, tuberculosis, oral contraceptives, bacterial meningitis

MULTIPLE SCLEROSIS

= most frequent form of chronic inflammatory demyelinating disease of unknown etiology, which reduces the lipid content and brain volume; characterized by a relapsing + remitting course

Prevalence: 6÷10,000 (higher frequency in cooler climates; increased incidence with positive family history)

Cause: ? viral / autoimmune mechanism

Peak age: 25–30 (range, 20–50) years; M÷F = 2÷3

Histo:

(a) acute stage: perivenular inflammation (at junctions of pial veins) with
- › hypercellularity (= infiltration of lipid-laden macrophages + lymphocytes)
- › well-demarcated demyelination (destruction of oligodendroglia with loss of myelin sheath)
- › reactive astrocytosis (= gliosis), initially with preservation of axons (= denuded axons) → scar (= white matter plaque)

(b) chronic stage: plaques advance to fibrillary gliosis with reduction in inflammatory component

Clinical forms: (a) relapsing remitting
(b) relapsing progressive
(c) chronic progressive

- waxing and waning course with
  - numbness, dysesthesia, burning sensations
  - signs of brain neoplasm: headaches, seizures, dizziness, nausea, weakness, altered mental status, ataxia, diplopia
  - optic neuritis = retrobulbar pain, central loss of vision, afferent pupillary defect (Marcus Gunn pupil)
  - trigeminal neuralgia (1–2%)
- Schumacher criteria:
  (1) CNS dysfunction
  (2) Involvement of two / more parts of CNS
  (3) Predominant white matter involvement
  (4) ≥ 2 episodes lasting > 24 hr less than 1 month apart
  (5) Slow stepwise progression of signs + symptoms
  (6) At onset 10–50 years of age
- Rudick red flags (suggests diagnosis other than MS):
  (1) No eye findings
  (2) No clinical remission

(3) Totally local disease
(4) No sensory findings
(5) No bladder involvement
(6) No CSF abnormality

@ Brain

Location:

subependymal periventricular location (along lateral aspects of atria + occipital horns), corpus callosum, internal capsule, centrum semiovale, corona radiata, optic nerves, chiasm, optic tract, brainstem (ventrolateral aspect of pons at 5th nerve root entry), cerebellar peduncles (CLASSIC), cerebellum; rather symmetric involvement of cerebral hemispheres; subcortical U fibers NOT spared

◊ 10% of MS lesions occur in gray matter!

◊ Number + extent of plaques correlate with duration of disease + degree of cognitive impairment

√ lesion size of 1–25 (majority between 5 and 10) mm:
- √ large lesions may masquerade as brain tumors
- √ mass effect / edema in active lesions (infrequent)

√ ovoid lesions (86%) oriented with their long axis perpendicular to ventricular walls ← perivenous demyelination (pathologically described as "Dawson fingers")

√ chronic plaques do not enhance ← intact blood-brain barrier

√ diffuse cerebral atrophy (21–45–78%) in chronic MS: enlarged ventricles, prominent sulci

√ lesion enhancement ← breakdown of blood-brain barrier in demyelinating process (irrespective of clinical symptoms):
- √ peripheral enhancement of lesion
- √ occasionally central enhancement

CT:
- √ normal CT scan (18%)
- √ periventricular (near atria) multifocal nonconfluent lesions with distinct margins (lesion location does NOT always correlate well with symptoms)
  - (a) NECT: isodense / lucent
  - (b) CECT: transient enhancement during acute stage (active demyelination) for about 2 weeks; may require double dose of contrast; ultimately disappearance / permanent scar

MR (modality of choice; 95–99% specific):
- √ well-marginated discrete foci of varying size with high signal intensity on T2WI + proton density images (= loss of hydrophobic myelin produces increase in water content); hypointense on T1WI
- √ abnormally bright signal of the optic nerve + variable swelling (optic neuritis) with loss of "doughnut" sign of the normal optic nerve complex
- √ Gd-DTPA enhancement of lesions on T1WI (up to 8 weeks following acute demyelination with breakdown of blood-brain barrier)
  - √ characteristically as a solid lesion / incomplete ring
- √ lesions on undersurface of corpus callosum (CHARACTERISTIC on sagittal images)

@ Spinal cord (in up to 80%)

◊ Most common demyelinating process of spinal cord!
◊ In 12–33% without coexistent intracranial plaques!
• number + extent of plaques correlate with degree of disability
Location: predilection for cervical cord
Site: eccentric involvement of dorsal + lateral elements abutting subarachnoid space
√ atrophic plaques oriented along spinal cord axis
√ length of plaque usually less than 2 vertebral body segments + width less than half of cross section
√ acute tumefactive MS = cord swelling with enhancement
√ cord atrophy in chronic MS
DDx: (1) Acute transverse myelitis
(2) Cord tumor (follow-up after 6 weeks without decrease in size of lesion)
(3) Trauma
(4) Infarct
(3) Postviral syndromes
Rx: steroids (incite rapid decrease in size of lesions with loss of enhancement)
DDx:
(1) Acute disseminated encephalomyelitis (ADEM), subacute sclerosing panencephalitis (lesions of similar age)
(2) Lyme encephalopathy (skin rash)
(3) **Susac syndrome** (encephalopathy + branch retinal artery occlusion + hearing loss)
(4) Small vessel ischemia (patients > 50 years of age, lesions < 5 mm, NOT infratentorial)
(5) Enlarged type II Virchow-Robin spaces
(6) AIDS, CNS vasculitis, migraine, radiation injury, lymphoma, sarcoidosis, tuberculosis, systemic lupus erythematosus, cysticercosis, metastases, multifocal glioma, neurofibromatosis, contusions

NEONATAL INTRACRANIAL HEMORRHAGE

Germinal Matrix Bleed

= GERMINAL MATRIX–RELATED HEMORRHAGE
Risk factors:
(1) Prematurity
(2) Low birth weight
(3) Sex (M÷F = 2÷1)
(4) Multiple gestations
(5) Trauma at delivery
(6) Prolonged labor
(7) Hyperosmolarity
(8) Hypocoagulation
(9) Pneumothorax
(10) Patent ductus arteriosus
Etiology: hypoxia with loss of autoregulation

Pathogenesis: rupture of friable vascular bed due to

(1) Fluctuating cerebral blood flow in preterm infants with respiratory distress
(2) Increase in cerebral blood flow with
  (a) systemic hypertension (pneumothorax, REM sleep, handling, tracheal suctioning, ligation of PDA, seizures, instillation of mydriatics)
  (b) rapid volume expansion (blood, colloid, hyperosmolar glucose / sodium bicarbonate)
  (c) hypercarbia (RDS, asphyxia)
(3) Increase in cerebral venous pressure with labor and delivery, asphyxia (= impairment in exchange of oxygen and carbon dioxide), respiratory disturbances
(4) Decrease in cerebral blood flow with systemic hypotension followed by reperfusion
(5) Platelet and coagulation disturbance

Incidence: in premature neonates < 32 weeks of age; in 43% of infants < 1,500 g (in 65% of 500–700 g infants, in 25% of 701–1,500 g infants); in up to 50% without prenatal care, in 5–10% with prenatal care

Time of onset: usually during first 24 hours of life; 36% on 1st day, 32% on 2nd day, 18% on 3rd day of life; by 6th day 91% of all intracranial bleeds have occurred

Location: region of caudate nucleus and thalamostriate groove (= caudothalamic notch) remains metabolically active the longest; in 80–90% in infants < 28 weeks of MA

GRADES (**Papile classification**):

I : subependymal hemorrhage confined to germinal matrix (GMH) on one / both sides
II : subependymal hemorrhage ruptured into nondilated ventricle (IVH)
III : intraventricular hemorrhage (IVH) with ventricular enlargement: (a) mild, (b) moderate, (c) severe
IV : extension of germinal matrix hemorrhage into brain parenchyma (intraparenchymal hemorrhage = IPH)

US (100% sensitivity + 91% specificity for lesions > 5 mm; 27% sensitivity + 88% specificity for lesions ≤ 5 mm):

1. **Germinal matrix hemorrhage** (grade I)
  √ well-defined ovoid area of increased echogenicity (= fibrin mesh within clot) inferolateral to floor of frontal horn ± body of lateral ventricle
  √ bulbous enlargement of caudothalamic groove anterior to termination of choroid plexus
    DDx: choroid plexus (attached to inferomedial aspect of ventricular floor, tapers toward caudothalamic groove, NEVER anterior to foramen of Monro)
  √ resolving bleed develops central sonolucency
  √ outcome: (1) complete involution (2) thin echogenic scar (3) subependymal cyst
2. **Mild intraventricular hemorrhage** (grade II)
  √ echogenic material filling a portion of lateral ventricles (acute phase) becoming sonolucent in a few weeks
  √ clot may gravitate into occipital horns
  √ vertical band of echogenicity between thalami on coronal scans (blood in 3rd ventricle)
  √ irregular bulky choroid plexus (clot layered on surface of choroid plexus)

√ temporarily increased echogenicity of ventricular wall (= subependymal white halo between 7 days and 6 weeks after hemorrhagic event)

3. **Extensive intraventricular hemorrhage** (grade III)
   √ intraventricular cast of blood distending lateral ventricles
   √ ± extension of hemorrhage into basal cisterns, cavum septi pellucidi
   √ hemorrhage becomes progressively less echogenic
   √ temporarily thickened echogenic walls of ventricles ("ventriculitis")
4. **Intraparenchymal hemorrhage** (grade IV)
   Frequency: 5–8%
   Cause: (a) extension of hemorrhage originating from germinal matrix (unusual)
   (b) separate hemorrhage within infarcted periventricular tissue (frequent)
   = **periventricular venous infarction** ← thrombosis of medullary veins draining periventricular brain
   Location: on side of largest amount of IVH, commonly lateral to frontal horns / in parietal lobe, rare in occipital lobe + thalamus
   √ unilateral triangular hemorrhage
   √ homogeneous highly echogenic intraparenchymal mass with irregular margins
   √ central hypoechogenicity (liquefying hematoma after 10–14 days)
   √ retracted clot settles to dependent position (3–4 weeks)
   √ complete resolution by 8–10 weeks results in anechoic area (= porencephalic cyst)

Serial scans: recommended in 5–10-day intervals

CT:

√ hyperdense bleed only visible up to 7 days before it becomes isodense

DDx: subdural hemorrhage, cerebral parenchymal hemorrhage, posterior fossa lesion

MR (gradient-echo, susceptibility-weighted sequences):

√ highest sensitivity for detecting small hemorrhages
√ useful for depicting periventricular venous infarction in grade 4 germinal matrix hemorrhages

Cx:

(1) **Posthemorrhagic hydrocephalus** (30–70%)

◊ Severity of hydrocephalus directly proportional to size of original hemorrhage!

Cause:
(a) temporary blockage of arachnoid villi by particulate blood clot (within days), often transient with partial / total resolution
(b) obliterative fibrosing arachnoiditis often in cisterna magna (within weeks); frequently leads to permanent progressive ventricular dilatation (50%)

√ thickened echogenic ventricular walls

Time of onset: by 14 days (in 80%)

• delayed clinical signs because of compressible premature brain parenchyma

√ ventricular dilatation, particularly affecting the occipital horns (amount of compressible immature white matter is larger posteriorly)

DDx: ventriculomegaly ← periventricular cerebral atrophy (occurring slowly over several weeks)

(2) **Cyst formation**

(a) cavitation of hemorrhage
(b) unilocular subependymal cyst
(c) unilocular porencephalic cyst

(3) Mental retardation, cerebral palsy
(4) Death in 25%
◊ IVH is the most common cause of neonatal death!

Prognosis:
(1) Grade I + II: good with normal developmental scores (12–18% risk of handicap)
(2) Grade III + IV: 54% mortality; 30–40% risk of handicap (spastic diplegia, spastic quadriparesis, intellectual retardation)

Choroid Plexus Hemorrhage

affects primarily full-term infants
Cause: birth trauma, asphyxia, apnea, seizures
√ echogenicity of choroid plexus same as hemorrhage
√ nodularity of choroid plexus
√ enlargement of choroid plexus > 12 mm in AP diameter
√ left-right asymmetry > 5 mm
√ intraventricular hemorrhage without subependymal hemorrhage
Cx: intraventricular hemorrhage (25%)

Intracerebellar Hemorrhage

Cause:
(a) full-term infant: traumatic delivery, intermittent positive pressure ventilation, coagulopathy
(b) premature infant (in 25%): subependymal germinal matrix hemorrhage in external granule cell layer and subependymal layer of roof of 4th ventricle up to 30 weeks GA

Incidence: 16–21% of autopsies
√ echogenicity of vermis same as hemorrhage
√ echogenic mass in less echogenic cerebellar hemisphere (coronal scan most useful)
√ nonvisualization / deformity of 4th ventricle
√ asymmetry in thickness of paratentorial echogenicity is a sign of subarachnoid hemorrhage
Prognosis: poor + frequently fatal

Intraventricular Hemorrhage

Etiology:
(a) germinal matrix hemorrhage ruptures through ependymal lining at multiple sites
(b) bleeding from choroid plexus

Route of hemorrhage:
blood dissipates throughout ventricular system + aqueduct of Sylvius, passes through foramina of 4th ventricle, collects in basilar cistern of posterior fossa

• seizures, dystonia, obtundation, intractable acidosis
• bulging anterior fontanel, drop in hematocrit, bloody / proteinaceous CSF
√ IVH usually clears within 7–14 days
Cx: (1) Intracerebral hemorrhage

(2) Hydrocephalus

Periventricular Leukoencephalopathy

Periventricular Leukomalacia

= WHITE MATTER INJURY OF PREMATURITY

= PVL = perinatal hypoxic-ischemic encephalopathy

= PRINCIPAL ischemic lesion of the premature infant characterized by areas of focal coagulation necrosis of deep white matter (= cystic variant) / more diffuse injury to premyelinating oligodendrocytes (= noncystic variant)

Cause: toxic injury to premyelinating oligodendrocytes ← cerebral ischemia ± reperfusion

Location: peritrigonal area of lateral ventricles and foramen of Monro (= watershed zones in periventricular white matter) involving particularly the centrum semiovale (anterior and lateral to frontal horns + body), optic (occipital horn), and acoustic (temporal horn) radiations

Vascular supply:

(a) ventriculopetal branches penetrating cerebrum from pial surface derived from MCA ± PCA ± ACA

(b) ventriculofugal branches extending from ventricular surface derived from choroidal ± striate arteries

Incidence: 7–22% at autopsy (in 88% of infants between 900 and 2,200 g surviving beyond 6 days); in 34% of infants < 1,500 g; in 59% of infants surviving longer than 1 week on assisted ventilation; MOST FREQUENTLY in infants born < 32 weeks GA

◊ Only 28% detected by cranial sonography!

Histo: edema, white matter necrosis, evolution of cysts + cavities / diminished myelin; nonhemorrhagic÷hemorrhagic PVL = 3÷1

Risk factors: hypotension, hypocarbia, infection, prematurity, asphyxia, sepsis, patent ductus arteriosus, multiple gestation, respiratory distress, maternal hemorrhage

Pathogenesis:

immature autoregulation of periventricular vessels ← deficient muscularis of arterioles limits vasodilation in response to hypoxemia + hypercapnia + hypotension of perinatal asphyxia (hypoxic-ischemic encephalopathy); ischemia reperfusion injury of white matter → free radicals → destruction of progenitor cells of oligodendrocyte with impaired myelination

- "cerebral palsy" (in 6.5% of infants < 1,800 g):
  - spastic diplegia (81%) > quadriparesis (necrosis of descending fibers from motor cortex)
  - choreoathetosis, ataxia, ± mental retardation
- severe visual / hearing impairment, convulsive disorders

US (50% sensitivity + 87% specificity):

Early changes (2 days to 2 weeks after insult)

√ increased periventricular echogenicity (PVE) (DDx: echogenic periventricular halo / blush of fiber tracts in normal neonates, white matter gliosis, cortical infarction extending into deep white matter)

√ bilateral often asymmetric zones, occasionally extending to cortex
√ infrequently accompanied by IVH

Late changes (1–3–6 weeks after development of echodensities):
√ periventricular cystic PVL = cystic degeneration of ischemic areas (= multiple small NEVER septated periventricular cysts in relationship to lateral ventricles; the larger the echodensities, the sooner the cyst formation)
√ brain atrophy ← thinning of periventricular white matter always at trigones, occasionally involving centrum semiovale
√ ventriculomegaly (after disappearance of cysts) with irregular outline of body + trigone of lateral ventricles
√ deep prominent sulci abutting ventricles with little / no interposed white matter (DDx: schizencephaly)
√ enlarged interhemispheric fissure

CT (not sensitive in early phase):
√ periventricular hypodensity (DDx: immature brain with increased water + incomplete myelination)

MR (NOT sensitive in early phase):
√ hypointense areas on T1WI
√ hyperintense periventricular signals on T2WI in peritrigonal region ← delay in maturation / injury
DDx: normal (SI subject to interpretation)
√ thinning of posterior body + splenium of corpus callosum (= degeneration of transcallosal fibers)

Prognosis: major neurologic problem / death in up to 62%; PVL localized to frontal lobes shows relative normal development; PVL in parieto-occipital location > 10 mm in size → cerebral palsy in close to 100%

DDx: tissue damage from ventriculitis (sequelae of meningitis), metabolic disorders, in utero ischemia (eg, maternal cocaine abuse)

Periventricular Hemorrhagic Infarction

= CYSTIC PERIVENTRICULAR LEUKOMALACIA
= leukoencephalopathy resulting from pre- / perinatal hypoxic-ischemic event

Incidence: in 15–25% of infants with IVH

Pathogenesis:
(a) germinal matrix hemorrhage with intraventricular blood clot (in 80%)
(b) ischemic periventricular leukomalacia → obstruction of terminal veins with sequence of venous congestion → thrombosis → infarction

Histo: perivascular hemorrhage of medullary veins near ventricular angle

Associated with: the most severe cases of intraventricular hemorrhage

Age: peak occurrence on 4th postnatal day

• spastic hemiparesis (affecting lower + upper extremities equally) / asymmetric quadriparesis (in 86% of survivors)

Location: lateral to external angle of lateral ventricle on side of the more marked IVH: 67% unilateral; 33% bilateral but asymmetric

Stages: vascular congestion → coagulative necrosis → cavitation

US:

Early changes (hours to days after major IVH):

√ unilateral / asymmetric bilateral triangular "fan-shaped" echodensities

√ extension from frontal to parietooccipital regions / localized (particularly in anterior portion of lesion)

Late changes:

√ single large cyst = porencephaly

√ bumpy ventricle / false accessory ventricle

MR:

√ increased signal intensity in periventricular white matter on T2WI + FLAIR

√ marked loss of periventricular white matter (predominantly in periatrial region)

√ adjacent compensatory focal ventricular enlargement

√ secondary thinning of corpus callosum

√ relative sparing of overlying cortical mantle

√ surrounded by gliosis easily depicted on FLAIR

Prognosis: 59% overall mortality with echodensities > 1 cm; in 64% major intellectual deficits

DDx: enlarged Virchow-Robin spaces

Encephalomalacia

= more extensive brain damage than PVL; may include all of white matter in subcortex + cortex

Associated with:

(1) Neonatal asphyxia

(2) Vasospasm

(3) Inflammation of CNS

US:

√ small ventricles (← edema) with diffuse damage

√ increased parenchymal echogenicity making it difficult to define normal structures

√ decreased vascular pulsations

√ transcranial Doppler:

(a) group I (good prognosis)

√ normal flow profile, normal velocities, normal resistive index

(b) group II (guarded prognosis)

√ increase in peak-systolic + end-diastolic flow velocities + decreased resistive index

(c) group III (unfavorable prognosis)

√ reduced diastolic flow + decreased peak systolic and diastolic velocities + increased resistive index

√ ventricular enlargement + atrophy

√ extensive multicystic encephalomalacia with cysts often not communicating

NEUROCUTANEOUS MELANOSIS

= rare sporadic congenital syndrome characterized by large multiple melanocytic nevi (in 5–15%) + melanotic lesions of CNS (in 40–60%)

Age: first 2 years of life (most); 2nd / 3rd decade (less common); M÷F = 1÷1
Cause: abnormal migration of melanocyte precursors, abnormal expression of melanin-producing genes within leptomeningeal cells, rapid proliferation of melanin-producing leptomeningeal cells
Histo: abnormal abundance of melanotic cells (which are normally found in basilar leptomeninges) with concomitant infiltration of perivascular spaces
• increased intracranial pressure
• seizures, ataxia, cranial nerve VI + VII palsies
√ high attenuation of melanin pigments on CT scan
√ hyperintense on T1WI, hypointense on T2WI (← paramagnetic effect of oxygen-free radicals in melanin)
√ leptomeningeal melanosis = foci of abnormally thickened leptomeninges
Location: inferior surface of cerebellum; inferior surface of frontal, temporal, occipital lobes; ventral aspect of pons; cerebral peduncles; upper cervical spinal cord
√ parenchymal melanosis (less common)
Location: cerebellum, anterior temporal lobes (esp. amygdala)
√ frankly hemorrhagic necrotic invasive mass with transformation into malignant melanoma
√ hydrocephalus
√ posterior fossa cyst
√ cerebellar hypoplasia
√ Dandy-Walker malformation
√ syringomyelia
√ intraspinal arachnoid cyst
√ intraspinal lipoma
Prognosis: rapid deterioration + death within 3 years of diagnosis ← development of malignant melanoma / complication of hydrocephalus

NEUROGLIAL CYST

= GLIOEPENDYMAL CYST = NEUROEPITHELIAL CYST
= rare benign epithelium-lined lesion
Incidence: < 1% of all intracranial cysts
Cause: sequestration of developing neural tube elements during embryogenesis
Histo: rounded smooth unilocular cyst lined by ependymal (columnar epithelium) / choroid plexus cells (low cuboidal epithelium) with CSF-like content
Location: anywhere (typically in frontal lobe); intraparenchymal > extraparenchymal
Size: up to several cm in diameter
• typically asymptomatic; symptomatic if CSF flow obstructed
√ spherical / ovoid lesion of CSF signal intensity:
  √ hyperintense to CSF on T2WI with proteinaceous content
  √ smooth rounded borders
√ NO enhancement, NO adjacent edema, NO soft-tissue mass, NO gliosis
DDx: choroid plexus cyst (commonly abnormal DWI); arachnoid cyst (typically extraaxial); enlarged Virchow-Robin space (no differentiating feature on imaging, typically multiple + clustered around basal ganglia); porencephalic cyst (communication with lateral

ventricle, surrounding gliosis); epidermoid cyst; infectious cyst of neurocysticercosis (< 1 cm, partially enhancing)

NEUROFIBROMATOSIS

= autosomal dominant inherited disorder, probably of neural crest origin affecting all 3 germ cell layers, capable of involving any organ system

Path: frequently combination of

(1) pure neurofibromas (= tumor of nerve sheath with involvement of nerve, nerve fibers run through mass)
  (a) localized neurofibroma (most common, 90%)
  (b) diffuse neurofibroma mostly solitary + not associated with NF1
  (c) plexiform neurofibroma (PATHOGNOMONIC of NF1)
    ◊ Often precedes development of cutaneous neurofibromas!

(2) neurilemmomas (= nerve fibers diverge and course over the surface of the tumor mass)

Histo: proliferation of fibroblasts + Schwann cells

◊ More frequent involvement of deep large nerves (sciatic nerve, brachial plexus) in NF1 in contradistinction to isolated neurofibromas without NF1!

Peripheral Neurofibromatosis (90%)

= NEUROFIBROMATOSIS TYPE 1 = NF1 = VON RECKLINGHAUSEN DISEASE

[Friedrich von Recklinghausen (1833–1910), pathologist in Königsberg, Würzburg and Strasbourg]

= fully penetrant autosomal-dominant disorder with variable expressivity characterized by dysplasia of mesodermal + neuroectodermal tissue with potential for diffuse systemic involvement

Genetics: NF1 gene = tumor suppressor gene localized in the pericentromeric region of chromosome **17** produces neurofibromin that functions as a negative regulator of Ras signaling proteins; 50% represent new spontaneous mutations
  mnemonic: 'von Recklinghausen' has **17** letters

Incidence: 1÷3,000; M÷F = 1÷1; all races
  ◊ One of the most common genetic diseases and phakomatoses!

Predisposing factor: advanced paternal age > 35 years (2-fold increase in new mutations)

Diagnostic clinical criteria (at least two must be present):

(1) ≥ 6 "coast-of-California" café-au-lait spots
  › > 5 mm in diameter in prepubertal individuals
  › > 15 mm in diameter in postpubertal individuals
(2) ≥ 2 neurofibromas of any type / ≥ 1 plexiform neurofibroma
(3) Intertriginous freckling (Crowe sign) in axilla / inguina
(4) Optic pathway glioma
(5) ≥ 2 Lisch nodules = pigmented iris hamartomas
(6) Characteristic skeletal lesion
  › sphenoid bone dysplasia
  › dysplasia + thinning of long bone cortex

(7) 1st-degree relative (parent, sibling, child) with NF1

CLASSIC TRIAD:

(1) Cutaneous lesions
(2) Skeletal deformity
  ◊ Musculoskeletal abnormalities predominate in NF1!
(3) Mental deficiency

May be associated with:

(1) MEA IIb (pheochromocytoma + medullary carcinoma of thyroid + multiple neuromas)
(2) CHD (10 fold increase): pulmonary valve stenosis, ASD, VSD, IHSS

Cx: malignant transformation to malignant neurofibroma + malignant schwannoma (2–5–29%), glioma, xanthomatous leukemia

Rapid episodes of growth of neurofibromas:

puberty, pregnancy, malignancy

CNS Manifestations of NF1

@ Intracranial

1. Optic pathway glioma
2. **Cerebral glioma** astrocytomas of tectum, brainstem, gliomatosis cerebri (= unusual confluence of astrocytomas)
3. **Hydrocephalus** obstruction usually at aqueduct of Sylvius
   Cause: benign aqueductal stenosis, glioma of tectum / tegmentum of mesencephalon
4. **Vascular dysplasia**
   = occlusion / stenosis of distal internal carotid artery, proximal middle / anterior cerebral artery
   √ moyamoya phenomenon (60–70%)
5. **Neurofibroma** of cranial nerves III–XII (most commonly V + VIII)
   ◊ 30% of patients with solitary neurofibromas have NF1
   ◊ Virtually all patients with multiple neurofibromas have NF1
6. **Craniofacial plexiform neurofibroma**
   = locally aggressive congenital lesion composed of tortuous cords of Schwann cells, neurons and collagen with progression along nerve of origin (usually small unidentified nerves)
   Location: commonly orbital apex, superior orbital fissure
   ◊ Plexiform neurofibromas are PATHOGNOMONIC for NF1
7. **CNS hamartoma** (up to 75–90%)
   = probably dysmyelinating lesion (may resolve)
   Location: pons, basal ganglia (most commonly in globus pallidus), thalamus, cerebellar white matter
   √ multiple foci of isointensity on T1WI + hyperintensity on T2WI without mass effect (= "unidentified bright objects")
8. **Vacuolar / spongiotic myelinopathy** (in 66%)
   Location: basal ganglia (esp. in globus pallidus), cerebellum, internal capsule, brainstem
   √ nonenhancing hyperintense foci on T2WI

@ Spinal cord

1. **Cord neurofibroma**
   - √ smooth round / tubular masses of varying sizes at nearly every level throughout spinal canal
   - √ spinal cord displaced to contralateral side
   - √ enlargement of neural foramen ← "dumbbell" neurofibroma of spinal nerves (in 30%)
   - √ smooth fusiform / spherical mass:
     - √ hypoattenuating mass (20–30 HU) in up to 73% ← cystic degeneration, xanthomatous features, confluent areas of hypocellularity, lipid-rich Schwann cells
     - √ areas of higher attenuation ← densely cellular components / collagen-rich regions
     - √ slightly hyperintense to muscle on T1WI, hyper-intense periphery + hypointense core on T2WI
     - √ hypoechoic heterogeneous well-circumscribed cylindrical lesion with variable through transmission
2. **Paraspinal / presacral plexiform neurofibroma**

   = regional enlargement of nerve root trunk (plexus / multiple fascicles of medium to large nerve); exclusive to NF1

   Localized and plexiform neurofibromas of the paraspinal and sacral region are the most common abdominal neoplasm in NF1.

   Location: retroperitoneal along lumbosacral plexus adjacent to psoas muscle at single / multiple vertebral body levels

   Form: ropelike = involving non-branching nerves; "bag of worms" = in branching nerves

   - √ heterogeneous echotexture with variable through transmission
   - √ smooth round / tubular symmetric / asymmetric paraspinal masses within / adjacent to psoas m.:
     - √ homogeneously hypoattenuating (20–25 HU) in up to 73% ← myxoid + mucinous stroma
     - √ focal areas of higher attenuation ← excessive collagen
     - √ homo- / heterogeneous enhancement to 30–50 HU on CECT in 50%
   - √ enlargement of adjacent neural foramen in 30%

   Cx: malignant degeneration
3. **Lateral / anterior intrathoracic meningocele**

   = diverticula of thecal sac extending through widened neural foramina / defects in vertebra

   Cause: dysplasia of meninges focally stretched by CSF pulsations ← pressure differences between thoracic + subarachnoid space superimposed on osseous vertebral defect

   - √ erosion of bony elements with marked posterior scalloping
   - √ widening of neural foramina ← protrusion of spinal meninges

   DDx: mediastinal / lung abscess

Skeletal Manifestations of NF1 *(in 25–40%)*

= skeletal dysplasias + pseudarthroses

Age: during first year of life

@ Orbit

√ Harlequin appearance to orbit = sphenoid wing dysplasia = partial absence of greater and lesser wing of sphenoid bone + orbital plate of frontal bone ← failure of development of membranous bone

√ hypoplasia + elevation of lesser wing of sphenoid

√ defect in sphenoid bone ± extension of middle cranial fossa structures into orbit

√ concentric enlargement of optic foramen ← optic glioma

√ enlargement of orbital margins + superior orbital fissure ← plexiform neurofibroma of peripheral and sympathetic nerves within orbit / optic nerve glioma

√ sclerosis in the vicinity of optic foramen ← optic nerve sheath meningioma

√ deformity + decreased size of ipsilateral ethmoid and maxillary sinuses

@ Skull

√ macrocranium + macroencephaly

√ left-sided calvarial defect adjacent to lambdoid suture = parietal mastoid (rare)

@ Spine

• dwarfism caused by scoliosis

√ sharply angled focal kyphoscoliosis (50%) in lower thoracic + lumbar spine; kyphosis predominates over scoliosis; incidence increases with age

Cause: abnormal development of vertebral bodies

√ hypoplasia of pedicles + transverse + spinous processes

√ posterior scalloping of vertebral bodies ← dural ectasia ← weakened meninges allowing transmission of normal CSF pulsations

√ dumbbell-shaped enlargement of neural foramina

@ Appendicular skeleton

√ anterolateral bowing of lower half of tibia (most common) / fibula (frequent) / upper extremity (uncommon) secondary to deossification → thinning → pathologic fracture

√ pseudarthrosis / nonunion after bowing fracture in 1st year of life

Location: tibia, fibula

√ atrophic thinned / absent fibula

√ periosteal dysplasia = traumatic subperiosteal hemorrhage with abnormally easy stripping of periosteum from bone

√ subendosteal sclerosis

√ bone erosion from periosteal / soft-tissue neurofibroma

√ intramedullary longitudinal streaks of increased density

√ multiple nonossifying fibromas / fibroxanthomas

√ single / multiple cystic lesions within bone ← deossification / nonossifying fibroma

√ focal gigantism = unilateral overgrowth of a limb bone ← overgrowth of ossification center

Site: marked enlargement of a digit in a hand / foot

Pulmonary Manifestations of NF1

@ Lung

- exertional dyspnea

√ intrathoracic lateral + anterior meningoceles

√ peripheral pulmonary nodule = pedunculated intercostal neurofibroma

√ progressive pulmonary interstitial fibrosis with lower lung field predominance (in up to 20%)

√ large thin-walled bullae with asymmetric upper lobe predominance

@ Mediastinum

◊ Neurogenic tumors account for 9% of primary mediastinal masses in adults + 30% in children

√ mediastinal mass:

√ well-marginated smooth round / elliptic mass

√ extensive fusiform / infiltrating mass

√ paravertebral neurofibroma

@ Chest wall

√ numerous small well-defined subcutaneous neurofibromas

√ twisted "ribbonlike" ribs in upper thoracic segments ← bone dysplasia / multiple neurofibromas of intercostal nerves:

√ localized cortical notches / depression of inferior margins of ribs (DDx: aortic coarctation)

√ chest wall mass invading / eroding / destroying adjacent rib

Abdominal Tumors in NF1

A. NEUROGENIC TUMORS IN NF1
   1. Neurofibroma
   2. Plexiform neurofibroma
   3. Malignant peripheral nerve sheath tumor
   4. Ganglioneuroma
   5. Ganglioneuromatosis

B. NEUROENDOCRINE TUMORS IN NF1
   1. Periampullary carcinoid
   2. Pheochromocytoma in adults
      Location: solitary + unilateral (84%); bilateral (10%); extraadrenal (6%)
   3. Paraganglioma

C. OTHER TUMORS ASSOCIATED WITH NF1
   1. GIST
   2. Embryonal tumor
   3. Adenocarcinoma
   4. Parathyroid adenoma
      - hyperparathyroidism

Vascular Lesions in NF1

= Schwann cell proliferation within vessel wall

Age: common in childhood

1. Cranial artery stenosis
2. Renal artery stenosis: very proximal, funnel-shaped

◊ Renal artery stenosis in NF1 is one of the most common causes of hypertension in childhood!

3. Renal artery aneurysm
4. Thoracic / abdominal aortic coarctation

GI Tract Manifestations in NF1 *(10–25%)*

Neurofibromas appear as well-defined masses but frequently infiltrate into adjacent fat, muscle, or viscera → local recurrence after resection is common.

1. Neurofibroma
   - most clinically occult
   - intestinal bleeding (hematemesis, melena, hematochezia) with mucosal involvement
   - obstruction with nausea, vomiting, abdominal distension (intussusception, volvulus, simulating Hirschsprüng disease with plexiform neurofibromas of colon)

   Location: jejunum > stomach > ileum > duodenum
   Site: myenteric > mesenteric / subserosal plexus
   Associated with: increased prevalence of carcinoid tumors + GI stromal tumors
   (a) single / **solitary neurofibroma**, neuroma, ganglioneuroma, schwannoma
   √ subserosal / submucosal filling defect ("**mucosal ganglioneurofibromatosis**")
   √ displacement of intestine
   √ external mass effect on serosal surface
   √ infiltrating submucosal / mucosal polypoid masses
   √ lobular mural thickening of soft-tissue attenuation with variable amount of luminal narrowing ← infiltration through intestinal wall
   (b) **mesenteric plexiform neurofibroma**
   Location: common in perirectal space
   Site: from root of mesentery to wall of intestine
   √ mass effect on adjacent barium-filled loops
   √ multiple eccentric polypoid filling defects involving mesenteric side of small bowel
   √ mesenteric fat trapped within entangled network (15–30 HU) CHARACTERISTIC
   √ multiple leiomyomas ± mucosal ulcers
   Cx: intussusception
2. Malignant peripheral nerve sheath tumor
   ◊ Most common malignant abdominal tumor in NF1
3. Ganglioneuroma
4. Carcinoid
   - more common in NF1 than in general population

   Location: near ampulla of Vater
   Histo: psammomatous somatostatinoma
5. Gastrointestinal stromal tumor

Genitourinary Manifestations of NF1 (rare)

1. Renal artery stenosis
   √ plexiform neurofibroma with vascular narrowing

2. Urinary bladder neurofibroma
   Origin: vesicoprostatic (male) / urethrovaginal neural plexus (female)
   • symptoms of urinary tract obstruction: frequency, urgency, incontinence, hematuria, abdominal pain
   √ solitary hypoechoic bladder wall mass
   √ diffuse bladder wall thickening; mass may surround uterus, vagina, sigmoid colon
   √ scalloped contour of urinary bladder
   Cx: hydronephrosis

Ocular Manifestations in NF1 *(6%)*
- pulsatile exophthalmos / unilateral proptosis (herniation of subarachnoid space + temporal lobe into orbit)
- buphthalmos

1. Plexiform neurofibroma (most common)
2. **Lisch nodules**
   = PATHOGNOMONIC asymptomatic melanocytic iris hamartomas < 2 mm in size
   • yellow / brown pigmented nodular elevations projecting from surface of iris; mostly bilateral
   • asymptomatic
   Age: 5–10 years; > 20 years of age in > 90%
3. **Optic glioma** (in 12% of patients, in 4% bilateral)
   Age: 75% in 1st decade
   √ extension into optic chiasm (up to 25%), optic tracts, optic radiation
   √ increased intensity on T2WI if chiasm and visual pathway involved
4. Perioptic meningioma
5. Choroidal hamartoma: in 50% of patients

Skin Manifestations in NF1
1. **Café-au-lait spots**
   = tan / light brown pigmented often ovoid cutaneous macules + patches with irregular borders
   ≥ 6 in number >
   5 mm in greatest diameter prior to puberty
   > 15 mm in postpubertal individuals
   • randomly distributed
   • "**coast of California**" type (= smooth outline)
   DDx: "coast-of-Maine" spots of McCune-Albright syndrome (with more jagged borders)
   Age: usually present at birth, increase in number over first 1–2 years of life
   ◊ One of the earliest manifestations of NF1
   Histo: increased melanin pigment in basal epidermal layer
   DDx: tuberous sclerosis, fibrous dysplasia
   Extent: often parallels disease severity
2. Intertriginous freckling (= Crowe sign)
   = pigmented cutaneous macules < 5 mm in size

Age: 3–5 years
Location: intertriginous skin of axilla (in 66%), groin, submammary fold, neck

3. Dermal (cutaneous) neurofibroma
Histo: benign mixture of Schwann cells + fibroblasts + perineural cells + mast cells
Age: begins to appear around early childhood / puberty subsequent to detection of café-au-lait spots
(a) localized = **fibroma molluscum** = string of pearls along peripheral nerve
• firm well-circumscribed movable tumor
• soft compressible fleshy nodule of cutis
• firm rubbery nodule of subcutis
Cx: NO malignant degeneration!
(b) **plexiform neurofibroma** = multilobulated tortuous entanglement / interdigitating network of tumor along a nerve and its branches
◊ Exclusively seen in NF1 (in 30%)
Age: noticeable by 4–5 years
• soft gritty often hyperpigmented tumor feeling like a "bag of worms / braided ropes"
• may become very large hanging in a pendulous fashion associated with massive disfiguring enlargement of an extremity (= **elephantiasis neuromatosa**)
√ ± osseous hypertrophy ← chronic hyperemia
Cx: may transform to malignant peripheral nerve sheath tumor (MPNST = neurofibrosarcoma) in 10%!
Dx: new onset of pain / neurologic deficit / rapid growth associated with preexisting plexiform neurofibroma → FDG-PET
(c) **diffuse neurofibroma**
Location: most common in subcutaneous tissue

Neurofibromatosis with Bilateral Acoustic Neuromas

= NEUROFIBROMATOSIS TYPE 2 = NF 2 = CENTRAL NEUROFIBROMATOSIS
= rare autosomal dominant syndrome characterized by propensity for developing multiple schwannomas, meningiomas, and gliomas of ependymal derivation *mnemonic:* MISME
Multiple Inherited Schwannomas
Meningiomas
Ependymomas
Incidence: 1÷50,000 births
Etiology: deletion on the long arm of chromosome 22; in 50% new spontaneous mutation
mnemonic: Neurofibromatosis **2** is located on chromosome **22**!
Symptomatic age: during 2nd / 3rd decade of life
Diagnostic criteria:
(1) bilateral 8th cranial nerve masses
(2) first-degree relative with unilateral 8th nerve mass, neurofibroma, meningioma, glioma (spinal ependymoma), schwannoma, juvenile posterior subcapsular lenticular opacity

• NO Lisch nodules, skeletal dysplasia, optic pathway glioma, vascular dysplasia, learning disability
• café-au-lait spots (< 50%): pale and < 5 in number

• cutaneous neurofibroma: minimal in size + number / absent

@ Intracranial

1. Bilateral acoustic schwannomas (SINE QUA NON)
   Site: superior / inferior division of vestibular nerve
   √ usually asymmetric in size
2. Schwannoma of other cranial nerves
   Frequency: trigeminal nerve > facial nerve
   ◊ Nerves without Schwann cells are excluded: olfactory nerve, optic nerve
3. Multiple meningiomas: intraventricular in choroid plexus of trigone, parasagittal, sphenoid ridge, olfactory groove, along intracranial nerves
4. Meningiomatosis = dura studded with innumerable small meningiomas
5. Glioma of ependymal derivation

@ Spinal

• symptoms of cord compression

A. Extramedullary
   1. Multiple paraspinal neurofibromas
   2. Meningioma of spinal cord (esp. in thoracic region)

B. Intramedullary
   1. Spinal cord ependymomas

NEUROMA

= ambiguous term and misnomer (really a schwannoma rather than a tumor of actual nerve tissue)!

Prevalence: 8% of all intracranial tumors

Age: 20–50 years

• slow growth; not painful

Vestibular Schwannoma

= ACOUSTIC NEUROMA = ACOUSTIC SCHWANNOMA
= NEURILEMMOMA

[Theodor Ambrose Hubert Schwann (1810–1882), German anatomist and physiologist, professor of physiology and comparative anatomy in Louvain and at the State University of Liège, Belgium]

◊ Most common neoplasm of internal auditory canal / cerebellopontine angle!

Prevalence: 6–10% of all intracranial tumors; 85% of all intracranial neuromas; 60–90% of all cerebellopontine angle tumors

Age: (a) sporadic tumor: 35–60 years; M÷F = 1÷2
(b) type 2 neurofibromatosis: 2nd decade

Histo:

encapsulated neoplasm composed of proliferating fusiform Schwann cells with
(a) highly cellular dense regions (Antoni A) with reticulin + collagen, and
(b) loose areas with widely separated cells (Antoni B) in a reticulated myxoid matrix; common degenerative changes with cyst formation, vascular features, lipid-laden foam cells

May be associated with: central neurofibromatosis (NF2)

◊ Solitary intracranial schwannoma is associated with type 2 neurofibromatosis in 5–25%!
◊ Bilateral acoustic schwannomas allow a presumptive diagnosis of type 2 neurofibromatosis!

- long history of slowly progressive unilateral sensorineural hearing loss mostly for high-frequency sounds (in 95%)
- tinnitus, pain; diminished corneal reflex
- unsteadiness, vertigo, ataxia, dizziness (< 10%)

Doubling time: 2 years

Location:

(a) arises from within internal auditory canal (IAC) in 80% / cochlea
(b) may arise in cerebellopontine angle cistern at opening of IAC (= porus acusticus) with intracanalicular extension in 5%

Site: (a) in 85% from the vestibular portion of 8th nerve (around vestibular ganglion of Scarpa / at the glial-Schwann cell junction) posterior to cochlear portion
[Antonio Scarpa (1752–1832), professor of anatomy at the Università di Pavia, Lombardia, Italy]
(b) in 15% from the cochlear portion

√ round mass centered on long axis of porus acusticus forming acute angles with dural surface of petrous bone
√ funnel-shaped component extending into IAC
√ IAC enlargement / erosion (70–90%)
√ widening / obliteration of ipsilateral cerebellopontine angle cistern
√ shift / asymmetry of 4th ventricle with hydrocephalus
√ degenerative changes (cystic areas and hemorrhage) with tumors > 2–3 cm

Plain film:

√ flaring porus acusticus
√ erosion of IAC: a difference in canal heights of > 2 mm is abnormal + indicates a schwannoma in 93%

CT:

√ small isodense / large hypodense solid tumor
√ cyst formation in tumor (= central necrosis in 15% of large tumors) / coexistent extramural arachnoid cyst adjacent to tumor
√ usually uniformly dense tumor enhancement with small tumors (50% may be missed without CECT) / ring enhancement with large tumors
√ NO calcification
√ intrathecal contrast / carbon dioxide insufflation (for tumors < 5 mm)

MR (most sensitive test with Gd-DTPA enhancement):

√ iso- / slightly hypointense relative to gray matter on T1WI
√ intensely enhancing homogeneous mass / ringlike enhancement (if cystic) after Gd-DTPA
√ hyperintense on T2WI relative to gray matter (DDx: meningioma remains hypo- / isointense)

Angio:

√ elevation + posterior displacement of anterior inferior cerebellar artery (AICA) on basal view
√ elevation of the superior cerebellar artery (large tumors)

√ displacement of basilar artery anteriorly / posteriorly and to contralateral side
√ compression / posterior and lateral displacement of petrosal vein
√ posterior displacement of choroid point of PICA
√ vascular supply frequently from ECA branches
√ rarely hypervascular tumor with tumor blush
DDx: ossifying hemangioma (bony spiculations)

Trigeminal Schwannoma

= TRIGEMINAL NEUROMA
Incidence: 2–5% of intracranial neuromas, 0.26% of all brain tumors
Origin: arising from gasserian ganglion within Meckel cave at the most anteromedial portion of the petrous pyramid / trigeminal nerve root
[Johann Lorentz Gasser (1723–1765), Austrian anatomist at the Universität Wien, Österreich]
Age: 35– 60 years; M÷F = 1÷2
• symptoms of location in middle cranial fossa:
  • facial paresthesia / hypesthesia
  • exophthalmos, ophthalmoplegia
• symptoms of location in posterior cranial fossa:
  • facial nerve palsy
  • hearing impairment, tinnitus
  • ataxia, nystagmus
Location: (in any segment of trigeminal nerve)
(a) middle cranial fossa (46%) = gasserian ganglion
(b) posterior cranial fossa (29%)
(c) in both fossae (25%)
(d) pterygoid fossa / paranasal sinuses (10%)
√ erosion of petrous tip
√ enlargement of contiguous fissures, foramina, canals
√ dumbbell / saddle-shaped mass (extension into middle cranial fossa + through tentorial incisura into posterior fossa)
√ isodense mass with dense inhomogeneous enhancement ← tumor necrosis + cyst formation
√ distortion of ipsilateral quadrigeminal cistern
√ displacement + cutoff of posterior 3rd ventricle
√ anterior displacement of temporal horn
√ angiographically avascular / hypervascular mass

NEUROSYPHILIS

= consequence of hematogenous dissemination
Risk of progression: 3% if treated with penicillin; accelerated in cell-mediated immunodeficiency (HIV, AIDS)
Types:
(1) **Meningeal neurosyphilis**
Latency period: < 2 years
√ thick nodular meninges + gummas (similar to tuberculosis / sarcoidosis)

(2) **Vascular neurosyphilis**
Latency period: 5–7 years
√ alternating arterial stenoses + dilatations ← large-vessel arteritis
√ parenchymal edema ← perivascular extension of subarachnoid infection / from rare deposition of cerebral gummas
Cx: large- / small-vessel infarctions

(3) **General paresis**
Latency period: 10–20 years

(4) **Tabes dorsalis**
Latency period: 15–20 years

OLIGODENDROGLIOMA

= uncommon form of slowly growing glioma presenting with large size at time of diagnosis

Incidence: 0.3÷100,000 annually; 3rd most common glioma; 2–5% of all primary brain tumors; 5–25% of all glial neoplasms; < 1% of pediatric CNS neoplasms

Path: (a) well-differentiated oligodendroglioma
(b) anaplastic oligodendroglioma (20–54%)
(c) "mixed glioma" containing neoplastic astrocytes (9%)

Histo: monotonous "fried-egg" appearance = uniformly rounded hyperchromatic nuclei surrounded by perinuclear halo of clear cytoplasm; "chicken-wire" pattern = delicate branching network of capillaries; little mitotic activity

Genetics: deletion of alleles at chromosome loci 19q (50–80%) and 1p (40–92%) in well-differentiated tumors

Median age: 35–45 years; M÷F = 2÷1; adult÷child = 8÷1, 6% in childhood (2nd peak at 6–12 years)
◊ Older age is associated with more aggressive tumor behavior!

- long clinical presentation > 5 years
- seizures (35–85%), headache, mental status change
- paralysis (50%), visual loss (49%), papilledema (47%)
  ◊ Worse prognosis with neurologic deficit!
- ataxia (39%), abnormal reflexes (37%), meningismus (10%)

Location:
(a) supratentorial: frontal lobe (50–65%); temporal lobe (47%); parietal lobe (7–20%); occipital lobe (1–4%)
(b) infratentorial: cerebellum (3%); brainstem & spinal cord (1%)
(c) others: leptomeninges ("**oligodendrogliomatosis**"); cerebellopontine angle; cerebral ventricles (3–8%) = "**subependymal oligodendroglioma**"; retina, optic n.

Site: mostly involving cortical gray matter and subcortical white matter; occasionally through corpus callosum as "**butterfly glioma**"

√ round / oval usually sharply marginated mass
√ large nodular clumps of calcifications (in 45% on plain film; in 20–91% on CT)

CT:
√ hypodense (60%) / isodense (23%) / hyperdense (6%) mass
◊ May NOT AT ALL be detectable by CT!

√ cystic degeneration (frequent)
√ hemorrhage (uncommon)
√ ± erosion of inner table of skull (exophytic growth)

CECT:
√ may be adherent to dura (mimicking meningiomas)
√ surrounding vasogenic edema (in 50% of low-grade, in 80% of high-grade tumors)
√ subtle ill-defined enhancement (15–20%) associated with high-grade tumor

MR:
√ well-circumscribed tumor of heterogeneous intensity:
√ hypo- / isointense compared to gray matter on T1WI
√ hyperintense compared to gray matter on T2WI
√ hyperintense signal on DWI + low ADC values in solid tumor portion of high-grade tumors ← restricted water diffusion + lowered extracellular hyaluronic acid
√ little edema / mass effect (common)
√ solid / mixed moderate peripheral enhancement:
› moderate to strong for high-grade glioma
› minimal / none for low-grade glioma
N.B.: lack of enhancement does not equal low-grade
√ calcification may not be detected

SPECT (^{201}Tl) & PET (^{11}C-L–methylmethionine):
√ metabolic rate correlates with histologic grade
√ detects hypermetabolic regions within tumor

Prognosticators of malignant behavior:
› increasing age of patient
› mass effect, cyst formation, necrosis
› moderate to strong enhancement ← disruption of blood-brain barrier
<u>however:</u> up to 25% of high-grade gliomas show faint / no enhancement
› ↓ ADC values in non-enhancing solid tumor portion of high-grade tumor
› ↑ rCBV on perfusion MRI in solid portions + peritumoral region ← tumor neoangiogenesis

Cx: leptomeningeal seeding via CSF (1–15%)

Rx: gross total resection; PCV chemotherapy (procarbazine, lomustine, vincristine); irradiation reserved for chemotherapy failure

Prognosis: 46% 10-year survival rate with low-grade; 20% 10-year survival rate with high-grade; 3–17 years median postop survival

DDx: (1) Astrocytoma (no large calcifications)
(2) Ganglioglioma (in temporal lobes + deep cerebral tissues
(3) Ependymoma (enhancing tumor, often with internal bleeding producing fluid levels)
(4) Glioblastoma (infiltrating, enhancing, edema, NO calcifications)
(5) Central neurocytoma

OSMOTIC DEMYELINATION SYNDROME

= CENTRAL PONTINE MYELINOLYSIS = OSMOTIC MYELINOLYSIS

Predisposed: chronic alcoholic with liver failure (60–70%); malnourished patient; chronically debilitated transplant recipient (liver transplantation with cyclosporine use);

prolonged use of diuretics; extensive burns

Etiology: unknown; comatose patient receiving rapid correction / overcorrection of severe hyponatremia > 12 mmol/L/d (following prolonged IV fluid administration)

Pathophysiology:

rapid correction of sodium → release of myelinotoxic compounds by gray matter components → destruction of myelin sheaths of oligodendrocytes (osmotic myelinolysis with intramyelinitic splitting, vacuolization, rupture of myelin sheath); preservation of neurons + axons

Histo: abundant foamy histiocytes without lymphocytes / neutrophils; luxol fast blue staining demarcates demyelination; neurofilament staining shows preserved neuronal axons

Age: middle age; M > F

- spastic quadriplegia + pseudobulbar palsy (= head and neck weakness, dysphagia, dysarthria)
- encephalopathy with seizures + acute mental status change
- progression to pseudocoma (locked-in syndrome) in 3–5 days
- serial measurements of serum sodium

Location: (a) isolated pons lesion (most commonly)

(b) combined type = central pons + extrapontine areas: globus pallidus, putamen, thalamus, cerebellar white matter, lateral geniculate body, caudate nucleus, subcortical cerebral white matter, corona radiata, hippocampi

typically spared: ventrolateral pons; pontine portion of corticospinal tract

CT:

√ diminished attenuation in central basilar region of pons without mass effect

√ hypoattenuated areas in basal ganglia + thalamus

MR (positive 1–2 weeks post-onset of symptoms):

√ single central symmetric midline pons lesion:

√ hyperintense symmetric trident-shaped / round (coronal scan) + bat-wing configuration (sagittal scan) on T2WI + FLAIR

√ hypointense / (less commonly) isointense on T1WI

√ sparing of ventrolateral pons + pontine portions of corticospinal tracts

√ bilateral symmetric well-demarcated lesions in basal ganglia ± other extrapontine sites

√ ± restricted diffusion (24 hours after onset of symptoms)

√ no enhancement of lesions

Prognosis: 5–10% survival rate beyond 6 months; significant neurologic sequelae (in most)

DDx: hypoxia, Leigh disease, Wilson disease

PARAGONIMIASIS OF BRAIN

= Oriental lung fluke (Paragonimus westermani) producing arachnoiditis, parenchymal granulomas, encapsulated abscesses

√ isodense / inhomogeneous masses surrounded by edema

√ ring enhancement

PELIZAEUS-MERZBACHER DISEASE

[Friedrich Christoph Pelizaeus (1851–1942), neurologist and balneologist in Nassau, Ilmenau, Kreischa and Bad Oeynhausen, Germany]

[Ludwig Merzbacher (1875–1942), neuropathologist and psychiatrist in Freiburg, Heidelberg and at the University of Tübingen, Germany and chief physician at German Hospital in Buenos Aires, Argentina]
= rare X-linked sudanophilic leukodystrophy (5 types with different times of onset, rate of progression, genetic transmission)
Age: neonatal period
• bizarre pendular nystagmus + head shaking; cerebellar ataxia
• slow psychomotor development
CT:
√ hypodense white matter
√ progressive white matter atrophy
MR:
√ lack of myelination (appearance of newborn brain retained)
√ hyperintense internal capsule, optic radiations, proximal corona radiata on T1WI
√ near complete absence of hypointensity in supratentorial region on T2WI
√ mild / moderate prominence of cortical sulci
Prognosis: death in adolescence / early adulthood

PERSISTENT EMBRYONIC INFUNDIBULAR RECESS

= rare congenital malformation of neurohypophysis
• abnormal pituitary function
√ unusual expansion of anterior aspect of 3rd ventricle into sella with loss of normal contours of recesses
√ empty sella = expansion of sella + thinning of pituitary

PICK DISEASE

[Arnold Pick (1851–1924), professor of psychiatry and neurology at the German University in Prague]
= FRONTOTEMPORAL DEMENTIA
= rare form of presenile dementia similar to Alzheimer disease; may be inherited with autosomal dominant mode; M < F
• social impairment + disinhibitive and impulsive behavior
√ focal cortical atrophy of anterior frontal + anterior temporal lobes
√ dilatation of frontal + temporal horns of lateral ventricle
PET:
√ hypometabolism in frontal + anterior temporal lobes + anterior cingulate gyrus
√ temporal lobe involvement extends to anterior aspects (NOT in Alzheimer disease)
√ frontal-predominant form = sparing of temporal lobes

PINEAL CYST

= small nonneoplastic cyst of pineal gland
Incidence: 25–40% on autopsy; 4–23% on imaging
Age: any, predominantly 40–49 years; M < F
Origin:

(a) developmental = persistence of ependymal-lined pineal diverticulum
(b) degenerative = glial-lined secondary cavitation within area of gliosis

Path: uni- / multilocular cyst; inner layer = gliotic tissue, middle layer = pineal parenchymal tissue, outer layer = connective tissue; proteinaceous / hemorrhagic cyst fluid

• rarely cause of hydrocephalus (← compression / occlusion of aqueduct) with headache / visual change
• NEVER associated with Parinaud syndrome

Size: 2–15 mm, remaining stable over time; may be symptomatic if > 15 mm

√ round / oval thin-walled well-circumscribed cyst
√ ± calcification

CT:
√ normal-sized gland (80%), slightly > 1 cm in 20%, can be > 2 cm in size
√ isodense to CSF in surrounding cistern (infrequently noted)

MR:
√ isointense to CSF on T1WI; may have higher signal intensity than CSF ← high protein content
√ slightly hyperintense to CSF on T2WI ← phase coherence in cyst but not in moving CSF
√ signal not completely suppressed on FLAIR ← proteinaceous content
√ typically incomplete enhancement of cyst wall ← fragmentation of pineal parenchyma as cyst enlarges
√ appearance of a solid mass on delayed contrast images (contrast may diffuse from enhanced rim of residual pineal tissue into fluid center ← NO blood-brain barrier)
√ slight impression on superior colliculi (sagittal image)

Prognosis: lack of growth over 9 years (in 75%); rarely "pineal apoplexy" = intracystic hemorrhage

Follow-up: for cysts ≥ 10 mm

DDx: cystic tumors (astrocytoma, pineocytoma, pineoblastoma)

PINEAL TERATOCARCINOMA

= highly malignant variant of germ cell tumors

Types:
1. Choriocarcinoma
2. Embryonal cell carcinoma
3. Endodermal sinus tumor

Histo: arising from primitive germ cells, frequently containing more than one cell type

Age: < 20 years; males

• Parinaud syndrome
• tumor markers elevated in serum + CSF

√ intratumoral hemorrhage (esp. choriocarcinoma)
√ invasion of adjacent structures
√ intense homogeneous contrast enhancement

Cx: seeding via CSF

PINEAL CELL TUMORS

= TUMORS OF PINEAL PARENCHYMAL ORIGIN

Incidence: < 0.2% of intracranial neoplasms

Histo: neuroepithelial neoplasm arising from pineocytes / their precursors

√ similar imaging appearance

√ peripheral displacement of preexisting normal pineal calcification (= "exploded pineal calcification pattern")

Pineoblastoma (40%)

= highly malignant tumor derived from primitive pineal parenchymal cells

Histo: unencapsulated highly cellular primitive embryonal neoplasm composed of diffuse sheets of small round cells with scant cytoplasm (similar to medulloblastoma, neuroblastoma, retinoblastoma) ±

(a) Homer-Wright rosettes (neuroblastic differentiation), or

(b) Flexner-Wintersteiner rosettes (retinoblastic differentiation)

Age: any age, most common in first 2 decades; M÷F = 1÷1

√ usually large lobulated mass

√ obstructive hydrocephalus in almost 100%

CT:

√ poorly marginated iso- / typically hyperdense mass

√ may contain dense tumor calcifications

√ intense homogeneous contrast enhancement

MR:

√ heterogeneous with solid portion iso- / moderately T1 hypointense on T1WI + iso- / mildly T2 hyperintense

√ reduced perfusion ← increased cellularity

√ dense heterogeneous Gd-DTPA enhancement

Cx: hemorrhage, necrosis, spread

Spread:

(1) direct extension posteriorly with invasion of cerebellar vermis + anteriorly into 3rd ventricle

(2) CSF dissemination (frequent) along meninges / via ventricles as most common cause of death

N.B.: common CSF dissemination → image the entire craniospinal axis!

Prognosis: 58% 5-year survival after resection

Pineal Tumor of Intermediate Differentiation (20%)

Age: any with peak in early adulthood; M < F

Histo: diffuse sheets of uniform cells + formation of small rosettes; low to moderate levels of mitotic activity + nuclear atypia

Prognosis: 39–74% 5-year survival after resection

Pineocytoma (14–60%)

= rare slow-growing unencapsulated tumor

Histo: low-grade small uniform mature pineal parenchymal cells with lobular architecture +

pineocytomatous rosettes

Mean age: 38 years; M÷F = 1÷1

Size: < 3 cm

CT:

√ well-marginated slightly hyperdense / isodense mass

√ dense focal tumor calcifications possible

√ well-defined marked homogeneous enhancement

MR:

√ well-circumscribed hypointense / isointense mass on T1WI + hyperintense on T2WI

√ avid homogeneous / internal nodular Gd-DTPA enhancement

Cx: cystic changes: rare CSF dissemination

Prognosis: 86–100% 5-year survival after resection

DDx: pineal cyst (NO trabeculations, NO enhancement)

Trilateral Retinoblastoma *(rare variant in 1.5–5%)*

= uni- / bilateral ocular retinoblastomas + midline small cell tumor

(a) most frequently in the region of the pineal gland (= neuroectodermal pineal tumor = pineoblastoma)

(b) suprasellar region

Frequency: 6% of patients with bilateral disease

• usually family history

◊ Usually diagnosed 21 (range, 6–141) months after discovery of ocular tumor

√ enhancing midline pineal mass

√ isoattenuating relative to gray matter on CT

√ isointense relative to gray matter on T1WI

Cx: intracranial / intraspinal leptomeningeal dissemination

Prognosis: mean survival up to 19 months

PITUITARY ADENOMA

= benign slow-growing neoplasm arising from adenohypophysis (= anterior lobe); most common tumor of adenohypophysis

Prevalence: 5–10–18% of all intracranial neoplasms; < 3% of patients have underlying MEN 1

• pituitary hyperfunction / hypofunction / visual field defect

Plain film (UNRELIABLE):

√ enlargement of sella + sloping of sella floor

√ erosion of anterior + posterior clinoid processes

√ erosion of dorsum sellae

√ calcification in < 10%

√ may present with mass in nasopharynx

NECT:

√ upward convexity of gland

√ increased height > 10 mm

√ deviation of pituitary stalk (nonspecific + unreliable)

√ erosion of floor of sella with adenoma > 5 mm

√ gland asymmetry

CECT (thin section SAG + COR with dynamic bolus injection):
- √ focal hypodensity (most specific for adenoma) before + after IV contrast administration
- √ "pituitary tuft" sign = displacement / compression of visualized capillary bed (sinusoids of mid-anterior lobe) of pituitary by adenoma

MR (thin-section SAG + COR with small field of view):
- ◊ Highest sensitivity on coronal nonenhanced T1WI (70%) + 3-D FLASH sequence (69%) + combination of both (90%)
- ◊ ⅓ of lesions are missed with enhancement
- ◊ ⅓ of lesions are missed without enhancement
- √ focus of low signal intensity on T1WI
- √ focus of high-signal intensity on T2WI
- √ focal hypointensity within normally enhancing gland

DDx: simple pituitary cyst (= Rathke cleft cyst)

Functioning Pituitary Adenoma

◊ Adenoma may secrete multiple hormones!

1. PROLACTINOMA (30%)

   = most common of pituitary adenomas; ~ 50% of all cranial tumors at autopsy; M << F

   • prolactin levels do not closely correlate with tumor size

   ◊ Any mass compressing hypothalamus / pituitary stalk diminishes the tonic inhibitory effect of dopaminergic factors, which originate there → hyperprolactinemia

   Female:

   Age: 15–44 years (during childbearing age)

   • infertility, amenorrhea, galactorrhea

   • elevated prolactin levels (normal < 20 ng/mL)

   ◊ > 75% of patients with serum prolactin levels > 200 ng/mL will show a pituitary tumor!

   Male:

   • headache, visual disturbance

   • impotence + decreased libido

   √ characteristic lateral location / anteriorly / inferiorly; variable in size

   Rx: bromocriptine

2. CORTICOTROPHIC ADENOMA (14%)

   Function: ACTH-secreting tumor

   Age: 30–40 years; M÷F = 1÷3

   • Cushing disease

   √ central location; posterior lobe; usually < 5 mm in size

   √ blood sampling of inferior petrosal sinuses (95% diagnostic accuracy compared with 65% for MR)

   Rx: (1) suppression by high doses of dexamethasone of 8 mg/d

   (2) surgical resection difficult because ACTH adenomas usually require resection of an apparently normal gland (tumor small + usually not on surface of gland)

3. SOMATOTROPHIC ADENOMA (14%)

   • gigantism, acromegaly, elevated GH > 10 ng/mL, NO rise in GH after administration of

glucose / TRH

Histo: (a) densely granulated type
(b) sparsely granulated type: more aggressive

√ hypodense region, may be less well-defined, variable size

4. GONADOTROPHIC CELL ADENOMA (7%)
   secretes follicle-stimulating hormone (FSH) / luteinizing hormone (LH)
   √ slow-growing often extending beyond sella
5. THYROTROPHIC CELL ADENOMA (< 1%)
   secretes thyroid-stimulating hormone (TSH)
   √ often large + invasive pituitary adenoma
6. PLURIHORMONAL PITUITARY ADENOMA (> 5%)

Nonfunctioning Pituitary Adenoma

1. NULL CELL ADENOMA
   = hormonally inactive pituitary tumor with no histologic / immunologic / ultrastructural markers to indicate its cellular derivation
   Prevalence: 17% of all pituitary tumors
   Age: older patient
   √ slow-growing
2. ONCOCYTOMA
   Prevalence: 10% of all pituitary tumors
   • clinically + morphologically similar to null cell adenoma

Pituitary Macroadenoma

= tumor > 10 mm in size
Incidence: 10% (= 70–80% of pituitary adenomas)
Age: 25–60 years; M÷F = 1÷1

• symptoms of mass effect: hypopituitarism, bitemporal hemianopia (with superior extension), pituitary apoplexy, hydrocephalus, cranial nerve involvement III, IV, VI
• usually endocrinologically inactive

Extension into: suprasellar cistern / cavernous sinus / sphenoid sinus + nasopharynx (up to 67% invasive)

√ occasionally tumor hemorrhage
√ lucent areas ← cysts / focal necrosis
√ invasion of cavernous sinus → encasement of carotid artery (SUREST sign)

CT:
√ tumor isodense to brain tissue
√ erosion of bone (eg, floor of sella)
√ calcifications infrequent

MR: (allows differentiation from aneurysm)
√ homogeneous enhancement

Cx:
(1) Obstructive hydrocephalus (at foramen of Monro)
(2) Encasement of carotid artery
(3) Pituitary apoplexy (rare)

DDx:

(1) Metastasis (more bone destruction, rapid growth)

(2) Pituitary abscess

Pituitary Microadenoma

= very small adenoma < 10 mm in size

• usually become clinically apparent by hormone production (20–30% of all pituitary adenomas)

◊ Prolactin elevation (> 25 ng/mL in females)

4–8 x normal: adenoma demonstrated in 71%

> 8 x normal: adenoma demonstrated in 100%

• **incidentaloma** = nonfunctioning microadenoma / pituitary cyst

√ NO imaging features to distinguish between different types of adenomas

MR:

√ small nonenhancing mass of hypointensity on pre- and postcontrast T1WI

√ occasionally isointense on precontrast images + hyperintense on postcontrast images

√ enhancement on delayed images

√ focal bulge on surface of gland

√ focal depression of sellar floor

√ deviation of pituitary stalk

PITUITARY APOPLEXY

= rare clinical syndrome of acute hemorrhagic / ischemic transformation of normal / tumorous adenohypophysis

Cause: massive hemorrhage into pituitary adenoma (especially in patients on bromocriptine for pituitary adenoma) / dramatic necrosis / sudden infarction of pituitary gland

Sheehan syndrome = necrosis of anterior pituitary gland ← postpartum infarct ← hemorrhagic shock of complicated delivery

◊ Only 25% of patients with intratumoral hemorrhage will present with apoplexy!

• severe headache, stiff neck, nausea, vomiting, hypertension

• sudden visual-field defect, ophthalmoplegia

• obtundation (frequent)

• hypopituitarism (eg, secondary hypothyroidism)

◊ Area of destruction must be > 70% to produce pituitary insufficiency!

√ enlargement of pituitary gland

NECT:

√ increased density ± fluid level

MR:

◊ 20% of all pituitary adenomas show evidence of hemorrhage by MR!

√ mass lesion of heterogeneous signal intensity:

√ sellar enlargement (= macroadenoma)

√ high signal on DWI (in acute stage) ← restricted diffusion

√ predominant T1 hyperintensity + predominant T2 hypointensity ← hemoglobin

√ intermediate SI on T1WI + T2WI ← deoxyhemoglobin

√ intratumoral fluid-debris level ← sedimentation of blood products (at later stage)
DDx: Rathke cleft cyst (NO hemorrhage, NO fluid-fluid level)
√ mucosal thickening of sphenoid sinus ← venous engorgement of acute stage

PONTINE TEGMENTAL CAP DYSPLASIA

= sporadic malformation with unknown genotype
• hearing loss, facial paralysis, trigeminal anesthesia
• difficulty in swallowing
√ flattened ventral pons
√ vaulted pontine tegmentum ("cap")
√ partial absence of middle cerebellar peduncles
√ vermian hypoplasia
√ molar tooth–like aspect of pontomesencephalic junction
√ absent inferior olivary prominence

PORENCEPHALY

= focal cavity as a result of localized brain destruction

A. AGENETIC PORENCEPHALY
= SCHIZENCEPHALY = TRUE PORENCEPHALY

B. ENCEPHALOCLASTIC PORENCEPHALY
Time of injury: during first half of gestation
Histo: necrotic tissue completely reabsorbed without surrounding glial reaction (= liquefaction necrosis)
MR:
√ smooth-walled cavity filled with CSF on all pulse sequences (= porencephalic cyst)
√ lined by white matter

C. ENCEPHALOMALACIA
= PSEUDOPORENCEPHALY = ACQUIRED PORENCEPHALY
= end result of destructive process with replacement by CSF
Prevalence: 2.5% of children with perinatal brain injury
Cause: intraparenchymal hemorrhage, infection, surgery
Time of injury: after end of 2nd trimester / postnatally (brain has developed capacity for glial response)
Location: parasagittal watershed areas with sparing of periventricular region + ventricular wall

CT:
√ hypodense regions
MR:
√ hypointense on T1WI + hyperintense on T2WI
√ surrounding hyperintense rim on T2WI (= gliosis)
√ glial septa coursing through cavity identified on T1WI + proton density images
US:
√ damaged area hyperechoic (during first days to weeks) following initial hemorrhagic event
√ subsequent conversion to area with anechoic center and echogenic border ← clot retraction

√ ultimately completely anechoic cystic area ← CSF:
√ septations in cavity well visualized
√ ± discrete wall calcifications

POSTERIOR REVERSIBLE ENCEPHALOPATHY SYNDROME

= (PRES) = REVERSIBLE POSTERIOR LEUKOENCEPHALOPATHY SYNDROME = HYPERTENSIVE ENCEPHALOPATHY
= heterogeneous collection of disorders associated with a breakdown in cerebral autoregulatory perfusion mechanisms
◊ Emergency condition as patient may proceed to cerebral infarction and death if untreated!
Cause: acute rise in systemic blood pressure, preeclampsia or eclampsia, hemolytic uremic syndrome, cryoglobulinemia, SLE, following immunosuppressive treatment with cyclosporine A, cisplatin, tacrolimus (= **T**sukuba m**acrol**ide **im**m**u**no**s**uppressan = FK-506)
Pathophysiology: vasogenic edema related to sparse sympathetic innervation in posterior circulation
• headache, nausea, vomiting, visual changes
• decreased alertness, seizures
Location: white matter of posterior half of brain
√ hypodense white matter on NECT
√ lesion hypointense on T1WI + hyperintense on T2WI ← vasogenic edema (= fluid extravasation into interstitium)
√ lesion hypo- to isointense on DWI + hyperintense on ADC map (due to a net effect of elevated diffusion coefficient from vasogenic edema + T2 shine-through effect)
√ NO contrast enhancement
Cx: infarction (lesions develop high DWI signal + normal ADC signal)
Rx: rapid control of blood pressure / withdrawal of offending drug

PRIMARY ANGIITIS OF CNS

= PACNS = idiopathic inflammatory disease of medium-sized to small arteries affecting CNS / peripheral nervous system WITHOUT evidence of generalized inflammation

Age: 5–6th decade
• acute / subacute confusion, hallucinations, headache
• paresis, cranial neuropathy, loss of consciousness
• elevated inflammatory markers: ↑ ESR
• CSF analysis: ↑ opening pressure, ↑ protein level
Location: spinal cord abnormalities (5%)
◊ Nonspecific CT and MR imaging findings!
CT:
√ areas of low attenuation ← suggestive of ischemic events
MR:
√ discrete / diffuse supra- and infratentorial lesions involving deep + superficial white matter
√ ± vessel irregularities
√ ± areas of infarct + hemorrhage

√ lesion enhancement in 90%

DSA (supports diagnosis in spite of negative biopsies):

√ focal / multifocal segmental narrowing / occlusion / irregularities in both hemispheres

√ collateral vessel formation

√ prolonged circulation time

√ microaneurysm (unusual)

Subsets:

1. Hemorrhagic form (11–12%)
   Cause: hemorrhagic transformation of recent infarction / focal necrosis of intracerebral blood vessel
   √ intracerebral > subarachnoid hemorrhage
2. Pseudotumoral form (15%)
   √ nonspecific mass lesions characterized by central necrosis, surrounding edema, infiltration of adjacent structures, mass effect, variable contrast enhancement
   N.B.: often misinterpreted as malignant neoplasms
3. Rapidly progressive primary vasculitis of CNS
   √ numerous bilateral lesions of large cerebral vessels
   √ several bilateral cerebral infarctions
   Prognosis: poor, often fatal
4. Angiography-negative, biopsy-positive PACNS
   Site: small arteries / arterioles
   • cognitive dysfunction, ⇑ CSF protein
   √ meningeal / parenchymal enhancing lesions at MR
   Prognosis: good with favorable response to treatment
5. Childhood PACNS
   Site: unilateral, proximal, multifocal, supratentorial involving gray + white matter with preference for basal ganglia / lateral lenticulostriate vasculature; frequently terminal segment of ICA and proximal segments of ACA + MCA

Dx: leptomeningeal + brain parenchymal biopsies

Rx: high-dose steroids, cytotoxic agents

PRIMITIVE NEUROECTODERMAL TUMOR

= PNET = PRIMARY CEREBRAL NEUROBLASTOMA

= group of very undifferentiated tumors arising from germinal matrix cells of primitive neural tube = rare presentation of neuroblastoma

Incidence: < 5% of supratentorial neoplasms in children, 30% of posterior fossa tumors

Age: mainly in children < 5 years of age/ early adolescence; M÷F = 1÷1

Path: most undifferentiated form of malignant small cell neoplasms grouped with Ewing sarcoma, Askin tumor

Histo: highly cellular tumor composed of > 90–95% undifferentiated cells (histologically similar to medulloblastoma, pineoblastoma, peripheral neuroblastoma)

• signs of increased intracranial pressure / seizures

Location:

(a) supratentorial: deep cerebral white matter (most commonly in frontal lobe), pineal gland,

in thalamic + suprasellar territories (least frequently)
(b) posterior fossa (= medulloblastoma)
(c) outside CNS: chest wall, paraspinal region, kidney

√ large (hemispheric) heterogeneous mass with tendency for central necrosis (65%), cyst formation, hemorrhage (10%)
√ intratumoral coarse dense calcifications (71%)
√ thin rim of edema
√ mild / moderate enhancement of solid tumor portion

CT:
√ large hypodense / mixed-density mass with well-defined margins
√ solid tumor portions hyperdense ← high nuclear to cytoplasmic ratio

MR:
√ mildly hypointense on T1WI + hyperintense on T2WI
√ remarkably inhomogeneous due to cyst formation + necrosis
√ areas of signal dropout due to calcifications
√ hyperintense areas on T1WI + variable intensity (usually intermediate) on T2WI due to hemorrhage
√ inhomogeneously moderately enhancing mass with tumor nodules + ringlike areas surrounding central necrosis after Gd-DTPA

Cx: meningeal + subarachnoid seeding (15–40%)
DDx: Neuroblastoma usually NOT metastatic to brain!

Primitive Neuroectodermal Soft-tissue Tumor

√ tumor of low to intermediate attenuation
√ NO evidence of calcification
√ low to intermediate signal intensity on T1WI + high signal intensity on T2WI
√ often peripheral low-SI vascular channels ← high-flow
√ areas of hemorrhage (common)
√ well-defined tumor margins with pseudocapsule / infiltrative appearance

PROGRESSIVE MULTIFOCAL LEUKO-ENCEPHALOPATHY

= rapidly progressive fatal demyelinating disease in patients with impaired immune system (chronic lymphocytic leukemia, lymphoma, Hodgkin disease, carcinomatosis, AIDS, tuberculosis, sarcoidosis, organ transplant)
Prevalence: 4% of AIDS patients
Etiology: reactivation of ubiquitous JC papovavirus
Pathophysiology: destruction of oligodendrogliocytes leading to areas of demyelination + edema
Histo: intranuclear inclusion bodies within swollen oligodendrocytes (viral particles in nuclei); lysis of oligodendrocytes → demyelination; absence of significant perivenous inflammation

• progressive neurologic deficits, dementia, ataxia, spasticity
• speech, motor and visual disturbances; normal CSF fluid

Location: frontoparietal > temporo-occipital cerebral hemispheres; white matter tracts in cerebellum, brainstem, deep gray matter; ? predilection for parieto-occipital region

Site: subcortical white matter spreading centrally into brainstem, deep gray matter
√ bilateral white matter lesions (92%); confluent (94%); discrete (67%) in periventricular region + centrum semiovale + subcortical white matter
√ gray matter lesions in thalamus + basal ganglia (from involvement of traversing white matter tracts)
√ sparing of cortical gray matter
√ mild cortical atrophy (up to 69%)
√ ventricular dilatation (50%)
√ NO contrast enhancement
CT:
√ multicentric confluent white matter lesions of low attenuation with scalloped borders along cortex
√ NO mass effect, NO edema
MR:
√ hypointense lesions on T1WI
√ patchy hyperintense lesions of white matter away from ependyma in asymmetric distribution on T2 + FLAIR
√ NO enhancement
Prognosis: death usually within 6 months
DDx in early stages: primary CNS lymphoma

RATHKE CLEFT CYST

[Martin Heinrich Rathke (1793–1860), professor of physiology and pathology at the University of Dorpat (Tartu), Estonia and professor of zoology and anatomy in Königsberg, Germany]
= usually asymptomatic benign cystic sellar lesion
Histo: lined with single layer of epithelial cells; CSF / mucopolysaccharide content
• often asymptomatic
• hypopituitarism, visual disturbance, headache (in older patients)
Location: commonly midline at junction of anterior + posterior pituitary lobes anterior to infundibular stalk; intra- and suprasellar (71%); purely suprasellar (rare)
√ may contain thick mucinous material
√ no contrast enhancement
√ calcifications rare
MR:
√ round well-demarcated lesion
√ variable SI ranging from hypo- to hyperintense on T1WI ← dependent on biochemical content:
√ homogeneously high T1 SI (50%) ← high protein content
√ low T2 intensity (30%) ← low intracystic water content
√ simple / complex cyst content ± fluid-fluid level
√ NO central enhancement / hemorrhagic component
√ small intracystic nodules of lower T2 + higher T1 SI (75%) ← proteinaceous concretions
√ wall enhancement due to squamous metaplasia / displaced rim of pituitary tissue
DDx: craniopharyngioma, macroadenoma (hemorrhagic fluid-debris level)

REYE SYNDROME

[Ralph Douglas Kenneth Reye (1912–1977), director of pathology of the Royal Alexandra Hospital for Children in Sydney, Australia]

= hepatitis + encephalitis following viral upper respiratory tract infection with history of large doses of aspirin ingestion

Age: in children + young adults

• obtundation rapidly progressing to coma

√ initially (within 2–3 days) small ventricles

√ later progressive enlargement of lateral ventricles + sulci

√ markedly diminished attenuation of white matter

Mortality: 15–85% (from white matter edema + demyelination)

Dx: liver biopsy

RHOMBENCEPHALOSYNAPSIS

= characterized by absence of vermis + continuity of cerebellar hemispheres, dentate nuclei, superior cerebellar peduncles

Associated with: Gómez-López-Hernández syndrome (parietal alopecia, trigeminal anesthesia, craniofacial dysmorphic signs); VACTERL

• truncal ± limb ataxia, delayed motor development

• abnormal eye movements

√ agenesis or hypogenesis of vermis

√ keyhole-shaped fourth ventricle ← horseshoe-shaped arch across midline ← fusion (continuity) of cerebellar hemispheres + superior cerebellar peduncles + dentate nuclei

√ abnormal transverse orientation of cerebellar foliae

Prognosis: varying between severe impairment and normalcy

ROSAI-DORFMAN DISEASE

= rare benign histiocytosis

Etiology: reaction to infectious agents / autoimmune process

Histo: polymorphous infiltrate of lymphoplasmacytic cells and histiocytes of varying size embedded in fibrous stroma; S-100 + CD68 positive; CD1a negativity excludes Langerhans histiocytosis; CHARACTERISTIC emperipolesis (= phagocytosis of lymphocytes) in 70%
[*em*, Greek = inside, *peri* = around, *polemai* = wander about]

A. EXTRACRANIAL

Age: primarily in children + young adults; M > F

• painless bilateral cervical adenopathy + involvement of nasal cavity, bone, orbit

B. INTRACRANIAL (40%)

Age: 4th–5th decades; M÷F=3÷1

Location: cerebral convexities, parasagittal, petroclival, suprasellar regions

• headache, visual change, seizures, numbness, paraplegia

√ well-circumscribed dural-based iso- to hyperattenuating single / multiple masses

√ isointense on T1WI + iso- to hypointense on T2WI:

√ central low SI on T2WI ← release of free radicals by inflammatory macrophages

√ marked enhancement + dural tail (common)
√ edema within adjacent brain parenchyma (frequent)
DDx: meningioma (iso- to hyperintense on T2WI)

SCHISTOSOMIASIS OF CNS

Transmission: embolic distribution of ova through venous shunts / anomalous migration of adult worms
Cause: granuloma formation

Cerebral Schistosomiasis

Organism: primarily S. japonicum
• fever, focal neurologic deficits, seizures
Location: cerebellum, cerebral hemispheres, thalamus, dura
CT:
√ single / multiple variably enhancing hyperattenuated lesions ± surrounding hypoattenuated edema ← focal granulomatous reaction
√ nodular / ring / patchy enhancement
MR:
√ bilateral symmetric T1 hyperintensities of globus pallidus + substantia nigra ← manganese deposition related to portosystemic shunt
√ "arborized" T1-enhancement pattern with central linear enhancement (? specific)

Spinal Schistosomiasis

Organism: primarily S. mansoni + hematobium
• acute / subacute transverse myelitis (common): back pain, urinary retention, motor + sensory disturbances
Location: distal thoracic spinal cord, cauda equina ← presumably via vertebral venous (Batson) plexus
MR:
√ T2 hyperintensity ← granulomatous involvement
√ "arborized" T1-enhancement pattern
Cx: (1) spinal cord compression (by focal granuloma)
(2) anterior spinal artery syndrome (rare)

SCHIZENCEPHALY

= AGENETIC PORENCEPHALY = TRUE PORENCEPHALY
= "split brain"
= rare CNS malformation consisting of a <u>full-thickness</u> CSF-filled parenchymal cleft lined by gray matter extending from subarachnoid space to subependyma of lateral ventricles
Frequency: 1÷1,650
Cause: ? vascular ischemia of portion of germinal matrix / genetic mutation → segmental developmental failure of neuronal cell migration to form cerebral cortex; NOT porencephaly
Time of injury: 30–60 days of gestation
Often associated with: polymicrogyria, microcephaly, gray matter heterotopia, septooptic

dysplasia

Types:

(1) **Closed-lip schizencephaly** (type 1) = gray matter-lined lips in contact with each other (may be missed in imaging planes parallel to the plane of cleft)
√ walls appose one another obliterating CSF space

(2) **Open-lip schizencephaly** (type 2) = separated lips
√ CSF-cleft from wall of lateral ventricle to pial surface

- seizure disorder
- motor + mental deficiencies correlate with extent of defect:
  - mild / moderate developmental motor delay
  - range of normal mentation to severe mental retardation
- blindness possible (optic nerve hypoplasia in 33%)

Location: most commonly near pre- and postcentral gyri (sylvian fissure); uni- / (mostly) bilateral; in middle cerebral artery distribution

√ cleft from ependyma of lateral ventricle to pial surface of cortex:
√ cleft lined by gray matter (PATHOGNOMONIC)
√ full-thickness cleft through hemisphere with irregular margins
√ asymmetrical dilatation of lateral ventricles with midline shift
√ wide separation of lateral ventricles + squaring of frontal lobes
√ ventricle wall may be tented pointing to defect
√ absence of cavum septi pellucidi (66%)
√ absence / focal thinning of corpus callosum
√ cleft lined by polymicrogyria (66%) + heterotopias (common)
√ abnormal gyral pattern adjacent to cleft = "gyri dive into cleft"
√ polymicrogyria / pachygyria adjacent / remote to cleft
√ bilateral often symmetric intracranial cysts, usually around sylvian fissure

Prognosis: severe intellectual impairment, spastic tetraplegia, blindness

DDx: (1) Pseudoporencephaly = acquired porencephaly = local parenchymal destruction ← vascular / infectious / traumatic insult (almost always unilateral, lined by gliotic white matter on MRI)
(2) Arachnoid cyst
(3) Cystic tumor

SEPTOOPTIC DYSPLASIA

= DE MORSIER SYNDROME

[Georges de Morsier (1894–1982), professor of neurology and director of the neurological clinic of the university of Geneva, Switzerland]

= rare anterior midline anomaly with
(1) Hypoplasia of optic nerves
(2) Hypoplasia / absence of septum pellucidum

◊ Often considered a mild form of lobar holoprosencephaly

Cause: insult between 5–7th week of GA; M÷F = 1÷3

Associated with: schizencephaly (50%)

- hypothalamic hypopituitarism (66%):

diabetes insipidus (in 50%), growth retardation (← deficient secretion of growth hormone + thyroid stimulating hormone)

- diminished visual acuity (hypoplasia of optic discs), nystagmus, occasionally hypotelorism; seizures, hypotonia

√ small optic canals
√ hypoplasia of optic nerves + chiasm + infundibulum
√ dilatation of chiasmatic + suprasellar cisterns
√ fused dilated boxlike frontal horns squared off dorsally + pointing inferiorly
√ bulbous dilatation of anterior recess of 3rd ventricle
√ hypoplastic / absent septum pellucidum
√ thin corpus callosum

STURGE-WEBER-DIMITRI SYNDROME

= ENCEPHALOTRIGEMINAL ANGIOMATOSIS = MENINGOFACIAL ANGIOMATOSIS

[William Allen Sturge (1850–1919), physician and pathologist to the Royal Free Hospital in London, England
Frederick Parkes Weber (1863–1962, dermatologist and honorary physician to the German Hospital, Queen Square, London, England
Vincente Dimitri (1885–1955), Austrian dermatologist in Argentina]

= vascular malformation with capillary venous angiomas in distribution of trigeminal nerve with ipsilateral leptomeningeal malformation + atrophy + calcification of subjacent cerebral cortex, malformation of choroid of eye, and face

Cause: persistence of transitory primordial sinusoidal plexus stage of vessel development; usually sporadic

- seizures (80%) in 1st year of life: usually focal involving the side of the body contralateral to nevus flammeus
- mental deficiency (> 50%); homonymous hemianopia
- increasing crossed hemiparesis (35–65%)
- hemiatrophy of body contralateral to facial nevus ← hemiparesis

@ FACIAL MANIFESTATION

- congenital facial **port-wine stain** (nevus flammeus) = telangiectasia of trigeminal region; usually 1st ± 2nd division of 5th nerve and usually unilateral
  - › V_1 associated with occipital lobe angiomatosis
  - › V_2 associated with parietal lobe angiomatosis
  - › V_3 associated with frontal lobe angiomatosis

@ CNS MANIFESTATION

√ leptomeningeal venous angiomas confined to pia mater
Location: parietal > occipital > frontal lobes
√ cortical hemiatrophy beneath meningeal angioma ← anoxia (steal)
√ "tram track" gyriform cortical calcifications > 2 years of age; in layers 2-3 (-4-5) of opposing gyri underlying pial angiomatosis; bilateral in up to 20%
Location: temporoparieto-occipital area, occasionally frontal, rare in posterior fossa
√ subjacent white matter hypodense on CT
√ slight prolongation of T1 + T2 relaxation times (gliosis)

√ choroid plexus enlargement ipsilateral to angiomatosis
√ ipsilateral thickening of skull + orbit ← bone apposition as result of subdural hematoma ← brain atrophy
√ elevation of sphenoid wing + petrous ridge
√ enlarged ipsilateral paranasal sinuses + mastoid air cells
√ thickened calvarium (= widening of diploic space)
Angio:
√ capillary blush
√ abnormally large veins in subependymal + periventricular regions
√ abnormal deep medullary veins draining into internal cerebral vein (= venous shunt)
√ failure to opacify superficial cortical veins in calcified region ← markedly slow blood flow / thrombosis of dysgenetic superficial veins

@ ORBITAL MANIFESTATION (30%)
Site: ipsilateral to nevus flammeus
• congenital glaucoma (30%)
√ choroidal hemangioma (71%)
√ dilatation and tortuosity of conjunctival + episcleral + iris + retinal vessels
√ buphthalmos
Cx: retinal detachment

@ VISCERAL MANIFESTATION
√ localized / diffuse angiomatous malformation
Location: intestine, kidneys, spleen, ovaries, thyroid, pancreas, lungs

DDx: Klippel-Trénaunay syndrome, Wyburn-Mason syndrome

SUBARACHNOID HEMORRHAGE

= blood between pia + arachnoid membrane

Cause:

A. Spontaneous
(1) Ruptured aneurysm (72%)
(2) AV malformation (10%)
(3) Hypertensive hemorrhage
(4) Hemorrhage from tumor
(5) Embolic hemorrhagic infarction
(6) Blood dyscrasia, anticoagulation therapy
(7) Eclampsia
(8) Intracranial infection
(9) Spinal vascular malformation
(10) Cryptogenic in 6% (negative 4-vessel angiography; seldom recurrent)

B. Trauma (common)
concomitant to cerebral contusion
(1) Injury to leptomeningeal vessels at vertex
(2) Rupture of major intracerebral vessels (less common)
Location:
(a) focal, overlying site of contusion / subdural hematoma

(b) interhemispheric fissure, paralleling falx cerebri
(c) spread diffusely throughout subarachnoid space (rare in trauma): convexity sulci > basal cisterns

Pathophysiology: irritation of meninges by blood and extra fluid volume increases intracranial pressure → vasospasm in 2–41%

- acute severe headache ("worst in life"), vomiting
- altered state of consciousness: drowsiness, sleepiness, stupor, restlessness, agitation, coma
- spectrophotometric analysis of CSF obtained by lumbar puncture

NECT (60–90% accuracy of detection depending on time of scan; sensitivity depends on amount of blood; accuracy high within 4–5 days of onset, 90% sensitive within 1st day):

√ increased density in basal cisterns, superior cerebellar cistern, sylvian fissure, cortical sulci, intraventricular
√ along interhemispheric fissure = on lateral aspect irregular dentate pattern due to extension into paramedian sulci with rapid clearing after several days
√ "cortical vein" sign = visualization of cortical veins passing through extraaxial fluid collection

MR (relatively insensitive within first 48 hours):

√ hyperintense sulci and cisterns on FLAIR and T2* (more sensitive than CT for small amounts of blood)
√ "dirty" CSF isointense to brain on T1WI + T2WI
√ low signal intensity on brain surfaces in recurrent subarachnoid hemorrhages (hemosiderin deposition)

Prognosis: clinical course depends on amount of subarachnoid blood

Cx:

(1) Acute obstructive hydrocephalus (in < 1 week) ← intraventricular hemorrhage / ependymitis obstructing aqueduct of Sylvius or outlet of 4th ventricle
(2) Delayed communicating hydrocephalus (after 1 week) ← fibroblastic proliferation in subarachnoid space and arachnoid villi interferes with CSF resorption
(3) Cerebral vasospasm + infarction (develops after 72 hours, at maximum between 5–17 days, amount of blood is a prognostic parameter)
(4) Transtentorial herniation (cerebral hematoma, hydrocephalus, infarction, brain edema)

SUBDURAL HEMATOMA OF BRAIN

= accumulation of blood in potential space between pia-arachnoid membrane (leptomeninges) + dura mater (= "epiarachnoid space")

Incidence: in 5% of head trauma patients; in 15% of closed head injuries; in 65% of head injuries with prolonged interruption of consciousness

Age: accident-prone middle age; also in infants + elderly (large subarachnoid space with freedom to move in brain atrophy)

Cause: severe trauma, hemorrhagic diathesis

Source of blood:

(1) pial cortical arteries + veins: direct trauma = penetrating injury
(2) large contusions: direct / indirect trauma = "pulped brain"; occasionally in blood clotting disorder / during anticoagulation therapy

(3) torn bridging cortical veins (indirect force) ← sudden de-/acceleration; also with forceful coughing / sneezing / vomiting in elderly

Elderly predisposed: longer bridging veins in brain atrophy

◊ NO consistent relationship to skull fractures!

Pathogenesis:

differential movement of brain and adherent cortical veins with respect to skull + attached dural sinuses → tear of "bridging veins" (= subdural veins which connect cerebral cortex to dural sinuses + travel through subarachnoid and subdural space)

Location: hematoma freely extending across suture lines, limited only by interhemispheric fissure and tentorium

- nonspecific headaches, nonlocalizing signs; low-voltage EEG
- lethargy, confusion; usually negative lumbar puncture

CT:

√ hyperdense 65–90 HU (< 1 week) / isodense 20–40 HU (1–2 weeks) / hypodense 0–22 HU (3–4 weeks)

False-negative CT scan:

high-convexity location, beam-hardening artifact, volume averaging with high density of calvarium obscuring flat "en plaque" hematoma, too narrow window setting, isodense hematoma due to delay in imaging 10–20 days post injury / low hemoglobin content of blood / lack of clotting, dilution by CSF from associated arachnoid tear

◊ 38% of small subdural hematomas are missed!

Aids in detection of acute subdural hematoma:

√ perceived "thickening" of ipsilateral portion of skull (hematoma of similar pixel brightness as bone)
√ "subdural window" setting = window level of 40 HU + window width of 400 HU
√ effacement of adjacent sulci
√ sulci not traceable to brain surface
√ ipsilateral ventricular compression / distortion
√ displacement of gray-white matter interface away from ipsilateral inner table
√ midline shift (often greater than width of subdural hematoma due to underlying brain contusion)
√ contrast enhancement of cortex but not of subdural hematoma

Aids in detection of bilateral subdural hematomas:

√ "parentheses" ventricles
√ ventricles too small for patient's age

US (neonate):

√ linear / elliptical space between cranial vault + brain
√ flattened gyri + prominent sulci
√ ± distortion of ventricles, extension into interhemispheric space

Limitations:

(a) convexity hematoma may be obscured by pie-shaped display + loss of near-field resolution
◊ Use contralateral transtemporal approach!
(b) small loculations may be missed

Prognosis: poor (due to association with other lesions)
DDx: (1) Arachnoid cyst (extension into sylvian fissure)
(2) Subarachnoid hemorrhage (extension into sulci)

Acute Subdural Hematoma

Cause: usually follows severe trauma, manifests within hours after injury
Time frame: < 7 days old
Associated with: underlying brain injury (50%) with worse long-term prognosis than epidural hematoma, skull fracture (1%)
Location:
(a) over cerebral convexity, frequent extension into interhemispheric fissure, along tentorial margins, beneath temporal + occipital lobes; NO crossing of midline
(b) bilateral in 15–25% of adults (common in elderly) and in 80–85% of infants
√ extraaxial peripheral crescentic / convex fluid collection between skull and cerebral hemisphere usually with:
√ concave inner margin ← hematoma minimally pressing into brain substance
√ convex outer margin ← following normal contour of cranial vault
√ hyperdense collection of 65–100 HU
◊ Hematoma hypodense if hematocrit < 29%!
√ "swirl" sign = mixture of clotted and unclotted blood
√ occasionally with blood-fluid level
√ after surgical evacuation → underlying parenchymal injury becomes more obvious
√ after healing → ventricular + sulcal enlargement
Cx: Arteriovenous fistula ← meningeal artery + vein caught in fracture line
Prognosis: may progress to subacute + chronic stage / may disappear spontaneously
Rx: evacuation, but with poor response ← high uncontrollable intracranial pressure from associated injuries
Mortality: 35–50% (higher number due to associated brain injury, mass effect, old age, bilateral lesions, rapid rate of hematoma accumulation, surgical evacuation > 4 hours)

Interhemispheric Subdural Hematoma

Most common acute finding in child abuse ← whiplash forces on large head + weak neck muscles
√ predominance for posterior portion of interhemispheric fissure
√ crescentic shape with flat medial border
√ unilateral increased attenuation with extension along course of tentorium
√ anterior extension to level of genu of corpus callosum

Subdural Hemorrhage in Newborn

Cause: mechanical trauma during delivery (excessive vertical molding of head)
1. **Posterior fossa hemorrhage**
(a) tentorial laceration with rupture of vein of Galen / straight sinus / transverse sinus
(b) occipital osteodiastasis = separation of squamous portion from exoccipital portion of occipital bone

√ high-density "thickening" of affected tentorial leaf extending down posterior to cerebellar hemisphere (better seen on coronal view)
√ mildly echogenic subtentorial collection
Cx: death from compression of brainstem → acute hydrocephalus

2. **Supratentorial hemorrhage**
   (a) laceration of falx near junction with tentorium ← rupture of inferior sagittal sinus (less common than tentorial laceration)
   √ hematoma over corpus callosum in inferior aspect of interhemispheric fissure
   (b) convexity hematoma ← rupture of superficial cortical veins
   √ usually unilateral subdural convexity hematoma accompanied by subarachnoid blood
   √ underlying cerebral contusion
   √ sonographic visualization of convexities difficult

Subacute Subdural Hematoma

Time frame: 7–22 days

CT:
√ isodense hematoma of 25–45 HU (during 1st–3rd week), may be recognizable by mass effect:
√ effacement of cortical sulci
√ deviation of lateral ventricle
√ midline shift
√ white matter buckling
√ displacement of gray-white matter junction
√ contrast enhancement of inner membrane
Aid in Dx: contrast enhancement defines cortical-subdural interface

MR (modality of choice in subacute stage):
√ high sensitivity for Met-Hb on T1WI (<u>superior to CT during isodense phase</u> concerning small subdural hematomas + for hematomas oriented in the CT scan plane, eg, tentorial subdural hematoma):
√ hyperintense on T1WI

Chronic Subdural Hematoma

Time frame: > 22 days old

Cause: mild unremembered head trauma ?

Pathogenesis: vessel fragility accounts for repeated episodes of rebleeding (in 10–30%) following minor injuries that tear a <u>fragile capillary bed within neomembrane</u> surrounding subdural hematoma

Predisposing factors:
alcoholism, increased age, epilepsy, coagulopathy, prior placement of ventricular shunt

◊ > 75% occur in patients > 50 years of age!

Histo: hematoma enclosed by thick + vascular membrane, which forms <u>after 3–6 weeks</u>

- history of antecedent trauma often absent (25–48%)
- ill-defined neurologic signs + symptoms: cognitive deficit, behavioral abnormality,

nonspecific headache
• progressive neurologic deficit; low-voltage EEG, normal CSF
√ often biconvex lenticular = medially concave configuration, esp. after compartmentalization ← formation of fibrous septa
√ low-density lesion of 0–25 HU (= intermediate attenuation between CSF + brain):
√ different attenuations within different compartments
√ sometimes as low as CSF
√ high-density components of collection (after common rebleeding)
√ fluid-sediment levels (= sedimented fresh blood with proteinaceous fluid layered above)
√ displacement / absence of sulci, displacement of ventricles and parenchyma
√ No midline shift if bilateral (25%)
√ absent "cortical vein" sign = cortical veins seen along periphery of fluid collection without passing through it (1–4 weeks after injury)
DDx: Acute epidural hematoma (similar biconvex shape)

SUBDURAL HYGROMA

= TRAUMATIC SUBDURAL EFFUSION
= localized CSF-fluid collection within subdural space
Cause: (a) minor trauma results in separation of dura and arachnoid; proliferation of dural border cell layer results in neomembrane with hyperpermeable capillaries + efflux of serous fluid into subdural space
(b) traumatic tear in arachnoid with secondary ball valve mechanism
Age: most often in elderly + young children
Time of onset: 6–30 days following trauma
• asymptomatic in majority; headaches, drowsiness
• decreased level of consciousness, confusion
√ radiolucent crescent-shaped collection (as in acute subdural hematoma) of CSF density
√ NO evidence of blood products (DDx to subdural hematoma)
MR:
√ isointense to CSF / hyperintense to CSF on T1WI (← increased protein content)
Prognosis: often spontaneous resorption; may develop into a chronic subdural hematoma
DDx: (1) Enlarged subarachnoid space
(2) Subdural empyema
(3) Chronic subdural hematoma
(4) Brain atrophy

SUBEPENDYMAL CYST

Etiology:

1. Acquired posthemorrhagic subependymal cyst:
   - › hemorrhage
   - › hypoxic-ischemic damage

   Site: caudothalamic notch
   - • frequently in preterm infant
   - √ tear-shaped, 2–11 mm in size
2. Congenital subependymal cyst ← germinolysis
   - › neurotropic infection: CMV, rubella
   - › metabolic disorders (esp. Zellweger syndrome)
   - › chromosomal abnormalities
   - › maternal cocaine consumption
   - › idiopathic in otherwise healthy newborn

Histo: cystic cavity with pseudocapsule of aggregates of germinal cells + glial tissue; NO epithelium; macrophage-like cells within fluid ← vascular origin

TERATOMA OF CNS

Incidence: 0.5% of primary intracranial neoplasms; 2% of intracranial tumors before age 15

Histo: mostly benign; occasionally containing highly malignant primitive elements

Location: pineal + parapineal region > floor of 3rd ventricle > posterior fossa > spine (associated with spina bifida)

√ heterogeneous midline lesion, occasionally homogeneous soft-tissue mass (DDx: astrocytoma)

√ contains fat + calcium

√ hydrocephalus (common)

Pineal Teratoma

= benign tumor containing one / all three germ cell layers (pineal region most common site of teratomas)

Incidence: 15% of all pineal masses; 2nd most common tumor in pineal region

Age: < 20 years; M÷F = 2÷1 to 8÷1

- • Parinaud syndrome; hypothalamic symptoms
- • headache, somnolence (related to hydrocephalus)

Histo: (a) mature teratoma = fully differentiated tissue
- › ectoderm: skin + skin appendages
- › mesoderm: cartilage, bone, fat, smooth muscle, skeletal muscle
- › endoderm: respiratory + enteric epithelium

(b) immature teratoma = complex mixture of fetal-type tissues from all 3 germ layers + mature tissue elements

(c) teratoma with malignant transformation of mature tissues

Location: pineal, parapineal, suprasellar, 3rd ventricle

√ well-defined rounded / irregular lobulated extremely heterogeneous multiloculated mass of fat, cartilage, hair, linear / nodular calcifications + cysts

◊ Fat is absent in all other pineal tumors!

√ may show heterogeneous / rimlike contrast enhancement (limited to solid-tissue areas)

Angio:

√ elevation of internal cerebral vein

√ posterior displacement of precentral vein

CT:

√ heterogeneous mass with fat, calcification, cystic + solid areas

MR:

√ variegated appearance on all pulse sequences:

√ hyperintense areas of fat on T1WI with chemical shift artifact

√ variable signal intensity on T1WI due to calcifications

√ iso- to hypointense soft-tissue component

√ enhancement of soft-tissue component

Cx: chemical meningitis with spontaneous rupture

TOXOPLASMOSIS OF BRAIN

Organism: obligate intracellular protozoan parasite Toxoplasma gondii, can live in any cell except for nonnucleated RBCs; reservoirs in feces of house cat (felines are definite host)

Infection: ingestion of undercooked meat (eg, pork, free-range chicken) containing cysts or sporulated oocysts / transplacental transmission of trophozoites; acquired through blood transfusion + organ transplantation

◊ Disease remains dormant for as long as normal host immunity is maintained!

Forms: (1) Cyst (bradyzoite)

(2) Trophozoite

(3) Oocyst: uniquely found in intestinal mucosa of cat; outside cat it can survive for > 1 year in warm moist soil

Hosts: birds, mammals, reptiles, cockroach, flea

Geographic exposure: France (75–90%) > Central America > urban USA (17–35%)

◊ 500 million persons infected with T. gondii worldwide!

Seropositivity: up to 20% of urban adults in USA; up to 90% of European adults

Transmission:

(a) fecal-oral: fruits, vegetables, poorly cooked meat; children especially susceptible via house cat / litter box

(b) hematogenous: blood transfusion

Spread: hematogenous

Histo: inflammatory solid / cystic granulomas (← glial mesenchymal reaction) surrounded by edema and microinfarcts (← vasculitis)

Affected tissue:

@ Gray + white matter of brain

◊ Most common cause of focal CNS infection mass effect in patients with AIDS!

@ Retina: most common retinal infection in AIDS

@ Alveolar lining cells (4%):
mimics Pneumocystis carinii pneumonia

@ Heart (rare):
cardiac tamponade / biventricular failure
@ Skeletal muscle
• asymptomatic; lymphadenopathy; malaise, fever

Toxoplasmosis is the most common opportunistic infection affecting the CNS in patients with AIDS!

A. AIDS INFECTION = **toxoplasmic encephalitis**
= reactivation of a chronic latent infection in > 95%
◊ Most common cerebral mass lesion in AIDS!
◊ 2–3 times more frequent than lymphoma!
Incidence: 3–20–40% of AIDS patients; 20–70% of normal adult population is seropositive for antibodies
Path: well-localized indolent granulomatous process / diffuse necrotizing encephalitis
• fever, headaches, confusion, seizures (15–25%)
• focal neurologic deficit of subacute onset (50–89%)
• pseudotumor cerebri syndrome
Location: (a) basal ganglia (75%)
(b) subcortical at gray-white matter junction scattered throughout brain parenchyma
(c) NO involvement of corpus callosum / leptomeninges
CT:
√ multifocal abscesses with a predilection for basal ganglia:
√ multiple / solitary (up to 39%) lesions < 2 cm with nodular / thin-walled (common) ring enhancement
√ surrounding white matter edema
√ double-dose delayed CT scans with higher detection rate for multiple lesions (64–72%)
√ ± hemorrhage and calcifications after therapy
MR:
√ multiple hypo- to isointense lesions on T2WI
√ T1 hyperintense lesion + hypointensity on GRE ← hemorrhage
√ prominent associated mass effect
√ marked edema
√ increased diffusivity related to underlying acellular core on DWI (opposite to pyogenic + fungal abscess)
√ nodular / ring enhancement
√ poorly defined peripheral enhancement = poor host response
√ HIGHLY SUGGESTIVE "eccentric target" sign (30%) = small enhancing nodule along lesion margin
√ diffuse cerebral volume loss (30%)
MR spectroscopy:
√ lipid breakdown products without elevated choline levels
Dx: improvement on antitoxoplasma therapy within 2–3 weeks / biopsy
DDx: CNS lymphoma (single lesion, hyperattenuation, T2 hypointensity, restricted

diffusion, periventricular location)
◊ Multiple lesions suggest toxoplasmosis!

B. INTRAUTERINE INFECTION
= devastating effects on fetal brain because maternal antibodies passed to child will be limited by blood-brain barrier
Time of fetal infection: chances of transplacental transmission greater in late pregnancy
Screening: impractical due to high false-positive rate
• Toxoplasma gondii found in ventricular fluid
• microcephaly, mental retardation, seizures; chorioretinitis
√ thickened vault, sutures apposed / overlapping
√ hydrocephalus → return to normal / persistent large head
√ intracerebral calcifications in posterior aspect of brain
√ multiple irregular nodular / cystlike / curvilinear calcifications in periventricular area + thalamus + basal ganglia + choroid plexus (= necrotic foci); bilateral; 1–20 mm in size; increasing in number + size (usually not developed by time of birth)
OB-US (as early as 20 weeks MA):
√ sonographic findings in only 36%
√ evolving symmetric ventriculomegaly
√ intracranial periventricular + hepatic densities
√ increased thickness of placenta
√ ascites
◊ Microcephaly is NOT a feature of toxoplasmosis!
Dx: elevated toxospecific IgM levels in fetal blood

Dx: demonstration of elongated teardrop-shaped trophozoites in histologic sections of tissue
Rx: empiric therapy (pyrimethamine + sulfadiazine for 3 weeks)

TUBERCULOSIS OF CNS

= slowly dividing facultative intracellular pathogen
Prevalence: 5% (15% with immunodeficiency)
Worldwide: 1.7 million deaths per year; latent infection in 2 billion persons → 10% lifetime risk for active symptomatic tuberculosis
Transmission: through respiratory droplets → active infection usually begins as Ghon focus

Cranial Tuberculous Meningitis

◊ Most common cause of chronic meningitis!
Pathophysiology:
rupture of initial subependymal / subpial tubercle (**Rich focus**) into subarachnoid space (after earlier hematogenous dissemination) into CSF → thick gelatinous inflammatory exudate settles at base of brain along cisterns + sylvian fissure + along traversing blood vessels

Predisposed: in AIDS patients + infants + small children (part of generalized miliary tuberculosis / primary tuberculous infection)
Location: basal cisterns (around M1 segment of MCA and sylvian fissure) > sulci > cerebral convexities, interhemispheric fissure

√ characteristic thick / nodular enhancement in basal cisterns

DDx: (1) other granulomatous disease: fungus, sarcoid
(2) neoplastic disease: carcinoma, lymphoma

CT:
√ iso- / hyperattenuating meninges relative to basal cisterns
√ often homogeneous contrast enhancement of meninges

MR:
√ normal at unenhanced SE (in early stage)
√ distention of affected subarachnoid spaces with mild shortening of T1 + T2 relaxation times compared with CSF

CEMR:
√ abnormal meningeal enhancement on gadolinium-enhanced T1WI (corresponds to gelatinous exudate)
√ abnormal enhancement of choroid plexus + ependymal lining (rare)

Cx: (1) Communicating hydrocephalus (most common) ← blockage of basal cisterns by inflammatory exudate
(2) Obstructive hydrocephalus (rare) ← mass effect of tuberculoma causing obstruction of CSF flow
(3) Ischemic infarction (20–41%) in basal ganglia and internal capsule ← vasospasm of penetrating vessels / vascular compression / occlusive panarteritis (mostly in MCA distribution)
(4) Cranial neuropathy (17–70%): CN2, CN3, CN4, CN7 ← extension of cisternal inflammation along traversing cranial nerves
(5) Pachymeningitis (rare) ← seeding to bone / dura

DDx: infection (nontuberculous bacteria, virus, fungus, parasite), inflammatory disease (rheumatoid disease, sarcoidosis), neoplasia (meningiomatosis, CSF-seeding neoplasm)

Parenchymal Tuberculosis

Tuberculoma of Brain 70%

= tuberculous granuloma formation within cerebrum as most common parenchymal form of tuberculosis

Incidence: 0.15% of intracranial masses in Western countries; 30% in underdeveloped countries

Age: infant, small child, young adult

Associated with: tuberculous meningitis in 50%

• history of previous extracranial TB (in 60%)

Location: more common in posterior fossa (62%), cerebellar hemispheres (frontal + parietal lobes)

√ solitary lesion; may be multiloculated

Progression: noncaseating → caseating → solid → liquid center

NECT:
√ hypo- / iso- (72%) / hyperdense round / lobulated lesion of 0.5–4 cm in diameter with mass effect (93%)
√ moderate surrounding edema (72%) less marked than in pyogenic abscess

√ central calcification (29%)

CECT:

√ homogeneously enhancing parenchymal tuberculoma

√ homogeneous blush in tuberculoma en plaque along dural plane (6%) (DDx: meningioma en plaque)

√ ring blush (nearly all) with smooth / slightly shaggy margins + thick irregular wall around an isodense center (DDx: pyogenic abscess less thick + more regular)

√ "target" sign (⅓) = central calcification in isodense lesion with ring-blush HIGHLY SUGGESTIVE (DDx: giant aneurysm)

MR:

√ single / multiple well-defined T2 hypointensities

√ solid / ringlike enhancement

√ varying central T2 hyperintensity depending on extent of liquefaction / caseation

√ "target" sign = small focal area of calcification / enhancement in center of ring-enhancing mass

MR spectroscopy:

√ lipid level peaks at 0.9 ppm, 1.3 ppm, 2.0 ppm, 2.8 ppm

√ NO amino acid resonance at 0.9 ppm

DDx: other CNS infection (esp. toxoplasmosis, cysticercosis, fungus), lymphoma, atypical meningioma, radiation necrosis

Tuberculous Abscess of Brain (rare)

Histo: numerous tubercle bacilli in the absence of tubercular granulomatous formation

• early rapid clinical deterioration favors abscess

√ hypointense lesion core on T1WI

√ hyperintense lesion core on T2WI

√ peripheral hypointense rim (= capsule)

Miliary Tuberculosis of CNS 30–60%

Usually associated with: tuberculous meningitis

√ multiple tiny < 2 mm T2-hyperintense foci with homogeneous enhancement

Spinal Tuberculous Meningitis

MR:

√ cerebrospinal fluid loculations with cord compression

√ obliteration of spinal subarachnoid space:

√ loss of outline of spinal cord in cervicothoracic spine

√ matting of nerve roots in lumbar region

√ nodular thick linear intradural enhancement of meninges

Cx: syringomyelia, syringobulbia

Tuberculous Vasculitis

= infectious vasculitis of small and medium-sized cerebral aa. in subarachnoid space

Location: lenticulostriate arteries, posterior cerebral branches, thalamoperforating arteries

Cx: small infarctions in basal ganglia and deep white matter (in up to 41%)

TUBEROUS SCLEROSIS

= TSC = BOURNEVILLE EPIPLOIA
[Désiré-Magloire Bourneville (1840–1909), French neurologist at Salpêtrière, Bicêtre, Hôpital Saint-Louis, Pitié]

= autosomal-dominant neuroectodermal disorder characterized by multifocal systemic hamartomas + malformations that may affect CNS, eye, kidney, lung, liver, skin, heart with a spectrum of phenotypic expressions

CLASSIC TRIAD (of Vogt, 1908) in only 29% of patients:
(1) Facial angiofibromas
(2) Epileptic seizures
(3) Mental retardation
mnemonic: zits, fits, nitwits

Prevalence: 1÷6,000 to 1÷150,000 live births

• family history of TSC in 25–50%

Cause: autosomal-dominant germ line mutation inhibiting cell proliferation with low penetrance (frequent skips in generations); sporadic mutations in 50–60–80%

Genetics: gene mutations of
(a) TSC1 on chromosome 9q34 → protein hamartin
(b) TSC2 on chromosome 16p13 → protein tuberin

Dx: A. Major features
(1) Cortical / subcortical tubers
(2) Subependymal giant cell astrocytoma
(3) Cardiac rhabdomyoma
(4) Facial angiofibroma
(5) Retinal hamartoma
(6) Renal angiomyolipoma
(7) Shagreen patches
(8) Ash-leaf spots
(9) Lymphangioleiomyomatosis

B. Minor features
(1) Gingival fibroma
(2) Dental pits
(3) Hamartomatous rectal polyps
(4) Renal cysts
(5) Cerebral white matter migration lines
(6) Confetti skin lesions
(7) Bone cysts

A diagnosis is definite with 2 major / 1 major + 2 minor features!

Prognosis: 30% dead by age 5; 75% dead by age 20

Rx: antiepileptic medication; ketogenic diet

@ CNS INVOLVEMENT (> 95%)
• intractable myoclonic seizures (75–80%): often first and most common sign of tuberous sclerosis with onset at 1st–2nd year, decreasing in frequency with age
• mental retardation (50–82%): moderate to severe cognitive deficits (⅔), mild to

moderate (⅓); progressive; observed in adulthood; common if onset of seizures before age 5 years

- autism, behavioral + sleep + psychiatric disorders

1. **Subependymal hamartomas**

Location: along ventricular surface of caudate nucleus, on lamina of sulcus thalamostriatus immediately posterior to foramen of Monro (most often), along frontal + temporal horns or 3rd + 4th ventricle (less commonly)

√ multiple subependymal nodules of 1–12 mm:
  √ "candle drippings" appearance
√ periventricular calcification with increasing age (in up to 88%)

MR:
  √ subependymal nodules protruding into adjacent ventricle isointense with white matter
  √ iso- to hyperintense on T1WI + hyper- and hypointense on T2WI relative to gray and white matter
  √ minimal contrast enhancement (in up to 56%)

2. **Giant cell astrocytoma** (in 15–20%)

= SUBEPENDYMAL GIANT CELL TUMOR (SGCT)

Incidence: 5–15%; M÷F = 1÷1

Mean age: 11 years (range, birth to 5th decade); typically < 20 years

Origin: ? subependymal nodule

Histo: low-grade astrocytoma (WHO grade I lesion) with large cells resembling astrocytes / ganglion cells with abundant cytoplasm

Immunohisto: markers for both glial + neuronal proteins

Location: in the region of foramen of Monro; uncommonly in other locations

√ well-circumscribed solid intraventricular neoplasm
√ typically > 13 mm in diameter with interval growth
√ ± variable degrees of calcification ± cystic changes
√ uniform avid enhancement
√ frequent extension into frontal horn / body of lateral ventricle
√ occasionally hemorrhagic

CT:
  √ hypo- / isodense well-demarcated round mass

MR:
  √ hypo- to isointense to gray matter on T1WI
  √ iso- to hyperintense to gray matter on T2WI

Prognosis: tendency to enlarge + growth into ventricles → obstruction at foramen of Monro → progressive obstructive hydrocephalus

Cx: degeneration into higher grade astrocytoma

Surveillance: imaging every 2 (3) years with TSC2 (TSC1) mutation; once identified follow-up imaging at yearly intervals

Subependymal GCT is considered PATHOGNOMONIC for TS (rare without manifestations of TS, then likely representing somatic mosaicism of the TS gene)

3. **Cortical / subcortical tubers** (in 56%)

= CORTICAL / SUBCORTICAL HAMARTOMAS

Histo: clusters of atypical glial cells surrounded by giant cells with frequent calcifications (if > 2 years of age)

Frequency: multiple (75%); bilateral (30%)

√ large misshapen broadened gyri with central hypodense regions ← abnormal myelination

√ masslike / curvilinear calcification of cortical tubers (in 15% < 1 year of age, in 50% by age 10)

MR:

√ relaxation time similar to white matter (if uncalcified)

√ multiple nodules hyperintense on T2WI / FLAIR + iso- to hypointense on T1WI ← fibrillary gliosis / demyelination

√ enhancement extremely rare

4. **Heterotopic gray matter islands in white matter**

Histo: grouping of bizarre and gigantic neuronal cells associated with gliosis + areas of demyelination

Frequency: in up to 93%

Location: along lines of neuronal migration

√ straight / curvilinear bands extending radially from ventricular wall

√ wedge-shaped lesion with apex at ventricular wall

√ conglomerate masses

√ calcification of all / part of nodule

√ may show contrast enhancement

CT:

√ hypodense well-defined regions within cerebral white matter

MR:

√ iso- to hypointense region on T1WI + well-defined hyperintense area on T2WI relative to normal white matter

DDx of CNS lesions:

(1) Intrauterine CMV / Toxoplasma infection (smaller lesions, brain atrophy, microcephaly)

(2) Basal ganglia calcification in hypoparathyroidism / Fahr disease (different location)

(3) Sturge-Weber, calcified AVM (diffuse atrophy, not focal)

(4) Heterotopic gray matter (along medial ventricular wall, isodense, associated with agenesis of corpus callosum, Chiari malformation)

(5) Focal cortical dysplasia

(6) Subependymal heterotopia

@ SKIN INVOLVEMENT (90%)

• **Facial angiofibroma** (former misnomer: adenoma sebaceum) in 80–90%

Path: small hamartomas from neural elements with blood vessel hyperplasia = angiofibromas

Age: first discovered at age 1–5 years; family history in 30%

• wartlike nodules of red-brown / red color averaging 4 mm in size with tendency to enlarge + increase in number over time

Location: CHARACTERISTIC bimalar distribution (“butterfly rash”); initially

nasolabial folds, eventually covering nose + middle of cheeks

- **Ungual fibroma** = Koenen tumor (15–50%)
  Age: develop in adolescent / adult
  Location: sub- / periungual region of toes
  √ erosion of distal tuft
- **Shagreen rough skin patches** (80%)
  = "pigskin" = "peau d'orange"
  Histo: connective tissue nevus (collagenoma) = patches of fibrous hyperplasia
  • irregularly shaped skin-colored / brown soft plaque
  Age: early childhood
  Location: posterior trunk / buttocks + intertriginous
- **Ash leaf patches** = hypomelanotic / hypopigmented macules shaped like ash / spearmint leaf
  • may be visible only under ultraviolet light
  Age: typically present at birth, persist throughout life
  Location: trunk, lower extremity
- "Thumbprint" / "confetti" macules
- Café-au-lait spots
  Incidence: similar to that in general population
  DDx: neurofibromatosis type 1, fibrous dysplasia
- Fibrous forehead plaques

@ OCULAR INVOLVEMENT (50%)

- **Phakoma** (> 5%) = whitish disk-shaped retinal hamartoma
  = astrocytic proliferation in / near optic disc, plaques often multiple + usually in both eyes

√ small calcifications in region of optic nerve head
√ optic nerve glioma

@ RENAL INVOLVEMENT (70–90%)

- usually asymptomatic; flank pain, hematuria, hypertension
- renal failure in severe cases (5%) ← mass effect of cysts and angiomyolipomas

◊ 75% of patients die from complications of renal failure by age 20

1. **Angiomyolipoma** (55–89%): usually multiple
   Cx: spontaneous retroperitoneal hemorrhage (subcapsular / perinephric) → shock
2. **Multiple cysts** of varying size in cortex + medulla mimicking adult polycystic kidney disease (15%)
   Path: cysts lined by columnar epithelium with foci of hyperplasia projecting into cyst lumen
   √ polycystic involvement in infants
3. **Renal cell carcinoma** / **Malignant epithelioid form of angiomyolipoma** (1–3%), bilateral in 40%;
   Average age: 28 years (= 25 years younger than for RCC in general population)
   √ rapid growth + presence of calcifications

Recommendation:
US evaluation every 2–3 years before puberty + yearly thereafter to identify growing lesions

@ LUNG INVOLVEMENT (1–4%)
Age: 3rd–5th decade; in women
• progressive respiratory insufficiency
√ interstitial fibrosis in lower lung fields + miliary nodular pattern may progress to honeycomb lung (**lymphangioleiomyomatosis** = smooth muscle proliferation around blood vessels)
√ multiple bilateral small cysts in lung parenchyma on CT (26–39%)
√ repeated episodes of spontaneous pneumothorax (50%)
√ chylothorax
√ cor pulmonale
@ HEART INVOLVEMENT in children
Prevalence: decreases with increasing age ← spontaneous tumor regression + better survival of patients without cardiac tumor
• congenital cardiomyopathy; typically clinically silent
√ circumscribed / diffuse subendocardial **rhabdomyoma** (in 5–30%) of ventricle (70%) / atrium (30%)
√ aortic aneurysm
@ BONE INVOLVEMENT
√ bone cysts with undulating periosteal reaction in distal phalanges (most common), metacarpals, metatarsals of hand (DDx: sarcoidosis, neurofibromatosis)
√ "**bone islands**":
√ dense sclerotic calvarial patches (45%)
Location: frontal and parietal diploe + internal table; pelvic brim, vertebral neural arch, long bones
√ bone thickening:
√ thickening of diploe ← long-term phenytoin therapy
√ expansion + sclerosis of rib (may be isolated)
√ periosteal thickening of long bones
√ dysplasia of sphenoid body (DDx: NF1 with dysplasia of sphenoid wing)
@ OTHER VISCERAL INVOLVEMENT
1. Adenomas + lipomyomas of liver
2. Adenomas of pancreas
3. Tumors of spleen
@ VASCULAR INVOLVEMENT (rare)
√ thoracic + abdominal arterial aneurysms
Path: vascular dysplasia with intimal + medial abnormalities of large muscular + musculoelastic arteries
Prognosis: 75% mortality by 20 years

UNILATERAL MEGALENCEPHALY

= hamartomatous overgrowth of all / part of a cerebral hemisphere with neuronal migration defects
• intractable seizure disorder at early age, hemiplegia
• developmental delay

√ moderate / marked enlargement of one hemisphere
√ ipsilateral ventriculomegaly proportionate to enlargement of affected hemisphere
√ straightened frontal horn of ipsilateral ventricle pointing anterolaterally
√ neuronal migration defects:
  √ polymicrogyria
  √ pachygyria
  √ heterotopia of gray matter
  √ white matter gliosis (low density in white matter on CT, prolonged T1 + T2 relaxation times on MR)
Rx: partial / complete hemispheric resection

VEIN OF GALEN MALFORMATION / ANEURYSM

= central embryonic AVM of quadrigeminal plate cistern directly drains into a secondarily enlarged ectatic vein of Galen (aneurysm is a misnomer)
Prevalence: < 1% of all vascular brain malformations
Cause: arteriovenous fistula between primitive choroidal vessels and embryonic **median prosencephalic vein of Markowski**; fistula prevents involution of this embryonic vein + leads to development of the vein of Galen
Anatomical types:
Type 1 = AV fistula fed by enlarged arterial branches → dilatation of vein of Galen + straight sinus + torcular herophili
Type 2 = angiomatous malformation involving basal ganglia + thalami ± midbrain draining into vein of Galen
Type 3 = transitional AVM with both features
Feeding vessels:
(a) posterior cerebral artery, posterior choroidal artery (90%)
(b) anterior cerebral artery + anterior choroidal artery
(c) middle cerebral artery + lenticulostriate + thalamic perforating arteries (least common)
Age at presentation: detectable in utero > 30 weeks GA; M÷F = 2÷1
(a) neonatal pattern (0–1 month)
  • high-output cardiac failure (36%) ← massive shunting
  • cranial bruit
(b) infantile pattern (1–12 months)
  • macrocrania from obstructive hydrocephalus; seizures
(c) adult pattern (> 1 year)
  • headaches ± intracranial hemorrhage ± hydrocephalus
  • focal neurologic deficits (5%) ← steal of blood from surrounding structures
◊ Rarely diagnosed > 3 years of age
Associated with: anomalous dural sinuses + sinus stenosis
May be associated with: porencephaly, nonimmune hydrops
Location: midline posterior to 3rd ventricle
Types:
(1) Choroidal type

√ multiple prominent choroidal + pericallosal and thalamostriate feeder arteries
√ drainage into anterior aspect of intensely enhancing aneurysmal median prosencephalic vein of Markowski

(2) Mural type
√ few prominent posterior choroidal / collicular feeder arteries
√ arteries fistulize with lateral walls of an intensely enhancing median prosencephalic vein of Markowski

→ both types drain via persistent falcine sinus into superior sagittal sinus

√ prominent serpiginous network of feeding arteries in basal ganglia, thalami, midbrain + nidus + draining veins

NECT:
√ round well-circumscribed homogeneous slightly hyperdense mass posterior to indented 3rd ventricular outlet
√ hyperdense intracerebral hematoma ← ruptured AVM
√ focal hypodense zones ← ischemic changes
√ rim calcification (14%)

CECT:
√ marked homogeneous enhancement of serpentine structures + vein of Galen + dilated straight + transverse sinus + torcular herophili

US / OB-US:
√ anechoic tubular midline structure superior to cerebellum
√ cardiac enlargement ← high-output heart failure
√ dilated veins of head + neck
√ hydrocephalus with dilatation of lateral + 3rd ventricle (in 37%) ← aqueductal obstruction / posthemorrhagic impairment of CSF absorption
√ brain infarction / leukomalacia ← steal phenomenon with hypoperfusion

Doppler US:
√ median tubular cystic space with high-velocity turbulent flow
√ variable thrombus + feeding vessels
√ tortuous network of dilated arteries

MR:
√ areas of signal void

Angio:
necessary to define vascular anatomy for surgical / endovascular intervention

Cx: subarachnoid hemorrhage

Rx: ligation, excision, embolization of vessels from transtorcular / transarterial approach

Prognosis: 56% (91%) overall (neonatal) mortality: death from cardiac + multisystem failure if untreated

DDx: (1) Aneurysmal dilatation of vein of Galen (= thalamic arteriovenous malformation of brain with deep venous drainage into secondarily dilated vein of Galen)
(2) Dural AV fistula
(3) Giant developmental venous anomaly
(4) Pineal tumor
(5) Arachnoid / colloid / porencephalic cyst

VENTRICULITIS

= EPENDYMITIS = PYOCEPHALUS
= inflammation of ependymal lining of one / more ventricles
Cause: (1) rupture of periventricular abscess (thinner capsule wall medially)
(2) retrograde spread of infection from basal cisterns
CECT (necessary for diagnosis):
√ thin uniform enhancement of involved ependymal lining
√ often associated with intraventricular inflammatory exudate + septations
MR:
√ intraventricular pus shows restricted diffusion on DWI
DDx: intraventricular blood (history!)
Cx: obstructive hydrocephalus ← occlusion at foramen of Monro / aqueduct
DDx: ependymal metastases, lymphoma, infiltrating glioma

Ependymitis Granularis

= symmetric focal areas of hyperintensity on T2WI in normal individuals
Histo: patchy loss of ependyma with paucity of hydrophobic myelin (astrocytic gliosis), which allows migration of fluid out of the ventricle into interstitium
Location: anterior + lateral to frontal horns
√ punctate / up to 1 cm in diameter
√ grossly triangular in shape

Pyogenic Ventriculitis

= frequent complication of meningitis in infants (uncommon in adults)
Risk factors: craniotomy, diabetes (predisposes to staphylococcus and enterobacter infections)
√ intraventricular debris ± restricted diffusion
√ periventricular edema ± enhancement
√ ventricular dilatation

VENTRICULOPERITONEAL SHUNT MALFUNCTION

◊ The peritoneum is an efficient site of fluid absorption
Components: ventriculostomy catheter, pressure-sensitive valve + reservoir, barium-integrated silicone peritoneal catheter

- symptoms of increased intracranial pressure: seizures, headache, nausea, vomiting, lethargy, irritability
- persistent bulging of anterior fontanel
- excessive rate of head growth
- slowed refill of shunt reservoir; abdominal pain, fever

Mechanical Shunt Failure

Cause: occlusion of catheter by choroid plexus / glial tissue, discontinuity of tubes
√ sutural diastasis + increased size of cranial cavity
√ increasing ventricular size:
√ interval increase since last exam

√ enlargement of temporal horns (earliest finding)
√ preferential enlargement of temporal horns in infants
N.B.: (1) no enlargement with scarring of ventricular walls
(2) marked ventricular dilatation does not necessarily indicate shunt malfunction
√ shuntogram (by scintigram / contrast radiography) determines site of obstruction
√ brain edema tracking along shunt + within interstices of centrum semiovale (with partial obstruction)
√ formation of white matter cyst surrounding ventricular catheter

Obstruction of VP Shunt

Location: ventricular end > peritoneal end
Cause: plugging of the catheter by brain parenchyma / choroid plexus / proteinaceous material / tumor cells; adhesions within peritoneum
NUC: ^{99m}Tc-albumin colloid injected into shunt tubing proximal to reservoir:
√ no uptake within ventricles + normal peritoneal activity (= proximal obstruction)
Contrast study (injection of nonionic contrast material into shunt reservoir):
√ collection of contrast material at peritoneal end of shunt without spillage (= distal obstruction)

Disconnection & Breaks of VP Shunt

Location: connection of tubing to reservoir, at Y-connectors, areas of great mobility (neck)
DDx: pseudo-disconnection ← radiolucent tube components

Migration of VP Shunt

A. Proximal catheter: into soft tissues of neck / unusual locations within CNS
B. Distal catheter: peritoneal cavity, thorax, abdominal wall, scrotum, perforation into GI tract

Leakage of VP Shunt

= CSF escape without complete break / disconnection
• palpable cystic mass
√ contrast verifies leak site

CSF Pseudocyst of VP Shunt

√ shunt tubing coiled in an abdominal soft-tissue mass
US / CT:
√ cyst surrounding catheter tip
Cx: bowel obstruction

Infection of VP Shunt

Incidence: 1–5–38%
Time of onset: within 2 months of shunt placement
• intermittent low-grade fever
• anemia, dehydration, hepatosplenomegaly
• stiff neck; swelling + redness over shunting tract; peritonitis

√ ventriculitis (= enlarged ventricles with irregular enhancing ventricular wall ± septations)
√ meningitis (= enhancement of cerebral cortical sulci)

Abdominal Complications of VP Shunt

1. Ascites
2. Pseudocyst formation
3. Perforation of viscus / abdominal wall
4. Intestinal obstruction
5. Metastases to peritoneum: germinoma, medulloblastoma, astrocytoma, glioblastoma

Subdural Hematoma / Hygroma of VP Shunt

Cause: precipitous drainage of markedly enlarged ventricles
Age: usually seen in children > 3 years of age with relatively fixed head size
Prognosis: small hematomas resolve on their own

Granulomatous Lesion of VP Shunt

= rare granulomatous reaction adjacent to shunt tube within / near ventricle
√ irregular contrast-enhancing mass along course of shunt tube

Slit Ventricle Syndrome (0.9–3.3%)

= proximal shunt failure from ventricular collapse
Cause: overdrainage of CSF, intermittent shunt obstruction, decreased intracranial compliance, periventricular fibrosis, intracranial hypotension
Incidence: 0.9–3.3%
• intermittent / chronic headaches, vomiting, malaise
• slowed refill of shunt reservoir
√ small / slitlike ventricles

VISCERAL LARVA MIGRANS OF BRAIN

Organism: roundworm nematode (Toxocara canis)
√ small calcific nodules, especially in basal ganglia + periventricular location
DDx: tuberous sclerosis

VON HIPPEL-LINDAU DISEASE

= vHL = RETINOCEREBELLAR ANGIOMATOSIS
[Eugen von Hippel (1867–1939)], professor of ophthalmology in Heidelberg, Halle and Göttingen, Germany
Arvid Vilhelm Lindau (1892–1958), chair of general pathology, bacteriology and general health science in Lund, Sweden
= autosomal dominant inherited neurocutaneous dysplasia complex grouped under hereditary phakomatosis (although the skin is not affected)
Prevalence: 1÷31,000 – 1÷53,000 births
Genetics: mutation of VHL tumor suppressor gene located on chromosome 3p25-p26 with 80–100% high penetrance + variable delayed expressivity (ie, different subset of 40 types of lesions in 14 different organs); in 20% familial

Effect: propensity to develop multiple clear cell neoplasms like retinal and CNS hemangioblastoma, clear cell renal cell carcinoma, pheochromocytoma, pancreatic serous cystadenoma, pancreatic endocrine tumor (PET)

Age at onset: 2nd–3rd decade; M÷F = 1÷1

Diagnostic criteria:

◊ Hemangioblastoma = almost always disease-defining tumor

(a) > 1 hemangioblastoma of CNS

(b) 1 hemangioblastoma + visceral manifestation

(c) 1 manifestation + known family history

Subclassification (NIH):

Type I = renal + pancreatic cysts, high risk for renal cell carcinoma, NO pheochromocytoma

Type IIA = pheochromocytoma, pancreatic islet cell tumor (typically without cysts)

Type IIB = pheochromocytoma + renal + pancreatic disease

@ CNS MANIFESTATION

Age at presentation: 25–35 years

- signs of increased intracranial pressure: headache, vomiting
- vision changes: reactive retinal inflammation with exudate + hemorrhage, retinal detachment, glaucoma, cataract, uveitis, decreasing visual acuity, eye pain
- cerebellar symptoms: vertigo, dysdiadochokinesia, dysmetria, Romberg sign
- spinal cord symptoms (uncommon): loss of sensation, impaired proprioception

1. Retinal angiomatosis = **von Hippel tumor** (> 50%) <u>earliest</u> manifestation of disease; multiple in up to 66%, bilateral in up to 50%

   Histo: hemangioblastoma of retina

   Dx: indirect ophthalmoscopy + fluorescein angiography

   √ small tumors rarely detected by imaging studies

   √ globe distortion

   √ thick calcified retinal density (calcified angioma-induced hematoma)

   US:

   √ small hyperechoic biconvex homogeneous solid noncalcified masses, usually in temporal retina

   √ NO choroidal excavation

   Cx: (1) repeated vitreous hemorrhage (frequent)
   (2) exudative retinal detachment posteriorly

2. Hemangioblastoma of CNS = **Lindau tumor** (40%)

   = benign nonglial neoplasm as the most commonly recognized manifestation of vHL disease

   Age: 15–40 years

   Site: cerebellum (65%), brainstem (20%), spinal cord (15%); multiple lesions in 10–15% (may be metachronous)

   ◊ 4–20% of single hemangioblastomas occur in von Hippel-Lindau disease!

   CT:

√ large cystic lesion with 3–15-mm mural nodule (75%)
√ solid enhancing lesion (10%)
√ enhancing lesion with multiple cystic areas (15%)
√ intense tumor blush / blushing mural nodule
√ NO calcifications (DDx: cystic astrocytoma calcifies in 25%)

MR (modality of choice):
√ hypointense cystic component on T1WI (slightly hyperintense to CSF ← protein content); hyperintense on T2WI
√ small tubular areas of flow void within mural nodule (= enlarged feeding + draining vessels); intense contrast enhancement of mural nodule
√ slightly hypointense solid lesion on T1WI; hyperintense on T2WI; intense contrast enhancement

Angio:
√ intense staining of mural nodule ("mother-in-law phenomenon" = tumor blush "comes early and stays late", very dense)
√ presence of feeding vessels

Prognosis: most frequent cause of morbidity and mortality; frequent recurrence after incomplete resection

@ LABYRINTH

1. **Endolymphatic sac neoplasm**

= aggressive adenomatous tumor with mixed histologic features
• sensorineural hearing loss

Location: retrolabyrinthine temporal bone
Site: endolymphatic sac
√ aggressive lytic lesion containing intratumoral osseous spicules + areas of hemorrhage
√ heterogeneous enhancement with hyperintense areas on T1WI + T2WI (due to hemorrhage)

@ HEART

1. Rhabdomyoma

@ KIDNEYS

• polycythemia ← elevated erythropoietin level (in 15% with hemangioblastoma, in 10% with renal cell ca.)

1. **Cortical renal cysts** (59–63%)

multiple + bilateral (may be confused with adult polycystic kidney disease); simple appearing cysts often contain small foci of renal cell carcinoma

2. **Renal cell carcinoma** (24–45%)

Age: 20–50 years
√ multicentric in 87%, bilateral in 10–75%; many arise from cyst wall
√ sensitivity: 35% for angiography, 37% for US, 45% for CT ← inability to reliably distinguish between cystic RCC, cancer within cyst, atypical cyst
√ 50% metastatic at time of discovery
Prognosis: slower growing with higher 10-year survival rate than RCC without vHL; RCC is cause of death in 30–50% as the 2nd most frequent cause of mortality!

Screening and management strategy:
follow solid lesion every 6–12 month until the largest lesion is 3 cm → nephron-sparing surgery

3. Renal adenoma
4. Renal hemangioma

@ ADRENAL pheochromocytoma (0–60%) bilateral in up to 40%; confined to certain families

@ epididymis

1. Cystadenoma of epididymis

@ PANCREAS

1. Microcystic serous pancreatic adenoma (12–56%)
2. Microcystic serous pancreatic carcinoma (rare)
3. Pancreatic endocrine tumor (PET in 5–17%)
   Mean age: 38 years (slightly younger than sporadic PET)
   ◊ multiple mostly nonfunctioning PETs (30%) with clear cell change (60%)
   Prognosis: metastases in 1.4% with > 3 cm tumor
4. Pancreatic hemangioblastoma
5. Pancreatic cysts (in 50–91%)
   Incidence: in up to 72% (autopsies)
   Location: pancreatic body + tail
   √ usually multiple multilocular cysts (spectrum from single cyst to cystic replacement of gland)
   √ ± peripheral calcifications
   ◊ Pancreatic cysts may be only manifestation for years
   ◊ Pancreatic cysts in a patient with a family history of von Hippel-Lindau disease are DIAGNOSTIC!

@ LIVER

1. Liver hemangioma
2. Adenoma

@ OTHERS

1. Paraganglioma
2. Cysts in virtually any organ: liver, spleen, adrenal, epididymis, omentum, mesentery, lung, bone

MULTIPLE ORGAN NEOPLASMS

@ Kidney : renal cell carcinoma (up to 40%), renal angioma (up to 45%)
@ Liver : adenoma, angioma
@ Pancreas : cystadenoma / adenocarcinoma
@ Epididymis : adenoma
@ Adrenal gland : pheochromocytoma

MULTIPLE ORGAN CYSTS

(1) Kidney (usually multiple cortical cysts in 75–100% at early age, most common abdominal manifestation)
(2) Pancreas (in 9–72% often numerous cysts; second most common affected abdominal organ)

(3) Others: liver, spleen, omentum, mesentery, epididymis, adrenals, lung, bone

WERNICKE ENCEPHALOPATHY

[Karl Wernicke (1848–1905), professor of neurology and psychiatry in Breslau and Halle, Germany]

◊ MEDICAL EMERGENCY!

Cause: vitamin B1 (thiamine) deficiency

Predisposed:

malnutrition ← chronic alcoholism, GI neoplasm, hematologic neoplasm, chronic dialysis, bowel obstruction, hyperemesis gravidarum, prolonged parenteral Rx

- classic triad of
  - altered consciousness
  - ocular dysfunction (= ophthalmoplegia)
  - ataxia
- anterograde amnesia

Affected areas: medial thalami, periaqueductal gray matter, mamillary bodies, tectal plate

MR:

√ symmetric T2 prolongation
√ petechial hemorrhage
√ diffusion restriction
√ contrast enhancement

Rx: IV replacement of thiamine

WILSON DISEASE

= HEPATOLENTICULAR DEGENERATION

[Samuel Alexander Kinnier Wilson (1878–1937), professor of neurology at King's College Hospital, London and founding editor of the Journal of Neurology and Psychopathology]

= autosomal recessive disorder with increased intestinal resorption of copper → excessive copper retention (= copper toxicosis) with deposition and cell damage in liver + brain

Prevalence: 1÷33,000–200,000; 1÷90 persons is a heterozygous carrier

Cause: alteration of chromosome 13 resulting in inability of liver to excrete copper into bile; hypothetically due to

(a) lysosomal defect in hepatocytes, or
(b) deficiency of biliary copper-binding proteins, or
(c) persistence of fetal mode of copper metabolism, or
(d) hepatic synthesis of high-affinity copper-binding proteins

Age of onset: 7–50 years; hepatic manifestations predominate in children; neuropsychiatric manifestations predominate in adolescents + adults

- ↓ levels of serum copper; ↑ urinary copper excretion
- ⇓ levels of ceruloplasmin (= copper transport protein)
- ↑ copper concentration in serum ceruloplasmin (BEST SCREENING TEST)
- ↓ incorporation of orally administered radiolabeled copper into newly synthesized ceruloplasmin

Stages:

1 Asymptomatic copper accumulation in hepatocytic cytosol
2 Redistribution of copper into hepatic lysosomes + circulation from saturated hepatocytic cytosol
(a) gradual redistribution is asymptomatic
(b) rapid redistribution causes fulminant hepatic failure / acute intravascular hemolysis
3 Cirrhosis, neurologic, ophthalmologic, renal dysfunction: may be reversible with therapy

Rx: life-long pharmacologic therapy with chelation agents (penicillamine / trientine / zinc); liver transplantation

@ CNS

= excessive copper deposition in brain

Location: commonly in lenticular nucleus (= lenslike configuration of putamen + globus pallidus)
<u>perhaps also in</u>:
caudate nucleus, ventrolateral aspect of thalamus, cortical and subcortical region, mesencephalon, pons, vermis, dentate nucleus

- Kayser-Fleischer ring (= green pigmentation surrounding limbus corneae) is DIAGNOSTIC
- dysarthria, dysphagia, dystonia
- tremors, ataxia, Parkinsonian symptoms
- intellectual impairment, emotional disturbance

√ diffusion restriction (in early stages)
√ cerebral white matter atrophy
√ areas of CT hypodensities + T2 prolongation

@ Liver

- jaundice / portal hypertension (with liver cirrhosis)

Histo: macrovesicular fat deposition in hepatocytes, glycogen degeneration of hepatocyte nuclei, Kupffer cell hypertrophy

<u>in children:</u>
√ normal hepatic attenuation (fatty infiltration + copper deposition cancel each other out)
√ normal T1 relaxation time (in spite of paramagnetic effects of copper)

Cx: acute fulminant hepatitis, macronodular cirrhosis

@ Skeletal manifestations (in ⅔)

- pain, stiffness, gelling of joints (in 75%)

Location: shoulder (frequent), knee, hip, wrist, 2nd–4th MCP joints

√ subarticular cysts
√ premature osteoarthritis (narrowing of joint space + osteophyte formation)
√ osteochondritis dissecans
√ chondrocalcinosis
√ premature osteoarthrosis of spine, prominent Schmorl nodes, wedging of vertebrae, irregularities of vertebral plates
√ generalized deossification may produce pathologic fractures

Cx: rickets + osteomalacia (← renal tubular dysfunction) in minority of patients

ZELLWEGER SYNDROME

[Hans Ulrich Zellweger (1909–1990), Swiss-American pediatrician at American University in Beirut, Lebanon and University of Iowa]
= CEREBROHEPATORENAL SYNDROME
= autosomal recessive peroxisomal disorder with disturbed myelination in oligodendrocytes during neonatal + infantile period
Path: ⇑ very long–chain fatty acids in plasma and fibroblasts
Associated with:
@ CNS: cortical dysplasia, hypomyelination
@ Bile ducts: intrahepatic biliary dysgenesis
@ Kidney: polycystic renal disease
• poor feeding + failure to thrive, muscular hypotonia
• hepatomegaly + prolonged jaundice
• craniofacial dysmorphism, abnormal vision (typical)
• seizures, mental retardation
MR:
√ hypomyelination
√ diffuse microgyria + regions of pachygyria, lissencephaly
√ subependymal germinolytic cysts in caudothalamic groove
MR spectroscopy:
√ ↑ lipid levels + ↓ N-acetylaspartate levels
√ renal cortical cysts
Prognosis: death within 1st year of life

ORBIT

DIFFERENTIAL DIAGNOSIS OF ORBITAL AND OCULAR DISORDERS

OPHTHALMOPLEGIA

Lesions of

1. Oculomotor nerve (CN III)
   innervates medial rectus, superior rectus, inferior rectus, inferior oblique muscle, pupilloconstrictor, levator palpebrae
2. Trochlear nerve (CN IV)
   innervates superior oblique muscle
3. Abducens nerve (CN VI)
   innervates lateral rectus muscle

ANOPIA

[numbers refer to drawing]

A. MONOCULAR DEFECTS

1 = monocular blindness (optic nerve lesion in fracture of optic canal, amaurosis fugax)

B. BILATERAL heteronymous DEFECTS

2 = bitemporal hemianopia (chiasmatic lesion)

C. BILATERAL HOMONYMOUS DEFECTS

3 = homonymous hemianopia

4 = upper right-sided quadrantanopia

5 = central hemianoptic scotoma

3,4,5 = most common type of hemianopia (CVA, brain tumor)

Monocular Blindness In Adulthood

1. Optic neuritis
2. Vascular ischemia
   (a) Amaurosis fugax = cholesterol emboli from ICA occluding central retinal artery and its branches
   (b) Occult cerebrovascular malformation affecting the optic nerve
3. Temporal arteritis
4. Malignant optic glioma of adulthood

ORBIT

Spectrum of Orbital Disorders

A. INFLAMMATORY DISEASE

1. Tissue-specific inflammation:
   orbital cellulitis, optic neuritis, scleritis, myositis, Graves disease
2. Panophthalmitis
3. Pseudotumor of orbit

B. CYSTIC DISEASE
1. Dermoid cyst
2. Mucocele
3. Retroocular cyst (developmental)

C. VASCULAR LESIONS
(a) arterial and arteriovenous lesion
1. Ophthalmic artery aneurysm
2. Arteriovenous fistula (rare) eg, Wyburn-Mason syndrome
3. Carotid-cavernous fistula

(b) capillary lesion
4. Capillary hemangioma / benign hemangioendotheliloma

(c) venous vascular malformation
5. Cavernous hemangioma
6. Orbital varix

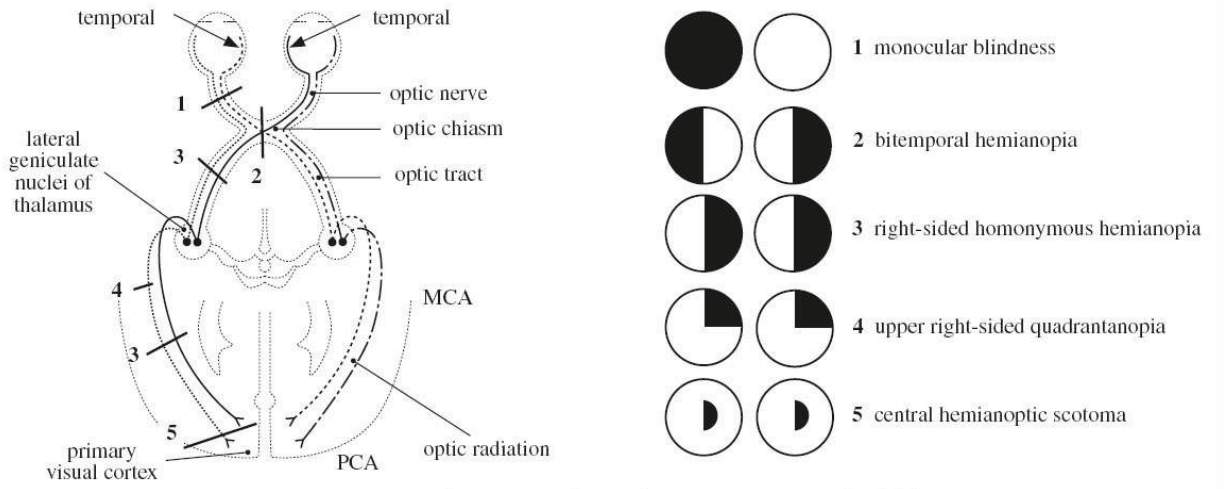
(d) venous lymphatic malformation
7. Capillary lymphangioma
8. Cavernous lymphangioma
9. Cystic lymphangioma

D. TUMORS
1. Rhabdomyosarcoma
2. Optic nerve glioma
3. Meningioma
4. Lymphoma
5. Metastasis
6. Hemangiopericytoma

Intraconal lesion

mnemonic: **M**el **M**et **R**ita **M**ending **H**ems **O**n **P**oor **C**harlie's **G**rave

Melanoma
Metastasis
Retinoblastoma
Meningioma
Hemangioma
Optic glioma
Pseudotumor
Cellulitis
Grave disease



Types of Anopia *(numbers refer to lesion location versus visual field deficits)*

Intraconal Lesion with Optic Nerve Involvement

1. Optic nerve glioma
2. Optic nerve sheath meningioma (10% of orbital neoplasm)
3. Optic neuritis
4. Inflammatory pseudotumor (may surround optic nerve)
5. Sarcoidosis
6. Intraorbital lymphoma (may surround optic nerve, older patient)
7. Elevated intracranial pressure
   → distension of optic sheath
   √ bilateral tortuous enlarged optic nerve-sheath complex

OPTIC NERVE TRAM-TRACK SIGN

1. Optic nerve sheath meningioma
2. Orbital pseudotumor
3. Perioptic neuritis
4. Perioptic hemorrhage
5. Sarcoidosis
6. Lymphoma / leukemia
7. Metastasis
8. Erdheim-Chester disease = systemic xanthogranulomatosis

Intraconal Lesion without Optic Nerve Involvement

1. Cavernous hemangioma
2. Orbital varix
3. Carotid-cavernous fistula
4. Arteriovenous malformation
   least common of orbital vascular malformations (congenital, idiopathic, traumatic)
   √ irregularly shaped intensely enhancing mass of enlarged vessels
   √ associated with dilated superior / inferior ophthalmic v.
5. Hematoma

6. Lymphangioma
7. Neurilemmoma
   √ commonly adjacent to superior orbital fissure, inferior to optic nerve
   √ local bone erosion
8. Rhabdomyosarcoma (mostly extraconal)

Extraconal lesion

Extraconal-intraorbital Lesion

A. BENIGN TUMOR
   1. Dermoid cyst
   2. **Teratoma**
      < 1% of all pediatric orbital tumors
      √ ± areas of fat, cartilage, bone
      √ expansion of bony orbit ± bone defect
   3. Capillary hemangioma
   4. Lymphangioma
   5. Plexiform neurofibroma
   6. Inflammatory orbital pseudotumor
   7. Histiocytosis X
      lesion usually arises from bone

B. MALIGNANT TUMOR
   1. Lymphoma / leukemia
   2. Metastasis
   3. Rhabdomyosarcoma

mnemonic: MOLD
Metastasis
Others (rhabdomyosarcoma, lymphangioma, sinus lesion)
Lymphoma, **L**acrimal gland tumor
Dermoid

Extraconal-extraorbital Lesion

A. FROM SINUS
   maxillary / sphenoid sinuses are rare locations of origin
   1. Tumor:
      squamous cell carcinoma (80%), lymphoma, adenocarcinoma, adenoid cystic carcinoma
   2. Mucocele
   3. Paranasal sinusitis:
      ◊ Most common cause of orbital infection!
      Origin: from ethmoid sinuses (in children), from frontal sinus (in adolescence)
      √ preseptal / orbital edema / cellulitis
      √ subperiosteal / orbital abscess
      √ mucormycosis (in diabetics) destroys bone and extends into cavernous sinus
      Cx: (1) Epidural abscess

(2) Subdural empyema
(3) Cavernous sinus thrombosis
(4) Meningitis
(5) Cerebritis
(6) Brain abscess

B. FROM SKIN
1. Orbital cellulitis

C. FROM LACRIMAL GLAND
√ mass arising from superolateral aspect of orbit

Dilatation of Superior Ophthalmic Vein

1. Carotid-cavernous sinus fistula
2. Cavernous sinus thrombosis
3. Venous varix
4. Graves disease
5. Normal variant

ORBITAL MASS

Orbital Mass in Adults

(a) vasculogenic orbital mass
1. Cavernous malformation
2. Hemangiopericytoma

(b) lymphoproliferative orbital lesion
1. Typical / atypical lymphoid hyperplasia
2. Lymphoma of orbit

(c) lacrimal gland lesion (5–14% of biopsied orbital masses)
› epithelial (largely neoplastic) lesion (40–50%)
1. Pleomorphic adenoma
2. Adenoid cystic carcinoma

› nonepithelial lesion
1. Dacryoadenitis
2. Lacrimal gland lymphoma

(d) optic nerve & meningeal lesions
1. Optic pathway glioma
2. Optic nerve sheath meningioma

(e) peripheral nerve sheath lesions
1. Schwannoma (rare)
2. Neurofibroma
3. Malignant peripheral nerve sheath tumor

(f) Primary orbital melanoma

(g) Metastasis to orbit

Orbital Mass in Childhood

1. Dermoid cyst 46%
2. Inflammatory lesion 16%
3. Dermolipoma 7%
4. Capillary hemangioma 4%
5. Rhabdomyosarcoma 4%
6. Leukemia / lymphoma 2%
7. Optic nerve glioma 2%
8. Lymphangioma 2%
9. Cavernous hemangioma 1%

mnemonic: LO VISHON

Leukemia, **L**ymphoma
Optic nerve glioma
Vascular malformation: hemangioma, lymphangioma
Inflammation
Sarcoma: ie, rhabdomyosarcoma
Histiocytosis
Orbital pseudotumor, **O**steoma
Neuroblastoma

Osseous Orbital Lesion in Children

(a) development of the osseous orbit
   1. Dermoid inclusion cyst
   2. Epidermoid inclusion cyst

(b) primary bone lesions
   1. Fibrous dysplasia
   2. Juvenile ossifying fibroma
   3. Cementifying fibroma
   4. Langerhans cell histiocytosis

(c) malignant tumors involving multiple sites
   1. Granulocytic sarcoma
   2. Hematogenous metastasis: neuroblastoma (most common primary tumor to involve orbit)

(d) primary malignant bone tumor
   1. Osteosarcoma

Nonosseous Lesion of Extraocular Orbit in Children

1. Rhabdomyosarcoma
2. Infantile hemangioma
3. Lymphangioma
4. Infantile fibromatosis

Primary Malignant Orbital Tumors

1. Retinoblastoma 86.0%
2. Rhabdomyosarcoma 8.1%

3. Uveal melanoma 2.3%
4. Sarcoma 1.7%

Pediatric Orbital Tumors

1. Retinoblastoma
2. Medulloepithelioma
3. Optic nerve glioma

Secondary Malignant Orbital Tumors

1. Leukemia 36.7%
2. Sarcoma 14.3%
3. Hodgkin lymphoma 11.0%
4. Neuroblastoma 9.2%
5. Wilms tumor 6.7%
6. Non-Hodgkin lymphoma 5.6%
7. Histiocytosis 3.9%
8. Medulloblastoma 3.5%

Orbital Cystic Lesion

1. Abscess
2. Intraorbital hematoma
3. Dermoid cyst
4. Lacrimal cyst
5. Lymphangioma
6. Hydatid cyst

Orbital Vascular Tumors

1. Orbital varix
2. Arteriovenous malformation
3. Carotid-cavernous fistula
4. Hemangioma: capillary / cavernous
5. Blood cyst
6. Arterial malformation
7. Glomus tumor
8. Hemangiopericytoma

Mass in Superolateral Quadrant of Orbit

1. Lacrimal gland tumor
2. Dermoid cyst
3. Metastasis (breast, prostate, lung)
4. Lymphoma
5. Leukemic infiltration of lacrimal gland
6. Sarcoidosis

7. Wegener granulomatosis
8. Pseudotumor
9. Frontal sinus mucocele

Granulomatous Orbital Apex Mass

√ avidly enhancing orbital soft-tissue mass with involvement of extraocular muscles + lacrimal glands

1. Granulomatosis with polyangiitis
2. Sarcoidosis

Extraocular Muscle Enlargement

A. ENDOCRINE
   1. Graves disease (50%)
   2. Acromegaly
B. INFLAMMATION
   1. **Myositis**
      • rapid onset of proptosis, erythema of lids, conjunctival injection
      Location: single muscle (in adults); multiple muscles (in children)
      √ enlarged extraocular muscle
      √ positive response to steroids
   2. Orbital cellulitis
   3. Sjögren disease, Wegener granulomatosis, lethal midline granuloma, SLE
   4. Sarcoidosis
   5. Foreign-body reaction
C. TUMOR
   1. Pseudotumor
   2. Rhabdomyosarcoma
   3. Metastasis, lymphoma, leukemia
D. VASCULAR
   1. Spontaneous / traumatic hematoma
   2. Arteriovenous malformation
   3. Carotid-cavernous sinus fistula

GLOBE

Spectrum of Ocular Disorders

A. CONGENITAL
   1. Persistent fetal vasculature
   2. Coats disease
   3. Coloboma
   4. Congenital cataract
B. VITREORETINAL
   1. Vitreous hemorrhage
   2. Retinal detachment
   3. Choroidal detachment

4. Endophthalmitis
5. Retinoschisis
6. Retrolental fibroplasia

C. TUMOR
1. Retinoblastoma
2. Choroidal hemangioma
3. Retinal angiomatosis
4. Melanocytoma
5. Choroidal osteoma

D. TRAUMA

Microphthalmia

= congenital underdevelopment / acquired diminution of globe

A. BILATERAL with cataract
1. Congenital rubella
2. Persistent hyperplastic vitreous
3. Retinopathy of prematurity
4. Retinal folds
5. Lowe syndrome
   √ small globe + small orbit

B. UNILATERAL
1. Trauma / surgery / radiation therapy
2. Inflammation with disorganization of eye (phthisis bulbi)
   √ shrunken calcified globe + normal orbit

Macrophthalmia

= enlargement of globe

A. WITHOUT INTRAOCULAR MASS

(a) generalized enlargement
1. Axial myopia (most common cause)
   √ enlargement of globe in AP direction
   √ ± thinning of sclera
2. Buphthalmos
3. Juvenile glaucoma
4. Connective tissue disorder:
   Marfan syndrome, Ehlers-Danlos syndrome, Weill-Marchesani syndrome (congenital mesodermal dysmorphodystrophy), homocystinuria
   √ "wavy" contour of sclera

(b) focal enlargement
1. Staphyloma
2. Apparent enlargement due to contralateral microphthalmia

B. WITH INTRAOCULAR MASS
(rare cause for enlargement)

(a) with calcifications:
1. Retinoblastoma

(b) without calcifications:
1. Melanoma
2. Metastasis

Posterior Wall Mass

Origin: vascular uvea

1. Melanoma
2. Metastasis
3. Melanocytic nevus
4. Choroidal hemangioma
5. Hemangioblastoma
6. Pseudomass: subretinal hematoma, granuloma

Deformity of Globe Contour

1. Open-globe injury
2. Posttraumatic orbital hematoma
3. Coloboma
4. Staphyloma

Orbital Calcifications

Extraocular Calcifications

1. Trochlear calcifications
   = aging-related normal variant / young diabetic patient
   Location: superomedial orbit

Intraocular Calcifications

1. Retinoblastoma (> 50% of all cases)
2. Astrocytic hamartoma
3. Choroidal osteoma
4. Optic drusen
5. Scleral calcifications
   (a) in systemic hypercalcemic states (HPT, sarcoidosis, hypervitaminosis D, in chronic renal disease)
   (b) in elderly: **scleral plaques** at insertion of extraocular muscles, esp. medial + lateral rectus mm.
6. Retrolental fibroplasia
7. **Phthisis bulbi**
   Cause: trauma or infection / inflammation
   √ small contracted / shrunken calcified / ossified disorganized nonfunctioning globe
7. Calcified cataract

mnemonic: NMR CT

Neurofibromatosis
Melanoma (hyperdense melanin)
Retinoblastoma
Choroidal osteoma

Tuberous sclerosis

Posttherapeutic Orbital Changes

1. Lens implant
2. **Scleral band / buckle**
   √ radiopaque / radiolucent device at midglobe level
3. Intraocular silicone oil injection
   √ silicone > 100 HU (DDx: blood < 90 HU)
   √ silicone-related chemical shift artifact
4. Pneumatic retinopexy
   √ gas within globe
5. Globe prosthesis

Noncalcified Ocular Lesion

1. Melanoma
2. Metastasis
3. Choroidal hemangioma
4. **Vitreous lymphoma**
   √ diffuse ill-defined soft-tissue density
5. Developmental anomalies
   (a) **Primary glaucoma** = enlargement of eye ← narrowing of Schlemm canal
   (b) Coloboma
   (c) Staphyloma

Vitreous Hemorrhage

Cause: trauma, surgical intervention, arterial hypertension, retinal detachment, ocular tumor, Coats disease

• visual loss frequent

US:

√ numerous irregular, poorly defined low-intensity echoes
√ echogenic material moving freely within vitreous chamber during eye movement
√ voluminous hyperechoic fibrin clots not fixed to optic nerve (DDx to retinal detachment)

Prognosis: complete absorption / development of vitreous membranes (repetitive episodes)

Cx: retinal detachment ← vitreous traction ← fibrovascular ingrowth following hemorrhage

Dense Vitreous in Pediatric Age Group

1. Retinoblastoma
2. Persistent fetal vasculature
3. Coats disease
4. Norrie disease
5. Retrolental fibroplasia
6. Sclerosing endophthalmitis

Echoes within Normal Anechoic Vitreous

1. **Vitreous degeneration**

√ usually bilateral small freely moving low-level echoes within vitreous

2. Asteroid hyalosis
3. Vitreous hemorrhage
4. Vitritis
   √ low- / medium-level echoes throughout vitreous
   √ membranes appear with progressive organization

Leukokoria

= abnormal white / pinkish / yellowish pupillary light reflex [*leuko*, Greek = white; *kore*, Greek = pupil]

Although leukokoria is suspicious for retinoblastoma, other disease processes may also cause leukokoria.

A. TUMOR
   1. Retinoblastoma 47–58%
   2. Retinal astrocytic hamartoma (3%)
      Associated with: tuberous sclerosis + von Recklinghausen disease
   3. Medulloepithelioma (rare)

B. DEVELOPMENTAL
   1. Persistent fetal vasculature 19–28%
   2. Coats disease 4–16%
   3. Retrolental fibroplasia (3–5%)
   4. Coloboma of choroid / optic disc (11%)

C. INFECTION
   1. Uveitis
   2. Larval endophthalmitis / granulomatosis 7–16%

D. DEGENERATIVE
   1. Posterior cataract (13%)

E. TRAUMA
   1. Retinopathy of prematurity 5–13%
   2. Organized vitreous hemorrhage
   3. Long-standing retinal detachment

Leukokoria in Normal-sized Eye

A. CALCIFIED MASS
   1. Retinoblastoma
   2. Retinal astrocytoma

B. NONCALCIFIED MASS
   1. Toxocara endophthalmitis
   2. Coats disease

Leukokoria with Microphthalmia

A. UNILATERAL
   1. Persistent fetal vasculature

B. BILATERAL
   1. Retinopathy of prematurity

2. Bilateral persistent hyperplastic primary vitreous

OPTIC NERVE

Optic Nerve Enlargement

A. TUMOR:
   1. Optic pathway glioma
   2. Optic nerve sheath meningioma
   3. Infiltration by leukemia / lymphoma

B. FLUID:
   1. Perineural hematoma
   2. Papilledema of intracranial hypertension
   3. Patulous subarachnoid space

C. INFLAMMATION:
   1. Optic neuritis
   2. Sarcoidosis

√ fusiform thickening of optic nerve-sheath complex
= lens-shaped thickening
(a) with central lucency: meningioma
(b) without central lucency: optic nerve glioma

√ excrescentic thickening of optic nerve-sheath complex
= single / multiple nodules along nerve-sheath complex usually due to tumor

√ tubular enlargement of optic nerve-sheath complex
= uniform enlargement of nerve-sheath complex
(a) with central lucency: subarachnoid process (metastases, perineuritis, meningioma, perineural hemorrhage)
(b) without central lucency: papilledema, leukemia, lymphoma, sarcoid, optic nerve glioma

LACRIMAL GLAND

Lacrimal Gland Lesion

A. INFLAMMATION
   1. Dacryoadenitis
   2. Mikulicz disease
   3. Sjögren syndrome
   4. Sarcoidosis
   5. Pseudotumor of orbit
   6. IgG4-related disease

B. TUMOR
   (a) benign: granuloma, cyst, benign mixed tumor (= pleomorphic adenoma)
   (b) malignant: malignant mixed tumor (= pleomorphic adenocarcinoma), adenoid cystic carcinoma, lymphoma, metastasis (rare)

Lacrimal Gland Enlargement

mnemonic: MELD

Metastasis
Epithelial tumor
Lymphoid tumor
Dermoid

Bilateral Lacrimal Gland Masses

mnemonic: LACS

Lymphoma
And
Collagen-vascular disease
Sarcoidosis

Lacrimal Sac Lesion

A. INFLAMMATION
   1. Sarcoidosis
   2. Wegener granulomatosis
B. BENIGN LESION
   1. Mucoceles
   2. Epidermoid cysts
C. MALIGNANCY
   1. Squamous cell carcinoma
   2. Lymphoma

ANATOMY OF ORBIT

ORBIT

[*orbita*, Latin = wheel track, course, path]; [*oculus*, Latin = eye]
= four-sided pyramidal space formed by 7 bones
Floor: maxilla, zygoma, palatine
Roof: orbital plate of frontal bone, lesser wing of sphenoid
Medial wall: ethmoid, lacrimal bone
Division:

A. Globe / ocular compartment
B. **Muscle cone**
   = 5 extraocular muscles (except inferior oblique m.) separating intra- from extraconal spaces
   √ converges at orbital apex to form tendinous ring (= annulus of Zinn)
   [Johann Gottfried Zinn (1727–1759), German anatomist and botanist, member of the Berlin Academy]
   Annulus of Zinn contains
   1. Optic nerve
   2. Oculomotor nerve (superior + inferior divisions)
   3. Abducens nerve
   4. Nasociliary branch of ophthalmic nerve
   5. Ophthalmic artery
C. Intraconal space
D. Extraconal space

Normal Orbit Measurements

6 extraocular muscles

medial rectus muscle	4.1 ± 0.5 mm
inferior rectus muscle	4.9 ± 0.8 mm
superior rectus muscle	3.8 ± 0.7 mm
lateral rectus muscle	2.9 ± 0.6 mm
superior oblique muscle	2.4 ± 0.4 mm
inferior oblique muscle	

Superior ophthalmic vein

axial CT	1.8 ± 0.5 mm
coronal CT	2.7 ± 1.0 mm

Optic nerve sheath

retrobulbar	5.5 ± 0.8 mm
waist	4.2 ± 0.6 mm

Globe position

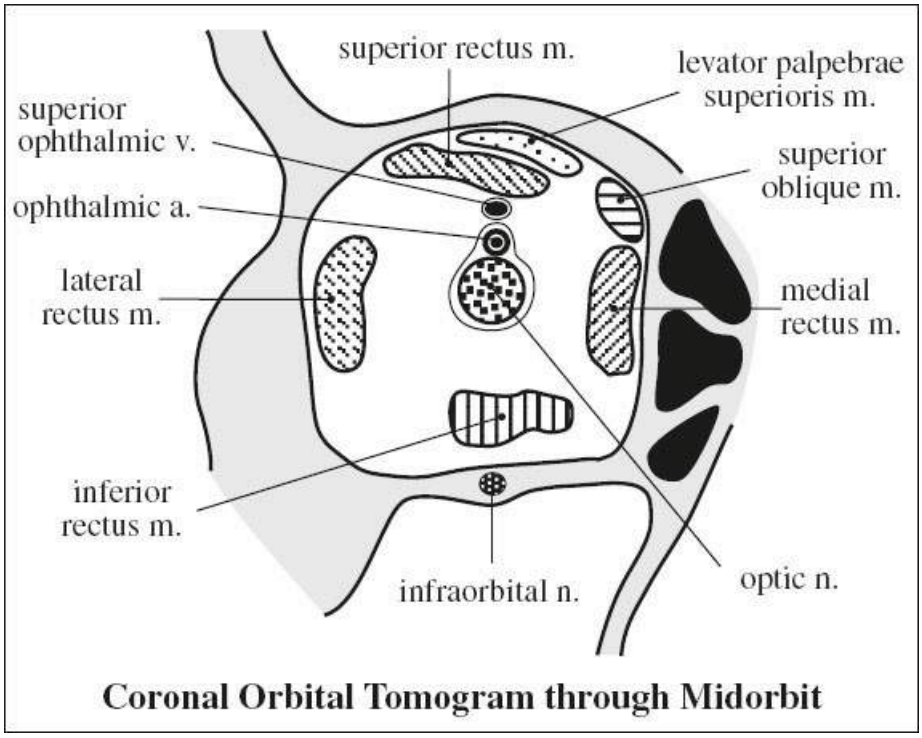
behind interzygomatic line 9.9 ± 1.7 mm

Orbital Compartments

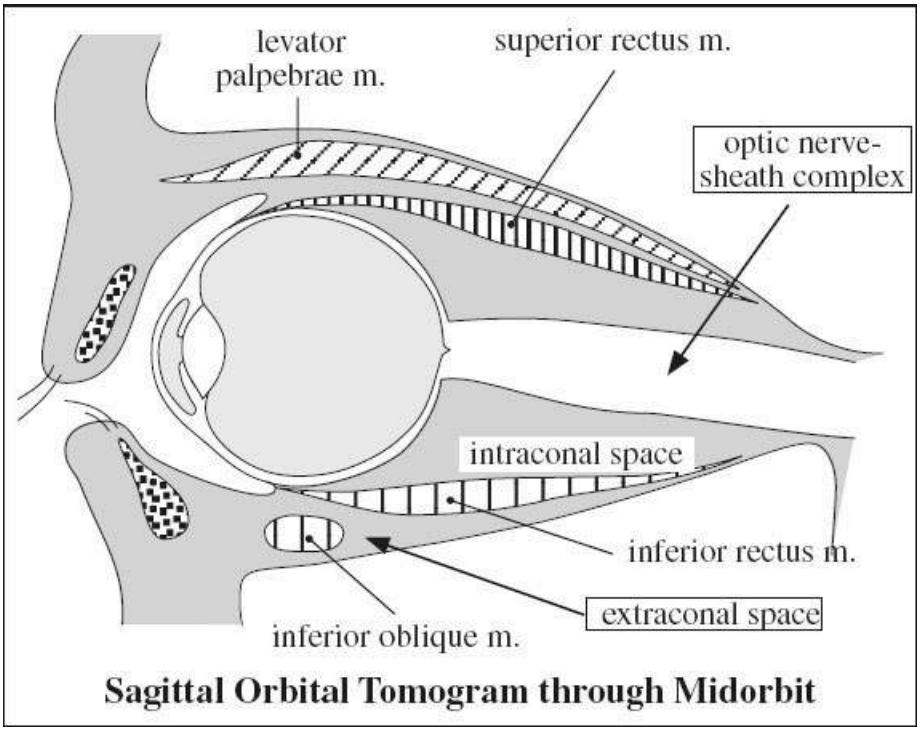
the orbital septum + globe divide orbit into

A. ANTERIOR COMPARTMENT

lids, lacrimal apparatus, anterior soft tissues



Coronal Orbital Tomogram through Midorbit



Sagittal Orbital Tomogram through Midorbit

Orbital Spaces	
globe:	subdivided into anterior + posterior segments by lens
optic nerve-sheath complex:	optic nerve surrounded by meningeal sheath as extension from cerebral meninges
intraconal space:	orbital fat, ophthalmic a., superior ophthalmic v., nerves I, III, IV, V_1, VI
conus:	incomplete fenestrated musculofascial system extending from bony orbit to anterior third of globe, consists of extraocular muscles + interconnecting fascia
extraconal space:	between muscle cone + bony orbit containing fat, lacrimal gland, lacrimal sac, portion of superior ophthalmic v.

B. POSTERIOR COMPARTMENT
= RETROBULBAR SPACE = cone consisting of extraorbital muscles + envelope of fascia divides retrobulbar space into
(a) intraconal space
(b) extraconal space

GLOBE

Ocular globe diameter: 22–25 mm
Wall: composed of 3 layers:
(a) fibrous outermost layer
Function: maintaining shape + pressure of globe
1. **Sclera** = collagenous tissue layer continuous anteriorly with cornea posteriorly with dura mater
2. **Cornea**

(b) **Uvea** = pigmented vascular middle layer
[*uvea*, Latin = grape]
3. **Iris**
4. **Ciliary body** (anteriorly)
5. **Choroid** (posteriorly) = most vascular structure of globe
Attachment: tethered to sclera by arteries + veins
◊ Most frequent site of intraocular metastases!

(c) innermost sensory layer
5. **Retina** = light-sensitive (sensory) inner layer
Attachment: firm at anterior margin (= ora serrata) and posteriorly at optic disc

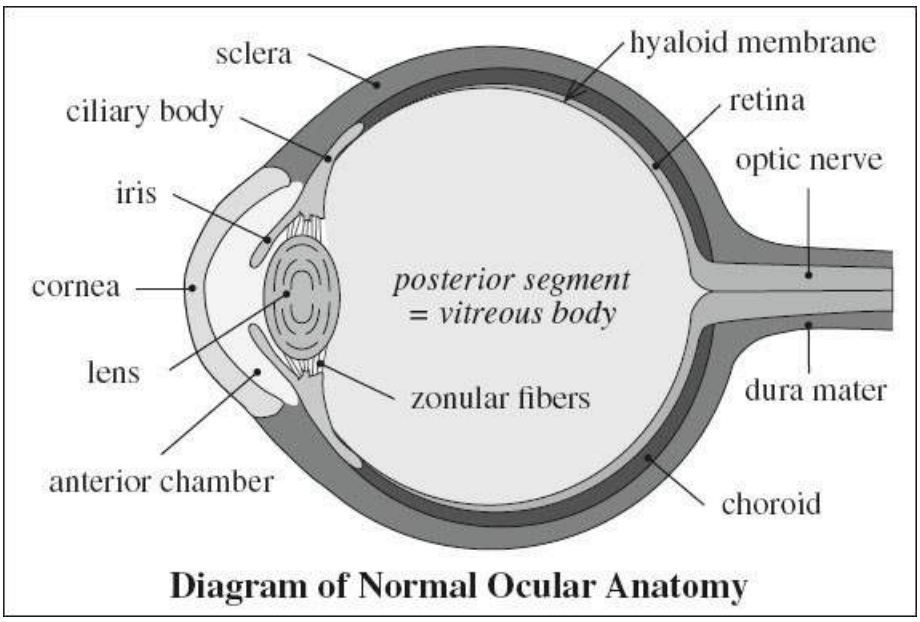


Diagram of Normal Ocular Anatomy

√ various layers of globe are NOT discernable at imaging, especially CT
√ sclera may be separated from choroid at high-res MRI
√ individually visualized in ocular (choroidal / retinal) detachments

Contents: (a) anterior segment containing
1. Aqueous humor subdivided by iris into:
› anterior chamber
› canal of Schlemm (*see below*)
› posterior chamber

(b) posterior segment containing
2. Vitreous humor

Potential ocular spaces:
(a) between retina + choroid → retinal detachment
(b) suprachoroidal space between choroid + sclera → choroidal detachment
(c) between vitreous + posterior hyaloid membrane → hyaloid detachment

Canal of Schlemm

[Friedrich Schlemm (1795–1858), German anatomist, sentenced for grave robbing, eventually

professor at the University of Berlin]
= SCLERAL VENOUS SINUS [misnomer - not a blood vessel]
= circular ringlike endothelium-lined tube lymphatic tube resembling a lymphatic vessel
Location: adjacent to outer angle of anterior chamber in pectinatum iridis (= periphery of cornea) between cornea + iris
Function: collects aqueous humor from anterior chamber and delivers it into the venous system

OPTIC NERVE SHEATH

= extension of dura mater
Content:
1. Optic nerve
2. Ophthalmic artery
3. Small veins

OPTIC NERVE (CN II)

Histo: CN II is an extension of brain = retinal ganglion cell axons myelinated by oligodendrocytes + enveloped within meninges
Segments:
A. Retinal segment leaves ocular globe through lamina cribrosa sclerae
B. Orbital segment travels in center of fat-filled orbit
√ surrounded by dural sheath containing CSF
C. Canalicular segment lies in optic canal below ophthalmic artery; frequently overlooked on radiologic images
D. Cisternal segment in suprasellar cistern leading to optic chiasm
√ anterior cerebral a. passes over superior aspect of nerve

OCULOMOTOR NERVE (CN III)

Exit: from brainstem anteriorly between posterior cerebral (PCA) + superior cerebellar arteries
Segments:
(1) cisternal segment courses through prepontine cistern
(2) cavernous sinus segment along cephalad portion of the lateral dural wall
(3) orbital segment through the superior orbital fissure
(4) division into superior + inferior branches
Function:
(a) motor fibers to
› levator palpebrae muscle
› all extraocular muscles except lateral rectus and superior oblique mm.
(b) parasympathetic fibers to
› internal eye muscles (pupillary sphincter and ciliary muscles) → constriction of pupil via Edinger-Westphal nucleus
Location: periphery of CN III → subject to compression by extrinsic masses
Disturbed function:

(1) "**pupil-sparing" oculomotor palsy** = loss of motor function in extraocular muscles with relative sparing of pupillary parasympathetic innervation ← compromised blood flow to central microvessels

(2) compression by **posterior communicating artery aneurysm** ← close association with posterior cerebral (PCA) + superior cerebellar arteries

(3) compression during transtentorial **uncal herniation** ← course over petroclinoid ligament

Nuclei:

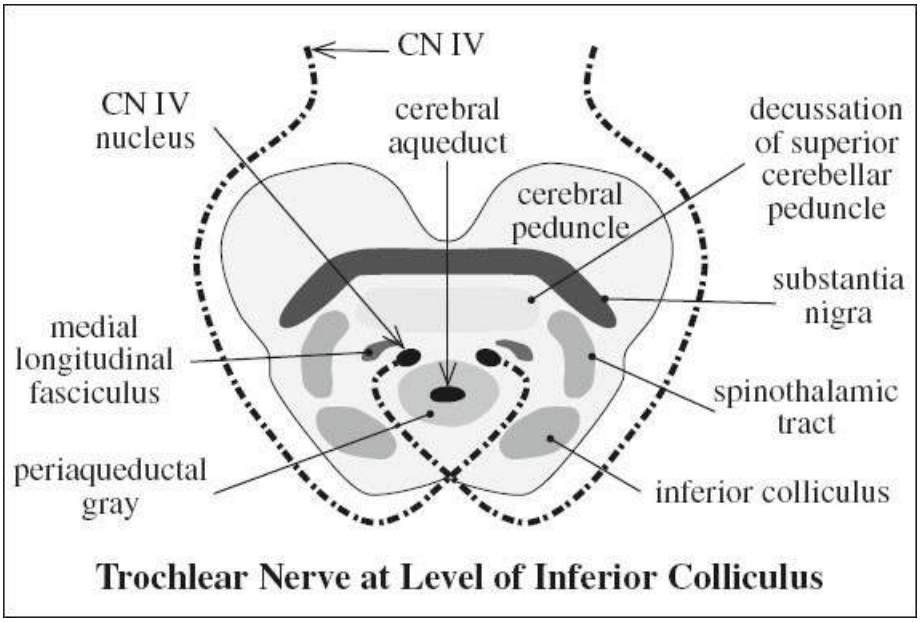
(1) Edinger-Westphal nucleus
located dorsally in periaqueductal gray matter

(2) Number of smaller nuclei arranged in an anterior and posterior group

TROCHLEAR NERVE (CN IV)

Function: pure motor nerve → innervates superior oblique m.

Nucleus: paramedian midbrain → fascicles course postero-inferiorly around cerebral aqueduct → decussation



Trochlear Nerve at Level of Inferior Colliculus

◊ Each superior oblique muscle is innervated by the contralateral cranial nerve IV nucleus!

Exit: dorsal midbrain

◊ The only cranial nerve to exit the dorsal brainstem!

Segments:

(1) Cisternal segment courses through ambient cistern traveling inferolateral to cranial nerve III between superior cerebellar and posterior cerebral arteries

(2) Cavernous sinus segment within dural investment inferior to CN III

(3) Orbital segment passes through superior orbital fissure above annulus of Zinn

ABDUCENS NERVE (CN VI)

Function: pure motor nerve for the lateral rectus muscle

Nucleus: located in pontine tegmentum near midline surrounded by a loop of the facial nerve (CN VII) causing a bulge in the floor of the 4th ventricle (= facial colliculus)

Segments:

(1) Cisternal portion exits brainstem near midline through a space between pons and pyramid of medulla oblongata

(2) Prepontine portion the nerve courses anteriorly within prepontine cistern + penetrates dura mater to enter Dorello canal

(3) Cavernous sinus portion the only nerve that travels within venous sinusoids of cavernous sinus inferolateral to cavernous ICA

◊ Cranial nerves III, IV, V_1, V_2 all lie within lateral dural wall of cavernous sinus!

Exit: enters orbit through superior orbital fissure

ORBITAL CONNECTIONS

Superior Orbital Fissure

Boundaries (Gray's Anatomy):

› medial : sphenoid body

› above : lesser wing of sphenoid = optic strut

› below : greater wing of sphenoid

› lateral : small segment of frontal bone

Contents:

(a) nerves: III oculomotor nerve
IV trochlear nerve
V_1 ophthalmic branch of trigeminal n.:
(a) lacrimal nerve
(b) frontal nerve
VI abducens nerve
sympathetic filaments of ICA plexus

(b) veins: superior + inferior ophthalmic vein

(c) arteries: 1. meningeal branch of lacrimal artery
2. orbital branch of middle meningeal artery

Inferior Orbital Fissure

Location: between floor + lateral wall of orbit; connects with pterygopalatine + infratemporal fossa

Contents:

(a) nerves: infraorbital + zygomatic nerves branches from pterygopalatine ganglion

(b) veins: connection between inferior orbital vein + pterygoid plexus

Optic Canal

completely formed by lesser wing of sphenoid
Contents:

(a) nerve: optic nerve (I) sympathetic fibers

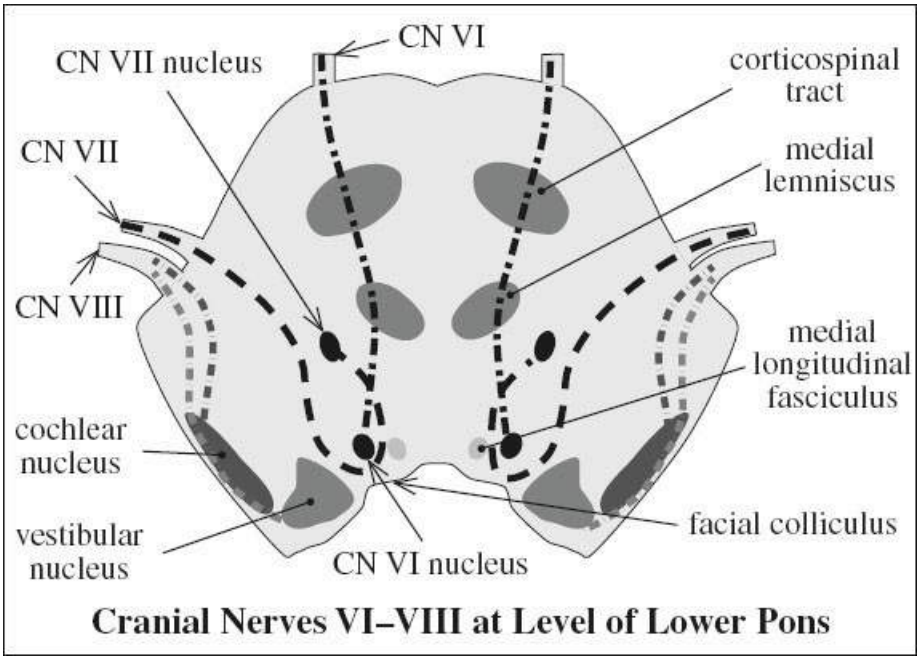
(b) vessel: ophthalmic artery

Infraorbital Canal

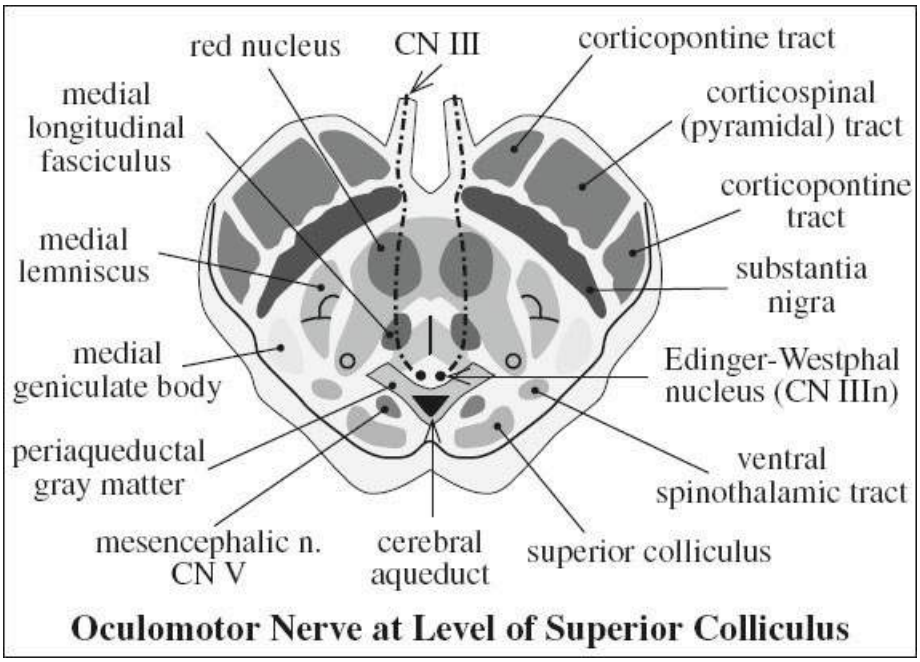
Contents:

(a) nerve: maxillary branch of trigeminal nerve

(b) vessel: infraorbital artery & vein



Cranial Nerves VI–VIII at Level of Lower Pons



Oculomotor Nerve at Level of Superior Colliculus

Superior Orbital Fissure **Optic Canal**

Axial CT of Orbital Foramina

ADENOID CYSTIC CARCINOMA

= most common malignancy of lacrimal gland

Frequency: 29% of all lacrimal epithelial neoplasms; ~ 5% of all primary orbital neoplasms
◊ 2nd most common lacrimal epithelial lesion

Age: 4th decade of life

Histo: nonencapsulated bland-appearing epithelial cells arranged in nests / chords forming a characteristic cribriform (swiss cheese–like) pattern

• pain (common presentation = indicative of malignancy)
• proptosis (may be minimal due to infiltrative pattern)
√ irregular borders with distortion of globe + orbital contents (with more advanced disease)
√ ± bone erosion + calcifications
√ perineural invasion (lacrimal branch of ophthalmic nerve)

Prognosis: poor; 20% 10-year–survival rate

ASTEROID HYALOSIS

= degenerative orbital condition with small white opacities of hydroxyl apatite (= calcium + phosphate / phospholipid deposits) attached to vitreous collagenous framework

Frequently associated with: hyperlipidemia, hypertension, diabetes mellitus

• small white vitreous opacities visible under direct illumination
√ small hyperechoic refringent mobile echoes (usually unilateral) ← calcified deposits

BUPHTHALMOS

= HYDROPHTHALMOS = MEGOPHTHALMOS
= diffuse enlargement of eye in children ← increased intraocular pressure

Cause:

1. Congenital / infantile glaucoma
2. Neurofibromatosis type 1: obstruction of canal of Schlemm by membranes / masses composed of aberrant mesodermal tissue
3. Sturge-Weber-Dimitri syndrome
4. Lowe (cerebrohepatorenal) syndrome
5. Ocular mesodermal dysplasia (eg, Axenfeld or Rieger anomalies)
6. Homocystinuria
7. Aniridia
8. Acquired glaucoma (rare)

Pathophysiology:

obstruction of canal of Schlemm located between cornea + iris → decreased resorption of aqueous humor (= anterior chamber fluid) → scleral distension

√ uniformly enlarged globe without mass of round / oval / bizarre shape

Rx: goniotomy (increases the angle of anterior chamber); trabeculotomy (lysis of adhesions)

CHOROIDAL DETACHMENT

= serous fluid / blood accumulation in potential suprachoroidal space separating choroid from sclera with sparing of optic disc due to anchoring effect of short posterior ciliary arteries and veins and nerves

Potential suprachoroidal space: extends from ora serrata to optic disc

Cause: trauma (accidental perforation), inflammation (uveitis), surgical intervention, spontaneous

Pathomechanism: ocular hypotonia → decreased pressure in suprachoroidal space → accumulation of serous / hemorrhagic transudate

US:

√ 2 convex lines projecting into the eye from periphery of globe + advancing to ciliary body with posterior fixation outside the optic disc (= macula) creating an obtuse angle

√ minimal / no choroidal membrane mobility during eye movement

CHOROIDAL HEMANGIOMA

= congenital vascular hamartoma

Mean age: 31 (range, 7–58) years (most common benign tumor in adults); M÷F = 1÷1

May be associated with: Sturge-Weber syndrome

Classification: capillary / cavernous / mixed

Location: posterior to equator, temporal to optic disc (70%)

• smoothly elevated slightly dome-shaped reddish-orange choroidal mass

√ lenticular mass of 7.5 (range, 3–11) mm

√ intense enhancement similar to choroid

√ focal thickening of posterior wall of globe

CT:

√ ill-defined mass with intense enhancement

MR:

√ hyperintense to vitreus on T1WI (rule)

√ isointense to vitreus on T2WI (rule)

US:

√ hyperechoic homogeneous mass

DDx: uveal melanoma (choroidal excavitation)

Cx: retinal detachment (frequent)

Rx: usually none; photocoagulation with retinal detachment

CHOROIDAL OSTEOMA

= rare juxtapapillary tumor of mature bone

Age: young woman

Location: may be bilateral

√ small flat very dense curvilinear mass aligned with choroidal margin of globe

DDx: calcified choroidal angioma

CMV-INDUCED RETINITIS

Frequency: in ⅓ of AIDS patents NOT on HAART (highly active antiretroviral therapy)

Location: unilateral → bilateral
√ uveal enhancement
√ retinal detachment
√ calcifications of retina
Cx: blindness ← retinal detachment within 3–6 months (in 33% prior to HAART)

COATS DISEASE

= RETINAL TELANGIECTASIA = PSEUDOGLIOMA
= congenital nonhereditary primary vascular malformation of the retina characterized by retinal telangiectasia (= multiple abnormal telangiectatic retinal vessels with aneurysm formation) and retinal exudation
Pathogenesis:
breakdown of blood-retina barrier at level of endothelial cells → leakage of lipoproteinaceous exudate of cholesterol crystals into retina + subretinal space → detachment of retina → progressive obliteration of vitreous space
Peak age: 6–8 years (range, 5 month – 75 years); M÷F = 2÷1
• ± leukokoria (if retina massively detached = 16% of leukokoria cases)
• strabismus, secondary glaucoma, loss of vision
• cholesterol crystals at funduscopy
Location: unilateral in 83–95%
Associated with: retinal detachment, slight microphthalmia
√ NO focal mass, NO calcification, NO enhancement of subretinal space (HALLMARK)
√ normal-sized / slightly smaller globe
US:
√ clumpy particulate echoes in subretinal space ← cholesterol crystals suspended in fluid
√ vitreous + subretinal hemorrhage (frequent)
CT:
√ unilateral dense vitreus ← proteinaceous subretinal exudate
√ linear V-shaped enhancement at anterior margin of subretinal exudate ← thickened retina composed of telangiectatic and aneurysmal vessels
MR:
√ subretinal exudate hyperintense on T1WI + T2WI ← mixture of protein + lipid
√ heterogeneous hypointensity on T2WI (with hemorrhage + fibrosis)
√ mild to moderate linear enhancement of retina at ora serrata and of detached retinal leaves
Cx: cataract, painful glaucoma, phthisis bulbi
Rx: photocoagulation / cryo- / laser ablation to obliterate telangiectasias (in early stages); enucleation
DDx: (1) Persistent hyperplastic primary vitreus (thick tubular retrolental mass)
(2) Retinopathy of prematurity
(3) Unilateral diffuse infiltrating noncalcifying retinoblastoma (< 3 years of age, no microphthalmia)

COLOBOMA

= COLOBOMA OF CHOROID = OPTIC DISC COLOBOMA

[*koloboun*, Greek = to mutilate]
= incomplete closure of embryonic choroidal fissure affecting eyelid / lens / iris / choroid / retina / macula (= gap in choroidal layer of globe between retina and sclera)
Genetics: autosomal dominant trait with variable penetrance (30%) and expression
Time of insult: 6th week of GA
May be associated with: encephalocele, agenesis of corpus callosum
Location: in 50–60% bilateral
• leukokoria ← exposed underlying sclera
√ cystic outpouching (= herniation) of vitreus at site of optic nerve attachment
√ scleral bulge on T2WI
√ small globe
US:
√ defect in optic disc + retroocular cyst
DDx: microphthalmos with cyst (= duplication cyst); axial (high) myopia

CATARACT

= opacification of lens
Etiology: congenital, age-related, infection, trauma

Congenital Cataract

Location: frequently bilateral
• leukokoria = white reflection with opaque lens
US:
√ increased thickness of lens
√ intralenticular echoes
√ echogenicity of posterior / both walls

DACRYOADENITIS

= infection of lacrimal gland
Organism: staphylococci (most common), mumps, infectious mononucleosis, influenza
√ homogeneous enlargement of lacrimal gland
√ ± compression of globe

DACRYOCYSTITIS

= inflammation / infection with dilatation of lacrimal sac
Cause:
(a) obstruction of nasolacrimal duct ← duct stenosis / dacryolith
(b) sarcoidosis, Wegener granulomatosis, benign lesions (eg, mucocele and epidermoid cyst), and malignant lesions (including squamous cell carcinoma and lymphoma)
Location: medial (internal / inner) canthus
• acute onset of pain, conjunctivitis
• medial canthus mass, lid swelling
• mucopurulent discharge from puncta
• conjunctivitis concurrent preseptal cellulitis

√ well-circumscribed round fluid collection along inner canthus
√ peripheral enhancement
√ adjacent inflammation + soft-tissue thickening
Cx: periorbital / orbital cellulitis

DACRYOCYSTOCELE

◊ 2nd most common cause of neonatal nasal obstruction (after choanal atresia)
Cause: congenital obstruction of nasolacrimal duct (imperforate Hasner membrane distally, reason for proximal obstruction unknown)
Location: inferomedial canthus of neonates
• tense blue-gray mass at medial canthus / in nasal cavity
CT / MR:
√ homogeneous well-defined mass of fluid attenuation extending into nasal cavity along course of nasolacrimal duct = nasolacrimal duct dilatation
√ enhancement of thin wall
√ superior displacement of inferior turbinate bone
√ contralateral shift of nasal septum
Cx: dacryocystitis, periorbital cellulitis
Rx: duct massage, duct probing with irrigation, prophylactic antibiotics, endoscopic resection, marsupialization
◊ Prompt treatment to prevent secondary infection!

INCLUSION CYST OF ORBIT

= congenital unilocular closed sac containing derivatives of single germ layer (monodermal)
Etiology: failure of surface ectoderm to separate completely from underlying developing neural tube; usually arises in fetal cleavage planes (sutures)
Prevalence: 5% of all orbital masses
◊ Most common benign developmental orbital tumor in childhood (45% of all masses)
Age: 1st decade; < ¼ diagnosed at birth
Location: in anterior extraconal orbit in close relation to frontozygomatic suture = upper temporal (outer) quadrant / lacrimal fossa (60–80%) or frontoethmoidal suture = upper nasal quadrant (25%)
Site: overwhelmingly superficial in lateral ⅓ of eyebrow
• slow progression of painless lesion
• proptosis (for deeper lesion in older child / adult)
Prognosis: slow enlargement over years / decades secondary to accumulation of debris
DDx: cephalocele (tracts leading to midline anterior cranial fossa, no lipid)

Dermoid Cyst of Orbit

= DERMOID INCLUSION CYST
Histo: thick vascularized capsule composed of stratified squamous epithelium identical to epidermis + additional ectodermal features like hair follicles / sebaceous glands containing oily secretions + proteinaceous keratin debris

√ thick surrounding capsule ± enhancement
√ ± expansion / erosion of bony orbit:
  √ periosteal and intradiploic remodeling of bone
  √ reactive sclerotic margin / shell of dense bone
US:
  √ encapsulated heterogeneous mass with variable cystic component
CT:
  √ encapsulated well-circumscribed unilocular cystic mass:
    √ ± fat-density of −60 to −90 HU
    √ ± high-attenuation foci in wall ← calcification
MR:
  √ high signal intensity on T1WI + T2WI ← lipids of sebum
  √ ↓ SI of lipid on fat-suppressed images

Epidermoid Inclusion Cyst

Path: white "pearly" tumor consisting of dry waxy / flaky keratin ← desquamated inner lining of squamous cells
Histo: exclusively squamous epithelium
√ water / CSF density ← high proteinaceous content
MR:
  √ high SI on T2WI
  √ internal signal NOT suppressed on FLAIR
  √ ↑ signal intensity on DWI + ↓ ADC map

ENDOPHTHALMITIS

Infectious Endophthalmitis

Organism: bacteria (rare in childhood, trauma, idiopathic), fungi, parasites
Cause:
  (a) exogenous endophthalmitis: most commonly related to eye injury / surgery
  (b) endogenous endophthalmitis: hematogenous spread from distant source of infection
US:
  √ medium- to high-intensity echoes dispersed throughout vitreus (DDx: vitreous hemorrhage echoes are more mobile)
CT:
  √ increased attenuation of vitreus
  √ uveal-scleral thickening
  √ decreased attenuation of lens

Sclerosing Endophthalmitis

= TOXOCARA CANIS ENDOPHTHALMITIS = OCULAR LARVA MIGRANS= NEMATODE ENDOPHTHALMITIS
= granulomatous uveitis resulting in subretinal exudate, retinal detachment, organized vitreus
Age: 2–6–12 years
Mode of infection: playing in soil contaminated by viable infective eggs from dog / cat

excrement (common in playgrounds)

Organism: helminthic nematode Toxocara canis / Toxocara cati causes visceral / ocular larva migrans (0.5 mm long, 20 μm wide); endemic throughout world; especially common in southeastern USA

Life cycle:

egg hatches into larva within intestines of definite host (dog) → develops into adult worm; alternatively dog may eat infective-stage larvae from intestines / viscera of other animals; in noncanine host (human) larvae will not develop into adult worm, but burrow through intestinal wall and migrate to liver, lung, and other tissue including brain + eye (= visceral larva migrans)

Accidental host: human

Pathophysiology: migration through human tissue produces a severe eosinophilic reaction that becomes granulomatous; spreads hematogenously to temporal choroid

Path: retina elevated + distorted + partially replaced by an inflammatory mass containing abundant dense scar tissue; subjacent choroid infiltrated with chronic inflammatory cells including eosinophils; proteinaceous subretinal exudate

Age: 5–10 years

• strabismus, red "hot" eye, pain
√ unilateral visual impairment, photophobia
• anterior chamber flare cells, keratic precipitates
• vitreous synechia; peripheral blood eosinophilia
• vitreitis = accumulation of cellular debris in vitreus
• leukokoria (16% of cases of childhood leukokoria)
• fever, hepatomegaly, pneumonitis, convulsions

Location: usually unilateral

√ eye of normal size
√ no calcifications

US:

√ hyperechoic mass in peripheral fundus / vitreus
√ ± calcifications

CT:

√ intravitreal mass
√ focal uveoscleral thickening (granulomatous reaction around larva) with contrast enhancement
√ increased density of vitreous cavity

MR:

√ granuloma isointense to vitreus on T1WI
√ mass usually hyperintense relative to vitreus on first-echo T2WI
√ mass may be isointense on second-echo T2WI compared to surrounding vitreus
√ granuloma may be of low SI ← dense fibrosis
√ moderate to marked enhancement

Cx: secondary retinal detachment (← subretinal fluid / vitreoretinal traction), cataract

Rx: antithelminthic albendazole ± vitrectomy

Dx: (1) Enzyme-linked immunosorbent assay (ELISA) on blood serum (less reliable) / vitreous aspirate

(2) Histologic identification of organism (larvae difficult to detect within inflammatory reaction)

DDx: retinoblastoma (calcifications); fascioliasis, ascariasis, ancylostomiasis, angiostrongylosis

GRAVES OPHTHALMOPATHY

= THYROID OPHTHALMOPATHY = ENDOCRINE EXOPHTHALMOS

= autoimmune disease unrelated to thyroid function with an increase in orbital pressure producing ischemia, edema, fibrosis of muscles

Etiology: produced by long-acting thyroid-stimulating factor (LATS); probably immunologic cross-reactivity against antigens shared by thyroid + orbital tissue

Age: adulthood; 5% younger than 15 years; M÷F = 1÷4

Histo: deposition of hygroscopic mucopolysaccharides + glycoprotein (early) + collagen (late); infiltration by mast cells and lymphocytes, edema, muscle fiber necrosis, lipomatosis, fatty degeneration

Time of onset: signs + symptoms usually develop within 5 years after the onset of hyperthyroidism

- proptosis
  - ◊ Most common cause of uni- / bilateral exophthalmos in adults!
- lid lag = upper eyelid retraction
- periorbital swelling, chemosis (= conjunctival swelling), conjunctivitis; progressive optic neuropathy (5%)
- ophthalmoplegia = restricted ocular motility (correlates with increase in mean muscle diameters)
- hyperthyroidism; euthyroidism (in 10–15%); severity of orbital involvement unrelated to degree of thyroid dysfunction

Staging (Werner's modified classification):

Stage I : eyelid retraction without symptoms
Stage II : eyelid retraction with symptoms
Stage III : proptosis > 22 mm without diplopia
Stage IV : proptosis > 22 mm with diplopia
Stage V : corneal ulceration
Stage VI : loss of sight

Location:

bilateral in 70–85%; single muscle in 10%; asymmetrical involvement in 10–30%; all muscles equally affected with similar proportional enlargements; superior muscle group most commonly when only single muscle involved [FORMER notion: inferior > medial > superior rectus muscle + levator palpebrae > lateral rectus muscle]

mnemonic: I'M SLow

Inferior
Medial
Superior
Lateral

√ eyelid edema

√ proptosis = globe protrusion > 21 mm anterior to interzygomatic line on axial scans at level of lens
√ "Coke-bottle" sign = swelling of muscles maximally in midportion (relative sparing of tendinous insertion at globe)
√ slight uveal-scleral thickening
√ tenting of posterior globe
√ apical crowding = orbital apex involved late → pressure on optic nerve
√ dilatation of superior ophthalmic vein ← compromised orbital venous drainage at orbital apex ← enlarged extraocular muscles
√ increase in diameter of retrobulbar optic nerve sheath ← dural distension ← accumulation of CSF in subarachnoid space ← optic neuropathy
√ stretching of optic nerve
√ increased orbital fat:
  √ increased density of orbital fat (late)
  √ intracranial fat herniation through superior ophthalmic fissure (best correlation with compressive neuropathy)
√ enlargement of lacrimal gland with anterior displacement

MR:
  √ high SI in enlarged eye muscles on T2WI (edema in acute inflammation)

Prognosis: in 90% spontaneous resolution within 3–36 months; in 10% decrease in visual acuity (corneal ulceration / optic neuropathy)

Rx: short- and long-term steroid therapy, cyclosporine, radiation, surgical decompression, correction of eyelid position

DDx: pseudotumor (usually includes tendon of eye muscles)

HEMANGIOMA OF ORBIT

◊ Most common benign orbital tumor in adults!

Location: 83–94% retrobulbar (intraconal)

√ sharply demarcated oval mass in superior-temporal portion of conus (⅔) often sparing orbital apex
√ displacement (NOT involvement) of optic nerve
√ expansion of bony orbit
√ uniform / inhomogeneous (when thrombosed) enhancement
√ small calcifications (phleboliths)
√ puddling of contrast material on angiography

US:
  √ well-defined encapsulated mass of intermediate echogenicity
  √ absent / poor predominantly venous flow

Capillary Hemangioma of Orbit

= INFANTILE HEMANGIOMA = BENIGN HEMANGIOENDOTHELIOMA

◊ Most common tumor of infancy (60% in head & neck)!

Frequency: most common vascular tumor of orbit in children; 3% of all pediatric orbital masses; 17% of vasculogenic orbital lesions

Age: first 2 weeks of life; 95% at < 6 months of age; M÷F = 2÷3

Path: nonencapsulated infiltrative mass consisting of multiple lobules separated by vascular fibrous septa

Histo: proliferation (lasting up to 10 months) of endothelial cells with multiple vessels of capillary size; involutional phase with progressive peripheral replacement by fibrofatty tissue → atrophy of mass

May be associated with: PHACES syndrome

- appears shortly after birth + rapidly increases in size for 6–12 months + then gradually involutes over 7–10 years
- proptosis, chemosis (= edema) of eyelid + conjunctiva exaggerated by crying for deep lesion
- associated with cutaneous red to bluish angiomas (90%); NO familial / hereditary association

Location: anterior part of orbit (red discoloration of skin - most frequently eyelid), subcutaneous (bluish discoloration of skin); occasionally posterior; multiple hemangiomas in 20%

Site: entirely extraconal / substantial extraconal component

√ displacement of globe (= proptosis)
√ lobulated irregularly marginated heterogeneous mass (suggesting malignant cause)
√ intense enhancement equal to / greater than orbital muscle
√ often transspatial → may extend intracranially through optic canal / superior orbital fissure
√ activity in radionuclide flow studies

US:
- √ smoothly contoured heterogeneous mass of variable (usually hyperechoic) echogenicity
- √ abundant intralesional flow decreasing with age:
  - √ high density of vessels (> 5 vessels per cm^2)
  - √ increased arterial and venous flow velocity (Doppler shift > 2 kHz)
  - √ arterial flow of low resistance

CT:
- √ fairly homogeneous mostly extraconal mass:
  - √ isoattenuating relative to muscle
  - √ hyperattenuating relative to brain ← blood in vessels
- √ scalloping / expansion of bony orbit
- √ invasion of bone (extremely rare)
- √ calcifications (rare)
- √ prompt marked uniform persistent enhancement
- √ shrinkage of mass with decrease in vascularity and progressive replacement by fat (during involution)

MR:
- √ lobulated mass with thin hypointense septa
- √ usually iso- to hyperintense to muscle on T1WI
- √ moderately hyperintense on T2WI
- √ intra- and perilesional flow voids (distinguishing feature)
- √ intense uniform enhancement (during proliferative phase)
- √ increased SI on T1WI + T2WI ← fibrofatty deposition during involutional phase

Angio (reserved for embolotherapy):

√ hypervascular mass with prolonged capillary stain and large feeding and draining vessels

Cx: profuse hemorrhage, thrombosis, calcification, corneal ulceration, optic nerve compression, amblyopia ("lazy eye"), visual axis occlusion, bone remodeling, ± visceral hemangiomas → severe consumptive thrombocytopenic coagulopathy (Kasabach-Merritt syndrome)

Rx: observation; topical / systemic oral / intralesional corticosteroids; interferon; laser; surgery

Prognosis: often increase in size for 6–10 months followed by spontaneous involution within 1–2 years

DDx: (1) Rhabdomyosarcoma (older age, may contain flow voids)
(2) Vascular malformations
(3) Infantile fibromatosis
(4) Infantile fibrosarcoma

Cavernous Hemangioma of Orbit

= CAVERNOUS MALFORMATION

= congenital vascular anomaly (1) present at birth (2) without spontaneous involution (3) slow growth over time

Frequency: low; 12–15% of all orbital masses; 1–2% of childhood orbital masses

Cavernous hemangioma is the most common benign orbital mass in adults!

Mean age: 45 (range, 18–72) years; M÷F = 2÷3

Histo: large dilated venous channels with flattened endothelial cells surrounded by fibrous pseudocapsule

- slowly progressive painless unilateral proptosis (most common presenting sign)
- visual field deficit (50%) ← mass effect on optic nerve
- acute-onset proptosis (occasionally) ← abrupt orbital enlargement ← cytokine + hormonal stimulation at puberty / during pregnancy
- recurrent episodes of diminished visual acuity (optic nerve compression)
- pain, eyelid swelling, diplopia, palpable lump (less common)

Location: lateral aspect of retrobulbar intraconal space; conal + extraconal cavernous malformation (rare)

CT:
√ well-circumscribed round / ovoid solitary homogeneously hyperattenuating mass
√ displacement of adjacent structures (extraconal muscles, optic nerve) without invasion
√ ± phleboliths (extremely rare)
√ ± bone remodeling with expansion of orbital walls
√ ± intracranial extension through superior orbital fissure (5–10%)

CECT:
√ poor enhancement during early arterial phase ← scant arterial supply
√ progressive filling from periphery to center (complete filling within 30 minutes) during delayed phase

MR:
√ mass isointense to muscle on T1WI
√ uniformly hyperintense to muscle on T2WI

√ internal septa in larger lesions
√ NO flow voids
√ progressive accumulation of contrast (late phase dynamic images / or delayed images after 1 hour!)

US:
√ well-defined borders (pseudocapsule)
√ honeycomb-like structure

Prognosis: no involution
Rx: conservative; surgical excision in cases of severe proptosis / optic nerve compression
DDx: other vascular lesions (arterial phase enhancement) like capillary hemangioma (pediatric diagnosis), hemangiopericytoma, arteriovenous malformation

PHACES Syndrome

= acronymic syndrome composed of
(1) **P**osterior fossa brain malformation (Dandy-Walker malformation, ventricular dilatation, ipsilateral cerebellar hypoplasia, cerebellar vermian hypoplasia, cortical dysgenesis)
(2) **H**emangiomas of face + neck: (segmental / plaquelike > 5 cm in diameter)
(3) **A**rterial anomalies related to ipsilateral intracranial circulation (persistent trigeminal artery, agenesis of internal carotid / vertebral artery)
(4) **C**ardiac anomalies / **C**oarctation of aorta (aortic aneurysm, aortic dissection, ASD, VSD)
(5) **E**ye abnormalities (cataract, coloboma, optic nerve hypoplasia, glaucoma)
(6) **S**ternal / ventral developmental anomalies

Incidence: > 150 cases
• endocrine abnormalities
√ occasionally absence / defect of sternum / supraumbilical raphe (= fibrous band / cleft in midline above umbilicus)

HEMANGIOPERICYTOMA OF ORBIT

= rare orbital neoplasm derived from pericytes (= contractile support cells surrounding small vessels) with cell lineage identical to solitary fibrous tumors
Frequency: 1% of all orbital masses
Mean age: 41 years; M = F
• proptosis, palpable mass (common)
• pain, diplopia, decreased visual acuity (less common)
Path: slow growing mass, may recur / metastasize (15%)
Histo: dense hypercellular tumor with spindle-shaped cells + "staghorn" vascular branching pattern, relatively bland to frankly malignant
Spread: lung
Location: extraconal (commonly adjacent to paranasal sinuses)
√ lobulated well circumscribed mass
√ ± infiltrative border + bone erosion (= aggressive lesion)
√ calcification (rare)
CECT:

√ marked enhancement during arterial + early venous phase with rapid washout

MR:

√ isointense relative to gray matter on T1WI + T2WI

DDx: cavernous malformation

INFANTILE FIBROMATOSIS OF ORBIT

= rare nonmetastasizing locally invasive fibrous proliferation with tendency to recur after surgical resection

Age: congenital (54%), < 2 years of age (in 89%)

Clinical forms: (1) solitary: M > F
(2) multicentric (= congenital generalized fibromatosis): F > M

Location: head & neck > trunk > lower extremity > upper extremity

Site: skin, subcutaneous tissue, deeper structures including visceral organs; combination of all

Mean size: 3.5 (range, 0.5–7.0) cm

• painless swelling / lump + skin discoloration ← vascularity

• proptosis

X-ray:

√ nonspecific expansion of orbit

US:

√ round well-circumscribed mass of heterogeneous texture

√ ± target appearance ← central necrosis / hemorrhage

CT:

√ ± orbital bone erosion ± small foci of calcifications

√ enhancing mass hyperattenuating to muscle

MR:

√ multilobulated / infiltrative margins

√ low to intermediate SI relative to muscle on T1WI + (frequently) foci of hyperintensity

√ heterogeneous predominantly hyperintense SI on T2WI:

√ T2 hyperintensity ← high cellularity + myxoid change

√ T2 hypointensity ← high collagen content

√ target appearance ← central hemorrhage / necrosis / cystic / myxoid change

√ intense diffuse / peripheral enhancement

Prognosis: spontaneous resolution (common); 7% recurrence rate after surgical resection

Mortality: 15% overall; 75% with visceral involvement

Rx: conservative; surgical resection for local complications

DDx of solitary disease:

(1) Rhabdomyosarcoma (occurs in older age group)

(2) Hemangioma (flow voids at tumor periphery)

INFECTION OF ORBIT

Cause: bacterial infection extending from paranasal sinuses (especially ethmoid + frontal sinuses), face, eyelid, nose, teeth, lacrimal sac through thin lamina papyracea + valveless facial veins into orbit

Organism: staphylococci, streptococci, pneumococci
• lid edema, ocular pain, ophthalmoplegia; fever, elevated WBC
Location: preseptal = periorbital soft tissue; subperiosteal; peripheral = extraconal fat; extraocular muscles; central = intraconal fat; optic nerve complex; globe; lacrimal gland
Cx: epidural abscess, subdural empyema, cavernous sinus thrombosis, cerebral abscess, osteomyelitis

Abscess of Orbit

= abscess of intraconal space
Cause: penetrating orbital injury, ocular surgery, metastatic process
• marked proptosis, chemosis, ophthalmoplegia
• impaired visual acuity
MR:
√ hyperintensity on T1WI + T2WI
Rx: surgical drainage for intraconal abscess

Subperiosteal Orbital Abscess

Cause: sinusitis, orbital inflammation
Location: along medial wall of orbit between lamina papyracea and medial rectus muscle
√ subperiosteal spindle-shaped fluid collection
√ displacement of thickened periosteal membrane + increased enhancement
√ displacement of adjacent fat + extraocular muscles
Cx: orbital abscess (extension to intraconal space)

Pott Puffy Tumor

= frontal osteomyelitis with subperiosteal abscess formation beneath galea aponeurotica
Cause: frontal sinusitis + periorbital cellulitis → thrombophlebitis of valveless emissary veins → frontal osteomyelitis
• enlarging broad swollen bump of doughy consistency in the region above brow
√ osseous destruction of frontal bone
√ frontal subgaleal fluid collection
Cx: epidural / subdural empyema; parenchymal cerebral abscess; meningitis; cavernous sinus thrombosis; thrombophlebitis; venous brain infarct

Orbital / Postseptal Cellulitis

= acute bacterial postseptal infection
Orbital septum = thin sheet of fibrous tissue originating in the orbital periosteum + inserting in palpebral tissues along tarsal plates; acts as barrier against spread of periorbital infection into posterior compartment of orbit
CT: √thin band paralleling superior orbital rim deep to facial musculature
Classification: intraconal, extraconal, subperiosteal
Source: paranasal sinusitis (most commonly) spreading via perivascular pathway
• limitation of eye movement ± proptosis
• visual acuity usually maintained

• fever
Location: mostly confined to extraconal space
√ proptosis
√ scleral thickening
√ enlargement + displacement of extraocular muscles (frequently medial rectus muscle ← ethmoid sinusitis)
√ increased attenuation of retroorbital fat + obliteration of fat planes
√ opacification of ethmoid + maxillary sinuses (extension through thin lamina papyracea into orbit)
MR (enhanced fat-suppressed images most sensitive):
√ hypointense on T1WI + hyperintense on T2WI
US:
√ diffuse hypoechoic area invading retrobulbar fat
Rx: IV antibiotics + corticosteroids
Cx: subperiosteal / intraconal abscess; thrombosis of superior ophthalmic vein / cavernous sinus; bacterial meningitis; epdidural / subdural abscess; brain abscess; loss of vision
DDx: edema, orbital pseudotumor, orbital myositis, intra- and extraorbital neoplasm (chloroma, leukemic infiltrate)

Preseptal / Periorbital Cellulitis

= preseptal infection limited to soft tissues anterior to orbital septum

Periorbital (preseptal) + orbital (postseptal) cellulitis are differentiated by location with respect to the orbital septum.

Source of infection: face, teeth, ocular adnexa, local trauma
• swelling + erythema of eyelid, chemosis
• limitation of eye movement (in severe cases) without proptosis
√ thickening of eyelids + septum
√ diffuse swelling of anterior orbital tissues with increased density + obliteration of fat planes
Rx: oral antibiotics in outpatient setting

Edema of Orbit

Location: usually confined to preseptal structures (eyelid, face); involvement of orbital structures (rare)
√ swelling of eyelids / face
√ increased attenuation of orbital fat + obliteration of fat planes
√ displacement + enlargement of extraocular muscles
MR:
√ hyperintensity on T2WI

LYMPHANGIOMA OF ORBIT

= VENOUS-LYMPHATIC MALFORMATION
= NO-FLOW / LOW-FLOW VASCULAR MALFORMATION
= LYMPHATICOVENOUS MALFORMATION

Prevalence: 3.5÷100,000; 1–2% of orbital childhood masses; 4–8% of expanding pediatric orbital lesions; 25% of vasculogenic orbital lesions

Origin: arises from a pluripotent venous anlage as a malformation (NOT neoplasm of proliferating cells!)

Path: unencapsulated diffuse multicompartmental lesion often with intra- and extraconal components insinuating between normal orbital structures

Histo: dilated lymphatics, dysplastic venous vessels, smooth muscle, areas of hemorrhage

(a) simple / capillary lymphangioma
= lymphatic channels of normal capillary size

(b) cavernous lymphangioma (most common)
= dilated microscopic channels

(c) cystic hygroma
= macroscopic multilocular cystic mass

May be associated with: intracranial vascular anomalies (70%): developmental venous anomalies (61%), AVM, cerebral cavernous malformation, sinus pericranii

Age: 1st decade or later (mean age of 6 years); M÷F = 1÷1; 43% before age of 6 years; 60% before age of 16 years

- proptosis:
  - slowly progressive proptosis with restriction of eye movement, optic nerve compression, vertical displacement of globe
  - sudden proptosis from intratumoral hemorrhage
    = CARDINAL FEATURE; often occurring spontaneously / after minor trauma / during upper respiratory infection
  - worsening proptosis from intralesional proliferation of lymphocytes during viral infection with subsequent resolution
- associated with lesions on lid, conjunctiva, cheek:
  - eyelid fullness from birth
  - purple discoloration of skin, usually in superomedial orbit
  - vesicles in conjunctiva, facial skin, oral mucosa
- restricted ocular motility (50%)
- growth with patient's growth ± accelerated growth in response to hormonal changes (during puberty / pregnancy)

Location: unilateral; usually medial to optic nerve with intra- and extraconal component, crossing anatomic boundaries (conal fascia / orbital septum)

Site: superficial (conjunctiva + eyelid) in anterior orbit (79%); deeper orbit (67%); pre- and postseptal orbit (73%)

√ poorly defined infiltrating multilobulated heterogeneous lesion
√ single / multiple cystlike areas with rim enhancement (after hemorrhage):
  √ solid-appearing microcystic component
  √ macrocystic component = cysts of 1–2 cm in size
  √ blood cyst = "chocolate cyst" associated with multiple recurrences
√ variably mild patchy low-flow enhancement (= venous channels) / ring enhancement (after hemorrhage)
√ rarely contains phleboliths (DDx: hemangioma, orbital varix)

US:
√ heterogeneous echotexture with ill-defined borders:
√ area of predominantly cystic low-level internal echoes with infiltrative borders
√ hyperechoic intracystic clot
CT:
√ poorly marginated lesion insinuating itself between normal structures:
√ well visualized ← inherent contrast between malformation + orbital fat
√ venous / solid components slightly hyperattenuating relative to brain tissue
√ macrocystic lymphatic components similar in attenuation to vitreous of globe
√ mild to moderate expansion / remodeling / hyperostotic / lytic lesion of bony orbit
√ ± widening of superior / inferior orbital fissure
√ frequent thickening of upper eyelid
MR (modality of choice):
√ iso- to slightly hyperintense relative to brain on T1WI + very hyperintense relative to brain on T2WI:
√ T1WI for lymphatic / proteinaceous fluid
√ fat-suppressed T1WI for blood / blood products
√ fat-suppressed T2WI for nonhemorrhagic fluid
√ fluid-fluid levels of hemorrhages of various ages / T2 shading in multiple cysts (almost PATHOGNOMONIC)
√ NO enlarged feeding vessels / flow voids

Prognosis: no involution; aggressive behavior with continued enlargement (in 64%) + recurrence after treatment; eventually loss of vision (in 40%); progression slows with termination of body growth

Rx: observation; intralesional injection with sclerosing agents (tetradecyl sulfate or OK-432) / steroids; surgery in case of optic nerve compression + for relieve of pain and for cosmetic improvement

DDx: orbital varix (affected by postural changes, communication with systemic circulation)

LYMPHOMA OF ORBIT

Usually presents without evidence of systemic disease; subsequent development of systemic disease frequent

Frequency: in 8% of leukemia; in 3–4% of lymphoma; 67–90% of orbital lymphoproliferative tumors; 24% of all space-occupying orbital tumors in patients > 60 years of age

Age: 50 years on average

Type: usually non-Hodgkin B-cell lymphoma; Burkitt lymphoma with orbit as primary manifestation; Hodgkin disease rare

- palpable mass, mildly restricted ocular motility
- painless swelling of eyelid (pain is uncommon)
- proptosis (late in course of disease)
  ◊ 3rd most common cause of proptosis (after orbital pseudotumor + cavernous hemangioma)

Location: extraconal (especially lacrimal gland, anterior extraconal space, retrobulbar) > intraconal > optic nerve-sheath complex; unilateral (76%)
◊ The lacrimal gland is a common site for leukemic infiltrates + lymphoma (40%)!

Growth types:
(a) well-defined high-density mass (most commonly about lacrimal gland)
√ smooth circumscribed mass (50%)
(b) diffuse infiltration (tends to involve entire intraconal region)
√ diffuse ill-defined lesion (50%)

√ tendency to mold to orbital structures (globe, optic nerve, orbital wall → ± bone remodeling

√ slight to moderate uniform enhancement
√ osseous erosion (rare)
√ isointense relative to muscle on T1WI
√ hyperintense relative to orbital fat on T2WI
US:
√ solitary / multiple hypoechoic homogeneous masses with infiltrative borders
DDx: pseudotumor (infiltration / thickening of ocular muscles, mass commonly T2-isointense relative to orbital fat, high ADC values, acute onset of pain)

MEDULLOEPITHELIOMA

= DIKTYOMA = TERATONEUROMA [*diktyon*, Greek = net]
= rare embryonal malignant (most) / benign intraocular neoplasm
Origin: primitive medullary epithelium in ciliary body
Histo: folded cords + sheets resembling a fisherman's net (diktyomatous pattern) surrounding fluid collections predominantly composed of hyaluronic acid; heteroplastic components of hyaline cartilage, rhabdomyoblasts, neuroglia, sarcomatous elements (a) teratoid (30–50%) (b) nonteratoid (50–70%)
Mean age: 5 years; M=F
• poor vision ← lens subluxation, lens notching, glaucoma, cataract formation, retinal detachment
• pain; leukokoria; mass of iris / ciliary body
• exophthalmos, buphthalmos. strabismus, ptosis
Location: ciliary body (common); optic nerve head / retina (rare); usually unilateral
√ dystrophic calcifications (in hyaline cartilage component) in 30%
US:
√ echogenic irregularly shaped /ovoid mass
CT:
√ dense irregular mass
√ moderate to marked enhancement
MR:
√ slightly to moderately hyperintense to vitreus on T1WI
√ hypointense on T2WI
√ marked homogeneous enhancement / heterogeneous (← cystic components)
Prognosis: local recurrence common; metastases rare

METASTASIS TO ORBIT

Prevalence: 1–13% of orbital tumors
Origin: source known in only in 50%

adults: carcinoma of breast + lung
children: neuroblastoma > Ewing sarcoma, leukemia, Wilms tumor

Frequency of metastases to orbit:
breast cancer (48–53% of orbital metastases) > prostate carcinoma > cutaneous melanoma > lung cancer

- proptosis, motility disturbance, pain, diplopia, ↓ vision
- **paradoxical enophthalmos** (10% of orbital lesions)
  = posterior globe retraction ← infiltrative + fibrotic contraction of orbital fat ← scirrhous breast cancer (most common) / scirrhous gastrointestinal carcinoma

Location: 12% intraorbital, 86% intraocular; bilateral in ⅓
Preferential site by type of metastasis:
› breast cancer → orbital fat + muscle
› prostate cancer → bone
› melanoma → muscle

√ diffuse enhancement of retrobulbar fat with abnormally heterogeneous hypointensity on T1WI + T2WI ← fibrotic infiltration

DDx: thyroid ophthalmopathy (bilateral, sparing tendinous insertions); orbital pseudotumor (typically painful involving tendinous insertion); sarcoidosis

Choroidal Metastasis

[choroid = posterior portion of uvea]
◊ Most common ocular malignancy in adults!
Origin: lung > breast, hypervascular + hematologic malignancy
Location: posterior half of globe near macula (access via short posterior ciliary arteries); extension along plane of choroid (in ⅓ bilateral + in ⅓ multiple)

- often asymptomatic (unless fovea involved)
- visual loss ← retinal detachment

√ small areas of broad-based flat thickening + increased density
√ subretinal fluid = retinal detachment
√ mild posterior choroidal thickening

US:
√ often multiple hyperechoic posterior wall masses: usually flat / discoid + with an irregular surface
√ higher flow than melanoma at Doppler

MR:
√ iso- to hyperintense on T1WI, hyperintense on T2WI
√ heterogeneous enhancement
√ may be T1 hyperintense + T2 hypointense ← high level of protein / hemoglobin degradation products ← metastasis from mucin-producing adenocarcinoma / hemorrhagic metastasis

NORRIE DISEASE

= RETINAL DYSPLASIA
= X-linked recessive disease: ? inherited form of persistent hyperplastic primary vitreus

- seizures, mental retardation (50%)
