Characteristics of the tasks used in sport goal-setting research have also been pointed to as explanations for the compromised effectiveness of goal setting in this setting. Specifically, it has been suggested that physical tasks in and of themselves tend to provide feedback. An individual can see and feel how one is doing and how hard one is trying (especially in the case of those sit-up studies!), regardless of whether one is focused on a more-or-less specific or a more-or-less difficult goal. Both the process of performing and performance outcomes per se are more overt in the physical domain when contrasted to tasks in other settings, such as industrial or academic environments.

According to Hall and Kerr, the anomalies in the sport goal-setting literature hold ramifications for the employment of goal setting in applied sport situations. Addressing the methodological and task-related problems identified above in subsequent research may indeed enhance the internal validity of future goal-setting studies. What would be the cost, however, in terms of external validity? That is, if we controlled for spontaneous goal setting and personal objectives, competition, the probability that those involved in the usually voluntary activity of sport are often motivated to participate and perform, and the nature of the task, what does such research have to say to the real world of athletic engagement?

A central conceptual ambiguity that plagues status quo sport goal-setting work based on Locke’s model is the premise that goals are merely end states or external standards that energize and direct behavior. Such mechanistic assumptions about the nature and connotations of goals do not provide insight into what contributes to differences in the goals that individuals adopt, whether assigned by the experimenter, set by the participant, and/or spontaneously generated in “no goal” or vague goal conditions. Moreover, such a perspective on the purpose of goals does little to inform us about the implications of such goals for variation in ensuing motivation-related responses and achievement behaviors.

Although Latham and Locke considered goal setting to be a “motivational technique” that is effective, a conceptual (or indeed, to some degree, even empirical) consideration of motivational processes is sorely missing in the goal-setting literature stemming from Locke’s contributions. For example, commitment is assumed to be an important moderator of the goal setting–performance relationship in Locke’s framework, but what contributes to variability in commitment to goals, both at the onset and throughout the goal-setting enterprise? Adequate ability is held to be fundamental for translating goals into desired performance, but goal-setting theory does not consider potential discrepancies in how individuals judge their level of competence or suggest when or why low ability would prove problematic. In Locke’s goal-setting theory, difficult goals are presumed to foster effort, and this enhanced exerted effort is held to be a central way by which difficult goals contribute to superior performance. It is important to recognize, however, that people do not always try when the situation or task becomes challenging. Indeed, they may even intentionally “hold back” in such circumstances. Why might this occur? In short, such broader motivational issues, which have important implications for the degree to which discrete goals would lead to better performance and enhanced task or activity engagement, are not adequately addressed in Locke’s initial conceptualization or later treatises on goal setting.

2. THE MEANING OF GOALS

A contemporary theory of motivation that emphasizes the meaning of personal goals and the consequences of this meaning for corresponding motivational processes

and achievement behaviors is achievement goal theory (AGT). Achievement goals are held to reflect different ways of construing one's competence in terms of the demands and standards placed on the individual and the different ways of subjectively defining successful performance and performance progress. It is assumed, based on AGT, that the demonstration of high competence (or avoidance of demonstrating low competence) is at the heart of striving for achievement and serves as the core of people's views regarding goal accomplishment. In the prevailing achievement goal conceptualizations that have dominated sport research over the past 10 to 15 years, two major achievement goals are deemed to be operating. One is a task-involved goal, which entails an emphasis on demonstrating self-referenced competence. In this case, witnessing personal improvement, learning, and/or task mastery provide a sense of subjective success. If centered on an ego-involved goal, however, revealing superior competence relative to others is fundamental to perceptions of goal accomplishment. Perceptions of adequate (or inadequate) ability are normatively referenced when ego-involved and, as a result, performance attempts stemming from high effort and reflecting personal progress are insufficient for feeling successful. Thus, although AGT considers the level of one's perceptions of ability (high/low) to have motivational significance, the hallmark of this framework is that we must bear in mind how the person judges whether he or she has exhibited high versus low ability when engaged in a task.

Drawing from AGT, it is proposed that a focus on task-involved goals, regardless of whether the person in question is confident or perceives her or his ability to be less than outstanding, will result in a positive and adaptive achievement pattern. That is, a task-involved person is expected to be more likely to perform up to her or his ability level, try hard and be invested in the activity, prefer challenging tasks, and persevere, even when the circumstances become difficult. As long as things are going well (i.e., the person is experiencing successful goal accomplishment and perceives his or her ability to be high), an individual striving to meet ego-involved goals should be committed to the activity at hand and perform well. In this situation, the person would not shy away from challenge and would be willing to work—as long as that level of exerted effort does not take the spotlight off or lead to questions regarding her or his level of superior competence. Short- and especially long-term motivational problems are hypothesized when there is a centering on ego-involved goals and the individual has reached the

conclusion that her or his competence is inferior relative to relevant others. Such a person would be expected to reduce the commitment to the activity and rescind effort (perhaps in an initial attempt to "save face," but eventually, if the situation does not change, as a step toward withdrawal from this endeavor). Optimally challenging goals would be especially worrisome for an individual who is trying to meet ego-involved standards and who has doubts about her or his competence. Rather, the preference would be to work toward easy goals (so the probability of failing is reduced) or set goals that are much too difficult (so that failure can be attributed to task difficulty rather than one's inadequacy).

As Hall and Kerr eloquently argued, a consideration of achievement goals provides insight into what may be the meaning of assigned goals in typical goal-setting protocols and what lays the foundation for the personal goals that study participants might set in goal-setting investigations. Variations in achievement goals are also relevant to what type of feedback is sought and how the feedback provided is understood and used in studies of goal-setting effectiveness. Achievement goals are pertinent to the extent that competition is created among study participants in goal-setting studies, the reasons for competing, and how the competitive experience is construed (e.g., as a challenge or a threat). Finally, as achievement goals are assumed to act like an interpretive lens impacting how we view the task and ourselves in relation to the task (e.g., does our task performance have implications for self worth?), differences in achievement goal emphases should correspond to variations in commitment to the discrete goals that are set and the effort given to reach those standards, especially over time. The focus placed on task and ego goals also has repercussions for individuals' level of anxiety, strategy use, degree of confidence or self-efficacy, and other psychological and emotional mechanisms that lead to differential performance. In short, achievement goals color our approach to and the behavioral, cognitive, and affective consequences of the setting and striving for discrete performance standards.

2.1. Basic Tenets of the Achievement Goal Framework

Achievement goal theory holds that, when performing achievement-related tasks, individuals can fluctuate in their state of involvement directed toward task or ego

goals. That is, they can be more or less task- and ego-involved at any point during task engagement. The likelihood of being task- and/or ego-involved is assumed to be influenced by dispositional tendencies regarding these states of goal involvement; i.e., people (once they have reached a particular level of cognitive development in late childhood and beyond) can vary in their degree of task and ego orientation. It is important to point out that these orientations tend to be orthogonal. Thus, with specific reference to goal setting, we are interested in how individuals who are high task/high ego, high task/low ego, low task/high ego, and low task/low ego might differ in the goals set, their processing of goal-related feedback, and the corresponding motivational processes and resulting behaviors. In the sport domain, two instruments with established validity and reliability have been developed to assess dispositional goal orientations, namely the Task and Ego Orientation in Sport Questionnaire and the Perceptions of Success Questionnaire.

Whether someone is striving to meet task- and/or ego-involved goal criteria during the goal setting process is also assumed to be dependent on the situationally and task-emphasized goals or the perceived motivational climate. In particular, the tasks involved and social environments surrounding individuals as they undergo goal setting vary in the degree to which they are more or less task- and/or ego-involving. With respect to the goal-setting process, these overriding climates are created by the type and level of the goals assigned, the nature of the feedback given, the evaluation criteria used to judge goal accomplishment, and the manner in which that goal accomplishment is recognized. If goal setting was undertaken in a task-involving climate, the goals set would be primarily improvement-focused and effort-dependent (i.e., process and performance goals), the feedback provided would be informational, self-referenced, and task-centered, the person himself/herself could be involved in the evaluation of goal accomplishment, and successful goal completion would be primarily tied to intrinsic satisfaction. The individual's level of commitment, perspective on goal challenge, and input would be strongly recognized in a task-involving goal-setting program.

Goal setting in an ego-conducive manner, on the other hand, would entail a preoccupation with normatively referenced goals (the majority would probably be outcome-oriented), the feedback given would be more judgmental and marked by social comparison, evaluation of goal accomplishment would make the person particularly aware of and concerned about his or her

relative ability, and the sources and nature of the recognition offered when goals are met (or not met) would help couple the individual's sense of self to successful (or unsuccessful) goal completion. Further, personal volition and the participant's contribution to the process would most likely take a back seat in an ego-involving goal-setting program.

Pertinent to sporting contexts, assessments have been developed to tap the perceived motivational climate created by the coach (e.g., the PMCSQ-2) and parents (e.g., the PIMCQ), in the view of athletes. Researchers have also pulled from the TARGET taxonomy formulated by Epstein to analyze the dimensions underlying the climates manifested in sport. The particular structures encapsulated in this taxonomy are the nature of the task, source of authority, bases and form of recognition, structure and focus of groups in the setting, criteria for evaluation, and use of time.

2.2. Achievement Goals, Discrete Goals, and Goal-Setting Styles

One source of confusion concerning goal setting in the achievement goal literature is the tendency to mistakenly equate task and ego goal orientations with differential goal-setting styles or discrete goal foci. As indicated above, contemporary work on goal setting acknowledges the existence of different types of discrete goals, i.e., process, performance, and outcome goals. Researchers and practitioners in sport psychology, when making their case that outcome goals and ego orientation should not be considered hazardous to achievement-related health, have implied that a pronounced ego orientation means that one predominantly aims to meet outcome goals. In contrast, it is suggested that a strong task orientation translates into a marked orientation toward process (and perhaps performance) goals. Other researchers and practitioners in the field have challenged these presuppositions. For example, Duda has argued that a person can interpret process-related, performance, and outcome standards in a task-involved as well as an ego-involved fashion.

According to Burton, the construct of goal-setting style refers to athletes' preferences regarding discrete goals during training or competition. Burton has proposed that there are three distinct goal-setting styles, namely performance-oriented, success-oriented, and failure-oriented. Performance-oriented athletes are assumed to have a pronounced task orientation.

Success- and failure-oriented athletes are held to be strongly ego-oriented. However, in the former instance, perceptions of ability are high and, in the latter, perceptions of ability are deemed inadequate. In Burton's competitive goal-setting model, athletes' dispositional goal orientations in concert with their perceived competence are hypothesized to result in the focus on particular discrete goals of varying difficulty (e.g., a performance orientation will likely lead to the setting of challenging performance goals, while a success orientation will most probably result in an emphasis on moderately difficult outcome goals). Once the discrete goal is selected, the direct and indirect effects embedded in Locke and Latham's framework should then come into fruition. Thus, achievement goals are presumed to primarily come to bear in terms of goal selection in this model.

In addition to these conceptual distinctions between goal orientations, discrete goals, and goal setting styles, Hall and Kerr pointed out that there is no compelling evidence supporting the errantly assumed linkages between these constructs (e.g., that highly task-oriented athletes do not set outcome goals). Moreover, discussed above, empirical studies of the goal-setting practices of athletes indicate that many athletes set process, performance, and outcome goals and focus on these divergent goals for different reasons. The achievement goal framework would offer the following to discussions regarding the variety in and relevance of discrete goals operating in sport: the prediction and understanding of an athlete's cognitive, affective, and behavioral responses over time are primarily a function of whether he or she is task- and/or ego-involved, not whether the athlete is currently striving to meet a process-, performance-, or outcome-based standard. That is, what such diverse standards mean to the athlete and the potential significance of meeting (or especially not meeting) the standard fluctuates depending on achievement goal emphases. It is these latter appraisals that color ensuing motivational processes.

With respect to research and applied work, therefore, it is important to keep in mind that athletes' goal orientations offer insight into their concerns when approaching, engaged in, or concluding involvement with achievement tasks. These goal orientations also provide awareness into different perspectives on the connotations of goal accomplishment (or the failure to meet goals). They can be conceptualized as a type of cognitive schema that influence the discrete goals that we may set in the physical domain as well as every

other facet of goal-setting and goal-striving processes. On the other hand, as stated by Hall and Kerr (2001) goals as considered in the goal-setting literature are "end states that regulate human action by specifying an aim or an objective standard for a specific task" (p. 227).

Perhaps it is best to illustrate these qualitative differences with a metaphor. Discrete performance standards are the star we envision visiting and the impetus for us to jettison into space. They are the dream or aim that comes closest to the landing on the star. Goal orientations, however, capture the reason for going into the "last frontier" in the first place. They guide the features and resiliency of the spaceship we decide to take, the characteristics of the long ride to that distant star, the reactions when we reach our destination, and the ramifications of such an achievement for the entire space program. That is, goal orientations and discrete goals are not one and the same.

2.3. Potential Mechanisms Influencing the Goal Setting- Performance Relationship

What might be the mechanisms by which achievement goals impact the goal setting- performance relationship? The contemporary sport psychology literature contains a plethora of studies examining the interplay between achievement goals and various cognitive, affective, and behavioral responses in the sport domain. It is beyond the scope of this article to adequately review and do justice to this body of work. As they seem particularly applicable to the goal-setting process, though, it is important to highlight that variation in achievement goals (whether dispositional and/or situationally induced) have been found to correspond to (1) perceptions of ability, (2) differential beliefs about the causes of success, (3) anxiety responses and ways of coping with stress, (4) learning and performance strategy use, and (5) preferences regarding performance feedback.

In terms of individuals' perceived competence, both task and ego orientation (in cross-sectional investigations) tend to be positively associated. The correlations in these studies, however, tend to be low (typically, $r = .2-.3$), which tells us that at any particular point in time, we can have highly task- and/or ego-oriented individuals who feel their competence to be high, moderate, or far from stellar. In research on the interdependence

between environmental achievement goal emphases and perceptions of ability, task-involving situational cues have been found to correspond to higher perceptions of ability. Ego-involving situational cues, however, seem more likely to lead to a deterioration of a sense of adequate competence, especially if perceptions of ability were already depleted or if the circumstances (e.g., experience of failure) are leading to questions about one's ability level. These findings make sense when one considers that a task goal emphasis means that one construes personal competence in a self-referenced way and centers on effortful attempts at task mastery and/or improvement. Such a perspective should contribute to a sense of demonstrated competence on numerous occasions. In the case of an ego goal emphasis, witnessing one's superiority with respect to others translates into high perceived ability. One's confidence to do what needs to be done would be more likely to "take some hits" when competence and success are construed in that manner.

Locke and Latham's theory of goal setting holds that a person must feel that he or she has what it takes for the setting of a discrete goal (especially a difficult one) to result in heightened performance. Whether one's capability is deemed to be sufficient to meet the standard set, it seems, is dependent on the achievement goal(s) manifested.

With respect to views about what leads to achievement, task orientation tends to be linked to the belief that hard work and training is essential. It is reasonable to suspect that such an outlook on the determinants of success should translate into a resilient tendency to not give up during the "failures" and continuously exert effort during the goal-setting process. Ego orientation, on the other hand, has been found to relate to the belief that the possession of high ability is necessary for success to occur. One cannot help but wonder, then, if someone is pursuing discrete goals in an ego-involved manner, what would be the impact of this corresponding belief when goal accomplishment has not been forthcoming?

A plethora of studies in the field of sport psychology have explored the anxiety-performance relationship. When stress levels go beyond what is optimal for the task and person at hand, performance debilitation ensues. Although much more work needs to be done on this topic, previous research has indicated that task orientation and a perceived task-involving climate tend to be negatively or unrelated to pre-competitive anxiety, whereas a positive association between dispositional or situationally induced ego goals (especially in the case of individuals with low perceived ability) and anxiety responses has received support. In terms of

coping responses, the literature typically points to a positive relationship between task goals and problem-focused strategies (which, in the short- and long-term, have been found to be effective). In contrast, ego orientation and a perceived ego-involving climate have been found to correspond to emotion- or avoidance-focused coping (which may be deemed beneficial at the moment, but does not correspond to long-term indicators of coping effectiveness).

Finally, preliminary work indicates that the achievement goals that are adopted have relevance for strategy use and preferences regarding performance feedback. In the studies to date, task goals have been coupled with more adaptive training and competition strategies such as trying to understand the coach's instructions and engaging in deep-processing when trying to learn a motor task. When athletes are high in ego orientation and/or perceive the climate as highly ego-involving, they have been found to be more likely to view avoiding practice as a viable strategy and to employ superficial learning strategies. Cury and his colleagues have conducted a series of interesting investigations regarding the type of feedback desired following task completion. Their research suggests that highly ego goal-focused individuals who doubt their ability tend to reject task-related or objective performance-related feedback. Clearly, it is difficult to see such people effectively enhancing their perceived or actual ability level with such feedback preferences. Strongly ego-oriented individuals who have high perceived ability seem more likely to seek out normative information (i.e., how good am I compared to others?) and reveal a low preference for objective performance-related feedback. Although seemingly not as debilitating as the feedback preferences of their high ego/lower perceived ability cohorts, such inclinations regarding preferred feedback are probably not optimal for meeting complex and difficult goals in the sport setting.

3. ADDITIONAL CONSIDERATIONS AND FUTURE DIRECTIONS

In the view of Hall and Kerr (2001), the attractiveness of the achievement goal framework is that it enables researchers and practitioners "... to understand considerably more about the direction of behavior and about why athletes make particular motivational choices than is possible from considering Locke and Latham's (1990)

goal-setting theory alone . . . [which] limits us to understanding changes in intensity and persistence once discrete goals are set" (pp. 230–231).

Systematic research that attempts to integrate the constructs and tenets of achievement goal theory with the hypothesized goal-setting process is needed. In essence, the aim of such work would be to better inform us about when and why goal setting would be effective or ineffective, and what might be the best ways to implement goal setting in the sport domain. With respect to the potential mechanisms involved, one research direction would be to test variations in the proposed direct and indirect effects of goals on performance as proffered in Locke's goal-setting theory as a function of the achievement goals manifested. In terms of differences in achievement goal emphases, it would be interesting to consider people's goal orientations and the motivational climate in which they are operating as well as the interaction between these two factors. It would also be conceptually intriguing and practically important to examine the relationship of achievement goals to the nature and motivational implications of the process, performance, and outcomes goals set by athletes in both training and competition. While pursuing such lines of inquiry, the impact of variability in athletes' perceived ability on the interdependence between achievement goals and the goal-setting process should be determined.

In the discussion of achievement goals in this article, the emphasis has been placed on what have recently been termed dichotomous goal models. Such models distinguish competence-based striving in terms of a task (or mastery) and ego (or performance) focus. This approach was adopted for several reasons. First, the two-goal approach to achievement motivation has laid the foundation to date for the large majority of achievement goal research in sport. Second, existing discussions in the literature concerning distinctions between the constructs of achievement goals and discrete goals have been grounded in dichotomous conceptualizations. Finally, space constraints precluded the possibility of fully describing and developing the recently proposed trichotomous goal models and "2 × 2" achievement goal framework in terms of the present discourse. These latter frameworks differentiate approach achievement goals [goals directed toward the attainment of favorable judgments of competence, whether that competence is self-referenced or task-based (i.e., approach task) or normatively referenced (i.e., approach ego)] from avoidance goal perspectives [goals centered on avoiding

unfavorable judgments of ability, whether those perceptions of ability are self-referenced or task-based (i.e., avoidance task) or normatively referenced (i.e., avoidance ego)]. As these multiple goals have been found to differentially link to motivation-related responses such as intrinsic interest, anxiety, and performance, incorporating the approach–avoidance distinction in forthcoming studies of achievement goals and goal setting should prove informative.

Duda made a distinction between the quantity and quality of athletes' motivation. The former refers to an athlete being energized at that point in time and performing adequately. The latter relates to whether (1) the athlete wants to and does invest over time, (2) the activity contributes to the athlete's physical, psychological, emotional, and moral growth and well-being, (3) the athlete usually is able to perform up to her or his ability, and (4) the athlete enjoys the activity and is self-determined. At best, goal-setting theory alone can provide an appreciation of whether motivation is high or low from a quantity perspective. Integrating goal setting within an achievement goal framework, however, promises insight into both aspects. In so doing, we emphasize other achievement behaviors (e.g., perseverance) along with performance. Most critically, though, we consider other motivational outcomes of significance besides achievement (e.g., the athletes' welfare). Finally, as pointed out by Hall and Kerr, we become cognizant of the fact that (and the reasons why) goal setting can help promote quality sport engagement or be maladaptive (i.e., contributing to the quantity of motivation but compromising the quality and/or eventually leading to an erosion of quantitatively high motivation as well). All in all, based on the tenets of AGT and related research, it seems that more task-involving goal setting is what will reap the greatest motivational gain in sport or any other achievement domain.

Group Counseling

Janice L. DeLucia-Waack

University at Buffalo, State University of New York, Buffalo, New York, USA

1. Introduction
 2. Definition of Group Counseling
 3. Therapeutic Factors Theory and Research
 4. Effective Interventions Theory and Research
 5. Considerations
 6. Conclusion
- Further Reading

This article provides a theoretical and empirical rationale for successful group counseling and therapy along with precise definitions. The literature is reviewed with regard to therapeutic factors and effective interventions in group counseling. Considerations for facilitating successful counseling groups are suggested.

GLOSSARY

group counseling A small group intervention that uses therapeutic factors and specific interventions to address personal and interpersonal problems and to promote personal and interpersonal growth and development (e.g., a women's group).

group therapy A small group intervention that uses therapeutic factors and specific interventions to address personal and interpersonal problems and to remediate perceptual and cognitive distortions or repetitive patterns of dysfunctional behavior (e.g., an eating disorders group).

psychoeducational and guidance groups A small group intervention that uses group dynamics and principles to teach skills in a preventive way (e.g., a friendship skills group).

task and work groups A small group activity that uses organizational and community dynamics to facilitate the goals of a group (e.g., a book club).

therapeutic factors An element of group therapy that contributes to improvement in a patient's condition and is a function of the actions of the group therapist, the other group members, and the client himself or herself.

1. INTRODUCTION

Current group counseling theory and practice has its roots in two divergent events: Sigmund Freud's famous Wednesday night meetings at his house in Vienna and John Pratt's treatment of tuberculosis patients in group "classes" in the United States. Many theoretical approaches and applications have emerged from these early beginnings to create an efficient and empirically validated treatment in psychology today. As research methods became more precise and more interest in studying the effectiveness of groups accrued, the focus moved from showing that groups were more effective than no treatment at all to establishing that groups for certain populations and problems were as effective as, or even more effective than, other active treatments. As research, theory, and practice developed in the field, the pertinent question changed from "Are groups effective?" to "What kinds of groups are effective for what types of people with what problems?"

2. DEFINITION OF GROUP COUNSELING

Toward the goal of answering the question of what kinds of groups are most effective for certain types of people with certain types of problems, the Association for Specialists in Group Work (ASGW) in 2000 delineated four types of groups based on their goals and interactional processes—task/work, psychoeducational/guidance, counseling, and therapy groups—to aid in the selection of the appropriate types of groups for different populations (e.g., age groups) with different goals (e.g., combating depression, learning social skills, preventing eating disorders). According to ASGW, counseling groups “address personal and interpersonal problems of living and promote personal and interpersonal growth and development,” whereas therapy groups “address personal and interpersonal problems of living, remediate perceptual and cognitive distortions or repetitive patterns of dysfunctional behavior, and promote personal and interpersonal growth and development.” Examples of counseling and therapy groups include general interpersonal groups, training groups for students learning to be counselors or therapists, and groups directed at the amelioration of specific problems such as depression, eating disorders, and sexual abuse. Both counseling and therapy groups, as defined by ASGW, use “group-based cognitive, affective, behavioral, or systemic intervention strategies.” Although by definition counseling and therapy groups are different in practice, these terms are often used interchangeably and are often difficult to differentiate in practice.

In contrast, task/work groups focus on “efficient and effective accomplishment of group tasks” and psychoeducational/guidance groups focus on skill development to prevent problems, according to ASGW. Both of these groups use “group-based educational and developmental strategies.” Examples of task/work groups include committees, clubs, and classrooms that have common goals to work toward, whereas psychoeducational/guidance groups teach specific skills and coping strategies such as anger management, social skills, self-esteem, assertiveness, and making friends.

In further contrast, counseling and therapy groups tend to be of longer duration and smaller in size than do psychoeducational groups, the latter of which are often only 6 to 10 sessions and may consist of 10 or more members. Whereas task/work and psychoeducational/guidance groups tend to use educational strategies and practice to teach new skills, the emphasis in

counseling and therapy groups is on the use of group process and dynamics to help members identify interpersonal difficulties, identify new ways of thinking and behaving to solve interpersonal problems, practice new behaviors, get feedback from other group members, and learn coping skills from other group members. The major premise inherent in counseling and therapy groups is that group members eventually act in the group in ways similar to how they behave in their relationships with others (e.g., significant others, friends, co-workers). Thus, as behaviors are enacted, group members can evaluate (with the help of other group members) the effectiveness of these behaviors and their impact (both positive and negative) on group members’ relationships. In addition, group members then have the opportunity to practice and try out new behaviors and to receive feedback from others about the perceived impact of the new behaviors.

3. THERAPEUTIC FACTORS THEORY AND RESEARCH

Over the years, many group researchers and practitioners have attempted to explain the process of group counseling and therapy by describing 11 therapeutic factors that operate in groups. Although Yalom was not the first researcher or theorist to use the concept of therapeutic factors, his work has had an enormous influence on group theory and research. In 1975, Yalom’s compendium of 11 therapeutic factors was built on earlier writings of group theorists and practitioners and on his research on important change mechanisms in group therapy. In 1985, Bloch and Crouch defined a therapeutic factor as “an element of group therapy that contributes to improvement in a patient’s condition and is a function of the actions of the group therapist, the other group members, and the client himself.” [Table I](#) provides the definitions of these 11 therapeutic factors.

Not only did Yalom define and describe 11 therapeutic factors, he also developed a research paradigm that has had a major influence on how researchers examine therapeutic factors in group settings. In a now classic study, Yalom and colleagues in 1973 developed a 60-item therapeutic factors Q-sort by writing five items that corresponded to each of the 11 factors described by Yalom (12 factors were used because interpersonal learning was split into interpersonal learning [input] and interpersonal learning [output] categories), asking group members to put items in

TABLE I
Descriptions of Therapeutic Factors

<i>Therapeutic factor</i>	<i>Definition</i>
Instillation of hope	Member recognizes other members' improvement and that group can be helpful; member develops optimism for his or her own improvement
Universality	Member perceives that other members share similar feelings or problems
Imparting information	Advice giving by therapist or fellow members
Altruism	Member gains a positive view of himself or herself through extending help to others in group
Corrective recapitulation of primary family group	Member experiences the opportunity to reenact some critical familial incident with members of the group in a corrective manner
Development of socializing techniques	Group provides member with an environment that allows member to interact in a more adaptive manner
Interpersonal learning (input)	Member gains personal insight through other members' sharing of their perceptions of the member
Interpersonal learning (output)	Group provides member with an environment that allows member to interact in a more adaptive manner
Cohesiveness	Feeling of togetherness is provided and experienced by the group
Catharsis	Member releases feelings about past or here-and-now experiences; this release leads to member feeling better
Existential factors	Member ultimately accepts that he or she must take responsibility for his or her own life
Imitative behavior	Member learns through the observation of others' learning experiences

categories ranging from "least helpful to me in group" to "most helpful to me in group." From these data, a ranking of the relative importance of the therapeutic factors, as perceived by successfully treated clients, was made from most important to least important as follows:

1. Interpersonal learning (input)
2. Catharsis
3. Cohesiveness
4. Self-understanding
5. Interpersonal learning (output)
6. Existential factors
7. Universality
8. Instillation of hope
9. Altruism
10. Family reenactment
11. Guidance
12. Identification

Yalom's paradigm for examining the importance of the therapeutic factors has spawned a large number of studies of therapeutic factors in groups. Several measures have been developed to assess therapeutic factors in groups (e.g., Critical Incidents Questionnaire, Therapeutic Factors Scale, Curative Factors Scale,

Therapeutic Factors Inventory). Group researchers have now amassed a number of studies that identify clients' ranking of the therapeutic factors across a number of different settings and patient populations. Studies over the years have assessed ratings of therapeutic factors and yielded inconsistent results. These inconsistencies may be due to differences in the groups surveyed or in the methods used to assess therapeutic factors. In an effort to make sense of the inconsistent findings, Kivlighan and Holmes used a cluster analysis of studies that rated the importance of therapeutic factors. Four clusters emerged from the analysis based on the therapeutic factors that were highest and lowest in each cluster. Cluster 1 (affective insight groups) rated acceptance, catharsis, interpersonal learning, and self-understanding as the most valued factors. These groups also rated both guidance and vicarious learning as relatively unimportant. Cluster 2 (affective support groups) rated acceptance, installation of hope, and universality as the most important group factors. Similar to Cluster 1, members of the groups in Cluster 2 rated guidance and vicarious learning as relatively unimportant. Cluster 3 (cognitive support groups) rated vicarious learning and guidance as highly valued while rating self-understanding much

lower. Cluster 4 (cognitive insight groups) rated interpersonal learning, self-understanding, and vicarious learning as the most valued therapeutic factors. The topic of therapeutic factors continues to be intriguing to researchers and practitioners alike, especially as related to the questions of importance in differential stages of group development and for different types of groups.

4. EFFECTIVE INTERVENTIONS THEORY AND RESEARCH

When leaders employ a given intervention during the course of a group session, there is the implicit assumption that their behavior will have a positive impact on individual members and/or on the processes and outcomes of the group. Recent research findings have indicated that group dynamics and outcomes are influenced by factors such as group leaders' interaction styles, personal characteristics, and attitudes. Researchers have found that leaders who are less controlling, exhibit warmth/caring, and set and reinforce clear norms are more likely to have cohesive groups. Increased cohesiveness, in turn, has been found to be positively related to a variety of group treatment outcomes. Morran and colleagues highlighted 10 specific group interventions with research and clinical support.

The first category of interventions, protecting group members and promoting safety, includes protecting, blocking, and supporting. These interventions are typically most useful in the leader's efforts to provide a group climate that is conducive to trust, openness, and cohesion. Research has indicated that members who are dissatisfied with their group experience often implicate the group leader for negligence in providing adequate protection. Sometimes, protecting can be indirect and might include member selection/exclusion procedures, the establishment of appropriate group norms, or the modeling of caring for group members. More direct protecting interventions might take the form of intervening to stop a member who is self-disclosing too much or at a level that is significantly more intimate than the that of the rest of the members. Blocking is a specific type of protection that is used to stop a member from storytelling, rambling, or inappropriately probing, gossiping, or invading the privacy of others. Research suggests that group members frequently attribute their damaging experiences to undue confrontation, criticism, and pressure to self-

disclose by other members. Thus, it is essential that the group leader use blocking to protect potentially vulnerable group members. Supportive interventions help to reassure, reinforce, and encourage members to participate in the group and try out new behaviors. One caution is that premature or excessive supporting interventions may foster dependency on the leader and be detrimental to the individual member and the group. However, when timed appropriately, supporting interventions can provide the encouragement needed for a group member to become involved in the group interaction.

The second category of interventions, energizing and involving group members, includes drawing out, modeling, linking, processing, interpreting, self-disclosing, and providing feedback. These interventions are most often used to stimulate forward progress, increase member participation, and enhance interpersonal learning. Drawing out occurs when the leader directly invites comments or involvement to encourage participation from members who find it hard to share with others or with those who share on a surface level but avoid deeper issues. The leader should encourage participation while still allowing members to choose their own levels of sharing. Modeling occurs when the leader demonstrates the skills, attitudes, and other characteristics he or she hopes to engender within group members, including respect and caring for others, appropriate self-disclosure, feedback (both giving and receiving), and openness. Many group theorists suggest that modeling is a common factor of nearly all interventions because members naturally observe group leaders and other members and tend to imitate what they see demonstrated. Research has found that behaviors displayed by the therapist, including interpersonal behaviors, feedback delivery and acceptance, and "here-and-now" communications; lead to increases in those same behaviors by group members. As a whole, studies suggest that leaders can use modeling interventions to shape positive group dynamics; however, care should be exercised to avoid the unintentional modeling of undesirable behaviors. Linking connects what one group member is saying or doing with the concerns of one or more other members. Linking has been shown to be particularly useful in promoting member interaction, cohesion, trust, and universality among group members.

Processing as an intervention occurs when the group leader and members capitalize on significant happenings to help members reflect on the meanings of their experiences; better understand their own thoughts,

feelings, and actions; and generalize what is learned to situations outside of the group. Simply experiencing events in the group is not sufficient for growth and must be augmented by processing that provides a framework for retaining, integrating, and generalizing the experience. Research findings have identified a positive relationship between higher levels of group processing and greater outcome gains related to both group productivity and individual member achievement and suggest that processing should go beyond emotional insight and also focus on cognitive dynamics or meaning attributions to help members frame and understand their emotional experiences. Effective processing of critical incidents requires that members engage in a process of sharing and exploring experiences among themselves to make sense of what happened, establish what they have learned from the incidents, and begin to plan and practice new behaviors to be used outside of group sessions.

Interpreting involves offering possible explanations for events, behaviors, thoughts, and feelings at a deeper level to be considered as part of the change process. Group members typically experience interactions that provide the opportunity to learn more about themselves. However, such insight may be difficult for members to acquire without some cognitive framework being provided by the leader. In such situations, the leader can assist group members by providing tentative interpretations that can be discussed and considered in the group. Research suggests that leader interpretations help members to integrate complex personal and group-related events, thereby encouraging their investment in the group experience and facilitating generalization from group experiences to personal experiences outside of the group. Interpretations about members' impact on the environment and their patterns of behavior are most associated with member change.

Leader self-disclosure is an intervention whereby the therapist reveals his or her personal feelings, experiences, or here-and-now reactions to group members. As a general rule, the leader should self-disclose only when the information or reaction is directly related to what is happening in the group, models a behavior for members, and/or is expected to result in a direct benefit to the group.

5. CONSIDERATIONS

Much research has been conducted about counseling groups, but there is still much more that needs to be

known about how to facilitate groups effectively. Several considerations are important in leading effective counseling groups. First, sufficient training is needed in the type of group to be facilitated. ASGW provides specific guidelines for the training and supervision of task, psychoeducational, counseling, and therapy groups. Research suggests that when group therapists lack supervision, they are not able to identify mistakes and generate new plans of action; instead, they become stuck in a cycle of repeated ineffective interventions. Co-leadership is also recommended as a training tool and generally to enhance group effectiveness. It is suggested that co-therapy is better for a variety of reasons such as efficiency (e.g., the group can still continue if one leader is sick or unavailable), effectiveness (e.g., two leaders can track group members more easily), supervision and training of new group therapists and as a way in which to model healthy communication patterns (e.g., male-female interactions) between co-leaders in front of the group members. It is also theorized that co-leaders who model appropriate interaction between themselves, such as resolving disagreements and compromising, will have group members who demonstrate better skills in these areas.

Second, diversity and multicultural issues groups are inherent in groups and are essential to consider. Group leader competence is critical, specifically multicultural group counseling skills. In addition, knowledge of other cultural worldviews and values, and of how these may inhibit or increase a potential group member's willingness to participate and behave in the group, is essential. Acculturation is noted as an important variable in predicting the behavior of potential group members. Effective groups must help members to understand themselves and others as individuals within the context of their culture and must choose interventions and methods of change based on the interplay between the individuals and their worldviews.

Third, there is support for conducting groups that are homogenous in age and gender due to the impact of cognitive development and different life tasks across age groups on the purpose and content of the groups. The structure of a group, types of exercises, focus on process versus content, and group goals all are determined by the abilities and needs of the group members.

Fourth, preventive and brief interventions can be effective and may ameliorate problems before they become more serious. Thus, psychoeducational groups may be useful, as may counseling and therapy groups.

6. CONCLUSION

Group counseling has been shown to be effective with various populations, in different settings, and for specific problem areas. Research clearly shows that group goals must be clearly defined, the leader must have specific leadership training and skills, and the leader must take into consideration group members' expectations about the group, willingness to participate, and cultural expectations and values when designing a group and implementing specific interventions.

GLOSSARY

athletics Pursuit of excellence characterized by dedication and intensity.

cohesion Sticking together to achieve group tasks and satisfy social needs.

dependence The extent of interactions among members in the performance of the team task.

group dynamics The processes within a group that contribute to its success or failure as well as the scientific study of such processes.

leadership The interpersonal process of influencing members toward the achievement of team goals.

player reaction The attitudes toward the coach, the team, and the sport cultivated as a function of leader behavior.

sport Pursuit of pleasure characterized by moderation and generosity.

sports team Two or more individuals sharing a common group identity, facing a common fate, and interacting with each other in interdependent activities in the pursuit of common goals.

variability The extent to which the environment changes during the performance of a task.

Group dynamics is a term used to refer to the processes within a group that contribute to its success or failure as well as the scientific study of such processes. In the context of sport, greater emphases have been placed on the processes of cohesion and leadership as they relate to performance and player affective reactions. This article outlines the multidimensional view of both cohesion and leadership and the measurement thereof. In addition, it summarizes research findings on the antecedents and consequences of cohesion and leadership.

1. INTRODUCTION

The popularity of sport around the world is evidenced in the economic worth of the sport industry. In the United States alone, the sport industry is estimated to be more than \$160 billion, making it one of the 10 or 12 largest industries in the country. The sport industry is based on the degree to which people are identified with and committed to a sport, a team, and/or an athlete. Such commitment very often translates into heated arguments about the performances of one's team. Most discussions of the successes and failures of a sport team focus on how well one or more athletes performed and on the strategic decisions made by the coach. The debate would also extend to how well members of the

team get along with each other and the rapport between the coach and his or her players. These speculations of the “armchair” experts have been the substance of analysis and critique in group dynamics, a significant scientific endeavor within the broad realm of sport psychology. In this description of the field, the terms “sport groups” and “sport teams” are used interchangeably. It must be noted that group dynamics has been studied in the context of exercise groups as well. However, the treatment of the chosen topics of cohesion and leadership is confined to sport teams as groups.

2. DEFINITION OF A SPORT TEAM

In 1998, Carron and Hausenblas defined a sport team as follows:

a collection of two or more individuals who possess a common identity, have common goals and objectives, share a common fate, exhibit structured patterns of interaction and modes of communication, hold common perceptions about group structure, are personally and instrumentally interdependent, reciprocate interpersonal attraction, and consider themselves to be a group.

This definition incorporates the significant attributes of a group highlighted previously by other scholars. One attribute is that the members of the group have a common identity. Although having their unique names, uniforms, coaches, and support groups indicates a separate identity for every team, it is equally important that members accept that identity, share it, and consider themselves to be part of the group. The goals and objectives of sport teams may vary across levels of competition (e.g., winning in pursuit of excellence, learning and having fun in pursuit of pleasure). Another significant attribute is that the group members share a common fate. When a team loses, everyone on the team loses. When a team is disqualified for rule violations committed by some members, all members suffer. Members of a sport team, in sharing a common goal and fate, also have a common understanding of the way in which the team is structured, the manner and mode of communications within the team (including the technical terminology associated with the sport, e.g., what do “screening” in basketball and “stealing” in baseball mean?), and the terms used in the special plays unique to the team. Members also recognize that they are interdependent on each other to achieve the team goals. Given these attributes, members tend to develop a liking for each other (i.e., the interpersonal attraction).

2.1. Unique Attributes of Sport Teams as Groups

Sport teams differ from other conventional groups in several respects. One unique attribute of a sport team is the constant roster size as specified by the rules of the game and/or the league (e.g., 12 members on a volleyball team, with 6 players on the court at any one time). It is also possible that a league, or a group of teams in a sport, may jointly decide to reduce the maximum roster size for financial reasons or other exigencies.

Another unique attribute is that most activities of the groups are stipulated and controlled by the rules of the game. For example, only certain positions are permitted to advance the ball in football, use of hands is forbidden in soccer except by the goalkeeper, and holding the ball is not allowed in volleyball. Thus, teams in a given sport are similar in their inputs, their throughput processes are based on shared technology, and their expected outputs are identical.

The league to which a sport team belongs can also regulate the processes to a considerable extent. For example, the National Collegiate Athletic Association (NCAA) stipulates the maximum number of athletic scholarships permissible for an intercollegiate athletic team. It also regulates when a team can start practicing and how many games it can play. In addition, it specifies the scholastic requirements for athletes to be a part of the team. The list goes on, but the point is that sport teams are distinct from other forms of groups due to these extensive external controls over internal processes.

Another important attribute that sets sport teams apart from traditional groups is the presence of clear standards of effort and performance. Members of a sport team recognize that all of them should report to the practice sessions, follow the instructions of the coaches, and work strenuously during every session. It is also clearly understood that during competitions, all players should put forth their best efforts and coordinate their activities in pursuit of victory. In interacting with each other on both task and social spheres, members of a sport team establish and commit themselves to these norms of effort and productivity. In general, these features contribute to the sense of “groupness” among members of a sport team.

Another distinguishing feature of sport teams is the simultaneous presence of competition among the members of the team (particularly in team sports) and the need for cooperation to achieve team success. For instance, because only 5 members of a basketball team can be on the floor at any one time, the team’s 12 members compete

with each other for starting status and/or playing time. At the same time, they cooperate with each other in coordinating their activities for performance success. Successful coaches are those who encourage competition among their players so that each one will try harder to be better than the other players and, at the same time, foster cooperation and coordination among them.

2.2. Purposes of Participation in Sport

One criterion for classifying sport teams is the purpose of participation in sport. In 1964, Keating distinguished between “athletics” and “sport.” Sport is derived from the French word *desporter*, meaning a diversionary activity seeking pleasure for both participants. Athletics, derived from the Greek words *athlos* (i.e., a contest), *athlon* (i.e., a prize), and *athlein* (i.e., to contend for a prize), is essentially a competitive activity. In sport, the pleasure and fun can be maximized with a spirit of moderation and generosity. In contrast, athletics is characterized by a spirit of dedication, sacrifice, and intensity. Because the term “athletics” refers to one form of sport, namely track and field in the international context, Keating’s other labels—“pursuit of pleasure” and “pursuit of excellence”—are used to denote these two distinct domains. This distinction parallels the one between recreational sport and competitive sport. Within the preceding broader classification, distinctions among youth sports, adult sports, scholastic and collegiate sports, community sports, and professional sports are also commonly made.

3. TASK TYPES IN SPORT

Beyond the distinction between pursuit of excellence and pursuit of pleasure, sport teams do differ in the kinds of tasks in which they are engaged. Two significant attributes have been used to distinguish among sport tasks: dependence and variability.

3.1. Dependence

Based on the criterion of dependence, sport tasks are categorized as independent, coactively dependent, proactively–reactively dependent, and interactively dependent. An independent task is one in which an individual can complete the task without interacting with other members of the team (e.g., high jumping,

discuss throwing, individual events in swimming, badminton singles). Individuals in coactively dependent tasks depend on a common but external source for initiation and/or control of their activities. In general, members in a coactively dependent team perform more or less similar tasks, and their collective contributions determine the group’s success (e.g., rowing, synchronized swimming). Reactively–proactively dependent tasks are those in which one team member initiates a task and depends on another team member to complete the task. Conversely, the second person depends on the first person to initiate the task (e.g., football quarterback and receiver, successive runners in a four-person track relay team). Finally, interactively dependent tasks require the team members performing various assignments to interact with each other effectively to complete the group task (e.g., basketball, soccer, hockey).

Sports such as soccer, volleyball, and football are characterized by a high degree of interdependence (i.e., members need to interact with each other during the competitions), whereas sports such as track and field, swimming, and diving are low on this attribute (i.e., performers do not interact with each other in performing their respective tasks). In common parlance, sports from the former set are called “team” sports and those from the latter set are called “individual” sports. Yet coaches, athletes, the public, and the media do conceive of “teams” in individual sports (e.g., the national swimming team, a collegiate track and field team). In general, several athletes in individual sports such as swimming are usually placed under one coach, who tends to organize practice sessions for all athletes at the same specified time and place. During the practice sessions, athletes interact with each other both on a task basis (e.g., competing with each other, setting the pace for each other) and on an interpersonal basis (e.g., encouraging each other, discussing personal matters). From this perspective, athletes on a swimming team are members of a group, and the elements discussed here would be equally applicable to athletes in team sports and those in individual sports.

3.2. Variability

Another characteristic distinguishing sports tasks is variability (i.e., the degree of environmental changes requiring participants to adjust to these changes). In high jumping (i.e., a low-variability task), an individual initiates the performance and executes the jump in a relatively stable environment (i.e., the uprights and crossbar are fixed). In basketball rebounding, the

actions are triggered by constantly varying environmental stimuli (e.g., the timing of a shot, the location of the rebound, the location of teammates and opponents).

4. MEASURES OF GROUP PERFORMANCE

In sport, the performance measures are very often contaminated by factors such as random chance (e.g., the bounce of the ball), an opponent's outstanding performance, strategic choices made by the team or coach, and bad calls made by officials. This section outlines the issues associated with performance measures in sport.

4.1. Subjective Evaluation

One issue in the measurement of sport performance relates to the subjective evaluation of performance in some sports such as diving, figure skating, and gymnastics. Because of the fallibility of subjective judgments, it is customary to take the averages of the ratings of a specified number of judges to give a score to a performance. Even in sports such as soccer, basketball, hockey, and football, the calls or rulings of referees and officials may be called into question. For example, when two players collide in basketball, a referee may call it a charge (i.e., an offensive foul), whereas a coach may view it as a block (i.e., a defensive foul). The subjective nature of these decisions can provoke heated arguments and catcalls during competitions. The new rules in professional football permit a coach to question a specific call made by an official (e.g., whether a receiver was in-bounds when he caught the ball). The chief referee is bound to look at the official replays and decide whether the official made the correct call or not. It must be noted that the subjective element of a decision may at times be masked by the so-called objective measures. For instance, in football, officials take extraordinary efforts to "bring in the chain" and carefully verify whether the ball crossed the requisite 10 yards for a first down. All of these efforts at objective measurement are based on the subjective judgment of a single referee on where the ball hit the ground when the play ended.

4.2. Zero-Sum Nature of Competitions

Another issue relates to the zero-sum nature of sports competitions. That is, for every winner, there is a loser.

To alleviate the problem, the win-loss record over an entire season is used as a measure of performance. Another issue is that a basketball team that loses by a score of 100 to 30 is given the same standing as a team that loses by a score of 100 to 99. One way in which to address this issue is to use the point differential (i.e., the difference between points scored for and against the team in a contest) or the ratio of the final score (of the two teams in a contest) as a measure of performance.

4.3. Team Performances in Independent Sports

Another issue is with the measurement of group performance where members are involved in individual tasks such as archery, badminton, boxing, tennis, golf, swimming, and track and field. For instance, in the international Davis Cup tennis competitions, there are four singles matches and one doubles match. The national team that wins the majority of these five matches is declared the winner. This format of deciding on team performance in individual sports is quite common across all levels of competition.

4.4. Perceptual Measures of Performance

Given that performance measures may be contaminated by several factors, some scholars have used the perceptions of athlete themselves regarding their personal performance and/or their teams' performance. The argument is that every athlete has set expectations for individual- and team-level performances and is aware of the efforts that he or she, and the team as a whole, had put forth toward achieving those expectations. Therefore, the athletes are the best judges as to whether they had attained their goals. By the same token, they could also be asked about the improvements they had made. These perceptual measures are ideal if the focus of the endeavor is on athletes' development and their affective reactions.

5. COHESION IN SPORT TEAMS

While the study of group dynamics in sport has gained steam during the past two decades or so, the most notable and sustained efforts have focused on group cohesion. In 1998, Carron and colleagues, incorporating

the thrust of earlier definitions, defined cohesion as “a dynamic process which is reflected in the tendency for a group to stick together and remain united in the pursuit of its instrumental objectives and/or for the satisfaction of member affective needs.” The definition underscores the dual focus of cohesion: task cohesion (i.e., instrumental in achieving group goals) and social cohesion (i.e., satisfying members’ social needs). Groups can be characterized by task cohesion, social cohesion, or both. It is a dynamic process in that the attributes of the members and the group may change over time; thus, the nature and intensity of cohesion may also be in flux. For instance, a newly formed sport team may be marked by task cohesion in the beginning, and continued task interactions among members may lead to interpersonal liking and, thus, to social cohesion.

5.1. Multiple Dimensions of Cohesion

A cohesive group is characterized by (a) individual attraction (i.e., an individual values membership in the group) and (b) group integration (i.e., there are perceptions of positive and effective interactions among members). The team would be deemed more cohesive if all members were attracted to the group and if all members perceived the team to be integrated. By crossing the task versus social aspects of cohesion with individual attraction and group integration, Carron and colleagues derived the four-component model of cohesion (Fig. 1), consisting of (a) Attraction to the Group–Task (ATG-T), (b) Attraction to the Group–Social (ATG-S), (c) Group Integration–Task (GI-T), and (d) Group Integration–Social (GI-S).

5.2. The Group Environment Questionnaire

From a social cognitive perspective, Carron and colleagues argued that (a) members of a group selectively process the information they gain through experiences of the group’s task and social properties and develop a set of beliefs about the group, (b) these member beliefs about the groups reflect the unity of the group, and (c) these social cognitions of members about the group reflecting its cohesiveness can be measured through a paper-and-pencil questionnaire. Accordingly, they developed a scale to measure the four components of the model. Their theory-driven Group Environment Questionnaire (GEQ) consists of 18 items to measure the four components of cohesion.

	Task Cohesion	Social Cohesion
Attraction to Group	Attraction to Group–Task	Attraction to Group–Social
Integration of Group	Group Integration–Task	Group Integration–Social

FIGURE 1 Multiple dimensions of cohesion. Adapted, by permission, from A. V. Carron, W. N. Widmeyer, L. R. Brawley, 1985, “The Development of an Instrument to Assess Cohesion in Sports Teams: The Group Environment Questionnaire,” *Journal of Sport Psychology*, 7(3): Figure 2.

5.3. Correlates of Cohesion

The following is a summary of Carron and Hausenblas’s 1998 discussion of the research on the relationships of cohesion in sport teams with other relevant variables. Higher perceptions of cohesion were associated with members’ tendency to undertake more of the team activities and to share the responsibility for negative outcomes. When members perceived that the team was cohesive, they tended to attend practices and games more regularly and to put in extra effort during practice sessions. By the same token, higher cohesiveness was related to reduced “social loafing.” Members’ cognitive anxiety was lowered on teams that were perceived to be cohesive.

When members perceived the group to be integrated over the task at hand (GI-T), they expressed higher levels of role clarity, role acceptance, and role performance. With increasing task cohesion, members tended to be defensive of the team and to severely self-handicap (i.e., identify external causes for future failures). Perception of cohesion was also related to higher performance by the group. In a 2002 meta-analysis of studies that investigated relationships between cohesion and performance in sport teams, Carron and colleagues found that the significant relationship varied from moderate to large. Contrary to findings relating to groups in general, both task cohesion and social cohesion were significantly related to performance of sport teams. These authors also found that the relationship between cohesion and performance was stronger in women’s teams than in men’s teams. Hence, they suggested

that team-building efforts should focus on cultivating task-oriented attitudes and understandings as well as interpersonal interactions and liking among members. Such a strategy would be particularly effective in the case of women's teams.

A factor that was found to enhance cohesion within a team is size of the group. Small size of the group facilitated higher levels of cohesion. It is noteworthy that sacrifice on the part of members enhanced task and social cohesion, and this in turn led to the conformity to group norms. When leaders emphasized cohesion within the team and executed appropriate actions, cohesion was fostered. Most of the sport teams are characterized by a hierarchical distinction between the leader (i.e., the coach or manager) and the members (i.e., the players). The two major streams of research on leadership in sports are based on the Multidimensional Model of Leadership and the Mediational Model of Leadership.

6. THE MULTIDIMENSIONAL MODEL OF LEADERSHIP

Chelladurai's Multidimensional Model of Leadership (Fig. 2) is a synthesis and extension of several theories from mainstream industrial/organizational psychology. In the model, group performance and member satisfaction are considered to be a function of the congruence among three states (or aspects) of leader behavior: required, preferred, and actual. The antecedents of these three states of leader behaviors are the characteristics of the situation, the leader, and the members.

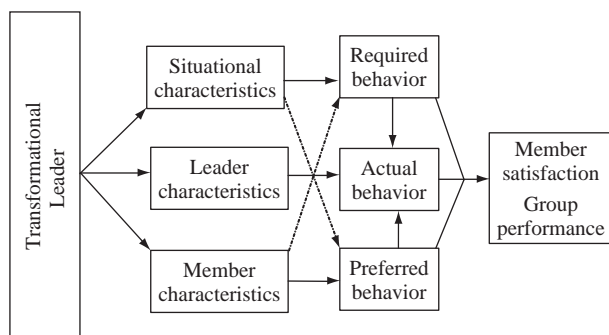

FIGURE 2 Multidimensional Model of Leadership. From *Handbook of Research on Sport Psychology*, by P. Chelladurai, Macmillan, ©1993 Macmillan. Reprinted by permission of the Gale Group.

6.1. States or Aspects of Leader Behavior

Required leader behavior refers to those behaviors shaped by the demands and constraints of the situational characteristics, that is, the parameters of the organizational characteristics, that is, the parameters of the organization and its environment. The goals and formal organizational structure of the team and the larger system (e.g., professional team vs high school team), the group task and the associated technology (e.g., team sport vs individual sport), social norms, cultural values, and government regulations are some of the situational characteristics that impinge on leader behavior.

Members' preferences for specific leader behaviors, such as coaching and guidance, social support, and feedback, are largely a function of the individual characteristics (e.g., personality variables, age, experience, ability). In addition, the situational characteristics also affect member preferences. If there is an organizational expectation that a leader will behave in a specific manner, this expectation is shared by both the leader and members. Thus, both the leader and members are socialized into the same behavioral expectations and/or preferences in a given context.

A leader's actual behavior is seen as a function of his or her personal characteristics, including personality, ability, and experience. In addition, a leader is considerably influenced by the demands and constraints of the situation as well as by the preferences of the members. As noted previously, the major proposition of the multidimensional model is that the team's performance and member satisfaction are a function of the degree of congruence among the three states of leader behavior.

6.2. The Leadership Scale for Sports

In conjunction with proposing the multidimensional model, Chelladurai developed the Leadership Scale for Sports (LSS), which consists of 40 items representing the following five dimensions of leader behavior:

1. Training and instruction (emphasizing and facilitating hard and strenuous training; instructing in the skills, techniques, and tactics of the sport; clarifying the relationship between the members and their tasks; and structuring and coordinating the members' activities)
2. Democratic behavior (allowing greater athlete participation in decisions pertaining to group goals, practice methods, and game tactics and strategies)

3. Autocratic behavior (making decisions independently and stressing personal authority)
4. Social support (being concerned about the welfare of individual athletes, promoting a positive group atmosphere, and inducing warm interpersonal relations with members)
5. Positive feedback (reinforcing athletes by recognizing and rewarding good performance)

6.3. Correlates of Leadership

Studies have found that males preferred their coaches to be more training oriented and more autocratic yet more supportive than did female respondents. As for perceived behavior, male athletes perceived their coaches to place greater emphasis on training, instruction, and rewarding behavior and less on democratic behavior, whereas females perceived their coaches to be more democratic and socially supportive. However, there was a tendency at the top levels of competition for the coaches of male and female teams to be similar in their behaviors.

Athletes high on task motivation preferred more training and instruction, whereas those high on affiliation motivation and extrinsic motivation preferred more social support. Athletes high on cognitive structure preferred significantly more training and instruction and less autocratic behavior from the coach, whereas those high on impulsivity preferred more social support behavior from the coach.

With increasing experience, athletes preferred more positive feedback, autocratic behavior, and social support. Preference for social support increased progressively with maturity (i.e., from the high school level to the university level). In general, as athletes gained experience and/or ability, they tended to prefer their coaches to be more autocratic and socially supportive. That leads to the concept of the coach as the benevolent autocrat. Another general trend was for the coaches to rate themselves more positively on these behaviors (i.e., higher on training and instruction, democratic behavior, positive feedback, and social support) than the players did.

As for the situational variables, members of competitive sport teams preferred greater training and instruction, greater social support, less positive feedback, and less democratic behavior from their coaches than did members of recreational sport teams. As for task attributes, athletes involved in interdependent tasks (i.e., team sports) or variable tasks (i.e., open sports such as basketball) preferred more training and instruction and autocratic behavior than did athletes involved in independent

tasks (i.e., individual sports) or nonvariable tasks (closed sports such as swimming). In general, increased task dependence and/or task variability seems to warrant the need for more training and instruction, autocratic behavior, social support, and positive feedback.

With regard to outcomes, athletes were satisfied with leadership to the extent that the coach emphasized (a) training and instruction that enhances the ability and coordinated effort by members that, in turn, contributes to task accomplishment, and (b) positive feedback that recognizes and rewards good performance. Performance as a consequence of leadership has been dealt with inadequately in the literature. The few studies indicate that higher perceptions of training, autocratic behavior, social support, and positive feedback were associated with success in athletics.

The relationships between leadership and performance were quite weak. Some scholars have used player perceptions as a measure of performance, and such perceptions may relate to performance and/or performance improvements. In contrast to performance, satisfaction has been studied more extensively. In 1998, Riemer and Chelladurai developed the Athlete Satisfaction Questionnaire (ASQ), consisting of 56 items to measure 15 facets of athlete satisfaction, including those relating to individual and team performance outcomes, individual and team social outcomes, individual and team task and social processes, and external agents.

7. THE MEDIATIONAL MODEL OF LEADERSHIP

The Mediation Model of Leadership (Fig. 3) was developed by Smoll and Smith with a focus on youth sport and

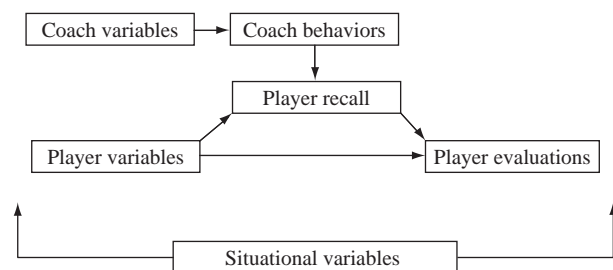

FIGURE 3 Mediation Model of Leadership. Reprinted with permission from *Journal of Applied Social Psychology*, Vol. 19, No. 18, pp. 1522–1551. ©V. H. Winston & Son, Inc., 360 South Ocean Boulevard, Palm Beach, FL 33480. All rights reserved.

emphasizes players' evaluative reactions as the outcome measures. The three critical elements of the model are coaches' behaviors, players' perceptions and recall, and players' evaluative reactions. Players' attitudes toward their coaches and their sport experience are mediated by their perceptions and recall of the coaches' behaviors. These three elements are affected by three sets of factors: coach individual difference variables, player individual difference variables, and situational factors.

7.1. Factors Influencing Leadership Dynamics

The coach individual difference factors include (a) coaches' goals, (b) coaches' behavioral intentions (i.e., the antecedents of actual behavior), (c) instrumentalities (i.e., a function of the perceived probability of an outcome and the value attached to that outcome), (d) the norms associated with the coaching role, (e) coaches' perceptions of players' motives, (f) self-monitoring (i.e., the extent to which coaches analyzes their own behaviors and their consequences), and (g) coaches' sex. Player individual difference variables include (a) the age that has been shown to affect players' perceptions and evaluations of their coaches, (b) players' sex, (c) players' perceptions of coaching norms, (d) the valence that players attach to various coaching behaviors, (e) players' achievement motive in the sporting context, (f) competitive trait anxiety, (g) general self-esteem (i.e., players' evaluation of general self-worth), and (h) athletic self-esteem (i.e., players' evaluations of themselves as athletes). The situational factors affect coaches' behaviors as well as players' perceptions of those behaviors and reactions to them. These factors include (a) nature of the sport, (b) level of competition (e.g., competitive sport vs recreational sport), (c) practice sessions versus game sessions, (d) previous success/failure record of the team, (e) current game/practice developments (e.g., whether the team is losing or winning), and (f) intrateam attraction.

7.2. The Coaching Behavior Assessment System

Smoll and Smith employed the observational method to assess the actual leader behavior and employed the paper-and-pencil method to assess players' perceptions and recall of that leader behavior as well as coaches' perceptions of their own behaviors. These authors'

Coaching Behavior Assessment System (CBAS) was developed over several years by observing and recording the behaviors of youth soccer basketball and baseball coaches, analyzing these recordings, and categorizing the relevant leader behaviors. The 12 behavioral dimensions measured by the CBAS are broadly classified into reactive and spontaneous behaviors. Reactive behaviors are coaches' responses to (a) desirable performance or effort, (b) mistakes and errors, and (c) misbehaviors. Spontaneous behaviors may be (a) game related or (b) game irrelevant.

The training of the observers has been quite extensive, including a programmed learning module, group instruction in use of the coding system, written tests, practice, and reliability checks. Such training resulted in the coders agreeing with the experts more than 90% of the time. The second coding of the same coaching behaviors after a lapse of 1 week was also consistent to the tune of 87.5% to 100%, with a mean of 96.4%.

To assess players' perceptions and recall of coaches' behaviors, players were provided with a description and an example of each of the 12 behavioral dimensions of the CBAS and were asked to indicate the extent to which their coaches had engaged in each of the behaviors. A similar format was followed in assessing coaches' perceptions of their own behaviors. The relationships among the three measures of coaching behavior—observation, coaches' self-reports, and players' perceptions and recall—were not strong. More specifically, coaches' self-reports of their behaviors did not bear much resemblance to the assessments made by either observers or players. Therefore, the use of coaches' self-reports of their behaviors should be viewed with extreme caution. Player evaluative reactions were scored with a 10-item scale measuring attraction of the coaches and attraction toward teammates.

7.3. Correlates of Leadership

In general, leaders' supportiveness (i.e., reinforcement and mistake-contingent encouragement) and instructiveness (i.e., general technical instruction and mistake-contingent instruction) were significantly and positively related to players' attitudes toward their coaches, the sport, and teammates, whereas punishment and punitive technical instruction had the opposite effect. Also, coaching behaviors affected players' liking for the sport after the season, their perceptions of team solidarity, their evaluation of their coaches, and their

self-esteem. Although general technical instruction was found to be more potent than the other categories, positive reinforcement had minimal effects.

Player self-esteem has been used both as (a) a moderator of the relationship between coaches' behaviors and player attitudes and as (b) an outcome measure. Children with low self-esteem tended to respond most positively to a supportive or an instructive coach-player relationship and tended to react most negatively to coaches who were not supportive or instructive. It was also found that coaching behaviors had far less impact on children with high self-esteem. As for self-esteem as an outcome, children playing for trained coaches exhibited higher levels of self-esteem than they had a year before. Such increases were not found among children playing for nontrained coaches. Coaching behaviors during practices were also shown to be significantly associated with changes in players' perceptions of their physical and cognitive competence as well as success expectancy.

The mediational model has been the foundation for training coaches to improve their behaviors, assess their behaviors, and measure the effects of changes in coaching behaviors on players' evaluative reactions. Research has shown that the trained group of coaches differed from the control group in both observed and perceived behaviors. That is, the former group engaged in behaviors consistent with the training program. Furthermore, the players of the trained coaches evaluated their coaches more positively and expressed higher levels of intrateam attraction than did the players of the control group of coaches. However, the two groups did not differ in performance as measured by win/loss records.

7.4. Commentary on Leadership Studies in Sport

Some hold that the Multidimensional Model of Leadership is meant for adult sport and that the Mediational Model of Leadership is meant for youth sport because these models were developed in the context of adult sport and youth sport, respectively, and have been employed predominantly in adult sport and youth sport, respectively. But there is nothing in either of the models to prohibit or inhibit its use in either level of sport. Although there are some conceptual differences between the two models, each of them is applicable to either level.

The distinguishing feature of the research carried out by Smoll and Smith is the manner in which leader

behavior is measured, that is, the observational method of the CBAS versus the paper-and-pencil LSS. However, a comparison of leadership behavior categories of the two systems shows that they are, to a large extent, similar to each other in content, although the labels are different. For example, the reinforcement and non-reinforcement categories of the CBAS resemble the LSS dimension of positive feedback; the mistake-contingent technical instruction, general technical instruction, and organization are subsumed by the LSS dimension of training and instruction; and general communication is similar to social support in the LSS. Despite these similarities, the CBAS is distinct in two significant respects. First, the larger number of categories in the CBAS permits a more thorough analysis of leadership in youth sport. Apart from this advantage, the CBAS also measures leader behavior in more specific situations. For example, although "encouragement" in the CBAS is subsumed by the "positive feedback" in the LSS, encouragement is divided into reactive mistake-contingent behavior and spontaneous general encouragement.

In 2002, Horn employed a working model as the framework for her review of coaching effectiveness. While incorporating significant elements of both the multidimensional and mediational models of leadership, she also introduced the construct of "coaches' expectancies, values, beliefs, and goals" as a factor mediating the effects of the "sociocultural context," "organizational climate," and "coaches' personal characteristics" on "coaches' behavior." Furthermore, she referred to self-efficacy, motivational style (i.e., intrinsic or extrinsic motivation), self-reflectiveness, critical thinking aptitudes, locus of control, and trait anxiety as possible predictors of coaches' expectancies, values, beliefs, and goals. Coaches' expectations referred to coaches developing expectations for the performance of their teams and their members that affects coaches' subsequent behaviors. Beliefs were narrowed down to stereotyped beliefs about gender, race and ethnicity, and sexual orientation.

8. MOTIVATIONAL CLIMATE

An emergent thrust in the study of group dynamics pertains to the motivational climate within sport groups created and fostered by coaches. The motivational climate is characterized as (a) task involving (i.e., mastery orientation) or (b) ego involving (i.e., performance orientation). In the climate of mastery orientation, hard work, trying hard, skill improvement, and contributions by all members are emphasized. In

contrast, comparisons with others and performing better than others are promoted in the performance-oriented climate. Research has shown that, in general, the mastery-oriented (task-involving) climate enhances athletes' level of enjoyment, satisfaction, and interest in the sport, whereas the performance-oriented (ego-involving) climate tends to increase tension, pressure, and performance anxiety. Insofar as coaches have considerable influence and control over the climate in which their teams operate, it could be speculated that coaches' own goal orientation would be reflected in their leadership behaviors, which in turn would create either the mastery-oriented climate or the performance-oriented climate. It is also possible that the organization itself may foster the performance orientation that impinges on both coaches and athletes. For example, coaches of Division I schools in the National Collegiate Athletic Association (NCAA) are likely to exhibit those behaviors that would foster a performance-oriented climate, and athletes are likely to endorse that orientation and flourish in it. The relative influences of the organizational goals and coaches' own goal orientation on the climate experienced by team members are yet to be determined. Finally, the idea that pursuit of excellence would be greatly facilitated if the climate reflected both task orientation and ego orientation is also worthy of investigation.

- Further Reading

Research on group performance mainly examines the conditions under which motivation losses and gains are produced when people work in groups. Motivation losses concern the reduction in individual effort to perform a task due to the fact that one works as part of a group. On the other hand, it has been suggested that motivation gains resulting from group settings need to be more thoroughly investigated.

GLOSSARY

free-rider effect The enjoyment of the benefits resulting from successful group performance without contributing to it.

production blocking Production blocking in brainstorming groups arises from the constraint that only one group member can talk at a time.

social compensation A group member compensating for the low performance of other group members for the desired collective goal to be accomplished.

social facilitation/inhibition effects The facilitation or impairment of individual task performance as a function of the presence of others either as an audience or as coactors.

social loafing The decrease in individual effort when one performs as a member of a group in comparison to performing alone.

sucker effect The expectation that others withhold efforts in performance groups, which can lead an individual reducing his or her contribution to prevent being a victim of free-riding.

transactive memory A knowledge shared by group members about who is good at what.

1. INTRODUCTION

Most people have at some point wondered if it is more productive to work as part of a team or alone. This is a simple but challenging question, which social psychology has faced since it appeared as a discipline. Researchers have worked hard for decades to answer whether group performance is superior to individual performance. In general, the findings have shown that groups are more effective than separate individuals because groups learn faster, produce a greater quantity and quality of work, and make fewer errors.

However, groups do not accomplish their full potential since their performance is not as high as the sum-total of the maximum individual performance of each group member. It has been suggested that coordination losses and motivation losses are responsible for groups performing less efficiently than expected. Researchers have also identified conditions under which motivation gains result out of working as part of a group. Social compensation refers to the increased effort of a group

member in order to compensate for the insufficient contribution of another member when the group product is perceived as valuable. Moreover, there is evidence that complex and self-involving tasks carried out by groups that are psychologically meaningful to their members do not lead to productivity losses but gains.

2. SOCIAL FACILITATION/ INHIBITION

The most elementary issue concerning the impact of social factors on individual task performance is whether the mere presence of others influences individual performance. Social facilitation and inhibition (SFI) refer to the positive and negative effects that audiences (as well as coactors) may have on individual task performance. Interest in how the presence of others affects individual performance dates back to 1898 when Tripplett conducted one of the first experiments in the field of social psychology. Tripplett had children spin fishing reels either alone or in coactive pairs and found that participants performed better coactively. Following Tripplett's work, many researchers replicated the finding that the presence of others facilitates individual performance, whereas others demonstrated the social inhibition of individual performance under the same conditions.

In 1965, these apparently inconsistent results were explained by Robert Zajonc, who proposed that the presence of others facilitates individual performance in the case of simple tasks, whereas it impairs performance at complex tasks. Zajonc put forward a drive theory of social facilitation suggesting that the mere presence of others increases generalized drive or physiological arousal. Arousal, in turn, leads to the generation of dominant responses—that is, responses that are well learned, habitual, or innate. Simple tasks are successfully performed when dominant responses are generated, whereas complex tasks being more demanding in nature cannot be accomplished by the emission of dominant responses.

A number of other theoretical accounts of how task complexity affects individual performance at social settings have been provided. Zajonc had such a great impact that some of these theoretical accounts did not challenge the drive approach of his theory and presented factors considered as determinants of drive/arousal. For example, (i) people's concern with evaluation and (ii) distraction/conflict caused by attending both to the task at hand and to other people were factors proposed by different theoretical approaches to account for elevated

arousal at social settings. Recent theories have challenged the biologically based explanation offered by Zajonc's theory and have focused on cognitive and attentional factors as determinants of SFI effects.

There is a strong empirical basis suggesting that task complexity is related to the manifestation of SFI effects as proposed by Zajonc. However, it has been found that physiological arousal is not increased by the presence of others irrespective of task complexity. Complex tasks do lead to an elevated drive when others are present, whereas simple tasks do not seem to provoke increased levels of physiological arousal. Finally, recent research, in accordance with an attentional view of social facilitation, has shown that the presence of unpredictable others facilitated performance at a complex task by the emission of a nondominant response. In summary, Zajonc's proposition that task complexity plays an important role in explaining SFI effects has been strongly supported by the findings, but the exact mechanism(s) leading to facilitation and impairment at simple and complex tasks, respectively, has not been identified.

3. STEINER'S THEORY OF GROUP PRODUCTIVITY

Although the literature on social facilitation suggests that under certain conditions one feature of group settings (i.e., the presence of others) enhances individual performance, most of the work on group performance argues that when people work together in groups they do not perform at the maximum level of their potential. In 1972, Steiner proposed an influential analysis of group productivity, which focuses on the notion of a group's potential productivity, the maximum possible performance level that the group can achieve. Potential productivity is determined by group members' resources and task demands. Member resources concern the capabilities, knowledge, and skills of group members that can be useful at completing the task at hand. Task demands mainly refer to the criterion that is used to estimate a group's performance level. The criterion of performance at a weight-lifting task is the total weight lifted, whereas in the case of a brainstorming task it is the number of novel ideas generated by the group.

Steiner's model assumes that a group is not in a position to achieve its potential productivity due to process loss (faulty group process), and that a group's actual productivity is potential productivity minus losses due to faulty process. Process loss refers to coordination as

well as motivation losses. When performing in groups it is necessary for group members to coordinate their actions to achieve the desired group goal. For example, in a rope-pulling task group members have to synchronize their actions to achieve their full potential. This need for coordination inevitably leads to loss in productivity since group members cannot pull at exactly the same time or direction. Regarding motivation losses, individuals are considered to exert less effort when working as part of a team than when working alone.

Steiner also provided a task classification or taxonomy (Table 1), which aimed at further assisting researchers in the investigation of group productivity. According to Steiner's classification, there are three task characteristics that can be used to categorize different tasks. The first task feature is whether a task can be subdivided to separate parts performed by different people. The tasks that cannot be subdivided are unitary, whereas the tasks that can be subdivided are divisible. An example of a unitary task is finding a solution to a mathematical problem. On the other

hand, a task that certainly (and hopefully) can be divisible among roommates is cleaning their apartment. The second task feature that Steiner used to classify tasks is the performance criterion mentioned earlier, leading to a distinction between maximizing and optimizing tasks. When a task performance criterion concerns the quantity or speed of production, the task is considered to be a maximizing task; the rope-pulling task is a good example of a maximizing task. On the other hand, optimizing tasks put a demand for a correct or optimal solution (e.g., a mathematical problem). Finally, the way that group members' inputs are related to the group product leads to four different types of tasks: disjunctive, conjunctive, additive, and discretionary tasks. In a disjunctive task, members make separate contributions and the best contribution must be chosen (e.g., a reasoning problem). In conjunctive tasks, group performance is determined by the contribution of the least capable member (e.g., climbing a mountain while members are tied to one another). In additive tasks, the individual contributions are simply added together (e.g., a rope-pulling task). Finally, in discretionary tasks, individual inputs are combined in any way the group chooses (e.g., roommates cleaning their apartment).

Steiner's model has been criticized on the basis that it explicitly makes the assumption that groups cannot reach their full potential. It has been argued that groups might be in a position not only to achieve performance at the highest level of their potential but also to overperform it. Steiner's theory has put emphasis on coordination and motivation losses that influence group performance, while discounting the possibility that groups may exhibit motivation gains.

4. SOCIAL LOAFING

Productivity loss in group settings has been defined in terms of both coordination and motivation losses. The first experiments on group productivity were conducted during the last decades of the 19th century by Ringelmann. In these experiments, individuals were asked to pull a rope either alone or in groups of various sizes. The results showed that when individuals worked in groups, the collective output was less than the sum total of the individual performance measured when individuals pulled the rope alone. This finding can be explained as the result of coordination loss. However, subsequent research showed that this finding

TABLE 1
Steiner's Task Classification^a

<i>Task characteristics</i>	<i>Task taxonomy</i>
Can a task be subdivided to separate parts performed by different people?	Yes → <i>Divisible tasks</i> No → <i>Unitary tasks</i>
Does the task performance criterion concern quantity/speed of production or a correct/optimal solution?	The performance criterion concerns Quantity/speed of production → <i>Maximizing tasks</i> Correct/optimal solution → <i>Optimizing tasks</i>
How are group members' inputs related to group product?	Members make separate contributions and the best contribution must be chosen → <i>Disjunctive tasks</i> Group performance is determined by the contribution of the least capable member → <i>Conjunctive tasks</i> The individual contributions are simply added together → <i>Additive tasks</i>

^aAdapted from Steiner (1972).

is caused by the joint effect of coordination problems and reduced effort exerted by group members.

Regarding motivation losses, there is a difference between the effort that individuals exert when working collectively and working coactively (or individually). When people work collectively, their individual contributions are combined to form a group product, whereas when they work coactively their individual inputs are not combined to a single product. Individuals' tendency to produce lower effort when working collectively compared to working coactively (or individually) was called social loafing by Latané and colleagues in 1979.

Social loafing has been observed in a wide variety of tasks, including physical tasks (e.g., rope pulling, shouting, and clapping), cognitive tasks (e.g., idea-generation tasks), perceptual tasks (e.g., maze performance), and evaluative tasks (e.g., evaluation of poems and editorials), suggesting that social loafing is a robust phenomenon. As a general phenomenon not restricted to physical tasks, it poses the important practical question of why and when less effort is exerted in group settings.

A number of theoretical explanations have been proposed to explain why social loafing takes place in groups. It has been suggested that social loafing occurs because (i) the pressure people feel as group members to accomplish the task at hand is less intense than the pressure one feels when working alone, (ii) the presence of other group members is drive reducing because others share the responsibility for carrying out the task, (iii) there is reduced identifiability or evaluation potential in collective action compared to individual action, and (iv) group members feel their contributions to the group product not to be essential but dispensable.

Apart from social loafing, two other effects have been reported, namely, the free-rider effect and the sucker effect. The free-rider effect concerns the enjoyment of the benefits resulting from the successful group performance without contributing to it. The free-rider effect might be seen as the result of a person's conscious decision to indulge in social loafing. On the other hand, members of a group who work hard to accomplish the group goal run the risk that others may free ride on their efforts and become suckers. The expectation that others withhold efforts in performance groups can lead to the individual reducing his or her contribution to the group in order to prevent being a victim of free-riding (the sucker effect).

The literature that examines group conditions leading to social loafing has also attempted to propose various solutions to remedy motivation loss in group settings.

On a practical level, the following can reduce or overcome social loafing in real-world contexts: (i) identification and evaluation of individual inputs, (ii) meaningful and self-involving tasks, (iii) close ties among group members, (iv) small rather than large groups, (v) uniqueness of individual contributions, and (vi) feedback on individual or group performance.

5. MOTIVATION GAINS IN GROUPS

Even though research on group performance has concentrated on productivity loss in group settings due to reduced motivation, there are findings showing that motivation gains can also result from performing within groups. In 1991, Williams and Karau demonstrated conditions under which people may actually increase their efforts when working collectively compared to when working individually (coactively). They call this effect social compensation. Social compensation refers to a group member compensating for the low performance of other members in order to accomplish the desired group goal.

One factor that might produce social compensation is the expectation that other group members are performing insufficiently. The perception of inadequate coworker inputs may be derived from a general lack of trust in the reliability of others to perform well when their contributions are pooled with those of others or/and direct knowledge of coworkers' insufficient efforts or inabilities. The second factor that may be necessary to produce social compensation is that the group product is in some way important to the individual. If the group output is not meaningful and important to group members, then one does not expect social compensation to occur.

Social compensation is not expected to occur in all situations in which individuals believe their coworkers are contributing less than their fair share. Besides group product meaningfulness previously mentioned, other factors are important for compensation to take place. Social compensation is more likely to occur (i) when the individual has to remain in the group working collectively, (ii) at earlier stages of the collective effort, and (iii) when the group size is relatively small. Finally, people may be motivated to compensate in some cases for their own prior underperformance rather than the underperformance of other group members.

According to social compensation, when group members of unequal strength work on an important task, the most competent member will compensate for the insufficient contribution of the other group

member(s). There are, however, findings showing that under specific conditions the weaker member of the group tries hard to match the performance level of the stronger member (the Köhler effect). One necessary condition for this effect to occur is that the group product must be meaningful to its members. The second condition is that the discrepancy in ability between the group members is of a moderate degree. A high discrepancy in individual performance is not expected to lead to more effort exerted by the weakest members because people believe that there is a limit to the discrepancy in ability that can be compensated for through increased effort.

The social loafing paradigm has been criticized on the basis that little effort is expended in making the participants feel that they are part of a group. In the paradigm, a number of individuals combine their efforts for a group output without interacting with each other, competing with other groups, or expecting any form of future interaction. Even though the findings of research on social loafing are discussed in terms of group membership, it seems that participants mainly act on the basis of their personal identity rather than a group-based sense of self. Motivation losses described by research on social loafing might be the result not of faulty group processes but of individuals acting as persons rather than group members. It has been demonstrated that when social identity is made salient there are motivation gains leading to the accomplishment of the desired goal as defined by the group rather than some external source of influence.

6. IMPLICATIONS FOR GROUPS AT WORK

Despite the fact that most research on group performance has emphasized the inefficiency of groups compared to individuals, groups feature in most essential aspects of everyday life. Their central role in real-world contexts might have to do with the fact that many tasks cannot be accomplished by individuals. If one considers how many people with different skills are involved in making a car or building a house, then it becomes clear that getting rid of groups cannot be a practical solution to increase performance.

Regarding groups at work, how can we use the accumulated knowledge on group performance to understand how groups function and to propose ways on a practical level for groups to become more effective?

In organizational settings, brainstorming groups are used in order for the organization to stimulate employees to think creatively. In brainstorming groups, members are asked to generate as many ideas as possible, not to criticize others' ideas, and to build on ideas presented by other group members. Research by Diehl and Stroebe in the late 1980s showed that brainstorming groups produce half the ideas produced by the same number of individuals who brainstorm alone (nominal groups). This productivity loss in brainstorming groups has been discussed as a coordination loss resulting from mutual production blocking. Mutual production blocking arises from the constraint that only one group member can talk at a time in a brainstorming group.

Although there is ample evidence showing brainstorming groups to be less effective than nominal groups, organizations of all kinds make wide use of brainstorming groups. A reason that might explain organizational members' confidence in brainstorming groups is that members of such groups are more satisfied with their performance in comparison to individuals who brainstorm alone. This discrepancy between satisfaction and productivity can be accounted for by the greater ease of idea generation in brainstorming groups compared to nominal groups. Since brainstorming is widely used at work, some advice needs to be given on the conditions that make brainstorming groups more effective. First, the size of the group should be kept as small as possible, not exceeding four members. Second, because time pressure negatively affects the productivity of brainstorming groups, groups should decide when it is the best time to stop. Finally, it is advisable that group members are heterogeneous in their knowledge about the brainstorming topic so that members can have a stimulating impact on each other.

Moreover, our knowledge on group productivity can be applied to training at work in order to improve organizational effectiveness. Interventions designed to increase productivity through learning, such as training programs, were found to have a strong positive effect. Regarding group training programs, it has been suggested that group learning is associated with a transactive memory system—that is, a knowledge shared by group members on who is good at what. When members of a work group are trained together, they develop complementary specializations that enable the group to share knowledge and skills. In this way, the group as a whole makes use of social compensation—that is, individual members compensate for each other's inadequacy. However, a practical problem related to group training at work involves the

disruption that employee turnover has on the smooth operation of the work group.

The business world has acknowledged the importance of one's ability to work within groups as a key factor to success. In this sense, groups are seen as capable of accomplishing more than the sum of their individual parts. However, the bulk of research on group performance suggests that, more often than not, groups are not as efficient as individuals.

GLOSSARY

availability heuristic Assessment of the frequency of a class or the probability of an event based on the ease with which instances or occurrences can be brought to mind.

defensive avoidance A condition in which an individual fails to engage in vigilant search and appraisal and instead adopts a dominant mode of coping that involves avoidance of cues that stimulate anxiety or other painful feelings.

groupthink A condition in which highly cohesive groups in "hot" decision situations display excessive levels of concurrence seeking that suppress critical inquiry and result in faulty decision making.

"hot" cognitions Thought processes regarding vital, affect-laden issues (i.e., in "hot" decision situations).

illusory correlation The tendency to see relations between variables where none exists.

mindguard In groupthink, a self-appointed individual who acts to shield a group from adverse information.

Pygmalion effect Self-fulfilling prophecy; it is the tendency to create something in the image that one has of it.

strong version of groupthink The view that groupthink characteristics cluster due to their common ties to specific

antecedent conditions and are linked in a causal chain from those antecedent conditions, to symptoms, to defects, to outcomes.

weak version of groupthink The view that groupthink may be evidenced by the presence of some subset of the characteristics proposed by Janis and that the causal ordering that he posited may be suggestive rather than necessary.

Groupthink is a condition in which highly cohesive groups in "hot" decision situations display excessive levels of concurrence seeking that suppress critical inquiry and result in faulty decision making. In the groupthink process, antecedent conditions are seen as resulting in a variety of symptoms of groupthink that lead to defective decision making and, in turn, to flawed decision outcomes. This article addresses the nature and history of the phenomenon, offers evidence of its validity and explanations for its widespread acceptance, and provides implications and suggestions.

1. THE GROUPTHINK MODEL DEFINED AND EXPLAINED

Janis proposed that highly cohesive groups are likely to suffer from groupthink, a strong concurrence-seeking tendency that suppresses critical inquiry and results in faulty decision-making processes and flawed outcomes. Janis discussed major historical fiascoes such as the lack of preparedness for the Japanese attack on Pearl Harbor,

the escalation of war in Korea, the failed U.S.-sponsored landing of anti-Castro rebels in the Bay of Pigs, and escalation of U.S. involvement in the war in Vietnam. First presented in a 1971 issue of *Psychology Today*, this groupthink phenomenon quickly gained remarkably broad and firm acceptance, dominating the literature on group decision making for decades.

At the individual level, Janis and Mann argued that thinking about vital, affect-laden issues generally results in “hot” cognitions, in contrast to the “cold” cognitions of routine problem solving, and that such hot cognitions can result in errors in scanning of alternatives. Such situations induce stress that results in defensive avoidance, characterized by lack of vigilant search, distortion of the meanings of warning messages, selective inattention and forgetting, and rationalizing. Groupthink is seen as the group analog of defensive avoidance or “a collective pattern of defensive avoidance.” In 1972, Janis wrote that he used the term “groupthink” to refer to a mode of thinking engaged in by people in cohesive in-groups, with members’ strivings for unanimity overriding their motivation to submit alternative courses of action to realistic appraisal. He further stated, “Groupthink refers to a deterioration of mental efficiency, reality testing, and moral judgment that results from in-group pressures.”

Janis chose the term “groupthink” due to its frankly Orwellian connotation, similar to “doublethink” and “crimethink.” In 1982, Janis wrote that “the invidiousness is intentional.” This view of groupthink as an undesirable phenomenon continued to be evidenced in Janis’s more recent work.

Janis explicitly defined the context in which groupthink is thought to occur and divided these antecedent conditions into three categories. First, a moderate to high level of group cohesion is a necessary, but not sufficient, condition for groupthink. In addition, structural faults and a provocative situational context are secondary antecedents that define situations in which groupthink is likely to occur. In the structural fault category are insulation of the group, lack of impartial leadership, lack of norms requiring methodical procedures, and homogeneity of group members’ social backgrounds and ideologies. The provocative situational context antecedents focus on the role of stress as a situational factor. The first stress factor is characterized as external threats of losses combined with a low hope of finding a better solution than that of the leader. The internal stress antecedent stems from temporary low self-esteem attributable to members’ recent failures, perceptions that the task is too difficult to

accomplish, and the perception that there is no alternative that is morally correct.

According to Janis, the antecedents lead to several proposed symptoms of groupthink, including an illusion of invulnerability, rationalization to discount warnings and other negative feedback, a belief in the inherent morality of the group, stereotyped views of members of opposing groups, pressure on dissenters, self-censorship, illusion of unanimity, and self-appointed “mindguards” acting to shield the group from adverse information.

According to Janis, groupthink results in a number of consequences that interfere with effective group decision making. For instance, the group limits its discussion to only a few alternatives. After a course of action is initially selected, group members ignore new information concerning its risks and drawbacks. At the same time, they avoid information concerning the benefits of rejected alternatives. Members make little attempt to use experts to obtain more precise information. In addition, because they are so confident that things will turn out well, members fail to consider what may go wrong and, as such, do not develop contingency plans. These “defects” are seen as leading to impaired performance and other undesirable outcomes.

Janis suggested methods to prevent or minimize the supposedly dysfunctional consequences of groupthink. These “remedies” included the following:

- Group leaders should encourage all group members to air their doubts and objections.
- Group leaders should adopt an impartial stance rather than initially stating their preferences.
- Group members should be encouraged to discuss the group’s deliberations with trusted associates and report their reactions back to the group.
- Outside experts should be invited to meetings and encouraged to challenge group members’ views.
- When a competitor is involved, time should be devoted to assessment of warning signals from the competitor and of alternative scenarios of the competitor’s intentions.
- When considering alternatives, the group should split into subgroups to meet separately from time to time.
- The group should hold a “second chance” meeting after a preliminary consensus is reached on a preferred alternative.
- The group should consider using dissonance-inducing group processes.

2. HISTORY AND IMPACT OF THE GROUPTHINK PHENOMENON

More than 30 years after its conception, the groupthink phenomenon retains a remarkably strong intuitive appeal and acceptance. A recent Google search revealed more than 42,700 groupthink "hits." Groupthink is presented as received doctrine in sources ranging from *Educational Gerontology* to the *Utne Reader*, from the *New Criterion* to *Vogue*, and is offered as the cause for everything from flawed jury deliberations, to problems of the Washington Redskins, to the U.S. decision to invade Iraq. The *New York Times* recently reported that groupthink is three decades old and still going strong, invoking the phenomenon as a potential explanation for the space shuttle *Columbia* disaster. In addition to its firmly entrenched status with practitioners in a wide variety of areas, groupthink continues to be featured in popular textbooks and to be the subject of theory and research.

3. EVIDENCE REGARDING THE GROUPTHINK PHENOMENON

Most support for groupthink has come from retrospective case studies that have focused on decision fiascoes rather than comparing the decision-making processes associated with good decisions with those associated with bad decisions.

Experimental studies of groupthink have considered only a small portion of the model, often without a cohesive group and in situations inconsistent with Janis's proposed antecedents. Furthermore, they have relied nearly exclusively on student samples dealing with hypothetical or simulated decisions, with potential resultant problems for external validity. In the laboratory, many real-world group characteristics, including ongoing power relationships and political maneuverings, have been necessarily ignored. Empirical studies of groupthink have tended to use short-term decision quality as the sole outcome measure and have contained serious threats to internal validity. Interestingly, Janis apparently discounted these experiments. For instance, in his 1989 book, he cited none of the experimental studies of groupthink, with his discussion of groupthink referring only to case studies and anecdotal pieces.

Another important aspect of prior research concerns the situations chosen for study. The groupthink

conceptualization is restrictive, primarily due to the model's antecedents and the international policy context for which groupthink was developed. The narrow focus of the model's antecedents is not surprising given the fact that Janis extracted them directly from major policy decision fiascoes. Early case evidence provided in support of groupthink was drawn largely from these and similar hot decision situations. The ability to generalize from such situations is questionable. For instance, the extremely high group cohesiveness and clearly unified goals in many major military policy decisions, or in groups facing natural disasters, are unlikely to be encountered often in other settings. Nevertheless, laboratory and survey research on groupthink has typically used settings considerably different from Janis's conceptualization.

Strong and weak interpretations of groupthink have emerged. The strong interpretation, commonly cited, suggests that groupthink is an integrated set of characteristics with deterministic linkages. That is, groupthink characteristics cluster due to their common ties to specific antecedent conditions and are linked in a causal chain from those antecedent conditions, to symptoms, to defects, to outcomes. The weak interpretation is sometimes presented in response to the failure of empirical examinations to provide results that are wholly consistent with groupthink. It suggests that groupthink may be evidenced by the presence of some subset of these characteristics and that the causal ordering posited by Janis may be suggestive rather than necessary.

When the weak interpretation is presented, it is crucial to ask which characteristics, if any, are unique to groupthink. That is, some groupthink characteristics, such as belief in the correctness of a decision and pressures to achieve consensus, are common to many group processes and, in fact, may be beneficial. For instance, convergence to the majority viewpoint may be desirable if the majority viewpoint is correct. Other characteristics, such as mindguards and self-censorship, better discriminate between groupthink and other group processes. It is difficult to accept the argument that the presence of characteristics common to most problem-solving groups is supportive of the existence of groupthink.

Janis did not accept this weak form of groupthink. To the contrary, he wrote the following in 1989:

It does not suffice merely to see if a few of the eight telltale symptoms of groupthink can be detected. Rather, it is necessary to see if practically all the symptoms were manifested and also to see if the antecedent

conditions and the expected immediate consequences—the symptoms of defective decision making—are also present.

Recent research has continued to show little empirical support for the groupthink phenomenon. For example, in 2000, Park conducted a comprehensive empirical investigation of Janis's model, including all 24 variables (antecedent conditions, symptoms of groupthink, signs of defective decision making, and outcomes). Of 23 predictions drawn from the groupthink model, only 2 were confirmed. Conversely, 7 of the 23 relationships were significant opposite the direction predicted.

As another example, in 1999, Choi and Kim examined groupthink and team activities in 30 organizational teams faced with impending crises. They found that groupthink symptoms consisted of two factors. Contrary to groupthink predictions, one of those factors (termed "group identity") was significantly positively related to team performance, whereas the other factor (termed "concurrence seeking") showed an insignificant negative relationship to performance.

Addressing what is probably the most-cited example of groupthink, the space shuttle *Challenger* disaster, Maier (who developed a popular documentary on the topic) noted in 2002 that new evidence regarding the disaster and further analysis of past evidence demonstrates convincingly that the disaster "emphatically is not an example of groupthink." He noted that two of groupthink's defining features, the conviction of invulnerability and the illusion of unanimity, were conspicuously absent. Maier discussed evidence that the decision to launch was driven by uncertainties rather than perceived infallibility and that certain actions were taken only when it was clear that opinions would not be unanimous.

In short, research continues to find very little empirical support for the groupthink phenomenon. Coupled with several theoretical critiques, such evidence calls into question the validity of the phenomenon. Elsewhere, it has been noted that others have attached a variety of possible meanings to groupthink, as indicated in what follows.

- Groupthink is overreliance on concurrence seeking.

This meaning, which seems to have gained considerable popularity, would grant no value added to groupthink. That is, overemphasis on concurrence seeking was a widely recognized phenomenon decades before Janis coined the term "groupthink" (e.g., by Schanck in 1932), and the groupthink phenomenon simply

adopted this element. If groupthink is to have any unique explanatory value, it must have additional meaning beyond this sole concept.

- Groupthink is a complete sequence of clusters of dysfunctional characteristics that result in flawed decision making.

As noted earlier, Janis accepted this view of groupthink, which is labeled a "strong view" in this article. Quite simply, there is no support for this interpretation of groupthink. No study conducted has ever supported—or come close to supporting—this strong view. Instead, researchers have adopted weak versions in which any partial support, regardless of the number of disconfirming findings and whether or not that partial support relates to elements unique to the groupthink model, is hailed as further evidence of groupthink's validity. Furthermore, support for the posited groupings of groupthink characteristics derives from anecdotes, casual observations, and intuitive appeal rather than from rigorous research. There has been no full factor analysis of groupthink variables. Incomplete factor analyses (in which exploratory factor analysis was applied to variables within sets rather than to all variables in the model) support a simpler model than that presented by Janis. Path analysis of the complete groupthink model has revealed only a scattering of the relationships proposed by Janis. In addition, in 1992, Tetlock and colleagues used a quantitative method, the group dynamics q-sort, for analyzing historical cases of group decision making to compare Janis's case interpretations with other historical interpretations of the same cases and to test the causal linkages predicted by the groupthink model. A test of the causal sequence of the groupthink model yielded only limited support. For example, group cohesiveness and provocative situational context proved to be only weakly related to concurrence seeking, with structural and procedural faults playing larger roles. In sum, there is no solid support for the clusterings of characteristics posited by the groupthink phenomenon or for their proposed causal sequence.

- Groupthink is an undesirable constellation of characteristics resulting from highly cohesive groups.

Again, there is no empirical support for this meaning. Cohesiveness, supposedly the critical trigger in the groupthink phenomenon, has simply not been found to play a consistent role. Conceptually, there are many reasons to question this view of groupthink. First, the

benefits of group cohesion, including enhanced communication among members, heightened member satisfaction, decreased member tension and anxiety, and higher levels of task accomplishment, have long been recognized. Furthermore, any general statement about the dangers of cohesiveness ignores critical contingency variables. As just one example, the stage of group development may be important because members of a fairly cohesive group in the mature stage of group development are likely to be secure enough in their roles to challenge one another. Given all of this, the findings relating to cohesiveness in the groupthink literature are unsurprising in that they demonstrate convincingly that cohesiveness does not regularly lead to negative outcomes. More than 25 years ago, Flowers stated that a revision of Janis's theory, one that would eliminate cohesiveness as a critical variable, may be justified. Any such elimination would, of course, largely eviscerate the groupthink phenomenon. Janis viewed cohesiveness and an accompanying concurrence-seeking tendency that interferes with critical thinking as the central features of groupthink.

- Groupthink is any set of group processes that are antecedent to poor decision outcomes.

This view is tautological, suggesting that groupthink is all of those bad things that precede poor outcomes. It is not surprising, then, when poor outcomes are found to follow these bad things. Furthermore, because many group processes and characteristics leading to poor outcomes had been identified long ago, this meaning, in which groupthink most clearly adopts the form of a metaphor for dysfunction, essentially grants groupthink no status—and Janis no contribution—beyond that of providing a memorable label. Nevertheless, much of the popularity of groupthink may be attributable to adoption of this perspective. That is, there is apparently a reluctance to abandon a compelling metaphor that encourages focus on flawed group processes.

4. BASES FOR GROUPTHINK'S APPEAL

In the current authors' view, groupthink has gained the status of received doctrine. Groupthink has a seductive intuitive appeal, and vivid examples that are superficially consistent with the phenomenon can readily be recounted. But how did groupthink come to be so widely and enthusiastically accepted in the absence of

compelling evidence? This section, based in part on Aldag and Fuller's earlier review in *Psychological Bulletin*, explores the bases for groupthink's appeal.

4.1. Implicit Assumptions

Groupthink's appeal appears to rest in part on a number of implicit assumptions. First, although groupthink assumes that groups are used primarily to enhance the quality of decisions, group decision making is often used specifically to increase the acceptance of a decision. Also, organizational members may choose to use groups for other reasons, including socioemotional benefits and accomplishment of members' own secondary goals (e.g., "hidden agendas").

Second, groupthink implicitly assumes that groups rationally pursue a unified goal. However, group processes are characterized by interplays of covert and overt motivations, concern not just about the current problem but also about residues of past problems and the anticipation of future problem-related interactions, and many other subtleties outside the typical focus of the rational model. Processes and outcomes that appear irrational to "objective" observers may in fact be functional from the point of view of individual members or even of the entire group. For instance, such processes and outcomes may serve to maintain the motivation of the group leader, help ensure the continued use of group processes, prevent the defection of certain group members, serve as a means for members to show allegiance to coalitions, and minimize the likelihood of the use of still other political acts.

A third implicit assumption is that actions taken to prevent or minimize groupthink will produce a more rational and effective group process. However, these remedies may have unintended consequences. That is, attempts to create a microrational decision process in an inherently political environment may prove to be misguided; other literatures have suggested the dangers of presenting an oasis of change in a nonreinforcing desert. The groupthink remedies are decision specific, whereas the causes for supposed group dysfunctions may be systemic. That is, the application of specific techniques to prevent or minimize group difficulties may amount to treating the symptom of a deeper problem.

Fourth, fundamental to groupthink is the assumption that a group's illusion of well-being is dysfunctional. However, in 1988, Taylor and Brown argued that such illusions actually promote many criteria of mental health, including the ability to care for others, be happy or

content, and engage in productive and creative work. They added that such positive illusions are especially useful when an individual receives negative feedback or is otherwise threatened and may be especially adaptive under these circumstances. Thus, this illusion of well-being may be most useful specifically in the hot decision situations described by Janis. Although Taylor and Brown focused on the individual, the processes that they detailed seem equally applicable to groups.

Such contentions are reinforced by consideration of the related literature of the self-fulfilling prophecy, referred to in some settings as the Pygmalion effect. The Pygmalion and similar expectation effects appear to be common in organizational settings. Taken as a whole, evidence concerning these related effects suggests that nonveridical perceptions may often yield positive consequences. The literature on optimism–pessimism leads to similar conclusions. That is, although pessimism is often found to be associated with more realistic worldviews, optimism typically yields superior outcomes. These arguments are not meant to imply that overly positive perceptions are necessarily desirable; they are only meant to imply that the opposite should not be automatically assumed.

A final groupthink assumption concerns causes of characteristic groupthink attitudes and behaviors. Rather than, or in addition to, stemming from individual psychological factors, conformity behaviors may be politically motivated. For instance, they may reflect compliance rather than internalization. Thus, many groupthink characteristics could be due to conscious actions by members to subscribe to political norms.

What the preceding implicit assumptions have in common is a beguiling, albeit unrealistic, simplicity.

The reliance on anecdotes in groupthink scenarios and case studies contributes to the availability heuristic. It does this in at least two ways. First, groupthink examples tend to be vivid and “catchy” and, thus, are salient and readily available in individuals’ memories. Second, such examples play to individuals’ preference for case, as opposed to base, data. A concrete instance of the appearance of groupthink symptoms in a fiasco may be seen as compelling evidence, especially in the absence of base data.

4.2. Implicit Theories of Group

The groupthink phenomenon is consistent with implicit theories of groups. The roles of implicit theories in influencing responses have been widely documented. One important characteristic of implicit theories is

their “gap-filling” function. In the context of groupthink, individuals observing a situation in which some groupthink characteristics are present may assume the existence of others. Furthermore, research shows that feedback given to group members or observers about group performance affects the characteristics ascribed to those groups. For example, feedback about group process has been shown to affect evaluations of outcomes, and feedback about outcomes has been shown to affect evaluations of process. Individuals who are told that a group has performed poorly are more likely to report instances of “poor” interaction processes such as lack of willingness to hear other members’ views. Thus, the focus on poor decision outcomes in groupthink research may lead to reports of poor group functioning.

4.3. Illusory Correlation

A focus on only the conjunction of groupthink characteristics and negative outcomes invites illusory correlation. In this sense, the groupthink phenomenon is similar to the “Friday the 13th” phenomenon; only the yes–yes (i.e., groupthink/Friday the 13th–poor outcomes/bad luck) cell is considered. If the yes–yes cell is not empty, support for the phenomenon is inferred. In fact, of course, support for the phenomenon requires examination of all cells. Furthermore, when research is used to explain a poor decision, the process used to “validate” groupthink nearly guarantees support, however partial. That is, in the aftermath of a fiasco, transcripts and other documents, videos, and casual observation may be sifted for “evidence” of groupthink. If that search unearths comments that deal with conformity, caution, or closed processes, a “hit” is registered in the yes–yes cell and the presence of groupthink is announced. However, some reference to such terms is nearly inevitable in the mass of evidence surrounding a fiasco.

4.4. Framing

The negative language of groupthink (e.g., “victims of groupthink,” “defects of groupthink”) and the focus on error can invite distortions in responses caused by scale use tendencies and related psychometric difficulties and can also result in framing effects. Individuals (whether research participants or researchers) presented with negatively framed terminology may adopt the readily available negative frame and respond accordingly. Therefore, even simple attempts by the participants to give responses that are consistent with the tone of the

questions would result in negatively oriented responses. On a more fundamental level, this framing has resulted in a focus on error rather than on decision quality *per se*. Janis noted in 1982 that he began studying fiascoes “for the purposes of studying sources of error in foreign policy decision making.” However, just as there is more to the performance of a football team than the absence of fumbles and interceptions, there is more to group decision quality than the absence of error. A focus on negative outcomes of group processes may divert attention from group synergies. One example is the assembly effect bonus, which is productivity that exceeds the potential of the most capable member as well as the sum of the efforts of group members working separately. Thus, one may learn little about superior group performance by focusing solely on fiascoes. Instead, a focus on decisions with a broad range of outcomes, including superior performance, is necessary.

In the current authors’ view, groupthink owes much of its popularity to a characteristic it shares with other popular concepts such as total quality management. A core concept with some validity (e.g., statistical quality control) is incorporated as an element of a broader renamed concept (e.g., total quality management). Support for the core concept is subsequently treated as confirmation of the broader concept and, by association, for its various elements. In the case of groupthink, a core concept with some validity (i.e., overemphasis on concurrence seeking may be harmful) is subsumed in a complex, essentially deterministic model. Subsequent instances of that core concept are then presented as evidence for the validity of the broader groupthink phenomenon.

5. IMPLICATIONS AND SUGGESTIONS FOR FUTURE RESEARCH AND THEORY

Groupthink has stimulated research on group dysfunctions, provided links to other literatures such as stress and vigilance, emphasized potentially important variables in group decision making, and encouraged policymakers to take remedies for excessive concurrence seeking seriously. Indeed, Janis’s recommendations for “remedies” for groupthink are themselves an excellent compilation of approaches to help preclude group dysfunction.

However, group problem solving is a complex and challenging phenomenon. Although the groupthink

model has played an important role in generating interest in group problem-solving processes and in acting as a catalyst for associated theory and research, it has not incorporated three decades of theory and research, has received limited empirical support, and is restrictive in scope. Recent theory and research, as well as critical evaluation of the model, suggest that more comprehensive models are necessary to guide researchers and practitioners in dealing with the group decision phenomenon.

It is not unusual for theories to generate initial widespread interest and enthusiasm and then to meet with subsequent revision, rejection, or reaffirmation. However, groupthink has generally resisted dispassionate reevaluation. This is perhaps due in large part to the raw intuitive appeal of the phenomenon as well as to the fact that studies of groupthink have often been searches for confirmation. Rigorous evaluation of the phenomenon is further rendered difficult by the fact that a variety of views of groupthink have emerged, as have contrasting positions on what level of evidence is needed to indicate support.

Similarly, popular acceptance of groupthink has been extraordinary. Perhaps this is understandable: Groupthink has served as a vivid bogeyman that can be readily summoned to illustrate the dangers of overemphasis on concurrence seeking, and it continues to serve its purpose. This article has provided a variety of potential reasons for this enthusiastic acceptance and has shown that they are consistent in yielding illusory support.

Although attention to groupthink has yielded some clear benefits over the past three decades or so, there is growing consensus that the phenomenon lacks conceptual and empirical support, is restrictive in scope, and is inappropriately deterministic. As such, future research should seek to build on decades of groupthink and other research and theory on group processes and outcomes to yield more encompassing, less causally constrained perspectives. New theories and models should generalize to a broad range of group types and situations (e.g., including self-managing groups and virtual groups), incorporate additional relevant variables (e.g., leader motivations, stage of group development, power relationships), and recognize that groups, as well as group leaders, may have multiple goals (e.g., sustained motivation of the group leader, continued use of group processes, prevention of defection of group members). Finally, the research should avoid selection on the dependent variable; instead, it should consider instances of both favorable and poor group

outcomes and should seek to be theory building rather than theory confirming. In this way, the energy, enthusiasm, and intellectual and other resources that have been directed toward the groupthink phenomenon for more than three decades may yield broader, more inclusive, and more valid models and theories of group decision processes.

6. PRESCRIPTIONS FOR EFFECTIVE GROUP PROBLEM SOLVING

As this analysis has indicated, the current authors believe that the topic of group problem solving should be viewed more comprehensively than within the confines of the restrictive groupthink phenomenon. Taking into account the broader literature on group problem solving, it is clear that there are legitimate threats to group processes beyond—and sometimes inconsistent with—those suggested by the groupthink model. With this in mind, the authors offer the following advice to increase the effectiveness of group problem solving.

The first recommendation is to pay careful attention to group process and provide structure and guidance to ensure that the full process proceeds effectively. There are five stages to the problem-solving process: problem identification, generation of alternatives, evaluation of alternatives, decision making, and decision implementation and control. It is important that a group proceed systematically through these stages, allotting appropriate time and attention to each stage. In addition to proper structuring of the process by the group leader, some tools (e.g., the nominal group technique) and computerized decision aids (e.g., decision insight systems) may also prove to be valuable for this purpose.

A second recommendation is to consider the level of conflict in the group. The leader must be able to assess the degree of conflict and strive to bring the group toward an optimal level, where different viewpoints are encouraged and accepted but where the differences are viewed as adding information and contributing to the discussion. In any group, or at any time, conflict might have to be reduced, stimulated, or maintained. If conflict levels are very low, productive dissent might be needed. That is, as suggested by Schanck and others, group decisions may suffer if there is a strong pressure to conform and remain silent against the dominant view. In such cases, techniques suggested by Janis (e.g., the devil's advocate, "second chance meetings") might be

useful. In addition, leaders can form subgroups that take different sides of an issue and can encourage norms that all employees, regardless of their positions, should fully express their concerns, doubts, and ideas, emphasizing that it is essential to examine issues critically and to find flaws and problems before competitors or customers do. Another approach to encourage productive dissent is to form task forces, made up of employees with various perspectives, outlooks, organizational positions, and backgrounds, to examine major problems and offer recommendations. Conversely, too much conflict will also result in poor group process and decisions. In such cases, it may be useful to encourage the group to focus on larger goals, directly intervene to alleviate conflict, separate conflicting parties, work to improve communication among members, train members in finding integrative solutions, or bring in third-party mediators.

Third, the discussion suggests that it is important to consider many outcomes of group problem solving rather than focusing just on short-term decision quality; decision implementation and commitment to decisions may be as important as the decision itself. Future motivation of the group and leader, future use of the group, and member affective responses may be important outcomes for the group and/or its members. The leader must recognize trade-offs among multiple goals, sometimes subordinating short-term decision quality to goals such as maintaining member satisfaction and enhancing the likelihood of future use of the group.

Fourth, caution must be exercised in the use of any individual technique. In an organization, a group functions within a broader environment, that is, the culture of the organization. As such, a specific remedy applied to a group may be ineffective if it contradicts the dominant cultural norms in the organization. Therefore, attempts to improve group functioning must be viewed within the broader context and should explicitly consider systemic issues. It may be more appropriate to assess and perhaps alter organizational culture or contingencies of reinforcement than to implement specific techniques in the hopes of overcoming the consequences of the group's decision environment.

Finally, it is important for the group leader to recognize and manage the complexity and challenges of group problem solving. The leader must strive to keep an open mind, avoiding limiting assumptions and models—no matter how alluring—and maintaining broad behavioral repertoires to permit flexible responses to the rich contingencies influencing group processes and outcomes.

GLOSSARY

balance model A model that describes health in terms of a harmonious balance between different elements or forces in the body.

culture Guidelines that are inherited from the social environment that guide how people in a particular cultural group view the world, respond to it emotionally, and behave in it.

machine model A model of the body as being an internal-combustion or battery-driven machine.

“plumbing” model A model that views the body as being a series of cavities or changes connected to each other through pipes or tubes.

This article examines the interrelationship of culture and health with emphasis on the ways in which culture influences health outcomes through its effects on health-related thoughts and behaviors as well as physiological responses. Examples are given of these influences and the article concludes with a discussion of how cultural influences can best be integrated into research and theory in health psychology.

Considerations of culture are becoming increasingly prevalent in psychology, and health psychology is no exception. This article explores the relationship between culture and health and ways in which considerations of culture are important in the development of a theoretically and empirically sound health psychology. Specifically, culture plays a key role in how people understand states of health and illness as well as the types of health-related behavior in which they engage. In addition, there is growing evidence that culture influences physiological responses. As such, considerations of culture are essential to understanding various aspects of health.

1. THE CONCEPT OF CULTURE

Many definitions have been given for culture. Most, however, view culture as a set of guidelines that people inherit from their social environments that guide how they view the world, respond to it emotionally, and behave in it relative to the natural environment, other people, and supernatural forces or gods. As such, culture provides a set of lenses that shape experience. These “lenses” are transmitted from one generation to the next in various ways and provide the basis for shared experience within the cultural group. One of the ways in which culture shapes experience is through the provision of categories for dividing and organizing experience. In the case of health, such categories are key to understanding how people experience health

and illness and how they report that experience to others, such as health professionals.

It is important to note that culture is not something that is uniform within a society; rather, any society is certain to have multiple cultures within it. These cultures may be differentiated on the basis of ethnicity, social class, gender, occupation, and any number of other attributes that are associated with shared experience within a group that differentiates it from other groups. Furthermore, cultures change over time as different cultural groups interact, conditions change, technology develops, and so on. Hence, culture is best seen as dynamic rather than static.

2. CULTURE AND HEALTH-RELATED COGNITION

One of the key ways in which culture influences health is through health-related cognition.

2.1. Variation

Variation in health and illness concepts between cultures is obvious even to the most casual observer. These variations are exhibited in a wide variety of ways, but four of these are particularly striking.

2.1.1. *The Basic Nature of Health and Illness*

First, there is substantial variation between cultures in conceptions of the basic nature of health and illness. For example, in Western societies placing a strong emphasis on the scientific understanding of health and illness, these concepts are understood in natural terms with disease viewed as pathology due to natural causes such as germs, genetic aberrations, or injury. In some other societies, however, as well as among some minorities in Western societies, illness may be understood more in interpersonal or supernatural terms. For example, illnesses may be seen as being the result of violations of social norms or standards of personal behavior, particular emotions (e.g., anger or jealousy), or transgressions of moral or religious taboos.

2.1.2. *Beliefs about Anatomy and Physiology*

Second, beliefs about anatomy and physiology often show marked cultural variation, with cultures often

differing in their basic model of the body and what constitutes health and illness. For example, a number of forms of traditional medicine, including Chinese traditional medicine as well as traditional medical beliefs in India, Latin America, and the Caribbean, hold to the balance model. This model describes healthy functioning of the body in terms of a harmonious balance between different elements or forces within the body. Illness is believed to be caused by imbalance, which must be rectified for the person to return to health. In contrast, in Western societies the body is often conceptualized in terms of the “plumbing” model and/or machine model. The former views the body as being a series of cavities or chambers (e.g., stomach and chest) connected to one another by pipes or tubes. In this model, health is maintained by an uninterrupted flow of various substances (e.g., blood, air, food, and urine) between cavities or between cavities and the exterior of the body. By the same token, disease is the result of blockage. The machine model, by contrast, views the body as a machine that operates according to the principles of physics and chemistry and that may run down or break down, requiring a doctor to repair it.

2.1.3. *Concepts and Terminology*

Third, cultures often differ markedly in the concepts and terminology used to describe various conditions. For example, symptoms often diagnosed as depression in the West may be interpreted as neurasthenia (nervous exhaustion) in China. Also, conditions defined in one culture may be undefined in another. For example, traditional Mexican American medical beliefs define conditions such as *susto* (fright), *empacho* (surfeit), *caida de mollero* (fallen fontenelle), and *mal de ojo* (evil eye), which have no direct referents among conditions known to medical professionals or Anglo-Americans.

2.1.4. *Underlying Structure of Illness Representations*

Finally, the underlying structure of illness representations often differs between cultures. Research has shown that the mental representations that people have of different diseases show a characteristic organization in memory that differs from culture to culture. For example, research has consistently found that disease representations among Anglo-Americans are organized along dimensions of contagiousness and severity. In contrast,

disease representations among Mexican Americans appear to be organized according to concepts of “hot” and “cold” and whether a disease is associated with children or old people, and those of Chinese Singaporeans are organized according to a combination of dimensions deriving from Chinese and Western medicine.

2.2. Implications

These cultural differences in health-related cognition have a number of important implications. First, the cognitive representations that people have of diseases may well have a strong influence on their interpretation of symptoms and bodily symptoms. The existence of specific disease concepts makes it possible and perhaps even likely that bodily experience will be interpreted in line with that concept, whereas the absence of that concept would foreclose that possibility. For example, the fact that Mexican Americans have available to them the concept of *empacho* makes it possible for them to experience this condition, whereas members of other groups not possessing this concept would not be able to experience it. Similarly, the prominence of the concept of *neurasthenia* in China and of depression in North America makes it more likely that the similar symptoms associated with these two conditions would be interpreted, and quite likely experienced, differently.

In addition, health-related cognitions have implications for what people do when experiencing distress. Illness representations provide a definition for when bodily distress represents illness and requires assistance from a medical professional or other healer. It has been noted, for example, that one of the reasons why heart attack victims delay seeking treatment is that they misinterpret the symptoms and underestimate the seriousness of the situation. Furthermore, once the person has determined that help is needed, mental representations of illness direct the person's help-seeking behavior. Research with Chinese Singaporeans has shown that whether a person seeks help from a practitioner of Western scientific medicine or Chinese traditional medicine depends on the extent to which the person endorses illness beliefs associated with Chinese traditional medicine. Finally, once help is sought, people's mental representations of their condition are likely to strongly influence whether they stay in treatment. Research with hypertensives, for example, has shown that the cognitive “model” they have of hypertension and its relationship to specific symptoms is a key determinant of whether they stay in treatment.

3. CULTURE AND HEALTH-RELATED BEHAVIOR

A second important way in which culture influences health is through behavior.

3.1. Behavior and Disease Risk

The relationship between behavior and health is well established and there is strong evidence for the importance of behavioral risk factors such as smoking, diet, exercise, and alcohol use. It is also obvious to even the most casual observer that these behaviors often differ dramatically between cultural groups. For example, alcohol use is very prevalent in some countries, such as Russia, Ireland, France, and Italy, but much lower in other countries, such as predominantly Muslim countries in which alcohol use faces religious prohibition. Also, dietary habits differ substantially between cultures with regard to what is defined as food as well as which foods are allowed or prohibited, how foodstuffs are prepared, and overall patterns of eating. For example, although dog meat is eaten in some societies, most Americans and many others are appalled at the idea of considering dogs to be a source of food. Also, religion often dictates what foods are allowed. Orthodox Hindus, for example, are forbidden to eat any kind of animal, whereas Jews and Muslims are prohibited from eating pork, and any meat they do eat must be slaughtered in specific ways.

Cultural differences in behavior have an important impact on diseases prevalent in different countries and among different cultural groups. For example, research on cultural differences in diet has shown that the “Western” diet, with its high saturated fat content, is associated with high levels of coronary heart disease (CHD), whereas the low-fat Japanese diet is associated with low levels of CHD. Furthermore, the “Mediterranean” diet, which is high in monounsaturated fats and antioxidants, has been found to be protective against CHD. Similarly, elements of the Japanese diet have been associated with the development of stomach cancer and the habit of chewing a mixture of tobacco, betel nuts, and other substances in countries such as India and Afghanistan has been associated with high levels of oral cancer. Also, studies of alcohol consumption have shown that cross-cultural differences in alcohol consumption are strongly related to the incidence of diseases such as liver disease, CHD, stroke, hypertension, and diabetes. Finally, the

prevalence of HIV infection and AIDS as well as other sexually transmitted diseases is strongly related to cultural attitudes toward sexuality and the acceptance of promiscuity, commercial sex work, and alternative sexual practices.

3.2. Help-Seeking

In addition to culture's role in the etiology of disease, it is also important to note cultural differences in help-seeking and the role of culture in treatment. As noted earlier, cultural differences in cognitive representations of disease are likely to influence whether a person seeks treatment for specific symptoms. In addition, there are also cultural differences in reasons for seeking treatment and the kind of treatment that is considered to be appropriate. For example, it has been noted that for Italian Americans, seeking medical care tends to be triggered by an interpersonal crisis or when the person perceives that the symptoms interfere with personal relationships. In contrast, Irish and Anglo-Americans tend to seek help when symptoms are perceived to interfere with work or physical functioning. Furthermore, when seeking help different cultural groups may present their symptoms differently and adopt a different "language of distress." Research has found that Irish Americans tend to underplay their symptoms, taking a stoical attitude toward them, whereas Italian Americans tend to present their symptoms in a more voluble, emotional, and dramatic manner. These differences, in turn, may have an influence on diagnosis and the treatment received.

After the person has sought treatment, culture may play an important role in the interaction with the health care practitioner. Due to migration, most societies are becoming increasingly multicultural, with the result that it is commonly the case that patients and health care practitioners may come from different cultural backgrounds. When this is the case, differing cultural assumptions may prove a barrier in communication as well as in the acceptance of medical advice. For example, it has been noted that Native Americans tend to underuse medical services that are available to them and often do not follow medical recommendations even when they do utilize services. Among the reasons for this are conflicts between scientific and traditional Native American understandings of disease as well as the history of oppression of Native Americans and differences in communication styles between nonnative health care practitioners and Native clients. The end result may be distrust of the nonnative health care practitioner unless the practitioner makes specific efforts to

understand Native beliefs and also approaches Native clients in a manner that employs both verbal and non-verbal behavior that is culturally appropriate.

4. CULTURE AND PHYSIOLOGICAL RESPONSES

In addition to the often very evident effects of culture on beliefs and behavior, there is also a growing body of evidence suggesting cultural differences in physiological responses that may have important health implications. There is often a tendency to assume that physiological functioning and disease processes are the same across cultural groups. However, this may not always be the case. For example, numerous studies have shown significant relationships between personality traits such as trait anger and hostility and cardiovascular responses to certain stressors. However, there is also evidence that this relationship may vary according to ethnicity. In one study, correlations between hostility and cardiovascular responses to stress that were negative among Caucasian participants were positive among African American participants and vice versa. Also, there is evidence that Asian Indians show a different pattern of cardiovascular responses to stress than do Chinese or Malays. Other research has shown that the relationship of socioeconomic variables and hostility to cardiovascular reactivity to stress and left ventricular mass is different between Caucasians and African Americans.

The reasons for these differences are not clear and they may be the result of either cultural differences between groups or genetic differences. There is evidence, however, that even genetic influences may vary by cultural group. For example, studies of the serotonin transporter gene have shown that although polymorphisms of this gene are related to both personality and cardiovascular responses to stress, this relationship differs between African Americans and Caucasians. This suggests an interaction between culture and genetics in physiological responses to stress that may have important implications for understanding health differences between groups.

5. INTEGRATING CULTURE INTO HEALTH PSYCHOLOGY

It is clear from the previous discussion that culture and health are closely intertwined, with cultural factors

having a strong influence on health through cognitive, behavioral, and physiological pathways. However, the study of cultural factors in health psychology has only recently begun, and there is a great deal more that needs to be done to fully integrate cultural considerations into health psychology.

Research on cultural differences has most commonly involved making comparisons between specified cultural groups, an approach sometimes referred to as the “packaged” approach. The assumption is that differences between cultural groups are the result of differing cultural characteristics. However, this approach suffers from the fact that it ignores potential genetic and other physical differences between groups and does not reveal which aspects of culture are responsible for the differences observed.

Because of the limitations of the packaged approach, cross-cultural psychologists strongly advocate going beyond the superficial aspects of existing cultural groupings by examining the underlying dimensions of culture. Any number of dimensions might be identified, but attention has focused primarily on dimensions identified in classic research by Hofstede (individualism–collectivism, masculinity–femininity, certainty avoidance, and power distance) as well as those based on cultural values. Only a few studies have examined the relationship between dimensions of culture and health-related variables, but results have been promising. For example, studies of Chinese values and their relationship to health have shown that the values of social integration and reputation are significantly related to both alcohol and tobacco consumption as well as to diseases such as cerebrovascular disease, heart disease, and cancer.

6. CONCLUSION

Culture plays a significant role in health through several different mechanisms. Cultures differ in their basic understanding of the phenomena of health and illness as well as in their concepts of specific health conditions.

These differences have important implications for the interpretation of symptoms and bodily symptoms and also for the kinds of help that people seek when experiencing distress and whether they stay in treatment once they seek help. Culture also plays a significant role in health-related behavior. Substantial cultural differences exist with regard to behaviors such as dietary practices, smoking, alcohol use, sexual practices, and exercise, which are known to have a significant impact on risk for various diseases. Also, cultural groups differ in their propensity to seek medical attention and cultural factors figure prominently in the type of care that people seek and in their relationship to health care providers. Finally, there is increasing evidence of cultural differences in physiological mechanisms related to disease. Although the evidence for the importance of culture in health is strong, there is a very real need to go beyond the study of differences between cultural groups to the examination of how underlying dimensions of culture are predictive of health-related cognition, behavior, and physiological responses.

GLOSSARY

health A state of complete physical, mental, spiritual, and social well-being, not merely the absence of disease or infirmity.

health-promoting school A place where all members of the school community work collaboratively to provide students with integrated and positive experiences and structures that promote their health.

health promotion A combination of behavioral, educational, social, spiritual, economic, and environmental efforts that support the development, maintenance, and enhancement of behaviors and lifestyles conducive to emotional and physical well-being.

indicated prevention programming Interventions designed for children or families demonstrating danger signs (e.g., multiple risk factors, substance abuse, and neglect) and that are more intensive and intrusive than other prevention programs.

initiative The dedication of cumulative effort over time to achieve any goal composed of the elements of intrinsic motivation, concentration, and challenge.

mental health The successful performance of mental function, resulting in generative activities, fulfilling relationships, and the ability to cope with adversity.

selective prevention programming Interventions targeted at high-risk populations. The target can be children, families, or a high-risk school. The focus is most often on reducing risk factors or targeted behavior changes.

social emotional learning Knowledge, habits, skills, and values that provide a foundation for a child's academic, personal, social, and civic development and are necessary for success in school and life.

universal prevention programming Interventions designed for the entire population, such as a districtwide program designed to prevent substance abuse and/or violence.

The most serious and expensive health and social problems in the United States today are caused by negative behavioral patterns. Unhealthy behavioral patterns have adversely affected the physical, emotional, and mental health of youth, resulting in problems with alcohol, drugs, diet, anger management, and poor impulse control. These health problems and unhealthy behaviors are largely preventable and studies of health education and promotion in schools have demonstrated that health education programming has effectively reduced the prevalence of health risk behaviors among youth. Individual and family interventions have shown some success, but programs that champion a seamless, comprehensive (kindergarten–12) system of health promotion demonstrate great promise.

1. INTRODUCTION

Despite advances in medical sciences, today's youth face complex health challenges that are especially daunting. A significant number of youth enter school with "pre-existing" health conditions (e.g., asthma and diabetes) that, without appropriate intervention, can affect both academic and social progress. By adding communicable diseases, malnutrition, behavior-related conditions (e.g., exposure to smoking, eating disorders, substance abuse, and sexually transmitted diseases including HIV), violence, suicide, and accidents and injuries to the mix, one quickly realizes that there is a formidable problem. In the past, schools and other health and social services played a major role in impacting the health of young people through their involvement in immunization, screening, and educational programming. However, schools' involvement in health promotion has been sporadic and not as coordinated as previous immunization efforts.

Added to the health factors are the multiple environmental risk factors that are often antecedents of a variety of disorders. An increase in health and behavior problems can be linked to significant family, school, and neighborhood changes that have occurred during the past few decades. These changes include a breakdown in the traditional family and neighborhood; a devaluing of parenting, teachers, and religious life; damaging television and media messages (e.g., sex, violence, marketing of unhealthy dietary behaviors, and promotion of immediate gratification); lack of positive role models and a reduction in meaningful contact with positive adult role models; and an increase in inadequate housing and unsafe environments (often inclusive of the school environment).

Problems with regard to living conditions and the environment have taken their toll and, in large part, led the Centers for Disease Control and Prevention (CDC) to use the Youth Risk Behavior Surveillance System (YRBSS) to monitor the following six categories of priority health risk behaviors among youth and young adults every 2 years since 1991:

- Behaviors that lead to intentional (e.g., violence) and unintentional injuries
- Smoking/tobacco use
- Alcohol consumption and other drug use
- Sexual behaviors leading to disease, HIV infection, or unintended pregnancy
- Poor nutrition/unhealthy dietary behaviors
- Lack of/inadequate physical activity

These are all behaviors that can increase during childhood. The YRBSS monitoring system enables states to compare their data to national data and trends.

Relatedly, vital statistics indicate that 70.6% of all deaths among youth and young adults aged 10–24 years result from motor vehicle accidents, unintentional injuries, homicide, and suicide. Analysis of this national school-based survey indicates that many high school students engage in behaviors that increase their risk for death from one of these four causes. For example, 14.1% of the youth surveyed had rarely or never worn a seat belt during the 30 days preceding the survey, and 8.8% had attempted suicide during the 12 months prior to the survey.

The leading causes of mortality and morbidity among all individuals in the United States are related to health risk behaviors that are frequently established during youth: tobacco use, alcohol and drug use, unhealthy dietary behaviors, physical inactivity, etc. Thus, a realistic analysis of the physical, behavioral, and mental health of youth appears to be in order.

2. CHILD AND ADOLESCENT HEALTH CONCERNS

2.1. Physical Health

In 2001, almost 14% of high school students surveyed were at risk for becoming overweight, whereas 10.5% already fit this category. The problem is greater for males (14% overweight) than females (7% overweight). Fewer than 22% consumed the recommended number of servings per day of fruits and vegetables and milk, and an increasing number of schools include fast-food choices on their lunch menus. Furthermore, eating habits that begin in childhood contribute to numerous chronic diseases in adulthood (e.g., heart disease, cancer, and osteoporosis).

In addition to the unhealthy trends in dietary habits of youth in the United States, there has been a decrease in opportunities for physical activity, with slightly more than half (51.7%) of high school students enrolled in physical education (PE) classes. Less than one-third of these students attended PE classes daily—an increase from 25.4% in 1995 but far below the 1991 level of 41.6% attending daily. The percentage of students reporting no vigorous or moderate physical activity in the past 7 days is 9.5%. Combining lack of physical activity with increasingly unhealthy eating patterns, in addition to 2 hours or more of television and/or video

and computer games per day, results in multiple risk factors. Not surprisingly, children who participate in regular physical activity have more favorable cardiovascular disease risk factors than less active children.

The vulnerable ages for tobacco use are 10–18 years, when most users start smoking, chewing, or dipping and become addicted to the substance. Very few individuals begin to use tobacco as adults; almost all first use occurs prior to graduation from high school. Slightly more than one in three persons use tobacco by age 18 (33.9% report using tobacco in the past 30 days). The earlier a young person begins to use tobacco, the more likely the person is to abuse the substance as an adult. A surgeon general's 1994 report directly linked the deaths of 434,000 million Americans each year to tobacco usage. Because both the duration and the amount of tobacco use are related to eventual chronic health problems, early interventions with youth concerning tobacco use must be stressed as a physical health issue.

2.2. Drugs and Alcohol

Underage drinking is a serious problem in the United States. Alcohol is the drug most commonly used and abused by children aged 12–17 years. Youth in the United States are reportedly drinking alcohol at an earlier age than ever before, typically beginning in early adolescence (approximately age 13). A recent survey found that more than half of eighth graders and 80% of high school seniors had used alcohol sometime in their lives, and that 25% of eighth graders and more than 60% of high school seniors had been drunk at some time. The percentage of middle and high school students who had five or more drinks of alcohol at one time (within a few hours) on one or more of the past 30 days reached a high in 1997 at 33.4% and was 29.9% in 2001.

Health-related risks of teenage alcohol use are significant. Children who begin using alcohol before the age of 15 are four times more likely to become an alcoholic as an adult than those who start drinking at age 21. Research indicates that more than 40% of teens that start drinking at age 14 or younger become dependent on alcohol as adults. The risk of death from car accidents and drowning increases with alcohol use. Drinking large amounts of alcohol can result in alcohol poisoning, which can lead to coma or even death. Adolescents who drink are much more likely to attempt suicide, engage in violence against others, and become victims of violent crime.

Young people who drink alcohol are also more likely to engage in other risky behaviors, including illicit

drug use: Youth who drink are 7.5 times more likely to use some type of illicit drug. The most widely used illegal drug is marijuana, despite declining usage. In 2000, almost half of all 7th–12th graders reported having tried marijuana sometime during their lives, which was down from 53% in 1997. The number of these kids who regularly use marijuana declined 13% during the same time period (approximately 21% reported being regular users in 2000).

Unfortunately, the downward trends observed in marijuana use have not been noted for other types of drugs, especially so-called club drugs. For example, since 1999, teen ecstasy (MDMA) use has increased 71%. More than 8% of high school seniors reported having used ecstasy at least once. Other club drugs, including rohypnol, methamphetamine, and LSD, are also gaining popularity. These drugs have sometimes been added to the beverages of unsuspecting females in order to sedate and sexually assault them. In addition, club drugs can produce a range of negative effects, including hallucinations, paranoia, brain damage and amnesia, and, in some cases, death. Numbers of emergency room visits by young persons under the influence of club drugs, especially ecstasy, increased approximately 60% from 1999 to 2000.

Drug and alcohol use increases risks in other areas as well. Adolescents who use drugs and/or alcohol are much more likely to be sexually active than youths who do not drink or get high. Furthermore, substance-abusing teens are more likely to start having sex at an earlier age and to have multiple partners. These youth are less likely to use protection/contraception. Despite these well-documented trends, very few prevention, treatment, and counseling programs deal with the combined problem of substance abuse and risky sexual behavior.

2.3. Sexual Health

Research indicates that slightly more than half of females and nearly two-thirds of males have had intercourse by their 18th birthday. Reported rates of sexual activity have declined among male teens in recent years. However, this trend has not been observed for females. In fact, increases in sexual activity for female teens have been noted for each year of age during the past several decades. The greatest increases have been noted for 14- to 16-year-old females, with twice as many of these girls engaging in sexual behavior as there were 15 years ago. This is concerning for several reasons. First, the younger females are when they first have sex, the more likely they

are to have had unwanted or involuntary first sex. Furthermore, the younger the age of first sexual intercourse, the greater the risk of unwanted pregnancy and sexually transmitted diseases and infections.

It is estimated that 40% of teen sex is unprotected. Relatedly, 7 in 10 teen pregnancies occur in teens not using contraception, resulting in approximately 500,000 babies born to teen mothers each year in the United States. The majority of sexually active youth say they used some form of contraception the first time they had sex, and 57.9% of youth report they used a condom during their most recent sexual encounter.

Substantial morbidity and social problems also result from the unprotected sexual behaviors of youth. Every year, more than 3 million teens—approximately 25% of those who are sexually active—contract a sexually transmitted disease. Teens appear to be especially at risk for contracting chlamydia and gonorrhea, with reported rates for adolescent females being much higher than those for sexually active adults. These infections are the leading causes of pelvic inflammatory disease, and chlamydia is a common cause of infertility, ectopic pregnancy, and perinatal complications.

Human papillomavirus, which is associated with most cases of cervical dysplasia (a precancerous condition of the cervix), and hepatitis B virus are also prevalent among sexually active teens. Some studies suggest that up to 15% of sexually active adolescent females are infected with at least one of these conditions. Rates of teen HIV are also high. It is estimated that approximately 25% of new HIV cases each year occur in young people ages 13–21. Most of these new cases are sexually transmitted. Further complicating these issues is the fact that teens are less likely to have health insurance or a primary health care provider; thus, screening, diagnosis, and treatment of sex-related health problems are often delayed. These delays may lead to medical complications that would otherwise be avoidable.

2.4. Mental Health

Today, children are faced with more challenges than ever before, but it is clear that the current system of providing services is keeping the prevalence of mental disorders in check but doing little to reduce the number (incidence) of youth affected. Professionals have estimated that more than 20% of the 70.4 million children aged 17 or younger in the United States experience the signs and symptoms of a *Diagnostic and Statistical Manual of Mental Disorders* disorder during the course of a year. However, 11% experience significant

impairment and 5% experience extreme functional impairment. The surgeon general's 1999 report estimated that 20.9% of youth met diagnosable criteria (≤ 70) on the Child Global Assessment Scale. Anxiety disorders (13.0) followed by disruptive disorders (10.3) and mood disorders (6.2) were the most common impairments (the rate is greater than 20% due to comorbidity). There is a link between child and adult disorders, but a significant number of youth “grow out” of their disorders and a significant number of adults develop a mental disorder later in life.

By examining self-report data, an argument can be made that these national estimates are low. For example, a 2001 CDC report found that the number of middle and high school students that reported an “attempted suicide during the past 12 months” was 8.8%. The percentage of students who, during the past 12 months, stated that they felt so sad or hopeless almost every day for 2 weeks or more in a row that they stopped doing some usual activities was 28.3%. The percentage of youth who reported that they had carried a weapon (gun, knife, or club) in the past 30 days was 17.4%. These behaviors and self-reports are consistent with mood disorders and disruptive disorders and appear to indicate that national estimates of incidence and prevalence are low.

On average, only approximately one-fourth of children in need of mental health care receive the help they need. The use of psychotropic medication for children and youth has increased sharply, with more than \$1 billion spent in 1998 for these medications, approximately two-thirds of which was spent on stimulants and antidepressants.

Schools are important settings in which children's mental disorders can be recognized and addressed; research suggests that schools may function as the de facto mental health system for children and adolescents. Of those receiving mental health care, 70–80% receive that care in the school setting. Furthermore, 83% of schools report providing case management for students with behavioral or social problems.

Approximately 60% of the 1500 school-based health centers in the United States have mental health professionals on staff. With support from primary care providers, nearly 80 of these clinics provide crisis intervention services. Zins and Wagner recognized the full spectrum of health services while providing numerous examples of mental health activities, such as helping with transitions from elementary to middle school and providing instruction in stress or time management.

Although there has been extraordinary progress in improving public health (including mental health)

through medical science, more is known about how to treat mental illness than about how to prevent mental illness and promote health. There are numerous research-based programs aimed at curbing at-risk behaviors, such as violence and drug use, but a rigorous applied psychology of how to promote positive youth development is lacking. However, the psychologist's role is obvious given the link between learning and health.

3. HEALTH PROMOTION

Today's changing world, in which political and market forces and monetary gain often dictate human behavior, is not the most favorable environment for children to develop moral and ethical values. Many children find at the end of their school years that they may be equipped with an academic qualification but not with the coping skills to face a competitive and often dangerous world. It is in this context that "health" in schools has come to occupy a place as important as learning the three R's. Zins and Wagner defined health promotion as a combination of behavioral, educational, social, spiritual, economic, and environmental efforts that support the establishment, maintenance, and enhancement of behaviors and lifestyles conducive to overall emotional and physical well-being. The definition is inclusive and systemic, and it directly encourages the mobilization of community resources and the development of environments that will lead to healthy behavioral patterns during the formative years of childhood and adolescence.

The health problems and unhealthy behaviors observed in young people are largely preventable and studies of health education in schools have demonstrated that programming has effectively reduced the prevalence of health risk behaviors among youth. Given these data, it appears that school health programs are becoming one of the most effective means available to prevent major mental and physical problems as well as significantly reduce the adverse social problems that affect children and youth. School-based clinics first began to appear in the 1980s. These early programs were problem focused (e.g., alcohol and drug use and teen pregnancy) and reported some success. For example, interventions in middle schools reported significant reductions in smoking, obesity, alcohol, and marijuana use.

Because the problem behaviors targeted by these individual programs often occur together, share risk and protective factors, and can be addressed by similar interventions, there is support for more comprehensive and coordinated models of risk prevention and

promotion of protective behaviors and environments. These comprehensive initiatives typically target multiple outcomes; span a number of years; and coordinate community, family, and school-based efforts.

Many schools have implemented programs targeting one or more categories of problem behaviors (e.g., violence and drug use). Unfortunately, adoption of multiple programs to address social and health issues can result in a variety of implementation problems. Often, multiple programs are poorly coordinated and compete with each other as well as core academics for limited instructional time and resources. Furthermore, these programs are often of short duration and are rarely sustained from year to year. They frequently lack the environmental supports at home and at school that allow for the maintenance of newly learned knowledge and skills.

Health promotion requires psychologists to be a part of a team of professionals from many fields working cooperatively with teachers, students, community members, religious leaders, and parents to provide comprehensive school health programs. These integrated efforts include such disciplines as health education, nursing, physical education, nutrition (food) services, counseling, and school psychology. The integrated approach better mobilizes community resources to enhance health-promotion efforts in the schools and society. Also, the comprehensive effort reaches virtually all children, creating an environment that builds on health in a more integrated manner.

Psychologists and other mental health professionals interested in introducing and gaining support for implementing a health-promotion program in their schools would be best served by beginning with a formal needs assessment. If such an assessment is not feasible, facilitating open discussion and active listening among staff is another strategy that can be utilized to delineate a hierarchy of concerns. After the needs have been identified, a system analysis is necessary to obtain an understanding of such things as the school board's philosophy, goals, and budget. Next, stakeholders, including school personnel, who are invested in health education should be identified. In 1995, Kelly suggested that internal support should be gathered before moving to external audiences. After input and approval of all involved school staff have been obtained, direct communication with external audiences can be initiated. Communication with community agencies, parents, churches and synagogues, hospitals, alternative health providers, and the business community is necessary to manage issues that may arise, including political groups that may perceive

health promotion as “too radical.” Furthermore, direct communication allows for the services provided to be designed around community needs.

School-based health programs are costly; therefore, those who govern funding seldom mandate such programs until serious problems arise. Federal and state health care policy is then tapped to address the remedial/tertiary concerns. A critical issue is the degree to which programs should be targeted to specific at-risk groups using selective or indicated prevention approaches or spread across all groups with no differentiation using universal prevention approaches. Research has shown universal approaches to be far more likely to be successful, produce lasting change, and reduce long-term health costs. However, universal prevention programs may not be of sufficient dosage or targeted enough to have a discernible impact on higher risk children.

Most school-based centers must seek multiple financial supports. Obvious initial sources include the local school board and the local private sector. Several states have adopted laws or officially supported the development of school-based clinics. Federal or state block grants are often used to fund such programs. Medicaid may also be a source of funds if medically necessary services are provided to children and families who are Medicaid eligible. Managed care is another funding option. School-based clinics or school-linked health programs may become certified as providers for students whose parents are enrolled in a managed care plan. Finally, the CDC provides resources to ensure that the identified curriculum to reduce risk behaviors is available for state and local agencies interested in using it. The CDC directly funds coordinated school health programs in a number of states.

4. COORDINATED SCHOOL HEALTH PROGRAMS

A health-promoting school is a school in which all members of the school community work together to provide students with integrated and positive experiences and structures that promote and protect their health. This includes both formal and informal curricula in health, the creation of a safe and healthy school environment, the provision of appropriate health services, and the involvement of the family and the wider community in efforts to promote health.

Full-service schools (schools in which health, mental health, social, and/or family services may be

located) or comprehensive health education are considered effective formats to promote healthy behaviors and prevent dysfunctional choices. However, without a radical change in school missions and society values (i.e., society choosing to directly address major issues such as poverty and unsafe environments), most of the 100,000 schools in the United States will not implement such a program in the near future. Selective or indicated prevention approaches are more consistent with current federal funding (need-based block grants) and perhaps offer the best option for the near future.

The School Health Programs has developed a comprehensive school health program model. According to the model, a comprehensive school plan provides

- A curriculum that addresses and integrates education about a range of categorical health issues at developmentally appropriate ages
- Programming for grades K–12
- Instruction for a prescribed amount of time at each grade level
- Integrative activities to help young people develop the skills they need to avoid the use of tobacco, dysfunctional behaviors, and engaging in a sedentary lifestyle
- Appropriate instruction from qualified teachers, health professionals, and concerned community members

Ideally, a school health-promotion model would be one that is holistic and that includes the interrelationships between the physical, social, emotional, and environmental (e.g., shaded play area) aspects of health. Health-promoting schools provide opportunities for families to take part in the development of health skills and knowledge of their children. Furthermore, an effective and comprehensive health-promotion model addresses the importance of the social ethos of the school in supporting a positive learning environment—an environment in which both healthy relationships and the emotional well-being of children are strengthened.

Schools, by themselves, should not be expected to address the nation’s most serious health and social problems. However, school health programs can be one of the most efficient means of preventing major health and social problems. By reducing the incidence of mental and physical health problems that afflict young people and often continue into adulthood, school health programs may reduce the spiraling cost of health care, improve educational outcomes, and increase productivity and quality of life. Schools are widely recognized as the major setting in which activities should be undertaken to promote competence and prevent the

development of unhealthy behaviors. Furthermore, from a primary and secondary prevention perspective, an economic perspective, and a demographic standpoint, it appears essential that social initiatives such as health promotion be linked to schools.

4.1. Positive Youth Development

According to Larson, high rates of boredom, alienation, and disconnection from meaningful challenge are typically not signs of psychopathology but, rather, signs of deficiency of positive youth development. Furthermore, many cases of problem behavior, such as drug use, aggression, premature sexual activity, and minor delinquency, may also be related to an absence of a positive life trajectory. Although involvement in extracurricular activities, such as sports, art, and drama clubs, has been clearly demonstrated as beneficial in reducing high-risk behaviors and increasing academic success, these advantages are not being fully promoted by schools or engaged by a significant number of today's youth. Due to a variety of factors, many schools are not fully addressing the mental and other health needs of children and youth. Unfortunately, most efforts have been focused on when and how things go wrong for youth, while neglecting the positive aspects. Indeed, today's schools are so focused on the development of academic skills and raising test scores that health promotion and the benefits of extracurricular activities are largely ignored.

After-school programs offer an alternative that can aid in the promotion of positive youth development and provide a diversion between 3:00 and 8:00 PM, the peak hours for violent juvenile crimes. The development of "assets" has been key to a number of successful after-school programs. Survey data collected by the Search Institute identified 40 developmental assets that young people need to build in order to be healthy and successful. The survey data revealed the protective power of assets: The more assets a child has, the more likely it is that he or she will do well in school, engage in community service, and value diversity, and the less likely it is that the young person will engage in risk-taking behaviors such as drug or alcohol abuse, drop out of school, or engage in violent behavior. These assets are commonsense values and experiences that help youth to grow up caring, healthy, and responsible. Applying the assets as a framework for positive youth development provides schools and communities with a set of factors that are associated with fewer risk behaviors and increased health. Furthermore, the assets provide a common language for talking about what young

people need and for pulling people together across different social groups.

Structured voluntary activities have promoted positive youth development and may be a key to successful in-school social and emotional learning. An adolescent's time is too often spent in two opposite experiential domains. In school, youth experience concentration and challenge without being intrinsically motivated. Conversely, in most leisure activities, they report experiencing intrinsic motivation but a lack of challenge and concentration. An exception to this is structured voluntary activities. Voluntary activities are those with rules, constraints, and goals as well as those in which the adolescent is highly motivated to be involved. They include sports, arts, hobbies, and participation in youth organizations. Based on a review of the literature, Larson concluded that involvement in structured voluntary activities is associated with multiple positive outcomes, including the development of initiative, greater achievement, and diminished delinquency. Thus, schools promote positive youth development when they provide opportunities for youth to engage in service learning and/or structured activities that contain the elements of intrinsic motivation, concentration, and challenge.

In recent years, a number of national reviews of school-based prevention programs have been performed to determine "best practices" in positive youth development. Using core competencies of social and emotional learning (SEL) as a basis for evaluation of programming and implementation, the Collaborative for Academic, Social, and Emotional Learning (CASEL) reviewed 81 programs that met its rigorous review standards. Following a 3-year review process, CASEL identified 22 programs that met its final criteria of outstanding SEL instruction, evidence of effectiveness, and outstanding professional development. Many of the programs selected were for all grade levels (K–12) because evidence-based/effective SEL programming typically begins at an early age and continues through high school.

5. SUMMARY

Today's youth face a plethora of risk factors and complex health challenges. In addition, the most serious and expensive health and social problems, as well as the leading causes of death for both youth and adults, result from negative behavioral patterns. Schools can be a dynamic setting for promoting health and an optimal entry point for enabling children to grow into healthy adults. Furthermore, health and education are

closely related: Good health provides children with better opportunities to pursue learning. Conversely, better education empowers children to engage in healthy practices and behaviors and act as change agents to promote the health of their families and communities. Thus, there are considerable gains to be made from partnerships between health and education.

A health-promoting school provides a setting in which education and health programs come together to foster health as an essential component of life. A health-promoting school responds to the health, educational, spiritual, and psychological needs of schoolchildren in an integrated and holistic way, in which interdisciplinary mechanisms are maximized. It is within this framework that schools can better assist students in becoming knowledgeable, responsible, and healthy citizens dedicated to the common good.

GLOSSARY

acculturation A process that occurs when people from one culture encounter and react to people from another culture; it may occur at an individual (psychological) level or at a group (social) level.

cross-cultural psychology A specialized field in psychology with an approach that compares and contrasts individual psychological functioning in various cultural contexts.

cultural psychology A specialized field in psychology with an approach that roots behavior in its cultural context; it views culture and psychology as “making each other up.”

ecocultural framework An approach that seeks to understand cultural similarities and differences as adaptations to various human and environmental contexts.

global health An attempt to address health problems that transcend national boundaries, may be influenced by circumstances and experiences in other countries, and are best addressed by cooperative actions and solutions; the underlying assumption is that the world's health problems are shared problems and, therefore, are best tackled by shared solutions.

health inequality A term that refers to disparities or variations in health status achieved by individuals, groups, or communities; in its frequent form of use, it refers to differences in the levels of health between men and women,

between majority and minority communities, and between the rich and poor within societies.

health psychology A specialized field in psychology that studies the psychosocial aspects of mental and physical health and illness as well as the contexts in which these occur.

HIV/AIDS Abbreviation for human immunodeficiency virus/acquired immune deficiency syndrome; HIV is a retrovirus that infects cells of the immune system (primarily the CD4 cells and macrophages) and then destroys or impairs their functions, leading to immune deficiency and resulting in a disease complex known as AIDS.

primary prevention Health activities that are designed to reduce or eliminate the risk of acquiring a health problem; for example, interventions that encourage sexual abstinence or avoidance of intravenous drug use represent primary prevention efforts against HIV infection.

secondary prevention Health activities that focus on minimizing or eliminating the impact of an already acquired health problem on the affected individuals, families, and communities or on slowing or stopping the progress of a disease during its early stages; an example among AIDS patients may include efforts aimed at preventing opportunistic infections and at managing pain and psychosocial distress.

Cross-cultural health psychology is defined by examining what each of the components of this term means in its own right and by acknowledging the challenges that arise by combining them. Cross-cultural health psychology incorporates aspects of health psychology, anthropology, behavioral medicine, and public health. It is primarily concerned with

understanding health and illness from a psychological perspective, but within the context of its cultural constructions. This article reviews some relevant models that combine these individual and community perspectives. For illustrative purposes, from the vast array of health problems that are addressed by cross-cultural health psychology, the article focuses its review on HIV/AIDS due to its pandemic nature. The article considers risk factors, determinants, and prevention; disease management and impact alleviation; and social inequalities and, more broadly, impacts on population health. It concludes by arguing for a broadening of the conceptualization of what “cross-cultural” means and notes seven themes that relate culture to health. The effects of globalization and the increasing complexities of what constitutes cross-cultural health psychology present the latter with an opportunity to make a valuable contribution to the emerging field of global health.

1. CONCEPTS AND DEFINITIONS

In defining cross-cultural health psychology, one needs to do so reflexively by unpacking each of the words in the term. If one takes “psychology” as the study of human behavior, one must qualify this further by acknowledging that “psychology” has mostly been understood to be synonymous with a particular perspective on human behavior. This perspective is characteristic of a broader rationalist, reductionist, and individualist approach to advancing knowledge that predominates in Northern and Western conceptions of what are valid means of truth seeking. This is problematic for psychology because such an approach is, in itself, a cultural construction. However, other psychologies, curiously referred to as “indigenous,” relate different conceptions of how one ought to account for human behavior. Thus, one first needs to acknowledge that there are different—culturally constructed—conceptions of just what psychology is and how it should study human behavior.

In some ways, “health” is easier to define, if only because the World Health Organization’s (WHO) definition is rather broad and inclusive in emphasizing biological, psychological, and social aspects of health and in acknowledging that health and illness are not “all or none” categories. All people are healthy or ill to some extent, and even those who suffer greatly through physically disabling diseases may be quite healthy in

other respects, whereas some icons of physical excellence and beauty may be quite ill in some ways. Of course, the way in which distress is expressed may differ among cultural contexts (e.g., by psychologizing or somatizing), as may the understanding of what it means to be healthy or ill and the ways in which to respond to illness.

Therefore, “health psychology” may be taken to be the study of how human behavior influences health, broadly defined. “Health” here refers to well-being in general and is not confined to either physical complaints or mental complaints. Health psychology seeks to bridge the Cartesian divide by acknowledging that human experience is mediated through the body and, thus, is embodied. The biopsychosocial model, so often identified with health psychology, should be seen not as multiple but rather as integrative, that is, as being of one—body and mind together. Furthermore, the contextual aspects of health, in terms of its social settings and conditions, should also be to the fore in health psychology.

“Cross-cultural” psychology must always first be “cultural” psychology for it to be meaningful. Cultural psychology seeks to understand how behavior is influenced by the social context in which it occurs. It further acknowledges that this context is woven through particular customs, rituals, beliefs, ways of understanding and communicating, and so on, so that distinctive patterns of behavior are cultivated. Only by understanding how a culture patterns meaning can we be sure to know that the sort of things we might want to compare among different cultures actually have some similarity. Having established a meaningful similarity in the structure or function of aspects of human behavior, it may then be enlightening to compare such behavior in different cultural contexts, that is, across cultures. Cross-cultural psychology may incorporate both the localized cultural perspective and the comparative cultural perspective.

In sum, cross-cultural health psychology seeks to describe the diversity of health (and illness) behavior and to link this to the cultural context in which it occurs. It recognizes that culture and psyche “make each other up” and that the ways in which they do this have implications for health. The value of cross-cultural health psychology is becoming increasingly recognized not only in the treatment of health problems that present in specific cultural contexts but also in how social and cultural factors must be understood for the prevention of illness and the promotion of health.

2. THEORETICAL FOUNDATIONS

Cross-cultural health psychology borrows theoretical and practical approaches from a wide variety of related disciplines, including the broader fields of psychology, anthropology, behavioral medicine, and public health. Health psychology and behavioral medicine contribute the biopsychosocial model of health and disease. A recently revised version of this model argues for the reorientation of the fields of health and medical sciences such that research and clinical practice encompass both health and illness. The model aims to decipher the interactive and reciprocal relationships among biophysical, psychological, and social processes in health and disease. It takes into account the social networks of the individual to achieve, maintain, and maximize health and well-being for individuals, their significant others, and society. The major challenge for this model is for its biological, psychological, and social aspects to truly act in synthesis rather than as simply parallel and complementary aspects of health and illness.

Cross-cultural psychologists, anthropologists, and others argue that current theoretical models and practice in medicine and health psychology are insufficient to capture the centrality of culture to the human experiences of health and illnesses. They argue for theoretical frameworks that recognize the ubiquitous effect of culture on health and illness; that treat culture as a system of meaning that links body, mind, and world; and that promotes the significance of cultural context as a resource. Frameworks that give greater weight to cultural and ecological contexts and process as they relate to health and health promotion have been suggested. For instance, Berry's ecocultural framework provides a scheme with which factors at both the individual (psychological) and community (cultural) levels are considered in cross-cultural application of research in cognitive, affective, behavioral, and social aspects of health phenomena. The community level of work typically involves ethnographic methods and yields a general characterization of shared health conceptions, values, practices, and institutions in a society. The individual level of work involves the psychological study of a sample of individuals from the society and yields information about individual differences (and similarities) that can lead to inferences about the psychological underpinnings of individual health beliefs, attitudes, behaviors, and relationships. There are important reasons why cultural- and individual-level factors need to be taken into account when dealing with health phenomena.

Cultural-level health phenomena are taken into account to establish the broad context for the development and display of individual health phenomena. Without an understanding of this background context, attempts to deal with individuals and their health problems may well be useless or even harmful; individuals are not "culture free." The reason for considering individual-level health phenomena is that not all persons in a cultural group hold the same beliefs or attitudes, nor do they engage in the same behaviors and relationships. Without an understanding of people's individual variations from the general community situation, harm may well be inflicted again; individuals are not "cultural dopes."

Health models that take into account broader cultural- and ecological-level factors have also been proposed in the field of public health. For instance, Airhihenbuwa proposed a theoretical model that places cultural and environmental factors at the core of the development, implementation, and evaluation of health programs. His PEN-3 model consists of three dimensions of health beliefs and behaviors: (a) health education, (b) educational diagnosis of behavior, and (c) cultural appropriateness of health behavior. Each of these three interdependent dimensions is influenced by three categories of factors (representing the acronym "PEN"). Accordingly, health education needs to be designed to address the health needs of all, involving the person, the extended family, and the neighborhood or community in which the person lives. Airhihenbuwa noted that educational diagnosis of health behavior helps researchers and program developers to determine the factors that influence individual, family, and/or neighborhood and community health actions. Critical elements that need to be assessed as part of such a diagnosis include perceptions, enablers, and nurturers. Health-related perceptions include attitudes, values, and beliefs within a cultural context that facilitate or hinder health-promoting or disease-preventing actions. Enablers are distal cultural, societal, systemic, or structural factors that may enhance or be barriers to health actions, whereas nurturers are relatively proximal influences on health behaviors originating from extended family, kin, friends, and the neighborhood. Finally, the most critical dimension of developing effective health programs is the determination of the cultural appropriateness of the health behavior. Within a given cultural context, some health beliefs and behaviors can be positive, endowing the person, the family, and/or the community with known health benefits. Other health beliefs and behaviors may be existential, having no harmful health consequences

but bearing important indigenous meaning to the community. Still others may be negative health beliefs and behaviors, contributing to the origin or exacerbation of health problems. Such an assessment of the cultural appropriateness of health beliefs and behaviors empowers health program developers to consider the cultural perspectives, knowledge base, and resources of the people for whom the programs are designed.

A relatively more extensive framework for planning health promotion programs is the PRECEDE/PROCEED model developed by Green and Kreuter. This model takes into account the myriad of factors that determine the health and quality of life of individuals and communities in planning, implementing, and evaluating health programs. The PRECEDE part of the model (the acronym stands for predisposing, reinforcing, and enabling constructs in educational/ecological diagnosis and evaluation) involves various phases during which the determinants of health are diagnosed. It begins with a social assessment to identify quality of life and concerns of the target population, followed by assessment of health problems and behavioral and environmental factors linked to these health problems. Then, the predisposing, reinforcing, and enabling factors that influence health behaviors are assessed during the educational and ecological assessment phase, followed by an assessment of the organizational and administrative capabilities and resources for the development and implementation of health programs to address the problems identified. The PROCEED part of the model (the acronym stands for policy, regulatory, and organizational constructs in educational and environmental development) offers additional steps for developing policy and initiating the implementation and evaluation process appropriate to the health outcomes, intervention types, and target populations. The PRECEDE/PROCEED model, like PEN-3, recognizes that health is determined by multiple factors and that interventions need to take multilevel and multidimensional actions to be effective.

More specific individual-level health behavior theoretical models (e.g., Health Belief Model, theory of planned behavior, social cognitive theory) are often used in health psychology and public health to explain and predict risk and protective behaviors. Embedded in these models is the belief that risk behaviors, cognitions, and their determinants are identifiable, modifiable, and causally linked to health outcomes. In general, these health behavior models propose that one or a combination of the following factors predict the adoption and maintenance of changes in health behaviors: (a) knowledge and information about the health threat; (b) perceived severity of

and personal vulnerability to the threat; (c) perceived control or self-efficacy to adopt the behavior change; (d) perceived efficacy of the behavior change to prevent the threat; (e) perceived benefits compared with costs associated with behavioral change; (f) intentions, attitudes, and social norms supporting the adoption of the behavioral change; (g) actual skills to bring about the behavioral change; and (h) availability of cues for behavioral change. Recognizing the limitation of individual-focused factors to behavior change, other theoretical models in public health and related disciplines have expanded this list by adding variables at the interpersonal (e.g., couple communication, power in relationships), community (e.g., supportive norms, social networks), and environmental and structural (e.g., accessibility services, policies) levels that have strong bearings on individual-level risk behaviors and cognitions.

In sum, combining applied individual- and community-level methodologies from clinical psychology and public health and the conceptual underpinnings from interactive biopsychosocial and ecocultural frameworks, cross-cultural health psychology focuses on factors that determine and maintain health and health outcomes in cross-cultural and multinational contexts. This approach presupposes consideration of multiple causal pathways and levels of analysis in research and practice of health psychology. Psychosocial, cultural, and environmental factors are believed to be causally linked to health directly through exposure to noxious and disease-causing conditions such as carcinogens and pathogens. Indirectly, psychosocial stress associated with adverse psychosocial, cultural, and environmental conditions influences health by affecting the performance of health-related behaviors as well as the functioning of the central nervous system and the endocrine system, primarily immune and cardiovascular functioning. Overall, it is believed that biological, psychological, sociocultural, and environmental processes interactively affect, and are affected by, health and illness.

3. CROSS-CULTURAL HEALTH PSYCHOLOGY IN PRACTICE

Applied health psychology consists of several research and practice areas that overlap with the broader fields of clinical psychology, behavioral medicine, and public health. In cross-cultural contexts, three areas of research and practice have been particularly predominant: (a) identifying health risk factors and their determinants

and taking preventive actions, (b) alleviating and managing the impacts of diseases, and (c) addressing social inequalities and population health. Although a vast range of health problems could be considered here, this section discusses each of these three areas by giving pertinent examples from the literature on human immunodeficiency virus/acquired immune deficiency syndrome (HIV/AIDS) due to its pandemic nature. Extensive coverage of cross-cultural applications of health psychology in understanding and tackling other major global health problems, including malaria, tuberculosis, nutritional deficiencies, and noncommunicable diseases, can be found elsewhere.

3.1. Risk Factors, Determinants, and Prevention

Before focusing exclusively on HIV/AIDS-related issues, the first two paragraphs of this section briefly consider the spectrum of disease and mortality globally. According to *The World Health Report 2002* published by the WHO, the leading causes of death in high-mortality “developing” societies (e.g., Sub-Saharan Africa, Latin America, Asia) are communicable diseases and maternal and child conditions, including HIV/AIDS, tuberculosis, malaria, respiratory infections, and childhood and maternal undernutrition. In highly “developed” countries (e.g., North America, Western Europe, Pacific Rim), the leading causes of death are noncommunicable diseases, including various forms of cardiovascular diseases, cancers, and psychiatric disorders. In low-mortality developing countries (e.g., Middle East, Eastern Europe, Southeast Asia), a mix of communicable and noncommunicable diseases and maternal and childhood conditions characterize the leading causes of death.

These differences in leading causes of death among countries and regions have been attributed to differences in risk factors to which individuals in these societies are exposed. This is a subject of interest in cross-cultural health psychology research and practice. According to the WHO report, in the high-mortality developing societies, childhood and maternal undernutrition, unsafe sexual activities, indoor smoke from solid fuels, and unsafe water, sanitation, and hygiene contribute the most to the total burden of ill health. In contrast, in highly developed countries, tobacco, high blood pressure, alcohol, high cholesterol, and high body mass index play major roles in the loss of health and functioning. In low-mortality developing countries, a mixed pattern of risk factors found in both high-mortality developing and

low-mortality developed countries seem to contribute significantly to disability and death. Two important themes appear to characterize this report. First, cross-cultural and cross-national differences in health and disease are associated with socioeconomic development and geopolitical situations of the countries and regions. Second, the single most important causes of burden of disease and disability in both developing and developed countries are modifiable health behaviors or conditions that are responsive to appropriate health measures.

Focusing on HIV/AIDS, the most extensively studied risk factor is unprotected sexual intercourse. With the rapid spread of HIV/AIDS, other sexually transmitted infections, and other reproductive health problems, increased attention has been given to understanding the patterns and determinants of sexual risk behaviors and to designing and implementing effective interventions. Although HIV as the cause of AIDS and risk factors for its transmission (e.g., unprotected sex, contaminated blood transfusion, mother-to-child transmission, unsterilized injections) have been known since the early 1980s, controlling its spread has been a formidable challenge to public health across the world, particularly in Sub-Saharan African countries where the epidemic has hit the hardest.

Health psychologists working in a cross-cultural context have applied health behavior and social psychological theories in both research and applied settings. In research, health psychologists are involved in the design and implementation of rapid assessment techniques to measure the level of knowledge, attitudes, and practices of individuals in general or of those who are considered to be particularly at risk for infection. These efforts have become expanded and standardized and are being used in multiple national surveys on a regular basis with the intent to collect comparable risk and protective data. An important example in these efforts is the Demographic and Health Surveys, a worldwide initiative supported by the U.S. Agency for International Development (USAID) and governments of several developing countries with the aim of providing comparable data and analysis on population health, including HIV/AIDS. These studies, and similar other studies, help to determine the levels of awareness and attitudes about HIV/AIDS and the extent of risk behaviors for HIV infection. Based on these data, it is known that awareness about HIV/AIDS and its primary routes of infection is high in nearly every country but that high-risk behaviors continue to be practiced to varying degrees in both developed and developing countries. For example, unprotected heterosexual intercourse is a significant means of HIV spread in

Sub-Saharan Africa, whereas unprotected homosexual intercourse and injecting drug use are major sources of infection in Western countries.

Research has also focused on the determinants of sexual risk (e.g., sex with multiple partners) or protective behaviors (e.g., condom use) using general health behavior theories (e.g., theory of planned behavior) or those that are developed specifically to address HIV/AIDS-related risk (e.g., AIDS Risk Reduction Model). According to a recent report on the epidemic by the UN Program on HIV/AIDS (UNAIDS), sexual risk taking or inconsistent condom use is closely intertwined with a variety of personal and interpersonal psychosocial factors, including poor knowledge, a low sense of threat to infection, high sensation seeking, and a strong need to comply with social norms, as well as with group- or community-level risk factors, including poverty, migration, and pervasive norms that perpetuate women's subordination within sexual relationships. In the context of Sub-Saharan Africa, negative attitudes toward sex with condoms, female sexual compliance to ensure economic security, a lack of negotiation skills to implement condom use, a desire for children, and an external locus of control have been identified as potential obstacles to condom acceptance and use. The relative strength of individual-, interpersonal-, community-, and structural-level factors varies from society to society, depending on the level of socioeconomic development, the spread of the disease, and the sociopolitical climate of the country. However, it is now recognized that sexual risk and protective behaviors, like other health behaviors, are determined by multiple factors and imply that interventions need to address many factors to be successful.

Interventions against risky sexual behaviors often teach recipients about facts related to HIV and reproductive biology, encourage positive attitudes toward those affected and infected by HIV/AIDS, instill skills in sexual negotiation and in the acquisition and use of condoms, and make condoms and voluntary testing and counseling more accessible. Given that sexual beliefs, attitudes, and activities are strongly influenced by cultural and broader structural factors, some interventions have addressed these factors appropriately. Most interventions include a combination of behavioral outcomes, theoretical approaches, and formats and methods of delivery. In some countries and regions, some formats are more acceptable and amenable than others. For instance, in Sub-Saharan Africa, radio and stage dramas are often used for communicating preventive messages. In more literate societies, print and other mass communication approaches are used.

Evidence from both more and less industrialized countries indicates that behavioral and psychosocial interventions are effective in enabling people to make and maintain necessary preventive sexual behavior changes. Reviews of these interventions generally conclude that psychosocial and behavioral interventions are effective in increasing awareness, skills in sexual negotiation, frequency of communications with sexual partners about safer sex, and skills in the acquisition and use of condoms as well as in reducing frequency of sexual intercourse, early sexual initiation among youth, and the incidence of sexually transmitted infections. Although intervention effectiveness varies by the type, length, and other characteristics of the intervention, the most efficacious HIV prevention programs have been directed specifically at groups at risk for infection, focused on relationship and negotiation skills, involved multiple sustained contacts, and used a combination of culturally appropriate media of delivery. Although most intervention studies have not explicitly studied the role that cultural variables play within cross-cultural contexts, those that have integrated cultural factors into their HIV prevention themes and contents have confirmed the pervasive influence of culture on risk perception, risk-taking behaviors, and adoption of protective behaviors.

3.2. Disease Management and Impact Alleviation

Advances in health sciences, care, and technology have created important new challenges and roles for cross-cultural health psychologists in the area of secondary prevention. Many of the acute and chronic medical problems facing the world, and the curative or palliative treatments for these problems, have profound impacts on numerous areas of patient functioning and quality of life. These impacts may involve physical and psychosocial disabilities and may originate directly from the health problems themselves, from treatment side effects, or indirectly as a consequence of the disabilities or limitations they impose on patients and families. In general, medical conditions present psychosocial challenges for patients and their families in the areas of (a) coping with and managing pain, (b) coping with psychosocial impacts of disease, (c) adhering to demanding medical regimens, and (d) coping with social stigma and discrimination.

Chronic health problems, such as HIV/AIDS, are accompanied by persistent pain and other psychosocial difficulties in the form of emotional distress, including

anxiety, depression, low self-esteem, and irritability, as well as disruptions in interpersonal relationships, including marital difficulties and family stress. Pain and other psychosocial consequences of diseases must be addressed not only because they contribute to diminishing quality of life of the patients and their families but also because studies have documented that psychosocial distress is related to length of survival, immunological functioning, and/or some measures of disease progression. Sources of persistent pain and psychosocial distress among people with chronic diseases are multiple. Among people living with HIV/AIDS, psychosocial problems occur as a consequence of the physical illness, disability, and wastage and also as side effects of the multitudes of medication taken. Neurological and cognitive impacts of HIV infection may also affect the day-to-day functioning of patients. Negative attitudes and reactions of others toward patients contribute to patients' sense of isolation and psychosocial distress. Furthermore, socioeconomic strains caused by the loss of jobs and incomes add to the psychosocial distress that the patients and their families experience. The actual level of psychosocial distress experienced by people living with HIV/AIDS depends on several factors, including the resources available to patients and their families, socioeconomic development of their countries, and the strength of national policies protecting the rights of HIV-infected people. For instance, the potential loss of jobs, housing, family support, and even life due to admitting to HIV infection is a major concern and source of distress in many developing societies, although such concerns are significantly reduced in Western societies.

Interventions against persistent pain and psychosocial distress due to HIV/AIDS involve multidisciplinary teams and a variety of components and strategies, including individual psychotherapy, social support in a group setting, cognitive-behavioral skills training, and pharmacological treatment to reduce and manage pain, anxiety, and depressive symptoms. Self-management interventions are also used when the aim is to help patients monitor and cope with their pain and illness and to maintain satisfactory quality of life. These interventions include providing information about treatment conditions, management of symptoms and psychological consequences, and communication and coping strategies such as relaxation and meditation.

Reviews of studies from various countries and using various outcome measures have found strong support for interventions against persistent pain and psychosocial consequences of HIV/AIDS. Although the positive effects of these interventions are not always consistent,

and it is difficult to discern the relative efficacy of their components, there is sufficient evidence that interventions against psychosocial consequences of diseases can affect quality of life as well as disease outcomes. Consistent with the biopsychosocial and ecocultural perspectives of both pain and psychosocial distress, there is strong evidence that culturally appropriate interventions that take into account sociocultural resources, explanatory models, and contextual factors are more likely to effectively reduce persistent pain, psychosocial distress, and negative disease outcomes. For instance, the use of traditional healers, midwives, and indigenous social support systems in developing countries and the use of "alternative and complementary therapies" in the West have been found to be potentially useful interventions for managing pain and for mitigating the psychosocial impacts of HIV/AIDS.

Low adherence to prescribed treatments is a ubiquitous problem among patients with chronic conditions, thereby contributing to undermining the potential benefits that may accrue from treatment. Adherence to highly active antiretroviral therapy (HAART) and other anti-HIV medication has been studied in various cultural settings. In these studies, health psychologists are involved in examining the reasons for nonadherence and in designing interventions to decrease its likelihood. Studies from several countries and cultures have identified several factors that are correlated with nonadherence. Poor adherence tends to occur in treatment regimens that are complex, have strong side effects, and place too many cognitive and scheduling demands. Psychosocial factors, including emotional distress, low self-efficacy beliefs, substance abuse, pessimism about prognosis, lack of social or provider support, and limited access to health service resources, have also predicted lower levels of adherence. Thus, both individual-level variables and cultural constructions regarding the meaning of AIDS are important regarding adherence to treatment regimens.

Interventions against nonadherence with anti-HIV medication involve a combination of cognitive, behavioral, and psychosocial components. Health psychologists, along with other health care professionals, provide structured dosing instructions, self-monitoring and problem-solving skills, behavioral reminders and strategies to increase compliance with medical advice, counseling and social support in either individual or group settings, and information about drug options, interactions, and side effects. Studies that evaluated these interventions showed that patients who participated in interventions had higher levels of adherence and lower levels of viral

load than did patients who took standard care, although these findings are not always statistically significant and long-lasting. In addition, it has been noted that comprehensive interventions that combine educational, behavioral, and affective components have led to better intervention outcomes than have single-focused interventions. Effective strategies are also characterized by effective communications with patients that are tailored to individual patients' needs, capacities, and resources.

Stigma refers to undesirable or discrediting socially constructed attributes that individuals possess and that affect their quality of life as well as their social standing. Perceived or felt stigma, as opposed to enacted stigma or discrimination, involves real or imagined fear of negative social attitudes and discrimination due to one's undesirable personal attributes or association with others who have such attributes. Stigma is a powerful force that often causes prejudicial thoughts, behaviors, and actions by individuals, groups, communities, and institutions. Although nearly all health conditions can lead to stigmatizing experiences, diseases that elicit fear of illness, contagion, and death, as well as those whose origins are uncertain and whose treatments are limited, tend to cause a relatively greater amount of stigmatization. Patients with diseases such as leprosy and tuberculosis have historically evoked fear and revulsion in others. Although advances in knowledge and treatment have increased acceptance of such patients, other more recent health conditions, such as HIV/AIDS, are currently among the most stigmatizing health conditions around the world.

Among HIV-infected individuals, stigma manifests itself in many ways. HIV-infected individuals may refuse to disclose their status to others due to fear of negative reactions from their partners, family members, employers, and community members. This has been found to be a major obstacle to preventive efforts in many Sub-Saharan African countries. These individuals may also refuse to receive the necessary health services due to potential negative reactions of health care providers or to fear of being discriminated against by others. HIV-infected people who belong to certain sectors of society, such as commercial sex workers in Sub-Saharan Africa and injecting drug users in Western countries, may face an extra layer of stigmatization due to their association with "deviant" or "immoral" behaviors. These and other stigmatizing experiences lead to negative effects on test-seeking behavior, willingness to disclose HIV status, health service-seeking behavior, quality of health care received, and social support solicited and received.

Reviews of intervention studies from the United States, Europe, and Sub-Saharan Africa indicate that antistigma efforts aim at increasing the tolerance of individuals and communities for people living with HIV/AIDS, the willingness of health care providers to treat people with HIV/AIDS, and the abilities of people living with HIV/AIDS to cope with stigma and discrimination. Interventions have used a combination of strategies, including providing information about HIV/AIDS and impacts of stigma, building skills to diffuse and cope effectively with conflict situations, counseling to address individual concerns and provide social support, and providing opportunities for public contact with people infected with, and affected by, HIV/AIDS. The review indicates that interventions that combine information, skill building, and contact with people living with HIV/AIDS reduce stigma significantly more than do interventions that include any one of these separately. Not all studies have brought appreciable reductions in stigma, due partly to limitations in the conceptualization, measurement, and methodological problems associated with the interventions.

3.3. Addressing Social Inequalities and Population Health

Recently, research and practice in social inequality in health has gained ground in health psychology and public health across nations. There is a growing awareness that socioeconomic hierarchies, defined by a wide variety of indexes such as social class, accumulated wealth, occupational prestige, income, and education, and negative social attitudes and actions associated with those hierarchies, including racism, discrimination, and stigmatization, have been linked to differences in levels of health outcomes. Major national and multinational studies indicate that unfavorable outcomes in many areas of health are relatively more prevalent among people occupying the lowest socioeconomic status and/or among historically marginalized ethnic groups and immigrants. For instance, African and Hispanic Americans in the United States, Bangladeshi and Pakistanis in the United Kingdom, and Africans and Asians in South Africa tend to have unfavorable socioeconomic standing as well as poorer overall health than do White people in their respective countries. Health psychologists, as well as other professionals, are involved in efforts directed at understanding the mechanisms through which these effects occur and the manner in which these social inequalities in health can be reversed.

Research on ethnic densities has found that the larger the number of people in a minority cultural group living within a given area, the lower the psychiatric admission rate for members of that group, suggesting that living in a neighborhood that encourages an unfamiliar lifestyle, culture, and language is a risk factor for the development of mental disorder. Such segregation may help to protect group members from direct prejudice and provide them with social support that operates through culturally familiar customs. Research into the broader mechanisms of socioeconomic differences in health attributes their origins to two broad factors: material deprivation and psychosocial disadvantage. Included in the material explanation of social inequalities in health are access to basic necessities of life (e.g., food, shelter), access to amenities that contribute to a comfortable and productive life (e.g., home ownership, means of transportation), and access to curative, preventive, and/or health-promoting services (e.g., health care, exercise facilities). The psychosocial interpretation of health inequalities proposes direct and indirect effects of psychosocial stress associated with occupying lower socioeconomic status. Stress and emotional distress associated with racism, discrimination, and living in an unfavorable social position may relate to health directly by affecting physiological systems or indirectly by affecting health behaviors.

Efforts to address social inequalities in health and to promote population health involve a wide array of interventions to increase disease-preventing/health-promoting resources of individuals, strengthen capacities of communities, improve access to essential facilities and services, and encourage macroeconomic and sociocultural changes by way of conducive policies and government actions. A strong argument in favor of bringing changes in social policies and government programs that directly address the fundamental social causes of social inequalities in health is critical. For instance, structural-level interventions focusing on increasing accessibility of HIV/AIDS preventive and treatment services and on enacting favorable national policies have shown considerable potential in addressing the disproportionate burden of HIV/AIDS among ethnic and racial minorities and vulnerable groups in both resource-poor and resource-rich countries. Cross-cultural health psychology contributes to knowledge about behavior change approaches that incorporate culturally appropriate strategies. It can also bring forth knowledge about the social world and community-level variables (e.g., supportive social networks, social cohesion) that contribute to resilience, wellness, and health. Social and

health policies that are evidence based and socioecologically appropriate are more likely to be effective in reducing social inequalities and improving individual and population health.

4. CURRENT ISSUES AND FUTURE DIRECTIONS

Traditionally, cross-cultural health psychology has sought to compare health in various cultural contexts, where those contexts either were geographically distant or involved migration from one geographical area into the culture of another geographical area. Although these fields of study are still of interest and relevance, perhaps a broader conceptualization of what “cross-cultural” means is required. Furthermore, it is important to recognize that cultural comparisons are naive if they fail to take account of the broader sociopolitical and economic context. This is particularly relevant to health when cultural differences are compounded by the disempowerment of one group relative to another. For instance, in thinking of the practical implementation of health promotion initiatives in Sub-Saharan Africa, it is clear that traditional indigenous approaches to health are not operating on an equal power base with more Western-oriented biomedical interventions. Aid agencies that provide resources for health care tend to support those perspectives that reflect their own cultural assumptions. Although this is not necessarily wrong, cross-cultural health psychology must be aware of this bias and power imbalance to be truly informative for effective action.

MacLachlan identified seven realms where culture and health are related to each other and where these relationships have implications for people’s sense of identity, empowerment, and well-being (Table I). These different realms reflect a range of new challenges for cross-cultural health psychology, where “cross-cultural” may be taken to mean between different realms of culture. Hermans and Kempen argued that cross-cultural psychology’s traditional emphasis on geographical location is becoming increasingly irrelevant. Instead, they emphasized the influence of interconnecting cultural and economic systems, of cultural hybridization creating multiple identities, and of increasingly permeable cultural boundaries. Most contemporary societies are patterned by a multiplicity of meanings and practices that likely contribute to greater uncertainty. As Hermans and Kempen stated, “Uncertainty is not primarily in a culture’s core but in its contact zones.”

Table 1
Realms within Which Culture and Health Interact

Cultural colonialism

Rooted in the 19th century, when Europeans sought to compare a God-given superior “us” with an inferior “them” and to determine the most advantageous way of managing “them” in order to further European elites.

Cultural sensitivity

Being aware of the minorities among “us” and seeking to make the benefits enjoyed by mainstream society more accessible and modifiable for “them.”

Cultural migration

Taking account of how the difficulties of adapting to a new culture influence the opportunities and well-being of geographical migrants.

Cultural alternativism

Different approaches to healthcare offer people alternative ways of being understood and of understanding their own experiences.

Cultural empowerment

As many problems are associated with the marginalization and oppression of minority groups, a process of cultural reawakening offers a form of increasing self and community respect.

Cultural globalization

Increasing (primarily) North American political, economic, and corporate power reduces local uniqueness and reinforces and creates systems of exploitation and dependency among the poor, throughout the world.

Cultural evolution

As social values change within cultures, adaptation and identity can become problematic, with familiar support systems diminishing and cherished goals being replaced by alternatives.

After MacLachlan (2004b).

Conventionally, cross-cultural health psychology has recognized the interplay between culture and health in colonialism, through sensitivity to minority groups, and in the acculturation issues of migrants. The recent enthusiasm for alternative medicine has also attracted the interest of some cross-cultural health psychologists because it can be seen as introducing greater pluralism into health care. However, less noticed by cross-cultural health psychologists are the distinctive (and often more complex) relationships between culture and health that are evident in the renewed enthusiasm for cultural empowerment, especially among marginalized indigenous groups. Another complex issue is the health effects of globalization, where a singular politicoeconomic system based on North American values, with

accompanying ontological assumptions about the causes of and cures for health problems, is in conflict with local practices and beliefs. Yet another challenge for cross-cultural health psychology is how rapid social and cultural changes within societies may bring in their wake what might be termed “disorders of acculturation.” For instance, cultural evolution and social change may require a process of temporal acculturation that has significant implication for health.

Although the realms described here may require cross-cultural health psychologists to rethink some of their discipline’s traditional assumptions, some aspects of traditional health psychology will be applicable in the “newer” realms where culture and health interplay. For instance, Berry’s framework for conceptualizing the acculturation strategies of (geographical) migrants has also been found to have predictive value for the well-being of people experiencing temporal acculturation through a period of rapid social change. There is no doubt that cross-cultural health psychology offers a valuable comparative perspective on the human experience of health across cultures. As an orientation, it has much to offer. As a methodology, it is challenged by a greater need for cultural authenticity than for universal applicability. However, a comparison of culturally sensitive efforts can identify generally applicable principles, although just how those are enacted must again be meaningfully translated into the matrix of local living.

Kazarian and Evans concluded that although health psychologists have made important contributions to developing a more holistic approach to health, they have not effectively integrated culture into their approach. Their emphasis on the role of cultural health psychology in the creation of culturally competent health professionals is timely given the recent enthusiasm for a broader conceptualization of health, referred to as “global health.” Global health is an attempt to address health problems that transcend national boundaries, may be influenced by circumstances and experiences in other countries, and are best addressed by cooperative actions and solutions. The underlying assumption is that the world’s health problems are shared problems and, therefore, are best tackled by shared solutions. As Lee wrote, “Health care systems are traditionally structured, regulated, and delivered at the national level. Health research is correspondingly focused on the state, sub-state and inter-state levels. . . . There is a clear desire for a fuller understanding of the links between globalisation and health, beginning with the development of relevant conceptual frameworks and rigorous empirical analysis.”

The health impact of globalization with regard to HIV/AIDS, coronary heart disease, and many other public health problems can be all the better appreciated by a comparative analysis—both conceptual and empirical—of how these difficulties affect people, and are affected by people, in a cultural context around the world. Beyond the needs for research, analysis, and policy development to which cross-cultural health psychology should contribute, there is also enthusiasm for new curricula that place global health center stage in the education of health professionals. With the increasing complexities of the contexts that may now be considered to constitute “cross-cultural” health psychology, and with greater recognition of the persuasive influence of global forces on human health, the value of cross-cultural health psychology may be increasingly realized in its contribution to addressing the challenges of global health.

GLOSSARY

evolutionism A doctrine that maintains the formation of complex real entities from simpler ones, through an evolving natural process that brings in differentiation and heterogeneity in more homogeneous situations.

institutionalization The process of creating certain social structures that will be in charge of some definite roles originally solved by people's personal and original behavior.

intervention A concrete action that tries to introduce some changes in a given situation, usually planned and devised according to some previous theory, and adapted to the here-and-now peculiarities.

positivism A philosophical doctrine, first formulated by French A. Comte (19th century), that maintains the primacy of scientific knowledge and the need for building society upon a scientific worldview.

school A group of persons working on a certain field, according to some idiosyncratic views, and usually organized in a master–disciples structure.

theory A conceptual construction that tries to represent a certain group of phenomena in order to explain and predict them.

1. INTRODUCTION

Theoretical and applied psychology have frequently been considered as two completely different ways of approaching and conceiving of mental and/or behavioral phenomena. Their lines of development have met one another from time to time. But most frequently they have remained unrelated, as different questions, instruments, and methodologies have dominated in each of them, creating two different worlds.

Interest in psychological questions goes back to ancient times, as proven by philosophical reflections and literary creations. The diversity of characters and the description of typical reactions to a variety of situations form the core of countless literary masterpieces all over the world. Nonetheless, neither philosophical reflections nor literary fantasies enter our tableau. Psychology conceived as an empirical science is little more than a century-old enterprise. For didactical purposes, Wilhelm Wundt's laboratory at Leipzig

University (1879) is credited with the honor of representing the first event in its history.

This new science tried to reformulate old questions about the nature of the human mind and its creations—knowledge, volition, choice, consciousness—and its connection with the biological organism that owned such a mind. Two main ideas dominated the second half of the 19th century: evolution and science (the third one would be democracy). While evolutionary theory brought forth the idea of a continuity between humans and the animal kingdom, positivism stressed the value of scientific knowledge in all empirical domains and stimulated the creation of a natural science of the human mind. In what relates to the third idea, democratic values would soon demand the application of that new knowledge to solve the problems of societies developing under the impulse of the industrial revolution.

Two main lines, biological and sociological, characterize the early developments of psychological research. While certain groups focused on physical and physiological determinants of human behavior, others insisted on socio-historical factors mediating mental processes. On the one hand, work in laboratories and theory construction were stressed; on the other hand, researchers relied on social and ethnological comparisons and became largely interested in practical knowledge.

In the early days of the 20th century, applied research was not an easy task. In the United States, Edward B. Titchener (1867–1927), a “pure scientist,” strongly opposed psychologists emerging from laboratories and facing daily life problems. He feared that their theories were not yet prepared for such a huge task. But demands could not wait unattended for long. Moreover, funds for research soon became dependent on practical results accredited by scientists. Little by little, applications began to follow theory, and science gave way to practical interventions; scientists were accompanied by practitioners, and psychology became a science as well as a profession, as it is at present.

Since its beginnings, interventions in psychology were characterized by the need for combining both a scientific background and information on the idiosyncratic characteristics of every practical problem. Applied science, in the case of psychology, has not only consisted of translating general principles to concrete circumstances, but also of creating new theoretical models that are fully in accordance with concrete data, trying to meet the particular demands, and gaining through such intervention new theoretical insights. Such circular interactions between research and theory were clearly stated by Kurt Lewin in his “action

research” doctrine and have been frequently found by researchers in most of the practical fields.

Developments in the field have been deeply influenced by national trends. Progress cannot be reduced here to a single common process covering all countries and specialties. Three main areas did emerge, however, as their problems were found in all well-developed societies: (1) children’s adaptation to school, (2) worker’s adaptation to job requirements, and (3) people’s adaptation to the requirements of “normal” life in a social world. These areas led to the formation of school and educational psychology, industrial and organizational psychology, and clinical psychology, respectively. As time passed, the mapping of specialties became more and more complicated.

Certainly, among all these differences there are some common traits in these applications that may serve to unit and define the field of applied psychology. These traits will be considered after a general discussion of the field.

2. EARLY LANDMARKS IN APPLIED RESEARCH

While the establishment of Wundt’s laboratory is a landmark that represents the first step, there is no formal beginning for applied psychology as such. In each specialty, however, the first steps have had some unique characteristics of their own that will be considered here.

2.1. Clinical Psychology

It is not easy to disentangle clinical psychology from the fields of mental hygiene and psychiatry, but it might be accepted that problems and deficits in mental aptitudes can be seen as psychological problems, whereas deep mental disorders require medical treatment. The former will impair normal adaptation to life, while the latter will prevent normal functioning of the person among his relatives and in his private world.

The first steps in the field of clinical psychology stem from the introduction of the idea that a mental process and its abnormal functioning could be treated through behavioral/mental means, instead of using somatic or chemical procedures. An empirical approach to the study of mental disorders was demanded in this new science of the mind, as these disorders began to be seen as natural disturbances capable of being treated. Some epochal events took place in the year 1896. In Germany, a student of Wundt, psychiatrist

Emil Kraepelin (1856–1926), first proposed the introduction of the psychological laboratory and the experimental study in psychiatry, in a seminal paper that has been called the first German program for clinical psychology. Kraepelin divided illnesses into two categories: those due to endogenous factors and those caused by exogenous ones; the former were viewed as usually incurable, while the latter had a better prognosis. Based on empirical grounds, he also worked on a classification of mental disorders that served for decades as a nosological system.

Also in 1896, an Italian psychiatrist, Giulio Cesare Ferrari (1868–1932), with G. Guicciardi, published a paper on mental tests that in their opinion could be employed in psychiatry to improve diagnosis. They tried to continue the pioneer work of Gabriele Buccola (1854–1885), who, working with patients suffering from mental disorders, found interesting variations in their reaction time measures. Ferrari and Guicciardi examined attention, associative abilities, and other mental capacities in patients in order to more accurately characterize their pathologies.

And it was in the same year when, in the United States, Lightner Witmer (1867–1956), another student of Wundt and Cattell, founded the first psychological clinic, at the University of Pennsylvania. Witmer became an apostle of the psychological intervention. At the American Psychological Association (APA) convention of that same year (1896), he maintained that psychologists had to assume two tasks: to study mental processes and to apply their knowledge to solve personal problems and social needs. He had to face the negative attitude of his colleagues, who did not wish to accept practical responsibilities. He decided to organize regular training courses at his university for people interested in applications of psychology, with case presentations and formation in diagnostic techniques, and also founded a journal, *The Psychological Clinic* (1907), that claimed to promote “orthogenics,” the knowledge of the correct development of individuals, both in physical and mental capabilities.

A different approach was carried out by William Healy (1869–1963), a physician who treated juvenile delinquency as a phenomenon he believed was rooted in certain psychopathological factors. He created a battery of proofs and applied them to young offenders, trying to determine their personalities and social factors in order to implement preventive and therapeutic interventions. His first clinic was established in Chicago (1909) and then he moved to Boston, where he retired.

In sum, demands for help from psychologists, coming from the social world, were based on the assumption that the new science of psychology, which was dealing with the normal functioning of the mind, could also say something about those pathologies now interpreted as mental disorders.

2.2. Educational Psychology

The 19th century saw the democratic rise of masses in Western countries, and basic education and training spread out to all individuals and classes. Many people became teachers, but they soon discovered that their job was not an easy one. Individuals are endowed with unequal learning capacities, and those prevented from normal schooling caused great disturbances in the classroom. Because their need for special treatment was ignored by most teachers, they turned to psychologists for orientation and help. Whereas old-fashioned schooling was based on memory and rote learning, some new tendencies stressed the role of an active process of learning and understanding, a true psychological topic. Teachers viewed psychology as the scientific basis for their own art of teaching.

The association paradigm became largely influential. In 19th century Germany, Johann F. Herbart's (1776–1841) association became the basis of the new science of education; in the United Kingdom, interest in these matters went back to empiricist philosophers, from John Locke to James Mill, whose ideas inspired 19th century psychologists such as Alexander Bain (1818–1903) and James Sully (1842–1923). Sully made careful empirical studies of language, perception, memory, and other faculties in children, and wrote one of the first textbooks, *Teacher's Handbook of Psychology* (1886).

French pedagogue Gabriel Compayré (1843–1913) wrote another textbook for teachers that included not only theoretical concepts on association and other mental aspects, but also practical topics, such as children's plays, how to improve curiosity and memory, and the technology of teaching. His book was translated into Spanish by the great Argentinian educator and president, D. F. Sarmiento, and became influential among Latin American teachers and pedagogues.

Largely under the influence of Wundt's psychology, an experimental pedagogy began to spread in Germany. Scientific knowledge of child development, based on observation and experiments, was systematized in the pioneering work of Wilhelm Preyer (1841–1897),

The Soul of a Child. Pedagogues such as Wilhelm A. Lay (1862–1926) and Ernst Meumann (1862–1915) multiplied their efforts to provide psychological support to educational practices. Some of them stressed the need for building a global knowledge of child life, and a first draft was accomplished by German Oscar Christmann in 1889, with his proposal of a “paidology”—or “pedology”—conceived of as a general science of the mental and physical development of the child. Centers for research and teaching were then founded, such as the Institute for Pedagogy and Experimental Psychology of Leipzig, and the Institute for Applied Psychology, created by William Stern and Otto Lipmann in Breslau, both founded in 1906. Specialized journals such as *Zeitschrift fuer Kinderforschung* (1895) also began to publish the results of their research.

Some educators spoke up against undue expectations of psychology. William James (1842–1910), in *Talks to Teachers* (1899) made clear the distinction between the science of psychology and the art of teaching, affirming that “sciences never generate arts directly out of themselves.” But some of his students, like Granville Stanley Hall (1846–1924), assembled a large body of knowledge about lifespan psychology (e.g., childhood, adolescence, senescence), and wrote a seminal work on “The Content of Children’s Mind on Entering School” (1883) in which he empirically explored the average knowledge of children in his society. This field soon became an active area of research. Hall expanded that paper into a book (1894), and founded the journal *Pedagogical Seminary* (1891), later renamed the *Journal of Genetic Psychology*.

Interactions between psychology and education multiplied rapidly, and benefited from the growing knowledge about children promoted by evolutionism. In Belgium, paidological topics received great attention, especially topics related to mental retardation. A. Sluys, J. Demoor, and Ovide Decroly (1871–1932), among others, made lasting contributions that became influential all over Europe. The latter encouraged the adoption of the New School model, which promoted the ideals of active learning and the view of the school as a laboratory.

Great attention was also paid to these topics in socialist countries. In Russia (in those days the Soviet Union), many centers oriented toward experimental study of child development and school education were founded, as the building of a “new man” was a political goal according to Marxist views. Lev Vygotsky (1896–1934), Pavel Blonsky (1884–1941), Aron Zalkind (1888–1936) and others worked on this, stressing the

social and practical roots of human consciousness. A Congress of Pedology gathered in 1928, a journal (*Pedology*, 1928–1932) was founded, and activity grew rapidly, until July 4, 1936, when a decree from the Communist Party headed by Josef Stalin halted testing and deemed nearly all psychological practices counter-revolutionary activities.

The ideals on active education were at the core of an institution created in Geneva, Switzerland in 1912 by Edouard Claparède (1873–1940), Pierre Bovet, and some collaborators, the Institute Jean Jacques Rousseau, which soon became a model for all who were interested in those topics. Claparède offered an overview of the field in his *Psychologie de l’Enfant et Pédagogie Expérimentale* (Child Psychology and Experimental Pedagogy, 1905), in which he stressed the idiosyncratic nature of child life and the need of an educative system that is well adapted to the individual nature of every child and capable of giving effective guidance to students.

Some early studies had great impact on the field, such as research on formal discipline and its effects on concrete learning. In the United States, Edward L. Thorndike (1874–1949) and Robert S. Woodworth (1869–1962) performed experiments on the transfer of training that showed poor or negative aftereffects of a first learning task upon another following it. In doing so, they destroyed the belief that some benefits might be obtained from disciplines such as Latin or technical drawing upon other matters included in the curriculum. But the study of individual differences among children and a more detailed knowledge of the evolution of intellectual abilities and interests enabled teachers to adjust their teaching to the children’s capabilities.

Apart from these descriptive studies, more effective instruments for assessing children in schools were demanded. In response, some psychologists built instruments for screening deficits and assessing effective teaching. They initiated the application of proofs and measures to education. This will be discussed in a following section on testing.

2.3. Early Work in Organizational Settings

Western societies have created all sorts of organizations in which the principles of impersonal work, labor division, cooperation, and leadership applied. In modern states, people operate under the leadership of certain elites, and technology introduced during the industrial revolution is changing the world through the work of

people working together. In the early decades of the 19th century, the need for a science of social movements and phenomena stimulated the creation of sociology, an accomplishment of French theorist Auguste Comte (1798–1857), the founder of positivism. Soon after, theorists tried to explain some dimensions of social life as mental phenomena, as well explain some psychological facts by social forces. Interactions between these fields multiplied, and psychological knowledge of individuals operating in a group or organization seemed more and more convenient. Aspects such as job–person fit, efficacy, performance quality, accident prone operators, and social competition were not without economic consequences. Enterprises in search of good operators soon incorporated psychological testing devices in order to find reliable and valuable workers. Psychology appeared as a science dealing with problems closely related to person–job adaptation, and soon society asked psychologists for help in the task of improving industries and social organizations.

The concept of applied psychology was first delineated by German William Stern (1871–1938). According to him, it was “the science of psychological facts that are relevant by their practical utility,” including both assessment and intervention (Dorsch, 1963, p. 9). Early essays on this topic are characterized by their spontaneity and diversity; frequently they were written by laymen interested in practical questions. For instance, Italian physiologist Angelo Mosso (1846–1910) stressed the importance of analyzing the fatigue curves of workers to improve their performances; his findings and methods spread rapidly in Europe. On the other hand, a U.S. engineer, Frederic W. Taylor (1856–1915), working for important steel companies, studied their production from the point of view of the productive behaviors and their timing and morphologies, giving place to a movement called the “scientific organization of labor,” that applied the scientific methodology to the study of people’s efficiency at work, and the ways to improve it. Although not a psychologist himself, he applied psychological techniques—reaction time, movement studies, cooperation among workers, economic incentives—in trying to combine personal satisfaction with greatest worker efficiency at the risk of being judged an inhumane manager. His proposals introduced a new concept to industries, and while social movements and trade unionism shook developed societies, the problems of people at work began to be viewed under the light of psychology. Taylorism paved the way for a more specialized organizational psychology.

The new climate brought new fruits. Frank Parsons created the Boston Vocation Bureau (1908), convinced that a test for discovering motives and aptitudes in individuals could improve their professional adaptation. As a philanthropist, he wanted to help people in search of a job, and his center considered many aspects: people’s abilities, technical and moral training needed, self-understanding, and the material conditions of the job.

A world becoming dominated by technical apparatuses and procedures demanded efficient people for using them. Car driving and traffic security also stimulated the screening of potential accident prone drivers via psychological testing, a task in which German researchers Walter Moede (1888–1958) and Curt Piorkowski (1888–1939) did significant work employing driving simulators. Motion studies of bricklayers done by Lillian M. Gilbreth (1878–1972) and Frank Gilbreth (1869–1924), and of typist’s abilities done by Jean M. Lahy (1872–1943), among others, stimulated the research, but it was Hugo Münsterberg (1863–1916), the “father of psychotechnics,” who was the first to face the problem in its entirety and gave a certain solution.

Trained under Wundt, then working with James at Harvard University, Münsterberg conceived of psychotechnology as the “science of practical applications of psychology in the service of culture” (1914). His books on industrial efficiency, teaching, and eyewitness testimony offered a broad view of psychology as a practical science. He devised proofs and testing situations that proved useful for personnel selection, and received much support from businessmen and industry managers. His works describe the new field of psychological intervention as a coherent whole, in which demands were idiosyncratic, but techniques were interspecific and largely versatile in themselves. Person, situation, and means-ends relations were the significant elements to take care of in every practical intervention.

2.4. Early Testing

Early psychophysics—the scientific study of stimuli and the correlated sensory experience—found systematic variations in sensory and motor abilities among individuals. One of the pillars of Darwin’s evolutionism was the existence of spontaneous variations among individuals who were unequally endowed, in order to cope with the challenges of their environment and subject to natural selection.

Francis Galton (1822–1911), who was deeply influenced by evolutionism, studied such variations and devised a battery of tests to measure differences in various types of capacities among subjects. He applied such proofs in an anthropometric laboratory at the International Health Exhibition of South Kensington in 1884, and created some statistics to sum up his data.

James McKeen Cattell (1860–1944), a U.S. student of both Wundt and Galton, had a long-lasting invention: the construction of standard proofs to compare the performance of different people. In 1890, he coined the expression “mental test” for measuring mental capacities, which spread out all over the world and became a symbol for psychology as a profession. His presidential address at the APA convention in 1895 enforced the need to present to society not only scientific but also material successes in the practical field, in order to enhance the status of psychology; the simplest experimental situation in which a person could be studied and measured was the test. For that reason, tests grew without limitation in the 1920s and 1930s.

In Germany, Hermann Ebbinghaus (1850–1909) devised a completion test, in which some missing letters had to be found, for assessing the effects of fatigue in school children, a type of proof frequently used since then. But it was Alfred Binet (1857–1911) who, with his collaborator Victor Henri (1872–1940), made an epochal contribution: the metric scale for intelligence (1905), a worldwide test for assessing intellectual abilities, allowing the determination of the relative position of a child (his “mental age”) among a certain population. Moreover, intelligence soon appeared to be highly correlated with most mental abilities, as a kind of broad cognitive strength or general factor influencing all types of performances in which those abilities operate, as found by Charles Spearman (1863–1945).

Evaluation and comparisons between individuals became then possible. Age was the basis for comparisons in Binet’s system; a further step to get a stable index across ages came from German psychologist William Stern (1871–1938), who introduced the concept of the intelligence quotient (IQ), the ratio of mental age to chronological age, a score that seemed to remain unchanged along the years. Its measure became a highly valuable index of a person’s capabilities and a good predictor of future performances.

Benefits from the possibility of measuring intelligence began to appear everywhere. School was only one field interested in such measures; social life, job selection, even clinical practice soon could profit in

different ways from this measurement. The various branches of psychological practice began, little by little, to cross-fertilize each other, and their methods and purposes approached each other, producing a certain unification of the applied field as a whole.

2.5. Interactions across Specialties

Three main facts caused the explosion of applications of psychology to social problems: the usefulness of intelligence testing for successful prediction of future performance; the growing need of a scientific explanation for the behavior of people in organizations shaken by social and political unrest; and the rise of a clinical view of abnormality in the light of psychological conflicts of personality, as in the contributions of Sigmund Freud (1856–1938). All these historical innovations converged in viewing mind and behavior as the Gordian knot of the problems of modern societies. Psychologists were asked to respond to those problems, and an external event, World War I (1914–1918), provided the opportunity to prove their social efficiency. As Cattell wrote, it “put psychology on the table,” and nobody could ignore it.

War and military needs can be considered as some of the strongest stimuli for developing psychology in societies. World War I gave a great impetus to all the applied branches; the areas of assessment and personnel selection, and also clinical intervention upon war-caused psychopathologies, quickly developed. Three main problems emerged during wartime: war neuroses (then called shell-shock), the health of munitions workers (menaced by industrial fatigue), and military personnel selection.

In the United States, psychologists from the APA, headed by R. Yerkes (1917) and considered as a part of the medical division, worked out a test battery (the Army Alpha for literates, and Army Beta for illiterates) for assessing soldiers. Both proved to be effective. Examinations were given to more than one and a half million people, and since then, tests have been an indispensable part of any personnel selection. The war also was the motivation for the creation of some clinical instruments, like the personal data questionnaire (1918) devised by R.S. Woodworth (1869–1962) to detect symptoms of a neurotic tendency. With the end of the war, these particular activities greatly diminished.

The war also promoted the introduction of psychology as part of the Army services in Germany. There some regular positions for psychologists were created

in 1925, mainly oriented toward officer selection. This number increased after 1935, as military psychology became synonymous with psychology under the Nazi government. In Great Britain, the war brought the problem of industrial fatigue to the forefront. In munitions factories, people had doubled their working time, and physical and mental disorders rapidly appeared, affecting the subjects' health and efficiency. To face the situation, a Health of Munitions Workers Committee was set up by the government in 1915; it was renamed the Industrial Fatigue Research Board (1917) and then became the National Institute of Industrial Psychology (1921), headed by Charles S. Myers (1873–1946). Similar efforts were carried out in other countries. Airplane pilots were urgently needed, and they were examined by psychologists. In Italy, Father Agostino Gemelli (1878–1959), founder of the first psychophysiological laboratory of the Italian Army, did his best to develop applied psychology in his country in the 1920s and 1930s; in France, Camus and Nepper (1915) did similar work.

Around the same time, the first centers for applied psychology began to appear. In the United States, a psychology department was established in 1915 at the Carnegie Institute of Technology, headed by Walter Van Dyke Bingham (1880–1952), and a year later, Walter Dill Scott (1869–1955) was appointed as professor of applied psychology, the first to receive that title in that country. Vocational counseling, industrial efficiency, and related topics began to be treated as academic matters, so the time was ripe for institutions to specialize in those questions. For example, the Kaiser Wilhelm Institut, the Laboratory for Industrial Psychotechnology from Charlottenburg, the Institute for Work in Moscow, the Institute of Professional Orientation of Barcelona, the Institute Jean-Jacques Rousseau at Geneva, the Psychological Laboratory at the Catholic University of Sacred Heart (Milan), the Institute of Scientific Organization at Warsaw, the Intercommunal Center for Professional Guidance at Bruxelles, the Laboratory for Ergonomics of the Institute of Higher Studies of Belgium, the Laboratory of Experimental Psychology of the School for Higher Studies at Paris, the Center for Professional Orientation, and the Bos Institute (the Netherlands), among others, became active centers for training, testing, and research. These institutions and centers were created to face social demands, and utility was the dominant criterion accepted by researchers, although in the long run many theoretical contributions were produced from such practical work.

3. THE INSTITUTIONALIZATION OF THE FIELD: EMERGING SOCIETIES OF APPLIED PSYCHOLOGY

The period that followed World War I brought with it the normal problems in a rapidly growing field without any internal regulation, mainly under external pressures. Psychology was acknowledged as a useful instrument for social work, and its techniques for personnel selection spread both to private firms and to governmental agencies.

To face the new demands, psychologists tried to set up several professional networks. The need for coordination and the convenience of employing common instruments for assessment stimulated the foundation of an international society for applied psychology, was the *Association Internationale des Conférences de Psychotechnique* (International Association for Psychotechnology). Rooted in Europe but open to the whole world, it held its first meeting, chaired by Swiss Edouard Claparède (1873–1941) in Geneva in 1920; in 1955 it changed its name to the International Association of Applied Psychology (IAAP). The society provided a useful platform for cooperation, but was greatly affected by the political circumstances that led to World War II; 15 years passed between the 8th Congress, held in Prague in 1934 and the 9th, held in Bern in 1949. Since then, it has gathered regularly. The IAAP has been headed by leading scientists: Edouard Claparède (1920–1941), Henri Piéron (1947–1953), Clifford Frisby (1953–1958), Morris S. Viteles (1958–1968), Gunnar Westerlund (1968–1974), Edwin A. Fleishman (1974–1982), Claude Lévy-Leboyer (1982–1990), Harry C. Triandis (1990–1994), Bernhard Wilpert (1994–1998), Charles D. Spielberger (1998–2002), and Michael Frese (2002–present).

Many other international associations have been created to serve the multiple interests of psychologists. The International Union of Psychological Science (IUPsyS) was created in 1951, grouping together many previous national associations. While its roots go far back (a first International Congress of Psychology took place in Paris in 1889), the IUPsyS now represents psychology in international councils of science and culture. Also, the Interamerican Psychological Society (*Sociedad Interamericana de Psicología*, SIP), was founded in 1951 to cover the needs of psychologists from the entire American continent; it is very active at present. Many other specialized societies have flourished in parallel to the growth of the profession and the scientific field.

An outstanding society as measured by its size and activities is the American Psychological Association (APA). Founded by G. S. Hall in 1892, in its beginnings it covered only scientific matters. Therefore, applied oriented psychologists created the American Association of Clinical Psychologists in 1917, but finally this group was included in the APA in 1919 as a clinical section dedicated to professional issues. A new group called the American Association for Applied Psychology was founded in 1937 to better serve practical interests. It edited a journal (*Journal of Consulting Psychology*), but eventually it too joined the APA in 1945, forming a strong society, organized in various divisions, oriented to both science and profession.

The growing complexity of the applied field necessitated a communication network that could disseminate specialized information. During the years of war, some periodicals began to appear. In Germany in 1916, the Institute for Applied Psychology of Leipzig edited the *Zeitschrift fuer Angewandte Psychologie* [Journal of Applied Psychology] under the care of William Stern and Otto Lipmann. In 1917 in the United States, G. Stanley Hall initiated the publication of the *Journal of Applied Psychology*, another one of the leading journals in the field. It was soon managed by James P. Porter (1920–1942), and later owned by the American Psychological Association. Other significant journals have been the *Revue de Psychologie Appliquée* [Review of Applied Psychology] (1920), and *Human Factor* (1932), under the sponsorship of the National Institute of Industrial Psychology and the initial editorship of C. S. Myers. Since then, the network has developed enormously, and the creation of the *Annual Review of Psychology* (1950) and more recently the data banks that have been built in many specialties have introduced a new order into the information chaos.

4. SIGNIFICANT PROBLEMS IN EARLY APPLIED RESEARCH

Some basic problems arose during the evolution of applied psychology. The following sections briefly describe some examples of these problems.

4.1. Inborn versus Learned (Acquired) Abilities

Theorists had to decide whether human abilities were innate or learned; testing procedures and measurements

raised suspicions and opposition among socially involved groups on political grounds. Large differences in measurements between various classes and ethnicities raised political doubts about the fairness of procedures that, in fact, introduced discrimination between races, classes, and individuals. In addition, an increasing number of dimensions of life were subject to study under this methodology.

One subject of intense debate was intelligence. Did the result of testing stem from the inborn characteristic of the person or from the social conditions of the person's life?

Early on, Francis Galton (1822–1911) was inclined toward a genetic solution to the dilemma. In the United States, H. H. Goddard (1866–1957), a Binet follower, reinforced that opinion. He compared two lines of descendants, both legitimate and illegitimate, flowing from a common ancestor and examined their achievements and life records. He concluded that hereditary factors explained most of the variance, as the legitimate family was largely superior to the other one in intellectual and moral qualities.

Different races and cultures were also compared on the basis of their performance on intelligence tests. Data from the Army Alpha and Beta tests were studied and reanalyzed in the United States. Significant differences in IQ among people from various ethnic origins were supposedly found. Among other questioned results, the intellectual weakness of African Americans seemed to be firmly established on these grounds. According to Garrett (1951), "Negro soldiers scored lower than whites on Alpha, southern Negroes lower than northern Negroes." Following these results, democracy was criticized by some groups on the grounds of offering political equality to unequally mentally endowed people. Racist arguments seemed to flow from psychological data. As a consequence, U.S. federal law regulating immigration excluded all "persons of constitutional psychopathic inferiority."

Other voices joined the choir. In Europe, data obtained by H. English and others suggested a strong correlation between economic level and IQ and pointed to non-inborn factors in intelligence scores. The discussion was deeply affected by political prejudices and attitudes. IQ testing was then criticized on political grounds. In the United States, an influential journalist, W. Lippmann (1899–1974), strongly criticized the testing procedures for taking scores as true measures instead of rough estimates of variable qualities in subjects.

In Russia, then under the Soviet regime, a ban on all testing activities in schools was imposed by the

Communist Party's Central Committee. They deemed such activities a "pedological perversion," considering tests as reactionary and anti-egalitarian techniques. Given the thesis of the social determination of consciousness caused by socioeconomic factors, the idea of inborn abilities was seen as unacceptable. Such a decision greatly impaired the development of empirical psychology in the country for decades.

As is well known, this debate has endured for an entire century and at certain moments has become intertwined with political attitudes. The works of A. R. Jensen (1967), H. J. Eysenck (1971), L. Kamin (1974), S. J. Gould (1981), R. Herrnstein, and C. Murray (1994) represent only a small part of the vast literature generated by this controversy.

Today, heredity and environment are placed in a completely different relationship, as genetic engineering has resulted in a complete mapping of genes. Proteins related to organic and mental functioning are now beginning to be discovered, and intervention at such microscopic levels will be possible in the future, opening the way to biological techniques of medical and psychological value.

4.2. Types of Measurement and Types of Diagnosis

A long-ranging debate commenced between those inclined to build diagnoses upon a collection of measures, including personality traits and abilities, and those who limited themselves to the study of the subjects' aptitudes directly related to the job they were applying for. In the early days, theorists such as German O. Lippmann (1880–1933) tended toward a holistic approach, while many others (e.g., Belgian A. Christiaens) favored the opposite view.

The debate evolved into the opposition between qualitative and quantitative (psychometric) procedures for assessing people. The former was frequently called clinical methodology, because it focused on concrete phenomena affecting a single subject (idiographic methods), while the latter was frequently referred to as statistical methodology, as far as it employed quantitative measures obtained from groups of subjects through psychometric tests (nomothetic methods). For instance, some theorists, such as Swiss cognitivist Jean Piaget (1896–1980), firmly rejected the use of psychometric proofs, convinced they gave wrong information about the child's mind, and systematically employed clinical procedures.

Researchers also developed instruments to generate and appreciate qualitative experiences that might be directly related to mental forces and impulses—the projective techniques, which included well-known proofs such as Rorschach's inkblot test (1921) and Murray's Thematic Apperception Test (1938). Hermann Rorschach (1884–1922), a Swiss psychiatrist, wrote *Psychodiagnostik* based on the experimental study of characteristic answers to some inkblots provided by different criteria groups of psychiatric patients. On the other hand, many psychologists tried to devise laboratory situations closely related to those found in real situations.

Opposition to mental measurement also grew from theoretical grounds. Behaviorism, which largely dominated U.S. psychology between the 1920s and 1960s, banned all mental-based concepts from its system, especially from all its clinical topics. It stated that psychology should deal only with behavioral facts and laws, and each individual should be tested in definite settings, in order to establish those precise S-R associations determining his or her behavior. Adaptive or maladaptive habits were substituted for old personality traits, and behavioral changes were evaluated in order to assess the effectiveness of various procedures of behavior modification. New instruments based on observational procedures were developed, employing sampling recording of target behaviors in single subject ($n = 1$) cases; these techniques substituted for traditional tests and questionnaires.

4.3. Studying People or Analyzing Situations

Early psychotechnology tried to study the adaptation of a person to a situation by comparing the person's qualities to the requirements of each type of situation. Typologies and professions were its main fruits. But some unfitting data opened the door to the study of work as a global social situation. Surprising data emerged from some studies on work efficiency carried out by George Elton Mayo (1880–1949) and collaborators on employees of the Western Electric Company in Hawthorne, Chicago. An in-depth study with those workers showed that their efficiency at work was mainly dependent not on physical factors at the workplace but on social characteristics of the group—informal rules, leadership, social climate, expectations, and fears—and also from the fact that they were receiving attention from researchers, a fact that influenced the feelings of those

workers. Mayo, F. G. Roethlisberger, W. J. Dixon, and G. Homans placed emphasis on human relations in industry and stressed the relevance of the “human meaning” of work and the necessity of a holistic approach to work problems. Significant developments in this theory were obtained when extra-organizational variables, such as technological and market changes, religion, race, and social class, were also taken into account by the Chicago school (W. L. Warner and colleagues) and other groups.

All these experiences showed the need to study the characteristics and behaviors of groups. Gestalt psychologist Kurt Lewin (1890–1947) emerged as a leader in that field. His ideas influenced not only the general field of social psychology, but also the study of applied aspects, such as the relationship between school climate and teaching efficiency. Lewin, R. Lippitt, and R. K. White evaluated the effect of different group atmospheres—democratic, authoritarian, and *laissez faire*—upon school teaching and group interactions. Leadership proved to be an important variable, and various models of it have been devised to explain empirical data. Results from industrial settings were transferred to educational and clinical fields. Group psychotherapies have been applied since the 1920s by Alfred Adler (1870–1937) and coworkers, and group interactions proved fruitful in handling feeling and personality disorders. Well into the 1950s, group psychology developed a variety of forms and applications: for instance, T (training) groups were created that offered training in skills and interpersonal communication; encounter groups were employed for therapeutic discussions in humanistic psychotherapies. A special place in this line of thought belongs to the Tavistock Institute (UK) founded in 1947. It focused on the interactions between technological and psychosocial aspects of organizations, and tried to combine psychoanalytic concepts and the group dynamics as developed by the Lewinian group of theorists. A. K. Rice, E. L. Trist, W. R. Bion, and many others helped the development of this movement, and its journal, *Human Relations* (1947) maintained a comprehensive perspective in the field.

4.4. Intervention versus Goal-Oriented Research

As applied psychology rapidly developed, more and more concrete questions absorbed the interest of researchers, who began to specialize in a small range

of topics and to sight of the entire field. An increasing distance began to appear between theory and applications, and as a result, some tried to restore the communication between both fields.

After World War II, clinical psychologists in the United States felt the necessity of combining practice with research. In a conference at Boulder, Colorado in 1949 they devised the so-called Boulder model, which recommended “the training of the clinical psychologist for research and practice, with equal emphasis on both” (Raimy, 1950). This model has been widely accepted, and is still in force among specialists.

Similarly, social psychologists doing research and intervention in social settings were warned by K. Lewin in 1948 that their interventions had to be organized “in a spiral of steps each of which . . . composed of a circle of planning, action, and fact-finding about the result of the action.” In combining planning, action, and evaluation, researchers will adjust themselves to a Lewinian “action research” model that puts together theory and action into a single operation, a model assumed by most social scientists. These innovations perceived practice and theory as two dimensions of the same impulse toward knowledge.

5. THE INFLUENCE OF WORLD WAR II (1939–1945)

World War II deeply changed the social scene, and all aspects of human life, including psychology, felt its impact. Numerous institutions, researchers, and schools of thought were destroyed or silenced by the war. In Europe, an enormous number of scientists and intellectuals belonging to Jewish families were persecuted and even killed in countries placed under the Nazi regime. Psychologists were no exception. Many of them fled to the United States or to other countries, and European psychology, until then considered the best in the field, lost its position of leadership to the United States.

In Germany, some psychologists carried out research for the new regime. The German army established a *Wehrmacht* psychological division, which performed the selection of specialists and officers; the Reich Institute for Psychological Research and Psychotherapy trained “doctor psychologists” for psychotherapeutic labor. Psychologists found new professional perspectives not limited to the academic field; at

the same time, people teaching in universities had to show their loyalty to the racist ideology then dominating the country.

Likewise, many psychologists in the United States worked for the U.S. army, doing personnel selection, training, and psychotherapy. Limited but important research was also carried out on topics like morals, propaganda, and psychological warfare. Well-known researchers such as R. M. Yerkes (1876–1956) and E. G. Boring (1886–1968), among others, made great contributions to that effort; more than a thousand professionals worked full time to face the emergency. During that time, a new test (the Army General Classification Test) was administered to some 12 million soldiers. Its results favored an in-depth study on aptitudes and abilities.

The war also brought to the fore new problems and research topics for psychologists. Studies on visual perception in flight situations fostered new research in ecological theory like that carried out by James J. Gibson (1904–1979); new techniques for radar detection systems paved the way for a new psychophysics, based on signal detection and decision theory; vigilance and task monotony induced new research on stimulus deprivation and attention processing; race prejudice and antisemitism stimulated research on authoritarian personality by Theodor Adorno (1903–1969) and colleagues; and information theory, developed by Claude Shannon (1916–2001), and cybernetics, by Norbert Wiener (1894–1964), were theoretical advances born from practical needs that soon induced new developments in psychological theory as well as in the world of automation; post-traumatic stress disorders and the demand for help from clinical psychologists stimulated research in this field emphasizing the relationship between organic (somatic) reactions and social experiences. War tied together theory and practice, after all.

6. THEORY AND PRACTICE: THE INFLUENCE OF THE ERA OF SCHOOLS

Theoretical psychology experienced in the first half of the 20th century an extraordinary diversification of its viewpoints. That period has been frequently called the era of schools. Some viewpoints became largely dominant, and conflicts between them arose both in theoretical and practical questions. Behaviorism, Gestalt,

psychoanalysis, and the humanistic approach were among the most influential perspectives in the United States; in the European countries, on the other hand, functionalism and factorialism became very influential. In certain cases, a special doctrine was dominant—as is the case of the Marxist-based Soviet psychology that monopolized Russia under the Soviet regime, or the Piagetian school that influenced European child and school psychology in the middle of the century. These schools of thought are briefly described in the following sections.

1. Behaviorism, created by John B. Watson (1878–1958), made behavior the proper object of study for psychologists, while excluding mind and consciousness as “subjective non-public entities” and, as such, unsuitable for science. Built upon an S-R (stimulus-response) paradigm, theory was conceived of as a guide for exerting technological control over behavior. Since its early days, behaviorism advocated significant applied research. Watson himself wrote a book on child training that was largely influential among U.S. families in the 1930s; he was also for many years a practitioner of commercial and advertising techniques.

Predicting and changing behavior became an essential function of psychologists; the practical value of such control gave birth to an entire field, “behavior modification,” that applied the laws of learning and motivation to changing people’s behavior. Pioneering work was carried out by one of Watson’s students, Mary Cover Jones, who, based on Watson’s ideas of conditioning, devised a successful treatment of a phobia in a child.

Behavior modification appears to be a case of a multiple discoveries that took place in the early 1950s. Burrus F. Skinner (1904–1990) in the United States, Joseph Wolpe (1915–1997) in South Africa, and Hans J. Eysenck (1916–1997) in Great Britain all had the same idea of conceiving mental disorders as learned (maladaptive) behaviors, subject to change for the better (re-learning) under adequate manipulation of effective variables. The new approach rapidly spread to the Western countries. In the United States, a large group of researchers oriented themselves toward the applied behavior analysis, devising interventions on social problems according to its principles. In Latin America, where psychoanalysis largely dominated in the 1940s and 1950s, behavioral techniques appeared as a greatly desired alternative in clinical practice. Under the influence of some U.S. specialists, the movement began to consolidate in the 1960s in Brazil, Mexico, Chile,

Venezuela, and Colombia, and the Latin-American Association for the Behavior Analysis and Modification (ALAMOC) was founded in 1975. A similar phenomenon took place in European countries, where these techniques proliferated in the 1960s, and the European Association for Behavior Therapy was created in 1970. Adepts to these principles were oriented toward practice or toward theoretical questions. Techniques for handling stimuli and motives have been devised and applied to nearly every human situation—schools, family, industries, therapies, and so on. While very effective in multiple settings, behaviorism has also been criticized for its appearance of merely dealing with symptoms, with total neglect for the causes of behavior. After the emergence of the cognitive paradigm, a combined approach—the cognitive behavior modification—was generated; it focused on cognitive control and influence upon behavior as a means of rebuilding a healthy state.

2. Psychoanalysis, created by Austrian psychiatrist Sigmund Freud (1856–1939), has turned into one of the biggest intellectual and social constructions of the 20th century, influencing all subject matters related to humankind, including religion, society, art, sex, and morality. In its applied version, it has largely influenced the clinical approaches to the treatment of mental and behavioral disorders. Two points should be mentioned here: (1) as a form of psychotherapy, psychoanalysis has a few core concepts—the unconscious determination of conscious behavior, the presence of dynamic conflicts between instinctual forces and other social and moral repressive ones, etc.—that have adopted an endless variety of forms maintained by hundreds of schools and groups, but that have raised strong doubts about the therapeutic efficacy and the scientific status of their basic assumptions. In many cases, hermeneutic and philosophical nature of psychoanalysis has been acknowledged, while leaving in suspense its scientific claims. And (2), most of its practitioners have received medical training and licenses, and their techniques are viewed as an essential part of contemporary psychiatry.

3. Gestalt psychology, initiated in Germany in 1912 under the inspiration of German psychologist Max Wertheimer (1886–1943), claimed that all behavior always follows a mental structure in which all stimuli coming from the outside world and from the subject's body form a mental whole that determines open responses to situations. Although it is mainly a theoretical construction, a large number of applications were devised by one of its leading figures, K. Lewin,

to solve problems in school and organizational settings. Gestalt theorists put great emphasis on mental variables such as perception, expectations, values, need for achievement, leadership, and group pressure that proved useful in predicting and explaining behavior in different types of social situations. Important developments on group processes were carried out by former Lewin students Dorwin Cartwright, Leo Festinger, and Stanley Schachter, among others; they received much attention in social and clinical settings.

4. Humanistic psychology (sometimes called “the third force”) is a reaction to the reductionism imposed by behaviorism and to the irrationality and unconsciousness emphasized by psychoanalysis. It stresses meaning and values as essential determinants of human behavior. Self-fulfillment, life goals, and personal growth are some of the concepts that are at the core of this movement. Born in the United States, it has been largely influenced by European philosophies such as M. Heidegger and J. P. Sartre's existentialism and E. Husserl's phenomenology. Abraham Maslow (1908–1970), Carl Rogers (1902–1987), and Charlotte Bühler (1883–1974) are some of the names associated with it; all of them significantly contributed to psychotherapy, and their insights were taken as bases for a technique of personal development that proved fruitful in the world of management and human relations. Close to these views are some other clinical approaches that also emphasize the role of subjective feelings, cognition, and emotions; these processes deeply influence the subject's mind in its interactions with the world. A. T. Beck's cognitive therapy, A. Ellis's rational emotive therapy, and F. Perls's Gestalt therapy, among others, have widened the spectrum of ways to intervene in psychopathological problems.

5. While these schools largely dominated the U.S. scene, different lines of thought were prevalent in Europe, such as functionalism, a movement with American roots (e.g., William James, John Dewey) but with robust development in Great Britain, Switzerland, and other Western countries. Functionalism stressed the relevance of the “what for” considerations when applied to psychological acts and aptitudes, and mainly focused on life's needs and demands. Industrial psychologist Charles S. Myers (1873–1947) exerted great influence on some of his students; among them was Sir Frederic Bartlett (1886–1969), who was interested in real life problems, and who did significant work on memory and thinking inside a functionalist framework. Swiss functionalist Edouard Claparède applied these views to child and educational psychology, and one of

his collaborators, the Swiss theorist Jean Piaget (1896–1980), deepened those insights and built a major system in epistemology and knowledge, offering a solid view on the biological bases of cognitive development—from reflex action to logical operations—and its sequential stages. As is well known, Piagetian ideas have greatly influenced education in many countries.

6. Last but not least, the Marxian philosophy (historical materialism) that inspired the Soviet regime in Russia (the Soviet Union between 1917 and 1990) also was the basis for a worldview embracing humankind and society that influenced all dimensions of knowledge. Psychology was no exception.

Political theorists such as Karl Marx (1818–1883) and Vladimir Lenin (1870–1924) were considered conceptual leaders in every scientific and cultural field. Human life, guided by the conscious mind, was organized through a process of active interactions with the world, but human actions received their ultimate meaning from the socioeconomic structure in which people lived. Consciousness ultimately depended on the production system dominating society. As a consequence, it stressed the unity between consciousness and activity, and, furthermore, between theory and practice.

Lenin, while denouncing “bourgeois exploitation” in Taylorism and other Western labor theories, gave priority to those studies related to work. In 1927, the All-Russia Psychotechnical Society was established, and in 1931 the 7th International Psychotechnical Conference took place in Moscow. Well-known specialists in educational matters, such as Nadezhda Krupskaya (1869–1939), Isaak N. Spielrein (1891–1936?), and Lev Vygotsky (1896–1934), tried to synthesize the Marxist view with recent Western developments; all of them suffered from prosecution in the days of Jozef Stalin’s personality cult in the late 1930s, and for nearly two decades their ideas and works were banned and silenced. During this time, psychology focused on practical (social) activity as causing mental organization through brain structures. Marxian views seemed to fit well with Pavlovian psychophysiology, and theoretical and applied questions became more closely connected. The significant growth of Soviet psychology since the 1950s was based on the cooperation of these two lines of thought. Alexei Leontiev’s (1903–1979) idea of activity, largely based on Vygotskian analyses, spread out to other fields, such as Alexander Luria’s (1902–1977) defectology and neuropsychology. The world race for space supremacy, that in the 1960s involved the United States and the USSR, stimulated man–machine

research, with outstanding contributions such as Boris Lomov’s (1927–1989) industrial psychology and Vladimir Zinchenko’s ergonomics, among others.

The end of the Soviet regime in 1990 brought with it the fall of its previous political and philosophical framework, and a new freedom for thought emerged, in which many Western schools and tendencies then flourished.

7. APPLIED PSYCHOLOGY IN THE SECOND HALF OF THE 20TH CENTURY

In the decades that followed World War II, enormous growth took place in psychology that covered most of the facets of human activity and work, in many cases producing interdisciplinary research. Theory also experienced significant changes that have been frequently interpreted as the rise of a new, cognitive paradigm. According to this paradigm, humans should be viewed as information-processing systems, and consciousness, cognitions, affections, and emotions reflect the richness and complexity of such a system. Substantial inspiration for the new paradigm came from applied areas. Swiftly developing computer technology opened new ways to the study of behavior based on the computer model (metaphor) of the brain.

Structure and qualities of behavior referred both to organism and to environment, whose complex interactions had to be analyzed into terms of plans, projects, expectations, and values. Plans and structure of the human operator parallel the software–hardware dimensions of a computer. A vast program launched to examine analogies and possibilities of the new metaphor for psychological research brought up new lines of thought: behavior simulation by computers, artificial intelligence, computer-assisted learning, expert programs of various specialized tasks (e.g., medical diagnosis), and mental activity viewed as the operation of an information-processing system (IPS). Such a system should be viewed as an “open system,” in which the operator unit and its environment exchange information signals, energy, materials, and causative interactions. The entire complex (P-E) integrates both person (P) and environment (E) in continuous interaction.

A cursory review of some of the more significant developments that took place in this period are presented here, without any pretension of exhaustiveness.

7.1. Ecological Psychology

The P-E model, as described above, is at the core of an ecological approach to psychology. The environment is mainly viewed in its material aspect, and human behavior is then examined in the light of the physical determinants of its medium and their influences and constraints upon the activity of the subject. Roger Barker (1968), influenced by Lewin's ideas, conceived of the field as a study of objective contexts influencing behavior, a hypothesis full of consequences for other disciplines such as urban and home designs, geriatrics, and child care, among others. At present, environmental psychology, defined as a study of the relationships between people and their physical environments, examines a large range of questions, from coping with disaster or crime and environment to developing positive attitudes toward nature and protecting nature against human destructiveness.

7.2. Traffic Safety Psychology

Closely connected with the preceding, psychology has developed conceptual and technical approaches to behavior of drivers and pedestrians in traffic. Many psychological functions (perceptual, motor, emotions, risk-seeking, and so on) have a strong influence in determining traffic accidents. Although this field is as old as applied research, recent developments in motivation, risky decisions, and accident-prone personality have added new dimensions to it. In several countries, psychologists are now working on the screening of potentially dangerous drivers and in the design of public campaigns for the promotion of safe attitudes in driving situations.

7.3. Organizational Psychology

Organizations are the most frequent social environment for women and men in developed societies. Industries, educative and health institutions, and political organizations are social structures imposing facilities and constraints on their members, which in turn activate their psychological abilities to adapt and to achieve their goals inside those structures. As a matter of fact, this denomination has nearly come to represent what industrial psychology was covering some decades ago (e.g., personnel selection, human relations), stressing its structural approach to these types of problems.

Some significant lines of thought on this field that developed in the early decades of the century were

noted earlier. In the second half of the century, organizational psychology has grown, and in some cases it has dominated the sociotechnological approach. Other groups stressed the relevance of humanistic aspects and of combining the needs of both the individual and the organization, trying to arrive at a situation of balanced forces contributing to the whole structure and viewing organizational behavior as based on bounded rationality.

Organizations operate in a changing world, and need to maintain their adjustment to the environment through changes taking place inside and outside their own boundaries. A vast technology has been developed to provide them with techniques and means for their development. Organizations, through changes in structure, culture, competence, and processes, aim at improving their problem solving and conflict resolution and their own climate and efficiency. Far from the old lines of rationalist scientific management, the organizational development, rooted in the action research theory designed by K. Lewin in the 1940s, operates with psychological variables through micro and macro techniques, including program assessment and redesigning of structures; its topics have become central in the research field.

Special cases of organizations are armies, churches, national administrations, and so on. These large social structures generate enough questions to become the particular object of psychological specialties covering them. The use of telematics and new information and communication technologies applied to organizations have also raised new demands on workers' formation and capacities, an interdisciplinary field that many psychologists are now entering.

Other fields, such as the large one of sport behavior or military psychology, can also be mentioned in this regard. In the former, psychologists have proved to be efficient technicians in dealing with variables that determine high quality sports performances (e.g., achievement motivation, emotional and attention control). The latter includes the study of specific organizations (armies) that were among the first clients of psychology during wartime. In this field, there is clear overlap with similar areas such as engineering psychology and equipment design and ergonomics. In recent times, emphasis has turned to relevant personality dimensions like authoritarianism, leadership, conformity, and prejudice that set the basis for social conflicts. During the so-called Cold War between Western democracies and the Soviet world, some topics also gained relevance, such as the "war of nerves," national morals, and conflict simulation.

In their approach to such complex problems, some theorists have explored the multiplicity of determinants that influence human action, trying to understand the cues and factors that operate in effective choices and decisions; such insights have enlarged the well-known Lewinian “action theory,” which tries to strengthen theory and practice bonds.

7.4. Health Psychology

This branch, which is closely related to the clinical field, has rapidly developed since the 1980s. It concentrates on all psychological questions related to health maintenance, illness prevention, and patient–practitioner interactions in treating diseases. This specialty deals not only with problems of the individual, but also with others of an organizational nature linked to health care systems and health policy. Prevention, adherence to doctor’s instructions, and people’s healthy life habits are now among the goals of psychologists working in this field.

Connected to this field is contemporary psychogerontology, a specialty that emerged from studies on lifespan developmental psychology and turned into one of the most active areas of research and social priority. In many Western countries, the elderly occupy one of the largest segment of the population, and retirement arrives at an age still able for productive activity. Leisure, social deprivation, loss of power and influence, depressive moods, and psychological losses became relevant targets for psychological intervention.

A special chapter has recently developed and is receiving great attention from society: stress research. Growing evidence shows a causal influence of psychological factors upon the immune system of organisms. Stress research largely deals with the relationship between psychological and organic variables and stressing experiences. The style of coping with negative effects seems not unrelated to serious diseases such as cancer, heart attacks, and AIDS, and with those organic processes connected with the end of such processes. For instance, much literature has been produced on A personality types, considered by some researchers to be risk factors of many serious diseases, mediating some changes in the bodily immune system.

It is also the important and complex role assumed by psychologists working on drug-dependence assistance, one of the most serious problems in contemporary society. Abuse and addiction therapies demand both physical and psychological attention, and patients require social support and advice for changing their

attitudes toward dangerous substances and to adhere to treatment.

Finally, the clinical field is also neuropsychology. This is one of the areas that has experienced extraordinary developments in recent times. It is usually described as the study of the brain machinery underlying psychological functions in patients suffering from brain damage, carried out for practical purposes of rehabilitation. Its conceptual roots can be found in the works of Alexander R. Luria (1902–1977) and Donald O. Hebb (1904–1985). Technical advances in brain diagnosis through direct imagery (positron-emission tomography and the like) have combined with systematic testing of behavioral effects of damage through batteries such as the Halstead-Reitan Neuropsychological test battery, the Luria/Christensen test battery, and many others. Cognitive and emotional deficits and perturbations, while significant for the clinician, are also relevant for the general theorist, who tries to combine the experimental cognitive approach with new neuropsychological information in order to deepen the knowledge on the mind–brain relationship. This is clearly an interdisciplinary field that needs the joint labor of neurologists, psychologists, and other scientists.

7.5. Law Psychology

Since its very beginning, applied psychology has been charged with the task of establishing the degree of credibility of eyewitness testimonies presented in court. Karl Marbe (1869–1953) studied child charges of sexual abuse, and, interested in the topic, wrote a pioneering handbook on forensic psychology. U.S. clinics for offenders’ rehabilitation created by Healey have been mentioned previously. Since then, questions of deception in testimonies, jury selection, legal evidence in court, deterrence from crime, rehabilitation of offenders, and assessment of convict personalities, among others, are under scrutiny and discussion. In the United States, an important court sentence that accepted the psychologist as an expert on mental states of defendants in court strongly promoted the specialty.

7.6. Other Specialties

Human behavior offers endless dimensions and aspects that may be considered by the psychologist. Apart from those mentioned above, other specialties that are now flourishing in developed countries include community

psychology, economic psychology, and political psychology. Psychological care is increasingly a right for people living in developed countries. These provide their citizens with a welfare system that offers security and support when individuals and groups have to cope with stressful events, which frequently include psychological connotations. Problems of family life, such as abuse and neglect of children and women, victimology, and crime and drug prevention, require planning that should include psychological assessment and measures in order to be effective.

Modern societies rely on a large economic system, that through tax policies and contributions supports the major needs of administrative and social services that are in charge of the state. While societies for centuries employed constrictive measures, more attractive ones have been introduced by democratic regimes, which try to persuade people to act lawfully by spontaneous motivation and reflection instead of by compulsion. Individuals who are forced to participate in supporting the state budget, and who are active members of the market system, are basically guided by their interests, beliefs, and fear of penal enforcement. Techniques employed to increase efficiency and motivation in business in the early days of applied psychology by W. D. Scott and other pioneers have recently been transferred and adapted to social policy by governments and social agencies. Economic psychology today covers a wide variety of topics, including behavior in market settings, taxes, investing, risk assumption, bargaining, publicity, and consumer behaviors.

8. GENERAL TRENDS

Most psychological professionals work in the field of applied psychology, and the field produces a large portion of the research in psychology. While it is usual to think that it deals with the mere application of some existing principles to certain circumstances, practical intervention frequently gives birth to new concepts and techniques in a continuous interaction among proposed goals, effective applications, and evaluations.

Applied psychology systematically uses evaluation techniques in order to determine the initial problem, to measure the changes produced in it by psychological intervention, and to assess the resulting costs and benefits. According to Gilgen and Gilgen (1987), "Whatever the country... it seems clear that support for academic research psychology is largely dependent

on how successful psychologists are at demonstrating their usefulness to society."

Modern technological devices (e.g., complex computer-assisted simulation, modeling and data analyses) have been introduced in all social organizations and working groups, and psychologists have assumed the demands created by that technology, and have incorporated them in their own practice. This has resulted in the task of training and recycling specialists as well as a redesign of groups in view of the new goals to be reached.

In every field, interventions have generated the creation of micro-level models that try to fit with concrete data, and whose roots on a general view of mind and behavior are loose and flexible. Assessment runs parallel with intervention, in order to introduce the needed corrections to the planned operation.

Interdisciplinarity has become dominant, and psychologists are approaching the views and methods of those groups with which they have to cooperate. At the present, tremendous development in fields such as genetics, bioengineering, and computer sciences demand further and deeper interaction with psychology, for both theoretical and practical reasons. The new situation demands specialization and competence in many scientific disciplines, but at the same time, all progress will depend upon the ability to connect these new ideas to the questions raised by the understanding of the human mind.

In recent decades, psychologists involved in professional practice clearly outnumber those oriented toward academic research. Their relative weight has turned upside-down the situation that existed in the early days. In addition to the debates on scientific topics, new questions are demanding solutions from professionals: the implementation of adequate training (in concepts and skills) and a qualifications for licensing in different specialties; the adaptation of some minimal technical standards to the peculiarities and idiosyncrasies of the different societies and cultures in which psychology is now applied; communication between academics and the practical world, benefiting from recent findings; the creation of mechanisms for accumulating and disseminating the growing body of knowledge in useful and standardized ways; the updating of ethical codes in view of the multiplicity of communication systems and computational technologies; and the increasing penetration of psychology in different aspects and dimensions of modern life.

Training for a professional career in psychology increasingly requires a specialization in concrete techniques that run the gamut of related topics. In many cases, this is deferred until the postgraduate level.

International cooperation provides additional possibilities for effective work. Associations such as the International Association of Applied Psychology, the European Federation of Professional Psychologists (recently renamed the European Federation of Psychological Associations), and the American Psychological Association are considering the requirements to become a well-trained professional in the various branches of psychology, and the technical and conceptual requirements required by the growing complex interactions between this professional and its clients.

GLOSSARY

congruence The degree of fit between personality type and work environment.

consistency The degree of relatedness between personality types or between environmental models.

differentiation The degree to which a person or environment is well defined.

identity The clarity and stability of a person's interests, abilities, and goals.

type A cluster of personal attributes.

John Holland's theory of personality types and model environments is a theory of vocational psychology, personality, and person–environment psychology. Holland's theory, as viewed by Helson and Mitchell, is tough, practical, and useful. The theory is operational, and there is much data to support it. In essence, the theory suggests that behavior is a function

of the complementary match between an individual's personality style and the psychological environment. Holland suggests that individuals enter environments because of their personalities and remain in those environments because of the reinforcements and satisfactions obtained through interpersonal interactions in the environments.

Holland's theory assumes that behavior is a function of personality and social environment. The theory emphasizes interests and personality since to Holland the choice of an occupation is an expression of personality; thus, interest inventories are personality inventories. The environmental component of the theory is linked to the notion that people in a particular environment tend to have similar personalities and histories of personal development. Because people in a given environment have similar personalities, Holland believes they tend to cope in similar ways. In general, Holland holds that complementary person–environment interactions are reinforcing and satisfying and contribute to job stability, work quality, and psychological well-being.

1. THE PERSONALITY TYPES

Holland attempts to explain behavior by using a few well-defined ideas. These assumptions of his theory

tend to be fairly practical, straightforward, and operational in terms of data-collection procedures. The first of these assumptions is that people learn to be one or more personality types. A type is defined as a cluster of personal attributes that may be used to assess the person. Holland's six personality types are described as follows:

1. The realistic (R) type likes realistic jobs such as automobile mechanic, farmer, or electrician. R's have mechanical abilities and tend to be conforming, honest, materialistic, natural, persistent, practical, modest, and stable.

2. The investigative (I) type likes investigative jobs such as chemist, physicist, biologist, or geologist. I's have mathematical and scientific ability and are described as analytical, independent, intellectual, introverted, methodological, and rational.

3. The artistic (A) type likes artistic jobs such as musician, writer, or actor. A's have writing, music, and/or artistic abilities and are described as complicated, emotional, expressive, imaginative, impulsive, nonconforming, and original.

4. The social (S) type likes social jobs such as teacher, counseling psychologist, clinical psychologist, or speech therapist. S's have social skills and are described as cooperative, friendly, helpful, insightful, responsible, sociable, and understanding.

5. The enterprising (E) type likes enterprising jobs such as salesperson, manager, or business executive. E's have leadership and verbal abilities and are described as ambitious, domineering, pleasure seeking, self-confident, and sociable.

6. The conventional (C) type likes conventional jobs such as bookkeeper, banker, or tax expert. C's have clerical and arithmetic ability and are described as conforming, conscientious, orderly, persistent, practical, and self-controlled.

A person's resemblance to each of the personality types is assessed by the use of the Vocational Preference Inventory, the Self-Directed Search, and the Strong Interest Inventory. All of these inventories are objective in nature and collect interval kinds of data that may be used in a variety of research settings. Much of the research on Holland's theory has used one of these instruments in a field research setting.

2. THE MODEL ENVIRONMENTS

A second idea used by Holland to explain behavior is that environments in which people live and work may be

characterized by their resemblance to one or more model environments. Holland suggests six model environments corresponding to the six personality types and believes that people tend to move toward environments congruent with their personality types: Realistic types tend to move toward realistic environments, enterprising types tend to move toward enterprising environments, and so forth. To assess environments, Holland and Astin developed the Environmental Assessment Technique. This assessment technique simply makes a count or a census of the number of different personality types existing or interacting in a given environment. The personality type occurring most frequently in a given environment is thought to be dominant in the environment and to have a psychological influence in that specific environment. In summary, Holland defined the environment psychologically according to the people who were actually interacting in it, or, as he would say, people define the environment. Thus, although the environment is determined by a count, the influence is thought to be psychological in nature.

3. PERSON-ENVIRONMENT CONGRUENCE

A third idea used by Holland is that person-environment congruence tends to be associated with satisfaction, productivity, personal stability, vocational stability, and well-being. The thought is that, for example, a realistic type in a realistic environment would tend to be more productive, more stable, more vocationally satisfied, and psychologically healthier. Complementary person-environment links are reinforcing and satisfying. Uncomplementary or incongruent person-environment interactions are punishing and contribute to change. This is not to say that congruence is good and incongruence is bad but suggests that a state of incongruence may be part of the learning and development process. Thus, there seems to be periods of incongruence in an individual's life span that need to be worked through in order to pursue personal and vocational goals and well-being.

Based on his six personality-environment types, Holland further suggests that the relations among types, among environments, and between types and environments tend to be hexagonal in nature (Fig. 1). Types and environments that are in closest proximity in Fig. 1 are more psychologically related. Types and environments that are further removed from one another are more psychologically different. For example, an artistic person

FIGURE 1 Hexagonal model for interpreting inter- and intra-class relationships. Correlations are between summary scale scores for females ($n = 1600$) in the 1994 normative sample. Reproduced by special permission of the publisher, from the *Self-Directed Search Technical Manual* by John L. Holland, Ph.D. Copyright 1985, 1987, 1994, by Psychological Assessment Resources, Inc. Further reproduction is prohibited without permission of PAR, Inc.

in an artistic environment is in a more congruent situation than an artistic person in a social environment. An artistic person in a conventional environment is in the most incongruent situation possible. In this way, the hexagonal model may be used to obtain and estimate different degrees or levels of person–environment congruence. The hexagonal model for the six personality types and environments has also been used to identify individuals in vocational or personal conflicts, compare different tests and inventories, organize occupational environments, and guide the layout of the Strong Interest Inventory.

4. CONSISTENCY, DIFFERENTIATION, AND IDENTITY

The previous assumptions, as noted by Holland, are extended by several secondary assumptions that may be applied to both persons and environments. The secondary assumptions include consistency, differentiation, and identity. Consistency is the degree of relatedness between personality types or between environmental models, as noted previously. Some pairs of types and

environments are more closely related than others. Differentiation refers to the degree to which a person or an environment is well defined. For example, a person closely resembling a single type is clearly differentiated (well defined). Identity is primarily concerned with estimating the clarity and stability of a person's vocational identity. High identity suggests a limited set of consistent and explicit goals.

5. RESEARCH

In general, research testing the theory (more than 500 studies) reported by Holland and Walsh and Holland clearly indicates that individuals tend to choose and enter environments consistent with their personality types. For example, enterprising types tend to enter and remain in enterprising kinds of environments. Furthermore, evidence suggests that congruent person–environment interactions are conducive to personal and vocational stability and satisfaction and, to a lesser extent, actual achievement. Specifically, the pattern of findings suggests to some extent that person–environment congruence is related to measures of job satisfaction and stability, job involvement, work quality, productivity, and well-being but not necessarily to measures of decision making, sociability, and problem-solving ability. In addition, meaningful data about adolescents and adults imply that person–environment congruence and job satisfaction may increase with age. Thus, it seems that people in congruent work situations will probably change little since their expression of interests, abilities, and personality is rewarded. Persons in incongruent work environments will probably change the most since they tend to be ignored and punished. This work, then, indicates that students and workers who tend to be functioning in environments congruent with their personal characteristics are probably psychologically healthier and more satisfied than people in incongruent situations.

6. SUMMARY

In Holland's theory, behavior is viewed as a function of person–environment interactions, and from this perspective person–environment congruence becomes a very important concept. Thus, Holland suggests, and the data tend to support, the notion that people in environments congruent with their personality types tend to be psychologically healthier, more satisfied,

and more productive than people in incongruent environments. In other words, person–environment congruence tends to facilitate personal growth, self-acceptance, and life purpose.

GLOSSARY

collaboration Working together toward a common goal or set of goals.

educators General education instructors, special education instructors, teaching aides, classroom volunteers, administrators, support staff, school psychologists, and any other persons within a school setting who contribute to the education of students within that environment.

parent The adult who is responsible for the care and well-being of the child (e.g., biological parent, caregiver, legal guardian).

partnership A coequal interdependent relationship that is established and developed over time, with the primary purpose of working together over an extended period of time toward a mutually determined set of goals and objectives.

system A particular environment with an emphasis on specific components of the environment, including people, physical objects, placement of people and objects, physical arrangement, and interactions among these components (e.g., home system; school system).

Home–school collaboration is a reciprocal dynamic process that occurs between at least one parent

(or guardian) and at least one individual within the school system (e.g., educators, administrators, psychologists) who share in decision making regarding mutually determined goals and solutions related to a student for whom all parties share interest and responsibility. Home–school collaboration may occur at three levels: system (i.e., between the home and school settings), school/classroom, and individual. With all participants (e.g., parents, educators) offering their unique roles and contributions, the collaboration process is guided by the primary emphasis on mutually determined academic and behavioral goals serving as the standard for progress toward overall outcomes.

1. HOME–SCHOOL COLLABORATION DEFINED

A common definition of the term “collaboration” is to work together toward a common goal or set of goals. As applied to relationships among parents, educators, and the systems in which they operate, the term has a rich meaning. Driven by academic, cultural, and political influences, the term “home–school collaboration” is a reciprocal dynamic process that occurs among systems (e.g., families, communities, partnerships), schools/classrooms, and/or individuals (e.g., parents, educators, administrators, psychologists) who share in decision making toward common goals and solutions related to students. Inherent in this definition is the notion that parents and educators involved in collaboration pool

their resources to create a cooperative interdependent relationship. For example, parents offer what they know about their children's academic and behavioral strengths and limitations in the home and other non-school settings, whereas teachers offer their knowledge of students' relative strengths and limitations in the classroom and other educational settings. The collaboration process is guided by a primary emphasis on specific cooperatively predetermined outcomes for students, with mutually established academic and behavioral goals.

2. BACKGROUND AND HISTORY OF HOME-SCHOOL COLLABORATION

2.1. Traditional Family Involvement in Education

During colonial times and throughout the early 1900s, parents had very little interaction with the educational system. In 1995, Welch and Sheridan noted that during that time in educational history, children were sent to school to learn academic skills, and parents were seen as responsible for educating their children regarding moral principles in the home setting. Parents entrusted the education of their children to school personnel and expressed little interest in participating in their children's education. These expectations and roles resulted in educators viewing the school as their territory, and parents who tried to become an active part of the school setting were viewed as intrusive. In response to this situation, the National Parent-Teacher Association (PTA) was founded on February 17, 1897, in Washington, D.C., with the goal of having a PTA in every school. Today, there are more than 6.5 million members of the National PTA, making it the largest child advocacy organization in the United States.

Welch and Sheridan reported that parents continued to assume a relatively "hands-off" approach to education until the late 1960s and early 1970s, when economic and political factors induced parents to change their views regarding their involvement in education. Fueled by economic situations that forced society to reconsider how money was being spent on education, as well as by a political climate in which legislation was identifying and defining specific roles for parents in their children's education, parents became more active in education. The National PTA continued to be a strong advocacy voice for parent involvement in education. In 1994, the federal government enacted "Goals 2000," and in 1997,

the National PTA released its National Standards for Parent/Family Involvement Programs. However, although parents advocated for participation in education, the educational system was not prepared for this type of parental involvement. Despite the efforts of the National PTA, when parents participated in education, their involvement was limited in both scope and depth. Unfortunately, parental involvement in education has continued to be limited. Many parents feel as though they are outsiders in their children's school. Merely opening the doors for parents to participate at an entry level is not enough. Epstein has written extensively about the need to develop family-school-community partnerships to enhance student performance. These partnerships reflect an important process that includes all families. The next subsection describes a philosophy to guide parental involvement in education: the home-school partnership model for working with families.

2.2. Partnering With Families in Education: A Modern Approach to Collaboration

The definition of home-school collaboration provided earlier is derived in part from the characteristics of a partnership philosophy for interacting with families in education. This philosophy represents the current standard for how parents and families can be included as a member of the educational system. A partnership philosophy regarding home-school collaboration recognizes that parents are invaluable members of the educational team. Just as educators and administrators are viewed as possessing educational information and expertise, parents are viewed as experts possessing equally critical information regarding the home system. When schools adopt this attitude, they are more likely to actively pursue meaningful parental participation in education. If parents and educators adopt this philosophy, it affords parents equal status with the school regarding critical activities and decision making related to their children's education.

A primary difference between home-school collaboration and home-school partnership is that home-school collaboration implies a process related to a specific goal or set of goals that may be relatively short term (but not necessarily), whereas home-school partnership implies a long-term, ever-evolving relationship between parents and members of the school setting extending beyond time-limited problem solving and goal achievement. A partnership allows parents and educators to work together to improve the educational

system such that it is possible for them to work toward preventing future problems, meaning that all students benefit from the partnership. Another characteristic of a partnership is that individuals learn from one another and pool together expertise and skills in support of a common focus, that is, improved education for all students. Goals and objectives remain at the heart of interactions between parents and educators as they form educational partnerships; however, with partnerships, these goals are likely to be more long term and more encompassing (e.g., creating a safe and diverse atmosphere that addresses the needs of all students). In addition, the quality of the partnership will depend heavily on the type of communication that occurs between parents and educators. Maintaining open communication is likely to make a meaningful contribution to a healthy balanced partnership.

When schools invest in building partnerships by seeking meaningful ways in which to involve parents, many can be considerably enriched. For example, instead of a traditional one-directional approach to parent-teacher conferences, a teacher might approach this event by asking for parental input regarding behavior patterns across nonschool settings and ask for ideas regarding potential solutions. Furthermore, if parents and teachers interact regularly outside of the designated parent-teacher conference time (e.g., through home-school notes, at school activities), conference time might be used more constructively to address goals and solutions that require face-to-face communication. A partnership is not formed and developed during one interaction or activity; rather, it is established and cultivated over time through multiple interactions during which parents and educators come to embrace the attitude and belief that meaningful relationships form the foundation of in-depth, long-term collaboration.

2.3. Potential Benefits of Home-School Partnerships

There are many potential benefits of home-school partnership. For example, collaboration through partnership can enhance communication between parents and educators. In addition, home-school relationships provide an opportunity for parents and educators to better understand what occurs across settings, and this in turn allows for a greater overall understanding of children's backgrounds and current levels of functioning. Establishing a home-school partnership also allows for "joint ownership" of problems and concerns

as well as joint commitment toward educational and behavioral goals for students. Parents and teachers may come to feel supported by each other as they work toward mutually determined goals. Working together also tends to improve relationships between teachers and parents as they begin to understand each other's perceptions regarding children's behavior across settings. In addition to these potential benefits for parents and educators, students may benefit from the process. For example, they may develop better attitudes toward school, improve their performance both in and out of the classroom (e.g., demonstrate higher rates of work completion at school while at the same time demonstrating an increase in homework completion), get along better with teachers and other school-based individuals, and improve specific academic skills (e.g., reading fluency). As with any relationship, the benefits of a partnership might not be immediate, and it will likely take time for all participants to yield such benefits.

3. FACTORS INFLUENCING HOME-SCHOOL COLLABORATION

The educational system in the United States has been heavily influenced by a systems-based approach to understanding and intervening with regard to the educational process. This approach is grounded in ecological theory. Based on the work of Bronfenbrenner, ecological theory is concerned with the interaction between an individual and various contextual systems: the microsystem, mesosystem, exosystem, and macrosystem. The microsystem is concerned with the individual and his or her immediate environment (e.g., a child interacting in a particular classroom), the mesosystem involves the interrelation between major systems in the individual's life (e.g., between home and school), the exosystem is concerned with environments not directly related to the individual but still influencing his or her life (e.g., a parent's workplace), and the macrosystem includes overall cultural or subcultural patterns and influences (e.g., policies, federal and state legislation, national and global economic factors). This framework illustrates how systems influence, and are influenced by, one another, stressing that individuals do not exist in isolation; rather, each individual's interactions across and within systems are multifaceted and multidetermined over time. Home-school collaboration is influenced by multiple factors, including (but not limited to) educational legislation, family characteristics,

school-based variables, and community-related influences. Factors across these systems are not mutually exclusive and are discussed in the following subsections.

3.1. Educational Legislation

Education in the United States has forever been changed due to federal legislation that ensures the right to a free and appropriate public education for all individuals, mandates the individualization of services for students with special needs, incorporates the provision of educational services in the least restrictive environment, provides guidelines for educational planning and programming, specifies procedures for identifying students with special needs, highlights roles and responsibilities for local educational agencies, and mandates specific roles for parents in education. Such legislation has led parents, educators, politicians, and others concerned with education to consider how best to foster relationships between parents and educators. Furthermore, it has changed the ways in which parents are involved in their children's education. The following subsections discuss major legislative and political factors affecting how parents and educators operationalize and designate roles and responsibilities in education.

3.1.1. Individuals with Disabilities Education Act

The Individuals with Disabilities Education Act (IDEA) is the latest manifestation of the public education law called the Education for All Handicapped Children Act (EAHCA, also referred to as Public Law 94-142). A major emphasis of the 1997 reauthorization of IDEA is the inclusion of specific requirements regarding the active recruitment and participation of parents throughout the evaluation process. Specifically, school personnel are now required to (a) notify parents in advance to ensure that they will have the opportunity to attend each meeting related to their children's educational programming, (b) schedule meetings at a mutually determined time and place (even in the home if necessary and appropriate), and (c) arrange other means of including parents if they are unable to attend the meeting (e.g., teleconferencing).

In addition to ensuring that parents are able to actively participate in meetings related to their children's educational programming, IDEA mandates and outlines several parental rights and responsibilities. Specifically, parents are entitled to input during evaluation, eligibility, and placement. That is, in addition to contributing to the

pool of information that will be used during the assessment of their children and that may result in special education placement, parents are afforded an opportunity to voice their opinions and contribute to the final decisions when the teams (of which parents are key members) determine (a) eligibility (i.e., declare whether students meet the specific predetermined criteria for placement under a qualifying category of disability as defined in IDEA), (b) accommodations that will be necessary to meet students' individual needs (as determined by goals and objectives outlined in the students' team-generated individualized educational plans [IEPs]), and (c) placement (i.e., where children will receive their educational programming, e.g., resource room, general education classroom, some combination thereof).

Once students are identified and placed under the umbrella of special education and related services, they are entitled to a reevaluation at least every 3 years from their initial or latest evaluation to determine whether they continue to meet eligibility criteria for services. Parental permission for reevaluation is mandatory. Parents are also entitled to receive regular reports on their children's progress, and parents may request changes to educational programming (i.e., revisions of children's IEPs) to address any lack of progress toward annual goals. This level of parent recruitment and participation is significantly different from the hands-off approach popular until the late 1960s and early 1970s described earlier. As such, this legislation represents a powerful impetus for change with regard to parent and teacher roles throughout the educational process.

3.1.2. No Child Left Behind

"No Child Left Behind" (Public Law 107-110) is the latest manifestation of the public education law called the Elementary and Secondary Education Act (ESEA). As with IDEA, No Child Left Behind designates roles and responsibilities for parents and educators that necessitate home-school communication and cooperation. Perhaps the most salient feature of this legislation is its emphasis on providing information to parents while at the same time holding schools accountable for the quality of education they provide to all students. In addition to mandating that schools provide information to parents regarding their children's individual progress, No Child Left Behind requires states and school districts to give parents information about the relative strengths of each school. Specifically, for each school, they must provide achievement data (combining the performances of all students) broken

out by race, ethnicity, gender, English-language proficiency, migrant status, disability status, and income status. If, on receiving this information, parents believe that their children are not receiving adequate services, they may opt to place the children in better performing schools or tap additional resources such as tutoring and after-school programs.

Although there are clear benefits to educators and administrators (e.g., they are able to have detailed information about each child from which they can adapt teaching techniques, they are able to determine what does and does not work and make decisions based on the data), the emphasis of this legislation is on protecting individual students, parents, and families through providing critical information and options. This legislation provides critical information for educational partners to use in making decisions regarding how to improve the quality and fairness of the educational system. It also provides equal access to information, ensuring that no party has the upper hand. As indicated earlier, equal participation is a defining characteristic of educational partnerships. In addition, Goal 8 of the 1999 National Education Goals report concerns parental participation and states, "By the year 2000, every school will promote partnerships that will increase parental involvement and participation in promoting the social, emotional, and academic growth of children."

In addition to clauses mandating the types of information to which parents are entitled, No Child Left Behind includes clauses mandating that parents have the right and responsibility to be involved at the school, district, and state levels. Specifically, No Child Left Behind states that every school must have a written parent involvement policy developed with and approved by parents. If developed and executed properly, this policy affords parents much power in decision making and in determining educational policy at a local level. No Child Left Behind also calls for a school-parent compact, developed with and approved by parents, that describes how educators and parents will build a partnership to improve student achievement. If a partnership philosophy guides this compact, it can open to doors to multiple levels and types of home-school collaboration, expanding and evolving over time.

No Child Left Behind has resulted in an increased emphasis on site-based management. Site-based management, an approach with a long history, is concerned with decentralizing decision making by transferring authority and resources from state- and district-level offices to more localized units such as governance councils, committees, and teams located within each school

building. This transfer of authority and power to a local level affords educational partners the opportunity to consider the data generated by schools to meet mandate requirements of No Child Left Behind and to make budget- and curriculum-related decisions at an individual school level. These site-based management teams, often composed of principals, teachers, parents, and other professionals, make decisions regarding policies for the schools. This structure necessitates input from parents as decision-making team members. Similar teams exist at the district and state board levels, whereby parents are involved as active developers and monitors regarding school board functions as well as district- and statewide governing bodies.

No Child Left Behind embodies the state of the nation regarding the pivotal role that parents play in the education of their children. This level of parental involvement requires communication and collaboration between parents and school-based personnel. As with IDEA, a complete discussion of No Child Left Behind related to home-school collaboration is beyond the scope of this article. Specific components of the legislation were discussed previously as a means of describing the rights and responsibilities of parents in education as mandated by federal law. How parents respond to such roles varies considerably across individuals and is likely influenced by multiple factors, some of which are described in the next subsection.

3.2. Home- and Family-Related Factors

There are many family-related factors that may influence how a family interacts with educators. The quality of the interaction is perhaps most heavily influenced by the family's history with the school, including how the family has been received by the school in the past. For example, during past interactions with the school, was the school hierarchical, that is, acting as if the parents' presence was an intrusion? Alternatively, was the family made to feel comfortable in the school setting? Has the family been proactively involved with the school (i.e., not just when their child is in need of assistance)? Does the family have a child who has been identified as at risk for, or as an individual with, a specific disability? If so, how was the family included in the related meetings and educational programming sequence? In general, the more positive the family's past experiences, the more likely the family is to feel accepted and welcomed as an educational partner.

Other factors that can potentially influence the nature of home-school collaboration are found under the broad umbrella of family culture. As used here, culture extends beyond race and ethnicity to include factors such as acculturation level, beliefs, values, and expectations. Acculturation level is concerned with families' adjustment to the immediate culture when they are not originally from the United States or when they are new to a particular region of the country. If they come from a place where the educational system varies considerably from that in their new surroundings, it may take them time to adjust to the new local norms regarding parental involvement in education. Some families might not view their role as that of active participants and may leave the majority of decisions and actions to educators, whereas others might take an active directive role in working with educators. Family culture also includes beliefs, values, and expectations regarding education and how to interact with the school system. Stemming from cultural, economic, and political influences, these factors are multidetermined. Regardless of whether families consist of first-time parents or parents who have been involved in the educational system long enough to witness significant changes in roles for parents in education, families will require time to adjust to their new roles.

3.3. School-Related Factors

The school is a dynamic system that is composed of multiple individuals and influenced by multiple forces (e.g., culture, economic conditions, politics). When considering school-related factors that may influence the nature of home-school collaboration, it is important to take into account both variables related to individuals within the school and building-specific traits and characteristics. With regard to school personnel, these individuals acquire beliefs, values, and expectations that are influenced by a myriad of cultural, economic, and political influences. These beliefs, values, and expectations evolve over time and influence interactions with parents. In addition, just as parents' behaviors are influenced by past experiences with the school, teachers' behaviors are influenced by past experiences with parents and families.

In addition to factors related to individuals within the school, factors related to the school itself may affect the nature of home-school collaboration. Just as each family is unique in its history and culture, each school takes on an identity that makes it unique. For example, is the school public or private? The choice to send children to

a private school may represent different values and have implications for how parents and educators interact. It is also true that the size and organizational structure of the school may influence the degree to which parents feel comfortable. In general, a larger school is less personal, and this may cause parents to feel somewhat overwhelmed, resulting in less contact and collaboration with the school. The organizational structure also influences how parents interact with school personnel. For example, are teachers and administrators readily available? Are there individuals who take it on themselves to make regular contact with parents? Some school administrators may encourage teachers to maintain regular contact with parents, whereas others may value a top-down approach in which parent contact occurs through administrator-initiated actions and activities (e.g., newsletters, organized meetings). Some schools are warmer, more inclusive, and generally more family-friendly than are others. How a school "feels" to parents and students is influenced by multiple factors, and this makes pinpointing salient factors a challenge.

3.4. Community-Related Factors

Community factors that influence interactions between parents and educators are difficult to isolate given their identification across multiple systems. However, one cannot overlook the powerful influence of the community in shaping individual and systemic behaviors. Broadening the definition of cultural influences, the community system posits its own set of norms, values, and expectations regarding home-school collaboration. Behaviors, attitudes, and values transmitted from individuals in the home and school settings culminate to form a message that guides community behaviors and actions, and this in turn influences individual parents and teachers engaged in collaboration. These may be based on religious, political, or other influences and may vary over time. In addition to influencing how parents and educators interact, the community has the power to support or hinder goals and objectives identified collectively by parents and educators. For example, if parents and teachers agree that having an after-school program might help to reduce problems related to latchkey children (i.e., children who care for themselves after school), will the community embrace this plan? Does it offer supports to make the vision a reality? Do role models exist in the community to encourage more advanced collaboration? Each community has a history that guides immediate behavior, which in turn affects future interactions between various

systems and individuals. This broad-based system is pivotal and cannot be underestimated with regard to the power it has in guiding home-school interactions.

4. APPROACHES TO FOSTERING AND MAINTAINING HOME-SCHOOL COLLABORATION

4.1. Underlying Assumptions, Roles, and Responsibilities

Stemming from a myriad of cultural, economic, and political influences, the educational system has called on parents to actively participate in both the general and special education processes. Parents are increasingly becoming more actively involved in planning and decision making at the local, district, and state levels. In addition to participating in traditional activities such as parent-teacher conferences and back-to-school nights, parental involvement occurs through volunteering, planning, and serving on various committees. In addition to these responsibilities, parents of children who are identified with specific disabilities are involved in the assessment and identification of their children's specific strengths and limitations as well as in co-constructing and facilitating their children's IEPs. Parent involvement also occurs in the home and community. When parents read with their children, observe and participate in play, and support homework completion, this type of parent involvement supports the education of their children. Identifying meaningful ways in which parents can participate in their children's education is a task assigned to both parents and educators. If parents and educators engage in an educational partnership, team members will collectively identify and use specific areas of expertise that each member brings to the collaboration process as they make progress toward a mutually determined set of goals and objectives. Furthermore, if a partnership philosophy guides home-school interactions, parents and educators will seek ways in which members of the school system can support the home system.

4.2. How to Involve Families in Education

Although state and federal legislation mandates specify roles, rights, and responsibilities for parents in education, they do not prescribe specific means for establishing relationships between the home and school settings. Building a partnership is a complex process that does

not follow a "cookbook" approach; rather, fostering this relationship is a process that must be approached with care based on a specific guiding philosophy. One such philosophy was described by Christenson and Sheridan, who in 2001 maintained that partnership is not an approach to home-school interactions; rather, it is a guiding philosophy for educators and parents as they attempt to build a meaningful long-term relationship. Specifically, these authors articulated four components necessary for building meaningful partnerships: approach, attitudes, atmosphere, and actions.

Approach is a means of interacting with families that embraces the values of both the home and the school in constructing the educational experiences of children. This is concerned with educators taking an approach with families that communicates their value, unique knowledge and skills, and necessity to be involved in education. When this approach is taken, it is assumed that parents will be involved in the school curriculum and that educators will support parents so that children are successful in the home setting. Attitudes are the perceptions that families and schools have of one another. This component is concerned with identifying strengths in partners, focusing on these strengths, and assuming a joint responsibility for students' development and education. Atmosphere is the overall climate set for families and educators. Finally, the actions component involves strategies for building long-term partnerships. Actions are not merely activities that include families in a passive manner; rather, they are intended to be behaviors that, over time, actively include families in the educational process. Perhaps the most salient feature of this model is its emphasis on the processes required to build relationships over time.

5. CONCLUSION

Cultural, economic, and political influences have created an educational system that values parental involvement in the education of all students. As parents and educators have adjusted to their evolving relative roles, they have engaged in home-school collaboration as a means of working together toward achieving mutually determined educational goals for all students. As parents, educators, and other professionals (e.g., school psychologists) have searched for a guiding philosophy regarding their approach to interacting with one another, many have adopted a partnership philosophy. Partnerships are long-term relationships based on the premise that coequal power and coequal participation

are prerequisite conditions for meaningful collaborative endeavors. When this philosophy is adopted, parents and educators share resources, ideas, decision-making power, and ownership for mutually determined goals regarding both the home- and school-based educational curricula. Partnerships in education allow parents to be more intricately involved in school-based educational processes as a means of enhancing home-school collaboration. In addition, schools can assist parents with the home curriculum by participating in activities such as conjoint behavioral consultation and solution-oriented family-school collaboration. Partnerships, like all relationships, take time to form and require mutual cultivation to develop and evolve. However, they can result in both meaningful and effective educational and developmental outcomes for children and yield benefits that cannot be achieved when families and schools work in isolation. With the appropriate approach, atmosphere, attitudes, and actions, home-school partnerships can create an essential condition for optimal success.

anatomical sex and seek some degree of sex reassignment procedures, whereas others express their gender identity through external self-presentation and behavior.

Homophobia refers to antipathy toward persons who are thought to be gay, lesbian, homosexual, or deviant from gender stereotypes in ways that suggest a same-sex sexual orientation. It is a form of prejudice and may be related to harassment or violence toward persons thought to be homosexual. Most people in cultures that embody heterosexist values, such as Western societies, adopt attitudes that stigmatize same-sex sexual, erotic, or affectional attractions. These attitudes tend to be more prevalent in men than in women and tend to be more potent when focused on male same-sex attractions than on female ones. Frequently, these prejudicial attitudes are internalized and can lower the self-esteem of lesbians, bisexuals, and gay men. They are also associated with hate crimes toward lesbians and gay men, and in many states such crimes are considered violations of civil rights ordinances. Casual use of terms such as “faggot” may stigmatize youth in school and other settings and should not be tolerated any more than are other prejudicial and derogatory terms. Education with regard to civil rights, diversity in gender-related behavior, and tolerance of individual differences is important at all levels of school and may be most effective when it is modeled by peer leaders and authority figures.

GLOSSARY

heterosexual bias The belief that heterosexuality is normal and that everything associated with heterosexuality is superior to anything associated with homosexuality.

homophobia Antipathy toward persons who are thought to be gay, lesbian, homosexual, or deviant from gender stereotypes in ways that suggest a same-sex sexual orientation.

internalized homophobia The negative attitude a gay man, bisexual, or lesbian holds about himself or herself as a result of growing up and living in a society with a potent heterosexual bias.

sexual minorities Lesbians, gay men, bisexuals, and transgendered persons.

sexual prejudice The negative attitude related to sexual orientation, especially toward homosexual behavior, people who have a homosexual or bisexual orientation, and the gay, lesbian, bisexual, and transgender communities.

transgendered persons Those whose gender identity, expression, or behavior is not the same as their birth sex; some experience their gender as incongruent with their

1. HETEROSEXIST BIAS IN WESTERN CULTURE

Intolerance of behavior that differs from stereotypes of masculine and feminine roles is frequent in some societies but relatively absent in others. Likewise, social prohibitions against certain forms of private, consensual sexual behavior are enforced in many, but not all, cultures. The United States continues to reflect a puritanical set of attitudes about gender roles and sexual behavior. These attitudes may be seen clearly in views of same-sex erotic or affectional attractions or relationships, which have been described by some commentators as a threat to traditional social or moral values and family structure.

In the United States, persons who are perceived to have a same-sex sexual orientation can be fired from a job or denied housing, credit, or service in a restaurant or hotel unless the state or local government has an explicit law prohibiting such discrimination. Members of the U.S. armed forces will be expelled, despite their service records or other qualifications, if they reveal their homosexuality—the “don’t ask, don’t tell” policy. In some states, foster parents who are gay or lesbian are not allowed to adopt their foster children—or any other children—due to their homosexuality. At least one private religious university has a policy that requires students and faculty to sign a statement attesting that they are not homosexual to be allowed to study for a degree or work at the school. Likewise, other religious and secular institutions, such as the Boy Scouts of America, discriminate against homosexuals. Moreover, persons thought to be homosexual are targeted for hate crimes, including violent attacks and harassment.

In the United States during the 1960s, a growing sentiment began to emerge that homosexuals were different from heterosexuals only with regard to the sex of the persons toward whom they felt attraction and erotic love. Psychological research by Evelyn Hooker on gay men and lesbians who did not seek psychiatric treatment found no difference in psychological adjustment, and her subsequent work with the Task Force on Homosexuality of the National Institute of Mental Health began to educate professionals about the gay and lesbian subculture. At the same time, the civil rights movement, protests against the war in Vietnam, and the women’s movement were challenging traditional views of social roles and institutions. Lesbians and gay men began to see the pathological view of homosexuality as something imposed on them by outside society rather than as an inherent condition of their inner selves.

Likewise, they were beginning to identify as a subculture that shared characteristics with other minority groups.

During the late 1960s, a heterosexual psychotherapist, George Weinberg, coined the term “homophobia” to refer to individual anti-gay behaviors and attitudes. Herek, in an article titled “The Psychology of Sexual Prejudice,” maintained that Jack Nichols and Lige Clark first used the term in print in their column on gay issues in the May 23, 1969, issue of *Screw Magazine*. One month later in New York City, a police raid on a gay bar called the Stonewall Inn ignited an extended protest against the harassment of gay people and is celebrated around the world as the touchstone of the modern gay, lesbian, bisexual, and transgender movement.

Homophobia is often criticized as being too clinical or pathological a term because it implies a pathological degree of fear (phobia). However, it might apply to a person who is afraid of being looked at or touched by a homosexual or who fears letting a child be in regular contact with a lesbian or gay male teacher. It could also involve hypervigilance or preoccupation with other people’s possible homosexuality. Likewise, it might apply to the fear expressed by officers in the U.S. armed forces that having homosexuals around would damage morale because the men and women would not want to shower or be in a foxhole with a homosexual. Such irrational fears and preoccupation may indicate a true phobia about homosexuals.

The term “heterosexual bias” is frequently a more accurate term to describe the belief that heterosexuality is normal and that everything associated with heterosexuality is superior to anything associated with homosexuality. Heterosexual bias often simply ignores anyone or any situation that is not heterosexual. For example, in psychological research on dating or attraction, participants often are not even asked whether they are heterosexual because they are presumed to be so.

2. DEFINITION OF SEXUAL PREJUDICE

Recently, the term “sexual prejudice” has come to be widely adopted in research and theory. Herek, in his seminal article on the topic, defined sexual prejudice as the negative attitude related to sexual orientation, especially toward homosexual behavior, people who have a homosexual or bisexual orientation, and the gay, lesbian, bisexual, and transgender communities. He noted that sexual prejudice, as with any prejudice,

has three components in that it (a) involves evaluation or judgment (an attitude), (b) is directed at a distinct social group, and (c) involves negative feelings (e.g., dislike, hostility). Several research instruments have been designed to measure homophobia as a prejudicial attitude, using questions regarding homosexuals or lesbians and gay men included in a group of questions about attitudes toward various groups and topics.

In research studies with large random representative population samples, sexual prejudice has been found to be associated with other dogmatic attitudes, rigid views of gender roles, conservative religious views, and authoritarianism. Herek found it to be more prevalent among those persons who are older, less educated, and living in rural areas and the southern and midwestern states in the United States. Sexual prejudice was also found to be more prevalent among persons with a fundamentalist religious orientation and among those who attend religious services frequently. In some studies, persons who believe that sexual orientation is the individual's "choice" tend to be less tolerant in their attitudes toward homosexuality than do those who believe that it is beyond the individual's control. Likewise, persons who have had personal contact with lesbians or gay men tend to hold more positive attitudes than do those who have had little or no contact of this kind.

Anti-gay attitudes are, in many settings, the only socially acceptable prejudice that can be openly expressed in the media and in public statements. Fear of homosexuals is often used by right-wing organizations to boost fund-raising and is sometimes used to stigmatize a political opponent.

Society likely pays a price for the effects of sexual prejudice, including the rigid enforcement of gender roles and stereotypes, the stigmatization of long-term same-sex relationships, and the secrecy, deceit, and hypocrisy forced on those in the armed forces and other careers. In contrast, reducing sexual prejudice can enrich society by providing new models of intimate relationships and gender roles for heterosexuals as well as for bisexuals and homosexuals. It may also remove the confusion often expressed between homosexuality and gender role stereotypes such as a lack of "masculinity" or "femininity" and homosexual sexual orientations.

3. INTERNALIZED HOMOPHOBIA

A particularly interesting focus of research is on internalized homophobia, which is the negative attitude that a

gay man, bisexual, or lesbian holds about himself or herself as a result of growing up and living in a society with a potent heterosexual bias. One line of research has focused on the effects of living as a sexual minority in society and the consequences that this minority stress may have on lesbian, gay, and bisexual individuals. To study this, Meyer in 1995 used an Internalized Homophobia Scale (IHS) that measures the extent to which gay men have discomfort about their sexual orientation and their efforts to avoid homosexual feelings. Two sample items included the following: "How often have you wished you weren't gay?" and "Have you thought that being gay was a personal shortcoming?" Internalized homophobia seems to be prevalent. Meyer found that 70% of a sample from the gay community expressed some internalized homophobic attitudes, although most had relatively low scores on the scale. In a study of respondents from the lesbian and gay community by Herek and colleagues, lesbians were found to have lower scores on the IHS than were gay men. For both groups, higher scores were associated with less disclosure to heterosexual friends, fewer connections with the lesbian and gay community, and higher scores on a measure of depressive symptoms and demoralization. Gay men with high scores also scored lower on a measure of self-esteem.

Internalized homophobia is a particular risk when young people first recognize their same-sex attractions. Typically, they have learned to fear and hate anything associated with homosexuality, so when they find that they might be a homosexual, they risk turning those negative attitudes in toward themselves by means such as increased incidence of depression, suicidal thoughts and attempts, and substance abuse. Lesbians, gay men, and bisexuals also are at risk for internalized homophobia if they have been victimized by hate crimes directed toward them due to their perceived sexual orientation, thinking that they have in some way deserved being victimized in this way. Although surveys have found relatively low levels of internalized homophobia in lesbians, gay men, and bisexuals over 60 years of age, it is thought that persons are at risk for internalized homophobia throughout their lives.

4. SOCIAL ATTITUDES, PHYSIOLOGICAL AROUSAL, AND HOMOPHOBIA

As with all attitudes, sexual prejudice is learned from peers, cultural media, and authority figures. It is likely

that pronounced homophobia has deeper roots than do other prejudices, however, given that it is so directly connected to gender stereotypes and sexual behavior, both of which are powerful themes in Western culture. For example, terms such as “faggot,” “sissy,” and “pussy,” when directed at boys who are not sufficiently competitive or aggressive, may be using homophobic imagery to maintain gender role conformity. The male role is often reinforced by homophobic imagery as it frequently becomes defined by an avoidance of anything “feminine,” including emotions that suggest vulnerability, tenderness, or uncertainty. Likewise, making an athletic woman who prefers short hair and is not interested in dating men to be the butt of jokes and sexual innuendos may be an example of homophobia as harassment. In both examples, homophobia is often used to reinforce gender stereotypes and to stigmatize those who deviate from the so-called traditional male and female roles. In a society that is becoming more gender irrelevant, this use of homophobia is actually an attempt to retard this change and may explain why it is stronger among both less educated and more conservative people.

Homophobia is also often linked with sexual behaviors and acts that are associated with homosexuals, especially male homosexuals. Those sexual acts, when the male is in the “passive” role, are highly stigmatized and are frequently described as ultimate humiliations of a male. Conversely, when performed by a female, even with another female, the same acts (e.g., oral sex, anal sex) may be regarded as erotic or even positively valued. Language is filled with expressions of fear regarding male anal exposure or penetration, so men try to “protect their asses” at all costs. Likewise, anything negative is said to “suck.” Although the term has now mostly lost its sexual connotation, its origins in the denigration associated with oral sex are obvious.

Psychoanalytic perspectives have long suggested that persons who are most virulent in their prejudice about some stigmatized group may be projecting their own inner conflict onto that group, although they are conscious of neither their own conflict nor its projection. For example, a man who feels same-sex sexual attraction, but who cannot accept that in himself and so represses the attraction, might project his own hatred of his same-sex attraction onto someone who he perceives to be homosexual. Expression of hatred toward the homosexual would have the added benefit of deflecting any suspicion of his own same-sex feelings by others who may perceive him as anti-gay. Lesbians, bisexuals, and gay men often must work with, or be

supervised by, persons such as this and are required to hide their pro-gay feelings.

One study provided empirical support for the idea that homophobic men may secretly be erotically excited by same-sex sexual acts. The experiment by researchers at the University of Georgia involved a device that measured change in the circumference of the penis and indicated the extent of erotic arousal as the men watched a series of sexually explicit videotapes. The men were also asked to rate their level of arousal by the tapes. Surprisingly, 54% of the men who scored high on a measure of homophobia before the study were definitely aroused while watching the same-sex male videos, according to the measure of penis erection, compared with 24% of the men who scored lower on homophobia. Despite their penile erections, the more homophobic men did not indicate a subjective erotic arousal by those tapes, rating their arousal as low as did the less homophobic men who showed no significant penile erections. Many of the men responded both subjectively and physiologically to videotapes of same-sex female sex acts and to male–female sex acts; these responses were unrelated to their scores on homophobia. It is possible, of course, that anxiety or other strong emotions—and not erotic stimulation—at the sight of male–male sex videos produced penile erections in the more homophobic men who did not experience subjective erotic arousal.

5. GENDER DIFFERENCES IN PREJUDICE: HOMOSEXUALS, BISEXUALS, AND TRANSGENDERED PERSONS

In general surveys of attitudes within the United States, heterosexual men express more anti-gay attitudes than do heterosexual women. Heterosexual women do not express more negative attitudes toward gay men than they do toward lesbians, whereas heterosexual men typically hold much more negative attitudes toward gay men than they do toward lesbians. A similar pattern was found in attitude research among African Americans, where the men had especially negative attitudes with regard to gay men, believing that their behavior was “unnatural.” It is thought that men who violate the male gender role, which is a highly valued role in Western society, are stigmatized more than are women who violate the female gender role. Moreover, because female gender roles are less rigidly defined

than male gender roles, there may be less concern among men about lesbian women or among women about gender role violations in general.

Prejudice also exists toward bisexuals, that is, persons who feel erotic or affectional attraction to either sex. This prejudice has been termed “monosexism” to reflect the view that either homosexuality or heterosexuality is better than a combination of both orientations. Some homosexuals even believe that bisexuals should be encouraged to admit that they are actually gay, as if bisexuality were not a legitimate orientation. Herek found that attitudes toward bisexuals are more negative than those toward homosexuals. Women rated homosexuals more favorably than they rated bisexuals of either gender, and men rated males more negatively than they did females regardless of whether they were bisexual or homosexual. In general, bisexuals were rated lower on a “feeling thermometer” than were all other groups, except injecting drug users, in the survey questionnaire.

Little research has been done on attitudes toward transgendered persons, that is, those who identify themselves as neither male nor female, those who were previously male or female but have changed or are changing gender, those who have both male and female identities and wardrobes, or those whose bodies have characteristics of both sexes. A poll in 2002 found that a slim majority in the United States believed that it is “all right” to be transgender, but more than one-third believed that it is wrong. Those who believed that being transgender is a matter of the individual’s choice were more likely to see it as a moral issue than were those who believed that transgendered persons were born that way. In some cultures, such persons are regarded as “two-spirit” persons and are given roles in society that fit their unique gender.

6. EDUCATION, CIVIL RIGHTS, AND PRIMARY PREVENTION OF HATE CRIMES

Research has shown that personal contact with lesbian or gay persons, such as friends, family members, classmates, and colleagues, is associated with lower degrees of sexual prejudice. Therefore, disclosing one’s sexual orientation to associates can be effective education, especially if a friendship exists before or after the disclosure is made. Likewise, having homosexual peers speak in schools or social group meetings can be effective education. Finally, recognizing that most

families have one or more homosexual members often helps individuals to understand that sexual prejudice may affect everyone’s friendship and family circles.

Sexual minorities, including lesbians, gay men, bisexuals, and transgendered persons, are sometimes a protected class under civil rights laws. Harassment, bullying, threats, and verbal or physical violence are generally illegal and may be the grounds for civil suits. Because school districts have been held responsible for protecting sexual minority students from persecution, they are beginning to take homophobia seriously.

Hate crimes related to sexual prejudice, such as the murder of Matthew Shepard in Wyoming, have drawn attention to the most destructive effects of homophobia. Other forms of victimization related to sexual orientation can also have lasting effects and, in some states, are punished more severely than are non-hate crimes. Primary prevention efforts are needed to make communities safe for sexual minorities and to minimize the cost to society of the discrimination and prejudice that has long stigmatized lesbians, gay men, bisexuals, and transgendered persons.

GLOSSARY

coming out Process of self-acknowledgment and disclosure to others, including friends and family, of attraction to, and desire for a sociosexual relationship with, another person of the same sex.

gender-stereotyped interests Childhood play and school and sports activities presumed to be appropriate for own gender; they are most often characterized as “rough-and-tumble” play for boys and as doll play and quiet activities for girls.

sex role Recognition and enactment of the socially constructed set of behaviors traditionally considered appropriate to one’s own gender.

sexual identity Construction founded on the confluence of social and historical circumstances and personal experiences of a sense at any point across the course of life of membership in that group of persons sometimes called homosexual, gay, lesbian, queer, or spectrum or in that group of persons sometimes called heterosexual or straight.

sexual lifeway Constellation of culturally defined expectations regarding the life course for persons self-identifying with a particular sexual orientation such as gay, bisexual, or lesbian.

sexual orientation Enduring awareness of sexual attraction to, or desire for, others of the same or opposite sex.

Homosexuality refers to both a socioerotic attraction to others of the same gender and an identity as a member of a community sharing this same-sex socioerotic attraction. Although it is a term preferred by men and women in earlier generation cohorts, younger cohorts view this as a medical term and one that implies opprobrium. Members of cohorts born during the postwar era and coming of age from the 1970s to the present prefer a term such as “gay” or “lesbians and gay men.” Members of the youngest cohort, born during the 1980s, often prefer a term such as “queer” or “spectrum,” referring to an other than normative (heterosexual) identity and beyond simple classification.

1. INTRODUCTION

The term “homosexuality” refers to the experience of exclusive or nearly exclusive erotic preference for others of the same sex in fantasy and, characteristically, through realization of sexual intimacy with others of the same sex. It can be conceptualized as desire, behavior, and identity (although it is not always congruent

within one person at any one time and so may represent a source of personal conflict). Homosexual desire is the affective experience of same-sex attraction. Homosexual behavior occurs when members of the same sex engage in sexual activity. Homosexual identity represents the assumption of a self-label in which one acknowledges the primacy of homosexual desire and behavior in his or her self-composition. In contrast to homosexual identity, homosexual orientation reflects the affective experience of primarily same-sex erotic desire beyond conscious control and outside the purview of historical and social construction.

The experience of same-sex sexual contact has occurred across cultures and historical eras. As such, it is difficult to generalize the meaning of homosexuality from one society or one time to another society or time. Even in American society, the meaning of homosexuality has undergone radical transformation and permutations during the past century. The current discussion is focused largely on the experience of men and women in contemporary Western society who self-identify as “homosexual” or, more recently, as “gay,” “lesbian,” or “queer.” This identity assumption in postmodern Western culture represents a particular sexual “lifeway” bound by culture and history. Thus, one’s conception is necessarily limited and rooted primarily in the experience of urban bourgeois gay men and lesbians in North America and Europe because these are the voices represented nearly exclusively in the literature on homosexuality. This article begins with a historical account of homosexuality in the current cultural context, followed by a discussion of the controversies regarding the origin of homosexuality. Next, it reviews theory and research on the gay and lesbian life course, beginning with the “coming out” process. Finally, the article considers four contemporary “problems” pertaining to gay men and lesbians related to the larger social and political ethos: mental health, social stigma and hate crimes, acquired immune deficiency syndrome (AIDS), and marriage.

2. HISTORY, CULTURE, AND THE PROBLEM OF DEFINING HOMOSEXUALITY

In much of the public health and gay and lesbian psychological literature, the emergence of the phrase “men or women who have sex with other men or women” has emerged in response to the phenomenon of consistent homosexual behavior in the absence of

homosexual self-identification. For example, many young adults eschew any sexual identity as a “natural kind,” represented in polarizing labels such as “gay” and “straight.” The term “queer,” as used by these young adults, is meant to defy such essentializing efforts and reflects a new view of sexual desire as less amenable to simplistic bifurcations.

Recent research and theory have highlighted the importance of studying gay and lesbian lives within the context of shared, cohort-specific understandings of sexual identities and lifeways. Following a series of more gradual shifts in the social organization of sexuality during the first half of the 20th century, gay and lesbian life exploded into the public consciousness following the advent of the gay rights movement during the late 1960s and early 1970s. Inspired by and modeled on the civil rights movement, gay liberation was ignited in the aftermath of a 1969 riot in a New York City bar, the Stonewall Inn. Although the gay rights movement, symbolized by the Stonewall Inn riot, forever altered the shape of gay and lesbian life, its impact was largely cohort specific. Not only are different generations defined by different historical moments, but they also react in somewhat distinct ways to the same historical events. Over the subsequent three decades or so, there was a dramatic change in discourse regarding sexuality and sexual identity that has led to recognition of same-sex socioerotic identity as “virtually normal.”

One’s understanding of homosexuality today is highly influenced by the cultural and historical context of the late modern West. In particular, World War II created a context in which individuals with homosexual desires who perhaps felt alone in their experience were able to discover one another. Following the war, they settled in large metropolitan centers and began to form distinct gay and lesbian communities or subcultures. The emergence of a distinct homosexual identity as a clearly definable social category, as well as the growth of the gay and lesbian community, was fueled in large part by the social ethos of the 1960s and its culture of sexual liberation. The resistance of larger social institutions to accepting same-sex intimacy or homosexuality as a legal, legitimate social identity inevitably led to the Stonewall Inn riot, which sparked the beginning of the gay civil rights movement. Within the backdrop of this cultural and historical context, individual lives unfolded, and tantamount to social acceptance of gay men and lesbians has been the search for a causal mechanism—one that would ultimately demonstrate the immutability of homosexual desire.

3. UNDERSTANDING SAME-SEX DESIRE: THE SEARCH FOR BIOLOGICAL ORIGINS

Our culture is one in which lives, like stories, are assumed to have a linear organization with beginnings, middles, and ends—or childhood, adolescence, adulthood, and old age. Our society is one in which particular emphasis is placed on beginnings and origins. From learning theory (with an emphasis on primacy and recency of learning, ethology, and the concept of the critical period) and psychoanalysis (with a stress on the nature of the experience of early ties with caregivers), personality theory and developmental study has focused on origins and “causes” of particular personality characteristics. Nowhere is this concern with origins more evident than in the search for the causes of same-sex desire. This concern has been manifest both in the study of presumed biological determinants of homosexuality and in the discussion of the early development of the boy or girl later destined to choose same-sex sexual partners.

The debate in research and theory on homosexuality between the essentialist and constructionist positions is particularly concerned with the question of origins. The more politically controversial constructionist position emerges from social theories of identity as created through practice, suggesting that gay identity is formed within and among individuals as a consequence of shared cultural practice. The essentialist position, in contrast, posits that homosexuality is an innate condition of human experience. The biological line of research on homosexuality is representative of this position. Because of its controversial nature, including the implication of gay men and lesbians as “others” with some congenital defect (believed by some gay activists as fostering the cause of gay and lesbian political rights), the biological account of homosexuality is explored in depth in this section.

3.1. The Four Areas of Biological Study of Homosexuality

The search for biological determinants of same-sex desire began during the 19th century and has continued to the current time with reports in scientific journals. Interest in this has been enhanced by those who believe that if a biological determinant can be found, same-sex desire might be viewed as an inherent and unchangeable attribute, much like hand preferences (right or left) or other differences, and then subject to legal protection.

Significantly, although there have been scattered references in the literature to the biological determinants of homosexuality among women, nearly the entire corpus of biological study focuses on the determinants of homosexuality among men.

The four areas in which biological contributions to the study of the origins of homosexuality have been reported are social biology and evolutionary theory, behavioral genetics and the search for the “gay” gene, hormones and prenatal development, and brain structure and anomalies from “normal” brain anatomy. Sociobiological models maintain that because the gene for homosexuality has not disappeared from the population, this gene must have some adaptive value. Claiming that gay men are more potent than their heterosexual counterparts, then, a heterosexual man who is heterozygous for the gay gene would have a reproductive advantage over a straight counterpart who is not carrying the gay gene. Other sociobiological theories suggest that parents recognize that some offspring are less biologically fit (e.g., lower intelligence, lower social adeptness) than others and so protect these children from challenging life experiences such as parenthood and “make” them into homosexuals. This perspective is virtually silent regarding homosexuality among women.

A second biological model focuses on behavioral genetics. Building on the observation that there is a “family disposition” toward homosexual interests, early reports contrasting monozygotic (MZ) and dizygotic (DZ) twins claimed that means of genetic transmission could be understood from a Mendelian perspective. More recent behavioral genetic studies have assumed polygenetic transmission. In 1991, Bailey and Pillard reported that the rate of concordance of homosexuality among MZ twin pairs is approximately 50%, whereas the rate among biological siblings is 22% and that among adopted brothers is 11%. This research group has also reported concordance rates for homosexuality among women who are MZ and DZ twins approximating those for homosexual men. After reports showing enhanced concordance for homosexuality among MZ twins as contrasted with DZ twins or brothers, Hamer and colleagues in 1993 reported a study of possible genetic linkage following the logic that if a trait is inherited through a single gene, relatives who share the trait will share the gene more often than would be expected by chance. Even if a gene that is responsible for a trait may not be identified, it may be shown to exist by means of transmission of another clearly inherited quality to which the trait is linked. Linkage studies are a common means for the study of inheritance. Following

this logic, Hamer and colleagues studied 40 families, each of which included two gay sons. Focusing on a gene located on the X chromosome that is transmitted from the mother but expressed only in men, the investigators located a marker on the Xq28 region that was concordant for 33 of the 40 pairs of gay brothers. In a large group of presumably straight brothers, the marker was randomly distributed. The chance of this association was less than 1 in 10,000. Hamer and colleagues maintained that this trait of homosexuality was transmitted through the maternal line, with the gene for homosexuality being located on the X chromosome, and confirmed this prediction in the reports by a group of gay men who attributed homosexuality to a greater number of maternal relatives than paternal ones.

A third area of biological study regarding the determinants of homosexuality focuses on the role of hormones, particularly during prenatal sexual development. This tradition presumes that same-sex sexual orientation, particularly among men, is a result of biosocial stress during critical periods of fetal development. Using animal models, prior observation had shown that in the absence of fetal androgens, the external genitalia develop as female, leading to the presumption that masculinization of brain centers also required the presence of these hormones. Particularly important for the development of homosexuality is the development of sex hormone receptors outside of the genital apparatus during the fourth through seventh months of gestation. Appropriate levels of testosterone appear to be necessary for these receptors to develop. The possible impact of disturbed intrauterine testosterone levels, such as might result from unusual stress or other environmental factors, has been a subject of continuing study. Aberrations in the hormonal receptor sites that might be caused by such changes would not be manifest until the time these receptors ordinarily begin to function. For example, males who had partially failed to develop testosterone receptor sites might not show the changes in muscle mass and strength that typically accompany pubertal development. Testosterone and its metabolite dihydrotestosterone (DHT) are necessary for male sexual arousal, so abnormal hormonal receptors might also influence sexual arousal. The impact of the failure to produce testosterone on the development of masculinity has been demonstrated in laboratory studies using rats.

This area of study has played an important role in work summarized in 2002 by Friedman and Downey regarding the emergence of homosexuality in men. Presuming androgen insufficiency that leads to

incomplete masculinization in boys destined to become homosexual, Friedman and Downey maintained both that parents implicitly recognize these boys' feminine nature and react to them as if they were less than masculine and that these boys avoid the "rough-and-tumble" play that is characteristic of typical boys. In fact, Friedman and Downey conflated gender-atypical interests (e.g., in theater or the arts) with femininity and assumed that these boys have some elements of a gender identity disorder that later becomes manifest as same-sex sexual orientation.

A fourth area of study regarding the biological determinants of sexual orientation, primarily homosexuality among men, was stimulated by reports of differences in the first through third interstitial nuclei of the anterior hypothalamus observed on contrasting groups of gay and presumably heterosexual men. These reports suggested that the hypothalamus, long believed to be important in determining sexuality, is sexually dimorphic. This study is closely related to that regarding intrauterine androgen exposure given evidence that the size of anterior nuclei of the hypothalamus in rats depends on prenatal androgens during a critical period of prenatal development, that this area is critical for rat sexual functioning, and that reported differences in the size of these nuclei in the human anterior hypothalamus are consistent with the prenatal stress-androgen hypothesis. This research presumes that gay men must be like women in preferring men as sexual partners because, for example, the third anterior nucleus of the hypothalamus has been shown to be larger in women than in men and so should be larger among gay men, who are like women in their preference for men as sexual partners, than among heterosexual men.

3.2. Problems Posed by Biological Study of the Origins of Homosexuality

Much of the study attempting to show some biological determinants of homosexuality has reflected serious problems related both to the method of study and to the measures used to evaluate sexual orientation. For example, the social evolutionary perspective has been challenged on the ground that this perspective is mired in stereotypes and unwarranted assumptions such as that gay men are more potent and more successful in finding sexual partners than are heterosexual men. In 1999, Stein observed that in behavioral genetics study, there is an "ascertainment bias," possibly leading gay

men with identical twins both to be more likely to volunteer for such studies than gay men with fraternal twins and to overreport concordance for same-sex desire. Stein noted that concordance rates for sexual orientation are considerably lower than had been claimed when issues of volunteering were explored and that they have been inflated by sampling bias. Furthermore, whereas the genetic hypothesis predicts equal rates of homosexuality among DZ twins and brothers, Bailey's research group reported that unrelated adopted siblings were more likely than brothers to report same-gender sexual orientation (11 vs 5%). Finally, because twins were reared together in virtually all studies, it is difficult to disentangle environmental and biological effects. In sum, various problems of method, including the manner in which participants were located, reliance on indirect reports regarding sexual desire, focus on behavior rather than fantasy, measurement of zygosity by self-report, use of possibly unreliable scales for measuring sexual orientation, and very small sample sizes, all compromise the findings from this research.

Further problems are found in studies of the gay gene, including sampling methods, problems in replicating earlier studies, and problems of volunteer bias that are further compounded by the use of mail-in questionnaires and the reports of a variety of sexual behaviors among these volunteering participants. An approach to the study of the biology of homosexuality fails to consider the complex interplay of genetics, hormones, and social context and also blurs the distinction between association and causation. Reviewing the research in the area of hormones and sexual orientation, Stein concluded that there is little evidence showing even an association between expressed sexual identity and presumed hormonal factors. All of these problems are replicated anew in studies of neuroanatomy and sexual orientation.

Stein was particularly critical of the assumption made in much research on sexual orientation that this orientation is of a "natural kind" and that gay men can be readily classified as either "gay" or "straight." Stein systematically examined the assumptions underlying claims that sexual orientation is founded on some essential (biological) attributes. He observed that the dilemma inherent in understanding sexual orientation from this essentialist position is founded in the very presumption of categories (either binary or bipolar) of "natural kinds" of human sexuality, such as those of homosexual or heterosexual, man or woman, and sexual identity or gender identity, rather than recognizing

the many ways in which persons understand or make meaning of their sexuality and the limitations imposed by historically and culturally available constructs to name one's own experience. There may be little merit in trying to fit people into these binary categories. As Chodorow observed in 1992, it is not even understood why men and women become heterosexual.

The politics of gender and sexuality in contemporary society have further contributed to the publication of studies believed to show that sexual categories are a natural kind. The question is not whether biology is involved (biology is involved in all aspects of human development) but rather how biology is involved in particular kinds of sexual desires according to a permissive model in which genetic factors influence aspects of neuroanatomy, which then influence particular preferences; a direct model that constrains or shapes a particular preference; or an indirect model in which genetic factors influence personality, which then interacts with life circumstances to shape sexual orientation. Stein suggested that most findings to date support an indirect model of determination. Stein questioned the assumption that persons who have sex with others of the same gender uniquely possess attributes that need to be explained or that sexual orientation may be regarded as either binary (gay or heterosexual) or bipolar (a continuum marked at one end by gay and at the other end by heterosexual).

4. REALIZATION OF A GAY OR LESBIAN IDENTITY AND THE LIFE COURSE

The process of coming to self-identify as a homosexual (or, more recently, as a gay or queer) man or woman is often termed "coming out" (of the closet). In 1994, Chauncey observed that this term may be traced back to the 1930s when it was used as a satire for the debutante experience. However, during the postwar period, this term was further refined to mean coming out into the gay life or the gay world and out of hiding (portrayed by the often used term "closet"), including first discovery of same-gender sexual experiences and, more recently, disclosure of same-gender sexual desire to family and community. The terms "gay," "lesbian," and "queer" that are preferred by many younger urban-living men and women experiencing same-sex desire reflect an effort to turn a spoiled identity into a positive one.

Coming out represents more than just the disclosure of one's same-sex desire to others. It is a process of

internal experience in which an individual's entire sense of identity is challenged, reformulated, and crystallized. Either concurrent with or proceeding the process of coming out to self, individuals engage in a cultural resocialization process, usually by attending a coming out group at a community agency or gay social services center, that results in the eventual assumption of a gay, lesbian, or queer identity. Models of the coming out process have typically assumed a developmental character, best exemplified by the stage models, and have been challenged by perspectives that are more reflexive, discursive, and social constructionist. The historical and cultural relativity of the experience of those with same-sex erotic desire questions the value of stage-based developmental models of the coming out process. Stage-based models are concerned with ideal types and ignore the complexity of intersections with other aspects of identity, such as ethnicity, and so should be used only as a very basic guide to conceptualizing the identity development process for gay men and lesbians.

Adopting a symbolic interactionist perspective from sociology, humans behave in accordance with their own perceptions of meaning that are constructed through social interaction. The idea of homosexuality represents a socially constructed category or dimension of sexual experience that resonates with individuals constantly engaged in meaning-making (i.e., symbolic) human interaction. One becomes "homosexual" in this framework through the enactment of a particular role in social interaction. Being homosexual occurs in and through practice. It is not an "essence" located within a particular anatomical or genetic substrate. Rather, it is a meaningful classification of identity formulated, negotiated, and maintained through real human social activity. The social constructionist account of sexual identity has also been promulgated by a number of scholars working with lesbians. Much of this work reveals that, for White middle-aged lesbians and bisexual women of European descent, coming out is a nonlinear process that cannot be mapped onto specific stages.

The psychological and sociological approaches are nicely complemented by anthropological perspectives on gay and lesbian identity development such as that proposed in 1997 by Herdt, who posited that coming out represents a ritual that marks the beginning of a cultural resocialization process in which individuals with same-sex erotic desire learn the history, lore, and customs of a larger gay culture. In sum, coming out represents a process that occurs both within the individual and his or her relationship to others through social interaction and within the larger gay and lesbian

culture. As such, it is useful to consider the gay and lesbian identity development process from psychological, sociological, and anthropological perspectives given that they complement one another in their emphases on the individual, society, and culture.

5. CHILDHOOD AND ADOLESCENCE

Research on the childhoods of gay men and lesbians has been based largely on adolescent or adult retrospective reports. A theme that is particularly salient during the childhoods of gay men and lesbians is that of difference. As children, gay men and lesbians often report feelings of being different from peers, although they often do not define this difference in terms of sexual desire. Yet most gay men report very early awareness of same-sex attraction, typically during the elementary school years. Research on childhood experiences of homosexuality are obviously biased by this reliance on retrospective reports, but one can conclude that the affective response to same-sex desire begins during childhood.

Many investigations of lesbian, gay, bisexual, and transgendered (LGBT) adolescents have focused on issues relating to mental health and psychological adjustment. Although some studies of the mental health of gay and lesbian adolescents have suggested that, in contrast to their heterosexual counterparts, LGBT adolescents report greater levels of depression, hopelessness, and suicidal preoccupations, after controlling for environmental factors such as stress and social support, significant differences between the groups disappeared. These findings suggested that changes in resources for LGBT youth have the potential to diminish negative psychological outcomes. Studies have suggested that reactions of parents and perceptions of parental support are particularly important in predicting levels of self-esteem among LGBT youth and adolescents (as well as among LGBT individuals as whole) who are at increased risk for victimization and harassment (i.e., acts of verbal and physical violence).

Acts of victimization and harassment have been associated with a number of problems commonly experienced by LGBT youth, including school-related problems, suicide, running away, substance abuse, prostitution, and conflict with the law (usually for substance abuse, prostitution, running away, and/or truancy). When acknowledging the relationship between these problems and victimization and harassment, it is clear that LGBT youth need support systems. Organizations committed to aiding LGBT youth must also commit

themselves to breaking down the stereotypes and prejudice that result in victimization and harassment.

5.1. Adulthood and Aging

Little research has focused explicitly on the lives of lesbians and gay men in their 20s and 30s, due in part to the rapidly changing life course for gay men and lesbians. For example, with ages of coming out decreasing, gay men and lesbians are more closely mirroring their heterosexual counterparts in terms of romantic relationships. Once youth come out during adolescence, they are free to explore intimate relationships with same-sex partners by late adolescence. Early adulthood, then, is often characterized by serial monogamous relationships among gay men and lesbians, just as it is among their heterosexual counterparts.

Most discussions of adult development occur within a framework that tends to assume heterosexuality. Work is a major issue for lesbians and gay men at middle age and is also an area that differentiates them from their heterosexual counterparts. There tends to be more continuity in the professional lives of lesbians than in those of their heterosexual counterparts because lesbians' careers are less often interrupted by child rearing. However, Patterson noted in 2000 that this is likely changing as more gay men and lesbians are raising children. Most lesbians are in committed relationships and working during midlife. However, there is enormous diversity in experience during midlife among both lesbians and gay men, and little systematic research has addressed the question of midlife development among gay men.

At middle age in our society, people begin to look backward in evaluating their own lives rather than looking to the future. The "crisis" that is so often portrayed for men in our society as they reach middle age might be exacerbated for gay men as a result of their perceived loss of physical attractiveness. Sense of a foreshortened life course is common among the cohort of now middle-aged men who are survivors of the AIDS pandemic that peaked during the 1980s and early to mid-1990s and who suffered the loss of so many lovers and friends to AIDS. However, because the developmental trajectory of gay men across the adult years does not necessarily follow that of their heterosexual counterparts, it is difficult to generalize from heterosexual to gay experience of self and others across the second half of life.

The experience of later life (i.e., after 65 years of age) for lesbians and gay men is becoming increasingly investigated as the field of gerontology and aging expands

exponentially (in conjunction with increased longevity). As with gay men and lesbians at middle age, the lives of older gay men and lesbians cannot be extracted from historical context and the view of the larger culture toward homosexuality. It is possible that the unique experience of coming out (a major life transition in which one evaluates the self), together with lifelong experience in dealing with stigma and anti-gay prejudice, leads to crisis competence that fosters the development of personal strengths and, among older gay men and lesbians, further leads to successful adjustment to the challenges posed in our society for older adults. Research with older lesbians and gay men reveals highly successful coping mechanisms in the face of considerable stressors and the expected course of aging.

6. HOMOSEXUALITY AND SOCIETY

This final section reviews four contemporary issues involving homosexuality and society. First, the research on homosexuality and mental health is reviewed, detailing briefly the current controversy over "conversion" therapy for gay men and lesbians. Second, the impact of social stigma on personality development is reviewed, with specific attention given to the social problem of hate or bias crime. Third, the relationship between homosexuality and the AIDS pandemic is discussed. Finally, the issue of gay and lesbian marriage, and its implications for the changing history of the gay and lesbian life course, is discussed.

6.1. Mental Health

The question of the mental health of lesbians and gay men has been a major focus of inquiry since the elimination of homosexuality as a diagnosable mental illness in 1975. As members of a social group that has been marginalized in contemporary society, gay men and lesbians continue to be at risk for a host of mental health and adjustment difficulties, especially those associated with the coming out process. For example, mental health problems that adolescents experience concurrent with coming out are experienced intrapsychically but are rooted in external sources of stress (e.g., prejudice, victimization) and lack of social support. As attitudes toward homosexuality become increasingly positive, and as institutional support for young gays and lesbians grows (e.g., through gay-straight alliances in high schools), sources of external stress will likely diminish, improving the overall coming out experience. Mental

health problems that are typically experienced during the coming out process include low self-esteem, depression, anxiety, and suicidal ideation.

A major mental health concern for lesbians and gay men involves the experience initially portrayed by Malyon in 1982 as internalized homophobia. Internalized homophobia occurs when a gay man or lesbian possesses negative feelings of self based on the larger social phenomenon of homophobia or anti-gay prejudice. That is, the individual fails to reject the anti-gay attitudes of the dominant ideology and, instead, assumes the veracity of these attitudes. Research has suggested that gay men and lesbians with higher levels of internalized homophobia are more likely to engage in self-destructive behaviors, such as substance abuse, and to experience a whole host of other adjustment difficulties. The experience of internalized homophobia is likely implicated in a host of mental health and adjustment difficulties for gay men and lesbians. In sum, the mental health of the vast majority of gay men and lesbians is comparable to that of heterosexuals. The mental health problems most commonly experienced by gay and lesbian patients center on their struggles to adapt to a heterosexist society.

Although the mental health field has a history of pathologizing homosexuality, the ideology underlying more recent clinical training and practice has been largely affirmative of gay and lesbian identity. Advocates of so-called conversion or reparative therapy have claimed success in changing the behavioral sexual orientation of gay men expressing dissatisfaction with their gay identity, although they have not been able to show that these men have given up their fantasies about same-sex experiences. Drescher's careful review of this controversial therapy in 1998, as well as the report of the Group for the Advancement of Psychiatry in 2000, highlights the problems with the assumptions on which this therapy is founded and also the validity of claims regarding presumed successful outcomes of this conversion psychotherapy. Currently, most of the major professional mental health associations regard practice of reparative therapy as problematic or even unethical.

6.2. Social Stigma and Development

A second major issue involving homosexuality and contemporary society is the impact of social stigma on personality, identity, and overall mental health. During the recent history of Western society, attitudes toward lesbians and gay men have largely been characterized by heterosexism and homophobia. In 1993,

Herek portrayed heterosexism as an ideology that denigrates and stigmatizes nonheterosexual lifestyles and privileges heterosexuality. Prizing heterosex reflects a value assumption that it is the only appropriate manifestation of love and sexuality and devalues all that is not heterosexual. Herek reported that heterosexist and anti-gay attitudes appear to be more common among heterosexuals who are more religious, adhere to a more "traditional" ideology of family and gender, and have friends with anti-gay attitudes. Heterosexuals who report more contact with gay men and lesbians tend to endorse fewer anti-gay attitudes than do heterosexuals who have not had extensive contact with gay men and lesbians.

The large-scale stigmatization of lesbians and gay men exerts negative social, economic, and emotional effects on their development. At both the cultural and individual levels, heterosexism is implicated in the increased experience of victimization and anti-gay violence. Gay men and lesbians, especially youth, continue to experience victimization based on their sexual identity. The highly publicized, tragic murder of Matthew Shepard in Wyoming was a poignant reminder of the deleterious effects of cultural heterosexism and individual anti-gay attitudes. Heterosexism assumes a powerful role in both the internal (e.g., feelings of difference) and external (e.g., victimization) aspects of the lives of gay men and lesbians. The elimination of attitudes associated with heterosexism and homophobia has implications for enhancing the optimal development of lesbians and gay men by creating a context in which prejudice and the devaluing of a homosexual identity are minimized.

6.3. Homosexuality and the AIDS Pandemic

Too often, homosexuality among men has been conflated with being positive for the virus leading to outbreak of symptoms of AIDS, to such an extent that young men coming of age and experiencing same-gender sexual desire during the subsequent decades became terrified that their attraction meant certain infection and death. The virus responsible for AIDS was isolated and a test for presence of the antibodies responsible for the human immunodeficiency virus (HIV) infection became widely available by 1985. However, with no known treatment, there was some reluctance to get tested. Even after the development of the HIV antibodies test, as men began getting sick and dying, few understood

that unprotected anal sex, which facilitated blood–semen contact, was the primary means of transmission.

It is well known that AIDS is ever less a “gay” disease as many millions of persons around the world have become infected through needle use and other means of transmission but cannot afford the expensive medication available to affluent men and women in the United States. Much of the effort in the mental health field has focused on means of risk reduction through education promoting safer sex. Belief in the efficacy of safer sex leads to safer sex practices. Men who are more comfortable with their sexual orientation as gay, and who are out in the community with a lessened focus on anti-gay prejudice as a stress for them, are also more likely to practice safer sex and, in turn, receive a sense of enhanced personal mastery from such practices.

6.4. “Normal” and Beyond: Gay and Lesbian Relationships, Marriage, and Parenthood

The gay identity is often a contested one on the part of gay and lesbian people and the larger community alike. On the one hand, findings from recent surveys have shown a decrease in anti-gay bias. On the other hand, efforts within the gay and lesbian community to “fit in” within the larger society have been contested both by the larger society and within the gay community itself. Much of this controversy is apparent in the recent heated debate with the Episcopal church regarding the election of “out” gay priest Gene Robinson as a bishop of the church. However, this contested identity as gay or lesbian is most clearly evident in the area of same-sex partnership. Marriage in the United States symbolizes both social order and compliance with traditional norms. Even though divorce marks the end of one in three marriages, shared beliefs reflect the larger belief that marriage has a special meaning in terms of prevailing concepts of love and romance between husband and wife.

Given the significance of this belief in the special quality of the marital tie, there was wide-scale protest in 1993 when the Hawaii Supreme Court held that same-sex couples shared the right with heterosexual couples to marry under the equal protection clause of the state’s constitution. This decision prompted a firestorm as many states and the federal government passed legislation banning same-sex marriages. In 1996, Congress passed the Defense of Marriage Act, signed into law by President Bill Clinton, that denied legal recognition to same-sex unions at the federal level. The Catholic

Church and most mainline Protestant churches prohibit clergy from performing marriage rites with same-sex couples. At the same time, there is increasing support for legal recognition of same-sex civil unions beyond support of domestic partnership, as was recently approved in Vermont. It appears that the word “marriage” has some symbolic significance reflecting traditional norms ever more important when confronting the reality of social change.

In November 2003, the Massachusetts Supreme Court held that a prohibition on same-sex marriages violated the equal protection clause of the state’s constitution. The court upheld the equality of all persons and noted that marriage confers legal, financial, and social benefits, and also brings stability, to society. The court saw no constitutional reason why such benefits should be denied on the basis of sexual orientation. After the Vermont decision to legally recognize same-sex civil unions came a decision by Canada’s province of Ontario to recognize same-sex marriages (soon to be extended across the country), legal recognition of same-sex marriages in The Netherlands, a move for such legal recognition in Australia, and a move for legal protection for same-sex unions in Scandinavia, there is emerging support for legal recognition of gay marriage. In response to this trend, federal officials in the United States, from the president to a majority of Congress, continue to be opposed to same-sex marriages, and the Massachusetts decision has sparked renewed discussion regarding a U.S. constitutional amendment that would define marriage as a union between a man and a woman.

Posner, a federal appeals court judge and legal scholar, maintained in 1992 that government must not discriminate against classes of citizens. Although he appeared to be in favor of same-sex marriages, he indicated that society was not yet ready for this change and suggested granting legal protection to same-sex couples, such as in granted in Scandinavia, as an interim solution. Underlying these legal decisions there is continuing controversy even within the gay community regarding same-sex marriages. In 1997, these disparate positions were included in Sullivan’s edited collection that includes summaries of important court cases, congressional debate on the Defense of Marriage Act, and passages from the works of both supporters and critics of same-sex marriages. In 1995, Sullivan himself argued in favor of same-sex marriages, noting that extending legal protection would enhance the stability of same-sex relationships. He refuted the position of many opponents to same-sex marriage that

homosexual lifeways are necessarily depraved and the argument that remaining single is a better social outcome for gay men and lesbians than is entering into a legally recognized union that would enhance personal and social stability. In 1999, Warner indicated a concern that such legal recognition might undermine the distinctive culture created by gay men and lesbians and noted that the high divorce rate undermines the argument that heterosexual marriage fosters social stability.

The court in the Massachusetts decision explicitly commented that a ban on same-sex marriages proved to be a disadvantage for children of same-sex unions. Indeed, one area in which legal protection for gay and lesbian unions would be particularly important concerns parenthood and child care. One of the numerous areas in which the social changes of the past decade have been significant concerns birth, custody, and adoption among gay and lesbian couples. Custody decisions in divorce cases have generally favored the wife and mother, even when she has self-defined as lesbian and has sought divorce so as to join her lover. In 2000, a report of the Group for the Advancement of Psychiatry on the problem of bias and mental health among gay men and lesbians reported that several states have ruled that sexual orientation does not by itself imply unfitness of a parent in a contested custody proceeding and that parental unfitness and evidence of harm to the child must be demonstrated. In the past, courts have been reluctant to award custody to the father in divorce cases. Most often, where gay couples have been involved in parenting, it has been through joint custody or visitation rights. Other case law has maintained that sexual orientation should not interfere with visitation rights. Other courts have opposed custody for gay and lesbian parents on the ground of possible problems posed for the children at school and in the community by having two same-sex parents.

The three principal routes to lesbian or gay parenthood are where (a) one member of the couple brings one or more children from a heterosexual marriage, (b) the couple adopts, and (c) one partner (among lesbian couples) becomes pregnant through donor insemination. Evidence reported from a number of studies has not shown that children living with gay or lesbian couples face the problems in adjustment that has been presumed by some courts. Whether considered from the perspective of teachers, parents, or children, findings regarding the adjustment of children of gay or lesbian parents point to relatively few problems. Patterson's report suggested that children of lesbian mothers reported somewhat greater stress than did children of heterosexual mothers,

but they also reported an enhanced sense of well-being and comfort with their own lives. Patterson's review of studies in this area showed that children of gay or lesbian parents have the expected social ties during middle childhood and report few problems at school as a result of having two same-sex parents.

Children of gay fathers have somewhat greater difficulty in accepting their parents' sexual orientation than do children of lesbian mothers, although the nature of children's acceptance depends on their age at the time of parental disclosure. School-aged children have a somewhat easier time than do adolescents in making sense of parental sexual orientation for their own lives. Patterson observed that early adolescence may be a particularly difficult time for children to learn about their parents' alternative sexual orientation. Where problems with having gay parents have been reported, most notable among gay couples with children either adopted or brought from prior marriages, the extent of problems reported by the children is related to the degree of comfort that their same-sex parents have with their own role as gay men and fathers.

Child care and division of labor in doing routine household tasks appear to be more of a problem among gay couples than among lesbian couples. Too often in our society, child care has been considered the work of women and fathers have served as children's primary caregivers less often than have mothers. Gay fathers often try to compensate for any hardship their sexual orientation may pose for their children. They characterize themselves as both warm and nurturing as well as more likely than heterosexual fathers to set limits. Among both gay and lesbian couples, the two partners are more likely to be supportive and involved in child care than is the case among heterosexual couples, where child care is most often seen as primarily the responsibility of the wife and mother. Gay fathers, in particular, have had to work so hard to attain custody or to adopt that they are particularly likely to be involved in parenthood.

Gay fathers and lesbian mothers sometimes report anecdotally that they are concerned that their children should adopt gender-appropriate roles and engage in gender-stereotyped activities that conflate gender and sex roles but provide assurance that their offspring will not adopt a gay or lesbian identity as a reflection of their own still unresolved feelings about their gay or lesbian identity. In the past, gay fathers expressed greater concern than did lesbian mothers regarding the impact of their sexual orientation on their children's development. Although the offspring of gay and lesbian parents are not more likely than the

offspring of heterosexual parents to report a gay or lesbian sexual orientation, their parents are particularly concerned that their offspring adopt gender-stereotyped interests and not show evidence of a same-sex sexual orientation. This somewhat exaggerated concern reflects their awareness of social bias, their own experiences of growing up in the midst of a hostile climate at school and in the community, and their own internalized anti-gay prejudice.

7. CONCLUSION

Understood as same-gender sexual orientation and the consequent assumption of a sexual identity as gay or lesbian, homosexuality has assumed a changed significance in postwar society. Formerly a furtive identity that necessarily required "covering" in a conservative heterosexual society, urban-living lesbians and gay men (and, to some extent, even those living in smaller towns) have enjoyed increased social acceptance and diminished prejudice over the past two decades or so. In turn, this enhanced acceptance has led to greater ease among youth disclosing to friends and family their gay or lesbian sexual identity and has permitted gay and lesbian adults to enjoy their lives with friends, family, and children, comparable to the lives of their heterosexual counterparts. Much of what is known about the impact of alternative sexual identity on personal development across the course of life has been based on these generations growing up in the midst of prejudice. Challenges for the next period of study include long-term study of the adjustment of children of gay and lesbian parents as they reach adulthood and the impact of sexual orientation on the adjustment to aging as "baby-boomer" lesbians and gay men reach later life.

GLOSSARY

collective rights Particular rights based on membership in cultural, religious, linguistic, or national groups. The main function of such rights is to maintain and further links between members of a community as well as to preserve their lifestyle.

contextualization of rights Processes that actualize a more or less broadening or restricting definition of rights that are deemed to be relevant in a given situation.

human rights Universal rights that all individuals should enjoy regardless of their belonging to different social groups or categories. Individuals are invested with these rights by the mere fact of being a member of the human species. The Universal Declaration of Human Rights, voted by the General Assembly of the United Nations in 1948, is the official document stating these rights.

normative social representations Representations that specifically allow humans to evaluate their relations and interactions. All social representations imply a normative aspect because they are beliefs embedded in systems of norms.

social representations Organizing principles of symbolic relationships between individuals and groups. They imply common understanding of social reality, organization of

individual positioning toward issues at stake in society, and anchoring of individual variations of positioning in social realities.

Human rights are defined as normative social representations embedded in institutional juridical definitions. Conclusions from psychological studies on matters of rights enforcement are ambiguous. Research findings show that human rights can be studied as normative social representations implying a degree of common understanding across cultures together with organized differences within and between cultures. Important factors in modulating individual positioning in the realm of human rights are experiences of social conflict and injustice, beliefs about the efficiency of various social actors to have rights enforced, and attitudes of liberalism or collectivism.

1. INSTITUTIONAL DEFINITION OF HUMAN RIGHTS

The Universal Declaration of Human Rights, adopted on December 10, 1948, by the General Assembly of the United Nations Organization, serves as the main institutional reference for defining human rights (HR). The declaration comprises six groups of articles. The first group of articles (Nos. 1 and 2) enunciates the basic principles of equality, freedom, and dignity; the second group (Nos. 3–11) focuses on rights of the individual,

such as security of the person and equal protection by the law; the third (Nos. 12–17) concerns rights relative to interindividual relations, among which there are freedom of movement and the right to found a family; the fourth (Nos. 18–21) involves civil rights, such as freedom of expression or equal access to public service; the fifth group (Nos. 22–27) deals with economic and social rights, such as social security and the right to rest and leisure; and the sixth (Nos. 28–30) covers societal rights relative to international law and order as well as to duties to the community.

When the declaration was drafted, it was not at all obvious that eventually all groups of articles would be retained by the vote of the general assembly. Fierce controversies opposed members favoring exclusively a declaration of individual judicial rights together with public and civil rights and members more concerned about providing individuals with socioeconomic rights, such as rights to a decent standard of living, education, and health care. This antagonism is still acute and is reflected in the contents of the two additional covenants of 1966 that have defined a more legal status for rights defined in the declaration, one covenant bearing on civil and political rights and the other on economic, social, and cultural rights. These resulted in procedures aimed at guaranteeing respect of specific rights, at least among the countries that signed them. Not all the countries that signed the universal declaration signed both additional pacts. Hence, the universal declaration remains the most universal and comprehensive reference in the realm of human rights.

Half a century after its adoption, it is more than evident that enforcement of the rights stipulated in the declaration is far from being guaranteed in many countries throughout the world. Reasons for this lack of HR respect are numerous and of diverse nature: political, economic, cultural, institutional, and also psychological.

2. THE AMBIGUOUS MESSAGE OF SOCIAL PSYCHOLOGY

Psychological dispositions without doubt influence the way individuals take into consideration the rights of others. In order to study such influences, one could borrow a lot of useful suggestions from studies on prosocial behavior. However, in the present context, human rights enforcement is considered, above all, a matter of institutions warranting rights of individuals. The functioning of institutions involves individuals

in that they participate in specific relationships. Therefore, I privilege here social psychological analyses of such functioning rather than analyses in terms of individual differences.

Lessons of social psychology in relation to human rights are often lessons in skepticism. In research performed by Stanley Milgram in 1974, participants went ahead in delivering what they thought to be dangerous electric shocks to a person refusing to be further shocked or who was already unconscious. In a series of critical replications published by Meeus and Raaijmakers in 1987, it was shown again that for the sake of an experiment on stress, many people prevented an unemployed man from being hired. Of course, unknown to the experimental subjects in these experiments, the unemployed man was an actor.

Another lesson of skepticism is that in order to uphold a basic belief in a just world, many people often denigrate and chastise other people for the simple reason that they suffer. According to Melvin Lerner in his monograph published in 1980, a just world belief, seemingly very widespread in Western societies, would imply that remuneration and punishment, positive sanctions, and negative sanctions are not distributed randomly in this world. If one suffers, there should be a reason, and therefore people who suffer are often denigrated and considered responsible of their own fate. Literature on victimization, as summarized by Janoff-Bulman and Hanson Frieze in 1983, is based on a similar hypothesis. This trend of research can be illustrated by a concrete example: Witnesses of a rape scene, and even the victim of such an aggression, often tend to blame the victim for having an important part of responsibility in the aggression.

Lerner puts forward the idea that the fundamental need for justice could easily turn to discriminatory practices. In order to satisfy one's own needs as well as those of one's next of kin in an appropriate manner, it would be necessary to keep one's distance from a large part of humanity that cannot satisfy its hunger and that lives in inequality and injustice. To interact with such people outside strictly regulated or even discriminatory terms is looked upon as risky behavior endangering the progress of justice at home. It would be precisely those people who subscribe most to the concept of a just world who would best accept institutionalized patterns of discrimination.

Note, however, that the principle of a just world can also be put forward to explain altruistic behavior. It would thus account for feelings of indignation felt when witnessing some blatant injustices and could

even occasionally be at the base of “heroic” attempts made to redress these torts.

Research on submission to authority as well as that on the perverse effects of a belief in a just world are examples of the various trends of research that justify an attitude of skepticism about the often optimistic vision maintained by human rights supporters. Another important point to be added to this rather grim picture is the diffusion of responsibility described by Latane and Darley in 1970. Their studies aim to explain why individuals often do not intervene when confronted with an emergency, such as when somebody is attacked by another individual or falls in a state of unconsciousness on the street. A robust finding is that the presence of other bystanders reduces to an important extent the willingness of individuals to intervene in such a situation. Apparently, people feel less concerned to intervene in a situation of emergency when others can also intervene. Theoretically, one can suppose that this is often the case in situations of human rights violations and that therefore a reaction of “it is not my responsibility to intervene” is very likely to be manifested. Taking the rationale further, individuals confronted with massive and institutionalized HR violations may think that their own role in redressing these violations is utterly insignificant. Fortunately, when broadening the realm of research covered by psychologists in order to include research on the social development of children and adolescents, indications favoring more optimistic conclusions start to emerge.

What characterizes modern thinking is the refusal that traditional bodies such as churches, authorities, or charismatic personalities decide what is right or wrong, what is good or bad. It is this refusal that necessitates the building of a constructivist concept of knowledge and ethics. This conception of modernity oriented the groundbreaking research by Jean Piaget published in 1932 on *The Moral Judgment of the Child*. His aim was to study the transition of morals among children based essentially on the approval of rules decreed by others to more autonomous morals allowing for contractual changes of these rules through discussion and agreement between parties involved. According to Piaget, participation of children in interaction with equals makes such a transition from heteronomous to autonomous morality possible.

To consider that this developmental hypothesis by Piaget has been empirically authenticated would be exaggerated. Nevertheless, it embodies a general concept that has been at the root of other investigations too numerous to list. Only a brief presentation of the

stages of moral development described by Lawrence Kohlberg in 1984 is provided. Indeed, Kohlberg has refined, to a large extent, Piaget’s distinction between the two kinds of morality. He describes no less than six stages in the moral judgment of individuals. It is important to briefly characterize these stages, especially because the final two offer foundations for a constructivist concept of human rights ideas.

The first four stages are not directly related to human rights. The first one is essentially governed by constraints issuing from rules and sanctions: The avoidance of punishment and respect of authority are considered as ends in themselves. During the next stage, an individualistic orientation still predominates, but it already includes an instrumental concept of trading and reciprocity. The respect of the interest of others is used to better guarantee one’s own interests. The third stage represents conformism and seeking of social recognition. Attitudes such as to be well intentioned, to respect others and to keep one’s promises, and to remain faithful in allegiances give rise to morals illustrated by the statement “Do not do unto others what you would not have others do unto you.” The fourth stage is based on the principle of duty—the need to follow laws, rules, and conventions in order to keep the social system functioning well. A majority of adults often seem to reason following principles of the third and fourth stages.

The fifth stage sees the explicit intervention of a relativist attitude by acknowledging that many individual values and opinions are characteristic of given groups or societies and that other social contracts could set a higher value on different attitudes. The problem of the universality of specific values such as freedom or respect for life is explicitly put forward and a great significance is assigned to the consensual definition of a procedure allowing the fixing of rights and values to be respected by all.

The sixth and last stage is hardly encountered elsewhere than in writings of specialists such as philosophers and human rights militants. Universal ethical principles should supersede rules and conventions when they are in conflict. Following Immanuel Kant, people are considered an end in themselves. The moral point of view is the one that all human beings should adopt toward each other as free and autonomous subjects. Reasoning characteristic of this stage should take into consideration the point of view of each person susceptible of being affected by consequences of a decision to be made; such reasoning is based on the hypothesis of reversibility, according to which everyone should be able to put themselves in the others’ positions.

This is not the occasion to start a technical debate on the theoretical value of Kohlberg's stage model in the frame of current developmental psychology. It would be equally wrong to pretend that a person would necessarily fit into only one stage, as well as to pretend that their order of succession in individual development would occur at random. For present purposes, the important point is that an idealized conception of human relationships has also been the object of psychological studies.

In *Minding the Law*, A. G. Amsterdam, an expert in U.S. constitutional law, and Jerome Bruner, whose contributions to the psychology of child development, cognition, education, language, and culture are well known, analyze a series of decisions by the U.S. Supreme Court related to racial discrimination and the equal protection clause of the Fourteenth Amendment. Studying relevant documents and opinions of the Supreme Court in terms of category processes, narratives, rhetorics (conceived as social influence devices), and cultural dynamics, the authors show how important variations occur over time. The cases they comment on more extensively deal with the rendition of a runaway slave (*Prigg v. Pennsylvania*, 1842), racial segregation in railroad transports (*Plessy v. Ferguson*, 1896), racial desegregation in public schools (*Brown v. Board of Education*, 1954), the death sentence of an African American (*McCleskey v. Kemp*, 1987), and restrictions on desegregation in public schools (*Freeman v. Pitts*, 1992, and *Missouri v. Jenkins*, 1995).

The main conclusion of the study on historical variations over more than a century and half in the decisions by the Supreme Court is framed by Amsterdam and Bruner in the following terms: "This trail can be seen as marking the fall, the rise, and the fall again of a brightly egalitarian and progressive American Creed—or as marking the rise, the fall, and the rise again of an equally potent, darkly suspicious American Caution" (p. 16). Indeed, as others before them, the authors conclude that a basic component of American culture is the principles proclaimed in the Declaration of Independence, but they also conclude that the evolution of this culture cannot be understood if one does not admit the intervention of an equally potent principle restraining and limiting these rights for long periods. In discussing the links between these two fundamental aspects of American culture, they echo ideas of Lerner: "So the preservation of the American Creed requires that We (sic) create a category of people who are essentially and immutably different and inadmissible" (p. 264).

Hence, taking into consideration various research traditions, there seems to be a double message: Psychologists deliver lessons of optimism as well as

lessons of pessimism concerning matters related to human rights. According to Piaget and Kohlberg, the ideal of human rights would be, in a certain way, a spontaneous product of democratic interaction patterns. According to Milgram, citizens of democratic states can easily be brought to violate fundamental rights of others, and according to Lerner the proper belief in a just world may be used to justify practices of social discrimination as well as attempts to restore justice. In their contribution to the study of U.S. law and culture, Amsterdam and Bruner conclude that adherence to an optimistic egalitarian credo in a liberal democracy can be accompanied by an equally strong belief that rights of certain groups of people should be severely limited.

At first sight, these messages carry insurmountable contradictions that should resist integration within a same theoretical framework. However, studying human rights as normative social representations can allow for a better understanding of these seemingly conflicting lessons and offer a possibility of integrating them in a common explanatory frame.

3. HUMAN RIGHTS AS NORMATIVE SOCIAL REPRESENTATIONS

Multiple relations interconnect members of the human species directly or indirectly. Between the different groups constituting mankind circulate not only genes, viruses, pollutants, epidemics, consumer goods, or money but also ideas and institutions. What inhabitants of one country practice affects to varying degrees the fate of people abroad, their way of farming land, their state of health, their access to all kinds of resources, and the functioning of their institutions. It is difficult to imagine that a group of humans would not be affected to some extent by the way of life of other groups. In this sense, apartheid does not exist, but on the other hand, there is no perception, no definition, nor exhaustive analysis of the numerous ties that bind humans together. Even if globalization is a new term for naming that general interdependence, it does not mean that the phenomenon can be described precisely and fully understood. It is also true that general terms, such as globalization, can be used to conceal the obvious reality of exploitation or of negative interdependence. Such realities, even though they are part of a larger relational field, exercise their own noxious effects in many ways.

Interaction and communication between humans initiate symbolic representations, social norms, and contractual principles that often remain implicit. When we enter into a relationship with other persons, we know that the fate of participants in such a relation will be affected by their interaction, in some measure, within certain limits, at a certain cost. Normative representations exist on what these effects should be. Multiple forms of interdependence exist, characterized by all sorts of differences in status, purpose, interdependency, and formality. Various models of acceptable relationships, prototypes of fair and just situations, and contractual principles govern evaluations of these relationships. Such evaluative criteria have been built in multiple interactions, they are culturally defined, and their application can be guaranteed by institutions. Some of them are culturally specific, whereas others are spread over different cultures.

Human rights are such evaluative principles or normative social representations that could allow, at least at the level of the intention, humans to evaluate and to organize their relations and interactions. For historical (i.e., economical, political, military, religious, and scientific) reasons, Western societies organized relationships within national and cultural boundaries as well as across them. Many encounters with foreign cultures were sources of continuous conflict, and much irremediable harm has been inflicted in the frame of these contacts. Nevertheless, revolutionary ideas about universal human rights that were initially formulated as reactions against the arbitrariness of established powers (at the occasion of the American Declaration of Independence in 1776 and the French Declaration of the Rights of Man and Citizen in 1789) were thereafter progressively invested with new meanings. These meanings were elaborated by diverse and sometimes antagonistic militant movements in the realms of antislavery, antiserfdom, antiracism, and anticolonialism causes; by movements defending rights of workers, women, cultural minorities, aboriginal peoples, wounded soldiers, displaced persons; and by movements furthering right claims of many other social categories. The visions of human rights elaborated by these movements, and often forged at the expense of much effort and struggle, became institutionalized in the Universal Declaration of 1948, which is to be considered according to its preamble

As a common standard of achievement for all peoples and all nations, to the end that every individual and every organ of society, keeping this Declaration constantly in mind, shall strive by teaching and education to promote respect for these rights and freedoms and by progressive measures, national and international

to secure their universal and effective recognition and observance, both among the peoples of Member States themselves and among the peoples of the territories under their jurisdiction.

Human rights are clearly normative social representations, even if they are also important political and judicial realities.

It is generally accepted that in interactions with others, independently from their origin, the principles adopted in the Universal Declaration compel the respect of corporal integrity of these others, their liberty and their dignity, their access to vital resources, and their integration in a societal order guaranteeing protection against arbitrary decisions. Logically, in order to respect commitments taken by public authorities, citizens of many countries should only involve themselves in relationships respecting these principles. However, it is a fact that in numerous situations basic rights of individuals are not respected, as evidenced by economic conditions imposed on Third World countries or when some people, even in First World countries, are deprived from basic health care or from subsistence-level resources.

Here, a huge field of research opens. If human rights are indeed normative social representations, social psychologists—at least those involved in social representation studies—have theoretical and methodological tools at their disposal to study them.

4. RESEARCH FINDINGS

Social representations (SRs) are defined as organizing principles of symbolic relationships between individuals and groups. A first assumption on which this definition is grounded is that various members of a population under study share common views about a given social issue. SRs are generated in systems of communication that necessitate common frames of reference for individuals and groups participating in these communications. Hence, studying human rights in SRs terms always implies a search for common reference systems and for their organization. To what extent does the Universal Declaration offer references that are common to different populations under study?

Mainly, three studies are discussed here because they deal with SRs of HR in a transcultural setting. Two of them are extensively described in the 2002 monograph by Doise.

The first study derived from an interdisciplinary interview study on representations of violations. In a

questionnaire study, students aged 13–20 years in four countries (Costa Rica, France, Italy, and Switzerland) were invited to answer 21 items presenting various situations involving violations or limitations of individual rights. Some of these situations (e.g., racial discrimination, imprisonment without trial or legal assistance, and starvation) can easily be referred to classical definitions contained in the Universal Declaration. Other situations, dealing with the rights of children or with family affairs, are less explicitly related to the declaration. Some situations dealing with economic inequality or health matters (e.g., prohibition of smoking or hospitalization in case of contagious illness) are not covered by official definitions of rights.

The results were clear: Across countries generally the same situations are more often considered to be human rights violations. These findings have since been confirmed by research in the United States and Romania.

In a second transcultural study, the complete text of the declaration was presented to students of 35 countries. Respondents (university students in psychology, law, science, social work, and various other fields from the five continents) were asked to answer questions about personal involvement, agreement and efficacy, as well as governmental efficacy for each of the 30 articles of the declaration. A hierarchical cluster analysis designed to accentuate intraclass homogeneity was performed on indices of the Euclidean distances between articles based on the sums of responses to the eight scales for each article. This analysis resulted in the division of the articles into two main classes, which in turn were divided into subclasses. These subclasses showed an almost complete correspondence with the groups of articles described at the beginning of this article.

A subclass of the first main class aggregates the more social articles, relational rights (group 3, except article 14 about asylum), public liberties (group 4), and articles dealing with economic, social, and cultural rights (group 5). The other subclass aggregates the three articles referring to the more basic individual rights (protection from torture and slavery and right to life; articles 3–5 from group 2).

The second main class can be subdivided into three classes: a subclass of judicial individual rights (remaining articles of group 2) together with the right to asylum (article 14), basic principles (group 1), and the three articles concerning societal order (group 6).

In each national group, respondents show greater adherence to the basic and social rights than to the rest of the rights. These results clearly support the idea of a common organization of responses in various

countries. Such a common organization was also observed by Spini in a follow-up study using other samples of respondents from 16 countries belonging to five different sociogeographical areas.

A third study was carried out by Herrera and Doise in the province of Quebec, Canada. Participants in this study were French-speaking and English-speaking Quebecois and members of the aboriginal Innu nation (Montagnais). Unlike the previous studies, the questionnaire used in this study started with two different open-ended questions asking respondents to mention the human rights they know and also the specific rights claims of respectively the Quebecois, the Quebecers, and the autochthones according to the ethnic group membership of the three samples under study. For instance, for the Innu sample, this question was worded as follows: “According to you, which are the five most important rights of autochthonous people that would do them justice?”

Analysis of answers for the three groups shows that most of the rights that were mentioned as examples of HR could indeed be related to the Universal Declaration of Human Rights. There was also a high convergence between evocations of HR by the three groups: The four groups of rights most often referred to by the three samples were public freedoms and political rights, basic human rights principles, fundamental individual rights, and economic social and cultural rights.

Such a convergence was not observed for the evocations of collective rights (i.e., rights of the Quebecois or of the Aboriginal people also investigated in this study). Even if almost all rights mentioned as collective rights could be related to both the Universal Declaration of Human Rights and the Draft Declaration of Rights of Indigenous People, the rights more often mentioned by respondents of the three groups were not the same. The members of the Innu sample mentioned rights to dispose of their own territory and resources, fundamental collective rights such as the right to autonomy, rights to the preservation of their traditions and language, and rights to self-government and specific indigenous laws more often than other categories of rights. Of the rights contained in the Draft Declaration of Rights of Indigenous Peoples, only the rights concerning language and tradition figured among the rights most often quoted by both other samples.

Findings of this study again showed to what extent ideas about human rights are shared across group boundaries, although collective rights are interpreted in a more diverse way.

Social representation theory does not imply that individuals sharing common references hold the same positions. It is therefore important to investigate differences in individual positioning. Modulators of positioning are beliefs about personal efficacy and the efficacy of institutions (e.g., governments) with respect to human rights. Human rights positions also bear a relationship with value choices. Values as measured by Rokeach's terminal values are considered general to the extent that they supposedly organize symbolic relationships within a social environment. Given the historical origins of human rights ideas in conditions of discrimination and conflict, it is also expected that HR representations will be modulated by individual experiences of injustice and of conflict between social groups and categories.

A typology was constructed of respondents in the study with the 30 articles of the declaration. Four groups were retained: A group of advocates and a group of skeptics had relatively the highest and lowest scores on scales concerning general importance of HR and personal and governmental involvement in enforcing rights. A group of personalists considered that HR concerned them personally but that it was not easy for governments to do something for their enforcement, whereas governmentals considered themselves rather powerless for having HR respected but considered the government as relatively more effective. Strong support for the values of universalism and social harmony was found to be systematically related to HR advocacy. Intense experience of collective injustice, together with less concern for personal happiness, was characteristic of personalists rather than of governmentals. It was also found that skeptics were relatively more numerous in Japan and India, and personalists were more often found in countries with serious human rights problems according to the 1992 assessment published by C. Humana and with human development problems according to the 1996 ratings by the United Nations Development Programme. Governmentals were relatively more numerous in developed countries or countries that changed recently to a democratic regime.

Individual positioning in the study on violations of HR was also investigated. For the respondents in the initial four-country study and the Romanian sample, a cluster analysis extracted three groups of individuals according to the similarity of their responses. The ranking of violations for the two main clusters clearly overlapped the ranking found for the total population. However, these two clusters could be differentiated mainly on situations related to family affairs. Obliging children to forego schooling or to attend mass, parental

child beating, and preventing one's spouse (wife or husband) from going out alone were less clearly perceived as human rights violations by a group of respondents sharing a restricted definition of human rights, as were the obligation for women to veil their faces and the refusal to rent an apartment to a black person or a gypsy family. Respondents adhering to a more extended definition considered all these cases to be violations of HR. On the other hand, responses given by members of a third cluster were clearly atypical, probably reflecting a relative disinterest for the HR cause, at least in the manner they were institutionally defined.

How were individual variations in social positioning toward human rights violations linked to positioning in other societal realms? In order to investigate these relations, five additive scores were computed for each individual on a series of anchoring variables, namely the number of governmental actions considered unacceptable (e.g., death penalty and suppression of elections or of television broadcasting critical of government), the number of queries made by government and business firms considered to be unfair (e.g., concerning health and militancy in unions), the number of official regulations (e.g., regarding vaccination and compulsory military service) interpreted as infringement of individual freedom, the number of individual actions reported as unacceptable (e.g., bribery, hiding an escaped convict, and giving in to blackmail), and the number of agreements with fatalistic assertions (e.g., there will always be rich and poor, good and bad people, and nations that do not respect HR).

These anchoring variables were then used as independent variables in a discriminant function analysis with the three clusters of the typology as dependent variables. The two functions were statistically significant. The first function depicts the specific anchoring of the cluster of adherents to a restricted definition. In comparison to members of the other two clusters, individuals adhering to a conception that adheres more closely to the institutional definition of human rights cultivate a relatively more fatalistic conception of social reality while expressing broader tolerance toward governmental interference and various social regulations. One can clearly identify the origin of a restricted definition of rights: increasing power given to the government and acceptance of various social regulations in the context of a fatalistic conception of social relations. The second function merges an extended definition with refusal of various governmental and managerial infringements, with a higher tolerance for questionable individual deeds and a better

adhesion to various social regulations. In other words, this conception focused on protecting the individual—even while occupying a marginal social position—against authorities while accepting their regulatory role. The location of the atypical or unconventional position on each of these two functions reveals the complete opposition of its anchoring to those described previously.

In the Quebec study by Herrera and Doise, some HR were mentioned as collective rights and vice versa. A factor analysis shows that answers to both questions are interrelated in various ways, but that individual scores on the factors are again related to the way respondents perceive the actual and possible contribution of different social actors in having human and collective rights respected as well as to their experience of discrimination and rights violations.

A nonhierarchical cluster analysis classifies respondents into three groups. The position of members of a first group can be called one of liberalism. Tenants of this position are observed to adhere above all to the basic principles of human rights and to public freedom rights. The position shared by members of a second group corresponds to the cause of sovereignty that privileges mainly cultural and linguistic rights, but this position also implies an awareness about self-government issues and problems related to socioeconomic rights compatible with HR principles. These two profiles were more characteristic of nonaboriginal French-speaking as well as English-speaking participants who seemed equally aware that in their socio-cultural context important issues in defining HR and collective rights are those of liberalism and sovereignty. Self-determination, especially in matters concerning the use of land and resources and self-government, characterizes the position of a third group of respondents. As could be expected, the latter profile was characteristic of the aboriginal sample.

The differences of the SR approach and other social psychological approaches in HR studies are difficult to assess because few psychologists have researched HR. In a 1995 study, Diaz-Veizades *et al.* shared some of the concerns mentioned in this article because they also used the Universal Declaration of Human Rights in order to study the organization of individual positioning as well as anchoring of this positioning. However, they undertook important adaptations of the original document, reformulating the 30 articles of the declaration into 116 more concrete items, such as “If a person does not make enough money to support his or her family adequately, the family should be aided by the

government,” “There are times when people should be kept from expressing their opinion,” “Men and women should have equal rights in a marriage,” and “A person’s home is his or her ‘castle’ and should not be interfered with by others.”

For each item, their respondents (mainly North American college students) expressed their degree of agreement on a 7-point scale. However, the authors report that many items “had very low variance because of high rates of endorsement, so they could not correlate highly with other items. After these low-loading items were deleted, 38 items were reanalyzed using an iterated principle factor analysis.” Clearly, we are confronted here with a logic different from the one adopted in this article. Diaz-Veizades and colleagues favored the study of systematic interindividual variations to the detriment of analyzing the common meaning aspect of SRs. When eliminating the most consensual items of their questionnaire, they could retain four factors for the remaining items that represented only one-third of all items presented to respondents. A first factor, called the social security factor, concerned access or entitlement to an adequate standard of living (e.g., food, housing, and medical care). A second factor, civilian constraint, dealt with the acceptability of limiting individual civil and political rights. The theme tying items together for the third factor was that of equality, evidenced most clearly by items dealing with equal access to basic rights for all individuals regardless of race, gender, or beliefs. Finally, items with highest loading on the fourth factor involved privacy issues. Diaz-Veizades and colleagues also analyzed anchoring patterns in showing, for instance, that respondents adhering more to a civilian constraint conception of HR were also those who obtained higher scores on a nationalism scale and lower ones on internationalism and civil liberties scales; their political preferences were more likely to favor Republicans over Democrats as opposed to the preferences of adherents to a social security conception, who favored Democrats and had higher scores on internationalism.

5. PUTTING THINGS IN PERSPECTIVE

An important issue that preoccupies colleagues from anthropology and cultural psychology is the problem of the universality of HR, and some of them envisage the possibility that HR are merely an expression of

Western ethnocentrism. Indeed, ethnocentric use of HR was experimentally evidenced by Moghaddam and Vuksanovic in 1990. In a first study, they asked undergraduate students in Montreal to answer a questionnaire about HR issues. The questionnaire is identical in three conditions, except for the fact that in a first condition the context referred to was Canada, in a second condition it was the Soviet Union, and in a third condition it was the Third World. Typical items were as follows: "All forms of censorship should be done away with in [Canada/Soviet Union/Third World] societies" and "Everyone in [Canada/Soviet Union/Third World] societies should have access to free health care." Overall, support for HR was stronger in the Soviet Union and Third World contexts than in the Canadian context. In a second study, three scenarios were used concerning a television news anchor woman who had been fired from her job, a member of a terrorist group who had been tortured, and a female shoplifter, again presented in three different contexts. As in the first study, support for HR was stronger in the conditions Soviet Union and Third World than in the condition Canada. Such results tend to confirm the opinion of critics who consider HR as a Western export article, considered useful for others but less so for Westerners themselves.

The previous discussion suggests that the HR issue is indeed a highly normative one. Individual stances are embedded in value choices and orient judgments about social reality also in the realm of international relations. In one's own environment, strong convictions about values are not necessarily applied in a consistent way. Clémence and Staerklé explored this issue and their findings are reported in the monograph by Doise. When comparing judgments on rights limitations reported in the realm of privacy, free education, or the death penalty, they found that Genevan participants in their study very strongly adhered to the relevant HR principles, giving average scores higher than 6 on a 7-point scale. However, scores dropped significantly when it was a matter of indicating their degree of acceptance (1, acceptable; 7, unacceptable) of violations of these rights in cases of a search without a warrant of a home by a police officer, refusal of free primary schooling to handicapped children, or the death penalty for minors. Furthermore, when these limitations of individual rights were merely reported as newspaper items ("faits divers"), their degree of rejection was on average 4.94, whereas when they were explicitly reported as extracts of HR reports, the average degree of unacceptability decreased by almost

1 point on the scale to 4.01. It seems as if references to HR for events in Western countries were less pertinent and prevented people from going into a more detailed analysis of the situation. Paradoxically, the absence of an explicit invocation of HR implies that individuals pay greater attention to reprehensible aspects of acts occurring in their own environment and, as a consequence, find them less acceptable. On the contrary, when general HR principles are explicitly evoked, concrete characteristics of events happening in one's own country are not taken into account, and in this way people can moderate their judgments.

The fact that HR are to be considered normative social representations invests them with very strong value connotations. As a consequence, in some situations violations of rights are considered less important when they happen in one's country, whereas HR violations far abroad are strongly condemned.

Without doubt, variations in enforcement of HR exist across countries. However, differences in beliefs related to the actual enforcement of HR in one's own country also exist between inhabitants of Western democratic countries. The principal component of a normative social representation will certainly remain its insufficient realization in many social contexts. Otherwise, it would no longer have reason to exist. It is precisely the awareness that rights are violated that often makes people claim that these rights should be enforced—that their enforcement has to become part of social reality.

GLOSSARY

humor A broad and multifaceted concept that is variously used to refer to the quality of communications, the emotions that such communications elicit, and a tendency to respond with amusement in a variety of situations.

state humor Emotions (e.g., amusement, mirth) that link stimulus materials (e.g., comedy tapes) and observable responses (e.g., laughter).

trait humor A readiness to find or create humor in different situations (i.e., sense of humor).

well-being Physical and emotional health.

Articles on humor and health frequently begin by reminding readers, for example, that “a merry heart doeth good like a medicine” (from Proverb 17:22 in the King James Bible). Although few would argue with the first part of this proverb—“A merry heart doeth good”—there is very little agreement about whether or not humor should be likened to medicine. On the one hand, it is easy to come away from movies such as *Patch Adams* and articles in *Reader’s Digest* with the

impression that “laughter is the best medicine” (a phrase that has been used in the titles of several scientific articles). On the other hand, scientists doing research on health and well-being have expressed a considerable amount of skepticism about the medicinal effects of humor. Probably no article has done more to stimulate interest in humor and well-being than one that appeared in the *New England Journal of Medicine* by Norman Cousins, who was then the well-connected editor of the *Saturday Review*. In this brief article, which was subsequently expanded into a best-selling book, Cousins described how he checked himself out of a hospital after being diagnosed with a progressive, and usually fatal, form of rheumatoid disease. Following a self-prescribed regimen of Marx Brothers movies and *Candid Camera* television episodes, Cousins concluded that “10 minutes of genuine belly laughter had an anesthetic effect and would give me at least two hours of pain-free sleep.”

1. MULTIPLE MEANINGS OF HUMOR

Humor is a broad and multifaceted concept that is variously used to refer to the quality of communications (e.g., funny or amusing stories), the emotions that such communications elicit (e.g., amusement, mirth), and a tendency to respond with amusement in a variety of situations (i.e., a sense of humor). As a stimulus, humor has been used to describe the

contents of literary material, television shows, movies, and (more recently) videotapes that are supposed to be funny. However, more than one study has reported checks on manipulations indicating that the individuals exposed to supposedly humorous material do not share the experimenters' definitions of "funny" or "amusing." This finding highlights the importance of individual differences. Few things are as idiosyncratic as people's preferences for different types of humor. If everybody agreed about what is funny or humorous, one would never have to endure the agony of seeing a comic "die on stage."

Serious problems are also encountered when one tries to define humor as a response or behavior such as laughing or smiling. No single behavior is a sure sign of amusement or mirth. For example, a subordinate may smile at the boss's joke for reasons that have nothing to do with how funny the joke is. To take another example, few movies provoke as much laughter in a college classroom as do Milgram's *Obedience to Authority*, which shows individuals forced to make stressful decisions. In such situations, laughter communicates anxiety rather than amusement. Furthermore, Provine's observational studies indicate that laughter in natural settings is typically preceded by mundane and pedestrian remarks. Provine could have used the familiar form of his first name, Bob, to illustrate this point. It was not long ago that the mundane greeting "Hi, Bob" (said by every person in a room) provoked laughter, first on *The Bob Newhart Show* and later whenever an individual named Robert entered a room.

Obviously, stimulus-based definitions of humor require that we observe some kind of response, and response-based definitions presume that evoking stimuli possess certain characteristics. These facts have led most theorists and researchers to define humor as an intervening variable. Following the lead of investigators doing research on emotions such as anxiety and anger, scholars frequently draw a distinction between state humor and trait humor. State humor describes emotions (e.g., amusement, mirth) that link stimulus materials (e.g., comedy tapes) and observable responses (e.g., laughter). Trait humor is a readiness to find or create humor in different situations. The latter corresponds to what is usually termed a person's "sense of humor." Investigators doing research on trait humor also draw a distinction between "getting a joke" (i.e., appreciative humor) and "telling a joke" (i.e., productive humor). In 1998, Craik and Ware identified several other types of humor. For example, the Humor Style Questionnaire highlights the well-known distinction between aggressive humor and friendly

humor. Although the questionnaire's originators have been concerned primarily with people's health, research on aggression highlights the importance of drawing such a distinction. It has consistently been found that friendly humor reduces aggression, whereas witticisms (i.e., jokes at the expense of others) and hostile humor usually provoke hostility and/or aggression.

2. MECHANISMS: POSSIBLE MEDIATORS AND MODERATORS

At a time when individuals are constantly reminded that good health requires that they engage in activities they would rather avoid, such as exercising and eschewing sweet and fatty foods, it is not surprising that the public has seized on the idea that humor is good "for whatever may ail a person." Those who favor humor might not state things so bluntly (e.g., "Here's something you will like"), but they make a point of noting that there is a fairly strong connection between negative emotions and illness. It has been argued that if things that people do not like cause stress, which is associated with illness, then things that people like should add to health and longevity. Of course, the same argument could be made for sugar, fatty foods, and addictive substances.

Positive affect is usually assessed by having individuals complete self-report measures, although investigators occasionally obtain nonverbal measures such as frequency of laughter and smiling. These responses have been treated as separate dependent variables in research on humor and health. However, the case for mediation would be stronger if investigators performed analyses showing that relationships between humor and well-being vanished or were reduced after investigators statistically controlled for the intervening variable of positive affect. Unfortunately, such analyses have not been performed. In addition, there is no evidence to support the frequently heard claim that endorphins are released when individuals are exposed to humorous material.

Early research tried to identify cardiovascular and endocrinological changes that might be responsible for humor's effects. The physiological effects of laughter are similar to those of brief bouts of exercise—faster breathing, rapid heart rate, elevated skin temperature, and increased blood pressure. Higher levels of circulating catecholamines and cortisol have also been recorded. Early researchers suggested that people benefit from

the relaxation that follows laughter. However, these physiological changes have not been shown to be intervening variables that lead to long-term improvements in health and well-being.

Physiological explanations can be contrasted with cognitive approaches that emphasize appraisal and distraction. It is possible that humor enables individuals to cope with stress by helping them to view events as less threatening (i.e., cognitive appraisal) and by putting their problems into perspective (i.e., cognitive reappraisal). The latter is typified by jokes that begin, "You think you have problems." Another possibility is that the task of processing humor (i.e., getting a joke) distracts attention away from unpleasant events and experiences such as pain.

Finally, some of the effects attributed to humor may be due to the demonstrable effects of social support. In 2000, Provine pointed out that individuals rarely laugh when they are alone. Unfortunately, social support has been introduced as a confound by the common practice of testing individuals in small groups. Research is needed to determine whether humor exerts salubrious effects when individuals are tested alone.

3. METHODOLOGICAL ISSUES

The distinction between state humor and trait humor is relevant to the procedures that investigators employ to assess the effects of humor. By and large, researchers interested in the effects of state humor have adopted an experimental approach, whereas those conducting studies of trait humor have employed correlational techniques. Typically, in experiments on state humor, behavioral and physiological measures are collected after some participants have been exposed to an audio or video recording of a comic (nearly always Robin Williams or Bill Cosby). This has been done in both field and laboratory settings. It is difficult to interpret the results from laboratory studies when the dependent variable is pain tolerance because it is likely that most participants (especially undergraduate males) guess that the experimenters want to find out whether they can "grin and bear it." Regardless of whether studies are conducted in laboratory or field settings, researchers must take care to assess and control for their expectations and demand characteristics. So-called placebo effects are a problem because it is hard to disguise manipulations of humor. Because so much has been written about humor's supposedly

beneficial effects, it is likely that most participants guess that the experimenter expects them to respond in a positive manner. This suggests that verbal ratings of stimulus materials, which are the usual checks on manipulation, might not be particularly useful or informative. As Provine pointed out, it is essential that researchers verify their inductions by monitoring behaviors such as smiling and laughter. Another necessity is to include a control group whose members are exposed to equally interesting and arousing but nonhumorous material. This type of control is needed to ensure that effects attributed to humor are not in fact caused by arousal or by distracting attention away from pain and unpleasant events.

In correlational investigations, participants typically complete several measures of humor and emotional states such as anxiety and depression. Two of the most widely used measures in this area are the Situational Humor Response Questionnaire (SHRQ) and the Coping Humor Scale (CHS). Lefcourt and Martin developed these to measure productive humor, but it is not entirely clear what these scales actually measure. Psychometric investigations indicate that these and other humor scales load heavily on a factor that Köhler and Ruch termed cheerfulness. The scales also tap a factor that has been termed "low seriousness" (or frivolity) that appears to accompany the detachment and perspective taking that humor is supposed to promote. Köhler and Ruch also found that correlations between self-report and behavioral measures of humor were low. These findings suggest that results obtained in this area might be due to other personality traits such as optimism, creativity, extraversion, and lack of social sensitivity. This is another way of saying that studies on trait humor lack discriminant validity. In addition, nearly all studies have been cross-sectional. Very few investigators have undertaken longitudinal investigations, which would strengthen claims that humor and well-being are linked in a causal fashion.

Although the distinction between trait humor and state humor is useful for organizing the literature, a few studies have combined the two approaches by measuring individuals' sense of humor before they are exposed to humorous material. It was thought that individuals with a well-developed sense of humor might benefit more from humorous viewing matter than would those with a less developed sense of humor. This hypothesis has not received support, but it is possible that people who have a sense of humor (or a cheerful disposition) go out of their way to expose themselves to material and situations that make them smile and laugh.

4. TRAIT HUMOR, DISTRESS, AND LONGEVITY

As might be expected, measures of trait humor are correlated with scales that assess positive emotions such as happiness and subjective well-being. Conversely, they are negatively correlated with measures of distress (e.g., anxiety, depression, hostility). However, this pattern may reflect little more than the operation of a more general trait such as cheerfulness. Thus, it is noteworthy that early studies by Lefcourt and Martin found that trait humor may act as a buffer that reduces the negative effects of stressful life events. These investigators concluded that humor is “an antidote to stress” after they had undergraduates complete three sets of self-report measures, including the previously mentioned measures of humor (SHRQ or CHS) and a measure of stressful life events. They used scores on these two measures to predict scores on a third measure (total mood disturbance), which was the sum of four negative mood states (e.g., anxiety, depression) and a negative score for positive mood. They found that some, but not all, types of humor acted as a stress-reducing buffer. In particular, people who scored high on productive humor (i.e., attempts at being funny) were less likely to report negative mood states when they encountered stressful life events than were those who scored low on productive humor. However, this finding received mixed support in subsequent studies. Overall, productive humor does not appear to be any more effective than humor appreciation in helping people to cope with stress. In addition, the effects of trait humor appear to depend on how stress is defined (i.e., stronger effects when adversity is recalled than when it is experienced), on how distress is operationalized (i.e., stronger effects for depression than for anxiety), and on gender (i.e., stronger effects for males than for females). These inconsistencies led Martin and Lefcourt to use words such as “ambiguous” and “uncertain” to describe the buffering effects of trait humor.

Suggestive and sometimes intriguing findings have also been obtained in studies that have examined relationships between trait humor and physical symptoms. Unfortunately, all of the findings are correlational and based on self-report measures. Because investigators have not controlled for negative affectivity, it is possible that people with a sense of humor report fewer symptoms because they are the kind of people who are less likely to appraise events in a negative fashion.

Nonsignificant and sometimes contrary results have been obtained when investigators have tried to relate trait humor to more objective measures such as longevity. One study found that famous humorists and comics, who earned their reputations by producing humor, did not live any longer than individuals who achieved eminence in other fields. Granted, this study can be faulted for failing to draw a distinction between friendly humorists (e.g., Fred Allen, Will Rogers) and comics whose witticisms and insults are associated with negative emotions (e.g., Don Rickles). This criticism does not apply to a longitudinal analysis of mortality rates of gifted individuals who were first tested at 12 years of age as part of Terman's Life Cycle Study. Friedman and colleagues combined teacher ratings of optimism and sense of humor into a measure of cheerfulness. Contrary to expectations, they found that individuals with a cheerful disposition died at earlier ages than did their more serious counterparts. This unexpected result was explained by suggesting that a cheerful disposition might lead individuals to ignore or discount threats to their health.

5. HUMOR AND PHYSICAL HEALTH

In addition to longevity, investigators have looked at the effects of humor on blood pressure, immune function, and pain tolerance. It appears that humor does not have long-term effects on cardiovascular measures such as heart rate and blood pressure. However, there is some reason to believe that trait humor acts as a buffer to reduce the systolic blood pressure of females but not that of males. It may be that females use humor to reappraise threatening events (e.g., “Look on the bright side”), whereas males show a preference for aggressive humor.

Mixed results have been obtained in studies that have looked at the effects of humor on the body's immune system. On the one hand, a few positive results have been obtained in studies that relied on blood assays, but immunological indicators vary from one study to the next—sometimes natural killer (NK) cell activity, sometimes interleukin cell activity, sometimes both, but more often neither. It is difficult to interpret these findings because investigators have not controlled for general emotional arousal and the pyramiding of Type I errors that occurs when a large number of tests of significance are conducted. On the other hand, several studies have found that humor leads to higher levels of secretory immunological A (SIgA), which is the body's first line

of defense against upper respiratory illnesses. However, nonsignificant results were obtained when investigators looked at the frequency of cold and flu symptoms. Of greater concern, studies on SIgA have lacked adequate controls for general emotional arousal, distraction, and diurnal variations in hormone production and immune function.

Finally, although research on most health variables has been disappointing, it is in some ways fitting that studies on pain provide partial vindication for the claims that Cousins originally made in 1976. Laboratory studies are fairly consistent in finding that individuals have a higher tolerance for pain after watching an amusing videotape than they do after watching one that is merely interesting or distracting. There is also some evidence that humorous materials help individuals to endure orthopedic and arthritic pain in hospital settings. For example, in a field experiment in 1996, Rotton and Shats compared the amount of pain medication that patients requested after watching either comedies or adventure movies following orthopedic surgery. They found that patients who watched comedies requested smaller doses of minor analgesics (e.g., aspirin) than did those who watched adventure movies or who were not given movies to watch. However, this beneficial effect did not extend to major analgesics (e.g., Percodan). Indeed, the results indicated that patients actually asked for more medication when they were not given a choice as to which films they could watch. As the researchers observed, having no choice but to watch comedies that fail in their attempts to be amusing probably elicits negative emotions.

6. CONCLUSIONS

Belief in the healing power of humor is so widespread that this article's skeptical tone might seem surprising to some. Those who question humor's medicinal effects run the risk of being labeled curmudgeons. Thus, it should be noted that this article's evaluation echoes conclusions found in books and articles by the most active and frequently cited researchers in this field. It should be cautioned that these conclusions are based on a relatively small number of empirical studies. For example, Martin reported that his recent review of health effects uncovered no more than 45 empirical studies.

It is possible to offer two reasons why very little research has been done to untangle relationships between humor and well-being. First, belief in the healing

power of humor is so widespread that it already seems to be taken as proven. That is, why do research to test a hypothesis that most people already believe is true? Second, one may recall that the concept of humor appears to load onto two factors: cheerfulness and lack of seriousness. Most people do not object to being termed "cheerful," but they find it difficult to have their work dismissed as lacking in seriousness. These two tendencies may explain why publications in this area rarely include footnotes that acknowledge funding sources.

Reviews usually address a paucity of research by suggesting that more is necessary. However, what is really needed is better research—experiments that contain necessary control groups and verifiable measures of humor (e.g., laughter, smiling), studies that rule out general arousal as a rival hypothesis, intervention studies that avoid all of the biases (e.g., expectancies, placebo effects) that self-report measures introduce, investigations whose results are based on a sufficient number of participants, and research that explores the possible mediating role of social support.

Rather than comparing humor to medicine, as has been done so frequently, it might be more appropriate to compare the effects of humor to those that may be produced by vitamin pills and the supplements one finds at health food stores. The government prohibits sellers from claiming that dietary supplements cure anything, but those who buy vitamins believe that they benefit from ingesting them. In the same way, the literature in this area contains intriguing results from unfortunately flawed studies suggesting that individuals may sometimes benefit from a dose of laughter. Stores can sell vitamins because they do not contradict the physician's edict: "First do no harm." The same can be said of humor. There is probably no harm in a regimen that keeps people in stitches—unless, of course, an individual is recovering from an appendectomy.

GLOSSARY

age regression In hypnosis, an experience in which the hypnotized person returns to a scene or an event experienced in the past.

analgesia A reduction in pain.

anesthesia A reduction in tactile sensation; in surgery, this is often accompanied by a general loss of consciousness.

conscious sedation A surgical technique in which the patient remains conscious during a procedure but receives analgesic drugs to reduce pain as well as sedative drugs to reduce anxiety and induce amnesia for the procedure.

false alarms In memory testing, an instance where the person incorrectly identifies an item as having appeared on a previously studied list.

hemispheric specialization The idea that the right and left hemispheres of the cerebral cortex are specialized for different psychological functions.

hyperesthesia Enhancement of sensory acuity and other perceptual abilities; it is the opposite of anesthesia.

hypermnnesia Enhancement of memory; it is the opposite of amnesia.

hyperpraxia Enhancement of muscular strength, endurance, and motor ability; it is the opposite of apraxia.

hypnotizability Individual differences in response to hypnosis, as measured by standardized psychological tests such as the Stanford Hypnotic Susceptibility Scales.

openness to experience A "Big Five" personality trait characterized by richness in fantasy life, aesthetic sensitivity, awareness of inner feelings, need for variety in actions, intellectual curiosity, and liberal values.

psychodynamic Broad label for a class of theories of personality and psychotherapy based on Freud's idea that behaviors are motivated by unconscious conflict.

psychosomatic The term applied to medical illnesses and other physical conditions that appear to be caused by mental states such as particular beliefs and attitudes.

self-fulfilling prophecy A situation in which a person's beliefs and expectations lead him or her to behave in such a manner as to make the expectations come true, thereby confirming the person's initial beliefs.

Hypnosis is a social interaction in which one person responds to suggestions given by another person (the hypnotist) for imaginative experiences involving alterations in perception, memory, and the voluntary control of action. In the classic instance, these suggested experiences are associated with a degree of subjective conviction bordering on delusion and an experience of involuntariness bordering on compulsion. Hypnosis has its origins in the "animal magnetism" promoted by Franz Anton Mesmer, an Austrian physician, for the treatment of medical illnesses.

Mesmer's theories were discredited in 1784 by a French royal commission chaired by Benjamin Franklin, but interest in his technique persisted. Over the years, animal magnetism was transformed into "mesmerism," then "artificial somnambulism," then "neurohypnotism," and finally hypnosis as we know it today. Since the time of William James and Ivan Pavlov, hypnosis has been of interest to psychologists and other scientists and philosophers for the insights it can yield about perception, memory, consciousness, and other basic psychological functions. However, it has also found its way into practical applications of various sorts.

1. HYPNOTIZABILITY AND ITS CORRELATES

It is important to understand that not everyone responds positively to hypnotic suggestions. Individual differences in hypnotizability are measured by performance-based tests such as the Stanford Hypnotic Susceptibility Scale and the Harvard Group Scale of Hypnotic Susceptibility. Some researchers and clinicians use alternative scales, such as the Hypnotic Induction Profile, but the Harvard scale is the most popular choice for this purpose and the Stanford scale remains the "gold standard" for measuring hypnotizability. The hypnotizability scales consist of a standardized induction procedure accompanied by a set of representative hypnotic suggestions, the response to which is scored according to objective behavioral criteria. As measured by the scales, most people are at least moderately responsive to hypnotic suggestions; relatively few people are refractory to hypnosis, and relatively few "hypnotic virtuosos" fall within the highest level of responsiveness. Some theorists have argued that hypnotizability can be enhanced by developing positive attitudes, motivations, and expectancies concerning hypnosis. As with any other skilled performance, hypnotic response is probably a matter of both aptitude and attitude. Negative attitudes, motivations, and expectancies can interfere with performance, but positive ones are not by themselves sufficient to create high hypnotizability.

Hypnotizability is not substantially correlated with most other individual differences in ability or personality such as intelligence and extraversion. One exception is absorption, that is, the tendency to have subjective experiences characterized by the full engagement of attention (narrowed or expanded) and blurred

boundaries between self and object. Absorption, in turn, is a facet of the "openness to experience" dimension in the "Big Five" structure of personality. However, even these correlations are too weak to permit hypnotizability to be predicted in advance on the basis of the usual sorts of personality questionnaires.

Although hypnosis is commonly induced by suggestions for relaxation and even sleep, the brain activity in hypnosis more closely resembles that of a person who is awake. The discovery of hemispheric specialization led to the speculation that hypnosis was a "right-brain" function, but it is obvious that response to hypnotic suggestions also requires the verbal functions normally associated with the left cerebral hemisphere. Because the experience of involuntariness is a central feature of hypnosis, some theorists have proposed that the state entails alterations in functioning of the frontal lobes of the brain that are known to be involved in executive control. However, a better understanding of the neural substrates of hypnosis awaits studies of neurological patients with focalized brain lesions as well as brain-imaging studies (e.g., positron emission tomography [PET], functional magnetic resonance imaging [fMRI]) of normal individuals.

2. PAIN AND ANALGESIA

By far, the most successful clinical application of hypnosis involves suggestions for analgesia to relieve pain. As early as the 1840s, John Elliotson and James Esdaile each reported that they had performed a large number of surgeries painlessly with artificial somnambulism as the only anesthetic agent. However, beginning in 1846, the introduction of chemical anesthetics, such as ether and chloroform, quickly supplanted hypnosis. Nevertheless, when chemical analgesics or anesthetics were unavailable or contraindicated, physicians still sometimes turned to hypnosis. Between 1955 and 1974, more than two dozen cases in which hypnosis had been used as the sole analgesic or anesthetic agent in surgery were published. Of even greater importance was the publication, during the early 1960s, of extensive case series documenting the successful use of hypnosis in obstetrics and in the treatment of cancer pain. Other clinical studies found that hypnosis can effectively relieve pain in dental patients. One comprehensive review of the clinical literature estimated that approximately half of medical, dental, and surgical patients could obtain significant pain relief through hypnosis alone. More recent reviews confirm that even when patients are unselected for

hypnotizability, hypnotic suggestions can have quite substantial effects on both acute and chronic pain. Hypnosis may be especially useful in cases of chronic pain, where chemical analgesics such as morphine pose risks of tolerance and addiction, and in childbirth, where the active participation of the mother may be desirable.

In addition to replacing chemical analgesics when circumstances warrant, hypnosis can serve as a useful adjunct to more conventional medical treatment of pain such as “conscious sedation” for outpatient surgery. Careful clinical studies by at least three independent groups of investigators have shown that the addition of hypnosis reduces both pain and anxiety. Patients request, and receive, less pain medication than do controls. Hypnosis is associated with a decrease in interruptions and adverse events during surgery. The procedure takes less time, and patients recover faster, when patients receive both hypnosis and medication. Although hypnosis can rarely substitute for the chemical analgesia and anesthesia that is the standard of care in modern medicine, it is a cost-effective adjunctive treatment (a complement if not an alternative) that improves the quality of patient care.

In addition to this increasing body of clinical research, a large amount of laboratory research has shed light on the mechanisms by which hypnotic suggestions have their effects. Hypnotic analgesia is not mediated by mere relaxation or by the release of endogenous opiates (endorphins). It is not merely a placebo effect (although there is a placebo component in hypnotic analgesia, just as there is in chemical analgesics). Hypnosis can reduce both sensory pain and suffering; in fact, suggestions specifically targeting one or the other of these components of pain have selective effects on activity in the somatosensory and anterior cingulate regions of the brain. Psychologically speaking, hypnotic analgesia seems to go beyond self-distraction, stress inoculation, cognitive reinterpretation, and tension management. According to one prominent theory, hypnotic analgesia involves a dissociation, or a division of consciousness, that effectively reduces patients’ awareness of pain.

3. OTHER CLINICAL APPLICATIONS

Hypnotic suggestion can have “psychosomatic” effects on aspects of bodily functioning other than pain, and these can also be useful in the practical sense. For example, it has frequently been observed that hypnotic suggestions can reduce bleeding from wounds and speed the healing of burns. However, these effects have not yet been subject to rigorous clinical and experimental study.

Several well-controlled laboratory and clinical studies have shown that hypnotic suggestion can affect allergic responses, asthma, and the remission of warts. Such successes have led some practitioners to offer hypnosis in the treatment of cancer, but there is no evidence that hypnosis affects tumors themselves as opposed to patients’ quality of life.

Hypnosis has also been used in psychotherapy. Some psychodynamic theorists, working in the tradition of Sigmund Freud, consider hypnosis to be a form of “adaptive regression” or “regression in the service of the ego,” and they use it to promote relaxation, enhance imagery, and generally loosen the flow of free associations. However, there is little evidence from controlled outcome studies that “hypnoanalysis” or “hypnotherapy” is more effective than nonhypnotic forms of the same treatment. In contrast, a recent review found substantial treatment gains when hypnosis was used adjunctively in cognitive-behavioral therapy for problems such as obesity, insomnia, anxiety, phobia, and hypertension. In view of the demands of managed medical and mental health care, it is important for practitioners who use hypnosis to document quantitatively the clinical (and economic) benefits of doing so.

An important but unresolved issue is the role played by individual differences in the clinical effectiveness of hypnosis. In the laboratory, as in the clinic, a genuine effect of hypnosis should be correlated with hypnotizability. Unfortunately, clinical practitioners are often reluctant to assess hypnotizability in their patients and clients due to a concern that low scores might reduce motivation for treatment. This danger is probably exaggerated. On the contrary, assessment of hypnotizability by clinicians who are contemplating the therapeutic use of hypnosis would seem to be no different, in principle, from assessment of allergic responses before prescribing an antibiotic. In both cases, the legitimate goal is to determine what treatment is appropriate for what patient.

It should be noted that clinicians sometimes use hypnosis in nonhypnotic ways, and these practices tend to support the hypothesis that whatever effects they achieve through hypnosis are related to its placebo component. For example, there is nothing particularly “hypnotic” about having a patient in a smoking cessation treatment rehearse therapeutic injunctions not to smoke and other coping strategies while hypnotized. It is possible that many clinical benefits of hypnosis are mediated by placebo-like motivational and expectational processes, that is, by the “ceremony” surrounding hypnosis rather than by hypnosis per se.

4. SENSORIMOTOR PERFORMANCE ENHANCEMENT

Much of the popular interest in hypnosis stems from claims that it permits people to transcend their normal voluntary capacities, yielding increased muscular power, endurance, resistance to fatigue, and sensory acuity as well as other special abilities. However, controlled research has largely failed to find evidence that hypnosis can enhance these and other aspects of human performance. Many early studies, which seemed to yield positive results for hypnosis, possessed serious methodological flaws such as the failure to collect adequate baseline information. For example, individuals may “hold back” on nonhypnotic trials so as to satisfy experimenters’ implicit expectations that they show “improved” performance during hypnosis. Of course, in some situations, benefits may be achieved indirectly through suggestions for reduced awareness of pain. For example, hypnotized persons may experience themselves as stronger, but this is not the same as a direct enhancement of human performance capacities *per se*.

In general, it appears that hypnotic suggestions for increased muscular strength, endurance, sensory acuity, and/or learning do not exceed what can be accomplished by appropriately motivated persons outside of hypnosis. Nevertheless, the folklore surrounding hypnosis may lead hypnotized persons to achieve performance enhancements through a kind of self-fulfilling prophecy. For example, instead of giving suggestions for increased muscle strength, one intriguing study asked hypnotizable persons to imagine themselves becoming stronger. These individuals actually outperformed controls who were merely exhorted to maximize their performance. If hypnosis does enhance human performance, it may be by virtue of hypnotic alterations in individuals’ self-concepts rather than by virtue of their skeletal musculatures.

Another highly intriguing line of research contends that hypnotic suggestions may enhance visual acuity in individuals with myopia (although not in individuals with normal vision). The research is especially intriguing because the investigators took special care to rule out “peripheral” factors, such as accommodation and other structural changes in the eyes, that might account for the effect. If hypnotic suggestions do in fact improve visual acuity in people with impaired vision (and this claim still must be confirmed by additional research), the effects appear to be mediated centrally, perhaps involving cortical centers associated with vision or visual attention.

It is sometimes claimed that hypnosis enhances “parapsychological” abilities such as clairvoyance, telepathy, and telekinesis. However, there is no good evidence that this is the case, not least because there is no good evidence of parapsychological effects in the first place.

5. LEARNING AND MEMORY

Similar conclusions apply to learning capacity. Many studies of hypnotically enhanced learning suffer from the same methodological defects as do the aforementioned studies of muscular performance and sensory acuity. One well-known line of research attempted to enhance learning by giving individuals hypnotic suggestions for time distortion. By extending the “subjective” interval of time devoted to studying the material, these investigators hoped to enable these individuals to learn more over short intervals of time. However, the promising results of early experiments have largely failed to be confirmed by more tightly controlled follow-up studies. Hypnotized persons may well experience time as flowing more slowly, or more rapidly, than it actually is, but this distortion in perception does not have positive consequences for learning.

A special case of performance enhancement pertains to hypnotic suggestions for improvements in memory or “hypnotic hypermnnesia.” Hypermnnesia suggestions are sometimes employed in forensic situations, to help forgetful witnesses and victims remember, and in therapeutic situations, to help patients remember childhood sexual abuse and other traumatic personal experiences. Sometimes, suggestions for enhanced memory are accompanied by suggestions for age regression in which hypnotized persons are asked to return to a previous period in their lives. Although the clinical literature contains a number of reports claiming success, most of these are anecdotal in nature and fail to obtain independent corroboration of the memories that emerge. There is no clinical evidence that hypnotically enhanced memories are reliable, that is, that they can be taken as true without independent confirmation.

In fact, evidence from carefully controlled laboratory studies shows quite the opposite. Hypnosis does not appear to increase accurate recollection over and above what can be achieved under nonhypnotic circumstances. To make things worse, hypnosis appears to increase the likelihood of “false alarms” on recognition tests and to inflate individuals’ confidence in their memories, independent of their accuracy. Moreover, by virtue of their

enhanced responsiveness to suggestion, hypnotized persons may be especially vulnerable to leading questions and other suggestive influences that might bias or distort their memories. Hypnotized persons may well believe that they are recovering forgotten memories, but that does not make the memories valid representations of the historical past. Any memories recovered by means of hypnosis must be subject to independent corroboration before they are taken seriously.

Similar considerations apply to hypnotic age regression. Although age-regressed individuals may experience themselves as children and may behave in a distinctly childlike manner, there is no evidence that they actually undergo either abolition of characteristically adult modes of mental functioning or reinstatement of childlike modes of mental functioning. Nor do age-regressed individuals experience the revivification of forgotten memories of childhood.

Given what we know about the unreliability of hypnotic hypermnnesia, the use of hypnosis to recover memories in clinical and forensic situations must be judged to be highly risky and not recommended. In fact, many legal jurisdictions severely limit the introduction of memories recovered through hypnosis due to a concern that such evidence might be tainted. The Federal Bureau of Investigation (FBI) has published a set of guidelines for those who wish to use hypnosis forensically, and similar precautions should be employed in the clinic. Although field studies have sometimes claimed that hypnosis can enhance memory in a powerful way, these anecdotal reports have not been duplicated under laboratory conditions.

6. RISKS OF HYPNOSIS

Hypnosis poses few risks to persons who are hypnotized. Because it requires the active participation of the hypnotized persons, people cannot be hypnotized unknowingly or against their will. Nor can even deeply hypnotized persons be led, by virtue of suggestion, to do something that they would not do under other circumstances. In experimental situations, the risks to individuals are usually limited to drowsiness or mild headache—no different in kind or severity from those that crop up when students take exams or listen to lectures. In most instances, these transient problems can be rapidly traced to some specific expectation on the part of the hypnotized persons, perhaps derived from inadvertent comments made by a stage performer or

television commentator seen recently. Occasionally, a hypnotized person actually dozes off during the procedure or rests his or her head in an uncomfortable position, leading to drowsiness or neckache on arousal. In any event, a few minutes of supportive interaction are usually sufficient to deal with the problem effectively. However, problems may be compounded when inexperienced experimenters find it difficult to cope with a minor problem and communicate their lack of competence and self-confidence to the hypnotized person, who may then proceed to make matters even worse. Problems may also occur in stage hypnosis, where the entertainment context has special effects on experience and behavior over and above the hypnotic context.

Untoward consequences are more likely to arise when hypnosis is employed during therapeutic, as opposed to experimental, procedures. A manipulative therapist who simply tries to “suggest away” symptoms may encounter problems that stem from his or her own therapeutic errors. When hypnosis is used to recover ostensibly forgotten memories, whether in therapeutic or forensic situations, the memories of the hypnotized person may be contaminated with information that is objectively false—with potentially serious negative consequences for other people. When hypnosis is used to control pain in athletic situations, competitors may ignore important information about the location and severity of bodily damage. In other cases of performance enhancement, it is possible that individuals will harm themselves through overexertion. Practitioners should not attempt to treat with hypnosis any condition that they are not qualified to treat without hypnosis.

7. CONCLUSION

Claims of hypnotically induced performance enhancement are nearly as old as hypnosis itself. In George DuMaurier’s novel *Trilby*, published in 1895, Svengali transforms the eponymous heroine into an accomplished singer. And reviewing the hypnosis literature nearly half a century ago, F. L. Marcuse referred to “The Generation of Hypers,” that is, the notion that hypnosis could produce hyperpraxia, hyperesthesia, and hypermnnesia as well as other special effects. Aside from the ability of hypnotic suggestion to control pain—a genuine phenomenon of substantial practical importance—most claims for hypnotic performance enhancement are dubious at best. Hypnosis is fascinating to observe, is interesting from a theoretical standpoint, and has many actual and potential

applications as an adjunctive treatment in medicine and psychotherapy, but it will not make us better people.

GLOSSARY

attitude A relatively enduring organization of beliefs around a concrete object or situation, predisposing people to respond in some preferential manner.

competition Value orientation that combines the acceptance of inequality with a focus on the individual. Central values are commitment to achieving wealth, social recognition, and social power.

conformity (to external authorities) Values stressing obedience to external norms and the need to follow the dictates of authority.

ideology A coherent set of attitudes and values, shared by a social group, that motivates their actions.

materialist Values expressing the need for economic and financial security, societal stability, personal safety, and law and order.

post-materialist Values referring to the need for political freedom and participation, self-actualization, personal relationships, creativity, and care for the environment.

self-direction Values emphasizing autonomy and the personal responsibility of the individual.

(socio-)cultural conservatism versus progressiveness Also labeled “sociocultural libertarianism–authoritarianism.” Ideological opposition related to the old cleavage between

the Church and the State, typical of pre-industrial sources of political conflict. Conservatism emphasizes traditional norms (e.g., traditional gender roles and strict child rearing practices). Progressiveness puts traditional norms into perspective, stressing, e.g., women’s emancipation and the autonomy of children, and supporting the liberalization of abortion.

(socio-)economic conservatism versus progressiveness Also labeled “socio-economic left-right.” Ideological opposition related to socioeconomic cleavages in industrial society. A progressive stand rejects social inequality as unfair and argues for government intervention and stronger trade unions in order to reduce economic inequality. Conservatives oppose government intervention and (militant) trade unions, and emphasize private initiative and individual competition as essential for proper economic functioning.

universalism Value orientation that combines equality and focus on others into a universalistic, altruistic value pattern. Equality, social justice, and true friendship are key values in this orientation.

values Abstract, fundamental goals. They are evaluative standards with normative power. Values are hierarchically ordered in a coherent pattern.

This article discusses the content and relevance of ideology and values for political psychology. Even though certain scholars advocated “the end of ideology” in the past, recent events suggest that ideology still plays an important role in contemporary society, in shaping and affecting the life of everyday people and of specific, politically active groups. The

terrorist attacks of September 11, 2001 are a powerful example of the impact of an extreme ideology on innocent citizens. This event also demonstrates that radical ideologies can motivate activists to perform extreme acts, by sacrificing their life for a “higher cause.” Less drastic examples of the relevance of ideology can be found in the rise of new political parties on the left (e.g., green parties) and the right (e.g., extreme right-wing parties), which attracted more voters than before during parts of the last decade.

In this article, first, the concepts of ideology and values are defined. Next, influential theories on values and value orientations in political psychology are reviewed, starting with the less complex ones, which will be integrated in more recent multidimensional theories at the end. The third section discusses the dimensionality of conservatism, and relates it to the values section, and to the specific groups that are holding this ideology. Fourth, the political consequences of ideology and value orientations are outlined. The article concludes with some crucial references for further reading.

1. IDEOLOGY AND VALUES: DEFINITIONS

The term ideology is used in various disciplines such as psychology, sociology, and political science. Consequently, it has many meanings. In psychological research, however, consensus exists regarding three core aspects of an ideology: it is a coherent set of attitudes and values, it is shared by and therefore typical of a given social group, and it motivates their actions.

Ideology is not a mixed bag of attitudes. Rather, it is a logical and (relatively) coherent world view and “portrayal of man” that provides an understanding of reality: it offers an interpretation and an explanation of how the world works and of the role and motives of the people in that world. This world view and vision of mankind are founded on certain values. As a consequence, an ideology does not only describe “what is” (first aspect), but also “what ought to be.” So, ideologies are not purely descriptive, they are also prescriptive or normative: they indicate what should be achieved and changed. They describe the desired goal and direct or motivate action (third aspect). This mobilizing function, or incentive to act, is linked to the collective nature of an ideology: ideologies refer to a set of attitudes and values that are shared by a larger

group (second aspect). They reflect the interests of a specific social group and offer identification possibilities to the members of these groups. By accepting the collective ideology, they can show that they too belong. These shared viewpoints can be used to make a distinction between those who belong (“us”) and those to whom this does not apply (“them”). An ideology also describes the group goals that must be achieved in order to secure the group’s interests or to improve the position of the group and its members.

Attitudes and values are part of an ideology. This means that these concepts must also be defined. A wide variety of definitions is used for the concept of “values” in the literature. There is, however, consensus on a number of basic features. Values are fundamental goals. They are evaluative standards with normative power: they control behaviors, thoughts, and feelings. Values are abstract, not directly observable constructs. They are not isolated from each other, but form a coherent pattern that is hierarchically ordered. Finally, values also have a certain continuity and stability. Most recent definitions of values broadly embrace these aspects of the concept. Schwartz (1994), for example, defines a value as “a belief pertaining to desirable end states or modes of conduct, that transcends specific situations, guides selection or evaluation of behavior, people and events, and is ordered by importance relative to other values to form a system of value priorities” (p. 20).

Rokeach, who can be considered one of the founding fathers of value research, emphasized the distinction between values and attitudes. He defined attitudes as a relatively enduring organization of beliefs around an object or situation, predisposing one to respond in some preferential manner. Attitudes are thus more concrete than values, because they refer to a specific object or specific situation. Values have a more abstract and fundamental character. A set of items that relates to the evaluation of income differences and to government intervention in the economy can therefore be considered as a set of attitudes. Because values are more fundamental, they are also more limited in number. An individual can subscribe to a large number of attitudes, but only to a limited number of values. Attitudes thus form “concretizations” of values, because a single fundamental value can be translated into a large number of attitudes with regard to actual topics. Finally, Rokeach also assumes that values occupy a more central position than attitudes within one’s personality and cognitive system. As a consequence, they are determinants of attitudes and behaviors.

2. VALUES AND VALUE ORIENTATIONS IN POLITICAL PSYCHOLOGY

Research into values and value orientations is of course not restricted to political psychology. In this field, numerous contributions of scholars in other fields of the social sciences and psychology are used and applied to the political sphere. The following sections discuss some of the most influential, starting with the most limited ones, focusing on just a selection of values. These will be integrated in more recent multi-dimensional accounts later on.

2.1. Kohn: Conformity versus Self-Direction and Its Relationship with Social Class

Kohn and his co-workers performed important research on the relationship between values and the position of individuals in the social structure. Their research shows that the middle class is oriented toward the value of self-direction. Respondents from the middle class find it more desirable to behave on the basis of their own insights and emphasize self-direction, autonomy, and the personal responsibility of the individual. In short, they value thinking for oneself. This value orientation has important consequences for their behavior in a variety of life domains. One of these domains is the upbringing of children, in which they value aspects such as consideration, curiosity, and self-control. Blue-collar workers, on the other hand, emphasize conformity to external authorities: they stress obedience to external norms, and the need to follow the dictates of authority. Examples of values stressed in the upbringing of children are obedience, good manners, and neatness. These scholars also demonstrate that self-direction and conformity (to external authority) are opposite poles of a single continuum.

Kohn and his co-workers stress that the difference in attitudes and values between blue-collar workers and white-collar workers is caused by the extent to which their work requires "occupational self-direction." This variable refers to autonomy in the workplace and is composed of three components: the complexity of the work, the amount of supervision, and the (non-)repetitive character of the job. The extent to which someone can work autonomously depends on his or her occupational position. Employees in higher professions can work more autonomously: their work is more varied,

less supervised, and more complex, so that they must make more decisions on their own. Through longitudinal research, Kohn and his co-workers demonstrated that one's capacity to work autonomously influences the values one develops. Work that requires autonomy leads to an orientation toward self-direction. When the work does not allow autonomy, then one has to adapt to the (work) environment by emphasizing conformity. The logic behind this link is that obeying external authorities forms the best adjustment to a situation in which one has little control of the course of events.

2.2. Inglehart: Materialism versus Post-Materialism

Inglehart's post-materialism thesis is an example of a theory that advocates the social and political relevance of a new set of values in society. According to Inglehart, advanced Western societies experience a shift from materialist to post-materialist values. Material values express the need for economic and financial security, societal stability, personal safety, and law and order. Post-materialist values refer to the need for political freedom and participation, self-actualization, personal relationships, creativity, and care for the environment. In modern societies, a "silent revolution" is taking place, in which the dominance of materialist values is being replaced by post-materialist values. This value change is caused by the continuous replacement of old generations by new ones. Crucial in this respect is the degree to which fundamental material needs have been met during the formative period of individuals of a given generation. The post-materialism thesis, therefore, combines two hypotheses: a scarcity hypothesis and a socialization hypothesis. The scarcity hypothesis states that individual priorities reflect their socioeconomic environment: the greatest subjective value is placed on what is in relative short supply. The socialization hypothesis assumes that one's values reflect the conditions during one's pre-adult formative years and are relatively stable over the individual life course. Per Inglehart (1990), "Taken together, these two hypotheses imply that, as a result of the historically unprecedented prosperity and the absence of war that has prevailed in Western countries since 1945, younger birth cohorts place less emphasis on economic and physical security than do older groups, who have experienced a much greater degree of economic insecurity and that, conversely, the younger birth cohorts tend to give a higher priority to nonmaterial needs,

such as a sense of community and the quality of life” (p. 56). Inglehart’s post-materialism thesis is based on the well-known need hierarchy of Maslow, suggesting that material needs must be fulfilled before immaterial or “higher” (growth) needs such as self-actualization become important. As a consequence, support for post-materialist values comes from post-war generations, the highly educated, and parts of the middle class. By contrast, pre-war generations, the less-educated, and members of the old middle class and the working class are more likely to support materialist values.

2.3. Rokeach and Braithwaite on the Political Importance of Values

Directly relevant to the domain of political psychology are the contributions of Rokeach and Braithwaite. Rokeach developed the two-value model of political ideology. He assumed that political ideologies differ from each other in terms of the social values freedom (independence, free choice) and equality (brotherhood, equal opportunity for all): the combination of these values enables us to describe and contrast all ideologies. According to Rokeach, socialism emphasizes both freedom and equality, whereas fascist ideology values neither freedom nor equality. Capitalism and communism both emphasize one of these core values more than the other: capitalism values freedom at the expense of equality, and communism values equality at the expense of freedom. Support for this model was found through a values content analysis of the writings of crucial authors advocating these different ideologies. Analyses of the values of supporters of different ideologies (such as voters or candidates of political parties), however, are less consistent with Rokeach’s theory. This research generally shows rather important differences in the importance attributed to equality, with leftist activists showing a greater emphasis on equality than right-wing or conservative supporters. This is in line with Rokeach’s theory. The value of freedom does not discriminate these different ideological groups, however, which refutes his claim.

These findings inspired Braithwaite to elaborate Rokeach’s two-value model. She reduced a large number of values to two broader value orientations. The first is called “international harmony and equality,” and covers values such as participation, cooperation, peace, and equal opportunities for all. The second refers to “national strength and order,” and covers values such as national security, economic

advancement, order, and security. Whereas the value orientation international harmony and equality captures Rokeach’s notion of equality, national strength and order refers to a concept different than freedom. Braithwaite also shows that both value orientations are highly relevant for political attitudes and behaviors. Those favoring international harmony and equality emphasized progressive political views, expressed a preference for a leftist political party, and were more inclined toward political activity. The opposite holds for supporters of national strength and order: they preferred conservative views and a right-wing political party and were less inclined to engage in political activity.

2.4. Schwartz and Triandis: More Encompassing Value Orientations

Next to the previous contributions, two broad, more encompassing theories on value orientations have been developed, integrating and expanding previous research in the area. Building on the work of Rokeach, Schwartz proposed a universal theory of the content and structure of values. This theory has been tested in more than 60 countries, and is proven to be cross-culturally stable. Rokeach’s value survey comprised 36 values, which were presented in two groups: 18 terminal values and 18 instrumental values. Respondents were asked to rank the values within each list according to their own preference. Schwartz increased this list to 56 values in his value inventory, and asked respondents to score each value on a 9-point scale. So, in addition to the increase in the number of values (again split up into two series), he also changed Rokeach’s method of scoring from “ranking” to “rating,” enabling the data to be analyzed with more sophisticated statistical methods. Schwartz divided the 56 values in his survey into ten motivational value types, according to the type of motivational goal they express. [Table I](#) summarizes these value types and their content.

An inspection of [Table I](#) shows that Schwartz’s ten value types cover all the different value orientations discussed in the preceding section. Kohn’s dichotomy between self-direction and conformity is covered by identical labels (with identical content), whereas Rokeach’s core value freedom is part of self-direction. Universalism is closely related to Inglehart’s post-materialism and Braithwaite’s international harmony and equality, and includes Rokeach’s core value of

TABLE I
Schwartz's Ten Motivational Value Types

Value type	Definition	Exemplary values
<i>Power</i>	Social status and prestige, control, or dominance over people and resources	Social power, authority, wealth
<i>Achievement</i>	Personal success through demonstrating competence according to social standards	Successful, capable, ambitious
<i>Hedonism</i>	Pleasure and sensuous gratification for oneself	Pleasure, enjoying life
<i>Stimulation</i>	Excitement, novelty, and challenge in life	Daring, varied life, exciting life
<i>Self-direction</i>	Independent thought and action—choosing, creating, exploring	Creativity, curious, freedom
<i>Universalism</i>	Understanding, appreciation, tolerance, and protection for the welfare of all people and for nature	Broad-minded, social justice, equality, protecting the environment
<i>Benevolence</i>	Preservation and enhancement of the welfare of people with whom one is in frequent personal contact	Helpful, honest, forgiving
<i>Tradition</i>	Respect, commitment, and acceptance of the customs and ideas that traditional culture or religion provide	Humble, devout, accepting my portion in life
<i>Conformity</i>	Restraint of actions, inclinations, and impulses likely to upset or harm others and violate social expectations or norms	Polite, obedient, honoring parents and elders
<i>Security</i>	Safety, harmony, and stability of society, of relationships, and of self	National security, social order, clean

Source: Schwartz (1994).

equality. Finally, security covers both Inglehart's materialism and Braithwaite's national strength and order. Schwartz, however, distinguishes more value types than these already suggested ones, thus enlarging the scope and possibilities of values research.

Schwartz represents his structure and value types by means of multidimensional scaling. This technique represents the values as points in a multidimensional space. The spatial distance between the points represents the relationship between the values. The more the ratings of a value correlate, the closer the values are located in the graphical representation. For Schwartz's universal values theory, this technique implies that the separate values of his motivational types must lie in each others' proximity and must be distinguishable as a separate field or region in the graphical representation. In contrast, values and value types that express opposing motivations should be discriminated clearly from one another. Fig. 1 shows the value structure obtained by Schwartz by means of such an analysis.

Schwartz claims that the oppositions in Fig. 1 can be classified into two bipolar dimensions. He describes the first dimension as openness to change, as opposed to conservation. This dimension contrasts value types such as stimulation, and self-direction (openness to

change) with value types such as security, conformity, and tradition (conservation). The second dimension is formed by the opposition between self-transcendence and self-enhancement. Value types such as universalism and benevolence are opposed to value types that refer to power and achievement. Schwartz's subsequent research shows that his model and the two abstract dimensions are (very nearly) universal.

Schwartz's use of both higher order dimensions fits in with a research school that classifies the structure of values on the basis of two dimensions, giving rise to four value orientations. The key scholar in this school is Triandis. The first dimension distinguished by Triandis refers to the opposition between individualism (focus on the self) and collectivism (focus on others). The value types tradition, benevolence, and conformity correspond to collectivism. Values such as hedonism and stimulation refer to individualism. The opposition between "vertical" and "horizontal" thinking constitutes the second dimension. Horizontalism means that people consider each other as equal. Universalism typifies this orientation. Vertical thinking accepts forms of inequality, hierarchy, and authority (cf. the value type power). Triandis' two fundamental dimensions allow a more unambiguous interpretation

FIGURE 1 Visual representation of Schwartz's value structure. From Schwartz (1994).

than the two abstract value dimensions advanced by Schwartz. Combining the views of both scholars leads to four value orientations:

1. Horizontal collectivism or universalism combines the idea of equality and the focus on others to form a universalistic, altruistic value pattern. Equality, social justice, and true friendship are key values in this orientation. This value orientation appears in the bottom left in Fig. 1.

2. Horizontal individualism or self-direction combines the idea of equality with a focus on the individual. This leads to an emphasis on autonomy (with values such as choosing one's own goals and freedom), with peaks such as stimulation (daring and exciting life) and (slightly less central) hedonistic values (such as pleasure and enjoying life). This value orientation is located at the bottom right in Fig. 1.

3. Vertical individualism or competition combines the acceptance of inequality (the existence of a hierarchically ordered society) with a focus on the individual. The central idea is that the individual can achieve the "top" in society by adopting a competitive attitude. Central values are the commitment to achieving wealth, social recognition, and social power. This value orientation is located at the top right in Fig. 1.

4. Vertical collectivism or conformity, finally, combines a focus on others with the acceptance of a hierarchy. Supporters of this view are prepared to submit themselves to the collective. Key values are obedience, politeness and respect for tradition. It is located at the top left in Fig. 1.

3. ON THE DIMENSIONALITY OF (CONSERVATIVE) IDEOLOGY

Values are the building stones of ideologies. The exact content of contemporary ideology, however, has been the subject of large-scale debates between scientists of different disciplines. Even though important differences in position exist, many scholars agree that (social and political) ideology can be captured under the heading of conservatism. The definition of conservatism, however, again proves difficult. Some, like Wilson (1979), proposed a one-dimensional concept, caused by "a generalized susceptibility to feeling threat or anxiety in the face of uncertainty" (p. 65). More prominent are multidimensional accounts. Van Deth and Scarbrough distinguished three important broad

value orientations (or ideologies), which cover important aspects of advanced industrial society as well as the legacies of industrial and pre-industrial societies. Inglehart's postmaterialism (as opposed to materialism) was selected as crucial for advanced (post-)industrial society. The distinction between left and right regarding economic issues was selected as a central value orientation reflecting the class conflicts typical of industrial society. Religious–secular value orientations were their third choice, referring to pre-industrial sources of political conflict.

3.1. Two Dimensions of Conservatism

Reviewing the field nevertheless makes clear that distinguishing a two-dimensional concept of ideology offers many advantages. This option is, first of all, suggested by several important scientists from different disciplines, such as Eysenck in psychology, and Lipset in political sciences. More importantly, these authors arrived at a rather similar structure, which corresponds closely to the thorough conceptualization of conservatism developed by the Dutch scholar Middendorp. On the basis of historical and theoretical considerations and a large body of empirical research, Middendorp distinguished two dimensions within conservatism and revealed their underlying values: freedom versus equality. The first was labeled socio-economic left-right and the second socio-cultural libertarianism-authoritarianism. In accordance with the literature in this field, these dimensions can be relabeled as economic conservatism (versus progressiveness) and sociocultural conservatism (versus progressiveness). Both dimensions are relatively stable over time, and—more surprisingly—are unrelated: respondents can combine a progressive view on one dimension with a conservative view on the other. Research also suggests that this two-dimensional conceptualization is rather universal.

The opposition between progressive and conservative attitudes in the socioeconomic domain points to socioeconomic cleavages in industrial society: conflicts between labor and capital. Middendorp showed empirically that the economic opposition between liberalism (in its European meaning of the concept) and socialism lies at the basis of this dimension: those who express progressive attitudes reject social inequality as unfair and unacceptable and argue for government intervention in the economy and for a more active trade union policy in order to reduce economic inequality.

Conservatives express opposition to government intervention in the economy and against (militant) trade unions. They equally reject the claim that social differences are caused by inequality of opportunity, and emphasize private initiative and competition between individuals as essential for proper economic functioning.

The opposition between conservative and progressive on a sociocultural level relates to societal norms and traditions with respect to individual private lifestyle and family life. Ethical topics (such as sexuality and bioethics) and more social themes (such as free speech and tolerance toward minorities) belong to this field. This ideological cleavage relates to Van Deth and Scarbrough's religious versus secular value orientation, typical of pre-industrial sources of political conflict. Cultural conservatism thus can be considered as a relic of the old cleavage between the Church and the State. Historically, the non-religious community in particular has opposed the norms and values dictated by the Church, whereas the latter promoted traditional norms and conformity to traditional institutions. In a conservative sociocultural view, traditional norms in society are emphasized: adherents plead to maintain existing social norms and traditions ("traditionalism"). They prefer the traditional division of roles between men and women and support severe child-rearing practices in which strictness and obedience are stressed. They also defend the traditional work ethic, which emphasizes the moral duty to work. Those who take a progressive stand in the sociocultural field generally hold opposite attitudes. Traditional norms and attitudes are put into perspective. They stress the emancipation of women and the independence of children, support the liberalization of abortion and euthanasia, and emphasize other reasons for work than strict duty-related ones (e.g., self-actualization).

3.2. Relationship with Values and Value Orientations

These two broad ideological dimensions are of course related to values. Middendorp argued that Rokeach's values freedom and equality are at the core of both conservatism dimensions. On the socioeconomic level, progressive thought emphasizes equality: unequal opportunities and an unequal distribution of welfare and well-being are rejected. In conservative thought, the emphasis on the socioeconomic level is on the value of (individual) freedom: private initiative and competition among individuals should not be limited. On the sociocultural level, this emphasis is

reversed. The progressive way of thinking emphasizes the freedom of the individual to arrange life according to one's own insight (self-direction). In the conservative way of thinking, such individual freedom is rejected and equality is stressed. Conservatives on the socio-cultural level emphasize that everyone should adhere to the traditional norms and values in society (conformity and traditionalism). So, individuals who emphasize the basic value of individual freedom adhere to opposing views on both ideological dimensions. On the economic level, they show conservative preferences, whereas on the sociocultural level they choose progressive viewpoints. The reverse is true for those emphasizing equality. They combine a progressive view on economic issues with a conservative one regarding sociocultural issues.

Both ideological conservatism dimensions are related not only to separate values, but also to larger value dimensions. Sociocultural conservatism is related to Kohn's distinction between self-direction and conformity. Those who emphasize conformity to external authorities find it equally important to obey the norms and traditions in society (traditionalism). These individuals stress external standards for their behavior: "others" have to tell us what to do. These others can be superiors in the hierarchy (vertical conformity), as well as equals (horizontal conformity). Individuals who take a progressive position on sociocultural issues defend freedom of thought and conscience. They emphasize the right to organize their lives according to their own insights, even if it means deviation from current norms. This view is closely related to self-direction, since the norm for one's own behavior is sought with oneself (internal standards for behavior).

Economic attitudes are related to value orientations as well. The value opposition between universalism and competition correlates with economic conservatism: economic progressiveness shows a positive correlation with the value orientation universalism and a negative correlation with the value orientation competition. The reverse is true for economic conservatism (positive correlation with competition and negative correlation with universalism).

3.3. View on Human Nature and Society, and Relationship with Social Groups

Earlier, ideology was defined as a (relatively) cohesive world view and portrayal of humans, reflecting the interests of a specific social group. How does our

treatment of conservatism relate to these aspects? Based on an historical analysis, Middendorp showed that the ideology of conservatism combines a rather negative view on human nature with a rather positive view on the nature of society. In conservatism, one emphasizes that people are inclined to egoism rather than to altruism. As a consequence, human beings have to be restricted and disciplined by society. Societal institutions, on the other hand, incorporate valuable traditions and wisdom, which enable human beings to behave in a civilized way. This logic, however, is an elite construction. Much knowledge of political and historical trends and a high level of conceptual and cognitive sophistication are needed to understand its logic. As a consequence, research shows that only members of the political elite (e.g., members of parliament) are capable of integrating both conservatism dimensions into one single dimension, ranging from conservatism to progressiveness.

This is not the case within the normal population. "Ordinary" citizens distinguish the two forms of conservatism discussed previously. Both forms of conservatism are related to specific groups, reflecting their interests. Low-income groups are prompted toward an economic progressive position, since this view promotes their interests. Groups with a higher level of education are prompted to stress progressive views regarding sociocultural issues, since these views enable them to organize their lives according to their own insights. Because cultural conservatism is linked to the cleavage between the Church and the State, religious respondents tend to stress this form of conservatism to a larger degree than do non-religious people.

4. POLITICAL CONSEQUENCES OF IDEOLOGY AND VALUE ORIENTATIONS

Ideology and values have important consequences for political behaviors of citizens. Before one can act at the political level, however, one must feel motivated to do so. Political interest and political efficacy play an important role in translating ideology and values into political action. Comparative research shows post-materialism and (to a lesser extent) cultural progressiveness to be associated with political interest. A similar finding applies to political efficacy: the self-image that one is an effective and influential participant in politics. Efficacious citizens see themselves

as comprehending, controlling, and mastering their political environments. People holding post-materialist values perceive themselves to be more efficacious and subjectively competent. This of course strengthens their wish to participate in the political process. Also, cultural progressiveness enhances people's sense of civic competence and political efficacy. However, the net impact of value orientations on political interest and political efficacy is modest, and other variables, such as the level of education, play a more direct and important role.

Given the results mentioned above, it comes as no surprise that post-materialism (and, to a lesser extent, cultural progressiveness) is found to influence different forms of unconventional protest activity, such as signing petitions, attending lawful demonstrations, and participating in boycotts or occupations of buildings. The motivating force of ideology is not limited to these unconventional forms of activity. Research shows that trade union participation is also linked to ideology and values. Economic progressiveness in particular seems relevant in this context, because it is associated with participation that requires a high level of effort, such as becoming a union activist or participation in industrial action (such as strikes). However, even though informal political activities became important in many countries, voting is still the most frequent mode of political participation. Interestingly, research shows that post-materialist values have little impact on electoral turnout levels.

The impact of ideology and values is much more substantial when one analyzes party choice. Here, ideological orientations play a rather important role in distinguishing the electorates of different parties. In analyzing the Dutch vote, Middendorp plotted all parties according to the mean score of cultural and economic conservatism of their voters. This results in an ordering of all parties on the economic dimension (the "left-right" vote) and on the cultural one (the "libertarian-authoritarian" vote). He concluded that the left-right vote is mostly explained by economic conservatism, social class, and income. The libertarian-authoritarian vote was mainly explained by cultural conservatism and religious involvement. A more encompassing analysis of different countries shows that these findings can be generalized across Europe. Socialist and communist parties (e.g., "leftist" parties) have the most economic progressive electorates. The electorates of the (economic conservative, "rightist") liberal parties are the most rightist in each country in continental Europe. Christian democratic voters tend to be centrists, leaning toward the center right of

economic conservatism. Green parties and left-wing socialist parties have the most post-materialist electorates in most countries. Conservative and Christian democratic electorates in most countries are predominantly materialist. In this comparative research, cultural conservatism was not included, so no conclusions regarding this ideology could be reached. Other research, however, suggests that this ideological dimension too is relevant in determining the political vote.

Interestingly, different scholars find that ideological dimensions explain more variance than background characteristics do. The discriminating power of variables such as social class and religion tends to decline somewhat over time, whereas the impact of values on voting intentions seems rather stable in most countries or increases slightly when compared to a more distant past. Some consider this finding an indication of the "ideologization" of the vote: ideology seems to determine the vote to a larger extent in recent elections than in prior ones. Other scholars suggest that instead we are witnessing the rise of issue voting. According to issue salience theory, voting is determined by those value orientations and issues that dominate the political agenda and party conflicts in given political systems and at a specific time. Because these issues are variable, the vote becomes more unpredictable than before, which explains the higher proportion of volatile voters, changing their party preference in between elections. Issues, however, are not unrelated to ideology or value orientations, but are embedded in more encompassing ideological orientations. This means that ideology is still relevant in issue salience theory, even though particular political circumstances might single out specific aspects of this ideology. A good example of this trend is the rise of extreme-right wing parties in Europe. Research consistently shows that these parties appeal to the negative attitude of citizens towards foreigners. Extreme right-wing parties have been successful in putting their anti-immigrant stands on the political agenda, and successfully persuaded the electorate that they will deal with this topic once elected. Negative attitudes toward foreigners are not an isolated domain, however, but are firmly rooted in cultural conservatism. The rise of extreme-right wing parties in Europe thus suggests that at least a part of this kind of conservatism grew in importance as predictor of voting behavior, compared to the past.

GLOSSARY

indecisiveness A global problem in making life decisions, trait anxiety associated with decision making, and chronic difficulty in resolving the decisional process.

logical positivism A philosophy of science that advances use of the scientific method to produce knowledge about what are believed to be discoverable facts in the world; it emphasizes objectivity and empirical data.

phenomenology A philosophy of science that views knowledge and meaning as derived from within the individual interpreter of experiences, events, and observations; it emphasizes subjectivity and intuitive meaning.

vocational indecision The inability to express an educational or occupational choice when asked to do so; it involves a delay in bringing closure to the career choice process, that is, a wavering, pause, or hesitation in vocational development and an openness to alternative career pathways.

Vocational indecision remains a core and complex construct in contemporary career psychology, linked intimately to the career choice and decision-making

process. It also persists among the most common concerns presented in career counseling and has served as the focus of a vast literature of empirical research and conceptual analysis. Historically, vocational indecision has denoted an inability to express an educational or occupational choice when asked to do so and a delay in bringing closure to the career choice process. Contemporary definitions further characterize indecision as a wavering, pause, or hesitation in vocational development and an openness to alternative career pathways. A synthesis of traditional and alternative interpretations enriches the meaning and the management of vocational indecision.

1. PERSPECTIVES ON INDECISION

A scheme useful for both elaborating on and dealing with the complexity of vocational indecision is to consolidate two principal perspectives on the construct that have emerged during the course of comprehending and intervening to address it. One perspective perceives indecision as an objective circumstance, whereas the other perspective views indecision as a subjective experience. An encapsulated history of career decision making, and indecision as a component of the decision-making process, provides a broader context for discussing these two perspectives in turn.

2. A BRIEF HISTORICAL SYNOPSIS: FROM PLATO TO PARSONS TO THE PRESENT

Inquiry into career decision making in the Western world dates back to the Greek philosopher Plato, who assisted individuals with their vocational decisions by proffering wisdom, advice, and recommendations about fitting work. In the East, teachings in the Tao Te Ching have long advised individuals to do what they enjoy in work. Before the dawn of the early 20th-century vocational guidance movement, other people (e.g., Lysander Richards) used quasi-scientific methods of graphology, physiognomy, palmistry, and phrenology to identify suitable work for people.

With the establishment in 1909 of the Vocation Bureau in Boston by Frank Parsons and his colleagues came an approach to understanding and alleviating vocational indecision grounded in logical analysis and scientific inquiry. By advocating the use of the scientific method, Parsons championed the positivist perspective on vocational indecision that predominated throughout the 1900s and continues to hold great sway in vocational psychology and career counseling today. An alternative perspective on vocational indecision, initiated by D. E. Super and his thematic extrapolation method at midcentury, advanced by D. V. Tiedeman and his colleagues during the 1960s, and propelled by prevailing constructivist and narrative approaches to career decision making, uses phenomenology to comprehend the individual experiences of decision makers. The positivist and phenomenological perspectives both contribute uniquely to comprehending and coping with vocational indecision.

3. VOCATIONAL INDECISION: THE POSITIVIST PERSPECTIVE

The traditional perspective on vocational indecision derives from logical positivism and views indecision as an objective phenomenon. It prizes the use of psychometric scales to yield scores that indicate degree and type of vocational indecision. Three distinct phases of this perspective spanning the past century have transformed indecision from a simple dichotomous concept into a complex multidimensional one.

3.1. A Dichotomy

Parsons initially defined indecision for vocational psychology as a dichotomy consisting of two groups. One group contained individuals decided about their educational or vocational plans, whereas the other group contained persons undecided about their educational or vocational plans. This rudimentary scheme (a) framed indecision as a problem, (b) sparked 40 years of empirical inquiry into personality and situational differences between members of these two groups, (c) characterized undecided persons as deficient if not pathological, and (d) engendered counseling efforts to treat the personality defect underlying the indecision. With the advent of the developmental perspective on careers during the 1950s, some theorists began to advance a view of indecision as a normal component of human development from which a career-decided state would emerge. This view preceded contemporary perspectives on indecision as a healthy state of adaptive uncertainty, openness to alternative career possibilities, and flexibility in coping with change and chance events.

3.2. A Unidimensional Continuum

Research based on a dichotomous concept of indecision produced mixed and inconsistent findings, with many studies supporting differences between decided and undecided individuals and many other studies indicating no differences between these groups. Two approaches, one psychometric and the other theoretical, were taken to address these inconsistencies. The psychometric approach sought to better measure career indecision and career decision-making status. The theoretical approach endeavored to better conceptualize what career indecision means.

Taking a psychometric approach, researchers during the 1970s turned to a view of indecision as a unidimensional continuum ranging from undecided to decided. Psychometric scales, such as the Vocational Decision-Making Difficulties Scale and the Career Decision Scale, were subsequently constructed to index positions on this continuum. So conceived, indecision reflected a continuous process operationally defined by scale scores indicating level of decidedness and difficulties that thwart choice.

3.3. A Multidimensional Construct

Advancing the psychometric approach to indecision, the objective perspective has evolved to the current

view of indecision as a multidimensional concept with distinct and measurable subtypes. Rather than perceiving all undecided persons as undecided for the same reasons, the multidimensional perspective recognizes heterogeneous undecided subgroups. Researchers consequently turned to either revising existing scales or developing new measures to assess degree of and reasons for indecision, which would then guide intervention. These measures now constitute two generations of instrument development. First-generation measures operate on a unidimensional definition of indecision and view groups of individuals with equivalent overall scale scores as homogenous. Second-generation measures construe indecision as multidimensional and seek to identify subgroups of undecided individuals and provide different interventions for each type.

3.4. Indecision Versus Indecisiveness

During the 1960s, a theoretical approach to resolving inconsistent research findings about differences between decided and undecided groups centered on distinguishing indecision from indecisiveness. Leona Tyler proposed that indecisiveness reflects a global problem in making life decisions, trait anxiety associated with decision making, and chronic difficulty in resolving the decisional process. Indecision, in contrast, reflects a specific problem to make an occupational choice, a state of situational anxiety about decision making, and a developmental delay in resolving the decisional process. This view on indecision has been propelled by subsequent theorizing about indecision as a natural component of career development, as an opportunity to explore, and as open-mindedness to random events and opportunities in shaping career-related decisions. The intuitively reasonable distinction between indecision and indecisiveness as differentially related to anxiety has met with little empirical support.

4. VOCATIONAL INDECISION: THE PHENOMENOLOGICAL PERSPECTIVE

Phenomenology offers an alternative to the positivist perspective on vocational indecision. Situated in constructivist and narrative approaches to career that have emerged more prominently during the past decade or

so, the phenomenological view conceives of indecision as a subjective experience. Consequently, rather than using psychometric inventories and objective scores to measure level and type of indecision, the subjective perspective prizes the use of narratives and stories to reveal life themes, patterns, projects, and goals that guide movement within the choice process. From the phenomenological perspective, indecision reflects a wavering or pause in vocational development and an openness to alternative career pathways. Individuals can use indecision to contemplate their directions in life, construct possible futures, and convert their identities into truer self-representations.

The subjective perspective on indecision emphasizes the personal meaning ascribed to the lived experience of being undecided. Exploring undecided individuals' subjective, qualitative, and personal realities leads to comprehending their unique experiences of indecision, preoccupations and intentions, and possibilities for constructing their future lives. By eliciting narratives, reviewing early recollections and family stories, and situating work in the context of people's lives, phenomenologically based approaches involve a collaborative endeavor to imbue indecision with personal meaning. Vocational decision making becomes a process of untangling a present filled with uncertainty and doubt to clarify and envision a future path that will provide purpose, direction, fulfillment, and satisfaction.

5. FUTURE DIRECTIONS

Vocational indecision has long been a focus of theory, research, and practice in vocational psychology. Decades of scholarship have examined indecision both as an objective circumstance, with distinct measurable subtypes, and as a subjective experience, wholly unique to the individual who experiences it. Future efforts to meld positivist and phenomenological perspectives on indecision will likely yield a more comprehensive approach to comprehending the career decision-making process and to dealing with vocational indecision as a problem that can interrupt that process. Emerging perspectives on vocational indecision that argue against decidedness as the optimal vocational outcome in favor of blending planfulness, flexibility, and more active engagement with random opportunities for shaping future decisions will also expand possibilities and potential for human development through work and career.

phenomenological knowledge Internal thoughts, feelings, and motives of a person.

practical validity Theories that can help one to understand, predict, and manage the world.

transactional model A scientific model in which phenomenological knowledge is systematically linked with the situation or event, on the one hand, and with behavior or performance, on the other.

GLOSSARY

amae A Japanese term referring to the act of asking for and receiving special favors in close relationships.

chong A Korean term meaning deep affection and attachment for a person, place, or thing.

extrinsic motivation A factor outside an individual (e.g., parental influence, social support, social reward) that can motivate a person into action.

guanxi A Chinese term meaning relationship.

indigenization from within Developing theories, concepts, and methods internally, with indigenous information being considered as a primary source of knowledge.

indigenization from without Taking existing psychological theories, concepts, and methods and modifying them to fit the local cultural context.

indigenous psychology According to Kim and Berry, “the scientific study of human behavior [or mind] that is native, that is not transported from other regions, and that is designed for its people.”

intrinsic motivation A factor within an individual (e.g., personal interest, preference, ability) that can motivate a person into action.

Indigenous psychology represents the cultural psychology tradition espoused by Wundt that examines human action by linking people’s intentions, skills, and goals with the situation or event, on the one hand, and with behavior or performance, on the other. It advocates studying people in their natural contexts, using concepts that are meaningful, and investigating the skills that people develop to manage their lives. The goal of indigenous psychology is to create more rigorous scientific theories that can be verified and applied in the natural setting. The phenomenal educational achievement of East Asian students is provided as an example to highlight this approach.

1. HISTORICAL BACKGROUND

Wundt is considered to be the “father of modern psychology.” In establishing psychology as an independent scientific discipline, he recognized two traditions in science: the natural sciences tradition and the

cultural sciences tradition. Wundt was instrumental in establishing the experimental method to study basic physiological, perceptual, and cognitive processes. However, he recognized the limitations of experimental method and emphasized the need to develop cultural psychology. He observed that thinking is heavily conditioned by language and culture. He regarded cultural psychology as a more important aspect of psychological research. General psychology represents the natural sciences approach, and indigenous psychology represents the cultural science tradition.

When psychology became established in North America, psychologists adopted the natural science approach, and eliminated the cultural approach, in search of abstract universal laws of human behavior. Behaviorism emerged as the dominant paradigm, and the subject matter of psychology became tailored to fit into the narrow definition of natural science. Early psychologists attempted to eliminate subjective aspects (e.g., consciousness, intentions, meaning) and to conduct controlled experiments in laboratory settings. Psychologists assumed that the results of laboratory studies could be generalized to explain complex human behavior in the natural setting.

Indigenous psychologies evolved around the world as a reaction against unjustified claims of universality of psychological theory. Although existing psychological theories and concepts are assumed to be objective, value free, and universal, in reality they are deeply enmeshed with Euro-American values that champion rational, liberal, individualistic ideals. Indigenous psychology represents an alternative scientific paradigm in which the human qualities (e.g., meaning, goals, creativity) and culture have been integrated as central elements of research design.

2. WHAT IS INDIGENOUS PSYCHOLOGY?

In 1993, Kim and Berry defined indigenous psychology as “the scientific study of human behavior [or mind] that is native, that is not transported from other regions, and that is designed for its people.” Indigenous psychology advocates examining knowledge, skills, and beliefs that people have about themselves and studying these aspects in people’s natural contexts. It represents a bottom-up approach in which the goal of psychology is to understand how people function in their natural contexts and to examine how people interact with their natural and

human worlds. Indigenous psychology recognizes that human psychology is complex, dynamic, and generative, and it recognizes the importance of agency, meaning, intentions, goals, and context in understanding behavior. Theories, concepts, and methods are developed to correspond with psychological phenomena. The goal is to create a more rigorous, systematic, universal science that can be verified both theoretically and empirically. In addition, there are seven facets of indigenous psychology that can be identified.

First, indigenous psychology emphasizes contextualized understanding rooted in a particular setting (e.g., ecological, political, historical, cultural). It emphasizes the discovery and use of natural taxonomies in search of regularities, general principles, and universal laws. It examines how people view themselves, relate to others, and manage their environment.

Second, contrary to popular misconception, indigenous psychologies are not studies of native peoples, ethnic groups, or people living in distant lands. Indigenous research has often been equated with anthropological analysis of “exotic” people living in distant lands. Indigenous psychology is needed for all cultural, native, and ethnic groups, including economically developed countries such as Canada, France, and the United States.

Third, acceptance of indigenous psychology does not affirm or preclude the use of a particular method. Indigenous psychology is part of the scientific tradition where an important aspect of the scientific endeavor is the discovery of appropriate methods for the phenomenon under investigation. Scientists should not, and cannot, be bound to a particular method. The use of multiple methods is recommended to increase one’s confidence that a particular finding is valid and not an artifact of the research method. Results from multiple methods should be integrated to provide a more comprehensive and robust understanding of psychological phenomena.

Fourth, it has been assumed that insiders have a better understanding of indigenous phenomena and that outsiders can have only a limited understanding. Although a person who has been born and raised in a particular community may have insights and understanding of indigenous phenomena, this might not be true in all instances. As Wirth observed in 1946, “The most important thing . . . that we can know about a person is what he [or she] takes for granted, and the most elemental and important facts about a society are those things that are seldom debated and generally regarded as settled.” An outsider, with an external point of view, can call attention to the fact that what is assumed to be natural is

actually cultural. Although an outsider may have a superficial understanding of indigenous phenomena found in other cultures, he or she may point out peculiarities, inconsistencies, and “blind spots” that insiders may have overlooked. Both internal and external points of view are necessary in providing a comprehensive and integrated understanding of psychological phenomena.

Fifth, many indigenous psychologists search philosophical and religious texts for explanations of indigenous phenomena. Too often, they use philosophical treatises (e.g., Confucian Classics) or religious texts (e.g., Koran, Vedas) as explanations of psychological phenomena. However, these texts were developed for philosophical and religious purposes several thousand years ago and not for psychological research in the 21st century. To use these texts, one must first translate them into psychological concepts and empirically verify how they influence the ways in which people think, feel, and behave. One cannot assume that because a person is Chinese, he or she will automatically follow the Confucian way, nor can one assume that Hindu Dharma can explain the behavior of an individual just because he or she is an Indian.

Sixth, as with other scientific traditions, one of the goals of indigenous psychology is the discovery of universal facts, principles, and laws that could explain human diversity. However, psychological universals must be theoretically and empirically verified rather than assumed *a priori*.

Seventh, human consciousness, agency, meaning, and goals are considered to be central constructs in explaining human behavior (or mind). The separation of the subjective and objective worlds that is important in the natural sciences is not possible in the human world because people are both the subject and the object of investigation. Researchers must recognize that research is a value-laden enterprise in search of a probabilistic understanding of human action rather than a search for objective and mechanical knowledge. Research topics and stimuli must be meaningful and contextualized rather than arbitrarily selected, manipulated, and controlled.

3. TWO APPROACHES IN INDIGENOUS PSYCHOLOGY

In 1993, Enriquez identified two approaches in indigenous psychology: indigenization from without and indigenization from within. Indigenization from without involves taking existing psychological theories, concepts, and methods and modifying them to fit the

local cultural context. The approaches advocated by cultural and cross-cultural psychologists are examples of indigenization from without. In this approach, rather than assuming that a particular theory is universal *a priori*, researchers modify and adapt psychological theories and integrate them with the local cultural knowledge. Those aspects that can be verified across cultures are retained as possible cultural universals. Existing theories in cognitive, developmental, social, and organizational psychology have been modified and extended by indigenous research.

In the indigenization from within approach, theories, concepts, and methods are developed internally and indigenous information is considered to be a primary source of knowledge. For example, one of the core values and assumptions that psychologists from East Asia question is the emphasis on individualism. In East Asia, the relatedness of one person to another person is considered to be fundamental. In East Asia, the word for human being can be literally translated as “human between.” In other words, it is what happens between individuals that makes them human. In Chinese culture, the concept of *guanxi* (literally “relationship”) occupies center stage, defining interactions in family, school, companies, and society. In Japan, the concept of *amae* (literally “the act of asking and receiving special favors in close relationships”) helps to define and maintain close interpersonal relationships. In Korea, the concept of *chong* (literally “deep affection and attachment for a person, place, or thing”) is a central emotion that binds family, friends, and colleagues together. Recently, both cross-sectional and longitudinal studies yielded results that confirm the importance of close relationships that are highly reliable, valid, and applicable in Korea.

4. HOW IS RESEARCH DONE?

Indigenous psychology advocates development and use of methods that are appropriate for psychological phenomena. It recognizes the existence of two types of knowledge: objective third-person knowledge (i.e., analytical, semantic, and declarative knowledge) and subjective first-person knowledge (i.e., phenomenological, episodic, and procedural knowledge). Analytical, semantic, and declarative knowledge represents information based on objective and impartial analysis. Phenomenological, episodic, and procedural knowledge represents experiential knowledge that people have about themselves and ways in which to deal with their physical and human worlds.

In natural sciences, the goal is to obtain objective knowledge through rigorous experimentation, observation, and mathematical analysis. In natural sciences, phenomenological knowledge (e.g., the thoughts, feelings, and motives of a tree, lion, or star) represents irrelevant research questions. For example, if a lion kills a deer, one assumes that the behavior is caused by, and explainable in terms of, instinct. However, if a woman kills a man, one does not simply attribute the killing to her instinct. One seeks additional information such as motive, agency, and responsibility. The same act (i.e., a woman killing a man) has different meanings and consequences based on one's knowledge of the person's motive and agency. If a woman killed her husband to collect an inheritance, it is premeditated murder. If a woman found her husband in bed with another woman and killed him out of rage, it can be classified as manslaughter. If a woman killed a man while she was driving drunk, it can be classified as involuntary manslaughter. If a woman killed a man while resisting being raped, it can be classified as self-defense. If a 5-year-old girl kills her friend while playing with her father's gun, it can be classified as gross negligence on the part of the father. Based on one's assessment of the person's intentions and responsibility, one assigns different outcomes, ranging from capital punishment (in the case of premeditated murder), to 10 years imprisonment (in the case of manslaughter), to no punishment (in the case of self-defense).

In human sciences, unlike in physical and biological sciences, it is essential to know the intentions, goals, and motives of people. This information can be obtained through self-reports. In the transactional model espoused by both Bandura and Kim, the subjective human qualities (e.g., agency, intentions, meaning, goals) can be systematically linked with the situation or event, on the one hand, and with behavior or performance, on the other.

In research, phenomenological, episodic, and procedural knowledge needs to be translated into analytical knowledge. However, many people do not possess the analytical skills in describing how they performed certain actions. For example, adult native English speakers can freely express their thoughts in English (i.e., procedural knowledge), but they might not know the grammatical syntax or structure of the spoken words (i.e., semantic knowledge). In other words, they know how to produce the sentences, but they might lack the ability to describe them analytically. This is the case because people are taught to use the language to communicate with others. Grammatical knowledge is taught as a part

of formal education in school. Conversely, Koreans might know the grammar of English, but they might have difficulty in speaking English because it is a different type of knowledge. It is the role of the researcher to analyze the grammar of psychological phenomena and to verify it to ensure that the analysis is correct. In human life, both experiential knowledge (e.g., a football player describing his experiences in playing a game) and analytical knowledge (e.g., a sport commentator providing a play-by-play analysis) are useful types of information that need to be integrated (e.g., a coach planning strategy for the next game). Indigenous psychological analysis has been conducted in the areas of achievement, conception of self, parent-child relationships, school violence, stress, occupational safety, trust, organizational behavior, and political culture. An example of educational achievement of East Asian students, focusing on Korean results, is provided in the next section.

5. AN EXAMPLE: EDUCATIONAL ATTAINMENT

In international comparisons of academic literacy of high school students (e.g., Third International Mathematics and Science Study [TIMSS], Program for International Student Assessment [PISA]), East Asian students are the top achievers in mathematics and science. Although the U.S. government spends more money per student to educate its children and adolescents, American schools have smaller classes, and many psychologists provide their expertise in developing U.S. educational programs, American students perform far below their East Asian counterparts. In the TIMSS, American students were ranked 19th in mathematics and 18th in science; in the PISA, they were ranked 15th in reading literacy, 19th in mathematical literacy, and 14th in scientific literacy. In contrast, East Asian students were ranked at the top in mathematics and science in both the TIMSS and PISA and were ranked near the top in reading literacy (Korea was ranked 6th and Japan was ranked 8th). These results baffle many psychologists because the results directly contradict existing psychological theories.

More than a century ago, psychological testing and assessment was initiated by Galton to measure innate ability. American psychologists (e.g., Terman at Stanford University, Yerkes at Harvard University, Garrett at Columbia University) continued the tradition. Terman developed the Stanford-Binet intelligence quotient (IQ)

test to measure inborn intelligence and to document individual, ethnic, racial, and sex differences. The results of the test were used to shape U.S. national policies (e.g., forced sterilization of “feebleminded” individuals, segregation of races, restricting Asian immigration). In 1924, Asians were considered a “genetically inferior” race, and the passage of the National Origins Act barred Asians from immigrating to the United States until 1965. Also, the IQ test scores were used to justify racial and sex segregation.

In 1977, Kamin stated that when the first version of the Stanford–Binet test was administered and published in 1916, one set of results contradicted the expectations in that girls of all ages outscored boys by an average of 2 to 4%. Terman unilaterally deleted, revised, or added new items so that this difference disappeared, and subsequently boys did better than girls. Thus, the IQ test was developed and revised not on a strict scientific basis but rather to fit the preconceptions at the time.

In 1960, Korea had one of the lowest literacy and educational achievement levels in the world. Currently, Korean students receive one of the highest scores in mathematics, science, and reading literacy. These dramatic reversals in sex and national differences cannot be attributed to genetic basis but can be attributed to social, economic, and cultural factors. Existing psychological theories argue that innate born differences (e.g., IQ, personality), ability attribution, intrinsic motivation, and self-esteem are important factors in predicting educational achievement. However, a series of studies conducted by Stevenson and colleagues and by Kim and colleagues challenged the basic assumptions of these theories.

The success of East Asian students can be traced to the strong sense of relatedness; social support provided by parents; belief in effort, hard work, and self-discipline; and coordinated efforts of parents, teachers, and governments. First, students, parents, teachers, and administrators agree that educational success is the most important goal for students, and they work together in achieving this outcome. Second, East Asians believe in effort, discipline, and persistence as a means to their goals. People believe that if they work hard and discipline themselves, they can accomplish their desired objectives. Third, the sacrifice and support provided by parents are essential ingredients in their children’s educational success. Emotional support in the form of encouragement, praise, security, and understanding, rather than expert advice from professionals, is reported as an important factor for their success. Fourth, East Asians believe that ability can be acquired and personality can be polished through persistent effort rather than believing that these characteristics are innate.

When self-concept in mathematics and science was assessed, Korean students were ranked 32nd and 21st, respectively, whereas U.S. students were ranked 1st and 4th, respectively (TIMSS). Korean students did not believe that they were good in mathematics and believed that they needed to work hard to do well, and this belief and persistent effort led to the attainment of high scores. In contrast, American students believed that they were good in math and did not feel the need to study hard because expending effort implied a lack of natural ability. As a result, they did not do well on these tests. In terms of motivation, when Korean students were asked about their reasons for studying mathematics, 85% indicated that attending a desired university was among their reasons, 62% cited pleasing their parents, and 44% cited obtaining a desired job. In other words, their reasons for studying mathematics were largely extrinsic motivation.

Finally, using the indigenous psychology approach, a 6-year longitudinal study was conducted to examine the factors that influence academic achievement of Korean students. The role of parents emerged as the most important factor, followed by the role of teachers and the role of friends. The current authors found, in a structural equation model, that influence from parents (e.g., social support, achievement pressure, expectations) had a direct effect on students’ achievement motivation, efficacy beliefs, and studying time and, in turn, had both a direct and an indirect effect on academic grades. Moreover, a feeling of indebtedness and respect toward their parents increased students’ achievement motivation and efficacy beliefs and, in turn, increased the amount of time they studied and improved their academic grades. The socioeconomic status of the parents affected how much support they provided to their children. These results point to the role of external factors (e.g., socioeconomic status of parents, the role of significant others) and the belief in effort as being responsible for the phenomenal academic achievement of Korean students. Individual factors (e.g., self-esteem, intelligence, personality, intrinsic motivation, ability attribution) had very little impact on academic achievement.

6. FUTURE DIRECTIONS

Although science can provide the most accurate understanding of the world, it can also blind and limit one’s understanding. Researchers start with an idea, model, theory, or method to uncover yet another secret of life. Researchers’ preconceptions can both aid and limit

scientific discovery. As noted previously, psychologists' emphasis and focus on individualistic and intrinsic factors limited their understanding of external factors that are critical to students' academic achievement. A number of external impositions have limited the development of psychology, and indigenous psychology represents being freed of these impositions.

First, psychologists used the natural sciences model to study humans. In the rush to become a respected branch of science, early psychologists tailored the psychological phenomena to fit the natural sciences paradigm. Psychologists were able to achieve a modest degree of methodological sophistication, but central human qualities such as intentions, meaning, and agency have been omitted to distort one's understanding of psychological phenomena. Indigenous psychology advocates the development and use of appropriate methods and concepts to study psychological phenomena.

The second imposition is the assumption of the universality of psychological theories. With very little development, testing, and data, psychological theories are assumed to be universal. This assumption is particularly problematic because most theories were developed in the United States and tested mainly on university students in laboratory settings. In other words, theories that were tested on less than 1% of the total population have been assumed to be universal. Indigenous psychology emphasizes the documentation and analysis of psychological variations before conclusions can be made about their universality.

Third, expert or professional knowledge has been imposed on the lay public. Psychological theories and concepts have been used to explain and modify behavior. In most cases, the predictive value of these theories is very low compared with that of the natural sciences. Psychologists have largely failed to describe psychological phenomena from the inside, that is, from the experiencing persons. Instead, psychologists have dissected the world into abstract concepts and theories that are removed from the "real world" in which people live.

Indigenous psychology advocates being freed of these external impositions and obtaining the phenomenological information as insiders as well as through impartial third-person analysis. Indigenous psychology advocates linking knowledge from humanities (which focus on human experience and creativity) with knowledge from social sciences (which focus on analysis and verification). Most attention has been focused on internal or external validity and not on practical validity. In other words, do the theories help to understand, predict, and manage human behavior? It

is known that most psychological theories (e.g., behaviorist, Freudian, Piagetian, humanist) do not withstand the test of empirical scrutiny. The main reason is that these theories have been developed using limited information (e.g., studying laboratory rats, interviewing too few patients, observing one's children), and they have not developed a process for systematic documentation, understanding, and verification of psychological phenomena.

The people who understand psychological phenomena well might not be psychologists. In fact, perhaps the greatest psychologist was Shakespeare. He was not an analyst like Freud or Piaget, and he did not conduct experiments like Skinner, but Shakespeare was able to capture human drama both on paper and on stage. His dramas have been performed for more than four centuries in many cultures and are loved throughout various parts of the world. In a similar vein, the greatest therapist might have been Beethoven or Mozart, whose music is able to soothe frazzled nerves and the frustrations of daily life. Disney could be considered as the most notable developmental psychologist because he was able to capture the hearts and minds of the young as well as the "young at heart." We might not think of these people as psychologists, but they captured and reproduced human psychology on stage, film, and paper. It is the role of indigenous psychologists to provide an understanding that is both analytical and phenomenological—that is scientific, practical, and relevant to people's daily lives.

GLOSSARY

culture Prevailing and shared values, norms, assumptions, belief systems, and behavioral patterns that differentiate one human group from another.

human resource management practices The policies and practices involved in carrying out the human resource aspect of a management position, including recruiting, screening, training, rewarding, and appraising.

motivation Set of processes that arouse, direct, and maintain human behavior toward attaining some goal.

organizational diversity Workforce variety with respect to gender, culture, national origin, handicap, age, and religion.

work attitudes and behavior Clusters of feelings, beliefs, and behavioral intentions toward any aspect of work or work settings.

Industrial and organizational psychology (I–O) is one of the major applied fields of psychology that is concerned with behavior in work situations. Because of globalization, there is an increasing interest in the influence of culture on work behavior among scientists and practitioners. In this article, the cross-cultural perspective in I–O psychology is discussed in four main areas. First, the influence of culture on work motivation is examined. Second, human resource management practices in the areas of staffing and performance management are presented. Third, research on managing cultural diversity is reviewed with a focus on expatriate management, women’s career development, and effective functioning of multicultural teams. Finally, cross-cultural research on work attitudes and behavior is summarized in the areas of job satisfaction, organizational commitment, organizational citizenship behavior, and organizational justice.

1. INTRODUCTION

Industrial and organizational psychology (I–O) was defined by Blum and Naylor as “the application or extension of psychological facts and principles to the problems concerning human beings operating within the context of business and industry.” During recent years, the interest in cross-cultural perspectives of I–O psychology has

increased, due mainly to changing economic and social conditions such as workforce diversity, availability of telecommunications across cultures, and globalization and global competition. This article provides an overview of the cross-cultural I–O psychology literature in the areas of motivation, workforce diversity, human resource management (HRM), and work attitudes and behavior. Although leadership is an area that has attracted the most cross-cultural I–O research attention, it is not included in this article because a full treatment of the topic is available elsewhere in this encyclopedia.

2. THE ROLE OF CULTURE IN INDUSTRIAL AND ORGANIZATIONAL PSYCHOLOGY

Organizations are complex systems that operate under the influence of multiple environmental forces that are both internal (e.g., size, type of work, industry and production, type of workforce, technology, stage of development) and external (e.g., political, legal, educational, institutional) to the organization. The challenge of cross-cultural I–O psychology is to disentangle the impact of culture (i.e., sociocultural context) from other internal and external environmental forces.

Since the early 1960s, comparative studies of organizations have focused on noncultural factors influencing organizational structure and practices. Among the most popular noncultural approaches is the “contingency” approach, within which there were four main streams. The first, referred to as the “logic of industrialization,” asserts that industrialization has a homogenizing effect on organizations around the world, irrespective of the political, economic, and cultural contexts. The second thesis, generally referred to as “technological implications,” suggests that technological advancement and automation leads to a transformation of social relations and attitudes at work (e.g., more control over work schedule and work processes, increased emphasis on developing social networks). The “culture-free contingency theory of organizations” approach emphasizes the role of contextual elements such as size of the organization, industry, and dependence on other organizations. The final thesis emphasizes the role of strategic development of organizations, according to which organizations are transformed from small, less hierarchical, and domestic structures to large, complex, professional, and international structures. This transformation has implications for practices such as planning, diversification, and role differentiation.

Another type of noncultural approach stems from the political–economy perspective. In this perspective, organizations in the same sociopolitical systems (e.g., capitalism vs socialism) are assumed to have similar characteristics, especially with respect to organizational objectives, control strategies, and degree of centralization and decision making. The final noncultural approach, namely the “societal effect approach,” takes into account the social context in which organizations operate, with specific emphasis on the educational system, the system of industrial relations, and the role of the state.

Critics of the noncultural approaches are concerned with the deterministic orientation of these approaches as well as their underestimation of the role of culture in explaining organizational phenomena. Some scholars take an interactionist perspective, suggesting that culture influences some aspects of organizational practices more than it does others. For instance, whereas organizational contingencies influence the “formal” characteristics of organizations (e.g., centralization, specialization, span of control), cultural variables influence the “interpersonal” aspects (e.g., power and authority structure, delegation, consultation, communication patterns) or the “organizational processes” (i.e., the way in which organizations function). Others assert that culture has a moderating effect on organizations; that is, even though the contingencies help to determine the organizational structure, culturally driven preferences influence the exercise of choice among alternative structures. For instance, the effect of industrialization on organizations is not homogenous in every country (e.g., the case of Japan). Similarly, within the capitalist system, there is wide variety among organizational and managerial practices. Researchers argue that similarities in socioeconomic systems resulted in similar organizational objectives, but the ways in which these objectives were materialized differed depending on the cultural contexts. The preceding discussion, therefore, underlines the important role that culture plays in understanding organizational phenomena. However, culture’s effect is more salient in some aspects of organizations than in others. The following sections present the state of affairs in those areas of I–O psychology where the impact of culture is significant.

3. CROSS-CULTURAL APPROACHES TO WORK MOTIVATION

Work motivation is one of the most popular research topics in cross-cultural I–O psychology. The “content

theories” of motivation address the question of what motivates employees, whereas the “process theories” attempt to answer the question of how employees are motivated. Studies conducted in both paradigms clearly demonstrate the influence of culture on motivation.

3.1. Cross-Cultural Differences in What Motivates Employees at Work: Content Theories

Cross-cultural research on motivation between the 1970s and the 1990s focused mainly on the comparison of needs and values. The content theories of motivation assert that goal-directed behavior is initiated to satisfy unfulfilled needs, and values are considered the cognitive representation and transformation of needs. Early cross-cultural research tested the validity of various need taxonomies, including those of Maslow, Alderfer, and McClelland. Employees in economically developed and developing countries were found to be motivated by different incentives due to variations in needs. For example, malnutrition was the main cause of low motivation and productivity in Nigeria, whereas job security was most needed, and hence most motivating, in India and Guatemala. Similarly, satisfaction of physiological and safety needs were more salient for cane cutters, whereas affection and esteem needs were most salient for fishermen.

In subsequent studies, it was shown that in collectivist societies, “self-actualization” (i.e., the highest order need) is replaced by “service to the in-group” or actualizing the in-group’s potential (i.e., “collectualization”) as the highest ideal to motivate workers. Also in collectivist cultures, “achievement” has collectivist overtones such as respect for others, fulfilling collective goals, and glorifying established virtues. The conclusion of the cross-cultural research on need-based theories of motivation is that the structure of needs may be universal (e.g., lower order needs such as safety, higher order needs such as esteem) but that the relative strength or the contents of the standards vary by culture.

The other strand of research under the content theories emphasizes the importance of “values” as a motivating force. A major research project was the Meaning of Work (MOW) studies by the MOW International Research Team that was carried out in the United States, Japan, and six Western European countries. The MOW team was primarily interested in the extent to which work is important in people’s lives in various cultural contexts. Their assumption was that

work is more motivating if it is central to one’s life. Results showed that work was most central in Japan and least central in West Germany (with the United States in the middle). More recent studies replicated these findings; Japanese employees are motivated most by the task itself, whereas their U.S. counterparts are motivated mostly by affiliation and recognition.

There are other large-scale cross-cultural studies on the motivating value of work. One was conducted by the Work Importance Study (WIS) group in 11 diverse countries, including Croatia, South Africa, and Portugal. The findings showed significant cross-cultural differences with respect to the extent to which work is a central life value compared with family, community, and leisure. Another study, called the Work Socialization of Youth (WOSY) project, examined the patterns of meanings of work from a longitudinal perspective in 7 West European countries and Israel. The results demonstrated that the meaning of work was changing across cultures and over time. Finally, the Chinese Culture Connection team demonstrated the salience of the “Confucian work ethic” emphasizing moral duty and obligation to the collectivity as being the primary motivating factors.

3.2. Cross-Cultural Differences in How Employees Are Motivated at Work: Process Theories

Process theories deal with the ways in which employees are motivated at work. There are four major process theories of motivation: goal-setting theory, job enrichment theory, equity theory, and expectancy theory. Among the four, goal-setting theory of Locke and Latham has received the most attention from cross-cultural researchers. The theory asserts that the existence of goals is motivating and that goals with particular characteristics (e.g., challenging, specific, accepted) are more motivating than others. Participation and joint decision making are considered to be a key factor in motivation. Participation enhances motivation in that it provides greater autonomy and control over work outcomes and reduces anxiety and uncertainties. The Industrial Democracy in Europe (IDE) International Research Group compared the participative decision-making practices in 12 European countries in 1981 and repeated the study 10 years later in 10 of the original 12 countries as well as in Japan and Poland. This was a major undertaking to show that participation had different meanings and practices across cultures. These

studies show that in the most collectivist cultural contexts, group participation is more motivating and effective in improving work outcomes than is individual participation. Individual and face-to-face involvement in decision making (i.e., the North American model) is, in fact, not desired in all cultural contexts. In cultures that Hofstede identified as high in power distance and uncertainty avoidance, participation may even result in demotivation because subordinates seek guidance from their superiors to reduce uncertainties. Research suggests that for participative goal setting to be motivating in developing countries, organizations should enhance employees' self-efficacy beliefs through empowerment, coaching, and mentoring.

The job enrichment theory of Hackman and Oldham suggests that workers are motivated to the extent that they experience meaningfulness in their jobs. This can be achieved through more autonomy and discretion in one's job, feedback on performance, opportunity to use multiple skills (i.e., skill variety), identification of the contribution of one's job to the overall work context (i.e., task identity), and knowledge of the significant contribution of one's job to others' lives (i.e., task significance). Jobs that are designed to have high autonomy, feedback, skill variety, task identity, and task significance are referred to as "enriched jobs." This theory is based on individualist assumptions of employees' desire for independence, freedom, and challenge. Thus, it is argued that job enrichment might not be as effective in countries with power hierarchies and avoidance of uncertainties. Increasing discretion and responsibility elevate anxiety and uncertainty, and worker autonomy defies the role of the authority. In more collectivist European countries, job design takes the form of "autonomous work groups" in which job enrichment principles are implemented at the group level (e.g., team autonomy, team-based feedback). However, this system is reported to have limitations in developing countries due to uncertainty avoidance and resource scarcity that is endemic to the majority of developing countries.

The equity theory of Adams purports that employee motivation is achieved by invoking the perception of fairness. One way in which to increase fairness is to establish an equitable relationship between "inputs" and "outputs" among workers. Inputs represent everything that employees perceive as their contribution to the job (e.g., training, skills, time, effort, loyalty, commitment to the organization), whereas outputs represent everything that employees perceive as received in return for their contribution (e.g., pay, promotion, praise, recognition and awards). Equity theory has not attracted much

cross-cultural research attention, but the available evidence suggests that what constitutes inputs and outputs varies across cultures. In collectivist cultures, loyalty, commitment, seniority, and tenure are more important inputs for promotion and rewards than is job performance. Also, in cultures where there are status hierarchies, the social class or caste to which one belongs is considered an input. Similarly, there are cultural variations in the perception of outcomes. Challenge and autonomy in the job and salary increases are considered to be valued outcomes in individualist cultures, whereas praise from supervisors can be an important outcome in collectivist cultures. There are ways in which to restore equity such as changing inputs (e.g., working less), changing the comparison group, changing the outcomes (e.g., asking for a salary increase), and leaving the organization. There is not enough research to indicate cross-cultural variations in the ways in which to restore equity. However, there is a large body of cross-cultural research in the area of organizational justice. Reward allocation based on an equity principle is not endorsed in all cultural contexts.

The final process theory of motivation is the expectancy theory of Vroom. According to the theory, employees are motivated to the extent that their expectations are met in the following ways. First, if they exert enough effort, their job performance will be at the desired level. Second, if they perform at the desired level, it will lead to some outcomes. Third, the outcomes will have high valence or attractiveness. Although there is no systematic research testing the validity of the theory across cultures, it seems to have more applicability in individualist cultures than in collectivist ones. In individualist cultures, employees are motivated if there is a high likelihood of meeting their own expectations, whereas in collectivist cultures, motivation is related to the probability of meeting the expectations of "significant others" (e.g., family, organization, superiors). "Face saving" is also an important motivator in collectivist cultures. Another cross-cultural variation may exist in people's beliefs in the controllability of events. In fatalistic cultures, employees do not believe that control of events is in their hands; that is, they have an "external locus of control." Thus, expectancy theory might not be useful in such cultural contexts.

3.3. The Culture-Based Model of Work Motivation

The first theoretical model explaining how culture influences motivational practices and their outcomes was

proposed by Erez and Earley in 1993. According to the cultural self-representation model, motivation is related to the employee's self-concept. Cultural context determines how one perceives oneself. To the extent that motivational practices are congruent with culturally based self-construals (e.g., the way in which the self is defined and perceived), there is a high likelihood of performance and satisfaction. For example, if in teamwork employees receive rewards based on their individual contributions to the team, this is congruent with the cultural context where the self is perceived as an independent entity (i.e., individualism), whereas group reward is more motivating in the cultural contexts in which employees have interdependent self-construals (i.e., collectivism). The congruence results in three self-derived motives: self-enhancement (maintaining a positive cognitive and affective state about the self), self-efficacy (perceiving oneself as competent and efficacious), and self-consistency (experiencing coherence and continuity). For employees who have interdependent self-construals, individual-based rewards in teamwork lower the positive self-representation and hence motivation. In general, employees are motivated through organizational practices that maintain and improve their self-enhancement, self-efficacy, and self-consistency.

4. CROSS-CULTURAL VARIATIONS IN HUMAN RESOURCE MANAGEMENT PRACTICES

With increasing globalization, staffing and performance management have become the keys to success of multinational firms. In the HRM field, these are the two topics that have received more cross-cultural research attention than have other areas of HRM (e.g., human resource planning, job analysis, compensation, reward management).

4.1. Staffing: Recruitment and Selection

Culture influences recruitment and selection in many ways such as in attitudes toward selection and testing, the purpose that staffing serves, and the perceived fairness and appropriateness of criteria and methods that are used in the process. The first theme of cross-cultural variation is the attitudes toward selection and testing. In the North American context, selection is a one-way process whereby applicants are tested to

predict their future work behavior. However, in the European context, selection is a mutual agreement and negotiation between the organization and the candidate. In some European countries such as Italy, France, Sweden, and Portugal, the issue of testing has a negative connotation because it is perceived as invasion of privacy, violating individuals' rights to control their own careers and creating a barrier to the holistic representation of oneself.

The main purpose of recruitment and selection also varies across cultures. In North America, strategic human resource planning is geared toward recruiting the right number of people with the best qualifications to do the job. In contrast, in India and Eastern Europe, organizations hire more employees than are needed so as to combat poverty and unemployment. In such cultural contexts, the strategic goal of organizations is to meet societal needs as well as economic ones.

The criteria for selection should be perceived as relevant to the job and as predictive of future performance. In the United States, some of the most commonly used criteria for selection include education, cognitive skills, job experiences, and personality traits. There is a paucity of cross-cultural research on the appropriateness of such selection criteria in other cultural contexts. However, the few existing studies cast doubt on the appropriateness of criteria such as education. It is argued that knowledge and skills acquired by formal education might not be the best predictors of performance in countries where education either is not available to everyone or is inadequate in preparing individuals for the workforce. A few studies suggest that criteria for selection are more interpersonal than individual in collectivist cultures. For example, in collectivist cultures, social selection criteria are used—team members' favorable opinions about the candidate in Japan; agreeableness, good interpersonal relations, and trustworthiness in Islamic Arab countries; belonging to the same in-group as the manager (e.g., the same family or homeland) in India; and positive attitudes toward family life in Latin America.

Once criteria are established, the next step involves determining the method of recruitment and selection. Fairness is related to the candidates' perception of the appropriateness of recruitment channels, the questions that are asked on application forms, and job previews (i.e., a brief and a realistic review of the job context and the work environment). Word-of-mouth is a common method of announcing a job opening in cultures where the hiring of in-group members is favored. Some questions on the job application forms (e.g., marital status, religious and family backgrounds, physical appearance)

could be perceived as offensive in some cultures more than in others. In job previews, a detailed description of a specific job position will not be a requirement of an ideal recruitment process in cultures where “generalists” are preferred over “specialists” (e.g., Japan).

The methods of selection used in various countries have attracted some cross-cultural research attention, but countries included in these studies have been limited mainly to those in North America and Northwestern Europe. In these studies, biodata was found to be among the least common methods of selection, whereas the interview was among the most common. In a majority of countries, references or recommendations are used for different reasons and to varying degrees. For instance, in the United Kingdom, the United States, and Australia, recommendations are used only as a final check, whereas they are relied on heavily in Southeastern European countries and in India.

In the North American literature, studies on the predictive validity of various selection methods have increased in number over recent years. However, the social validity (i.e., perceived fairness and acceptability of a particular practice) is an issue that is overlooked in the cross-cultural literature. For instance, in one study, French job applicants perceived written ability tests to be less impersonal and perceived personality tests to be more offensive in violating privacy than did American applicants.

This brief review of the literature shows that there are cross-cultural variations in various aspects of the recruitment and selection process.

4.2. Performance Management: Criteria, Evaluation, and Development

Criterion development and measurement has been an issue of ongoing debate among I-O psychologists. There is neither a uniform description of “performance” nor consensus on the dimensions of it. The criterion problem is exacerbated at the cross-cultural level because both the definition and structure of “good performance” are culture bound. According to some of the recent North American theoretical formulations, the most salient dimensions of performance are job-specific knowledge and proficiency, communication competence, effort, mentorship/supervision, quality of output, productivity, interpersonal competence/teamwork facilitation, and administrative competence. Cross-cultural replications of these dimensions have yet to be done.

What constitutes good performance in various cultural contexts? Performance-orientated cultures place more emphasis on the end result rather than on the process. As such, performance criteria are objective and measurable. In collectivist and high-power distance cultures, employee loyalty is valued more than productivity. Outcomes are important, but social and relational criteria, which are more subjective, are weighted heavily in evaluating employees. Such criteria include good human nature, harmony in interpersonal relations, trustworthiness, respectful attitude, loyalty and deference toward superiors, effort and willingness to work, awareness of duties and obligations, gratitude, organizational citizenship, conformity, and contribution to team maintenance.

Unlike individualist cultures, collectivist cultures downplay individual differences. Therefore, the primary purpose of performance evaluation is not differentiating among individuals but rather justifying decisions on compensation and promotion. Some authors purport that appraisal is used to control and instill loyalty. Formal evaluations are conducted less frequently (because the primary purpose is not to provide feedback), and their timing coincides with salary adjustment and promotion periods. In high-power distance cultures, performance evaluations may also serve the purpose of reinforcing the authority structure. In such cultural contexts, performance is usually evaluated by superiors (i.e., immediate supervisors, managers, and/or several levels up). Because performance appraisal is a top-down unilateral process, evaluation of superiors is rare in high-power distance cultures. Therefore, the 360-degree performance appraisal method (i.e., self-evaluation plus evaluation by superiors, subordinates, peers, and customers) that is popular in the United States is not appropriate in high-power distance cultures. In collectivist cultures, the 360-degree evaluation may disturb group harmony due to constant monitoring of the behavior of one’s colleagues. The accuracy of such evaluations is also jeopardized because in-group favoritism and loyalty prevent assignment of low performance ratings to in-group colleagues and superiors.

Rating errors are barriers to obtaining reliable performance evaluations. The most pervasive ones include attribution and leniency errors. The accuracy of the process depends partly on the correctness of attribution of success and failure. Cross-cultural variations in attribution are well documented. For instance, Asians usually attribute their success to luck and help received from others, whereas they usually attribute failure to their lack of ability and inadequate personal effort. In a collectivist cultural context, those who

engage in self-effacement gain acceptance by peers, whereas those who take pride in individual achievements receive disapproval. Modesty in self-evaluations leads to negative leniency bias, that is, assigning a lower evaluation to oneself than is deserved.

The final topic is related to the communication of performance feedback. Culture has a bearing on the way in which feedback is given and received. Regardless of the cultural context, performance feedback is not easy to give or receive, especially when the feedback is of a negative nature. However, in some cultures where the distinction between life and work space is blurred, feedback on one's job performance is perceived as equivalent to a rejection of the person, who then experiences loss of face. On the other hand, positive feedback on performance is also not common in collectivist cultures. Positive feedback on individual performance could disturb group harmony because it may induce jealousy and resentment among those who did not receive such feedback. Also, in collectivist cultures, positive feedback is expected to come from the outside. If a manager praises his or her own employees, it could be perceived as inappropriate and self-serving.

If neither negative nor positive feedback is appreciated, this implies that no feedback could be the most preferred condition in collectivist cultures. There is at least one empirical study that supports this view, showing that Japanese and Chinese employees do not take any initiative in seeking feedback on individual performance. This is explained by three factors. First, as mentioned previously, there is avoidance of negative or positive feedback. Second, seeking feedback on individual performance, rather than on group performance, is perceived as "self-centeredness." Finally, communication is indirect and subtle in collectivist cultures. Performance-related information is usually embedded in contextual cues rather than revealed in a direct and confrontational manner.

The final phase in performance management concerns the improvement of performance. The most frequently administered practices used to improve performance include performance-based rewards, training, and coaching/mentoring. Are rewards contingent on performance? The answer depends on the cultural context. It was found that in collectivist and fatalistic cultures, there is a weak performance–reward contingency due to a number of factors. First, in fatalistic cultures, managers believe that employees are not malleable; therefore, managers do not see any point in rewarding employees as a means of changing work behavior. Second, individualist cultures use the norm of equity in allocating

rewards. Therefore, there is one-to-one correspondence between performance and reward in individualist cultures, whereas reward allocation in collectivist cultures depends on contingencies other than performance. Finally, in collectivist cultures, rewarding the group as a whole is preferred over rewarding individual members. As mentioned previously, individual gratification may result in disturbed group harmony and resentment.

The second practice used to enhance performance is training. One of the first questions to ask is whether or not training needs are determined on the basis of performance outcomes. This seems to be the case in individualist and performance-oriented cultures. In low-performance-oriented and high-power distance contexts, decisions about who will participate in trainings are based on criteria other than job performance. Employees who maintain good relations with higher management are sent to desirable training programs (i.e., training overseas or at resorts) as a reward for their loyalty. Because training is given as a favor or reward, trainees provide highly favorable feedback on trainings and introduce a bias to the evaluation of training effectiveness.

The next practice in performance development is coaching and mentoring, which involves a personalized subordinate–superior relationship to enhance performance. Mentors are senior and more experienced people who provide guidance to employees. The role of a mentor includes modeling correct behavior, setting clear performance standards and goals with employees, coaching, monitoring and giving constructive feedback on performance, and making necessary adjustments to tasks and work environments to improve performance. Mentors work with and for employees. High power distance is not compatible with mentorship. In high-power distance cultures, superior–subordinate relationships are not personalized and managers are not usually participative in goal setting. However, mentorship is more likely when high power distance is combined with paternalism. In paternalistic cultures, superior–subordinate relationships are personalized and managers guide employees in professional as well as personal matters.

4.3. The Culture-Based Model of Human Resource Management

Kanungo and colleagues proposed and tested a theoretical model explicitly linking culture to HRM practices.

The model of culture fit asserts that variations in HRM practices are due to the internal work culture, which in turn is influenced by both the sociocultural context and the enterprise environment. The internal work culture is composed of managerial beliefs and assumptions about two fundamental organizational elements: the task and the employees. Managerial assumptions pertaining to the task deal with the nature of the task and how it should be accomplished best, whereas those pertaining to the employees deal with employee nature and behavior.

Organizations design and implement HRM practices based on the prevailing managerial assumptions about the nature of both the task and the employees. These assumptions, in turn, are influenced by two major environmental forces. First, the enterprise environment includes the ownership status (private sector vs public sector), industry, market competitiveness, and resource availability. Second, employee-related assumptions are influenced by the characteristics of the sociocultural environment.

The model of culture fit was tested in various cultural contexts, including Canada, the United States, Romania, Germany, Israel, India, Pakistan, China, Turkey, and Russia, with the following key findings. In fatalistic cultures, managers assume that it is not possible to change employee nature and behavior. Accordingly, they do not provide feedback or try to improve performance through rewards. In cultures where there are power hierarchies, managers do not hold the assumption that employees are proactive; rather, they assume that employees are reactive (i.e., expecting close guidance and supervision). As a result, managers do not give autonomy and discretion to employees in their job assignments. In collectivist cultures, managers assume that organizations and employees should fulfill obligations to one another. Based on this assumption, they provide empowering supervision both to fulfill their obligations toward workers and to enable workers to fulfill their obligations toward others in the organization. The model of culture fit is an important initial step toward understanding how, and to what extent, culture influences HRM practices. Cross-cultural and multilevel testing of the model is continuing.

5. MANAGING CULTURAL DIVERSITY

This section examines cultural diversity under three categories: expatriate management, women's career advancement, and multicultural teams.

5.1. Expatriate Management

Expatriates are employees of business or government organizations who are sent by their organizations to related units in countries other than their own for pre-designated temporary time periods of usually more than 6 months and less than 5 years. In global competition, successful expatriation not only gives multinational companies a competitive edge, it also contributes substantially to professional growth of expatriates. Despite the importance attached to international assignments, failure to complete the full cycle of such an assignment and failure to work effectively on the job remain major problems. Criteria for effective expatriation include both adjustment to the new cultural context and high job performance. Difficulties in adjustment and performance result in high turnover rates and, therefore, failure to receive a return on investment. Stimulated by the observed problems in expatriation and the costs associated with it, this topic has emerged as one of the most popular topics for cross-cultural researchers.

Studies have identified a number of key factors influencing expatriates' cross-cultural adjustment and performance. The individual factors include those related to expatriates and their families. There is some research suggesting that personality characteristics, such as openness to new experiences, agreeableness, and tolerance for ambiguity, predict better adjustment outcomes. Competence in interpersonal relationships and willingness to learn about a new culture are factors that facilitate both adjustment and performance. Recent research also suggests that those individuals who have had cross-cultural interactions during their childhoods stand a better chance of succeeding in international assignments. Expatriate-related factors also include family adjustment issues. Expatriates whose families have adjustment difficulties are more likely to leave their assignments prematurely.

Organization-related factors include the preparatory stage and the HRM practices of the company. The majority of expatriates who fail in their assignments have been selected solely on the basis on technical and managerial competencies. Their adjustment potential and interpersonal competencies are usually not assessed. Similarly, many organizations fail to provide cross-cultural and country-specific training prior to departure. These problems are exacerbated by the uncertainties related to the assignment terms and job specifications. Difficulty in finding positions in the parent company on repatriation also lowers job motivation and performance after the employees return. Furthermore, the receiving

organization (i.e., the local unit) is usually ill prepared to manage the cultural diversity resulting from expatriates' arrival. Local units that offer training on multicultural team management provide better support and assistance to the incoming expatriates, thereby facilitating their adjustment and performance. Finally, cultural factors influence expatriation outcomes. In assignments to countries with large cultural distance (i.e., dissimilarity between the culture of origin and the culture of the host country), expatriates experience more difficulties.

5.2. Women's Career Development

According to the reports of international organizations (e.g., United Nations' *Human Development Reports*, *World Bank Reports*, International Labor Organization reports), women receive less pay, less occupational status, and less career advancement all around the world. Although women share similar experiences at work and in family, cross-cultural differences contribute to the magnitude of discrimination and conflict between work and family. The literature canvasses various approaches to explain women's difficulty in gaining equal access to career development opportunities. First, there is compelling evidence suggesting the effect of gender role stereotypes. In all cultures, women's primary responsibility is toward the family. In some cultures, women feel the freedom to choose between pursuing a career and raising a family; however, in the majority of countries, women do not have such a choice. Cross-cultural differences exist with respect to norms in childbearing. Career women may opt to have children in some economically developed countries (e.g., France), whereas this is not an option for women in many traditional cultures of developing countries. Moreover, in many collectivist cultures, women's family responsibilities include taking care of extended family members, in-laws, and aging parents, adding to women's total workload.

A second difficulty stems from the attitudes toward working women. In the majority of countries in the world, organizations hold negative attitudes toward women's career development. A common belief is that women are cognitively and psychologically ill prepared to become leaders in the business world. This belief is derived from socialization values and practices. In many traditional cultures, women are socialized to be shy, unassertive, dependent, passive, and obedient to the men in their lives. For example, according to the traditional beliefs in China, it is a virtue for a woman to have no leadership ability. Women themselves internalize

these norms and develop unfavorable attitudes toward their career development.

Women are also cut off from male networks. As a result, they miss opportunities that would help them to advance in their careers. For instance, in Japan and Taiwan, evening gatherings in pubs or clubs are very common. However, because women's participation in such social gatherings is considered inappropriate, they are inadvertently cut off from the critical social (and hence informational) networks. Another negative attitude stems from the concern about women's and men's changing status in the family. In traditional societies, if a woman works, it is perceived to be the failure of the husband to provide for the family. It is also feared that women's economic independence will decrease men's power in the family.

Finally, women receive insufficient support, especially with respect to child care, from their families and the organizations for which they work. One of the most important sources of support is the spouse. In traditional societies, a man's helping out his wife with her family duties is uncommon. Husbands who do housework are stigmatized as being "woman-like," "submissive," "passive," or simply "weak." In such cases, the values and behaviors of husbands, especially those from high educational backgrounds, oscillate between traditional and modern. Support is also rare in organizations. Family-friendly work schedules and day care facilities are rare in many countries. Although managers are more tolerant and understanding of women's family responsibilities in paternalistic and collectivist cultures, such tolerance does not indicate support for women's career advancement.

5.3. Multicultural Teams

Teamwork is one of the key factors for organizational success. With increasing globalization, effective management of multicultural teams has become a critical issue. Research in this area is still developing, and conclusive findings are few. There are mixed findings regarding the performance of culturally heterogeneous teams compared with that of homogenous ones. There are four factors that influence the functioning of multicultural teams. First, differences in core values and norms regarding how members should behave and interact with one another lower the performance at initial stages. For example, members from a collectivist culture value interpersonal harmony more than they do task accomplishment. As such, they avoid confrontations and giving negative performance feedback.

There is at least one study indicating that social loafing (i.e., the tendency to withhold effort when performing a group task) occurs less in teams in collectivist cultures than in teams in individualist cultures. In collectivist cultures, team members work hard to achieve the group goals, and members feel obligated to contribute to the team. Members of high-power distance cultures prefer teams with leaders who guide them closely, whereas members of low-power distance cultures may function better in autonomous or leaderless teams. Differences in norms, values, and preferences are potential barriers to effective functioning in multicultural teams.

The second factor that influences team performance is the perceived cultural distance of the team members. Recent research found a curvilinear (i.e., inverted U-shaped) relationship between the perceived cultural distance and team performance in such a way that culturally homogenous and highly heterogeneous teams outperform moderately heterogeneous teams. Formation of subgroups is more likely to occur in moderately heterogeneous teams than in highly diverse teams. This lowers the team coherence and performance.

The third factor is time. Performance in diverse teams is a function of time. Heterogeneous teams are found to outperform homogenous teams over time. It takes more time for diverse teams to build trust and shared values and norms. Initial inefficiencies (i.e., process losses) due to inadequate communication and feedback may be overcome in time.

Finally, task structure affects performance of multicultural teams. In jobs that require an in-depth understanding of a particular cultural context (e.g., launching a new product in a new cultural context), cultural knowledge is task related and, hence, increases team performance. Multicultural teams perform better at tasks requiring idea generation and creativity than they do at production tasks requiring little discretion. Diverse teams function better under structured and noncompetitive task environments. Superordinate goals (i.e., goals that group members cannot reach without the help of the other group members) also facilitate team performance in multicultural teams.

Teams working in virtual environments (e.g., the Internet, videoconferencing) experience further difficulties in adjusting to uncertainties arising from technological problems. Virtual teamwork is more difficult for members who prefer face-to-face interactions (e.g., members of collectivist cultures) as well as contextual cues in communication (e.g., members of high-context cultures).

6. CULTURE AND WORK ATTITUDES

Work attitudes focus on how employees feel about their jobs and the organization. Exploring the cultural factors influencing work attitudes is one of the most popular research topics in cross-cultural I–O psychology because work attitudes are related to various work outcomes, including performance, productivity, turnover, and absenteeism. This section discusses the following cross-cultural differences in work attitudes: job satisfaction, organizational commitment (OC) and organizational citizenship behavior (OCB), and organizational justice.

6.1. Job Satisfaction

Work conditions (e.g., interpersonal relationships, pay, benefits, developmental opportunities) that are satisfying in one cultural context might not be satisfying in another cultural context. Research evidence suggests that workers in individualist cultures report more job satisfaction than do those in collectivist cultures. The higher level of job satisfaction in individualist countries is attributed to the fact that workers enjoy more individual freedom and rights and are more likely to fulfill their self-actualization needs. It has also been shown that people living in individualist countries report more life satisfaction, and this has a “spillover” effect in that it increases job satisfaction. However, recent research suggests that collectivism, rather than individualism, is positively correlated with job satisfaction. First, it is argued that employees “put up with” unpleasant work conditions because they believe that their work group members also suffer from the same conditions. The sense of sharing of this “common destiny” reduces dissatisfaction. Second, positive interpersonal relationships at work (e.g., collaboration, nonconfrontation) create a pleasant work atmosphere and enable workers to better cope with unpleasant conditions.

These seemingly conflicting findings are reconciled by research that identified contextual factors influencing job satisfaction. For instance, intrinsic job characteristics (e.g., opportunity for development, use of multiple skills, challenging job, autonomy) are more satisfying to employees in individualist cultures, whereas extrinsic job characteristics (e.g., pay, benefits, sense of security) and interpersonal aspects of the job are more satisfying to those in collectivist cultures. This variation is meaningful because job satisfaction is closely related to the

fulfillment of needs. In collectivist countries, people need to satisfy primarily their basic and interpersonal needs. As such, job characteristics such as challenge and autonomy do not yield job satisfaction unless salient needs are fulfilled. Furthermore, intrinsic job characteristics are positively associated with job satisfaction in countries with high social security (e.g., welfare system, national wealth) and small power distance, whereas this relationship does not exist in countries with low social security and large power distance. Employees in high-power distance cultures do not expect to participate in decision making, receive performance feedback, or be autonomous in their jobs. Lack of such intrinsic job characteristics does not result in dissatisfaction.

6.2. Organizational Commitment and Organizational Citizenship Behavior

OC is conceptualized as the extent to which employees feel a sense of allegiance toward their employers. The growing body of literature on OC suggests that it is an important organizational attitude predicting performance indicators (e.g., absenteeism, turnover intention), employee reactions to work, and employee well-being at work. In 1990, Allen and Meyer proposed a model of OC that consists of three components: affective commitment (i.e., employees' emotional attachment to and identification with the organization), continuance commitment (i.e., the perceived necessity to stay with the organization due to the high cost of leaving it), and normative commitment (i.e., the belief that one is obligated to stay loyal and committed to the employer).

Cross-cultural studies of OC have focused on two issues: structure of the construct (i.e., whether or not the three-factor model replicates across cultures) and correlates of OC. There is mixed support for the generality of the factor structure of the North American OC measures, and this casts doubt on the "universal" meaning of OC in various cultural contexts. The psychometric properties of these measures did not completely replicate in countries that are characterized by high collectivism, high power distance, and strong uncertainty avoidance (e.g., Korea). In such cultural contexts, the measurement holds better with the addition of some emic (i.e., culturally relevant) items. Cross-cultural variations are also found with respect to the correlates of OC. Antecedents and consequences of OC in Western European countries (e.g., Germany) were very similar to those in North America. Affective commitment was the best predictor of turnover

intention in individualist cultures with high employment mobility, whereas normative commitment was the best predictor in collectivist cultures emphasizing long-term employment. Desirable organizational outcomes (e.g., low absenteeism, job satisfaction, employee well-being) are strongly correlated with affective commitment in North America but are linked to normative commitment in collectivist, high-power distance, and paternalistic cultures where loyalty is valued and rewarded.

OCB is described as the contribution of employees to the welfare and effectiveness of the organization by engaging in behaviors that are neither required nor expected. These behaviors are referred to as the "good soldier" or "extra-role" behaviors. Similar to the case of OC, cross-cultural research on OCB addresses the issues of whether or not its meaning and structure transcend culture. The original theory, as proposed in North America by Organ in 1988, describes five dimensions of OCB: altruism (e.g., voluntarily offering help to others), conscientiousness (e.g., being punctual, following company rules and regulations), courtesy (e.g., being mindful and respectful of others' rights), civic virtue (e.g., participating in the political life, attending meetings, speaking up on issues), and sportsmanship (e.g., not complaining, not nursing petty grievances, not gossiping, not falsely magnifying problems). Limited cross-cultural research in this area suggests that some of these behaviors, as described in the North American literature, are not appropriate in some cultural contexts (e.g., speaking up in high-power distance cultures), whereas others are not considered as in-role rather than extra-role behaviors (e.g., voluntarily offering help in collectivist cultures). Some evidence suggests that there are emic dimensions of OCB in collectivist cultures such as protecting company resources. Because of such variations, it is tentatively concluded that the dimensionality (e.g., the factor structure) of the Western OCB construct and its measures do not transcend culture. Similarly, there are variations in the predictors and outcomes of OCB. OCB is found to be predicted by the organizational justice perception in Western literature, whereas collectivist values are seen as better predictors of OCB in Eastern traditional cultures. OCB was correlated more strongly with turnover intention and productivity in individualist cultural contexts rather than in collectivist ones.

6.3. Organizational Justice

Organizational justice is concerned with the perception of fair treatment of employees in organizations. Justice perception has important implications for organizations

because it relates to OC, productivity, trust, and compliance with decisions. For more than a century, philosophers have been debating the concept of fairness with little agreement. Disputes over this issue are magnified when cross-cultural differences in values and norms regarding justice are involved in research. Despite such challenges, organizational justice has proven to be a fruitful area that has attracted a great deal of cross-cultural I–O research attention.

The literature draws a distinction between two types of organizational justice. The first is referred to as “distributive justice” and is concerned with the fairness of norms or criteria used in distributing resources. The second is “procedural justice” and refers to the fairness of the means (e.g., procedures, practices) used to achieve the organizational results.

Earlier cross-cultural research on distributive justice was limited to examination of the criteria used in performance appraisal. With respect to procedural justice, the focus was on the fairness perception of various leadership styles (e.g., participative leadership). The overarching assumption was that criteria influencing justice perception had similar meanings across cultures, but the cross-cultural differences consisted of different weights being given in different cultures. Social and organizational psychology literature during the 1980s offered an “interactionist” perspective purporting that the social context cued the application of fairness criteria. Such sophisticated models advanced the literature in such a way that some authors claimed that cross-cultural research had a significant influence on the mainstream (mainly North American) theories in the area of justice.

In the area of distributive justice, cross-cultural research has investigated the differential norms that are used in distributing resources. Resources are distributed on the basis of three norms: equity, equality, and need. The equity principle uses the input–output ratio as a method of allocating resources to employees, the equality principle advocates similarity in resource allocation regardless of the differences in inputs, and the need principle promotes the distribution of resources on the basis of need. Earlier cross-cultural research found that employees in individualist cultures perceive justice as being done when the equity norm is used, whereas those in collectivist cultures favor use of the equality and need norms. However, later studies showed that collectivist cultures prefer different norms depending on the context.

In 1997, Leung proposed a model describing situational variables interacting with individualism–collectivism in cueing differences in distribution criteria. According to the model, goal-directed behavior

is the most immediate predictor of selection of the distributive criterion. For instance, the equity principle is perceived to be more appropriate in collectivist cultures when applied to out-group members if the salient goal is to increase productivity, whereas the need principle is favored when the immediate goal is to protect the well-being of others under the condition of resource scarcity. In applying the equity principle, what constitutes inputs and outcomes is culturally determined, but there is surprisingly little research on this topic. Limited available research suggests that in collectivist cultures, loyalty, family size, and networks (e.g., *guanxi*) are considered to be appropriate inputs. The criteria to be used also depend on power distance. In hierarchical societies, in-group favoritism is perceived to be fair in distributing resources. Moreover, in interpersonal comparisons, it is accepted that the more powerful ones are entitled to receive more benefits than are those at the bottom of the hierarchy. Researchers urge caution regarding changes in the perception of power, and hence the perception of justice, over time.

Cross-cultural research in procedural and interactional justice is very limited, but available evidence suggests that the perception of fairness in procedures and interpersonal treatment depends largely on cultural norms. For example, in individualist cultures, having a feeling of control over decisions increases the perception of justice, and this finding is also replicated in some collectivist cultures. Similarly, voice (i.e., the opportunity to express one’s opinions) is perceived to be fair in individualist cultures, and this perception is mediated by one’s relationship with the people in authority. In collectivist cultures, procedures that follow tradition are accepted as fair, suggesting that norms have a stronger impact on the perception of justice in collectivist cultures than in individualist ones.

There are three factors that increase the perception of procedural fairness. The first is the benevolent intent of the authority. Cross-cultural variations exist in the perception of the intent underlying the behavior of superiors. Some research suggests that workers in high-power distance cultures are more likely to tolerate harsh treatment by their superiors, partly because this behavior is perceived to be for the good of the workers and the organization. Therefore, such actions are perceived to be less unfair and less likely to harm loyalty. The second factor is neutrality, that is, the belief that behavior is unbiased. In conflict resolution among workers, supervisors’ active involvement and interference are expected and appreciated in high-power distance and paternalistic cultures, whereas it is perceived to be breaching

supervisors' neutrality in low-power distance and individualist cultures. Finally, the third factor is status recognition, that is, the extent to which decision makers show respect toward employees. People feel valued when they are shown respect, but what constitutes respecting behavior is culturally determined. There is a dearth of cross-cultural research in this exciting area.

The section on industrial/organizational (I/O) psychology presents a broad overview of the multiple topics studied under its rubric. Some of the topics are quite broad, such as motivation taxonomies, while some are rather specific, such as system safety. The goals of the section are to provide the reader with an introduction to the many areas of concern to I/O psychologists with respect to the areas in which they conduct research and practice. The purpose of this overview article is to (1) define and describe industrial and organizational psychology as a field, (2) provide a brief history of the field, (3) summarize the contents of the section, (4) provide brief summaries of topics not covered in this section, and (5) present one view of the trends in research and practice.

1. DEFINITION

Broadly speaking, psychology is the study of behavior. With this general definition as the basis, industrial/

organizational (I/O) psychology can be defined as the study of behavior that takes place within the context of an organization (e.g., a work setting). Adopting such a broad definition provides the opportunity for I/O psychologists to address research and practice questions that most other psychologists study most often in isolation of a context. For example, cognitive psychologists study information processing. An I/O psychologist may also study information processing, but in the context of decision making. Or, a personality psychologist may study the basic dimensions of personality. An I/O psychologist may study personality psychology to determine the traits and characteristics of individuals that will lead to effectiveness as leaders or success in organizations. Yet another example can be drawn from social psychologists, who study small group behavior and attitudes. I/O psychologists could study similar topics, such as team behavior and job satisfaction, respectively. One additional example can be taken from biological psychology, which can focus on stress and circadian rhythms. Here, I/O psychologists might be interested in stress due to conflict between work and family, and in the attitudinal and behavioral outcomes that result from shift work in organizations. These examples demonstrate the broad range of topics that I/O psychologists are concerned with and the issues that they address. They also illustrate the approach taken by I/O psychologists, which is to conduct research that derives principles

of individual, group, and organizational behavior and to apply that research base to the solution of problems in organizational settings.

One cautionary note about the preceding illustrations: they are not intended to suggest that I/O psychologists predominantly or exclusively address practical, field, or applied issues. Though many I/O psychologists conduct their research in viable organizations, and may do so to address particular problems inherent to those environments, their research is both basic and applied. That is, much of the research that is conducted by I/O psychologists contributes to the understanding of behavior as well as serves to remedy or prevent problems in organizations.

For a more complete overview of the profession of I/O psychology, see the Web site of the professional association for I/O psychologists, the Society for Industrial and Organizational Psychology (www.siop.org). This site provides complete information about the profession, which has over 6,000 members from 50 U.S. states and approximately 40 countries. I/O psychologists conduct research and consult with organizations on the following topics:

Employees:

- Testing
- Selection and placement
- Training and development
- Employee attitudes
- Employee motivation
- Leadership

Organizations:

- Change management
- Organizational climate
- Organizational culture
- Job design
- Job evaluation
- Organizational structure
- Team building
- Decision making
- Workplace planning

Before proceeding with the history of I/O psychology, another term, organization, must be defined. An organization exists when two or more people get together for the purpose of accomplishing a common goal. This is a very broad and general definition of an organization, adopted to highlight the flexibility available to I/O psychologists for their context of study. The organization can be one that is global, national, or local; it can be an organization that is intended to last

for a long period of time, or it can be one that is assembled for a short-term mission, such as a political campaign. The members of the organization may be paid for their services or may be volunteers; thus, the organization can be either for profit or non-profit. The members of the organization may be selected or elected to be part of the organization. The organization can be in business for the purposes of being in private industry, the public sector (government agency), or an educational institution.

One final topic for this section of the overview pertains to who is an I/O psychologist. Generally, I/O psychologists receive their training from doctoral level psychology departments that have special programs in I/O psychology. Thus, these individuals generally have a broad background in the research and methodology of psychology as well as in data analysis. Another route for education is to obtain a doctorate in organizational behavior (OB) from schools of business administration. Such programs often interact closely with psychology departments to provide the basic background in psychology needed to conduct research and practice in the domain of behavior. In addition, these programs provide a greater emphasis on business-related topics such as strategic planning, finance, and marketing. Often, however, the perspectives of the I/O psychologist and OB student may vary. For example, the former may be interested in individual differences and micro-level issues regarding how the individual behaves within the context, whereas the latter may prefer to focus on more macro-level issues such as the organization's impact on the individual. Note that this distinction is fuzzy and not rigid—the ideal prototype I/O psychologist is one who understands both micro- and macro-level issues.

2. HISTORY

This section identifies the primary individuals and events that have defined and distinguished the field of I/O psychology. This history is presented in a chronological order to show how the field has developed over the last 100 years and how the field has been influenced by historical and social events.

The formal history of the field begins in the early 1900s. One of the earliest psychologists recognized for his application of psychological principles to problems of the work setting is Hugo Munsterberg. Munsterberg studied in the laboratory of Wilhelm Wundt, an experimental psychologist who studied perception in Germany. When Munsterberg arrived in the United

States, he established a psychological laboratory at Harvard University, where he studied issues concerned with industrial accidents and the relationship between abilities and performance and industrial efficiency. He wrote one of the earliest books on I/O psychology in 1913, *Psychology and Industrial Efficiency*. Perhaps one of his earliest contributions was his applied work, his studies on the characteristics of successful motormen for the Boston streetcar system.

Another early pioneer, who also studied with Wundt, was James McKeen Cattell. Cattell studied individual differences in people; the critical notion for him was that differences between people should not be considered as “errors,” which was the way experimental psychologists viewed them, but rather as reliable characteristics that differentiated people and that explained why people differed from each other. Cattell was one of the first to use the term “mental test,” and, in many ways, is the founder of the field of selection and personnel.

Two other psychologists who were active in the early 1900s are Walter Dill Scott and Walter Van Dyke Bingham. Scott was active in two areas: he explored the field of advertising as well as the issue of selecting sales personnel. Regarding the latter, he was one of the earliest to demonstrate that the typical interview lacked reliability and validity. He was also interested in training and learning curves, performance rating systems, trade tests, occupational families, and job specifications. Another distinction for Scott is that he was a professor of applied psychology at Carnegie Institute of Technology in the mid-1910s.

Another landmark in the 1910s was the work of Frank and Lillian Gilbreth. They applied the “scientific management” principles of Frederick W. Taylor (1911) to educational institutions. Scientific management basically promoted the simplification of work processes. Work methods were designed to be efficient, and workers were selected who could be trained to perform the tasks. The Gilbreths applied time and motion studies to the ways in which workers performed tasks, both to understand how those tasks were performed and to design a more efficient way in which to perform those tasks in order to reduce fatigue and to increase productivity. These events were the forerunners for work on job analysis as well as human factors engineering—both topics of relevance today for I/O psychologists.

A significant historical event impacted the role of psychologists in the early 1900s—the entry of the United States into World War I in 1917. Scott, along with Bingham, adapted an intelligence test that was

designed for individual testing to a format that could be used with groups of test takers; such a test was needed for use with large numbers of candidates to determine who was fit to serve in the armed forces. The result was the Army Alpha test, which was used to select recruits into the armed forces. This was an instance of applying principles of individual differences to selection problems; it was also the forerunner of major efforts to develop selection tests and systems for organizations, a trend that continues today.

The 1930s introduced another trend in I/O psychology: the study of human relations and attitudes. Elton Mayo was interested in studying the relationship between work—particularly boring work—and attitudes and performance. Mayo, Roethlisberger, and Dickson are the main researchers identified with a classic set of studies—the Hawthorne studies—that took place in the Hawthorne plant of the Western Electric Corporation. The study began in 1926 and lasted for more than 10 years. The initial goal of the study was to explore the relationship between productivity and plant conditions, such as lighting, heating, work hours, rest breaks, and other manipulations that were under the control of the organization. The results were contrary to what was expected: even when the conditions were made worse, productivity increased. This finding led the researchers to interview the workers, who indicated that they were “pleased” that the organization was paying attention to them, as represented by the efforts to study the problems; as a result, they increased their performance. This finding—that performance can be increased when workers are attended to—is now known as the Hawthorne Effect. This research led to a trend toward greater concern for the individual workers and an emphasis on social relations, known as the human relations movement. Topics that resulted from this movement include motivation, job satisfaction, and morale.

World War II (early 1940s) was also instrumental in inspiring psychologists to begin new explorations for the purpose of helping the war effort. Of particular significance is the role psychologists played in the design of cockpits for the new fighter planes that were being used in the war. The different types of planes and their cockpit controls required pilots who could function in environments with all sorts of new airplane controls, gauges, and displays. Consequently, the psychologists helped in the design of the cockpit, to facilitate quicker recognition of the dials and controls and with less error in their use. This is another example of human factors engineering as well as work design.

In addition to human factors engineering, World War II was the catalyst for research on selection and assessment. New selection tests were developed to help match recruits to jobs that fit their abilities. In addition, attempts to identify personnel who could serve as spies for the United States resulted in the development of the “assessment center” procedure. The assessment center is a mixture of multiple types of assessment, e.g., individual tests, personality assessment, interviews, role-plays, and group exercises, many of which are simulations of actual job behavior. The set of exercises is designed to provide a picture of the individual and how he or she is likely to behave in a work setting. Today, assessment centers are a major industry used to select people for all levels within an organization.

After WWII, I/O psychology became more recognized, and as a result, degree programs were established at major universities and colleges in the United States. Many of the early pioneers in the field brought their training in experimental or social psychology to the programs, producing new Ph.D.s with interests in applied psychological problems. Some of the issues studied were leadership, participative decision making, and job satisfaction.

The role of the I/O psychologist was again challenged in the 1960s, with the passage of the 1964 Civil Rights Act. This act made it illegal to discriminate in selection, hiring, and promotion of employees based on race, ethnicity, national origin, and gender. As a result of this act, the hiring and promotion practices of many organizations were challenged, which led to the organizations’ attempts to demonstrate the validity and usefulness of their selection procedures. For I/O psychologists, this meant increased efforts and research in understanding issues of selection and validation as well as better understanding of how tests can be used in the workplace environment. This law spurred research on validation models, the development of job analysis procedures, concerns about the measurement of performance, and the concept of validity generalization.

In the latter part of the 20th century (1970s to 2000), even though there was still a major focus on personnel psychology, a considerable amount of research and practice focused on the individual within the organization. Topics such as goal setting, satisfaction, organizational commitment, motivation, organizational climate, person–organization fit, organizational citizenship behavior, and justice received increasing research attention. From an economic perspective, some issues of interest were mergers, acquisitions, and downsizing.

The late 1990s and the early part of the 21st century have continued to see the interest in the social aspects of behavior. But this also has been influenced by the changing nature of work and the reliance on technology for that work. This trend will be revisited at the end of this overview. For now, and as a summary, the presentation of this brief history was intended to show that practical problems, within a context, often influenced by politics, economics, conflicts (war), and legislation, have been instrumental in defining what I/O psychologists studied.

3. CONTENTS OF THE SECTION

One way of structuring how I/O psychologists study their topics is to view the study of organizations in three levels or phases along with their associated issues: (1) the need to develop the organization, (2) the need to obtain members for the organization, and (3) the need to maintain (and retain) the organization as a viable entity with members who contribute to its mission. Developing the organization refers to the issues that must be considered when starting an organization. These topics include organizational philosophy, organizational theory, organizational structure, leadership, communications, decision-making strategies, and other issues that relate to how the organization and its jobs will be designed, established, and conducted.

3.1. Development Phase

This section of the encyclopedia contains articles relevant to the development phase on the topics of organizational structure (authored by Tetric and Camburn), power, authority, and leadership (Munduate Jaca and Medina), organizational culture and climate (Peterson and Fischer), decision making (Jungermann), and organization development (Burke). These are more global topics that focus on organizational characteristics. But there are also very specific concerns, such as how the jobs will be designed and analyzed. A particular article within this section that is relevant to this concern focuses on job analysis, design, and evaluation (Smither). In addition to interest in the tasks needed to be performed and the knowledge, skills, and abilities (KSAs) needed to perform those tasks, organizations are also concerned with the safety of work, which is discussed in articles on system safety (Wilpert) and work safety (Zohar).

The topics described above are critical for the establishment of an organization, since they impact the type

of recruits attracted to the organization and the types of systems that will be developed to maintain the organization. Note, however, that as stated earlier, these are not isolated topics that are restricted to the development phase of setting up the organization. Here, as in the other two phases, the individual topics are appropriate for discussion and consideration for all phases. For example, although it is critical to identify the organizational structure at the outset, concerns about performance and satisfaction could lead to the need for organizational development activities that would take place several years after the establishment of the organization. After studying an organization that has been in operation for several years, it may be necessary to make changes in the structure to accommodate changes in the nature of the workforce, the demands of the public regarding the product produced by the organization, and new laws that govern how products should be produced and what materials they contain. The critical points to appreciate are that all of the topics are interrelated and all are important at any and all phases in the life of an organization.

3.2. Selection Phase

Once an organization is designed and there are plans for its operations, the next issue is the second phase: obtaining members to participate in that organization. When considering how to select employees at all levels within the organization, the I/O psychologist is concerned with the bridge between design of jobs and how recruits are selected to perform those jobs; that bridge is based on the previously mentioned article on job design and analysis. In addition, there is the related issue of how employees will be compensated for the work they perform in their roles, which is discussed in an article on compensation (Thierry).

Once jobs are designed, it is necessary to understand how employees will be evaluated in their positions or jobs—the topic of performance appraisal. Here, I/O psychologists need to understand what contributes to success and effectiveness in the job and organization, and how to measure employees on the relevant criteria. Two articles deal with the measurement of individual and organizational performance on the tasks: one on competence at work (DeNisi) and one on productivity (Pritchard). High individual performance and high organizational productivity are the criteria that the organization selects employees to achieve. Another criterion used to measure the organization's success is turnover; this is discussed in the article on labor

turnover (Hom). The selection system is designed to identify those who can meet these goals.

This section also contains three critical articles that set the stage for the other topics within the selection phase—occupational choice (Hansen), recruitment (Breugh), and personnel psychology (Chan). The occupational choice article considers how people choose the careers they want to pursue, focusing on the individual and what he or she wants to do as a career. The personnel psychology article focuses on the organization's choice of individuals, which is obviously related to what individuals decide to do in terms of careers. How the organization goes about identifying candidates for its positions is discussed in the article on recruitment. In other words, there is a reciprocal relationship between one's choice of a career and the organization's recruitment and choice of people.

Once the organization is ready to implement a selection system, it needs to consider the issues discussed in the articles on employment discrimination (Tenopyr) and employment interviewing (McDaniel and Whetzel). The former deals with laws that exist, particularly in the United States, that influence what selection devices can be used and under what conditions, as well as the litigation surrounding the use and validation of the tests. Related to the topic of discrimination and selection is the issue of affirmative action, which is discussed in an article by Kravitz. The topic of validation is covered in the previously mentioned article on personnel psychology (Chan) as well as in the article entitled "Personnel Selection" by Ones, which appears in another section of the encyclopedia.

A link between obtaining members for and maintaining the organization is the topic of training and development. Organizations can select employees who have the aptitude to be trained, or employees who are already trained and capable of producing and performing rather quickly after entry into the job. Training is a critical issue of concern for I/O psychologists. A special topic related to training is that of executive coaching and executive development, discussed in an article by Silzer, which is concerned with working with employees to enhance and develop their skills for management positions. This not only is an issue when deciding who to select and whether training is needed, but also can serve as a motivational tool for employees.

3.3. Maintenance Phase

Once the organization has determined how it will obtain its employees and implements the systems needed

to obtain those members, it turns its attention to the maintenance phase: how to retain the members in the organization and to further maintain and develop the organization to sustain itself in the marketplace. This phase is concerned with issues such as reward systems, motivation, job satisfaction, organizational climate and culture, work and family, conflict, and stress.

Articles relevant to the maintain phase are those on the topics of motivational taxonomies (Vancouver), motives and goals (Kleinbeck), and boredom (Balzer, Smith, and Burnfield). These articles address issues such as how to motivate employees to perform better and how to make the work more motivating and satisfying for the employees. Articles that deal with group and team issues include those on organizational participation (Heller), organizational socialization (Bauer), and cooperation at work (Salas). These issues relate, in part, to whether there is a person–environment fit, discussed in an article by Ostroff and Aumann that deals with selection, motivation, organizational characteristics, recruitment, and other factors that determine whether the organization’s choice and the individual’s choice are consistent. There may be problems, or conflict, discussed in an article by Castro and Ryan.

While attempting to maintain and further enhance the organization’s position in the marketplace, the organization can undertake programs designed to assess how well it is functioning. This issue is discussed in the article on organizational diagnosis (Bussing). Another article in this section pertains to downsizing and outplacement (Cascio), a topic important and timely in today’s economic environment. Organizations are merging and downsizing in order to achieve greater economies of workforce and productivity.

Note that the above trichotimization into development, selection, and maintenance phases is not exhaustive or mutually exclusive; rather, the topics are integrated. That is, it would be difficult to consider issues of selection without considering issues of training and motivation. This means that if an organization determines that it needs to place employees into position “X,” it could do so by selecting those who already have the “X” abilities and skills; it also means their compensation would be affected by the fact that the hired are skilled. In contrast, the organization could decide to hire those individuals who demonstrate the aptitude or ability to learn and gain the abilities and skills needed to perform the tasks. This would mean that there would be greater emphasis on training those hired, which in turn might mean that their compensation could initially be lower because they

are relatively less skilled. For both types of hires, however, motivation is critical. How do organizations motivate workers to be fully productive? Does the fact that the organization provides the training to relatively less skilled employees mean that those employees will be more committed to the organization, and consequently the organization will have a lower turnover rate? These issues and questions need to be considered jointly. Although the articles in this section treat the topics separately, the challenge for the reader is to recognize the necessary integration.

4. OTHER TOPICS

An encyclopedia often provides information on all topical phrases that are used within the discipline. Those who are somewhat familiar with I/O psychology might wonder why there are no specific articles in this section on topics such as job satisfaction, incentives, test fairness, and work performance. The reason for the omission of articles on such specific topics is because their essence is conveyed in other articles appearing in this or other sections of the encyclopedia. For the topics just mentioned, for example, the reader is referred to the articles on boredom, motivational taxonomies, personnel psychology, and competence at work, respectively. The point is that this section on I/O psychology is reasonably complete and provides an overview of the major topics and issues in the field.

5. FUTURE TRENDS

An obvious point of interest for readers of this section is what the future holds for the field of I/O psychology. Our crystal ball suggests that the major topics covered in this section will remain the same, but that the nature of work—how it is performed, what it is composed of, and where it is performed—will change. That is, I/O psychologists will always be interested in how organizations should be developed, how to obtain people for those organizations, and how to maintain and promote the survival and growth of the organization. But what people do in the form of work, and how and where they perform that work is likely to change.

To elaborate, let us return to the history of the field. Reviewing the “older” textbooks, such as one by Viteles, shows that their tables of contents cover many of the topics included in this section of the encyclopedia. Among the 27 chapters of the Viteles text are chapters

on individual differences, the social foundations of industrial psychology, vocational selection, job analysis, the interview, tests for different skills and industries, safety, training methods, industrial fatigue, motives, monotony, and supervision. The topics have remained the system—the way that I/O psychologists have approached the research problems and analyzed the data have become more sophisticated and elegant.

So, what has changed and what will continue to change? The answer is that (1) work, (2) the worker, and (3) the context will change. First, the nature of work will change. It is obvious that more and more work will be driven by computer technology and that employees will be producing less manually. More and more employee work will focus on providing information and services. Thus, I/O psychologists need to be concerned with systems that can describe the tasks to be performed (job analysis and job design), identify the KSAs needed to perform those tasks (personnel psychology), and figure out how to measure effectiveness on those tasks (competence at work). Work will become more fluid; jobs will not be well-defined. Much of this work is likely to be done in groups and teams, which means emphasis on how to select and motivate team members. Also, it is likely that much of the work will be done in virtual teams. An obvious implication of all of this change is that the relationship between the worker and the client will change. There will be less direct contact and more reliance on the worker fulfilling the client's expectations without being on site to push for services.

Second, workers may interact differently with their peers and supervisors. More and more meetings may take place via teleconferencing instead of face-to-face. Accordingly, I/O psychologists will need to pay more attention to cross-cultural psychology, to topics of personality and interpersonal relations, and to work and non-work balance.

The third issue that will impact I/O psychology, context, is concerned with the globalization of doing business and multiculturalism of the workforce. I/O psychologists will need to address the performance of work in the context of the globalization of the economy with a workforce that is more culturally diverse than it was in the past. This means that workers will need to be more adaptable to where they work and with whom they work. Not only will workers be asked to interact with others from different cultures and backgrounds, but they also may be asked to work in locations foreign to them (e.g., other countries).

The challenge for the I/O psychologist will be to develop systems (selection, training, compensation,

motivation, etc.) that recognize the changes in the work that is being performed, how it is being performed, who is performing it, and in what context. Workers will need to be more flexible and agile, and work at faster paces and speeds. Workers may need to be more self-driven and work in contexts in which they are empowered and in which there will be self-learning. Workers will need to adjust to uncertainty and the temporary nature of their work. They will need to adapt to flexible work patterns. And, they may need to assume that they will have multiple careers over their life.

6. CONCLUSION

This section focuses on the study of behavior for those who operate within an organizational context. It presents the issues and interests of I/O psychologists as they attempt to study how work is performed, who performs it, and where it should be performed. The topics contained within this section are integrated and should be studied in relation to each other—focusing on one article without considering others will lead to inappropriate assessments, conclusions, and solutions. Hopefully, the section conveys the message that the study of work and workers is complex and that many variables need to be considered when attempting to provide solutions to work problems. The literature shows that less than 50% of the variability in individual and group performance can be explained by the variables I/O psychologists study as they attempt to explain and predict that behavior. The goal for the future is to explain more of this variability.

GLOSSARY

athletic identity The degree to which one identifies with the athlete role.

proprioceptive Sensory or perceptual awareness of body movement and position, particularly with respect to the limbs.

psychosocial risk factors Physical and psychological conditions existing prior to injury that predict the occurrence of injury.

rehabilitation adherence The extent to which one follows a prescribed rehabilitation protocol.

sport injury Physical injury sustained during participation in recreational or competitive sport activity.

tough-mindedness A personality orientation characterized by assertiveness, self-assurance, independence, and a tendency to place stress on oneself.

Psychological factors are important elements in most aspects of the injury process in athletes. Psychological factors have been identified in both the occurrence and aftermath of sport injury, and psychological interventions have been used to reduce injury risk

and to facilitate physical and psychological recovery from sport injury.

1. INTRODUCTION

Physical injury is a common by-product of sport participation. Literally millions of athletes around the world sustain one or more injuries each year, incurring billions of dollars of medical costs in the process. Although most of the injuries are minor and require minimal medical treatment, many of the injuries require extensive and costly diagnostic testing, surgery, and rehabilitation. In the short term, sport injuries can impair performance both on and off the athletic field. Athletes can be prevented from training or competing as a result of injury, and their daily activities can be disrupted by injury-related pain or disability. In the long term, certain sport injuries may place athletes at increased risk for developing arthritis and other chronic medical conditions. Some of the more severe injuries may bring about the end of athletes' sport careers and result in permanent disabilities.

Historically, injury has been considered primarily as a physical phenomenon within the sport community, with an emphasis on identifying the physical factors that cause injuries to occur and on helping athletes to recover from injuries. Unfortunately, even with all of the medical and technical advances that have been made over the past several decades in equipment, playing surfaces, and other safety features, the number of sport-related

injuries has continued to increase. This unexplained rise in injury rates has been accompanied by a growing recognition of the possible role of psychological factors in the sport injury process. Psychological factors are now thought to contribute to not only the occurrence but also the rehabilitation of sport injuries. Indeed, psychological interventions have been implemented to assist in the prevention and treatment of sport injury.

2. PSYCHOSOCIAL RISK FACTORS FOR SPORT INJURY

Athletes and coaches are well aware of physical factors that can precipitate injury, including overuse, muscular tension, and trauma. Psychosocial factors can also place athletes at increased risk for injury. Over the past three decades or so, elevated life stress has emerged as a highly consistent predictor of sport injury. In American football and a variety of other sports, athletes who have recent histories of stressful life events are more vulnerable to injury than are those without such stressful experiences. Life events perceived as negative (e.g., loss of a loved one, getting fired from a job) typically have the most adverse impact on the occurrence of sport injury, although even events perceived as positive (e.g., academic achievements, new romantic relationship) can be stressful and can result in increased injury risk.

In addition to life stress, personality and coping resources are psychosocial factors that can affect susceptibility to sport injury. Injury risk appears to be elevated for athletes low in social support or high in trait anxiety, Type A behavior, negative mood, and/or tough-mindedness. Athletes who are not satisfied with the amount of technical assistance, informational guidance, and emotional comfort they receive from people important to them are at increased risk for injury. Similarly, athletes who are generally anxious, hard driving, hurried, hostile, assertive, self-assured, depressed, and/or angry are more vulnerable to injury than are those without such characteristics. Personality and coping resources can also influence the impact of life stress on the occurrence of sport injury. For example, the adverse effect of stressful life events on sport injury is especially pronounced for athletes who tend to be anxious in competitive sport situations, lack social support, and/or have difficulty coping with stress.

It is not known exactly how life stress, personality, and coping resources affect vulnerability to sport injury, although there is reason to believe that both

cognitive and physiological factors are directly involved in injury occurrence. Life events, both positive and negative, often elicit stress reactions that can cause athletes' muscles to be tense, peripheral vision to narrow, and attentional focus to diminish, all of which may place athletes at increased risk for injury during sport participation.

3. PSYCHOLOGICAL EFFECTS OF SPORT INJURY

In addition to the obvious detrimental effects of sport injury on physical functioning, sport injury can have a deleterious effect on various aspects of psychological functioning. In particular, injury can have an adverse impact on the thoughts, feelings, and actions of athletes. With respect to thinking, sport injury is associated with reduced self-esteem and physical self-confidence as well as with elevated confusion. From an emotional standpoint, it is not uncommon for athletes to experience negative feelings such as anger, confusion, depression, fear, and frustration following injuries. Although clinically meaningful levels of emotional distress have been found in approximately 5 to 24% of athletes with injuries, most negative emotions tend to dissipate over the first month following the injuries. Once athletes adjust to the initial changes caused by their injuries, they are typically able to focus primary attention on their rehabilitation programs. For example, injury appears to spur athletes' use of active coping strategies such as vigorously pursuing rehabilitation goals and seeking support or information from others. As athletes become more invested in their rehabilitation regimens, their moods return to typical preinjury levels.

Athletes' psychological responses to injuries are influenced by characteristics of the athletes themselves and the situations in which they sustain their injuries, including characteristics of the injuries themselves. Athlete characteristics associated with emotional reactions to injury include age, athletic identity, and hardiness, with athletes who are younger, more strongly identified with the athlete role, and less hardy reporting greater emotional disturbance following injuries. The extent to which athletes adhere to their injury rehabilitation programs—a behavioral response to injury—is related to athlete characteristics such as internal health locus of control, pain tolerance, self-motivation, and tough-mindedness. Athletes who consider themselves

responsible for maintenance of their health, tolerate pain well, and are self-motivated and tough-minded tend to demonstrate high levels of adherence. Injury is also a prominent factor leading to dropout in youth sport participation.

With respect to characteristics of the situations in which injuries occur, athletes report greater postinjury emotional disturbance when they perceive their injuries as severe, their life stress as high, their rehabilitation progress as poor, and their social support as low. Athletes tend to stick with their prescribed rehabilitation programs better when they perceive their injuries as severe, their level of social support as high, the treatment as effective, the clinical environment as comfortable, and the rehabilitation appointments as conveniently scheduled. Emotional and behavioral responses to injury are also related to each other; that is, athletes with high levels of mood disturbance tend to adhere well to their rehabilitation programs, whereas athletes with low levels of mood disturbance tend to adhere poorly to their rehabilitation programs.

Athletes who incur sport career-ending injuries are vulnerable to considerable psychological distress, particularly if they are competing at a high level and view themselves primarily or exclusively as athletes. Intercollegiate athletes who sustain career-ending injuries tend to be less satisfied with life 5 years after the conclusion of their playing careers, particularly if they believe that they have not achieved their sport goals.

Individuals incurring catastrophic sport injuries that result in permanent functional disabilities, typically from damage to the head or spinal cord, must make profound physical, emotional, social, and lifestyle adjustments. Although catastrophic injuries are rare occurrences, they happen with enough frequency that the National Center for Catastrophic Sports Injury Research was established in 1982 to track prevalence rates and make recommendations for safety and prevention that have been implemented in most contact sports as well as in gymnastics and cheerleading.

In addition to injury severity, other aspects of the injury itself—onset, course, history, and type—can affect psychological responses to sport injury. The onset of a sport injury can be either acute or gradual. Sudden and unexpected injuries are classified as acute and often place different demands on athletes' personal coping resources and elicit a different response from their social support systems compared with nagging or overuse injuries that eventually cause athletes to stop

competing due to the gradual accumulation of physical damage or discomfort.

Sport injuries can also be classified by the course to recovery. Progressive-type injuries show a continual stepwise process toward either full recovery or permanent disabilities. The speed of the progression may vary, but the course is predictable with few surprises or unknowns. Constant-type injuries require athletes to adjust to physical impairments that remain stable or invariant over time. In episodic-type injuries, athletes must learn to cope with injuries that recur or flare up periodically and unexpectedly. Injury course is important because individuals' perceptions of control and predictability in various situations have been linked to the amount of anxiety that they manifest in those situations.

History and type of injury can also affect athletes' psychological responses to injury. Athletes who have previous histories with the same injury tend to be more knowledgeable of what to expect and may have less anxiety than do athletes who experience the injury for the first time. Athletes with injuries of a type that requires a cast or involves some form of visible impairment may experience different reactions from their social support networks compared with athletes with nonvisible injuries who are forced to answer repeated questions about why they are not competing.

The ways in which athletes respond psychologically to injury may have important implications not only for the athletes' quality of life following injury but also for their physical recovery. As shown in [Table I](#), a variety of psychological factors are related to sport injury rehabilitation outcomes. In general, athletes who recover faster or more effectively tend to be those who demonstrate a favorable mental health profile, receive adequate social support, and adopt an approach to their rehabilitation in which they maintain a positive attitude, apply psychological coping strategies, take responsibility for achieving desired rehabilitation outcomes, and adhere to their rehabilitation programs.

Athletes' readiness to resume training postinjury requires both physical and psychological assessment. Warning signs that could help to identify athletes who are not ready psychologically to return to competition include dwelling on minor somatic complaints just prior to the recovery target date, withdrawing suddenly from teammates and/or coaches, exhibiting striking changes in affect or behavior, and engaging in exaggerated storytelling or bragging about accomplishments in and out of sports.

TABLE I
Examples of Psychological Factors Associated with Sport Injury Rehabilitation Outcomes

<i>Variable type</i>	<i>Variable</i>
Athlete factors	Age Athletic identity Gender Optimism Personality
Situational factors	Social support
Cognitive factors	Attitude toward rehabilitation Attributions for recovery Goal-setting use Imagery use Injury appraisals Pain coping
Emotional factors	Mood disturbance Psychological distress Rehabilitation anxiety
Behavioral factors	Adherence to rehabilitation Physical activity Social support seeking

4. SPORT INJURY PREVENTION

Just as psychological factors can contribute to sport injury, psychological treatments can help to prevent sport injury. Initial evidence of the potential preventive impact of psychological interventions on the occurrence of sport injury was obtained almost by accident as an unintended side effect of interventions designed to enhance sport performance. Training athletes in attentional control, biofeedback, imagery, and relaxation can reduce conditions (e.g., distraction, muscular tension, perceived stress) that not only hamper sport performance but also increase vulnerability to injury. Teaching athletes psychological strategies for managing stress (due to both positive and negative life events) can lower their risk of sustaining sport injuries. In situations where athletes have experienced successful competitive performance, such interventions can help athletes to reduce their injury risk by maintaining their focus and avoiding complacency.

Developing athlete social support groups that provide forums for individuals to share their life events, both positive and negative, may buffer the amount of

stress induced by these experiences and thus moderate injury susceptibility. Peer mentoring systems within teams or athletic departments can also strengthen the overall social support system and offset the potentially adverse consequences of stress.

5. PSYCHOLOGICAL INTERVENTIONS IN SPORT INJURY REHABILITATION

As shown in Table II, a variety of psychological interventions have been successfully implemented to alter the psychological responses, rehabilitation processes, and rehabilitation outcomes of athletes with injuries, particularly knee injuries. As with interventions targeted at preventing sport injuries, the reasons why the interventions work are not fully understood. However, most of the interventions are thought to increase motivation for rehabilitation, and this may in part account for the therapeutic effects of the interventions. It has also been proposed that biofeedback enhances athletes' awareness of their body movements and positioning and that relaxation and imagery influence physiological processes central to healing such as immune/inflammatory responses and the regeneration and repair of body tissues.

TABLE II
Psychological Interventions in Sport Injury Rehabilitation

<i>Intervention</i>	<i>Therapeutic outcome</i>
Biofeedback	Knee/Leg strength Electromyogram (EMG) output Range of motion
Goal setting	Rehabilitation adherence Rehabilitation self-efficacy Knee strength
Relaxation/Imagery	Pain Reinjury anxiety Knee strength
Positive self-talk	Leg strength
Multimodal treatment package	Physical recovery Pain Anxiety Positive mood Positive attitude

GLOSSARY

absolutism The viewpoint that holds that cognitive processes are the same across the globe and that emphasizes the context-independent nature of cognitive processes and basic intellectual processes.

bricoleur A metaphor often underlying studies in the informal tradition; a bricoleur (i.e., “jack-of-all-trades”) is not interested in a solution that is correct as defined by an external standard (which is typically the case in the formal tradition) but rather is interested in a solution that solves a practical problem (e.g., a leaking roof) using available means.

culture-fair test A test that has been designed in such a way that culture does not differentially influence performance on the test (i.e., item formats are so easy that everyone is supposed to not experience any problem with the test); the concept has been abandoned as unattainable.

culture-free test A test that has been designed in such a way that culture does not influence performance on the test; the concept has been abandoned as unattainable.

everyday intelligence The study of the relationship between culture and intelligence by the observation of intellectual processes in everyday behavior (e.g., arithmetic behavior of shoppers who compare bargains).

formal tradition The study of the relationship between intelligence and culture by the administration of psychometrically adequate tests in different cultures; the scientific approach is seen as the normative model of good problem solving, with an emphasis on the solution of formalized problems that are unlikely to be met in everyday life and on the correctness of solutions.

informal tradition The study of the relationship between intelligence and culture by studying how people solve everyday intellectual problems; the “bricoleur” (i.e., jack-of-all-trades) is seen as the implicit model of problem solving.

nature–nurture debate The scientific controversy about the question as to what extent cross-cultural differences in scores on intelligence tests are due to genetic factors (nature) or environmental factors (nurture).

relativism The viewpoint that holds that intelligence comes into existence in a specific cultural context and that intelligence and culture are so closely linked that any attempt to compare intelligence across cultures is futile.

universalism The viewpoint that basic cognitive processes are universal but that manifestations of these processes may well vary across cultures.

This article discusses three views on the relationship between culture and intelligence. The first, called the relativist viewpoint, holds that intelligence comes into existence in a specific cultural context and that intelligence and culture are so closely linked that any

attempt to compare intelligence across cultures is futile. The second, called the absolutist viewpoint, maintains that cognitive processes are the same across the globe and emphasizes the context-independent nature of cognitive processes and basic intellectual processes. The third, called the universalist viewpoint, also holds that basic cognitive processes are universal but argues that manifestations of these processes may well vary across cultures. Assessment has always been an important part of the work on intelligence. This article provides a brief history of cross-cultural assessment of intelligence, ending with an overview of what are currently seen as major issues. Then, it presents a description and examples of two kinds of studies of the relationship between culture and intelligence: formal (usually based on a comparison of scores on intelligence tests) and informal (based on the observation of everyday behavior). Then, the article discusses everyday definitions of intelligence and argues that, particularly in non-Western countries, social aspects such as obedience and social skills are seen as part of intelligence alongside reasoning and memory. The article concludes that the universalist position, according to which the basic constituents of intelligence are panhuman, is best supported. However, within predefined limits, cultures define the way in which these constituents are merged into ability patterns.

1. CULTURE AND INTELLIGENCE: AN EMERGING FIELD

It was more than a century ago that the French psychologist Alfred Binet was asked to devise a test that could be used to inform teachers about which pupils have learning difficulties. Tests to predict school performance nowadays are known as intelligence tests and are one of the most successful and widespread applications of psychological assessment. Intelligence test scores were, and still are, the best predictors of success in school and at work. The success has undoubtedly added to the received view that intelligence tests measure intelligence both within and across cultures. However, on closer scrutiny, the relationship between an intelligence quotient (IQ) score and the theoretical concept of intelligence turns out to be complex. At the beginning of the 20th century, Porteus set out to measure the cognitive skills of various cultural groups. He administered his Maze Test, a paper-and-pencil instrument in which the testee must find a way out of a schematically drawn

maze, to various cultural groups, including the Bushmen in the Kalahari Desert. Porteus concluded that the Bushmen's visuospatial skills (an important aspect of intelligence) were poorly developed, obviously not realizing that his conclusion clearly contradicted the superb tracking skills of Bushmen in the relatively cueless environment of the Kalahari.

Two further examples are presented to illustrate the close link between intelligence and culture. In the cognitive anthropological literature, there are various examples of expert cognitive performance. For example, the Trukese of the Pulawat atoll in the South Pacific have remarkable navigating skills; they sail over hundreds of miles of open ocean without compasses, sextants, or star tables. The second example comes from studies on Quranic schooling. Some Muslims learn (parts of) the Scripture by heart. In particular, when the learner does not speak Arabic (the language of the Scripture), massive training is needed. This is done by using an incremental learning method in which the first word is learned first, followed by the first and second words, followed by the first, second, and third words, and so forth. Studies have shown that this training leads to improvements of these people in learning in an incremental paradigm. However, their memory skills are not remarkable on tasks that do not require this type of learning. Cultural practice implies frequent exposure to a very specific task, and this leads to the advanced development of a skill.

2. THREE VIEWS ON THE RELATIONSHIP BETWEEN INTELLIGENCE AND CULTURE

With some alleged simplification, one could say that in cross-cultural psychology, three kinds of views can be found on the relationship between intelligence and culture: relativist, absolutist, and universalist.

2.1. Relativist Viewpoint

According to the relativist viewpoint, intellectual processes are closely linked to their cultural context and can be studied only with explicit reference to this context. The visuospatial skills of the Bushmen play an important role in tracking game needed for their everyday survival. The skills of Western individuals are developed to survive in a completely different environment. Therefore, the skills are embedded in different

contexts in both cultures. As a consequence, the skills are not comparable across these two cultures, and it is impossible to design an instrument that can be used to compare these skills across the cultures. Furthermore, there is no need to compare these skills given that all cultural groups are well adjusted to their natural habitats; one cannot say that Bushmen are better (or worse) adapted to the desert than Westerners are to the urban industrialized context. In this view, as socialization progresses, cognitive skill patterns of individuals from different cultures become increasingly dissimilar. Each culture produces its own type of intelligence that is well suited for everyday functioning in that specific cultural context. In this framework, it is important to identify these patterns: How does Bushman intelligence differ from Japanese intelligence?

2.2. Absolutist Viewpoint

The absolutist viewpoint is often associated with a small group of influential researchers such as Arthur Jensen, the late Hans Eysenck, Richard Lynn, and Philip Rushton. It is the opposite of the relativist viewpoint; absolutists argue that cognitive processes are the same across the globe. They emphasize the context-independent nature of cognitive processes. Basic cognitive operations, such as transitivity (e.g., "If John is taller than Mary and Mary is taller than Peter, then John is taller than Peter") and syllogisms (e.g., "If all humans are mortal and Socrates is a human, then Socrates is mortal"), are independent of their context of occurrence. Because of this independence, tests can be designed in such a way that they have a panhuman validity. A test of intelligence that is both reliable and valid in San Francisco will also be valid in the Australian outback and in Sub-Saharan Africa (assuming that the test does not measure information that is available only to a single cultural group). It is clear that with such a strong confidence in the value of intelligence tests, far-reaching conclusions about intellectual skills of various cultural groups can be drawn. Absolutists often assume that these differences are biologically rooted; not surprisingly, they often use the term "race" to describe these differences. Jensen has provided much evidence showing that European Americans show higher IQ scores than do African Americans (approximately 15 IQ points on average). Eysenck has argued that if the races are split up according to skin color, the "yellow race" has the highest IQ scores, followed by the "white race" and then the "black race."

2.3. Universalist Viewpoint

The universalist viewpoint holds that the same basic cognitive structure of humankind is shared by all cultural groups. Cognitive skills and structures, such as reasoning and memory, are present in all cultures, and these skills are called universal. Still, it is clear from cross-cultural studies that culture exerts a powerful influence on intellectual functioning. Culture defines the context of intellectual functioning by determining what, when, and how individuals will learn. A universalist perspective on the navigational skills of the Trukese would hold that these skills consist of universal building blocks that are combined and refined in a lengthy learning process, with the skill being learned by observing experts. In a universal perspective, there are no different types of intelligence. However, cultures differ in terms of which building blocks are used to a greater or lesser extent, and this could lead to cross-cultural differences in mean scores on the more extensively trained skills. Cultures also differ in the specific skills taught (e.g., navigational skills among the Trukese, computer games in Western societies). Such complex skills are based on the universal building blocks that are applied to cultural knowledge.

It is probably fair to say that the universalist viewpoint is the most popular one in cross-cultural psychology. A basic problem of the relativist position is that all cognitive processes are assumed to be context bound. If one is interested in a comparison of cognitive processes across various cultures, the position that these processes are not comparable by definition is not very fruitful. The main problem with this position is the implied overstatement of what could be a valid position in some domains of cognition. Take short-term memory span as an example. A number of items, usually digits, are presented at a rate of one item per second, and the respondent must repeat the items in the same order. The test starts with short series and then continues until the respondent can no longer recall the items correctly. There are strong indications that at least within school-going populations, short-term memory span is relatively invariant across cultures. A relativist viewpoint can quickly become counterproductive when studying these basic universalities in human cognitive functioning. The other extreme position, absolutism, can be equally counterproductive. It is difficult to understand how one could measure visuospatial skills of Bushmen and New Yorkers with one and the same test that gives a valid reflection of their skill levels and that could give a good prediction of real-life behavior in both

environments in which these skills are relevant. In general, it is naive to assume that Western cognitive tests “travel well” and that they easily allow for direct numerical score comparisons of different cultural groups. The popularity of the universalist viewpoint can be easily derived from the shortcomings of the relativist and absolutist viewpoints. The empirical record shows clearly that neither the culture-bound nature of the relativist viewpoint nor the essential denial of cultural influences on cognitive processes is strongly supported. The universalist viewpoint, which is more prudent, has the most face validity.

3. THE MEASUREMENT OF INTELLIGENCE IN A CROSS-CULTURAL CONTEXT

The measurement of intelligence has always played an important role in the literature. If one works in a relativist tradition, one must make sure that his or her assessment of intelligence is adequate for the cultural context. A measure of vocabulary should provide a score that gives an adequate picture of the testee’s knowledge of the lexicon. Within the universalist tradition, one must deal with an additional question: Is a test (possibly translated or adapted) adequate to be used in different cultures? It cannot be taken for granted that a test (or its items) developed in one cultural context (typically a Western context) can be simply translated and employed in a different cultural context without any problems. For example, words in a vocabulary subtest might be inadequate or relatively easy or difficult for some cultural groups as compared with other cultural groups. In a Dutch study involving Turkish and Moroccan migrant children and Dutch autochthonous children, it was found that the word “bacon” was much more difficult for the migrant groups, presumably due to the food taboo on pork meat in Islam. The adequacy of a test to measure intelligence in a cross-cultural context cannot be assumed but must be demonstrated.

The question of whether intelligence tests can be applied in different cultural contexts is answered in different ways by relativists, universalists, and absolutists. Relativists argue that basic cognitive processes come into existence in a specific cultural context and that process and context constitute each other; in this view the search for a cross-culturally applicable intelligence test is needless and pointless. Within the absolutist tradition, and particularly within the universalist

tradition, the view is more common that there are good and bad intelligence tests, from a cross-cultural perspective, and that it is possible in principle to develop cross-culturally adequate intelligence tests.

Although the terms of relativism, absolutism, and universalism are recent, the theme of how to design intelligence tests that are adequate in various cultures is old. It was recognized a long time ago that familiarity with test stimuli (e.g., figures and words used in a test) could play a role in assessment; that is, people more familiar with the stimuli can be expected to obtain higher scores. Back in the 1940s, Cattell proposed using very simple stimuli in cognitive tests to deal with the problem that various groups were not equally familiar with test material. This led to the development of “culture-free tests.” However, the assumed independence of test performance and, among other things, socioeconomic status could not be demonstrated. Subsequently, “culture-fair tests” were developed. Not surprisingly, the existence of culture-free and culture-fair tests has come under critical scrutiny.

Tests that claim to be culture free or culture fair must deal with two related issues. The first is the problem of differential stimulus familiarity. If cognitive tests are administered to cultural groups with widely different educational backgrounds, differences in stimulus familiarity are nearly impossible to avoid and overcome. The second issue is the implicitness of cultural knowledge in tests. Tests and testing situations imply much cultural knowledge, even when this knowledge is not the topic of a test. For example, a situation in which an individual asks questions with answers he or she knows and expects the testee to answer the questions without the help from anyone else is uncommon in everyday life, with experience with this situation being more common among schooled populations. The implicit references to cultural knowledge and customs in intelligence tests are numerous. Indeed, it could be argued that these references are impossible to avoid. It has been argued repeatedly that cross-cultural differences in intelligence test scores that are often reported are strongly influenced by the differential knowledge of the culture of the test. Individuals who share a cultural background with the test developer are more likely to obtain higher scores than are people from other cultural groups.

During recent decades, various guidelines have been formulated to describe best practices in the design of cross-cultural tests and preparing translations. For example, the International Test Commission defined a set of 22 guidelines that are useful when designing cross-cultural instruments.

Various procedures can be employed to examine the adequacy of an instrument, for example, an analysis of the contents of a test by a person (or group) with a thorough knowledge of the target culture. This person should be able to answer the question of whether the cognitive constructs of the test (e.g., memory, visuospatial skills) could be measured in this group with this instrument. In addition, various statistical techniques can be applied. These techniques require that data be collected in various cultural groups. The most frequently employed techniques address the question of whether it is reasonable to assume that the data obtained in various cultural groups can be treated statistically as coming from a single population: Can the two cultural groups be seen psychologically as belonging to the same (imaginary) statistical population? A frequently employed technique is factor analysis that examines the intertest correlations. If subtests of different tests measure entirely different psychological processes in different groups, it is very likely that test scores are interrelated in different ways across these groups. Suppose that two tests have been administered in each of two countries. Both of the tests measure reasoning in one country, whereas one test measures reasoning and the other test measures memory in the other country. It can be expected that people in the first country who score high on the first test will also score high on the second test (leading to a positive correlation between the tests), whereas a different pattern is expected in the second country because the people with high reasoning skills are not necessarily also the people with high memory skills. The intertest correlations will be higher in the first country than in the second country. So, a study of correlations of (sub)tests can yield valuable information about the psychological composition of an intelligence test in different countries.

4. FORMAL VERSUS INFORMAL STUDIES OF INTELLIGENCE

There are two research traditions in cross-cultural psychology to study the relationship between culture and intelligence: formal and informal (Table I). The formal and informal research traditions are comparable to (but not completely reducible to) the distinction between the universalist and relativist viewpoints, respectively.

In formal studies of intelligence, the scientific approach is seen as the normative model of good problem solving. There is an emphasis on the solution of

TABLE I
Differences of the Formal and Informal Traditions of the Study of Intelligence

<i>Formal tradition</i>	<i>Informal tradition</i>
Closed problem spaces	Open problem spaces
Deterministic problems	Probabilistic problems
Formalized artificial problems	Problems with a high ecological validity
Focus on correctness of solution	Focus on practical value of the solution (uncertainty reduction)
Context independence	Context dependence
The scientist as the model of the problem solver	The bricoleur as the model of the problem solver
Product oriented (psychometric approach) or process oriented (Piagetian approach)	Process oriented
Cross-cultural comparisons of test performances	Intracultural studies
Algorithmic solutions	Heuristic solutions
Brief assessment of many problems	In-depth assessment of a single problem
Solution requires conceptual theoretical knowledge	Solution requires procedural practical knowledge

Source. Van de Vijver and Willemsen (1993).

formalized problems that are unlikely to be met in everyday life and on the correctness of solutions (e.g., "What is the capital of Poland?"). Nearly all intelligence tests are based on the formal tradition. Studies in this tradition have enlarged our insight on the relationship between culture and intelligence. First, administration of intelligence tests in various cultures has provided impressive evidence that the structure of intelligence is universal. The structure of cognitive abilities constitutes the universal "building blocks" that are combined by cultures in specific skill patterns useful in these cultures. (In a currently popular model of intelligence developed by Carroll in 1993, these cognitive abilities consist of fluid intelligence, crystallized intelligence, memory and learning, visual perception, auditory perception, fluency, and speed of cognitive and simple decision processes.) This finding provides a strong empirical argument against the view that all cognitive processes are culture bound. The importance of the panhuman structure of intelligence should not be underrated. It means that basic cognitive processes involved in memory are very likely to be the same across various cultures, even though

cultures have an impact on what kind of information is stored and retrieved. Views have been expressed that there are various kinds of intelligence across the globe and that, for example, Libyan intelligence is different from Japanese intelligence. Findings on the panhuman identity of intelligence show that the notion of multiple kinds of intelligence culturally cannot imply major differences in structure. The statement could also be interpreted to mean that Libyans and Japanese do not show the same scores on various subtests. The latter interpretation brings us to a second line of research in the formal tradition: determining and interpreting cross-cultural differences in mean scores on intelligence tests.

It is well established that cultures differ in mean scores on intelligence tests. The nature of these differences is debated, ranging from genetic differences to schooling differences. Furthermore, the quality of these tests to assess intelligence in groups for which such tests have not been developed and validated has been questioned. Although this controversy will not be solved in the near future, it is clear that the competition among these three competing explanations is unlikely to have a single winner. For instance, consider the evidence in favor of the genetic position. There are twin studies in behavior genetics in which a large proportion of individual differences in intelligence scores is found to be caused by genetic differences. Genes are nearly always found to be more important than the environment as determinants of score differences. However, the generalization of this finding to a cross-cultural context is not simple. The assessment problems discussed previously will also affect the size of the cross-cultural score differences observed. So, there is a problem of estimating the relative contributions of all relevant sources of variation. The current state of knowledge, and of the level of assessment procedures, is insufficient to deal with the question of the relative contributions in a decisive way.

A recent project by Georgas and colleagues compared data obtained with the third version of the Wechsler Intelligence Scale for Children (WISC-III) from various countries: Canada, Dutch-speaking countries (The Netherlands and Flanders), German-speaking countries (Germany, parts of Switzerland, and Austria), Greece, Japan, Lithuania, South Korea, Slovenia, Sweden, and the United States. The WISC-III test, one of the most widely employed intelligence tests for children, contains various subtests and yields an overall IQ score. The most salient finding of the study was the absence of major mean score differences on any subtest. No subtest showed a difference of more than 15 IQ points between the smallest and largest scores; in fact, the means of

most countries on most subtests differed by less than 5 IQ points. The authors did not find the major differences that had been reported previously. One of the reasons for finding only small differences may be related to the sampling procedure. The samples in all countries were carefully drawn so as to represent the national populations of that age as accurately as possible, whereas older studies usually did not work with random samples. Although the mean differences of the WISC-III scales were not large, their patterning was meaningful. Countries that are richer and that spend more money on education tended to show higher scores.

The informal tradition is known by various names such as “everyday cognition,” “indigenous cognition,” and “practical intelligence.” The bricoleur (i.e., “jack-of-all-trades”) is the implicit model of problem solving. A bricoleur is not interested in a solution that is correct as defined by an external standard (which is typically the case in the formal tradition) but rather is interested in a solution that solves a practical problem (e.g., a leaking roof) using available means. Various studies have examined how individuals solve everyday cognitive problems such as mental arithmetic by shoppers who compare prices of products when both prices and weight of brands differ, planning behavior by cooks, and estimation by carpenters of how much wood is needed for making a table.

Results of research in the informal tradition show some consistent findings. Contrary to what might be expected, there is little or no relation between performances in informal tasks and those in formal tests. Street vendors who are very skillful in addition and multiplication when dealing with numbers familiar to them do not always show high levels of performance on tests of mental arithmetic that cover areas and numbers less familiar to them. Second, there is little transfer of cognitive skills from a familiar problem-solving situation to an unfamiliar one. This problem is well known in schooling; when confronted with a new problem, students do not recognize it as an application of a solution procedure they know. Third, there are remarkable differences between experts and novices regarding accuracy and strategies they use in problem-solving tasks.

5. EVERYDAY DEFINITIONS OF INTELLIGENCE

The most frequently quoted definition of intelligence is that given by Boring in 1923: “Intelligence is what an

intelligence test measures.” This definition is nearly circular. A listing of the skills assessed by the subtests of an intelligence test, such as memory and reasoning, is not an informative definition of intelligence. The long tradition of theorizing and research about intelligence has not produced a satisfactory definition of the concept. Yet everyone seems to have an implicit idea of what the concept entails. During recent decades, an interesting series of studies of what laypeople mean by “intelligence” have been conducted, and many of these were done in infrequently studied groups (e.g., some rural groups in Kenya and Tanzania). In these studies, informants were asked to indicate the characteristics of both smart and dull children, to describe characteristics and behaviors of intelligent persons in their environment, and so forth. Basic constituents of Carroll’s model, such as reasoning, memory, and speed, seem to be viewed as core elements of intelligence in many cultures. However, social aspects of intelligence, usually not considered to be salient aspects of the concept in psychological theories of intelligence, are important in everyday definitions. Obedience, knowing one’s place in the family, knowing when to speak and when not to speak, and performing a task in the household without being asked were mentioned as examples of activities deemed to be relevant for intelligent children.

Recent developments in psychology can be seen as broadening the concept of intelligence and as being in line with this more context-informed conceptualization of intelligence. Sternberg introduced the concept of “successful intelligence,” and Salovey introduced the concept of “emotional intelligence.” Both of these concepts include elements that are hardly covered by classical theories, for example, creativity and empathy. The litmus test of these new tests is their power to predict important real-life criteria such as predicting which children will do well in school and which job applicant will become a good manager. The future will tell us whether predictions of real-life behavior can be improved by broadening the measures.

6. CONCLUSION

The relationship between intelligence and culture was not exactly love at first sight. Much intelligence research has been carried out from the implicit assumption that findings done in a single culture, typically a Western country, have panhuman validity. More recent studies have challenged this view. There is

growing support for the view that intelligence is always situated in a specific cultural context and that cross-cultural variation is an important feature of intelligence. Yet the cross-cultural variation is not endless. There is important evidence for the universality of the basic processes. Cultures define how these building blocks are combined to produce culture-relevant skills. When differences among cultures are large, the ability patterns may show quite a bit of variation. Many examples can be found in the literature of cognitive specializations that are part of regular socialization patterns (e.g., the learning of tracking skills among the Bushmen). An important task for the future of intelligence theory and research is to combine the patterns of cross-cultural differences and similarities into one or more overarching models specifying which aspects of intelligence are influenced by culture (thereby also implicitly indicating which areas are not influenced) and how these aspects are influenced. It is only by combining models and findings of the various research traditions that the universalities and cultural specificities of intelligence can be appreciated.

GLOSSARY

cognitive ability An ability is a cognitive ability if (a) an individual's performance does not depend on any particular sensory or motor system and (b) individual differences in the ability are not correlated with sensorimotor measures.

cognitive system design An approach that includes a conceptual and procedural framework to interface item design principles with test validity; the conceptual framework broadens construct validation such as cognitive research results as supporting data, whereas the procedural framework includes several steps in which cognitive theory is integrated into test development.

g Psychometric construct resulting from the positive correlation among several diverse ability tests; *g* is what is shared or common to all of the different measures of intelligence that form a positive manifold.

intelligence General mental ability to reason, plan, solve problems, think abstractly, comprehend complex ideas, learn quickly, and learn from experience.

intelligence quotient (IQ) A score on a test that has certain characteristics, the test's raw score is usually standardized in a large representative sample, and the standardization is done within narrow age intervals, so that the standardized

scores (IQ) will have the same mean and standard deviation at every age level.

In this article, intelligence is first defined and the structure of human cognitive abilities is described. Second, well-known data regarding the reliability and validity of intelligence measures are presented. Third, several remarkable intelligence assessment tools are briefly described, noting a movement from measures that are not derived from theory to measures that are theory driven. Finally, the cognitive system design approach is described as one noteworthy example of a recent advance in intelligence assessment.

1. WHAT IS INTELLIGENCE?

Intelligence is a very general mental capability involving the ability to reason, plan, solve problems, think abstractly, comprehend complex ideas, learn quickly, and learn from experience. Contrary to popular belief, psychologists are nearly unanimous in their view that reasoning and problem solving are crucial landmarks of intelligent behavior.

Human cognitive abilities can be organized hierarchically on three levels or strata. On Stratum I, there are specific cognitive abilities such as general sequential reasoning, language development, associative memory, spatial relations, speech sound discrimination, ideational fluency, numerical facility, and choice reaction

FIGURE 1 Hierarchical organization of cognitive abilities.

time. On Stratum II, there are several broad cognitive abilities such as fluid intelligence, crystallized intelligence, general memory and learning, broad visual perception, and broad auditory perception. At the top of the hierarchy, there is *g* or general intelligence. *g* accounts for half of the variability in intelligence in the general population. Figure 1 displays this hierarchical organization of cognitive abilities.

2. THE MEASUREMENT OF INTELLIGENCE

Intelligence tests are among the most reliable and valid of all psychological tests and assessments. Table I shows reliability coefficients of some of the most employed intelligence tests around the world. In addition to those reliability indexes, intelligence measured by standardized tests is the most stable psychological factor. Table II shows test–retest reliability coefficients taken from several classical longitudinal studies. These coefficients demonstrates that intelligence is a very

stable human trait. Furthermore, intelligence measured by standardized tests predicts more than 60 social phenomena. Table III shows some examples.

There are different types of intelligence tests, but they all measure the same intelligence (i.e., *g*). Some

TABLE II
Correlations Computed in Several Longitudinal Studies between a Test and a Retest Measure

Test (Years)	Retest (Years)	Correlation coefficient
2	15	.78
11	77	.73
14	42	.68
17	48	.83
19	61	.78
25	65	.78
30	43	.71
50	70	.90

Intelligence test	Reliability coefficient
Stanford–Binet IV	.98
WPPSI-R	.96
WISC-III	.94
WAIS-III	.98
Woodcock–Johnson III	.97
Cognitive Assessment System	.96
Kaufman Adolescent and Adult Intelligence Test	.97

TABLE IV
Criteria Associated with IQ Levels

IQ level	Criteria
40	Adult can mow lawns, do simple laundry
50	Adult can do simple carpentry, domestic work
60	Adult can repair furniture, harvest vegetables, assist electrician
75	Adult can keep small store, perform in orchestra
90	Adult can perform jobs requiring some judgment
100	Average for total population
105	Fifty-fifty chance of passing in academic high school curriculum
110	Fifty-fifty chance of graduating from college
115	Mean of freshmen in typical 4-year college
120	Mean of college graduates
130	Mean of persons receiving PhD degrees

use words or numbers and require specific cultural knowledge. Others do not and instead use shapes or designs and require knowledge of only simple universal concepts. The measurement of intelligence through a standardized intelligence quotient (IQ) test arranges people. The spread of people along the IQ continuum, from low to high, can be represented by the normal curve. Table IV shows some examples of IQ levels for various external criteria.

Psychological science has several assessment devices with high-quality standards. The remainder of this article presents some of the most remarkable intelligence tests.

3. INTELLIGENCE ASSESSMENT TOOLS

Intelligence is currently assessed through tests that are not derived from theory and through tests that are theory driven. The Wechsler scales (Wechsler Preschool and Primary Scales of Intelligence–Revised [WPPSI-R], Wechsler Intelligence Scale for Children–Third Edition [WISC-III], and Wechsler Adult Intelligence Scale–Third Edition [WAIS-III]) are examples of the former type of tests, whereas the Das–Naglieri Cognitive Assessment System (CAS) and the Woodcock–Johnson III (WJ III) are examples of the latter type of tests. Those tests can be described in terms of theoretical background, the measurement

scales included, and psychometric properties such as reliability and validity.

3.1. The Wechsler Scales

David Wechsler supports the definition of intelligence as a global entity. The Wechsler scales measure intelligence from 3 to 89 years of age. The latest versions are the WPPSI-R for preschool and primary-grade children, the WISC-III for elementary and high school children, and the WAIS-III for older adolescents through old age.

3.1.1. Wechsler Preschool and Primary Scale of Intelligence–Revised

The WPPSI-R battery provides a full-scale IQ but also has separate verbal and performance scales. The verbal subtests include information, comprehension, arithmetic, vocabulary, similarities, and sentences. The performance subtests include object assembly, block design, mazes, picture completion, geometric design, and animals/pegs. The battery allows the examiner to assist the child on early items to ensure that the child understands the test requirements.

The overall verbal IQ, performance IQ, and full-scale IQ are standard scores with the mean set at 100 and the standard deviation (SD) set at 15. The range of possible WPPSI-R full-scale IQs is 41 to 160. Standard scores are provided for the separate subtests, each with a mean of 10 and an SD of 3. The battery was standardized in the United States on 1700 children from 3 years to 7 years 3 months of age and matched 1986 census bureau estimates on the stratification variables of sex, race, geographic region, parental occupation, and parental education.

The internal consistency coefficients were .95 for the verbal IQ, .92 for the performance IQ, and .96 for the full-scale IQ. The coefficients for the individual performance subtests ranged from .63 for object assembly to .85 for block design, with a median coefficient of .79. For the individual verbal subtests, the values ranged from .80 for arithmetic to .86 for similarities, with a median coefficient of .84. The test–retest coefficient for the full-scale IQ was .91 for 175 children tested twice with a time interval of 4 weeks.

The battery's manual provides several validity studies, factor-analytic results, research overviews, and interpretive tables that provide a great amount of information.

3.1.2. Wechsler Intelligence Scale for Children—Third Edition

The WISC-III battery offers standard scores on four factors: verbal comprehension, perceptual organization, freedom from distractibility, and processing speed. The first two factors consist of verbal subtests, and the latter two factors consist of performance subtests. The verbal mandatory subtests are information, similarities, arithmetic, vocabulary, and comprehension. The performance mandatory subtests are picture completion, picture arrangement, block design, object assembly, and coding. There are verbal and performance complementary subtests: digit span for verbal and mazes and symbol search for performance. Processing speed results from symbol search and coding. Freedom from distractibility results from arithmetic and digit span. The range of possible WISC-III full-scale IQs is 40 to 160.

The battery was standardized in the United States on 2200 children 6 to 16 years of age and was stratified by age, sex, race, geographic region, and parents' education. The average reliabilities across the age groups were .95 for the verbal IQ, .91 for the performance IQ, .96 for the full-scale IQ, .94 for the verbal comprehension index, .90 for the perceptual organization index, .87 for the freedom from distractibility index, and .85 for the processing speed index.

3.1.3. Wechsler Adult Intelligence Scale—Third Edition

The WAIS-III battery was designed to parallel the WISC-III. The WAIS-III consists of verbal, performance, and full-scale IQs as well as indexes on four factors. There are seven verbal subtests and seven performance subtests. Three factors have the same names as do WISC-III factors: verbal comprehension, perceptual organization, and processing speed. The fourth factor is called working memory. In addition to arithmetic and digit span, the working memory factor includes the letter–number sequencing subtest.

The WAIS-III has six regular verbal subtests and five mandatory performance subtests. The verbal subtests are vocabulary, similarities, arithmetic, digit span, information, and comprehension. The performance subtests are picture completion, picture arrangement, block design, matrix reasoning, and digit–symbol coding.

The battery was standardized in the United States on 2450 adults (selected according to 1995 census data) and was stratified according to age, sex, race, geographic

region, and educational level. The participants were divided into 13 age groups, ranging from 16–17 to 85–89 years, with each group consisting of 100 to 200 people. The average split-half reliability coefficients across the age groups were .97 for the verbal IQ, .94 for the performance IQ, and .98 for the full-scale IQ. The average individual subtest reliabilities ranged from .93 for vocabulary to .70 for object assembly, with a median coefficient of .85. The stability coefficients were .95 for verbal IQ, .90 for performance IQ, and .97 for full-scale IQ (those coefficients were computed from 394 participants tested twice with a time interval of 5 weeks).

The range of possible WAIS-III full-scale IQs is 45 to 155. The WAIS-III computes scaled scores for each individual based exclusively on chronological age. The use of four indexes derives from the results of factor analysis. Several factor analyses have shown that the Wechsler performance scale measures visual–spatial ability (*Gv*), but some researchers argue that the performance scale measures a mixture of *Gv* and nonverbal reasoning (*Gf*).

3.2. Cognitive Assessment System

The CAS was developed according to the PASS (Planning, Attention, Simultaneous, Successive) theory of intelligence. The theory proposes that human cognitive functioning is based on four essential activities:

- Planning (which provides cognitive control, use of processes and knowledge, intentionality, and self-regulation to achieve a given goal)
- Attention (which provides focused, selective cognitive activity over time)
- Simultaneous processing (one form of operating on information)
- Successive processing (another form of operating on information)

The subtests are organized into four scales. Planning subtests require devising, selecting, and using efficient plans of action to solve the problems, regulate the effectiveness of the plans, and self-correct if necessary. Attention subtests require attending selectively to a particular stimulus and inhibiting attending to distracting stimuli. Simultaneous processing subtests require integrating stimuli into groups. Successive processing subtests require integrating stimuli in their serial order or appreciating the linearity of stimuli.

The CAS yields scores for the planning, attention, simultaneous, successive, and full scales, with a

normative mean of 100 and an SD of 15. All subtests are set at a normative mean of 10 and an SD of 3.

The battery was standardized in the United States on 2200 participants 5 to 17 years of age and was stratified by age, sex, race, geographic region, educational placement, and parents' education according to census reports and matches population characteristics in the variables used.

The internal consistency reliability estimates for the CAS were as follows: full scale = .96, planning and attention = .88, and simultaneous processing and successive processing = .93. The test-retest reliabilities for the CAS were as follows: full scale = .91, planning = .85, attention = .82, simultaneous processing = .81, and successive processing = .86. A total of 215 participants were tested twice, with a time interval of 21 days.

3.3. Kaufman Adolescent and Adult Intelligence Test

The Kaufman Adolescent and Adult Intelligence Test (KAIT) is based mainly on the Horn-Cattell theory of intelligence. Fluid intelligence (*Gf*) involves culture-fair novel tasks and taps problem-solving skills and the ability to learn. Crystallized intelligence (*Gc*) refers to acquired skill, knowledge, and judgments learned within a given society.

Thus, the battery provides fluid, crystallized, and composite IQs, with a mean of 100 and an SD of 15. It consists of a core battery of six subtests and an expanded battery. Each subtest yields age-based scores with a mean of 10 and an SD of 3. Crystallized intelligence measures the acquisition of facts and problem-solving ability using stimuli derived from schooling and cultural experiences. Fluid intelligence measures a person's adaptability when solving new problems. The KAIT fluid subtests emphasize reasoning rather than visual-spatial ability (contrary to the Wechsler performance scale).

The KAIT was standardized in the United States on 2000 participants 11 to 94 years of age and was stratified according to sex, race, geographic location, and socioeconomic status. The reliability coefficients were .95 for *Gc* and *Gf* and .97 for composite IQ. Test-retest reliabilities were .94 for *Gc* and composite IQ and .87 for *Gf*. A total of 153 participants were tested twice, with a time interval of 1 month.

Both exploratory and confirmatory factor analyses support the construct validity of the KAIT. Moreover, a correlation of .82 was observed between WISC-R full-scale IQ and the KAIT composite IQ, and a correlation

of .85 was observed between WAIS-R full-scale IQ and the KAIT composite IQ.

3.4. Woodcock-Johnson III

The WJ III consists of two distinct batteries: the WJ III Tests of Cognitive Abilities and the WJ III Tests of Achievement. Together, these batteries comprise a wide age range system for measuring general intellectual ability (*g*), specific cognitive abilities, oral language, and academic achievement. This subsection reviews only the WJ III Tests of Cognitive Abilities, where the standard battery and the extended battery can be found.

The standard battery includes verbal comprehension, visual-auditory learning, spatial relations, sound blending, concept formation, visual matching, numbers reversed, incomplete words, auditory working memory, and delayed visual-auditory learning. The extended battery includes general information, retrieval fluency, picture recognition, auditory attention, analysis-synthesis, decision speed, memory for words, rapid picture naming, planning, and pair cancellation.

The WJ III is based on current theory and research on the structure of human cognitive abilities. The theoretical basis is derived from the Cattell-Horn-Carroll theory of cognitive abilities (Fig. 1). The WJ III is a measurement model of this theory, and the design criteria place emphasis on providing the greatest practical breadth in Stratum II abilities: comprehension knowledge, long-term retrieval, visual-spatial thinking, auditory processing, fluid reasoning, processing speed, and short-term memory. The measured abilities are as follows:

- *Gf* (fluid intelligence) through concept formation (induction), analysis-synthesis (general sequential deductive reasoning), and planning (general sequential reasoning)
- *Gc* (crystallized intelligence) through verbal comprehension (lexical knowledge and language development) and general information (general verbal information)
- *Glr* (long-term retrieval) through visual-auditory learning (associative memory), delayed visual-auditory learning (associative memory), and retrieval fluency (ideational fluency)
- *Gv* (visual-spatial thinking) through spatial relations (visualization and spatial relations), picture recognition (visual memory), and planning (spatial scanning)
- *Ga* (auditory processing) through sound blending (phonetic coding synthesis), incomplete words

(phonetic coding analysis), and auditory attention (speech sound discrimination and resistance to auditory stimulus distortion)

- *Gs* (processing speed) through visual matching (perceptual speed), decision speed (semantic processing speed), rapid picture naming (naming facility), and pair cancellation (attention and concentration)
- *Gsm* (short-term memory) through numbers reversed (working memory), auditory working memory (working memory), and memory for words (memory span)

The data for WJ III norms were collected from a large, nationally representative sample of 8818 participants gathered in more than 100 geographically diverse U.S. communities. The preschool sample (2–5 years of age) was composed of 1143 participants. The kindergarten through 12th-grade sample was composed of 4783 participants. The college/university sample consisted of 1165 undergraduate and graduate students. The adult sample was composed of 1843 participants. The norming sample was selected to be representative of the U.S. population from 24 months to 90 years of age or over. The participants were randomly selected within a stratified sampling design that controlled for census region, community size, sex, race, type of school, type of college/university, education of adults, occupational status of adults, and occupation of adults in the labor force.

The WJ III general intellectual ability score is a general intelligence (*g*) score. It represents the first principal component obtained from principal component analyses. Using weights based on principal component analyses means that all subtest weights are optimal. In contrast, tests such as the Wechsler intelligence scales weight all subtests equally. Using principal component analyses of cognitive measures as a basis for prescribing different test weights gives the best statistical estimate of general intelligence.

Reliability coefficients ranged from .74 for planning to .97 for rapid picture naming. The construct validity of WJ III was tested by confirmatory factor analyses. The breadth of abilities measured by the WJ III is described by *g* plus several broad cognitive abilities plus several narrow cognitive abilities. Nearly all tests load exclusively on a single factor, suggesting that the cognitive tests have minimized the influence of construct-irrelevant variance.

The WJ III general intellectual ability scores had correlations ranging from .67 to .76, with composite

scores from the WPPSI-R, the WISC-R, or the Stanford–Binet IV. The WJ III matches its intended theory closely. It is a good translation of theory into practice.

4. INTERPRETATION: SOME WORDS

The examiner must produce hypotheses about an individual's strengths and weaknesses based on theory, research knowledge, and clinical ability. The survival hypotheses must form practical recommendations.

Intelligence assessment devices must be selected prudently. These devices must meet sound psychometric standards, but the examiner should keep in mind that each examinee has unique characteristics. Alan Kaufman articulated five basic principles for intelligence assessment:

1. The items on an intelligence test measure what the individual has learned.
2. The subtests included on an intelligence test are nonexhaustive samples of behavior.
3. The items on an intelligence test assess mental functioning under fixed conditions.
4. The subtests on an intelligence test are useful when interpreted within an information processing model: how information enters the system, how it is interpreted and processed, how it is stored for later retrieval, and how it is expressed.
5. The hypotheses produced from an intelligence assessment should be supported from several sources: the person's behavior during test administration, the pattern of responses across several subtests, background information from parents, teachers, and/or peers, and so forth.

These basic principles are appealing, but the examiner must be cautious because there is always the temptation to neglect objective data in the face of other sources of much more subjective evidence. Therefore, the examiner must consider asking some colleagues when the distance between the objective result and the subjective appreciation increases.

5. RECENT ADVANCES

Intelligence assessment is moving from an exclusively empirically rooted test construction to a more

theoretically based one. The WJ III and the KAIT are some examples. But there are other instances as well. The following focuses briefly on the recent applied research development known as the cognitive system design (CSD) approach.

The CSD approach emphasizes manipulating construct validity by the cognitive complexity of the items. These items can be designed to measure targeted aspects of processing by detailed specifications of the stimulus features that influence processing. The stages are as follows:

- Specify general goals of measurement.
- Identify design features in task domain (task-general features [e.g., model, format, conditions] and task-specific features).
- Develop a cognitive model (review theories, select or develop model for psychometric domain, revise model, and test model).
- Evaluate cognitive model for psychometric potential (evaluate cognitive model plausibility on current test, evaluate impact of complexity factors on psychometric properties, and anticipate properties of new test).
- Specify item distributions on cognitive complexity (distribution of item complexity parameters and distribution of item features).
- Generate items to fit specifications.
- Evaluate cognitive and psychometric properties for revised tests domain (estimate component latent trait model parameters, estimate plausibility of cognitive model, evaluate impact of complexity factors on psychometric properties, evaluate plausibility of the psychometric model, and calibrate final item parameters and ability distributions).
- Conduct a psychometric evaluation (measuring processing abilities and bank items by cognitive processing demands).
- Assemble test forms to represent specifications (fixed content test and adaptive test).
- Validate.

Cognitive item response theory (IRT) models are mathematical models of cognitive processes and IRT models of response patterns. These models contain parameters to represent the cognitive demands of items as well as the person's ability.

Susan Embretson has applied the CSD approach to develop a test of abstract reasoning called ART. ART contains matrix problems very similar to those of the Advanced Progressive Matrices (APM) test. A bank of 150 items was generated analytically from a list of

objects and attributes. Empirical results supported the CSD approach to test development. Working memory capacity was the primary cognitive aspect of item solving. Memory load predicted item difficulty. Items were banked by their cognitive demands by use of the memory load scores from the cognitive model. Moreover, ART scores were indistinguishable from APM scores. ART achieved the same internal consistency and factorial validity as did APM but from fewer items, suggesting that the CSD approach may eliminate features from items that are irrelevant to abstract reasoning.

Designing intelligence tests from cognitive theory is now feasible. Good results may be expected for a broad array of items if a high-quality cognitive theory about the item stimulus features that influence processing is developed. Future testing may change if the generating potential of cognitive theory is realized. The potential size of the generable items bank is quite large. Even item construction could be fully computerized for future tests. The test of the future will be a set of generating principles with previously known relationships to people's performance. This obviously requires a fully developed cognitive model.

Emotional intelligence refers to a set of abilities that involve the way in which people perceive, express, understand, and manage their own emotions as well as the emotions of others. Although there are several different definitions and models found in the literature, there is considerable overlap among them. At the core of every definition are the abilities to perceive emotion clearly in oneself and in others, to use emotions to facilitate thought and action, to understand how emotions affect one's own behavior and that of others, and to regulate one's own emotional reactions.

1. WHY THE INTEREST IN EMOTIONAL INTELLIGENCE?

For more than 100 years, psychologists have been trying to identify, measure, and modify those aspects of personality and behavior that most strongly affect a person's ability to adapt successfully to the demands of living. Many of these efforts have focused on cognitive ability, that is, the way in which one acquires, codes, stores, and retrieves information about the environment. However, no matter how one measures cognitive ability, the amount of variability in outcomes attributable to it always proves to be rather limited. Estimates vary depending on the nature of the task and context, but cognitive ability, as measured by intelligence quotient (IQ) tests or other tests of general mental ability, usually accounts for approximately 10% of the variability in performance outcomes—and sometimes much

GLOSSARY

cognitive abilities Higher order mental faculties that involve the acquisition, analysis, and categorization of information as well as reasoning and problem solving.

competency A learned capability that contributes to superior performance.

conative abilities Having to do with motivation as opposed to emotion or cognition.

360-degree assessment An assessment in which a number of people who know an individual answer questions about that individual's attitudes, ability, or behavior; in the workplace, the raters are usually the individual's supervisors, peers, and subordinates.

tipping point A point in the linear relationship between two variables at which an additional small increase in the first variable results in a sharp increase in the second variable.

less. Up to now, the largest percentage attributable to cognitive ability has been approximately 25%. In addition, many tests of cognitive ability prove to be culturally biased; thus, the use of such tests perpetuates discrimination against many groups within society.

The significant but ultimately limited role of cognitive ability alone in helping people to adapt successfully has led to several attempts to identify other kinds of abilities that contribute to effective performance in school, interpersonal relationships, and the workplace. Emotional intelligence (EI) represents one such set of abilities.

2. HISTORICAL ROOTS OF AND PRECURSORS TO THE CONCEPT

Even before psychologists began to measure intelligence, Darwin wrote about the adaptive importance of emotion in human and animal life. In 1872, he published a book in which he proposed that emotions serve two important survival and adaptive functions. First, they energize and motivate activity. Fear, to take an obvious example, helps one to be more vigilant and, when danger is spotted, to run faster from it. Second, emotions also serve a signal function, conveying important information from one animal in a group to others. If an elk, grazing in a herd, notices a mountain lion off in the distance, the elk's fear reactions alert the rest of the herd, and the entire herd quickly sets off in flight, helping the elk to survive and pass on their genes to the next generation.

As early as 1920, some of the pioneers in the study and measurement of intelligence recognized the need to move beyond purely cognitive-based abilities in their conceptions and to include other kinds of abilities. Thorndike, for instance, wrote about "social intelligence" in an article published in 1920. In 1943, Wechsler wrote that "nonintellective" factors or "affective and conative abilities" should be considered part of general intelligence, based on their capacity to facilitate intelligent behavior. During the early 1980s, Gardner developed his concept of "multiple intelligences," which included "intrapersonal" and "interpersonal" intelligences as well as the more traditional cognitive-based types. Also during the early 1980s, Bar-On began to study what he later referred to as "emotional and social intelligence." Around the same time, Sternberg began to write about "practical intelligence." In 1990, Salovey and Mayer published an article in which they

used the term "emotional intelligence" in the title, and they subsequently began developing their own model and measures of the construct.

There was another stream of activity in psychology that was a relevant part of the concept's history, even though it was not explicitly linked to intelligence. For decades, personality and social psychologists had been studying personal attributes that seemed to help people be more effective in a variety of contexts, and some of these attributes involved one's ability to perceive, express, and/or manage emotions in oneself and in others. For instance, there was research on empathy, defined as the ability to sense what others are feeling and to take their perspective, suggesting that both children and adults who scored higher in this quality tended to be more successful in both vocational and academic contexts. Similarly, there was research suggesting that the ability to express emotion in a clear and compelling way could have a positive impact on individual and group performance in a variety of contexts. Moreover, clinical work on anger and anger management suggested that awareness of one's emotional reactions and what triggers them can greatly influence one's ability to regulate emotion, which in turn affects well-being and success. Current research and applications relating to EI draw on all of these historical roots.

3. VARIOUS MODELS OF EMOTIONAL INTELLIGENCE

Several different models of EI have emerged since 1990, and such diversity has contributed to a certain amount of controversy. Although there are important differences among the models, there also are many similarities. In fact, there probably is as much consensus about the EI construct as there is about the concept of general intelligence, a topic that has certainly seen its own share of conflict and controversy.

Salovey and Mayer called their model an "ability" model. Using a deductive approach, they identified four "branches" that are related in a hierarchical way: (a) the ability to perceive emotions accurately, (b) the ability to use emotions to facilitate thought, (c) the ability to understand emotions, and (d) the ability to manage emotions.

A second popular model is Goleman's "performance-based" model. Like Salovey and Mayer's model, the first component of Goleman's model involves perception of emotion. In this case, however, the focus is on awareness

of one's own emotions (Self-Awareness). A second component of the model involves awareness of emotions in others (Social Awareness). These first two components involve recognition of emotion. The other two components involve regulation of emotion: Self-Management and Relationship Management. Also like Salovey and Mayer, Goleman proposed a kind of hierarchical relationship among these components, with Self-Awareness constituting the foundation for Self-Management and Social Awareness, which in turn provides a foundation for Relationship Management. Goleman added another level to his model, consisting of approximately 20 "competencies" that are linked to the four basic dimensions of EI. For instance, under the Self-Management dimension, there are competencies such as flexibility and initiative. Goleman stressed that these competencies are not synonymous with EI, although EI provides the foundation for them. They are learned capabilities that contribute to superior performance.

Another model that has attracted considerable attention is Bar-On's model, which also is a competency-based model. Bar-On's model is composed of five dimensions: (a) Intrapersonal, which includes competencies such as emotional self-awareness and assertiveness; (b) Interpersonal, which includes empathy and interpersonal relationships, among others; (c) Stress Management, which incorporates stress tolerance and impulse control; (d) Adaptability, which consists of flexibility, reality testing, and problem solving; and (d) General Mood, covering optimism and happiness.

One reason why the models differ is that they were developed in different ways and for different purposes. Salovey and Mayer's model was developed deductively. Those researchers began with a general conception of EI and then defined their components based on that conception. Goleman, on the other hand, developed his model inductively. He identified the competencies that previous research suggested are most predictive of superior performance and then arranged them in clusters that seemed closely related to the basic components of EI. Bar-On's approach also was more inductive. Beginning with clinical work on life adjustment, he identified a set of skills that seemed to help people cope with demands and pressures. Then, using factor-analytic procedures, he ended up with his model of five major dimensions and 15 competencies.

Despite these differences in the models, a careful comparison suggests that there is considerable overlap. For instance, Salovey and Mayer's Perception of Emotion and Understanding Emotion dimensions seem to be similar to Goleman's Self-Awareness and Social Awareness

dimensions as well as to the emotional self-awareness and empathy subscales of Bar-On's model. Similarly, Salovey and Mayer's Emotional Facilitation of Thinking and Managing Emotions dimensions seem to be similar to Goleman's Self-Management and Relationship Management dimensions as well as to the Interpersonal, Stress Management, and Adaptability dimensions of Bar-On's model. Thus, although there are important differences among the three models, there also are many similarities.

4. MEASUREMENT OF EMOTIONAL INTELLIGENCE

Measures for various aspects of EI have existed for some time. For instance, there are measures of empathy that can be used to assess one's ability to perceive clearly another person's mood or emotional response. Similarly, there are measures of emotional self-awareness and self-regulation. However, during the past decade or so, there also has been a concerted attempt to develop and refine instruments explicitly designed to measure all of the major facets of EI.

The first such instrument is Bar-On's Emotional Quotient Inventory (EQ-i). The EQ-i is a self-assessment instrument that asks an individual to answer a series of questions about his or her own emotional and social competence based on the way in which the respondent feels, thinks, and behaves most of the time. Bar-On originally developed the instrument during the 1980s and has done considerable research on it over the years. Plake and Impara's critical review in 2002 suggested that the EQ-i has good reliability and validity.

Another instrument is the Mayer, Salovey, and Caruso Emotional Intelligence Test (MSCEIT), which is an ability test in which an individual performs a number of tasks designed to test various aspects of EI. For instance, in one section of the test, the individual is shown a series of faces and must rate how much sadness, anger, jealousy, and the like are displayed in each one. This section is designed to assess the Perception of Emotion dimension. The MSCEIT is the latest in a series of tests that this research group has developed; thus, it has less psychometric research behind it at this point. But a study by Mayer, Salovey and Caruso provided some promising support for the instrument's reliability and validity.

A third test that sometimes is used to measure EI is the Emotional Competence Inventory (ECI), developed by Boyatzis and Goleman. The original version of this test

was a “360-degree assessment” in which a number of people who know an individual answer questions about that person’s social and emotional competence. Many of the items are based on earlier research that identified the competencies most important for success in the workplace. Like the MSCEIT, the ECI is relatively new, but the body of research reported by Sala in 2002 suggests that the instrument has good reliability and validity.

There have been several other attempts to develop measures of EI, but these have received less attention than have the EQ-i, MSCEIT, and ECI. Also, there has been less psychometric research reported on those other measures.

5. THE RELATIONSHIP BETWEEN EMOTIONAL INTELLIGENCE AND PERSONALITY

One of the controversies surrounding the concept of EI concerns whether it is simply a new name for a set of personality traits that have been studied often in the past. Empirical research has addressed this issue by examining the strength of the relationship between common measures of EI and various personality traits. Most attention has focused on the relationship between EI and the Five-Factor Model of personality. A meta-analysis by Van Rooy and Viswesvaran, based on 69 studies involving more than 12,000 individuals, found that although there is some overlap, the relationships generally tend to be modest. The highest correlate of EI among the “Big Five” factors was Extraversion ($r = .34$). This same study also found that EI demonstrated significant incremental validity over the Big Five factors but that the Big Five did not add to EI, suggesting that EI is a better predictor of performance than is personality.

6. THE CONTRIBUTION OF EMOTIONAL INTELLIGENCE TO HEALTH, WORK, AND EDUCATIONAL ADJUSTMENT

Although there is some controversy about how much EI contributes to health, work, and educational outcomes, there is considerable research showing that it does have an impact. The research comes from two sources. First, there are recent studies that have used one of the explicit measures of EI that have appeared during the past decade or so. Van Rooy and Viswesvaran’s meta-analysis

found that, across all studies and measures, the correlation between EI and work performance was .24. For academic performance, the relationship was weaker; the overall correlation was .10. As is often the case with meta-analyses, the strength of the relationship varied considerably depending on the context of the study and the measures used. For instance, studies using an early measure of EI developed by Salovey and Mayer found a correlation of .32 between EI and performance, whereas researchers using the EQ-i published canonical correlations between EI and occupational performance as high as .74. Some researchers also have reported stronger associations between EI and academic performance. For example, one study found a correlation of .41 between EQ-i scores and grade point average in a group of American high school students.

Another source of research on the link between EI and important outcomes are the countless studies that have examined specific facets of EI during the past half-century or so. Such research has shown, for instance, that awareness of one’s own emotional reactions plays a vital role in stress regulation, anger management, and other processes that affect both physical and behavioral health. Emotional self-regulation plays an even greater role in health outcomes and also is a strong predictor of success in school and the workplace. Similarly, empathy (i.e., the ability to perceive emotions in others) has been shown to predict academic and vocational adjustment and to provide the foundation for positive social relationships that contribute to physical and behavioral health in various ways.

Most of the research on the link between EI and important outcomes probably provides an underestimation of EI’s significance because researchers typically look only at simple linear relationships. There is some research and theory suggesting that the relationship between EI and health or performance is more complex. For instance, Goleman suggested that EI is especially important in determining which individuals, among those occupying a particular role in an organization or occupation, will become superior performers or “stars.” Research on competence in work organizations summarized by McClelland in 1998 tends to support this view. Also, McClelland and his students showed that there tend to be “tipping points” in the relationship between emotional competencies and performance. This means that up to a certain level of competence, increases in competence do not result in significant increases in performance; however, once the level of competence passes a tipping point, there is a sharp increase in performance. Such complex relationships

could tend to suppress the strength of simple correlational and regression estimates.

7. CAN EMOTIONAL INTELLIGENCE BE TAUGHT?

At least since Freud's early work in psychoanalysis, psychotherapists of various kinds have been teaching their patients to become more aware of their emotional responses, to develop greater understanding of their emotions, to perceive the feelings of others more accurately, and to regulate their own emotions more effectively. Similarly, since the beginning of civilization, parents and teachers have been helping children to better understand and control their emotions and those of others. If these efforts had not been effective, civilization as we know it probably could not exist. Thus, it seems obvious that EI can be taught.

However, less obvious is the question of how EI can best be taught and how much change an intentional intervention can actually bring about in children or adults. The evidence suggests that EI can be taught but that the process is more time-consuming and difficult than many self-appointed gurus, teachers, and trainers often suggest. Perhaps the clearest indication that EI can be taught comes from efforts to help people better manage their emotions. Recent research on stress and anger management programs suggests that methods are now available to help many people who have problems with self-regulation of emotion. There also have been experimental procedures developed to help people become more aware of others' emotions and to identify those emotions more accurately. Moreover, a number of applied psychologists have developed educational curricula and teaching methods that seem to be effective in helping many children to develop social and emotional competence.

Unfortunately, all of these intervention strategies require a highly favorable context to be effective for many individuals. First, and most important, the individual usually must be highly motivated and willing to devote considerable time and effort to the change effort. Second, the teacher or trainer must have a high

degree of skill, particularly in the social and emotional domain, to be helpful. Third, the social environment needs to provide support and encouragement of various kinds. When all of these critical ingredients are present, well-designed and -implemented interventions can help children and adults to become more emotionally intelligent.

GLOSSARY

crystallized intelligence One of two major subfactors of general intelligence; it represents the accumulation of knowledge over the life span of the individual and may be measured by tests in areas such as vocabulary, general information, and achievement.

deviation IQs A means of determining intelligence test scores, based on deviations from an average score, calculated such that the normative equivalent for the median score is 100, approximately 68% of the scores are computed to fall between 85 and 115, and approximately 95% of the scores are computed to fall between 70 and 130.

emotional intelligence The ability to perceive and express emotion, assimilate emotion in thought, understand and reason with emotion, and regulate emotion in the self and others.

fluid intelligence One of two major subfactors of general intelligence; it represents the acquisition of new information or the grasping of new relationships and abstractions about known information.

heritability coefficient The degree to which heredity contributes to individual differences in intelligence, expressed in terms of a number on a scale from 0 to 1 such that a coefficient of 0 means that heredity has no influence on

variation among people, whereas a coefficient of 1 means that heredity is the only influence on such variation.

intelligence The ability to implement goal-directed adaptive behavior.

mental age A means of indicating a person's level of intelligence (generally in reference to a child), based on the individual's performance on tests of intelligence, by indicating the chronological age of persons who typically perform at the same level of intelligence as the test taker.

mental retardation Low level of intelligence, usually reflected by both poor performance on tests of intelligence and poor adaptive competence, that is, the degree to which a person functions effectively within a normal situational context.

ratio IQ A means of indicating performance on intelligence tests, based on a quotient of mental age divided by chronological age multiplied by 100.

reaction range The broad limits within which a particular attribute (e.g., intelligence) may be expressed in various possible ways given the inherited potential for expression of the attribute in the particular individual.

theory of multiple intelligences A theory suggesting that intelligence is composed of eight distinct constructs that function somewhat independently but may interact to produce intelligent behavior: bodily-kinesthetic intelligence, interpersonal intelligence, intrapersonal intelligence, linguistic intelligence, mathematical-logical intelligence, musical intelligence, naturalist intelligence, and spatial intelligence.

triarchic theory of successful intelligence A theory of intelligence asserting that intelligence is composed of three aspects that deal with the relationship of intelligence to the internal world, to experience, and to the external world.

Intelligence is the ability to implement goal-directed adaptive behavior. In this article, the concept of intelligence in humans is examined. The article opens with a review of theories of intelligence, then discusses development of intelligence, next measuring intelligence, and finally, the heritability and malleability of intelligence.

1. THEORIES OF INTELLIGENCE

1.1. Implicit Theories

How do psychologists know what intelligence is? One way in which they find out is to ask people. For example, they might ask experts. In a 1921 symposium on the definition of intelligence, an American psychologist, Lewis M. Terman, emphasized the ability to think abstractly. Another American psychologist, Edward L. Thorndike, emphasized learning and the ability to give good responses to questions. In a similar 1986 symposium, however, psychologists generally agreed on the importance of adaptation to the environment as the key to understanding both what intelligence is and what it does. They also emphasized learning skills and understanding one's own cognitive processes.

In a set of studies published in 1981, Sternberg and colleagues asked laypeople in the United States what they thought intelligence was. Three factors emerged from the responses: practical problem solving, verbal ability, and social competence. However, the conceptions that arise depend on who is asked. In a comparable set of studies carried out in Taiwan, five factors emerged: cognitive skills, getting along with other people, understanding oneself, knowing when to show one is smart, and knowing when not to show one is smart. In other studies conducted in Kenya, cognitive skills also were emphasized less than in the West, whereas obedience, respect, and understanding people were emphasized more.

Most theories of intelligence are explicit rather than implicit; that is, they are elicited not by asking people what they mean by intelligence but rather by having people perform tasks alleged to require intelligence and then analyzing the way in which people perform. There are several different kinds of explicit theories.

1.2. Psychometric Theories

Psychometric theories have generally sought to understand the structure of intelligence: What form does it take, and what are its parts (if any)? Such theories have

generally been based on and tested by the use of data obtained from tests of mental abilities. These tests include items such as vocabulary, completing series of numbers, seeing analogies between words, and visualizing what forms would look like if they were rotated in space.

The first of the major psychometric theories was that of the British psychologist Charles E. Spearman. In a 1904 article, Spearman argued that just two kinds of factors underlie all individual differences in test scores. Spearman called the first and more important kind of factor the "general factor" or *g*. It was said to pervade performance on all tasks requiring intelligence. The second kind of factor was specific to each test. But what exactly is *g*? In 1927, Spearman proposed that it might be something he labeled "mental energy."

An American psychologist, L. L. Thurstone, suggested instead that seven factors, or "primary mental abilities," pervade test performance: verbal comprehension (knowledge of vocabulary and in reading), verbal fluency (writing and producing words), number (solving simple arithmetical computation and reasoning problems), spatial visualization (mentally visualizing and manipulating objects), inductive reasoning (completing a number series or predicting the future based on past experience), memory (remembering people's names or faces), and perceptual speed (rapidly proofreading to discover typographical errors in a typed text).

Other psychologists, including Raymond B. Cattell and John B. Carroll, suggested that abilities are hierarchical. At the top of the hierarchy is *g* or general ability. But below *g* in the hierarchy are successive levels of gradually narrowing abilities, ending with Spearman's specific abilities.

Cattell suggested that general ability can be divided into two broad kinds of abilities: fluid and crystallized. Fluid abilities are the reasoning and problem-solving abilities measured by tests such as the analogies, classifications, and series completions. Crystallized abilities can be said to derive from fluid abilities and are viewed as their products, which would include vocabulary, general information, and knowledge about specific fields. John L. Horn suggested that crystallized ability more or less increases over the life span, whereas fluid ability increases during the earlier years and decreases during the later years.

Carroll proposed a "three-stratum" model of intelligence that is considered by some to be the most definitive psychometric model of intelligence because it is based on reanalysis of hundreds of data sets. According to this model, general ability is at the top of a hierarchy

of abilities. At the next lower stratum are various broad abilities such as learning and memory processes and the effortless production of many ideas. At the bottom of the hierarchy are many narrow specific abilities such as spelling ability and reasoning speed.

J. P. Guilford, an American psychologist, proposed a “structure of intellect” theory that, in its earlier versions, postulated 120 abilities. For example, in an influential 1967 work, Guilford argued that abilities can be divided into five kinds of operations, four kinds of contents, and six kinds of products. These various facets of intelligence combine multiplicatively for a total of $5 \times 4 \times 6$ or 120 separate abilities. An example of such an ability would be cognition (operation) of semantic (content) relations (product), which would be involved in recognizing the relation between lawyer and client in the following analogy problem: lawyer: client: doctor:?. In 1984, Guilford increased the number of abilities proposed by his theory, raising the total to 150.

1.3. Cognitive Theories

In a 1957 address to the American Psychological Association, Lee J. Cronbach proposed that psychologists unite the “two disciplines of scientific psychology”—experimental and differential (i.e., the study of individual differences). His proposal led to cognitive theories of intelligence that are derived by experimental means.

Underlying most cognitive approaches to intelligence is the assumption that intelligence is composed of a set of mental representations (e.g., propositions, images) of information and a set of mental processes that can operate on the representations. A more intelligent person is assumed to mentally represent information better, and also to operate more quickly on these representations, compared with a less intelligent person.

In 1973, Earl B. Hunt, Nancy Frost, and Clifford E. Lunneborg showed that a critical ability underlying verbal intelligence is that of rapidly retrieving lexical information, such as letter names, from memory. A few years later, Sternberg identified key mental processes alleged to underlie many cognitive tasks, especially ones involving inductive reasoning. They included encoding stimuli, inferring relations between stimuli, and applying what one has learned.

Ian Deary and colleagues have sought to understand intelligence through the study of inspection time. They have found that more intelligent individuals can discriminate the lengths of the lines with less stimulus duration (inspection) times than can less intelligent individuals.

Two leaders in the field of cognitive psychology, Allen Newell and Herbert A. Simon, used computers to model intelligence. The underlying idea is that computers can, in some sense, show a kind of intelligence similar to that shown by humans. During the late 1950s and early 1960s, they worked with a computer expert, Clifford Shaw, to construct a computer model of human problem solving. Called the “General Problem Solver,” it could solve a wide range of fairly structured problems such as logical proofs and mathematical word problems. In 1972, Newell and Simon proposed a general theory of problem solving, much of which was implemented on the computer. It involved heuristics such as means–ends analysis, whereby at each step of problem solving, one seeks to reduce as much as possible the distance between the solution and where one is in the problem.

More recently, Marcel Just and Patricia Carpenter showed that complex intelligence test items, such as figural matrix problems involving reasoning with geometric shapes, could be solved by a computer program at a level of accuracy comparable to that of human test takers.

The models described heretofore are serial-processing models, whereby the computers take steps in sequence. David E. Rumelhart and Jay L. McClelland proposed what they called “parallel distributed processing” models of the mind. These models postulated that many types of information processing occur at once rather than just one at a time.

1.4. Cognitive–Contextual Theories

Cognitive–contextual theories deal with the way in which cognitive processes operate in various environmental contexts. Two of the major theories of this type were proposed by Howard Gardner and Sternberg.

In 1983, Gardner proposed a theory of what he called “multiple intelligences.” In the 1999 version of the theory, the multiple intelligences include (at a minimum) linguistic, logical–mathematical, spatial, musical, bodily–kinesthetic, naturalist, interpersonal, and intrapersonal intelligences. Gardner also speculated as to the existence of an existential intelligence.

An alternative theory that also takes into account both cognition and context is Sternberg’s “triarchic” theory of successful intelligence. According to Sternberg, intelligence is the ability to succeed according to one’s own definition of success within one’s sociocultural context. People succeed by recognizing and capitalizing on strengths and by recognizing and either compensating for or correcting weaknesses. Intelligence has three

aspects. These aspects relate intelligence to what goes on internally within a person, to what goes on in the external world, and to experience that mediates between the internal and external worlds.

The first aspect is the set of cognitive processes and representations that form the core of all thought. Sternberg distinguished among three kinds of processes: those involved in deciding what to do and later in deciding how well it was done, those involved in doing what one had decided to do, and those involved in learning how to do it in the first place. The second aspect is the application of these processes to the external world. According to Sternberg, mental processes serve three functions in the everyday world: adapting to existing environments, shaping existing environments into new ones, and selecting new environments when old ones prove to be unsatisfactory. According to the theory, more intelligent persons not only can execute many cognitive processes quickly or well but also know what their strengths and weaknesses are and capitalize on the strengths while remedying or compensating for the weaknesses. More intelligent persons, then, find a niche in which they can operate most efficiently.

The third aspect of Sternberg's triarchic theory is the integration of the internal and external worlds through experience. One measure of intelligence is the ability to cope with relatively novel situations. The abilities to cope with relative novelty and to automatize cognitive processing are seen as interrelated; the more a person is able to automatize the tasks of daily life, the more mental resources there are left to cope with novelty.

In 1990, Peter Salovey and John Mayer proposed the construct of emotional intelligence. This construct was then popularized by Daniel Goleman in a 1995 book. Emotional intelligence is the ability to perceive accurately, appraise, and express emotion; the ability to access and/or generate feelings when they facilitate thought; the ability to understand emotion and emotional knowledge; and the ability to regulate emotions to promote emotional and intellectual growth. Several tests are now available to measure emotional intelligence. They generally show modest to moderate correlations with conventional tests of intelligence.

1.5. Biological Theories

Biological theories are based in the neuropsychological functioning that produces, at least in part, intelligent behavior. Several biological approaches have been used. One approach has been the investigation of types of intellectual performance as related to the regions of

the brain from which they originate. A researcher in this area, Jerre Levy, found that the left hemisphere is superior in analytical functioning, with the use of language being a prime example. The right hemisphere is superior in many forms of visual and spatial performance, and its functioning tends to be more synthetic and holistic, compared with the left hemisphere.

A second approach to research has involved the use of brain wave recordings to study the relation between these waves and either performance on ability tests or performance in various kinds of cognitive tasks. Researchers have found a relationship between certain aspects of electroencephalogram (EEG) and event-related potential (ERP) waves and scores on standard psychometric tests of intelligence.

A third approach involves the measurement of blood flow in the brain, which is a fairly direct indicator of functional activity in brain tissue. In such studies, the amount and location of blood flow in the brain is monitored while participants perform cognitive tasks. Horn found that older adults show decreased blood flow to the brain relative to younger adults. He also found that such decreases are greater in some areas of the brain than in others and that the decreases are particularly notable in those areas that are responsible for close concentration, spontaneous alertness, and the encoding of new information. Using positron emission tomography (PET), Richard Haier discovered that people who perform better on conventional tests of intelligence often show less activation in relevant portions of the brain than do those who do not perform as well. Presumably, this pattern of results reflects the fact that the better performers find the tasks to be easier and, thus, invoke less effort than do the poorer performers.

2. DEVELOPMENT OF INTELLIGENCE

There have been diverse approaches to studying the development of intelligence. Psychometric theorists, for instance, have sought to understand how intelligence develops in terms of changes in the factors of intelligence over time and changes in the amounts of the various abilities that children have. For example, the concept of mental age was popular during the first half of the 20th century. A given mental age was believed to represent an average child's level of mental functioning for a given chronological age. Thus, an average 10-year-old would have a mental age of 10 years, but an above-average

8-year-old or a below-average 12-year-old might also have a mental age of 10 years. The concept of mental age has fallen into disfavor, however, and is now used only rarely. The concept does not work well over a chronological age of roughly 16 years, and its assumption of perfectly smooth continuous mental development is questionable.

2.1. Piaget's Theories on Intelligence

Jean Piaget, a Swiss psychologist, suggested that the child explores the world, observes regularities, and makes generalizations much as a scientist does. Two fundamental cognitive processes, assimilation and accommodation, are alleged to work in somewhat reciprocal fashion. Assimilation involves incorporating new information into an already existing cognitive structure. Accommodation involves revising or adapting a cognitive structure to incorporate new information. Cognitive development, according to Piaget, represents a dynamic equilibrium between these two processes of assimilation and accommodation.

Piaget also postulated that there are four major periods in intellectual development: sensorimotor, preoperational, concrete–operational, and formal–operational. The first, the sensorimotor period, extends from birth until roughly 2 years of age. During this period, the child learns how to modify reflexes to make them more adaptive, to coordinate actions, to retrieve hidden objects, and (eventually) to begin representing information mentally. The second period, the preoperational period, is from approximately 2 to 7 years of age. During this period, the child experiences the growth of language and mental imagery. The child also learns to focus on single perceptual dimensions such as colors and shapes. The third period, the concrete–operational period, is from approximately 7 to 12 years of age. During this period, the child develops an important set of skills that are referred to as conservation skills. The child will recognize that substances stay the same in amount, regardless of their form. Finally, children emerge into the fourth period, the formal–operational period, which begins at approximately 12 years of age and continues throughout life. The formal–operational child develops thinking skills in all logical combinations and learns to think with abstract concepts.

2.2. Post-Piagetian Theories

Later, so-called “post-Piagetian” theories of intellectual development, which have been heavily influenced by

Piaget (although they have substantially departed from his ideas), have taken several courses. One has been to expand on Piaget's work by suggesting a possible fifth (adult) period of development such as problem finding. A second course has been to suggest periods of development related to, but different from, those suggested by Piaget. A third course has been to accept that intellectual development occurs through the periods that Piaget proposed but to hold that the cognitive bases of development differ from those recognized by him. Some of these theories emphasize the importance of memory or knowledge rather than reasoning capacity.

2.3. Vygotsky's Theories on Intelligence

Lev S. Vygotsky, a Soviet psychologist, suggested that intellectual development may be largely influenced by a child's interactions with others. That is, a child sees others thinking and acting in certain ways and then internalizes and models what is seen. Vygotsky also proposed the notion of a zone of proximal development (ZPD), which is the range of ability between what a person can do on his or her own versus what the person can do with socially derived guidance. The zone is not directly observable but may be detected by providing a context in which the individual can perform both with and without guidance. The ZPD is sometimes termed the zone of potential development.

3. MEASURING INTELLIGENCE

3.1. Early Historical Background

In 1859, the publication of Charles Darwin's *The Origin of Species* had a profound effect on many lines of scientific work. Darwin suggested that the capabilities of humans are, in some sense, continuous with those of lower animals. Hence, they can be understood through scientific investigation. One person who was strongly influenced by Darwin's thinking was Sir Francis Galton, Darwin's cousin. For 7 years, between 1884 and 1890, Galton maintained a laboratory at the South Kensington Museum in London. For a small fee, visitors could have themselves measured on a variety of psychophysical tasks. These tasks included weight discrimination and sensitivity to musical pitch. Galton believed that these tests measured more than just psychophysical abilities. He believed that psychophysical abilities are the basis of intelligence and, hence,

that his tasks were measures of intelligence. Therefore, Galton's intelligence test required a person to perform simple tasks such as deciding which of two weights was heavier and showing how forcefully the person could squeeze his or her hand. The Galtonian tradition was taken to the United States by the psychologist James McKeen Cattell.

3.2. The IQ Test

A more influential tradition of mental testing was developed in France by Alfred Binet and his collaborator, Theodore Simon. In 1904, the minister of public instruction in Paris named a commission to study or create tests that would ensure that mentally retarded children received an adequate education. The minister was also concerned that certain children were being placed in classes for the retarded not because they were retarded but because they had behavioral problems and teachers did not want them in their classrooms. Binet and Simon proposed that tests of intelligence should measure skills such as judgment, comprehension, and reasoning—the same kinds of skills measured on most intelligence tests today. Binet's early test was taken to the United States by a Stanford University psychologist, Terman, whose version came to be called the Stanford–Binet test. This test has been revised frequently and continues in use.

The Stanford–Binet test and others like it have traditionally yielded, at the very least, an overall score referred to as an intelligence quotient (IQ). In its most recent form, this test yields an overall IQ and other scores as well, as does the Wechsler Adult Intelligence Scale (WAIS) and the Wechsler Intelligence Scale for Children (WISC).

More recent tests of intelligence have expanded the range of abilities tested. For example, in 1997, J. P. Das and Jack Naglieri produced a test, the Cognitive Assessment System, based on a theory of intelligence first proposed by a Russian psychologist, Alexander Luria. The test measures planning abilities, attentional abilities, and simultaneous and successive processing abilities.

IQ was originally computed as the ratio of mental age to chronological (physical) age multiplied by 100. Thus, it is sometimes referred to as a ratio IQ. For example, if an 8-year-old child had a mental age of 10 years (i.e., performed on the test at the level of an average 10-year-old), the child would be assigned an IQ of $(10/8) \times 100$ or 125. If the 8-year-old had a mental age of 6 years, the child's IQ would be $(6/8) \times 100$ or 75. A score of 100, whereby the mental age equals the chronological age, would be average.

As discussed previously, the concept of mental age has fallen into disrepute, and few tests continue to involve the computation of mental ages. Many tests still yield an IQ, but it is most often computed on the basis of statistical distributions. The scores are assigned on the basis of what percentage of people in a given group would be expected to have a certain IQ. Scores computed in this way are called deviation IQs.

3.3. The Distribution of IQ Scores

Intelligence test scores follow an approximately normal distribution, meaning that most people score near the middle of the distribution of scores. Scores drop off fairly rapidly in frequency in either direction from the center of the distribution. For example, on the IQ scale, approximately two-thirds of all scores fall between IQs of 85 and 115 and approximately 95% of all scores fall between IQs of 70 and 130. Put another way, only 1 of 20 scores differs from the average IQ (100) by more than 30 points.

It has been common to associate certain levels of IQ with labels. For example, at the upper end, the label “gifted” is sometimes assigned to people with IQs over a certain point such as 130. At the lower end, mental retardation has been classified into various degrees depending on IQ so that, for example, IQs of 70 to 84 have been classified as borderline retarded, IQs of 55 to 69 as mildly retarded, IQs of 40 to 54 as moderately retarded, IQs of 25 to 39 as severely retarded, and IQs below 25 as profoundly retarded.

Many psychologists now believe that IQ represents only a part of intelligence and that intelligence is only one factor in both mental retardation and giftedness. Most current definitions of mental retardation stress adaptive skills as well as IQ, and they also emphasize attributes such as creativity, motivation, and achievement in conceptions of giftedness.

4. THE HERITABILITY AND MALLEABILITY OF INTELLIGENCE

Historically, intelligence has been viewed as a more or less fixed trait. This view conceives of intelligence as something with which people are born. Thus, the function of development is to allow this genetic endowment to express itself. A number of investigators have suggested that intelligence is highly heritable and that it is transmitted through the genes. Heritability is here

defined as the proportion of individual differences variance that is genetically transmitted. Other investigators believe that intelligence is only minimally heritable, if at all. Most authorities take an intermediate position. However, all agree that heritability operates within a reaction range, meaning that a given genotype for intelligence can result in a wide range of phenotypes, depending on how environmental factors interact with genetic ones.

Several methods are used to assess the heritability of intelligence. Perhaps the most well known is the study of identical twins reared apart. For a variety of reasons, identical twins are occasionally separated at or near birth. If the twins are raised apart, and if it is assumed that when the twins are separated they are randomly distributed across environments (often a dubious assumption), the twins would heritability have in common all of their genes but none of their environment except for chance environmental overlap. As a result, the correlation between their performances on tests of intelligence can provide an estimate of the proportion of variation in test scores due to heredity. Another method of computing the hereditary effect on intelligence involves comparing the relationship between intelligence test scores of identical twins and those of fraternal twins.

It appears that roughly half of the variation in intelligence test scores is caused by hereditary influences. However, Robert Plomin and others have shown that the heritability of intelligence increases with age, suggesting that genetic factors become more important and that environmental factors become less important to individual differences in intelligence with increasing age. During adulthood, heritability may reach as high as 70% or more. The estimates are computed, for the most part, on the basis of intelligence test scores, so that the estimates are only for that part of intelligence measured by the tests.

Whatever the heritability factor of IQ, an entirely separate issue is whether intelligence can be increased. Work by a New Zealand researcher, James Flynn, has shown that scores on intelligence tests rose rather steadily throughout the world during the mid- and late 20th century. The precise reason for the increase is unknown, although speculations include better education, better nutrition, and advances in technology.

Despite the general increase in scores, average IQs continue to vary both across countries and across socioeconomic groups. For example, many researchers have found a positive correlation between socioeconomic status and IQ, although they disagree over the reason for the relationship. Most psychologists agree that

differences in educational opportunities play an important role, and some investigators believe that there is a hereditary basis for the difference as well. But there is simply no broad consensus on the issue of why the differences exist. Again, the differences are based on IQ, not broadly defined intelligence.

No matter how heritable intelligence is, some aspects of it are still malleable. Heritability of a trait is a separate issue from malleability of the trait. For example, height is highly heritable but also highly modifiable by nutrition and other environmental factors. Thus, with intervention, even a highly heritable trait can be modified. There is a growing body of evidence that aspects of intelligence can be modified as well. In the view of many psychologists, intelligence is not merely a fixed trait. A program of training in intellectual skills can increase some aspects of a person's level of intelligence. No training program—no environmental condition of any sort—is likely to make a genius of a person with low measured intelligence. But some gains are possible, and a number of programs have been developed for increasing intellectual skills. A main trend for psychologists working in the intelligence field has been to combine testing and training functions so as to enable people to optimize their intelligence.

GLOSSARY

attitude One's overall feeling of favorableness or unfavorableness with respect to a given object or action.

behavior A directly observable action performed with respect to some target, in some context, at some point in time.

behavioral categories Broad categories of behavior (e.g., prejudice, exercising, dieting) that are inferred from the observation of one or more behaviors.

behavioral intention A readiness to engage in a particular behavior.

behavioral norm One's perception of whether important others are (or are not) performing a given behavior.

correspondence The principle that measures of behavioral determinants and behavior involve exactly the same action, target, context, and time elements.

goals Desired conditions, occurrences, or states that may be outcomes of performing one or more behaviors (e.g., losing weight, staying healthy, getting an A on an exam).

meta-analysis A statistical procedure to quantify and summarize results from a number of different studies.

self-efficacy One's perception that he or she can perform a given behavior, even in the face of various obstacles.

subjective norm One's perception of what important others think he or she should (or should not) do.

Although it has been argued that many behaviors are performed automatically, without reflection on or awareness of intention, it would be hard to argue that most behaviors of interest to an applied psychologist are either automatic or habitual. In fact, most people can quickly and easily report the likelihood that they will or will not perform given behaviors, and when these measures of intention (or self-prediction) are assessed appropriately, they are highly related to actual behavioral performance.

1. DEFINING BEHAVIOR

Although behavior is often taken as a given, it is important to distinguish among behaviors, behavioral categories, and goals. All too often, investigators fail to distinguish between behaviors per se and occurrences that may be the outcome of those behaviors. For example, weight loss and success (or failure) on an exam have often been used as behavioral criteria. Unfortunately, neither of these is a behavior. Success on an exam is a possible outcome of specific actions

such as attending lectures, reading books, memorizing materials, and even copying answers from another person's test paper. Another problem is that investigators often treat inferences from behaviors as if they themselves were behaviors. For example, aggression, discrimination, dieting, and exercising have often been viewed as behavioral criteria. Unfortunately, none of these is a directly observable behavior. Instead, these are broad behavioral categories that are inferred from the observation of one or more behaviors. That is, although it is possible to observe specific actions that are assumed to be instances of a general class or category of behavior, the category per se cannot be directly observed. Thus, knowing that someone was "exercising," for example, might reveal very little about the specific "exercise" behaviors that the person did (or did not) perform.

In contrast to goals (or outcomes) and behavioral categories, behaviors are directly observable actions. Note, however, that the direct observation of any behavior always occurs in a given context at a given point in time. This implies that both context and time should be included in the definition of a behavior. Moreover, because most actions are directed at some object or target, a behavioral definition should involve four elements: the action (e.g., enlisting, buying, using), the target (e.g., the army, cigarettes, condoms), the context (e.g., after graduating high school, at the supermarket, for vaginal sex with one's spouse), and the time (e.g., yesterday, during the past month). Clearly, a change in any one of the elements changes the behavior under consideration. For example, enlisting in the army is a different behavior from enlisting in the navy (a change in target), using a condom for vaginal sex with one's spouse is a different behavior from using a condom for vaginal sex with a new partner (a change in context), and asking someone whether he or she purchased a car during the past 3 months is assessing a different behavior from asking whether someone purchased a car during the past 2 years.

Although all four elements should be considered in arriving at one's behavioral criterion, the level of specificity or generality used to define each element should be determined by the substantive questions being asked. Thus, a behavior may be assessed at a fairly general level (e.g., people could be asked whether they have ever [time] purchased [action] cigarettes [targets] [context unspecified]) or at a more specific level (e.g., people could be asked whether they had purchased [action] Marlboro Light 100s [target] from

their local supermarket [context] during the past 2 weeks [time]).

2. DEFINING INTENTIONS

Intentions can be conceptualized as a readiness to engage in a particular behavior. This readiness to act can be assessed by asking people to indicate the extent to which they agree (or disagree) with statements such as "I will engage in the behavior," "I intend to engage in the behavior," "I expect to engage in the behavior," "I am willing to engage in the behavior," and "I will try to engage in the behavior." A number of investigators, however, have proposed that some of these items assess distinct constructs. For example, it has been suggested that it is important to distinguish between intention and behavioral expectation. More specifically, it was hypothesized that behavioral expectations are better predictors of behavior than are behavioral intentions because the former are more likely to take into account possible impediments to performance of the behavior. Thus, items such as "I intend to . . .," "I will try to . . .," and "I plan to . . ." have been used to assess intentions and items such as "I expect to . . ." and "I will . . ." to assess behavioral expectations. Available evidence to date suggests that there is little to be gained by this proposed distinction. For example, a meta-analysis of a broad set of behaviors found no difference in the predictive validity of expectations and intentions. Thus, this article uses the term "behavioral intention" to refer to measures that assess one's readiness to engage in a specific behavior. In addition, it should be noted that people may also form intentions to engage in a behavioral category (e.g., to exercise) or to pursue some goal (e.g., to lose weight).

3. INTENTIONS AS PREDICTORS OF BEHAVIOR

Empirical research over the past three decades or so has led to the recognition that behaviors can be predicted with considerable accuracy by appropriately assessing intentions to engage in the behaviors under consideration. For a measure of intention to correlate closely with behavior, the intention measure must involve exactly the same elements as does the behavior itself.

3.1. The Principle of Correspondence

The requirement that measures of intention and behavior involve exactly the same action, target, context, and time elements is known as the principle of correspondence or compatibility. The principle of correspondence is sometimes misunderstood to mean that intentions and behaviors should always be defined and measured at a very specific level. In reality, the principle simply suggests that the two variables—intention and behavior—should be measured at equivalent levels of generality or specificity. If, for whatever reason, investigators are interested in a very specific behavior performed in a particular context and at a given point in time, the intention should be assessed at that same level of specificity. However, investigators might not be interested in a particular context or time, and they can generalize across these elements in their measures of behavior and in their measures of intention. To the extent that the assessments of intention and behavior comply with the principle of correspondence, they should correlate highly with each other.

Many studies have substantiated the predictive validity of behavioral intentions. When measured appropriately, behavioral intentions account for an appreciable proportion of variance in actual behavior. Meta-analyses covering diverse behavioral domains have reported mean intention–behavior correlations ranging from .45 to .62. Studies in specific behavioral domains, such as condom use and exercise, have produced similar results, with intention–behavior correlations ranging from .44 to .56. A meta-analysis of these and other meta-analyses reported an overall correlation of .53 between intention and behavior.

Thus, there is considerable evidence that the performance or nonperformance of a given behavior is determined primarily by the strength of a person's intention to perform (or to not perform) that behavior, where intention is defined as the subjective likelihood that one will perform (or try to perform) the behavior in question. In contrast to the strong relationship between behavioral intention and behavior, however, intentions to reach goals and intentions to engage in behavioral categories might not provide very good prediction of goal attainment or the performance of a specific behavior within the behavioral category. In the latter case, the problem is largely methodological and in many ways is nothing more than a case of failure to obtain correspondence. That is, people are asked their intentions to engage in a class of behaviors (e.g., to diet

or exercise), but the behavioral criterion is a measure of whether they have or have not performed one or more specific behaviors that are assumed to be a good indicant of the category. With respect to goal attainment, it should be clear that achieving a goal often requires more than a behavioral performance on the part of an individual. Achieving a goal often depends on the decisions or actions of other people or on the occurrence of certain events. To put this somewhat differently, goal (or outcome) attainment is often not completely under an individual's control, and the less control one has over attaining some goal, the lower the intention–goal attainment relation. In the same sense, one could argue that the less a given behavior is under one's control, the lower the intention–behavior relationship. Fortunately, as pointed out earlier, most human behaviors (and certainly most that are of interest to an applied psychologist) are under volitional control. Nevertheless, people do not always act in accordance with their intentions.

4. MODERATORS OF THE INTENTION–BEHAVIOR RELATION

Perhaps the two major factors that prevent one from acting on his or her intentions are (a) a lack of necessary skills and abilities and (b) the presence of environmental constraints (or the absence of environmental facilitators). Other factors may also account for observed low intention–behavior relations. As discussed previously, low correlations may be due to a lack of correspondence between the measures of intention and behavior. In addition, intentions may change over time; the longer the time interval between the assessment of intention and the assessment of behavior, the greater the likelihood that the intention will change. This implies that the longer the interval between the assessment of intention and the observation of behavior, the lower the intention–behavior correlation.

5. AN INTEGRATED THEORETICAL MODEL

Although there are many theories of behavioral prediction and behavior change in the literature (e.g., the theory of planned behavior, the theory of subjective culture and interpersonal relations, the transtheoretical

model of behavior change, the information/motivation/behavioral skills model, the health belief model, social cognitive theory, the theory of reasoned action), a careful consideration of these theories suggests that there are only a limited number of variables that need to be considered in predicting and understanding any given behavior.

5.1. Attitudes, Perceived Norms, and Self-Efficacy

In general, one can identify three factors that may directly influence an individual's intentions and behaviors: (a) the individual's attitude toward performing the behavior (i.e., the person's overall positive or negative feelings of favorableness or unfavorableness with respect to performing the behavior) that is based on the person's beliefs that performing the behavior will lead to various positive or negative consequences (or outcomes), (b) perceived normative pressure that includes the perception that the individual's important others think that one should (or should not) perform the behavior in question as well as the perception that these important others are (or are not) themselves performing the behavior, and (c) self-

efficacy or personal agency that involves the individual's perception that he or she can perform the behavior in question under a variety of difficult or challenging circumstances. These and other considerations suggest the following integrative model of behavioral prediction (Fig. 1).

6. DETERMINANTS OF BEHAVIOR

In Fig. 1, it can be seen that any given behavior is most likely to occur if one has a strong intention to perform the behavior, if one has the necessary skills and abilities required to perform the behavior, and if there are no environmental constraints preventing behavioral performance. Indeed, if one has made a strong commitment (or has formed a strong intention) to perform a given behavior, if one has the necessary skills and abilities to perform the behavior, and if there are no environmental constraints to prevent the performance of that behavior, the probability is very high that the behavior will be performed.

In some populations or cultures, the behavior might not be performed because people have not yet formed intentions to perform the behavior. In other populations,

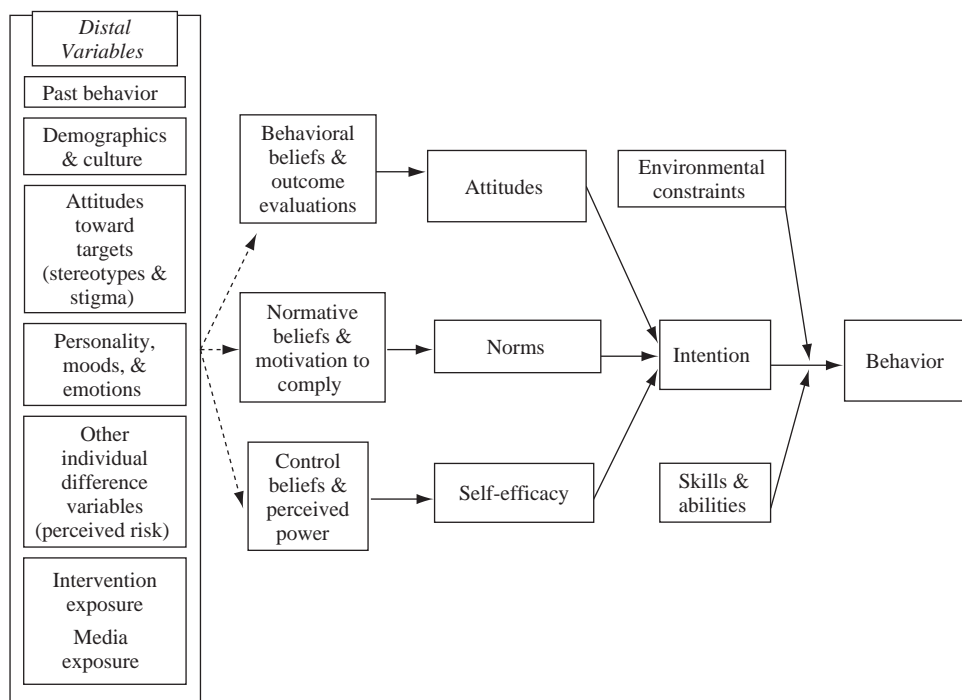

FIGURE 1 An integrative model of behavioral prediction.

the problem might be a lack of skills and/or the presence of environmental constraints. In still other populations, more than one of these factors may be relevant. Clearly, if people have formed intentions but are not acting on them, behavioral performance will depend on enhancing their skills and abilities or on removing (or learning to overcome) environmental constraints.

7. DETERMINANTS OF INTENTION

On the other hand, if strong intentions to perform the behavior in question have not been formed, the model suggests that there are three primary determinants of intention: the attitude toward performing the behavior, perceived norms concerning performance of the behavior, and one's self-efficacy with respect to performing the behavior. It is important to recognize that the relative importance of these three psychosocial variables as determinants of intention will also depend on both the behavior and the population being considered. For example, one behavior may be determined primarily by attitudinal considerations, whereas another behavior may be influenced primarily by feelings of self-efficacy. Similarly, a behavior that is attitudinally driven in one population or culture may be normatively driven in another population or culture. Thus, to understand intentional behavior, it is important to first determine the degree to which that intention is under attitudinal, normative, or self-efficacy control in the population in question.

8. DETERMINANTS OF ATTITUDES, NORMS, AND SELF-EFFICACY

The model in Fig. 1 also recognizes that attitudes, perceived norms, and self-efficacy are themselves functions of underlying beliefs—about the outcomes of performing the behavior in question, about the normative proscriptions and/or behaviors of specific referents, and about specific barriers to behavioral performance. Thus, the more one believes that performing the behavior in question will lead to “good” outcomes and prevent “bad” outcomes, the more favorable one's attitude toward performing the behavior should be. Similarly, the more one believes that specific others are performing the behavior and/or the more these others think that one should (or should not) perform the behavior in question, the more social pressure one will feel with respect to performing (or not

performing) the behavior. Finally, the more one perceives that he or she can (i.e., has the necessary skills and abilities to) perform the behavior even in the face of specific barriers or obstacles, the stronger one's self-efficacy will be with respect to performing the behavior.

It is at this level of underlying beliefs that the substantive uniqueness of each behavior comes into play. Clearly, a change in any one element in the behavioral definition will usually lead to very different beliefs about the consequences of performing that behavior, about the expectations of relevant others, and about the barriers that may impede behavioral performance and, thus, will usually lead to very different attitudes, subjective norms, and perceptions of self-efficacy and intentions. For example, the barriers to, and the outcomes (or consequences) of, always using a condom for vaginal sex with an occasional partner may be very different from those associated with always using a condom for vaginal sex with one's spouse. Yet it is these specific beliefs that must be considered if one wishes to fully understand intentions and behavior. Although an investigator can sit in her or his office and develop measures of attitudes, perceived norms, and self-efficacy, the investigator cannot know what a given population (or a given person) believes about performing a given behavior. Thus, one must go to members of that population to identify salient outcome, normative, and efficacy beliefs. To put this somewhat differently, one must understand the behavior from the perspective of the population that one is considering.

9. THE ROLE OF DISTAL VARIABLES

Finally, Fig. 1 also shows the role played by more traditional demographic, economic, personality, attitudinal, and other individual difference variables (e.g., perceived risk, sensation seeking). Although it is clear that these types of variables may often be important determinants of a given behavior, the model suggests that these types of variables play primarily an indirect role in influencing behavior. That is, these “background” factors may or may not influence the behavioral, normative, or self-efficacy beliefs underlying attitudes, norms, or self-efficacy. For example, although men and women may hold different beliefs about performing some behaviors, they may hold very similar beliefs with respect to performing other behaviors. Similarly, rich and poor, old and young, those from developing countries and those from developed countries, those who plan to go to college and those

who do not, those with favorable attitudes toward law enforcement and those with unfavorable attitudes toward law enforcement, those who are happy and those who are sad or angry, those who have used drugs and those who have not—all may hold different attitudinal, normative, or self-efficacy beliefs with respect to one behavior but may hold similar beliefs with respect to another behavior. In other words, there is no necessary relation between these “distal” or “background” variables and any given behavior. Nevertheless, distal variables, such as cultural and personality differences, moods and emotions, and differences in a wide range of values, should be reflected in the underlying belief structure.

10. CONCLUSION

In general, most human behavior is intentional; that is, people typically perform behaviors that they intend (or plan) to perform, and they do not perform behaviors they do not intend to perform. In addition, they usually intend to perform (or not perform) a behavior for one or more of three reasons: they think that performing the behavior is a “good” thing to do, they feel strong social pressure to perform the behavior, or they believe that they have the necessary skills and abilities to perform the behavior. These attitudes, perceived norms (or social pressure), and feelings of efficacy are themselves determined by underlying beliefs—about the expected outcomes of performing the behavior, about the expectations and behaviors of others, and about their ability to overcome specific barriers that could impede behavioral performance. The full understanding of the performance or nonperformance of a given behavior ultimately rests on understanding which of these underlying beliefs is (are) responsible for the performance or nonperformance of that behavior.

GLOSSARY

contact hypothesis A theoretical framework that assumes that intergroup relations can, under certain conditions, be improved by increasing intergroup contact.

cultural distance Cultural differences between two groups; the more different the languages, family structures, religion, standard of living, and values of the two groups, the greater the cultural distance between them.

discrimination Unequal treatment of members of a social group on unacceptable grounds (e.g., ethnic/cultural origin, language, religion, skin color).

immigrants Persons of foreign nationality moving to a country for the purpose of staying there; in time, they may form new ethnic groups in the society of settlement.

minority groups Social groups in a numerical minority in the society; numerical inferiority is often combined with low status, but there are also high-status minorities.

prejudice Negative stereotypical beliefs about a social group combined with negative feelings toward that group.

social identity Those aspects of an individual's self-image that derive from the social categories to which the individual perceives himself or herself as belonging; these

aspects contribute positively or negatively to the individual's self-esteem.

stereotyping A generalizing view of a social group that ignores individual differences among the group members.

Intergroup relations have traditionally been studied by social psychologists, whereas intercultural relations have traditionally been studied by cross-cultural psychologists. All humans can fall prey to stereotyping, discrimination, and racism, but culture determines acceptable levels of expressed bias. Collective representations about the past influence current intergroup relations. Minority members have differing attitudes about retaining their culture of origin and becoming part of the mainstream society. These attitudes interact with those of the majority population and with official minority policies. The most harmonious intergroup relations are predicted when both majority and minority members share integration, assimilation, or individualist orientations. Explicit outgroup attitudes and stereotyping operate in a conscious mode, but there are also attitudes and stereotypes that function in an unconscious fashion. The translation of prejudiced beliefs (stereotypes) and evaluations (attitudes) into action (discrimination) depends on both personal and social factors. Thus, both individual and intergroup approaches can make important contributions to the reduction of intergroup bias. Interventions used for reducing bias usually focus on the need to increase the quantity and enhance the quality of intergroup contact. Some interventions can be effective

under particular contact conditions, whereas others may fail, particularly with respect to generalization from the individual out-group member to the out-group as a whole and to finding an intervention that works for both majority and minority groups.

1. IN THE CROSSROADS OF VARIOUS RESEARCH TRADITIONS

Issues on cultural pluralism or multiculturalism, ethnicity, and migration are hotly debated in many countries. These issues pose many political, legal, social, and economic questions. In addition, they raise many social psychological questions regarding acculturation, integration, stereotyping, “new” or “subtle” racism, ethnic identity, and intergroup relations. It is obvious that a clear understanding of intergroup relations can facilitate the processes of immigration, acculturation, and integration.

Intergroup relations have been studied mostly by social psychologists, whereas intercultural relations have been studied mostly by cross-cultural psychologists, but traditionally these two research traditions have largely tended to ignore each other. In addition, generations of researchers in the field of intergroup relations have alternated individual versus contextual levels of analysis, sometimes pushing them as far as they can go before collapsing under the accumulated complexity of evidence (pro and con) and forgetting the advantages of previous approaches. Individual difference approaches to stereotyping, prejudice, and racism all apparently emerge from U.S. researchers. Coupled with an explicit constitutional ideology of equality, the U.S. cultural focus on individualism places responsibility for bias on individuals and privileges individual autonomy over ethnic group identity. In Europe, the histories of intergroup encounters are centuries older. Coupled with the importance of linguistic, cultural, religious, and geographical boundaries, a lesser focus on individualism makes Europe the logical birthplace of more contextual approaches to intergroup relations.

Intergroup behavior can be defined as actions by members of one group toward members of another group. The most studied social psychological phenomenon related to intergroup relations is intergroup bias. Forms of intergroup bias range from prejudice and stereotyping (via discrimination, injustice, perpetuation of inequality, and oppression) to ethnic cleansing and genocide. Various forms of prejudice (i.e., the holding of derogatory attitudes

about members of a social group) are more common than outright manifestations of intergroup conflict. In practice, therefore, the vast majority of social psychological studies have investigated weaker forms of bias, as expressed by persons with relatively mild prejudice.

Within both social and cross-cultural psychology, it has been customary to look at social behavior from a perspective that reflects the predominantly individualist emphasis of many contemporary North American researchers. Research on intergroup relations, however, more often applies a perspective that still focuses on individual behavior but that takes group membership as the determinant of that behavior. The individualist approach sees group behavior as an aggregated result of the social cognitions and resultant behaviors of its members. The more contextual approach reverses this presumed causal chain of events in that the individual's identity and consequent behaviors are seen as defined by his or her group memberships. The principal theorists proposing this perspective have been Europeans, but the influence of their ideas is now widely diffused. Most researchers would probably agree that social psychology should be able to offer explanations of both individual and small group behavior. European researchers tend to include explanations at the level of intergroup relations and of society as a whole. It is through an emphasis on these more macroscopic levels of influence that recent European work has become distinctive.

However, social psychology has also been criticized for being traditionally more concerned with general processes and structures than with particular contents related to historical, cultural, and contextual circumstances. Consequently, the growing interest within social psychology in content, culture, and context is very welcome. Perceptions of history and common ancestry, as well as assumed cultural characteristics, play a central role in interethnic/intercultural relations. Many questions and problems in studying cultural features are discussed extensively in cross-cultural and cultural psychology. It is the contextual, rather than the individualist, approach to intergroup and intercultural relations that dominates the bulk of this article.

2. CULTURE: THE MISSING LINK IN INTERGROUP RELATIONS

2.1. What Is Culture?

Various aspects of the environment are more or less important for members of different cultures. Culture

has been defined in numerous ways. It can be seen as consisting of a set of human-made objective and subjective elements that in the past have increased the probability of survival and resulted in satisfaction for participants in an ecological niche and, thus, have become shared among those who could communicate with each other because they had a common language and they lived in the same time and place. Cultural differences can also be seen as being tied to historical experiences, some of which are based on socioeconomic stratification of a relatively recent nature and others of which are rooted in a distant path of which nobody is conscious. This historically older culture is sometimes called “deep culture” because it is embedded in language, ethnicity, religion, and/or nationality as such.

For the purpose of this article, culture is conceptualized as shared patterns of belief and feeling toward issues such as child-rearing practices, family systems, and ethical values or attitudes. These are elements of what Triandis has called “subjective culture” that is created in interactions among people. In this perspective, there are as many cultures as there are languages and ways of life within each language (e.g., physicians have a culture that is somewhat different from that of lawyers). Thus, culture can be viewed as a relatively stable and characteristic system of shared meanings that define or determine perceptions and behavior. This approach is typically taken when different ethnic groups are compared, especially within cross-cultural psychology. Changes are not denied, but a more long-term perspective is taken. More gradual changes are examined in research on acculturation that focuses on psychological and behavioral changes that an individual or group experiences as a result of sustained contact with members of another cultural group(s).

2.2. Culture in the Research on Intergroup Bias

The groups involved in intercultural encounters are mostly large-scale ethnic or cultural groups. Yet much of even the more contextual branch of social psychological research on intergroup relations concentrates mainly on status differences between groups. Although an exclusive social position perspective offers important insights into intergroup relations, there are limits to using such a perspective. History and culture are the two main ingredients of ethnicity. Ethnicity, in turn, is most often thought of as culture that is transmitted across generations.

All humans can fall prey to stereotyping, discrimination, and racism. At a more global level, however, little is known about individual differences in these phenomena. In some Asian cultures, which have a history of being more ethnically homogenous within nations and more collective in general, social psychologists rarely study individual variation in stereotyping and prejudice. Likewise, Latin American and African social psychologists still have much to say on this topic. However, the importance of cultural and local norms in predicting discriminatory behavior should not be underestimated. Culture channels stereotyping and prejudice by defining who constitutes “us” and who constitutes “them.” Culture also determines acceptable levels of expressed bias, from subtle to overt. In addition, cultures differ in norms for describing perceived differences between social categories as either inherent and traditional or unacceptable and controllable.

It must be acknowledged that the vast majority of research on intergroup issues, such as stereotyping, prejudice, and discrimination, is carried out in societies that are low on cultural measures of hierarchy, power distance, and conservatism. Such systems tolerate considerable public discussion about inequalities and their legitimacy. Given the egalitarianism of such societies—or at least their ideal of egalitarianism—one must be cautious in generalizing globally some of the psychological processes that have been identified by this research.

3. INTERCULTURAL CONTACT AS INTERPERSONAL ADJUSTMENT

3.1. Intercultural Relations and Sociocultural Adaptation

When groups of individuals having different cultures come into continuous firsthand contact with each other, the consequence is likely to be subsequent changes in the original cultural pattern of either group or both groups. This is how the process of so-called acculturation is traditionally defined. This process refers to groups in contact, thereby explicitly placing acculturation within the realm of intergroup relations. However, within cross-cultural psychology, theoretical frameworks in relation to the acculturation process have not been borrowed from social psychology; instead, they have been borrowed from different areas of mainstream psychology, notably the stress and coping literature, on the one hand, and research on social learning and skills acquisition, on the other.

In both perspectives, acculturation is nearly exclusively seen as an individual-level process of adjustment and adaptation to a new culture. As a consequence, the acculturation literature has dealt more with interpersonal relations than with intergroup relations.

Ward and colleagues have argued that adaptive outcomes of acculturation are meaningfully divided into psychological (emotional/affective) and sociocultural (behavioral) domains. The former has traditionally been the focus of study for the stress and coping framework, and the latter has traditionally been the focus of study for the social learning framework. Individuals who are exposed to acculturative demands are motivated to maintain psychological well-being as well as to acquire culturally appropriate knowledge and skills. Empirically, these dimensions are moderately and positively related. This interrelation is understandable given that successful social adaptation to a new culture arises in part from psychological well-being and leads to a feeling of greater self-efficacy. This, in turn, enhances psychological well-being and vice versa.

It is obvious that good social relations with members of the other cultural group are a vital part of sociocultural adaptation. The more different the languages, family structures, religion, standard of living, and values of the two groups, the greater the cultural distance between the groups. The greater the cultural distance, the more the norms are likely to be different and the more difficult it is for the two groups to develop good intergroup relations. Cultural distance results in perceived dissimilarity, which can lead to conflict if there are different goals and interests. Individuals confronting new environments with greater cultural dissimilarities in values will experience more difficulties with adaptation. A robust relationship has been consistently observed between cultural distance and sociocultural adjustment problems—the greater the cultural similarity, the less difficulties with adaptation. This outcome also holds for perceived degrees of cultural differences.

Scholars approaching the problem of cross-cultural adaptation from a skills perspective emphasize the role of culture-specific knowledge for sociocultural adaptation. Depending on which particular cultural groups are involved, people will need specific knowledge of the rules of interaction with their hosts. Knowledge about normative patterns of behavior in the new culture will then have to be put into practice. For example, in training programs, Arab nonverbal skills can be taught to normally “stand-offish” English persons, thereby enhancing the impressions they give to Arabs. Various types of cross-cultural training can be very effective,

although some persons will already have culturally fitting skills through personalities or previous cross-cultural experiences. Powerful effects of cross-cultural training have been demonstrated for several factors such as better interpersonal skills with members of the other cultural group and better understanding of the social system and values of the other cultural group.

One important skill worth identifying separately is language competence. Greater fluency in the language of the other cultural group greatly increases the likelihood of successful intercultural communication. Of course, because the vast majority of cultural sojourners or immigrants will have no access to any cross-cultural training programs, they will have to adapt as best as they can. It is here that broad personality dispositions and the intercultural attitudes of the individuals, on the one hand, and the specific social, cultural, and historical context of the encounter, on the other, will influence the ultimate outcome of the intercultural contact.

4. THE SOCIAL PSYCHOLOGY OF INTERGROUP BIAS

4.1. Individual- and Group-Level Explanations

A popular view of the origins of prejudice is that that it is primarily a personality problem. The most influential example of this type of theory was that proposed by Adorno and colleagues in 1950. Working from a Freudian perspective, they believed that a child's natural aggression toward his or her parents (an inevitable consequence of being subjected to constraints) was displaced onto alternative targets due to the feared consequences of displaying it directly. The likely choice of targets would be those seen as weaker than or inferior to the child such as members of deviant groups or ethnic minorities. The end result was the so-called authoritarian personality. The association between authoritarianism and various forms of prejudice has been confirmed in several intergroup contexts. Recent work points to a positive relationship between prejudice and right-wing authoritarianism (i.e., submitting to established authorities and adhering to social conventions).

A similar individual-level theory of prejudice is the so-called frustration-aggression theory, which implies that aggression is often not directed at the true source of the frustration people feel (e.g., the capitalist system that causes an economic recession); instead, it is often diverted onto vulnerable and easily accessible targets

such as members of minority groups. Attempts to confirm this so-called scapegoat theory of prejudice have, however, met with mixed success. It seems that absolute levels of hardship and frustration are less potent instigators of aggression than is a sense of relative deprivation, that is, a perceived discrepancy between what one has and what one feels entitled to have.

However, it is important to note the limitations of this kind of individual difference perspective. It underestimates the importance of current social situations shaping people's attitudes and tends to neglect sociocultural determinants of prejudice. For example, Pettigrew found during the 1950s that although White South Africans showed very high levels of anti-Black prejudice, they did not appear to have particularly high levels of authoritarianism as compared with populations in other countries. In addition, the personality approach cannot explain the widespread uniformity of prejudice in certain societies or subgroups within societies. In prewar Nazi Germany, as well as in many other places since then, consistently racist attitudes and behavior were shown by hundreds of thousands of people who must have differed on most other psychological characteristics. Yet another problem concerns the historical specificity of prejudice. For example, increases in racist attacks on various ethnic minority populations in Western Europe during recent decades have sometimes taken place over the space of just a few years—much too short a time for whole generations to have adopted new forms of child-rearing practices giving rise to authoritarian and prejudiced children.

4.2. Social Identity Theory

The individual difference approaches make the assumption that people's behavior in group settings is essentially similar to their behavior in all other situations. However, in group settings, people's behavior is often qualitatively different. This led Tajfel to suggest during the late 1970s that it is important to distinguish between interpersonal behavior and intergroup behavior, where the former means acting as an individual with some idiosyncratic characteristics and a unique set of personal relationships with others and the latter means acting as a group member. Any social behavior falls somewhere along a continuum defined by these two extremes. At the group level of contextual analysis of intergroup relations, the social identity theory, originally formulated by Tajfel and colleagues, has blossomed within the European context into a primary international approach to intergroup relations.

Social identity theory proposes that the social part of one's identity derives from the groups to which one belongs. By favorably comparing attributes of one's own groups with those of out-groups, this theory suggests that a person acquires both a positive sense of who he or she is and a clear understanding of how he or she should act toward in-group and out-group members. From a social psychological perspective, therefore, intergroup discrimination can be perceived as an attempt to establish a positively valued distinctiveness for one's in-group in order to achieve or maintain a positive social identity, that is, a positive collective self.

In this perspective, prejudice is perceived as stemming partly from the normal cognitive process of categorization; that is, people accentuate differences between categories and minimize differences within categories. They view categorized groups as homogenous and privilege category-confirming information in memory as well as category-confirming covariation in judgment. This means that prejudice-consistent information is attended to and rehearsed more frequently, and is remembered more accurately, than is inconsistent information.

Studies from a broad range of nations have shown that members of various ethnic groups often maintain biased systems of belief about the positive qualities of their own groups and about the negative qualities of other groups. For example, group membership determines group-serving attributions in that such membership can completely reverse the pattern of attributions made about an individual's behavior. Positive behaviors performed by members of one's own group are believed to arise from internal dispositions, whereas their negative behaviors are seen as the result of external forces. Similarly, desirable behaviors of out-group members are seen as externally caused, whereas undesirable behaviors are seen as internally caused.

However, there is a danger in overemphasizing the categorization approach to intergroup bias. It may suggest that prejudice might be inevitable, or even desirable, for cognitive adaptation. Although perceptual schemas undoubtedly simplify information, it is not clear that linguistic categories must do so. Language can be used to both categorize and particularize. The difference between prejudiced views and unprejudiced views lies in the content of these views and not the structure. It is true that people tend to interpret information in accordance with their category-based expectations. For example, if they are confronted with information about a group that disconfirms their stereotype of that group, they tend to perceive that information as nonrepresentative of the group; that is, they use the stereotype to "explain away"

deviant information. However, what is crucial here is the “category-based expectations”; whereas these expectations regarding out-groups are likely to be negative for a prejudiced individual, they may be as positive for the in-group as for out-groups for a tolerant individual. In the latter case, the person would need to explain away (i.e., particularize) the additional negative information as opposed to the additional positive information.

4.3. The Role of Perceived Threat and Unequal Position in Intergroup Bias

An in-group is a set of people who perceive each other as having something in common. There are cultural differences in the way in which in-groups are defined; that is, the bases for judging other people as in-group members can be different. There are also degrees of being in-group members; that is, people identify with in-groups in varying degrees. Typically, the more people perceive themselves as belonging together because they experience a common fate, have a common ancestry, or are similar in their gender, age, ethnicity, geographic origin, language, religion, social class, occupation, way of life, attitudes, beliefs, norms, role definitions, and/or values, the more they see each other as in-group members. Also, in-groups are dynamic constructs; that is, people change their perceptions of in-groups and out-groups according to the situation. An out-group consists of a set of people who are not members of the in-group. Members of the in-group are likely to refer to out-group members as “them” and to other in-group members as “us”.

Research has identified a number of key moderators of intergroup bias. Potential moderators range from culture to education. Higher education is generally related to less intergroup bias. Culture as a moderator is discussed in more detail later. Other moderators studied include perceived threat, power or status, group size, identification, and self-esteem. Threat is a central explanatory concept in several theories of intergroup bias, although its interpretation varies greatly. Threat can be perceived in terms of the in-group’s social identity, its goals and values, its position in the hierarchy, and even its existence. Threat can be realistic (e.g., intergroup competition over scarce resources) or symbolic (e.g., blocking the in-group’s values, customs, and traditions). Perceived threat increases intergroup bias.

Intergroup relations among real groups tend to involve groups of unequal power. In general, members of high- and equal-power groups show more bias than do

members of low-status groups, and discrimination by members of numerical minorities with high power is especially strong. Although size, status, and power tend to become confounded outside of the laboratory, these factors have also been shown to have independent effects; that is, groups in numerical minorities express more bias than do those in numerical majorities, regardless of whether the groups are real or artificial. However, when identification is experimentally induced, both majority and minority groups show bias. Members of low-status groups show more bias when status differentials are perceived as unstable and/or illegitimate and when group boundaries are perceived as impermeable. However, low-status groups may simultaneously show out-group favoritism, especially on status-relevant evaluation and when they define their inferiority as legitimate and stable.

4.4. Identification and Strategies for Escaping an Unsatisfactory Social Identity

A central idea in social identity theory is that biased intergroup comparisons are directly linked to social identification. Presumably, the more important a group is to its members, the more bias group members should show in its favor. However, in many studies, there have been rather unstable correlations between group identification and in-group bias. Hinkle and Brown suggested that the psychological processes proposed by social identity theory might not be operative in all groups. They hypothesized that this would depend on the prevailing level of individualism or collectivism in the group or group members, on the one hand, and their inclination to engage in intergroup comparisons, on the other. Group comparisons may be more important for relational groups (e.g., sports teams) and less important for autonomous groups (e.g., families). A strong link between group identification and in-group favoritism would be expected only in groups simultaneously characterized by collectivist and relational orientations. Some support has been found for this idea.

For low-status groups, the outcome of available group comparisons is often negative for their self-esteem. One reaction to this is simply to leave the group, and there are many examples of members of “inferior” groups distancing themselves physically or psychologically from their groups. Such an individualist strategy of social mobility might not always be possible, especially if the group boundaries are relatively fixed and impermeable, as is

the case with many ethnic and religious groups. In cases such as this, social identity theory suggests that a number of other avenues may be pursued. One is to limit the comparisons made to other similar or subordinate groups. Another is to sidestep the main dimensions of comparison and to either invent new dimensions or change the value of existing dimensions. These ways are expressions of social creativity. Yet another route is to directly confront the dominant group's superiority by agitating for social and economic change.

Which of these tactics will be chosen might well depend on the prevailing social climate. If it is such that no real alternatives to the status quo may be conceived, subordinate groups are unlikely to openly challenge the existing order and attempt social change. A key factor in generating social unrest among subordinate groups is a sense of relative deprivation, either in relation to their own groups in the past or (more often) in relation to the dominant group. The implications of broader social and cultural influences for intergroup bias are discussed further in the next two sections.

5. CULTURE AS A MODERATOR OF INTERGROUP BIAS

5.1. Individualist and Collectivist Cultures and Individuals

Research on culture as a moderator of intergroup bias is often conducted within an approach to cross-cultural psychology that combines individual and cultural levels of analysis and focuses on the self-concept and values. This approach has offered a perspective, the key concepts of which are individualism and collectivism (I–C). Originally, these terms were employed in reference to dimensions that differentiate cultures, describing individualist societies as those emphasizing autonomy and emotional independence and describing collectivist cultures as those showing concern for solidarity, sharing, and interdependence.

Individualist cultures, such as those found in Western societies, are defined by certain tendencies. First, people in individualist cultures see the self as independent of groups, whereas people in collectivist cultures (e.g., those found in Asia, Latin America, and most traditional societies) see the self as an aspect of one or more groups. This implies that in collectivist cultures, the goals of the in-group tend to dominate over personal goals, in-group norms are slightly more important than personal attitudes, and communal

relationships tend to be more important than relationships based on personal gain. Such differences result in different definitions of the in-group and out-group and in different pressures to conform to in-group norms, with major implications for intergroup relations.

However, Triandis and Trafimov in 2001 emphasized that individuals in different cultures include in their cognitive systems both individualist and collectivist elements in different mixtures, depending on the situation. Thus, the same constructs (I–C), when studied at the individual level of analysis, are renamed idiocentrism–allocentrism (I–A), although a similar distinction was also proposed by Markus and Kitayama during the early 1990s in their description of independent and interdependent selves. Triandis has argued that the social identity of allocentrics and collectivists is more core and salient than that of idiocentrics and individualists. Consequently, competition with out-groups and ethnocentrism also are more readily apparent in the former. These contentions have yet to be tested in the realm of ethnic perceptions and relations, but researchers consider I–C and I–A to be useful constructs in the analysis of ethnocentrism in a cross-cultural context.

5.2. Empirical Evidence and Limits of Generalizability

Most commentators would agree that the hypotheses of social identity theory are more likely to be supported in collectivist cultures than in individualist ones. However, Lee and Ward during the late 1990s found only partial support for the hypothesis of stronger ethnocentrism among allocentrics. Although allocentrics had more positive in-group attitudes than did idiocentrics, no difference was found between allocentrics and idiocentrics on out-group attitudes. Thus, in-group favoritism in both Malays and Chinese was due to the ethnocentrism bias of allocentric respondents. These findings are in broad agreement with Triandis's theorizing on the heightened significance of social identity, social categorization, and social comparison for allocentrics. The evidence for allocentric ethnocentrism, however, was limited to an in-group bias. Contrary to Triandis's suggestions, there was no distinction in the out-group attitudes held by idiocentrics and allocentrics in Lee and Ward's study.

The taxonomic model proposed by Hinkle and Brown suggests that the relationship between group identification and intergroup bias would be strongest in groups that are both relational and collectivist,

whereas this link would be weak in individualist and autonomous groups. Although there is some empirical support for this model, there is little information as to whether a relational orientation is important within collectivist cultures. Triandis suggested that members of collectivist cultures are not interested in comparing themselves with out-groups. The social comparison in which allocentrics engage might not be quite the same as that envisaged by social identity theory. Allocentric group members might not be so preoccupied with their identity as group members. Instead, they may focus on their group as a whole and on threats to its well-being.

Although Triandis has taken great pains to distinguish I-C as a cultural-level label and I-A as an individual difference measure, the terms have been used interchangeably in the cross-cultural literature. In comparative studies, the constructs frequently have been operationalized through the examination of individuals from two or more cultures either a posteriori labeled or a priori selected on the basis of some overarching conceptualization of I-C. In the more sophisticated investigations, the selection, definition, and classification are based on previous empirical research, but even this approach can pose inadvertent problems, and researchers often fall prey to the "ecological fallacy," that is, the assumption that because two cultures differ on a specific dimension, individual members of those countries will reliably differ in the same predictable manner.

Lee and Ward's study among Chinese and Malays in Singapore provides a case in point. Singapore has been previously labeled and commonly classified as a collectivist culture. Triandis has argued vigorously that members of collectivist cultures are expected to display pronounced ethnocentric attitudes. However, the ethnocentric biases that Lee and Ward found in their study were limited to allocentric subjects. This highlights the necessity of the distinction between I-C and I-A as well as the awareness and acknowledgment of theory generalizability.

6. THE ROLE OF HISTORY AND SOCIAL CONTEXT IN INTERGROUP BIAS

6.1. History and Social Context: Neglected Factors in Research

Norms, beliefs, behavioral intentions, feelings, and stereotypes determine intergroup behavior. These may be both the result of the history of previous intergroup

contact and the cause of future intergroup behavior. However, they may also be affected by factors other than previous intergroup contact. Sometimes it is in the interest of certain members of a group to induce other members of that group to have negative thoughts about a different group. More generally, a variety of social factors (e.g., relative power of the in-group and out-group; zero-sum conflict resulting in competition, domination, or scapegoating) affect norms (e.g., antagonism, paternalism, persecution, submission, rebellion, repression, conciliation), stereotypes (e.g., threatening, inferior, superior, oppressive, powerful, weak), feelings (e.g., accepting/rejecting), and behavioral intentions (e.g., to hurt, to derogate, to punish, to submit, ambivalence) regarding out-groups.

Collective representations about the past influence current intergroup relations, perceptions, and behavior. One should be careful not to neglect the importance of more enduring identities with long-term commitments and connections to, for example, former and future generations. A sense of enduring group membership may be related to cultural features such as a strong collectivist value orientation in which "in-group-centrism" predominates and identification is more of a nominal variable than a continuous one. The history of intergroup conflict has generally been neglected in the social psychological literature. Especially in collectivist cultures, history is often a major factor in intergroup relations (e.g., the case of the former Yugoslavia).

Groups and group members derive their identities from particular contexts. However, the notion of context is ill defined across many psychological paradigms. For example, context can be taken to refer to the particular task or activity in which people are engaged, to historical and cultural circumstances, to general immigrant conditions, and/or to actual social situations (e.g., schools, neighborhoods, workplaces). Many existing psychological models are not specific enough for the study of ethnic minority groups. An understanding of such groups would require explicit attention to negative social circumstances, such as racism and discrimination, in relation to concrete environmental influences.

6.2. The Special Circumstances of Minority Groups

Many real-life intergroup contexts consist of groups that hold either a minority or a majority position vis-à-vis each other. In real life, numerical asymmetries often, but not necessarily, covary with power or status asymmetries.

Simon and colleagues described the so-called cognitive-affective crossfire of minority members as follows. On the one hand, numerical distinctiveness makes group membership highly salient and difficult to ignore, both for minority members themselves and for others who may continually remind them of it by word and deed. In this way, group membership becomes a much more central self-aspect for minority members than for majority members. On the other hand, minority membership entails specific risks and stressful experiences that may be largely unknown to majority members. These risks and the negative affective consequences are further exacerbated when a numerical inferiority is also associated with status and/or power inferiority. In other words, there are stronger cognitive forces pushing minority members toward their group (or keeping them in it), while at the same time there may also be stronger affective forces pulling them away from it (or keeping them out of it).

Depending on the perceived opportunity structure of the social context (e.g., the permeability of group boundaries), minority members may opt for individualist strategies involving psychological dis-identification or actual exit from their group, for collectivist strategies involving assertive intergroup behavior, or for a combination of both. Majority group members can be more “mindless” than minority group members regarding group membership, at least so long as the former do not feel threatened by an assertive minority. Both minority and majority group members are likely to adopt an intergroup perspective when minority group members show assertive intergroup behavior to escape from or cope with the cognitive-affective crossfire (or worse) because such assertiveness may incite defensive intergroup behavior on the part of majority group members. Note that, on the surface, the assertive behavior of a minority and the defensive behavior of a majority may take the same form such as intergroup discrimination. From a theoretical point, however, the underlying meanings are different because such phenotypically similar behavior serves different purposes for minority and majority members.

6.3. The Special Circumstances of Immigrants

Historical circumstances, group norms, and ideologies also play a crucial role in the intergroup relations between immigrants and host populations. Immigrant groups, as well as individual immigrants, arrive in a new country with differing attitudes about retaining their culture of origin and becoming part of the new

society. In the new society, these attitudes interact with the actual and perceived levels of acceptance of immigrants and with official policies toward immigration. For example, assimilationist societies expect immigrants to abandon their own cultural and linguistic distinctiveness for the sake of adopting the culture and values of the dominant group, whereas ethnist societies often define who can be citizens of the state in exclusive terms.

The particular norms and ideologies reflected in the public rhetoric on the integration of immigrants provide the specific environmental context within which hosts and immigrants develop their cognitive representations of each other. They can perceive each other as one single in-group, as two subgroups within a common in-group, as two separate groups, or as separate individuals.

The most harmonious intergroup relations are predicted when both host community members and minority group members share integration, assimilation, or individualist orientations. In contrast, negative intergroup stereotypes and discriminatory behaviors can result when immigrant group members prefer integration but host community members insist that immigrants assimilate to the host society. However, host community members who want to segregate or exclude immigrants are likely to foster the most conflictual intergroup relations with targeted immigrant groups. These host community members are likely to have negative stereotypes regarding immigrants and to discriminate against them in many domains. Nonviolent segregationists may simply think that cultures should not mix, whereas radical exclusionists are more likely to launch violent racist attacks against immigrants. Of the targeted immigrant groups, it is those with separatist attitudes that are most likely to resist or even retaliate against host community persecutions. This promising so-called interactive acculturation model, developed by Bourhis and colleagues during the late 1990s, has received some empirical support.

6.4. Is Intergroup Bias Ubiquitous?

Stereotypes are likely to be particularly clear and consensually held if one's group has a long history of dealings with an out-group. If groups share a history of conflicts, out-group stereotypes are often extreme, simple, negative, and symmetrical, with each group rating its own group members positively while denigrating the out-group members. In general, group members rate their own group members higher on beneficence (e.g., honest, kind, loyal, trustworthy)

than they do out-group members. Out-group members do the same, resulting in a “mirror image” pattern.

The critical question for intergroup harmony is the size of the gap between the in-group and out-group ratings, especially on perceived values. Stereotypes can serve the societal function of acting as ideological representations that are used to justify and legitimize existing social and power relations within society. People can hold intense stereotypes about persons from other cultural and ethnic groups, even though they have never met them. These polarized attitudes probably arise from the home, the media, and the educational curricula. However, there are studies that have not found in-group bias in stereotyping. It is obvious that one must consider the effects of prevailing social and cultural norms on the expression of intergroup bias.

6.5. The Influence of Social and Cultural Norms on the Expression of Prejudice

Theoretically, prejudice and stereotypes are related but still distinct concepts. Attitudes are evaluative responses, whereas stereotypes are specific beliefs about a group. Responses to explicit measures of intergroup bias are given consciously. Typically, explicit attitudes are assessed by self-report measures, including attribution of group traits (stereotypes), group evaluations (prejudice), and differential behavior toward in-group and out-group targets (discrimination). However, measures of these cognitive, affective, and behavioral components, respectively, are often only modestly or weakly related in most Western societies.

Explicit attitudes and stereotyping operate in a conscious mode, whereas implicit attitudes and stereotypes are evaluations and beliefs that are automatically activated by the mere presence (actual or symbolic) of the attitude objects. Implicit attitudes commonly function in an unconscious fashion and are typically assessed using response latency procedures, memory tasks, physiological measures (e.g., galvanic skin response), and indirect self-report measures. Thus, the promise of implicit measures is to assess the true extent of people’s bias given pressures to conform to socially desirable or politically correct norms. When such norms prevail, individuals may be motivated to express their prejudice in indirect ways that do not threaten their nonprejudiced self-images.

The translation of prejudiced beliefs (stereotypes) and evaluations (attitudes) into action (discrimination)

depends on both personal and social factors. Highly prejudiced persons feel less guilt and shame, less ambivalence, and less internal conflict about discrepancies between internal and/or social standards of egalitarianism and actual discriminatory behavior. Less prejudiced individuals are self-critical about their departures from more egalitarian standards prevailing in their cultural and social environments. There may be a greater correspondence between implicit and explicit attitudes for issues that are not socially sensitive than for those that are socially sensitive or that are associated with more prejudiced historical norms or traditional socialization.

However, there is more to discrimination than personal proclivities. Social groups may feel that they are under political and economic threat by other groups or may be fueled by ideologies of antagonism passed down from the past and sustained by racist talk common to in-group members. These social inducements to discrimination may be further unrestrained by a wider political ideology of intergroup harmony (e.g., Canada’s policies of multiculturalism and human rights observance). Such a volatile mix can be exacerbated by societal factors and cultural values supporting a sense of cultural superiority.

Discriminatory behavior need not result in open intergroup hostility if the social ideology surrounding differential access to material and social resources is accepted by members of all competing groups. Alternatively, unequal group access to resources may prevail and be resented by members of groups facing discrimination. However, the consequences of challenging this order may be too destructive to contemplate, or the social basis for group mobilization may be lacking. Conflict behavior is less in societies with crosscutting ties than in societies with ties that reinforce polarization between groups and in societies where scapegoating ideologies concerning specific out-groups are firmly entrenched.

7. THE REDUCTION OF INTERGROUP BIAS

7.1. The Contact Hypothesis

Intergroup bias has psychological, social, and cultural components; hence, both individual and intergroup approaches can make important contributions to the reduction of intergroup bias. Some interventions attempt explicitly to decrease bias on an individual level by invoking guilt for holding socially undesirable attitudes. Although this approach may sometimes seem successful, it capitalizes on the good intentions of

low-prejudiced people (whose bias is surely not the main problem) and demands appropriate levels of awareness, effort, and practice over time. Other individual-level approaches use more indirect means such as inducing empathy for out-groups.

However, most of the interventions used for reducing bias employ more intergroup methods and focus on the need to increase the quantity and enhance the quality of intergroup contact. This approach derives from the so-called contact hypothesis, which was originally developed by Allport during the 1950s and is one of the most influential ideas for the reduction of intergroup prejudice. Broadly speaking, it suggests that contact between members of different groups, under the appropriate conditions, lessens intergroup prejudice and hostility.

In 1998, Pettigrew's review of recent research pointed to the increased knowledge of the mediating processes by which contact can reduce intergroup bias and anxiety. Allport held that the positive effects of intergroup contact occur only in situations marked by four key conditions: equal group status, common goals, intergroup cooperation, and the support of authorities, laws, or customs. Many other factors have since been advanced, for example, the acquaintance potential and intimacy of the contact. Some researchers emphasize equal group status coming into the situation as part of the equality requirement, whereas others find this to be less important than group status within the situation. Social and institutional support means that those in authority (e.g., the politicians implementing new legislation and the judges and police monitoring its administration) should be unambiguous in their endorsement of measures designed to promote greater contact and integration. Creating a social climate in which more tolerant norms can emerge, and sanctioning the violation of such norms, constitutes the essence of social and institutional support.

Allport's formulation continues to receive support across a variety of situations, groups, and societies. Most studies report positive contact effects, even in situations lacking key conditions. Overall, face-to-face interaction between members of distinguishable groups is importantly related to reduced prejudice, and intergroup contact relates to a wide range of prejudice measures (e.g., belief, social distance, stereotype) and affective measures. Testing the possibility of an opposite causal sequence (i.e., that prejudiced people avoid contact more than contact lowers prejudice), it has been shown that the path from contact to reduced prejudice is stronger than the other way around. Although it concentrates on school and housing situations, the contact literature ranges from Chinese students in the United

States and interracial workers in South Africa to German and Turkish school children and Americans getting to know Southeast Asian immigrants.

7.2. Mechanisms by Which Contact Reduces Intergroup Bias: The Role of Category Salience

The contact hypothesis does not specify the processes that are responsible for the positive effects or how the positive effects of contact generalize beyond the immediate situation to other situations, from the specific out-group member encountered to the out-group as a whole, or to other out-groups not involved in the contact. Recent work suggests that four interrelated processes operate through contact and mediate attitude change: learning about the out-group, changing behavior, generating affective ties, and in-group reappraisal.

Although cognitive research has uncovered a host of mechanisms that limit learning material that counters our attitudes and stereotypes, the research literature suggests that positive effects are more common than the contact hypothesis or cognitive analyses predict. The basic reason is that learning about the out-group is only one of several processes involved. For example, optimal and continuous intergroup contact has the potential to produce attitude change by revising attitudes in accordance with behavior and by reducing the anxiety often experienced in intergroup encounters. Positive emotions aroused by intergroup friendship may be pivotal in reducing intergroup prejudice. It has been shown that having an out-group friend may even generalize to other out-groups besides that of the particular friend. In addition, optimal intergroup contact reduces prejudice by providing insight about the in-group as well as the out-group, leading to a less provincial view of out-groups in general.

As for the generalization of contact across situations, research has generally shown that positive effects on intergroup attitudes might need repeated optimal situations. Research supporting the salient categorization model proposed by Hewstone and Brown during the 1980s shows that stereotype change generalizes best to the intergroup level when the individuals involved are typical out-group members. This approach argues that, to protect against loss of distinctiveness for groups involved in contact, two factors are important. First, the salience of group boundaries should be maintained during contact (i.e., group memberships are made salient or the partner is typical [rather than atypical] of the out-group as a whole) to promote generalization across members of

the target group. Second, groups should recognize and value mutual superiorities and inferiorities.

Thus, there seems to be some advantage in maintaining the original group boundaries in the interaction while otherwise optimizing contact conditions. Positive contact is more likely to be associated with favorable out-group attitudes when contact takes place with a typical out-group member. However, this poses a problem. Typical members of real groups are different in many ways, but people tend to seek out people with similar interests and status. Maintaining category distinctions during contact involves the risks of reinforcing perceptions of group differences and increasing intergroup anxiety, thereby increasing bias.

One way of maintaining category salience while still diminishing anxiety associated with intergroup contact is offered by a recent development of the contact hypothesis called the extended contact effect. This model proposes that the awareness that one's fellow in-group members have close friendships with out-group members can help to reduce prejudice toward the out-group. A likely reason for this is that the in-group "exemplars" provide normative information regarding how one should behave and also may contribute to the redefinition of the intergroup relationship as less negative. Such an "extended contact effect" does not require personal intergroup friendship for the perceiver. Correlational and experimental evidence of this idea is emerging. Underlying this model is the idea that both in-group and out-group role models should be seen as typical or representative of their groups and not as exceptions to the rule.

7.3. The Decategorization and Recategorization Models for Reducing Intergroup Bias

The so-called decategorization model of intergroup relations holds that intergroup contact is more effective when group salience is low and the intergroup situation is personalized. However, individual-to-group generalizations are unlikely in very personalized contact situations. In contrast, the so-called common in-group identity model holds that intergroup attitudes are best improved when the category boundaries are drawn so that the out-group becomes subsumed into a new and larger superordinate category. There is now an impressive literature supporting this claim. However, most studies of this model have not examined generalization. The fundamental limitation of both the decategorization and recategorization models is that they threaten to deprive individuals

of valued social identities in smaller, less inclusive groups. A common in-group identity may be only short-lived or unrealistic in the face of powerful ethnic/racial categorizations (e.g., the former Yugoslavia). In addition, for groups with histories of antagonism and for minorities whose members are likely to resist assimilation into a superordinate category that is dominated by a majority out-group, the prospect of a superordinate identity may constitute a threat that actually increases bias.

7.4. Integrating Different Models of Contact

To overcome these problems, various solutions have been proposed. Hewstone and colleagues in 2002 proposed that the categorization salience model of contact needs to be integrated with the more personalized models and that, in contrast to original social identity theory, interpersonal and intergroup contact should be viewed as orthogonal dimensions that together can create highly effective conditions of out-group contact (i.e., contact should simultaneously be both highly intergroup and highly interpersonal).

The dual-identity model developed by Gaertner and colleagues takes this idea as a starting point as it aims to maximize the benefits of both the "common in-group identity" and the mutual intergroup differentiation model. According to this model, subgroup identity is maintained while the groups also share membership in a common superordinate group. A dual identity leads to more positive out-group attitudes than does a superordinate identity alone. Gaertner and colleagues conducted a correlational study in a multiethnic high school and found less bias when students identified themselves at both the subgroup (i.e., ethnic group) and superordinate (i.e., American) levels rather than at the subgroup level only.

The dual-identity model resembles the bidimensional interactive acculturation model suggested by Bourhis and colleagues. According to this model, as well as to the original acculturation theory developed by Berry during the 1980s, members of cultural minorities can adopt different acculturation strategies. These strategies are formed by the crossing of two orthogonal orientations: in the interactive acculturation model, these are defined as identification with one's own culture (high/low) and identification with the dominant culture (high/low). Research suggests that the "intergration" strategy (high on both orientations) is often the preferred strategy among minority groups and seems to be associated with less acculturative stress and better educational outcomes.

A major problem for the dual-identity approach is that members of minority and majority groups may have different preferences for what model of intergroup relations to adopt. Dominant majority ethnic groups tend to favor assimilation, whereas racial/ethnic minorities favor pluralistic integration. Thus, dual identity may reduce bias for the minority group but not for the majority group. This asymmetry between minority and majority strategies is also reflected in the interactive acculturation model itself in that the strategies of majority members concern only their preferences for the identification strategies they would like the minority members to adopt. As a consequence, minority and majority members can, at best, agree only on the most preferred strategy for the minority group members. Even then, majority members might not be prepared to change their own identification patterns accordingly.

A successful superordinate category and identity must be inclusive rather than reflect the superior characteristics of a dominant majority group too strongly. Even if this is the case, however, subgroup categorizations and identities are likely to be stronger and more stable than superordinate ones. One simple way in which to reduce intergroup bias is to ensure that the contact partners can be simultaneously classified as in-group and out-group members on multiple dimensions. Shared or overlapping category memberships reduce bias simply because they make social categorization more complex and decrease the importance of any one in-group/out-group distinction. However, the effectiveness of crossed categorization is limited when one category distinction is functionally dominant and/or categories are correlated, and this is normally the case in real-life intergroup encounters.

All of the models for reduction of intergroup bias presented here should be seen as complementary and reciprocal rather than as competing and exclusive. This integrative approach responds to the fact that each model can be effective under particular contact conditions but that each model also has its weaknesses and limitations, particularly with respect to generalization and to finding an intervention that works for both majority and minority groups.

One way in which to combine the various models was proposed by Pettigrew in 1998. He suggested that time sequence is crucial. Diminished category salience can be important when intergroup contact is initiated, but category salience may be required later for the positive effects to generalize to the intergroup level. At an even later stage, the recategorization strategy proposed by the common in-group identity model may become possible. After continuous contact, people may begin to think of

in-group and out-group members as members in a more inclusive common in-group, although this final state is seldom reached by interacting groups.

7.5. Realistic Goals for Real-Life Intergroup Relations

Prior attitudes and experiences influence whether people seek or avoid intergroup contact and what the effects of the contact will be. High intergroup anxiety and threat can impede both contact and its positive effect. In addition, institutional and societal norms structure the form and effects of contact situations. Optimal contact situations are difficult to achieve if a struggle for power fuels the larger intergroup conflict. In contrast, normative support makes attainment of optimal conditions much easier. Although the beneficial effects of contact with typical out-group members have been confirmed in a number of studies, if the intergroup encounter goes wrong, structuring the encounter as intergroup rather than interpersonal could make matters worse. Therefore, there is a fine line to be drawn in designing situations of intergroup contact. Enough category salience must be retained to permit the positive change to generalize, but not so much as to allow the regression into familiar patterns of prejudice that are associated with category divisions that are too firmly drawn.

Given the corrosive nature of many real-world conflicts, out-group liking is often unlikely; and achieving other outcomes may be more realistic and just as important, including increases in perceived group variability, out-group knowledge, and perspective taking as well as decreases in intergroup anxiety. To reduce full-blown intergroup conflict, effective interventions also need to build trust. It is true that relevant research and theoretical developments on intergroup bias have been directed at its relatively mild forms. However, social categorizations play a role in even extreme forms of prejudice. Severely prejudiced individuals and ideologies delegitimize victims, assigning them to an extreme social category that enjoys no projection, and dehumanize victims by morally excluding them from the in-group of humanity where justice, fairness, and morality prevail.

However, real-world intergroup relations owe at least as much to intergroup history, economics, politics, and ideology as they do to social psychological variables such as categorization, self-esteem, in-group identifications, group size, and group threat. Social conflict is more complex than intergroup bias. Consequently, intergroup bias should not be analyzed from just one disciplinary

perspective, regardless of how important the psychological antecedents and consequences of intergroup bias may be. The current trend to study culture in social psychology has yet to address intergroup bias in full force, but there is little doubt that it will. Culture and societal influences are neglected at our peril.

The *International Statistical Classification of Diseases* (ICD) was worked out and proposed by the World Health Organization (WHO) to facilitate communication and study on organic and mental diseases among health workers and clinicians worldwide. In 1893, Jacques Bertillon, head of statistical works for the city of Paris, presented a new classification of *Diseases and Causes of Death* to the International Congress of Statistics in Chicago. The Bertillon classification was the first of a series that gave rise to the ICD, published by WHO from 1948 onward, to improve diagnosis and classification of diseases and to promote international comparability

in the collection, processing, classification, and presentation of mortality and morbidity statistical data. Since then, the ICD has been revised periodically to incorporate changes in the medical field. This article includes a historical approach to the ICD, and its general principles and structure. The article specifically discusses Chapter 5 of the 10th revision of the ICD (ICD-10), on mental and behavioral disorders, describing the phenomenological rigor, consistency, diagnostic stability, and clinical utility of the psychiatric diagnoses. Finally, it incorporates a brief comparison of ICD-10 and the 4th edition of the *Diagnostic and Statistical Manual of Mental Disorders* (DSM-IV) and mentions WHO collaborating centers for classification of diseases and procedures for ICD-10 updating.

1. INTRODUCTION

International collaboration began a century ago with the aim of drawing up a classification of diseases. The systematic classification of diseases began in the 18th century with the publication of the *Nosologia Methodica* by Lacroix and of the *Genera Morborum* by Linnaeus. In 1785, Cullen published the *Synopsis Nosologiae Methodicae*, which was used in various European countries until the middle of the 19th

century. A classification of diseases and death causes was approved in 1855 during the Second International Congress of Statistics in Paris. This classification, which combined the English tradition (based on anatomical region) and the French tradition (based on etiology), had wide repercussions but did not garner complete acceptance.

In 1893, Jacques Bertillon, head of statistical works for the city of Paris, presented a new classification of *Diseases and Causes of Death*, based on the one employed in Paris, to the International Congress of Statistics in Chicago. The Congress approved it and recommended its use and revision every 10 years. The Bertillon classification of diseases was the first of a series that gave rise to the *International Statistical Classification of Diseases* (ICD), edited and published by the World Health Organization (WHO) from 1948 onward, to improve diagnosis and classification of diseases and to promote international comparability in the collection, processing, classification, and presentation of mortality and morbidity statistical data. Since then, the ICD has been revised periodically to incorporate changes in the medical field. Bertillon himself did the work in 1900, 1910, and 1920. WHO assumed the task from the 4th revision (in 1929) onward. The 4th revision and the next one (in 1938) maintained the basic structure of the Bertillon classification. In both of these, the mental diseases were included without any special section; instead, they were distributed throughout 9 of the 14 sections.

In 1948, WHO's 6th revision included a chapter specifically dedicated to mental diseases (Chapter 5), and this remained unchanged until the 9th revision (ICD-9). This new chapter contained three sections dedicated to (a) psychosis, (b) psychoneurotic disorders, and (c) disorders of character, behavior, and intelligence. The 1955 edition dedicated more space to mental disorders but maintained these three sections.

Since the beginning of the 1960s, WHO has stimulated a series of works on mental disorders, supported projects to improve diagnosis and classification of mental diseases, and encouraged research on classification instruments. Emphasis was placed on the reliability, consistency, and diagnostic stability of classification instruments. These efforts culminated in a program with four main subprograms dedicated to (a) the improvement of the diagnosis and classification of psychiatric disorders, (b) cross-cultural research of the most important psychiatric disorders, (c) an epidemiological study, and (d) training in social and psychiatric epidemiology. A network of individuals and institutions

was created, and they worked on proposals to be included in the draft for the 8th ICD revision (in 1968). In this 8th revision, the diagnostic categories for mental diseases were reorganized into three sections: (a) psychosis; (b) neurosis, personality disorders, and other nonpsychotic mental disorders; and (c) mental retardation. A glossary defined each diagnostic category and standardized its use.

The 9th revision of the ICD (in 1978) contained four sections dedicated to mental disorders: (a) organic psychosis; (b) other psychoses; (c) neurotic disorders, personality disorders, and other nonpsychotic mental disorders; and (d) mental retardation. The difficulties of diagnosis and classification of some nosologic entities revived interest and research into psychiatric diagnosis, and WHO again took on the leadership in the preparation of the 10th ICD edition.

The rules and study areas for classification of mental disturbance were defined during an important conference in Copenhagen in 1982. Also identified were those areas in which improvement in classification required further research work and more evidence. A trial classification was then staged in 55 countries with the participation of more than 700 clinicians from at least 100 centers, coordinated by a group of 13 centers. More than 15,000 patients were assessed in the trial classification.

Some special notes should be made here with regard to the development of disease classification in the 10th revision (ICD-10) in 1992. First, it was developed simultaneously in several languages, and it enabled compatible definitions among many countries. Second, the different versions of ICD-10 allowed different uses in accordance with different necessities. Third, the classification was based on the evidence found in research. Fourth, the classification was accompanied by standard instruments for the evaluation of symptoms and other diagnosis elements.

The results of this project were very positive.

2. INTERNATIONAL STATISTICAL CLASSIFICATION OF DISEASES AND RELATED HEALTH PROBLEMS, 10th REVISION

In the 10th revision, the title was changed to clarify the content and goals and to reflect the progressive extension of the scope of the classification.

ICD-10 is much longer than the 9th revision. Printed in three volumes (the 9th revision was printed in two volumes), ICD-10 has adopted an alphanumeric coding scheme (rather than using numeric categories) and has significantly enlarged the number of categories available for classification. The first character in the coding system is now a letter for each chapter, as well as a number, and each chapter is assigned 10 two-character categories and 100 three-character major categories. ICD-10 has nearly twice as many categories as did the 9th revision. Finally, some slight changes have been made in the coding rules for mortality. For instance, in the case of Chapter 5 (on mental and behavioral disorders), the three-character categories go from F00 to F99. F20 is “schizophrenia,” and every category has different subcategories (e.g., F20.0 is “paranoid schizophrenia,” F20.5 is “residual schizophrenia”).

The first volume of ICD-10 contains 17 chapters dedicated to different diseases (from “certain infectious and parasitic diseases” to “congenital malformations, deformations, and chromosomal abnormalities”), special tabulation lists for mortality and morbidity, the definitions, and the nomenclature regulations. The second volume includes new background information, instructions, and guidelines for users of the tabular list and historical information about the development of the ICD classification. The third volume incorporates a detailed alphabetical index. The index includes diagnostic terms commonly used as synonyms for the terms officially accepted in the classification, and it facilitates more efficient coding.

The ICD-10 manual includes not only the disorders but also other attributes of patients’ interactions with their social contexts. Consequently, it includes a multi-axial system with three axes, with Axis I covering clinical diagnoses of both mental and physical disorders, Axis II covering disabilities due to impairments produced by the disorders, and Axis III covering the contextual or environmental and personal lifestyle factors influencing the appearance and course of the disorders. The ICD-10 manual is accompanied by the ICD-10 Multi-axial Diagnostic Formulation Form, the WHO Short Disability Assessment Schedule (WHO DAS-S), and Axis I and Axis III glossaries.

ICD-10 is intended for use in clinical, educational, and research activities. It has been prepared by an international team of experts and has been field-tested in 20 countries. It has been shown to be easy to use and applicable in a wide range of cultures and settings.

3. ICD-10’S CHAPTER 5: MENTAL AND BEHAVIORAL DISORDERS

ICD-10 dedicates Chapter 5 to mental and behavioral disorders. This chapter, under the letter F of the coding system, substantially extends the space given previously to mental disorders.

Chapter 5 in ICD-10 offers important differences compared with the previous revision. That chapter in the 9th revision had only 30 three-character categories (290 to 319), whereas it includes 100 major three-character categories in ICD-10. Two other important changes have been made. First, differentiation between psychoses and neuroses has been abandoned. Second, disorders showing common elements or properties are grouped together.

Chapter 5 in ICD-10 contains the following sections: F00 to F09, organic (including symptomatic) disorders; F10 to F19, mental and behavioral disorders due to psychoactive substances; F20 to F29, schizophrenia, schizotypal, and delusional disorders; F30 to F39, mood (affective) disorders; F40 to F49, neurotic, stress-related, and somatoform disorders; F50 to F59, behavioral syndromes associated with physiological disturbances and physical factors; F60 to F69, disorders of adult personality and behavior; F70 to F79, mental retardation; F80 to F89, disorders of psychological development; F90 to F98, behavioral and emotional disorders with onset usually occurring during childhood or adolescence; and F99, unspecified mental disorders.

The most recent Chapter 5 also contains clinical guidelines for the classification of mental disorders in several languages; compatible versions dedicated to classification, clinical, and investigation work; and a multi-axial presentation with three axes: clinical diagnosis, the development of factors related to disorders, and the disability level related to them. In addition, ICD-10 includes a version for primary care doctors.

The publication of the ICD-10 classification of mental and behavioral disorders has been an extremely important event for both psychiatry and clinical psychology. For the first time, psychiatry has produced a classification based on the worldwide consensus of experts and schools of psychiatry. ICD-10 constitutes an essential basis that enables the development of a unique language for national and international communication in the field of mental health, facilitating collaboration across cultures and countries.

Chapter 5 of ICD-10 has been translated into more than 35 languages and presented in different versions for

different purposes. Everywhere, the code numbers and titles of the disorders are exactly the same, but details and styles of presentation are adapted to specific purposes. Furthermore, two major documents have been developed from ICD-10: a version for general clinical practice and educational use (*ICD-10 Clinical Descriptions and Diagnostic Guidelines*) and another version for research purposes (*ICD-10 Diagnostic Criteria for Research*).

4. PHENOMENOLOGICAL RIGOR, CONSISTENCY, AND DIAGNOSTIC STABILITY OF ICD-10 PSYCHIATRIC DIAGNOSES

ICD-10 Clinical Descriptions and Diagnostic Guidelines and *ICD-10 Diagnostic Criteria for Research* have been analyzed for their internal consistency and phenomenological soundness. The operational definitions of all categories have been considered both for their agreement with the core text of ICD-10 and for their internal consistency within each category. The soundness of all operational criteria and concepts used in the clinical descriptions has also been assessed. The results indicate a high degree of consistency and phenomenological rigor as well as a high level of interrater reliability. Nonetheless, some inconsistencies have been detected in a few categories related to mania, hypomania, cyclothymia, schizotypal disorder, and behavior disorder. Especially in the schizotypal disorder category, a low interrater reliability and poor face validity were found, and this could lead to the label of mental illness being applied to otherwise healthy people.

Temporal stability of diagnosis, a measure of the degree to which diagnoses remain unchanged at later hospital admissions, seems to be high for schizophrenic and affective disorders, whereas it is not so high for neurotic, obsessive-compulsive, stress-related, and adjustment disorders. Further research is required in this area.

5. CLINICAL UTILITY OF ICD-10

ICD-10 has led to a major innovation in clinical psychiatry. The criteria-based classifications are no longer simple coding conventions; instead, they have become part of the conceptual framework of the discipline itself. Consequently, comprehensive clinical evaluation should work at two separate levels: (a) the syndrome

diagnosis and (b) the evaluation of factors possibly influencing the course and outcome of psychiatric disorders. Only when both are taken into consideration is it possible to get a complete understanding of the disorders and optimal treatment.

6. COMPARISON BETWEEN ICD-10 AND DSM-IV

During the 1940s, the American Psychiatric Association drew up a psychiatric classification system of mental diseases titled *Diagnostic and Statistical Manual of Mental Disorders* (DSM), and since then it has been the main reference for contrasting the ICD. The DSM is produced at intervals of at least 10 years, reflects U.S. national trends and opinions, and has probably been the most important of the national classifications. Therefore, although ICD-10 is the official coding system in many countries, DSM-IV appears to be more popular among mental health professionals.

Both systems, ICD-10 in the *Diagnostic Criteria for Research* and the 4th edition of the DSM (DSM-IV), have introduced descriptive, nonetiologic classifications with operationally defined categories based on diagnostic criteria and have proposed explicit diagnostic criteria. There are differences between the two systems, with the most significant ones being the avoidance of social dysfunction criteria in ICD-10 and the hierarchical order preventing comorbidity diagnoses in ICD-10. Results from separate studies show high levels of concordance in diagnoses of depression, dysthymia, substance dependence, and generalized anxiety disorder. They also show a moderate concordance in social phobia, obsessive-compulsive disorder, and the three panic/agoraphobia disorders. Results show only a low concordance for posttraumatic stress disorder and drug use/abuse. Concordances and differences basically reflect similarities and dissimilarities in concepts and diagnostic criteria between classification systems.

Both systems have multiaxial presentations, but it is doubtful that the ICD-10 multiaxial presentation could be used to the same extent as can the DSM-IV multiaxial assessment. ICD-10 has sought to place psychiatric disorders in the context of the different religions, nationalities, and cultures of the world community, whereas DSM-IV lacks this degree of cultural sensitivity, perhaps because it is a system that originates from only one country. The concern for cultural universality increased the length of the document but curtailed and

simplified some operational definitions by omitting culturally biased criteria. However, ICD-10 does contain some questions that are not culturally sensitive because it is based on premises that are inherent in its construction. Consequently, and in spite of efforts to coordinate ICD-10 and DSM-IV as much as possible, major differences in important areas remain, although the two systems use the same coding system in some cases.

7. COLLABORATING CENTERS FOR CLASSIFICATION OF DISEASES AND PROCEDURES FOR ICD-10 UPDATING

To assist users with problems in the development and use of disease classifications and in the use of the ICD, 10 WHO Collaborating Centers for the Classification of Diseases have been created: 3 centers for English-language users (in London, United Kingdom; Canberra, Australia; and Hyattsville, Maryland, United States), 1 center for French- users (Le Vésinet, France), 1 center for Arabic users (Safat, Kuwait), 1 center for Chinese users (Beijing, China), 1 center for Nordic users (Uppsala, Sweden), 1 center for Portuguese users (Sao Paulo, Brazil), 1 center for Russian users (Moscow, Russia), and 1 center for Spanish users (Caracas, Venezuela).

Proposals for changes or additions to ICD-10 should first be presented to the relevant collaborating center. All proposals for changes must be sponsored by, and submitted to WHO through, a collaborating center. Different meetings of WHO Collaborating Centers for Classification of Diseases have approved specific procedures for updating ICD-10.

GLOSSARY

attribution mechanisms Ways in which to assess the motivation for the behavior of self and others; in conflict relationships, these often lead to confirmation of the negative attitudes toward the adversary.

coalition across conflict lines A working relationship between members of opposing parties seeking common ground in the pursuit of their respective interests.

conflict A relationship between two parties characterized by the fact and/or perception that each party, in the pursuit of its own interests, threatens or undermines the interests of the other party.

conflict norms A set of social expectations within groups or societies in conflict that require members to manifest hostility and distrust toward the adversary in their feelings, language, and actions.

enemy image The tendency among parties in conflict to demonize and delegitimize the adversary and to perceive the other party as inherently aggressive, dangerous, and inauthentic.

groupthink A tendency within groups tasked with decision making in crisis situations to seek concurrence among their members, discourage dissenting views, and thereby maintain group cohesiveness.

human needs approach A view of conflict as generated and maintained by the nonfulfillment and threat to the parties' basic human needs and of conflict resolution as a process that addresses the basic needs of both parties.

integrative solutions “Win–win” solutions to a conflict that meet the needs and interests of both parties; these are in contrast to “win–lose” solutions, in which one party prevails at the expense of the other.

interactive problem solving An unofficial approach to conflict resolution in which the parties are encouraged to treat the conflict as a shared problem that requires joint efforts to shape mutually satisfactory solutions.

mirror image formation The tendency among parties in conflict to develop parallel images of self and the enemy, except with the values reversed, for example, for each party to see the other as inherently aggressive and the self as entirely defensive in response.

mutual reassurance A form of influence in conflict relationships designed to demonstrate each party's awareness of the other's concerns and requirements and thereby to reduce the other party's fears of the risks entailed by negotiation.

negotiation of identity An informal process whereby parties in conflict explore and invent ways in which to accommodate their group identities and national narratives to one another, particularly by removing negation of the other from their own identities and narratives.

prospect theory A theory of decision making under conditions of risk that proposes that people are more prone to take risks to avoid losses than to achieve gains, for example, to go to war in defense of threatened interests than to pursue a potential opportunity for peace.

realistic empathy Taking the perspective of the adversary to gain a realistic understanding of the other party's thoughts and feelings.

responsiveness An influence strategy based on attempts to elicit cooperation from the other party by addressing the other's needs, fears, and constraints.

self-fulfilling prophecy A relationship tendency whereby one party's expectations of the other cause the other party to behave in ways that confirm these expectations.

zero-sum thinking A view of the conflict as a relationship where every gain by the other party represents a loss for one's own side and where every loss by the other party represents a gain for one's own side.

The end of the cold war has changed the character of international conflict, but it has not reduced the prevalence of violent conflict, the human suffering that it causes, or the threat that it poses to the well-being and survival of the human species. Thus, during recent years, there has been a proliferation of deadly, deep-rooted conflicts between ethnic and other identity groups within and across nation-states—conflicts often marked by violence against civilians, ethnic cleansing, and genocidal actions. There has also been a rise in terrorism and counterterrorism around the world, undermining the peace and development of established and emerging states.

1. INTERNATIONAL CONFLICT AS A CONTEMPORARY PROBLEM

Psychological theory and research can make useful contributions to the understanding and amelioration of the violent manifestations of international conflict. Indeed, psychological concepts and findings have been used increasingly in the study of international conflict and international relations more generally as well as in the development of new approaches to conflict resolution. This article offers a perspective on international conflict that is anchored in social–psychological theory and research and that, in turn, informs the practice of conflict resolution. Social–psychological analysis is designed to complement (and not to replace) approaches based on structural or strategic analysis by providing a special lens for viewing international conflict that brings some of its less explored dimensions into focus.

In this spirit, the article begins with a discussion of several propositions about the nature of international conflict that flow from a social–psychological perspective and that have clear implications for conflict resolution. It then describes social–psychological processes characteristic of conflict interaction that contribute to the escalation and perpetuation of conflict and that must

be reversed if such conflict is to be resolved. [These ideas are presented in greater detail in Kelman's chapter in *Peacemaking in International Conflict* (edited by Zartman and Rasmussen), and linked to a discussion of approaches to conflict resolution in Kelman and Fisher's chapter in the *Oxford Handbook of Political Psychology* (edited by Sears, Huddy, and Jervis).]

2. SOCIAL–PSYCHOLOGICAL PROPOSITIONS ABOUT THE NATURE OF INTERNATIONAL CONFLICT

A social–psychological perspective can expand on and enrich the analysis of international conflict provided by the realist or neo-realist schools of international relations or other, more traditional approaches. While acknowledging the importance of objectively anchored national interests, it explores the subjective factors that set constraints on rationality. Without denying the primacy of the state in the international system, a social–psychological perspective opens the “black box” of the state as unitary actor and analyzes processes within and between the societies that underlie state action. Fully recognizing the role of power in international relations, it postulates a broader range of influence processes (and, indeed, of definitions of power) that play a role in international politics. And while affirming the importance of structural factors in determining the course of an international conflict, it conceives of conflict as a dynamic process, shaped by changing realities, interests, and relationships between the conflicting parties.

These observations suggest four general propositions about international conflict that call for social–psychological concepts and data. The four propositions are particularly relevant to existential conflicts between identity groups, that is, conflicts in which the collective identities of the parties are engaged and in which the continued existence of the groups is seen to be at stake. Thus, the propositions apply most directly to ethnic or ideological conflicts, but they also apply to more mundane interstate conflicts insofar as issues of national identity and existence come into play—as they often do.

2.1. Conflict as a Process Driven by Collective Needs and Fears

According to the first proposition, international conflict is a process driven by collective needs and fears

rather than entirely a product of rational calculation of objective national interests on the part of political decision makers. Human needs are often articulated and fulfilled through important collectivities such as the ethnic group, the national group, and the state. Conflict arises when a group is faced with nonfulfillment or threat to the fulfillment of basic needs, not only obvious material needs such as food, shelter, physical safety, and physical well-being but also psychological needs such as identity, security, recognition, autonomy, self-esteem, and a sense of justice—needs featured in the 1990 volume *Conflict* and other writings by Burton, a pioneer in the field of conflict resolution. Moreover, needs for identity and security and similarly powerful collective needs, as well as the fears and concerns about survival associated with them, contribute heavily to the escalation and perpetuation of conflict once it has started. Even when the conflicting parties have come to the conclusion that it is in their best interest to put an end to the conflict, they resist going to the negotiating table or making the accommodations necessary for the negotiations to move forward out of fear that they will be propelled into concessions that, in the end, will leave their very existence compromised. The fears that drive existential conflicts lie at the heart of the relationship between the conflicting parties, going beyond the cycle of fears resulting from the dynamics of the security dilemma discussed by Jervis in 1976.

Collective fears and needs, although more pronounced in ethnic conflicts, play a part in all international conflicts. They combine with objective factors—a state's resources, the ethnic composition of its population, its access to the sea (or lack thereof), and the like—in determining how different segments of a society perceive state interests and what ultimately becomes the national interest as defined by the dominant elites. Similarly, all conflicts—interstate as well as ethnic—represent a combination of rational and irrational factors, and in each type of conflict the mix may vary from case to case. Some ethnic conflicts may be preponderantly rational, just as some interstate conflicts may be preponderantly irrational. Furthermore, in all international conflicts, the needs and fears of populations are mobilized and often manipulated by the leadership, with varying degrees of demagoguery and cynicism. Even when manipulated, collective needs and fears represent authentic reactions within the population and become the focus of societal action. They may be linked to individual needs and fears. For example, in highly violent ethnic conflicts, the fear of

annihilation of one's group is often tied to a fear of personal annihilation (and for good reason).

The conception of conflict as a process driven by collective needs and fears implies, first and foremost, that conflict resolution—if it is to lead to a stable peace that both sides consider just and to a new relationship that enhances the welfare and development of the two societies—must address the fundamental needs and deepest fears of the populations. From a normative point of view, such a solution can be viewed as the operationalization of justice within a problem-solving approach to conflict resolution. Another implication of a human needs orientation noted by Burton is that the psychological needs on which it focuses—security, identity, recognition, and the like—are not inherently zero-sum, although they are usually seen as such in deep-rooted conflicts. Thus, it may well be possible to shape an integrative solution that satisfies both sets of needs, which in turn might make it easier to settle issues such as territory and resources through distributive bargaining. Finally, the view of conflict as a process driven by collective needs and fears suggests that conflict resolution must, at some stage, provide for certain processes that take place at the level of individuals and interactions between individuals, for example, taking the other society's perspective (what White called "realistic empathy" in 1984 and elsewhere) as well as creative problem solving, learning, and insight.

2.2. Conflict as an Intersocietal Process

Focusing on the needs and fears of the populations in conflict reminds one that international conflict is an intersocietal process, not merely an intergovernmental or interstate phenomenon. The conflict, particularly in the case of protracted ethnic struggles, becomes an inescapable part of daily life for each society and its component elements. Thus, analysis of conflict requires attention, not only to its strategic, military, and diplomatic dimensions but also to its economic, psychological, cultural, and social-structural dimensions. Interactions along these dimensions, both within and between the conflicting societies, shape the political environment in which governments function and define the political constraints under which they operate.

An intersocietal view of conflict points to the role of internal divisions within each society, which often play a major part in exacerbating or even creating conflicts between the societies. They impose constraints on

political leaders pursuing a policy of accommodation in the form of accusations by opposition elements that the leaders are jeopardizing national existence as well as in the form of anxieties and doubts within the general population that are both fostered and exploited by the opposition elements. However, the internal divisions may also provide potential levers for change in the direction of conflict resolution by challenging the monolithic image of the enemy that parties in conflict tend to hold and by enabling them to deal with each other in a more differentiated way. They point to the presence of potential partners for negotiation on the other side and, thus, provide the opportunity for forming what Kelman called pro-negotiation “coalitions across the conflict lines” in 1993. To contribute to conflict resolution, any such coalition must necessarily remain an “uneasy coalition,” lest its members lose their credibility and political effectiveness within their respective communities.

Another implication of an intersocietal view of conflict is that negotiations and third-party efforts should ideally be directed not to mere settlement of the conflict, in the form of a brokered political agreement, but to its resolution. A political agreement may be adequate for terminating relatively specific, containable interstate disputes, but conflicts that engage the collective identities and existential concerns of the adversaries require a process conducive to structural and attitude change, to reconciliation, and to the transformation of the relationship between the two societies. Finally, an intersocietal analysis of conflict suggests a view of diplomacy as a complex mix of official and unofficial efforts with complementary contributions. The peaceful termination or management of conflict requires binding agreements that can be achieved only at the official level, but many different sectors of the two societies must be involved in creating a favorable environment for negotiating and implementing such agreements.

2.3. Conflict as a Multifaceted Process of Mutual Influence

International conflict is best understood as a multifaceted process of mutual influence and not just a contest in the exercise of coercive power. Much of international politics entails a process of mutual influence in which each party seeks to protect and promote its own interests by shaping the behavior of the other party. Conflict occurs when these interests clash, that is, when attainment of one party's interests (and

fulfillment of the needs that underlie them) threatens, or is perceived to threaten, the interests (and needs) of the other party. Therefore, in pursuing the conflict, the parties engage in mutual influence, designed to advance their own positions and to block the adversary. Similarly, in conflict resolution, by negotiation or other means, the parties exercise influence to induce the adversary to come to the table, to make concessions, to accept an agreement that meets their interests and needs, and to live up to that agreement. Third parties also exercise influence in conflict situations by backing one party or the other, by mediating between them, or by maneuvering to protect their own interests.

Influence in international conflict typically relies on a mixture of threats and inducements, with the balance often on the side of force and the threat of force. Thus, the U.S.–Soviet relationship during the cold war was predominantly framed in terms of an elaborate theory of deterrence, that is, a form of influence designed to keep the other side from doing what one does not want it to do, as described in important books by Schelling in 1963, by George and Smoke in 1974, and by Jervis and colleagues in 1985. In other conflict relationships, the emphasis may be on compellence, that is, a form of influence designed to make the other side do what one wants it to do. Such coercive strategies entail serious costs and risks, and their effects may be severely limited. For example, they are likely to be reciprocated by the other side and lead to escalation of the conflict, and they are unlikely to change behavior to which the other side is committed. Thus, the effective exercise of influence in international conflict requires a broadening of the repertoire of influence strategies, at least to the extent of combining “carrots and sticks,” that is, of supplementing the negative incentives that typically dominate international conflict relationships with positive incentives (e.g., economic benefits, international approval, a general reduction in the level of tension). An example of an approach based on the systematic use of positive incentives is Osgood's GRIT (Graduated and Reciprocated Initiatives in Tension reduction) strategy. Egyptian President Anwar Sadat, in his 1977 trip to Jerusalem, undertook a unilateral initiative with the expectation (partly prenegotiated) of Israeli reciprocation, but—unlike GRIT—he started with a large fundamental concession in the anticipation that negotiations would fill in the intervening steps.

Effective use of positive incentives requires more than offering the other party whatever rewards, promises, or confidence-building measures seem to be most readily available. It requires actions that address

the fundamental needs and fears of the other party. Thus, the key to an effective influence strategy based on the exchange of positive incentives is responsiveness to the other party's concerns, that is, actively exploring ways in which each party can help to meet the other's needs and allay its fears as well as ways in which the parties can help each other to overcome the constraints within their respective societies against taking the actions that each wants the other to take. The advantage of a strategy of responsiveness is that it allows each party to exert influence on the other through positive steps (not threats) that are within its own capacity to take. The process is greatly facilitated by communication between the parties to identify actions that are politically feasible for each party and yet are likely to have an impact on the other.

A key element in an influence strategy based on responsiveness is mutual reassurance, which is particularly critical in any effort to resolve an existential conflict. The negotiation literature suggests that parties are often driven to the table by what Zartman in 1989 described as "a mutually hurting stalemate," which makes negotiations more attractive than continuing the conflict. But parties in existential conflicts are afraid of negotiations, even when the status quo has become increasingly painful and they recognize that a negotiated agreement is in their interest. To advance the negotiating process under such circumstances, it is at least as important to reduce the parties' fears as it is to increase their pain.

Mutual reassurance can take the form of acknowledgments, symbolic gestures, or confidence-building measures. To be maximally effective, such steps need to address the other party's central needs and fears as directly as possible. When Sadat spoke to the Israeli Knesset during his dramatic visit to Jerusalem in 1977, he clearly acknowledged Egypt's past hostility toward Israel and, thus, validated Israelis' own experiences. In so doing, he greatly enhanced the credibility of the change in course that he was announcing. At the opening of this visit, Sadat's symbolic gesture of engaging in a round of cordial handshakes with the Israeli officials who had come to greet him broke a long-standing taboo. By signaling the beginning of a new relationship, it had an electrifying effect on the Israeli public. In deep-rooted conflicts, acknowledgment of what was heretofore denied—in the form of recognition of each other's humanity, nationhood, rights, grievances, and interpretation of history—is an important source of reassurance that the other party may indeed be ready to negotiate an agreement that addresses one's own

fundamental concerns. By signaling acceptance of the other side's legitimacy, each party reassures the other that negotiations and concessions no longer constitute mortal threats to its security and national existence. By confirming the other side's narrative, each party reassures the other that a compromise does not represent an abandonment of its identity.

An influence strategy based on responsiveness to each other's needs and fears, and the resulting search for ways in which to reassure and benefit each other, has important advantages from a long-term point of view. It does not merely elicit specific desired behaviors from the other party but can contribute to a creative redefinition of the conflict, joint discovery of mutually satisfactory solutions, and transformation of the relationship between the parties.

2.4. Conflict as an Interactive Process with an Escalatory, Self-Perpetuating Dynamic

The influence strategies employed in a conflict relationship take on special significance in light of the fourth proposition, which views international conflict as an interactive process and not merely a sequence of action and reaction by stable actors. In intense conflict relationships, the natural course of interaction between the parties tends to reinforce and deepen the conflict rather than reduce and resolve it. The interaction is governed by a set of norms and is guided by a set of images that create an escalatory, self-perpetuating dynamic. This dynamic can be reversed through skillful diplomacy, imaginative leadership, third-party intervention, and institutionalized mechanisms for managing and resolving conflict. But in the absence of such deliberate efforts, the spontaneous interaction between the parties is more likely than not to increase distrust, hostility, and the sense of grievance.

The needs and fears of parties engaged in intense conflict impose perceptual and cognitive constraints on their processing of new information, with the resulting tendency to underestimate the occurrence and the possibility of change. The ability to take the role of the other is severely impaired. Dehumanization of the enemy makes it even more difficult to acknowledge and access the perspective of the other party. The inaccessibility of the other's perspective contributes significantly to some of the psychological barriers to conflict resolution described by Ross and Ward in a 1995 review. The dynamics of conflict interaction tend

to entrench the parties in their own perspectives on history and justice. Conflicting parties display particularly strong tendencies to find evidence that confirms their negative images of each other and to resist evidence that would seem to disconfirm these images. Thus, interaction not only fails to contribute to a revision of the enemy image but actually helps to reinforce and perpetuate it. Interaction guided by mirror images of a demonic enemy and a virtuous self (a concept introduced by Bronfenbrenner in 1961 and elaborated by White in 1965 and elsewhere) creates self-fulfilling prophecies by inducing the parties to engage in the hostile actions they expect from one another.

Self-fulfilling prophecies are also generated by the conflict norms that typically govern the interaction between parties engaged in an intense conflict. Expressions of hostility and distrust toward the enemy are not just spontaneous manifestations of the conflict; they are normatively prescribed behaviors. The assumption of political leaders that their publics' evaluations of them depends on their adherence to these norms influences their tactical and strategic decisions, their approach to negotiations, their public pronouncements, and (ultimately) the ways in which they educate their own publics. For the publics, in turn, adherence to these norms is often taken as an indicator of group loyalty. Thus, the discourse in deep-rooted conflicts is marked by mutual delegitimization and dehumanization. Interaction governed by this set of norms—at both the microlevel and macrolevel—contributes to escalation and perpetuation of the conflict. Parties that systematically treat each other with hostility and distrust are likely to become increasingly hostile and untrustworthy.

The dynamics of conflict interaction create a high probability that opportunities for conflict resolution will be missed. Parties whose interaction is shaped by the norms and images rooted in the history of the conflict are systematically constrained in their capacity to respond to the occurrence and possibility of change. Each party finds it difficult to communicate the changes that have occurred on its own side, to notice the changes that have occurred on the other side, and to explore the possibilities for change that would serve both sides' interests. Therefore, conflict resolution efforts require promotion of a different kind of interaction that is capable of reversing the escalatory and self-perpetuating dynamics of conflict—an interaction conducive to sharing perspectives, differentiating the enemy image, and developing a language of mutual reassurance and a new discourse based on the norms of responsiveness and reciprocity.

3. PSYCHOLOGICAL PROCESSES PROMOTING CONFLICT

Social-psychological analysis can be particularly helpful in explaining why and how, once a conflict has started, normative and perceptual processes that promote its escalation and perpetuation are set into motion and create or intensify barriers to conflict resolution. By the same token, social-psychological analysis, in helping to identify and understand these barriers, can also suggest ways in which to overcome them.

3.1. Normative Processes

A variety of interaction processes at the mass and elite levels of conflicting societies that influence the evolving course of the conflict are governed by a set of powerful social norms that tend to encourage actions and attitudes conducive to the generation, escalation, and perpetuation of conflict and that tend to inhibit the perception and occurrence of change in the direction of tension reduction and conflict resolution.

3.1.1. Formation of Collective Moods

With periodic shifts in collective mood, public opinion can act as both a resource and a constraint for political leaders in the foreign policy process. In principle, public opinion can provide support for either aggressive or conciliatory policies, but under the prevailing norms in an intense protracted conflict, leaders are more likely to expect—and mobilize—public support for aggressive policies than for conciliatory policies. Apart from transitory moods, certain pervasive states of consciousness underlie public opinion in a society engulfed in a deep-rooted conflict, reflecting the existential concerns and central national narratives widely shared within the population. In many cases, such as Serbia, Northern Ireland, and the Middle East, historical traumas serve as the points of reference for current events. Although these memories may be manipulated by demagogic leaders, they are part of the people's consciousness and are available for manipulation, as is the associated sense of injustice, abandonment, and vulnerability. The effect of such collective moods is to bring to the fore powerful social norms that support escalatory actions and inhibit moves toward compromise and accommodation. When fundamental concerns about survival and identity are tapped, national leaders, with full expectation of public support, are far

more ready to risk war than to take risks for peace, in line with the proposition derived from prospect theory (as applied to international relations by Levy and others) that people are more reluctant to take risks to achieve gains than to avoid losses. Any change in the established view of the enemy and of the imperatives of national defense comes to be seen as a threat to the nation's very existence.

3.1.2. Mobilization of Group Loyalties

Public support is an essential resource for political leaders engaged in a conflict relationship, both in ensuring the public's readiness to accept the costs that their policies may entail and in enhancing the credibility of their threats and promises to the other side. The primary means of gaining public support is the mobilization of group loyalties. Arousal of nationalist and patriotic sentiments, particularly in a context of national security and survival, is a powerful tool in garnering public support. It may evoke automatic endorsement of the policies that the leadership defines as necessary and a willingness to make sacrifices that cannot be entirely understood in terms of rational calculations of costs and benefits. The nation generates such powerful identifications and loyalties because it brings together two central psychological dispositions: the need for self-protection and the need for self-transcendence.

Group loyalties can potentially be mobilized in support of conciliatory policies. Political leaders may promote painful compromises and concessions to the adversary on the grounds that the security, well-being, integrity, and survival of the nation require such actions. Indeed, leaders with impeccable nationalist credentials, such as Charles de Gaulle, Yitzhak Rabin, and F. W. de Klerk, are often most effective in leading their populations toward peaceful resolutions of conflicts once they have decided that this approach best serves their national interests. In general, however, group loyalties are more readily available to mobilize support for aggressive policies than for conciliatory ones. Proposals for aggressive actions can more easily rely on the vocabulary of nationalism, which characteristically marks off the in-group from the out-group to the detriment of the latter. An appeal to defend the nation against an imminent attack, in particular, is more compelling than an appeal to seize a promising opportunity, as prospect theory might predict. Also, such an appeal elicits a nearly unanimous response among members of the population, whereas an appeal to take advantage of an opportunity

for peace holds no attraction to that segment of the population that equates peace with surrender.

Processes of group loyalty create barriers to change in a conflict relationship. Group loyalty requires adherence to the group's norms, which call for a militant, unyielding, and suspicious attitude toward the enemy in an intense conflict. Militancy and intransigence thus become the measures of loyalty. Hence, particularly in situations of perceived national crisis, the militants exercise disproportionate power and often a veto over official actions and policies. They impose severe constraints on the ability of leaders to explore peaceful options. Dissent from the dominant conflict norms becomes defined as an act of disloyalty and is suppressed, further undermining the exploration of peaceful alternatives.

3.1.3. Decision-Making Processes

The way in which decisions are made in a conflict situation tends to inhibit the search for alternatives and the exploration of new possibilities, particularly when decision makers are operating in an atmosphere of crisis. These tendencies are by no means inevitable, and there are historical instances of creative decision making in dangerous crisis situations, for example, the Cuban missile crisis (as analyzed by Allison in 1971). However, conflict norms do impose serious burdens on the decision-making process.

A major source of reluctance to explore new options is the domestic constraints under which decision makers labor. In an intense conflict situation, adherence to the conflict norms tends to be seen as the safest course of action. Cautious decision makers assume that they are less vulnerable domestically if they stay with the conflict's status quo, adhere to a discourse of hostility and distrust vis-à-vis the other side, and/or threaten escalatory actions than if they take steps toward accommodation and compromise. The search for alternatives in response to changing realities is also inhibited by institutionalized rigidities in the decision-making apparatus. Decision makers and their bureaucracies operate within a framework of assumptions about available choices, effective strategies, and constituency expectations—shaped by the prevailing conflict norms—that may make them unaware of the occurrence and possibility of change. Furthermore, they often rely on established procedures and technologies, which are more likely to be geared toward pursuing the conflict—by military and other means—than toward resolving it.

The microprocesses of action and interaction in crisis decision making further inhibit the exploration of new options. At the level of individual decision makers, the stress they experience in situations of crisis, when consequential decisions must be made under severe time pressures, limits the number of alternatives they consider and impels them to settle quickly on the dominant response. In intense conflicts, this dominant response is likely to be aggressive and escalatory, as shown in books by Holsti in 1972 and Lebow in 1987. At the level of decision-making groups, crisis decision making often leads to what Janis termed “groupthink,” that is, a concurrence-seeking tendency designed to maintain the cohesiveness of the groups. Decision making under these circumstances is much more likely to produce policies and actions that perpetuate and escalate the conflict than to produce innovative ideas for conflict resolution.

3.1.4. Negotiation and Bargaining Processes

The norms governing negotiation and bargaining between parties involved in long-standing conflict strongly encourage zero-sum thinking, which equates the enemy’s loss with one’s own gain. Negotiation, even distributive bargaining in its narrowest form, is possible only when the parties define the situation—at least at some level—as a win-win, mixed-motive game in which they have both competitive and cooperative goals. Each party, while pursuing its own interests, must actively seek out ways in which the adversary can also win and appear to be winning. But this is precisely the kind of effort that is discouraged by the conflict norms.

At the microlevel, negotiators in an intense conflict tend to evaluate their performance by the forcefulness with which they present their own case and by their effectiveness in resisting compromise. To listen to what the other side needs and to help the other side achieve its goals would violate the conflict norms and might subject the negotiators to criticism from their own constituencies, particularly from their hard-line domestic opposition. At the macrolevel, the parties tend to pursue an overall outcome that strengthens their own strategic position and weakens that of the adversary, even when they recognize their common interest in negotiating certain specific issues. Such a strategy reduces the other party’s incentive for concluding an agreement and its ability to mobilize public support for whatever agreement is negotiated. Zero-sum thinking at both levels undermines the negotiating process, causing delays, setbacks, and repeated failures.

3.1.5. Structural and Psychological Commitments

Finally, conflict creates certain commitments that take on a life of their own and contribute to structural changes conducive to the escalation and perpetuation of the conflict, as described in Rubin and colleagues’ *Social Conflict* in 1994. Most obviously, in a conflict of long standing, various individuals, groups, and organizations (e.g., military, political, industrial, scholarly) develop a vested interest in maintaining the conflict as a source of profit, power, status, and/or *raison d’être*. Others, although not benefiting from the conflict as such, may have a strong interest in forestalling a compromise solution because it would not address their particular grievances or fulfill their particular aspirations. Vested interests do not necessarily manifest themselves in deliberate attempts to undermine efforts at conflict resolution. They may take indirect and subtle forms such as interpreting ambiguous realities and choosing between uncertain policy alternatives in ways that favor continuation of the conflict.

Vested interests and similar structural commitments to the conflict are bolstered by psychological commitments. People involved in a long-standing and deep-rooted conflict tend to develop a worldview that is built around the conflict and would be threatened by an end to the conflict. Resistance to change is likely to be more pronounced when the cognitive structure or ideology in which the view of the conflict is embedded is more elaborate, because changing this view would have wider ramifications. In an intense conflict, the image of the enemy is often a particularly important part of people’s worldview, with implications for their national identity, view of their own society, and interpretation of history. This is one reason why images of the enemy are highly resistant to change and contribute to the escalatory and self-perpetuating dynamic of conflict.

3.2. Perceptual Processes

Perceptual and cognitive processes, that is, the ways in which people interpret and organize conflict-related information, play a major role in the escalation and perpetuation of conflict and create barriers to redefining and resolving the conflict despite changing realities and interests. Two perceptual processes that characterize mutual images of parties in conflict can account for this effect: the formation of mirror images and the resistance of images to contradictory information.

3.2.1. *Mirror Image Formation*

As noted earlier, Bronfenbrenner and White, social psychologists writing about U.S.–Soviet relations, first noted the formation of mirror images as a characteristic of many conflict relationships. Both parties tend to develop parallel images of the self and the other, except with the values reversed. The core content of mirror images is captured by the good–bad dimension. Each side sees itself as virtuous and peaceful, arming only for defensive reasons and prepared to compromise. The enemy, in contrast, is seen as evil and hostile, arming for aggressive reasons and responsive only to the language of force.

A typical corollary of the good–bad images in protracted conflicts is the view that the other party's aggressiveness is inherent in its nature (e.g., ideology, religion, national character, political system), whereas any signs of aggressiveness on one's own part are entirely reactive and defensive. In the language of attribution theory, the enemy's aggression is explained in dispositional terms, whereas one's own aggression is explained in situational terms. Another common corollary of the good–bad image, one that derives from the virtuous self-image, is the assumption on each side that the enemy knows very well that “we” are not threatening them. Each side's own basic decency and peacefulness, and the provocation to which it has been subjected, are so obvious to one's own party that they must also be obvious to the other side. Apart from such generic features of mirror images, which arise from the dynamics of intergroup conflict across the board, mirror images in any given case may reflect the dynamics of the specific conflict. Thus, ethnic conflicts may be characterized by mutual denial of the other side's national identity accompanied by efforts to delegitimize the other's national movement and claim to nationhood, by mutual fear of national and personal annihilation, by a mutual sense of victimization by the other side, and/or by a mutual view of the other side as a source of one's own humiliation and vulnerability.

The mirror image concept implies that certain symmetries in the parties' reactions arise from the very nature of conflict interaction and that they play an important role in escalating the conflict. There is no assumption that all images of the self and the enemy are mirror images, that images on the two sides are equally inaccurate, or that there is empirical symmetry in the two sides' historical experiences and current situation or moral equivalence in their positions. However, the dynamics of the conflict relationship produce a

degree of parallelism in some of the images developed by both participants in that relationship, arising out of the motivational and cognitive contexts in which they operate. At the level of motivation, each side is concerned with “looking good” when blame for the conflict events is being apportioned. Therefore, political leaders feel a strong need to persuade themselves, their own people, the rest of the world, and future historians that the blame rests with the enemy. Cognitively, each side views the conflict from its own perspective and is convinced that it is acting defensively and with the best intentions (painfully aware of its own needs, fears, historical traumas, grievances, suspicions, and political constraints) and that this is so self-evident that it must be equally clear to the enemy.

Mirror images produce a spiraling effect (exemplified by the classical pattern of an arms race) because each side interprets any hostile action by the other as an indication of aggressive intent against which it must defend itself, yet that side's own reactions—the defensive nature of which presumably should be obvious to the enemy—are taken by the other side as signs of aggressive intent. The effect of mirror images is accentuated insofar as the enemy's ideology or national character is perceived to be inherently aggressive and expansionist. In addition to the escalatory effect of mirror images, they tend to make conflicts more intractable because the sharp contrast between the innocent self and the aggressive other makes it difficult to break out of a zero-sum conception of the conflict. However, the concept of mirror images may be a useful tool in conflict resolution. For example, in problem-solving workshops, the parties' discovery that their own actions are perceived differently by the other side than by themselves may open them up to the possibility that the reverse may be true as well. Thus, they may gain access to each other's perspective, insight into the escalatory effects of such two-directional differences in perception, and awareness of the need for mutual reassurance to set a deescalatory process in motion.

3.2.2. *Resistance to Contradictory Information*

The second feature of conflict images, their high propensity to resisting contradictory information, inhibits the perception of change and the expectation of future change. A great deal of social–psychological theorizing and research has addressed the general phenomenon of the persistence of attitudes and beliefs in the face of new information that, from an outside point of view, challenges their validity but is somehow neutralized or

ignored. Research has focused on several types of mechanisms that account for resistance to contradictory information, including selectivity, consistency, attribution, and the self-fulfilling prophecy. The concepts of selective exposure, selective perception, and selective recall all point to the fact that people's attitudes help to determine the kind of information that is available to them. People are more likely to seek out and be exposed to information that confirms their existing attitudes and to perceive and remember new information in ways that fit into their preexisting cognitive framework. The various models of cognitive consistency (e.g., Heider's theory of cognitive balance, Festinger's theory of cognitive dissonance) suggest that, in the interest of maintaining consistency, people tend to screen out information that is incongruent with their existing beliefs and attitudes. Although inconsistent information may also instigate attitude change, it is more likely to be resisted when the existing attitudes are strongly held and have wide ramifications, as is the case with enemy images. Attribution mechanisms, linked to what Ross called "the fundamental attribution error" in 1977, also promote confirmation of the original enemy image. Hostile actions by the enemy tend to be attributed dispositionally, providing further evidence of the enemy's inherently aggressive, implacable character, whereas conciliatory actions are explained away as reactions to situational forces, requiring no revision of the original image (a phenomenon observed in research by Rosenberg and Wolfsfeld in 1977, by Heradstveit in 1981, and by Rouhana in 1997). Finally, interactions between conflicting parties tend to create self-fulfilling prophecies by causing one's adversaries to behave in line with one's expectations—to take on the roles in which they have been cast by the other side—thereby confirming the parties' original attitudes.

The mechanisms that account for resistance to disconfirming information are particularly powerful in a conflict relationship for several reasons. First, images of the enemy and conflict-related self-images are central aspects of the national consensus; therefore, resistance to disconfirming information is reinforced by strong normative pressures. Second, in a conflict relationship, the opportunities and capacity for taking the perspective of the other side are limited, and this reduces the impact of potentially new information about the varieties, changes, and signs of flexibility in the other side's views. Third, the resistance of enemy images to disconfirmation is magnified by strong beliefs about the unchangeability of the enemy and is reinforced by the view that it is dangerous or even

treasonous to propose that the enemy has changed or will change.

Despite all of the reasons why conflict images are particularly resistant to contradictory information, they are not immutable. Social-psychological evidence suggests that they can change, and historical evidence shows that they do change. The challenge for scholars and practitioners of international conflict resolution is to devise the means to overcome their resistance to change.

4. IMPLICATIONS FOR CONFLICT RESOLUTION

Social-psychological analysis can contribute to international peacemaking by identifying the psychological and social processes that generate and escalate violent conflicts and impede their peaceful resolution as well as by identifying the conditions and procedures required for breaking and reversing the conflict cycle and setting into motion a process of change in the direction of conflict resolution and reconciliation. Social-psychological principles have also informed the development and application of various unofficial microlevel efforts at conflict resolution, designed to complement official diplomacy in a larger multidimensional peace process. Efforts along these lines were pioneered by Burton, who described and conceptualized them in his 1969 book and in numerous subsequent publications. Fisher's *Interactive Conflict Resolution* in 1997 summarized and integrated the range of psychologically based models for intervening in protracted conflicts between identity groups. Kelman's model, interactive problem solving, is described in a 1998 article and a series of other publications, as are the problem-solving workshops through which the interactive problem-solving model is operationalized.

The implications of social-psychological analysis for the macroprocess of conflict resolution, as well as for the microprocess of problem-solving workshops and related activities, can be summarized by returning to the four propositions about the nature of international conflict spelled out earlier in this article.

The view of conflict as a process driven by collective needs and fears serves as a reminder that a conflict cannot be genuinely resolved until these needs and fears of the parties are addressed. Only solutions that satisfy the fundamental needs and allay the deepest fears of each party can serve as the basis of a stable, long-term peace and a cooperative, mutually enhancing

relationship. Unofficial interactive approaches to conflict resolution, such as problem-solving workshops, can contribute to resolving contentious issues in ways that meet the basic needs of one party without raising the fears of the other. They do so by enabling unofficial but politically involved representatives of the two parties to engage in exploratory noncommittal communication in which they can enter into each other's perspective, gain insight into the other's (and indeed their own) main concerns, and jointly shape creative new ideas for mutually satisfactory solutions to the conflict. The insights and ideas generated by this process can then be injected into the political debate and the decision-making process within the two societies.

The view of conflict as an intersocietal process points to the limits of political agreements signed by governments, often under the pressure, or with the mediation, of outside powers or international organizations. At least in the case of a protracted existential conflict between identity groups, a durable peace requires movement beyond settlement of the conflict to its resolution. The agreement must address both parties' basic concerns, must be widely accepted within the two societies, and must reflect and further promote structural and attitude change conducive to a transformation of the relationship between the societies. Another implication of the intersocietal nature of conflict is a view of diplomacy as a complex array of complementary official and unofficial processes. Unofficial interactions make it possible to explore potential openings for mutual accommodation and help to create a political atmosphere that is conducive to negotiation. Furthermore, awareness of the intersocietal nature of conflict helps to counteract the monolithic image that parties in conflict tend to have of each other by encouraging them to attend to what is happening within the other society and to the diversity of tendencies that it encompasses.

Problem-solving workshops and related forums for interactive conflict resolution can be seen as coalitions across conflict lines, enabling pro-negotiation elements on the two sides to find common ground in the pursuit of their respective interests. They engage in a process of direct interaction designed to generate ideas for resolving the conflict that address the needs of both parties and to which both parties can feel committed—essential conditions for agreements that will be widely accepted within the two societies and, thus, conducive to a durable peace. Binding agreements can be reached only at the official level, but unofficial interactions can contribute to enhancing the probability and quality of

official agreements. They can also promote and model the new relationship between the conflicting societies on which a long-term peace must ultimately rest.

The third proposition, positing conflict as a multifaceted process of mutual influence, suggests which strategies and tactics of influence between conflicting parties are most conducive to conflict resolution and to the development of a long-term peaceful relationship. Coercive strategies, which are the dominant mode of influence in conflict relationships, entail serious costs and risks and tend to produce only short-term effects. Therefore, there is a need for a shift of emphasis from the use or threat of force to the use of positive incentives. Moreover, positive inducements are most effective when they are deliberately chosen to be responsive to the needs, fears, and constraints of the other party. A key element of an influence strategy based on responsiveness is mutual reassurance, which can take the form of acknowledgments, symbolic gestures, and/or confidence-building measures. A strategy of responsiveness and reassurance is most effective when it addresses the other party's most basic concerns about identity and security and when it adheres to the principle of reciprocity.

The unofficial, noncommittal setting of problem-solving workshops can be particularly useful in identifying and formulating acknowledgments, gestures, and confidence-building measures that each side can offer to the other. Through a process of joint thinking, the parties can help each other to devise steps of mutual reassurance that would be meaningful to the recipient without entailing unacceptable costs to the actor. This process often involves some informal negotiation, including "negotiation" of national identities and national narratives. Parties cannot be expected to abandon their identities or their national narratives, but each party may be able to adjust its own identity so that it is no longer contingent on denial of the other party's identity and to accommodate its own narrative to the narrative of the other.

Finally, the view of conflict as an interactive process with an escalatory, self-perpetuating dynamic suggests that conflict resolution efforts must be designed to counteract and reverse this conflict dynamic. A conflict relationship generates images and norms that entrench the conflict and create barriers to change that inhibit conflict resolution. Therefore, conflict resolution efforts must be geared to discovering the possibilities for change, identifying the conditions for change, and overcoming the resistances to change. Openness to change and reversal of the conflict dynamic depend on the

establishment of a new discourse among the parties characterized by a shift in emphasis from power politics and threat of coercion to mutual responsiveness, reciprocity, and invitation to a new relationship.

At the microlevel, problem-solving workshops and similar approaches to conflict resolution are designed to contribute to the reversal of the escalatory dynamic of conflict interaction by promoting a different kind of interaction characterized by a deescalatory dynamic. To this end, workshops encourage the parties to penetrate each other's perspective, to differentiate their images of the enemy, to develop a deescalatory language and ideas for mutual reassurance, and to engage in joint problem solving designed to generate ideas for resolving the conflict that are responsive to the fundamental needs and fears of both sides.

GLOSSARY

blog (*Web log*) A publicly accessible Web page, updated regularly and often, that serves as a personal journal of the site owner.

chat Text-based synchronous (real-time) conversation between two Internet users through special software.

chat room A virtual environment in which numerous Internet users may “meet” and converse with one another in synchronous communication through typed text.

cyberspace The virtual space that people enter and experience when connected to the Internet, following an idea used in Gibson’s *Neuromancer*.

e-mail Abbreviated term for electronic mail; a typed letter sent to a virtual mailbox over the Internet.

e-mail list (*listserv*) Electronic mailing list where e-mails are sent by subscribers to all other subscribers on the list.

emoticon A cluster of punctuation or a small graphical sign or picture that may be used in online communication to compensate for the lack of nonverbal cues to indicate a facial expression or gesture.

encryption Coding of text through special software so that only the intended receiver of the message can decipher it (i.e., decryption).

forum (*message board or discussion board*) A Web site designed to allow asynchronous group communication.

instant messaging Software that allows text-based synchronous communication, with possible time delays (i.e., users control level of synchronicity), between two Internet users.

post Publishing a message on the Internet, including sending a message to an e-mail list or publishing a message in a forum.

synchronous Coinciding in time of communication that is carried out with all parties present at the same time (e.g., chat).

thread A multiple-part virtual “conversation” on a given topic in an e-mail list or a forum composed by a leading (first) message and responses.

virtual communication Communication between two or more anonymous individuals through the mediation of computers where the looks, appearance, and nature of these individuals are basically the products of their imaginations.

Internet counseling is a general term referring to a wide spectrum of approaches and techniques that exploit the Internet’s special capabilities in facilitating counseling and psychotherapy online. Growing evidence suggests that despite the lack of in-person contact and the consequent lack of nonverbal cues, professionals do provide effective interventions online. However, in addition to focused training in Internet counseling,

special precautions are necessary, especially regarding unique ethical and legal issues.

1. INTRODUCTION

Internet counseling is a generic term that refers to various methods used by psychologists to provide professional services through, or with the help of, the Internet. Common terms that have been used include online (psycho)therapy (or counseling), e-therapy, cybertherapy, and virtual therapy. Although attempts have been made to differentiate among these terms, it has become clear that they refer to similar, if not identical, processes and techniques. Internet counseling involves a variety of online communication technologies that generally fit into 2×2 dimensions: synchronous versus asynchronous communication and individual versus group communication. Individual synchronous communication is conducted by means of personal chat or instant messaging, individual asynchronous communication is conducted by e-mail exchanges, group synchronous communication is carried out through a chat room, and group asynchronous communication is managed by a forum (discussion board) or an e-mail list (listserv). Internet counseling may also include other online methods and tools such as Web site-accompanied therapy and online personal journals. Although currently less prevalent, Internet counseling may also use computer sound and camera (Webcam or videoconferencing) facilities.

Internet counseling is usually text based. Consequently, it is characterized by the invisibility of counselors and clients, lack of nonverbal and physical cues, and absence of eye contact—three factors that significantly influence social communication and interpersonal relations. These characteristics, in addition to other factors such as (possible) anonymity and aloneness by the computer, create the “online disinhibition effect” that brings about greater and faster openness and closeness, on the one hand, and less controlled behavioral expressions (often aggression), on the other. Thus, the therapeutic process accelerates more intensively and rapidly in comparison with face-to-face therapy, resulting in faster disclosures and greater exposure of intimate contents. In addition, unique features of Internet use—availability, flexibility of use (in terms of time and place), affordability, anonymity, acceptability, aloneness, interactivity, hypertextuality, updatibility, multimedia capability, easy departure (escape), and richness of contents—have gradually caused Internet counseling to

become a convenient accepted channel through which people seek psychological consultation and help.

2. HISTORICAL DEVELOPMENT

Although not documented, it seems that serious professional attempts to harness the Internet for therapeutic purposes were first made during the mid-1990s. At that time, e-mail was used as the primary technology to communicate between practitioners and clients, either individually or in groups. Despite positive experiences reported by therapists, traditional mental health practitioners voiced their opposition to the new method, citing its limitations and possible risks. Five major problems were highlighted: (a) counselors' inability to accurately and correctly perceive and evaluate clients' full emotional states due to the lack of visual and physical cues (e.g., tears, smiles, gestures, body movements); (b) therapists' difficulty in communicating warmth and empathy owing to a similar lack of nonverbal cues; (c) the unclear, intangible, easy-to-break boundaries between therapists and patients; (d) the possibility of erroneously dealing with clients from other countries and cultures without being aware of indigenous customs, rules, norms, or other pertinent information; and (e) the risk of dealing with severe pathological cases, especially suicidal clients, brought on by problems relating to identifying and locating them at critical moments. Criticisms also were made in regard to problems of privacy, confidentiality, and security; the possible undesirable effects of clients' individual disadvantages, such as those related to computer and verbal skills, on the therapeutic process and outcome; discrimination against economically distressed potential clients (what has been termed “the digital divide”); and the potential for impersonation, lying, and other abuses of the system. Several professional associations, in addition to individual professionals, published warnings to prevent (or minimize) online counseling or at least to try restricting its possible dangers to clients.

However, with the help of continuously upgraded hardware and software, as well as growing awareness of and experience, training, and pioneering research in this developing field, many of the criticisms have been answered and gradually been overcome. Moreover, arguments began to be advanced that the opposition reflected mainly resistance to change in general and ignored (or downplayed) a growing body of evidence that supported and pointed to the success of Internet counseling.

Evidently, Internet counseling has now been established and is generally accepted as legitimate professional conduct. During recent years, a growing number of publications—theoretically, practically, and empirically oriented—have emerged in professional outlets as well as in professional conferences. A major portal (www.metanoia.org) lists many relevant issues relating to psychotherapy through the Internet. Quite a few professional and scientific books have been published on the subject. A major professional association, the International Society for Mental Health Online, has been formed in an attempt to provide a common organization for professionals interested in this emerging area and to promote the understanding, use, and development of mental health online.

3. THE PRACTICE OF INTERNET COUNSELING

Internet counseling is diverse, heterogeneous, and multifaceted. The following 10 points describe its characteristics and provide some distinctions from traditional counseling. First, unlike traditional face-to-face therapy, Internet counseling can be practiced through various alternative communication channels. These channels differ from one another in terms of synchronicity (usually synchronous or asynchronous communication, whereas instant messaging allows a changing degree of synchronicity), mode (individual or group communication), means of communication (usually typed text, but pictures and voice communication are also possible), and the degree of on-site human involvement (direct human interaction, self-help by using information and instructions published on a Web site, or online interactive software). Thus, clients have a wide range of choices. Counselors may specialize and offer a specific service modality and provide it through numerous channels. Likewise, clients may receive service through one or more channels of communication.

Second, Internet counseling may be practiced as a complementary, adjacent, or adjunctive process to face-to-face counseling or as an independent process of therapy. As an accompanying procedure, clients may use online communication with counselors in between their face-to-face sessions (according to preestablished agreed-on rules); manage online diaries (i.e., specific behavior monitoring and recording) relevant to the therapeutic process that may be inspected and reviewed by themselves and their counselors at a time and place of choice; deliver materials relevant to the therapy

process such as articles, important links, and necessary or urgently needed documents; and publish and maintain a Web site in which consequences or the offspring thoughts of face-to-face sessions may be expressed or implemented (i.e., a blog). Cyberspace may also be used to search for materials and information found to be relevant in the face-to-face meetings or for exercises and practice activities suggested in face-to-face sessions. In all of these procedures, counselors attempt to integrate offline and online therapeutic experiences at different rates and to different degrees to promote clients' change. Independently, clients and counselors may meet online (usually, but not necessarily, through a designated Web site) and interact virtually through an online channel(s) of communication. In using this procedure for therapy, counselors and clients may be distant from each other geographically, interact in different time zones, and become involved with the therapeutic interaction at a time of choice (if asynchronous communication is used). To overcome the lack of standard, normal, and familiar therapeutic procedures in these cases, such as checking and evaluating therapists' credentials, payment procedures (often done through third-party payment), emergency contacts, and termination of the therapy, a set of instructions and rules is usually established and agreed on between counselors and clients at a preliminary stage. Internet counseling methods, rates of sessions, and lengths of interactions vary among counselors according to their approaches, their availability, the clients' particular problems, communication channels, costs, and other professional considerations.

Third, Internet counseling generally relies on text-based communication between counselors and clients. Writing can often be healing. For many people, venting their personal concerns, expressing their deepest feelings, and sharing their intimate thoughts—all while alone and writing as though talking to themselves, free of therapists' scrutinizing eyes, feeling more secure and protected in their own habitats than in counselors' offices, having the ability to preserve a full record of counseling dialogues, and experiencing less intimidation in developing relationships with virtual (but trustworthy) figures—contribute to creating a unique therapeutic experience, much different from traditional “talking and listening” counseling. The ability of clients to read back, cite, and quote themselves or counselors adds a special value to the counseling dialogue. For many people, sharing their writings—even from the past—with trusted individuals gives them a feeling of relief and sometimes even of elation.

Fourth, Internet counseling may be provided to individuals for either long-term or short-term interventions as well as for single consultations. Although continuous counseling process enables the establishment of relationships between counselors and clients as well as the development of trust and greater exposure, a one-time question-and-answer psychological service is quite common on the Internet. Similar to advice columns in newspapers and magazines, clients present (usually either through sending e-mails or posting messages on online bulletin boards) personal issues and expect counselors to provide advice or solutions. However, there are several differences. First, online consultations are not necessarily public given that clients may discretely send e-mails to counselors and receive private answers from counselors who offer such a service (through Web sites or other means of communication). Second, accumulated questions and answers can be (and actually are) edited and posted on the Internet, classified by problem area, target population, and the like, with the help of an index and an internal search engine for the benefit of many visitors. Third, such an online service is convenient and relatively fast, and it enables people in distress to consult anonymously with experts during times of need for quick assistance.

Fifth, Internet counseling enables consultation and treatment through various theoretical therapeutic approaches, methods, and techniques. For example, psychodynamic, cognitive, and behavioral approaches have been used online, with each one finding the Internet to be a convenient—or even an ideal—platform for interacting with clients according to counselors' own conceptions and principles. For psychodynamic counselors (and even more so for psychoanalytic counselors), cyberspace represents a ready desirable environment for psychotherapeutic encounters because it is characterized by ambiguity. Thus, dynamic processes activated by projection, transference, and object relations usually prevail. In other words, the perceived disadvantages of Internet relationships, such as invisibility and blurred boundaries, become advantageous to counselors who hold to the psychodynamic approach. Therefore, analyzing clients' personality dynamics becomes easier, generally faster, and perhaps more valid than traditional therapy. For cognitive counselors, the straightforward use of clients' verbalization of thoughts and feelings obviously represents a major advantage. Compared with traditional therapy, cognitively oriented counselors are more able to assess and identify thought patterns that may be responsible for negative emotions and consequent problematic behaviors.

Because all online verbal interactions with clients are recorded (when using the common text-based therapy), clients' statements are easy to cite, compare, analyze, and manipulate. In this context, it is important to mention that therapists who apply bibliotherapy and therapists who claim that writing and reading can heal also find online, text-based therapy to be a highly effective therapeutic means. Likewise, users of narrative psychotherapy can exploit written interactions with patients to effectively help them construct and reconstruct personal "stories." Yet behaviorally focused counselors also find Internet counseling to be ideal medium in many senses in that it allows a structured, programmed, straightforward, easy to construct and maintain set of instructions to be communicated to clients, whether through personal contact or through Web sites. Moreover, clients' continuous recording of behavioral data and their delivery to counselors are simple and efficient. Counselors may guide, supervise, and monitor clients' behavior management from a distance and use in vivo simulations of various behavior tasks, accompanied by immediate feedback. Various theoretical approaches, then, can be applied through Internet counseling, as can any eclectic combination desired by counselors. It is important to note, however, that the unique psychological environment created in cyberspace might eventually result in a unique or new adaptation of traditional therapeutic approaches that previously were used solely in the face-to-face physical environment.

Sixth, not only does Internet counseling allow more than a single, standard, and invariable way of communication, its alternative modalities also enable a variety of interactions and activities that may enrich the counseling experience and contribute to client change. In addition to the obvious advantage of Internet counseling in terms of flexibility of location and time, several other features provide added value to the interactions. Asynchronous personal communication through e-mail enables the occurrence of several psychological processes that may improve the counseling experience. For clients, the ability to express feelings and thoughts at times of their choosing—especially at times of personal distress—and not at periodic predetermined meetings with counselors, is a significant advantage. The ability to reread counselors' messages as often as desired, and at any time, is also important. Patients' ability to reflect, associate, consider, recall, and process these interactions in between e-mail exchanges contributes to psychologically desirable incubation and reflection processes. Moreover, the ability to go back and compare notes—the clients' own notes or their counselors'

notes—is very useful during the therapy process. In addition, the simplicity of attaching other documents to e-mail messages, including drawings and links, possibly makes e-mail interaction more effective than mere talk. For counselors, e-mail interaction enables referring to clients at times of their choosing and convenience, providing more opportunities to analyze, compare, recall (i.e., retrieve previous messages), use quotes, and enrich response messages with important relevant links and documents. Likewise, counseling through asynchronous group communication—by using e-mail lists or forums—enables all group participants to benefit from the same advantages. An additional special ingredient that exists in asynchronous online groups is the ease of members' interacting individually with one another through a back channel of communication, a factor that might contribute to groups' dynamics and change so long as there are certain rules that participants must follow. Synchronous individual counseling, executed through a chat or an instant messaging program (e.g., ICQ), enables real-time communication between patients and their therapists from nearly any location. Unlike telephone conversations under similar circumstances, the use of computers allows conversations to be saved for future recall, analysis, and/or quoting. The disinhibition effect of online communication brings about a rapid exposure of significant and essential material for counseling. In many instances, clients open up in minutes about matters that would have taken weeks or even months to reveal in face-to-face interaction with therapists. Moreover, by experiencing less intimidation (and, consequently, being less defensive) and feeling more egalitarian and equal in status, patients have a greater chance of constructively processing and adopting therapists' messages. One of the unique features of synchronous communication that is available to counselors only on the Internet is "multiconversing," that is, conversing privately with several individuals in parallel. Although the technology requires certain technical and cognitive abilities and skills that might be acquired and promoted through training and experience, multiconversing allows a counselor to make use of the time required for one client to read the counselor's message, process it, and type a response to communicate with other clients. Although special concentration and refocusing abilities are obviously required, possible benefits of this activity are clear, especially when providing counseling services to a population through an Internet-based support center. However, synchronous online group therapy (through a chat room) is quite difficult to manage due to the lack of nonverbal

communication and the difficulty in controlling participants' behavior. If practiced, it is important to have a strict, well thought out set of rules and a small number of participants (usually not more than seven).

Seventh, the practice of Internet counseling allows nonhuman interventions; that is, providing interventions through psychoeducational Websites, as well as through interactive software. Advanced sophisticated Web sites employ interactive software that communicates with users in an attempt to assess and provide tailored intervention in specific problem areas. This is done through various alternative methods, including interactive conversations with robotic therapists, adaptive and tailored instructions in dealing with a specific problems, meditating and relaxation suggestions, and interactive decision-making assistance (e.g., about a career direction or school major). More recently, attempts have been made to adapt virtual reality software in the field to the Internet, thereby allowing mass use and continuous central upgrades. Therefore, the ability of advanced (and continuously developing) software to deliver professional information and interventions in an efficient, attractive, rich, and friendly way makes this a prevalent and pervasive type of communication with clients. Regardless of the areas of distress or problems, whether quitting smoking, obtaining sexuality education, experiencing posttraumatic stress disorder following a sexual assault, facing the death of a loved one, choosing a major in school, or going through a divorce, a well-designed, thoughtful, updated, interactive, sophisticatedly linked (to other Web resources), and stimulating Web site can provide effective psychological interventions for people in need. As in any process of self-help, users' commitment, on the one hand, and counselors' monitoring, on the other, may be problematic. However, the cost-benefit advantage, in addition to factors mentioned earlier (e.g., anonymity), has turned this into a common and successful approach.

Eighth, free Internet counseling, by means of information, advice, and support, has flourished. Despite the clear problem of potential abuse of the system by nonprofessionals or even criminals (e.g., practicing without a license), the use of the Internet has enabled people in need to reach out for psychological help when, for whatever reasons, they could not receive it in standard ways. People in remote locations, the physically disabled, the elderly, the sick, those with financial limitations, and those who are too shy, introverted, or afraid of exposure (e.g., celebrities and their families) all fall into this category. Online support services for a variety of areas of distress are operated by governments,

organizations (e.g., schools), professional associations, and private people for free. Usually, e-mail consultation is offered to individual referrals. One of the main activities of such free counseling services, however, is the provision of online support groups, in which participation is usually open. This type of Internet counseling, with or without the active participation of trained counselors, is widespread and considered to be successful.

Ninth, Internet counseling is effectively and conveniently used as a vehicle for communicating with clients before beginning and after terminating face-to-face counseling. Information provided through Web sites regarding counseling approaches, counseling methods, the counseling process, specific counselors, costs, insurance coverage, and technicalities equip clients with important and relevant knowledge before starting counseling. Questions and unclear matters are easily dealt with through e-mail. This preparatory stage not only saves time and effort but also helps to build realistic constructive expectations about therapy. After termination, e-mail is conveniently used to contact former clients at any point in time, either for professional follow-up or for research purposes (e.g., questionnaires may be attached). On termination, Internet counseling clients are often urged to make e-mail contact with their counselors when needed. This step provides not only a convenient way in which to communicate but also reassurance for patients departing from close, and sometimes dependent, therapeutic relationships. It should be noted, however, that this option might hinder clients from working through successful terminations.

Finally, Internet counseling may include and coincide with online psychological assessment procedures. Online psychological tests, usually in a multiple-choice format, are very common on the Internet, although they do not necessarily produce valid assessments due to the nonprofessional construction and publication of these tests. However, much effort has been made to develop online tests and questionnaires that meet rigorous psychometric standards and make valid assessments. In addition, other assessment procedures, such as online interviewing through videoconferencing, have been implemented. Counselors who operate on the Internet may use professionally established online diagnostic tests that integrate with the counseling process, thereby avoiding cumbersome paper-and-pencil testing of clients with whom they interact online. Several methods have been developed to ensure test quality and to verify clients' identities if necessary. It should be kept in mind, however, that whereas

online tests produce test-based assessment, counselors miss the opportunity to diagnose clients in relation to their test-performing behaviors (e.g., nervousness).

These 10 principles characterize Internet counseling and make it unique and different from any previously practiced psychological interventions. These principles represent a significant revolution in the traditional conception of psychotherapy. Perhaps this is the reason why many have voiced concern about its implementation and growing acceptance by practitioners.

4. RESEARCH ON INTERNET COUNSELING

As a relatively new area of conduct, Internet counseling has been subjected to empirical study in only a limited scope. Yet published research reports, or those presented at public conferences, can shed some light on intriguing questions regarding therapeutic process and outcome as well as on other important subjects (e.g., training of counselors). It is important to note that the methods used for research on Internet behavior and Internet-related interventions are somewhat different from those used for research on offline counseling. In Internet counseling, individuals often are anonymous and unidentifiable, people's behaviors often parallel their written scripts (and not their observed behaviors), technical difficulties might interfere with the durability of data, imposters and fakers among participants are possible, dropout rates are higher than usual, and so forth. Research has been conducted on various questions that are important for Internet counseling, including some issues relating to the process and outcome of a variety of online counseling interventions, the impact of online support groups, and the quality of measurement of online testing. In addition to research, quite a few case studies have been presented in publications and at conferences.

An overview of the empirical research on Internet counseling provides support of an emerging approach. Process-related research has found that clients of online therapy actually build therapeutic relationships, communicate and express themselves effectively, experience therapeutic alliances, and find relationships with therapists to be satisfactory. Outcome research in numerous areas of distress, such as depression, several types of anxiety, recurrent headaches, eating disorders, pathological grief, panic disorder, and general concerns, often provides positive results, usually in comparing effects with those of parallel offline treatment. Most of this

research has found that Internet counseling leads to results that are similar to, and sometimes even better than, those of traditional counseling. Feedback from Internet counseling users frequently highlights their appreciation of flexibility of use in terms of place and time, the value of experiencing sensitive (and sometimes threatening) relationships and avoiding physical proximity and eye contact, the importance of written records of conversations, and the reassuring feeling due to the options of anonymity and easy termination.

More research has been published on online support groups than on online psychotherapy. Studies have reported that online group dynamics are generally similar to those of offline groups in terms of therapeutic factors and group processes, although the weight and impact of these factors may vary. Outcome research on online support groups has consistently found a great impact on participants in terms of emotional relief and symptom reduction. Users of online support groups repeatedly praise this activity and highlight the ability to find a place where other people go through difficulties similar to their own and to share feelings and thoughts with them, receive and provide advice, and experience nonjudgmental acceptance.

Research on Internet-based assessment, especially online testing, has generally been very supportive. In most published research, it has been found that when online diagnostic tests are professionally constructed and managed, they offer psychometric qualities similar to those of their offline equivalents. Moreover, most test takers find this activity to be convenient and satisfactory. However, research does show that test parameters may change significantly from offline to online versions. Thus, a new standardization is suggested, as is caution in interpreting raw scores derived from the Internet.

In contrast to those findings, research on self-help Web sites has consistently found the validity of information provided to users to be questionable. Problems have been found regarding wrong or even misleading information, superficial and nonprofessional information, obsolete information and the slow pace of updates, and biased and selective information (in many cases reflecting Web site owners' agendas). Not only may these problems result in not helping users' behavioral and/or emotional states, they might even cause more harm in extreme situations.

Very little research has been published on software-managed Internet counseling. Although experimental data from laboratory studies seem to be promising, there is still much to be investigated in terms of actual effectiveness and the impact on real online clients.

5. ETHICAL, PROFESSIONAL, AND LEGAL CONSIDERATIONS

The special challenges introduced by online provision of psychological applications, especially treatment interventions, have generated debate, especially on ethical issues. It seems that two significant differences from the traditional counseling encounter—the invisibility of therapists and patients, on the one hand, and the communication from a distance, on the other—have triggered much criticism, at times even leading to a point of total debarment. This outcome comes on top of the reliance on new and developing technologies and unstable communication technology, many people's uncertainty and anxiety over technology in general, the lack of computer knowledge and skills, the discriminating digital gap, and the fluidity of professional boundaries, to mention just a few factors. All of these have created the need for thorough ethical and professional considerations and subsequent remedies. Several professional organizations (e.g., American Psychological Association, Clinical Social Work Federation) have published statements emphasizing the concern and need for special caution. Other professional organizations (e.g., American Board of Certified Counselors, American Counseling Association, International Society for Mental Health On-line) have endorsed special ethical codes regarding the provision of Internet counseling.

The ethical standards according to which professionals are advised to practice Internet counseling correspond to, and coincide with, general ethical guidelines for counseling practice. These standards also complement their special online environment and connection with clients. Several major principles form the center of the common ethical codes. First, because online communication is essentially different from regular face-to-face communication, clients ought to be oriented about online limitations in communicating (e.g., lack of nonverbal cues, technological failures) and how to deal with them. Second, counselors must reveal some of their personal details (e.g., full names) and share their professional qualifications with clients. Third, counselors are expected to explain to clients the potential benefits as well as the potential risks of Internet counseling. Fourth, counselors are advised to create and come to an agreement with clients on rules according to which counseling will take place (e.g., frequency of and reaction time to e-mails). Fifth, counselors ought to practice special safeguards in protecting the secrecy of clients' records and correspondence (e.g., use encrypted e-mail, chat through a secure site,

protect computer records by means of a password). Sixth, counselors should discuss emergency situations with clients, including alternative channels of communication and local backup service.

There are quite a few other ethics-related, professional, and legal issues and considerations of which counselors must be aware. The easy access to and reception of Internet counseling by minors necessitates special attention to clients' ages and acquiring guardians' legal consent (where the law requires it) in cases where minors are referred to counseling. Obviously, this is not an easy task to deal with given that many young referrals want to maintain secrecy—often from their parents—and preserve anonymity. The ability to provide counseling services to clients from other states, provinces, and countries introduces complicated legal problems that reflect issues of jurisdiction, legal accountability, and the like, leading to possible lawsuits. In addition, the ability and ease of being referred to counselors from other cultures—a very common phenomenon—necessitates a special awareness of language limitations and intercultural differences that might significantly intervene in the counseling process and outcome. Standard malpractice insurance might not cover online professional practice; hence, counselors must take special cautionary steps.

Another issue deals with providing counseling to anonymous clients. As indicated previously, this factor has a significant impact on the special value of Internet counseling; however, it also raises concerns of a possible legal (e.g., parental consent for minors, duty to report of crime) and professional (e.g., emergency action at a time of potential suicide or violence) nature. It should be noted here that special attention has been given to suicidal referrals and to people who are in emergency situations. Perhaps related to the harboring of traditional conceptions and habits—assuming that physical proximity and face-to-face visibility have special value in helping people and in saving lives in extreme situations—is the fact that many Internet counselors prefer not to accept clients in such situations for therapy and instead prefer to refer them to face-to-face services or to telephone hotlines. It should be noted, however, that the support provided through online channels to suicidal people and to people who were extremely disturbed emotionally has proven to be as successful as that provided through offline traditional services. Owing to anonymity, ease of termination, and the lack of eye contact, it seems that people in these situations may be drawn to online counseling more easily than to offline counseling, thereby giving them a better chance of being helped.

To deal with the identity and authenticity of online counselors, a system of credentials checking has been suggested. Counselors who desire this service would supply full details and documents relating to their identities and qualifications (i.e., professional training and experience). These would be checked and verified with the authorizing bodies and institutions. When confirmed, counselors would receive special icons to be posted on their Web sites. Concomitantly, the system would educate potential users to apply only to counselors whose sites carry the permit. Although this idea might solve a major problem that currently characterizes Internet counseling, its application is still in the developmental stage.

Payment for Internet counseling is another professional issue. Although it was originally thought that fees for online counseling would be lower than those for face-to-face counseling, the fees (where counseling is not provided free of charge) are actually similar to those for in-person counseling. It seems that the special expenses for technology and continuous upgrades, the cost of required security measures, and the extensive time needed for counselors to type (as opposed to talk) made the preliminary expectations concerning reduced fees premature.

6. LIMITATIONS AND PROBLEMS

Internet counseling is not flawless or simple to use and is vulnerable to quite a few problems. The heavy dependence on technology, including electricity, the numerous components of personal computers, and complicated Internet communication, makes the whole system vulnerable and fragile. Working with sensitive clients in shaky situations under these circumstances imparts an uncertainty, or even risk, to Internet counseling. Internet counseling also requires that both counselors and clients be skilled in the use of computers and the Internet because a lack of skills or limited skills directly affects the counseling process. Unskilled counselors might, for example, lose contact with clients in the midst of highly sensitive sessions without preparing the clients for such incidents, where the consequences might be detrimental. Moreover, this type of counseling, suits those who find Internet communication to be easy and convenient, who prefer reading and writing over listening and speaking, and who do not find computer technology and Internet surfing to be intimidating. Still another problem has to do with the “digital divide,” that is, discrimination

against “economically challenged” individuals. Although free Internet services are available in some public places, this certainly cannot be considered to be a solution to a problem that prevents many from receiving counseling.

The existence of sophisticated hackers and computer-savvy individuals who might infiltrate private computer zones and copy, alter, or eavesdrop on confidential materials represents another severe problem. Although developing legislation worldwide and changing the policy and priorities of the police regarding hackers might seem to lessen this problem in the future, and although offices and/or file cabinets certainly are not impenetrable themselves, Internet counseling is still considered to be less secure than face-to-face counseling. However, the growing use of encrypted online correspondence reduces the severity of this problem. Finally, a major problem has to do with untrained professionals who practice online. The practice of Internet counseling requires special incremental training, on top of standard counseling education, that focuses on the specific knowledge needed to practice counseling online. Professionals who offer Internet counseling without appropriate training might not provide optimal counseling to clients, at best, and might cause harm to them, at worst.

7. SUMMARY

Internet counseling harnesses advanced computer and communication technology so that professionals can provide consultation and therapeutic services to people who can and want to use the Internet for these purposes. Despite the criticisms voiced by individuals and organizations alike regarding problems and disadvantages of the new approach compared with traditional face-to-face counseling, this movement has been growing in size and scope. With proper awareness of the risks and limitations, appropriate professional training, strict and well-communicated ethical codes, public education, and perhaps legal actions, Internet counseling might prove not only to be useful and efficient but also to exceed traditional counseling in many ways. The possibility of reaching remote populations that do not receive counseling services regularly and of providing convenient access to disadvantaged, shy, and disabled people as well as people who want to avoid exposure, the importance of automatically stored records for reflection and further psychological analysis, and the great opportunities for education, supervision, and research all make

Internet counseling unique and useful. In the current trend, it seems that professional associations are cautiously and gradually endorsing Internet counseling as a legitimate, but not problem-free, method of providing counseling.

because of their association with a releaser or unconditioned stimulus).

socialization A lifelong process through which every person learns cultural, social, and group norms, both explicit and implicit, through the influence of parents, siblings, peers, teachers, the media, and social organizations.

socially desirable characteristics Characteristics of a subject that are perceived as positive for the majority of a society.

GLOSSARY

arousal Physiological activation level of a person at a given moment, which varies according to many situational and psychological variables.

complimentary of needs An interpersonal state in which one's needs tend to be satisfied by another's behavior, and one's behavior tends to satisfy the other's needs.

personally desirable characteristics Characteristics of a subject that are perceived as positive by another, regardless of whether they are socially desirable or not.

pheromones Biochemical hormone-like substances that seem to be involved in eliciting sexual attraction and perhaps also interpersonal attraction (and a promising and intriguing future area of research).

propinquity Physical proximity between two (or more) persons, which increases the possibility of interaction and therefore familiarity, with a tendency to increase interpersonal attraction.

releasers In sociobiological language, stimuli that tend to elicit an automatic, unconditioned attraction response (in contrast to conditioned stimuli, which raise attraction

Interpersonal attraction (IA) plays a major role in human lives, improving both personal well-being and interpersonal relationships, or on the contrary, resulting in adaptive, interpersonal, and psychological problems if one fails to attract others or to find others attractive. The main factors that provoke IA are socially and personally desirable characteristics (including physical attractiveness), similarity, reciprocity of attraction, propinquity, familiarity, high arousal level, complimentary of needs and, presumably, pheromones. People feel attracted to both unconditioned and conditioned stimuli, thus not only are biological processes relevant, but also sociocultural, interpersonal and psychological factors all play a role. Sociopsychological knowledge can be applied to try to improve IA so as to construct better interpersonal relationships and improve quality of life. This can be done in a variety of fields and contexts, such as within organizations, sports teams, school, the family, the couple, therapy, politics, and international and intercultural relationships.

1. INTRODUCTION

All human beings are heavily influenced by interpersonal attraction (IA) in their everyday lives, and this has been the case throughout the history of humankind. In this threatening and problematic world, IA may be one of the keys to harmonious relationships, and its absence leaves the door open to negative feelings and negative interpersonal behavior patterns. Clearly, it would be blithe to suggest that social problems can be solved through increased IA; rather, attention should be focused on the major role IA can play in improving personal well-being and interpersonal and social relationships.

Although it contrasts in important ways, IA is firmly linked to other basic feelings and behavior patterns essential for personal well-being and everyday social interaction, such as the need for affiliation (and group processes), fondness, friendship, and love itself. Failure to attract others or to find others attractive often results in adaptive, interpersonal, and psychological problems.

2. WHAT IS IA AND WHAT GENERATES IT?

IA is usually described as a positive attitude toward someone, or an attitude or evaluation of other people in terms of how much one likes or dislikes them. Being an attitude, IA has an affective, a cognitive, and a motivational behavior component, and is mainly learned via the socialization process and in everyday interaction. Like all other attitudes, IA influences (and is influenced by) people's behavior, cognition, and feelings.

In summary, IA is based on the need for affiliation of he or she who is attracted, and its origins can be found in a feature or features of the attractor as they are perceived by the attracted. This article does not provide an exhaustive list of different factors and processes that psychological research has shown to generate IA, nor an attempt to identify those that are strictly necessary, but rather a general overview of such complex phenomena is presented, based on the main findings of empirical psychological research, whose general conclusions, despite exceptions, lead to a better overall understanding of IA. The characteristics that social psychological research has shown to generate IA, then, are the following, as shown in [Table I](#).

TABLE I
Main Factors That Generate IA from A to B

• Socially desirable characteristics of B (perceived by A)		
• Physical attractiveness	• Social skills	• Intelligence
• Competence	• Affection	• Kindness
• Sense of humor	• Generosity	
• Personal characteristics of B (perceived by A) specially valuable for A		
• Similarity between A and B (perceived by A)		
• Values	• Attitudes	• Interests
• Customs	• Opinions	• Likes (and dislikes)
• Reciprocity of attraction between A and B (perceived by A)		
• Propinquity between A and B		
• Familiarity between A and B		
• Complementarity of needs between A and B (e.g., talkative and a good listener, protective and vulnerable, etc.)		
• High arousal level of A		
• Pheromones of B		

1. Socially desirable characteristics of the subject of attraction, such as social skills, intelligence, competence, affection, kindness, a sense of humor, and generosity. It is important not to underestimate the influence of physical attractiveness, which has been shown to have stronger links with IA and with other positive attributions than most would like to acknowledge. Whether this is due to the halo effect, to the learned association of "what is beautiful is good," or to both, the fact of the matter is that although it may seem unjust, there are clear indications of this effect.

2. Personally desirable characteristics of the subject of attraction: personally desirable for the attracted, meaning that some features not universally considered as positive are specially relevant for the attracted. Examples of such traits include self-sufficiency, modesty, seriousness, being easygoing, eroticism, femininity, masculinity, leadership, sociocultural status or prestige, knowledge, or even a particular hobby or interest, a reminder that "beauty is in the eyes of the beholder." This is one of the more interesting questions regarding IA: what leads a person to feel attracted toward one kind of person and not another? Where does attraction to specific traits come from? In this section, this question is addressed, calling on the biological, cultural, social, interpersonal,

and finally personal (psychological) forces that exert their influence on the individual's feelings of attraction toward some particular trait or person. In simple terms, the socialization process, life experiences, history of reinforcements, and everyday interaction that contribute to one's personality all offer some of the most coherent answers to these often-asked questions.

3. Similarity between attractor and attracted, not only in core values, but also in many other areas: attitudes, interests, customs, opinions, likes and dislikes, etc. This is one of the most firmly established and empirically supported findings in social psychology, although it is not always accepted by the general public. And whereas similarity generates attraction, dissimilarity tends to generate rejection.

4. Reciprocity of attraction: it is also well known that being liked by another is a good predictor for being attracted toward him or her, because people certainly like to be liked (just as being rejected is a good predictor for rejecting someone). The strength of this effect is such that the mere perception of reciprocity is sufficient to trigger IA, regardless of whether this perceived reciprocity is real.

There are some other factors that have been related to IA, such as propinquity (although the curious phenomenon of IA across the Internet is becoming increasingly pertinent); familiarity, in accordance with the "mere exposure" effect; a high arousal level, such as the one evoked by a new, risky, uncertain, or ambiguous situation, or a situation in which our senses are overloaded; or complementarity of needs, something that leads people to the often mistaken conclusion that "opposites attract." Alongside these other factors, some authors have outlined the role of biochemical substances named pheromones, which seem to be related to sexual attraction and probably also to IA. Thus, popular references to the "chemistry" of a relationship may have some real foundations. And there is one last factor that may be just as crucial to IA as it is in the rest of human lives: mere chance (though perhaps somewhat difficult for some scientists to accept). To be in the same place at the same time, with the same aims and attitudes, and to be introduced, or simply informed of the other's existence, clearly introduces a note of randomness to the incidence of attraction. IA, therefore, is one of the bases for friendship and love, but these other interpersonal relationships imply other factors outside the scope of this section.

As with any interpersonal process, IA is not a static but a dynamic phenomenon. It begins at a certain moment, develops, and can be maintained (through

intermittent reinforcement, by establishing a good balance between costs and rewards, or through cognitive processes like attribution or dissonance, for example) or diminished (through the learning laws of habituation and satiation, or a bad costs-rewards balance). It is just as important to focus, then, on factors that tend to maintain or diminish IA as well as those that generate it.

3. CAUSES AND EXPLANATIONS FOR IA: THEORIES OF SOCIAL PSYCHOLOGY AND LEVELS OF ANALYSIS

There is already an overwhelming body of literature on IA, ranging from classic studies to the most recent work. In the last few decades, there has been a constant stream of research in the field, and hundreds of papers have been published. Some research is serious and systematic; some, quite frankly, is not. With reference to the former, many theories have been offered regarding IA, to explain why humans feel particularly attracted to some individuals. Some of those theories propose explanations in terms of reinforcement, others focus on cognitive processes, others still on the concepts of social exchange. Taking the findings as a whole, it could be said that an individual will probably feel IA for those who match one or more of the following conditions: those who reinforce his or her behavior, those who produce reinforcement expectations in the individual, those who show similar attitudes to him or her, those who satisfy his or her needs, those who decrease everyday worries and negative feelings, those who provide more benefits than costs to the individual, those who provide him or her approximately the same benefits as costs, those who provide just the type of resources the individual desires, those who the individual chooses of his or her own "free will," those who are attracted by the individual, those who the individual feels he or she should not feel IA for, those whose behavior is reinforced by him or her, those who reinforce the individual "freely," and/or those who give him or her positive information.

Each one of these different conditions is upheld by one or more of the many different theories of social psychology that have been applied to explain IA. Many of them are classic, well-known theories, such as theories of reinforcement (and its application to IA, such as Byrne's famous attraction paradigm), of balance, of cognitive dissonance, of social comparison, of reactance, of self-perception, of social exchange, of

TABLE II
Factors from Different Levels of Analysis That Influence IA from A to B

<i>Level of analysis</i>	<i>Factors influencing IA</i>
Species	Biological factors, pheromones, releasers
Culture	Esthetic criteria, cultural trends, culturally valued traits
Society	Social norms of IA, social influences, social pressures, socialization agents, and organizations
Interpersonal	Everyday interaction, group processes (conformity, modeling, etc.), propinquity, familiarity, reciprocity, complementarity
Individual	Personality (specific characteristics, values, attitudes, attraction to certain specific characteristics), physical attractiveness, needs, arousal level (generated by interaction with the situation)

gain-loss, of interdependence, and of equity. However, the process of IA, as with many other interpersonal processes, is deeply influenced by a wide range of factors, which can be understood more easily if some different levels of analysis are considered, as shown in Table II.

3.1. Species

As a member of the human species, we are often physically attracted to physical stimuli called “releasers,” which tend to elicit an automatic response of attraction. Thus, sociobiological researchers have found that as a general rule, despite usually quite significant cross-cultural differences, men tend to feel more attracted by women with neotonous (child-like) facial characteristics, large and firm breasts, narrow waists, fine eyebrows, moderately wide hips, a slim and curvaceous figure (commonly reinforced by high-heeled shoes in some cultures), long and slender legs (exaggerated by the use of short skirts), a slightly protruding backside, and a lack of body hair. According to the same kind of studies, women, meanwhile, tend to feel attracted by a strong jaw, rough skin, bushy eyebrows, a firm and compact backside, a robust frame, tall stature, large eyes, and a flattish stomach. Furthermore, the role of pheromones,

mentioned previously, is another biological factor related to IA. Of course, IA is not the same as physical attraction, but many social psychology researchers have demonstrated a very strong link between the two phenomena, such that people often feel IA for those who seem physically attractive to them, just as they tend to perceive those whom they feel IA for as more physically attractive than they supposedly are. Moreover, as was previously mentioned, neither IA nor physical attraction are evoked only by unconditional (automatic, instinctive) stimuli, but rather by conditioned (learned) ones, which each individual has learned to associate with that response throughout socialization processes. This is exemplified, for example, by changes in the concept of “beauty” through the ages.

3.2. Culture

IA is also strongly influenced by aesthetic criteria and cultural trends and values, which vary from one culture to another, which is to say that they also vary from one historical moment to another. In fact, one of the main factors that often precedes IA, the presence of socially desirable characteristics in the attractor, is something that depends mainly on the norms of each culture. One culture (at a given moment in time) may value the capacity to defend oneself in the face of adversity, while another may value the capacity to ask for help and community support, to give one simple example. Cross-cultural social psychology has shown us, for example, the variability between individualist versus collectivist cultures in terms of the norms and rules that prevails in interpersonal relationships.

3.3. Society

Social norms, continuously constructed and reconstructed in everyday interactions and transmitted by the socialization agents (family, school, social and work organizations, church, mass media, etc.), play an important role in the process of IA. Social factors influence what is socially desirable, as well as the configuration of an individual’s personality, which in turn influences what each person considers personally desirable in others. Thus IA, as well as physical attraction and love, is not simply a psychological process, as it is commonly perceived by laypeople, but more precisely is a sociopsychological (in fact, biosociopsychological) process.

3.4. Interpersonal Interactions

Social pressures and social influence are usually exerted through interpersonal relationships, especially within the groups in which people interact every day. Group attitudes and group norms regarding other groups and other people (according to their ages, race, gender, attitudes, etc.) have a major influence on the factors that are likely to elicit and to maintain IA. Conformity, polarization, or even group thinking may all have a role to play. Readers should be aware that the behavior (actions, feelings, and cognitions) of the people with whom a person interacts every day has an important effect on that person's attitudes and behavior, including the IA he or she feels toward other people, and including the decisive role of reciprocity of attraction. Others' opinions and the pressure they exert are often quite relevant to people's feelings of IA toward someone (whether they lead to conform to their standards or to reject them by means of a "reactance process").

3.5. Individual

Finally, of course, the individual is also important. For some authors this is the main factor in any case; for others, the individual is less relevant than people would like to admit, being strongly shackled by biological and social forces. People's behavior in general, and more specifically feelings of attraction toward others, are constrained by biological, cultural, social, and interpersonal processes and factors but in truth are "acted out" or felt by a specific individual with specific psychological characteristics. Psychological studies have revealed that some features are more relevant to IA, such as physical attractiveness, social skills, or personality variables that happen to be socially recognized as valuable. In addition to these, and as mentioned previously, each person will feel attracted to certain specific features that are especially valued by the individual in question. Furthermore, one's own psychological characteristics are of considerable importance, because their similarity to the psychological characteristics of the other is one of the main factors (if not the main one) responsible for IA. In addition to these, complementarity of needs (between attractor and attracted) and personal need for affiliation are two further relevant variables affecting the IA process. Clearly, there are too many factors here to ignore, underlining the crucial role that the individual characteristics of each person play in establishing his or her feelings of IA toward one person rather than another. Nevertheless, psychological researchers are still far from

establishing any kind of simple (and probably simplistic) taxonomy of types of personalities associated with tendencies to feel IA for other specific types of personalities.

4. APPLICATIONS OF THE PSYCHOLOGY OF IA

Psychological knowledge of IA not only leads to a better understanding of the human being, but also offers opportunities to apply that knowledge, and thus solve some personal and interpersonal problems, increasing subjective well-being and quality of life.

As was pointed out earlier, the absence of feelings of IA to others and/or not being the object of attraction for others will probably result in severe psychological difficulties. So, psychological knowledge about what generates IA can be used to assess and train people in these characteristics, at least to some extent. Using sociometry, social-skills training, role-playing, and other systematic and well-established psychological techniques, it is possible to assess IA and to teach people ways to make themselves more attractive, not only physically but also personally. Sociopsychological knowledge of IA can be used to give guidelines for attracting others and initiating and establishing relationships, with a reasonable degree of success, by taking into account factors such as propinquity, context, physical appearance, verbal and nonverbal communication (conversational and listening techniques, attractive body language etc.), overcoming fear of rejection, self-presentation strategies, socially desirable characteristics, accurate rhythm of self-disclosure, and so on. More constructively, psychologists can design programs conceived to increase tolerance of differences, so as not to diminish the attraction felt for someone other than oneself.

However, there is far more basic research than there are application programs for IA, and the majority of these applications are centered on the couple as the fundamental context of application. Furthermore, it is physical attraction, much more than IA, that has been applied in various fields. And, in addition, normal "applications" of IA are frequently no more than research studies concerning IA applied to a specific area (e.g., the study of the role of IA on the personnel selection process, sports team performance, jury decisions, or consumer behavior), much more than the true application of IA knowledge on solving personal and interpersonal problems and increasing quality of life.

Nonetheless, it is possible to find examples of studies concerning IA applied to certain contexts, in which those studies (and future ones) have at least a potential field of application (see Table III).

There are some well-known sociopsychological (and unconscious) processes that have been verified in some applied contexts, such as the halo effect (the influence of first impression on psychological inferences about a person), the physical attractiveness bias (the attribution of positive characteristics to attractive people and not-so-positive ones to unattractive people), and the relevance of IA on persuasion processes (IA as one of the main factors of communication agents related to success in persuasive communication). An IA halo effect has been detected in teacher expectations about his or her students (the Pygmalion effect), in falling in love, and even in contexts such as personnel selection processes and jury deliberations. A physical attractiveness bias (in some ways related to the halo effect, but not exactly the same) has been noted almost everywhere, from work organizations to everyday interactions. The impact of IA on persuasive communication is especially relevant in areas in which the capacity for influence should rely on sources other than IA, e.g., advertising, politics, or therapy.

TABLE III
Real and Potential Contexts of Application of Social Psychology of IA

<i>Context of application</i>	<i>Type of relationships</i>
Work organizations	Horizontal relationships, vertical relationships, personnel selection process, promotion process
Education	Teacher–students, among students
Family	Parents, parents–children, siblings
Intimate relationships	Intimate friendships, loving relationships
Therapy	Therapist–client
Sports	Manager–players, among members of a team
Courtroom	Among all figures: jury, judge, defendant, lawyer, etc.
Politics	Politicians–citizens behavior (e.g., voting)
Advertising	Salesmen and models–consumer behavior (e.g., buying)
Health	Social models—healthy/unhealthy behavior (e.g., smoking)
Everyday life	Interracial and intercultural relationships

One promising and highly relevant context of application is IA in work organizations. There is some evidence to support the influence of IA in both vertical and horizontal interactions, including the personnel selection process, and therefore in productivity and the quality of one's working life. For example, in general, data indicate a positive relationship between IA and interview outcomes, taking into account measures of personal attraction, physical attraction, and even some physical measures such as height and weight; in addition, IA moderates interactions in recruitment interviews by gender. Along the same lines, other results indicate that physically attractive applicants in jobs requiring high (but not low) levels of social competence were recommended for hire more often, were expected to perform at a higher level, and were perceived as more representative of successful employees than were unattractive applicants. It is well established that professionals are as susceptible to this bias as are college students and laypeople.

Other fields of application include the following relationships:

- between teacher and students, in which the relevance of IA has been shown to be a determinant of first impressions (and thus, as is generally accepted, on attributions and behavior), not only among students but also on the teacher's expectations and behavior toward his or her students;
- between parents and children, a field in which IA is no doubt more important than physical attraction;
- between lovers, an area in which there are real applications, such as modeling strategies to become (or to seem) more attractive to another (and, for single people seeking a relationship, psychological knowledge of IA can be applied as a serious means to form relationships);
- between therapists and clients, which might seem intriguing, given its supposed irrelevance;
- between the members of a sports team, and between players and coaches; here, IA has an effect in terms of improving results, cohesion, and satisfaction;
- between judge, jury, and defendant, with potentially dramatic consequences—for example, the fact that, in general, people tend to look more favorably on victims and defendants who are good looking;
- between politicians and citizens, IA influencing, for example, voting intention and even voting behavior, to some extent;
- between the seller (or its advertising models) and consumer, since it is well established that the IA of the

seller (or the model who advertises a product) has a major role on the success of the persuasion process for people to buy the product (here physical attraction plays a part as well as IA in general);

- between social and TV models and common people, knowing that the IA of social models (mainly perceived via TV) influences the extent to which people imitate their behaviors. This is relevant, for example, in relation to good and poor health (smoking, anorexia, etc.), violence/nonviolence, social/unsocial behavior;

- and finally, of increasing importance nowadays, there are international, interracial, and intercultural relationships in which IA is especially difficult to raise (for all of the aforementioned reasons), but at the same time is especially important in today's global environment.

GLOSSARY

circumplex models Models of the structure of personality traits, behavior, or emotions that are characterized by a circular arrangement of their components.

cultural syndromes Patterns of behavior, cognitions, and emotions that characterize whole cultures or groups of cultures and account for psychological diversity across cultures; the most popular cultural syndromes are individualism (which emphasizes individual autonomy) and collectivism (which focuses on interdependence among group members).

distal versus proximal determinants of behavior Causes of behavior that are remote (other causes may intervene between them and the behavior) versus causes that are immediately connected to behavior.

ecocultural framework A framework for cross-cultural psychology that views human behavior both as the result of shared psychological processes and as a series of adaptations to ecological challenges.

in-group A group of people who feel strong emotional and psychological ties and who perceive that they share a common fate.

internal (dispositional) versus external (situational) attributions Explanations of one's own behavior, or of the behavior of others, that focus on the internal personal characteristics of the individual engaging in the behavior as opposed to external demands and social pressure.

interpersonal structure The psychological dimensions that describe the meaning of interpersonal relations or behavior.

resource exchange theories Theories of social behavior that view interaction as the exchange of physical and psychological resources needed for individual survival and well-being.

utilitarian models Explanatory models of human action that emphasize the purpose, function, and expected consequences of the action.

Psychological theories about the determinants of interpersonal behavior traditionally have either postulated intraindividual causes (e.g., attitudes, personality traits) or looked at the immediate social situation (e.g., group pressure, influence of the social or physical environment). However, a number of recent approaches have emphasized the role of culture in the production of behavior. In these approaches, culture has been conceptualized as a system of adaptations that transcends the individual human individual or as a subjective meaning system (or, in some instances, as both). Interpersonal behavior, then, can be viewed in part as a consequence of cultural influences or as part of a set of constructs that constitute culture. Either perspective provides considerable theoretical insight

into the meaning, origins, and function of interpersonal behavior and facilitates a fresh examination of established social psychological phenomena.

1. THE INTERFACE OF CULTURE AND INTERPERSONAL BEHAVIOR

There have been numerous attempts to provide a psychologically relevant definition of culture, but there is no single definition that has met with widespread agreement. One difficulty stems from disagreements between those who view culture as a purely subjective and ideational construct and those who emphasize its observable characteristics (e.g., behavioral processes). A second disagreement stems from an ontological question: Is culture a set of invented convenient categories for the classification of certain observations, or does culture have an existence of its own (i.e., independent of the individual person)?

Whatever their definition of choice, many psychologists accept the notion that culture can be viewed as a series of adaptations to environmental challenges that enhance the lives of a group of people and, therefore, are transmitted from one generation to the next. In this context, culture provides a functional basis for the analysis of interpersonal behavior. In other words, interpersonal behavior is understood as serving a purpose and as having some sort of utility in the lives of people. In a broader sense, it should be clear that any definition of culture may have profound implications for the psychological explanation of interpersonal behavior.

2. THEORETICAL APPROACHES TO CULTURE AND INTERPERSONAL BEHAVIOR

During the past two decades or so, we have witnessed a significant growth in the number of psychological theories of interpersonal behavior that are framed within a cultural perspective. Although not exhaustive, the following classification provides a sense of the direction of these efforts.

2.1. Structural Models

The pioneering work of Osgood on the measurement of connotative meaning across cultures has been an important influence on the development of structural

models of social behavior. Osgood showed that three psychological dimensions—evaluation (*E*), potency (*P*), and activity (*A*)—appear to be universal (culture-common) structures involved in the understanding of the implicative meaning of things. In other words, Osgood proposed that, regardless of specific linguistic or cultural practices, humans understand the meaning of things by judging, among other attributes, how good or bad (*E*), strong or weak (*P*), and fast or slow (*A*) they appear to them.

Inspired by this work, a number of psychologists explored the structure of the interpersonal domain. The fundamental aim underlying much of this research has been the identification of a set of psychological dimensions that remain (relatively) invariant across cultures and that reveal how humans understand and communicate the meaning of interpersonal behavior. Particularly noteworthy in this effort has been Triandis's approach, which significantly influenced cross-cultural psychological research during the 1970s and later years. Triandis developed methods that could be used to study what he termed "subjective culture," that is, a group's characteristic way of understanding its social environment. This process often involved exploring belief and value systems, norms, roles, attitudes, and expectations in various cultural groups.

Central to the approach was the structural analysis of social behavior within and across cultures using a variation of Osgood's "semantic differential" technique, which Triandis called the "behavioral differential." This instrument consisted of scales gauging the perceived likelihood that people engage in different behaviors in various social contexts. Data reduction techniques were then employed to extract both culture-common and culture-specific dimensions that captured the variety of meanings of interpersonal behavior in very different cultures.

As in the case of connotative meaning, structural analyses of interpersonal behavioral intentions observed in many cultures showed an impressive convergence of findings. It appears that social behavior, regardless of what other local features may also characterize it, is understood across a wide range of cultures in terms of a few fundamental dimensions: (a) association–dissociation, (b) superordination–subordination, and (c) intimacy–formality. Specifically, the first dimension appears to gauge the extent to which an interpersonal behavior involves affiliating, approaching (as opposed to avoiding) another person, and generally giving (as opposed to denying) resources to others. The second dimension involves the notion of dominance and

control over one's social environment and gauges the extent to which a particular behavior communicates the exercise of authority and status (as opposed to submissiveness and acceptance of another's authority). Finally, the third dimension captures the extent to which a behavior involves social and physical proximity and seems to be independent of the rewarding or negative characterization of the specific behavior.

This dimensional structure, part of which has been confirmed by independent research exploring the interpersonal domain of personality, has been quite useful in summarizing the array of behaviors exhibited in daily activity and in focusing theoretical analyses of social interaction. Most significant theories in social psychology explore the behavioral domains covered by the three dimensions. For example, work on prosocial behavior or aggression clearly falls within the domain of the first dimension (association–dissociation), research on obedience and conformity falls within that of the second dimension (superordination–subordination), and the study of personal relationships falls within the domain of the third dimension (intimacy–formality).

The psychological comparison of any two or more cultures based on the three interpersonal dimensions can offer a very broad understanding of fundamental similarities and differences between or among the cultures. For example, Triandis and colleagues have shown that although research participants in the United States, India, and Japan use the three dimensions in understanding behavioral intentions in interpersonal contexts, the meaning of particular behaviors may be quite different in each of the three cultures. For example, excluding a person from one's neighborhood may imply dissociation and dominance in the United States and Japan, whereas it may be considered primarily a formal behavior in India, where the caste system plays an important role in determining the range of personal interactions.

A final question regarding this approach concerns the origins of the dimensions as psychological universals. It is generally assumed that judgments of the social environment based on the three structures offer a significant survival advantage to humans and, thus, led to their emergence over time and across various cultures. Alternative views, also based on utilitarian notions, are discussed later in this article.

2.2. Cultural Syndromes

Early work on culture and interpersonal behavior was successful in identifying a large number of cross-cultural differences (and similarities) in interpersonal behavior.

For example, rates of conformity in an Asch-type situation, where group members who report an incorrect perceptual judgment induce naive research participants into also making incorrect perceptual judgments, may differ across seemingly similar cultures. However, this work was relatively unsuccessful in explaining such differences or similarities in a systematic manner. A basic problem was the relative absence of broad cultural theories appropriate for psychological research.

This situation began to change during the 1980s when a number of dimensions that could be used to describe behavioral patterns within and across cultural groups began to emerge. Hofstede's examination of work-related values in a large number of cultures provided the impetus for the development of the notion of "cultural syndromes," that is, patterns of behavior, beliefs, values, attributions, judgments, and emotions that are characteristic of whole cultures (and often groups of cultures). These patterns can be used to describe, in a systematic and predictable fashion, cross-cultural similarities and differences in interpersonal behavior. The approach has been one of the most important directions of research in the area during the past 20 years or so and has been particularly emphasized in the work of Triandis.

Whereas a number of cultural syndromes have been identified, the most successful and popular ones by far have been those of individualism and collectivism. As applied to the analysis of interpersonal behavior, individualism is a cultural pattern that is characterized by a preference for control of the social environment, personal achievement and fulfillment, self-reliance, competition, and (perhaps most important) a desire for autonomy and independence in thought, action, and emotion. Collectivism, on the other hand, is characterized by a preference for interpersonal harmony, in-group cohesiveness, and an emphasis on the interdependent nature of human relations, thoughts, and emotional experiences.

The success of these two constructs, which had been available in the social sciences for a long time before psychologists began to employ them in their work, centers entirely on their usefulness in making predictions about cultural differences in interpersonal behavior and social judgment. For example, the finding that individualism is characteristic of cultures found mainly in North America and Europe (particularly Western Europe), whereas collectivism is characteristic of Asian cultures, leads to the rather obvious prediction that social values and attitudes, as well as interpersonal behavior, will be more similar among European and

North American cultures than among European and Asian cultures.

Results of research tend to support these predictions, but not without occasional contradictory findings. In general, however, agency and independence are the building blocks of Western philosophical, value, and moral systems, whereas responsibility to community, duty, and interdependence are often the foundations of morality in collectivist cultures (e.g., India, China). Individualism–collectivism differences have also been described regarding patterns of and preferences for competition (individualism), cooperation (collectivism), and conformity (collectivism), although the particular situation (e.g., whether an interaction takes place within or outside the context of an in-group) often is critical in determining the direction of the difference. In a relevant finding in this area, collectivists have been shown to exhibit greater subordination and conformity toward in-group members, but also greater dissociation and hostility toward members of out-groups, than have individualists.

Other major differences between individualist and collectivist cultures have been identified in attributional processes. For example, collectivists are not as likely to commit what has been (mis)labeled in Western social psychology as the “fundamental attribution error,” that is, the tendency of observers of behavior to rely overwhelmingly on internal and dispositional explanations for the behavior of others. Obviously, differences in attributional style can lead to differences in behavior toward others because others’ behavior is perceived to be motivated by very different causes. In other words, our reactions to what others do toward us will be substantially shaped by how we tend to interpret their actions and by whether we tend to focus on personality-based or situational explanations for their behavior.

The usefulness of the constructs of individualism and collectivism has been demonstrated repeatedly during the past two decades or so. With increased reliance on these constructs, however, comes the danger of confusing description with explanation. Critics of the approach have pointed to the problem that often what is predicted as a consequence of individualism or collectivism (e.g., a behavioral difference between people of two cultures) is actually nothing more than a constitutive part of the construct itself, rendering a seemingly theoretical prediction nothing more than a tautology. With care, such problems can be avoided and these constructs can continue to provide a rich theoretical basis for the discussion of cross-cultural differences in interpersonal behavior, cognition, and the like.

2.3. Utilitarian Approaches

An implicit theme underlying much cross-cultural research over the past half-century has been the notion that much of what is observed and identified as either a difference or a similarity among cultures is functional for members of a particular group or for humans at large. This theme has either been articulated explicitly or been given a central role in several theories of interpersonal behavior.

2.3.1. Behavioral Prediction Models

Concern with the determinants of social behavior, particularly with the attitude–behavior relationship, during the 1960s and 1970s led to the development of several models that boasted fairly good behavioral prediction. The models’ predictive success has been demonstrated in a variety of applied settings, from advertising to fertility-related practices, in a number of different cultures. These models, particularly those formulated by Fishbein and Triandis, have a number of common features. For example, they all treat attitudes and other intrapsychic variables as major causes of interpersonal behavior, but they also emphasize the influence of the social environment in determining behavior. Invariably, the models assume that this latter influence is filtered through internal processes. For example, the effect of others’ opinions is thought to lead to the formation of personal norms of appropriate behavior. In turn, the norms are expected to affect the formation of behavioral intentions or self-instructions to engage in particular social behaviors.

These models have an explicitly utilitarian character because they consider expectations of the consequences (negative or positive) of a behavior to be among its most important determinants. The models are not always in agreement regarding the precise mechanism through which perceived behavioral consequences affect behavioral outcomes. For example, Triandis’s model treats this influence as an independent process, whereas Fishbein’s model embeds the influence within the attitude formation process. In either case, however, a utilitarian component of human social behavior is explicitly taken into consideration. In other words, these models rely on a combination of utility and rationality to offer explanations of interpersonal behavior.

Cultural influences are not considered explicitly in such models. However, there is a clear assumption that the set of beliefs, expectations, and personal norms that

function as proximal determinants of behavior are themselves influenced substantially by cultural inputs. Thus, culture is viewed as an important but distal behavioral determinant. For example, cultural beliefs about the role of a woman in the family, coupled with local religious or moral values about contraception and conception, may lead to the formation of personal norms that influence a woman's decisions about the size of her completed family. It would be expected, of course, that such norms would play a far more significant role in determining the behavior of collectivists, whereas personal wishes and attitudes would be more influential determinants of the behavior of individualists. Indeed, there is some empirical evidence that cultural norms about appropriate behavior tend to become internalized among collectivists, presumably having an even greater effect on their behavior.

2.3.2. Resource Exchange Theories

Another class of utilitarian models has been developed to account for systematic relationships among various dimensions of interpersonal behavior. These models typically are based on the assumption that all human social interaction involves—indeed, is designed for—the exchange of physical and psychological resources. Foa and colleagues established that any social behavior appears to involve the exchange of one or more of six classes of resources: (a) love, (b) services, (c) goods, (d) money, (e) information, and (f) status. These resource classes form a circumplex model defined by the dimensions of abstractness–concreteness and universalism–particularism. The first dimension refers to the material (concreteness) as opposed to the symbolic (abstractness) nature of a behavior, whereas the second dimension refers to the extent that the relationship of the actor to the target of the behavior plays a significant (particularism) or trivial (universalism) role in the satisfactory completion of the interaction.

Extensions of this work have led to formulations that attempt to explain the emergence of the culture-common psychological dimensions of social behavior reviewed earlier and of cultural syndromes such as individualism and collectivism. Adamopoulos has argued that the dimensions of concreteness and particularism, along with the question of whether a resource is given or denied, form fundamental constraints on human interaction and are components of a differentiation process that yields uniquely defined features of interpersonal meaning. For example, superordination is defined as the denial of abstract and particularistic

resources. In this fashion, the interpersonal dimensions discussed earlier may be conceptualized as emerging from this process of constraint differentiation over long periods of time. Adamopoulos extended this idea in 1999 to account for the emergence of individualism and collectivism as cultural patterns of interpersonal behavior. In this case, an additional constraint, the orientation of a particular behavior to secure resources for the self as opposed to another person, was included in the theoretical model.

In general, these resource exchange models attempt to account for two major problems: (a) the fundamental structure of interpersonal behavior and the interrelationships among its major dimensions and (b) the emergence of interpersonal structure as a function of basic social constraints. This orientation is necessarily of a universalistic nature. In other words, these models tend to focus on themes that transcend cultural boundaries. At the same time, resource exchange models can be sensitive to cultural differences by taking into consideration the extent to which various cultures expose their individual members to different constraints. It is assumed that such differential exposure leads to behavior systems with different interpersonal emphases. For example, if ample symbolic resources are available for exchange to members of a particular culture, they are more likely to engage in behaviors that involve power and superordination than are members of cultures that provide primarily concrete resources in interpersonal exchanges. The systematic description of resource availability in various cultures is, unfortunately, a task of enormous complexity and one that is likely to take a very long time to complete.

2.3.3. Sociality

Fiske's theory of sociality proposes that there are four basic types (elemental forms) of social relationships: (a) communal sharing, where individuals within an in-group share pooled resources; (b) authority ranking, where powerful leaders control and dispense necessary resources as needed; (c) equality matching, where individuals of equal status and rank enjoy comparable resources; and (d) market pricing, where interpersonal relations are a function of market demands and expectations of profit.

Fiske has argued that these four types of relationships account for most of the variability in interpersonal exchanges across very different social situations. In the context of this theoretical model, the role of a culture is to shape and present particular forms of the

four types of relationships to its individual members in ways that are relevant to their lives. For example, authority ranking may be manifested very differently in the context of a military organization than in that of a cult or gang. At the same time, the theory facilitates connections among seemingly unrelated contexts.

The relative simplicity of this theoretical model makes it quite attractive. However, critics have pointed out that, in fact, the four types of sociality deal with only a portion of the range of interpersonal relations. Specifically, the four types can easily be classified along the dimensions of association–dissociation and superordination–subordination. This, of course, indicates that this model cannot explain other aspects of interpersonal behavior.

2.4. Ecocultural Framework

The view of culture as a series of individual and group adaptations to the environment has a long history in the social sciences. During recent years, many psychologists have used Berry's "ecocultural framework" as a means of embedding such notions about adaptation into psychological research across cultures. This framework rests on two fundamental assumptions. First, humans share a number of basic psychological processes in thought and action, although such "psychological universals" appear with nearly infinite variation across the world's cultures. Second, human behavior is adaptive in that it rises in response to ecological, cultural, and situational challenges that account for the tremendous diversity evident in human life.

As elaborated by Berry and colleagues in 2002, the ecocultural framework is a dynamic system of population- and individual-level variables with multiple sources of influence. Despite its dynamic nature, however, the emphasis in the framework is clearly on the manner in which ecological and sociopolitical systems of variables affect psychological processes and behavior at the group or individual level. This is accomplished through a series of biological and cultural adaptations, although once again the emphasis is overwhelmingly on the process through which cultural adaptations are transmitted at the group level and, thus, determine the psychological functioning and behavior of individual humans.

The framework has been primarily a useful guide to research on cognitive and perceptual processes across cultures, but it has also been used to account for certain cross-cultural differences in interpersonal behavior. In general, the advantage of the ecocultural framework is

that it can facilitate the exploration of behavioral phenomena by transcending standard explanations in experimental psychology. Such explanations typically revolve around intrapsychic or, at best, interindividual processes. For example, personality traits, attitudes, and the presence and behavior of others (i.e., the immediate social situation) are the most typical determinants of behavior found in psychological theory. The ecocultural framework focuses attention on the role of physical resources and subsistence economies in determining the range of human activities. Often, such accounts can be quite insightful and add considerable depth to psychological explanation.

3. THEMATIC APPROACHES

Traditionally, the investigation of interpersonal processes and behavior has been organized topically due to the large number of theoretical perspectives available and the inability of any single theoretical model to account for the variety of the observed phenomena. A comprehensive review of cross-cultural research on interpersonal behavior is beyond the scope of this article. Instead, this section outlines four major areas of relevant research and, in each case, provides examples of how cultural variables may contribute to better understanding the behavior of interest.

3.1. Social Norms and Conformity

Norms, or rules for appropriate behavior in particular social contexts, demonstrate the influence of culture on interpersonal behavior because they reflect the opinions and actions of others. Norms can be internalized and become embedded in individual belief systems, particularly among collectivists. Thus, it is expected that conformity to norms varies significantly across cultures.

Considerable research, much of it done in the context of the ecocultural framework, has demonstrated the validity of this hypothesis. Specifically, consistent differences in conformity to group norms have been found between cultures with highly structured and rigid interpersonal relationships (high conformity) and cultures with considerable autonomy in how individuals fulfill their role obligations (low conformity).

A plausible, but partially speculative, explanation of such differences rests on fundamental ecological and structural differences between the two types of cultures. Cultures in which the ecology favors the emergence of agricultural economies must develop vertical

authority systems in which the presence of powerful and respected leaders facilitates the coordination of human activities involved in agricultural production. In turn, this process necessitates the development of socialization practices that encourage conformity to authority figures and social norms. In contrast, ecologies that favor the development of, for example, subsistence economies based on hunting (an activity that requires much less cooperation among many people) may lead to a relatively greater emphasis on individual autonomy during socialization and, thus, to less pressure to conform to group norms in social life.

3.2. Prosocial Behavior

Cross-cultural differences in prosocial or positive forms of interpersonal behavior have been demonstrated consistently. These differences range from being willing to mail a letter for someone else, to asking for directions, to helping a disabled person cross the street. In fact, the variety of helping behaviors studied over the past 30 years or so has been limited only by the ingenuity of the investigators and implementation constraints.

Research findings in this area are not easy to interpret because the specific cultural characteristics that may account for prosocial behavior patterns are not always well understood. However, a consensus appears to be emerging that the cognitive load associated with everyday life, and the resulting demands on people's attention, may explain the relatively higher likelihood of helping in rural (as opposed to urban) and poor (as opposed to affluent) areas.

Other cultural characteristics may also account for observed rates of helping in interpersonal contexts. For example, cultures differ in their traditions regarding how one behaves toward strangers or foreigners. Thus, it is possible that in some cultures the influence of norms for helping others may be moderated by the relationship between the person requesting help and the person offering it. In some collectivist cultures, where social interaction is guided by norms of interdependence and where people often rely on each other for the acquisition of resources necessary for survival, interpersonal behavior follows particular cultural scripts. Such scripts inform people's notions about responsibility and duty, and they lead to expectations that others will be of help if the circumstances demand it.

3.3. Aggression

Aggression is generally defined as behavior intended to harm another person physically or psychologically.

The study of aggression has been of great interest to social and biological scientists of diverse persuasions and has resulted in a number of universal findings. Two of the best-known findings are as follows. First, aggression and violence are truly ubiquitous phenomena but are manifested in very different ways and occur at different rates around the world. Second, with very few exceptions, boys and men tend to behave more aggressively across cultures than do girls and women, respectively.

The precise processes that explain these findings are not clearly understood. Biological mechanisms have been proposed on occasion, but the supporting evidence is typically not very strong. Most psychologists have instead relied on a variety of sociocultural processes. For example, child-rearing practices, socialization, and social learning have often been evoked as explanations for both male-female and cross-cultural differences in the incidence of aggressive and violent acts. It appears that, in many cultures, men not only learn to engage in more aggressive behavior than do women but also learn to interpret aggressive behavior differently than do women. Furthermore, as documented in recent work on "cultures of honor," the incidence of violence may be higher in some cultures because their members are socialized to protect themselves and their possessions. This results in increased tolerance for aggressive behavior because such behavior is viewed as serving a self-protective function.

The preceding processes all explain aggression in terms of normative influences. A contrasting perspective may also be formulated, although it is one that receives scant attention from psychologists. According to this view, aggression may be more likely to occur in those domains of interpersonal interaction for which there are no strong sociocultural norms of appropriate behavior. In such contexts, aggression becomes instrumental for individuals in acquiring certain classes of resources. The investigation of this intriguing proposal necessitates a fundamental shift in research orientation away from social influence processes and toward the manner in which humans attempt to establish agency within a complex and often threatening social environment.

3.4. Interpersonal Relationships

The study of relationships between people has been the focus of research primarily in European and American psychology. The impetus behind this work has been a growing concern with intimacy, personal relationships,

attraction, love and marriage, and dissolution processes in relationships. In all of these areas, culture is thought to play a significant role, but in many instances, actual empirical research is lacking. For example, we may understand the mythology that sustains (and often destroys) American and European personal relationships, but similar research in non-Western cultures is practically nonexistent.

Intimacy has been traditionally defined as self-disclosure that is largely a rewarding experience for two persons. The negative aspects of intimacy as a psychological phenomenon have generally been ignored or considered only in the context of relationship dissolution processes. An alternative view of intimacy is that it is the exchange of particularistic and concrete resources. In this context, intimacy is considered a universal phenomenon whose manifested form and functions are shaped and modified by culture. For example, collectivists tend to have few but highly intimate relationships, whereas the reverse is true for individualists. It is possible that this is because the greater availability of social norms in collectivist cultures makes intimate interactions more concrete experiences. In contrast, individualists must search for appropriate information to clarify the social situation. Thus, developing intimate relationships may require more work for individualists and may explain why individualists tend to consider a romantic component critical for many intimate relationships. The strong kinship and community ties that often bind collectivists may diminish the importance of romantic love in personal relationships.

Interactions involving self-disclosure that have traditionally dominated Western conceptualizations of intimacy are, by definition, based on the rather abstract process of searching for information to better define the situation. Such conceptualizations are clearly inadequate in light of the better-defined and predictable nature of interpersonal exchanges in collectivist cultures. Consequently, alternative views of intimacy that also take into account systems of social interaction from non-Western cultures must be developed.

4. APPLICATIONS: CROSS-CULTURAL INTERACTION

The theoretical approaches to the analysis of interpersonal behavior reviewed earlier typically provide explanations not only for similarities but also for

differences in the actions in which people engage during their everyday lives. Thus, these approaches can offer considerable insight into understanding a variety of situations in which people with different cultural backgrounds interact with each other.

Psychologists have studied cross-cultural interaction extensively and from diverse perspectives that have emphasized both its positive and negative consequences. For example, Berry and colleagues have developed models of psychological acculturation and the effects of cross-cultural contact on individual psychological processes. These models specify some of the conditions under which persons who come into contact with another culture may select to replace their cultural identity with that of the new culture (assimilation), may choose some form of biculturalism (integration), or may reject either the new cultural identity or both the new and the old cultural identities.

Other analyses of cross-cultural interaction have focused on the concept of adjustment, that is, the ability to develop and maintain psychological well-being even in the context of interpersonal exchanges with considerable conflict and communication difficulties. Research has established that successful adjustment to changing conditions following cross-cultural contact improves performance on a variety of tasks and, of course, decreases the amount of stress typically associated with cross-cultural experiences.

Cross-cultural interaction often involves exchanges between people who rely on very different value systems to interpret each other's behavior. As mentioned earlier, there appear to be some fundamental differences in the manner in which individualists and collectivists make attributions about social behavior. Specifically, individualists seek the causes of behavior in people's personalities, attitudes, and belief systems (i.e., internal attributions), whereas collectivists tend to prefer attributions that involve the experience of social pressures, obligations, duty, and group membership (i.e., external attributions).

Interaction between members of these two distinct types of culture may be problematic and may lead to substantial misunderstandings. For example, an individualist is likely to attribute a perceived lie in an interpersonal exchange to some flaw in the actor's personality, whereas the (collectivist) actor may attribute the lie to the constraints of the social situation (e.g., an obligation to be polite and respectful). The need to resolve conflicts of this sort—quite common in cross-cultural contact—has led to the

development of a number of instruments and programs for cross-cultural training during recent years. One of them, the culture assimilator, has been shown to increase the chances that people from different cultures will make similar attributions in various social situations.

5. CONCLUSION

The influence of culture on psychological processes is nowhere more evident than in the study of the generation and specific manifestation of interpersonal behavior. At the same time, the task of explicating the role that culture plays in behavioral processes is enormous given the range of behaviors that humans produce and the variety of processes necessary to account for them.

A number of theoretical models are available to accomplish this task, each with its unique strengths and weaknesses. Often, these models make very different assumptions about the manner in which culture is involved in the production of interpersonal behavior. This diversity of assumptions may actually be helpful at this stage given that we still know relatively little about the culture–behavior link. What is needed is a cultural theory appropriate for psychology with considerable power for description, prediction, and

explanation. Such a theoretical system does not exist at this point.

GLOSSARY

correspondence of outcomes The degree to which the outcomes of one partner in an interdependence relationship can be attained without preventing the other partner from attaining his or her outcomes; perfectly correspondent outcomes lead to pure coordination, whereas perfectly noncorrespondent outcomes lead to pure conflict.

dispositional attributions Identifying as causes of behavior internal factors and processes such as intentions, motives, and personality traits.

interdependence or outcome interdependence A social situation involving two or more individuals who depend on one another for achieving individually valued outcomes and goals.

interference Describes Partner A's actions in obstructing Partner B's effort to bring about a personally desirable outcome; interference may be actual or perceived and may be intentional or unintentional.

interpersonal skills training Developing skills that are pertinent to constructive conflict resolution such as building problem-solving relationships with other disputants,

seeking multiple solutions to conflict situations, and viewing conflict issues from an "outsider's" perspective.

maximum minimum The best possible of the worst outcomes that one is willing to accept in a negotiation setting, where agreements can be attained only by lowering both disputants' outcome levels.

mediation The intervention of an independent third party in a dispute to facilitate disputant interaction, identify sources of conflict, and promote constructive communication toward a mutually satisfying resolution.

minimum maximum The lesser among the best outcomes that one is willing to accept in a negotiation setting where disputants cannot attain their optimal outcomes.

outcome A general term employed to indicate how drives and motives shape preferences and goals worth pursuing in social situations of interdependence; outcomes may be material possessions (e.g., money, a house, a car) or abstract states (e.g., social status, security, happiness).

relative deprivation A perception that outcomes in some realm that is valued and important to self are inferior to a reasonable standard; relative deprivation is a potential source of conflict.

social comparison Using others as a comparison standard in evaluating own qualities such as efficacy, ability, judgments, and attitudes.

social norm A consensually accepted rule about behaving in social settings that has been internalized by individual society members; breeching of a social norm by an individual is sanctioned but may also cause pangs of conscience.

Interpersonal conflict is a process triggered when one of the parties in a relationship perceives that the other adversely interferes with the attainment of own

outcomes and goals. It may also be a consequence of perceiving own outcomes as severely inferior to those of the other in the relationship and to a commonly accepted standard.

1. UNDERSTANDING AND MANAGING CONFLICT IN INTERPERSONAL RELATIONSHIPS

Interpersonal conflict is a by-product of individuals' need to establish and maintain relationships for their intrinsic wellness and survival value. Relationships ensure that personal goals, such as a comfortable life, a rewarding professional career, security, fulfillment, and love, can be attained to a qualitative and quantitative level that either would have been impossible outside a relationship (as in the case of love) or would have required much more effort, time, and resources. Despite their motivation to uphold relationships, individuals will often come into conflict with their partners as the realization of their respective goals clash, impede one another, or become the medium of an unfavorable comparison with the other's achievements. Conflict can be a painful process, with destructive consequences for the well-being of individuals and for the potential of relationships to yield valuable outcomes for their members and society. Of course, many conflicts cause little rancor and are resolved peacefully. Intimate couples, friends, roommates, and office colleagues can often find mutually satisfying ways in which to eliminate their differences. In professional settings, managers and employees can frequently settle their disputes through simple discussions or, when matters get more complicated, through mutual demands with official labor-management negotiations. However, there are times when people will resort to overt or subdued hostility, or to verbal or physical aggression, so that they can force the resolution of differences in their favor. Hostility in all forms will also occur as a means of expressing displeasure about what is perceived as an unfair resolution of relationship differences. In either case, the ambience of personal or professional relationships is severely disturbed. Simple human interaction becomes unproductive and harmful not only for the disputants but also for those directly or indirectly related to them. For example, consequences of persistent conflict often involved in divorce are numerous and distressing for the personal development of the disputants and their

children. Unfortunately, divorce rates involving intense conflict in the United States, in European Union member countries, and in other Western countries continue to be high. In professional settings, even subdued conflict between fellow employees can undermine the productivity and creativity of an entire work unit, adversely affecting the quality and quantity of products and services. Considering how threatening conflict can be to the stability and productivity of relationships, individual well-being, and the cohesiveness of society, it is not surprising that it has attracted a lot of scientific theory and research.

Social psychology, in particular, has dealt with conflict in an effort to understand it and identify ways in which to manage it. Because managing conflict requires knowledge and understanding of conflict, social psychologists have tried to develop a theory that would allow the prediction and control of conflict. The agenda of such a theory includes questions such as "What is conflict?," "What causes conflict?," "Under what circumstances does conflict occur?," "How is conflict expressed?," and "What are the social and psychological consequences of conflict?" If one could have answers to at least some of these questions, one would be able to perhaps predict, for instance, when conflict would be manifested and with what intensity. As such, one would be able to manipulate the timing and circumstances of its manifestation so as to divert or even prevent it. Unfortunately, despite efforts, there is no true comprehensive conflict theory that can permit concise prediction and control of conflict behavior. Nevertheless, there are numerous theoretical approaches that have contributed importantly to a fair understanding of the variables involved in conflict. Thus, one might not be able to totally predict and control conflict, but one knows that its basic source is the motivational structure of the relationship in which the conflict parties are involved, namely, the fact that they are, to a certain degree, interdependent for achieving their valued outcomes. One also knows that other, more qualitative features of the relationship will influence how conflict will be expressed and that attributions about the causes of conflict to the other's internal dispositions and character will escalate conflict expression. The major psychological processes implicated by social-psychological theory in conflict production are "interference" and "relative deprivation." Interference is based on the perception that the significant other in the relationship interferes with own goals, whereas relative deprivation is based on perceiving that own outcomes are relatively inferior to those of the other and to a commonly accepted outcome

standard. By means of another intermediary process, social comparison, the first two may work to undermine self-esteem, and this in turn generates conflict to preserve, restore, and enhance self-esteem. This loose mechanism of conflict production, put together for the purposes of the current discussion by what is known about conflict so far, provides directives and keys with which to understand the development of conflict resolution and management methodologies. For example, the role of self-evaluation and self-esteem in the conflict mechanism strongly suggests that the aim of conflict resolution should not be limited to removing the “realistic” difference between disputants but rather should also ensure that the self-esteem of the conflicting parties is preserved, restored, and enhanced (if possible). The importance of knowing conflict in developing conflict management is also illustrated by the way in which conflict management skills have used the research finding that dispositional attributions escalate conflict. Conflict mediators and disputants are trained to eschew from articulating inferences about others’ intentions in the relationship and personality characteristics.

The theoretical understanding of conflict not only has contributed to the development of conflict resolution methodologies but also has been conducive to diluting two lay misperceptions. First, most people commonly perceive conflict as a negative event of destructive consequences without paying sufficient attention to its more subtle positive effects. This is due mainly to the saliency of destructive consequences and to the survival value intrinsic in paying more attention to negative events. Second, people believe that disputants themselves cannot handle conflict and that conflict management skills cannot be learned. These misperceptions are perhaps even more destructive than conflict itself because they discourage people from training in conflict resolution and encourage people to avoid conflict at all costs, even in cases where conflict is called for and potentially beneficial to their personal interests and relationships. Indeed, research has indicated that people can be trained to handle conflict effectively, making the best out of it for their self-interests, self-respect, and self-expansion. Conflict can also be a creative and constructive process, helping in relationship functionality and development toward greater productivity and fruitfulness for both partners.

This article first explicates, by reference to theory, research, and real-life examples, the role of relationship features and psychological processes in yielding conflict. By pointing to how this knowledge is put into practice, the article then turns to analyzing major

conflict management methodologies. It concludes by underscoring the main issues underlying conflict escalation and conflict resolution.

2. RELATIONSHIP FEATURES AND PSYCHOLOGICAL PROCESSES INVOLVED IN CONFLICT

The basic relationship feature involved in generating conflict has to do with motivational structure, that is, with the fact that the partners’ goals are interdependent. This so-called structural feature of outcome interdependence forces people to compare their outcomes, triggering social comparison. Thus, the next subsection discusses relationship structure along with the psychological process of social comparison. Social comparison, with its self-evaluative results (e.g., “I am better off than others,” “I am worse off than others”), leads to two other psychological processes: interference and relative deprivation. These latter processes, being different in nature, are discussed in separate subsections. Nevertheless, their aim is the same, that is, to determine the extent to which the relationship partner is the culprit of negative self-evaluation. This section concludes with a discussion of how conflict experience and conflict expression are regulated by the qualitative characteristics of relationships.

2.1. Relationship Structure and Social Comparison

Interpersonal conflict springs from interdependence, an intrinsic characteristic of interpersonal relationships. Relationship partners depend on one another for achieving their wishes, goals, and preferred end states, generally called outcomes. Outcomes refer to material possessions (e.g., money, a house, a car) or to abstract states (e.g., social status and recognition, security, happiness, love). In addition to being attractive for satisfying specific needs, outcomes carry desirability and status value assigned by society. Thus, they contribute to identity definition and self-evaluation by means of social comparison. By comparing material and abstract possessions with those of others, people come to an understanding of where they stand in relation to others. In this way, relationship outcomes surreptitiously influence self-worth and establish potential for conflict within the relationship.

Relationship outcomes cannot be attained to the same qualitative and quantitative levels with the same ease and economy (in time, effort, and energy) outside a relationship. Hence, people are strongly motivated to enter relationships for optimizing their individual outcomes. That is not to say that individuals are indifferent to the common relationship outcomes or ignorant of the fact that others enter relationships motivated by the same individual outcome optimization goals. To the contrary, they are usually aware that no interdependent parties can ignore others in pursuing their goals and that all can influence one another's experiences, motives, preferences, behavior, and outcomes. As Lewin put it in his classical work on social conflict, relationship partners know that their "locomotion" toward attaining their goals may cross or be crossed by that of others. A lot of cognitive work needs to be carried out in planning the pursuit of own goals in an interdependence situation because others' plans must also be understood and predicted. Possibly, individuals will have to cooperate with others to maximize joint outcomes or compete for their own on the basis of some commonly agreed rules. Of course, rather than putting that cognitive effort into coordination and negotiation with others, direct and immediate access to desirable objectives may be demanded, and then conflict and fighting might arise. Success and failure will occur in predicting and planning, cooperating, and competing in conflict and fighting. In either case, there will be consequences for own outcomes as well as psychological repercussions for both self-worth and the continuing interaction of actors in the relationship. Others may facilitate, accelerate, and promote the attainment of own outcomes or, in contrast, may obstruct, delay, block, or simply interfere with their attainment by merely unilaterally pursuing their own goals in a relationship. The strong motivation of people to stay in a relationship and benefit from the advantages of outcome interdependence explains why they are willing to tolerate the nuisance of others' interference with personal outcomes.

2.2. Interference

It is reasonable to expect that people sharing the same social milieu may also see commonly desirable outcomes as worthwhile to pursue. Unfortunately, outcomes, whether material or abstract, may be limited; they might not be available to all, at all times, and in the same quality or quantity. Actually, some may be depleting fast as more people claim them for

themselves and as more people claim more of them. Realizing this fact, social norms have been instituted in nearly all organized societies about coordinating, cooperating, and competing in claiming commonly valued outcomes. People also hold general implicit expectations, known as lay theories, about fair and accepted practices in pursuing such outcomes.

If partners sharing a relationship decide to pursue similar depleting outcomes, their ways are likely to cross. In that case, they might perceive each other as interfering with own outcomes, and conflict might erupt to remove interference and restore unhindered and direct access to desired outcomes. Conflict is most probable when each of the two partners insists on unilaterally claiming for self the maximum of the desired objective and eschews coordination, cooperation, or competition along norms and lay theories.

Money is an obvious example of a material outcome that depletes quickly as the needs to be satisfied in an intimate relationship increase. For instance, consider a married couple whose members must decide how to allocate their budget to satisfy common and individual objectives. Couple members have to reach an agreement on prioritizing objectives, and their first option likely would be to accept a norm about distribution of resources between the spouses. One such norm is that maximizing of joint outcomes must come first. Alternatively, they may devise their own rule of prioritizing, give up on some of their personal goals, and take turns in having money allocated to each member at different times. For some couples, particularly those whose members maintain a relatively rich profile of activities outside the relationship, budget allocation agreements are not easy to devise without minor or major conflict.

Another example of a more abstract outcome that depletes quickly and happens to be in great demand in interpersonal relationships is time. How much time should friends spend with each other, how often, and in what quality (e.g., leisurely time in doing things together, discussions about each other's plans and dreams, simple chatting on the phone)? How does a person decide how much time to spend with each friend and in what way? Social and cultural norms about this issue are variable and also depend on individual expectations about the quality of the specific friendship. Friend A's allocation of time to Friend B might not correspond to Friend B's willingness to allocate time for the friendship. Friend B might have expected more and higher quality time from Friend A and, thus, might interpret Friend A's decision as intentional devaluation of their friendship. In a way, although the valued commodity (i.e., time) seems

the same, it acquires different meanings and values for each friend because each appears to have different expectations about friendship. In reality, the friends' valued outcome called "friendship time" is noncorrespondent. If one friend could be satisfied in terms of his or her valued outcome (i.e., be given abundant time with friend), the other friend would have to be dissatisfied. Of course, this situation may give rise to displeasure, resentment, open conflict, or even a falling out.

Actors in an interpersonal setting may indeed come into conflict due to noncorrespondent outcomes. Correspondence describes the degree to which the outcomes of one partner in an interdependence relationship can be attained without preventing the other partner from attaining his or her outcomes. Noncorrespondence, then, refers to a situation where for one partner to attain his or her goals, the other partner must fail to do so. Perfect noncorrespondence of outcomes leads to pure conflict, whereas perfect correspondence leads to pure coordination. Noncorrespondence implies that interference and conflict may arise not only by the fact that the members of an interpersonal relationship pursue similar, albeit depleting, outcomes. They could just as well pursue dissimilar outcomes that happen to be incompatible. For instance, a married couple might not realize that when one spouse pursues a high-profile career while the other seeks a low-key family life, potential for conflict may be accumulating. One spouse's lifestyle generates outcomes that are noncorrespondent to those yielded by the other's lifestyle. Scarcity of time invested in home or family activities and an abundance of time spent with nonfamily make difficult the common pursuit of a low-key family life. Spouses must pursue their aspirations unilaterally, hoping that this will not negatively influence relationship maintenance. Alternatively, they could both change their lifestyles so as to be able to carry out more joint activities and enjoy common outcomes.

Other's interference with own goals may have cognitive and emotional ramifications because it makes other and own outcomes salient to self, thereby triggering social comparison. Self-evaluation may then ensue, typified by thoughts such as "Do I really merit this goal?" and "Am I able to achieve this target?" Social comparison may also yield perceptions of threat to self-worth projected onto the other such as "Her goal is to prove that I am ineffective" and "His aim is to humiliate me."

Either category of cognitions contributes to the multiplication of conflict manifestations and to conflict escalation. Removal of interference might not be sufficient to settle conflict because disputants are focusing

on the perceived threat to their self-esteem rather than on the interference per se. Other's interference may have already severely damaged perception of self-worth and efficacy, and conflict may persist with the aim of restoring them.

2.3. Relative Deprivation

Paradoxically, noninterference may also contribute to interpersonal conflict. This situation is referred to as relative deprivation. People experience relative deprivation when they realize that own outcomes are severely inferior to a commonly accepted standard and that reaching the standard by own efforts is infeasible. In a situation of this sort, significant others (who meet the standard) with whom people have relationships may unknowingly aggravate people's own predicaments. Social comparison again works to underscore both inferiority of outcomes and self-debasement. The likelihood of these effects is high when a person is comparing self to a significant other with respect to outcomes having a central role in self-definition of both parties. If the relationship is a stable personal one and the social norms encourage it, the person with the poorer outcomes is particularly likely to expect the other to interfere so as to alleviate the former's own predicament. Of course, the significant other might not agree that he or she should assist and might not be willing to do so. Noninterference or lack of assistance may cause envy and bitterness in the person with the poorer outcomes. Moreover, it might be interpreted as an active attempt by the significant other to denigrate him or her and to contemptuously seclude him or her from "what everyone has a right to have." Conflict is bound to follow. Relative deprivation as a cause of conflict is more common between social groups than between persons given that people generally either find themselves in social settings with people whose level of outcomes is similar to their own or tend to choose significant others with similar outcomes rather than dissimilar ones.

2.4. Experiencing and Expressing Conflict: The Role of Qualitative Relationship Features

Some manifestations of conflict remain discreetly in the background until conflict has fully erupted. However, most of them are not discreet at all and need no introduction. At times, all people have

experienced behavioral manifestations such as arguments, intense disagreements, antagonism, fights, and even physical violence against other people. They have experienced the emotions involved such as apprehension and mistrust as well as being irritated, hostile, angry, bitter, resentful, sullen, and ominously silent. All people have also ruminated on thoughts regarding the causes of other people's behavior, the ways in which other people interfered with their own wishes and goals, their intentions in so doing, and their predispositions and characters. People probably have experienced conflict in their relationships with acquaintances, friends, family members, spouses, and lovers as well as in their professional or more formal relationships.

Overt behavioral manifestation of conflict and the subjective experiences involved, emotions and cognitions, may differ both quantitatively and qualitatively depending on the relationship type. Relationships have been characterized in many ways. The previously discussed feature of outcome interdependence is primarily used to characterize the motivational structure of relationships because interdependence of outcomes is intertwined with the potential of developing conflict in relationships. Thus, relationships of high interdependence, such as intimate ones, are very likely to yield conflict. The more individuals depend on one another for more of their positive outcomes, the more likely they are to interfere with one another's positive outcomes. High interdependence provides a lot of opportunities for conflict while at the same time motivating people to insist on claiming their relationship outcomes because (a) they value the relationships in themselves (i.e., what they can derive from the relationships specifically), (b) they might not have alternative options (i.e., alternative relationships offering just as good outcomes), and/or (c) they might not be willing to invest in the costly procedure of seeking and constructing new relationships.

However, conflict expression per se seems to be influenced by three other qualitative (rather than structural) dimensions of relationship features: formality, stability, and personal/task orientation. More specifically, a relationship may be formal or informal, stable or transient, and personal or task oriented. A formal relationship is governed by strong social norms providing salient guidelines about appropriate interpersonal behavior. In contrast, although an informal relationship may also embed implicit behavioral guidelines, it is less directing and leaves more room for partners themselves to define interaction rules. A

transient relationship is temporary and tends to occur with irregular timing, often in different places. To the contrary, a stable relationship lasts longer, has relative time regularity, and tends to occupy identifiable spaces. A task-oriented relationship is established for the sake of accomplishing specific tasks, whereas a personal relationship is initiated mainly for its own sake and the outcomes are accrued through the relationship. Communication in the former focuses on tasks and actions, whereas communication in the latter focuses on the people and their dispositions.

An example of a relationship type that is highly interdependent for outcomes while being informal, stable, and personal is, of course, the married couple. Married couples may experience conflict over any number of issues, including budget allocation, division of household chores, family roles, failed mutual expectations, jealousy, neglect, and infidelity. In fact, it appears that the more a person knows another person, the closer the relationship is and the more likely the partners are to have had experienced a broader spectrum of all the preceding behaviors, emotions, and cognitions to different degrees. Consider the common example in married couples counseling of neglect that may give rise to particularly intense and expressively "rich" conflict. When one member of the relationship maintains a high level of rewarding life outside the relationship, allowing that area to absorb more and more of that person's interest, energy, and time, the other member may start perceiving the gap between past level of personal rewards from the relationship and present outcomes to grow. Failed expectations, deterioration of outcomes, and the inevitable social comparison with the significant other will soon trigger perceptions of interference with own relationship aspirations and a sense of relative deprivation. Feelings of frustration and self-deprecation may follow, and conflict behaviors on the part of the "underbenefited" member to restore level of outcomes and reclaim loss of self-esteem will be manifested. Because the focus in close relationships tends to be on the partners and their dispositions, attributions will be made about the "meaning" of the other's interference or lack of interference (i.e., relative deprivation). Representative thoughts could include "This is another sign that her feelings about me have changed," "He does not care about me," and "I am unable to attract her anymore." Dispositional attributions escalate conflict, and removal of interference might not be sufficient to settle it because the disputants are then focusing on perceived intentional threat to self-esteem rather than on the outcomes of their relationship. Conflict in such cases may be constructive

in the sense that a relationship member is painfully made aware of the fact that he or she is entangled in a relationship that does not accrue positive outcomes to him or her anymore. Restructuring or even leaving the relationship may be necessary to extinguish negative outcomes. Nevertheless, high interdependence, as well as the possible misperception that there are no alternative solutions, might not allow an individual to see conflict as a positive and constructive opportunity. Third-party assistance may be required in this situation.

The adage that the more people know one another, the more likely the conflict, in no way implies that conflict cannot erupt between strangers and acquaintances. More often than not, conflict will occur within a transient formal or informal relationship, that is, with people who one hardly knows or who one never actually meets, for example, the inconsiderate driver who will not allow one's car to overtake his car despite one's desperate signaling and horn honking that one is rushing to an emergency or the "high hat" assistant at the store in the posh side of the town who will answer one's naive questions with a polite yet reluctant and indignant smile. Expression of conflict in transient relationships may include a different, possibly more limited, and yet more extreme set of behaviors compared with those identified in other kinds of relationships.

The anonymity of informal transient relationships may diminish respect for social norms. The brevity and superficiality of the contact with the unknown others, the nonsaliency of social norms in such situations, and the expectation that the interactions will not be followed up all may result, by means of disregarding the human qualities of the others, in particularly acute and exceptional expressions of conflict behavior involving verbal aggression or even physical assault. The anonymous crowds at athletic events have often promulgated intense expressions of interpersonal conflict among spectating fans. Similarly, continuous movement and speed, and the impersonal indirect communication through signaling and horn honking, may precipitate antagonistic behavior between drivers on highways. Extreme behavior is not as likely in formal transient relationships, such as the encounter with the store assistant, because the environment is rich with salient norms of conduct dictating limits to appropriate "protest" behavior and sanctions for inappropriate behavior. There is less anonymity, and the likelihood that the interaction with the same person might be followed up is not negligible. As a consequence of these factors, conflict expression in formal transient relationships is usually subdued and restrained.

What about formal stable relationships such as work and professional relationships? These bear a characteristic that could breed conflict, that is, increased interdependence for outcomes. On the other hand, these relationships usually include a strong set of norms due to their formality. Because they are also stable, individuals cannot discount the future consequences of their negative behaviors. Finally, because these relationships have survival value for the individuals involved, they cannot be easily abandoned for other relationships and so members are particularly motivated to retain them.

Consider a small health care institution that hires two psychologists without a clearly delineated profile for each one's duties. In such a work setting, one is given the chance to define his or her exact job profile and to enjoy the work while gaining recognition and credit toward future promotion. Hence, the two psychologists are likely to compete in demonstrating effectiveness, diligence, and expertise—a productive state of affairs for both the institution and its patients. However, assuming that this small institution has only one higher status position for a psychologist, competition for recognition and credit may soon degrade to antagonism. In patient assessment multispecialist meetings, the two may try to undermine each other's input. They may selectively use scientific knowledge and data that counter each other's specific analyses just to raise generalized hard criticism of each other's approach. Alternatively, they may resort to side remarks and whispers to other members of the team or to personal comments about the rival colleague's personality and way of working. The result is, of course, detrimental to the productivity of the whole team and potentially threatening to patient care. The team must divert attention away from case analysis to the arguments of the two psychologists and must invest time and energy in deescalating conflict and refocusing on the task at hand.

3. OVERVIEW OF THE CONFLICT MECHANISM: DIRECTIVES AND KEYS TO MANAGING CONFLICT

Interference and relative deprivation are the two basic psychological processes involved in conflict outbreak. Both processes implicate the self, particularly self-evaluation and self-esteem, because they activate social comparison with the significant other in the relationship and with a commonly accepted outcome standard. Thus, conflict is not solely about securing for self the

valued resources of interpersonal relationships but also is about enhancing, defending, and restoring self-esteem. Social comparison is a third intermediary process that acts as the interface of the other two to the self. Interference and relative deprivation lead to social comparison with the informational input that the self requires to understand where it stands in relation to others and to evaluate own abilities, achievements, social status, and more abstract personal end states such as satisfaction, happiness, and well-being. If the result of such social comparison is negative self-evaluation, conflict behavior is likely to arise because the self implicates the other in obstructing attainment of own outcomes (i.e., interference) or in nonintervening to assist in attaining better personal outcomes (i.e., relative deprivation). The saliency of self-evaluation, brought about by social comparison, diverts attention of relationship parties away from realistic conflict issues to dispositional attributions about each other's behavior. These attributions usually implicate the other in intentional threats to own self-esteem and are highly conducive to conflict escalation. All three processes are inconceivable outside a relationship that is desirable in its own outcomes by both parties. Underlying these processes is a relationship structure of outcome interdependence. The members of the interpersonal dyad depend on one another for their valued outcomes, and it is this very dependence that motivates them to remain in the relationship despite the hurdle of interference and the increased risk of relative deprivation. Therefore, a paradox results. Conflict behavior is more probable, and often more enduring, the greater the interdependence in the relationship. How conflict will be manifested, however, will be greatly influenced by the more qualitative features of the relationship. The specific repertoire of behaviors used to manifest conflict—their aggressiveness, intensity, persistence, and other behavioral characteristics—will be regulated by the formality or informality, stability or transience, and orientation (task vs personal) of the relationship.

The preceding overview of the most important concepts that have been implicated by research and theory in generating interpersonal conflict also attempts to assemble a loose framework for a general understanding of the psychological mechanism yielding conflict behavior. The framework, depicted in [Table I](#), connects relationship features to the psychological processes of interference and relative deprivation through social comparison. The core cohesive concept mobilizing the supposed psychological mechanism of conflict

production is self-esteem, that is, the need of the self to self-enhance by self-evaluating and comparing with others.

This loose mechanism of conflict production provides basic directives in conflict resolution and several keys to conflict management methodology. First, it suggests that in conflict resolution, the ultimate aim is to protect, preserve, restore, and (possibly) enhance the self-esteem of the parties involved in conflict. The "realistic" goal of eliminating the source of interference or relative deprivation should be viewed only as a step toward self-esteem preservation or enhancement. Attempting to eliminate interference and relative deprivation without taking into consideration that this action reflects on the self-esteem of the disputant parties will only temporarily appease the conflict. In conflict management methodology, skills development is inconceivable without taking into account the role of dispositional attributions in conflict escalation. Among the most important negotiating skills is avoiding allusions to the personality and intentions of disputant parties (e.g., "name calling," "reading between the lines"). A third party intervening to assist in resolving conflict cannot possibly proceed to realistic problem-solving propositions that satisfy both parties without a full analysis of the motivational structure in the relationship. The analysis should show the different ways in which each disputant's valued outcomes could be attained to a maximum possible level of individual desirability considering that the other wants to do the same. The intervening party should identify the maximum minimum (i.e., the best possible of the worst outcomes that one is willing to accept in a negotiation setting) and the minimum maximum (i.e., the minimum among the best outcomes that one is willing to accept in a negotiation setting). Furthermore, the mediator should have a good understanding of the dimensions used by conflicting parties to self-compare with the other in the relationship. Which outcomes are significant to each party, and why are they used as referents of comparison with the other and (possibly) with a common social standard? What are the consequences of such comparisons for a party's self-esteem? The nature of interference should also be clearly understood. How do the parties interfere with each other's outcomes, and with what costs and benefits for self and other? How will changes in the interference pattern change the cost-benefit ratio for self and other? Answering such questions can provide an indication of how motivated and willing the parties will be to shift their behavior to less interference or noninterference during negotiation.

TABLE I
Relationship Features and Psychological Processes Involved in Interpersonal Conflict

<i>Relationship features</i>	<i>Processes</i>		
	<i>Intermediary</i>	<i>Basic</i>	
	<i>Social comparison</i>	<i>Interference</i>	<i>Relative deprivation</i>
Structural–Motivational		Informational input	
Outcome interdependence (high or low)	Self-evaluation becomes salient. Outcomes are compared with other's and with common standards. Result is input to "basic" processes	Perception of other as interfering with own outcomes Self and other's outcomes	Perception of self-outcomes as inferior to other's and to common standards
		Mediating cognitive–affective output	
		Self-attributions, self-devaluation (e.g., "Do I really merit this goal?") Dispositional attributions about other (e.g., "His aim is to humiliate me")	Self-attributions and self-debasement Dispositional attributions about other (e.g., "She intends to deprive me of what everyone has a right to have")
Qualitative		Behavioral output: Conflict expression	
Stability–transience Formality–informality Task–personal orientation		Conflict expression is regulated in terms of persistence, intensity, restraint, and behavioral repertoire by the qualitative features of the relationship.	

4. MANAGING CONFLICT

The fact that conflict is more or less natural to interpersonal relationships perhaps accounts for the common perception that disputants can do little to manage conflict themselves. However, research indicates that disputants trained in interpersonal skills may be able to contain, resolve, and make the best out of conflict, turning it into a constructive and creative process. Indeed, at the individual level, when a person has the skills to handle conflict, this otherwise destructive and painful process may work to mobilize and enhance individual abilities, resources, and ingenuity. It may further motivate self-knowledge, assert self-determination, clarify personal goals and desires, and encourage self-expansion. At the dyadic level, when each of the disputants possesses the skills to handle conflict (to a greater or lesser extent), the disputants may turn a poor interdependence relationship into a fruitful one for both parties. It appears that when

individuals appreciate their outcome interdependence, conflict may provide the thrust that pulls together resources, knowledge, and abilities into devising ideas and solutions that probably would not have been as innovating and productive without conflict.

Unfortunately, the notion of interpersonal skills training for managing conflict has not yet been met with wide social acceptance. For instance, educational systems have done little to integrate such training into their programs. Unfortunately, lack of skills in managing conflict continues to be widespread, and people often find themselves unable to understand how they got involved in escalating conflict and how to handle it. A solution often sought in these situations is intervention by a third party, usually someone with good training in interpersonal skills in conflict management. This section first reviews some of the well-known interpersonal skills for managing conflict. Then, it describes the basic principles and forms of third-party intervention.

4.1. Interpersonal Skills in Managing Conflict

Six basic interpersonal skills for managing conflict have been identified in the past. The first five are viewed as antecedents of the sixth. These basic interpersonal skills must be well acquired and put to effective use before any attempt is made to proceed on to learning how to practice the sixth, that is, problem solving. The latter is the most critical interpersonal skill involved in conflict resolution and, thus, is presented in more detail than the others.

4.1.1. Active Listening

This skill involves listening carefully to what the other person has to say and reflecting on the points he or she is trying to make. Feedback should be provided about what is understood. Points perceived to have ambiguous or double meanings should be clarified with the other by questions that do not include answers and do not assume interpretations.

4.1.2. Empathy

This skill refers to trying to see things from the perspective of the other person. It involves attempting to identify with expectations, fears, and concerns that seem to underlie the other's arguments and responses.

4.1.3. Assertion

This skill suggests that one's point of view, thoughts, feelings, and pursued outcomes are expressed clearly in concrete terms.

4.1.4. Avoiding Dispositional Attributions

Attributing events to the other person's personality, motives, and/or intentions should be avoided at all costs. Communication should be about tasks and issues, whereas affect expressed should not deviate from personal respect and recognition to the other's right to have claims in the relationship.

4.1.5. Constructive Feedback

This skill refers to identifying and rewarding positive behaviors toward resolution while not failing to mention or ignoring negative behaviors. Reasoning should

be provided as to why behaviors are positive or negative on the basis of their consequences to self, other, or both.

4.1.6. Problem Solving

Alternative solutions aimed at satisfying the goals and needs of both parties should be generated. This requires (a) each party developing separately a clear hierarchy of goals and needs, with his or her optimum goals placed on top and followed by the maximum minimum and the minimum of the maximum; (b) discussing proposed solutions, beginning with the target of fulfilling optimum goals for both parties and then, if discussions come to an impasse, discussing on the basis of satisfying maximum minimum goals for both parties and then, if this also fails, further discussing on the basis of minimum maximum goals; (c) examining whether maintaining the relationship and maximizing joint outcomes is indeed preferable to pursuing own optimum goals independently; and (d) repeating Steps b and c until both parties concede to aim for lower than their initial outcomes so that a mutually satisfying solution (referred to as "satisficing") can be reached. If necessary, the hierarchy list of preferred outcomes should be reviewed and restructured.

The conflict resolution process may last a long time and may require the control and manipulation of several parameters. Hence, it is important that disputants monitor their effectiveness in managing conflict. Based on Deutsch's 1994 analysis of conflict resolution training, four criteria captured by the following questions can be used to evaluate whether the preceding skills have been put to work effectively. First, has a cooperative, problem-solving relationship with the other person been initiated, and how well is it maintained? Second, do disputants discuss a reasonable range of alternative and mutually satisfying proposals as a result of problem solving? Third, do disputants seem to gradually adopt an "outsider's" perspective or an analytic perspective to the conflict? Fourth, are the various forms of conflict expression kept to a minimum during the process?

Influential applied research, such as Johnson and Johnson's 1994 research on constructive conflict in schools, has consistently documented the benefits of systematic interpersonal skills training in interpersonal educational as well as in other settings. However, as noted previously, educational systems have not yet integrated such training into their programs. Unfortunately, rather than preparing to personally handle the relatively frequent, inevitable, and potentially harmful life events of conflict, people seem to prefer resorting to the

intervention of a third party after conflict has already escalated and negative consequences are already difficult to bear. Although such persistent conflict may have caused a lot of damage or even irreparable harm, it is usually never too late to seek the help of a specialist.

4.2. Third-Party Intervention

A third (independent) party can often be invited by the disputants to resolve conflict. This is more likely when disputants are motivated to maintain their relationship despite its temporary negative outcomes or when they intend to exit the relationship with the maximum possible gain and minimum possible damage for self and other. Third-party intervention may also be offered when conflict has damaging consequences for others indirectly related to the disputants and when the functionality of their social setting is threatened. For instance, in the earlier example, negative consequences had resulted from the conflict between the two psychologists for the functionality of group multispecialist meetings, the work ambience, and the welfare of patients in the small health care institution. In this case, the chief administrator of the institution might have intervened in a number of informal ways. The administrator could have advised the psychologists individually to behave “professionally,” to avoid hostility, and to focus on patient care, or the administrator could have facilitated a constructive dialogue between the two. Alternatively, the administrator could have arranged so that the two psychologists never interact or interfere in each other’s duties. If these informal approaches had proven to be ineffective, the administrator could have employed a more formal approach such as mediation.

In general, intervention strategies differ in terms of their legalistic and nonlegalistic character as well as the intervening party’s interaction with the disputants.

4.2.1. Adjudication

This involves a judge or jury in a court setting. The interaction of these parties with the disputants is strictly formal and follows legally prescribed channels. Disputants are obliged to abide by the court’s decision.

4.2.2. Arbitration

This involves little interaction of the intervening party with the disputants. The arbitrator listens to both sides and decides what the solution should be. This

approach is also legalistic, to a certain degree, in that norms and prescribed rules must be taken into account in providing a solution. Disputants may have agreed before arbitration to abide by the arbitrator’s decision. However, they are not obliged to do so.

4.2.3. Fact Finding

This involves even less interaction with the disputants. The third party’s role is to gather information so as to arrive at an independent judgment regarding the dispute. This strategy could also be said to have a legalistic character in the sense described in the preceding subsection (on arbitration). The input of the “fact finder” is only advisory.

Conciliation and mediation, described next, are non-legalistic processes and tend to be more psychological in nature.

4.2.4. Conciliation

This involves a lot of interaction with the disputants, albeit limited to opening and maintaining communication channels and exchange of information. The conciliator does not get actively involved in disputants’ discussions and agreements.

4.2.5. Mediation

This involves an independent third party who must actively interact with the disputants and work with them in identifying the source of conflict and in reaching a mutually satisfying agreement. Mediation is largely preferred to other forms of third-party intervention in many types of interpersonal relationships. This may be due to its relatively lower cost to other, particularly legalistic, conflict resolution procedures or, more important, to the willingness and commitment of anyone choosing mediation to actually resolve conflict. The latter may, in part, account for the finding that mediation yields more effective, lasting, and satisfactory resolutions for disputants. It is also noteworthy that even when conflict is not resolved in a satisfactory way, the mediation process per se tends to improve disputant relations both within and outside the mediation framework.

Psychological research has dealt more with mediation than with any of the other intervention processes, focusing on understanding its mechanisms and its effectiveness. Following is a succinct description of the basic features of this procedure.

The mediator must be a person who is trained in interpersonal skills and has a good understanding of the theoretical underpinnings of conflict and experience in monitoring conflict. Mediation usually starts with preliminary contacts between the mediator and each disputant. The aim of these contacts is twofold: (a) to evaluate disputants' willingness and commitment to resolving conflict and (b) to identify the fundamental source of conflict and of minor issues causing friction. Setting the rules of subsequent interactions follows this stage. The mediator explicates the procedure, delineates his or her role as a neutral moderator, and states emphatically the modes of communication that will and will not be allowed during interaction, usually giving specific examples. For instance, interruptions, dispositional attributions (e.g., name calling), and generalizations and interpretations of the other's arguments should be avoided. Mediation proper then begins. Each disputant is asked to present his or her view of the conflict situation within a specific time limit. The mediator makes sure that no one is interrupted and that the rules are followed. Once both disputants have presented their views, the mediator may summarize each position and asks disputants for further clarifications. This is followed by the problem-solving phase, during which the two disputants and the mediator all collaborate in reviewing (a) each party's interests, goals, and desirables outcomes; (b) each party's sources of interference and nuisance; and (c) as many feasible and desirable solutions to conflict as is possible. Common discussion is followed by separate discussion with each disputant, during which the same issues are reviewed with an emphasis on discussing as many feasible and desirable solutions to the conflict as is possible. During these contacts, the mediator must reevaluate commitment to conflict resolution and exclude the possibility that mediation is being used by either disputant as a strategy to attain a hidden agenda. Furthermore, points of resistance, reluctance, and apprehension regarding the constructive process must be identified, and their causes must be discussed. If this stage yields a range of mutually acceptable alternatives, an agreement can be reached. Agreements are recorded, typed, and signed by both parties. Language used in documents should be specific, concrete, and unambiguous. Disputants are expected to honor their signatures. If the problem-solving stage does not produce a mutually acceptable solution, agreement cannot be reached and the entire procedure must be repeated. The stages described do not necessarily follow one another. An earlier stage might need to be rerun at any point during the

mediation procedure. Thus, mediation can be painstaking and time-consuming. Nevertheless, as has often been observed in relevant research, the procedure *per se* may improve the relationship of the conflicting parties, providing them with a thrust to proceed on to resolving conflict on their own.

5. CONCLUSION

Conflict can undermine the integrity of a relationship and generate negative consequences for the relationship members. However, such detrimental outcomes are due to uncontrollable escalation of conflict and not to conflict *per se*. In fact, conflict is an integral part of all interpersonal relationships. It is a product of the interdependence that is necessarily developed between two (or more) parties so that they can both (or all) enjoy valued outcomes that could not be enjoyed to the same degree, or with the same ease and quality, outside the specific relationship. Conflict can be managed so as to yield outcomes constructive for the relationship and positive for its individual members. Relationship members should be on guard for uncontrollable conflict escalation, which is usually due to (a) actual or perceived interference of the other with the attainment of own goals, (b) actual or perceived relative deprivation of own outcomes with respect to a commonly accepted standard and the standard attained by the significant other in the relationship, (c) perceiving interference or relative deprivation as a threat to self-esteem, (d) focusing on enhancing self-esteem rather than on specific conflict issues, (e) maximizing own outcomes unilaterally by ignoring the other's or at the expense of the other's outcomes, (f) manifesting and retaliating conflict behaviors, and/or (g) making dispositional attributions about conflict behaviors.

Training in interpersonal skills, such as active listening, empathy, assertion, constructive feedback, and problem solving, can deescalate conflict and turn it into a constructive process. Mediation by a third party is often required when people lack conflict resolution skills. The mediator attempts to facilitate interactions between disputants so that they can negotiate for themselves. Mediation requires analyzing facts, goals, outcomes, and conflict behaviors as reported by each party in individual and common sessions with the mediator. As a constructive process, conflict can regulate self-interest in a relationship. Moreover, it can maintain the relationship's productivity of positive outcomes to a maximum level for the members involved. It can work to clarify needs and goals and to delineate the

role of individual members. It can focus disputants on mutually satisfying solutions of objective conflict differences, moving them away from the persistent and futile effort to restore self-esteem by means of conflict behavior. Last, but not least, it can disentangle individuals from an unproductive relationship that perpetuates their negative outcomes by precipitating exit.

GLOSSARY

meta-accuracy How well a person knows how she or he is viewed by others.

metaperceptions The way in which people believe others perceive them.

reciprocity The degree to which people view each other the same (or differently).

self-perceptions How individuals perceive themselves.

self-other agreement How much a person's self-perception is similar to the way in which others see him or her.

target accuracy How well a person really knows another person.

People, whether strangers or marriage partners, form perceptions of one another, and these perceptions have played an important role in social science research. For instance, leadership style was measured by Fiedler using an interpersonal perception measure called LPC, and Newcomb argued that the co-orientation of interpersonal perceptions is key to understanding the formation of friendships. This article considers the types of interpersonal perceptions, the relations among them, and their statistical analysis.

1. TYPES OF PERCEPTIONS

There are three major types of perceptions: perceptions of others, metaperceptions, and self-perceptions. Very often, researchers studying groups and relationships ask people to make judgments of one another. For instance, they may ask people in a work group how hard-working and friendly the other members of the group are. Sometimes, researchers ask observers or outsiders to form perceptions of group and dyad members. Thus, much of what is called an interpersonal "perception" is not so much a perception as an inference made about another person. Nonetheless, the term "interpersonal perception" continues to be used.

Besides asking for perceptions of others, researchers may ask people how they think others view them. These perceptions of perceptions are called metaperceptions or reflected appraisals. Finally, they may ask people how they perceive themselves (called self-perceptions). Although self-perceptions are not themselves interpersonal, they are thought to be closely tied to interpersonal perceptions.

In 1966, Laing and colleagues developed a simple notation for such perceptions. The perception that Person A has of Person B is denoted as A(B), the metaperception is denoted as A(B(A)), and the self-perception is denoted as A(A).

Other more complicated types of interpersonal perceptions are relatively less studied. Laing and colleagues discussed meta-metaperceptions (e.g., What does Person A think that Person B thinks that Person A

thinks?) and even meta-meta-metaperceptions. Others have studied triadic perceptions (e.g., What does Person A think that Person B thinks of Person C?).

The content of these perceptions is quite varied and is limited only by the imagination of the investigator. Among the topics studied are personality (e.g., Does Person A think that Person B is friendly?), liking (e.g., Does Person A think that Person B likes Person A?), interests and attitudes (e.g., Does Person A think that Person B is politically conservative?), and emotional states (e.g., Does Person A think that Person B is currently angry?). In general, researchers ask perceivers to make judgments about several variables. For instance, a person might be asked whether his or her roommate is friendly, intelligent, lazy, and/or organized.

2. RELATIONS AMONG PERCEPTIONS

Very often, researchers are interested in the relationship among different interpersonal perceptions. In 1994, Kenny, extending the pioneering work of Laing and colleagues, defined a series of questions that relate interpersonal perceptions to each other. Among the most common questions are the following:

- *Consensus*: Do two people agree in their perception of a common target?
- *Reciprocity*: Do two people view each other in the same or opposite ways?
- *Target accuracy*: Does a person really know what another person is actually like?
- *Meta-accuracy*: Does a person know how he or she is viewed by another person?
- *Self-other agreement*: Is a person's self-perception similar to how another person views him or her?

Very often, researchers and theorists use these relations among interpersonal perceptions. For instance, a key tenet of symbolic interactionism is that self-other agreement between a person and a significant other is due to the meta-accuracy of the person knowing how the significant other views him or her and then the incorporation of that view into the self-concept.

3. STATISTICAL ANALYSIS

Research in interpersonal perception can be either ideographic or nomothetic. In ideographic work, the

focus is on variation of relationships between perceptions by persons or relationships. An example of an ideographic question is that of whether married couples who know their partners better are more satisfied in their relationships. Most researchers who study interpersonal perception are interested in the ideographic level of analysis.

Alternatively, the focus might be nomothetic or general laws that are true of most persons. For instance, research might ask how much meta-accuracy there is. One advantage of a nomothetic analysis is that it is possible to decompose effects at the level of the individual and the dyad using the Social Relations Model. For instance, one can determine whether meta-accuracy is true of persons across relationships (e.g., Do people know how they are generally seen across relationships?) and whether meta-accuracy is true of particular relationships (e.g., Do people know how they are uniquely seen by particular others?).

There are several difficulties that arise in the analysis of interpersonal perceptions. For instance, researchers sometimes compute the absolute difference or discrepancy between two interpersonal perceptions. Following Cronbach's 1955 work, such scores lead to several interpretive issues. Other issues arise in the analysis of data from interpersonal perception. Despite difficult methodological and statistical issues, interpersonal perception and the relations between perceptions will continue to be important in social science theory and research.

cognitive interview Forensic tool composed of a series of memory retrieval techniques designed to increase the amount of information that can be obtained from a witness.

ethical interviewing A police interview technique, based on three principles, designed to encourage a suspect to tell his or her side of the story; the use of deceit is forbidden, and psychological pressure is not used.

Reid technique A police interrogation technique, consisting of nine steps, designed to encourage reluctant suspects to talk during police interviews; the technique allows interrogators to use deceit and to build up psychological pressure.

suggestibility The act or process of impressing something (e.g., an idea, an attitude, a desired action) on the mind of another.

The purpose of a police interview or interrogation is to obtain information about a possible crime. Effective interviewing is difficult because interviewers risk eliciting inaccurate information that they may misconstrue as accurate.

1. INTRODUCTION

The purpose of a police interview with an alleged victim, witness, or suspect is to obtain information about a possible crime. During this information-gathering process, interviewers should attempt to obtain statements that are complete (i.e., include all the relevant information that the interviewee knows) and reliable (i.e., contain only accurate information). Those two aims are not always compatible. Certain interview techniques readily result in more information, but the information is often less reliable. Psychologists have developed interview techniques that increase the likelihood of obtaining both accurate and reliable information. However, these techniques might not work with interviewees who are reluctant to talk. For this reason, other more persuasive interview techniques have been developed, especially for interviewing uncooperative suspects. Those techniques have been criticized extensively by psychologists. A major problem is that they may induce false confessions, that is, suspects admitting to having participated in crimes when in fact they did not actually participate in those crimes. Obtaining unreliable information would be less problematic if

police officers could distinguish reliable information from unreliable information.

2. THE PROBLEM: THE INTERVIEWEE DOES NOT PROVIDE ENOUGH INFORMATION

Obtaining information from witnesses, victims, and suspects is critical for effective police investigations. However, the answers to questions such as “Tell me exactly, and in as much detail as possible, what you witnessed” and “Tell me exactly, and in as much detail as possible, what happened to you” are typically incomplete. In nearly all cases, interviewees initially report less information than they actually hold in their memories. Routinely, interviewers want more information than is initially provided. It is not surprising that guilty suspects fail to report all of the information that they are able to recall. Why would they volunteer information that will indisputably link them with their crimes? However, witnesses and victims also rarely volunteer all of the information they know. There are several reasons for this. First, it is a matter of ignorance. Police interviews require witnesses and victims to describe people, objects, and events in more detail than is customary in casual conversation. Often, interviewees do not realize that the police want them to disclose all of the information they know rather than just the information that the interviewees believe is relevant. Second, information is often lacking or incomplete due to cognitive reasons. For example, young children’s first accounts of an event are particularly incomplete. Cognitive abilities and command of language develop throughout childhood, making it gradually more feasible to offer detailed accounts of what was witnessed. Older children and adults use more complex and successful retrieval strategies than do younger children, increasing the amount of information they can retrieve independently. People cannot verbally recall experiences that occurred before they learned to speak. Therefore, they cannot verbally relate events that they experienced before 2 years of age. Third, social factors contribute to incomplete accounts. For example, socially anxious people who feel discomfort in the presence of strangers spontaneously volunteer less information. Other people may be too embarrassed to talk freely about certain events that they have experienced or witnessed. For all of these reasons, interviewers must ask further specific questions to learn more about events. However, by asking a series of specific follow-up

questions, interviewers run the risk that the questions selected will reflect what the interviewers believe happened rather than what the interviewees actually witnessed or experienced. This risk is most pronounced when the interviewers’ questions are suggestive.

3. THE PROBLEM WITH FURTHER QUESTIONING: SUGGESTIBILITY

Despite considerable controversy concerning the extent to which children and adults are susceptible to suggestion in forensic contexts, three conclusions can be drawn. First, there are individual differences in suggestibility. Second, there are age differences in suggestibility. Younger children are more suggestible than older children, and children are more suggestible than adults. Third, the manner in which an interview is conducted can affect suggestibility as well as the quality and extent of information elicited.

4. THE SOLUTION: QUESTIONING TECHNIQUES TO MINIMIZE SUGGESTIBILITY

Research on questioning witnesses and victims in a forensic context has focused on ways in which to avoid suggestibility. Perhaps because children are particularly sensitive to suggestibility, much research has centered on interviewing children. This research shows that open-ended questions (e.g., “Tell me what happened”) are best for gathering information because the interviewee has the opportunity to give an open unrestricted answer and to control the flow of information. This type of question produces responses that are longer and richer in relevant details than are responses to other types of questions. Most “wh-” questions (e.g., what, where, when, why, who) can be classified as open-ended questions. These questions should be asked at the beginning of the interview. Facilitative responses by the interviewer, such as “okay” and “mm,” encourage the witness to continue the account. Focused questions can be asked later in the interview. These are questions that focus the witness’s attention on details or aspects of the event that the witness described previously. For example, “Tell me what the man looked like” is an example of a focused question after an interviewee mentioned a man but did not describe his appearance. Leading questions (e.g., “Was the man Black?”) are problematic because the interviewee may respond by

simply repeating the information conveyed in the question rather than by relying on his or her memory. Option-posing questions, or questions that offer alternatives (e.g., “Was the man Black or White?”), are preferable in that respect because they are less leading. However, there is still the chance that the interviewee’s preferred option might not be incorporated into the alternatives posed by the interviewer. An open-ended question (e.g., “What was the color of the man’s skin?”) is a less suggestive question format. Where leading questions are asked (e.g., “Did he touch you?”), they should be followed by open-ended questions designed to elicit further information about the topic (e.g., “Tell me everything about that”).

Few practitioners apply these principles in forensic interviews. For example, in 2002, Westcott and Brace reported an analysis of 119 interviews with children by police officers and social workers in England and Wales. The analysis revealed that open questions were rarely asked (6%) and that focused questions were most common (47%). Questions that included alternatives occurred more frequently (29%) than did facilitative responses (13%), and some questions were leading (5%). Similar studies conducted in Sweden, Israel, and the United States provided similar results.

5. THE SOLUTION: INTERVIEW TECHNIQUES TO ENHANCE INFORMATION RECALL—THE COGNITIVE INTERVIEW

Another line of research has explored whether the quality and amount of information provided by cooperative interviewees can be improved by certain interview techniques. One such technique, the cognitive interview, has been adopted by police forces around the world, including Australia, Germany, the United Kingdom, and the United States.

The cognitive interview, developed by psychologists, has three core elements: social dynamics, memory/general cognition, and communication. Social dynamics and communication refer to interpersonal communication and ways in which to deal with anxious or inarticulate witnesses. The interviewing police officer has ostensible social authority and more control over the interview than does the witness and, therefore, may dominate the interview. To avoid counterproductive dynamics, when interviewing an cooperative witness, the police officer should explicitly ask the witness to take an active role in the interview.

Officers should communicate with witnesses in the style that the witnesses prefer by adopting witness-compatible questions. Most often, depictions will be verbal, but some witnesses find it easier to describe certain events nonverbally. For example, if the event that a witness experienced involved a tactile element such as brushing against a fabric, the witness might prefer to recall this experience in a similar mode by touching various fabrics.

The memory/general cognition element consists of four components. A “report everything instruction” is given to encourage witnesses to report everything they remember without any editing, even if the details seem trivial or their memory of a particular aspect of the event is partial or incomplete. Memory retrieval is most efficient when the context of the original event is mentally reinstated at the time of recall. Therefore, interviewees are instructed to reconstruct in their minds the environmental features (i.e., location where the event took place) and personal features (i.e., how they felt at the time) of the event. Different retrieval cues may access different aspects of a complex event. Therefore, after witnesses recount the event in their own order during free recall, they should be asked to recall the event using a variety of different temporal orders, for example, in reverse order (i.e., from the end of the event to the beginning of the event). People have a tendency to report events from their own perspective. An instruction to change perspective asks interviewees to recall the event from the perspective of another person who was present (e.g., “Go through the event again and tell me any further information witnessed by that other person you mentioned”).

Studies testing the efficacy of the cognitive interview have revealed that this technique elicits more accurate information than do conventional interview techniques. This technique also elicits more inaccurate information in that it increases the absolute number of errors; however, it does not increase the rate of inaccuracy. In other words, the percentage of information that is inaccurate is not higher using the cognitive interview than that obtained using conventional interview techniques.

6. THE PROBLEM: PERSUADING RELUCTANT INTERVIEWEES TO TALK

The stereotypical view, often promoted in police manuals, is that suspects are reluctant to talk and that, therefore, tough interrogation techniques, rather than

interview techniques, are needed to persuade suspects to talk. The assumption that suspects are unwilling to talk is plausible because confessing to a crime dramatically increases the likelihood of a conviction. For example, Dutch research revealed that in cases where the suspects confessed, convictions were nearly inevitable (a 94% conviction rate was found), whereas without a confession, the conviction rate was only 44%. However, the view that suspects are generally uncooperative is not supported by research. Studies in England and Wales revealed that 80% of suspects are cooperative during interviews and that 55 to 60% of suspects confess. (Much research on this topic has been carried out in England and Wales because, by law in those countries, all police interviews with suspects must be audiotaped.) These studies also examined what prompts suspects to confess. The most important factor seems to be the perceived strength of evidence; suspects are more likely to confess if they perceive the evidence against them to be strong. Another influential factor is the seriousness of the crime; suspects are less inclined to confess when they are suspected of committing more serious offenses. Hence, suspects are reluctant to confess when they are suspected of serious crimes and/or the evidence against them is weak.

Several interrogation methods have been proposed to persuade reluctant suspects to talk. Probably the most well known is the “Reid technique” proposed by Inbau and colleagues. The back cover of the latest edition of their manual, published in 2001, proclaims that their technique is “the standard in the field” and that it has been used successfully by “thousands of criminal investigators.” The Reid technique is meant to apply to suspects who are likely to be guilty. Interviewers are advised to make preliminary assessment of the likelihood of guilt by observing suspects’ verbal and nonverbal responses. For example, according to Inbau and colleagues, verbal responses typical of untruthful suspects include giving delayed, evasive, and/or vague answers; displaying unusually poor memory; making statements against self-interest (e.g., “as crazy as it sounds”); and answering questions with questions (e.g., “Why would I do that?”). Assumed behavioral clues to deception include changing posture, maintaining a retreating posture (e.g., crossing arms in a tight fashion), making grooming gestures, placing a hand over the mouth or eyes when speaking, averting one’s gaze, and hiding hands (by sitting on them) or hiding feet (by pulling them under the chair).

6.1. The Reid Nine Steps of Interrogation

The Reid technique strives to break the (guilty) suspect’s resistance to confess. It consists of the following nine steps:

1. Engaging in a positive confrontation
2. Developing a theme
3. Handling denials
4. Overcoming objections
5. Retaining the subject’s attention
6. Handling the suspect’s mood
7. Creating an opportunity to confess
8. Obtaining an oral confession
9. Converting an oral confession into a written one

Step 1 consists of a direct presentation of real or fictional evidence regarding the suspect’s involvement in the alleged crime (e.g., “Our investigation shows that you are the one who . . .”). This accusation is followed by a brief pause during which the suspect’s behavior is observed closely. The interrogator repeats the accusation. Suspects who fail to make a denial after the second direct confrontation are presumed to be guilty.

Step 2 deals with theme development tailored to emotional versus nonemotional suspects. In the case of an emotional suspect, the interrogator is advised to build rapport by offering the suspect a moral excuse for committing the offense. This can be achieved by rationalizing the situation, suggesting that anyone else in the same situation might have committed the same type of offense, minimizing the moral seriousness of the offense, suggesting a more morally acceptable motivation for the offence, condemning others, and so on.

Suspects who appear to listen attentively to these suggestions are presumed to be guilty. The following example, from Inbau and colleagues, illustrates this technique: “Joe, no woman should be on the street alone at night looking as sexy as she did. . . . It’s too much a temptation for any normal man. If she hadn’t gone around dressed like that, you wouldn’t be in this room now.” Critics of the technique label it the minimization approach and describe it as a technique in which the police interrogator tries to lull the suspect into a false sense of security by offering sympathy.

Nonemotional suspects are expected to perceive an interrogation as a “contest of endurance,” that is, as “pitting their willpower against the interrogator’s persistence.” Effective techniques for these cases are (a) to seek an admission of lying about some incidental aspect of the crime so that the interrogator can say

“You lied to me once and you will lie to me again” and (b) to encourage the suspect to associate himself or herself with the scene of the crime, pointing out that all of the evidence leads to the suspect’s guilt, that it is futile to resist telling the truth, and so on. Critics call this the maximization approach, a technique in which the interrogator tries to scare and intimidate the suspect into confessing by exaggerating the seriousness of the offense and the magnitude of the charges and, if necessary, by making false claims about the evidence.

Step 3 describes how to respond to denials of guilt. The goal is to curtail the suspect’s repetition or elaboration of the denial (using techniques described in Step 2) and is seen as a crucial step because the more frequently a guilty suspect repeats a lie, the harder it becomes for the interrogator to persuade the suspect to tell the truth. The theory is that an innocent suspect typically will persist in denying guilt, whereas a guilty suspect is more likely to allow the interrogator to return to the conversation theme. An innocent suspect is expected to maintain denial, and a guilty suspect is expected to offer reasons why the accusation is wrong (e.g., “I couldn’t have done that; I don’t own a gun”).

Step 4 consists of overcoming the suspect’s objections. For example, the interrogator is advised to show understanding and then return to the conversation theme (e.g., “That may be true, but the important thing is . . .”). Once the suspect observes that his or her objections are ineffective, the suspect is expected to become uncertain and display signs of withdrawal. The interrogator is advised to react by retaining the suspect’s attention (Step 5), for example, by moving physically closer to the suspect, leaning towards him or her, and maintaining eye contact. Step 6 involves strategies to manage the suspect’s passive mood. When the suspect appears to be attentive, the interrogator is directed to focus the suspect’s mind on possible reasons for committing the crime. The interrogator should exhibit signs of understanding and sympathy and should urge the suspect to tell the truth. Finally, the interrogator should attempt to elicit a remorseful mood, for example, by pointing out the negative consequences of the crime for the victim. In Step 7, alternative question forms are recommended to offer the suspect the opportunity to provide an explanation or excuse for the crime, and this will make an admission easier to achieve (e.g., “Was this your own idea or did someone talk you into it?”). Whichever alternative a suspect chooses, the net effect of an expressed choice is an admission. Following the selection of an alternative, Step 8 consists of the development of the initial

admission into a detailed confession that discloses the circumstances, motives, and details of the crime. Inbau and colleagues advised that the questions asked by the interrogator should be brief, clear, and designed so that they can be answered in a few words. Furthermore, they should not contain harsh or emotionally charged terminology. Step 9 deals with converting an oral confession into a written one. This step is seen as important because the suspect might deny ever making an oral confession.

6.2. Concerns with the Reid Technique

The Reid technique has been criticized extensively by academic researchers. Numerous assumptions presented in the manual, such as “two denials imply guilt” (Step 1), have never been tested empirically. Other assumptions, such as how liars behave and what they say, have been tested but not supported.

By asking (during the confession phase, i.e., Step 8) leading questions that can be answered by the suspect in a few words, the interrogator runs the risk that the confession will reflect more about what the interrogator believes happened than what actually transpired.

In addition, bluffing (i.e., making up evidence) may backfire. For example, if an interviewer lies and tells a burglar that his or her fingerprints have been found at the scene of the crime, a burglar who wore gloves now knows that this statement is a lie and will probably realize that the police do not actually have much evidence against him or her. Inbau and colleagues acknowledged this problem and recommended that this tactic be used only as a “last resort effort.” Researchers have demonstrated that North American police detectives can be very creative in devising examples of bluffing such as introducing nonexistent technology (e.g., “The Cobalt Blue test has proven that the fingerprints on the body of the victim belong to you”). Research has revealed that confronting a suspect with false evidence is quite common in the United States and happens in approximately 30% of custodial interviews. Although these sorts of tricks are allowed in the United States, they are illegal in several Western European countries. Police detectives who try to apply the Reid technique in those countries run the risk that subsequent confessions will be dismissed in criminal courts.

The Reid technique of psychologically manipulating people through trickery and deceit may lead to false confessions. One problem with tricks and deceit is that

both guilty and innocent suspects become more willing to confess. There is no strategy that motivates only guilty suspects to talk. As a result, the more successful a strategy is in eliciting confessions from guilty suspects, the more likely it is that this strategy will also produce false confessions from innocent suspects.

6.3. The Solution: Ethical Interviewing

In the United Kingdom, an ethical framework of police interviewing is advocated. The British outcry for, and subsequent legislation of, less oppressive police investigative interview techniques has probably been heavily influenced by cases such as “The Guildford Four” and “The Birmingham Six,” well-known cases of British miscarriages of justice. Ethical interviewing is based on three principles: (a) to shift the police service from its traditional reliance in getting a suspect to confess to encourage a search for the truth, (b) to encourage officers to approach an investigation with an open mind, and (c) to encourage officers to be fair. Police training in this ethical framework emphasizes the importance of detailed information gathering at the beginning of the police investigation. It is argued that before the interview starts, the detectives should have been to the scene of crime and, therefore, know how it looks; should know all of the facts of the crime (e.g., evidence obtained at the scene of the crime, statements of witnesses, any peculiarities); and should know the suspect (e.g., background characteristics, family circumstances, possible addictions, possible diseases).

It is further stressed how to use open and closed questions in police interviews. An information-gathering strategy at the beginning of the interview is advocated because this increases the possibility of eliciting an account from the suspect. The use of open questions is generally preferable. They usually elicit longer answers and, therefore, more information. They are an invitation to the suspect to present his or her point of view and will increase the likelihood of the suspect believing that the interviewer is taking him or her seriously. Open questions encourage the suspect to talk and, therefore, facilitate the desired format of a police interview; that is, the suspect talks and the interviewer listens and asks for clarifications. An interviewer who is prepared to listen is more likely to be liked by the suspect, and this might make the suspect more willing to talk. Closed questions are also useful in interviews, particularly to obtain short factual answers

on specific points. However, these questions should be used sparingly at other times and rarely during the early stages of the interview.

Several strategic tactics are offered, including the “blocking escape routes” method, which is used to strengthen the evidence in a case. Evidence is sometimes thin and open to multiple interpretations. Presenting this evidence at an early stage of the interview may give the suspect the opportunity to “escape” by providing alternative explanations. The blocking escape routes method is designed to prevent this from happening. For example, suppose that the suspect’s car was noticed near the scene of the crime just after the crime took place. This might be a link, but the link is not strong. If the suspect is confronted with this piece of evidence at an early stage of the interview, the suspect might, for example, say that he or she used the car to go to a store. The evidence is much stronger if, before the evidence is presented, the suspect has told the interviewer (after being asked about this) that he or she did not use the car on that particular day, that he or she never lent the car to anyone else, and that nobody else has the keys to the car. After the escape routes have been blocked, the suspect could be confronted with his or her own statements and evidence (e.g., “You told me that you are the only one who uses that car, right? Well, a high-speed camera provided evidence that you drove with your car at high speed near the scene of the crime just after the crime took place. Could you explain that?”).

At first sight, the ethical interviewing approach appears to be “softer” than the Reid technique; however, this is not necessarily the case. Although the use of trickery and deceit is forbidden in an ethical interviewing framework, a “tough” interview is allowed. It might be that suspects who decided not to talk during their interviews will remain silent without the use of trickery and deceit, and in such cases the ethical approach will not be successful for the interviewing of uncooperative suspects. This poses a problem, especially if these uncooperative suspects are believed to have committed serious crimes. Ethical methods designed to make silent suspects more willing to cooperate have yet to be developed. The difficulty is that any such methods are likely to make both guilty and innocent suspects more willing to cooperate, and the latter could lead to false confessions. Inbau and colleagues acknowledged the problem of false confessions and offered the following solution:

A guideline that an interrogator may use in any case situation where he may be in doubt as to the

permissibility of any particular type of trickery and deceit, is to ask himself the following question: "Is what I am about to do, or say, apt to make an innocent person confess?" If the answer is "no," the interrogator should go ahead and do or say what was contemplated. On the other hand, if the answer is "yes," the interrogator should refrain from doing or saying what he had in mind.

The obvious problem, not addressed by Inbau and colleagues, is that the police detective never knows for sure whether he or she made a correct judgment.

7. FALSE CONFESSIONS

How often false confessions occur is unknown, but estimates range from 35 to 600 convictions on the basis of false confessions per year in the United States alone. It is often difficult to establish whether a confession is false. Police coercion during the interview is not determinative because a confession obtained using an oppressive interview style could be truthful. The retraction of a confession is another potential indicator. On the one hand, a confession may be truthful even though the suspect retracts the confession after the interview; on the other hand, suspects convicted on the basis of confessions do not necessarily appeal their convictions but still could have confessed falsely. Finally, one might consider the accuracy of the confession. On the one hand, a confession in which accuracy cannot be established beyond doubt (e.g., because independent case facts are not available) is not necessarily false; on the other hand, innocent suspects may at times give accurate accounts of what has happened because police detectives provided case information to the suspects, who subsequently incorporated the information into their statements.

Why suspects make false confessions is difficult to determine, but several factors are often present, for example, a combination of tricks employed by the police, a susceptible suspect, and interviewers determined to secure a confession.

7.1. Types of False Confessions

Psychologists distinguish among three psychologically distinct types of false confessions: voluntary false confessions, coerced compliant false confessions, and coerced internalized false confessions.

7.1.1. Voluntary False Confessions

Voluntary false confessions are given without any external pressure from the police. Most often, people voluntarily go to the police station and inform the police that they have committed crimes reported on television or in newspapers. Voluntary false confessions occur for several reasons. One reason is a "morbid desire for notoriety," that is, a pathological need to become infamous and to enhance self-esteem, even if it entails the prospect of imprisonment. One serial false confessor, Henry Lee Lucas, is estimated to have confessed to more than 600 murders during the early 1980s. When asked why he confessed to all of these crimes, Lucas answered that prior to his arrests, he had no friends and nobody listened to him or took any interest in him; however, once he began to make false confessions, all that changed and he now had many friends and enjoyed his celebrity status. Other people may voluntarily falsely confess because they are unable to distinguish facts from fantasy. Schizophrenic people, in particular, are prone to this type of confession. Yet another reason why people may voluntarily falsely confess is that they want to protect the real criminals. For example, a father might falsely confess to a crime that he knows or believes was actually committed by his son. Finally, people may voluntarily falsely confess because they see no possible way in which to prove their innocence and hope that confessing will secure reduced punishment.

7.1.2. Coerced Compliant Confessions

Coerced compliant confessions occur when, as a result of police interviews, suspects confess to acts they know are untrue. This type of confession results from the pressures of police interviews and from the strategies used by the police in the interviews. As a result, suspects believe that the benefits of confessing outweigh the costs, and so they confess to escape from the police interviews, which they consider stressful and intolerable. Alternatively, they confess due to police promises of rewards following their confessions, or they confess due to a combination of the two.

7.1.3. Coerced Internalized False Confessions

Coerced internalized false confessions occur when people come to believe, during police interviewing, that they have committed the crimes of which they are accused, even though they have no actual memories of committing the crimes. One vivid example is

the case of Tom Sawyer, a socially anxious man and former alcoholic who came to believe that he committed a murder that he in fact never committed. In trying to engage Sawyer in conversation about the crime, the detectives asked him to help them create a scenario describing how the murder might have happened. Sawyer, who loved to watch detective shows on television, was eager to help and joined in. The police let Sawyer outline several scenarios and accused him of having committed the murder. The police claimed that Sawyer knew nine facts that only the killer could have known. Analysis of the interrogation transcripts showed that all of the crucial information was introduced into the interrogation by the police. Following the accusation, Sawyer strongly denied his guilt. The police obtained fingerprint and hair samples from Sawyer and suggested a polygraph examination. Sawyer believed that the polygraph would prove his innocence and agreed to the examination. After the test, the examiner told Sawyer that the test proved he was lying. (Subsequent rescoring of the test by a polygraph expert revealed that the test outcome was inconclusive.) Once told that the polygraph showed him to be lying, Sawyer's confidence began to erode. He was no longer able to express firm denials of guilt, and he could say only that he still did not believe he had done it. His main defense against the police demands to confess was his lack of memory of having committed the crime. The police replied that he was blocking his memory of the crime and that he had a blackout, just as he often did when he had been drinking. Sawyer still refused to fully accept that he had committed the crime, and he hoped that the fingerprint and hair tests would prove his innocence. The detectives decided to lie and told Sawyer that his hair samples matched hairs found on the victim's body. On receipt of this information, Sawyer's resistance collapsed, and he agreed that "all the evidence was in" and that he must have committed the crime.

The fact that police deception leads to false confessions might appear to be surprising. However, police suspects are often not average people. Typically, their intelligence quotients (IQs) are lower than average. A sample of 160 suspects in England had an average IQ of 82. People with lower IQs are more suggestible. Sawyer was also socially anxious and a former alcoholic. The combination of police deception and the vulnerability of the suspect may have led to the false confession.

Internalized false confessions do not imply that suspects become convinced that they have committed crimes. They occur because suspects form opinions

that it is more likely than not that they are guilty. They typically have no memory of committing the crimes, but tactics used by the police diminish the suspects' confidence in their memories, make them less certain about their innocence, and make them consider whether it is possible that they had committed the crimes.

7.2. How to Detect False Confessions

The best way in which to distinguish between false and true confessions is to look for intimate knowledge and impossibilities. Intimate knowledge is present when a suspect provides information that only the guilty person could know (e.g., information about the location of a disposed body). Impossibilities refer to providing evidence that demonstrates conclusively that the person could not have committed the crime. For example, Lucas's confession could not be true because he was more than 1,300 miles from the scene of the crime on the day of the murder. The psychologist who conducted a psychological evaluation of Lucas considered the uncritical willingness to accept his confession as the most fundamental mistake made by the police. However, police officers claim that it is the responsibility of the courts, and not the police, to check the veracity of a confession. Courts tend to attribute impossibilities to errors in confessions rather than considering them as evidence of false confessions.

Obtaining unreliable information, such as false confessions and incorrect answers to leading questions, would be less problematic if police or jurors could distinguish reliable statements from unreliable ones. A distinction should be made between unreliable (inaccurate) information, which is given deliberately and which the presenter himself or herself knows is inaccurate, and inaccurate information, which is given unwittingly (e.g., because the person is mistaken or no longer knows for certain what happened). Virtually no research has been carried out examining whether people can detect these latter fortuitous truth distortions. The few findings that do exist are not encouraging. Considerable research efforts have examined whether observers can distinguish between truths and deliberate truth distortions (i.e., lies).

8. DETECTING DECEIT

Research has demonstrated convincingly that catching liars is a difficult task and that people frequently

err when they attempt to detect deceit. In scientific studies on the detection of deception, observers are typically given videotaped statements by a number of people who are either lying or telling the truth. After each statement, observers (often college undergraduates) are asked to judge whether the statement is truthful or false. In such tasks, guessing whether someone is lying has a 50% chance of being correct. A review of 37 lie detection studies, in which undergraduates attempted to detect truths and lies told by people (adults) with whom they were unfamiliar, revealed a total accuracy rate (percentage of correct answers) of 56.6%, barely above the level of chance. People are shown to be capable of detecting truths to some extent (i.e., 67% accuracy in correctly judging that someone is telling the truth) but are particularly poor at detecting lies (i.e., 44% accuracy in correctly judging that someone is lying). In fact, 44% is below the level of chance. In other words, people would be more accurate at detecting lies if they simply guessed. The superior accuracy rate for truthful messages is the consequence of the truth bias. People are more likely to expect messages to be truthful than to be deceptive, and as a result, truthful messages are identified with more accuracy than are deceptive ones.

In other studies, people attempted to detect children's truths and lies using the same methodology except that the liars and truth tellers were children rather than adults. That research revealed that detecting children's lies is difficult as well, with accuracy rates typically in the 50 to 65% range.

Undergraduates are not habitually called on to detect deception, whereas police officers and customs officers have more experience in interviewing people. However, studies in which professionals such as police officers attempted to detect truths and lies told by adults revealed accuracy rates similar to those found in studies with undergraduates, mostly in the 45 to 60% range. This research suggests that professionals are no better than laypersons at detecting deceit. However, some professionals (e.g., members of the Secret Service, U.S. federal officers with experience and a special interest in deception and demeanor, sheriffs identified by their departments as outstanding interrogators) were better than others. Professionals are less susceptible to the truth bias than are lay observers, possibly because their jobs make them more suspicious and, hence, more likely to conclude that a person is lying.

9. COMMON PITFALLS IN DETECTING DECEIT

There are numerous reasons why people are generally poor at detecting deceit. Above all, lie detection is a notoriously difficult task because there are no typical behaviors associated with deception. In other words, a cue such as Pinocchio's growing nose does not exist. Despite this, people, laypersons, and professionals have strong views about how liars behave. Interestingly, their views do not differ substantially. In particular, people believe that liars display clear signs of nervousness such as averting one's gaze and making grooming gestures. In reality, however, gaze behavior and grooming gestures are unrelated to deception. If there is a relationship between movements and deception, it is more likely to be the converse, that is, that liars tend to decrease their movements rather than increase them. There are several explanations for this. First, it might be the result of cognitive load. Sometimes, liars find it difficult to lie because they must think of plausible answers, avoid contradicting themselves, and tell lies that are consistent with everything the observers know or might find out. Moreover, liars must remember what they have said so that they can say the same things again when asked to repeat their stories. This might be more difficult than truth telling, especially when liars are unprepared and must make up their stories instantly. Increased cognitive load results in a neglect of body language, reducing overall animation. Second, liars might worry that several cues will give their lies away and, therefore, try to suppress such signs and to make convincing impressions. However, it is not easy to suppress nervousness effectively, to mask evidence of concentration, to know how they normally respond so as to make honest and convincing impressions, and to display the intended responses. It may well be the case that, when trying to appear truthful, liars "overcontrol" their behavior and exhibit a pattern of behaving that appears planned, rehearsed, and lacking in spontaneity. For example, liars may believe that making lots of movements will give their lies away and, therefore, will move very deliberately and tend to avoid any movements that are not strictly essential. This will result in an unusual degree of rigidity and inhibition because people do normally make movements that are not essential. Another possible cue that may result from inadequate control of behavior is that performances might look flat due to a lack of involvement. For example, someone who applies for a job because the money appeals to him or her might not be enthusiastic when the

person talks about the job during the selection interview, and this in turn might result in a lack of animation.

Police officers' incorrect beliefs about cues to deception, such as liars' gaze aversion and grooming gestures, are particularly harmful for suspects who exhibit these patterns of behavior naturally. There is evidence that people from Western cultures exhibit this pattern of behavior less frequently than do people from other ethnic origins such as Black/African Americans and people from Mediterranean countries (e.g., Turkey, Morocco). Some behaviors are culturally defined. For example, looking an authority figure straight in the eyes is considered to be impolite in many cultures, but the opposite is true for Caucasian people living in, for example, North America or Western Europe. For them, averting gaze from a conversation partner is suspicious. Therefore, when a White police officer interviews a suspect from a different ethnic background, cross-cultural nonverbal communication errors may arise. Specifically, natural truthful behavior displayed by a member of a different ethnic group (e.g., gaze aversion) may be incorrectly interpreted as a sign of deceit.

Another pitfall in lie detection is that experiencing and displaying negative emotions is not the exclusive domain of liars. Truth tellers might experience similar negative emotions, albeit for different reasons. For example, lying suspects might be nervous during police investigations because they fear that they will be caught in their lies. Innocent suspects might also be nervous because they fear that they will not be believed by the police detectives when they maintain their innocence. Therefore, lie detectors should be careful in interpreting signs of fear as signs of deceit, and they should avoid making the mistake committed by Othello in Shakespeare's play. Othello falsely accused Desdemona (his wife) of infidelity. He told her to confess because he was going to kill her for her treachery. Desdemona asked for Cassio (her alleged lover) to be called so that he could testify to her innocence. Othello told her that he had already murdered Cassio. Realizing that she could not prove her innocence, Desdemona reacted with an emotional outburst. Othello misinterpreted this outburst as a sign of her infidelity.

10. TECHNIQUES TO IMPROVE PEOPLE'S ABILITY TO DETECT DECEIT

To date, a truly accurate lie detection technique has yet not been developed. All of the proposed techniques

produce frequent errors. Police training manuals often emphasize that lie detectors should pay attention to someone's behavior to detect deceit because people are less able to control their behavior than to control their speech. Researchers expressed a similar view for many years. However, more detailed analyses of people's speech, starting in the late 1980s, revealed that there are many more speech-related cues to deceit than was thought previously. For example, compared with stories told by liars, truth tellers' stories sound more plausible and less ambivalent. Liars also tend to tell their stories in chronological order (this happened first, and then this, and then that, etc.), whereas truth tellers sometimes tend to give their accounts in unstructured ways, particularly when talking about emotional events. Sometimes, when people are clearly upset, they report what happened in chaotic and incomprehensible ways. In fact, their stories can be so incomprehensible that listeners must ask them to sit down for a while, to calm down, and to describe again exactly what happened, starting from the beginning. This unstructured production effect disappears when people have already told their stories a couple of times, or when they have frequently thought about the events, because this results in the telling of stories in a more chronological order. Moreover, truth tellers include more visual details (i.e., describe things they saw) and more auditory details (i.e., describe things they heard) in their accounts. Often, they also tend to repeat what was said literally (e.g., "Then he said, 'How are your parents?'" rather than "Then he asked me about my parents"). Moreover, truth tellers mention more spatial details (e.g., "He stood behind me," "The book was on the table under the window," "We were in the living room") and more temporal details (e.g., "He switched on the television first and then the video recorder," "The phone rang again approximately 15 minutes later," "He stayed with me for about 3 hours"). Research has demonstrated that observers who concentrate on these speech-related cues typically make better lie detectors than do observers who do not attend to these cues.

Another way in which to improve people's ability to detect deceit is to use a so-called baseline method. There are large individual differences in people's speech and behavior. Some people typically make many movements, whereas others do not. Some people are very talkative, whereas others are not. Because of these individual differences, a given response is often difficult to interpret given that it leaves the observer with a dilemma: Is a particular response a sign of deceit, or is it someone's natural truthful response? Therefore, it might facilitate

lie detection if someone's natural truthful speech style and behavior are known to the observer so that the behavior and speech style under investigation can be compared with their natural truthful speech style and behavior. A deviation from the natural truthful response might indicate that a person is lying. Research has shown that this baseline method works and that people are better lie detectors when they know somebody's natural truthful behavior. However, employing this method is more difficult than people might think initially. Not only do different people behave differently in the same situation (i.e., interindividual differences), but the same person behaves differently in different situations as well (i.e., intraindividual differences). Therefore, in applying the baseline method, it is crucial that only parts of the interview that are truly comparable be compared. Comparing the wrong parts of an interview is a common practice in police interviews, and unfortunately, police manuals sometimes advise police detectives to make comparisons that are inappropriate. Typically, comparisons are made between responses during "small talk" at the beginning of the interview and responses during the actual interrogation. This is an incorrect way in which to employ the technique because small talk and the investigative core of the police interview are fundamentally different. The formal interview matters to suspects because severe negative consequences may follow if they are not believed. In other words, this is a high-stakes situation. The small talk has no such consequences and, therefore, is a low-stakes situation. People tend to behave differently in low-stakes situations than they do in high-stakes situations. Both guilty and innocent suspects tend to change their behavior the moment their formal interviews start. For comparisons to be truly comparable, they must be made within formal interviews. For example, a suspect could be asked to describe in detail his or her activities during a particular day (i.e., the day the crime was committed), and the interviewer could observe the suspect's reactions while he or she gives the description. However, even when correct comparisons are made, the lie detector should be cautious about drawing conclusions. A difference in response between two comparable parts of the interview does not indicate conclusively that someone is lying; it only indicates that this is a possibility. Other explanations for the change in response should be taken into consideration as well. For example, there is some evidence that some behaviors are topic related. ("Topic" is not synonymous with "stakes." During a high-stakes interview, different

topics can be discussed.) Analyses of the behavior by Saddam Hussein when he was interviewed by Peter Arnett during the first Gulf War revealed that the supportive arm and hand movements Hussein made were, to some extent, related to the topics he discussed. When discussing Israel, he made specific movements with his left forearm. This behavioral pattern emerged only when he was discussing Israel and Zionism. Therefore, the lie detector should consider whether different response patterns shown during a high-stakes interview might be topic related.

11. CONCLUSION

People, including professionals, have difficulty in discerning lies. It is unlikely that detection of unintentional truth distortions is easier (although this is rarely investigated). Police investigators should question interviewees—witnesses, alleged victims, and suspects—in ways that decrease the likelihood of obtaining inaccurate information, as outlined in this article.

self-determination A sense of personal initiative, freedom, and choice in behavior.

self-determined motivation Motivation that is characterized by high levels of intrinsic motivation and identified regulation but low levels of external and introjected regulation and amotivation.

top-down effect The impact of more generalized motivational orientations on more specific motivations.

GLOSSARY

amotivation A lack of purpose and intentionality in one's action, that is, the relative absence of motivation.

extrinsic motivation Engaging in an activity as a means to an end and not for the activity's own sake.

intrinsic motivation Engaging in an activity for itself and for the pleasure and satisfaction derived from participation.

motivation The hypothetical construct that is used to describe the internal and/or external forces that lead to the initiation, direction, intensity, and persistence of behavior.

need for autonomy The desire to be the origin of one's behavior.

need for competence The desire to interact effectively with the environment.

need for relatedness The desire to be connected to significant others in one's interaction with the environment.

recursive bottom-up effect The impact that specific motivations have in a repeated matter over time on more generalized forms of motivation.

The purpose of this article is to provide an overview of what is known about intrinsic and extrinsic motivation in sport. After some definitional issues, the article focuses on the assessment of intrinsic and extrinsic motivation. It then proceeds to a discussion on the determinants and outcomes of intrinsic and extrinsic motivation. The article concludes with a discussion on intervention issues.

1. INTRODUCTION

Motivation represents one of the most important variables in sport. In fact, coaches and athletes agree that motivation is one of the key elements that will facilitate not only performance but also a positive experience in the sport area. But what is motivation? More specifically, what are intrinsic motivation and extrinsic motivation? Why do certain athletes seem more motivated

than others? Does motivation matter with respect to outcomes? If so, how can coaches and other practitioners best facilitate athletes' motivation? The purpose of this article is to deal with these questions and, thus, to provide a better understanding of the nature and functions of intrinsic and extrinsic motivation in sport.

2. DEFINITIONS AND ASSESSMENT

2.1. On Motivation

Motivation has been the subject of attention from a host of individuals, including playwrights, philosophers, and psychologists. Psychologists, in particular, have looked at the concept for the past two centuries and have provided some general definitions of the construct. A widely accepted definition of motivation is that it represents the hypothetical construct used to describe the internal and/or external forces that lead to the initiation, direction, intensity, and persistence of behavior. Thus, motivation leads to action.

One of the difficulties in defining motivation is that it is not directly observable. Thus, one strategy used to define motivation, implied by the preceding definition, has been to look at behavior to determine whether someone is motivated or not. For instance, a coach would infer that a player is motivated to perfect his or her dribble if the player stays after practices and works on dribble drills.

2.2. On Intrinsic and Extrinsic Motivation and Amotivation

2.2.1. Intrinsic Motivation

Over the years, psychologists have come to realize the existence of different types of motivation. Two broad types that have been studied extensively are intrinsic

motivation and extrinsic motivation. Intrinsic motivation refers to engaging in an activity for itself and for the pleasure and satisfaction derived from participation. An example of intrinsic motivation is an athlete who plays basketball because he or she finds it interesting and satisfying to learn new moves with the ball. In 1992, Vallerand and colleagues proposed and showed that there are at least three types of intrinsic motivation: intrinsic motivation to know (engaging in the activity for the pleasure of learning), intrinsic motivation toward accomplishments (engaging in the activity for the pleasure of trying to surpass oneself), and intrinsic motivation to experience stimulation (engaging in the activity out of sensory and aesthetic pleasure).

2.2.2. Extrinsic Motivation

When extrinsically motivated, individuals do not engage in the activity out of pleasure but rather do so to derive some kind of rewards that are external to the activity itself. An athlete who participates in the Olympics to obtain a gold medal and the associated fame and fortune that go with it represents an instance of an extrinsically motivated athlete. Avoiding punishment also pertains to extrinsic motivation.

In 1985, Deci and Ryan published a very influential book titled *Intrinsic Motivation and Self-Determination in Human Behavior*. In their book, they proposed the existence of a number of types of extrinsic motivation that vary in terms of their inherent levels of self-determination. From the lowest to the highest level of self-determination, these types of extrinsic motivation are external regulation, introjected regulation, identified regulation, and integrated regulation. Figure 1 presents the various types of motivation on the self-determination continuum.

FIGURE 1 The various types of motivation on the self-determination continuum. Adapted from Vallerand and Perreault (1999).

External regulation refers to behavior that is regulated through external means such as obtaining rewards (e.g., medals, trophies) and avoiding constraints (e.g., social pressure). For instance, an athlete might say, "I'm going to today's practice because I don't want the coach to make me sit on the bench during the next game." A second type of extrinsic motivation is introjected regulation. With this type of regulation, the individual has started to internalize the reasons for his or her actions. However, such internalization merely replaces the external source of control with an internal one, that is, self-imposed guilt and anxiety. Thus, an athlete might say, "I go to practices because I would feel guilty if I did not." To the extent that the behavior becomes valued and judged to be important for the individual, and especially to the extent that it is perceived as chosen by oneself, the internalization of extrinsic motives becomes regulated through identification. For instance, an individual might say, "I choose to go to practices because it will help me to perform better during the next game." Finally, an integrated regulation also involves engaging in an activity from an extrinsic perspective in a "choiceful" manner. However, in this case, one's choices are made as a function of coherence with the various aspects of the self. For instance, the integrated athlete might decide to stay home on a Saturday night, rather than go out with friends, so that the athlete will be ready for the next day's soccer game.

2.2.3. Amotivation

Finally, psychologists have also proposed the existence of the construct of amotivation, which refers to a lack of purpose and intentionality in one's action. When amotivated, athletes experience feelings of incompetence and expectancies of uncontrollability and an important loss of motivation. For instance, an amotivated athlete might feel incompetent and start to wonder whether participating in sport still represents a worthwhile option. Amotivation amounts to the relative absence of motivation.

2.3. Assessment of Intrinsic and Extrinsic Motivation and Amotivation

In his 1997 article on the hierarchical model of intrinsic and extrinsic motivation, Vallerand proposed that intrinsic and extrinsic motivation and amotivation,

exist at three levels of generality. From the highest to the lowest level in the hierarchy, these are the global, contextual, and situational levels.

Motivation at the situational level refers to a motivational state. It is the motivation that people experience toward a given activity at a specific point in time. For instance, situational motivation toward swimming would be the motivation experienced by a swimmer while training in the pool at 6 o'clock on a Friday morning.

Intrinsic motivation at the situational level has been typically measured in two ways. First, psychologists have used what is called the free choice period. Participants, after having been subjected to experimental conditions, are told that the experiment is over and are provided with the opportunity to engage again in the activity if they so desire. Participants are then left alone and observed unobtrusively. The number of seconds spent on the activity represents the measure of participants' intrinsic motivation toward the experimental task. The more time spent on the task, the higher participants' intrinsic motivation.

This behavioral index of intrinsic motivation is particularly useful in laboratory conditions. However, it is not as useful in real-life conditions, such as sport, where the free choice measure cannot be readily used for practical reasons. Researchers increasingly are turning toward self-report questionnaires to assess participants' motivation. In line with the definition of intrinsic and extrinsic motivation, psychologists have used participants' reasons to participate in the activity as a measure of intrinsic and extrinsic motivation. One self-report instrument that has been used at the situational level with much success in sport is the Situational Motivation Scale (SIMS). Developed by Guay and colleagues in 2000, the SIMS measures four types of motivation: intrinsic motivation without distinguishing the three types, identified regulation, external regulation, and amotivation. Only four subscales of four items each are used to keep the scale brief so as to capture situational motivation in field and laboratory situations. The scale has shown high levels of validity and reliability.

Motivation at the contextual level refers to a relatively stable and general motivational orientation that pertains only to activities that are subsumed under a specific broad life domain such as education, interpersonal relationships, or sport. Thus, individuals come to develop motivational orientations with respect to intrinsic and extrinsic motivation and amotivation in different contexts. A given contextual motivation always refers to one specific life domain. For instance, an

athlete with a high externally regulated motivational orientation toward basketball would generally tend to engage in various basketball situations to receive rewards and/or avoid punishment. Interestingly, a person's contextual motivational orientation may vary from context to context. Indeed, an athlete may have a high level of contextual intrinsic motivation toward his or her sport but a low level of contextual intrinsic motivation toward education.

One instrument that has been used to measure motivation in sport at the contextual level is the Sport Motivation Scale (SMS). In this questionnaire, validated by Pelletier and colleagues in 1995, athletes are asked the following question: "Why do you practice your sport?" Each item represents a perceived reason for engaging in the activity, thereby reflecting the various types of motivation seen previously. Items are assessed using a 7-point Likert-type scale. Sample items appear in Table I. As can be seen, the various types of intrinsic and extrinsic motivation and amotivation are assessed through the reasons for people's participation in sport. There are four items per subscale and seven subscales. The total score of each

subscale is a sum of the four items. It should be noted that the concept of integrated regulation is not assessed in the SMS because research has shown that this construct has not yet crystallized in adolescents and young adults. Research using the French and English versions of the SMS reveals that the scale has high levels of validity and reliability. The scale has also been validated in several other languages, including Chinese, Italian, Japanese, Russian, and Spanish.

Finally, motivation at the global level refers to a general motivational orientation to interact with the environment in an intrinsic, extrinsic, or amotivated way. Contrary to contextual motivation, global motivation does not pertain specifically to one given life domain or set of activities but rather is akin to a broad personality trait. Thus, certain individuals may have a global external regulation orientation. Such a personality orientation would predispose individuals to have an external regulation toward several life contexts, including sport. Guay, Pelletier, Vallerand, and others have developed the Global Motivation Scale to assess the seven types of motivational constructs that appear in Fig. 1 (except for integrated regulation) at the global level. It has shown high levels of reliability and validity.

TABLE I
Sample Items from Each of the Seven Subscales
of the Sport Motivation Scale

"In general, why do you practice your sport?"	
• Intrinsic motivation—knowledge	"For the pleasure of discovering new training techniques"
• Intrinsic motivation—accomplishments	"For the pleasure that I feel while executing certain difficult movements"
• Intrinsic motivation—stimulation	"For the pleasure I feel in living exciting experiences"
• Identified regulation	"Because it is one of the best ways to maintain good relationships with my friends"
• Introjected regulation	"Because I must do sports to feel good about myself"
• External regulation	"For the prestige of being an athlete"
• Amotivation	"I don't know anymore; I have the impression of being incapable of succeeding in this sport"

3. ON THE DETERMINANTS OF INTRINSIC AND EXTRINSIC MOTIVATION

Because motivation is present in people at three levels of generality, it is important to look at the determinants of motivation at each of the three levels: global, contextual, and situational.

3.1. Where Does Situational Motivation Come From?

Research reveals that at least three types of variables produce an important effect on situational motivation: the task, the person, and the environment.

3.1.1. The Task

Clearly, tasks differ in terms of their intrinsic properties in that certain tasks are more enjoyable than others. For instance, playing basketball would be more interesting to most basketball players than would running up the stairs of a stadium. Thus, it is

not surprising that certain tasks generate higher levels of situational intrinsic motivation than do others.

Yet individual differences and environmental variables may affect perceptions of tasks in such a way that even dull tasks may, at times, be experienced as enjoyable. Thus, much research has focused on the impact of environmental and individual difference variables on intrinsic and extrinsic motivation.

3.1.2. The Environment

Historically, research on intrinsic and extrinsic motivation started during the early 1970s by looking at the effects of rewards on situational intrinsic motivation. In what is recognized as the first contemporary publication on intrinsic motivation, Deci showed in 1971 that receiving rewards to engage in an enjoyable activity produces a decrease in situational intrinsic motivation. Specifically, individuals who received monetary rewards to engage in a fun activity spent less time on the activity subsequently than did individuals who did not receive rewards to engage in the same activity. Subsequent research showed that the negative effects of rewards are especially potent when the rewards are expected and provided to entice participants to engage in the activity. Although there have been some controversies over the years, a meta-analysis of more than 100 studies conducted by Deci and colleagues in 1999 provided overwhelming support for the negative effects of rewards on situational intrinsic motivation. Research in sport, by researchers such as Orlick and Mosher in 1978, has replicated these findings and shown that trophies and awards do undermine intrinsic motivation.

Over the years, research in sport has expanded and looked at the impact of other situational factors on intrinsic motivation. Situational factors are variables that are present at a given point in time. Research has shown that factors such as competition, winning or losing, and performing well or poorly affect situational intrinsic and extrinsic motivation. Specifically, competing to win at all costs, as well as losing or not playing well, produces a decrease in intrinsic motivation and identified regulation and an increase in introjected and external regulation and amotivation. However, noncompetitive situations, as well as winning and doing well, produce the opposite effect.

Why do factors as diverse as rewards, competition, and losing influence athletes' intrinsic and extrinsic motivation? According to Deci and Ryan's self-determination theory, social factors influence motivation through their

impact on one's perceptions of competence, autonomy, and relatedness. Because individuals experience the needs to feel competent, autonomous, and related to significant others in their interaction with the environment, activities that allow people to satisfy these needs will be engaged in choicefully and on a regular basis. In other words, athletes experience important and powerful needs to feel connected to others in the sport milieu, to behave in an effective manner in that milieu, and to experience a sense of personal initiative in the process. Variables that nurture those needs help intrinsic motivation and identified regulation to flourish. Variables that thwart those needs produce negative effects on the latter types of motivation and facilitate the development of external and introjected regulation and amotivation. For instance, performing badly in a sport leads one to feel incompetent, and this in turn fuels a loss of intrinsic motivation and identified regulation and a concomitant increase in external and introjected regulation and amotivation. Research using sophisticated statistical analyses, such as structural equation modeling and path analysis, has shown that the impact of the environment on intrinsic and extrinsic motivation is indeed mediated by perceptions of competence, autonomy, and relatedness.

3.1.3. Individual Differences

We have seen how social factors can have a very important impact on athletes' situational motivation. Yet athletes who play on the same team, and who are subjected to the same environmental conditions, often display different levels of situational intrinsic and extrinsic motivation. Why is this the case? Psychologists propose that these differences take place because athletes may differ with respect to their motivational orientations. A motivational orientation typically refers to a more or less stable predisposition to be intrinsically or extrinsically motivated or even amotivated. Such an orientation can be present at the contextual or global level. For instance, an athlete with an intrinsic contextual motivation toward basketball is more predisposed to display higher levels of intrinsic motivation in various basketball situations than is an athlete with a contextual motivation characterized by low intrinsic motivation. This refers to what Vallerand called the top-down effect. It is important to note that such effects appear to hold only for contextual motivational orientations related to the activity in which the individual is engaging. Thus, having a contextual intrinsic motivational orientation toward hockey would help an athlete to maintain a high level of situational

intrinsic motivation toward hockey. However, having a contextual intrinsic motivational orientation toward school would not produce such an effect. Finally, global motivation will influence situational motivation only when the activity being engaged in is rather ambiguous and unrelated to a given contextual motivation. In such instances, global motivation has room to exert its influence on situational motivation.

3.2. On the Determinants of Contextual Motivation

One's contextual motivation toward a specific set of activities can also be affected by the same three factors just reviewed. Thus, task factors are also important influences on contextual motivation. For example, a baseball player's contextual motivation will likely be more intrinsic for actual baseball games than for weight training.

Social factors at the contextual level have been also found to affect contextual motivation. Such factors are those that are present on a general or recurrent basis in one life context (e.g., the sport in which one participates) but not necessarily in other life contexts (e.g., education, interpersonal relationships). Contextual factors studied in sport can be loosely classified into three categories: structural variables (e.g., the types of leagues in which athletes play), motivational climates that prevail in team settings, and interpersonal variables (e.g., the coach's managerial style). Highly structured and competitive league environments, performance-oriented team climates, and playing for a highly controlling coach who does not leave room for autonomy in the athletes all produce decreases in intrinsic motivation and identified regulation while producing increases in introjected and external regulation and amotivation. However, more relaxed league structures, mastery-oriented team climates, and playing for an autonomy-supportive coach who provides understanding, care, and room for decision making on the athletes' part all produce the opposite effect on contextual motivation.

A third source of influence on contextual motivation originates from individual differences. Just like situational motivation, contextual motivation is also subjected to top-down effects originating from individual differences. However, in this case, the influence comes from global motivation. Thus, athletes who entertain a high level of global intrinsic motivation generally possess high levels of intrinsic motivational orientations in various life contexts, including sport.

A final influence on contextual motivation comes from the cumulative effects of experiencing various motivational states on a regular basis. This refers to the recursive bottom-up effect. For example, a tennis player who interacts daily with an autonomy-supportive coach will likely experience daily doses of situational intrinsic motivation that, over time, should have positive recursive effects on the athlete's contextual motivation toward tennis. In the long run, the athlete's contextual motivation will likely become increasingly intrinsic in nature.

3.3. Motivational Determinants at the Global Level

Very little is known about the determinants of global motivation, especially as it relates to the realm of sport. One source of influence that has been documented deals with the recursive bottom-up effect discussed previously. Thus, experiencing high levels of intrinsic motivation at the contextual level in sport leads to the development of a more intrinsic global motivation. Of course, this effect takes place to the extent that this life domain is important for the individual, as would be the case for athletes.

An additional source of influence comes from the impact of global factors. These refer to social factors that are present in most contexts of a person's life on a relatively permanent basis. Global factors help to shape a person's global motivation. In this regard, the motivational impact on global motivation of enrolling at a young age in soccer boarding schools, such as those found in several countries around the world, deserves attention. Such boarding schools represent a global environment in that athletes not only learn how to play soccer, in the hope of becoming professional soccer players in the future, but also go to school and actually live at the boarding schools, away from their families, for years. Therefore, boarding schools should profoundly affect the development of young individuals' personalities, including their global motivation. The type of effect induced, however, will likely depend on the climate that prevails in such schools. If the climate is one of autonomy support, care, and understanding, athletes will likely develop a self-determined global motivation. However, tightly controlling boarding schools will likely lead to the development of non-self-determined global motivation. Thus, being subjected to such global factors shapes athletes' global motivation and personalities. Such a global motivation,

in turn, greatly affects athletes' motivation toward sport through the top-down effect.

4. ON MOTIVATIONAL OUTCOMES

4.1. Motivation Causes Outcomes

It is intuitively thought that high levels of motivation will likely lead an athlete to play hard, persist more at training, and display more intense behavior compared with a less motivated athlete. But is it the case? Does motivation actually cause the outcome? The answer to this question is an unequivocal yes. Indeed, several studies have shown that experimentally inducing intrinsic motivation, as opposed to extrinsic motivation, leads to several positive outcomes, including enhanced creativity, performance, and persistence. In other words, motivation matters.

4.1.1. Outcomes as a Function of the Various Types of Motivation

The type of motivation that one entertains toward an activity also matters in that outcomes are decreasingly positive as one moves from intrinsic motivation to amotivation (see Fig. 1). Because the various types of motivation are located on a continuum ranging from high to low self-determination, and because self-determination is associated with enhanced psychological functioning, a corresponding pattern of consequences ensues. Thus, the most positive outcomes result from the self-determined forms of motivation (intrinsic motivation and identified regulation), whereas negative outcomes follow from the least self-determined forms of motivation (external and introjected regulation and especially amotivation). This pattern of results has been obtained in sport and physical activity with the following outcomes: concentration, sportsmanship, and positive affective experiences such as flow, interest, enjoyment, satisfaction, and less anxiety as well as behavioral outcomes that include expanded effort, behavioral intentions, and actual levels of persistence, adherence in sport, and performance.

It should also be noted that these findings have been obtained with different populations, including elite and recreational athletes, athletes of various ages, physically challenged athletes, intellectually challenged children, and coaches. Thus, it would appear that the role of motivation in producing outcomes is well established

and that the more self-determined the motivation, the more positive the outcomes.

4.1.2. Outcomes as a Function of Levels of Generality

Just like motivation, outcomes are experienced at various levels of generality. For instance, having the sudden intention to drop out of basketball is not the same as making such a decision after several weeks or months of reflection. Similarly, feeling momentarily dejected after a loss in a tennis tournament is different from experiencing a generalized negative mood each time one plays tennis. Why is this the case?

Psychologists have shown that outcomes not only differ in terms of generality but also are produced by motivations that differ in terms of their levels of generality. Thus, situational types of outcomes, such as feeling momentarily disappointed and not wanting to play any more at that point in time, originate from situational motivation. On the other hand, more contextually generalized thoughts, feelings, and behaviors that go beyond the moment and pertain to a specific area, such as tennis or football, are produced by sport contextual motivation specific to tennis or football. Finally, broad-level types of outcomes, such as full-fledged depression and apathy experienced across life domains, are typically the fruit of global motivation.

5. INTERVENTIONS

It is well known that participation in sport and exercise produces several physical and psychological benefits. Thus, it is unfortunate to see that a large number of children drop out of sport at a young age. For instance, in Canada, there is a 30 to 35% annual dropout rate in young competitive swimmers, some of whom have great potential. In 1999, Vallerand and Losier proposed the following causal sequence: Social Factors → Psychological Mediators → Motivation → Consequences. Such a sequence integrates the determinants and outcomes of motivation and, as such, charts the nature of the psychological processes through which athletes come to experience various outcomes, including dropping out of sport (Fig. 2). Indeed, research has shown that coaches who display controlling behavior (a social factor) undermine young athletes' sense of competence, autonomy, and relatedness (the psychological mediators). This, in turn, undermines their self-determined motivation,

FIGURE 2 The motivational causal sequence: From social factors to outcomes. Adapted from Vallerand and Losier (1999).

leading to their dropping out of sport (a consequence). These findings have been obtained with both male and female athletes who engage in various sports such as handball and swimming.

If motivation has a causal influence on persistence, it might be possible to increase athletes' motivation and, in turn, their persistence toward sport by using the causal sequence depicted previously. This could be done by modifying social factors known to negatively affect motivation such as coaches' controlling interacting style. Although very few intervention studies have been conducted in the realm of intrinsic and extrinsic motivation, one sport study has followed this lead. In 2003, Pelletier and colleagues reported the development of an intervention program dealing with swimmers' motivation and persistence. This 18-month program mainly focused on the following:

- Helping coaches to become more autonomy supportive, thereby enhancing athletes' feelings of competence and autonomy
- Teaching athletes how to deal with the increased levels of competence and autonomy and to become more proactive in their sport environment

It was anticipated that changing coaches' interacting style to a more autonomy-supportive approach would trigger the previously described causal sequence and would lead athletes to experience higher levels of competence and autonomy, higher levels of intrinsic motivation, and higher levels of persistence in swimming.

Results supported this hypothesis. Approximately 1½ years into the intervention program, athletes perceived their coaches as significantly less controlling and as more autonomy supportive. In turn, athletes' levels of perceived competence and intrinsic motivation toward swimming increased, leading to several adaptive consequences. The levels of attendance in the practices increased dramatically, and the annual dropout rate

decreased from 35% to less than 5%. A control group of swimmers who were not part of the intervention still displayed a 35% dropout rate. In addition, 85% of athletes who were part of the intervention reached the national performance standards, four were selected to the Canadian Olympic swimming team, and one won a silver medal in the Seoul Olympics. Although preliminary, results from this intervention study underscore the potential for intervention programs that use the proposed motivational sequence as a guiding light.

6. CONCLUSION

Sport motivation is a complex and multidimensional phenomenon. It is influenced by numerous factors and can lead to a host of consequences. Furthermore, not only are intrinsic motivation and identified regulation important for allowing athletes to experience satisfying participation in sport, but these self-determined forms of motivation also lead to higher levels of achievement. In this vein, interventions that promote these forms of motivation have been found to be effective. The road to enjoyable and successful participation in sport has been mapped out.

intrinsic motivation Doing an optimally challenging activity that is interesting, has an internal perceived locus of causality, and is energized by the basic psychological needs for competence, autonomy, and relatedness; such an activity does not require a contingent outcome that is separate from the activity itself.

introjection A form of internalization in which people take in an external control without ever really accepting it as their own and then use it to pressure and control themselves.

GLOSSARY

autonomy support A quality of a person's interpersonal environment in which others acknowledge the person's perspective, provide choice, encourage initiative, and minimize the use of pressure and control.

controlling environments Environments in which people in positions of authority, expertise, or power pressure others to think, feel, or behave in specific ways; it is the antithesis of autonomy support.

extrinsic motivation Doing a behavior because it will lead to some separate outcome such as a reward, approval from others, or the avoidance of punishment.

integration The fullest type of internalization in which people take in an extrinsic motivation, identify with it, and integrate it into their sense of self.

interpersonal context The ambience or "climate" of a particular setting that can vary from supporting people's autonomy to controlling their behavior.

Self-determination in human behavior is based in autonomous motivation, which encompasses both intrinsic motivation and integrated extrinsic motivation. Intrinsic motivation involves doing an activity without the necessity of external prompts or rewards because it is interesting and satisfies the basic psychological needs for competence, autonomy, and relatedness. Extrinsic motivation involves doing an activity because it leads to some separate outcome such as a reward, approval from others, or the avoidance of punishment. Intrinsic motivation is invariably autonomous, whereas extrinsic motivation varies in its degree of autonomy. Extrinsic motivation becomes autonomous through the processes of internalization and integration. Both intrinsic motivation and integrated extrinsic motivation are facilitated in home, school, work, and clinical settings that are interpersonally supportive, that is, where people's perspectives are acknowledged and where people are

encouraged to experiment, allowed to try their own solutions to problems, provided with choice, and responded to when they initiate. Under such supportive conditions, individuals are more engaged and persistent, perform more effectively, and display higher levels of psychological health and well-being.

1. INTRODUCTION

The delight of discovery and the joy of leisure pursuits are experiences known to most everyone. They are stimulating, satisfying, and sustaining of the behaviors that promote them. Within the field of motivation, these experiences and the psychological processes that underlie them are encompassed by the concept of intrinsic motivation, which was introduced to the field by Harlow in 1950 and began receiving empirical attention two decades later. The concept has become pivotal in our understanding of human motivation and has provided important insights even about people's motivation for life's mundane activities such as studying uninteresting topics and doing boring work.

Intrinsic motivation is readily observable in young children; indeed, play is the "business of their lives." They happily turn random objects into toys, they role-play others such as their parents, and they invent all kinds of games. Intrinsic motivation is also apparent in older individuals, although perhaps not so ubiquitously. Leisure activities such as playing golf, looking at paintings, and pursuing a bargain on a new dress are often intrinsically motivated (i.e., done for the spontaneous satisfaction provided by the activities themselves), and some people are fortunate enough to be intrinsically motivated for their jobs.

Psychologists began to treat the experience of delight and joy (i.e., of interest and enjoyment) as an important motivator following from the realization that a fuller understanding of human motivation required distinguishing among types of motivation rather than just focusing on the amount of motivation. Stated differently, most theories of motivation or behavioral control, beginning with behavioral theories such as that of Hull and continuing through the cognitive theories of Bandura and Seligman, treated motivation as if it differed only in amount and not in type. People who were more motivated for a particular activity (or class of activities) were expected to do the activity more often and to do it more effectively than were people with less motivation. It was the amount of motivation that was considered critical.

The idea that there are different types of motivation implies that if two people have the same amount of motivation for a particular activity but the types of motivation are different, the quality of their engagement in and persistence at the activity will also be different. For example, there are times when employees may be highly motivated to do an activity at work because they are fearful that they will be punished if they do not do it, and there are other times when employees are equally highly motivated for such an activity because they find it interesting and personally important. Any individuals who can relate to this probably recognizes that these different types of motivation, even if the amounts are the same, can have a major effect on the quality of their engagement with the activities and perhaps even on their feelings about themselves.

2. EXTRINSIC MOTIVATION VERSUS INTRINSIC MOTIVATION

The first important differentiation of motivation into types distinguished between extrinsic motivation and intrinsic motivation. Extrinsic motivation refers to doing a behavior because it will lead to some separate outcome such as a reward, approval from others, or the avoidance of punishment. The concept of extrinsic motivators is linked to behaviorist theories that were prominent in psychology during the 1940s and 1950s, although those theories did not use the term "extrinsic motivation." Behavior modification, for example, was based solely on extrinsic motivators—do a desired behavior and get a reward (which behaviorists termed a reinforcement). Behavior modification was in widespread use in education, therapy, and job training during the 1970s, and then its use gradually tapered off.

2.1. Extrinsic Motivation and Behaviorism

The two primary strands of behaviorism, Hullian drive theory and Skinnerian operant theory, both were built around the concept of reinforcement. In both theories, people learn behaviors when they are reinforced. However, the two theoretical approaches define the concept of reinforcement very differently.

In drive theory, reinforcers are events that reduce basic physiological drives such as hunger and thirst. For example, food reinforces behaviors that lead to it while the hunger drive is operative. In contrast, within

operant theory, reinforcers are defined as any separable consequence (e.g., a food pellet, a dollar bill) that increases the likelihood of a particular response being emitted. In operant theory, reinforcers are not tied to underlying drives.

In operant theory, anything is a reinforcer if it increases the rate of a particular behavior, whereas in drive theory, only those things that reduce drives are called primary reinforcers. However, drive theory includes a concept of secondary reinforcers, which are other things (e.g., monetary rewards, smiles) that take on reinforcing value by being paired with primary reinforcers. For example, money can reinforce because it becomes associated with eating and/or drinking.

2.2. Intrinsic Motivation

Intrinsic motivation is based in people's inherent tendency to be proactive, to interact with the world in an attempt to have an effect, and to feel a sense of accomplishment. Indeed, when people are at their healthiest, they are curious, eager to take on challenges, partial to novelty, engaged with interesting tasks or stimuli, and ready to learn. All of these are manifestations of intrinsic motivation, and they are critical for optimal development across the life span.

The concept of intrinsic motivation arose, in part, in response to problems that became apparent within each strand of behaviorism. Accordingly, there were initially two different characterizations of the concept. The first suggested that not all behaviors are derived from the basic drives such as thirst, hunger, and sex. For example, children often forgo eating, even if they have not eaten for a long time, so as to continue playing a game they find to be fun. Accordingly, White asserted that, just as people have biological needs—the so-called drives—that must be satisfied for them to remain healthy, people also have psychological needs that must also be satisfied for them to thrive. White specified the need for competence as being important. Subsequently, Deci and Ryan maintained that there are three fundamental psychological needs—the needs for competence, autonomy, and relatedness—that are operative for all humans and must be satisfied for them to develop and function optimally.

The other approach to defining intrinsic motivation suggested that intrinsically motivated behaviors are those for which the behaviors themselves are rewarding and, thus, do not require separable consequences. This, of course, stands in contrast to the Skinnerian

perspective that suggests that all behaviors are controlled by reinforcing consequences that are separate from the behaviors themselves.

When the two characterizations of intrinsic motivation are considered together, the conclusion is that not all behaviors are controlled by reinforcements and that inherent psychological needs for competence, autonomy, and relatedness underlie those behaviors. Other discussions of intrinsic motivation have helped to flesh out the definition. DeCharms used attribution theory to suggest that extrinsic motivation is operative when people perceive the locus of causality for their behavior to be external to themselves, whereas intrinsic motivation is operative when people perceive the locus of causality to be internal or within themselves. For example, when people are doing an activity to get a reward, they would likely see the reward as the cause of their behavior; thus, the perceived locus of causality (PLOC) would be external. When people are doing an activity because they find it interesting and fun, they would likely see the enjoyment as the cause of the behavior, and so the PLOC would be internal. The idea of PLOC relates to the need for autonomy in that people will be satisfying their need for autonomy to the extent that the PLOC for a behavior is internal.

Another characterization that has been widely used in discussions of intrinsic motivation is that being intrinsically motivated for an activity involves doing an activity because people find the activity interesting. The idea is that people do not need a reinforcement or reward if the activity itself interests them. Thus, the concept of "interest" has been considered central to intrinsic motivation. Using the concept of interest highlights that intrinsic motivation exists in the relation between individuals and activities. That is, a person is intrinsically motivated for some activities and not for others, and not everyone is intrinsically motivated for any particular activity. Rather, an individual is intrinsically motivated for a task to the degree that he or she finds the task interesting, and people differ in the extent to which they find any particular task interesting.

A final important piece of the overall characterization of intrinsic motivation states that optimal challenge is central to intrinsic motivation. That is, people are intrinsically motivated to take on optimal challenges because those are the activities that are most interesting, facilitate competence, and promote development.

In sum, intrinsic motivation involves doing an optimally challenging activity that is interesting, has an internal PLOC, and is energized by the basic psychological needs for competence, autonomy, and

relatedness. Such an activity does not require a contingent outcome that is separate from the activity itself.

3. THE INTERACTION OF EXTRINSIC MOTIVATION AND INTRINSIC MOTIVATION

When extrinsic motivation and intrinsic motivation were identified and defined, researchers began to wonder whether the two might interact. Are these two types of motivation additive, such that the amount of one's intrinsic motivation and the amount of one's extrinsic motivation for a particular activity can be summed to yield one's total motivation for the activity? Stated differently, would anything happen to people's intrinsic motivation for an activity if people began to receive extrinsic inducements for doing it? Would intrinsic motivation itself be enhanced, unchanged, or diminished? If the answer is anything other than "unchanged," this implies that the different types of motivation are not simply additive and, thus, that environmental conditions, such as reward contingencies and deadlines, could affect people's intrinsic motivation when they are operating within those environmental conditions.

3.1. Reward Effects

The first studies of intrinsic motivation in humans, published in 1971 by Deci, examined the effects of monetary rewards on the intrinsic motivation of college students. In subsequent studies that included participants from preschool and high school, the effects of other tangible rewards, such as prizes and good player certificates, were also examined. The studies consistently revealed that tangible extrinsic rewards, whether payments or prizes, undermined intrinsic motivation. Specifically, the undermining occurred when the activity was initially interesting, the rewards were salient, and the rewards were contingent on and expected while doing the activity. Deci interpreted these results as indicating that the extrinsic rewards tend to leave people feeling controlled by the rewards (rather than feeling autonomous). Accordingly, their PLOC tends to become more external.

The general finding that tangible rewards tend to undermine intrinsic motivation has been replicated numerous times, but the finding has remained controversial for three decades. Because rewards are the

easiest motivators to use, some people resist recognizing their potentially detrimental effects. Nonetheless, in 1999, Deci and colleagues published a meta-analysis involving 128 experiments on reward effects and showed definitively that tangible extrinsic rewards do reliably and clearly undermine intrinsic motivation for the rewarded activity.

3.2. Other External Events

Additional research has shown that other external events, such as threats of punishment, deadlines, directives, and competition, also undermine intrinsic motivation, presumably because people experience them as controls. On the other hand, the opportunity to make choices about what to do and how to do it was found to enhance intrinsic motivation by facilitating a greater experience of autonomy and a more internal PLOC.

The effects of all these studies were interpreted in accord with the postulate that people have a basic need for autonomy. Accordingly, factors that support people's autonomy and experience of an internal PLOC (e.g., choice, acknowledgment) tend to enhance intrinsic motivation, whereas those that leave people feeling controlled with an external PLOC (e.g., tangible rewards, deadlines, pressures) tend to diminish intrinsic motivation.

3.3. Performance Feedback

Other research relates to the basic psychological need for competence. Studies have shown that positive performance feedback (which is sometimes referred to as verbal rewards) enhances intrinsic motivation, that negative feedback diminishes it, and that perceived competence mediates these effects. There is also evidence, however, that the enhancement of intrinsic motivation following praise is less likely to occur for children than for college students. Furthermore, studies have found that increases in perceived competence must be accompanied by feelings of autonomy for the perceived competence to enhance intrinsic motivation. If people feel forced to perform well, their good performance and the positive feedback that might follow it are unlikely to enhance their intrinsic motivation.

3.4. Interpersonal Contexts

A final set of studies has shown that the ambience or "climate" of a particular setting (i.e., the general feeling of the setting) has an effect on people's intrinsic motivation. This factor is frequently referred to as the

interpersonal context, and the critical issue is whether the interpersonal context tends to support people’s autonomy or to control their behavior. For example, the coaching climate of some sporting teams tends to encourage athletes to take initiative and experiment, whereas the climate surrounding other teams conveys that athletes must do what the coach tells them to do. Studies show that if the interpersonal context tends to be autonomy supportive, people within it will be more intrinsically motivated, whereas if it tends to be controlling, people will be less intrinsically motivated. For example, if teachers use a lot of controlling language—demands and imperatives as well as words such as “should,” “must,” and “have to”—their students tend to be less intrinsically motivated. In fact, this issue has been studied in the laboratory, and it seems that if environmental factors such as rewards are administered in relatively autonomy-supportive ways, they are less likely to undermine intrinsic motivation. Furthermore, if factors such as positive feedback are administered in relatively controlling ways, they are less likely to enhance intrinsic motivation.

3.5. Summary

Research has shown that intrinsic motivation and extrinsic motivation are not additive; instead, they are interactive. That is, the addition of extrinsic motivators may either diminish or enhance intrinsic motivation. As such, the social environments within which people operate will significantly affect the degree to which they are intrinsically motivated for the target activity. Contextual factors that allowed satisfaction of the basic psychological needs for competence and autonomy were found to enhance intrinsic motivation, whereas those that thwarted satisfaction of these basic needs were found to undermine intrinsic motivation (Table I).

3.6. Intrinsic Motivation and Outcomes

Numerous studies have shown that intrinsic motivation was associated with better conceptual learning, greater creativity, more cognitive flexibility, greater behavioral persistence, and more enhanced well-being than was extrinsic motivation. For example, experiments showed that autonomy-supportive environments led both elementary school and college students to learn better than did controlling environments, especially when

TABLE I
Summary of the Effects of External Motivators on People’s Intrinsic Motivation

Monetary rewards	Tend to decrease intrinsic motivation
Other tangible rewards	Tend to decrease intrinsic motivation
Deadlines	Tend to decrease intrinsic motivation
Threats of punishment	Tend to decrease intrinsic motivation
Competition against others	Tends to decrease intrinsic motivation
Directives and evaluations	Tend to decrease intrinsic motivation
Negative feedback	Tends to decrease intrinsic motivation
Controlling interpersonal climates	Tend to decrease intrinsic motivation
Choice	Tends to increase intrinsic motivation
Acknowledgment	Tends to increase intrinsic motivation
Encouragement for self-initiation	Tends to increase intrinsic motivation
Positive feedback	Tends to increase intrinsic motivation
Autonomy-supportive interpersonal climates	Tend to increase intrinsic motivation

the material was complex and required conceptual understanding.

Other research conducted in real-world settings such as homes, sport teams, and work groups has revealed that an autonomy-supportive environment catalyzes not only intrinsic motivation but also performance, level of satisfaction, and general well-being. Indeed, many studies have shown strong positive relations between being intrinsically motivated and having a higher level of psychological health and well-being. Such research makes clear why the differentiation of types of motivation is so important and confirms that the distinction between intrinsic motivation and extrinsic motivation is an empirically useful one.

It is critical to remember that intrinsic motivation is operative only for activities that hold intrinsic interest for individuals, for example, those that are novel and challenging. For activities that are not interesting, intrinsic motivation does not represent a potent motivator. Still, there are many activities that parents, teachers,

managers, coaches, and physicians believe are important for people, even if the activities are not interesting. To understand the motivation for these activities, one must examine the dynamics of extrinsic motivation.

4. EXTRINSIC MOTIVATION

As it turns out, many of the activities people do are not intrinsically motivated, especially from the time they move out of early childhood and face increasing demands to assume social roles and accept responsibilities. Children must begin to interact congenially with playmates, then to do schoolwork that they do not find interesting, and eventually (as adults) to hold gainful employment and function within the laws of society. Evidence shows, for example, that even during children's years in elementary school, their intrinsic motivation tends to become weaker with each passing year.

Recall that extrinsic motivation is operative when people do an activity to attain some separable outcome such as a pat on the back or a monetary bonus. When children are not intrinsically motivated for an important activity, parents or teachers must rely on the inducement of extrinsic motivators. Although extrinsic motivators have typically been found to be controlling rather than supportive of autonomy, there is still the important question of whether it is possible for people to be autonomous or self-determined when doing a task that is uninteresting and, therefore, was extrinsically prompted. The reason this question is so critical is that if it were possible for people to be autonomous while doing an activity for extrinsic or instrumental reasons, perhaps some of the performance and adjustment advantages that have been found for intrinsic motivation might also accrue when people are autonomously extrinsically motivated.

Deci and Ryan's self-determination theory (SDT) proposed that intrinsic motivation is invariantly self-determination but that extrinsic motivation can vary greatly in the degree to which it is self-determination. For example, a boy who takes out the garbage only because he knows that his mother will praise him for doing so is extrinsically motivated because the behavior is instrumental to the separate consequence. A girl who takes out the garbage because she personally values family harmony and believes that her participation in doing this task will help to maintain that harmony is also extrinsically motivated. The second instance, although still extrinsic, is characterized by a greater sense of personal endorsement and choice than is the

first instance, which involves compliance with the control that has been explicitly or implicitly created by the boy's mother. These two cases of extrinsically motivated behavior vary in the degree to which they are relatively autonomous.

4.1. Internalization of Extrinsic Motivation

Within SDT, extrinsically motivated behaviors can become more autonomous through a process in which people internalize the values and regulations associated with the behaviors. Internalization is the process of taking in a value or regulation and making it one's own. When the process functions optimally, individuals will have transformed an externally regulated extrinsic motivation into an internally regulated extrinsic motivation by integrating the regulation and its value into their sense of self.

Internalization has long been an important concept in many psychological theories. The idea is that the challenge of becoming self-regulating of activities that are important for people but are not themselves personally compelling can be met through the process of internalization. To be self-regulating, people must make internal what was initially external. The thing that makes SDT's conceptualization of internalization different from most others is that it includes different types or degrees of internalization. In other words, SDT proposes that regulations can be internalized more or less fully, such that people will, to differing degrees, accept the regulations as personally important for themselves and, thus, be more or less autonomous in enacting them. As such, there will be differences in the extent to which people do a behavior because they want to rather than because they believe that they have to, and this will reflect the degree to which the regulation has been internalized.

Thus, SDT views internalization in terms of a continuum that describes how fully the person has transformed an external prompt into an internal regulation that will allow volitional or "choiceful" behavior. This continuum, therefore, illustrates how instrumental (i.e., extrinsic) motivation for a behavior can range from passive compliance to active personal commitment.

One reason why this relative autonomy continuum is so important is that it addresses an important problem about internal regulation of behavior. Specifically, there are behaviors that people force themselves to do because they think they should do them and know they

will feel guilty if they do not. The regulation of these behaviors is certainly internal to these people, but it does not exhibit the qualities of volition or autonomy that, for example, are so evident in intrinsic motivation. SDT uses the concept of introjection to refer to the type of internalization that leads to this internally pressured regulation. In contrast, there are behaviors that people do not find interesting but that have become meaningful and important for their own self-selected goals and personal life plans. As such, people do these behaviors quite autonomously, even though the behaviors themselves are not inherently satisfying. In SDT, this is said to occur as people identify with the importance of the activities for themselves and then integrate that identification with other aspects of themselves. When this has occurred, people will feel fully autonomous as they enact an extrinsically motivated behavior because it would then emanate from their integrated sense of self.

The former example, of introjection, is about controlling oneself, and the process bears considerable similarity to being controlled by other people. The latter example, in contrast, is more about making a choice to do the activity because, all things considered, doing so feels desirable and right. Thus, in the latter case, people experience a truly internal PLOC, even though the behavior is still instrumental, that is, done for reasons other than the enjoyment of the activity itself. This important contrast, between what might be thought of as self-control and self-regulation, is highlighted in the SDT model of extrinsic motivation.

More specifically, the theory states that there are various forms of extrinsic motivation: one where the regulation is external to the person, one where the regulation has been merely introjected and so must be buttressed by internal reward or punishment (e.g., guilt) contingencies, one where the person has identified with the importance of the behavior for himself or herself, and one where the regulation has been fully integrated with other aspects of the person's self. Although the latter three of these all represent internal motivation, they vary in the degree to which the behaviors they motivate are autonomous. Integrated regulation represents a relatively full sense of volition and personal commitment, with introjection representing a relative lack of these qualities (Fig. 1).

Intrinsic motivation and fully integrated extrinsic motivation are the two bases for autonomous or self-determined behaviors. More than three decades of research have now shown that the quality of people's experience and performance vary as a function of the

<i>Extrinsic Motivation</i>			
External regulation	Introjected regulation	Identified regulation	Integrated regulation

FIGURE 1 Types of extrinsic motivation based on the degree to which a regulation and its underlying value have been internalized. They range from external regulation (least autonomous) to integrated regulation (most autonomous).

degree to which a behavior is autonomous or self-determined. Thus, when people have identified with and integrated the regulation of an extrinsically motivated behavior, the behavior shares many of the qualities of behaviors that are intrinsically motivated. Not only do people feel a sense of choice and experience an internal PLOC, but more importantly, autonomous extrinsic motivation, like intrinsic motivation, is positively related to psychological well-being as well as to learning outcomes and effective performance, especially on activities that require a deeper or fuller engagement with the activity.

4.2. Internalization in Social Contexts

Various studies have examined how the social conditions within which a regulation is internalized affect how fully it is internalized and, thus, how autonomous the subsequent behavior will be. One factor that affects how self-determined people will become for behaviors that were initially externally prompted is whether the behaviors were clearly valued by others to whom they feel connected. This suggests, for example, that the starting point for facilitating internalization in children, students, or employees is providing them with a sense of personal relatedness, that is, the feeling of being cared about. In other words, it is the basic psychological need for relatedness that leads people to be willing to take on the regulation of behaviors that are valued by significant others or relevant reference groups.

In addition, people must feel sufficiently competent at the focal behavior to do it satisfactorily; that is, people will be more likely to internalize a goal if they have the relevant skills and understanding to become successful at it. Thus, supporting competence by offering optimal challenges and providing effectance-relevant feedback will also facilitate internalization. Finally, for people to become autonomous with respect to a behavior, they must grasp its personal meaning for themselves; that is, they must have their own perspective acknowledged and

must feel a sense of choice about doing the behavior. This suggests that whereas people may at least partially internalize a behavioral regulation if they feel a sense of (or desire for) relatedness to a relevant other or group and if they feel effective in doing the behavior, they are unlikely to fully integrate the regulation unless the relevant others in their social world provide autonomy support with respect to that behavior. Notably, then, whereas supports for autonomy and competence are particularly important for maintaining intrinsic motivation for an activity, supports for relatedness are also important for internalization. In short, when people feel supports for relatedness, competence, and autonomy with respect to an extrinsically motivated behavior, they are likely to internalize its value and regulation quite fully.

In sum, self-determination, which is based in intrinsic motivation and integrated extrinsic motivation, has been associated with a variety of positive performance and adjustment outcomes and has been found to depend on interpersonal supports for relatedness, competence, and autonomy. In these regards, then, one can now see how the study of joy and delight provided a starting point for an examination of how to facilitate optimal motivation for even the mundane tasks that are encountered each day in people's lives. By providing the kinds of supports that help to maintain intrinsic motivation, one can also facilitate internalization and integration that will enhance the quality of motivation and engagement with the more mundane activities as well as the more interesting ones.

5. APPLICATION OF RESEARCH ON SELF-DETERMINATION

In various domains of life, there are people who have responsibility for motivating others—their children, their students, subordinates, patients, athletes, and the like. This can be a daunting challenge. Because research has shown that autonomous motivation, based in intrinsic motivation and integrated extrinsic motivation, is unequivocally linked to superior conceptual learning, greater creativity, more flexible problem solving, and better psychological health and well-being, it seems clear that working to facilitate autonomous motivation, rather than taking the easier route of relying on controls, is indeed important.

Numerous studies have examined the effects of supporting autonomy versus controlling behavior in

a variety of real-world domains. We now turn to a brief consideration of a few of these studies in some of the more important domains of life.

5.1. Autonomy Support in Parenting

Supporting autonomous motivation and promoting healthy development begin in the home. Parents have the task of providing a context that will allow their children to experience a sense of autonomy, competence, and relatedness, and it is those contexts that foster autonomous motivation, internalization of values, and psychological well-being.

Parents, of course, are genuinely concerned about their children acquiring the skills and values that are necessary for functioning effectively in school, on the playground, and in their subsequent careers and personal development. Parents are also hopeful that their children will behave appropriately in a variety of everyday settings so as not to bring rejection or embarrassment on themselves and their families. At times, parents' concerns and desires can prompt conflict because their expectations can conflict with the interests and desires of the children. Children are not always eager to do their homework, take out the garbage, or attend the religious services in which their parents are invested. This resistance may prompt an urge in parents to apply pressure in an attempt to ensure that their children do the behaviors that the parents believe are in the children's best interests. Research makes clear, however, that the children pay a cost in terms of their motivation and self-reliance to the extent that parents' motivational strategies involve pressure and control. Whether the controls are blatant or subtle, and whether they are coercive or seductive, they seem to have some negative psychological consequences for children.

One common approach to motivation and discipline used by many parents is conditional regard, that is, providing more attention and affection when children do what the parents value and withdrawing affection and regard when the children do not. This parenting strategy turns out to be quite controlling, however, and research has shown that it leads children to merely introject behavioral regulations rather than integrate them. In other words, children will tend to do the behaviors on which affection and regard were made contingent, but they will experience a sense of inner compulsion and anxiety about the behaviors rather than a sense of choice and desire. Furthermore, this pressured form of regulation is associated with poorer well-being—with lower and more fragile self-esteem,

greater feelings of guilt and shame, and the like. In addition, to the extent that parents use conditional regard as a socializing strategy, their children still harbor resentment toward the parents many years later. Other more overtly coercive forms of control have been found to have even more negative effects.

The alternative to pressure and control, of course, is autonomy support, which has been found to enhance motivation, performance, and well-being. In one interview study, for example, Grolnick and Ryan went into the homes of late elementary school-aged children. The researchers conducted separate interviews with mothers and fathers of the children regarding how the parents motivate the children to do schoolwork and to carry out chores around the house. Results of the study made clear that when parents were autonomy supportive—when they took their children’s perspective into consideration, encouraged initiative, and provided choice—the children were more autonomously motivated, felt better about themselves, and were rated by teachers as being more engaged in their schoolwork and more competent.

Autonomy support represents a challenge for parents. To try to understand children’s behavior from their perspectives can be a formidable undertaking when parents have their own perspectives and desires. To allow and support children’s choices when it is easier to impose parents’ own choices is asking a lot of parents, especially if they are stressed or tired from dealing with demands in other domains of their lives. Yet the evidence is clear that it is only through autonomy support that children will come to the point of accepting responsibility for the behaviors that are in their best interests. In other words, pressure and control can prompt compliance in the immediate situation (although it sometimes prompts rebellion), but even when it prompts compliance, it is a relatively ineffective socializing strategy because the behavior tends not to persist over the long term. Autonomy support, in contrast, promotes internalization and integration of the behaviors so that they become part of the children’s own values and sense of self and, thus, are more likely to be maintained over time.

It is very important to recognize that autonomy support is not the same thing as permissiveness. To be autonomy supportive does not mean to allow children to do anything they want. Rather, autonomy support involves the use of limits and discussions about the reasons why certain behaviors are important. The important thing, however, is the style in which that is done. When parents demand that their children accept

limits and punish them for not accepting these limits, the parents are creating a power struggle that is doomed to fail. For limits to work effectively, it is important to acknowledge the children’s point of view, for example, recognizing that they might not want to behave in the way that is being discussed. It is also important to provide a meaningful rationale for doing the behaviors and to refrain from using interpersonal pressure. It is the pressure, rather than the limits, that creates the problem. As such, autonomy support means being neither pressuring nor permissive; instead, it involves working with children to support their acceptance of the values and behaviors that are important for their own development and well-being.

5.2. Autonomy Support in Education

Several studies, using questionnaires, observational methods, and experimental designs, have examined the facilitation of motivation and performance in students. Studies have shown that there is substantial variability in public school classrooms regarding the degree to which teachers tend to support students’ autonomy versus control their behavior. Furthermore, evidence from research in elementary school classrooms indicates that when teachers are more supportive of students’ autonomy—when teachers provide meaningful explanations for why certain behaviors are important, allow students to experiment with alternative ways of doing things, and encourage students to take initiative and try solving their own problems—students display higher levels of intrinsic motivation, curiosity, and desire for challenge and also are more likely to internalize extrinsic motivation in a relatively full way. One study showed that within 2 months in classrooms, students had made an accommodation to the teachers’ styles such that students of relatively controlling teachers had become less intrinsically motivated. Because controlling methods have been related to poorer conceptual learning, poorer performance on problem-solving tasks, less creativity, and lower feelings of self-worth, the evidence is compelling that more autonomy-supportive approaches in classrooms have substantial advantages for learning, performance, and development.

During recent years, there have been some efforts to include the concept of supporting students’ and teachers’ autonomy within school reform approaches, and initial evidence suggests that this is an important element of effective reform. For example, the Institute

for Research and Reform in Education has carried out districtwide reform programs that have the concept of autonomy support as a central element, and these efforts have resulted in a variety of positive educational outcomes, including decreased dropout rates, enhanced engagement in classroom activities and homework, and improved performance on standardized tests.

At the college and medical school educational levels, comparable results have been reported. For example, in a study of undergraduates learning organic chemistry, results indicated that when instructors were perceived as more autonomy supportive, students became more autonomously motivated over the semester, resulting in better performance on a standardized course exam. Studies of medical students similarly showed that instructors who were more autonomy supportive had students who were more likely to maintain interest, internalize important values associated with the course, feel more competent, and perform better in the practical application of course material.

5.3. Autonomy Support in the Workplace

Work groups, like classrooms, often vary in their climate or ambience. Some managers tend to encourage subordinates to participate in goal setting, performance evaluation, and other important decisions that are relevant to the subordinates' work lives, whereas other managers prefer to make the decisions by themselves and then tell the subordinates what needs to be done. The former approach tends to integrate the planning and doing of the work, with subordinates being involved in both, whereas the second tends to separate them, with the managers planning and the subordinates doing.

Research has shown that when managers have a more autonomy-supportive orientation toward their employees, the employees are more motivated, satisfied, and trusting and also perform more effectively than when managers have a more controlling orientation. In one study, researchers developed an intervention in which a change agent worked with managers in a major corporation to train the managers how to be more autonomy supportive in their interactions with subordinates. Results of the study indicated that over the period of the study, managers did become more autonomy supportive. More importantly, however, the subordinates of those managers who had been involved

in the training became more motivated and more satisfied with their work than did comparable employees who worked for managers who had not received the training. It appears that when managers become more autonomy supportive, the change in their orientation and behavior radiates to their subordinates, resulting in improved engagement and effectiveness of the organizational unit.

In other research, Deci and colleagues studied managers and their subordinates in Bulgaria and the United States to confirm whether the positive effects of autonomy support would appear in a collectivist totalitarian society (Bulgaria) as well as in an individualistic democratic society (United States). Results showed that when managers were autonomy supportive, their subordinates experienced greater satisfaction of the basic needs for competence, autonomy, and relatedness, leading to greater engagement in work and better psychological health. Thus, autonomy support seems to be important in the workplace regardless of cultural values or the economic and political systems that are operative in the culture.

5.4. Autonomy Support in Health Care

The importance of supporting autonomy versus controlling behavior for the promotion of maintained health behavior change has also been demonstrated in several studies. Specifically, research has shown that health care practitioners who are more autonomy supportive are more successful in promoting healthy behavior among their patients. Because unhealthy behaviors—tobacco use, poor diets, lack of exercise, and the like—are responsible for well over half a million American deaths each year, facilitating change toward healthier behaving is clearly a critical issue.

Williams and colleagues have examined practitioner autonomy support with respect to a variety of health behaviors. For example, provider autonomy support has consistently been found to promote more autonomous motivation for healthier living and greater feelings of competence about making successful maintained change. In one study, these enhanced experiences of autonomy and competence among patients with diabetes resulted in physiologically indexed improvement in glucose control over a year-long treatment period. In another study, the enhancement of patients' autonomous motivation by autonomy-supportive physicians led patients to be more adherent to long-term

medication prescriptions. Because only approximately half of all prescriptions written by physicians in the United States are followed to a degree necessary for the medications to be effective, promotion of adherence is an important issue for health care. It seems that when providers engage patients as partners in the health care process by encouraging them to be more active in their own care, the patients become more autonomously motivated and are more successful in carrying out these difficult health-relevant behaviors.

Another study examined the autonomy support of providers in a weight loss program where morbidly obese individuals were on a medically supervised, very low-calorie diet. Results indicated that the degree of provider autonomy support made a significant difference. Specifically, patients who experienced the staff as more autonomy supportive reported more autonomous motivation for participating in the program, attended weekly program meetings more regularly, and lost more weight during the program. Furthermore, at a 2-year follow-up, they were exercising more regularly and were more effective in maintaining the weight loss.

In one study, autonomy-supportive principles were used as the central element in developing a medically based counseling intervention for smokers. Using more than 1000 smokers whose educations and incomes were significantly below those of the urban county where they lived, the study evaluated the new counseling intervention relative to the usual care for treating tobacco dependence that is available in the community. Results indicated that the new intervention was substantially more effective than typical community care and that it also linked provider autonomy support directly to patients' autonomous motivation for smoking cessation. This, in turn, was a significant predictor of the patients' 6- and 18-month biochemically validated smoking cessation.

5.5. Autonomy Support in Athletics

Field studies have also shown the importance of supporting autonomy and competence for enhancing autonomous motivation in the domain of sport and exercise. There is a popular image of coaches as tyrants who care only about winning and who pressure their players to work hard and win. Although that might not be the norm, there does appear to be a tendency toward pressure and control in sports. Many parents put strong pressure on their young children to win at Little League baseball, for example, and college athletics has become something of a professional endeavor, at least in

some circles. Professional athletics, of course, is increasingly tied into huge salaries, endorsement contracts, and intense pressure to win. Studies of competition and motivation in athletics indicate that this may be counterproductive, however, both for performance and for the health and well-being of athletes. For example, there is evidence that pressuring athletes to win decreases their intrinsic motivation for the sport, and athletic scholarships to college football players have been found to have a negative motivational impact.

An interesting study by Pelletier and colleagues showed that when coaches of competitive swimmers were autonomy supportive, the athletes tended to be autonomously motivated and, in turn, persisted at the sport over a 22-month period. On the other hand, when coaches were controlling, the athletes tended to be either external or introjected in their motivation. Externally motivated swimmers had a high rate of dropout from the sport by the time of a 10-month follow-up, and those who were introjected in their motivation tended to persist through the 10-month follow-up but evidenced a high rate of dropout by the 22-month assessment point. It seems clear, then, that although controlling approaches to motivation can bring about some behavior change, that change is unlikely to persist over the long term, whereas autonomy-supportive approaches are much more likely to promote maintained long-term change.

6. SUMMARY AND CONCLUSIONS

Autonomous motivation, which is the basis for self-determination in human behavior, consists of intrinsic motivation (i.e., doing an activity because it is interesting and does not require a separable reward) and integrated extrinsic motivation (i.e., doing an activity because it has become personally important for the person's self-selected values and goals). Both intrinsic motivation and integrated extrinsic motivation are facilitated in situations that are interpersonally supportive, that is, where parents, teachers, managers, health care providers, and coaches understand and acknowledge the perspectives of their children, students, employees, patients, and athletes, respectively, and encourage them to experiment, allow them to try their own solutions to problems, provide them with choices, and respond to their initiations.

Under conditions that are supportive of individuals' autonomy, those individuals are more engaged with the task and persist longer, perform more effectively

(especially on tasks that require greater creativity, flexibility, and conceptual understanding), and display higher levels of psychological health and well-being.

GLOSSARY

autonomy The level of independence the worker has in deciding how to accomplish the tasks associated with the job.

commensurable factors Behaviors typical of different levels of skill and assigned a number that reflects those differences.

critical incidents Method of job analysis that studies jobs by having knowledgeable individuals provide real workplace examples of successful and unsuccessful job performance.

feedback The degree to which a worker receives information about his or her performance.

growth need strength A worker's need for personal growth through job performance.

hygiene factors Herzberg's term for conditions of work, including salary, management, work environment, and other factors.

job An ongoing set of cognitive or physical activities performed by one person that furthers organizational goals.

job analysis Identification of tasks or behaviors necessary to perform a job successfully.

job design Structuring of tasks and behaviors that creates a job.

job elements A method of analyzing the duties associated with a job.

job enlargement The redesign of a job to make it more interesting by adding duties.

job enrichment The redesigning of a job so that workers have more responsibility for their accomplishment, thereby motivating workers to accomplish their jobs at a higher level of performance.

job evaluation A means of determining the economic value of a job and the setting of salary levels.

job grading A job evaluation method that places jobs into levels or grades.

job ranking A method of job evaluation in which an expert ranks all jobs in an organization or a department in terms of the importance of their contribution to the overall organizational goals.

job simplification The belief that jobs should be designed so that any worker with the requisite skills could perform the job successfully by knowing the procedures to follow.

motivators Tasks and opportunities for advancement and professional growth associated with a job.

physical abilities An analytical approach that focuses on the strength, cognitive abilities, stamina, and other factors required by a specific job.

point method A method of job evaluation in which dimensions of a job are described by subject matter experts and considered the basis for assigning salary levels.

skill variety Abilities that a worker uses to accomplish a job.

subject matter experts (SMEs) People who are familiar with the requirements of a job, such as incumbents, former job performers, supervisors, and job analysts.

task identity The degree to which the worker sees the outcome of his or her efforts.

task significance The impact of a job on others, both inside and outside the organization.

In its most basic sense, a job is an ongoing set of cognitive or physical activities performed by one person that furthers organizational goals. Information about jobs comes from job analysis, which is the identification of tasks or behaviors, sometimes referred to as the knowledge, skills, and abilities, necessary to perform a job successfully. Job analysis is used for a variety of organizational purposes, including setting selection standards, designing departments and divisions, training, performance appraisal, job design, and job evaluation. Job design refers to the structuring of tasks and behaviors that creates a job and is often undertaken after a job analysis. Job evaluation is the procedure for determining the economic value of a job and the setting of salary levels.

1. JOB ANALYSIS

Researchers often trace the beginnings of job analysis back to the work of Frederick W. Taylor, an industrial engineer at Bethlehem Steel, at the beginning of the 20th century. Taylor's goal was to find what he considered the one best way to perform a specific job and then develop step-by-step procedures for jobholders to follow. Taylor's approach focused solely on the tasks associated with a job—he did not consider social, organizational, or motivational factors in studying jobs. Nonetheless, his studies resulted in significant improvement in efficiency and productivity at Bethlehem Steel.

Taylor's research was guided by the concept of job simplification, or the belief that jobs should be designed to minimize individual differences in workers so that any worker with the requisite skills could perform the job successfully by knowing the procedures to follow.

A few decades after Taylor's original studies, however, the context of most jobs had changed dramatically and job analysis became a more complex procedure than simply identifying tasks and the best way to perform them. For example, Taylor had assumed that worker motivation was primarily economically based. Later research, such as the Hawthorne bank wiring studies or studies regarding the longwall method of coal getting, suggested that factors other than economics affect worker performance.

This increased knowledge about the complexities of worker motivation affected the field of job analysis by broadening the area of study to motivational, social, and organizational considerations in addition to the tasks associated with performing the job. Recently, changing demographics of the workforce, and concerns about making jobs equally available to all persons who can perform them, further broadened the field of job analysis. Although the most basic model of job analysis still consists of identifying tasks, worker characteristics, and working conditions, this identification is now done in the context of a much broader range than the issues Taylor originally considered.

Information about the tasks or behaviors associated with a particular job can be collected in a variety of ways. Typical methods of collecting data include observation of the person performing the job; interviews with the job incumbent, the incumbent's peers, immediate supervisor, or other supervisory personnel with the organization; diaries and other forms of record keeping; and questionnaires. Sources for job analysis information can include, in addition to job incumbents and their supervisors, vendors, customers, or other organizational members who interact with the incumbent.

Throughout the years, researchers have developed a number of approaches for analyzing the duties associated with a job. These procedures, which focus on different aspects of the job, can be quite precise and detailed, and they can focus mainly on either tasks to be performed or characteristics needed to perform the tasks. The job elements approach, for example, focuses on the knowledge, skills, and abilities (KSAs) necessary to perform a job successfully. Information about the KSAs comes from job incumbents and supervisors, who are considered subject matter experts (SMEs). Other approaches take a more generic approach to analyzing jobs. The Position Analysis Questionnaire method, for example, relies on the assumption that there is an underlying taxonomy to all jobs, and that all tasks associated with a job can be classified into six categories.

Another approach to job analysis is to focus on the physical abilities associated with successful job performance. This approach considers strength, cognitive abilities, stamina, and other factors required by a specific job. Physical abilities job analysis has been particularly important in addressing gender issues in personnel recruitment and selection.

Finally, the critical incidents method of job analysis studies jobs by having incumbents and other knowledgeable individuals provide real workplace examples of successful and unsuccessful job performance. From

these examples, job analysts identify the abilities and behaviors necessary to perform a job successfully.

Although each of these methods takes a different approach to job analysis, the basic steps associated with analyzing a job are illustrated in Fig. 1. From the perspective of job design, the writing of task statements and identifying functions of a job is one of the most important parts of a job analysis. Job functions are groups of activities that relate to a particular purpose or outcome. Figure 2 lists some typical job

functions. Each job function consists of several tasks necessary to complete the job function. Tasks generally refer to an action that changes an input to an output.

From the identification of functions and tasks, the job analyst should be able to draw a fairly accurate picture of what a job entails. Nonetheless, a thorough job analysis also considers other important information that might affect performance, such as nonroutine tasks (tasks performed only occasionally), interactions with other individuals both inside and outside the organization, tasks performed as part of a team, and the position of the job within the overall organizational context.

2. JOB DESIGN

Using the information gathered from a job analysis, jobs can be designed, redesigned, created, or eliminated. Most job design starts by determining where a job fits in the overall organizational process. One way to do this is to identify the precise steps a worker is expected to perform to change an input into an output—for example, to change a consumer's application for a mortgage loan into either a commitment or denial from a mortgage lender. From this information, the job designer can identify aspects of a job aside from the specific tasks and functions identified in the job analysis. These aspects may affect performance of a job's tasks and functions. In addition, knowing each step in the process of changing an input to an output allows the job designer to evaluate the expectations associated with the job.

However, as suggested previously, focusing solely on the major functions and tasks associated with a job may not provide a complete picture of the requirements for successful performance. Other factors that may affect job performance include (i) the technology the worker would be expected to use in performing tasks and functions (e.g., machinery vs computers), (ii) the environment in which the work is performed (e.g., indoors vs outdoors or in front of customers vs producing goods for inventory), and (iii) the structure of the work organization (e.g., assembly line vs team environment).

The final part of the job design considers matching the job functions and tasks to worker abilities. That is, the job design may be affected by the abilities of workers expected to perform the job. For example, an ideal job design may call for workers to handle both production and customer service duties, but it may be unrealistic to expect workers to have high levels of ability in both these areas. In this case, the job designer would need to

Administering operations	Filing, sorting, and routing
Analyzing competition	Financial planning and review
Analyzing financial data	Gathering information
Buying, ordering, and stocking	Handling outside contacts
Checking and testing	Improving work procedures and practices
Cleaning and maintaining	Maintaining and operating
Communicating orally	Machines/computers
Composing or editing	Managing the floor
Computing	Merchandising and displaying products
Controlling expenses	Operating the plant
Coordinating interdepartmental communications	Operating the store
Coping with difficulties and emergencies	Processing records
Developing and implementing technology	Promoting community relations
Developing and improving oneself	Promoting safe attitudes and practices
Developing employee potential	Relating to customers
Developing group cooperation and teamwork	Scheduling
Developing sales	Setting organizational objectives
	Supervising employees

Scott, Copyright 1995 by PAR, Inc. Further reproduction is prohibited without permission of PAR, Inc.

modify the design to reflect the practical reality of the abilities of the workers expected to perform the job.

Another consideration in job design mentioned earlier is the issue of fairness. Although it may be expedient to design jobs best suited to the mental or physical characteristics of a particular group, this kind of job design may not meet either the legal requirements or goals of the organization with regard to workforce composition. The job designer may need to modify the ideal design to reflect considerations other than performing the tasks associated with the job functions. Another important consideration in job design is worker motivation, which is discussed next.

2.1. Job Design and Worker Motivation

Three influential models of job design that consider the issue of worker motivation are the two-factor model, sociotechnical systems, and the job characteristics model.

2.1.1. The Two-Factor Model

The job simplification model developed by Taylor was later challenged by Frederick Herzberg and associates, who argued that motivational factors are a critical aspect of job design. In Herzberg's formulation,

known as two-factor theory and illustrated in Fig. 3, different aspects of jobs could be categorized into what he called hygiene factors and motivators. Hygiene factors refer to the conditions of work and include salary, management, work environment, and other factors.

Motivators, on the other hand, include the tasks associated with the job as well as responsibility, autonomy, and opportunities for advancement and professional growth. According to two-factor theory, motivators have a more important impact on job performance than hygiene factors. Whereas employees may complain if they are dissatisfied with hygiene factors, their performance is more influenced by motivators. For this reason, job designers need to pay particular attention to motivators.

Herzberg's theory contradicted Taylor's belief that simplification should be the basis for designing jobs. By recognizing that performance is affected by factors other than tasks, Herzberg advocated an approach known as job enrichment. Job enrichment refers to designing jobs so that workers have more responsibility for their accomplishment. In this way, workers are more motivated to accomplish their jobs at a higher level of performance. Job enlargement is a kind of enrichment that attempts to make jobs more interesting by adding duties rather than adding responsibility.

Although studies of the two-factor model indicate that motivation and performance are more complex

FIGURE 3 Motivators and hygiene factors. *Because of its ubiquitous nature, salary commonly shows up as a motivator as well as a hygiene factor. Although primarily a hygiene factor, it also often takes on some of the properties of a motivator, with dynamics similar to those of recognition for achievement. From Herzberg, F. (1982). *The managerial choice: To be efficient and to be human* (2nd rev. ed.). Salt Lake City, UT: Olympus.

than the model suggests, Herzberg’s theory had significant intuitive appeal when applied to understanding worker motivation. From the perspective of job design, a shortcoming of two-factor theory is its lack of specificity in identifying how job tasks become motivators that affect performance.

2.1.2. Sociotechnical Systems

A second important influence on job design was developed at the Tavistock Institute of Human Relations in England. This model, developed during the period after World War II as Europeans introduced technology into their factories, argued that organizations consist of two systems—the social and the technical—that affect worker performance. According to sociotechni-

cal systems theory, jobs should be designed with both their social and their technical aspects in mind.

Sociotechnical theorists believe that introducing technological changes into a workplace almost always disrupts the social system. These disruptions, in turn, are likely to lower worker satisfaction and productivity. Therefore, a job design that does not consider the social aspects of a job is unlikely to result in optimal performance.

An important aspect of the sociotechnical approach to job design—and an important difference from job simplification—is its emphasis on work groups rather than individual jobs. Sociotechnical theorists believe that designing jobs in terms of work groups that have autonomy to plan how to accomplish their tasks results in both greater productivity and greater worker satisfaction. They also argue that increases in productivity

occur more often if workers develop multiple skills and if jobs have a variety of duties, which is a kind of job enrichment.

2.1.3. The Job Characteristics Model

Probably the most influential approach used by modern job designers is the job characteristics model developed by J. R. Hackman and Greg Oldham. Although Hackman and Oldham’s research focused on worker motivation, their identification of five domains associated with any job has been useful in the study of job design. Figure 4 illustrates the job characteristics model.

Skill variety refers to the abilities a worker uses to accomplish a job. According to the job characteristics model, jobs that require a wider range of skills are more motivating. Task identity refers to the degree to which the worker sees the outcome of his or her efforts, and task significance relates to the impact of the job on others, both inside and outside the organization. According to the theorists, the three aspects of skill variety, task identity, and task significance affect the worker’s assessment of the importance of his or her job.

The other two factors in the model address the responsibility associated with the job and the worker’s perception of outcomes. Autonomy refers to the level of independence the worker has in deciding how to accomplish the tasks associated with the job, and

feedback describes the degree to which the worker receives information about his or her performance.

A final aspect of the job characteristics model addresses an important individual difference variable that affects job performance. Growth need strength refers to the worker’s need for personal growth through job performance. Growth need strength can affect job design in that workers with high growth need strength seek jobs that offer challenge and a variety of duties; workers with low growth need strength prefer more routine types of jobs. If a job designer is dealing with jobs requiring a highly educated workforce, for example, growth need strength may require that jobs be made more complex and that levels of autonomy be higher.

3. JOB EVALUATION

As suggested previously, job evaluation is the procedure used to determine the relative worth of jobs within an organization. Most jobs are evaluated in terms of education required, skills involved in job performance, level of responsibility, working conditions, and factors in the local economy. Information from the evaluation is used to determine salary levels for jobs.

There are several methods for job evaluation. The point method is the most widely used. Under this procedure, subject matter experts identify job dimensions

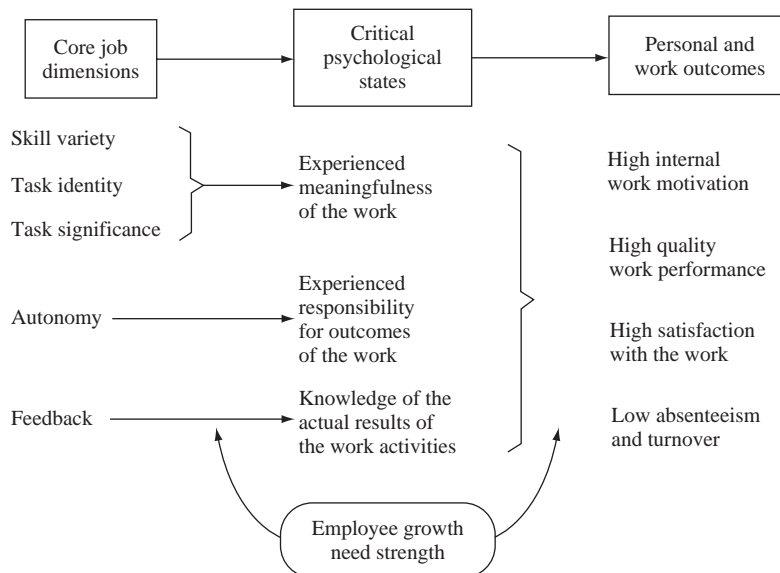

FIGURE 4 Job characteristics model. Reprinted from *Organizational Behavior and Human Performance*, 16, Hackman, J. R., & Oldham, G. R., Motivation through the design of work: Test of a theory, 250–279, Copyright 1976, with permission from Elsevier.

that will be the basis for assigning salary level. These dimensions—known as commensurable factors—are then described in terms of behaviors typical of different levels of skill and assigned a number that reflects differences in skill levels. Jobs can then be scored in terms of the number of points and compared to each other to determine salary level.

Job ranking is the most straightforward method of job evaluation and is most often used in small organizations. In this procedure, a SME ranks all jobs in an organization or a department in terms of the importance of their contribution to the overall organizational goals. In contrast to the point method, job ranking is a subjective procedure that does not consider the magnitude of the difference between jobs.

Finally, the job grading method places jobs into levels or grades. Jobs requiring less skill, for example, would be placed together—irrespective of the work performed—in a lower grade, whereas jobs requiring more skill would be grouped in a higher grade. The U.S. government's GS system is an example of job grading.

Regardless of the procedure used, job evaluation results in a hierarchical ranking of the worth of each job within the organization. The final step in determining salaries is external validation of pay scales. This is usually done through surveys of salaries paid for similar jobs in other organizations.

4. OTHER ISSUES IN JOB ANALYSIS, DESIGN, AND EVALUATION

Because of the complexities of modern organizations, considerations other than functions and tasks affect the way jobs are structured and salary levels assigned. Some issues that may influence the way an organization analyzes, designs, and evaluates jobs include individual differences, organization development, and teams.

4.1. Individual Differences

When Taylor first starting designing jobs at Bethlehem Steel, his goal was to standardize procedures for job performance so that any person could do the work. In general, standardization remains the basic principle of job design, which is that anyone with the requisite KSAs should be able to do the work.

However, as mentioned previously, job performance is greatly influenced by level of motivation, which is an individual difference variable. When

motivation to perform is high, jobs can be designed that encompass a variety of tasks and challenge the worker. When motivation is lower, jobs may need to be simpler, encompassing fewer tasks. Similarly, ability may also impact a worker's motivation and performance.

Another relevant individual difference variable is the tendency of individual workers to redesign their jobs so that they spend more time performing duties they enjoy and less time performing duties they find unappealing. In these cases, the job design provides a general outline for performance rather than a strict guideline. An employee may redesign a job so that he or she spends more or less time on certain tasks and still maintain a high level of performance overall.

4.2. Organization Development

During the 1990s, organizational theorists increasingly argued that the organization of the future would emphasize flexibility over structure. This argument was based on a variety of factors, but among the most important were changes in workforce demographics, technological innovations, and globalization.

As the U.S. workforce widened to include individuals from different races and cultural backgrounds, some theorists argued that traditional models of workplace organization were not appropriate for everyone. In particular, U.S. managerial practices were criticized for not taking differences such as race, culture, and gender into consideration. These criticisms, in turn, gave rise to the diversity movement. Diversity considerations may not affect the design of every job, but, at a minimum, they may be a factor in determining the physical requirements for performing the tasks associated with a job. For example, women, as a group, are not as physically strong as men, and Asians, as a group, are not usually as large as Westerners. Changes in the composition of the workforce may require job designers to consider the type of person most likely to do the job being designed as well as the tasks and functions associated with the job.

Technology is also likely to change job design. Although technology minimizes certain differences between workers (e.g., physical strength), technology often requires specific skills, such as facility with computers and computer programs, vigilance, and an ability to grasp the underlying model under which technology operates. A related challenge to traditional job design and evaluation is the changing nature of technology. Because technology changes rapidly in

some occupations, constant revision of the design and requirements of specific jobs may be necessary.

Finally, globalization affects job design in a variety of ways. Aside from confronting cultural differences, workers with foreign colleagues or who produce products for foreign markets may encounter factors such as language differences, time differences, incompatibilities in technology, or even political considerations that affect the way jobs are designed and evaluated.

4.3. Teams

During the 1980s, organizations began to pay more attention to the role of teams in the work environment. Although sociotechnical theorists had advocated teamwork as a means of both making work more meaningful to the worker and enhancing productivity since the 1950s, only a few U.S. organizations had adopted a teamwork approach. Building on an interest in Japanese quality circles that emerged in the 1970s, U.S. managers began to adapt team concepts to their workforces. In the modern team approach, teams often have responsibility for determining work schedules, methods, and hours, as well as team leadership and communication procedures, all of which can affect job design.

Teamwork calls for a radically different approach to job design. Rather than focus on requirements associated with a specific job, job design for teams requires the analysis of several jobs concurrently as well as the establishment of requirements based on the relationship of each job to other jobs represented by team members. This can be a complicated procedure, and most approaches to job design have not addressed the question of interrelationships among

jobs held by members of the same team. Similarly, organizing workers into teams responsible for accomplishing a particular task may complicate the job evaluation process.

GLOSSARY

active job search behavior Applying for positions by sending out resumes and interviewing with prospective employers.

assertive job seeking The ability to identify one's rights and choices during job search and to act on them.

coping resources Individual and environmental factors and conditions that an individual can draw on in coping with involuntary job loss and that have direct and indirect effects on coping strategies.

emotion-focused strategies Attempts to change the way that the stressor is construed through techniques such as distancing and avoidance.

emotional response model Job seekers experience high levels of stress and frustration that can lead to avoidance, helplessness, and withdrawal.

employment commitment The importance and centrality of employment to the job seeker.

employment outcome Whether or not a job seeker obtains employment and the nature of that employment.

employment quality Job search outcomes that occur once the job seeker assumes a position and begins working, such as job satisfaction and intentions to quit.

employment status Whether or not a job seeker has obtained employment.

formal sources Public intermediaries such as advertisements, employment agencies, and campus placement offices.

informal sources Private intermediaries such as friends, relatives, or persons who are already employed in an organization.

job-finding club An intensive, highly structured, group-based behavioral counseling program that emphasizes motivation, maintenance of behavior, feedback and reinforcement, imitation, role playing, and practice activities.

job information sources The means by which job seekers learn about job opportunities.

job search A dynamic process through which individuals pursue employment goals.

job search effort The amount of energy, time, and persistence that a job seeker devotes to his or her job search.

job search intensity The frequency with which job seekers, during a set period of time, engage in specific job search behaviors or activities, such as preparing a resume or contacting an employment agency.

job search outcomes The immediate outcomes that occur during one's job search and lead to subsequent employment outcomes.

job search self-efficacy Confidence in one's ability to perform a variety of specific job search tasks and activities.

job-seeking social support The network of friends and family who provide counseling, assistance, and encouragement to job seekers.

JOBS intervention A job search intervention that includes problem-solving and decision-making processes, inoculation against setbacks, social support, and job-seeking skills.

learning model Job seekers learn more efficient and effective search techniques during their job search.

networking Contacting friends, acquaintances, and referrals to obtain information and leads about job opportunities.

preparatory job search behavior Gathering job search information and identifying potential leads during the planning phase of job search.

problem-focused coping strategies Activities directly aimed at eliminating the source of stress (i.e., job loss) such as proactive job search.

sequential model Job search follows a logical and systematic progression of stages.

symptom-focused coping attempts Attempts to eliminate the symptoms of stress through involvement in nonwork activities or seeking social support from friends and family.

Job search is a dynamic process through which individuals pursue employment goals. Whether one is entering the workforce for the first time, seeking reemployment following job loss, or changing jobs to pursue new career opportunities, job search is a necessary and inevitable part of the process. Numerous individual difference variables and situational factors combine to shape a person's job search. In turn, the nature and scope of an individual's job search can influence the probability and speed that one will obtain employment. For unemployed job seekers, job search is a form of problem-focused coping in response to job loss. An effective job search can increase an individual's chances of reemployment following job loss and improve long-term psychological well-being. Among employed job seekers, job search is a major predictor of voluntary turnover. The extent to which one engages in an effective job search and finds satisfactory employment can be enhanced through job search training interventions.

1. THE JOB SEARCH PROCESS

Job search is a process that consists of gathering information about potential job opportunities, generating and evaluating job alternatives, and choosing a job from the alternatives. These activities determine the type and amount of information that job seekers obtain about job openings as well as the number of job opportunities from which a job seeker has to choose.

The job search process has often been conceived of as a logical sequence of activities. Soelberg's model of job search consists of two phases: planning job search

and then job search and choice. Thus, job search begins with an extensive search to gather information and identify job opportunities followed by a more intensive search that involves the acquisition of specific information about jobs and organizations. Job search has also been described as consisting of a preparatory and active phase. Preparatory job search behavior involves information gathering about job opportunities, and active job search behavior involves applying for positions.

Kanfer *et al.* conceptualized job search as a self-regulatory process that involves "a purposive, volitional pattern of action that begins with the identification and commitment to pursuing an employment goal." Employment goals activate job search behaviors that are intended to obtain employment. Thus, "individuals identify, initiate, and pursue actions for the purpose of obtaining new employment or reemployment." Job search and the self-regulatory process ends when the employment goal has been achieved or is abandoned.

Finally, it is worth noting that during the search process job seekers change their behaviors. Three models describe how the behavior of job seekers can change during their job search. As indicated previously, the sequential model proposes that job search follows a logical and systematic progression of stages. According to the learning model, job seekers learn more efficient and effective search techniques during their job search. The emotional response model asserts that job seekers experience high levels of stress and frustration that can lead to avoidance, helplessness, and withdrawal.

Two studies have examined changes in job seeker's search behavior. Barber and colleagues measured the job search activities of college and vocational-technical school graduates early in the search process, at graduation, and 3 months following graduation for those who remained unemployed. They found a significant decrease from initial search to late search in the use of formal sources, job search intensity, and in information related to obtaining a job. They also reported a significant increase in the use of formal sources and intensity following late search for unemployed job seekers.

Saks and Ashforth studied recent university graduates who had not found a job just prior to graduation. Follow-up 4 months later indicated that job seekers increased their active job search behavior, formal job source usage, and search effort and decreased their job search anxiety.

2. JOB SEARCH RESEARCH

Research on job search can be distinguished in terms of the major area or domain of interest as well as the sample. Job search research has tended to fall into one of the following areas: (i) coping with job loss and reemployment, (ii) job search interventions, (iii) job search and voluntary turnover, and (iv) antecedents and consequences of job search.

The samples used in job search research have varied across and within the main research areas. For example, research on coping with job loss and reemployment necessarily includes unemployed and recently laid-off workers. Research on job search and turnover includes samples of employed job seekers. Research on the antecedents and consequences of job search has included new entrants to the workforce (e.g., college graduates), employed job seekers, as well as unemployed job seekers. However, it is worth noting that college students have been used most extensively in job search research, followed by unemployed job seekers.

2.1. Coping with Job Loss and Reemployment

Studies on job search and involuntary job loss focus on the coping strategies of recently unemployed individuals. Job loss coping strategies can be problem-focused, emotion-focused, and symptom-focused. Problem-focused coping strategies involve activities directly aimed at eliminating the source of stress (i.e., job loss) such as proactive job search. Emotion-focused strategies involve attempts to change the way that the stressor is construed through techniques such as distancing and avoidance. Symptom-focused coping attempts to eliminate the symptoms of stress through involvement in nonwork activities or seeking social support from friends and family.

Research on coping with job loss measures the predictors and consequences of coping strategies. Predictors of coping strategies consist of a number of coping resources, including individual and environmental factors and conditions that an individual can draw on in coping with involuntary job loss and that have direct and indirect effects on coping strategies. Coping resources such as education, financial resources, and social support predict cognitive appraisal of job loss and coping strategies, including job search activities. Reemployment coping goals and gender also predict proactive job search. Men engage in more problem-

focused coping strategies such as job search, whereas women engage in more symptom-focused strategies such as social support.

The consequences of coping behaviors include mental health and reemployment. Problem-focused coping (i.e., proactive job search) relates to obtaining reemployment but can also reduce mental health in the short term.

2.2. Job Search Interventions

Job search interventions can lessen the negative effects of job loss and improve individuals' job search and probability of reemployment. Research on employment counseling and job loss has found that the job-finding club is one of the most effective methods of job search training.

The job-finding club is an intensive, highly structured, group-based behavioral counseling program that emphasizes motivation, maintenance of behavior, feedback and reinforcement, imitation, role playing, and practice activities. Participants receive assistance in all areas of job search, including coping with discouragement, preparing resumes, obtaining and pursuing job leads, learning interviewing skills, scheduling time and record keeping, dress and grooming, and using the telephone for making inquiries and contacts.

Job seekers who have attended a job-finding club have been found to be more likely to obtain employment compared to individuals in a control group or who participated in other types of programs. Some studies have also found the job-finding club to result in higher starting salaries, more work hours, lower depression, and greater advancement and job satisfaction.

A number of other job search interventions have also been shown to be effective for coping with job loss and reemployment. For example, Caplan and colleagues developed a program called the JOBS intervention to improve the motivation and skills necessary for unemployed job seekers to engage in job-seeking behavior. The intervention includes problem-solving and decision-making processes, inoculation against setbacks, social support, and job-seeking skills.

Compared to a control group, the JOBS intervention resulted in higher rates of reemployment as well as higher quality reemployment in terms of earnings and job satisfaction for its participants. For those who remained unemployed, participants in the JOBS program have higher job search motivation and self-efficacy compared to control group participants. The benefits of the intervention for reemployment and employment quality have been shown to persist. Individuals who have participated in the JOBS program have higher levels

of employment, higher paying jobs, work more hours, and had fewer changes in jobs and employers up to 2½ years following the program. The JOBS intervention also has a significant effect on the mental health of individuals at high risk for depression.

Eden and Aviram studied the effects of a behavioral modeling job search workshop designed to boost the general self-efficacy (GSE) of unemployed vocational workers. Participants who attended the workshop had higher self-efficacy at the end the workshop and 2 months later compared to those in a control group. The workshop also increased the job search activity and reemployment of individuals with low initial GSE. Furthermore, the effect of the workshop on reemployment was mediated by job search activity.

Finally, a disclosive writing intervention in which laid-off professionals wrote about their thoughts and feelings about the layoff and how it affected their personal and professional lives resulted in higher levels of full-time employment compared to those for a control group.

2.3. Job Search and Voluntary Turnover

Models of turnover and the turnover process often include job search as a key predictor of voluntary turnover. Several studies have found that job search is highly predictive of turnover and even more strongly related to turnover than more traditional predictors such as perceptual, affective, attitudinal, and intention measures.

In terms of specific job search variables, Gary Blau has shown that active job search behavior is a better predictor of voluntary turnover than preparatory job search behavior and general search effort, and that preparatory job search behavior is indirectly related to turnover through active job search behavior. In addition, active job search behavior predicts voluntary turnover beyond job attitudes and withdrawal cognitions. Job search has also been found to predict the voluntary turnover of managers and to mediate the relationship between motivation variables and turnover.

Thus, it appears that job search, rather than turnover intentions, is the best predictor of voluntary turnover. Although this stream of research does not measure the employment status of those who quit, it is safe to assume that if an employee has quit he or she has found another job. Therefore, the finding that job search is related to turnover is akin to stating that job search is related to finding a new job.

2.4. Antecedents and Consequences of Job Search

In 1987, Schwab and colleagues presented a job search model in which self-esteem and financial need predicted job search intensity, and job search intensity predicted employment. Since then, additional antecedents, job search variables, and outcomes have been investigated. Given that this research represents the most extensive area of job search and overlaps with the other areas, the following sections focus on job search behaviors, antecedents, and consequences.

As indicated previously, research on the antecedents and consequences of job search has varied as a function of sample type (i.e., new entrants, employed, and unemployed job seekers). Since the characteristics of these samples differ in terms of experience, motivation, and the use of job search strategies, the antecedents and consequences of job search might differ across studies and samples. In fact, in a meta-analysis on the antecedents and consequences of job search conducted by Kanfer and colleagues, sample type was a significant moderator variable.

3. JOB SEARCH BEHAVIORS

In their review of the job search literature, Schwab and colleagues indicated that job search success and employment outcomes are a function of the sources used to acquire information about job openings and the intensity with which one pursues such information. Although sources and intensity are among the most often studied job search dimensions, job search research has included a number of other dimensions of job search, the four most prominent being job information sources, job search intensity, job search effort, and job search information.

3.1. Job Information Sources

Job information sources is considered to be one of the most important dimensions of job search and is among the most often studied. Sources refer to the means by which job seekers learn about job opportunities. Both the recruitment and the job search literature have tended to distinguish between formal and informal job sources. Formal sources involve the use of public intermediaries, such as advertisements, employment agencies, and campus placement offices. Informal sources are private intermediaries, such as friends,

relatives, or persons who are already employed in an organization.

3.2. Job Search Intensity

Job search intensity refers to the frequency with which job seekers, during a set period of time, engage in specific job search behaviors or activities, such as preparing a resume or contacting an employment agency. Various indicators have been used to measure search intensity, such as the number of employers contacted, the number of hours per week spent searching, and the number of sources used.

In response to the failure to distinguish between job search activities at different stages of the job search process as well as the frequent use of single-item measures and dichotomous response scales, Gary Blau developed two distinct measures of job search intensity that he called preparatory job search behavior and active job search behavior. Preparatory job search behavior involves gathering job search information and identifying potential leads during the planning phase of job search. Active job search behavior involves the actual job search and choice process, such as sending out resumes and interviewing with prospective employers. It reflects an individual's behavioral commitment to job search.

Several studies have measured specific job search behaviors that have been recommended in the popular job search literature, particularly assertiveness and networking. Assertive job-seeking applies the concept of assertiveness to job search and refers to the ability to identify one's rights and choices during job search and to act on them. Specific behaviors include making follow-up calls regarding the status of a job application and making calls to arrange meetings with organizational representatives to discuss employment opportunities. Networking is another specific job search behavior and involves contacting friends, acquaintances, and referrals to obtain information and leads about job opportunities. Networking involves the use of informal job information sources.

3.3. Job Search Effort

Job search effort refers to the amount of energy, time, and persistence that a job seeker devotes to his or her job search. Unlike measures of job search intensity, they do not focus on particular job search behaviors. Blau developed a scale to measure general effort in job search that asks respondents about the time and effort they have devoted to their search. Based on confirmatory factor

analyses across these diverse samples, he found empirical support that general effort is related to, but distinguishable from, preparatory and active job search behavior.

3.4. Job Search Information

Barber and colleagues argued that the type of information sought and acquired is also an important dimension of job search because individuals use this information to make job choice decisions. In addition to information about employment opportunities, job seekers also require accurate, detailed, and specific information about job and organizational attributes. Few studies, however, have actually examined this dimension of job search.

4. ANTECEDENTS OF JOB SEARCH BEHAVIORS

A number of variables have been found to influence job search and employment outcomes. In general, the antecedents of job search can be categorized into three groups: biographical/demographic variables, individual difference variables, and situational factors.

However, the size of the relationships between the antecedents and job search behavior has been found to differ as a function of the job search measure and the sample type. In a meta-analysis, Kanfer and colleagues concluded that a number of antecedents–job search relationships were stronger for measures of job search intensity compared to measures of job search effort. Also, for some antecedents (i.e., extroversion, neuroticism, conscientiousness, and education) the relationships were stronger for new entrants, whereas for other antecedents (i.e., self-esteem, employment commitment, and social support) the relationships were stronger for unemployed job seekers. In addition, tenure related positively to search behavior for new entrants but related negatively to search behavior for employed and unemployed job seekers. It is also worth noting that the relationships between the antecedents and search behavior tend to be stronger than the relationships between the antecedents and employment outcomes.

4.1. Demographic/Biographical Variables

Demographic/biographical variables in job search research include age, gender, education, race, and tenure.

In general, biographical variables tend to be only weakly related to job search behavior and to a lesser extent than the other antecedents. In their meta-analysis, Kanfer and colleagues concluded that age, race, gender, education, and tenure were related to job search behavior; that is, older, nonwhite, female, less educated, and longer tenured individuals engaged in less job search behavior than younger, white, male, more educated, and less tenured individuals. Furthermore, men have been found to be more likely to use informal sources than women.

Demographic variables are also related to job search outcomes. Younger job seekers as well as more educated ones and males (new entrants only) are more likely to find employment, and more educated and white job seekers experience a shorter period of unemployment.

Finally, there is evidence that cognitive ability may also play a role in job search. For example, the cognitive ability of employed managers has been shown to relate positively to job search. Also, grade average, a surrogate measure of cognitive ability, has been found to correlate positively to active and preparatory job search behavior as well as employment status among a sample of recent graduates.

4.2. Individual Difference Variables

Individual difference variables tend to be personality variables (e.g., self-esteem), motivational factors (e.g., self-efficacy), and attitudes toward employment and work (e.g., employment commitment). Among the personality variables, self-esteem has been found to relate negatively to the use of formal job sources and relate positively to job search intensity and assertive job-seeking behavior, as well as a shorter period of unemployment, the number of job offers received, and the likelihood of obtaining employment.

There is evidence that the dimensions of the five-factor model of personality are related to job search behaviors. In their meta-analysis, Kanfer and colleagues organized personality constructs used in job search research on the basis of the five-factor model of personality. They found that extroversion and conscientiousness were the strongest positive predictors of job search behavior, followed by openness to experience and agreeableness. Neuroticism related negatively to job search behavior. In addition, higher levels of extroversion, conscientiousness, openness to experience, and agreeableness related to a shorter period of unemployment, and conscientiousness was also related to employment status.

A motivational variable that has received a considerable amount of attention is job search self-efficacy—that is, confidence in one's ability to perform a variety of specific job search tasks and activities. The results of several studies indicate that job search self-efficacy predicts preparatory and active job search behaviors, assertive job search behavior, job source usage, and search intensity, as well as search duration, number of job offers, and employment status.

Another motivational variable that has been shown to be important is job seekers' perceived control over the outcomes of their job search. Although locus of control has been found to relate only weakly to job search behavior, perceived situational control over the outcomes of job search has been found to relate positively to job search behaviors and employment status.

In terms of employment attitudes, employment commitment or the importance and centrality of employment to the job seeker has been found to relate positively to job search intensity. Among employed job seekers, job attitudes such as job satisfaction and organizational commitment have been found to relate negatively to job search behavior.

4.3. Situational Variables

Among the situational variables, financial need and social support have received a considerable amount of attention. Job seekers who have a greater financial need tend to be more intense in their search for employment. Financial need has been shown to relate positively to both preparatory and active job search behaviors. Job seekers with higher benefit levels or a longer duration of benefits tend to remain unemployed for longer periods. Thus, financial hardship tends to result in a shorter period of unemployment.

One of the most important situational variables in job search and coping with job loss is social or job-seeking support. Social support refers to the network of friends and family who provide counseling, assistance, and encouragement to job seekers. Social support has been shown to be particularly important in assisting individuals following job loss and to predict job search behavior and employment status.

Finally, several other situational factors have been found to predict the job search behavior of employed individuals. In particular, compensation, perceived organizational success, and organizational work–family balance policies have been found to relate negatively to job search. Job insecurity and desire for more work–family balance have been found to relate positively to

job search. These results are particularly noteworthy because they suggest that organizations have some influence over a number of job and organizational variables that affect employees' job search behavior.

5. CONSEQUENCES OF JOB SEARCH BEHAVIORS

In their model of job search, Schwab and colleagues proposed two outcomes of job search: employment and the quality of employment (e.g., job satisfaction and tenure). Job search research, however, has focused primarily on preentry outcomes, especially employment status (i.e., whether or not the job seeker has obtained employment). In general, the consequences of job search can be categorized in terms of (i) job search outcomes (outcomes that occur during the search process), (ii) employment outcomes (outcomes that are a result of one's job search), (iii) psychological well-being (the job seeker's mental health), and (iv) employment quality (outcomes that occur on-the-job).

5.1. Job Search Outcomes

Job search outcomes refer to the immediate outcomes that occur during one's job search and lead to subsequent employment outcomes. This includes the number of job interviews and job offers that a job seeker receives as well as the speed with which one obtains employment. Research supports a positive relationship between job search intensity and the number of job interviews and offers received and a negative relationship with search duration.

5.2. Employment Outcomes

Employment outcome measures assess the result of one's job search and refer to whether or not a job seeker obtains employment and the nature of that employment. The most common outcome measure of job search is employment status. There is strong support for a positive relationship between job search behavior and employment status. Furthermore, as indicated previously, research showing a relationship between job search intensity and turnover provides additional support that job search results in subsequent employment. Job search behavior has also been found to relate positively to preentry person–job (P–J)

fit and person–organization (P–O) fit and the initial compensation of recent graduates.

Interestingly, Kanfer and colleagues found that measures of job search effort related more strongly to employment duration and employment status compared to measures of job search intensity. In addition, the relationship between job search behavior and employment status was strongest for employed job seekers, followed by new entrants and unemployed job seekers.

Research on job sources has consistently found that job seekers are more likely to find employment through the use of informal sources of information. In particular, friends and personal acquaintances tend to be the main source through which job seekers obtain employment.

However, although informal sources may be more likely to result in employment, there is evidence that formal sources are more likely to result in a better job. For example, graduates who used formal sources have been found to be more likely to find work in higher level occupations and jobs that are more closely related to their college training than those who used informal sources. Also, the number of formal sources used by recent graduates has been found to be positively related to preentry perceptions of P–J and P–O fit. Formal sources have also been found to result in higher paying jobs.

5.3. Psychological Well-Being

A major concern in the job search literature is the psychological well-being of job seekers. This is especially the case in research on job loss, unemployment, and job search interventions. It is well known that the experience of job loss and unemployment is associated with negative physical and psychological effects, including symptoms of psychiatric disorder, distress, and depression.

Unlike the other outcomes discussed in this section, indicators of psychological well-being tend not to be directly associated with job search behavior but, rather, the experience of (un)employment. In this regard, job seekers who obtain satisfactory employment tend to show an improvement in their mental health and psychological well-being. However, given that job search is related to (re)employment, it is fair to say that job search behavior is indirectly related to psychological well-being through its influence on employment status.

Finally, job search interventions have also been shown to influence job seekers' psychological well-being. A number of such interventions have improved unemployed job seekers' self-esteem, self-efficacy, depression, and mental health.

5.4. Employment Quality

Employment quality refers to job search outcomes that occur once the job seeker assumes a position and begins working. With the exception of research on recruitment and job sources, job search research has seldom measured the quality of employment. Research on unemployment has also tended to neglect the quality of reemployment.

The relationship between recruitment sources and postentry outcomes has been extensively studied in the recruitment literature. Accordingly, job seekers who find employment through informal sources tend to have more positive job attitudes and lower turnover.

Job search research, however, has only recently begun to examine the links between job search behavior and employment quality, and the results have not been very supportive. For example, Wanberg and colleagues did not find a significant relationship between job search intensity and job satisfaction, job improvement, and intentions to turnover. In another study, they found that neither job search nor networking intensity related to job satisfaction or intention to turnover. Werbel also failed to detect a significant relationship between job search intensity and job satisfaction. Furthermore, research on involuntary job loss has also failed to detect a significant relationship between problem-focused coping and the quality of reemployment.

However, there is evidence that job search behavior is indirectly related to employment quality. Saks and Ashforth found that job search behavior was indirectly related to job and organizational attitudes through a direct relationship with preentry perceptions of P-J and P-O fit. In a related study, they found that preentry fit perceptions mediated the relationship between job information sources and job satisfaction, intentions to quit, and turnover.

6. CONCLUSION

Job search is a major factor in the experience of job loss, turnover, psychological well-being, and (re)employment. Both individual differences and situational factors influence job search behavior, and the nature and scope of one's job search are related to the probability, speed, and quality of employment that one obtains. Given that workers today are expected to experience more than a dozen job transitions during the course of their careers, the need for individuals to have job search skills is

critical for job seekers' continued employment and psychological well-being. Fortunately, the knowledge exists for career counselors to assist job seekers in coping with job loss and finding satisfactory (re)employment.

tertiary prevention The treatment or caregiving intervention to heal a person's strain.

trauma A highly stressful, deeply disturbing, or dramatically unexpected stressful event experienced as traumatic by the individual.

Job stress is the psychophysiological arousal resulting from workplace demands. Optimally, it results in enhanced job performance. When mismanaged, job stress leads to job strain, which includes psychological, medical, and behavioral costs.

GLOSSARY

eustress The healthy, positive, constructive outcome of stressful events and the stress response.

job stress The mind-body arousal resulting from physical and/or psychological stressors associated with a job and work.

preventive stress management An approach and set of principles for promoting eustress and health while preventing strain and dysfunction.

primary prevention The modification, reduction, or management of sources of stress.

secondary prevention The modification, reduction, or management of the individual's stress response.

strain The physiological, psychological, and/or behavioral deviation from an individual's healthy functioning.

stress response The generalized, patterned, unconscious mobilization of the body's natural energy and resources.

stressor A physical or psychological stimulus that causes the individual stress response.

1. INTRODUCTION

Job stress is important for two reasons, one economic and one humanitarian. Direct and indirect organizational costs result from mismanaged job stress. In addition, mismanaged job stress causes physical and emotional suffering in the workplace. The National Institute for Occupational Safety and Health (NIOSH) identified job stress and psychological disorders among the top 10 occupational health hazards in the United States and the American Institute of Stress determined that job stress reached epidemic proportions in the by the end of the 1990s. When life expectancy at birth is used as the standard, Americans are passing the stress test. However, although Americans are living longer, they are suffering more. Anxiety disorders affect one in every six people in

the United States and one in every five employed people in the United Kingdom. In 2001, 35% of Americans reported that jobs were harming their physical and emotional health. Layoffs and downsizing during the 1990s had adverse effects on employee, managerial, and executive stress. Translated literally from the Greek, epidemic means "upon the people." Epidemiology is the basic science and fundamental practice of public health and preventive medicine. Treatment alone is rarely effective in the management of epidemics. Prevention is the preferred mode of epidemic management.

2. CAUSES OF JOB STRESS

Job stress is caused by demands within the work environment or by contextual or nonwork demands. The major categories of job stressors are physical demands, task demands, role demands, and interpersonal demands. In addition, extraorganizational stressors (e.g., marital discord) and transitional factors (e.g., preparing for retirement) can have spillover effects into the workplace, in part through role conflicts. Understanding an individual's stress and strain requires examining the entire life experience (i.e., work plus nonwork).

Physical stressors vary by occupation and working environment. Extreme work conditions, such as in tropical or arctic work environments, are a source of physical stress, as are strenuous working conditions, such as in industrial construction or steel making. Business travel is a major physical stressor for those who must engage in this activity.

Task stressors include a wide range of job content and job context factors. Work overload, time pressure, and changing tasks or activities are among the greatest sources of job stress for people in many occupations and organizations. Four other task-related sources of job stress are lack of control, career progress, future job uncertainty, and new technologies. Lack of control and lack of decision latitude are major contributors to job strain, especially when work demands are very high for a particular job. Blocked career progress leads to strain from frustration of natural achievement drive and ambition, whereas future job uncertainty creates strain from the anxiety of job loss. New technologies cause job stress due to the requirement for developing one's abilities and learning new skills.

Role stressors are among the best understood sources of job stress. The two major categories of roles stressors are role conflict and role ambiguity. Role conflict may emerge in a variety of ways. Interrole conflict occurs

when the expectations of different roles (e.g., the role of employee and the role of wife) are in conflict with each other. Intrarole conflict occurs when the expectations from different role senders (e.g., one's supervisor and one's colleague) are in conflict with each other. A variation of intrarole conflict occurs when one role sender, such as one's supervisor, sends conflicting expectations. Person-role conflict occurs when one's personal beliefs or values are in conflict with the expectations of one's job. Role ambiguity occurs in several forms. Ambiguity may arise when it is unclear what the consequences might be for failure to meet others' expectations, or it may arise as to exactly what others' expectations really are or what they really mean.

Interpersonal stressors are somewhat broader and more personal than role stressors. Leadership styles, abrasive personalities, organizational politics, poor diversity management, and sexual harassment give rise to interpersonal stress on the job. The two most stressful leadership styles for people at work are rigid, autocratic leadership behaviors and *laissez-faire*, or very passive, leadership behaviors. Abrasive personalities can be the source of intense interpersonal stress and emotional pain on the job. Organizational politics is a source of job stress, with some research showing that it has a greater adverse impact on women than men. Poor diversity management leads to job stress for the minority worker who feels there are unequal workplace barriers to success. Sexual harassment is a major job stressor, most often for women. In addition to being significant interpersonal stressors, diversity issues and sexual harassment can lead to tens of millions of dollars in legal costs and settlements.

Nonwork stressors, such as marital and family expectations, child-rearing responsibilities, and parental care, create role conflicts for people on the job and have spillover effects into the work environment. Traumatic events outside of the workplace, such as the loss of loved ones or the reality of terrorism and war, also may have spillover effects into the workplace, thus magnifying any job stress for the individual.

3. CONSEQUENCES OF JOB STRESS

The two broad categories of job stress consequences are functional (eustress, or healthy stress) and dysfunctional (strain). The former includes both health and performance benefits. The health benefits of well-managed job stress include enhanced focus during peak work activities and workplace emergencies, as well as

cardiovascular efficiency from aerobic fitness. The performance benefits include enhanced activity level and arousal with their accompanying bursts of physical strength and peak performance. The state of active engagement in meaningful work that produces eustress represents the healthy side of stress consequences. Workers who experience eustress can translate their experience into benefits for the organization, including productivity, organizational agility, and efficiency.

The dysfunctional consequences of job stress are individual and organizational strain. Because job stress triggers a systemic response within individuals and organizations, individual and organizational strain may manifest in a wide variety of ways. Job strain's manifestation is importantly influenced by the particular vulnerability of the individual or weak link in the organization. This is commonly called the Achilles' heel phenomenon or weak organ hypothesis. Some individuals, for example, tend to respond to stress via the respiratory system. They may find that their allergies worsen during periods of high stress. In some organizations, the weak link may be ethical behavior, with more unethical actions occurring during periods of high stress. For both individuals and organizations, it is at the point of the Achilles' heel that many strain symptoms emerge.

Individual strain can take the form of psychological disorders, medical illnesses, and/or behavior problems. Anxiety and depression are two of the more common psychological consequences of strain. Individuals may also experience family problems and sleep disturbances related to work strain. Within the services sector, individuals are particularly prone to burnout, another psychological consequence. Among the medical consequences of strain are heart disease and stroke, cancer, diabetes mellitus, and emerging diseases such as HIV and chronic fatigue syndrome. Behavioral consequences include tobacco and alcohol abuse, eating disorders, and violence.

Because of the exchange relationship between employees and organizations, the consequences of strain for employees translate into costs for the organization. Organizational strain can take the form of direct costs and/or indirect costs. Direct costs include strikes and work stoppages, declining quality and quantity of performance, compensation awards, and increased health care costs. Among the indirect costs of distress are employee dissatisfaction, communication breakdowns, faulty decision making, and diminished quality of work relationships.

4. MODIFIERS OF THE STRESS RESPONSE

The stress response is the psychophysiological pattern that results when an individual is exposed to stressors. The stress response pattern is universal; the intensity, frequency, and consequences of the stress response are not. The ways in which the stress response is exhibited in any individual are moderated by individual and interpersonal factors, including interpersonal communication abilities, personality differences, emotional intelligence, and gender differences. The interaction of these variables with the stress response determines whether the stressor results in positive outcomes (eustress) or negative outcomes (strain). Although many of these moderators are inherent traits, most can also be consciously changed through prevention efforts.

Poor interpersonal communication has been cited as one of the precursors to strain. Therefore, an individual's ability to effectively communicate when faced with stressors can positively influence the outcomes of the stress. Interpersonal communication can be in the form of effective management of difficult work situations, people, or role conflicts. It can also involve effective use of communication forums to gain social support and to positively funnel stress-induced emotions. Effective interpersonal communication skills are in some cases inherent skills related to personality variables, but they can also be acquired through active learning of productive communication processes.

Personality differences also modify the individual's response to stressors and the consequences of the individual's response. Personality affects the person's perception or appraisal of a specific situation as stressful and also affects the person's response to the perceived stressor. Although multiple personality traits influence the stress response, the most often cited is Friedman and Rosenman's type A vs type B behavior patterns. Research has consistently shown that type A individuals exhibit more distress than their type B counterparts. The type A individual's high-intensity work level, incessant need for achievement, inability to relax, and general tendency to lack a balanced life approach result in both a higher number of situations being perceived as stressful and poor coping responses when stressors occur. Another perspective on personality and stress is illustrated by the Myers-Briggs Type Indicator. This popular measurement tool for personality traits depicts a combination of traits that describe how a

person perceives the world, processes information, and makes decisions. The individual's personality type explains why one person who is comfortable with less structure, independent work, and frequent changes may have a more positive response to an organization in flux than an individual who prefers structure, stability, and has a strong need for closure. Two other personality variables linked to the stress response are hardiness and self-reliance. Hardiness is defined as responding to stressful situations with commitment (vs alienation), control (vs powerlessness), and challenge (vs threat). Self-reliance is defined as the ability to form and maintain multiple healthy and mutually supportive interpersonal attachments that are used appropriately to deal with stressors. Some personality traits may be malleable, such as "learned optimism," and thus can be developed in order to help individuals manage stress more effectively.

Emotional intelligence (EI) includes a set of competencies that refer directly to the way an individual deals with emotions, a key determinant of how they also deal with stress. The components of EI include the abilities to be self-aware of emotions, to express them appropriately, to judge sincere vs insincere expressions of emotions, to distinguish and prioritize different emotions, and to assess problems from multiple emotional perspectives. EI components also include the ability to understand complex dual emotions and natural transitions from one emotion, such as fear, to another, such as anger or hostility, and to connect or disconnect from an emotion depending on its usefulness to the situation. EI may naturally occur in some individuals, but it can also be improved through targeted learning.

Gender differences also moderate the stress response. Research suggests that the natural response to stressors differs for women from the traditional fight-or-flight pattern. In addition to the fight-or-flight response, women "tend and befriend" in times of high stress. The moderating effects of tend and befriend may explain differences in psychophysiological consequences of stress for men and women. There are also issues related to the conflict between work and family roles that appear to affect women to a larger extent than men.

5. MEASURES OF JOB STRESS

Valid, reliable job stress measurement requires multiple psychological, environmental, and medical measurements. There are four construct categories for

stress instruments: measures of (i) environmental demands and sources of stress; (ii) healthy, normal stress response; (iii) modifiers of the stress response; and (iv) psychological, behavioral, and medical strain. For the purposes of workplace stress measurement, the focus is on four measures that offer a range of construct assessment. For a more clinical assessment of organizational stress, Levinson's classic organizational diagnostic approach may be used.

5.1. Job Stress Survey

Spielberger's Job Stress Survey (JSS) measures job pressure and lack of organizational support as the two primary sources of job stress. The JSS measures the severity and the frequency of 30 different job demands. Examples from the JSS scale items are "excessive paperwork" and "poorly motivated coworkers." Severity and frequency scores are also computed for 10-item job pressure and organizational support subscales that were factor analytically derived from the 30 JSS items. The subscales show adequate internal consistency and reliability.

5.2. NIOSH Generic Job Stress Questionnaire

The Generic Job Stress Questionnaire was developed by NIOSH and contains measures of 13 different job stressors as well as a host of measures of individual distress and modifiers of the stress response. The questionnaire assesses constructs within domains contained in the NIOSH job stress model. Specific stressor, strain, and modifier variable constructs were selected for inclusion in the instrument on the basis of a content analysis of the job stress literature, and the scales selected to measure these constructs were adapted from scales with known reliability and validity. The instrument was designed to be modular in form so that the diagnostician or stress researcher can select individual scales, or the entire instrument can be used.

5.3. Occupational Stress Inventory

The Occupational Stress Inventory (OSI) measures three domains of adjustment: occupational stress, personal strain, and coping resources. Six occupational stress scales measure role overload, role insufficiency, role ambiguity, role boundary, responsibility, and the physical environment. Four personal strain scales

measure vocational strain, psychological and/or emotional problems, interpersonal problems, and physical illnesses. Four coping scales measure recreational activities, self-care, social support, and rational/cognitive coping. Plotting standardized scores on each of the 14 scales produces a “stress profile” for an individual manager or executive, or the scales can be used to develop organizational profiles.

5.4. Pressure Management Indicator

The Pressure Management Indicator (PMI) is a measure developed from the earlier OSI and based on the Cooper and Marshall’s stress model. The PMI is used increasingly as a diagnostic instrument in Europe. It is more reliable, more comprehensive, and shorter than the OSI. The PMI measures sources of pressure, such as workload, relationships, work–home balance, and daily hassles; individual differences, such as type A behavior/drive, locus of control, and social support; and job stress effects, such as job satisfaction, security, mental health, and physical symptoms.

6. EARLY WARNING SIGNS OF STRAIN

From the prevention perspective, it is important to recognize the earliest warning signs of strain in order to intervene early in the process. Worker strain can result following prolonged exposure to stressors when paired with poor response patterns. Pains of unknown origin, fatigue, inability to concentrate, and irritability are early warning signs for individuals. In addition, symptoms of depression, increased anger and hostility, increased accidents, or signs of substance abuse can be clues that interventions are warranted. These early warning signs may be accompanied by increased aggressive behavior, disrespect, and withdrawal from relationships.

For organizations, early warning signs that normal work stressors are leading to strain include general patterns such as slight changes in productivity with decreased quantity and/or quality of work, increased absenteeism, decreased commitment to the organization, poor interpersonal work relationships, increased tardiness, and more conflict among workers. Other early signals of distress include general dissatisfaction, low motivation, and low morale. Increased accident rates and machine breakdowns may also constitute early warn-

ings. There may be a general loss of vitality within the organization and an atmosphere of distrust and animosity.

As with any preventive strategy, early detection of strain can help to reduce the long-term negative consequences. Key to early detection and sound prevention is vigilance on the part of the management team.

7. PREVENTIVE STRESS MANAGEMENT

Prevention is the best public health strategy for any disease epidemic. Because job stress is a health epidemic, prevention holds the best hope for addressing this epidemic. The theory of preventive stress management translates the public health notions of prevention into an organizational context and overlays them on a stress process model as shown in Fig. 1. Stress is one of several chronic organizational health problems—with others being workplace violence, sexual harassment, and suicide—for which prevention is appropriate.

Preventive stress management is an organizational philosophy and set of principles that employs specific

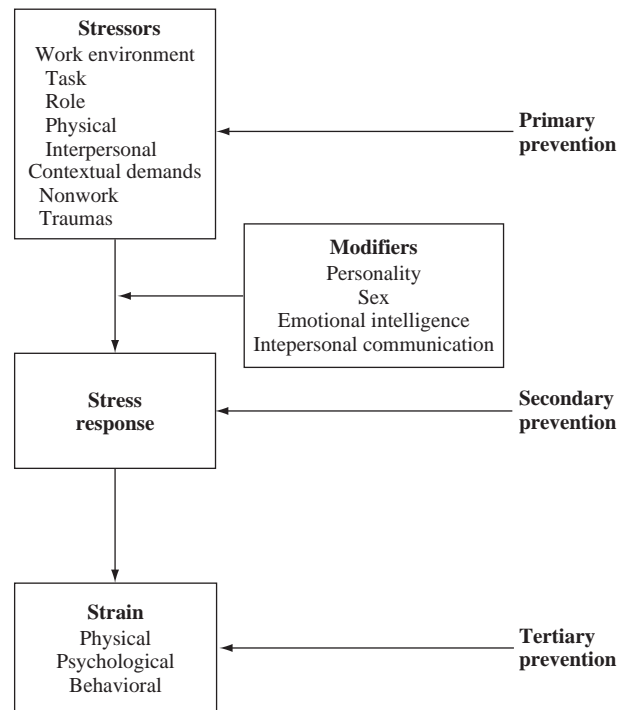

FIGURE 1 Preventive management model for job stress.

methods for promoting individual and organizational health while preventing individual and organizational distress. This philosophy is based on the following five guiding principles that motivate the practice of preventive stress management and provide a framework for healthy organizations and healthy leaders:

Principle 1: Individual and organizational health are interdependent.

Principle 2: Leaders have a responsibility for individual and organizational health.

Principle 3: Individual and organizational distress are not inevitable.

Principle 4: Each individual and organization reacts uniquely to stress.

Principle 5: Organizations are ever-changing, dynamic entities.

Chronic diseases do not arise suddenly; instead, they develop gradually through a progression of disease stages, a “natural life history.” This is true for chronic individual disorders, such as heart disease, as well as for chronic organizational problems, such as workplace violence. The natural history of most diseases is one of evolution from a stage of susceptibility to a stage of early disease and finally to a stage of advanced or disabling disease. At the stage of susceptibility, the individual is healthy but is exposed to certain risk factors or disease precursors. For example, individuals who choose a sedentary life or who choose to smoke cigarettes are at the stage of susceptibility for coronary artery disease as well as several other diseases. When these and other risk factors lead to the development of arteriosclerosis or hardening of the arteries to the heart, the individual is at the stage of early disease or preclinical disease. In other words, the person’s body has responded to the disease precursors, but there are few, if any, symptoms. As the disease advances, it becomes symptomatic or clinical disease. Angina pectoris (heart pains) and heart attacks are advanced manifestations of coronary artery disease.

Preventive stress management is rooted in the public health notions of prevention, which were first used in preventive medicine. The term public health encompasses a broad array of health protection activities inspired by the practice of viewing illnesses within a social context. The dominant diagnostic model in public health involves the interaction between a host (the individual), an agent (health-damaging organism or substance), and the environment. One of the fundamental concepts of preventive medicine is that there is an

opportunity for preventive intervention at each stage in the life history of a disease, as noted previously and depicted in Fig. 1. These interventions are aimed at slowing, stopping, or reversing the progression of disease.

As Fig. 1 shows, there are three stages of prevention strategies: primary prevention, secondary prevention, and tertiary prevention. Primary prevention aims to modify and manage the job stressors and other demands in the work environment. Secondary prevention aims to modify and manage the individual’s response to these job stressors and other demands. Tertiary prevention aims to help and provide aid to those who are experiencing behavioral, psychological, or medical strain symptoms. From a public health perspective, primary prevention is always the preferred point of intervention. For job stress and workplace health, this implies that job redesign efforts and other interventions that alter, modify, or eliminate stressful work conditions are the preferred category of preventive stress management interventions.

Primary prevention is the protection of health directed at the stage of susceptibility and aims to eliminate or reduce the impact of risk factors; it is intervention before the onset of problems or disorders. Primary prevention may be either organizational or individual. Organizational strategies include the following:

- Job redesign
- Participative management
- Flexible work schedules
- Career development
- Design of physical settings

Individual strategies include the following:

- Learned optimism
- Planning and time management
- Social supports and secure attachments
- Maintaining a work–home balance
- Changing type A behavior pattern

It is important to recognize that some primary prevention techniques directly alter stressors. Job redesign, for example, may incorporate more control into a job, or more decision latitude, thereby reducing the stress from lack of control. On the other hand, some primary prevention methods alter the individual’s perception of the stressor. Social support, for example, can help individuals reframe stressors as challenges because they believe they possess the resources to manage a stressor. In both cases, pri-

mary prevention is the preferred first defense against stressors.

Secondary prevention aims at the early detection of problems or disorders and prompt, early interventions to correct departures from health. Secondary prevention may also be either organizational or individual. Organizational strategies aim at improving relationships in the work environment. Organizational strategies include the following:

- Goal setting
- Role analysis
- Team building
- Social supports and secure attachments
- Diversity training and programs

Individual strategies include the following:

- Relaxation training
- Prayer, spirituality, and faith
- Emotional outlets
- Physical fitness and exercise
- Nutrition

Secondary prevention efforts focus on the development of strengths for both individuals and organizations. Team-building efforts, for example, can lead members to understand each other better, manage conflict more effectively, and be more productive. Individual strategies, such as relaxation training, meditation, and exercise, make the body and mind more resilient and more capable of dealing with stress.

Tertiary prevention is prevention of more serious problems, disorders, or death. It is directed at expediting or improving treatment for symptomatic or advanced disease and aims to alleviate discomfort and restore effective functioning. Tertiary prevention is primarily focused at the individual level rather than the organizational level, as is done in treating mental health referrals. Tertiary prevention also includes psychological counseling and medical or surgical treatment. Individual strategies include the following:

- Individual psychotherapy
- Behavior therapy
- Medical care and treatment
- Traumatic event debriefings
- Physical therapy

Tertiary prevention is thus focused on procuring care from qualified professionals who can help

individuals heal. The goal of the preventive stress management approach is to utilize sufficient primary and secondary prevention such that individuals seldom, if ever, need to turn to tertiary prevention for relief.

8. IMPLICATIONS FOR EXECUTIVES AND LEADERS

Job and work stress, as a component of the contemporary organization, do not show signs of decreasing in frequency, intensity, complexity, or outcomes. Effective management of organization and worker stress by executives and leaders begins with the effective management of their own stress. Learning preventive stress management can benefit the individual leader and positively affect stress management throughout the organization. As the workforce continues to change with increased globalization, diversity, and age variation, effective leaders must learn better ways to deal with the inevitable stressors of the workplace. Future leaders may very well set themselves apart by developing the stress prevention skills needed to move the response to stress in a positive direction so that individuals and organizations can reap the benefits of eustress and avoid the pitfalls of strain.

The key tasks for managers and executives are clear. Within the preventive stress management framework, the goal is to increase eustress—the healthy, positive consequence of stress—and to prevent or resolve distress. The three-tiered model presented in Fig. 1 can be used as a road map for these prevention efforts. Primary prevention represents the most efficacious set of techniques because it consists of modifying the stressor or the individual's response to the stressor. Secondary prevention efforts, focused on increasing individual and organizational resilience, should supplement primary prevention methods. Finally, tertiary prevention methods are available for targeting symptoms and healing the wounded within organizations.

Increasing eustress within organizations presents a challenge to managers and to researchers, who are beginning to identify the aspects of work that many employees find pleasurable and motivating. The feeling of eustress has been described as being in the “flow,” similar to a “runner's high” in which time suspends and the person is fully absorbed in the joy of work. It is a state of active engagement, zest, and achievement. Eustress is characterized by feelings of hope,

commitment, and meaningfulness of work. Managers and executives must explore ways to design jobs that tap this positive experience for employees. Managers should also find opportunities to improve policies, procedures, and the physical work environment in an effort to enhance employees' exposure to work that they find engaging and to eliminate potential barriers to eustress.

Executives are vulnerable to the same medical, psychological, and behavioral consequences that affect any workers. They are at increased risk for isolation and loneliness, anxiety, burnout, workaholism, and depression. Their positions in organizations place them as role models whom others look to for guidance regarding effective stress management. Because of their positions, they can model effective prevention efforts that others can follow, thus benefiting the entire organization. By taking a holistic view of health and developing its multiple dimensions (physical, psychological, spiritual, and ethical), executives can lead the way in tapping into the benefits of eustress and possessing the strength and security to effectively manage distress.

Because job stress leads to a systemic response both within the organization and within the individual, executives and workers alike can benefit from strengthening themselves through physical fitness, psychological well-being, spiritual development, and strong character. Physical fitness includes cardiovascular well-being, muscular flexibility, and appropriate muscular strength. Psychological well-being centers on the ability to deal constructively with reality, the capacity to adapt to change, relative freedom from tension or anxiety-related symptoms, and the capacity to love. Spiritual development should not be confused with religious affiliation and is characterized by hope, a sense of purpose, and healthy relationships. Finally, strong character is achieved through ethical behavior and positive personal integrity.

In addition, executives can be proactive in creating healthy work environments in which job stress is optimized, rather than either maximized or minimized. High-performance, healthy work environments are ones characterized by a sense of challenge coupled with a sense of psychological safety and security. Healthy job stress leads to a work environment in which people may produce, serve, grow, and be valued.

Future areas of study in work and job stress include exploration of the individual differences in the stress response and how to incorporate the positive traits into effective stress prevention. Training in skills shown to increase the positive outcomes of stress and reduce strain needs to be incorporated into educational

programs at an early stage and throughout an individual's work life. Finally, shifting the perception of job stress to a neutral construct is both necessary and inevitable. The human response to stress, not the stress itself, determines whether negative or positive outcomes prevail.

(strain). Contemporary definitions of stress view it as relational, resulting from the transaction between the individual and the environment. This approach has provided an opportunity to consider those processes that link the individual to the environment. The shift in emphasis away from the different components of the stress process to the process itself has raised a number of issues in terms of how measurement practices should develop and how researchers fulfill their obligations to those whose working lives they study.

GLOSSARY

appraisal The processes an individual goes through in determining the significance and meaning of a stressor (primary appraisal) and what resources are available to cope (secondary appraisal).

strain Responses that indicate that the individual is under stress.

stress management programs Interventions at the level of the individual and organization aimed at reducing stress and allowing the individual to fully contribute to the goals of the organization.

stressors Situations or properties of a situation that have the potential to cause stress.

Job stress has traditionally been defined in terms of a stimulus, response, or an interaction between the two. These approaches to defining job stress have allowed researchers to identify an array of different causes of job stress (stressors) and relate them to different responses

1. INTRODUCTION

The growing awareness of the impact of job stress is best illustrated by the sheer increase in the volume of job stress research in recent years. Job stress is a condition familiar to many. In some form or another, it influences all working lives, leaving those who experience job stress emotionally drained and frequently more vulnerable to other illnesses and disease. It is not just individuals who experience the impact of job stress. Organizations, families, communities, and society all bear the costs of job stress to such an extent that job stress is frequently viewed as an inevitable feature of 21st-century living. However, when sifting through all the information on job stress it is important to maintain a sense of perspective. It is necessary to guard against feeling that the problem of job stress has been overexaggerated, that it is not worth worrying about, or that it is someone else's responsibility. The

issue is not whether there is too much or too little stress in our working lives but what actually causes job stress, what can be done to cope with it, and what needs to be done to provide a working environment within which individuals can maximize their potential and enhance their well-being. This is the responsibility that job stress researchers have to those whose working lives they study.

2. DEFINING JOB STRESS

The difficulty when talking about job stress is that it means different things to different people, with the result that the term stress has taken on a variety of meanings. Traditionally, stress research has been influenced and guided by definitions that focus on stress as a stimulus, a response, or on the interaction between the two. These three approaches to defining stress frequently reflect the discipline or orientation of researchers. Stress as a stimulus is defined in terms of those events or properties of events that place demands on an individual over and above what is normal. Response definitions of stress are concerned with identifying particular responses or patterns of responses that indicate that the individual is confronted with a demanding event. Stimulus and response definitions of stress have provided researchers with an opportunity to identify both a range of events that have demanding properties and responses that indicate that the individual is under stress. However, such definitions have been criticized because each reflects just one aspect of the stress process; defining stress in this way fails to provide any understanding of the nature of the stress process. They have also been criticized because they fail to take into account individual differences and therefore cannot account for the fact that what may be stressful for one individual may not be stressful for another.

Interactional definitions of stress tried to overcome these difficulties by describing stress in terms of the interaction between the stimulus and the response. This definition is one in which a relationship, usually correlational, is hypothesized between the stimulus and the response. Cooper *et al.* argue that defining stress like this, where the focus is simply on the interaction between the stimulus and the response, fails to provide any understanding of the complexity of the interaction or of the nature of the processes that may be involved. As a consequence of the difficulties associated with stimulus, response, and interactional

definitions of stress, more contemporary definitions adopt a definitional approach described by Lazarus in which stress is viewed as relational in nature involving some sort of a transaction between the individual and the environment. Transactional definitions of stress imply that stress is neither solely in the individual nor in the environment but in the transaction between the two. It is the transaction that links the individual to the environment. Furthermore, it is by thinking of stress in transactional terms that draws attention to what the nature of the transaction may be. In this way, defining stress in transactional terms achieves what earlier definitions failed to do: It focuses attention on those processes that link the individual and the environment and that are at the heart of the transaction.

Lazarus describes these processes as primary and secondary appraisal. Primary appraisal is when the individual evaluates the importance of the event in terms of harm, threat, or challenge to well-being. In short, it is the realization by the individual that something important is at stake. Secondary appraisal is when the individual considers what can be done. It involves an evaluation of those resources that are available to cope with the stressful event. Identifying the processes that are at the heart of a stressful transaction in terms of how an event is appraised and how it can be coped with means that contemporary definitions of stress are more concerned with capturing its transactional qualities than focusing, as was once the tradition, on individual components to that transaction. As a result, stress is best defined in terms of those encounters in which the demands from the encounters are appraised as taxing the individual's resources, thus threatening well-being.

3. MODELS OF JOB STRESS

Models of job stress have, quite naturally, closely followed how stress has been defined. Early models of job stress followed an interactional framework. That is, they were interested in the interaction between the cause of job stress (stimulus) and its impact (response). As outlined, the interactional framework suggests a relationship between the perceived presence of demanding work conditions (stressors) and different stress responses (strain). The relationship, usually correlational, postulated that the more demanding the stressor, the greater the probability it would result in strain. As job stress researchers began to explore different relationships between stressors

and strains, they soon realized that the stressor–strain relationship may be influenced by other variables, such as age, gender, organizational level, and individual differences. Therefore, a second stage in the development of job stress models began. This stage is described as the moderator stage and was concerned with identifying organizational and individual variables that moderate (influence) the stressor–strain relationship.

The interactional and moderator models, although important in providing information on the causes and consequences of job stress and on variables that influenced the relationship between the two, were limited in their ability to explain the stress process. So began in the development of job stress models the transactional stage. Transactional models, like transactional definitions of job stress, were concerned with the sequence of events and the processes that linked the stressor to the strain. McGrath had for some time urged researchers to approach the investigation of job stress by developing models of job stress that mirrored the sequencing of events from stressor to strain. To capture this sequence, many models of job stress adopted the concept of fit. The idea of fit was coupled with the idea of equilibrium or balance. In general, where there was a misfit or imbalance between the person and the environment, such as in the case of a person failing to cope with the demands of a job, a state of disequilibrium would exist and this state would be associated with strain. Implicit in the concept of misfit is the notion of an individual's ability to manage or deal with a demanding job event.

As job stress researchers began to explore the nature of this misfit, models of job stress began to outline more explicitly what misfit may involve. Job stress models began to build into their frameworks different transactional qualities, such as how stressors are appraised, how individuals cope, and organizational and individual resources available to individuals to manage the demanding encounter. What distinguishes the transactional model from the earlier interactional and moderator models is its focus on process. It requires researchers to identify the processes that link the individual to the environment and to consider the sequencing of those processes and their role over time. However, although job stress researchers have long accepted at the theoretical level the importance of identifying process elements in job stress models, empirical work is predominately still being carried out using a interactional–moderator perspective. Nevertheless, job stress research has contributed much to our

understanding of its causes and consequences, not at times without controversy and intense debate.

4. CAUSES OF JOB STRESS

The causes of job stress are many and varied. Perhaps the easiest way to develop a comprehensive picture of what causes job stress is to start with the early work of Kahn and colleagues and two causes of work stress: role conflict and role ambiguity. These two work role demands along with role overload have become the most frequently researched causes of job stress. In general, role conflict refers to job situations in which individuals are confronted with conflicting demands while performing their organizational role so that by complying with one of the demands it is very difficult to comply with the other(s). Role conflict frequently arose from having to work under policies that conflicted with one another, being responsible for tasks over which there was very little control, and having to do things that were likely to be accepted by one person but not accepted by another. Perceived role conflict led many to experience dissatisfaction and strain. Similar findings have been found for role ambiguity. In the case of role ambiguity, the significant issue was a lack of information. Individuals experiencing role ambiguity more often than not found that they lacked the relevant information to perform their work roles, determine how their performance was being judged, and consider whether the decisions they made were the right ones. Role ambiguity was consistently associated with levels of psychological strain.

A third form of difficulty associated with performing one's role in the organization was role overload. Role overload was first measured in terms of the demands that arose from the volume of work that had to be done. Frequently associated with time pressures, this type of role overload became known as quantitative overload and was measured in terms of the amount of work to be done in the available time, the idea that all tasks have a sense of urgency, not being able to do the work because of constant interruptions, and the belief that no matter how much work was done there was still as much to be done at the end of the day as there was at the beginning. As organizational roles became more complex, role overload took on a second dimension. This type of role overload was described in terms of qualitative role overload and referred to demands on individuals required to ensure that their skills matched the increasing requirements of the job. This form of

role overload was concerned with the need to keep up with the technical requirements of the job, having to spend increasingly more time learning new policies and procedures, keeping up with constant job changes, and sensing that at times there was an imbalance between current skills and required skills. Both these forms of role overload had negative consequences in terms of well-being and satisfaction on those who perceived them to be present in their jobs.

The importance of discussing these types of role demands in such detail is that even though they were first identified in the 1960s, they are—despite the significant social, economic, political, and organizational changes that have occurred since that time—still by far the most frequently measured causes of job stress. Other causes of job stress have been identified, and it is worth exploring these as well. In addition to organizational roles, in 1976 Cooper and Marshall identified a range of different causes of job stress, including extrinsic aspects of the job, such as working conditions and job design; structure and climate issues, such as levels of participation, supports, controls, and rules and regulations; career development issues, such as promotion, job security, and goal achievement; and relationship issues involving, for example, subordinates, colleagues, and the boss, and difficulties in delegating and dealing with sensitive interpersonal issues.

Cooper and Marshall also included “extraorganizational sources of stress” in their list of causes of job stress. These sources relate to the home–work interface and include balancing family and work responsibilities; family problems; financial and other life difficulties; and the interference of work with nonwork activities, such as leisure, hobbies, community life, and social activities. Other sources of job stress include the level of local and international travel, working abroad, life-threatening events and safety at work, redundancy, bullying, harassment, social responsibility, and ethics. Beehr also provided a similar list of the causes of job stress.

Although a wide range of events, usually defined as stressors, can be identified as having the potential for causing job stress, there has been considerable debate about how best to measure such stressors. The common approach has been to use self-report measures in which individuals generally indicate on a 5-point scale whether they agree or disagree as to the presence of different stressors in their job. The major criticism of this approach is that simply agreeing or disagreeing that a stressor is present in a job does not actually

indicate how demanding that stressor may be or its significance in terms of well-being or complexity. As a consequence, a number of refinements to self-report measures have been suggested. First, there has been discussion as to whether stressors should be measured globally, allowing comparisons to be made across different occupational groups, or tailored to meet the requirements of specific occupations so that the unique stressors for that occupation can be identified. This discussion, particularly in relation to global measures, often spills over into what events should be measured. That is, have job stress researchers, by focusing too much on organizational role stressors, overemphasized the presence of these work role events and ignored the significance of other events, particularly those that reflect the enormous change that has occurred in society and organizations?

Second, when measuring stressors should more attention be paid to the characteristics of the stressors? This would include measuring the frequency, duration, and intensity of the event; how demanding it is; and the way in which different events may result in the accumulation of stress. Then, thinking of stress in transactional terms, there is a need to consider the difference between the presence of an event and its significance and meaning. Here, the emphasis shifts to determining how an event is interpreted or appraised. This means developing measures that capture the meanings individuals give to the event. In this way, the focus would be on whether the event is appraised in terms of, for example, harm/loss and threat or challenge. Focusing on the meaning and salience of an event may be a more significant predictor of job stress than the more traditional measurement approach that simply captures whether the event is present in the job. Of course, focusing on the meanings that individuals give to events raises the issue of subjective versus objective measurement and the fact that objective measures are also an important component contributing to our understanding of the causes of job stress.

Debating how to refine self-report measures of stressors is one way of capturing the complexity and character of different stressors. However, as Cooper *et al.* suggest, there are other more qualitative ways of measurement that should not be overlooked, including the use of critical incident techniques, daily diaries, and structured interviews. These measurement strategies allow stressors to emerge from the narrative allowing individuals to identify the significant events in their working lives. Whatever measurement method is selected, it is clear that identifying stressors is a crucial

part of furthering our understanding of the stress process and in considering the development of different interventions strategies.

5. COPING WITH JOB STRESS

When stress is defined in transactional terms, coping is fundamental to our understanding of the stress process. Coping is part of what Lazarus describes as secondary appraisal. Secondary appraisal is concerned with “what can be done” to deal with the demanding situation and involves identifying and evaluating the available coping resources. Secondary appraisal therefore involves what a person actually thinks and does; thus, as Dewe *et al.* suggest, coping can be defined as “the cognitions and behaviors, adopted by the individual following the recognition of a stressful encounter, that are in some way designed to deal with that encounter or its consequences.” From their review of the coping literature, Dewe *et al.* suggest that it is possible to identify three themes associated with defining coping in this way: Coping is (i) relational in the sense that it reflects the relationship between the individual and the environment, (ii) process focused, and (iii) integrative in that it is part of the appraisal process that links the different dimensions to the stress process.

The most common approach to researching coping in relation to job stress is what Cox describes as taxonomic, where researchers describe and categorize different coping actions that appear broadly applicable to work situations. By far the most popular schema for classifying coping strategies distinguishes between what Lazarus and Folkman describe as problem-focused and emotion-focused strategies. Problem-focused strategies are primarily concerned with problem solving or altering the source of the problem, whereas emotion-focused strategies are aimed at reducing the emotional discomfort. This is not the only schema for classifying coping strategies. In general, however, most classification attempts describe variations on the problem- and emotion-focused themes. Nevertheless, O'Brien and DeLongis suggest that any classification of coping strategies should include what they describe as relationship-focused coping. They argue that it is important to recognize that coping requires, in addition to problem solving and emotional management, relationship maintenance, and that coping classifications should be expanded to include this type of coping. From their more detailed examination of coping functions, Ferguson and Cox suggest that

there is a degree of consensus among researchers that there may be four qualitatively distinct coping types: emotional regulation (dealing with the emotional consequences of the problem), approach behaviors (aimed at directly confronting the problem), reappraisal (strategies for readjusting and reinterpreting the meaning of the event), and avoidance behaviors (ignoring the existence of the event).

Classifying coping strategies into different categories such as problem- and emotion-focused should not be regarded as indicating that one form of coping is better than another. Placing different strategies into one or another category is not the same as understanding how they work or the manner in which they are used. Researchers have come to realize that, when considered in the context of a particular stressful encounter, what function a coping strategy may be performing is not as easy as to define as independently describing the focus of separately derived categories. Dewe noted that researchers have commented on the fact that the same coping strategy may play a number of different functions depending on the particular encounter. Similarly, the sequencing, patterning, and combined use of different coping strategies all contribute to the difficulties of determining whether a coping strategy is problem- or emotion-focused.

Despite these difficulties, coping research has expanded to explore the influence of personality and gender on the use of different coping strategies, the categories of coping strategies associated with different work stressors, the relationship between different categories of coping and different outcomes, the role of different coping types over the longer term, the nature of the organizational culture and climate and its impact on the use of different coping strategies, and the role of coping as a mediator or moderator in the stress process. Many studies have, somewhat implicitly, drawn attention to the question of coping effectiveness. Regarding the issue of how to determine coping effectiveness, the following question needs to be answered: Effectiveness for whom and at what cost? This has led researchers, when faced with the question of how to establish coping effectiveness, to identify a range of issues that need to be considered, including the need to distinguish between coping and ordinary everyday adapting; short-term versus long-term effectiveness; the difference between effort and effect; the individual's competency to use different coping strategies; the goals an individual may be trying to achieve; the nature of the encounter, particularly in terms of the levels of control an individual may have; and the goodness of fit between how an event is appraised and the coping strategy used.

In addition to the work on identifying specific coping strategies that individuals may use, classifying them, and evaluating their use, research has also focused on “capacity techniques” for coping with job stress. These strategies are not so much designed to deal specifically with a stressful encounter as to develop a person’s capacity to deal with a stressful encounter should it occur. This is often done in a number of ways—exercise, relaxation, meditation, biofeedback, and a philosophy of life—but the end result is to provide an inner sense of energy and well-being and a greater sensitivity to the signals our bodies may send us and thus a greater capacity for dealing with and building resistance to stressful encounters. Moreover, these techniques are frequently discussed in terms of lifestyle changes, how they can play a supportive role in conjunction with more specific coping strategies and so become part of a repertoire of coping activities, how they depend to a considerable degree on individual commitment and preference, and how each technique should be reviewed occasionally so that the intended results continue to be positive.

Many of the issues discussed previously, in terms of both classifying coping strategies and determining their effectiveness, have led researchers to consider how best coping strategies should be measured. Again, researchers have considered changes to self-report coping instruments, including considering the type of instructions given so as to differentiate between what individuals may generally use and what they specifically use in a particular situation, the way in which coping strategies are worded so as to avoid ambiguity in meaning, and whether scoring coping strategies in terms of the frequency with which they are used best captures the nature of the coping process. The general consensus from the debate on coping measurement is that identifying circumstances that perhaps best suit the use of coping checklists will provide researchers with the opportunity to bring other more qualitative techniques to the study of coping so that our understanding can continue to develop.

6. BURNOUT

Cooper *et al.* describe burnout as “a special form of strain.” These authors point to the concept of burnout as reflecting a state of psychological strain initially associated with those working in the human service professions. Since the early studies on burnout, researchers have extended their investigations of the

phenomenon to working life in general, considering in detail the consequences of burnout for individuals and their organizations. In the early 1980s, Maslach provided a description of burnout involving three major elements: emotional exhaustion described in terms of not having the emotional energy to sufficiently manage the encounter; depersonalization, in which individuals simply become seen as objects and are treated in a detached way; and a lack of personal accomplishment, in which the tendency is to devalue performance in negative ways. Since this three-dimensional view of burnout was first proposed by Maslach, much discussion has centered on whether emotional exhaustion is the essential feature of burnout, with the roles played by the other two dimensions being disputed.

Cordes *et al.* describe burnout as a developmental process. These authors go on to describe burnout as a gradual eroding process and note that by emphasizing the process of burnout, researchers and organizations are provided with a mechanism for understanding what to look for and the types of interventions that may be necessary. Their work supports a process in which the onset of burnout is marked by emotional exhaustion. Depersonalization follows, as Ashforth and Lee suggest, because it is a “means (albeit futile) of staunching the flow of emotional energy, of coping with growing exhaustion.” The issue of whether, as depersonalization occurs, the individual begins to sense a loss of accomplishment and hence a degrading of achievements is less clear. Cordes *et al.* note that one possible reason for this is that a lack of personal accomplishment may also be explained in terms of a range of constraining organizational factors and hence depersonalization may develop somewhat independently of the other two dimensions.

Correlates of burnout are many and varied, and researchers have explored these at a number of levels, including the individual level (e.g., gender, age, commitment, and individual differences), the job level (e.g., work role demands, client relationships, and autonomy), and the organizational level (e.g., organizational culture, management style, and communications). In general, it is clear that a range of individual, job, and organizational level factors influence the experience of burnout. However, it is also clear that more work is still needed to understand where in the process these different factors have their most significant effect, how far their effect can be generalized, and what this means in terms of the development of intervention strategies.

7. OTHER JOB STRESS RESPONSES

The fact that “being under stress” has become such a common phrase has meant that an array of responses (strains) have been measured as indicating that an individual is stressed. The general approach to outlining job-related stress or strain is to divide the different strains into three categories: physiological, psychological, and behavioral. Reviews of physiological indicators used to measure strain would include measures that capture cardiac, biochemical, and gastrointestinal activity. Under the heading of “poor physical health” associated with job stressors, Kahn and Byosiere list increased pulse rate, high blood pressure, high cholesterol levels, ulcers, and cardiovascular heart disease. Physiological indicators may also include, as Jex and Beehr suggest, behaviors that are closely associated with disease, such as smoking and drinking. The use of physiological measures presents researchers with a range of measurement challenges. However, evidence suggests that the demands of the job can produce physiological reactions and so this approach to measurement offers what Cooper *et al.* describe as important causal pathways with considerable explanatory potential.

Not surprisingly, as Jex and Beehr note, psychological strains are by far the most common type of strain measured. To give an idea of the range of psychological strains measured, these authors list strains from recent studies such as depression, alienation, boredom, frustration, anxiety, hostility, and dissatisfaction. All are correlates of job-related stressors. Similarly, Kahn and Byosiere, in their table of “psychological responses to work stress,” identify 43 different strains, including in addition to those noted previously, confusion, irritation, resentment, tension, and emotional arousal. Kahn and Byosiere conclude that the psychological effects of job stressors are “real, painful, and costly.” Moreover, they extend to health behavior, job performance, and the enactment of other life roles.

Jex and Beehr note that behavioral strains are the least studied. They discuss two broad categories of behavioral strain: organizationally relevant behaviors (e.g., job performance, absenteeism, and turnover) and individually relevant behaviors (e.g., smoking, drinking, and substance use). Similarly, Kahn and Byosiere identify degradation/disruption of the work role, aggressive behavior at work, flight from the job, degradation/disruption of other life roles, and self-damaging behaviors. Both sets of authors agree that behavioral

effects both on and off the job are extremely costly to both the individual and the organization and warrant more research. Such behaviors are the result of a complex process, and researchers need to try to develop an understanding of the process and the role that job stressors play in it.

Although different emotional responses are included among the list of psychological strains, there is growing acceptance that more attention should be paid to workplace emotions. If, as Lazarus suggests, stress is essentially about emotional reactions, then exploring the specific role of emotions in the stress process may help to provide a richer understanding of what happens to a person in a stressful encounter. Lazarus explains that it is the way an event is appraised that gives that event its emotional quality. Taking this one step further, Lazarus suggests that different emotions are associated with particular appraisals, thus providing a causal pathway for investigation. Lazarus identifies 15 different emotions and categorizes them as negative (e.g., anger, shame, envy, and guilt), positive (e.g., pride and relief), and mixed (e.g., hope and gratitude).

8. JOB STRESS INTERVENTIONS

The most common approach to describing stress management programs is to divide them into three categories depending on the level at which the intervention takes place. The first category describes primary interventions aimed at reducing job stressors, including, as Newman and Beehr suggest, strategies for changing organizational characteristics (e.g., organizational restructure and redesigning organizational processes), changing role characteristics (e.g., redefinition of roles, increasing participation in decision making, and reducing ambiguity), and changing task characteristics (e.g., better match of individual abilities with job requirements, provide skill training, and job redesign).

The second category describes secondary interventions. The focus here is on providing stress management training. Secondary interventions are probably the most common job stress interventions and involve a range of techniques, strategies, and skills aimed at equipping individuals to better manage the demands of the job. Newman and Beehr identify four categories of intervention: those aimed at psychological conditions (e.g., planning ahead and realistically assessing one's expectations), those aimed at physical or physiological

conditions (e.g., diet, exercise, and sleep), those aimed at changing one's behavior (e.g., learning relaxation strategies, taking time off, and developing supportive networks), and those aimed at changing one's work environment (e.g., changing to a less demanding job).

The third category describes tertiary interventions, and here the provision is in terms of employee assistance programs (EAPs). Defining EAPs is somewhat problematic because of the array of perceptions and the range of programs. The definition developed by Berridge and Cooper reflects this need to be comprehensive. They define EAPs as

A programmatic intervention associated with the work context, usually at the level of the individual employee, using behavioral science knowledge and methods for control of certain work-related problems that adversely affect job performance, with the objective of enabling the individual to return to making her or his full job contribution and to attaining full functioning in personal life.

The components of an EAP should reflect a preferred model of practice that reflects the needs of the employees, the goals of the organization, and the underlying principle that for both humanitarian and economic reasons rehabilitation is better than replacement. EAPs are generally operated in two modes: in-house provision of the program and the counseling service or externally located EAP and counseling service. Referrals can be through constructive discussion, in which typically the supervisor or manager makes the referral, or through self-referral, in which the employee initiates proceedings. Most EAPs are developed around a systematic set of procedures designed to identify and respond to personal issues that interfere with work performance. These procedures include a needs analysis to determine the nature of the problem; the development of a program of counseling, advice, and assistance depending on the nature of the problem; a procedure for referrals; a protocol outlining ethical issues, including informed consent, confidentiality, and anonymity; follow-up procedures; and a program of evaluation.

Although EAPs have become an established part of many organizational stress management procedures, less attention has been given to evaluating their impact. A number of reasons have been given, including methodological difficulties in relation to collecting and analyzing what is confidential data, establishing appropriate criteria against which success can be gauged, and establishing what is best practice with regard to carrying out evaluative procedures. Although both

qualitative and quantitative criteria have been suggested as criteria for evaluation, the reported findings are mixed. Because of the variety of different programs, it may be best to focus on whether the goals of specific programs have been successful rather than attempt to identify universal criteria that cover all programs.

One of the issues regarding stress management programs is whether many of the programs assume that work environments have the same impact on everyone and therefore many of these programs fall short because they offer only partial solutions, place all responsibility for change on the individual, or fail to take into account the wider organizational structure and context within which behavior takes place. This debate has widened to include discussion about the role that theory should play in the design and development of stress management programs. The thrust of these arguments has been that by viewing stress in transactional terms, stress management programs need to acknowledge that stress does not reside solely in the individual or solely in the environment but in the transaction between the two. In this way, the focus for the design of a stress management program would shift to the relational nature of stress and the need to consider both individual and environmental issues rather than simply placing the responsibility on one. The continuing debate reflects a wider concern held by those researching job stress; that is, what needs to be done in terms of measurement practices and theory development so that we can contribute significantly to those whose working lives we research.

This article discusses trial by jury, including empirical jury research and applications. The use of the jury allows laypersons, rather than legally trained judges, to decide court cases. Critics question whether juries are able to decide cases competently and fairly. Addressing these criticisms, social scientists have examined the influence of individual factors and group variables on the jury decision-making process. Scholars have also studied the effects of jury reforms aimed at improving jury decision making. After summarizing the empirical findings and applied research, the article closes by discussing new directions in research on jury decision making.

GLOSSARY

anonymous jury A jury for which the jurors' names are not revealed to the defendant or to the media. Used most often in high-profile trials or trials with security risks.

evidence-driven deliberation When jurors engage in general discussion of evidence in the case prior to voting, in contrast to verdict-driven deliberation, in which voting typically precedes evidence discussion.

hung jury A case in which the jury cannot agree on one or more verdict outcomes.

jury selection The process by which individual citizens are chosen for the jury.

scientific jury selection The use of scientific techniques by jury consultants to determine the individual demographic and attitudinal characteristics that are linked to views of a case. Techniques include community surveys, mock trials, focus groups, and in-court selection.

story model Theory of juror decision making in which jurors arrange evidence in the form of a narrative or story and match the story to the closest verdict alternative.

voir dire Questioning process during jury selection.

1. INTRODUCTION

Trial by jury, in which citizens from the community hear evidence and decide on a verdict, is an important symbol of democracy. It allows peers, rather than legally trained judges or magistrates, to evaluate cases and reach binding decisions. As a vehicle for injecting lay participation into legal decision making, the jury has broad democratic appeal. Many contemporary legal systems incorporate juries, including those of the United States, Great Britain, Canada, Australia, New Zealand, and more than 40 other nations in Africa, Asia, South America, and the South Pacific. Some newly democratic countries, such as Spain, following the Franco regime, and Russia, after the breakup of the Soviet Union, have recently introduced or reintroduced the jury.

Public participation in the jury system is said to foster numerous important social and political purposes. First, it promotes accurate decision making that reflects community values. Close scrutiny of an individual case allows the jury to consider the specific facts as well as any extenuating circumstances, increasing the likelihood that the verdict will be fair and equitable. It permits citizens to engage in a key governmental function, educating them about the courts and law in the process. Juries also protect individuals against government oppression and provide a check on politically corrupt prosecutors and judges. Juries send signals through their verdicts about the community's standards and expectations. Thus, although juries today decide relatively few cases compared to earlier times, their verdicts remain important.

Although the jury system serves many positive functions, it has been subject to sharp criticism. The jury's competence has been attacked. Are juries able to comprehend the increasingly complex technical and scientific evidence in today's criminal and civil trials? Critics voice doubts concerning the jury's fairness, and express worry that verdicts are tainted with biases and prejudices of various kinds. For example, juries are viewed as overly sympathetic toward injured plaintiffs, yet at the same time as unduly harsh toward corporations and the wealthy. Jurors are described as "bleeding hearts" who acquit guilty defendants. Jurors are seen as too gullible in accepting illegitimate psychological defenses to criminal charges, such as the insanity defense, battered women's syndrome, battered child's syndrome, and post-traumatic stress disorder. In addition, there is also widespread sentiment in the United States that litigation has spiraled out of control, in part because of the promise of excessively generous jury awards to undeserving plaintiffs.

Debates surrounding the jury provide fertile ground for the application of psychological theory and research. Critically examining these debates and criticisms, psychologists have researched a wide range of jury topics, using mock jury simulation experiments, juror interviews, case analysis, and other methodologies. Psychological research on individual cognition, as well as the impact of juror demographic characteristics, attitudes, biases, prejudices, and personalities on verdict preferences and persuasion has uncovered important individual differences. This research has been applied to such areas as pretrial questioning, voir dire, and jury selection. Psychologists have also analyzed jurors' ability to integrate information, their perceptions and comprehension of evidence, and the dynamics of group decision making. Psychologists

have used this research to propose specific jury reforms to trial procedure. In sum, the jury trial is a complex and fascinating institution that has been the site for advances in the field of applied psychology.

2. DECISION MAKING OF INDIVIDUAL JURORS

2.1. Individual Differences among Jurors

Psychological research has found a juror's decision to be the product of a complex set of factors. Not surprisingly, the trial evidence has the greatest impact. The evidence presented at a trial, and its strength and quality, constitute the prime determinants of jury verdicts. That finding has been replicated in both actual and mock jury studies time and again.

Nonetheless, research has also found certain other aspects of the trial that can affect juror judgments. In deciding criminal and civil cases, jurors draw on their life experiences such as crime victimization or physical injury. Jurors' own knowledge is brought to bear as they evaluate evidence in the case. Other factors that potentially impact individual cognition include a juror's social background, character, ideology, attitudes, and values. The nature of the evidence presented at trial, the way that attorneys structure their arguments, and the order in which witnesses testify can also influence evidence assessments.

2.1.1. Impact of Juror Demographic Characteristics

Although the strength of the evidence presented at a trial is the strongest predictor of the jury's verdict, many legal actors continue to believe that the juror's demographic characteristics are critically important. Oftentimes attorneys will exercise their peremptory challenges on the basis of characteristics such as race, ethnicity, occupation, gender, and religious preference. However, psychological research indicates that utilizing juror demographic characteristics is not a particularly useful or reliable method for predicting a prospective juror's propensity to favor one side over the other. The factors of age, gender, or race generally bear no relationship to verdict preferences, or have only slight predictive power. In fact, most individual differences among jurors typically account for only a small proportion of the variance in verdict outcomes. As a result,

eliminating or selecting prospective jurors based upon individual demographic characteristics may have little impact or might even backfire on attorneys.

Jury research on capital punishment is one of the few areas in which demographic variables are consistently related to punishment preferences. Women and racial and ethnic minorities are more likely than men and whites to oppose capital punishment. Even though strong opponents of the death penalty punishment do not sit as capital jurors, race and gender continue to play a role in capital jury decision making. Juries with a greater number of white men, for example, are more likely to recommend a death sentence than juries composed of more women and minorities. A juror's gender is also a reliable predictor in cases of rape and sexual harassment, with women generally giving more credence to the victim's testimony and evidence.

Demographic variables have low predictive ability in most cases. A prospective juror's knowledge, ideologies, beliefs, and experiences appear to be more significant than demographic characteristics in helping to explain why a juror reaches a particular decision.

2.1.2. Role of Juror Attitudes

Attitudes tend to be more reliable predictors of verdicts than demographic characteristics. Jurors' attitudes are influential in shaping their views and judgments of the parties, the attorneys, and the evidence presented at the trial. In turn, these assessments of evidence are related to the juror's verdict choices.

Psychological research on attitudes related to criminal jury trials has identified clusters of crime control and due process views. Those who endorse crime control beliefs and attitudes tend to have greater concern about crime, more distrust of defense attorneys, greater support for the police and prosecution, and more worry about defendants going free because of legal technicalities and illegitimate defenses. Crime control adherents tend to favor the prosecution in criminal trials. In contrast, those whose views reflect more due process concerns, such as worry about false convictions and support for the insanity defense and the exclusionary rule, are more likely to favor the defense. Research has also found a relationship between jurors' attitudes toward capital punishment and their verdicts about guilt or innocence. All else being equal, jurors opposing the death penalty are relatively more likely to favor acquittal than supporters of capital punishment.

In civil jury trials, found mostly in the United States, attitudes also play a role. Civil jurors frequently consider

the plaintiff's claim with skepticism. They often question the severity of the plaintiff's claimed injury, sometimes blaming the plaintiff for the injury. Two psychological phenomena, the belief in a just world and defensive attribution, are linked to victim blame. In order to believe in a just and stable world, those observing an injury may minimize the injury and derogate the victim. To believe otherwise, that an innocent person is suffering, would challenge the prevailing belief that the world is predictable and fair. Psychologists have also theorized that when a victim is severely injured, observers are motivated to distinguish themselves from the victim and the threatening possibility of their own injury by engaging in defensive attribution. Defensive attribution may result in derogating the victim, blaming the victim for the injury, or minimizing the injury.

As for attitudes toward defendants in civil cases, civil jurors hold corporate defendants to a high standard of responsibility, and judge civil liability against this elevated standard. Respondents in several polls were found to have negative views of corporate management, and said they would be unable to be fair and impartial in cases involving tobacco companies and health maintenance organizations. However, whether general attitudes toward such businesses and organizations actually affect jury verdicts has not been established.

Pretrial publicity is another important factor that can help to shape initial views of trial evidence in a case. Exposure to pretrial publicity, particularly certain kinds of publicity such as criminal record information or emotional material, can influence the jury's decision making. Research has shown that negative pretrial publicity works in multiple ways: creating negative initial judgments of the defendant's character, shaping the processing of evidence, and influencing jury deliberations.

2.2. Psychology of Persuasion

The adversary trial is a two-way effort at persuasive communication. Psychologists as well as communication scholars have tested and applied theories of communication to the jury trial context. Expertise and trustworthiness are two dimensions of witnesses that influence how jurors view their credibility. Expertise is influential in creating attitude change, especially when the position advocated by the communicator is quite different from the recipient's initial attitude. Communicators arguing against their vested interests tend to be more persuasive compared to those arguing for their personal benefit; in addition, communicators with persuasive intent are viewed as less trustworthy.

An expert witness who is paid a sizeable amount of money to testify and does this for a living may be viewed by jurors as having low credibility compared to an expert witness who does not make a career from providing expert testimony.

Other factors found to increase persuasiveness include the communicator's attractiveness, similarity, and message comprehensibility. The more attractive the communicator, the more favorably he or she is viewed. Greater similarity to the observers (jurors) also leads to more positive appraisals. When it takes less effort to comprehend a message, individuals are more persuaded and are able to recall the information and arguments in the message to a greater extent. The degree of comprehension can become especially crucial during expert testimony, such as when scientific evidence is being presented. A juror's difficulty in comprehending complex evidence may reduce the juror's recall and hence the testimony's impact.

2.3. Applications

2.3.1. *Voir Dire*

During a typical jury selection, the judge and the attorneys may pose questions to prospective jurors during a period called the *voir dire*, to assess whether jurors can be fair and impartial in the upcoming case. The judge has unlimited ability to remove jurors for cause, if the judge determines that a prospective juror's views, attitudes, experiences, or connections to the parties or the case would make it difficult or impossible for the juror to be fair and impartial. In a number of countries, including the United States, attorneys may also remove a limited number of prospective jurors through peremptory challenges, without providing justification. Psychologists have studied the U.S. *voir dire* process and the effectiveness of attorneys' peremptory challenges. In past years, some attorneys systematically used their peremptory challenges in order to remove racial and ethnic minorities from the jury. The Supreme Court outlawed relying on race or gender in peremptory challenges, yet racial patterns in peremptory challenges persist.

From a psychological perspective, the *voir dire* questioning period is far from an ideal vehicle to assess the existence of bias and prejudice. Often the opportunity to question prospective jurors is severely limited. The questions may be close ended, in which only a yes or no response is called for, rather than open ended, allowing citizens to speak more fully about their views. This problem is compounded by the fact that it is usually clear which response is "right" or socially desirable.

Even if the questioning is more expansive, it relies on jurors themselves to admit their own biases. It is difficult for jurors to become aware of their personal biases and admit them to a high status figure such as the judge.

Some scholars have drawn on psychological theory to propose and support recommendations for reforming the questioning of prospective jurors during the *voir dire* process of jury selection. More expansive *voir dire* should assist attorneys and the courts in their quest for impartiality. Incorporating both close-ended and open-ended questions during pre-trial questioning permits jurors to communicate their views and experiences in their own words, as opposed to answering with the less informative "yes" or "no." An individual rather than a group *voir dire* provides the judge and attorneys with more useful material for exercising challenges. These reforms would likely promote juror candor in disclosing pertinent information and discussing personal private experiences.

2.3.2. *Jury Consulting and Jury Selection*

Jury consulting is one tool used by lawyers to assist in identifying attributes of jurors that may negatively impact a case. Psychologists and other social scientists, operating as jury or trial consultants, have developed various techniques to assist in jury selection, collectively labeled scientific jury selection. Jury consulting is a fast-growing industry, with clients willing to pay large sums of money for this method of trial preparation assistance. It is largely an American phenomenon, employed only rarely in other countries.

Two prime methods used in scientific jury selection are telephone surveys and mock trials. In telephone surveys, members of the public are asked questions about their background characteristics, beliefs, attitudes, and views of the upcoming case. Analysis shows whether significant relationships exist between individual variables and case preferences. Jury consultants use these data to create profiles of favorable and unfavorable jurors.

Mock trials, ranging from the presentation of short statements of the evidence in front of focus groups to elaborate trial simulations, are also employed. Groups of community members observe the mock trial, discuss the evidence, reach a mock jury decision, and answer questions about the strengths and weaknesses of the case. The mock trial tests lay reactions to the evidence within the case and the arguments anticipated by the prosecution and defense. By analyzing mock jurors' reactions, the jury consultant can assist the attorney in preparing opening statements, trial presentation materials, and closing arguments.

Augmenting these methods are pretrial investigation of the jury pool, in-court jury selection assistance, witness preparation, and the use of “shadow juries” during the trial. A shadow jury consists of mock jurors who are chosen to mimic the actual jurors in the trial. They sit in court while the trial is going on, and periodically report their views of the evidence to the lawyers. In sum, research undertaken by jury consultants can assist attorneys in jury selection and the conduct of the trial, or even whether to go forward with a trial.

2.3.2.1. Limitations of Scientific Jury Selection The effectiveness of jury consulting is debatable. It has been argued that there is no convincing empirical evidence of the impact of scientific approaches to jury selection. Predicting jury decisions on the basis of telephone polls and mock juries is an inexact science. Critics point out the many differences between mock juries and real juries, who sit through the entire case, listen to all the evidence presented, hear the arguments by both sides, and have the responsibility for a final verdict. That is imperfectly captured by the empirical techniques that jury consultants employ. Many commentators believe that jury consulting about witness preparation and evidence presentation is likely to have more impact on trial outcomes than suggestions for jury selection.

2.3.2.2. Ethical Issues When scientific jury selection links jurors’ demographic characteristics to trial evidence and arguments, ethical issues surface. First, any peremptory challenges based on the most obvious demographic characteristics, gender and race or ethnicity, contravene the U.S. Supreme Court’s *Batson v. Kentucky* (1986) line of decisions. Categorizing individuals into particular groups based upon how they are predicted to behave or think establishes, enforces, and supports stereotypes and biases. A final ethical concern is related to the fact that scientific approaches to jury selection are expensive. In most cases, only wealthy clients can afford the full range of services. As a result, the disparity between the trial resources of the rich and poor is further aggravated.

3. THE PSYCHOLOGY OF EVIDENCE

3.1. Psychological Models of Juror Decision Making

The critical role of evidence in jury decision making has led to extensive study and debate. Many critics

have charged that jurors misunderstand or incorrectly apply complex evidence in reaching their verdicts. To evaluate the merits of these criticisms, psychological research has examined the different ways that jurors comprehend and organize evidence.

Researchers have identified three distinct models of juror decision making: a Bayesian approach, an information integration model, and the story model. Each attempts to elucidate the process by which jurors interpret, evaluate, and combine evidence to arrive at a final verdict.

3.1.1. Bayesian Models

Bayesian models entail a formal approach to examining jurors’ fact-finding process. This perspective focuses on how jurors update their beliefs about the likelihood of a certain event occurring based on the presentation of new evidence. As new evidence is presented throughout a criminal trial, jurors combine the pieces of evidence together on a single dimension that represents the probability of a defendant’s guilt or innocence. Bayesian theory has been described as the “mental meter” model because it theorizes that jurors adjust their subjective probability of an event occurring as new evidence is presented. However, Bayesian models have been criticized for being too simplistic and for failing to capture the multidimensionality of thought processes during decision making.

3.1.2. Information Integration

The second popular model used to examine how jurors make decisions is the information integration model. Unlike Bayesian models, which are based on probability theory, the information integration model is an algebraic modeling approach. Information integration theory specifies how discrete information is combined into a final verdict. During trial, information may come from a number of different sources, including pre-existing biases of the jurors, jurors’ observations of the defendant, the content of the testimony, the judge’s instructions, and the attorneys’ arguments. Jurors place a value and weight on each bit of important evidence. The evaluative information is integrated into a single judgment about the defendant’s guilt or innocence.

3.1.3. Story Model

The story model posits that as jurors hear evidence, they actively construct it into a story or narrative. The

coherence of the story is shaped by the consistency, plausibility, and completeness of the evidence. The story may include character evaluations, motives, important events, and states of mind. Jurors actively fill in gaps in the testimony to complete the narrative through the incorporation of prior knowledge and preconceptions. When all these aspects of evidence are combined, they create a coherent story, and from this story jurors determine the appropriate verdict. Psychological research conducted on juror decision making has revealed a relationship between constructing a narrative and selecting a verdict that best fits the narrative account.

Importantly, jurors may ignore or reject information that is contradictory to their developing narrative or story. Jurors' rejection of evidence that is contrary to their expectations or individual beliefs is not only a critical component of decision-making models, but also a key to understanding and improving how jurors perceive evidence. For example, evidence may be presented in a way that is difficult to understand or inconsistent with expectations, resulting in jurors disregarding it and focusing on more understandable evidence. However, if legal actors are aware of this potential, the presentation of evidence can be altered to increase juror understanding and comprehension.

3.2. Perceptions of Evidence

The presentation and comprehensibility of different types of evidence also merit investigation. Jury perceptions of three types of evidence have been examined: general evidence, eyewitness evidence, and expert evidence.

3.2.1. General Evidence

In terms of general evidence, one of the consistent concerns among critics is jury comprehension. Critics charge that the jury is unable to understand simple and complex trial evidence. However, research studies of jury decision making are largely at odds with this conclusion. The classic early study of jury decision making, conducted by Kalven and Zeisel (1966) in the 1950s, examined judicial opinions about jury verdicts in thousands of trials. The study revealed that the majority of judges agreed with the jury's verdict in the case. When judges disagreed with jury verdicts, they did not do so more frequently in difficult cases, suggesting that case complexity was not the source of the disagreement. A high rate of judicial agreement with jury verdicts has also been found in subsequent studies.

Nonetheless, concerns about jury competence have persisted. Research on jury performance confirms that even in fairly complex cases, jurors are generally able to understand enough of the evidence to reach a competent verdict. Research on comprehension of legal instructions, however, is more negative about the jury's ability.

The timing of evidence or legal instructions has been examined for its impact on juror decisions. Traditionally, the judge gives legal instructions to the jury at the end of the trial, right before deliberations. This was based on the assumption of a recency effect, in which immediate past events are remembered better than more distant events. On the other hand, the primacy effect posits that early information has great impact. Jurors usually form some opinions about the trial before the closing remarks by attorneys. Therefore, the primacy effect suggests that giving jurors instructions at the beginning of the trial would have greater impact. Introductory legal instructions at the start could help jurors assess legally relevant evidence throughout the rest of the trial. In addition, applied research shows that jurors who receive instructions at the beginning of the trial report greater satisfaction with the process and a better ability to evaluate evidence according to the proper legal principles.

3.2.2. Eyewitness Evidence

Eyewitness identification is another example of evidence that may have a significant impact on jury decision making. Although eyewitness identification is perceived as the most influential evidence in jury decision making, research has revealed it to also be one of the most unreliable forms of evidence. Studies have shown that an eyewitness's confidence is only weakly associated with an accurate identification; however, the greater an eyewitness's confidence, the more likely the jury will perceive the identification to be accurate. In addition, the status of the eyewitness has an effect on jurors' beliefs about witness credibility. For example, jurors are more likely to give weight to police officers' identifications than those of regular citizens, believing that training promotes police officers' accurate identifications. However, research reveals that police officers are no better at eyewitness identification than regular citizens.

Psychological research reveals important flaws in eyewitness testimony and the types of procedures that police use to confirm eyewitness identification. Yet, many of these flaws are not common knowledge among the jurors. Because of the importance of eyewitness testimony, the courts have come to recognize

the value of informing jurors about them so that eyewitness identification is allocated an appropriate weight. Psychologists have helped to reform police identification procedures, and now routinely testify as experts in jury trials, educating juries about the research findings concerning eyewitness evidence.

3.2.3. Expert Evidence

The use of expert testimony is another important factor affecting juror decision making. The use of complex evidence during trials has greatly increased within the last few decades. As a result, there has been an increasing reliance on expert witnesses to explain the evidence. Therefore, the question of how juries handle expert evidence on scientific and technical topics has become of great interest.

It has been claimed that expert witness credentials overly impress jurors, resulting in too much weight being given to their testimony. On the other hand, juror comprehension of expert testimony is also criticized on the theory that if it is too complex jurors will simply dismiss it. Also, critics and legal actors fear that permitting expert testimony will result in opening the door to trials becoming a battle between expert witnesses.

Research has revealed that jurors do have difficulty comprehending complex evidence. However, lack of juror comprehension can often be attributed to inadequate presentation of evidence and testimony, not the inherent inabilities of jurors. Improving instructions and evidence presentation will in turn increase juror comprehension. In addition, research has cast doubt on a number of assumptions that depict jurors as rubber stamps who passively accept expert testimony. According to empirical studies, instead of being unduly influenced by experts, jurors critically and adequately evaluate both the credentials of the experts and the quality of their testimony. Finally, even if some complex evidence is beyond the ability of the average juror, case studies indicate that jurors can usually understand enough of it to be able to arrive at a justifiable verdict.

3.3. Applications

3.3.1. Promotion of Juror Competence through Trial Reform

Understanding how jurors comprehend and utilize different types of evidence has led to a number of proposed reforms of the traditional adversary trial, several of which have been adopted by multiple jurisdictions.

Adhering to the traditional idea of jurors as passive observers has contributed to jurors' difficulty in comprehending evidence and trial procedures. One general reform is first to accept jurors as more active participants in the trial process, acknowledging the fact that jurors are not blank slates and that they begin to assimilate and integrate evidence long before the end of the trial.

To maximize juror comprehension and decision making, reformers suggest permitting jurors to take notes during trial, allowing jurors to ask questions of witnesses through the judge, simplifying the language used in legal instructions, giving instructions at the beginning versus the end of the trial, giving written instructions to each juror, and giving jurors multi-purpose notebooks to better organize large amounts of evidence and information during complex trials.

Many judges and attorneys are apprehensive about trial reform and concerned about changing traditional aspects of the adversary jury trial. Yet, some of these fears, when tested, have proved to be unfounded. For example, the idea that juror note taking distracts jurors, causes them to miss important information, and offers an advantage to jurors who are better note takers is not borne out. Research shows that jurors are not distracted and do not miss important evidence due to note taking. In fact, note taking encourages jurors to stay alert during trial, serves as a very good memory aid, and increases juror satisfaction with the trial process.

4. THE JURY AS A GROUP

4.1. Group Decision Making: Theory and Research on Group Performance

4.1.1. Decision-Making Process

During deliberation, the door to the jury room is locked. No one other than the jurors is present. Therefore, what transpires behind the closed door of the jury room has been, until fairly recently, something of a mystery. Researchers have acquired information on the deliberation process by interviewing actual jurors following their jury duty and also through mock jury experiments.

Once a foreperson or jury leader has been selected, typically one of two types of discussion follows. In an evidence-driven discussion, jurors first take up a general discussion of the evidence in the case. Jurors attempt to develop a joint account of the events related to the trial. Once the evidence has been thoroughly discussed, the

group takes a vote about the verdict preferences of individual jurors. In contrast, in a verdict-driven discussion, jurors begin by taking a vote at the start of deliberations. Discussion is subsequently organized around jurors' votes (e.g., innocent or guilty) and evidence is typically discussed in terms of supporting one side or the other. Another dynamic that occurs during deliberation is the tendency for jurors to align themselves with others holding similar positions.

Psychological research has found the amount of group participation to be associated with individual characteristics. For example, men typically speak more than women during deliberation. Individuals with more education and higher-status occupations tend to dominate group discussion. The foreperson is also quite active in the deliberation process and may serve as an influential voice during deliberation. Studies have shown that most juries have several nonparticipating jurors during the deliberation process. They speak rarely during the group discussion and have little impact on the group; their only contribution may consist of taking part in voting. As a result, during deliberations the jurors who dominate discussions have more potential to influence the views of other jurors. At the same time, jurors who withdraw from critical discussion may be less influential in deliberations.

In most deliberations, the first vote, or ballot, will often reveal what the verdict will be. The majority opinion is usually the final verdict. However, minority votes can sometimes prevail. In criminal trials, they are often more successful in persuading the majority to overturn their votes when arguing for an acquittal as opposed to conviction. Minority jurors can also influence the majority in civil trials. If the jury is asked to award damages, minority jurors can be influential in creating a compromise on the verdict or award amount.

Jury deliberation serves critical functions. Research shows that it promotes jury competence by providing the opportunity for a collective pooling of information and the correction of mistaken memories or conclusions. In addition, deliberation also clarifies and solidifies jurors' positions. The consensus about the evidence and the verdict that typically emerges also increase the legitimacy of the jury's eventual decision in the case.

4.1.2. Persuasion during Deliberation

Social psychologists have used the vehicle of jury deliberation to examine social influence and persuasion processes in small groups. In turn, theoretical advances

have been applied to jury phenomena. Theories about group phenomena, including conformity effects and group polarization, have been examined in the context of the jury deliberation process. Conformity effects of the majority's initial opinions have been documented in jury deliberations, where the initial vote distribution is a strong predictor of the jury's final verdict.

Informational influence and group polarization found in mock jury deliberations suggest that juries operate in much the same fashion as many other task groups. Social psychological theories about group process have been used to assess the impact of different structural variables related to the jury such as composition, size, and decision rule, as discussed below.

4.1.3. Hung Juries

Many factors can impact why a jury deadlocks, or is "hung," including individual, group, evidentiary, and institutional factors. Individual factors could be incompetence, attitudes, and lack of social skills. An ineffective foreperson or group leader can impede deliberation, for example, by not permitting everyone to speak, allowing one or two jurors to dominate the deliberation, and ignoring arguments by minority jurors. An ineffective decision-making process, by balloting at the start of deliberations as opposed to thoroughly discussing the evidence prior to voting, can also influence vote outcome. Evidentiary factors are also significant; the ambiguity of the evidence can influence the propensity for a jury to deadlock.

Jury research has found that members of hung juries tend to vote earlier than members of verdict juries. Their deliberation appears to be verdict driven, as opposed to evidence driven. When juries do hang, group dynamics are at work. There may be a conflict on the jury, there may be unreasonable jurors, or one or two jurors may dominate the deliberation. Jury members may not be open minded, and may spend too much time and effort attempting to persuade and convince fellow jurors. Numerous factors act and interact with one another to influence jury verdict outcomes, from individual characteristics to group dynamics.

4.2. Applications

Understanding the jury decision-making process in terms of group interaction has important implications and applications for real-world situations. For example, psychological research has examined the impact of decreasing jury size, altering the decision rule

requirement for juries, allowing jury anonymity, and improving jury decision making through jury reforms.

4.2.1. Impact of Jury Size and Decision Rule

The jury's size and its decision rule have gone through a number of controversial changes. With respect to jury size, what was once long assumed to be a constitutional guarantee, a trial by a 12-member jury, was dismantled by a number of important U.S. Supreme Court cases during the early 1970s. The U.S. Supreme Court decided the number 12 was a "historical accident," finding that state court juries of six did not violate the Constitution. Decreasing the requirement from a 12- to a six-member jury was seen as a way to decrease expenses, save time, and increase efficiency at no cost to the jury trial system.

However, psychological research has identified a number of negative consequences of reducing jury size. The larger the jury size, the more likely it is to be representative, and in turn the more likely it is to reflect community views. In reverse, the smaller the jury size, the less likely it is that minorities in the community will be represented on the jury. In addition, the unpredictability of jury verdicts increases as jury size decreases. The smaller juries used in civil trials are more likely to result in a wider range of jury awards.

Furthermore, six-person juries appear to deliberate differently than larger juries. Larger juries have more people to rely upon to recall evidence with greater accuracy, which decreases the likelihood of relying on incorrect information. Jurors in larger groups are more likely to be diverse in terms of backgrounds, experiences, and opinions. This diversity of perspectives increases the overall quality of jury deliberations and increases the validity of the final verdict. One juror within a six-member jury proposing an opposing position is in a significantly weaker position compared to two jurors in a twelve-member jury.

In addition to changing jury size requirements, countries have modified the long-held requirement that juries must be unanimous in their verdict. During the 1970s, the U.S. Supreme Court decided that unanimous juries in state courts were not constitutionally mandated. The United Kingdom switched from requiring unanimity to permitting majority verdicts as well. These changes were again based on unsupported assumptions about how juries deliberate. Subsequent research shows that eliminating jury unanimity has negative effects on the quality of juror deliberations. For example, jurors with majority rule verdicts instead of unanimous verdicts are more likely to be verdict driven than evidence driven.

Although verdict-driven deliberations may occur in jury trials that require a unanimous verdict, they are more likely to occur in majority rule juries and are more likely to decrease the quality of the deliberation process.

Jurors deliberating under a unanimity rule requirement are more likely to be evidence driven, and evidence-driven juries are more likely to have longer and more thorough deliberations. A unanimity requirement increases the likelihood that all viewpoints will be appropriately addressed during the decision-making process. Majority rule juries are more likely to be verdict driven, resulting in deliberations that are less thorough and significantly shorter. Verdict-driven deliberations are shorter and less thorough because once the majority requirement is reached, there is no need to listen to the remaining minority opinion, resulting in a termination of deliberations. The quality of deliberation decreases because minority opinions do not get as much attention; when they are addressed, they are not sufficiently discussed. As a result, it should not be surprising that jurors on non-unanimous juries report less satisfaction with the process and the verdict, while jurors on unanimous juries report greater satisfaction with both the process and the final verdict.

4.2.2. Anonymous Juries

Another controversial technique used to improve the decision-making process is juror anonymity. Juror anonymity means withholding the identities of the jurors from the public, the media, and the attorney. There are a number of reasons why judges have felt it necessary to order that the jury members be anonymous: to prevent corruption, to decrease fear of criticism from unpopular decisions, and to decrease fear of retaliation or harassment in high profile cases.

Many critics have claimed that jury anonymity decreases juror accountability, the ability of lawyers to adequately investigate juror bias during voir dire, and public confidence in the fairness of jury trials. However, some of these concerns can be managed. With anonymous jurors, lawyers have access to the same questionnaires used in regular trials and also maintain the ability to question jurors; the only difference is that jurors are identified by numbers instead of names. Preserving the questioning process during voir dire, which uncovers important background and attitudinal information of a potential juror, seems more important for creating an unbiased jury than knowing the juror's name.

Juror anonymity is also viewed as improving the overall deliberation process. For example, jurors in high-profile

cases may fear retaliation or harassment from the defendant, the lawyers, the media, or the public. As a result, maintaining anonymity may increase general participation from the population and also increase the quality of deliberations, due to decreased fear of retaliation. Anonymous jurors may be more comfortable discussing unpopular or controversial topics, resulting in an increased richness of deliberations. Also, anonymous juries may be freed from the pressure of following popular opinion in high-profile trials. There are many potential benefits to anonymous juries, psychological and otherwise, that could increase the quality of the overall decision-making process, and in turn increase the fairness of jury verdicts. They deserve systematic examination and study.

4.2.3. Active Jury Reforms

Psychological research indicates that modifying jury size and decision rule may produce some negative consequences for jury decision making. In addition, psychological research has suggested that other jury reforms may improve the overall trial process and jurors' individual and group decision making. One controversial reform proposition is based on the idea of active jurors, allowing jurors to discuss evidence throughout the trial, instead of waiting until the end of the trial as is commonly the case. Permitting trial discussions is based on the belief that jurors form opinions about evidence and testimony throughout the trial, and discussing evidence and questions as they arise will help dispel inaccurate interpretations or beliefs and improve the quality of final deliberations.

The state of Arizona is one place where the concept of the active juror has been vigorously pursued. Following substantial jury reforms, Arizona now permits juror note taking, question asking, and trial discussions, all with the aim of improving juror competence. Research studies of some of these reforms show strong support among jurors and judges, but less enthusiasm for the reforms among attorneys. Attorney fears about distraction and prejudice, however, have not been borne out in systematic studies of the operation of the reforms.

5. COMPARATIVE RESEARCH ON JURIES

Much of the empirical jury research to date has taken place within the United States, England, and Canada,

studying how the jury within a single country operates. Yet, countries that have adopted the jury have molded the institution to fit their unique circumstances and cultures. Researchers have only recently begun to take a comparative approach, analyzing how different jury systems function.

Examining how different procedures in various countries affect jurors' decision-making ability is an emerging area for psychological research. For example, although both the United States and England use adversarial models of procedural justice, the degree of involvement of judges and lawyers varies significantly. English judges, who are permitted to comment upon the evidence, may be more influential in the typically more civil and cooperative British jury trial, while U.S. juries may be more distracted by the greater adversariness of the typical American trial.

Another important question that may be answered through comparative research is how juries measure up to other methods for injecting lay sentiment into law, such as lay judges, lay magistrates, and mixed tribunals, which combine lay judges with law-trained judges. One key finding is that when lay judges decide cases together with law-trained judges, the legally trained judge tends to dominate, minimizing the input of lay perspectives. In contrast, the jury decides in isolation, relatively protected from the direct influence of the law-trained judge. This new comparative work, now in its infancy, holds promise for understanding the consequences of different types of lay participation systems.

6. CONCLUSION

The jury represents an important vehicle for the expression of public perspectives on justice. Critics of the jury system would prefer to weaken or silence the public's voice. Yet psychological research offers empirical evidence that has revealed the basic soundness of jury decision making while simultaneously pointing toward effective reforms of the jury system. Acknowledging jurors as active yet imperfect actors in the trial process allows legal practitioners and researchers to propose jury trial reforms that have the ability to improve the presentation of evidence and maximize the quality of deliberations to not only increase the satisfaction of jurors, but also reinforce the legitimacy of their final verdict.

GLOSSARY

ecological fallacy The assumption that the relationship between two variables is the same across different levels of analysis (e.g., individual vs organizational).

employee turnover Voluntary cessation of organizational membership by members who receive monetary payment for their participation and labor.

expectation-lowering procedure Orientation for new recruits that deflates initial job expectations without providing a realistic preview about a particular job.

fit A component of job embeddedness that represents employee compatibility with the company or environment.

image violation An experienced event that violates personal ideals or aspirations, inducing thoughts of quitting.

job avoidance Less extreme forms of avoiding the workplace.

job embeddedness A composite construct representing the web of connections that keep employees from leaving.

job satisfaction The favorability of an employee's attitude toward the job.

links The formal and informal relations that an employee forms with members in the organization and community.

matching script A preexisting plan to exit the job once some preconditions are met.

met expectations The alignment between the prehire job expectations of beginning employees and their later work experience that affects their socialization to the job and retention.

organizational commitment Employee identification with the values and goals of the employing institution and feelings of loyalty toward that institution.

realistic job previews Full communication of the positive and negative aspects of the job to new entrants during hiring or orientation to the job.

sacrifices A component of job embeddedness that refers to material or psychological benefits that an incumbent forfeits when he or she vacates the job.

shocks Jarring events that trigger thoughts of quitting.

weighted application blank A detailed application form that is converted into a selection test to screen out job applicants with a high propensity to quit.

work-family interference Organizational interference with employees' ability to participate in family or extraorganizational activities.

Employee turnover is the voluntary termination of membership in employing institutions that is initiated by employees. Over the years, scholars have identified which employees tend to sever their employment ties, why they do so, the process by which they leave, and how they might be prevented from quitting. Although important strides toward the understanding and prediction of turnover have been made, several areas of inquiry remain unresolved or unexplored.

1. INTRODUCTION

Employee turnover is the voluntary cessation of membership in an organization by an individual who receives monetary compensation for participation in that organization. This phenomenon has long been an inquiry of investigation for industrial and organizational psychologists, with more than 1000 studies having appeared over the years. This article briefly reviews the theoretical and practical significance of this behavior, investigations of the identities of leavers, theory and research about the causes of employee turnover, and the prevention and control of this behavior.

Turnover attracts the attention of organizational scientists and employers alike because this highly visible behavior may signal poor quality of working life and ineffective organizational processes. In particular, turnover often imposes significant financial costs to firms. When employees quit, employers must expend funds to find and train replacements. To illustrate, human resources professionals project that the cost of one turnover incident ranges between 93 and 200% of the leaver's salary. Apart from direct financial costs, turnover may engender broader costs. For example, excessive personnel attrition may impair customer service and/or harm patients. Moreover, many chief executive officers of leading corporations, such as Microsoft and General Electric, believe that the flight of top talent jeopardizes firm performance. Finally, U.S. corporations worry that excessive attrition among minorities and women may hamper their efforts to diversify their workforces, especially top management teams.

2. IDENTIFYING WHO QUITS

2.1. Demographic and Personality Correlates of Turnover

Turnover researchers have long sought to identify who quits. According to a comprehensive meta-analysis, Griffeth and colleagues observed that employees who are prone to quit generally are young and single, are not married to working spouses, have no (or few) children, and/or have short tenure in the organization. Contrary to popular opinion, this meta-analysis detected no racial or gender differences in quit rates. Nonetheless, these conclusions should be regarded with caution. Griffeth and colleagues' meta-analysis included only seven studies on the race–turnover relationship and combined all racial minorities together (ignoring racial

differences in quit rates) while failing to examine subgroup differences among women (e.g., educated women and uneducated women quit at different rates). In comparison, the Attrition and Retention Consortium, which is composed of 25 Fortune 500 corporations that share quit statistics on managers and professionals for benchmarking, found that women quit more than do men. Based on a combined sample of 81,346 racial minorities, this consortium further observed that Hispanic and African Americans leave at higher rates than do European and Asian Americans during the early period of employment. Because such findings may expose consortium participants to litigation or embarrassment, such data are not available from the academic literature (and so their omission biases demographic meta-analyses).

In addition to demographic traits, turnover researchers have examined other personal attributes of leavers. Specifically, a meta-analysis of the “Big Five” personality dimensions reported that long-tenured employees tend to be conscientious, agreeable, and open to experience. Supporting the old maxim that the “best predictor of future behavior is past behavior,” it was further demonstrated that employees with a history of unstable employment exhibit a greater risk of quitting.

2.2. Performance–Turnover Relationship

By far, the personal characteristic attracting most turnover studies is job performance because whether high or low performers tend to quit greatly determines the costliness of turnover. Organizations may even welcome personnel attrition if those who are exiting are their less valuable or less valued job incumbents. Testing the performance–turnover relationship, several meta-analyses have concluded that substandard performers are more prone to quit, whereas outstanding performers are more stable.

Despite such impressive consistency, some researchers have witnessed inverted U-shaped turnover–performance relationships, such that superior performers (because they have greater employment opportunities) and poor performers (because they are unhappy or face impending dismissals) terminate employment more often than do moderate performers. Conventional wisdom had long assumed that greater flight among top performers occurs only in occupations where achievements are publicly known (e.g., professional athletes, university scholars). Because their professional accomplishments are visible

FIGURE 1 Job survival rates as a function of job performance and firm tenure.

signals to the external marketplace of their ability, superior performers can readily secure alternative employment elsewhere (including receiving more unsolicited job offers from outside employers). Recently, a few studies have detected that this trend toward greater job mobility among productive incumbents is more common, reporting higher turnover rates among high-performing managers and Swiss bankers (Fig. 1). As a result, these recent findings qualify traditional observations that low performers exit voluntarily at greater rates than do high performers. When professional accomplishments are externally visible or objectively verifiable (e.g., fast-track promotion history for managers), curvilinear (rather than inverse) relationships between performance and turnover may well emerge.

3. THEORIES ABOUT WHY EMPLOYEES QUIT

3.1. Theories about Intermediate Linkages between Job Dissatisfaction and Quits

More than 45 years ago, March and Simon pioneered a theory about why employees quit that continues to dominate current perspectives. They conceptualized two prime turnover determinants—"ease of movement" (e.g., job opportunities that allow employees to quit) and "desirability of movement" (e.g., job dissatisfaction that motivates employees to leave)—that persist in recent theorizing. Extending this line of thinking, Mobley first elaborated the various stages of the withdrawal process. Specifically, he theorized that job dissatisfaction prompts employees to begin

thinking about quitting. Dissatisfied incumbents next evaluate their prospects of obtaining employment elsewhere and the costs of quitting (e.g., loss of seniority benefits). If attractive alternatives exist and turnover costs are low, disgruntled employees form intentions to search for other jobs and actively pursue other work. After securing other job offers, these employees compare them with their current positions. If this comparison favors an alternative, they will ultimately quit.

Since its inception, Mobley's model had dominated theory-testing research throughout the late 1970s and 1980s, yet empirical tests failed to sustain Mobley's causal structure. Instead, in 1991, Hom and Griffeth validated an alternative sequence of structural linkages among withdrawal antecedents (Fig. 2).

In 2001, Hom and Kinicki validated an extended version of this model (Fig. 3) with a national retail store sample. This version additionally considered local unemployment conditions, work-family conflict (i.e., job interference with employees' ability to attend to family and/or extraorganizational pursuits), and job avoidance (i.e., less extreme forms of avoidance such as absenteeism and tardiness).

In this theory, interrole conflict increases dissatisfaction and withdrawal cognitions, whereas unemployment conditions directly lower quit rates. Furthermore, job dissatisfaction increases job avoidance, which in turn augments withdrawal cognitions.

3.2. Structural Determinants of Turnover

Apart from theoretical accounts of how dissatisfaction translates into exits, Price and Mueller introduced another framework that also initiated a long research

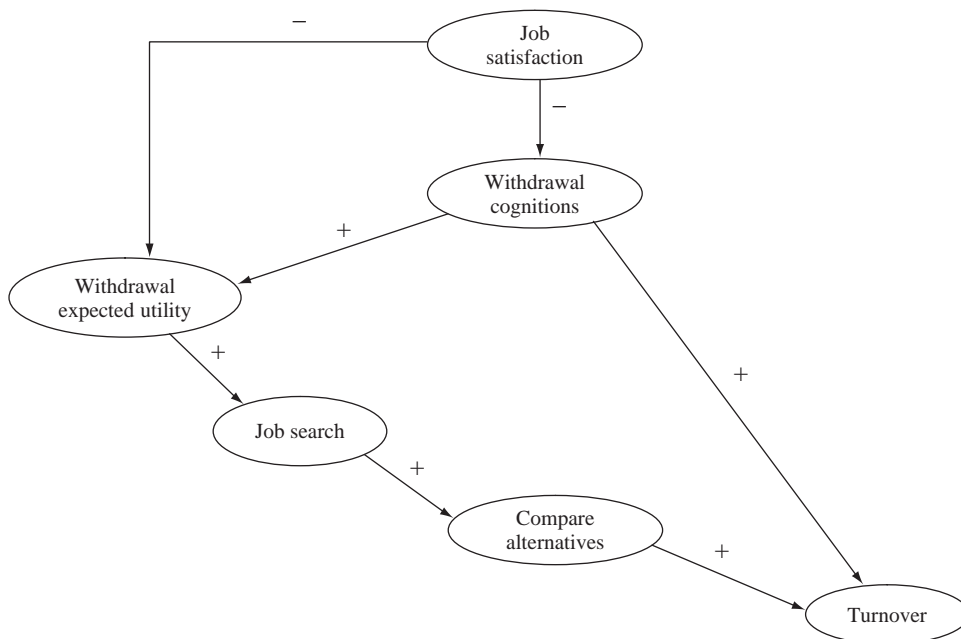

FIGURE 2 Hom-Griffeth model of dissatisfaction-initiated quits.

stream. Unlike psychologists (who focus on micromediation among psychological constructs), these sociologists identified a broad array of more distal structural antecedents of turnover (e.g., characteristics of the work setting, patterns of social interaction within the workplace) as well as influences external to the workplace

(e.g., occupational commitment, family obligations). Price and Mueller theorized that role overload, routine work, centralized decision making, work-related communications, social integration (i.e., friendships at work), pay, fair reward allocation, and promotional opportunities affect job satisfaction, whereas

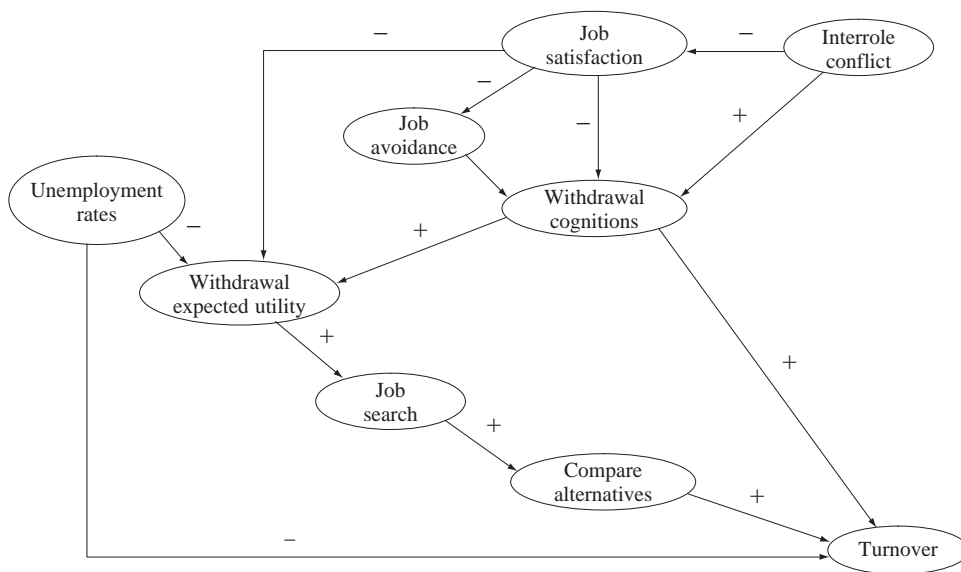

FIGURE 3 Hom-Kinicki model: Expanded theory of dissatisfied quits.

professionalism (i.e., commitment to one’s professional standards and norms), general training, and “kinship responsibility” (i.e., family responsibilities and relatives living nearby), as well as job satisfaction, underpin organizational commitment (i.e., firm identification and internalization of firm values). Commitment and perceived job opportunities, in turn, stimulate the decision to quit, and this decision, as well as perceptions of job opportunities, affects turnover. Although studies have not validated every pathway in the Price–Mueller model, studies have broadly established that structural determinants affect either job satisfaction or organizational commitment—or both—and that environmental antecedents affect quits (although whether their effects are direct or indirect via commitment or quit intentions remains indeterminate).

3.3. Unfolding Model

Marking a radical departure from traditional perspectives, Lee and Mitchell proposed a provocative new theory to overcome the shortcomings of these viewpoints. They argued that conventional thinking wrongly assumes that job dissatisfaction is the prime impetus for quitting and that prospective leavers quit only for other employment. Prevailing schools of

thought also presume that prospective leavers evaluate alternatives using a rational analysis of their costs and benefits. Instead, Lee and Mitchell’s “unfolding model” posits that nonattitudinal causes—namely “shocks” or jarring events that stimulate thoughts of quitting—instigate quits more often than do attitudes toward the job (Fig. 4). Their formulation also holds that some leavers exit without jobs in hand (including, e.g., exiting the workforce to return to school) and that leavers often make quick “compatibility” evaluations of alternative jobs rather than subject them to rational subjective expected utility analyses.

The unfolding model further proposes that leavers follow one of several pathways when exiting. Some leavers follow Decision Path 1, which is precipitated by a shock (typically some expected personal event). This shock causes incumbents to probe their memory for a “matching script” or preexisting action plan, and if one is detected, this can lead to automatic withdrawal. For example, a woman may quit when she becomes pregnant (the shock) because she had already planned that she would stay at home to raise her first child on becoming pregnant. Other leavers follow Decision Path 2 because they experience a shock that triggers an “image violation.” Lee and Mitchell defined three types of images: value image (e.g., personal

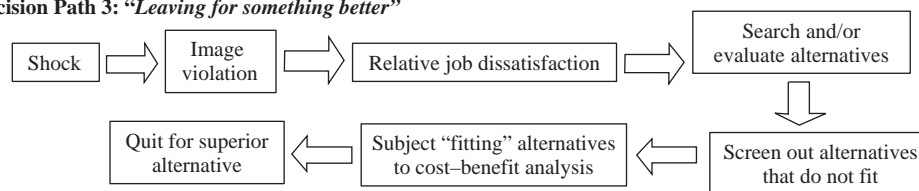

Decision Path 1: “Following a plan”

Decision Path 2: “I’m outta here”

Decision Path 3: “Leaving for something better”

Decision Path 4: “Leaving dissatisfying job”

FIGURE 4 Lee and Mitchell’s unfolding model.

values), trajectory image (e.g., personal goals), and strategic image (e.g., behavioral strategy toward goal attainment). In this turnover path, a shock violates employees' images and causes them to feel dissatisfied and to directly quit. For example, a hospital may shift to team-based nursing (the shock), which violates a nurse's image because the nurse values individual-based nursing. The nurse becomes unhappy and leaves the hospital without engaging in a prior job search.

Still other leavers follow Decision Path 3, which is initiated by some unsolicited job offers or inquiries (the shock). This shock leads job incumbents to compare these new jobs with their current ones and leads to "relative" dissatisfaction if the alternatives are superior (i.e., incumbents experience "opportunity costs" by staying). The prospects of "greener pastures" elsewhere motivate incumbents to pursue and evaluate other alternatives (including the unsolicited jobs). They first screen alternatives using a quick compatibility test to determine fit with their personal images, rejecting those that lack such a fit. Next, the job seekers engage in more deliberate cost-benefit analyses among alternatives meeting the fit test and ultimately quit to take the "best" alternative. To illustrate this path, Lee and colleagues described a nurse who received a job offer from a private clinic (the shock). She had been frustrated for a while but had not contemplated leaving until someone offered her a better position. She then investigated this clinic position thoroughly before exiting the hospital.

Finally, some leavers take Decision Path 4 (regarded by Lee and Mitchell as the conventional path, similar to that portrayed by the Hom-Kinicki model). Here, leavers gradually become disenchanted with their jobs as they progressively experience image violation. Some may quit as soon as their dissatisfaction reaches some threshold. This is what Jim Manzi, chief executive officer of Lotus Development, did when IBM bought his company. Manzi became unhappy with the direction and vision for the newly merged companies and left without a new job in hand. Alternatively, some leavers who take Decision Path 4 seek and judge other employment options and exit once they secure better positions.

Using qualitative methodology, empirical tests of the unfolding model interview former employees to delineate the routes by which they withdrew from their previous jobs. More than 92% of leavers followed one of the four decision paths depicted by the unfolding model. Moreover, the studies employing these tests report that 25% of leavers quit without searching for employment elsewhere and that shocks prompt more turnover than does job dissatisfaction. Finally, 39% left

due to external shocks such as pregnancies, unsolicited job offers, and spousal relocations. Despite these provocative findings, retrospective reports, which may be distorted by postdecisional dissonance and faulty recall, provide inadequate validation for the unfolding model. Further verification of this theory requires predictive longitudinal designs—a standard methodology for verifying turnover models.

3.4. Job Embeddedness

In 2001, Mitchell and colleagues proposed explanations for why people stay. Existing formulations explain why people leave but fail to account for why people stay, possibly implicating different psychological processes. Mitchell and colleagues introduced "job embeddedness" as a composite construct representing the web of connections that keep employees on the job. Job embeddedness is composed of three dimensions: links, fit, and sacrifice. Links represent the formal and informal connections between employees and institutions and others. Thus, friendships at work and in the community, as well as extended family in the community, may keep employees from abandoning their workplaces. Fit represents employee compatibility with the company and environment. If employees have values compatible with those of the workplace, enjoy recreational and entertainment activities in the community, and belong to local community organizations (e.g., churches), they may stay. Finally, sacrifices correspond to the costs of material and/or psychological benefits that are forfeited by resignations. Thus, employees stay if they have nonportable job benefits (e.g., pensions), seniority-based benefits, and community advantages (e.g., live in safe neighborhoods close to work, have prime seating at sporting events). Testing this construct, Mitchell and colleagues documented that job embeddedness accounts for unique variance in the prediction of turnover that is not explained by conventional predictors.

4. METHODS FOR CONTROLLING TURNOVER

In contrast to the substantial explorations of turnover theories, examinations of ways in which to reduce turnover remain limited. In 2001, Griffeth and Hom discussed the more promising approaches that have been supported empirically.

4.1. Employee Selection

The most widely validated selection tool is the weighted application blank (WAB), that is, a detailed application form converted into a selection test. To develop a WAB, an employer would compare application blank responses of former employees (leavers) and current employees (stayers). When these groups answer a particular question differently (e.g., stayers might report higher incomes on their last jobs than do leavers), a scoring key is generated for that question and “scores” the leavers’ response (low wage) higher than the stayers’ response (high wage). Scoring keys are developed for all questions that discriminate between stayers and leavers. The sum of the special scores for all items yields an overall score for quit propensity. When used for hiring, the WAB essentially compares job applicants’ answers on the application blank with those of leavers (former employees). If certain applicants closely resemble leavers in their application responses, these applicants would receive high WAB total scores and would be disqualified from hiring. Despite the simplicity and proven success of WABs, few employers use them because questions about certain background attributes may disproportionately reject minority or women applicants (and prompt discrimination lawsuits) or may constitute an invasion of privacy.

In addition to assessing background attributes to identify applicants at risk for quitting, organizations might consider personality testing. However, conventional personality scales are susceptible to faking by job seekers who (mis)portray themselves in a favorable light to gain employment. To overcome such social desirability, Bernardin suggested a personality-like measure of quit propensity using a forced-choice format. In this approach, respondents choose a descriptor (about themselves) from a pair of descriptors that are matched on equal discomfort, although only one is a valid answer. To create this test, employers must interview current employees and their superiors to identify discomforting aspects about a job (e.g., “your schedule for work changes from day to day”). They then write statements based on these events (questionnaire items). Next, employers also write statements about discomforting situations that are irrelevant to the job (e.g., “buying a new television and later learning that it goes on sale next week”). Then, a set of judges is recruited to rate the discomfort levels of relevant and irrelevant statements. Then, employers pair one relevant statement with an irrelevant statement that is matched for discomfort. Once many sets of paired statements are identified,

they are included in the final personality test. When taking this test, prospective employees would select a statement from each pair depicting an event most distressing to them. If they choose the “valid” statement (representing an actual negative job experience) from a given pair, they would earn a “higher” score for that answer. The test would indicate that applicants are a poor fit for a job if they accumulate high test scores (based on summing their responses to all statement pairs). Put differently, these individuals would likely be upset by discomforting events that are part of the job. They would ultimately become dissatisfied and quit. Bernardin and colleagues established that this personality inventory predicts turnover among customer service representatives and motion picture theater personnel.

Finally, selection interviews have potential for identifying prospective leavers if they are properly designed and executed. Notably, Schmidt and Rader described a promising structured telephone interview. To develop this screening device, employers must carry out in-depth interviews with outstanding performers in a particular job to identify their behavioral tendencies and traits (i.e., “themes”). Next, potential interview questions assessing each theme are written out as potential interviewees would be asked how they exhibit such traits. During the next step, two groups of employees—30 high performers and 30 low performers—are interviewed with these questions individually, and their remarks are transcribed. Questions differentiating between high and low performers are retained, and a scoring guide that credits interview responses indicative of the presence of high-performer themes is created. During telephone interviews, job applicants would be asked to respond to these questions (and to provide examples). Applicant responses would also be recorded and later scored by trained analysts to derive scores that assess how well applicants exhibit the high-performer themes. Summarizing multiple validity studies, Schmidt and Rader estimated that this interview predicts employment stability moderately accurately ($r = .39$).

4.2. Interventions for Reducing Turnover

Turnover scholars have most validated realistic job previews (RJPs), that is, comprehensive profiles of a job—portraying its positive and negative aspects—that are communicated to new hires during hiring or orientation. Meta-analyses conclude that RJPs modestly reduce exits among beginning employees in a wide range of

jobs (e.g., nursing, military) with a variety of media (e.g., booklet, audiovisual). To account for the effectiveness of job previews, theorists have often cited met expectations and self-selection as underlying mechanisms. According to met expectation theory, RJPs reduce reality shock by decreasing the gap between newcomers' initial (often inflated) expectations about a new job and subsequent work experience. RJPs clarify what the job entails and increase the odds that newcomers' expectations will be met on the job, thereby improve retention. The self-selection mechanism posits that RJPs help job applicants to make more informed job choices, in turn helping them to better decide whether or not their needs would be satisfied by the job. Those who self-select themselves for the job (despite the RJPs) are better suited for the job and will likely stay, whereas those who are "misfits" will decide not to accept the job (and avoid becoming future turnover casualties). Despite the popularity of these explanatory schemes, empirical corroboration of RJP explanations remains limited.

In 1998, Buckley and colleagues introduced the expectation-lowering procedure (ELP), which reduces job expectations without providing actual information about the job. After all, expensive job analyses are needed to properly design RJPs, and they may lose their efficacy if job content changes. To offset these limitations, Buckley and colleagues designed a special orientation for new hires, who are instructed in the theory of met expectations (and are explained the causes and consequences of unmet expectations) and share their own personal experiences with reality shock. In an experimental test, Buckley and colleagues showed that the ELP reduced turnover among new assembly line workers as much as did an RJP.

Finally, turnover scholars have validated job enrichment—increasing the intrinsic rewards of a job by expanding skill variety and empowering incumbents—as another means to promote job loyalty. Indeed, a meta-analysis concluded that job enrichment is more effective than are RJPs for promoting retention, supporting Wanous's maxim that RJPs cannot substitute for good jobs.

5. CONCLUSION

Organizational studies have greatly expanded our understanding of the turnover phenomenon. Nonetheless, much theoretical and empirical work remains. Specifically, empirical verification of turnover formulations has lagged theoretical advances. Conventional static designs typically assess turnover causes at one time and

use them to predict turnover at a later time. This standard methodology overlooks the implicit causal assumption inherent in most theoretical frameworks that changes in turnover's antecedents foreshadow its occurrence. To better corroborate causality, more rigorous evaluations of prevailing theories should apply latent growth modeling or hierarchical linear modeling to longitudinal data (i.e., multiple waves of predictor assessments).

Moreover, conceptual models of the withdrawal process have been validated primarily in North American samples. Yet American transnational firms increasingly employ global workforces and face the daunting challenge of how to bind their workers to employment. Because retention strategies based on ethnocentric domestic theories may falter abroad, it is imperative that researchers validate turnover models (and loyalty-inducing practices) in various cultural settings. Furthermore, theorists have narrowly focused on explaining why individuals quit and derive organization-wide practices for reducing aggregate quit rates from individual-level findings. Yet inferring company-wide prescriptions from individual-level data and theories risks committing the "ecological fallacy." Accordingly, future research should develop (and test) formulations that account for why rates of personnel attrition vary across organizations.

GLOSSARY

accommodating strategy When one party in a conflict gives all of his or her rights for another's to win.

collaboration strategy When two parties focus on the problem and the best solution in which both can win.

competitive strategy When one party in a conflict is focused on him- or herself to win at all cost.

compromising strategy When parties negotiate a settlement.

consideration Behavioral style that is friendly, open to input, respectful to others, etc.

contingency approach Model of leadership that describes leadership in context.

derived etic approach The coalescence of theories or measures about a concept that are developed in two different cultures.

emic approach A method of studying culture theories, models, and measures as evolved from inside a culture.

endogenous researchers Researchers who conduct research within their own culture.

etic approach A method of studying culture in which existing theories, models, and measures in one country or culture is validated in another.

exogenous researchers Researchers who conduct research outside their own culture.

global leaders Leaders who perceive complexity and are inclusive, respecting people of all cultures equally, and who are concerned about what is the best solution in the long run.

idealized influence Behavioral styles that provide vision and unify the team behind a common goal.

imposed etic approach Approach using existing theories or measures from one culture in another culture with almost no modification other than translations.

individual consideration Style of behaviors such as attentiveness to diversity of needs and values of team members and addressing each on their own basis.

initiating structure Behaviors that focus on getting the job done, such as goal setting, clearing expectation, criticizing wrong behavior, rewarding good behavior, planning, etc.

inspirational motivation Behavioral style that exudes energy and emotion in the actions to be taken.

intellectual stimulation The process of getting team members to think critically.

international leaders Leaders who have the tendency to impose their own cultural values and policies on others.

leader-member relationship The leader's certainty that the team is united and supportive of him or her.

position power The leader having a title, and the legitimacy and resources to reward and punish team members.

situational control A leader's amount of control and influence in a given situation.

task structure A leader's knowledge of how to get information or conduct a task.

withdrawal When parties to a conflict leave the relationship.

Globalization of work economy has made the interplay of culture and leadership an important topic of consideration. This article covers the topic of leadership and culture, demonstrating a symbiotic relationship between the two. It is shown that the definition and methods used in the study of culture in leadership can affect the results. Culture as determined by economic-political conditions had the most impact in determining differences in leadership across cultures. Accordingly, managers in countries that are similar in terms of industrialization and modernization have more similarity in their values and even their behaviors. Through the analysis of studies on behavior of leaders across cultures, it became evident that the definition of leadership is highly cultural dependent. More specifically, the meaning of the behavior, the effect of the behavior, and the level of the behavior varied across cultures. One outstanding finding was that Asian cultures do not seem to consider task-related and people-related behaviors as two separate leader behaviors. Additionally, more recent issues of leadership, such as working in multicultural settings and global leadership, are addressed.

1. INTRODUCTION

Globalization is an inevitable and challenging evolution in today's society. Leaders in any social and economic institution are at the helm of this evolution of multicultural interdependence. Therefore, a deep understanding of the concept of leadership within cultures, across cultures, and globally is of paramount importance. To gain an appreciation of the interaction between the leader and culture, consider the following anecdote: An Asian manager in the United Kingdom noticed that one of his employees was absent from work due to ill health. The manager visited the employee at home, bringing flowers and a box of sweets, as was customary in the manager's culture. In his mind, he was showing individualized consideration and social support for his employee. Nevertheless, the employee, acting according to his own cultural norms, filed a complaint, charging the manager with distrust and invasion of his privacy. The issue here is not who was correct, but the elucidation of the role that culture plays in interpreting behaviors.

The preceding anecdote illustrates the fact that leadership is embedded in culture, and that the two have a symbiotic relationship. To explore this, this article presents a brief definition of culture and the cross-cultural methods. Next, different leadership definitions and the

role of culture in their universality is discussed. The topics of leadership as seen in some countries, the leader in cultural exchange, and global leadership conclude this presentation of culture and leadership.

2. CULTURE

2.1. Definition of Culture

"Without men, no culture, certainly; but equally, and more significantly, without culture, no men." Clifford Geertz made this powerful if not precise definition of culture, highlighting the importance of culture in the study of human beings. Scholars concur that culture refers to a constellation of a group's collective values, expectations, attitudes, and behaviors. In addition, the symbiotic relationship between culture and humans is interactive. While cultural environments model humans, humans also affect the culture. In other words, culture refers to an all-encompassing and long-lasting depiction of a human social entity.

Regardless of the definition of culture used, in cross-cultural psychology, researchers focus on two distinctions of culture: cultural values and physical characteristics. Cultural values primarily include (1) collectivism and individualism, (2) power distance, (3) uncertainty avoidance, (4) masculinity or industriousness, (5) Confucianism, and (6) time orientation. Physical parameters include country of origin or residence, as well as physical attributes of individuals, such as gender and color.

2.2. Cross-Cultural Methodology

Because results of cross-cultural research are dependent on the method used to study leadership, this section defines the various alternatives to and factors in cross-cultural research. The methods used to incorporate culture into psychological research have evolved since almost 50 years ago. Traditionally, two types of approaches have been recognized: (1) when existing theories, models, and measures in one country or culture are validated in another, or the etic approach, and (2) when theories, models, and measures evolve from inside a culture, or the emic approach. The etic approach is further expanded to include imposed etic and derived etic. Imposed etic refers to using existing theories or measures from one culture in another with almost no modification other than translations. Derived etic, on the other hand, refers to an

approach in which a theory or measure developed in two different cultures coalesces; it is that which is common between the two cultures.

In addition to the different approaches to cross-cultural research, the researcher's cultural background can impact the formation of the research question and the interpretation of results. Therefore, cross-cultural researchers can be categorized by their level of involvement with a culture as either exogenous or endogenous investigators. Exogenous researchers are those who conduct research outside their own culture. Therefore, they are not entangled with the culture, and high degree of objectivity is the outcome. Danger, however, lies in the fact that exogenous researchers' assumptions may be derived from their own culture or their stereotypic view of the culture they are studying. Endogenous researchers, those who conduct research within their own culture, may be less objective but are more sensitive to nuances and meanings of their own culture.

Thus, cross-cultural research usually starts with emic measures in one culture, which then can be tested in the other cultures as imposed etic measures. The items that best describe both cultures will form the derived etic measure. Most research on leadership thus far can be categorized as imposed etic, particularly the validation of theories developed in the United States in other cultures. Additionally, U.S. scholars have conducted most of the research and developed most of the main theories of leadership; hence, the existing knowledge about leadership is heavily influenced by North American values and expectations. Therefore, given the extent to which exogenous researchers from one specific culture have dominated the theories and conceptualizations of leadership, it is mostly representative of one perspective. For this reason, multicultural research teams that include endogenous researchers are the new trend and the recommended form of cross-cultural research.

3. LEADERSHIP RESEARCH ACROSS CULTURES

Concern for leadership has a long history. In China in 5000 BC, Confucius advised the Chinese emperors; in 12th-century Persia, Unsur-u'l-Ma'ani wrote an essay advising the Ziari rulers, and in 15th-century Europe, Machiavelli wrote *The Prince*, guiding the rulers of the time. In the late 19th century, Carlyle formulated the Great Man theory, later known as the leadership trait

approach, which had the most impact on the majority of research on leadership in the United States.

Initially, leadership was approached with a focus on either the leader alone, or the leader as part of a social context. When the attention was focused on the leader, his or her traits and values were considered as well as his or her leadership behaviors. The models of leadership that describe leadership in context are referred to as contingency approaches. In the following sections, the etic approaches to leadership highlight the effect of culture on the universality of the leader's traits and behaviors and the validity of contingency approaches to leadership across cultures.

3.1. Etic Approach: The Leader's Characteristics

The trait approach to leadership is the oldest approach that initially incorporated both dispositional characteristics, including values, attitudes, and traits (e.g., intelligence, locus of control, confidence, optimism, and adaptability), and physical characteristics (e.g., height and attractiveness). More than two-thirds of the 20th-century research on leadership focused on identifying dispositions that best describe a leader. Intelligence, adaptability, adjustment, aggressiveness, dominance, independence, originality, self-confidence, and optimism were dispositions that most studies identified as separating leaders from non-leaders.

Cross-cultural comparison has most often focused on managers' attitudes and values. Two approaches are used to examine the effect of culture on managers' similarity of values. One approach examines the values of managers in different countries; the other compares managers from a similar country of origin living in different countries.

When different nationalities were compared, it accounted for approximately 28% of the variance in managers' attitudes. In contrast, when the effect of similarity among managers from Australia, India, Japan, Korea, and the United States was assessed, and nationality versus industrialization was compared, it was the closeness in the level of the societies' industrialization, language, and traditionalism that accounted for most of the leaders' value similarity, not the country they lived in. Although managers from Australia and the United States shared similar values, the Japanese and Korean managers did not show a similarity of values. Such differences were attributed to varying levels of industrialization of the two countries. Therefore, it is not the country or nationality per se, but the proximity in

socio-economic conditions of those countries that determines similarity between managers/leaders.

To isolate the impact of culture from national origin, researchers have contrasted the effect of social/ethnic culture and country of residence. In these studies, the values of managers from various countries were compared to the values of managers who lived in the United States. The result showed that those managers who came from countries that were at similar levels of modernization as the United States had similar values. So, for example, the U.S. managers of both Caucasian and Chinese background had values more similar to those of managers from Hong Kong and more different from those of Mexican and Mexican American managers. This result not only illustrated issues related to difference in industrialization between the United States and Mexico, but it also alluded to the potential reason that Mexico's adaptation to industrialization is relatively more difficult.

Likewise, the results of a study that compared managers with Chinese heritage from three different countries (the People's Republic of China [PRC], Singapore, and the United States) showed that the values of the Chinese managers who lived in Singapore and the United States were quite similar to each other, and were quite different from those who lived in the PRC. Again, the role of modernization and industrialization of the country of residence seems to contribute to the similarity between the leaders' values.

In short, the aforementioned studies illustrated that industrialization and education are powerful societal forces in unifying managers' values across countries. No one specific set of values defined all managers. However, the conditions in which the managers functioned did have an impact in making them more similar.

The majority of research and theories on leader behavior in the United States relies heavily on subordinate perception of the leader's behavior. The content of these behaviors has been as specific as conflict management strategies and influence, and as broad as transactional and transformational leadership. All the various theories have reported some cross-cultural validity in predicting outcomes and some level of universality in the presence of these behaviors.

To review this aspect of leadership and the role of culture, first the behaviors are briefly defined. Subsequently, three cross-cultural concerns that have been presented in testing the universality of these behaviors are discussed. These concerns are (1) comparative level of occurrence of these styles across cultures, (2) difference in behaviors determining the styles across cultures, (3) their functionality across cultures.

Theorists and researchers have identified many leader behaviors with a plethora of empirical research. The oldest leadership behavioral styles studied in U.S. research are consideration and initiating structure. Consideration refers to behaviors that are friendly, open to input, respectful to others, etc. Initiating structure includes behaviors that focus on getting the job done, such as goal setting, clearing expectation, criticizing wrong behavior, rewarding good behavior, planning, etc. These were identified as two distinct categories of leadership behavior that help a group meet its goals of maintaining harmony and accomplishing tasks successfully.

Subsequently, leadership researchers acknowledged that these are transactional-type behaviors, and they recommended that effective leaders go beyond the status quo. Thus, the transactional and transformational leadership paradigm was presented. Behaviors included in transactional leadership style were active or passive monitoring of performance and giving feedback, also the act of giving rewards when due. Transformational leadership included four behavioral styles, intellectual stimulation, individual consideration, inspirational motivation, and idealized influence. Intellectual stimulation is getting team members to think critically. Individual consideration includes styles of behaviors such as attentiveness to diversity of needs and values of team members and addressing each on their own basis. Inspirational motivation consists of behavioral styles that exude energy and emotion in the actions to be taken. Finally, idealized influence includes behavioral styles that provide vision and unify the team behind a common goal. Theorists such as Bass and Avolio have been explicit in clarifying the relationship between the transformational and transactional styles. The issue is not that the leader should engage in one or the other style, but rather that transformational style augments the effects of transactional style. Overall, men and women leaders do not differ greatly in these behaviors; however, women leaders are perceived to be slightly more participative than men leaders. Additionally, women leaders are perceived to be slightly more transformational and to give more contingent rewards as compared to men leaders.

Conflict management and influence tactics are significant leadership behaviors; many scholars define leadership as a process of influencing others to do what they would not do otherwise. Rahim's conflict management model identifies two adversaries and the strategies they may take in managing the conflict between them. When one party is focused on winning at all costs, this is known as competitive strategy. When one party gives all his or her rights for another's to win, this is

considered accommodating strategy. If both parties leave the relationship, it is known as withdrawal. If the parties negotiate a settlement, this is a compromising strategy. Finally, if the two parties focus on the problem and the best solution in which both can win, this is referred to as collaboration strategy. Influence tactics are behaviors identified empirically when people were asked how they influence others. The tactics most commonly supported in U.S. research were rational persuasion, ingratiation and coalition tactics, inspirational and personal appeals, exchange, and assertiveness.

Overall, each of these behavioral paradigms in the United States has received support across settings and populations. That is, both the reliability of the measures assessing the styles and the functionality of the styles in relation to organizational outcomes have received empirical support. Next, the effect of culture on these behaviors is examined.

The first question that many cross-cultural researchers have had when using these theories across cultures is, Do all managers behave similarly across cultures? Empirical studies have found that the magnitude of the manifestations of these styles vary across cultures. This was established by comparing the mean scores of the frequency of occurrence of the various styles in different countries. For example, it was found that New Zealander managers were described as more transformational than transactional, whereas the Taiwanese managers were seen as behaving equally in both transformational and transactional styles. It was also reported that in a manufacturing telecommunication transmission equipment industry, the U.S. managers, in comparison with the German managers, were described as more charismatic and were reported as being more inspirational when motivating their employees.

Some cross-cultural leadership researchers became aware that specific behaviors that define a style might vary from culture to culture. For example, it is reported that in Indonesia for leaders to be able to inspire and motivate their subordinates, they must first persuade their subordinates that they are competent leaders, so leaders boast about themselves. This behavior, on the other hand, is not acceptable in Japan or in some other countries. In another study, comparing Taiwanese responses to those of Americans, it was found that the value system of the respondent had an effect on which specific behavior was related more to transformational or transactional leadership. Also, in a recent multicultural study, it was found that the behaviors contributing to each dimension of transactional and transformational leadership styles varied

when the respondents were not culturally homogeneous. However, in comparing U.S. managers to those from Bangladesh, the results showed that the five-conflict management styles, as defined in the United States, were also valid for Bangladesh. Therefore, the meanings of the conflict management styles is the same across these cultures.

In regard to universal functionality of leader behavior, we can examine two studies assessing the relationship between leader behavior and organizational outcomes. A five-country (Japan, South Korea, Taiwan, Mexico, and the United States) comparison illustrated that charismatic, supportive, and contingent rewards had a positive impact across cultures on employee work-related attitudes, whereas participative, directive, and contingent punishment in relation to these organizational outcomes varied by country.

In an experimental study in the United States, two confederates acted as either a transformational leader or a transactional leader, and they both led a group of Asian Americans or Caucasians. It was found that the Asian groups were more collectivist while the Caucasian groups were more individualistic; the collectivist groups (Asian) generated more ideas when the leader was a transformational leader than when the leader was transactional. However, the individualistic groups (Caucasian) generated more ideas with a transactional than with a transformational leader. These studies demonstrate that the team members' cultural values and experiences moderate the functional relationship between transactional and transformational leadership and organizational outcomes. Examining the effect of culture on the effect of influence tactics cross-culturally, two cross-cultural studies with managers from Hong Kong, the PRC, Switzerland, and the United States were examined. The findings supported the fact that cultural values affected the effectiveness of managers' choice of influence tactics. The Western managers, as compared to the Chinese managers, rated direct task-oriented influence more effective, and they rated influence tactics that were based on personal relations less effective. More specifically, Schmidt and Yeh quoted the Chinese saying, "Give benefit, but show authority." This quote is a good example of the impact of a society with high power distance and high collectivist cultural values.

The cross-cultural evidence shows that although the notions of the U.S.-driven concepts of leadership are present in all cultures, they do not manifest at the same level or in the same way, or have similar effects on employees. Therefore, it is necessary to recognize that

the cultural context in which a leader is functioning will impact the behavioral choices he or she makes; it also impacts the interpretation of their behavior. Ultimately, culture moderates the effectiveness of these leader behavior styles. On the other hand, the managers from cultures with similar level of socio-economic development seem to be more similar compared to those from societies with various level of development. Thus, it is possible that as the gap between level of education and advancement shrinks, the similarity among leaders across cultures will also increase.

3.2. Etic Approach: Contingency Approach to Leadership

Three main contingency models of leadership are recognized in leadership research: Fielder's contingency model and leadership effectiveness, Mitchell and House's path-goal theory, and Vroom's leadership decision-making theory, which has the most empirical research. Because the path-goal theory of leadership has received mixed support, this article focuses on the role of culture in two models: Fiedler's contingency model of leadership effectiveness and Vroom's normative decision-making theory.

3.2.1. Contingency Model of Leadership Effectiveness

The contingency model of leadership effectiveness is a leadership model that combines the leader's trait and its match with the situation in predicting leadership effectiveness. The results of past research have found support for the model across various industries and populations. The situation in this model is defined by assessing the leader's amount of control and influence in the situation, referred to as situational control. In high and low situational control conditions, leaders who are more task-motivated than interpersonal are more effective; whereas in moderate situational control, leaders who are more relationship-motivated rather than task-motivated are more effective.

Fielder identified three factors that contribute to situational control. In order of importance, they are the leader-member relationship, the task structure, and the position power. The leader-member relationship refers to the leader's certainty that the team is united and supportive of him or her. Task structure refers to the leader's knowledge of how to get information or conduct a task. Position power refers to the

leader having a title and the legitimacy and resources to reward and punish team members.

The trait of the leader is assessed with the least preferred coworker (LPC) scale. This construct assesses the leader's motivational orientation, that is, whether the leader gives priority to task accomplishment or to people's feelings. High score is indicative of relationship orientation and low score is indicative of task orientation.

The model has been tested in across multiple cultural settings, and in many it has shown to be successful in predicting a leader's effectiveness. This model is sensitive to cultural milieu, as the culture of the situation can be assessed by the situational control factor in the model. Thus, the model has not only gained cross-cultural support, it has also demonstrated that it can incorporate culture as part of its assessment of the situation.

The LPC score, depicting the leader's trait in this model, has a normal distribution in the United States with a mean of 65. The range of leaders' LPC scores varies across cultures. For example, the average score for Mexican managers on this scale was higher than the U.S. samples, and the average for Iranian managers was higher than both the United States and Mexico. On the other hand, the managers from England, Thailand, and the United States were not different on their scores on LPC scale. Also, no gender difference was found when comparing men's and women's LPC scores. Furthermore, the distributions of the score vary across cultures. For example, almost all respondents from Navaho nation (a Native American tribe) scored so high on this scale that it was not possible to identify any individual with low scores (task oriented).

The model, therefore, allows for the assessment of the interference of culture on leadership effectiveness, and it has shown varying degrees of cross-cultural validity. However, due to varying ranges and distribution of the LPC scores, it could be concluded that across the respondents from the United States, Mexico, Iran, and Navaho nation, the U.S. managers tend to have the prepotency to give higher priority to task accomplishment than to their relationships compared to the managers from other cultures. Nevertheless, the premise that task-motivated leaders do better when they feel in control, and relationship leaders do better when engaging team members, seems to be valid across cultures.

3.2.2. Normative Model of Decision Making

Based on group dynamic and decision-making principles, this prescriptive model of leadership decision-making

strategy was developed. The model states that leaders typically are confronted with five decision-making strategy options that range from very authoritative, to consultative, to participative. This model assists the leader in assessing the situation and choosing the most effective decision-making strategy. The situation in this model is assessed through answers to questions on the leader's knowledge, the team's receptivity to the decision made, and the time available to make the decision. In brief, when leaders have the information and are not dependent on the subordinates to carry out the decision, they can choose more autocratic decision-making styles and spend less time on this process. However, if the leader either does not have all the facts or is dependent on the subordinates' support, he or she needs to take more time and use more consultative and participative styles of decision making.

The validity of the model was tested on both men and women leaders. It was found that male leaders who were perceived as autocratic were evaluated as moderately positive. In contrast, female leaders who were perceived as autocratic were rated negatively.

Cross-cultural studies using this model showed that the choice and success of decision-making style is dependent on politico-economic conditions. For example, when this model was tested in Austria and Poland, it was found that Polish managers had a harder time following the model's prescription to use participative decision-making styles when necessary. This became more evident as the decision became more important. Furthermore, results showed that only after the fall of communism in Poland did Polish managers show a trend toward more participative practices. Therefore, these two studies demonstrated the impact of politico-economic condition on the leader's decision-making choice. Also, when the ideal leader's decision-making style was compared across the three German-speaking countries of Austria, Germany, and Switzerland, the results showed that the managers in all three countries preferred a team-oriented leader. However, the Germans and Austrians favored a "lone fighter," whereas the managers from Switzerland did not support this style.

Thus, the model is cross-culturally supported. The aforementioned studies demonstrate that the political and economic conditions should be considered as part of the situational factors. Some social situations give leaders more choices in using different decision-making strategies. As can be noticed in the case of women and the Polish managers before the fall of communism, the leader is devalued if he or she does not behave according to the expectations of the majority.

Different definitions of leadership that was developed mostly in North America and was validated in various countries or across men and women in leadership positions have been reviewed, and the influence of culture on leadership has been discussed. In summary, it seems that the validity of a universal characteristic of leaders is questionable. In contrast, contingency or situational leadership models showed more cross-cultural validity. However, culture must be considered as a situational factor, a moderator that influences the relationship between the leaders' traits, behavioral styles, and effectiveness.

3.3. Quasi-Emic and Emic Approaches: Implicit Leadership Theory

The previous sections reviewed the results of etic studies, in which the leadership theory, model, or measure was transported from one culture and applied to another to validate it. In these studies, however, implicit leadership theories of people of various cultures have not been the focus of research. It is through the emic approach that cultural uniqueness of leadership may come to light.

To illustrate the importance of subjective meaning of leadership in various cultures, the word that describes the activity in the workplace in different languages can be compared. For example, in English, the word "business" is used as a generic term for what goes on in the workplace. This word—denoting the condition of being busy—implies a sense of activity and energy to accomplish goals. In Spanish, however, the term used to refer to the same exchange is *negocio*. Etymologically, the root of this word is similar to negotiation, and it brings to mind exchange, social interaction, and give and take. Therefore, the comparisons of words used in different cultures that refer to activities in the work place may reflect the perspectives and priorities of these cultures. That is, in one culture the main focus may be getting the job done, in another, establishing relationships. Thus, cultural nuances are depicted by slight variations in the priorities on task versus relationships.

In cross-cultural leadership, two sets of emic studies can be identified: first, those that were inspired initially by Western conceptualizations and then arrived at an emic concept, which are referred to as quasi-emic; second, those studies that emerged empirically from within the culture, known as emic.

3.3.1. Quasi-Emic Approach

Three main leadership behavior models have emerged from the studies of leadership behavior in Iran, India, and Japan. These models did not support the two-factor model of leader behaviors (consideration/people orientation and instrumental/task orientation) that were present in North America. We refer to these endeavors as quasi-emic, because they were originally based on theories or measures that were inspired by researchers in North America. By examining the findings in each Asian country, similarities and uniqueness can be noticed.

In Iran, Ayman and Chemers reported that the behaviors describing consideration and initiating structure behavior style were both highly correlated with "My leader is like a father to me" and "My leader is effective"; the two styles were inseparable. Comparing the results of the studies in Iran, in which the leader was either American or Iranian, showed that Iranians maintained a perception that the two types of leader behaviors need to occur simultaneously for a leader to be effective and acceptable. Thus, the label "benevolent paternal" was coined for the Iranian leadership.

To illustrate the significant contrast of acceptable leadership behavior in Iran and the United States we can consider this anecdote: Iranians in the United States have commented with amazement that their bosses are "all about business" and are impersonal, which is judged as inappropriate and rude. For example, it is said that first thing in the morning, the bosses walk into the offices, and without greeting employees and asking about their well-being, state their business, make task requests, and leave the room. However, when Iranians share this experience with their American peers, the response they get is that this is an acceptable behavior at work. That is, in the U.S. workplace, it is acceptable to forego exchange of social pleasantries. In Iranian culture, however, the expectation is for the leader to be personally warm and courteous as well as professional.

Examining the application of quasi-emic approach in India, J.B.P. Sinha and colleagues explored leader behaviors. They used the two leader behaviors of consideration and initiating structure, but also added culturally unique leadership behaviors they labeled as "nurturant-task." As a result, a unique conditional behavior that resembled the benevolent paternal leadership style in Iran emerged. In other words, leaders' behaviors included simultaneously expressed demand for getting the job done and caring for the person.

Concurrently, in Japan, Misumi developed a PM (performance/maintenance) theory of leadership behavior.

He took the concept of performance-emphasis and maintenance-emphasis functions from Cartwright and Zanders' conception of leadership. The concepts resembled other leader behaviors popular in the United States, such as consideration and initiation of structure. However, PM is distinct from the leader behavior models in the United States. Misumi's theory emphasized that the two behaviors of attending to the task and to the people are not polar opposites, nor do they function separately. In addition, Misumi believed that leader behavior cannot be generic but should be put in context of the job. Therefore, not only was the PM model similar to the other Asian studies in the inseparableness of leader behaviors but it also mentioned the importance of context.

In summary, there is similarity across the studies in Asia, where the accepted leadership behavior style is a combination of consideration and initiating structure. In these cultures, focusing on only one aspect of work, that is, either getting the job done or attending to people, is not considered appropriate. The social protocols and pleasantries are significant elements of effective leadership. In these societies, business is about building trusting relationships through which the job gets done, not just about getting the job done.

In addition to the above studies, Schein and her colleagues conducted a series of studies around the world examining the image that people have of a manager compared to the image they have of a woman and a man. The results of these studies have shown that across cultures; there is a male image of a manager. This finding is very significant, as the number of women managers is increasing, and they will be faced with expectations that may be contrary to their style and habit. Interestingly, this may be the first universal finding in leadership that was not moderated by culture.

In summary, each culture cultivates a unique set of expectations of their leaders. The universal concept that emerges from these studies seems to underline the fact that leaders need to attend to task and to relationship. Across cultures, the importance of these two styles and their distinctions seem to vary. In Asia, it seems that effective leaders are expected to engage in task- and people-oriented behaviors simultaneously.

3.3.2. Emic Approach to Leadership

Earlier, the various types of cross-cultural approaches and the role of the endogenous and exogenous researcher were discussed. The previous section reviewed the results of the findings of studies conducted

by endogenous researcher. Based on their interpretations, an emic understanding of the leadership process in Asia evolved. This section presents two studies, in which, through a series of interviews and observations, two exogenous researchers explored leadership in China and Japan.

The first study's objective was to understand women leaders in China at the early stage of that country's decision to open itself to a capitalistic economy. Through a series of interviews, Korabik (1990) contended that Chinese women managers, compared to men, attributed their success mostly to interpersonal social skills. On the other hand, most of the men managers, as compared to women managers, attributed their success to skill, training, and experience. Interestingly, both Chinese men and women managers said, "It is possible to be both tough and caring. I try to combine patience and firmness." This finding reconfirmed the quasi-emic models of Asian leadership, in which the two task and interpersonal behaviors needed to occur simultaneously.

Pascale, in a 1978 case study of Japanese managers' style of leadership, presented comments from Japanese managers about how American and Japanese managers differ in their style. As an example, he quoted a Japanese manager as saying, "You Americans are fond of announcing things. It sets everything astir." Pascale described the Western leaders as those who are "out standing," whereas Eastern culture values leaders who stand "in" rather than "out." The general but important difference between Japanese and American managers is that Americans are more explicit in their communication and the Japanese more implicit.

The emic studies of leadership, therefore, portray cultural subtleties in the leadership process. For example, across the world, leaders are expected to act more masculine. Also, if one were to use a continuum in which one end represented attention to performance and the other interpersonal relationship, the emic studies have demonstrated that Asian leaders seem to put more priority on a balance of interpersonal relationship and task accomplishment and see them as intertwined, whereas managers in the United States may prioritize task accomplishment at the possible expense of interpersonal relationship. The culture of men compared to women is typically more focused on task activities than emotions and interpersonal relationship. Hence, one could conclude that in the United States, men managers compared to women managers put more priority on performance than on interpersonal relationships. Also, one could surmise that since Asian managers seem to combine the relationship and task behaviors, their

culture would be more similar to that of American women managers than to American men managers.

4. NEW TOPICS IN CULTURE AND LEADERSHIP

In recent years, three topics have emerged in the study of culture and leadership. One is related to the method of research in the study of cross-cultural leadership and the call for a multicultural team. Another is leadership when cultures collide, that is, when leaders operate in a multicultural environment. The third topic focuses on the evolving role of a transnational leader, that is, the difference between an international leader and a global leader.

4.1. Multicultural Research Teams

The majority of studies discussed so far have examined either the validity of one leadership paradigm cross-culturally or the unique meaning and function of leadership in a given country. Several recent research teams have explored culture and leadership. The GLOBE project, a recent cross-cultural research endeavor, has systematically examined similarities and differences of respondents over the question of leadership expectations and prototypes in several industries within each country.

In the late 1990s, House, Hanges, and Ruiz-Quitaniella described the GLOBE project as a multi-phase and multi-method research project that included collaborators representing various cultures around the world. They reported that the project presented data from 62 cultures and included 170 indigenous and exogenous social scientists. In their view, the concept of leadership is defined as "the ability of an individual to influence, motivate and enable others to contribute toward the effectiveness and success of the organizations of which they are members." The key research questions of this project focused on identifying both universal and culture-specific leadership attributes, behaviors, and organizational practices. Additionally, it identified in what way culture affected the type of leadership attempted and the effective leadership, and it presented the comparative standing of various cultures on the cultural dimensions. Finally, the project examined the potential for an underlying theory that could explain both national differences and the universal leadership attributes and practices.

To accomplish this, three measures were developed. One focused on the cultural and societal values attached to an effective leader (i.e., what they should be) and how they observed leaders behaving (i.e., what they are). The second measure addressed the practices of their organization. The third measure examined the attributes that impede highly effective leadership. (A detailed representation of the method and sampling of the GLOBE project is beyond the scope of this article.)

This project will eventually allow the examination of similarities and differences across cultures based on agreed-upon definition of leadership. Nonetheless, the preliminary findings attest to the same phenomenon that has been stated throughout this article. That is, although there may be some general universal qualities of leadership behavior, the acts manifesting them will vary and have different meanings across cultures.

4.2. Cultural Collision and Leadership

Multicultural work settings have been around for centuries. Immigrant workers and cross-national trade have existed around the globe for centuries. However, the intensity of cross-cultural exchanges has a more noticeable economic impact in today's global society than in the past. In previous centuries, those with resources and military might imposed their ways on others. Now, the competitive global economic market does not allow for a company or a nation to mistreat others for long, as there are competitors and potentially better options. Also, the presence of global communication systems has increased the accountability for social responsibility and human rights in business exchanges.

In today's global economy, expatriates can be migrant workers or expatriate managers of large, multinational corporations. Leader-member exchange theory can assist understanding the impact of culture on leadership in a multicultural setting.

The leader-member exchange defines leadership as a relationship. It has demonstrated that leaders have varying levels of intensity in their relationships with different employees. When the leader and the subordinates are in a close, trusting relationship, they enjoy an enriched relationship in which the leader is more apt to engage in transformational behavior styles. When the subordinates are at the periphery of the team, are not closely involved with the leader, and do not have a strong trusting relationship, the leader tends to behave

more transactionally with them. Leader-member exchange theory, therefore, demonstrates that like any relationship, the leadership process also goes through a maturation process, from being strangers to being confidants. What makes this model appealing to multicultural setting is that at the core it assumes that leaders and subordinates develop unique dyad relationships.

In a multicultural setting, it is conceivable that leaders will develop closer relationships with subordinates who are similar to them; the leader may stay distant from those who are different. The research on this model is still young, yet the opportunities to explore the role of culture in leader-subordinate dyad relationship building are promising. Exploring the cultural factors that contribute to building strong leadership relationships in multicultural settings is necessary.

Independent of this theory of leadership, practitioners and cultural anthropologists have developed cultural guides to help expatriate leaders adjust to working in cross-cultural settings and with people from various cultures. However, in this type of cultural awareness training, two issues are overlooked. The first is that the cultural prototypes are used. That is, in this training, the leader is told what typically may occur in a country or what to expect from people of a certain culture. This can create stereotypes, as most people do not fit the cultural prototypes or stereotypes, and so can lead to misunderstanding. Second, this method of cultural awareness assumes that culture is static. Trompenaars and Hampden-Truner stated that international managers are faced with layers of cultural demands that are fluid and need balancing. In addition, in this type of training there is a tendency for the leader to try to act similar to the natives. This can be a no-win situation, as it has been demonstrated that natives do not trust expatriate leaders who act like them. Consequently, the value of knowing about the norms of the other culture is the awareness of the range of accepted behaviors that can equip leaders with alternative explanations when they observe behaviors that may be strange to their own cultural norms.

In summary, our knowledge about leadership in multicultural settings is still evolving. For years, cross-cultural trainers such as Foa and Triandis have recommended that those interacting in cross-cultural settings defer judgment and view situations through the eyes of the member of the other culture. They also developed the cultural assimilator training programs, which teach the individual faced with a heterogeneous team to be aware of his or her cultural assumptions and potential biases, as well as the beliefs

and assumptions of the others. This technique trains the sojourner or expatriate to be more attentive and to think before acting.

Therefore, it is most helpful for the leaders in multicultural settings to be aware of the cultural norms of their own culture and those of the others. This awareness gives them a perspective of the range of behaviors to be expected. In addition, keeping an open mind and asking questions before judging is the best way to adjust to a team composed of various cultures and styles.

4.3. Global versus International Leadership

Many scholars use the terms global and international interchangeably. A number of scholars, however, use the terms to refer to two distinct mindsets. International leaders are those who have the tendency to impose their own cultural values and policies on others. On the other hand, global leaders perceive complexity and are inclusive, respecting people of all cultures equally, and are concerned about what is the best solution in the long run. This strategy is not much different than that referred to earlier as the collaborative approach to managing conflict.

Two forces affect the leaders who cross country boundaries or take part in cross-cultural functions. One is that most managers are faced with a universality of the technology and education in various fields. The other is that the international managers are faced with the diverse expectations and norms of the cultures they visit. The global leader has the ability and mindset to create the needed balance and harmony between these two. The international leader, though, will focus on the universal, and may not be skilled in or aware of the important cultural needs and expectations. The global leader incorporates this diversity when establishing his or her business plan and policies.

Global leadership requires awareness and acceptance of the diversity of the needs present in the world. In global leadership, the cultural interests and values of all are included; this process, due to its complexity, requires more time. Global leadership is inclusive and, through a balancing process, brings a sense of unity in diversity. As this is a new phenomenon, its representation is limited and difficult to examine empirically. But it is the type of leadership needed for the global society to progress and prosper. Some have proposed that perhaps a federation, committee, or

council representing global-minded individuals with different cultural background is the best choice for a global leadership.

5. SUMMARY AND CONCLUSION

As this article has demonstrated, the study of culture and leadership is very complex. The progress in exploring this symbiotic relationship was explored through various perspectives, and the importance of including culture in understanding a social phenomenon such as leadership in a diverse and culturally heterogeneous setting was well documented. Imposed etic, emic, and derived etic studies were reviewed, and their findings were summarized. Overall, although the various approaches to leadership were validated in different cultural settings, these findings need to be considered with caution.

It seems that most countries, other than those with Anglo-Saxon background, place importance on the interpersonal relationship aspect of leadership. Also, the most powerful aspect of culture in determining leadership values or behaviors seemed to be economic environment such as urbanization. Additionally, although the various definitions of leadership functions were validated across cultures, the specific behavior that is perceived by one culture as contributing to one style is not the same across cultures. This fact alerts the sojourner managers of a multicultural team to be attentive as to how their specific acts may be interpreted differently by different members of their team.

In conclusion, to understand leadership in various cultures or globally, one must review multiple studies and approaches across time. This article provided a glimpse into the complexity present in the interplay between culture and leadership, highlighting the dangers of oversimplification and overgeneralization of the universality of leaders' behaviors. At the same time, some of the paradigms that have evolved so far in leadership, in principle, seem to be working globally. The challenge of a multicultural and global leader is to be attentive to the nuances present in different cultural groups and be accepting of them; in essence, to pursue a balance in unity and diversity.

GLOSSARY

declarative knowledge Involves knowledge of facts, concepts, vocabulary, and the usual bits of information that are stored in memory.

formative assessment The observation or measurement of student learning outcomes prior to and during the learning experience. Formative evaluation provides a starting point for determining change as well as periodic assessment during the learning episode.

no child left behind (NCLB) Federal legislation that was enacted to redefine the manner in which federally supported programs are held accountable for the impact of educational interventions on all students in the classroom. Target behavior for defining impact is the improvement of academic achievement in mathematics, reading/literacy, and science.

pedagogy The art and science of teaching.

problem-solving transfer The ability of students to apply prior knowledge in the form of academic problem-solving strategies to new and novel problem situations in academic subject matter areas.

procedural knowledge This type of knowledge is observed in the classroom when students demonstrate the ability (knowing how) to combine, refine, incorporate, and accommodate (in the Piagetian sense) declarative knowledge so that it can be used in a course of action.

self-efficacy Personal beliefs concerning one's capabilities to organize and implement actions necessary to perform behaviors at designated levels (efficacy expectations).

self-regulation The process whereby students personally activate and sustain behaviors, cognitions, and affects, which are systematically oriented toward the attainment of learning goals.

strategic knowledge This type of knowledge is observed in the classroom when students demonstrate "knowing when" to use prior knowledge that is in the form of declarative and procedural knowledge. This type of knowledge is observed in problem-solving situations.

summative assessment The assessment that occurs at the end of an educational intervention or teaching episode. A comparison of formative and summative assessment is the basis for the determination of change.

Academic learning is receiving increased attention in the early 21st century. The educational shibboleth is "no child left behind." This federal mandate has impacted the nation in a way that will continue to reverberate for several years. At the classroom level, teaching practices are being impacted by the emphasis on accountability

and impact measures that are being implemented. At the school district level, the accountability and impact data are to be used for policy analysis and to guide educational reform. The professional educator involved with the evaluation of educational practices and programs must produce credible data that meet the criteria of scientifically based evidence. In all cases, the target behavior for these efforts is the improvement of student achievement in reading, mathematics, and science. Assuming that we send our children to school to learn these academic subjects, we must also ask the questions, “what do we mean by academic learning and what are the processes by which students develop their knowledge of academic subjects?” These two questions serve as the focus of this article. Coming from the psychology side of educational psychology, the context is current research findings from the memory, cognition, and learning literature that have potential application to educational practices. Thus, it goes without saying that the perspective is “learner centered” and the unit of analysis includes both the individual and the group, as implied in the phrase “no child left behind.”

1. ACADEMIC LEARNING

Learning as a proper noun has so many meanings that it is almost impossible to communicate effectively without first adding a qualifying term. For example, in the applied setting we call the classroom, there are different types of learning theories and models. Some theories describe and explain motor learning that serves as the basis for motor skill development. In other cases, some learning theories focus on learning that serves as the basis for social skills development. However, the focus of this article is academic learning that relies on cognitive learning theories and information processing models to describe and explain the development of personal knowledge about the subject matter we teach in the classroom.

I use the term academic as a descriptive adjective to communicate in one sense something about the nature of the thinking and remembering processes a student must engage in to successfully interact with classroom academic demands. In a second sense, I also draw attention to the fact that the curriculum content we commonly refer to as literature, mathematics, and science has a logically organized structure that must be understood by the student. In other words, in addition to simply acquiring information in the form of vocabulary, facts, or concepts, these building blocks for personal knowledge must be organized in a manner consistent

with the epistemological demands of the subject matter being taught. Examples include knowledge of the syntactical structure of the language in which a third-grade student is writing, the logic for translating and representing a fifth-grade math story problem as an equation to be solved with the use of appropriate solution algorithms, and the formal prepositional logic involved with the ability to use combinations and permutations when solving ninth-grade algebra problems. From these examples, it is readily apparent that academic learning is quite different from social learning or motor learning, which also play a major role in students' efforts to adjust and cope with the demands of schooling.

2. LEARNING AS ENDURING CHANGE

Having identified academic learning in terms of a “type” of learning activity, a closer look at a commonly accepted definition of learning will serve as a means of considering what is frequently referred to as the learning process. In the third edition of *Learning Theories: An Educational Perspective*, Dale Schunk offers a suggestion. Although experts disagree about the precise nature of learning, the following is a general definition of learning that is consistent with a cognitive focus and captures the criteria most educational professionals consider central to learning: “Learning is an enduring change in behavior, or in the capacity to behave in a given fashion, which results from practice or other forms of experience” (Shuell, 1986, as cited in Schunk, 2000, p. 2).

There are three elements to Schuell's definition of learning that deserve further attention (change, endurance, and practice) because these elements help define the level of analysis involved in the present use of the term personal knowledge. This level of analysis is also driving the new “no child left behind” (NCLB) legislated mandates. These mandates emphasize the idea that all children can learn, and the key to success according to NCLB mandates is in the assessment and analysis of learning from a scientifically based perspective. Within this context of academic learning our discussion of the construction of personal knowledge can be critically examined.

3. DEFINING ELEMENTS

Behavioral change or change in the capacity for behavior is basic to any attempt to distinguish between information

processing and learning. Daily, each of us processes information through contact with our environment as well as information retrieved from memory in the form of ideas, recollections, etc. However, some of this information processing is at a level that does not initiate change in our behavior or our capacity to adapt. Academic learning involves the development of new behaviors or capacities, not simply the replication of previous habits. Furthermore, the demonstration of change is not left to conjecture. Rather, change can only be demonstrated by measuring the behavior at two different points in time. Typically, this is prior to and following instruction.

Enduring change must have some permanency about it. In other words, the important elements of instruction to which a student is exposed should be remembered. In fact, our curriculums in the public schools are designed around this primary assumption. Unfortunately, the empirical evidence for enduring change is scanty at best. In our discussion of personal knowledge, we focus on the individual learner as the unit of analysis, not the class as a whole. This is in fact the reason that the NCLB mandates are framed within a consideration of the individual student (no child left behind). This in no way ignores the fact that academic learning occurs in a group context. Rather, it focuses attention on both the individual and the collective we call a classroom. This makes common sense when one considers that the basis for knowledge permanency is the individual student's memory system.

Practice is an interesting concept in the academic community. A basketball coach teaching motor skills will tell you that "practice makes perfect," a music teacher will insist that students practice between lessons, and the school administration will stress the practice of civility and social behavior. However, the classroom teacher responsible for academic content frequently views practice as a "hit-or-miss" proposition that gets attention during seatwork or homework. Interestingly, although all these practice episodes can be observed in any school, the episode that typically lacks any organization or rationale is seatwork or homework.

Together, these three basic elements of our definition of academic learning stress the idea that academic learning is not a one-shot instructional experience. It is a process of acquiring new information, the refinement and organization of what is already known, and the successful use of that knowledge. Academic learning is the product of practice that provides the basis for relatively long-term change in one's personal knowledge. Ideally, this change increases students' ability to be successful as they move from grade to grade where

the curriculum requires more complex and specialized forms of personal knowledge.

4. TYPES OF PERSONAL KNOWLEDGE CONSTRUCTION

The following discussion is based on a common theoretical assumption that pervades educational psychology: Cognitive change must occur as a student progresses through the curriculum in order to be successful. Jerome Bruner, in his discussion of the spiral curriculum, made this point. Still valid today, this assumption is frequently presented in the form of a hierarchical schema, from simple to the complex, in terms of both the cognitive processing demands made on students and the nature of the subject matter to be learned. The following discussion takes this form and reflects a prevailing attitude among educational psychologists that the construction of personal knowledge can be identified as falling within three major typologies: declarative knowledge (concepts and facts), procedural knowledge (strategies, procedures, and schemata), and strategic knowledge (expertise in academic problem solving).

The study of knowledge can take many forms. Within the context of academic learning, the following analysis is functional in nature and involves an information processing perspective. The functional nature of the following discussion involves addressing the "what" and "how" questions of personal knowledge construction. Phye (1997a) stated,

A particular value of the information processing perspective for the classroom teacher is the assumption that, while each student in the classroom will have a unique set of prior experiences that influences entry learning level, rate of learning, style of learning, and so forth, all nondisabled students in the classroom will be approaching the learning assignment with essentially the same set of processing components. Consequently, when learning is not successful, an assessment can be quickly conducted in order to determine cognitive processing strengths and weaknesses. (p. 53)

5. DECLARATIVE KNOWLEDGE

Basically, declarative knowledge involves those things teachers refer to as facts, vocabulary, concepts, etc. These bits and pieces of information are the building blocks for academic learning. These are the "basics" that

cut across all curriculum content areas. For the student, the construction process involves not only attending and remembering but also the bringing of meaning to this newly acquired information. By connecting new information with prior knowledge or using new information to refine what is already known, meaning is changing from the concrete to the complex.

Three examples make the point. Outside the classroom as well as in the primary grades, a commonly accepted mathematical fact is that $2 \times 2 = 4$. However, as one progresses through the mathematics curriculum, a part of any student's academic learning involves the following refinement of prior knowledge. The $2 \times 2 = 4$ mathematical fact applies only in a base 10 mathematical system. Thus, $2 = 2 = 4$ may not be a fact in other mathematical systems. This mathematical fact is refined or deemed to be "true" only within a specific context. For most students, this refined knowledge would have little or no relevance outside the classroom.

The second example is a common classroom learning experience that is observed when dealing with concepts in science. During the early grades, the concept of "animal" is introduced and students typically use the term to mean a large group of "nonpeople living things" of one type or another. However, as science lessons progress, the student is challenged to refine this general concept into a more specific organizational system that includes people within the subcategory of mammals and that mammals are still animals. This bit of declarative knowledge refinement has both high academic relevance and relevance outside the classroom.

Having touched on examples from mathematics and science, the last example comes from early reading. As a child progresses from kindergarten to the fourth grade, vocabulary building, fluency in reading, phonetic awareness, word attack skills, and comprehension are reading skills that are practiced in oral reading groups. As these basic reading skills become integrated, a child's reading performance improves. A primary goal of learning to read involves the ability to comprehend what is being read. One part of this process is taking individual words and their meanings and putting them together into sentences. Interestingly, in English many words have different meanings depending on whether they are used as a noun or a verb in a sentence. The word "desert" used as a noun means a dry, barren, often sandy region that can naturally support little or no vegetation. Desert used as a verb means to forsake or leave, especially when most needed. Obviously, the key to understanding the meaning of the word desert depends on having both

meanings available and selecting the appropriate meaning based on the context (rest of the sentence).

Students process information every waking moment of their lives. Some of the information is organized and some is fragmented or organized around real-world survival skills. However, academic knowledge is a special case in which the organizational principles are unique to the subject matter being taught. Consequently, remembering becomes a valuable cognitive skill for any student. Thus, as we go back to our basic definition of academic learning, the emphasis on enduring change becomes more apparent. As learners, we remember facts and concepts not only so we can demonstrate the acquisition of new declarative knowledge but also so this new knowledge becomes prior knowledge to be added to and refined at a later point in time. The reading example described previously also demonstrated the vital role that memory plays in academic learning. The student who encounters the word desert must remember two different meanings and successfully retrieve from memory the appropriate meaning, depending on the cues provided by the rest of the sentence. The ability to do this fluently requires a great deal of practice so that the process of remembering meanings occurs almost automatically.

Reading fluency is a good example of an academic behavior that improves with practice and is a critical academic survival skill. By the intermediate grades, students are asked to take increasingly more responsibility for their own learning. Most classroom environments change at the middle school level and students are expected to acquire a great deal of their own declarative knowledge by reading texts, working through Web-based instructional modules, etc. This expectation on the part of educators suggests that students should be practicing their reading skills during the primary grades so that they can successfully adapt to the demands of the middle school.

6. THE ROLE OF PRACTICE

Although practice is an essential element of the learning process, a frequently asked question is, "Does practice make perfect?" It goes without saying that practice of some type is typically more beneficial than no practice. However, not all practice is equally effective. This statement is simply the recognition that practice plays an important role in two quite different ways. In terms of acquiring academic knowledge, repeated exposures or repetition provide the basis for memory storage that is critical for remembering. In terms of reading

vocabulary, the association of the word desert with its meaning and the remembering of this pairing will require several repetitions in order for the information to be stored in long-term memory. This may be accomplished with a simple practice strategy that involves developing a set of what were called “flash cards” when I was a youngster. However, to successfully retrieve and use the appropriate meaning across a number of different reading passages requires the successful application of prior knowledge. The ability to successfully apply one’s knowledge is really a disposition or personality characteristic. This disposition is also acquired through practice and has been identified by Albert Bandura as a sense of “self-efficacy” or competence. In other words, successful practice strategies involve both multiple exposures to the task and actively seeking potential applications of prior knowledge. This is a simple example of “training for transfer.”

7. PROCEDURAL KNOWLEDGE

Within the context of academic learning, procedural knowledge is demonstrated when a student can combine, organize, refine, or accommodate declarative knowledge so that a course of action can be taken. This is “knowing how” to use declarative knowledge (what one knows). Procedural knowledge in the classroom is what we commonly strive to teach and we ask our students to learn.

In teaching circles, constructivist or student-centered approaches to instruction place a great deal of emphasis on promoting procedural knowledge. This is frequently the case in the areas of science education and mathematics education. The caveat is that students must have a solid background of declarative knowledge in order to successfully move to a more complex level of cognitive processing. The cognitive processing that serves as the basis for procedural knowledge is domain specific. For example, if we think of algebra as a part of the mathematics domain, there are basic mathematical facts and concepts (declarative knowledge) that have been learned in earlier grades that serves as the foundation for success in algebra. However, in algebra we are also asked to take our prior knowledge about mathematics and use that knowledge to develop new rules, concepts, strategies, algorithms, etc. This is really a case of taking what we know and learning how to use that knowledge to develop new and more complex ways of thinking.

For example, by the time students reach middle school, where they usually take algebra, the teaching

of reading shifts from a focus on teaching basic reading skills to using reading skills to promote self-directed learning in literacy. At this point in students’ academic careers, emphasis is on procedural knowledge involving “knowing how to read” in order to successfully perform other educational tasks (write a poem, give a persuasive speech, read a science or mathematics textbook, etc.). These complex academic tasks are built on the declarative knowledge any student remembers from the earlier grades. This is why remembering (memory storage and retrieval) is the key to academic learning because complex subject matter that students are asked to learn is always built of declarative knowledge and simpler forms of procedural knowledge.

These descriptions of our expectations for students as they progress through the primary and middle school grades again draw our attention to the key academic learning element of enduring change that is couched in practice (seatwork, homework, study hall, etc.). Interestingly, there is little evidence in the research literature that teachers systematically teach study skills. This means that teachers should not only present information in the classroom but also teach students how to use the information being conveyed. Thus, teachers must teach not only declarative knowledge (what) but also procedural knowledge (how). A position frequently taken by educational psychologists is that domain-specific procedural knowledge strategies must be a part of any teacher’s instructional repertoire.

8. STUDENT SELF-EFFICACY: A SENSE OF COMPETENCY

Self-regulation or self-regulated learning emphasizes the motivational side of human behavior. As such, it is a complementary view of the information processing approach to academic learning. Metaphorically, cognitive theory and motivational theory are two sides of the “coin” called academic learning. Research efforts by educational psychologists studying self-regulation emphasize how learners direct their thoughts, feelings, and actions toward the attainment of their academic goals.

Bandura’s concept of self-efficacy was discussed previously within the context of study or practice. Generally speaking, self-efficacy is the exercise of control by the individual in the daily task of adapting to a complex environment. Self-regulation and the development of a sense of self-efficacy grow out of a complex interaction of behaviors, interpersonal factors,

and environmental demands. In the classroom, a simplified example involves teacher variables, curriculum demands, and students' sense of success with the curriculum being taught (math, reading, etc.). This sense of success translates on a personal level for the student as being competent in the subject being taught. Furthermore, the success breeds a sense of self-efficacy: "I can do this, I understand how to take what I already know and use it to learn more about this because I understand what it takes to get better." "I am a good reader." "I am good at math."

Self-efficacy was introduced earlier within the context of practice because of the position taken by Bandura that it is the demonstration of being competent (a good reader or good at math) that precedes the sense of self-efficacy. Over the long term (from kindergarten to grade 12), it is the sense of self-efficacy in academic subject matter areas that provides the motivational basis for successfully making the transition between procedural and strategic knowledge construction by a student.

This sense of self-efficacy is what sustains a student when academic problem solving becomes complex and difficult. When confronted with a complex academic problem, a successful problem solver has sufficient declarative knowledge to bring to the task; sufficient procedural knowledge to synthesize, integrate, and evaluate the declarative knowledge; and can strategically (knowing when) translate this into a successful solution for a specific problem. It is self-efficacy, the sense of being able to exercise personal control over the process of knowledge construction in an academic setting, that characterizes strategic knowledge.

9. STRATEGIC KNOWLEDGE

Strategic knowledge is viewed as an extension of declarative and procedural knowledge. Whereas declarative knowledge involves learning facts, concepts, etc. and procedural knowledge involves learning how to use declarative knowledge to construct domain-specific rules, algorithms, etc., strategic knowledge involves knowing when to use prior knowledge. In other words, when confronted with a novel or problem-solving situation, emphasis is on the retrieval of prior declarative and procedural knowledge that has been stored from long-term memory. When this type of information processing is successful, we observe academic learning behaviors such as problem solving in mathematics, critical thinking in science, or creative thinking in the writing of fiction. This last type of knowledge demonstrated

as a learning outcome emphasizes the active construction of a learning outcome and places the student at the center of the teaching–learning process. In addition to reflecting a competency dimension, primary consideration is given to motivational aspects of academic learning. This involves helping students develop a disposition frequently referred to as intellectual curiosity or academic expertise.

The development of strategic knowledge may be based largely on student characteristics that are very difficult to teach. Furthermore, some students may simply have difficulty with this level of cognitive functioning because of their cognitive limitations or personality characteristics.

Regardless, a teacher should provide opportunities that foster the development of strategic knowledge for those students who are capable. Strategic knowledge is a primary learner outcome of a self-regulated learning process we frequently identify as academic problem solving. Academic problem solving is observed when students can take primary responsibility for demonstrating the learning outcomes of problem identification, problem representation, strategy construction, and solution verification (evaluation).

Emphasis is on the student taking responsibility for identifying a problem, representing the problem, developing a strategy for solving the problem, and then evaluating the success of the strategy employed. This academic problem-solving perspective has been a major contribution to the teaching literature that is based to a large extent on the research efforts of Richard Mayer. These stages of the problem-solving process can be taught in any of the previously identified academic areas (mathematics, science, and literature). Any self-regulated learning process places a premium on remembering—the use of prior knowledge. The student is responsible for knowing what, how, and when. As demonstrated by Barry Zimmerman and colleagues, if we are successful, some of our students will become self-regulated learners. The choice is theirs, and the reward will be ours.

10. IMPLICATIONS FOR KNOWLEDGE ASSESSMENT

The implications for pedagogical practice are again derived from our definition of academic learning. Consistent with the NCLB legislation, the focus is on every child. This calls for the recognition of individual

differences in the classroom. In a single classroom on any given day, some students will be dealing with the development of declarative knowledge in a subject area while others will be grappling with issues involving procedural knowledge. A few may even be working at the strategic knowledge level of construction. On a daily basis, this means that classroom teachers will have to be well grounded in both the subject matter being taught and effective teaching strategies. In addition, since change is the focus of our definition of academic learning, this means that when appropriate, teachers are responsible for guiding students from one level of knowledge construction to another. This is a long-term view and involves change over the academic year within a grade. Consequently, for future change to occur, the student must remember today's lesson, which is tomorrow's prior knowledge. The implications for practice are obvious since the effective use of memory storage and retrieval is not easily accomplished.

Formative and summative assessment of academic learning is required since enduring change can be verified only to the extent that it can be measured. As mentioned previously, measurement at a minimum of two points in time is required for the assessment of change. Furthermore, a classroom environment in which student progress is monitored effectively would require multiple assessment techniques. The major obstacle facing most teachers is the assessment issue. There are numerous sources available for teachers that provide the basis for developing assessment activities that measure declarative knowledge. Most of these activities involve the assessment of memory retention using standard teacher-made tests.

The assessment of procedural knowledge and strategic knowledge also requires the assessment of memory retention, but it must also include the assessment of a student's ability to use the knowledge in a manner that reflects the transfer of higher order thinking skills (e.g., Bloom's taxonomy). This means that the assessment will require evidence of strategy transfer or problem-solving

transfer on the part of students. Thus, as we promote the development of procedural and strategic knowledge through the use of instructional practices that foster such thinking, we must not forget that assessment practices must align with the instructional efforts and the learning expectations we have for our students. In simple terms, there are two assessment questions we must ask ourselves as teachers: Do our students remember what we taught, and can they effectively use what they remember?

11. DEVELOPMENTAL AND INDIVIDUAL DIFFERENCES

A model for knowledge assessment is provided in Table I. As mentioned previously, declarative knowledge can be assessed in the traditional manner and is frequently a one-time occurrence. In contrast, procedural knowledge and strategic knowledge require both a measure of memory retention and a measure of transfer. This dual-assessment procedure is required because transfer is based on prior knowledge. If we simply measure transfer performance and transfer performance is poor or nonexistent, as teachers we cannot determine if our students fail because they cannot remember or because they cannot use their declarative knowledge. In other words, memory retention is a necessary but not sufficient condition for transfer. Thus, teaching for transfer is based on teaching for declarative knowledge but also involves helping students understand how and when to use their knowledge.

Having made a distinction between an assessment procedure for declarative knowledge and procedural or strategic knowledge in terms of single or dual assessment, a distinction is also to be made between the assessment of procedural and strategic knowledge. In contrast to procedural knowledge, in the discussion of strategic knowledge, the volitional nature of strategic knowledge was emphasized. During procedural

TABLE I
Model for Functional Knowledge Assessment

<i>Type of learning outcome</i>	<i>Memory retention performance</i>	<i>Transfer performance</i>	<i>Kind of knowledge</i>
Nonlearner	Poor	Poor	None
Non-problem solver	Good	Poor	Declarative
Guided problem solver	Good	Good	Procedural
Self-directed problem solver	Good	Good	Strategic

knowledge assessment, if students can transfer procedural knowledge “when asked to do so,” guided understanding is demonstrated. From a problem-solving transfer perspective, these students are demonstrating the last three stages (problem representation, strategy selection, and solution verification) of the aforementioned problem-solving process. Unfortunately, we lack information about problem identification. The assessment of strategic knowledge, where no teacher guidance is provided, provides information about students’ ability to identify problems. Here, students must volitionally construct an awareness of what knowledge is appropriate, how that knowledge can be organized into a solution strategy, and when the strategies are to be employed. Such students not only demonstrate the learning outcome of understanding but also the characteristics of successful problem solvers. This distinction between the assessment of procedural and strategic knowledge must always be considered when developing performance assessments in the classroom.

12. CONCLUSION

The multiple assessment approach to promoting understanding and problem solving in the classroom is at the heart of the NCLB legislation. No child should be left behind as a nonlearner. Every child can learn to a level that is determined by the individual differences in the academic abilities each of us exhibit. The hope is that as teachers, we facilitate to the best of our ability

the personal knowledge construction efforts of all our students.

programs and their “response to the intervention” is observed and used in decision making.

GLOSSARY

formative evaluation The process of using data collected frequently and repeatedly over time to determine the effectiveness of a treatment program.

learning disability As used in this article, a heterogeneous group of disabilities that result in deficits in one or more of the basic psychological processes involved in understanding or in using language, spoken or written, that may manifest itself as an imperfect ability to listen, think, speak, read, write, spell, or do mathematical calculation.

modality instruction The practice of assessing certain characteristics of the learner (i.e., modalities) such as whether the individual is a visual, auditory, or kinesthetic learner, and then matching treatments to the individual's strengths.

perceptual-motor training The most frequent form of “process training” in special education, . it assumes that children with learning disabilities, or at least some of them, have problems in sensory integration to which some or all of their learning problems can be attributed. The purpose of the training is to remediate these deficits.

response to intervention (RTI) An approach to assessment and treatment of persons with learning problems that can, in many cases, assist in identifying individuals with learning disabilities. In this method, students with specific learning problems are placed in a validated intervention

This article describes the development of our understanding of learning disabilities in the United States. It begins with a brief history of learning disabilities, then the struggles for a universal definition are described, along with the federal legal definition and the emerging consensus on definition within the field of learning disabilities. Finally, a sampling of both proven effective and proven less-effective treatments for learning disabilities is presented.

1. HISTORY OF LEARNING DISABILITIES

The existence of learning disabilities has been documented for approximately 200 years. The origins of what are currently called learning disabilities began with early attempts to match functioning within certain areas of the brain to human behavior. Early physicians noticed that patients with certain types of brain injury experienced specific types of behavioral problems. Most relevant to learning disabilities were patients with injuries to the left hemispheres of their brains, who in many cases experienced problems such as slow, laborious speech and the inability to name objects or persons. In the late 1800s, a more specific set of cases was identified in which persons' ability to speak and write remained

intact, but their ability to comprehend spoken or written words was impaired. These conditions were termed word deafness and word blindness.

From these studies, during the early 20th century, physicians began to notice children and adults who experienced what was at the time considered to be defects in their ability to recognize words and letters, despite no obvious brain damage or injury. The inference was made that perhaps these individuals suffered from some sort of neurological disorder that mimicked the effects of people with brain damage. Moreover, a number of cases appeared to run in families, providing further evidence for a possible physical cause. The medical diagnosis for this condition was congenital word blindness.

Beginning around 1920, and building on this early work in medicine and neurology, a group of American pioneers including Samuel Orton, Grace Fernald, Marion Monroe, and Samuel Kirk began landmark work on understanding reading disabilities. While still clearly linked to foundations in medicine, reading disabilities were attacked by these researchers and clinicians as much from an educational perspective as from a clinical one. Indeed, some of these pioneer's names have become synonymous with specific approaches to educational treatment for students with learning disabilities. For example, the Orton-Gillingham approach to treatment is a phonics-based, multisensory approach to instruction that uses the kinesthetic, auditory, and visual modalities for teaching decoding and spelling.

Parallel to developments in educational understanding of students with these disorders, additional work was being pursued between about 1920 and 1960 on the perceptual, perceptual-motor, and attentional abilities that often accompanied damage, injury, or dysfunction in persons' brains. Physicians and psychologists such as Kurt Goldstein, Heinz Werner, Newell Kephart, and William Cruikshank conducted many research studies documenting deficits such as hyperactivity, perseveration, figure-ground confusion, and distractibility. Again, it was reasoned that if persons with documented damage to their brains exhibited perceptual and attentional problems, persons with presumed damage to these brain areas might be expected to have these problems as well.

It was between approximately 1960 and 1975 when the field of learning disabilities began emerging as a discipline unto itself. On April 6, 1963, another pioneer in the field of learning disabilities, Samuel Kirk, told a parent advocacy group for children with "perceptual handicaps" that "Recently, I have used the term 'learning disability' to describe a group of children who have disorders in development, in language,

speech, reading and associated communication skills needed for social interaction. In this group, I do not include children who have sensory handicaps such as blindness or deafness, because we have methods of managing and training the deaf and blind. I also exclude from this group children who have generalized mental retardation" (Kirk, 1975, p. 9). Most educators attribute coinage of the term "learning disability" to Kirk. Moreover, some of the parents who heard Kirk's speech in 1963 established the Association for Children with Learning Disabilities, which has now evolved into the Learning Disabilities Association of America. This organization is widely known as one of the most influential learning disabilities advocacy organization in the United States.

2. DEFINITION

2.1. Historical Definitions

One of the biggest challenges in the field has been coming up with a definition of learning disabilities that a large majority of people can agree with. Part of the challenge has been the heterogeneous nature of problems associated with learning disabilities. That is, persons with learning disabilities do not all have the same problems, and the types of problems experienced are very broad. While most persons with learning disabilities have problems with reading and the use of language (roughly 80%), not all do. Some have problems with memory, others do not. Still others have perceptual difficulties. And the list goes on.

In the years between 1960 and about 1975, there was considerable disorganization and disagreement on the specific nature of what constitutes a learning disability. Though Sam Kirk and his student Barbara Bateman had offered a series of definitions in the early and middle 1960s, definitions created by different advocacy and professional groups continued to stress different components of the disability. It was at this time that the federal government began taking interest in learning disabilities and began working toward definitions of its own.

2.2. United States Legal Definition

A series of federal task forces on learning disabilities and legislative actions occurred throughout the 1960s and into the early 1970s. These set the stage for the federal government's enactment of Public Law 94-142, the Education of the Handicapped Act, in 1975 (EHA). Coming on the heels

of the civil rights movement, EHA provided a mechanism for the federal government to provide funding to states to support the provision of special education services to students with disabilities. Based on the law, children with disabilities could not be excluded from receiving an education solely on the basis of their disability. Major components of the law included ensuring students with disabilities a right to a free, appropriate public education, heightened access to due process and procedural safeguards to ensure appropriate provision of services, and provision of an Individual Education Program that was reasonably calculated to provide benefit to students with disabilities (in this case, learning disabilities).

EHA was an impressive and ambitious step by the federal government. At the time, however, the promise of EHA could not be realized unless an acceptable definition of learning disabilities could be written. Recall that at the time, there was considerable professional disagreement on the nature of learning disabilities. Congress and the U.S. Office of Education considered much testimony, research, and advocacy in selecting the definition of learning disabilities that finally made its way into federal law. Indeed, many components of historical definitions were considered, and the final definition of learning disabilities was finally written. According to federal law, a learning disability is as follows:

General. The term learning disability refers to a disorder in one or more of the basic psychological processes involved in understanding or in using language, spoken or written, that may manifest itself as an imperfect ability to listen, think, speak, read, write, spell, or do mathematical calculation, including conditions such as perceptual disabilities, brain injury, minimal brain dysfunction, dyslexia, and developmental aphasia. Disorders not included: The term does not include learning problems that are primarily the result of visual, hearing, or motor disabilities or mental retardation, of emotional disturbance, or of environmental cultural or economic disadvantage [U.S.C. 300.7(C)(10)].

In addition to the definition provided in the U.S. federal law, the U.S. Department of Education provided regulations that further direct states and territories in determining the presence of specific learning disabilities. As stated in the regulations:

- a. A team may determine that a child has a specific learning disability if:
 1. The child does not achieve commensurate with his or her age and ability levels in one or more of the areas listed in paragraph a.2 of this section, if provided with learning experience appropriate for the child's age and ability levels; and

2. The team finds that a child has a severe discrepancy between achievement and intellectual ability in one or more of the following areas:
 - i. Oral expression
 - ii. Listening comprehension
 - iii. Written expression
 - iv. Basic reading skill
 - v. Reading comprehension
 - vi. Mathematics calculation
 - vii. Mathematics reasoning
- b. The team may not identify a child as having a specific learning disability if the severe discrepancy between ability and achievement is primarily the result of:
 1. A visual, hearing, or motor impairment
 2. Mental retardation
 3. Emotional disturbance
 4. Environmental, cultural, or economic disadvantage

Based on the language in the law and the language in the regulations, each of the 50 states and U.S. territories needed to establish specific procedures that would be used to identify individuals with specific learning disabilities.

2.3. Converging Professional Perspectives on Definition

The federal definition of learning disabilities set the stage for greater stability within the learning disabilities professional community and general movement toward agreement on a definition. One reason for this progress between about 1975 and 1985 was the considerable research conducted across the country that was funded by the U.S. Office of Education. Five learning disability research institutes were funded at major research universities across the country, each focusing on a different component related to understanding and treating individuals with specific learning disabilities in the schools. The institutes included the following:

- The Columbia University Institute, directed by Dale Bryant, focused primarily on information-processing problems of students with disabilities. Within this program, memory skills, arithmetic, study skills, basic reading, and reading comprehension (among other areas) were studied.
- The University of Illinois at Chicago Institute, directed by Tanis Bryan, focused primarily on the social competence of children with learning disabilities and their attributions of success or failure.
- The University of Kansas Institute, directed by Donald Deshler, focused primarily on school-based

interventions for secondary (adolescent) students with learning disabilities.

- The University of Minnesota Institute, directed by James Ysseldyke, focused their energies on the decision-making process related to identification of students with learning disabilities as well as methods for monitoring academic progress for students with learning disabilities. It was from the Minnesota Institute that curriculum-based assessment and curriculum-based measurement technologies were developed initially.

- The University of Virginia Institute, directed by Daniel Hallahan, focused their research efforts on students with learning disabilities who also had attentional problems. Additionally, the Virginia site also conducted research on the use of academic strategy training to improve the performance of students with learning disabilities.

During the 10 years following the work of the learning disabilities institutes, a series of new definitions of learning disabilities was offered by professional organizations and federal task forces. These definitions, though having some different nuances, all describe learning disabilities as (1) intrinsic to the individual, of presumed neurological dysfunction, (2) related to the use of language such as reading, writing, and reasoning, and (3) able to impact the individual in other areas of their lives such as social skills, mathematics, and attention.

Throughout the years between about 1985 and 2000, much additional research was conducted on the nature of learning disabilities. While there are many significant and important findings in this literature base, it appears that there are two large strands of research emerging related to the definition of learning disabilities. The first major area is in phonological processing. In 2000, a group of distinguished researchers (called the National Reading Panel) came together to examine and synthesize what is known about the acquisition of reading. In their report, these researchers synthesized the major skills that a person must have to be able to read proficiently. These include the following:

Phonemic awareness: The ability to hear and manipulate the sounds in spoken words and the understanding that spoken words and syllables are made up of sequences of speech sounds.

Phonics: Includes both the understanding that words are composed of letters that represent sounds and the ability to use letter-sound correspondence to pronounce an unknown printed word.

Vocabulary: Includes both expressive vocabulary, which is the ability of a speaker or writer to produce a

specific label for a particular meaning, and receptive vocabulary, which requires a reader to associate a specific meaning with a given word (either read or spoken).

Fluency: The ability to read words with no noticeable cognitive or mental effort. It is having mastered word recognition skills to the point of overlearning.

Comprehension: This has been defined many ways by many authors. Comprehension includes active and intentional thinking in which meaning is constructed through interactions between the text and the reader.

The importance of these five “big ideas” in reading is that we now have both a roadmap for directly measuring the subcomponents of reading and specific strategies, linked with each of these ideas, that can be used to directly teach the skill. As noted before, a majority of students with learning disabilities have problems with reading, and this new knowledge provides us both a very specific way to identify specific skill deficits and a sensitive way to identify students with problems. As research progresses, we can expect this strand of research to provide increasingly effective treatments for students with learning disabilities.

The second major strand of learning disabilities research has to do with the identification of a biological basis for learning disabilities. Since the early years of learning disabilities identification, there has been a presumption of a neurological basis for these disabilities. Not until the late 1980s and 1990s has our technology caught up with our intuition and allowed us to study and document these findings. There are a number of different converging sets of data at this point. We know now from postmortem studies that the brains of persons with reading disabilities differ from those of persons without reading disabilities. We know from neuroimaging studies that there are differences in critical brain functions between proficient readers and nonproficient readers. We know also through systematic evaluation of heredity that about 40% of first-degree relatives of students with reading disabilities, speech and language disabilities, and spelling disorders also experience these problems.

2.4. Proposed Future Definitions

While all of these new research studies and findings were being created, the federal legal definition of learning disabilities (1975) has remained virtually unchanged. Our new research base, coupled with the practical and political realities associated with learning disabilities, has created a context for reexamination of the federal definition. A major political and practical

challenge is that since the inception of the Education of the Handicapped Act, both the number and percentage of students identified with learning disabilities in U.S. schools has consistently and steadily risen. This rise creates both fiscal and practical challenges. Currently, approximately 50% of all children with educational disabilities served under the IDEA are students with learning disabilities. There are many reasons for this rise, including that (1) the assessment and identification process in schools has been in many cases unreliable, (2) the use of technically inadequate tests is widespread, and often little functional information about how to teach a child with a learning disability is provided from the comprehensive evaluations required by federal law, and (3) different states use very different practices and criteria for determining the presence of learning disabilities. Moreover, some experts contend that learning disability numbers are increasing due to an increasing number of students who are what has been called curriculum casualties. That is, they have not learned because either the curriculum is not geared to meeting their learning needs or their teachers are not skilled in providing instruction in reading, language arts, and/or mathematics. When curriculum and instruction fail, special education is there to fill the gap. In short, the identification and special education service delivery process worked somewhat well from an administrative perspective of allocating resources, but it did not work well from the standpoint of remediating critical skill deficits nor in creating a consistent identification system for learning disabilities.

Added to our research base and the practical challenges we have experienced, additional evidence has been added in very recent years to our understanding of learning disabilities. Headed up by Reid Lyon, Chief of the Child Development and Behavior Branch of the National Institute of Child Health and Human Development of the National Institutes of Health, and a national team of researchers from many major universities, critical insights and definitive studies have begun to emerge that are causing researchers, policy-makers, and practitioners to reconsider the way we identify and serve individuals with learning disabilities in our schools. Perhaps the most critical addition to our common knowledge base is that the prevailing practices used in our schools to identify and serve students with learning disabilities are problematic from the standpoint of improved outcomes for students. Our emerging knowledge is compelling.

1. We know that most students with learning disabilities have important problems with the use of language

and acquisition of reading skills (approximately 80%) and that these problems begin early in life.

2. We know that in American society there are serious, important, and life-long consequences of not learning to read.

3. We have learned that there is a critical period for children to develop language and early reading skills. There are five major component skills that proficient readers master, typically in kindergarten to grade 3. They are phonemic awareness, phonics, vocabulary, fluency, and reading comprehension. All of these skills are directly teachable.

4. We know that the most effective interventions for reading problems are those that begin early and teach students in these critical skills.

5. The learning disabilities identification system in practice in most U.S. schools does not allow the identification of students with learning disabilities until measures of academic achievement can demonstrate a severe discrepancy between measured potential and academic achievement. Typically, this is not possible until second or third grade, past the time when intensive instruction has the best chance of remediating students' early deficits. In short, the system is problematic because we have delayed intervention to a point where it may be less effective and until we are playing catch-up.

As of 2004, the federal government is actively looking at making changes to the definition of learning disabilities in the federal law. A national center for research on learning disabilities was established in 2002 that is a collaborative effort between Vanderbilt University and Kansas University. One task that this center has undertaken is the examination of alternative models for the identification of learning disabilities. An emerging approach to identification of learning disabilities is called response to intervention, or RTI. In short, RTI is an approach in which individuals with learning problems often experienced by students with learning disabilities are placed in high-quality treatment, research-validated intervention programs across relatively short periods of time. The student's response to these interventions is monitored. Students whose performance is both far below age/grade-level peers and who do not respond positively and sufficiently to the validated treatment approaches may be considered for learning disabilities services. Much research is ongoing with regard to RTI approaches to identification of learning disabilities, and it is anticipated that successful implementations of RTI will inform and influence the learning disabilities definition that will be a part of federal law in the very near future.

3. TREATMENTS FOR LEARNING DISABILITIES

As important as defining learning disabilities has been the process of conducting research on effective treatments. The literature on treatment for learning disabilities is broad and extensive, so this summary will necessarily be abbreviated. To focus this section further, primarily school-based treatments will be discussed, though individuals with learning disabilities experience challenges beyond the school setting. Finally, instead of attempting to chronicle every researched school-based approach, this summary is organized around three topics: treatments without widespread research support, general principles undergirding generally effective treatments, and selected examples of effective approaches for educating students with learning disabilities. At a general level, the treatments reported in this section reflect well-established intervention methodologies with significant research examining their effectiveness.

3.1. Treatments That Do Not Have Widespread Research Support

3.1.1. Modality Instruction

Modality instruction is the practice of assessing certain characteristics of the learner (i.e., modalities), such as whether the individual is a visual, auditory, or kinesthetic learner, and then matching treatments to the individual's strengths. It has long been thought that matching treatment to measured processing strengths can provide one mechanism to improve learning for persons with learning disabilities. The assumption is that if we teach individuals through their preferred modality, then they will learn more and/or better than they would if we did not tailor our instruction in this way. These approaches, sometimes called aptitude-by-treatment interactions or diagnostic-prescriptive teaching, have great intuitive appeal. They sound logical and reasonable. Unfortunately, the effectiveness of these approaches has not been empirically proven on a wide scale. For these methods to work, we need to be able to demonstrate that individuals with certain characteristics learn better with instruction matched to their strengths. These effects have been very difficult to find. Instead, treatments that are generally effective for students with learning disabilities also tend to be effective for students without learning disabilities.

3.1.2. Psycholinguistic Training

Psycholinguistic training is an approach to training people in processes that they are believed to be deficit in. It was at one time a major intervention approach for students with learning disabilities. Training approaches were often based on results from a very popular test called the Illinois Test of Psycholinguistic Abilities (ITPA). This test measured integrative, receptive, and expressive linguistic abilities through presenting test subjects with information through visual and auditory channels. The assumption was made in this treatment approach, as in others, that discrete psycholinguistic abilities can be measured directly and then remediated. This assumption has been the subject of intense research scrutiny throughout the 1970s and 1980s. There were those who claimed with data that psycholinguistic training was generally not effective, and others with data who refuted these claims, stating that psycholinguistic training provided discrete benefits. The claims and counterclaims become a bit confusing. However, based on a review of the existing literature by this author, it appears that at least some of the areas measured by psycholinguistic assessments can be enhanced by psycholinguistic training. Particularly in the "expressive" areas of manual expression and verbal expression, evidence appears to confirm that these areas can be improved moderately through direct training. In the other 10 subareas measured by the ITPA, it appears that the effects of training are more modest.

Despite these moderately positive findings, a number of researchers have questioned the practical utility of gains of the magnitude reported. That is, it may be possible that gains in specific psycholinguistic variables are possible. The question is, do these gains translate into important gains in functioning in other areas of a person's life such as reading or language use? In the absence of these types of evidence, we must question whether these psycholinguistic interventions should be the highest priority for persons with learning disabilities.

3.1.3. Perceptual Motor Training

Probably the most frequent form of "process training" in special education has been the use of what is generally called perceptual motor training. The theory goes that children with learning disabilities, or at least some of them, have problems in sensory integration to which some or all of their learning problems can be attributed. These problems may include disorders in the postural, ocular, and bilateral integration, a disorder in the ability

to plan and execute motor acts, a disorder in form and space perception, auditory language problems, and/or tactile defensiveness. Numerous clinical measures intended to measure these problems have been created over the years. For children with such problems, the idea is that direct sensory motor training could remediate these children's underlying problems, and hence mitigate the effects of their disability. There have been many testimonials to the effectiveness of perceptual motor training, and a number of clinical trials have fanned the popularity of these treatments. Research support on a broad scale, however, has not emerged for these therapies. It may be that persons with learning disabilities have problems in these areas, but consistent, effective treatments that result in consistent, large-scale positive effects have not been identified and validated on students' perceptual/sensory motor skills, their academic achievement, or their cognitive performance or aptitude.

3.1.4. Placement in Special Education

Perhaps the most frequent treatment for children with learning disabilities in U.S. schools is placement in special education (as allowed by the IDEA). It is difficult to make blanket statements about special education as an enterprise, because so many different practices exist in these settings. Moreover, there are methodological problems associated with measuring the overall effectiveness of such a diverse enterprise. Despite these challenges, a number of studies have examined the effectiveness of special education placement for students with mild disabilities such as learning disabilities. In general, these studies have found weak effects for special education placement as a treatment. These findings, however, must be tempered by the awareness that many of the research-based effective practices identified in the last section of this article are most frequently carried out in special education placements. As such, it is probably most accurate to say that practices in special education are effective or ineffective, as opposed to placement. The extent to which any particular placement will be effective or ineffective for students with learning disabilities is a direct result of the effectiveness of practices used in that setting.

3.2. Characteristics of Generally Effective Instructional Interventions

Researchers have identified a series of components that characterize generally effective instructional

interventions. These components do not guarantee that a specific program or approach will be effective with individuals with learning disabilities. However, when these principles are implemented in classrooms, children generally learn better and more. Some of the principles of effective instruction are listed below.

3.2.1. Teacher Organization

Instructional groups should be organized for efficiency and sustained focus on the instructional content. This means that students in small group instruction should be seated so that the teacher can work with each student, transitions from one instructional activity to another should be quick (which may require instruction on how to transition), and lessons should be started quickly at the beginning of lesson time.

3.2.2. Student Engagement

Students should not just be attending to academic material, but should be actively responding to material that is geared to their instructional skills. Students should be placed in materials that are challenging, in which they can respond briskly and in which they will not make large numbers of mistakes. They should experience high rates of success in the materials.

3.2.3. Opportunities to Respond

Students should receive many opportunities to respond during instruction and should get clear feedback on the correctness of their performance from the teacher.

3.2.4. Overlearning

Skills should be taught to a level of overlearning, with new skills being introduced gradually. That is, students need to be taught to a level at which they are able to perform skills almost automatically, without great effort.

3.3. Treatments for Learning Disabilities with General Research Support

In addition to treatments that have not demonstrated high levels of effectiveness and broad research support, there are a host of treatments for learning disabilities that have been found to be generally effective. This section reviews some of the most widely used and

familiar treatments in schools for learning disabilities. The list is not exhaustive, but is intended to highlight some of the most effective approaches.

3.3.1. Early Intervention

The goal of early intervention is the early detection and remediation of negative effects of disability and the prevention of developmental and learning problems for children who are at risk of developing these problems. There have been some very impressive results reported from the implementation of early intervention programs, though methodological issues have made it difficult to make large-scale, conclusive statements. In general, however, children who participate in early intervention programs have demonstrated gains in IQ, language development, motor development, and academic achievement.

One of the most exciting recent developments in learning disabilities is improvement in our understanding of early language development and early literacy. At the same time, assessment technologies have been developed that allow us to identify and remediate the problems of students with learning disabilities early, before they grow into larger ones. With these developments, learning disabilities advocates and professionals have moved one step closer to realizing their longstanding desire to provide meaningful, effective treatments for persons with learning disabilities early, when interventions can be maximally effective. We now know many critical “building blocks” of early reading and we have direct measures of these skills and each is directly teachable. Initial results for directly teaching children these building block skills appear promising. That is, many children who are at risk of learning failure seem to maintain and build upon their early gains after experiencing direct and focused reading instruction early in their educational careers.

3.3.2. Direct Instruction

Direct instruction is a method of teaching that was developed by Siegfried Engelmann and Wesley Becker at the University of Oregon. These researchers married the positive effects seen in using behavior modification with a systematic analysis of how to teach different knowledge forms (e.g., facts, rules, concepts). To this knowledge, they applied the principles of effective instructional design and developed a series of curricula for teaching academic skills that have widespread and powerful research supporting their effectiveness. These

include the DISTAR and Corrective Reading series, among others. These programs provide explicit, step-by-step guidance for teachers, strategies for correcting student errors, gradual removal of teacher direction as students become more independent, the use of adequate, systematic practice with many different examples, and consistent review of recently learned materials. They have also generated some of the most widespread and consistent research support on program effectiveness of any instructional methodology.

3.3.3. Reading Comprehension Strategy Instruction

Because many students with learning difficulties have problems with language variables that often translate into reading difficulties, a large number of studies have examined the effectiveness of teaching reading comprehension strategies to students with learning disabilities. Many different approaches have been examined, including the use of advance organizers, vocabulary interventions, the use rules to help comprehend text, self-questioning, the use of previewing and reviewing strategies, and memory enhancement strategies, to name a few. Though the effectiveness of different comprehension strategies varies, the results are generally in the good to excellent range. These findings are especially encouraging because they collectively demonstrate that reading comprehension can be enhanced significantly for students with learning disabilities and that a wide variety of strategies are available that can have significantly positive effects.

3.3.4. Behavior Modification

Behavior modification is an approach to treatment that is based on the science of applied behavior analysis. Basically, this approach works through careful application of behavior change principles to the problems experienced by students with learning disabilities. In behavior modification, the behaviors that are the subject of change are defined precisely, very explicit and complete instructional procedures are used to teach new behaviors, the results are measured directly, and teaching procedures are modified to produce optimal effects. People who use behavior modification consider academic performance to fall in the realm of behavior just as they view social behavior. Indeed, behavior modification procedures have a very strong research base, underlying their use for both helping improve social behavior and developing academic

skill. Behavior modification has demonstrated consistent and strong relationships to improved student performance.

3.3.5. Peer Tutoring

Peer tutoring is a set of strategies in which students serve as both teachers and learners. In general, students work with each other in a 1-on-1 setting, learning together. Typically, students serving as “teacher” at any given time follow directions regarding what and how to interact with the student serving as the “learner.” Peer tutoring has the advantage that it can individualize instruction for students based on individual needs. In many cases, all students participating in peer tutoring get to serve both as instructors and as learners. A range of positive effects have been documented in the peer-tutoring literature, including positive effects on academic achievement in reading, mathematics, and language, increases in students’ attitudes toward school, and improved school behavior. Gains have been documented for both tutors and tutees.

3.3.6. Progress Monitoring, Graphing, and Data-Based Decision Making

One of the few universals that can be identified at the current state of our knowledge about individuals with learning disabilities is that we cannot predict with certainty which strategies will work prior to trying them. As a result of this situation, much research and development has been devoted to identifying ways to measure growth and development for individuals with learning disabilities. The process of monitoring progress across time, graphing data, and using these data for the purpose of determining effectiveness of treatments is called formative evaluation. Recall that development of formative evaluation tools was a major purpose for one of the federally funded institutes for research on learning disabilities in the late 1970s and early 1980s. Not only have progress-monitoring and decision-making tools been developed that are specifically useful with students with learning disabilities (e.g., curriculum-based measurement), but also research has proven that using these technologies to give teachers feedback on instruction improves student performance significantly. The idea is that if teachers can get feedback on the effectiveness of their instruction over a short period of time (say 6 weeks), they will be in a good position to either keep effective instructional strategies or move on to other potentially

effective strategies if what they are doing is not working. Progress monitoring, graphing, and data-based decision making provide teachers these tools.

3.4. Maximizing Results for Persons with Learning Disabilities

In general, the specific problems associated with learning disabilities are lifelong, though many of the problems can be attenuated by instruction and accommodation. Students with learning disabilities can learn to read and can become functional readers. Students with learning disabilities who have memory problems can learn specific strategies to assist with remembering. Students with learning disabilities with organizational problems can learn strategies to assist with planning and keeping themselves organized. To maximize their functioning, however, individuals with learning disabilities may need a variety of supports throughout life.

During the school years, the problems associated with learning disabilities impact students’ performance in academic skill development, primarily in reading, language arts, and mathematics. In turn, students’ grades and academic achievement, two important success indicators in schools, are affected. As students mature and transition into adult life, the problems they experience can affect their lives in different and important ways. Low levels of academic achievement can diminish students’ likelihood of pursuing college, which can translate into less lucrative employment, less independence, or even lower standards of living. Specific skill deficits can preclude access to or participation in certain professions, and for some, deficits in social skills can make it difficult to maintain steady employment. For many individuals with learning disabilities, however, some of the most negative effects associated with their disabilities can be mitigated through instruction, advocacy, and advanced planning. Indeed, there are many, many persons with learning disabilities who have minimized the effects of their disabilities and have excelled personally and professionally.

To maximize the chances of success for students with learning disabilities, a number of scholars have argued that it is critical that increased attention be paid to the issue of preparing students for adult life while they are in school. Supports need to include vocational instruction and experiences, assistance in finding and securing employment, assistance in finding and participating in post-secondary education options, and assistance in learning to use community resources to the students’

advantage. For optimum effectiveness, transition services should include students themselves in planning their transition from school to adult life. Specifically, these services should include the student's family, should begin early (some advocate as early as elementary school), should be sensitive to familial and cultural factors, and must be comprehensive. It is through this careful planning and service delivery that successful results for individuals with learning disabilities can be achieved.

Further Reading

Learning styles are relatively consistent preferences for adopting particular learning processes, irrespective of the task or problem presented but generally relating to educational or workplace settings. Learning strategies and approaches to studying are specific to education and training, being more context-specific ways of tackling learning tasks that involve characteristic combinations of intentions, learning processes, and study activities.

GLOSSARY

approach to studying A context- and content-specific way of carrying out academic tasks.

cognitive style A habitual and distinctive way of attending to, and processing, perceptual and cognitive information.

disposition A composite concept bringing together ability, inclination, and sensitivity to context.

learning strategies The way of learning adopted in tackling more specific types of tasks.

learning style A preferred and relatively consistent way of learning, usually related to educational or workplace settings.

study orientation A habitual way of tackling tasks presented in educational contexts.

teaching-learning environment The instructional activities, learning resources, assignments, and assessments set up to encourage and support learning.

thinking style A preferred way of thinking, described in general terms to apply to various contrasting situations.

1. HISTORICAL AND CONCEPTUAL INTRODUCTION

The term “cognitive style” was first used in the psychological literature during the 1940s to describe individual differences in perceptual ability, especially Witkin’s identification of “field independence,” that is, the ability to separate an object visually from its background. The meaning of cognitive style has since been widened to refer to other strong, relatively consistent individual differences in the way in which people cognitively process, as well as perceive, information.

Conceptually, cognitive styles have links to both personality and ability. Like personality traits, they are relatively fixed characteristics that affect the way in which people respond across a variety of situations, but their theoretical and empirical underpinnings are much less secure. Like abilities, cognitive styles affect

mental processing, but instead of indicating the content, speed, and effectiveness of mental operations, they describe characteristic processes through which information is handled. In addition, the level of ability (measured on a low-to-high scale) will affect performance, whereas cognitive style is indicated by the position on a bipolar scale, with each pole being equally adaptive but for rather different kinds of learning.

The term “thinking style” represents a concept intermediate between cognitive style and learning style but is seen as having broader applicability than the latter. Distinctive differences between convergent and divergent thinking scores were recognized as contrasting modes of thinking, equivalent to styles, but the term “thinking style” has more recently become associated with the work of Sternberg through his theory of mental self-government.

During the 1960s, the term “learning style” was introduced to describe individual differences in the more specific preferences shown by people learning in educational and workplace settings. Work focusing on study methods and study strategies began earlier within educational psychology, but the term “approaches to learning” emerged from educational research during the mid-1970s and its meaning was subsequently broadened to cover approaches to studying.

Generally speaking, “styles” describe relatively stable personal preferences in how cognitive processing or learning is undertaken, whereas “strategies” and “approaches” are contextually more specific, being influenced by the content and setting within which learning and studying take place.

2. LEARNING STYLES

The early work on cognitive style, led predominantly by Witkin, focused on individual differences in perceptual processing, but Witkin’s later work also distinguished broader “articulated” and “global” ways of thinking that influenced more recent work on styles. A vast array of terms has been accumulated in the attempt to describe distinctive preferences, with those associated with education and the workplace being known as learning styles. By 1976, Messick had already found 19 different sets of categories, and more styles have been introduced since then. This vast array of competing conceptualizations, with no widely agreed theoretical framework to connect them, makes it difficult to single out specific contributions, but the work of Kolb was influential in the early conceptualization of learning style. Kolb

identified two dimensions: one differentiating between preferences for either convergent or divergent thinking and the other indicating the relative reliance on the Piagetian mental processes of assimilation or accommodation. Relative closeness to each of the poles of the two dimensions was used to suggest four stylistic “types” that were labeled accordingly.

The subsequent proliferation of concepts describing learning styles, each with its own related learning style instrument, has led to confusion in the essential meaning of the term. However, it is possible to make sense of the literature from integrative reviews in terms of a few recurring dimensions, although with different labels. Recent reviews by Sternberg and Riding, among others, suggest that the main learning styles cover either individual preferences for a particular modality of sensory input (e.g., visual, auditory, kinesthetic) or different forms of mental representation in learning. These latter styles are exhibited in terms of preferences for one or the other pole of dimensions described as analytic/wholist, concrete/abstract, or verbal processing/visual imagery. There has been some suggestion that aspects of learning style may reflect differences in hemispheric brain functions, but the evidence for this is still contested.

Another way in which learning style constructs can be systematized usefully is by contrasting those that focus on the learning process itself (e.g., Pask’s version of analytic/wholist, which he labeled serialist/holist) with others that look at instructional and environmental preferences (e.g., the Dunns’ extensive array of categories related to classroom contexts).

3. LEARNING STRATEGIES AND APPROACHES TO STUDYING

Two distinct research traditions have developed for defining and measuring learning and study strategies: one applying preexisting psychological constructs and the other developing concepts from studies within the specific educational context. However, the most recent work can be seen as merging those traditions. After early attempts at using Likert scales to measure study methods and motivation, research in the United States drew heavily on cognitive psychology to describe students’ typical ways of tackling academic tasks, being particularly influenced by the distinction between active elaboration of information received and routine memorization of it. During the early 1980s, the work of Weinstein brought together these ideas with

practical advice on effective studying to link the measurement of study strategies with courses designed to help develop students' studying. Around the same time, Schmeck also used insights from cognitive psychology to develop an inventory of learning processes that described deep and elaborative processing as well as fact retention and methodical study.

More recently, Pintrich introduced several additional motivational constructs into the measurement of study strategies, including aspects of expectancy, value, and affect. Expectancy refers to students' beliefs about whether they can perform a task and involves self-efficacy and control beliefs about learning. The value component indicates why students engage in particular academic tasks and is covered partly by contrasting intrinsic and extrinsic goal orientation and partly by task value. This latter concept introduces affect by exploring the extent to which students find a particular task interesting, useful, and important. Learning strategies, as in the earlier work, focus on elaboration and are seen in relation to explicit and detailed metacognitive activities and self-regulation as well as volition. Interesting interplay among expectancies, motivation, and self-regulation, with consequent influences on achievement, has been reported in the most recent work, with tentative suggestions about possible gender and ethnic variations.

Whereas much of the research on learning strategies in the United States has increasingly been extended to work in schools, the alternative tradition, describing approaches, developed in Europe and Australasia and focused mainly on university students. The early work of Biggs was influenced by information processing theory, but most of the subsequent work has established conceptual frameworks out of interview and inventory studies carried out specifically in the higher education context. Using a distinctive form of qualitative analysis of interview data, Marton and his research team found a marked contrast among students in how they described reading an academic article in a naturalistic experiment. They distinguished a deep approach (which involved reading with the intention of understanding) from a surface approach (which relied on routine memorization to "get by"). The researchers argued that these approaches were specific to a particular academic context and were also dependent on the content of the learning task. However, the successful introduction of inventory measures indicated that approaches had a certain consistency, at least across similar learning environments and subject matter. Some researchers have suggested that such typical approaches should be referred to as "study

orientations," but there is still terminological disagreement in the literature.

Subsequent work by Entwistle and Biggs, working independently, described approaches to learning in terms of a combination of intention (or motive) and processes. For example, the deep approach involved the motive to understand for oneself combined with learning processes that involved an alternation between holist and serialist thinking. These descriptions were based partly on interviews and partly on factor structures of specially designed inventories, but it became clear that a third approach was necessary to explain the variations in studying reported. The strength of students' concern about their grades leads to the adoption of a strategic or achieving "approach to studying." The strategic approach seems to draw on either achievement motivation or a sense of responsibility for achievement, while the processes involve organized studying, effort, and attempts to monitor the effectiveness of studying.

This work was developed further by Vermunt, who introduced additional components relating to students' beliefs about the nature of knowledge, aims, and goals as well as to the balance between external regulation and self-regulation in studying (or the absence of regulation). This trend—seeing learning strategies in relation to epistemological beliefs—can also be found in the work of Pintrich and others in the United States. However, the most recent work by both Vermunt and Entwistle and their colleagues is distinct from the research on learning strategies in the United States in creating constructs that are composites. These cover a series of concepts that hang together so consistently that separating the component parts tends to destroy the sense of the experience reported by students. In this sense, they act rather like the "dispositions," described by Perkins, that bring together ability, inclination, and sensitivity to context.

4. MEASUREMENT INSTRUMENTS

A wide and disparate range of learning style inventories exists. This is due in part to the failure to reach any strong consensus on the theoretical basis of learning styles. Thus, the instrument that is chosen will depend largely on the context to which it is applied and the type of learning style that the investigator wants to assess. Furthermore, as Coffield and colleagues recently argued, the inventories vary considerably in how much evidence of reliability and validity is provided and in the extent to which the evidence is independent of the originator of

the inventory. This is particularly problematic where the inventories have been vigorously marketed, with strong claims for their value in educational or workplace contexts yet without convincing psychometric substantiation. In contrast, there is greater agreement and fewer inventories describing the main learning strategies and approaches to studying, and the psychometric properties of the most fully developed inventories have been firmly established.

However, uncertainties about the instruments used in this area of research do remain because the majority of instruments have been operationalized in self-report formats, usually Likert scales. Thus, the validity of these instruments depends on the extent to which individuals are conscious of the strategies they typically use in their learning and studying and can accurately reflect on them. The items are sometimes quite transparent in meaning and value loading, and students can, to some extent, present whatever impressions they like. However, the style items tend to offer alternatives that can be viewed as equally attractive, and the factor structures of the strongest learning strategy and approaches to studying inventories are sufficiently consistent across both subject area and educational system to substantiate their validity claims. Some instruments have adopted forced-comparison formats or ratio scoring, but both of these methods create difficulties for conventional statistical analysis. Messick recently argued that the uncertainties of measurement that exist in the measurement of styles necessitate the use of normative and ipsative scoring techniques in combination as well as the collection of data from contrasting populations.

5. RELATIONSHIPS TO ACHIEVEMENT AND TO LEARNING ENVIRONMENTS

The underlying purpose in using both learning style and approaches to studying concepts in educational research is to find ways of helping learners to become more aware of their styles and approaches and, thus, to seek ways of improving the effectiveness of their learning and studying. Evidence for the validity of the inventories rests, in part, on the relationships that exist between the scale scores and the measures of academic achievement. The unconvincing or inconsistent relationships often obtained are not surprising given the psychometric problems with several of the style

inventories, but these results could just as well be attributable to the varied definitions of achievement and its sometimes unreliable measurement in educational institutions. However, subscales of both learning strategy and approaches to studying inventories do relate to student achievement more convincingly but are still dependent on the type of learning being assessed. Although few studies have reported consistent gender differences, suggestive cultural and ethnic variations are emerging.

Theoretically more interesting research has been relating both style and approaches or strategies to teaching and learning in various subject areas, contrasting learning environments, and different educational stages. For example, in the style literature, there has been considerable debate about whether it is better to match or mismatch learner preferences with teaching preferences, how this should be done, who benefits from this, and who should decide from among the alternatives. Few large-scale, independent studies have been done to investigate this, but the findings do suggest that when the styles of the teacher and the learner are matched, learning is perceived as more congenial and teachers are rated more positively.

In the approaches literature, it is becoming clear that a deep, self-regulated approach can be encouraged through methods of teaching and assessment that focus explicitly on conceptual development and subject-specific thinking skills and that also require students to reflect on their own ways of studying. But the most recent work from both Biggs and Entwistle has stressed the necessity of thinking about the influence of teaching-learning environments on learning in terms of interacting systems. The students' approaches to studying and perceptions of teaching are part of one system in which the separate constructs used by researchers artificially separate aspects that are integrated within the individual and have their origins in earlier experiences. The idea of a "disposition to learn through personal understanding" would bring together ability, conceptions, intentions, style, motivation, strategies, and approaches, seen as constructs with different levels of generality and relative stability that work together to influence an individual's study behavior. The teaching-learning environment is a system that can be described at different levels as well, concentrating on the specific content and teaching methods devised by teachers, the broader social experiences of students, or the institutional and sociopolitical context within which education takes place. All of these

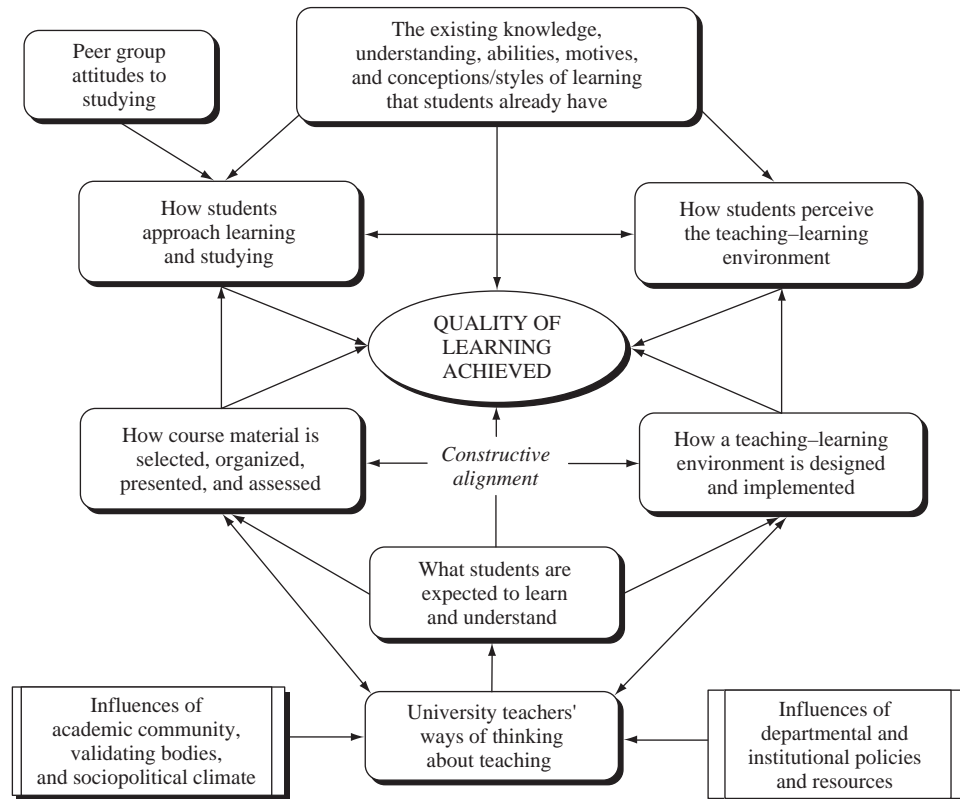

FIGURE 1 Interacting systems affecting the quality of student learning.

act together to influence student learning, but their influence is not uniform due to the different ways in which individual students react to the environment they experience. Figure 1 suggests what such interacting systems might look like in an outline based on ongoing research into teaching-learning environments in higher education.

However, the interacting systems do not show which aspects of each component of the environment are most likely to promote “deep learning.” For that, one must bring together a series of studies in schools such as Project Zero at Harvard University on “teaching for understanding” and de Corte and colleagues’ study in Belgium on “powerful learning environments.” Work at the university level also contributes to the listing shown in Table I, drawing on recent studies by Biggs in Australia on “constructive alignment” and by Entwistle, Hounsell, and their research team in the United Kingdom on ways of “enhancing teaching-learning environments.”

TABLE I
Teaching Activities Encouraging a Deep Approach to Learning

<ul style="list-style-type: none"> • Specifying broad generic aims emphasizing understanding and using “throughlines” to remind students of those aims on a regular basis • Ensuring that teaching methods and assessment procedures work in consort to support those aims, thereby providing constructive alignment • Using instructional methods that provide clear conceptual explanations, are presented with enthusiasm, and demonstrate empathy with the learners • Providing authentic tasks and realistic problems that have personal meaning and involve understanding performances • Using group discussions of both the content and the process of learning and studying • Promoting students’ awareness of their own cognitive processes and approaches to studying as well as their ability to control their motives, feelings, and efforts
--

6. OTHER APPLICATIONS IN EDUCATION AND BUSINESS

In spite of the lack of convincing evidence about the predictive validity of learning style inventories, they have been used widely in both education and the business world because the underlying conceptualizations tend to make intuitive sense to the users. The process of reflecting on the meaning of the scores then encourages metacognitive activity about learning preferences. However, learning style inventories have also been used for selection and promotion in companies, where any lack of convincing evidence about the instruments' psychometric properties and predictive validity has serious consequences.

Learning strategy and approaches to studying inventories have been used to identify students who reveal ineffective study strategies as well as to monitor the effects of innovations in teaching and learning. Although these inventories do seem to provide valid findings at the group level, their use in guiding individuals is much more problematic and needs to be supplemented by individual discussion of the responses prior to any changes in approach being suggested. Experience in using the research findings to encourage more effective studying strongly suggests that stand-alone teaching of study techniques is much less effective than building repeated suggestions and advice into the curriculum itself, thereby making them specific to the tasks that students undertake on a regular basis.

GLOSSARY

adjudicative competence Functional legal abilities that a criminal defendant must have in sufficient degree in order for the adjudicatory process to go forward. Also called competence to stand trial, competence to proceed, and fitness to proceed.

forensic assessment instrument (FAI) An assessment test, tool, or device designed to measure or to inform a clinical judgment about specific functional legal abilities required in a given legal context.

functional legal ability A legally prescribed capacity that an individual must have in sufficient degree in order to participate in a legal proceeding (e.g., to face prosecution in a criminal court) or to avoid legal intervention into his or her affairs (e.g., to manage one's own financial affairs or to make decisions about one's medical treatment independent of a court-appointed guardian).

mental state at the time of an offense (MSO) General term inclusive of various legally recognized mental states (e.g., insanity, diminished capacity, and automatism) that provide the bases for a defense to culpability for criminal behavior.

Legal competence refers to a legally prescribed ability, or set of abilities, that a person must have in sufficient degree in order to enjoy, without government intervention, the rights, benefits, and opportunities to which citizens are ordinarily entitled. Issues of legal competence generally arise in discrete legal contexts (e.g., during police interrogation or court procedures), although some may arise in clinical (e.g., competence to make decisions about one's own medical treatment) or research (e.g., competence to consent to research participation) contexts. The conceptual and contextual framework for assessments of legal competence differ from those that guide more traditional therapeutically oriented assessments, and an array of forensic assessment instruments have been developed to assist mental health professionals whose evaluations address these legally focused competencies.

I. INTRODUCTION: THE STRUCTURE OF MENTAL HEALTH LAWS

In the United States and many other democratic societies, the government cannot arbitrarily deny citizens the rights, benefits, and opportunities to which they are entitled. However, under either of two legal doctrines, citizens may be deprived of such rights and benefits if it is determined that they lack the requisite mental capacity to exercise such rights. One legal doctrine is police protection, which permits the

government to interfere in the lives of citizens whose behavior poses too substantial a risk to their own safety or the safety of others. This doctrine underlies, for example, involuntary hospitalization laws that permit the government to impose mandatory psychiatric treatment on individuals who pose a substantial risk of harm to others. The other doctrine is the *parens patriae* doctrine, in which the motive for state intervention is a paternalistic one. Procedures such as the appointment of legal guardians are intended to protect individuals from adverse outcomes in day-to-day situations that might result from their own poor judgments that stem from mental impairment. This doctrine underlies, for example, procedures that provide for the appointment of legal guardians to manage a person's personal and/or financial affairs.

Intrusions into citizens' lives on the basis of these rationales are prescribed in a collection of laws, broadly conceived as mental health laws. Associated with each of these laws is a legal competency that people must have in order to avoid state intrusion and to retain the full array of rights to which citizens are ordinarily entitled. As Morse elucidated most clearly in 1978, the structure of such laws involves three components: (i) a predicate mental condition that (ii) "causes" (iii) impairment in functional legal ability.

Most commonly, the predicate mental condition is described in legal terms, such as "mental disease" or "mental defect." Although in most instances there is no direct translation of these terms into contemporary psychological or psychiatric nosology, for more than a century mental health professionals have been utilized by the courts to provide evidence about the legal competence of parties to litigation. Historically, clinicians approached issues of legal competence using diagnostic interviews and general psychological tests (e.g., intelligence tests, general personality inventories, and projective tests) that they routinely employed in, and that were developed for, therapeutic applications. Today, however, the limitations of such methods for assessing legal competencies are widely recognized. Although the information gleaned from diagnostic interviews and traditional tests may be informative to judgments about the first element—predicate mental condition—these methods typically have not been normed or validated on relevant legal populations in ways that help inform the causality and functional impairment elements. In other words, the components of legal competencies involve considerations that go beyond what can be gleaned from conventional clinical assessment approaches.

2. COMPONENTS OF LEGAL COMPETENCIES

Grisso identified five features of legal competencies that distinguish them from more general competence constructs: a functional component, a causal component, an interactive component, a judgmental component, and a dispositional component.

2.1. Functional Component

The primary concern in forensic evaluations is the person's functional legal ability—the third element in the structural equation of mental health laws. As far as the law is concerned, it is the degree of impaired legal functioning, not the mere presence of mental disorder or generally impaired mental functioning, that determines whether a person's usual rights or privileges may be denied.

Several additional observations are important here. First, the particular functional abilities of concern vary from one legal context to another; to compare a couple of contexts alluded to previously, involuntary hospitalization proceedings focus on (among other things) a person's capacity to provide adequately for his or her basic needs (i.e., food and shelter), whereas guardianship proceedings focus on the capacity to manage one's personal affairs (e.g., to manage money and to enter contracts). Second, although a person's general mental condition is a relevant consideration insofar as a legally cognized predicate condition must be established, diagnosis is of secondary importance to functional legal ability. A person may have no mental disorder or several of them, but state intervention is justified not on the mere finding of mental impairment. Third, for any given legal context the relevant functional abilities are relatively narrow, and it is for this reason that some traditional clinical measures may be limited as a basis for inference about legal incompetence. Intelligence tests can provide information about a person's general problem-solving ability, but the legal questions will often be more narrowly focused and therefore require a more nuanced analysis as a basis for inference about impaired legal functioning.

2.2. Causal Component

Judgments about legal competence require causal inferences about the reasons for a person's functional abilities or deficits. Legal criteria for competence, often found in statutes governing a particular type of

proceeding or conflict (although criteria may also appear in appellate cases, administrative regulations, or other legal sources), often specify that the third element—impaired legal functioning—must be “as a result of” the predicate mental condition (first element).

Research that relates specific mental disorders, symptom patterns, neurological impairments, cognitive capacities, and so forth to functional legal abilities provides a basis for bridging the assessment of mental condition and legal competence. A further consideration in legal competence assessments is to distinguish legally relevant “causes” from irrelevant ones. For example, the legal context of adjudicative competence—more familiarly called competence to stand trial—requires (among other things) that a criminal defendant be able to adequately assist his or her attorney. For a defendant who is not able to do so because of impairments attributable to mental disease or defect, the adjudicatory process must be postponed until he or she regains such ability. However for a defendant, even one who has a mental disorder, who is merely unwilling to work with his or her attorney, the process can go forward. Assessments of legal competence may call for mental health professionals to aid the legal system in making such distinctions.

2.3. Interactive Component

Judgments regarding a person’s legal competence are not dependent merely on his or her mental capacity or the absolute level of his or her functional ability. His or her particular circumstances within the legal context may also be of relevance. It is the fit or congruence between capacity and demand that is ultimately of importance. From this perspective, one can see that courts (or other legal decision makers) might reach different conclusions about the legal competence of two individuals who have the same (measured) abilities.

Consider the adjudicative competence context, for example, for two individuals of modest mental capacity (e.g., judgment, memory, and general knowledge). One might be facing very simple charges such as driving without a valid license; the only issues of contention in the case are likely to be whether he or she was behind the wheel of a car and whether he or she possessed a valid license at the time. The other individual may be charged with intention to commit securities fraud, for which the defense (and required degree of assistance to counsel) is likely to be much more prolonged and complex. A mentally disordered individual of modest functional capacity might reasonably

be judged “competent to proceed” in the first case but perhaps not in the second.

As this example illustrates, it will be not only the individual’s measured level of psycholegal functioning but also the match of capacity with anticipated demand that will be relevant to the ultimate legal judgment of competence. Thus, to the degree possible, assessments of legal competence may require that the mental health professional assess and take into account the anticipated demands of the situation on the defendant.

2.4. Judgmental Component

In considering the adequacy of the fit between a person’s abilities and the demands of his or her legal situation, the law applies a variety of flexible legal tests. As will be evident in the next section, words such as “sufficient,” “reasonable,” or “substantial” are common qualifiers of the degree of capacity that the law demands.

There are at least three important consequences of the use of these qualifiers. First, these terms facilitate individualized judgments by legal decision makers. The competency criteria, although explicit, are not of the “hard-and-fast,” “one-size-fits-all” variety. Such terms permit a reasoned application of complex rules in judging cases that may vary radically in their particulars. Second, these terms reflect that most legal judgments about competence also involve social and moral considerations. In a criminal case involving an insanity defense, for example, such as the notorious case of John Hinckley, the decision about the accused’s mental state at the time of the offense is ultimately one of moral culpability. That is, within the framework of the written definition of legal insanity, was this particular individual’s impairment of the type that would warrant his or her exclusion from moral culpability for criminal behavior?

Following from the first two observations, the third consequence is that mental health professionals are (or at least logically should be) limited in the scope of conclusions that they draw in legal competency evaluations. The social and moral issues alluded to here are of a type that go beyond and stand outside the scope of scientific inquiry. Psychology and psychiatry have no “capaci-meters” for distinguishing the moral gradations that are part and parcel of legal competency judgments. Thus, the challenge to forensic examiners in legal competence evaluations is to provide clinical information that informs the judgment about competency while stopping short of offering conclusory opinions as to what that ultimate judgment should be.

2.5. Dispositional Component

Legal outcomes or dispositions hinge on the judgmental question—tersely put, whether or not the individual is judged “competent” (or “insane” or other analogous terms). The preceding section suggests that mental health professionals should not venture categorical conclusions about the competency judgment due to the social and moral nature of such decisions. It follows, therefore, that they should not presume to tell a legal decision maker what the appropriate disposition should be in a given case. Rather, clinical input regarding dispositions is best framed using “if—then” formulations that do not constrain the range of possible legal judgments. Whether, how, and the type of clinical assessment and treatment or other intervention might be provided can be discussed separately for different hypothetical outcomes; for example, “If the court decides X, then If the court decides Y, then”

3. CONTEXTS FOR THE ASSESSMENT OF LEGAL COMPETENCY

Issues of legal competency arise in many situations, several of which have been alluded to previously. In this section, several of the more frequently occurring legal competency questions are discussed in-depth. The reader is warned that not all legal competency

issues are recognized in all jurisdictions; for example, legal insanity is a recognized defense throughout most of the Western world, although in the United States there are approximately four states in which this defense is not available. Similarly, the formal legal criteria or “tests” of competency or capacity are not identical across jurisdictions. Thus, the presentation here is necessarily more conceptual and generic in nature.

3.1. Competencies in the Criminal Justice Context

Table I summarizes several issues of “competence” that arise in the criminal adjudicatory process.

3.1.1. Competence to Waive Miranda

Confessions are the primary evidentiary basis for many criminal convictions. In the United States, the legal basis for challenging the admissibility of defendants’ confessions resides in the Fifth and Sixth Amendments to the Constitution, which protect the defendant from compulsory self-incrimination and guarantee the right to the presence of legal counsel at all relevant stages of the adjudicatory process. Thus, when the accused individual is questioned by the police he or she must be informed of the legal rights that apply at the time of questioning. These include the right to have an attorney present during

TABLE I
Issues of Legal Competence in the Criminal Adjudicatory Process

Competence issue	Fundamental inquiry	Legal criteria (generically)
Competence to waive Miranda rights	When giving a statement to the police, did the defendant competently waive his or her right against self-incrimination?	Cognitive issue: Was the defendant’s waiver made knowingly and intelligently? Volitional issue: Was the defendant’s waiver made voluntarily?
Adjudicative competence	Can the defendant competently participate in any of several phases of the adjudicatory process?	Does the defendant have a factual and rational understanding of the proceeding, and can he or she adequately assist counsel at the proceeding?
Mental state at the time of the offense	Retrospective inquiry: Was the defendant morally culpable for his or her criminal behavior?	Cognitive issues: Did the defendant know right from wrong? Understand the nature and quality of his or her acts? Volitional issues: Could the defendant control his or her behavior? Was his or her will overcome by an irresistible impulse?
Competence to be executed	Does the offender understand the nature and purpose of the sentence of death?	Effectively the same as for adjudicative competence but applied at the post adjudication phase of sentencing.

questioning, the right to have an attorney appointed for them if they cannot afford to hire their own attorney, and the right to refuse to answer questions altogether. They must also be advised that what they say during interrogation may be used in court to prove their guilt.

Challenges to the competence of a defendant's waiver are almost always made after-the-fact. Defense counsel hopes to have the defendant's prior statement ruled inadmissible at a pretrial "suppression hearing" on grounds that the defendant did not competently waive his or her rights. To the degree that the state's case depends on incriminating information obtained from the defendant, the outcome of such suppression hearings may be critical.

One key feature of clinical assessment of competence to waive Miranda is that the evaluations are almost always retrospective. The attorney finds out days or weeks later that the defendant has given a statement to the police. The mental health expert who consults with the defense is asked to evaluate the nature and circumstances of that prior interrogation and to develop clinical information that informs the judgment of the defendant's competence at that time. Thus, the evaluation often hinges in part on archival information (e.g., transcripts or recordings of the defendant's statement) and the recollections of those present (e.g., interviews with the defendant and police) as bases for reconstructing the defendant's prior mental state.

Another feature is that the legal "test" for evaluating this particular legal competence, unlike most others, does not involve an explicit "mental disease" or "mental defect" type of predicate. Rather, the court is required to consider "the totality of the circumstances" that may have impinged on the defendant's competence to waive his or her rights, including a consideration of the appropriateness of the police behavior during the interrogation.

The criteria, as indicated in Table I, note the relevance cognitive factors—whether the waiver was made knowingly and intelligently. Personality features such as general intelligence and susceptibility to suggestion or influence of authority figures are often relevant in these cases. Similarly, whether one's capacity to make a rational or well-reasoned waiver was adversely affected by drug or alcohol intoxication or symptoms of mental illness is a relevant inquiry. Some standardized tests of Miranda comprehension, modeled after more general vocabulary and verbal comprehension tests, have been developed to assist in making a highly focused inquiry into the relevant cognitive capacities.

Although Table I also indicates that volitional issues—the "voluntariness" of a waiver—are relevant,

the law in this area has developed in a way that limits severely the relevance of clinical input on this issue. The higher courts have generally held that there must be clear evidence of inappropriate behavior by the police (e.g., excessive threats or other coercive behavior and interrogation periods of unreasonable duration) in order to infer that the defendant's waiver was not of his or her own free will. Intrapersonal factors, including the presence of symptoms such as delusional beliefs, obsessive thoughts, or hallucinations that "urge" the defendant to confess, have generally not been accepted as a basis for concluding that a waiver was not voluntary. Because mental health professionals will typically have no particular expertise in judging when and whether the police have exceeded legally acceptable norms in their interrogations, their assessments are typically limited in relevance to issues of cognitive capacity.

3.1.2. Adjudicative Competence

Adjudicative competence refers to a defendant's capacity for meaningful participation in the adjudicatory process. Historically, the term *competence to stand trial* was often used, although it seems clear in retrospect that this term was inappropriately narrow. In particular, criminal justice data reveal that more than 90% of defendants resolve their cases by entering pleas rather than by going to trial; thus, competence to stand trial is literally a moot concern in the vast majority of cases, and "competence to enter a plea" is a much more relevant consideration. Although competence for both of these phases—participating in a trial or entering a plea—involves the "understand and assist" test shown in Table I, so too does competence for other adjudicatory activities, including sentencing. Thus, the more comprehensive term adjudicative competence better describes the breadth of this legal competency test.

In the United States, the legal basis for adjudicative competence questions reside in the Sixth and Fourteenth Amendments to the Constitution. The Sixth Amendment guarantees the right to the assistance of counsel and to confront one's accusers; these rights cannot be effectively implemented by an individual whose mental capacities are too eroded by "mental disease or defect." The Fourteenth Amendment, which deals with issues of fairness in legal proceedings, is also implicated. Although these legal foundations reflect the defendant's concerns, the state has its own independent rationale for ensuring that only competent defendants are prosecuted. That concern is with public opinion in the larger world

community about the kind of justice afforded citizens in this country.

Because of these multiple rationales for the adjudicative competence inquiry, questions about the defendant's competence can be raised by either party or by the court on its own motion. When such motions are granted, the adjudicatory process is temporarily suspended pending the result of clinical evaluations of the defendant's competence. Every state and the federal government make provisions for government-funded evaluations of the defendant's competence to proceed; both the state and the defense may also privately retain mental health consultants at their own expense if they want to obtain independent evaluations. When the clinical evaluations are completed, a hearing may be held before a judge or jury (depending on jurisdiction rules) to determine whether the defendant is competent to proceed. If the defendant is found competent, the adjudicatory process continues (e.g., a date for entering a plea, or a trial date, may be set). If the defendant is found incompetent, then he or she is typically referred for psychiatric treatment to "restore" competence. At such time as the defendant's competence is restored, he or she is returned to court and the adjudicatory process resumes.

Unlike competence to waive Miranda, adjudicative competence is a present state evaluation. The focus is on whether the defendant is now (and in the reasonably short-term future) able to understand the proceedings and assist counsel. Also, in most (if not all) jurisdictions it is explicit that only impairments resulting from "mental disease or defect" are legitimate bases for finding the defendant incompetent.

The relevant functional legal abilities for adjudicative competence are shown in Table I. Factual understanding concerns a defendant's awareness and comprehension of how the proceedings (e.g., entering a plea or a trial) are designed to work in principle. Relevant queries include knowledge of the proper roles of participants (e.g., "What is a judge, prosecutor, or jury supposed to do?"), the nature of the proceedings themselves (e.g., "What is the nature of a plea agreement?"), and so forth. Rational understanding is more specifically focused on the defendant's beliefs about his or her own case; that is, even if a defendant has a good "civics book" understanding of how the process is designed to work, is his or her view of how the process will play out in this particular case compromised by delusional beliefs (e.g., that God will intervene to assist in the defense)? Capacity to assist counsel comprises the ability to understand the defendant's role (i.e., as the one who stands accused and whose freedom is in jeopardy); to recognize and put

forth information that will facilitate the defense attorney's efforts to construct a defense; and the ability to participate, with the degree of autonomy that the law requires, in decisions that the attorney is proscribed by law from making on behalf of the defendant (e.g., whether to enter a guilty plea and whether to testify).

A number of measures or tools, most developed with substantial input from mental health professionals, are available for use in forensic evaluations of adjudicative competence. They range widely in design and structure, from some that constitute little more than menus of topics or issues to raise with defendants to others that constitute semistructured interviews with ratings of (in)capacity on explicit dimensions (e.g., knowledge of roles of court participants and comprehension of available pleas) and measures that have standardized inquiries and interpretive norms for selected psycholegal abilities.

3.1.3. Mental State at the Time of the Offense

Retribution and deterrence are two of the primary legal justifications for adjudication and punishment of individuals who violate society's laws. However, dating back to antiquity, various cultures have recognized that it is morally inappropriate to hold certain classes of individuals fully responsible for criminal behavior. Mentally disordered individuals constitute one such class of individuals. Compassion, rather than vengeance, has been recognized as a more appropriate emotional reaction to individuals who were so mentally impaired that they "did not know what they were doing" or "could not help themselves." Furthermore, such individuals would not likely be deterred from future criminal behavior through the usual mechanisms of punishment. Hospitalization and treatment have been recognized as morally more appropriate societal responses to such individuals. Thus the rationale for the insanity defense and other mental state defenses.

The insanity defense is premised on the presence of legally defined mental disease or defect. Although there are no direct translations of recognized psychiatric diagnoses into such categories, empirically it is clear that this defense is usually reserved for individuals afflicted with the more debilitating disorders (primarily psychoses) or other acute symptom presentations that resulted in severe impairments in rational judgment (e.g., "knowing right from wrong" or capacity to control one's behavior) (Table I). The defense usually will not accommodate a defendant who was generally anxious, mildly depressed, disgruntled, or was merely "having a bad day."

The clinical inquiry into a defendant's sanity is a highly focused, retrospective evaluation. As with other legal competencies, the issue is not whether, at the time of the offense, the defendant merely had symptoms of a mental disorder that the trier-of-fact might judge constitutes a mental disease or defect. Mentally ill individuals may commit crimes for the same reasons that non-ill individuals do; having schizophrenia or bipolar disorder does not insulate one from the avarice that can motivate theft or robbery, nor do such disorders protect one from aggression based on anger or vengeance.

Thus, the critical linkage is the causal relationship (if any) between the symptoms of mental disorder and the alleged criminal behavior, and these linkages may be quite subtle or complex. For example, consider the case of a mentally ill person who fires a handgun through the skylight of his apartment because of delusions and hallucinations that space invaders are circling overhead in flying saucers, trying to destroy his brain with invisible radioactive rays that they beam into his home. On charges related to improper or illegal discharge of a firearm, this person may qualify for a judgment of insanity under at least some of the criteria listed in Table I. However, if this person is an ex-convict, then he may also be charged with parole violation because of his being a "felon in possession of a firearm." For this charge, the pertinent inquiry is the nature and quality of his reasoning in relation to obtaining the firearm in the first place. If he obtained the gun many months earlier for reasons unrelated to mental disorder (e.g., "I got it for protection because I live in a bad neighborhood"), presumably the insanity defense would not be relevant to his charge of parole violation.

As should be obvious, the defendant's recollection of his or her thoughts, feelings, and behavior at the time of the offense is critical to mental state at the time of the offense (MSO) evaluations. However, such self-reports may not be completely valid for a variety of reasons. MSO evaluations are often arranged weeks or months after the occurrence of the crime in question or the arrest of the accused. In the intervening period, the defendant's mental condition may have been affected by any number of factors—the natural course of illness, psychiatric treatment received (e.g., in jail or as a result of a finding of incompetence to proceed), or his or her emotional reaction to the offense (e.g., emotional reaction to having killed a loved one). Furthermore, when no other defense is viable, the potential for a defendant to feign insanity in an effort to escape prison must be considered. Consequently, as in the case of other retrospective assessments, the clinical evaluation of MSO often relies

extensively on archival, historical, and third-party information.

3.1.4. Competence to Be Executed

In the United States, the courts have held that it is a violation of the Eighth Amendment protection against cruel and unusual punishment for the state to execute an "insane" person. Perhaps the closest the courts have come to defining the criteria for this particular competence was Justice Powell's concurring opinion in *Ford v. Wainwright*, which stated that the state is forbidden from executing only "those who are unaware of the punishment they are about to suffer and why they are to suffer it." A broader criterion suggested by the American Bar Association includes the provision that a defendant be able to recognize and convey to counsel (or a court) any facts that might constitute a basis for appealing this sentence.

Conceptually, these provisions constitute a particular instance of the general criteria for adjudicative competence—the defendant must understand (rationally and factually) the nature and object of the proceedings against him or her and be able to assist counsel. In terms of assessment, the considerations described previously regarding adjudicative competence are relevant here, with a particular substantive focus on the purpose (retribution) and nature (loss of life) of capital punishment.

For a defendant who is judged incompetent for execution, the proceedings are stayed and he or she is referred for psychiatric treatment to restore competence. Perhaps more than for any other forensic issue, mental health professionals feel ethically compromised when they consider that the outcomes of their evaluations or treatment of such defendants may provide the final legal basis for putting them to death. Consequently, this is one area of forensic assessment that some clinicians exclude from their practices.

3.2. Civil Competencies

Apart from the criminal justice system, there are a variety of other social contexts in which concerns about citizens' legal capacities arise. Table II provides a brief description of several such civil competencies.

3.2.1. Guardianship

Some citizens develop mental disabilities that substantially impair their capacity to make, or to communicate, reasonable decisions in day-to-day situations, such as

TABLE II
Civil Competencies

<i>Competence issue</i>	<i>Fundamental inquiry</i>	<i>Legal criteria (generically)</i>
Need for a guardian to manage one's personal affairs	Should the individual's right to self-determination in day-to-day affairs be limited or removed due to mental incapacity?	Lacking sufficient understanding or capacity to make or communicate responsible decisions (in any of a wide array of day-to-day aspects of living)
Competence to make treatment decisions	Can the person make decisions about medical or psychiatric treatment that are in his or her best interest?	Understand and/or appreciate information relevant to one's illness and alternative treatment options Rationally weigh the risks and benefits, advantages and disadvantages, of treatment alternatives
Competence to consent to research participation	Can the person consent to research participation?	Adequate understanding of the required elements of informed consent in a research consent disclosure Capacity to make a rational decision to participate in the proposed research study
Testamentary capacity	Is the person competent to make a will?	Knowing the extent of their property and the "natural objects of their bounty" (potential heirs) Know that they are making a will and the manner in which their property will be distributed when the will is executed

attending to food and shelter needs, managing finances, and entering contractual agreements (including marriage). One common situation is that of elderly individuals afflicted with Alzheimer's disease or other dementia; some individuals with chronic mental disorders or substance abuse-related illnesses are also so afflicted. Under the *parens patriae* doctrine, most states have provisions for the appointment of responsible third parties (often relatives) to make decisions for individuals who are substantially impaired in this regard.

Of the various legal competencies, the guardianship issue is potentially one of the most sweeping in its scope. As the previous examples illustrate, the ability to "manage one's affairs" can cover a multitude of decisional domains. In recognition of the potentially extensive degree of intrusion that guardianship judgments may entail, the law in many jurisdictions distinguishes between plenary and specific (or limited) guardianships. In the former situation, the court appoints a legal guardian with the authority to make decisions in all (or nearly all) domains of a person's life; in the latter, only specific

decisions or types of decisions are placed under the authority of a guardian. A special instance of guardianship is conservatorship, in which a guardian is appointed only for purposes of managing the individual's financial assets (e.g., conducting financial transactions). Out of respect for individual autonomy, there is a preference for specific, as opposed to plenary, guardianship arrangements when the clinical circumstances permit. Thus, when mental health professionals participate in clinical assessments to inform guardianship decisions, their task is not only to determine whether and how severely a respondent's decision making is impaired but also to attempt to determine whether there are areas of decision making in which the respondent's capacity for judgment remains relatively intact.

As with other legal competencies, the mere presence of a mental disorder (i.e., diagnosis) is of little value to the legal decision maker. Although a predicate condition may be required, the legal criteria (depending on, and varying by, jurisdiction) often demand that impairment in specific mental functions (e.g., alertness and attention,

memory, and thought process) be demonstrated and the impact of these impairments on specific decisional behavior (e.g., how to manage finances) be elucidated.

3.2.2. Competence to Make Treatment Decisions

A specific decisional capacity that might be considered a special area of application for guardianship is the capacity to make decisions about medical treatment. This issue arises with respect to both medical and mental health treatment, although it is one for which special procedures and venues (outside formal guardianship proceedings) have developed. As with guardianship proceedings, the situation is one in which a person's right to self-determination (autonomy) is the focal point.

As Table II indicates, the substantive issues involve a person's capacity to comprehend, and to act rationally on, information relevant to making a decision about treatment. Such information includes awareness of one's own illness, the array of potential treatments available, the risks and benefits anticipated with each treatment, the likely course of illness if no treatment is accepted, and so forth. In the context of decision making about whether to accept psychiatric treatment, the courts have recognized varying tests of capacity. These tests parallel, to some degree, the factual understanding, rational understanding, and capacity for autonomous decision making discussed previously in the adjudicative competence context. The person should be aware of the symptoms, nature, and anticipated course of the illness with which he or she is diagnosed; appreciate (i.e., acknowledge) that he or she in fact has the illness and that the probabilities regarding course and outcome—with and without treatment—apply to him or her; and be able to identify and compare risks and benefits in a way that informs judgment about which course of treatment (including refusal of treatment) to follow. Grisso and Appelbaum offer an extensive discussion of the legal framework for treatment decision making and a research-based procedure for clinical evaluations of treatment competence.

Unlike the other legal competencies discussed so far, in some jurisdictions treatment competence determinations are not made in a formal legal arena (i.e., in court) by legal decision makers (i.e., judges or juries). Rather, in some jurisdictions determinations of treatment competence regarding the acceptance or refusal of psychiatric treatment (mainly, psychotropic medications) are left to mental health professionals. Although there may be provisions for administrative review or appeal of clinicians' decisions about the person's need for treatment, the initial judgment whether to impose

involuntary treatment may rest with the attending physician and professional colleagues who provide an independent review of that physician's judgment. In these situations, the clinical judgments do involve the judgmental and dispositional components of legal competencies that are left to judges and juries in other contexts.

3.2.3. Competence to Consent to Research Participation

The Nuremberg Code and subsequent guidelines established by governmental administrative bodies, such as the Belmont Report, provide the legal and conceptual frameworks for research involving human subjects. Briefly, no person can be involved as a research participant unless he or she gives competent consent to such participation. In order to give consent, the prospective research participant must be provided information relevant to the decision (whether or not to participate) and demonstrate adequate comprehension of that material. As in the situation involving medical treatment, the research investigator may be liable for a battery against an individual who has not consented to research participation.

As with guardianship and treatment competence, individual autonomy and self-determination are central values at stake in this context. People with sufficient mental capacity to understand research disclosures and the parameters, risks, and potential benefits of research described therein should be allowed to decide for themselves whether or not to participate. However, impaired decision-making capacity can derive from a variety of situational (e.g., stress) or intrapersonal (e.g., mental illness) sources, and some individuals may not be capable of the degree of comprehension and rational judgment necessary to give informed consent. Research suggests that people with dementias (e.g., Alzheimer's patients) and major mental disorders with psychotic features (e.g., schizophrenia) may have the greatest difficulty comprehending research consent disclosures.

Locally, research procedures are approved and monitored by institutional review boards (IRBs). Procedures for eliciting informed consent may vary depending on the type and level of risk that the research entails. Some studies involve minimal or virtually no risk to participants (e.g., an anonymous survey study that does not involve questions about personal or sensitive issues) and in certain circumstances the IRB may waive the requirement that informed consent be obtained. In studies involving greater than minimal risk, investigators are routinely required to obtain written informed consent.

This legal competency is one for which the determination of capacity is not made in a legal forum (e.g., a courtroom) or by a formal legal decision maker (i.e., a judge or jury). Almost universally, the judgment that a person has given competent consent to research participation is made by the study's principal investigator (PI) or research team members trained by the PI in informed consent procedures. The substantive elements of research consent are identified in the U.S. Code of Federal Regulations, and IRBs are responsible to see that PIs include required elements in their written consent disclosures.

There are currently no standardized or objective procedures for evaluating a prospective research participant's level of comprehension of research consent disclosures, which can vary radically in length and complexity from one type of study to another. Miller and Willner recommended brief objective testing of consent disclosure comprehension as one approach to the systematic evaluation of capacity to consent, and Poythress suggested ways that normative assessments of competence to consent might be structured. Currently, research investigators' ad hoc questioning and request for paraphrasing of disclosed material is likely the approach taken with most prospective study participants.

3.2.4. Testamentary Capacity

Planning for the disposition of one's property after death commonly involves making a will. For a will to be valid, the person must have been "of sound mind" at the time that the will was prepared. As Table II indicates, this criterion is ordinarily framed in terms of awareness of the extent of one's property and due consideration of the family members and friends who might be considered the most likely heirs to one's money or estate.

As with other legal competencies, testamentary capacity does not hinge on the mere presence or absence of mental disorder. Mentally disordered individuals may make valid wills, and in order to invalidate a will the courts require a showing that the mental disorder "caused" impairment in the person's ability to evaluate the nature and extent of his or her estate or to consider those to whom the estate might naturally be passed on. Knowledge of one's property does not necessarily have to be detailed, and merely forgetting a distant relative with whom one was marginally involved does not necessarily invalidate a will.

Thus, the assessment will often focus on the individual's capacity to describe the various facets of the estate and to explain the reasons for including, or excluding,

potential heirs or the amount of property to be distributed to each. An individual may exclude or severely limit the property planned for distribution to presumably natural heirs (e.g., children or other close relatives) for reasons based in reality (e.g., residual animosity from prior disputes). In contrast, delusional beliefs about such individuals might be judged as a wrongful basis for excluding an otherwise deserving relative or friend, and evidence of such delusions might persuade a court that the person was not of sound mind when the will was prepared.

Challenges to testamentary capacity are likely to be brought by individuals, often family members or friends, concerned about the anticipated distribution of the individual's estate. Such challenges may be brought at the time the person prepares to make a will, in which case the evaluation is a present state assessment. Challenges brought after a will has been made and filed, including challenges after the person is deceased, result in necessarily retrospective evaluations in which the focus is on the testator's mental state at the time the will was made. As in other retrospective evaluations discussed previously, third-party information that helps to reconstruct the testator's thoughts, feelings, and attitudes from the relevant prior point in time may be essential to the assessment.

4. ISSUES IN FORENSIC ASSESSMENT

As should be clear from the foregoing discussion, assessments of legal competencies differ in significant ways from more traditional psychological and psychiatric evaluations that target primarily the diagnosis of mental disorder and the development of treatment plans. The following sections highlight some of the important ethical and assessment features that distinguish evaluations of legal competencies.

4.1. Ethical Issues

Clinicians who participate in the assessment of legal competencies face a number of ethical issues with which they must be prepared to cope. An excellent resource in this regard is the work of Greenberg and Shuman.

One primary issue is that of role clarification. The person whose legal competence is at issue is rarely the person who contacts the clinician for a consultation; rather, the court or an attorney is generally the referring agent, and it is this entity to whom the mental health

professional owes certain obligations. These obligations may need to be discussed and explained in detail with the individual whose competence is being evaluated to ensure that this person does not mistakenly view the clinician as “my doctor” or as having a primarily therapeutic purpose for conducting the assessment. Although there may be some legitimate exceptions, generally mental health professionals should decline to conduct evaluations of legal competency on individuals with whom they have a preexisting therapeutic relationship.

The rules that govern privacy and confidentiality are different in forensic assessments, and these must also be carefully explained to the individual, who may otherwise assume that the usual doctor–patient relationship rules govern subsequent disclosures of information gathered during the assessment.

Another ethical consideration, and one perhaps easily overlooked by forensically naive practitioners, is that of scope of practice. As the foregoing discussion indicates, assessments of legal competence often require an awareness of particular legal tests or criteria, as well as competence in the administration of forensic assessment instruments, that may not be part and parcel of standard mental health training. Thus, some additional training and/or supervised experience in evaluating legal competencies may be required before one can claim adequate education, professional preparation, or competence in conducting such evaluations.

4.2. Instrumentation

It should also be clear from the previous discussion that the assessment approaches and formal instrumentation employed to evaluate legal competencies may vary considerably from those routinely used in therapeutically focused evaluations. Although conventional assessment devices (e.g., EEGs, brain imaging equipment, tests of intelligence or neuropsychological functioning, and personality tests) may have some role in forensic evaluations, legal competencies often involve a more narrow and nuanced inquiry concerning particular functional abilities for which traditional tests were neither developed nor normed. Conventional testing will more likely be helpful in illuminating the background question of an existing mental impairment that might constitute a basis for impaired functioning; independent assessment of the relevant psycholegal abilities and functional capacities is often required and may best be approached using forensic assessments designed especially for such applications. Grisso provides perhaps the most comprehensive review of forensic assessment instruments.

A unique feature of some legal competencies, such as competence to waive Miranda, MSO evaluations, and (some) assessment of testamentary capacity, is their retrospective focus. More often than in therapeutically oriented evaluations, mental health professionals will need to obtain and evaluate archival or third-party information that may be helpful in reconstructing the person’s prior mental condition.

4.3. Communicating with Attorneys and Courts

Because evaluation reports from legal competency assessments are written primarily for consumers in the legal community (judges and attorneys), mental health professionals must also learn to write reports that are appropriate for this audience. Perhaps most obvious is the fact that judges and attorneys will not be familiar with the jargon or terms of art that are commonly found in reports written for other mental health colleagues. Clinicians must learn to present clinical material in more of a “plain language” format to ensure that they are understood. Also, as noted previously, clinical diagnoses—diagnostic labels in particular—are less important in forensic contexts. Because of the need to explain whether and how mental impairment affects functional legal capacity, a greater emphasis is needed on description of particular symptomatology and the ways that such symptoms affect competence. Guidelines for communicating with legal professionals can be found in Melton *et al.* and other sources.

GLOSSARY

benefit production process The psychodynamic mechanism that intervenes between a leisure experience and the psychological benefit the individual receives from that experience.

compensation hypothesis A theory that work activities provide only some of the benefits that most people desire, so they engage in leisure activities that provide the benefits their work activities do not provide.

dual-process theories Theories that derive from Wundt's theory of hedonic tone, which postulates that stimulation has both a pleasant and an unpleasant effect, and the individual's evaluation of the stimulus is a function of the relative salience of these pleasant and unpleasant components.

flow A transcendent experience postulated by Csikszentmihalyi to occur as a consequence of an optimal match between the demands of an activity and the skills possessed by the participant.

idle hands theory A widely held belief, rooted in the Protestant work ethic, that people are happiest and mentally healthiest

when they are busy. This view regards industry as good and idleness as bad. Having unoccupied time is seen as psychologically and behaviorally risky.

optimal arousal One of the conditions postulated to be essential for an individual to interpret an experience as leisure. The level of cognitive stimulation (i.e., optimal arousal) that is maximally motivating and satisfying to the brain.

peak experiences A transcendent experience postulated by Maslow that is characterized by high levels of the attributes of leisure experience.

residual/discretionary models Early definitions of leisure that defined leisure in terms of the time remaining after one's obligations had been satisfied.

spillover hypothesis A theory that individuals seek the same benefits from their leisure and work activities.

transcendent leisure experiences theory A theory that when four conditions postulated as necessary to experience leisure are satisfied, (i) an individual will experience the activity as leisure, (ii) the experience will be characterized by high levels of the attributes of leisure experience, and (iii) some psychological needs of the individual will be satisfied.

Psychological investigations of leisure behavior have focused on the causes, attributes, and benefits of leisure experiences. The attributes of leisure experience—the subjective perception of leisure from the perspective of the participant—have received much less attention than the other areas. More attention has been given to the conditions necessary for an individual

to interpret an experience as leisure (i.e., the causes of leisure experience). Freedom of choice, intrinsic motivation, optimal arousal, and psychological involvement have been proposed as essential conditions for individuals to interpret an experience as leisure. The largest body of research concerns the benefits of leisure experience. Most work on the benefits of leisure has focused on the psychological needs satisfied by leisure experiences, but attention has been given to the effects of leisure experiences on physical health, mental health, life satisfaction, and personal psychological growth. Psychologists also have given attention to the application of leisure psychology to counseling and recreation resource management.

1. RESEARCH ON LEISURE

Only sporadic studies of leisure were undertaken prior to the 1980s. These studies were conducted almost exclusively by psychologists identified with vocational guidance, the forerunner of the modern-day disciplines of vocational psychology and counseling psychology. The most extensive investigation was undertaken under the leadership of E. G. Williamson, a renowned vocational psychologist and one of the intellectual founders of counseling psychology. The influence of vocational psychology is further evident in the narrow focus of this research on leisure activity choice and on the amount of time devoted to various leisure pursuits. A quasi-moral tone is apparent to the contemporary reader in many of these reports; activities such as drinking and playing cards were regarded with less tolerance than is typical in North American society today.

The residual and discretionary definitions of leisure guided leisure research and practice until the 1980s. Both definitions reflect the lay view of leisure as the discretionary time remaining after obligations have been satisfied. Renowned French scholar Joffre Dumazedier gave popular expression to the residual view with his notion of “three eights” (i.e., daily life consists of 8 hours of work, 8 hours of sleep, and 8 hours of leisure). As late as 1980, leisure psychologists, such as Seppo E. Iso-Ahola in his influential book, *The Social Psychology of Leisure and Recreation*, were still defining leisure as the time left after work.

The discretionary model defined leisure as an activity—apart from the obligations of work, family, and society—to which individuals return at will for relaxation, diversion, social participation, broadening their knowledge, or the exercise of their creative

capacity. This definition improved on the residual definition by focusing attention on leisure activity rather than time, by recognizing that an individual has family and social obligations, and by suggesting that leisure involves the exercise of free will.

Two newer models of the relation between work and leisure have received research scrutiny. The spillover hypothesis postulates that individuals seek the same benefits from their leisure and work activities. In contrast, the compensation hypothesis postulates that work activities provide only some of the benefits that most people desire, so they engage in leisure activities that provide the benefits their work activities do not provide.

The compensation model makes better intuitive sense. Few people have an occupation that satisfies all of their important desires. It is only logical, therefore, that people obtain the most fulfilling occupation possible and then attempt to satisfy their remaining needs through family, social, and leisure activities. In this instance, however, common sense leads to a false conclusion. The research evidence provides much stronger support for the spillover hypothesis: People generally receive similar benefits from leisure and work activities. This suggests that people seek to obtain the benefits they value most in all aspects of their lives. For example, people who value interpersonal interactions seek both an occupation and leisure activities that provide this benefit.

The first psychologists to study leisure behavior encountered two serious shortcomings in the existing leisure theory and research. First, the residual and discretionary models defined leisure as a void (i.e., time left over after accounting for other activities). These models were not useful in identifying the essential features of leisure, the role of leisure in the life of the individual, or the effects of leisure on the individual. Second, the theory and research on work and leisure through the 1960s reflected a Western European, male, middle-class perspective. The work and leisure experiences of women, working-class individuals, and individuals from other races and cultural heritages were largely ignored. Psychologists have addressed these issues in creating a uniquely psychological perspective on leisure.

2. EMERGENCE OF A PSYCHOLOGICAL PERSPECTIVE

Sporadic investigations of the interaction between individuals and their leisure activities began to appear in the 1960s. The 1974 publication of John Neulinger's

The Psychology of Leisure stimulated the birth of a psychological perspective on leisure and influenced the research and conceptual efforts of psychologists for the next two decades. Neulinger defined leisure as a state of mind and identified perceived freedom and intrinsic motivation as necessary preconditions for leisure to occur. He distinguished among six types of activities based on the extent to which the activity was freely chosen and whether participation was motivated by a desire to receive intrinsic rewards, extrinsic rewards, or a combination of intrinsic and extrinsic rewards. Pure leisure activities occur when individuals freely choose intrinsically satisfying activities; pure job activities occur when individuals respond to behavioral constraints to achieve extrinsic rewards. Although leisure and work were considered to be polar opposites by recreation philosophers, Neulinger argued that leisure was more than the mere absence of work. His definition of leisure and work in terms of the conditions under which they occur enabled scholars to investigate ways in which they are similar.

Initial reactions to Neulinger's model were vigorous. His attempt to redefine leisure as a synonym for "phenomenological experience" was criticized for "confusing communication." His suggestion that only intense experiences could be regarded as leisure ignored the diversity of leisure experiences that occur in everyday life. The ensuing debate focused attention on the nature of leisure experiences and the conditions that are necessary for them to occur. Neulinger's emphasis on the individual's subjective experience and his recognition of the possibility that leisure and work might have similar attributes and benefits highlighted phenomena and issues of interest to psychologists. As a consequence, his model was instrumental in shifting attention away from activity participation patterns and time budget studies.

The theory of transcendent leisure experiences by Howard E. A. Tinsley and Diane J. Tinsley expanded Neulinger's work to include optimal arousal and psychological commitment as additional conditions that are necessary for experiencing leisure. Furthermore, this theory postulated seven attributes of leisure experiences and it suggested that leisure experiences were necessary for physical health, mental health, and personal (psychological) growth.

The transcendent leisure experiences theory highlighted the importance of distinguishing between the causes, attributes, and benefits of leisure experiences. For example, if freedom of choice is a necessary condition for experiencing leisure, individuals who are asked to describe their feelings during a leisure experience might say "I feel free." Since feelings of freedom

can be both a necessary prerequisite for leisure experiencing and an attribute of the experience, the failure to distinguish between the causes, attributes, and benefits of leisure experiences leads to confusion. The following sections describe the attributes of leisure experiences, the causes of leisure experiences (i.e., the conditions necessary for leisure experiences to occur), and the benefits of leisure experiences.

3. ATTRIBUTES OF LEISURE EXPERIENCE

Leisure experiences vary from intense, life-transforming experiences to the routine experiences that occur on a daily basis. Nevertheless, psychologists have focused on the most intense forms of leisure experience because the attributes of these experiences are more readily identifiable. Five theorists have postulated attributes of leisure experiences. Abraham Maslow's theory of peak experiences is the earliest and most comprehensive theory. Tinsley and Tinsley's transcendent leisure experiences theory was influenced by Maslow's work, but it deals more directly with leisure behavior. Mihaly Csikszentmihalyi proposed a theory of flow experiences that formed the basis for Chester F. McDowell's theory of leisure consciousness. Csikszentmihalyi and McDowell focus on the most intense leisure experience. Kathleen D. Noble's theory of transcendent religious and meditation experiences is narrower in scope, but it identifies some attributes that are not included in the other four models. In contrast to the others, Maslow and Tinsley and Tinsley believe that the attributes of routine leisure experiences are the same as but less intense than the attributes of transcendent leisure experiences.

Several common themes are discernable in these theories. The greatest consensus exists for the following attributes of leisure experiences:

Unity: Maslow was the first to propose that the individual and the experience become integrated. Participants report a sense of unification with the world during leisure experiences.

Absorption: Participants focus exclusively on the activity and become unaware of or forgetful of themselves.

Enriched perception: Continued participation across time leads to a greater awareness of the nuances, details, patterns, and complexities of the experience.

Positive outcome: Leisure experiences provide a desirable way of truth finding that can lead to insights into universal truths.

Passive awareness: Participants suspend their will and allow the experience to unfold without attempting to organize or control it.

Loss of inhibition: Anxiety, defensiveness, restraint, and self-criticism are set aside; the individual feels confident, unique, expressive, and daring.

Perceptual distortion: Participants lose track of time and space; hours can seem like minutes.

Feelings of freedom: The individual feels free—unconstrained by rules.

Intrinsic motivation: Individuals gain enjoyment from the mere act of participating in the activity (i.e., from their experiencing of the pattern and structure of the activity and their use of the skills required by the activity).

4. PREREQUISITES OF LEISURE EXPERIENCE

Leisure psychologists have proposed that perceived freedom, intrinsic motivation, optimal arousal, and psychological commitment are necessary for an individual to experience leisure. “Leisure” (and “license”) derive from *licere*, a Latin word indicating permission, so it is not surprising that leisure theorists view freedom of choice as essential to experience leisure. Social psychologists refer to freedom of choice as the “illusion of control” because the individual’s subjective perception or interpretation of the situation is the critical determinant of the person’s experience. Individuals may perceive themselves as freely choosing to engage in behaviors that appear to external observers to be the result of external constraints. The illusion of control can vary from one of no control to complete control.

4.1. Control and Reactance

Psychologists from many subdisciplines have noted the importance of freedom of choice or the illusion of control. Developmental psychologists cite the desire to develop personal competence as a strong influence on the behavior of the child. Motivation psychologists view the desires for personal autonomy and competence as two of the most powerful motivations underlying human behavior. According to social psychologists, the need to feel in control leads people to perceive themselves as having control over situations even when they do not. Illusions have genuine consequences; innovative research studies have revealed that the illu-

sion of control is important for maintaining mental health and successful functioning.

Threatening an individual’s sense of freedom generates psychological reactance, an aversive feeling that increases the attractiveness of the threatened freedom, stimulates aggressive feelings, and motivates the person to undertake action to restore the lost or threatened options. Thus, the imposition of constraints has a boomerang effect. The strength of reactance is influenced by the strength of the initial expectation of freedom, the importance of the freedom, the amount of freedom lost, and the effects of the loss of freedom. Leisure psychologists believe that reactance influences people’s willingness to accept a substitute activity in place of a lost activity. An individual’s willingness to substitute one leisure activity for another is inversely related to the amount of external pressure to make the switch.

4.2. Intrinsic Motivation

Intrinsic motivation refers to the desire for rewards that are obtained from the act of participation. For example, an individual who desires social contact would find visiting with close friends to be intrinsically rewarding because the very act involves social contacts. Extrinsic motivation refers to the desire for rewards that do not occur automatically as a consequence of performing the activity. Common extrinsic motivations include external coercion, the desire to avoid negative outcomes, and rewards such as money, grades, and recognition.

4.2.1. Two-Factor Theory of Motivation

The distinction between intrinsic and extrinsic motivation received attention in vocational psychology long before it became of interest to leisure scholars. The two-factor theory of work motivation views this distinction as critical to understanding vocational behaviors (e.g., job performance) and outcomes (e.g., job satisfaction). Most job satisfaction inventories provide measures of both intrinsic rewards (e.g., feelings of accomplishment and a sense of creativity) and external rewards (e.g., recognition and working conditions). Job-enrichment efforts typically involve changes in the work environment that increase the intrinsic rewards of the job.

4.2.2. Autonomy and Competence

Psychologists who study human motivation believe autonomy, competence, and relatedness are the three

primary intrinsic motives. Autonomy refers to the desire for self-determination and personal choice. As such, autonomy is related to freedom of choice and the illusion of control, and the loss of autonomy is a cause of reactance. Developmental psychologists define competence motivation as the desire to feel in control of the situation and to exercise control for its own sake. These definitions of autonomy and competence reveal a conceptual overlap with the illusion of control. Additional research and conceptual development are needed to illuminate these constructs and eliminate their conceptual redundancy.

4.2.3. Relatedness

Relatedness refers to the desire to feel loved, connected to others, and meaningfully involved with the broader social world. As early as the 1950s, vocational psychologists had identified relatedness as the primary dimension distinguishing among occupations. Early theories postulated that an orientation toward people as opposed to an orientation away from people (or an orientation toward things) was a critical dimension distinguishing among occupations. The strength of a person's preference for working with people is one of the primary factors influencing occupational choices. An extensive body of research supports this view. Some leisure psychologists have also suggested that this is the primary dimension that distinguishes among leisure activities. Research has shown that the desires to affiliate with and nurture others are important dimensions distinguishing among leisure activities.

4.2.4. Overjustification

Providing extrinsic rewards for behaviors that initially are intrinsically rewarding can destroy intrinsic motivation if the extrinsic rewards become too salient (i.e., overjustification). A classic study conducted in 1973 by Lepper *et al.* demonstrated that preschool children who originally chose to play with colorful felt-tip markers during free play were much less willing to play with the markers after an intervening time in which they had been promised and subsequently given a reward for playing with the markers. Leisure theorists believe this is because the extrinsic reward diminished the child's perception of control. They caution against providing extrinsic rewards to encourage individuals (particularly children) to participate in activities that are intrinsically satisfying.

4.2.5. Extrinsic Regulation

Extrinsic rewards regulate the behavior of individuals, thereby lessening their illusion of control. There are three forms of extrinsic regulation. Extrinsic motivation, the most coercive form of extrinsic regulation, occurs when behavior is controlled by external factors. Interjected regulation occurs when internal pressures not associated with one's sense of personal identity (e.g., feeling obligated to perform the behavior) influence behavior. Integrated regulation occurs when behavior is motivated by the person's self-concept (i.e., when the failure to perform the behavior would have negative implications for the person's self-concept).

4.3. Optimal Arousal

Optimal arousal is a third condition believed to be essential to experience leisure. Psychologists believe that individual differences in sensation seeking, curiosity, and exploratory behaviors are the result of individual differences in optimal arousal level.

4.3.1. Homeostasis and Optimal Arousal

Cannon observed in 1932 that all living organisms have a natural tendency to maintain a state of internal balance or equilibrium. He called this tendency homeostasis. The maintenance of homeostasis is largely automatic (e.g., we breathe without having to think about how much oxygen we need). Nissen extended this concept in 1954 to include the function of the brain in perceiving and knowing things. He reasoned that there is an optimal level of cognitive stimulation (i.e., optimal arousal) that is maximally motivating and satisfying to the brain.

4.3.2. Wundt's Law of Hedonic Tone

In 1874, Wundt proposed a general law of hedonic tone to explain how humans interpret stimuli. He theorized that stimulation has both a pleasant and an unpleasant effect. As the strength of a stimulus increases from barely discernable (i.e., neutral) to weak and then to mild, the strength of its pleasantness component increases much more rapidly than the strength of its unpleasantness component. Therefore, the stimulus is perceived as increasingly more pleasant. However, the pleasantness component of each stimulus reaches its maximum while the unpleasantness

component is still relatively weak. Increases in the intensity of the stimulus beyond this point increase only the strength of the unpleasantness component. Wundt's model explains why increases in the intensity of a stimulus (e.g., increasing the tartness of a lemon meringue pie) result in more pleasant sensations up to a point, but further increases beyond that point actually make the sensation less pleasant.

4.3.3. Dual-Process Model

William James, Daniel Berlyne, Marvin Zuckerman, and Charles Spielberger all have used Wundt's dual-process model to explain optimal arousal. Berlyne suggested that increases in the strangeness, novelty, complexity, and information provided by a weak stimulus will produce increases in curiosity or exploratory behavior. As the stimulus becomes stronger, however, its negative component begins to cause avoidance or withdrawal.

Zuckerman offered a similar explanation of sensation-seeking behavior. Research evidence shows that persons who seek varied, novel, or complex sensory experiences tend to need greater levels of stimulation (i.e., have a higher optimal arousal level) than people who do not value these qualities. Research also has revealed the existence of an inverse relation between sensation seeking and anxiety.

Spielberger proposed a dual-process model in which curiosity and exploratory behavior result from the simultaneous influence of curiosity and anxiety. Both are psychological states that arouse and motivate behavior; both fluctuate as a function of novelty, incongruity, and ambiguity. However, these states are antagonistic drives. Pleasure is optimal when there are strong feelings of pleasantness, curiosity, or arousal accompanied by mild feelings of anxiety or fear. As the negative side effects of anxiety and fear increase, the overall quality of the experience becomes less pleasant.

The presence of both curiosity and anxiety in approximately equal strengths leads to uncertainty and an approach-avoidance conflict. Approach-avoidance conflicts occur when a single goal has both undesirable (i.e., risk) and attractive (i.e., possibility of gain) features. These conflicts often produce vacillation. The individual moves closer to the goal until the avoidance motive becomes stronger than the approach motive and then moves away from the goal until the approach motive once again becomes stronger. The result is that the person vacillates around the point at which the approach and avoidance motivations are equally weighted.

4.4. Commitment

A sense of psychological involvement (or commitment) is the fourth condition suggested as a prerequisite for leisure experience. The concept of psychological involvement is useful in distinguishing meaningful participation (e.g., watching one's favorite television show) from inconsequential dalliance (e.g., watching television for 5 minutes while waiting for a companion to arrive). "Commitment" and "involvement" are used somewhat interchangeably in the literature and psychologists have not proposed a formal distinction between them.

In 1947, Muzafer Sherif and Hadley Cantril proposed the concept of psychological involvement to explain the process by which individuals relate their personal sense of identity to a social object (e.g., a sports fan's elation when a favorite team wins). Involvement is a psychological state of arousal, interest, or motivation that has personal relevance to the individual. The strength of involvement influences the extent to which a person will seek out and process information about an activity, expend time and energy pursuing the activity, and continue to pursue the activity across time. Involvement has been investigated most extensively in the area of marketing and advertising behavior.

In leisure theory, involvement (commitment) has been described as a psychological attachment to an activity that guides both long- and short-term behavior. Psychological involvement is determined by a person's satisfaction with the leisure activity, investment in the activity (i.e., the things a person would lose if he or she quit the activity), and perception of the potential benefits available from other activities. A person's level of commitment to a leisure activity predicts his or her activity persistence. Committed individuals have more ability to respond positively to any negative aspects of the activity.

5. BENEFITS OF LEISURE EXPERIENCE

Research has examined a wide variety of potential benefits of leisure, including physiological and physical health benefits, mental health benefits, social benefits, economic benefits, environmental benefits, and benefits to the community. Both individuals and social groups obtain benefits from leisure. Individuals obtain benefits such as increased life satisfaction, but this outcome may also contribute to an improvement in the morale of a family, a classroom, a school, and a community. Thus, social

groups may receive second-order benefits that derive from the first-order benefits individuals obtain from their leisure experiences. Social groups may also receive direct benefits, such as when vandalism is reduced or community pride increased as a result of introducing a new leisure program in the community. Determining the benefits of leisure to social groups is more complicated than determining the benefits received by an individual.

5.1. The Meaning of Benefit

A benefit is a beneficial change or the maintenance of a desirable situation (i.e., a positive outcome). Determining that a positive outcome is a benefit of leisure requires evidence that participation in leisure is responsible for the outcome and that the outcome is an improvement over what would have occurred otherwise. This determination involves a series of subjective judgments. First, psychologists must operationally define leisure. Although much leisure research and theory focuses on the nature of the individual's phenomenological experience, research on leisure benefits has not adopted this approach. Another alternative is to define leisure in terms of a particular setting (e.g., in the mountains) or time (e.g., Sunday afternoons). Research on the benefits of leisure typically has investigated the benefits associated with particular leisure activities (e.g., backpacking or knitting).

Next, the value of the outcome (i.e., positive, neutral, or negative) must be determined. This judgment will vary across individuals and social groups. Some people vandalize property, write graffiti, use drugs, and visit prostitutes during leisure. The individuals involved and some small social groups appear to value the consequences of these activities, but society in general interprets most of the consequences of activities such as these as negative outcomes (i.e., costs). Outcomes such as unwanted pregnancies and contracting a sexually transmitted disease are changed conditions that can occur as a result of leisure activity, but society in general and most individuals would not regard these outcomes as benefits. Leisure psychologists have given virtually no attention to the process by which the value of leisure outcomes is determined.

5.2. Methodological Problems

Finally, it is necessary to determine whether an outcome is a consequence of leisure. A critical difficulty encountered when interpreting research on leisure benefits is that almost all the evidence linking leisure to benefits

was obtained using correlational research designs. For example, a typical research finding is that active retirees are more satisfied than passive retirees. Causal inferences cannot be drawn from correlational data.

There are three difficulties inherent in drawing causal inferences from such data. First, the direction of causation is not clear. Perhaps active retirees are more satisfied because they engage in leisure more often, but it is just as plausible to conclude that people who are satisfied with life in general (i.e., not depressed) are more likely to engage in leisure activities. Second, reciprocal causality may exist. Perhaps participation in leisure activities increases retirees' life satisfaction, which causes them to engage in more leisure activities, which in turn further increases their life satisfaction. Another possibility is that a third variable may be the cause. For example, active and inactive retirees may differ in their physical health. Poor health may prevent retirees from participating in leisure activities and detract from their life satisfaction. It should be clear, therefore, that data obtained using correlational research designs do not yield an unambiguous interpretation.

Despite the limitations of correlational research designs, psychologists rely on them almost exclusively when investigating the benefits of leisure. An experimental research design would require psychologists to deprive some individuals of leisure opportunities while enhancing leisure opportunities for others. This would be unethical because of the strong likelihood that leisure has positive, life-enhancing benefits and the possibility that the lack of leisure could harm the individual. Likewise, it would not be ethical for psychologists to manipulate potential leisure benefits, such as life satisfaction, physical health, and morale, to determine if this influenced leisure behavior. For these reasons, it is not possible for psychologists to conduct controlled experiments to identify the benefits of leisure.

5.3. Theories of Benefit Production

Psychologists are unsure of the mechanisms whereby participation in leisure produces the benefits of leisure. Numerous explanations of some aspect of the leisure benefit production process have been offered, but most of these are little more than sketchy outlines of vague ideas. Among these are psychological hedonism theory (psychological well-being requires many small moments of pleasure, which are obtained through leisure), identity affirmation theory (people's interpretation of their own behavior, including their leisure behavior, shapes their personal identities), and buffer and coping theory

(leisure indirectly influences health and well-being by improving one's ability to cope with stressful life experiences).

5.3.1. Idle Hands Theory

A widely held belief is that people are happiest and mentally healthiest when they are busy. This view is rooted in the Protestant work ethic, which regards industry as good and idleness as bad. Having unoccupied time is seen as psychologically and behaviorally risky. For example, community groups frequently express a concern that the absence of recreation facilities increases the likelihood that adolescents will engage in delinquent behavior. They justify recreation facilities as a means of preventing antisocial behavior.

Governmental agencies also cite the idle hands theory to justify their policies. For example, Daniel L. Dustin's analysis of the recreational pastimes provided at Manzanar, a World War II concentration camp for Japanese American internees, revealed that the camp provided a wide variety of recreational pastimes. Most common were art, followed by sports and games, clubs and organizations, and nature appreciation. These opportunities were plentiful because the war relocation board believed that keeping the internees busy would reduce their resistance and help maintain peace in the concentration camp.

There has been very little research on the idle hands theory. One study of approximately 3000 high school students found that those who were bored with their leisure were more likely to engage in risky behaviors, such as drinking, drug use, bulimia, and attempted suicide. Another study of more than 80 older women found that more active women reported lower levels of guilt, sadness, and emotional distress. Both studies used correlational research designs, however, so unambiguous causal interpretations are not possible for the reasons stated previously.

An even more telling criticism is that idle hands theory does not identify the mechanisms that produce leisure benefits. This view replaces an unknown intervening variable with activity, but it does not explain how activity produces positive consequences nor how low levels of activity produce negative consequences. Further conceptual development is necessary before idle hands theory can be considered to be more than a folk adage stimulated by a belief in the Protestant work ethic. Nevertheless, idle hands theory is widely

endorsed by the lay public and government agencies and tacitly assumed by many psychologists.

5.3.2. Theory of Transcendent Leisure Experiences

Tinsley and Tinsley's theory of transcendent leisure experiences integrates need compensation theory, personal growth theory, identity formation and affirmation theory, and buffering and coping theory within the framework of person-environment fit theory. This theory postulates that when the necessary prerequisites are satisfied, participation in leisure activities enables individuals to have leisure experiences. These experiences are characterized by the attributes described earlier and they satisfy some of the individual's psychological needs. For example, intrinsic motivation is a prerequisite for leisure experience, so some of the participant's needs for autonomy, relatedness, and competence will be satisfied whenever a leisure experience occurs. The illusion of control is an attribute of leisure experience, so leisure experiences provide some satisfaction of the individual's needs to feel competent and in control. Leisure experiences are characterized by enriched perception so it is likely that some gratification of the individual's needs for mastery and intellectual stimulation will be obtained. The loss of inhibition that characterizes leisure experiences should reduce an individual's feelings of anxiety, defensiveness, restraint, and self-criticism.

According to the theory of transcendent leisure experiences, the satisfaction of personal needs through leisure experiences enhances an individual's mental health and contributes to improved physical health. These, in turn, increase overall life satisfaction. This process frees psychological resources that otherwise would be needed to satisfy psychosocial needs and maintain health. The result is that the individual has sufficient psychological resources to undertake the self-exploration and personal risks that are necessary for psychological growth. In the terminology of Maslow's theory, leisure experiences enable the individual to strive toward self-actualization.

A goal of Tinsley and associates was to identify the psychological needs satisfied by the full range of leisure activities. Their exhaustive study of psychological needs led to the development of the Paragraphs about Leisure, a research questionnaire that measures the extent to which 44 psychological needs are satisfied by participation in a leisure activity.

Statistical analysis of the data from more than 4000 research participants revealed 11 dimensions that are important in distinguishing among leisure activities. In order of their importance, these dimensions are as follows:

Exertion: Activities high on this dimension emphasize vigorous physical activity; activities low on this dimension offer relaxation and stress reduction. This finding stands in marked contrast to occupational research, which has subsumed this dimension under rubrics such as occupational level and given it scant attention.

Affiliation: Activities high on this dimension provide opportunities to be with other people; activities low on this dimension satisfy the need to be alone and enjoy solitude. The importance of this dimension is consistent with motivation theorists' conclusion that relatedness is one of the primary intrinsic motives and with vocational psychologists' conclusion that orientation toward people versus orientation toward things is the primary dimension underlying vocational interests.

Enhancement: Activities satisfying the need for enhancement give individuals an opportunity to use their talents and develop their skills; activities low on enhancement provide little opportunity for personal development. This and the following dimension are consistent with motivation theorists' conclusion that competence is an important intrinsic motive.

Self-expression: Activities high on self-expression emphasize variety and they afford participants the flexibility to try their own unique approaches and ideas. Activities low on self-expression provide an opportunity to follow a familiar, comfortable routine.

Nurturance: Like affiliation, activities that satisfy this need offer a chance to be with and enjoy the company of others, but they also provide opportunities to support, encourage, and help others. Activities low on nurturance satisfy individuals' needs to pursue their own self-interests.

Compensation: Activities high on compensation provide an opportunity to make up for things that are missing from one's job or other routine activities; activities low on compensation provide pleasures similar to those obtained from other aspects of one's daily routine. As noted previously, the available research provides stronger support for the spillover hypothesis than for the compensation hypothesis.

Sensibility: Activities high on sensibility provide intellectual and artistic stimulation; those low on sensibility provide opportunities to reduce cognitive demands.

Conscientiousness: Leisure activities high on conscientiousness emphasize responsible behavior and personal restraint; activities low on conscientiousness allow individuals to escape feelings of obligation and duty and to focus on pleasant aspects of the present situation.

Status: Activities high on status provide opportunities to receive attention, influence others, and feel important; those low on status allow individuals to avoid attention and the obligations of leadership.

Challenge: Activities high on challenge tend to be goal-directed activities that emphasize personal skill and high levels of performance; activities low on challenge emphasize process more than outcome. Csikszentmihalyi identified challenge as the critical determinant of the flow experience. However, research on the benefits of leisure reveals that leisure activities provide a complex array of psychological benefits and that challenge explains relatively little of the variability among activities.

Hedonism: Activities high on hedonism provide immediate pleasure without the need for long-term planning or commitment; activities low on hedonism require a long-term commitment or special effort and typically involve long-term goals.

6. APPLICATIONS OF PSYCHOLOGY OF LEISURE

6.1. Leisure Counseling

In the 1970s, counseling psychologists and recreation professionals began to advocate the development of a leisure counseling specialty. Papers appeared in the leading journals of both disciplines (e.g., *The Counseling Psychologist* and *Journal of Leisure Research*), and several books appeared that emphasized the need for a leisure counseling specialty, explained the potential benefits of the specialty, and elaborated its conceptual underpinnings.

Advocates of leisure counseling were encouraged by the research evidence that shows a relation between leisure activity participation and enhanced physical and mental health. They reasoned that helping clients select leisure activities that were well suited to meet their needs would result in long-term physical and mental health benefits, and they recommended an integrated approach to career and leisure counseling. Furthermore, they argued that knowledge of the substitutability of leisure pursuits would be useful in helping clients respond to the changes that occur as a result

of factors such as physical injury, unemployment, or the aging process.

Robert T. Overs and associates at the Curative Workshop of Milwaukee, Wisconsin, an agency specializing in rehabilitation counseling, developed an innovative leisure counseling program. Their program was designed to address the needs of clients with disabilities and older persons. They developed a series of questionnaires to be used in assessing the needs of their clients, and they included a research component to evaluate the benefits of their interventions. Their books and monographs represent the most detailed and informative description of an effort to implement a leisure counseling program.

In addition to Overs and associates, several practitioners in the United States began to specialize in leisure counseling. Despite the encouraging results reported by Overs and others, however, mainstream counseling psychology and the recreation profession have given leisure counseling scant attention.

6.2. Recreation Opportunity Spectrum

Beverly L. Driver and associates developed the idea of the recreation opportunities spectrum as a means of summarizing information about the leisure benefits available in an outdoor recreation area. For example, a national park might have many discrete areas. One area might provide opportunities for boating, fishing, hiking, and camping. Another area might provide an opportunity for rock climbing and rappelling, and a third area might be set aside for picnicking and interpretative lectures from park rangers. Each area of the park offers a different sample of leisure benefits because different activities occur in each area.

The recreation opportunities spectrum provides an inventory of the potential benefits provided by an outdoor recreation area. This information is intended for the use of management personnel who oversee public areas such as national parks and wilderness areas. It allows administrators to frame decisions about the addition, modification, or discontinuation of facilities and programs in terms of their effects on the array of psychological benefits provided by the area.

6.3. Amenity Resource Valuation

An issue that often confronts management personnel is how to balance the competing claims of stakeholders

to an area. For example, an oil company that wanted to drill for oil in a wilderness area would support its request by promising to add millions of dollars to the economy. When called upon for comment, leisure psychologists and recreation professionals would express concerns that drilling for oil would degrade the quality of the psychological experience for backpackers and other recreational users. In the past, when situations such as this arose the concerns of leisure psychologists and recreation professionals were dismissed summarily. In response to these difficulties, leisure economists and leisure psychologists developed a series of methods for placing a dollar value on leisure experiences.

Three general classes of methods have been developed for valuing leisure amenities. Travel cost methods, the simplest of the approaches, attempt to place a dollar value on recreational experiences by estimating the cost per visit to the site. These methods assume that the user's travel expenditures were made solely for the purpose of using the recreation site. Hedonic pricing methods are based on the notion that the price one would pay for a recreation experience on the open market provides an estimate of the value of an experience obtained in a public area. For example, the cost of renting a canoe from a commercial vendor at a lake in the countryside provides an estimate of the value of canoeing in the boundary waters canoe area. Contingent value methods rely on data obtained using research questionnaires that ask participants how much they are willing to pay for various recreation experiences. Participants' responses are transformed into monetary values that indicate the relative preferences of the respondents for alternative leisure experiences.

7. SUMMARY

In many ways, psychological investigations of leisure have paralleled the study of occupations. This is true not only when viewing the developmental progression of the two disciplines but also when examining the research on the benefits of leisure and work experiences. For example, many of the benefit dimensions identified in research on leisure are similar to those that have been identified in studies of occupational interests, thereby providing a form of convergent validity. However, there is evidence that the relative importance of the benefit dimensions differs. Exertion, a benefit that has received little attention in vocational

psychology, appears to be a more significant dimension than previously recognized.

Important differences are also apparent in the focus of leisure and vocational psychologists. Leisure psychologists have delved into the nature of participants' phenomenological experiences to a greater extent than have vocational psychologists. Although much of the focus has been on extreme (i.e., transcendent) experiences, more is known about the causes and attributes of leisure experiences than is known about work experiences. In contrast, vocational psychology is far more advanced than leisure psychology with regard to the development of practical applications to benefit individuals and social groups.

Almost everyone experiences leisure in some form, and almost everyone enjoys and values leisure. Therefore, leisure represents an important and understudied aspect of life. It seems likely that leisure will be of central importance in the newfound emphasis of the profession on developing a positive psychology of the healthy personality. Leisure behavior provides an amazingly fertile applied laboratory within which to study phenomena of interest to a broad array of sub-disciplines in psychology, including cognitive, social, motivation, human factors, vocational, and counseling psychology.

GLOSSARY

apprenticeship A cultural mode of learning where the child (learner) is considered to be a novice who participates in cultural activities as performed by parents (knower) or other experts.

attachment The unique emotional bond that develops between an infant and his or her primary caregivers; the internalization of the mode and quality of these special relationships is supposed to influence the development of later relationships.

collectivism A value system that maximizes and prioritizes harmony and interdependence of the group, especially the family; other terms that are sometimes used to denote this value framework are sociocentrism and communitarianism.

cultural conflict The confrontation of different cultural value systems within an institutional setting (e.g., a school) or a quasi-institutional environment (e.g., a pediatrician's office); in particular, individualist and collectivist value systems

have been described as cultural scripts that often specify mutually exclusive choices for individuals' behavior.

cultural learning The processes of verbal interaction, participation in cultural activities, observation, and instruction so as to acquire cultural knowledge.

individualism A value system that maximizes and prioritizes individual choice, independence, and technological mastery.

life stages Functional historical units during ontogeny that can be characterized by universal developmental tasks such as development of attachments during infancy and becoming a productive worker during adulthood (not everyone is a parent); the optimal solution of the universal tasks depends on the sociocultural environment and, therefore, is context and culture specific.

parental ethnotheories Belief systems that specify values with regard to children, parents, and developmental processes; parental ethnotheories are shared among members of cultural communities and set the frame for parental behavior.

peer relations The socioemotional bonds among age mates and between younger children and older children; peers are differentially defined in different cultural environments, being mainly unrelated friends in individualist societies and related children (e.g., siblings, cousins) in collectivist societies.

socialization The process of growing up in a cultural environment; it stresses the active acquisition of information and knowledge of the developing child in the context of a social relational matrix.

Culture can be perceived as external to the individual in terms of artifacts and institutions; internal to the individual in terms of knowledge, skills, and values; and interactive to the individual in terms of social practices and social interactions. The role of culture in behavior is pervasive and should be considered carefully in any examination of human development over the lifespan. Human development can be understood as the lifelong interactional processes of perceiving and experiencing culture as triggered from the outside, created from the inside, and cocreated with others. Thus, processes of development and processes of culture are inextricably intertwined. Although groups of people share culture and negotiate cultural issues conjointly, at the same time, culture is a subjective individual process.

1. CONCEPTUAL ISSUES IN CULTURAL LIFESPAN PSYCHOLOGY

This section first presents the ecocultural approach as informed by cross-cultural methodology. Then, it presents the sociohistorical approaches that mainly represent the cultural perspective. Finally, it introduces the developmental pathway approach as a new synthesis that incorporates the ecocultural and sociohistorical approaches and takes the whole lifespan into account.

1.1. The Ecocultural Approach

The ecocultural approach emphasizes the role of culture in adapting to the environment and derives from the work of John Berry as well as John and Beatrice Whiting. Berry performed large-scale studies in 21 different sites around the world to analyze how ecocultural information is transformed into styles of perception and cognition. He demonstrated how parameters of the ecological environment (e.g., spatial layout of the landscape) and the mode of subsistence (e.g., farming, foraging) shape the perceptual style of field dependence/independence as the boundedness of perception of patterns to the surrounding visual field.

The Whittings' six-culture study, including research sites from the major parts of the world, was designed on the basis of their ecocultural model linking ecology to modes of subsistence, modes of subsistence to child rearing, child rearing to child personality, and child personality to adult personality. The Whittings' study

examined this developmental trajectory using a set of consistent methods across different cultures.

Recent theoretical formulations of the ecocultural approach have moved research practice away from the cross-cultural transfer of a set of consistent methods to a more cultural approach with methods appropriate for study in each culture. For example, in 1984, Weisner developed a theory in the Whittings' tradition that considers different aspects of the ecocultural model such as subsistence patterns, child-rearing behavior, and assigned roles for men, women, and children—all of which affect behavior. Subsequently, in 1997, Harkness and Super applied the ecocultural approach to their concept of the developmental niche. The developmental niche is defined as the physical and social settings in which children live, the customs of child rearing, and the psychology of caretakers. Their approach emphasizes the importance of parental cultural belief systems as the link between elements of the larger culture to parenting practices and the organization of the daily routine.

Moreover, the ecocultural approach has become synthesized with evolutionary considerations, specifying the course of development conceptualized in the ecocultural model as following an implicit reproductive logic of optimizing an individual's inclusive genetic fitness resulting from his or her own reproductive success as well as from the reproductive success of genetically related individuals.

1.2. The Sociohistorical Tradition

The sociohistorical research tradition in developmental psychology is derived from the work of Vygotsky. It emphasizes that human development is constructed through social interaction, cultural practices, and the internalization of symbolic cultural tools. An example of a cultural tool that is internalized is money; each culture's system of currency influences the development of certain mental strategies for doing mathematics. Cultural practices and tools are developed over long periods of time. Therefore, they have an important historical dimension.

In addition to artifacts taken in isolation, some cultural psychologists, such as Gauvain and Schliemann and colleagues, have explored the cognitive effects of subsistence practices and trades in terms of representation and cognitive operations, respectively. Cultural practices involve everyday experiences and education (both informal and formal). Therefore, practices such as reading and writing, candy selling, and tailoring shape cognitive development. For example, it has been found that carpenters in Brazil have formal operations in the

domain of proportional reasoning that they use for their trade, even though they do not use this level of reasoning when solving some of Piaget and Inhelder's original tasks. These latter tasks use the much less familiar domains of chemistry and physics.

The locus of social interaction is most often between parents and children due to the importance of parents' caring for their young and for transmitting cultural knowledge from generation to generation. However, teacher-child and peer interactions are also important influences on children's development. Some researchers, such as Maynard and Zukow-Goldring, also recently found that sibling interaction is an important socialization force in both technological and nontechnological societies. Social contexts and the interactional patterns within these social dyads and groups influence both cognitive and social development.

Some researchers, such as Bruner, Tomasello and colleagues, and Shweder, have developed some generalized conceptual approaches to cultural psychology. Bruner noted how the structure of language embodies a structuring of human action in terms of agency and intentional actions. The mutual understanding between people of these categorical structures of intentional action is diagnostic of a theory of other minds. It follows that as language develops, so does this mutual understanding of intentional human action. It is the comprehension of other minds that is central to social sharing and, therefore, to culture.

Tomasello and colleagues, in contrast, emphasized the apprenticeship processes, such as imitation and direct teaching, that enable cultural knowledge to be transmitted from generation to generation. Moreover, they emphasized that cultural learning depends on people's empathic understanding of other minds.

Shweder has developed a notion of environmental constraints versus cultural preferences. This distinction integrates an ecocultural approach with the values approach discussed in the next section. Preferences in cultural practices are guided by an individual's cultural value system. However, the nature of the environment provides constraints to which ideal practices must be adapted.

1.3. Cultural Pathways through Universal Development: A New Synthesis

LeVine was the first to argue that developmental goals guide cultural practices of child care and parenting.

He proposed a universal hierarchy of parental goals with survival and health as the foundation, followed by goals relating to economic independence and finally by goals related to the cultural definition of the personality. Systems of developmental goals and values that guide child rearing and socialization for particular parents or groups of parents are called parental ethnotheories of development. Parental ethnotheories can also be thought of as a stage in the lifespan development of cultural values. Two particularly salient models, derived from the industrial and social psychologies of Hofstede, Triandis, and Markus and Kitayama, are individualism and collectivism. These two models are considered to represent different cultural value systems. Each model is adaptive in different ecological environments, thereby incorporating the ecological approach. Each model is actualized through different kinds of social interactions and emphasizes different kinds of social activities and cultural tools, thereby incorporating the sociohistorical approach.

The cultural models are supposed to be linked to the individual's conception of the self in terms of an independent (cf. autonomous, self-contained, and separate) self linked to individualism and an interdependent orientation (cf. allocentrism and relationalism) toward self linked to collectivism. Accordingly, the primary goal of socialization in the independent model is an autonomous, individuated, self-fulfilled person who enters into social relationships and responsibilities by personal choice. The primary goal of socialization in the interdependent model is for the mature person to be embedded in a network of relationships with responsibilities to others. Personal achievements are ideally in the service of a collectivity, most importantly the family. With these cultural goals in mind, many researchers (e.g., Greenfield and Cocking in 1994) have examined the influence of independent and interdependent goals on parenting styles and child development.

The independent pathway can be characterized as follows. Parents and society socialize children to see themselves as predominantly separate from the social context, that is, as bounded individuals who are unitary and stable by definition. The tasks of development are for children to express themselves, their uniqueness, and their own goals. The role of others is to provide reflections for self-evaluation. This model is fostered by, and adapted to, large-scale commercial societies with complex technologies.

The interdependent pathway can be characterized as follows. Parents and society socialize children to

see themselves as connected to the social context and as having flexible and variable selves. The tasks of development are for children to occupy their place in society, to fit in, and to promote the goals of others. The role of others is to provide self-definitions. This model is fostered by, and adapted to, small-scale subsistence societies with simpler technologies.

There are important developmental changes in both of these orientations over the lifespan and over historical time. From a lifespan perspective, the two pathways travel through universal developmental nodes with particular issues that must be negotiated at particular points in each person's lifespan. Each issue presents a particular transformation of the basic value orientations.

For example, a universal node of infancy is attachment, which can be negotiated by maximizing independence (e.g., with a separate crib and baby room as cultural practices) or interdependence (e.g., by cosleeping between mother and baby, by carrying the baby on the caregiver's body). However, Shweder's distinction between preferences and constraints would also call attention to the fact that if a family is living in a small space, ecological constraints might dictate closer sleeping arrangements than their preferred ideal.

Another universal node of development is peer relations. In a culture that prioritizes independence (e.g., mainstream U.S. culture), peer relations focus on separating from the family. In contrast, in cultures that prioritize interdependence, peer relations often focus on relationships with cousins and siblings. Inherent in the pathway approach, with the conception of nodes that organize developmental progress, is the assumption that life trajectories are meaningful, continuous, and coherent. This implies that the early socialization experiences set the stage for the subsequent developmental tasks during the lifespan. After childhood socialization has resulted in an early conception of a more independent or more interdependent self, adolescence constitutes the transition to adulthood. The independent pathway conceives of adolescence as an educational moratorium with the distinct socializing instruction to develop a separate and unique identity. The interdependent pathway conceives of adolescence as a short transition period that is immediately followed by starting one's own family. Accordingly, ages at marriage and birth of the first child differ significantly across these cultural orientations. Adulthood in the interdependent pathway is primarily defined by procreation and parenting. For example, in Cameroonian Nso, a person is considered

an adult only if he or she has children (a badge of interdependence), irrespective of age and expertise. Adulthood in the independent pathway is defined, apart from legal boundaries, mainly through educational attainments and economic independence from the family of origin. Finally, old age differs with regard to the greater integration in the families of offspring and especially the respect and care that is focused on the older generation in the interdependence framework. From the historical perspective, Greenfield in 2000 explored the impact of historically driven ecological change on cultural apprenticeship and cognitive representation. Studying two generations of Zinacantan Mayan families over a period of two decades, she demonstrated that the historical transition from a subsistence ecology to a commercial ecology transformed the apprenticeship from a more interdependent style of cultural learning to a more independent one. At the same time, artisanal products, the fruits of a changing apprenticeship process, moved away from a model of community creativity toward a model of individual self-expression.

Critics of these views often argue that the conception of these two cultural orientations is overly simplistic and does not cover the complexity of human psychology within and across cultures. Although everyone exists as both an individual and a group member, and although this dualism is part of the evolutionary heritage and is a structured part of each social group, each social group also denotes a complex system with its own set of priorities. A system of priorities, by its very nature, includes both kinds of components. It is simply that the independence components dominate in one kind of system, whereas the interdependence components dominate in the other. In addition, individualist systems prefer certain forms of social relationships, whereas collectivist systems prefer others. Logically (although less is known about this), individualist systems prefer certain forms of independence, whereas collectivist systems prefer others. Adding to the complexity, priorities shift through processes of ecocultural change and intercultural contact.

Nonetheless, it is heuristic to envision two idealized systems that form two extremes of ecology and values. Each system is not simply a collection of individuals with their individual traits. Instead, each system constitutes a deep structure paradigm that generates many characteristics in a multitude of domains and developmental periods. Although every culture has individual differences, one must note that these differences play a

larger role and are valued more in individualist cultures. Note too that each orientation has its own mode around which individual differences are organized. The two cultural types are structured systems; they are not simply overlapping distributions on a common scale or two. Finally, cultural traits are, by definition, coconstructed and shared among a defined group of people. Consequently, they are less variable than non-cultural characteristics.

The nature of development as an individual acquisition process precludes the development of uniformity. Thus, even if there is an ideal modal picture of personality in a cultural community, different real pictures of personality constitute the actual spectrum of the population. Nevertheless, there are obvious differences in developmental pathways that can be captured best by these different value orientations. Indeed, the concept of two paradigmatic pathways allows continuities across developmental pathways to be revealed for the first time. In addition, individuals develop genuine profiles from which they experience themselves as consistent and coherent.

2. DEVELOPMENTAL PATHWAYS IN A MULTICULTURAL SOCIETY: CONSEQUENCES FOR APPLICATION

Intergroup contact is a major source of diverse developmental pathways in multicultural societies such as the United States, Canada, and Australia. As conflicting ethnotheories of development come into contact, many different combinations of values and practices arise. Often, the developmental pathway of the dominant majority tends to be taken for granted as normative, or even universal, rather than as cultural. Intergroup contact raises ethnic identity awareness, often bringing the self-identity of racially distinctive groups to the forefront of developmental issues. This generates more complex processes of cultural learning such as those involved in bilingual and bicultural development.

The distinctive patterns of socialization and development manifest in various groups in the United States and other multicultural societies derive, to a great extent, from ancestral values. Therefore, the specific values that ethnic groups maintain must be understood with respect to ancestral homelands. However, the type of power relation between dominant groups and less dominant groups, as well as the

interactions among various groups, also molds cultural development.

Acknowledging cultural influences as a genuine component of development also implies that there is not one (normative) conception of health and psychological well-being. Rather, the definition of healthy development is relative to overarching developmental goals that vary from culture to culture. The following section highlights the implications of incorporating culture into our understanding of developmental problems and health. It introduces two examples. First, it discusses different views on developmental regulation during infancy. Second, it discusses intercultural misunderstandings and their alleviation in the school setting.

2.1. Application of Cultural Pathways During Infancy

As discussed earlier, the early socialization environment reflects cultural values pertaining to highly valued developmental goals within specific contexts. During infancy, developmental contexts and parenting practices that support interdependent developmental goals imply a close union between mother and baby. Cosleeping, nursing on demand, and constant close body contact constitute the invisible foundation of cultural practices with babies. In this context, mothers often meet their infants' needs before such needs are explicitly expressed.

In contrast, in cultures that subscribe to independent developmental goals, developmental contexts and parenting practices during infancy imply separateness and early autonomous functioning. From birth onward, infants are geared to sleep alone and to sleep through the night to establish the circadian rhythm as early as possible. From early infancy, mothers orient their babies to the object world to foster the infants' exploration and to develop attachment to objects that can potentially replace the caregivers (e.g., security blankets, snuggly toys). As a consequence of these different cultural views on closeness and separation, what is regarded as ideal in the interdependent model of the early parent-child relationship (e.g., establishing constant bodily contact between baby and mother) is evaluated as pathological through the cultural lenses of the independent developmental pathway.

For multicultural societies, conflicts between cultural value systems are the inevitable consequence. These conflicts become especially pertinent when both cultural value systems need to interact. For example, the ideology of a society's health care system, including the

expressed views of pediatricians, is usually oriented to the value system of the majority culture.

When the first Turkish families immigrated into Germany during the 1950s, the common practice of Turkish mothers to swaddle their infants for at least a couple of hours per day was strongly discouraged by pediatricians and health care professionals. They claimed that the infants' freedom of movement and their possibilities to explore their environments were largely disrupted by the swaddling; that is, the Germans' independent cultural values did not mirror the interdependent value system of the Turkish immigrants. In this example, the trust of parents in the health care system on which they must rely is deeply affected and constitutes a major risk factor for minority children's development.

Therefore, culturally sensitive developmental counseling and intervention with babies should rely on the assessment of the preferred modes of parenting as related to the cultural values, resources, and constraints that are available to a particular group. Instead of orienting the parents to the cultural ideals of the majority culture (e.g., encouraging working-class Turkish parents to allow their infants more freedom of movement and exploration possibilities), the cultural reality of the parents must be negotiated in terms of meeting the needs of both the infants and the parents.

2.2. Applications of Cultural Pathways in Schools

Another locus of conflict for the interaction of diverse cultural value systems is the school environment, including school-home interaction. Research on Asian American and Latino children in the United States indicates that their families maintain interdependent and collectivist cultural orientations, although the collectivist orientation becomes more restricted in its expression across the generations (e.g., reserved for family celebrations such as weddings). This reduction across the generations results from a contrasting set of priorities in the individualist host culture. These individualist priorities are especially salient in the institution of the school, where they are strongly socialized.

Children and adolescents often experience these divergent value systems as they go between home and school environments in their daily lives. Greenfield, Raeff, and Quiroz analyzed the cultural values of parents, teachers, and children in two schools in Los Angeles. In one study, the sample in one school

consisted of groups of predominantly European American children. As expected, the value systems of parents, teachers, and children were consonant with each other (the expressed values were primarily individualist) and there was no cultural conflict among the three groups.

In the other school, the population consisted entirely of Latino immigrant families from Mexico and Central America. As expected, the value systems of parents, teachers, and children differed markedly from each other. The parents held mainly interdependent or sociocentric values, and the teachers held mainly individualist values. The value systems of the children either were between those of the teachers and the parents or were more similar to those of the teachers. Therefore, the children had to serve incompatible developmental goals at the same time (e.g., being obedient and self-effacing at home while being verbally expressive and self-enhancing at school). This type of conflict can produce emotional distress and alienation from either home or school. Although the teachers in both schools were multiethnic, they were monocultural. Regardless of their ethnic backgrounds, their education and teacher training had made them highly individualist in their teaching practices and educational values.

In a subsequent phase of the research, Greenfield, Rothstein-Fisch, and colleagues developed "Bridging Cultures," a series of teacher training workshops to help teachers understand the two developmental pathways and create a bridge between them for students and their families. In this way, it was hoped that the developmental stress caused by the conflict between the two cultural pathways could be ameliorated. Teachers and researchers found that parents participated more in school activities and that children were less conflicted in their classroom interactions.

Another source of developmental stress may emerge from the peer interactions of children with different value systems. In still another study, Suzuki and colleagues analyzed the reactions of adolescent girls to praise and criticism on school sports teams in Los Angeles. These authors demonstrated that reactions to praise and criticism differed with respect to self-enhancement and self-effacement, as predicted by the ethnic origins of the families. Asian American and Latina players valued self-effacing strategies to a greater extent, whereas African American and European American players valued self-enhancing strategies to a greater extent. Self-effacement serves the collectivist goal of fitting into the group, whereas

self-enhancement serves the individualist goal of standing out from the group. In line with their own value preferences, Asian Americans and Latinas generally evaluated self-enhancement negatively (e.g., as conceit), whereas European Americans and African Americans generally viewed self-effacement negatively (e.g., as hurting the team). In sum, there was a tendency to view as negative violations of one's own cultural model. These negative interpretations of differences may form the roots of cross-cultural misunderstanding and conflict.

During a later phase of the project, an intervention was carried out to try to use the same workshop methodology to help teams and coaches understand the two cultural orientations. The goal was to increase intercultural understanding by introducing the notion of distinct basic value systems. Rather than increasing tolerance and understanding for different points of view, the intervention simply made students more collectivist. Further research is needed to develop means appropriate to the high school level to increase tolerance and understanding of values for the two contrasting pathways of development.

3. CONCLUSION

The sociohistorical approach to the role of culture in development emphasizes the importance of social interaction and cultural tools as socializing forces in individual development. The ecocultural approach notes that socialization practices that are typical of a particular culture mold behaviors that are adaptive in particular ecocultural niches. The cultural pathways approach organizes cultural differences into two underlying paradigms that guide universal developmental tasks, such as attachment and peer relations, in distinctly different directions. Each of these pathways is created through cultural processes identified by the sociohistorical approach, and each is adapted to a different type of ecocultural niche. Most important, each pathway provides a cultural lens for viewing and evaluating the social world. Therefore, different cultural frameworks may affect people's relationships with each other, resulting in conflicts in multiethnic societies. Many such conflicts could be avoided if understanding of cultural frames of reference were part of the educational system. In conclusion, the theory of cultural pathways through universal development provides an important theoretical framework for real-world application.

GLOSSARY

academic language A formal style of language use found in schools, businesses, and other “ceremonial” settings such as courts and hospitals.

achievement gap The substantial and continuing difference in test performance between students from lower- and middle-class backgrounds, often indexed by “Free and Reduced Lunch” programs.

balanced Programs of reading instruction that aim to combine elements from a variety of more extreme positions.

curriculum-based measurement Assessment systems that attempt to directly measure what is being taught on a daily or weekly basis.

design experiment A research method that combines elements of case studies and field experiments, including both quantitative and qualitative data and emphasizing collaboration between researchers and practitioners.

dynamic assessment Techniques for measuring student learning that allow departures from complete standardization; as with many clinical procedures, the tester uses the informant’s responses to decide on additional questions and probes.

dyslexia/learning disabilities Related labels for describing students with reading problems; learning disability is a formal identification used to assign students to special programs supported by federal funding, whereas dyslexia

connotes a medical-like syndrome in which brain dysfunction is presumed to be the source of the problem.

initiate–respond–evaluate (IRE) A frequent pattern in classroom discourse during reading lessons whereby the teacher asks a question, a student responds, and the teacher evaluates the response.

linguistic register A style of language use or discourse that is dependent on the individual’s background and the demands of a particular situation; in explaining a traffic ticket, a person is likely to use different language when describing the situation to the police officer, to an acquaintance, and to a judge.

No Child Left Behind A multifaceted educational program, promulgated in 2001 by the federal government, calling for widespread testing and accountability.

phonics A system for describing the relations between letter and sound patterns and a set of instructional techniques for teaching students how to decode and spell words; it is often associated with the “simple view” that reading depends on acquiring phonics skills that will then connect to the student’s oral language.

student-centered instruction versus direct instruction The contrast between educational techniques that emphasize student input and engagement in a lesson and techniques that emphasize the teacher’s role in transmitting information.

whole language A system for early reading instruction that relies on immersion of students in printed material that will then lead to the natural acquisition of literacy skills without the need for extensive phonics instruction.

Since the emergence of psychology as a science, literacy has been a significant topic theoretically, empirically,

developmentally, and practically. Studies range from word perception to comprehension strategies, from motivational correlates to neurophysiological profiles, and from laboratory studies of college undergraduates to classroom observations of beginning readers. These endeavors often aim to inform basic psychological issues, but possibilities for practical contributions are always close to the surface. “Improving literacy” offers several opportunities for applied psychologists: (a) enhancing performance across the range of tasks in this domain, (b) developing effective methods to support acquisition of skills and knowledge, (c) creating models to undergird instruction and assessment, and (d) incorporating technological inventions that continue to transform the meaning of literacy. In addition, literacy, unlike piloting or driving, is seen as a public “good” that is supported by educational systems and is everyone’s business. Psychologists aiming to understand and improve literacy must also deal with social, cultural, organizational, and policy issues. This article is divided into three sections. The first defines literacy for the current analysis, lays out several problems that call for “improvement,” and sketches the knowledge base bearing on these problems. The second centers on application and examines the psychological contributions to (a) assessment techniques, (b) evaluation of programs and interventions, and (c) individual differences. The final section offers thoughts about the prospects for improving literacy during the next decade given the current knowledge base and the policy environment.

1. LITERACY: TOOLS FOR THINKING AND COMMUNICATING

1.1. Definition of Literacy

The definition of literacy shapes the problems, claims about what is known about the phenomenon, and strategies for addressing various issues. This section is far more than a philosophical exercise.

Hunt, in a provocative review of DiSessa’s *Changing Minds*, suggested in 2003 that “an individual’s material intelligence is determined by literacy, the ability to use the intellectual tools that the culture provides.” In contrast, reading and writing, viewed as basic skills, may resemble assembly-line routines whereby repetitions with feedback are the primary psychological elements. Hunt’s characterization built on the concept of academic language, that is, an acquired and specialized capacity to use various forms of language for thinking

and communicating. As basic skill, literacy takes shape as associative learning to be acquired in the primary grades, allowing students to move on to serious topics. As academic register, literacy spans the entire course of schooling and beyond, where print serves as a technology for reducing demands on both short- and long-term memory. The Greeks, before refining their alphabet, employed a variety of mnemonic strategies to support and amplify language capacity, all in the service of organizing thoughts and clarifying communication. This article focuses on the years from preschool through adolescence and spans the continuum from basic to academic literacy.

Academic literacy might seem to entail privilege, and it does. The reference is to a formal style of language use that emphasizes explicitness, expository techniques, coherence, and dependability. The style is typical of educational institutions but also appears in business and the professions. Whether writing a term paper, negotiating a contract, or debating a traffic ticket, individuals in modern society are at an advantage when they can call on the strategies and tools associated with this register.

The acquisition of literacy can be viewed through developmental, sociocultural, and educational lenses. Literacy is rooted in language. Virtually all children progress through developmental stages during which they attain increasing competence in the various elements that constitute language—phonology, semantics, syntax, and discourse. These developments reflect children’s sociocultural environment. Much like sponges, children internalize the features of the particular linguistic environments in which they are immersed, leading to variations in linguistic registers or particular styles of use. Children enter schooling with wide variations in their natural registers reflecting their background experiences, but they all possess a full-fledged language system.

A major goal of the educational system is to inculcate students in the academic register. In 1983, Heath offered an exquisite portrait of the encounters of children from varying backgrounds with “school language.” The story described the task of learning about print—letters, books, “reading and writing”—but more fundamentally the theme was about variations in language registers and ways of using language individually and in social settings. This article focuses on the role of schools in supporting the acquisition of literacy within a policy context that struggles with numerous issues, including the definition of goals and values.

1.2. Areas Calling for Improvement

What needs to be fixed? At the time of this writing, the answer might seem to be “nearly everything.” The U.S. federal government is in the midst of a major initiative, No Child Left Behind, that holds states, districts, and schools accountable for guaranteeing that by 2010 virtually every student will achieve proficiency in the primary school subjects, most especially reading and writing, with dire consequences if the goal is not met. Leading the list of problems are results from the National Assessment of Educational Progress (NAEP) showing that (a) two-thirds of U.S. students are not proficient in reading and (b) there has been little improvement in literacy achievement levels during the past three decades or so. The claim is that the United States is a nation of illiterates, undermining both economic and social capacity.

The second problem is the achievement gap. The NAEP data show that children from poor families do poorly in school, especially in literacy. The differences are enormous and have not diminished during the past several decades despite substantial investments by the federal government through various entitlement programs.

The third problem, which is more diffuse, centers on individual differences in the capacity to read and write and in facility with language. The labels are school centered: special education, learning disability (more than 80% of students in this category have “reading problems”), and dyslexia. The correlates are demographic: students from underrepresented minorities (for whom English is a second language) and boys more often than girls.

The fourth problem is essentially technological on the surface: What is the best method for promoting the acquisition of literacy? The response clearly depends on the definition of literacy, but one might think that for acquisition of basic skills, it should be possible to find an answer. The First Grade Reading Study, a large, federally sponsored field experiment comparing various reading programs, showed some short-term differences favoring intensive phonics programs. But student learning depended more on teachers within programs than on differences among programs. What began as a technological matter of instructional program design metamorphosed into issues of professional development, classroom practice, and organizational interactions.

The context for all of these problems depends on the interpretation of literacy. This article emphasizes behavioral and cognitive perspectives. But in the background are issues of motivation, social and cultural influences, and political–organizational opportunities and constraints.

1.3. The Knowledge Base

During the past several years, the National Academy of Science has conducted several project reports in the areas of language, literacy, and learning to which psychologists have contributed significantly and that provide enormously useful summaries and reviews: Snow and colleagues' 1998 *Preventing Reading Difficulties in Young Children*, the National Reading Panel's 2000 *Teaching Children to Read*, Donovan and Cross's 2002 *Minority Students in Special and Gifted Education*, August and Hakuta's 1997 *Educating Language-Minority Children*, Bransford and colleagues' 2000 *How People Learn*, and Pellegrino and colleagues' 2001 *Knowing What Students Know*. In addition to these resources is the “Rand Report,” that is, Snow's 2002 *Reading for Understanding*. Other fundamental resources appear in several handbook series: the three volumes of the *Handbook of Reading Research*, the *Handbook of Research on Teaching Literacy Through the Communicative and Visual Arts*, and the *Handbook of Research on Teaching the English Language Arts* as well as pertinent chapters in the *Handbook of Educational Psychology* and the four volumes of the *Handbook of Research on Teaching*.

The several thousands of pages in these collections constitute a compendium of extraordinary proportions, spanning nearly a half-century of theory and research in the literacy arena, with critical pointers to primary research documents. Included are references to the activities of several educational research centers sponsored by the federal government to explore the application of basic research to school settings as well as numerous large-scale evaluation projects designed to explore the improvement of literacy.

Numerous themes emerge from this collection, three of which are explored in detail in the following section. Three additional points are mentioned briefly due to the relevance to applied psychology. The first point centers on the role of research psychologists as collaborators with other educators, including curriculum developers, assessment designers, and program evaluators. Not so many years ago, experimental and educational psychologists focused on laboratory studies and quantitative data analysis. During the past few decades, increasing numbers of researchers have “taken to the field,” moving their investigations into classrooms and schools and joining with other educators in the construction and implementation of programs incorporating theoretical concepts. In many instances, theoretical concepts have not arisen from laboratory findings; rather, field settings have provided the context for generating and refining

theoretical concepts, often taking shape as design experiments that combine the rigor of the laboratory with the messiness of the classroom, joining both quantitative and qualitative sources of data.

A second observation centers on the acquisition of literacy, a process spanning the decade from preschool through adolescence and beyond. The literature provides snapshots of this progression but offers few dynamic portrayals of individual trajectories during the shift from novice to expert. The lack of such intensive data is understandable; research funding comes in 3- to 5-year packages and is “results oriented.” The few longitudinal databases available to educators tend to rely on inexpensive and convenient indicators. Much is known about the psychology of skilled reading, that is, the performance of college students in laboratory settings. Perceptual activities in word recognition and sentence comprehension, strategic processes in text comprehension, and “think aloud” protocols during comprehension and composition exemplify domains where substantial work is available regarding expert performance. Less frequent are convincing portraits of the “expert reader/writer” such as those available for mathematicians, aircraft pilots, and chess players. The impediment may be the breadth of the domain encompassed by literacy compared with the other examples. Another set of snapshots comes from the early stages of learning to read, primarily the acquisition of letter–sound skill and knowledge. The bottom line is that research offers perspectives on early and late facets of literacy, but much less is known about the succession of learning in between.

A third point is the challenge of conducting research in school settings, including the task of “scaling up.” In other fields of applied psychology (e.g., human engineering, organizational psychology), tradition connects researchers with practitioners. In education, these liaisons are much looser. The researcher approaches schools for “access to subjects,” which may be “book-ended” by a technical report of the findings presented to the schools at the end of the project. The client relation, in brief, is often rather distant. During the past several years, the federal government has reintroduced the scaling-up concept, encouraging researchers to move a concept or program from experimentation to wide-scale implementation within a fairly short time frame. The researcher-entrepreneur can be found in other domains, including applied psychology, but in education the tasks are extremely complex, clients range from classroom teachers to state superintendents of education, and researchers might lack the skill, knowledge, and incentives to pursue such endeavors.

2. IMPROVING LITERACY: TASKS FOR APPLIED PSYCHOLOGY

Three arenas have particular relevance in the application of psychological theory and research for the improvement of literacy: assessment, intervention, and individual differences. Assessment is fundamental in operationalizing the constructs that define literacy. Intervention covers a broad and complex array of activities, and psychologists are one of several players in this endeavor. Finally, conceptualizing and investigating individual differences has been a specialization since the beginning of modern psychology.

2.1. Assessment Concepts and Tools

“Literacy is whatever literacy tests measure.” This take-off on a well-worn phrase overstates the matter only slightly. Two dimensions frame much of the activity in the assessment field. The first contrast can be characterized by objectives-based versus performance-oriented approaches to capturing information about individuals and groups. The second facet ranges from the classroom-level practice to large-scale tests used for surveys and policy purposes. The two dimensions are not completely independent, but examples can be found in the “four corners” of the matrix.

Across the spectrum, psychological contributions provide the foundation for virtually all assessments. The Standards for Educational and Psychological Testing establish guidelines for policy and practice, laying out fundamental constructs such as validity and reliability, establishing significant practical criteria (e.g., important decisions should rest on multiple sources of evidence), and defining the ethical responsibilities of practitioners.

Within the classroom, assessments can serve several functions such as grading, monitoring progress, and shaping instructional decisions. Assessments may be externally mandated (e.g., the school district requires a writing test), incorporated within instructional materials (e.g., an end-of-unit test), or developed by the teacher. Techniques range from formal activities (e.g., “Close your books and sharpen your pencils; this is a test”) to informal and observational (e.g., the teacher listens to a first-grader’s reading of a sentence).

Across these settings, the objectives–performance contrast offers an important psychological dimension. In objectives-based assessments, learning outcomes are

defined by highly specific behaviors, and instruments are designed to indicate student mastery of each outcome. In 1971, Bloom and colleagues' *Handbook of Formative and Summative Evaluation of Student Learning* was the progenitor of this approach, which is foundational for the basal reading series widely used for reading instruction in the elementary school grades. The tasks include multiple-choice and short-answer activities, "drawing" answers, and so on. The strategy is to specify outcomes as precisely as possible in behavioral terms. In curriculum-based measurement, a recent addition to this approach, fluency is a primary indicator of mastery (e.g., how many words or sentences can a student read aloud in a minute?).

Performance-oriented techniques rely on cognitive (and metacognitive) constructs as the basis for assessment design built around broader domains and with greater emphasis on explanation. The reading-writing portfolio is a typical artifact in this category, relying on judgmental rubrics to quantify complex performances, much as in the Olympics. A related activity emerges in dynamic assessment, where the task varies in response to student responses so as to explore conditions that evoke student success. This end of the spectrum most often serves for writing assessment.

Externally mandated assessments typically take shape as the standardized multiple-choice test, arguably one of the most significant contributions of applied psychology. Reading is the centerpiece of standardized testing in the elementary grades, soundly established in the "vocabulary-comprehension" subtests. These instruments, although not intended for instructional decisions, can be critical for policy and program evaluation. Writing poses a substantial challenge for large-scale assessment due to the difficulty in capturing complex performances in a cost-effective manner. During recent years, however, several projects have explored the possibilities in this field, most notably in the states of Kentucky, Maryland, Vermont, and California. The importance of these projects arises from showing that it is possible to design systems that connect classrooms with large-scale assessments. Unfortunately, all of these projects have been abandoned in response to the No Child Left Behind initiative.

2.2. Interventions: Programs and People

This segment is organized around three necessarily selective topics: early reading acquisition, the reading-

writing connection in the later grades, and pedagogical strategies. The first is a long-standing field of applied psychology, the second illustrates the collaboration of psychologists with others, and the third is more generic.

The First-Grade Reading Study mentioned earlier, Project Literacy, and Chall's landmark review all engaged psychologists in research on beginning reading. Most of the centers and laboratories established by the federal government during the 1960s included projects for the improvement of early reading. Much has been learned as a result of these efforts. For instance, it was previously thought that young children with reading problems suffered from visual perceptual deficiencies, but research demonstrates that the primary correlates are phonological. Another example comes from analyses of English spelling, which is often characterized as inherently chaotic. Research demonstrates the coherence of the system when viewed through historical and phonomorphological constructs. A final example is the discovery that, although direct instruction phonics-oriented programs in the primary grades produce higher scores on standardized tests, (a) program effectiveness varies substantially among teachers within programs and (b) the short-term outcomes tend to "poop out" over the grades. Two general observations seem to hold up. First, much has been learned about the early stages of the acquisition of literacy, including substantive ideas about how to deal with the problems laid out at the beginning of this article. Second, a substantial chasm remains in the practical application of these findings within the complexities of the public education system.

The contributions of psychologists to the study of writing are generally less recognized than those to the study of reading, but the former are nonetheless substantial. The integration of reading and writing, and of language and literacy, becomes increasingly significant as students move through the elementary grades into secondary education and beyond and is not so well studied. From a practical perspective, integration is the key to competence in adult literacy tasks, including college work, jobs in business and industry, and the complexities confronting adults in today's society. Schools tend to teach reading comprehension skills in isolation from composition tasks, and researchers tend to follow this model both conceptually and methodologically. The practical reality is the individual who needs to obtain information from a variety of sources, extract (and record) the key ingredients, and transform the results into a package that serves a practical purpose.

Investigations of pedagogy are generic, although reading often provides the context for research on instructional methods. Psychologists have played a major role in these endeavors, with the first three volumes of the *Handbook of Research on Teaching* being edited by psychologists. Two items warrant particular attention from studies of classroom teaching in the elementary grades: (a) the contrast between strategies that rely on teacher-based direct instruction and those that emphasize student involvement and engagement and (b) explorations of understanding the nature of classroom processes and of the role of teacher decision making in these complex activities.

Probably the most clear-cut finding about classroom instruction is that teachers do most of the talking. This is captured in the initiate–respond–evaluate (IRE) cycle, where the teacher asks a question designed to evoke a particular response, a student responds, and the teacher evaluates the result, turning to other students for a correct answer if necessary. In the primary grades, reading instruction also entails a considerable amount of oral reading, where students take turns reading portions of the day’s passage, with IRE events following each student’s performance. In the later elementary grades, students are more likely to read the daily passage silently, followed by discussion, but still following the IRE pattern. These techniques, known collectively as direct instruction and typically associated with an emphasis on objectives-based curriculum design, lend themselves to the preprogrammed materials found in teachers’ manuals.

The contrastive strategy, often labeled student-centered instruction, places the teacher in the role of building an environment that “scaffolds” student involvement in learning tasks. Students often work in small groups on various projects, with the teacher circulating among the groups to monitor and assist. In whole-language programs, which have gained notoriety during the past decade or so but spring from a much longer history, students can select readings from a range of authentic literature (unlike the tailored passages found in basal readers), with occasional whole-class sessions to introduce learning outcomes (phonics objectives but also vocabulary and comprehension) and to allow students to report their responses to readings. The implicit (and sometimes explicit) assumption is that literacy, like language, will emerge as children are immersed in literary artifacts and supported in gaining mastery of the technical elements, including the technology of print. The assumption that the learning of literacy is as natural as the learning of language is not essential to these programs, nor is it particularly well founded.

Research has illuminated the benefits and limitations of the extreme positions, leading to a search for a middle ground, that is, a balanced approach. Although the concept appears to be attractive, the challenge of defining and designing instruction that incorporates widely dissimilar assumptions and techniques is substantial for both program developers and classroom teachers. It requires more than allocating some time to direct instruction and some time to student-centered activities, a mix that might be programmed into instructional materials and manuals. Investigations of expert teachers show that they create a middle ground that is quite different from either extreme. They typically construct a principled plan for the school year that they constantly modify based on continual assessments of student progress.

Studies of classroom processes and teacher decision making over the past half-century did not begin with expert teachers. During the 1960s, the process–product paradigm employed classroom observations and standardized achievement measures to establish correlational patterns that then led to experimental interventions. For example, if the teacher established effective classroom management techniques, more time was available for academic learning, leading to increased student achievement. By the 1980s, attention turned to issues related to how teachers negotiated the complexities of classroom practice, bringing to bear a range of perceptual, cognitive, and decision-making concepts. Psychologists have played a significant role throughout this progression, moving from a predominantly quantitative perspective to one that incorporates qualitative concepts and techniques and that requires significant collaboration with other disciplines. This paradigm is illustrated by studies of the progression of teachers from novice to professional expertise.

2.3. Individual Differences

Threading through the previous material has been the notion that people vary, an important theme from the earliest days of applied psychology. For the literacy field, attention to individual differences is important in its own right but also provides guidance in practical issues such as identification and assistance for students with special needs. Again, three topics emerge in the literature.

The first and most obvious correlate linking individuals with literacy achievements, in the United States as well as worldwide, is poverty—the achievement gap. Understanding the mechanisms that underlie this correlation, and the exceptions to the generalization, is

perhaps the greatest challenge confronting the United States during the decade ahead, not only for the nation's well-being but also in its role as world leader. Correlational and observational studies of the problem abound. Missing from the mix are sustained and intensive longitudinal studies that might illuminate the processes by which poverty undermines the capacity of students to realize their full potential and to point toward practical interventions. "Success stories" that stand the test of time are in short supply.

The second arena centers around the collection of constructs referred to as learning disabilities or dyslexias. A complete treatment of this topic would require much more space. "Learning disability" is, practically speaking, a bureaucratic label. Students who meet certain behavioral and achievement criteria are identified for federal funding to provide special assistance. The recent history of these programs is generally problematic. Although early intervention seems most likely to make a difference, students often have to "wait to fail" in order to receive assistance. Evaluations suggest that the programs have limited effectiveness. Most of the clients are boys, behavior is the most frequent referral "flag," and low reading achievement is a correlate in more than 80% of the cases.

The various dyslexias spring from medical models, with frequent references to neurological processes and studies of brain functioning. The latter area has burgeoned during recent years with the development of new technologies such as functional magnetic resonance imaging (fMRI). Practically speaking, the overlap with learning disabilities is quite substantial when it comes to the practical aspects of identification and treatment. Substantial federal investments in research and development in these arenas, primarily under auspices of the National Institute for Child Health and Human Development (NICHD), has supported much of the fundamental research in early literacy reported previously, especially in the neurological and brain-imaging areas.

The third area in this category focuses on linguistic and sociocultural differences among students. As noted earlier, language development mirrors children's linguistic environments. Socioeconomic status is a significant dimension in that children from the middle and upper classes are immersed in the academic register virtually from birth. A related issue centers on the increasing proportion of students for whom English is a second language. The growing Hispanic population presents the greatest impact, especially along the nation's southern border, but immigrants from Asia and Eastern Europe are also part of the picture. The

issues are quite complex, involving socioeconomic status, cultural styles, home and community languages, and correspondence between student and teacher backgrounds and experiences. English language learners, as they are now labeled, perform poorly on standardized tests across the various programs—bilingual, dual immersion, sheltered English—that have been proposed as remedies. Their performance in mathematics achievement is noticeably stronger, suggesting a linguistic basis for the literacy scores.

3. PROSPECTS FOR IMPROVING LITERACY

Those reading this article are literacy experts who bring their experiences to bear on the definition of the concept, the nature of the problems, and ideas about how to improve literacy. The research literature by no means speaks with a single voice; indeed, the National Reading Panel Report evoked considerable debate due to the selectivity of the investigations and interpretations. Nonetheless, a few generalizations and projections appear to be warranted.

First, several areas call for advancements in theory, research, and practice, most clearly in the achievement gap but also in the pragmatics of curriculum and instruction represented in the concept of balance as an alternative to the continual pendulum swings.

Second, the knowledge base available for improving literacy achievement is substantial, albeit rather contentious, in scope and variety. By any criterion, however, the practices of literacy instruction are quite distant from this base. Literacy teachers learn how to implement various "methods" for teaching reading and writing but are less likely to manifest expertise in linguistics, child development and learning, rhetorical concepts, and methods of behavioral and social science research. The elementary school teacher typically relies on materials and mandates to shape practice along with the occasional counsel of others in the school when time allows, and that is not often.

Third, the application and evaluation of the results of literacy research will call increasingly for studies on application and evaluation, including analysis of the range of policy environments that affect public education. In fields such as engineering and medicine, practitioners are much more closely connected with the methods and findings of the underlying disciplines than with those of education. Once in the classroom,

the individual teacher has considerable leeway about practice (imagine a similar situation for the doctor in the operating room). Schools are described as “decoupled,” referring to the disconnections among various levels of the system from district to school to classroom. Those engaged in research and development in the literacy arena are often frustrated by this state of affairs. The remedy might be for these individuals, many of whom are psychologists, to include organizational and contextual elements as an integral part of their research and development agendas.

GLOSSARY

behavioral marital therapy Behaviorally based couple treatment focusing on behavior exchange and training in communication and problem-solving skills.

brief strategic couple therapy Family systems-based couple treatment emphasizing a reduction in attempts to solve problems when such attempts may maintain or even worsen problems.

cognitive-behavioral marital therapy Couple treatment combining a behavioral marital therapy approach with a focus on partners' cognitions.

emotion-focused therapy Couple treatment focusing on resolution of insecure attachment patterns and processing of emotion.

insight-oriented marital therapy Couple therapy emphasizing resolution of unconscious maladaptive relationship patterns that arise from previous developmental experiences.

integrative behavioral couple therapy Acceptance-based couple treatment combining a behavioral marital therapy approach with a paradoxical reduction in the struggle to change.

Prevention and Relationship Enhancement Program (PREP)
One of several approaches attempting to prevent couple

distress; it is often applied to couples prior to their wedding or early in their marriage.

The term "marital therapy" is something of a misnomer because the same therapies apply for couples who are not married, including those who are cohabiting and those who do not live together. However, some treatments specifically target couples at certain points in the marriage process such as prior to marriage or during the first years of marriage, particularly during the transition to parenthood. Often, treatments during the early stages of marriage focus on prevention. Treatments during subsequent stages of marriage usually aim to ameliorate relationship distress. Because individual psychological disorders, such as depression and anxiety, are major risk factors for relationship distress, several investigators have also evaluated the efficacy of treating individual disorders through couple therapy. When relationship problems are contributing to or maintaining individual disorders, couple therapy can assist in treatment of the individual disorder or can change relationship patterns that influence the individual disorder. The current focus, however, is on couple therapies that address relationship problems. Several couple therapies have been empirically supported, meaning that randomized clinical trials have found couples undergoing the treatments to have superior outcomes to couples not experiencing those treatments. Although several approaches have been shown to benefit distressed couples, important questions remain about whether specific therapies can be matched

to specific couples and whether couple therapy has long-term effectiveness.

1. INTRODUCTION

The vast majority of partners report high satisfaction at the beginnings of their marriages. Yet relationship satisfaction tends to decline over the first 10 years of marriage. Nearly half of all U.S. marriages end in divorce, and most couples are likely to have suffered considerable marital distress prior to divorce. Many other couples whose members remain together also experience marital distress. Marital distress is not stable across the life span. Researchers generally report one of two patterns over time: either a steady decline of marital satisfaction or a complex pattern in which satisfaction is high initially, declines during the child-rearing years, and returns to a higher level during the later years. Marital distress is linked to a variety of individual psychological and physical health problems (e.g., depression, substance abuse). Children growing up in families with marital distress, especially high levels of overt marital conflict, are at risk for psychological problems such as aggression and anxiety. Although approximately 30% of marrying couples receive some form of preventive premarital counseling or relationship education, only 10 to 20% of divorcing couples have met with mental health professionals. The most common sources of disagreement in marriage are money, children and other relatives, the division of housework, communication, and sexual intimacy. It should be noted that the specific interventions available to treat individual or couple sexual problems are not presented in this article.

2. ASSESSMENT

Before commencing treatment, it is important that the clinician perform a thorough assessment of the couple. Such an assessment can encompass a variety of methods. The clinician virtually always interviews the partners, whether separately or together, about their individual and relationship histories, aspects they would like to change, and areas of strength. Couples can complete standardized questionnaires about various aspects of their relationship and individual functioning. These questionnaires provide a measurement of partners' overall marital satisfaction relative to that of other distressed and nondistressed spouses. The

questionnaires also evaluate the extent and nature of disagreements in specific relationship domains (e.g., household management, sex, religion, personal habits). Some clinicians perform a formal behavioral observation in which the partners spend a short period interacting with each other so that the clinician can observe their communication style. Patterns of conflict escalation and differences in affective expression are important relationship features that can be observed directly. Clinicians who do not conduct a formal observation invariably observe these dimensions of couple interaction throughout the course of the sessions. Finally, some couples are asked to systematically record information reflecting the nature and tone of their everyday interactions on a daily basis between sessions. These data can include tallies of salient relationship behaviors, both positive (e.g., instances of emotional support) and negative (e.g., arguments), and ratings of important relationship dimensions (e.g., feeling understood by the partner).

3. COMMON CONSIDERATIONS ACROSS TREATMENT APPROACHES

A defining feature of couple therapy is that both partners are seen together in the therapy sessions. This mode of therapy, known as conjoint therapy, raises unique ethical issues. For example, will the therapist keep individual confidences of the partners or will the therapist share information between the partners? How the therapist manages these issues has important consequences for therapeutic alliances and the development of therapeutic goals. Even if the therapist schedules occasional individual sessions with each partner, an overarching principle of conjoint therapy is to balance the therapeutic relationship with both partners and to guard against benefiting one partner to the detriment of the other. Having both spouses in therapy means that the therapist must plan interventions that take into account the well-being and goals of both individuals, and this is a challenge when the partners' goals are at odds.

A common goal in marital therapy, regardless of the specific theoretical perspective, is to improve partners' communication. This goal generally involves exploring new ways of sending and receiving messages so that communications are clearer, less polarized, and more productive. An important benefit of doing conjoint

therapy is that the therapist can directly observe dimensions of the couple's communication style that contribute to relationship distress. The therapist can observe problematic styles such as withdrawal from emotional or conflict-laden discussions and escalation of hostility. The way in which partners communicate in the therapy sessions reveals recurring relationship patterns and provides opportunities to explore how each partner thinks about and responds to those patterns.

Although most marital therapies are designed to relieve distress and to help partners become more satisfied with their relationship, therapy also can be used to help partners decide whether or not to end their relationship. The therapist must balance the extent to which he or she promotes improvement of the partners' relationship versus acknowledges irreconcilable differences between the partners.

4. SPECIFIC THERAPIES

4.1. Behavioral Marital Therapy

Behavioral marital therapy, as originally presented by Jacobson and Margolin, grew out of a social learning perspective of marital distress that focuses on the ways in which partners shape each other's behaviors and on couples' skills deficits. Behavioral marital therapy has two major interventions: behavioral exchange and training in communication and problem-solving skills. Behavioral exchange, through a variety of specific strategies, enables partners to engage in a greater number of pleasing and positive interactions. The therapist assists the partners in planning and carrying out mutually enjoyable activities as well as in showing their affection and caring in small everyday actions. An important part of this intervention is getting partners to switch their focus of attention from negative relationship events to positive ones by becoming more mindful of the exchange of pleasing interactions. The second major intervention is training in communication and problem-solving skills. Communication is one of the most common areas of concern and intervention; partners who communicate well are most likely to maintain high levels of satisfaction. The therapist instructs the partners in listening skills as well as in skills for brainstorming solutions to specific, carefully identified problems. The skills training is designed to help partners discuss important problems in a non-blaming fashion and to develop a specific course of action that reflects the objectives and opinions of

both spouses. Concrete plans are made to try the solution on a time-limited basis, to reevaluate the plan at a specific point in time, and (if necessary) to revise and try a modified solution to the problem.

Behavioral marital therapy, with its focus on reducing negative relationship interactions and increasing positive interactions, generally emphasizes the present over the past. One goal of the clinician is to make the partners self-sufficient in solving their own future problems once therapy has ended. Partners who are more attuned to the positive dimensions of their relationship and who have had some success with resolving major conflicts are then more prepared when they are confronted with the future problems that are inevitable in any relationship.

4.2. Cognitive–Behavioral Marital Therapy

Cognitive–behavioral marital therapy, as described by Baucom and Epstein, supplements the elements of behavioral marital therapy by additionally focusing on partners' cognitions about one another and the marriage. Each person brings his or her own interpretation to every moment of every interaction. Sometimes, these interpretations are faulty or can lead to relationship distress as well as individual distress. For example, a wife's disappointment in her husband depends not only on the husband's behavior but also on the wife's expectations of the husband. If the wife's expectations of her husband are unreasonably high, she will find him to be disappointing more often. Cognitive–behavioral therapy might address this problem by focusing on a combination of the wife's expectations and the husband's behavior.

Cognitive–behavioral marital therapy is based on the premise that understanding and changing relationship distress must take account of ways in which partners interpret and evaluate their relationship and one another. In addition to focusing on unrealistic ideals of marriage, this mode of therapy also considers discrepancies in the values and standards that spouses bring to marriage. For example, partners often disagree on how much time should be spent together versus in independent activities, whether it is acceptable to maintain friendships with members of the opposite sex after marriage, how special events (e.g., birthdays, anniversaries) are to be celebrated, and who makes decisions about spending money. In cognitive–behavioral marital therapy, as in behavioral marital

therapy, an important goal is helping spouses to pay attention to the positive aspects of their relationship and not just to notice what is wrong with their relationship. Although this form of therapy also considers partners' behaviors and emotions, its unique contribution is the focus on partners' beliefs, that is, where they came from and what are the advantages and disadvantages of maintaining those beliefs.

4.3. Integrative Behavioral Couple Therapy

Integrative behavioral couple therapy was developed by Jacobson and Christensen to address marital problems that represented serious irreconcilable differences between marital partners and that were not amenable to the change strategies of traditional behavior marital therapy. In integrative behavioral couple therapy, the overriding goal is to increase each partner's acceptance and understanding of the behaviors they would like to see changed in the other partner. Once partners better understand and accept one another and develop a more collaborative approach to their problems, they are more willing to make desired changes. Paradoxically, as each partner "lets go" of the struggle to change the other partner, some changes that could not be achieved before can become possible when both partners accept the situation. Alternatively, for other problems, the therapist's validation of each partner's point of view leads to greater acceptance and greater intimacy, albeit not to specific behavioral change.

An important component of integrative behavioral couple therapy is the formulation of the couple's problems. A couple's problems are understood in terms of thematic issues such as struggles over one partner's desire for closeness and the other's desire for more distance and struggles over which partner has control over a particular area of the relationship. The way in which a couple attempts to solve these differences often polarizes the partners to extreme positions and makes the problems worse. During a feedback session, the therapist shares the formulation about how the partners have become divided over certain issues, with the goal of increasing tolerance of their differences. An important role of the therapist throughout this treatment is to validate each partner's perspective and to highlight how each partner feels hurt and sad, rather than just angry and disappointed, by what has transpired. As initially described in 1981 in Wile's collaborative marital therapy approach, eliciting spouses'

vulnerable emotions facilitates closeness and acceptance in their relationship.

4.4. Brief Strategic Couple Therapy

Shoham and Rohrbaugh modified family systems approaches to develop brief strategic couple therapy. The primary focus of this model is the identification and disruption of "ironic processes." Ironic processes are the negative patterns that develop when partners' efforts to solve a problem actually maintain or even worsen the situation. The goal of therapy is to identify and then interrupt this cycle by reducing the partners' attempts to solve the problem. Thus, this approach requires spouses to do less of their currently used solution or even to do the opposite of what they had been doing. An important part of therapy is accepting the partners' definitions of the problem but also reframing and reshaping their understanding of the problem so that they will interact differently around the problem situation. Less of the solution should lead to less of the problem, and this in turn will require even less of the solution, and so on.

Although the focus on interrupting couples' own solutions to their problems is similar to integrative behavioral marital therapy, other features of this approach set it apart from previously described models. In this model, therapy is directed to the specific complaints that clients present. No attempts are made to assess or identify problem areas beyond what the partners themselves have specified. This therapy can be done with one spouse so long as that person is motivated toward change. This approach does not require that the partners understand or have insight into why their problematic patterns have developed. This approach is particularly applicable to those partners for whom skills-based approaches reaffirm and replicate the ineffective solutions that the partners already have tried, for example, structuring more interaction between partners when one spouse already has been criticized about withdrawing from the relationship.

4.5. Emotion-Focused Therapy

As its title suggests, emotion-focused therapy, developed by Johnson and Greenberg, focuses on the emotional experiences of spouses and how these experiences define and maintain interaction patterns. Emotion-focused therapy integrates gestalt/experiential and systems approaches with attachment theory. As an experiential approach, emotion-focused therapy fosters corrective

emotional experiences in therapy sessions. As a systems approach, this model attempts to interrupt repeating negative cycles of interaction. According to this model of therapy, rigid and insecure attachment styles make it difficult for partners to be emotionally open and responsive in marriage, and this in turn creates marital distress. Thus, treatment goals include using the therapy situation to evoke new interactional experiences that create a more secure bond between the partners through reprocessing and restructuring of each partner's inner experiences. When partners develop a sense of security and a better understanding of attachment needs, they can communicate more clearly due to increased empathy and decreased defensiveness.

As contrasted with therapy models that focus on skill building or on relationship beliefs, the emotion-focused therapist helps partners to identify, experience, and express clearer and more poignant emotional needs. These deeper emotional experiences generally reveal vulnerable rather than hostile emotions and lead to a need for connection with the partner. An underlying assumption of this model is that when partners are emotionally engaged with one another, conflict can deescalate and new patterns of interaction can emerge.

4.6. Insight-Oriented Marital Therapy

Insight-oriented marital therapy, developed by Snyder and more recently called affective reconstruction, is similar to emotion-focused therapy in its focus on unidentified and unexpressed affect as the source of relationship distress. However, this approach asserts that maladaptive relationship patterns arise from previous developmental experiences and exist primarily on an unconscious level. Correction of the current marital difficulties is accomplished through the use of clarification and interpretation to uncover each partner's underlying dynamics. A goal of insight-oriented marital therapy is to reconstruct affective experiences and relationship schemas through exploration of each partner's own relationship history. This treatment is flexible and inclusive and often incorporates traditional behavioral techniques of communication training and behavioral exchange.

4.7. Prevention

Prevention-based approaches, such as Markman and colleagues' Prevention and Relationship Enhancement

Program (PREP), attempt to improve the quality of the relationship prior to the emergence of problems. Couples can enroll in prevention programs before marriage, early in their marriages, or in long-term committed relationships. Based on research showing that the quality of communication is related to marital distress, skills training in constructive communication, problem solving, and conflict management is a major component of programs such as PREP. Other foci of prevention programs include exploration of each partner's relationship expectations, reinforcement of the partners' commitment, and enhancement of the positive aspects of the relationship. Prevention approaches generally are conducted in groups of couples with a strong educational component through lectures, demonstrations, the practice of new skills through communication exercises, and feedback from the group facilitators. For some couples, the goal of prevention programs is to reduce the likelihood of later distress. For others, the goal is to reverse a downward trend in satisfaction that already has begun.

5. OUTCOME RESEARCH

Most research to evaluate whether couple therapy is effective has compared couples receiving therapy with a control group of couples receiving no therapy. These comparisons have consistently concluded that couple therapy increases satisfaction and decreases distress more than does no treatment. The possibility that another outcome, such as divorce, might be the best outcome for a given couple is generally not addressed in outcome research. The meta-analysis in 1993 by Shadish and colleagues found an effect size of approximately .60, indicating that the average therapy couple has a better outcome than do 70% of controls. Although reviews generally indicate that more than half of couples receiving couple therapy demonstrate reliable improvement, a smaller proportion of couples show improvements by both partners or show movement from distressed to nondistressed status. Long-term follow-up studies have found that most couples maintain gains over the first year but that some couples deteriorate several years following therapy.

Multiple studies have indicated efficacy for the specific types of couple therapy reviewed in this article—behavioral, cognitive-behavioral, integrative behavioral, brief strategic, emotion focused, and insight oriented—as well as for prevention approaches such as PREP. As yet, there is no consistent evidence

that any one of the treatments is better than any other. Although each of these marital therapy treatments seeks to disrupt recurring dysfunctional interaction patterns, the treatments differ in their emphases on behaviors, cognitions, or emotions. Future efforts to match type of treatment to type of presenting problem or to characteristics of the partners might afford higher rates of treatment efficacy.

GLOSSARY

constructivism An epistemological stance claiming that humans actively construct knowledge in ways that are viable and useful for getting along in the world but that knowledge does not necessarily match an external reality. One educational implication of this stance is that knowledge cannot be transferred from person to person, so that teaching becomes a process of providing experiences that will promote and guide knowledge construction.

cultural psychology The study of the role that culture and society play in the mental life of human beings.

understanding Learning with understanding refers to the acquisition of a richly connected network of knowledge, including facts, procedures, concepts, and habits of mind that allow for retrieval and application of knowledge in appropriate situations.

The teaching of mathematics refers to actions specifically intended to promote the learning of mathematics, usually in formal classroom settings.

The specific actions taken depend on views of what is fundamental to mathematics itself, what prior knowledge students have, and the environment in which they can best learn mathematical habits of mind.

1. INTRODUCTION

The problem of how mathematics can best be taught and learned has been a matter of concern throughout the past century. Facility with mathematics is seen as a fundamental skill and is increasingly important in modern society. At a time when international studies draw attention to performance gaps, the question of improving students' mathematical understanding has great political and social currency. Applying psychological principles in order to solve this problem seems natural. Indeed, modern psychology has been applied to the learning and teaching of mathematics at least since the 1920s, when E. L. Thorndike published *The Psychology of Arithmetic*. Since that time, various psychological theories, including behaviorism, Piaget's genetic epistemology, and current connectionist and cognitive theories, have been applied with varying success to explain and facilitate mathematical learning.

At the same time, such application is not straightforward. The prototypical question, "How might a teacher best help a student to learn X?" that administrators, policymakers, and even parents would naturally ask presupposes common interpretations of what it means to learn X and in what sense an approach might be "best."

That these common interpretations might not be in place is partly a result of shifting views of what it means to know mathematics. It is thus important to know how this issue is currently conceived and how it affects the application of psychology to learning mathematics.

2. CURRENT VIEWS OF MATHEMATICAL UNDERSTANDING

In many ways, the foundational issue in mathematics education is the nature of mathematics itself. The decisions we make about teaching mathematics and the kinds of understanding we value in students both depend on what we believe to be most fundamental about mathematics. Mathematics has traditionally been seen as a collection of facts and procedures to be mastered and later applied to appropriate situations. Certainly, learning mathematics does involve mastery of some basic information—multiplication facts, procedures for solving equations, and so forth. Many early applications of psychology to mathematics learning viewed mathematics in just this way. However, it is increasingly recognized that mathematics is more than a collection of facts and procedures. Knowing mathematics involves having the conceptual understanding and habits of mind that enable one to use mathematics powerfully in daily life. Conceptual understanding of mathematics involves understanding how the facts and procedures fit together and when they apply. It involves knowing why procedures work and how to use them to solve problems. In short, it is connected knowledge that provides an organized framework for understanding. Mathematical habits of mind include the ability to reason logically with mathematics ideas, to justify procedures and answers, and to explain mathematical ideas to others—in short, to engage in the practices of mathematics. The acquisition of all these skills, concepts, and habits of mind is what is meant by learning mathematics with understanding. When this becomes our instructional goal, it significantly affects the psychology of teaching mathematics.

3. APPLICATIONS OF COGNITIVE PSYCHOLOGY TO TEACHING MATHEMATICS

Early attempts to apply psychological theory to mathematics teaching were dominated by associationist and behaviorist models of learning. However, the so-called disaster studies of the early 1970s demonstrated

that children could attain a degree of computational proficiency without any clear idea of what the computations meant, how they should be applied, or how they were related to other knowledge. Such studies pointed to the inadequacy of “black box” models of human cognition for educational purposes. This realization prompted the more careful study of how children thought (as opposed to whether their answers were right or wrong) and a focus on children’s conceptual as well as procedural knowledge. The tools of such study became clinical interviews and the careful observation of children doing mathematics—tools still fundamental to the study of mathematical learning.

As part of this focus on student understanding, and against the behaviorist models, there arose the theoretical stance of constructivism, which has had a profound effect on how mathematics learning is viewed. Grounded in the works of Piaget and explicated by von Glasersfeld and colleagues, constructivism holds that knowledge is actively built up by learners, not in ways that mirror reality but in ways that have viability or fit—ways that help learners make sense of and work in their world. Thus, the understandings built are those that both work for learners and fit with their previous understandings; however, these understandings do not necessarily match an external reality, nor do they necessarily match those of a teacher. One implication is that knowledge cannot be transferred from teacher to student. The teacher can only encourage the construction of viable knowledge by arranging learning situations that support that construction. Teachers who accept constructivist principles focus less on providing students facts and explanations and more on designing the learning environments that help students confront the viability of their knowledge.

Emerging from this background are two critical factors affecting the learning and teaching of mathematics: prior knowledge and mathematical activity. Tasks given to students must connect with students’ prior knowledge in order to be approachable at all. Moreover, they must challenge that understanding so there is a need to construct richer and more useful understanding. Thus, tasks must give rise to reflection on what is known and allow for restructuring of knowledge.

3.1. Studies of Early Number Learning

An example of how these ideas bore fruit is provided by the study of how children develop early arithmetic understanding. In the early 1980s, researchers began to document the strategies children used to solve

addition and subtraction word problems as well as the typical developmental paths from simple to more advanced strategies. These studies demonstrated that children's strategies were strongly affected by the action in the word problems (whether two collections of objects were joined together or whether one collection was separated into two, for example) as well as the role of the unknown quantity in the story (e.g., whether the unknown quantity was the result of joining two collections or was one of the two collections being joined).

These studies showed that although children's understanding of arithmetic differed quite dramatically from adults', their knowledge was robust and very useful. Without formal instruction, children were able to develop modeling and counting strategies that allowed for the solution of a wide number of problems. Later studies have repeatedly shown that students come to school with a wide range of mathematical concepts and informal problem-solving strategies. Similarly, studies of older children's mathematics use outside of school have demonstrated that they can develop quite sophisticated and successful contextual strategies for doing mathematics. Research also demonstrates that unless these informal strategies are taken into account when planning instruction, students' abilities to solve problems actually diminish over time. Rather than developing meaningful and useful problem-solving strategies, students come to see mathematics as a collection of arbitrary rules that they have great difficulty applying to word problems.
