In contrast, instruction that builds on informal knowledge and provides tasks that push students to reflect on that knowledge has been shown to be effective. For example, studies have shown that elementary teachers who are given information about students' typical strategies, together with tools for assessing students' thinking, can use it to guide their instructional decisions with beneficial results. Thus, a fundamental tool for teachers is the ability to assess their students' understanding of mathematics. The purpose of their assessment is not merely to discern if their students have achieved mastery but also to know the informal knowledge on which students' further understanding can build. Such teaching, heavily dependent on understanding individual students' concepts and strategies, has become an important focus for mathematics educators, with the result that capturing students' mathematical understandings has become a critical issue for both researchers and teachers.

The studies of children's solutions to word problems revealed that the knowledge required to solve word problems did not comprise a set of isolated skills but was indeed a connected network of understandings. These include mathematical ideas associated with

number, counting, and order, as well as understanding of problem situations, story structure, and how strategies and problem types were connected. The research also showed that as children developed more advanced solution strategies, their knowledge became even more richly connected and flexible. Thus, "learning with understanding" results in richly connected knowledge structures. Such rich knowledge structures have become the goal of instruction. Because of this, the problem of capturing and describing them becomes critical.

In an attempt to capture students' knowledge, a number of psychological constructs and methods have been employed by mathematics education researchers. These began, perhaps, with Piaget's early structural approach and the approaches of Bruner and Dienes, all of which had a profound effect on early thinking in the field. In the 1980s, information processing psychology became popular as a way to find, describe, and categorize the schemata used by students in the production of mathematical knowledge. Researchers attempted to develop production systems that modeled students' actual performance on mathematical tasks as a means of putting forward rigorous hypotheses about these schemata. Recently, researchers in mathematical thinking have been turning to other areas of cognitive science in order to capture both knowledge structures and the means by which they are created and updated. English and Halford emphasize the importance of analogical processes to learning. Another promising approach is the application of theories of embodied cognition to mathematics learning.

3.2. Summary

The tools of cognitive psychology are critical to the capturing of student's knowledge, which in turn is important to understand both where students are and where we would like them to be. Unfortunately, there has been less success with finding applications of cognitive psychology that help us understand how our students move from current understanding to richer understanding, or of the situations we must create to facilitate this move. It is partly to address this concern that recent work in mathematics education has turned to a focus on social and cultural aspects of learning.

4. THE DISCURSIVE TURN IN MATHEMATICS EDUCATION

Although the focus on individual students' knowledge structures and cognitive processes has met with some

success, it has also been subject to some criticism. In general, cognitive psychology has done a better job of capturing static “snapshots” of students’ understanding than in describing the processes of change and learning. Additionally, the cognitive approach often does not capture the full complexity of the classroom, where, after all, much learning and certainly most teaching are thought to occur.

In part because of these criticisms, and in part because of changes in the view of knowledge and learning in general, recent scholarship has focused much more on the social and cultural context of learning mathematics. In some cases, this has taken the form of attending to the ways that social interaction among students and teachers affects the ways that individual understanding is developed in students. A more radical approach calls into question the way we look at mathematical knowledge. From this perspective, understanding mathematics is seen as the ability to participate in particular discourse communities, or communities of practice. This viewpoint has been motivated in part by the recognition that at the highest professional levels of mathematics use, doing mathematics is a social phenomenon with well-established ways to collaborate, share mathematical ideas, and negotiate what counts as mathematically valid. Other influences include the discovery of cultural psychology, as represented in the work of Lev Vygotsky, Michael Cole, and others. All of this has tended to shift attention from mathematics as a purely cognitive activity to include a focus on social practice and cultural acquisition, particularly as played out in classrooms.

In this emerging tradition, the focus shifts from students’ individual understanding of mathematical ideas to careful observation of how teachers and students together construct meanings in a social and cultural context, and how these social meanings are appropriated by the students as cognitive tools. The research tools then become participant observation, ethnographic interviews, and similar techniques aimed at describing the social life of the classroom.

5. APPLICATIONS OF CULTURAL PSYCHOLOGY TO TEACHING MATHEMATICS

A good deal of research has focused on learning mathematics in classroom settings, paying particular attention to the sociocultural aspects of learning. In this

context, the teachers’ responsibilities expand beyond attending to individual students’ cognition and providing appropriate mathematical tasks to include the establishment of norms and expectations for social behavior in the classroom. A number of studies have begun to converge on similar descriptions of effective classrooms.

In such classrooms, teachers do provide appropriate tasks that take into account students’ prior understanding. However, they also seek to establish expectations that students will (i) seek to learn with understanding, rather than memorizing rules without meaning; (ii) try to understand other students’ ideas and solution methods; (iii) explain and justify their thinking to others; (iv) view mistakes as opportunities for learning; and (v) evaluate the usefulness of mathematical ideas based on reason and argument, not solely on the authority of the text or teacher. Such expectations create an environment in which students can safely engage in the mathematical practices of reasoning, justifying, testing conjectures, and communicating and evaluating ideas. In such a classroom, the teacher serves as a representative of the larger mathematical discourse community and can therefore help make needed connections, facilitate the use of established terminology, and provide needed counterexamples or questions as appropriate. In this way, students engage in a sort of “legitimate peripheral participation” in mathematical activity as a way of gaining greater access to the full community of adult users of mathematics. This participation in turn helps students to build the habits of mind that are part of knowing mathematics with true understanding.

6. CONCLUSION

The tools of psychology applied to the problem of teaching mathematics have allowed researchers to gain access to students’ existing knowledge, which in turn allows teachers to build on that knowledge through the selection of appropriate tasks. In addition, careful observations of classroom life, made from the perspective of cultural psychology, have allowed teachers to create classrooms in which students engage in mathematical activity as a means of learning what it means to do mathematics.

GLOSSARY

assessment The application of measurement to achieve a “snapshot” of a particular variable (e.g., behavior, emotion, ability, interest); counseling psychologists are interested in typical performance on the dimension or variable.

measurement The technique of assigning a dimensional or quantitative representation to a psychological construct; it is usually an attempt to place a numerical value on a person’s behaviors, thoughts, emotions, or physiological reactions so as to study a construct.

psychometrics The field of study devoted to psychological measurement; psychometricians investigate the properties of measures used in behavioral science research.

reliability The consistency or dependability of a measuring technique.

validity The extent to which a measurement procedure actually measures the variables intended to be manipulated or measured.

As a cornerstone of counseling psychology, the quantitative method of measurement allows for assessing

human behaviors, thoughts, feelings, and attitudes to aid in further developing an individual’s potential for personal growth and understanding.

1. INTRODUCTION

Since the age of antiquity, people have sought to differentiate individuals according to abilities so as to select qualified individuals for specific tasks and duties. The earliest record of this type of testing dates back to ancient China (2200 BC) when oral exams were administered to people seeking entrance into the civil service. History is replete with other examples of formal testing on individuals and groups, but these efforts often failed to make reliable and valid predictions. It was not until the 19th century that a breakthrough occurred when psychologists developed quantitative methods to reliably assess individual differences in mental abilities. This quantitative method of assessment, as well as other historical influences that are discussed later, contributed to the emergence of counseling psychology as a specialty field of psychology. In counseling psychology, professionals are trained to assess the interests and abilities of individuals using a variety of methods and to provide reasonable recommendations regarding school, work, and personal life. This article briefly reviews the history of measurement and its relevance to counseling psychology.

2. BRIEF HISTORY OF PSYCHOLOGICAL MEASUREMENT

The modern-day measurement of psychological attributes dates back to the late 1800s and early 1900s when some of the early founders of psychology, such as Galton, Pearson, Cattell, Binet, Spearman, Thurstone, and Thorndike, attempted to quantify and measure individual differences in mental ability (what later became known as human intelligence). During this heyday period, numerous statistical procedures that now serve as the foundation for psychological measurement were developed. Two of the most important statistical advances were the correlation method and factor analysis. A correlation refers to the strength of the relationship between a pair of variables, with the understanding that knowledge about one variable may carry information about the other variable (e.g., grade point average [GPA] and Scholastic Aptitude Test [SAT]). Factor analysis is a method of analyzing a set of correlations to discover which variables in the set are correlated with each other but are largely independent of the other variables. Thus, factors represent the underlying processes that hold together each subset of correlations.

Using these new statistical procedures, psychologists were able to develop more reliable and valid tests of mental ability or intelligence. These tests were composed of many subtests, and each subtest consisted of multiple items or questions that were intended to measure a specific ability or attribute. The correlation method and factor analysis allowed psychologists to determine whether the items in one subtest (e.g., vocabulary items) were correlated with each other to a greater extent than they were with items from another subtest (e.g., math items). Psychologists also were able to determine which of these tests and subtests correlated with observable behaviors (e.g., school grades and income level).

In short, the pursuit to accurately measure mental ability or intelligence led to the development of the field of psychological measurement, with its emphasis on the construction of reliable and valid scales and instruments, standardization of test administration, and use of probability statistics to aid in the interpretation of test results. Perhaps more important, the advent of psychological measurement as a scientific method allowed psychologists to empirically investigate individual differences in a wide range of attributes and behaviors (not just intelligence) as well as the

relationship among these variables. Today, the field of psychological measurement can be divided into psychometrics (i.e., the theory and techniques of measurement) and psychological assessment (i.e., the application of measurement).

The first widespread use of psychological assessment occurred during World War I. Psychologists developed a group intelligence test that was used by the U.S. Army to select and train military personnel for various occupations. This type of assessment began an influx of mass testing and personnel selection—two psychological innovations that continue to play a significant role in society today. Shortly thereafter, psychologists developed measures for a wide range of psychological attributes, including people's attitudes, values, interests, abilities, and personality traits. Among the three most widely known today are the Wechsler Intelligence Scales for children, adolescents, and adults (which measure cognitive functioning); the Minnesota Multiphasic Personality Inventory (which measures personality and psychopathology); and the Strong Interest Inventory (which measures occupational interests).

As society became more concerned about the educational and occupational needs of its citizens, psychologists adapted these measurement advances to everyday practice. The end of World War II is a well-known example of how the fields of measurement and counseling became united. After the war, thousands of veterans needed assistance in their adjustment back to civilian life. They were struggling psychologically with the traumas of combat while seeking higher education opportunities and trying to select appropriate occupations and careers. The Veterans Administration hired counseling psychologists to help returning war veterans overcome personal and vocational adjustment difficulties. Counseling psychologists responded by providing guidance and counseling that was informed by the psychological assessment of individual differences in interests and abilities.

3. RELEVANCE OF MEASUREMENT TO COUNSELING PSYCHOLOGY

Counseling psychology has its earliest historical roots in the vocational guidance movement at the turn of the 20th century. During this period, the rapid industrialization of the United States was accompanied by a diversity of new occupations and careers available to young adults. Vocational guidance helped people

to make appropriate educational and occupational choices based on their abilities and interests. To assist in this guidance process, counseling psychologists turned to recent developments in psychological measurement and the broader study of individual differences to assess these abilities and interests accurately and to ensure a proper fit between people and their environment. The previous example of counseling psychologists working with returning war veterans is an apt case in point and is one of the earliest examples of the use of measurement in counseling psychology.

Measurement and counseling psychology have, in many ways, developed a mutually beneficial relationship over the years. Perhaps the best example of this reciprocity is the development of person–environment fit theory. The person–environment fit theory is derived from the original “trait and factor” work of Frank Parsons, the founder of the vocational guidance movement during the early 1900s. Parsons construed vocational guidance as a three-step process of learning about one’s interests and abilities (i.e., trait), understanding the requirements of a given occupation (i.e., factor), and finding a reasonable solution to one’s vocational options. E. G. Williamson and John Holland also are credited with advancing the idea that a match or fit between a person’s personality and the work environment is the best predictor of occupational satisfaction and success. Although this idea might not seem revolutionary by today’s standards, it was groundbreaking during the mid-1900s and set the stage for a plethora of psychological research on the measurement of the person and the environment and on the interaction of person and environment to predict behavior and adjustment.

Furthermore, person–environment fit theory has influenced other developments in measurement and counseling psychology. For example, the concept and measurement of aptitude can be credited to counseling psychologists who sought to understand the readiness and potential of individuals and not simply their levels of intelligence. This emphasis on human potential remains a strong influence in counseling psychology, which as a profession focuses on individual differences in normal development and ways in which to encourage growth and overcome barriers in one’s environment. Counseling psychologists also have been at the forefront of multicultural issues in counseling and development. For example, counseling psychologists have contributed to our understanding of test bias in measurement—caused by poorly constructed test items and improper interpretation of test results—and

its societal impact on the occupational and educational opportunities and barriers for women and members of minority groups. The ways in which racial/ethnic minorities adapt to a majority culture environment is another major emphasis in counseling psychology. Counseling psychologists have developed numerous theories and measures of racial/ethnic identity development, and have established standards for multicultural competencies in counseling and research, to assess the impact of minority–majority status on behavior and adjustment.

As suggested, numerous psychological instruments were developed and used worldwide in vocational guidance and counseling, including the Strong Vocational Interest Blank (commonly known as the Strong Interest Inventory) in 1943, the American Council on Education Psychology Examination (forerunner to the SAT) in 1943, and the General Aptitude Test Battery (which actually dates to pre-World War II) in 1968. These tests have been revised over the years; however, these tests, along with more recently developed ones, continue to provide individuals with an empirical basis for making informed choices about which occupations and careers to pursue. Counseling psychologists have developed and used psychological instruments for many purposes beyond vocational and educational needs. Some current examples include the measurement of identity development, self-concepts, leisure interests, personal attitudes and biases, cultural values and expectations, and multicultural counseling competencies. In all of these instances, counseling psychology uses measurement to understand the ways in which the person and the environment interact and thereby affect normal development and adjustment.

4. COUNSELING PROCESS AND OUTCOME

By using measurement to assess individual differences in psychological attributes and then applying this knowledge to guidance and counseling, psychologists developed what is now known as differential individual diagnosis. Donald Paterson and others who worked at the University of Minnesota’s Employment Stabilization Research Institute during the 1930s are often credited with developing differential individual diagnosis, which involved the use of psychological assessment to form a diagnosis of a client’s employment

potential or presenting problem. By the 1970s, this technique was gradually refined from a “shotgun” approach to a “rifle” approach. In the shotgun approach, psychologists administered a standard battery of tests to every client who was referred for an assessment regardless of the presenting problem. In the rifle approach, psychologists selectively administered tests that would provide the specific information necessary to make an appropriate diagnosis and treatment plan. Today, differential individual diagnosis is a cornerstone technique of all counseling approaches.

A nagging question for psychologists has been whether differential individual diagnosis is very accurate. That is, do these diagnoses actually predict behaviors and outcomes? In 1954, Meehl wrote his seminal book, *Clinical Versus Statistical Prediction*, which compared the accuracy of actuarial tables with clinical judgments. To the surprise of many, Meehl found that actuarial (or statistical) method based on psychological test scores was far better than were clinical judgments (or diagnoses) made by psychologists in predicting behaviors and outcomes.

Meehl’s finding caused quite a controversy in psychology because it seriously questioned the validity of a psychologist’s expertness in making diagnoses. Also, this finding spurred many changes in the ways in which psychologists are trained to use assessment data and make diagnoses. Nowadays, counseling psychology training programs embrace what is referred to as the scientist–practitioner model. This model emphasizes a balanced training in how to conduct counseling and how to conduct empirical research that informs and is informed by the counseling experience. Moreover, the model ensures that psychologists, whether scientists or practitioners, understand how to best formulate, test, and revise hypotheses (or diagnoses) using data generated from psychological assessments and other relevant sources of information (e.g., clinical interviews, medical histories).

Over the years, other questions regarding the effectiveness of counseling have been asked and addressed with the help of refinements in measurement. In his 1966 book, *Revolution in Counseling*, Krumboltz was among the first to ask what is now a popular question in psychology research: Which techniques are most effective with what kinds of clients when used by what kinds of counselors? Counseling researchers have responded to this multifaceted question by focusing mostly on how to best measure and study the process and outcomes of counseling. Researchers have investigated, among many other variables, the

ways in which counselors use social influence and persuasion to change client behavior, the importance of a close working relationship between a counselor and a client to effect behavioral changes, and (more recently) the relevance of minority and cultural factors in the counseling experience. In all of these instances, the research has required the construction and validation of scales and instruments that assess client and counselor attributes as well as the interaction between client and counselor.

5. CONCLUDING REMARKS

The role of measurement in counseling psychology helps to distinguish counseling from other helping professions such as psychiatry, social work, and clinical psychology. In contrast to these professions, which tend to operate from a medical model of providing remedial treatment to individuals with more serious psychopathology, counseling psychology uses psychological assessment to identify people’s strengths and assets and to evaluate their adjustment to the environment. Armed with these assessment data, counselors are able to provide education, prevention-based programs, and goal-oriented counseling to help individuals prepare and cope with situational problems that arise in everyday living (e.g., school-to-work transition, unemployment, marital and family conflict).

GLOSSARY

absolutism The viewpoint that holds that cognitive processes are the same across the globe and that emphasizes the context-independent nature of psychological processes.

bias A generic name for potential sources of error in cross-cultural measurement; it refers to the presence of nuisance factors in cross-cultural measurement.

construct bias Bias that occurs when the construct measured is not identical across groups.

equivalence Comparability of test scores obtained in various cultural groups; it involves the question of whether scores obtained in various cultures can be compared in a meaningful way.

item bias A generic term for all disturbances at the item level.

measurement unit equivalence The type of equivalence that instruments show if their scales have the same units of measurement but a different origin (e.g., the Celsius and Kelvin scales in temperature measurement).

method bias A label for all sources of bias emanating from the method and procedure of a study, including factors such as sample incomparability, instrument differences, tester and interviewer effects, and the mode of administration.

relativism The viewpoint that holds that intelligence comes into existence in a specific cultural context and that psychological processes and culture are so closely linked that any attempt to compare these across cultures is futile.

scalar (or full score) equivalence The only type of equivalence that allows for the conclusion that average scores obtained in two cultures are different or equal; it assumes that identical interval or ratio scales are applicable across cultural groups.

structural equivalence When an instrument administered in various cultural groups measures the same construct in all of these groups.

universalism The viewpoint according to which basic cognitive processes are universal, although manifestations of these processes may well vary across cultures.

Comparing individuals from various cultures on psychological constructs, such as depression and intelligence, is more involved than comparing individuals from a single cultural group on the same constructs. This article describes the methodological background of such comparisons. It defines two key concepts: bias and equivalence. Bias is a generic term for potential sources of error in cross-cultural measurement due to the presence of nuisance factors. Equivalence refers to the comparability of test scores obtained in various cultural groups, addressing the question of whether scores obtained in different cultures can be compared in a meaningful way. The article discusses taxonomies of bias and equivalence and uses the assessment of personality and intelligence as an illustration.

1. CULTURE AND MENTAL MEASUREMENT

Suppose that we are interested in cross-cultural differences in the nature and levels of depression across cultures. Following Berry and colleagues, three approaches can be distinguished: absolutist, relativist, and universalist. A proponent of an absolutist (or etic) position would start from a validated instrument (usually developed in a Western culture) and would administer the instrument in other cultures. Depression is assumed to be a pan-cultural phenomenon, and instruments that were tried and tested in one culture presumably also work in other cultures. Differences in average scores of various countries on the scale are likely to be interpreted as pointing to country differences in depression. The only challenge to this interpretation would be the occurrence of response sets. For example, if there are strict norms in a culture not to disclose information about one's personal feelings to strangers, a depression inventory asking for reports about these feelings may give a poor rendering of the psychological status of the participant or client.

A proponent of a relativist (or emic) view is much less likely to take cross-cultural score differences at face value, as an absolutist does. Depression, like all psychological phenomena, is always expressed in a specific cultural way. Each culture has its own way of dealing with it, and we cannot expect invariance of symptoms and the accuracy of questionnaires developed in another culture. If we want to understand (and measure) depression, we should try to understand the culture and assume the culture's perspective on depression. Instruments are not assumed to travel well across cultures due to the close link between culture and psychological phenomena.

The intermediate view, called universalist, tries to combine both approaches by emphasizing that basic processes are universal but without ruling out the existence of culture-specific expressions of a particular phenomenon. It is an essential property of the universalist position that the (in)variance of behaviors and attitudes associated with an underlying construct (e.g., symptoms of depression) is not assumed but rather is open to empirical examination; cross-cultural studies should determine to what extent depression is pan-cultural, and questions used in Western cultures are relevant for the measurement of depression elsewhere. A universalist attempts to keep an open mind to all possible sources of cross-cultural differences and to verify or falsify specific interpretations of these differences.

It is proposed that an exclusive focus on either etic or emic measurement will not solve measurement issues in cross-cultural psychology. Instead, both are needed because they address different aspects of the same phenomenon; an etic measure focuses on the pan-cultural aspects, whereas an emic measure focuses on the culture-specific aspects. A universalist approach may offer the most fruitful approach to cross-cultural differences because it is the only approach that is sufficiently flexible to deal with the multiple ways in which cultural factors can affect mental measurement.

A good starting point for appreciating the universalist approach is provided by an overview of bias, a generic name for potential sources of error in cross-cultural measurement. The next two sections of the article discuss bias and equivalence (comparability of test scores); an overview of the concepts is provided in [Table I](#). The subsequent section gives a brief overview of the main findings in the cross-cultural studies of personality and intelligence. Conclusions are drawn in the final section.

2. BIAS

Bias refers to the presence of nuisance factors in cross-cultural measurement. If scores are biased, their psychological meaning is dependent on the culture in which they have been obtained. Differences between cultural groups in assessment outcome are due, at least to some extent, to cultural or measurement artifacts. For example, differences in scores on self-esteem obtained by Korean and American participants may be influenced by a norm of modesty, which is stronger in Korea than in the United States, and may be contaminated by social desirability.

2.1. Construct Bias

Construct bias occurs when the construct measured is not identical across groups; examples of sources of bias can be found in [Table II](#). Construct bias precludes the cross-cultural measurement of a construct with the same measure. An example can be found in work on filial piety, defined as the psychological characteristics associated with being perceived as a good son or daughter. The Chinese conception, according to which children are supposed to assume the role of caretaker of elderly parents, is broader than the Western concept, which is more restricted to showing love and respect. An

TABLE I
Definitions of Types of Bias and Equivalence

<i>Concept</i>	<i>Definition</i>
<i>Bias</i>	Nuisance factors that threaten the comparability of scores
Construct bias	Construct measured is not identical across groups
Method bias	Nuisance factors result from factors such as sample incomparability (sample bias), instrument characteristics (instrument bias), and tester effects and communication problems (administration bias)
Item bias	Nuisance factors are at the item level
<i>Equivalence</i>	Comparability of test scores across cultures
Construct inequivalence	Comparisons lack a shared attribute ("comparing apples and oranges")
Structural or functional equivalence	Instrument measures the same construct in all of the groups studied
Measurement unit equivalence ^a	Measurement scales have the same units of measurement but different origins (e.g., the Celsius and Kelvin scales in temperature measurement)
Scalar (or full score) equivalence ^a	Scores are fully comparable across cultures (same origin and measurement unit in all cultures); this does not imply that means are identical across cultures

^aAssumes interval- or ratio-level measurement in all cultures studied.

inventory of filial piety based on the Chinese conceptualization will cover aspects unrelated to the concept among Western individuals, whereas a Western-based inventory will leave important Chinese aspects uncovered. Construct bias can also be caused by differential appropriateness of the behaviors associated with the construct in the different cultures. Depression is often taken to consist of somatic aspects (e.g., loss of appetite, sleeplessness) and psychological aspects (e.g., loss of motivation, pessimism). Cross-cultural studies show that the psychological symptoms usually show up as a single cluster, whereas the somatic symptoms do not

always form a single cluster or do not form a cluster that is related to the somatic symptoms.

2.2. Method Bias

Method bias is a label for all sources of bias emanating from the method and procedure of a study, including factors such as sample incomparability, instrument differences, tester and interviewer effects, and mode of administration. There are three types of method bias: sample bias, administration bias, and instrument bias. The first type, sample bias, refers to confounding sample differences. Research on the cognitive differences between literate and illiterate individuals, for example, has been plagued by sample bias because a comparison of literates and illiterates is nearly always a comparison between schooled and unschooled persons. So, a study of the influence of literacy almost inevitably becomes a study of the influence of schooling. A few studies have been carried out in cultures where literacy in a local script is transmitted in other than school settings. It is interesting to observe that these studies (which successfully avoided sample bias) found smaller differences between literates and illiterates than did the older studies in which schooled and unschooled individuals were compared. Sample bias tends to increase with the cultural distance between the samples.

Administration bias, the second source of method bias, can be caused by differences in the procedures or mode used to administer an instrument. For example, when interviews are held in participants' homes, physical conditions (e.g., ambient noise, presence of others) are difficult to control. Participants and clients are more prepared to answer sensitive questions in (anonymous) self-completion questionnaires than in the "shared" discourse of an interview. Another source of administration bias is ambiguity in the questionnaire instructions and/or guidelines or a differential application of these instructions (e.g., answers to open questions are considered to be ambiguous and require follow-up questions). The effect of test administrator or interviewer presence on measurement outcomes has been studied empirically. Larger effects have been found in interview studies of attitudes than in standardized testing of cognitive abilities. Deference to the interviewer has been reported; participants were more likely to display positive attitudes to a particular cultural group when they were interviewed by someone from that group. A final source of administration bias is constituted by communication problems between the

TABLE II
Sources of Bias in Cross-Cultural Assessment

Type of bias	Source of bias
Construct bias	<ul style="list-style-type: none"> • Only partial overlap in the definitions of the construct across cultures • Differential appropriateness of the behaviors associated with the construct (e.g., skills do not belong to the repertoire of one of the cultural groups) • Poor sampling of all relevant behaviors (e.g., short instruments) • Incomplete coverage of all relevant aspects/facets of the construct (e.g., not all relevant domains are sampled)
Method bias	<ul style="list-style-type: none"> • Incomparability of samples (e.g., caused by differences in education or motivation)^a • Differences in environmental administration conditions, either physical (e.g., recording devices) or social (e.g., class size)^b • Ambiguous instructions for respondents and/or guidelines for administrators^b • Differential expertise of administrators^b • Tester/Interviewer/Observer effects (e.g., halo effects)^b • Communication problems between respondent and tester/interviewer (including interpreter problems and taboo topics)^b • Differential familiarity with stimulus material^c • Differential familiarity with response procedures^c • Differential response styles (e.g., social desirability, extremity scoring, acquiescence)^f
Item bias	<ul style="list-style-type: none"> • Poor item translation and/or ambiguous items • Nuisance factors (e.g., item may invoke additional traits or abilities) • Cultural specifics (e.g., incidental differences in connotative meaning and/or appropriateness of the item content)

^bAdministration bias.

^cInstrument bias.

tester and the participant or client. Language problems may be a potent source of bias when, as is not uncommon in cross-cultural studies, a test or an interview is administered in the second or third language of one of the parties involved.

The third source of method bias is instrument bias, which involves general features of an instrument that lead to unintended cross-cultural differences. Individuals from various cultures do not deal in the same way with Likert-type rating scales such as 5- or 7-point scales for assessing agreement. For example, Hispanics have been found to show more extreme scores than have European Americans on a 5-point scale but not on a 10-point scale.

In addition to the construct and the method, items can be the source of bias. Item bias, also known as differential item functioning, is a generic term for all disturbances at the item level. According to a definition that is widely used in psychometrics, an item is biased if respondents who have the same standing on the underlying construct (e.g., equally intelligent), but who

come from different cultures, do not have the same mean score on the item. For instance, if a geography test administered to pupils in Poland and Japan contains the item "What is the capital of Poland?" Polish pupils can be expected to show higher scores on this item than can Japanese students, even when pupils with the same total test score are compared. The item is biased because it favors one cultural group across all test score levels. Several psychometric techniques are available to identify item bias. The most common sources of item bias are poor item translation, ambiguities in the original item, low familiarity or low appropriateness of the item content in certain cultures, and the influence of cultural specifics such as nuisance factors or connotations associated with the item wording. For example, in a translation of the American word "aggression," it is difficult or even impossible to maintain the combined meaning of violence (e.g., "an aggressive predator") and enterprising energy (e.g., "an aggressive salesperson") of the original.

3. EQUIVALENCE

Equivalence refers to the comparability of test scores obtained in various cultural groups. It involves the question of whether scores obtained in different cultures can be compared in a meaningful way. Equivalence and bias are related. If scores are unbiased (free from nuisance factors), they are equivalent and can be compared across cultures.

Four different types of equivalence can be distinguished: construct inequivalence, structural equivalence, measurement unit equivalence, and scalar equivalence. Construct inequivalence amounts to “comparing apples and oranges.” Many examples of inequivalent constructs can be found in the clinical literature on culture-bound syndromes. For example, “Latah,” a syndrome that can be found only among some Asian groups, consists of a sudden fright, resulting in uncontrollable imitative behaviors (e.g., verbal repetition of obscenities).

An instrument administered in various cultural groups shows structural equivalence if it measures the same construct in all of these groups. Statistical techniques, notably factor analysis, are employed to examine structural equivalence. If an instrument yields the same factors in various cultural groups, there is strong evidence that the instrument measures the same underlying construct(s). Structural equivalence does not presuppose the use of identical instruments across cultures. For example, a depression measure may be based on partly or entirely different indicators in each cultural group and still show structural equivalence. Structural equivalence has been addressed for various cognitive tests and personality measures.

The third type of equivalence is measurement unit equivalence. Instruments show this type of equivalence if their scales have the same units of measurement but different origins (e.g., the Celsius and Kelvin scales in temperature measurement). This type of equivalence assumes interval- or ratio-level scores (with the same measurement units in each culture). It applies when a source of bias with a fairly uniform influence on the items of an instrument affects test scores of various cultural groups in a differential way. Social desirability and stimulus familiarity may exert this influence. If these factors have a differential influence on the scores obtained in various cultural groups, observed score differences are hard to interpret due to the confounding of valid score differences and measurement artifacts. Empirical research shows that the role of response sets (in personality and attitude measurement) and stimulus

familiarity (in cognitive testing) cannot be neglected. For example, there are country differences in social desirability; more specifically, because social desirability is inversely related to national wealth and educational level, individuals who come from richer countries or who are better educated tend to show lower scores on social desirability.

Only in the case of scalar (or full score) equivalence can direct comparisons be made using statistical tests such as the *t* test and analysis of variance (ANOVA). This is the only type of equivalence that allows for the conclusion that average scores obtained in two cultures are different or equal. Scalar equivalence assumes that identical interval or ratio scales are applicable across cultural groups.

Structural, measurement unit, and scalar equivalence are hierarchically ordered. The third type presupposes the second type, which presupposes the first type. As a consequence, higher levels of equivalence are more difficult to establish. It is easier to verify that an instrument measures the same construct in various cultural groups (structural equivalence) than to identify numerical comparability across cultures (scalar equivalence).

4. CULTURAL FACTORS IN THE ASSESSMENT OF PERSONALITY AND INTELLIGENCE

There are various examples of emic models of personality. These do not provide a pan-cultural view of personality but rather try to describe personality in a specific cultural context as accurately as possible. For example, Sow developed a model of African personality in which personality consists of various layers. Important elements in the model are spirituality and the role of ancestors and the extended family. Doi described a Japanese model of personality in which “*amae*” plays an important role. *Amae* refers to “indulgent dependency” and the passive love and dependence that find their origin in the love of mother and child and that form the template of relationships later in life. Because these studies are not comparative, bias and equivalence might not seem to be an issue. However, from a slightly more distant perspective, these studies address the bias in Western models because they indirectly show where Western models of personality fall short. It is suggestive that in both models (as well as in other non-Western models of personality), social and relational aspects of personality play a more central role than is common in Western models of personality.

A few Western-based personality inventories have been administered in many countries. A notable one is the Eysenck Personality Inventory. According to Eysenck, personality consists of three aspects: neuroticism, psychoticism, and extraversion. The inventory, used to assess these factors, shows these three factors with remarkable consistency. The factors underlying the instrument tend to be stable, indicating that the structural equivalence of the instrument is good. Another currently popular personality instrument is based on the Five-Factor Model of personality. Extensive research has shown that the five factors in this model that are assumed to underlie personality (Extraversion, Neuroticism, Agreeableness, Conscientiousness, and Openness) are remarkably consistent across cultures. However, studies of the measurement unit equivalence of the scales tend to produce more ambiguous results. Statistical tests (e.g., confirmatory factor analysis) do not provide clear support for measurement unit equivalence, but it is unclear to what extent this problem is due to the high sensitivity of the statistical tests employed to test the equivalence or to real differences in the measurement unit across cultures.

It can be concluded that cross-cultural research on personality has shown that the Western models can claim a broader generality than their cultural contexts of origin. Structural equivalence is strongly supported. It should be noted that studies have been restricted to schooled populations, so it is still unclear to what extent these results also apply to illiterates. It is still unclear to what extent non-Western theories and models could add other universal factors. Recent studies suggest that the Five-Factor Model of personality may be incomplete. Researchers from Hong Kong found a sixth factor, Interpersonal Relatedness, in China and replicated its existence in a Fijian sample. If new factors emerge and it turns out that Western models are incomplete, it is likely that the new factors will be located in the social and relational domains.

The domain with probably the most widely documented cross-cultural research is intelligence. Standard (Western) intelligence tests have been administered in a wide variety of cultures. In many multicultural societies, these tests have been administered to majority group members and usually at least one of the larger ethnic minority groups. Instruments such as Raven's Progressive Matrices and the Wechsler intelligence scales for adults and children have been found to reveal a remarkably stable factor structure across cultures, supporting the structural equivalence of intelligence as measured by these tests.

Statistical tests of measurement unit and full score equivalence of intelligence test scores tend to produce more ambiguous results. It is often difficult to decide whether equivalence in a given case is scalar equivalence or measurement equivalence. For example, the debate about ethnic differences in cognitive test performance can be largely seen as focusing on the level of equivalence of cross-cultural score comparisons and on the presence of biasing factors (notably method bias). For example, Herrnstein and Murray argued that when appropriate intelligence tests are used, cross-cultural differences in test performance reflect valid intergroup differences and show full scalar equivalence. The implication is that group differences in the intelligence test scores reflect differences in intellectual abilities, whereas group differences reflect mainly (or exclusively) method bias in the reasoning of their critics. Many of these critics argue that common intelligence tests show problems such as differential familiarity and that this method bias will allow only measurement unit equivalence.

Despite the disagreement about the higher levels of equivalence of cognitive test scores, cross-cultural studies show that it is very unlikely that intellectual processes are fundamentally dissimilar in various cultures. The findings are not supportive of theories that hold that different cultures produce their own kinds of intelligence; instead, they are more supportive of theories according to which cultures can shape the same set of human cognitive processes in a differential way. However, recent cross-cultural work points to another possible one-sidedness of Western tests. These tests tend to focus on two aspects of intelligence: reasoning and memory. Implicit theories of intelligence have been investigated in a number of countries by asking participants which characteristics they associate with intelligence. Social aspects are nearly always found to be important, yet social intelligence is not part of all intelligence tests. It is interesting to note that the social domain has also been mentioned in relation to personality research as an area where expansion of Western models might be needed to accommodate non-Western models.

Thus, cultural factors affect mental measurement in various ways. Some of these factors, such as a poor item translation, may be artifactual. Other factors, however, are more basic and may refer to problems with the whole instrument or even with the concept measured by the instrument. It is clear that methodological and substantive considerations cannot be separated when dealing with cultural factors in mental measurement. Knowledge of both mental measurement and the culture

being dealt with is essential in establishing quality in cross-cultural mental measurement.

role modeling The protégé's interest in modeling himself or herself after the mentor.

separation When the mentoring relationship changes after the cultivation period; typically, the protégé becomes more independent and is less needing of the mentor's career assistance.

sponsorship When the mentor nominates the protégé for promotions and/or important lateral moves either verbally or simply by association with the mentor.

GLOSSARY

acceptance and confirmation The feeling that both parties (mentor and protégé) have toward each other whereby they feel comfortable in expressing their views.

challenging tasks The demanding or stimulating work assigned by the mentor, who gives feedback to help the protégé grow on the job.

coaching The career advice provided by the mentor to the protégé; the mentor suggests strategies and tactics for accomplishing work objectives and reaching career goals.

cultivation When career and psychosocial functions are enhanced during the 2 to 5 years after the mentoring is initiated.

initiation When the mentoring relationship begins to develop during the first year; both the mentor and protégé see it as mentoring.

redefinition The phase after the separation phase when the mentoring relationship may end or change qualities (e.g., the protégé becomes more like a peer).

Mentoring refers to a developmental relationship that exists between two persons, typically a more experienced senior person and a less experienced junior person. The mentoring relationship can also exist among peers or others within and outside an organization. Most mentoring relationships develop according to four phases: initiation, cultivation, separation, and redefinition. Mentors serve two primary functions: fostering career development of their protégés and providing psychosocial support. Numerous benefits have been reported from mentoring relationships for both mentors and protégés as well as for the organization.

1. DEFINITION OF MENTORING

Traditionally, mentoring has been defined as a developmental relationship that occurs between a more experienced senior employee and a less experienced junior employee. This involves a single dyadic relationship that often exists within one organization. However,

given the changing nature of organizations today (e.g., use of more project teams, flatter organizational structures), mentoring relationships are also formed among peers within and outside the organization. Mentoring generally consists of a close relationship between two people, with the primary goal of helping one of them (i.e., the protégé) develop in his or her career. This enables the protégé to address career challenges and take advantage of opportunities to grow on the job. In addition, the relationship is often a mutually enhancing one given that the mentor also receives some benefits (e.g., protégé support, work done by the protégé).

2. FUNCTIONS PROVIDED BY MENTORS

It is commonly accepted that mentors serve two basic types of functions to protégés: career development and psychosocial support. These are described in the following subsections.

2.1. Career Development

Career development refers to those aspects of the relationship that enhance the protégé's career advancement or growth. The mentor is able to help the protégé due to the mentor's experience, organizational rank, and/or influence in the organization. As a result of these functions, the protégé is often able to learn the "ropes" of the organization, gain exposure, and obtain promotions more quickly. In fostering career development, the mentor may serve any of the following roles:

- *Sponsorship*. The mentor nominates the protégé for promotions and/or important lateral moves either explicitly or simply by association with the mentor. The mentor opens doors and makes connections for the protégé that will advance his or her career.
- *Exposure and visibility*. The mentor gives the protégé opportunities to interact with senior managers or other important people through either written proposals or oral presentations. By initiating relationships with other key people, the protégé becomes visible to them and gains access to future opportunities.
- *Coaching*. The mentor provides career advice to the protégé and suggests strategies and tactics for accomplishing work objectives and reaching career goals. The mentor might provide feedback on assignments and offers ideas to improve work. In addition, the mentor helps the protégé to know who the key players are in the organization

and describes strategies for working with them successfully. Essentially, the mentor teaches the protégé the ropes for how to be successful in the organization.

- *Protection*. The mentor guards the protégé from potentially damaging conflicts or problems with others. The goal is to protect the protégé's reputation from harm. Thus, the mentor might take the blame for mistakes that are beyond the protégé's control or might act as a buffer. The mentor might limit the protégé's exposure to senior people if the mentor believes that the protégé is not experienced enough to meet with them.
- *Challenging tasks*. This usually refers to mentoring provided by a manager to a subordinate. The manager assigns demanding or stimulating work and gives feedback to help the protégé grow on the job. The mentor could also place the protégé on various project teams to help expand the latter's knowledge and skills.

2.2. Psychosocial Support

Psychosocial support refers to those aspects of the relationship that enhance the protégé's competence, identity, self-worth, and effectiveness in a professional role. The close interpersonal relationship that exists between the mentor and the protégé encourages the development of trust and intimacy and enables the various roles to be fulfilled. These include the following:

- *Counseling*. This refers to the mentor serving as a sounding board to the protégé so that the latter can share with someone who will listen to his or her concerns and doubts about self, work, and family. The mentor provides empathetic listening and serves as a confidant or as someone who provides advice and encouragement.
- *Acceptance and confirmation*. This refers to the feeling that both parties (mentor and protégé) have toward each other that allows them to feel comfortable in expressing their views. The feeling of acceptance by the mentor enables the protégé to feel that he or she can try new things and speak candidly. The mentor shares positive feedback that he or she has heard about the protégé. The mentor sends encouraging messages (e.g., e-mail, phone) to the protégé to help him or her deal with pending challenges.
- *Friendship*. The mentor and protégé spend time together in a nonwork setting or in leisure activities or more relaxed settings (e.g., meals, sports, outings).
- *Role modeling*. This refers to the protégé's interest in modeling himself or herself after the mentor. In this case, the protégé has great respect and admiration for the

mentor and identifies with him or her. The protégé tries to emulate the mentor's relationships with others or the ways in which the mentor works on tasks. The mentor explains what he or she is doing and why. This is so common among mentors and protégés that some researchers consider it a third (separate) function in addition to career development and psychosocial support.

3. PHASES IN MENTORING RELATIONSHIPS

Mentoring relationships typically develop according to four phases: initiation, cultivation, separation, and redefinition.

1. *Initiation.* During the first year, the relationship begins to develop and the mentor and protégé both see it as becoming a mentoring relationship. The mentor provides career development (e.g., coaching, visibility) and some psychosocial support (e.g., role modeling). Typically, both individuals sense a feeling of excitement and challenge as they begin to work together. The protégé feels that someone is assisting him or her, and the mentor feels that he or she is taking on someone to groom, develop, and coach.

2. *Cultivation.* During the next 2 to 5 years, the career and psychosocial functions are enhanced. The mentor and protégé both benefit from the relationship and develop a stronger connection. However, not all mentoring pairs will develop in the exact same way. It depends on the needs and interests of the mentor and protégé. In general, both parties view this period in a positive light.

3. *Separation.* In general, after the cultivation period, the relationship changes. Typically, the protégé becomes more independent and is less dependent on the mentor for career assistance. If the protégé has achieved the same organizational level as the mentor, this limits the opportunities that the mentor can provide. In addition, if the mentor experiences job obsolescence or plateauing, this limits the type of career support that he or she can provide to the protégé. Similarly, if the individuals are no longer working at the same geographical location or in similar industries, they might drift apart. During the separation phase, there may be some feelings of sadness or confusion as the relationship ends or changes.

4. *Redefinition.* After the separation phase, the relationship may end or change qualities. For example, the protégé and mentor may become more like peers, and

they may redefine their relationship as being more of a friendship. There may be some ambivalence and discomfort as they alter their relationship. At the same time, the protégé may feel a great sense of self-confidence and autonomy by "making it" to the next level.

4. OUTCOMES OF MENTORING

Research has indicated numerous positive benefits associated with mentoring for the protégé, the mentor, and the organization. These are described in the following subsections.

4.1. Benefits for the Protégé

The mentoring relationship enhances the protégé's personal and professional development, including subjective and objective indicators of career success. Through enhanced career opportunities (e.g., by sponsorship, by exposure and visibility), the protégé acquires critical learning experience that helps him or her to be able to demonstrate competence on the job. The protégé also gains an appreciation for the informal networks and political processes in the organization. This has typically led to greater career progress, faster promotion rates, and greater career satisfaction. It has been well documented that, when comparing individuals who had mentors with those who did not, protégés report significantly less work-family conflict, greater job satisfaction, greater salary growth, lower turnover intentions, and greater perceived career success. They also have greater socialization into the organization by gaining valuable information about the firm's practices.

4.2. Benefits for the Mentor

The mentor also reaps benefits from the mentoring relationship. By sponsoring the protégé for important positions or promotions in the organization, the mentor also gains. If the protégé is successful, others view the mentor as having made the right choice, and this enhances the mentor's credibility in terms of finding and developing talent in the organization. In addition, if the mentor's views are adopted by the protégé, this ensures that the mentor's perspectives will be carried forward in the organization for the future. By providing challenging work to the protégé and delegating to him or her, the mentor gains valuable technical assistance and support that enables him or her to be able to work

on other projects. In addition, the mentor has the loyalty of the protégé and is often kept informed by him or her about new work developments that facilitate the mentor's job performance. The psychosocial support that the mentor provides to the protégé also makes the mentor feel important and valued. If the protégé looks up to the mentor and tries to emulate him or her, this makes the mentor feel respected and appreciated in the workplace. If the mentor is asked to serve as a confidant or "counselor," this may make the mentor feel helpful and enhance his or her feelings of accomplishment. The mentor's satisfaction may also increase due to helping a less experienced colleague.

4.3. Benefits for the Organization

The organization also benefits from the mentoring relationship. In fact, of the rated "100 best companies to work for" in the United States each year, the majority indicate that they have established formal mentoring programs. One benefit to the organization is that protégés are better socialized into the corporate culture because mentors spend time teaching them the ropes. This means that protégés learn about the organization's values and performance metrics more quickly. In addition, mentoring is also related to lower protégé turnover intentions. This higher retention can save the firm considerable money and time that would have been spent recruiting new employees.

5. CHALLENGES WITH MENTORING RELATIONSHIPS FOR THE ORGANIZATION

There are a number of challenges associated with having a formal or informal mentoring program in the organization. Some of these are described in the following subsections.

5.1. Role Modeling Identification

As noted earlier, one important component of mentoring relationships is the degree to which the protégé identifies with the mentor. In some cases, this may be relatively easy due to similar backgrounds or life experiences. In other cases, it may be more problematic. For example, research has indicated some potential problems with the mentoring relationship where the mentor and protégé differ in their gender or race. In both cases, there may be

difficulties with the protégé being able to identify with the mentor and vice versa. For example, a female protégé who has children and is trying to balance work and family may have some trouble relating to an older male mentor who has a wife who takes care of all of the family issues. Likewise, the female protégé's experiences in being given stereotypical tasks may be difficult for her male mentor to understand. Thus, a female protégé may get more support from a female mentor who has experienced similar life and career issues. Interestingly, male protégés often are also better able to identify with role models of the same gender. Consequently, the outcomes that protégés may reap from mentoring relationships may differ depending on whether they are in cross-gender or same-gender mentoring relationships. Similarly, an African American protégé who is placed on numerous committees at work to make sure that there is "diversity of views" may have difficulty in expressing his or her concerns to a White mentor who has never had to deal with tokenism issues. Generational differences in values and concerns may also make it more difficult for protégés to relate to mentors in the organization. For example, "Generation X" protégés who are more concerned with leisure and family pursuits may have more difficulty in identifying with the serious work ethic of their "baby-boomer" mentors.

5.2. Perceptions by Others of the Mentoring Relationship

In some cases, there are no problems with the mentoring relationship, yet others' perceptions may cause problems. For example, with a cross-gender relationship, others may make false assumptions about the nature of the relationship (i.e., assuming it is personal/sexual). This might force the mentor and protégé to curb their social activities (e.g., having lunch, playing golf) and, thus, limit the extent to which psychosocial support or friendships can be nurtured. Consequently, they may limit their interactions to a professional or work setting only. In addition, a cross-gender relationship might cause rumors to fester about why the protégé was given various opportunities. Peer resentment and public scrutiny might force the protégé and mentor to deal with new issues and dilemmas.

5.3. Establishing Formal Versus Informal Relationships

Formal mentoring relationships are those established by the organization. Typically, mentors and protégés

are matched up based on some criteria such as similarity of interests and experiences. In contrast, informal mentoring relationships evolve spontaneously and without a formal mandate. Either the mentor or the protégé seeks the other one out or they both initiate the relationship. These informal relationships are considered to be voluntary, whereas formal mentoring is considered to be prescribed by the organization. In general, research has indicated that informal mentoring results in more benefits (e.g., greater support), possibly due to the closer bonds that are formed in the relationships. Yet having formal assigned relationships ensures that everyone receives some type of mentoring. Thus, the challenge for the organization is to design effective formal relationships while still facilitating the development of informal relationships.

5.4. Risks Associated with Mentoring

There may be risks associated with mentoring someone in the organization. For example, a mentor who sponsors or provides exposure and visibility to a protégé who performs poorly in front of senior managers might make the mentor look bad (i.e., the mentor's judgment in picking this person may be called into question). In addition, a mentor who is overly protective of a protégé by holding him or her back from potential opportunities can limit the career advancement of the protégé. Research has indicated that this is more likely to happen in relationships where the mentor and protégé are of a different gender or race. A senior White male mentor might be worried about showing off a female or African American protégé because he assumes that the protégé will be watched very closely and that if he or she does not do well, it will reflect poorly on the mentor. This may keep the protégé from developing critical learning experiences to grow on the job. When establishing mentoring relationships in the organization, it is important to train mentors and protégés on what their roles should be in these relationships and on what obstacles they may encounter and how to deal with them.

5.5. Dysfunctional Mentoring Relationships

Often, the assumption is that all mentoring relationships are positive or of high quality during all phases of development. Recent research has shown that this is not the case. Sometimes, mentoring relationships can

be dysfunctional or only marginally effective. For example, cases have been reported where protégés receive assistance that actually derails their careers. In other cases, there are instances of deception, sabotage, harassment, bullying, jealousy, gamesmanship, and/or poor performance by either mentors or protégés. More research is needed to further define the types of behaviors that are considered dysfunctional and their implications for protégés, mentors, and the organization. In addition, strategies to address these problems and enhance the quality of the mentoring relationship need to be defined.

6. SUGGESTIONS FOR IMPROVING MENTORING RELATIONSHIPS IN THE ORGANIZATION

6.1. Make Sure That Everyone Has Access to Mentoring

Research indicates that not everyone has equal access to mentoring, yet given its importance for the success of protégés, the organization should ensure that everyone can have mentors. Creating opportunities for social activities and cross-functional work teams can facilitate the development of informal mentoring relationships. In addition, the formation of formal mentoring relationships can ensure that everyone is assigned to a mentor. The use of mentoring circles to bring multiple senior people together with several junior or mid-level people can enable a diverse group of individuals to work together.

6.2. Encourage Individuals to Establish Multiple Mentoring Relationships

Protégés should form relationships with several mentors and not rely solely on one mentor to fulfill all career and psychosocial functions. Sometimes, aligning with only one mentor can prove to be troublesome if protégés are required to follow only that one person's ideas and advice. This gives protégés only one perspective on how to be successful. It would be more advantageous if they formed alliances with several mentors at various points in time. It has been shown that professionals with multiple sources of mentors have higher levels of career success and feelings of career satisfaction than do those with only a single mentor or with no mentor at all. In fact, research on successful Black

executives indicates that they draw on multiple sources for mentoring rather than rely on a single mentor. It is also important for mentors to form relationships with several protégés. This enables them to gain support and technical assistance from multiple sources and also reduces charges of favoritism.

6.3. Establish a Culture That Encourages Mentoring Relationships

Mentoring requires time to develop productive relationships. An organization that rewards individuals for developing each other (based on the performance management and incentive systems) will enable mentoring to flourish. However, a firm that focuses only on “bottom line” results and has no incentives for employees to spend time assisting others will discourage mentors from taking on protégés. Likewise, establishing formal social opportunities (e.g., lunches, celebrations) and work activities (e.g., teams) will enable the formation and growth of informal developmental relationships, some of which could lead to mentoring relationships. The organization should also support individuals’ efforts to establish relationships outside of the firm. This is particularly important given the trend today for employees to work at a variety of organizations rather than just one firm during their lifetimes.

7. NEW DIRECTIONS FOR MENTORING RESEARCH

There is considerable research in the field of mentoring today. Some of the current topics for investigation were described previously, and other ideas for future research are listed in the following subsections.

7.1. Clarify the Mentoring Construct

Traditionally, mentoring referred to a single dyadic relationship between a senior person and a junior person. This made mentoring relatively easy to study because it was clearly defined in this manner. Recently, many new ideas have been generated about what mentoring refers to within the broader array of developmental relationships and networks that people form. As such, the degree to which mentoring differs from coaching, support groups, advising, and counseling needs to be better explicated.

7.2. Examine Alternative Forms of Mentoring

Although it has always been suggested that mentoring can take a variety of forms, during the past few years, researchers have encouraged more investigation into these different types of relationships. Future work should examine the nature of peer relationships as well as other developmental networks. It seems clear that people use a variety of relationships to gain both career and psychosocial assistance, yet more research is needed to understand how they develop these relationships and what benefit these relationships have for protégés and mentors over time.

7.3. Explore Mentoring for Diverse Types of Employees

Today’s rapid changes in technology and organizational structures, as well as the emergence and decline of companies, open up new challenges for workers trying to get ahead or stay marketable. Research is needed to study mentoring among some of these workers.

7.3.1. Cross-Generations

Given differences in the values and work ethic among employees of various generations, it seems important to view what cross-generational mentors and protégés are looking for in these relationships. Do mentor-protégé pairs from different generations have unique obstacles and difficulties? If so, how can these be addressed?

7.3.2. Free Agent Workers

These refer to independent employees whose goal is to be marketable and flexible enough to move where the opportunities present themselves. Research is needed to determine the type of mentoring they need and seek. Compared with traditional workers, are they more inclined to seek mentoring from a variety of sources and networks?

7.3.3. Entrepreneurs

With the greater numbers of new business start-ups, especially among women, it will be increasingly more important to examine the types of assistance and mentoring that are needed to help them be successful.

7.3.4. Global Workforce

As firms continue to “go global,” it is important to examine the type of career counseling, mentoring, and training that employees need to be successful in international assignments. For example, research has indicated that mentoring for women managers in international assignments is critical for their career success. What type of mentoring is needed, and how does it differ depending on the global assignment?

8. CONCLUSION

Mentoring involves a developmental relationship between two people that has benefits for the mentor, the protégé, and the organization. The career and psychosocial support that are given to the protégé enhance the personal and professional development of all parties involved. Although generally positive in nature, these relationships occasionally encounter difficulties and/or obstacles. With effective support and training provided from the organization, some of these issues can be better managed. Future research is needed to examine the underlying dynamics and processes involved in the mentoring relationship.

GLOSSARY

cognitive architecture Provides a broad theory of cognitive capabilities and limits; when operationalized in Adaptive Control of Thought (ACT-R) or Soar, it provides a high-level programming language for simulating human cognition that includes many of the cognitive limits and constraints that guide human performance.

concurrent real-time model A model that generates output in parallel with driver behavior; this type of model may make it possible to infer driver state and intention when it is not possible to measure these variables directly.

driving performance The description of the driver and vehicle trajectory relative to important performance limits such as lane boundaries and speed limits; typical driving performance metrics include lane deviation, steering wheel reversals, speed variation, and brake reaction time.

driving safety The description of the likelihood of an event that compromises driver safety; typical driving safety metrics include crashes per million miles driven, injuries

per million miles driven, and fatalities per million miles driven.

process model A model that predicts not only the outcome but also the response process that generates the outcome; this type of model is based on theoretical principles that go beyond the data used to develop the model.

product model A model that produces an output for given inputs but does not describe the causal links between the inputs to the model and the output; this type of model is typically based on interpolation of experimental data using linear regression, lookup tables, and neural nets.

Driver performance models can help to develop safe in-vehicle information systems by helping to coordinate experiments, evaluate systems, and modulate information flow. This article describes the dimensions of model purpose, scope, and transparency and then uses them to identify how several specific models may help to develop in-vehicle technology. As in-vehicle technology becomes increasingly complex and adaptive, driver performance models may need to address the effect of driver attitudes and preferences on behavior. This brief overview of four modeling approaches demonstrates some of the trade-offs in developing models of driver performance.

1. INTRODUCTION

This article focuses on models of driver performance that might address the challenges of integrating technology into the driving environment. Models of driver

performance can support evaluation of in-vehicle technology in several ways. First, models make it possible to examine design options before the systems are actually implemented. In this way, design concepts can be explored without the expense of developing prototype systems. Second, models can support extrapolation beyond experimental data. Experiments typically identify the relative merit of two to eight design options, whereas designers might need to understand the merit of hundreds of design options. Models can be used to estimate the merit of the design options that are not included in the experiments. Also, although catastrophic failures such as crashes are very rare and are unlikely to occur in an experiment, it may be important to understand how design parameters affect the frequency of those events. Models can help to extrapolate from measures of driving performance to measures of driving safety. For example, a model might help to translate measures of performance (e.g., lane deviations) to a measure of safety (e.g., accident rates per million miles driven). Beyond evaluating systems, models of driver performance can also play a useful role in the in-vehicle information systems themselves. Real-time models of driver capabilities can be used to modulate the information flow to the driver. In this way, a driver performance model can help to manage the flow of information so that it is consistent with the perceptual and cognitive limits of the driver.

These benefits of driver performance models are balanced by the challenges of developing such models. Fortunately, substantial research has focused on developing models of driver performance. For some applications, these models can be adapted and used without the cost of developing new models. Unfortunately, there is a great diversity of driver performance models, and understanding whether a particular model meets the needs of a particular evaluation is often unclear. This article describes the dimensions of model purpose, scope, and type and then uses these dimensions to describe how several specific models might be modified to address the demands of evaluating in-vehicle technology.

2. MODEL PURPOSE

Every model is created for a purpose. The purpose for which a model is developed has a major influence on the range of applications for which the model can generate useful results. The wide range of purposes of driver performance models demonstrates the challenge of finding a model capable of meeting the needs of

a particular application. Driver models have been developed to investigate vehicle dynamics, suspension, and handling characteristics. They have also been developed to support the design of roadway geometry. Recently, models have also been developed to address driver response to in-vehicle technology such as warning systems and the visual and cognitive demands on in-vehicle information systems. Another class of models has been developed to address the safety implications of personality variables and their influence on driving behavior. For example, researchers have created statistical models that link risk-taking tendencies to driving safety. Others have created statistical models that predict accident involvement based on cognitive and perceptual deficits such as the driver's effective field of view.

3. MODEL SCOPE

Driving is a complex multifaceted task that has been modeled in many ways. For example, traffic models have been developed to describe the combined behaviors of many drivers. These models of traffic behavior play a critical role in understanding the effectiveness of in-vehicle technology aimed at traffic management and congestion reduction. Some models of traffic behavior describe driver behavior only at the aggregate level. These models often represent macro-level behavior by using principles of fluid dynamics to describe traffic flow. Other models of traffic behavior rely on micro-level description of the decision-making and response patterns of individual drivers that make up the traffic.

Beyond models of traffic flow, many models have been developed to describe the behavior of individual drivers. These models range from those that describe the entire range of driving activities to those that describe a small subset of activities (e.g., steering behavior for lane keeping) or a small subset of driving scenarios (e.g., response to rear-end collision situations). Michon defined three levels of driver activity: vehicle control (e.g., speed control, lane position), tactical maneuvering (e.g., speed choice, turn choice), and strategic decisions (e.g., choice of route, decision to initiate a trip). These three levels define qualitatively different types of behavior that might be included in a model. Models that address strategic decisions, such as route choice and trip timing, are often represented as statistical choice models. These model results provide important information for both marketing and design of in-vehicle information systems. Most models do not

combine a representation of strategic behavior with a representation of vehicle control or tactical maneuvering.

4. MODEL TYPE

In addition to distinguishing among models based on the scope of activities that they address, models can be distinguished based on whether they describe the driver's response process or just the outcome of that process. Models that describe only the outcome or product associated with a driving technology tend to be static models that pair an outcome with a set of inputs. More sophisticated static product models can combine many variables to predict driver performance in a wide range of situations; however, product models do not describe the causal links between the inputs to the model and the output. In contrast, a process model not only predicts the outcome but also specifies the response process that generates the outcome. In other words, process models are based on theoretical principles, whereas product models are based on interpolation, lookup tables, and curve fitting. Process models tend to be dynamic in that they take time-varying inputs and generate time-varying outputs. One benefit of process models is that they can predict driver responses over a range of conditions not included in the data used to create the models. Another benefit is that process models tend to make assumptions explicit. Rather than drawing on data that embody hidden assumptions, process models make assumptions easy to see because they are explicitly coded into the algorithms. Although dynamic process models have many advantages, they are not always feasible. In many cases, theory may be lacking, making it impossible to construct a process model. In addition, process models are often more complex, and the underlying mathematics may be less understandable. In contrast, product models have the advantage of providing simple solutions to complex problems. The cost of these simple solutions is the uncertainty regarding their accuracy and underlying assumptions.

5. EMERGING MODELS OF DRIVER PERFORMANCE

Several recent modeling efforts demonstrate the potential of driver models to address important questions regarding driver performance and vehicle design. The

following discussion of these models does not present a complete survey of driver models but instead represents a sample of the more promising developments. In addition, these models illustrate the distinctions of model purpose, scope, and type that are important for developing a modeling strategy.

Table I summarizes the three models, showing three distinctly different approaches to modeling driver performance. The first model, the Driver Performance Model (DPM), is an ambitious attempt to model the dynamics of driver behavior. This process model produces a time history of vehicle position and speed as well as a time history of driver state. The second model, Design Evaluation and Model of Attention Demand (DEMAND), is a comprehensive product model that identifies a level of demand associated with a task performed with an in-vehicle information system such as entering a destination for a route navigation system using a touch screen. The third model, the Attention-based Rear-end Collision Avoidance Model (ARCAM), is a much less ambitious process model that generates a time history of a driver's response to the very specific scenario of emergency braking to avoid an imminent rear-end collision. The following discussion also briefly addresses the potential of general cognitive architectures to act as a foundation for a driver performance model.

6. DRIVER PERFORMANCE MODEL IN THE INTERACTIVE HIGHWAY SAFETY DESIGN MODEL

DPM will help designers to understand the demands that a particular curve or other aspect of roadway geometry places on the driver. DPM is a very ambitious model that intends to capture both vehicle control (e.g., speed and path control) and tactical maneuvering aspects of driving (e.g., speed and path choice). This broad scope is bounded by a focus on driver response of road geometry of two-lane rural roads. DPM is a detailed process model. It generates predictions of driver behavior based on algorithms that are tied to elements of human cognition that are relevant to driving. These algorithms are based on a theoretical framework that relates cognitive resources, such as attention, perception, and motor control, to the driving demands associated with moving down a virtual roadway. As a process model, DPM produces a response to state

TABLE 1
Characteristics of Three Representative Driver Models

	<i>Purpose</i>	<i>Scope</i>	<i>Type</i>
DPM	Support geometric design of roadways	The control and tactical aspects associated with speed and path maintenance on a two-lane rural road	Process model based on a nested closed-loop feedback control
DEMANd	Support interface design of in-vehicle information systems	The control aspects of interacting with in-vehicle technology Considers driving only implicitly as it is degraded by competition for common attention resources	Product model based on lookup tables and linear regression
ARCAM	Support selection of appropriate algorithm parameters for a rear-end collision warning system	The control and tactical aspects of driver response to imminent collision situations	Process model based on a field theory of driving and a combination of open-loop and closed-loop control
Cognitive architecture	Model high-level cognition in a variety of settings	Aspects of cognition that correspond to control and tactical aspects of driving	Process model based on empirical data collection and experimental validation

changes that are updated at each time step of the simulation. This results in time history of the driver state and vehicle position on the road. Because the developers created DPM using a general framework with a strong theoretical basis, it is feasible to extend DPM to go well beyond its current purpose. Adapting it to address distraction associated with in-vehicle devices seems feasible.

7. IN-VEHICLE INFORMATION SYSTEMS DEMAND MODEL

The emergence of a wide array of in-vehicle technology has promised increased safety, mobility, convenience, and efficiency. The purpose of DEMANd is to help engineers evaluate design options before creating a prototype in-vehicle information system. More specifically, this system enables engineers to compare two competing options, evaluate a modification to an existing system, and evaluate a task or design feature against safety criteria.

The focus of DEMANd is on in-vehicle tasks, and driving performance is modeled indirectly; that is, driving performance decrements are estimated based

on the demands of tasks associated with in-vehicle information systems. DEMANd takes the tasks and subtasks associated with an interaction with an in-vehicle device and produces estimates of the attentional demands of those tasks. DEMANd summarizes the consequence of these attentional demands in terms of expected decrements in driving performance. Unlike DPM, DEMANd does not generate a time history of driver actions and driving performance; instead it combines data across in-vehicle tasks to estimate a general indicator of the safety consequence. Because the model does not generate output for the entire time history of the interaction among the driver, the system, and the roadway, it might not reflect how peaks in attentional demand could overwhelm the driver.

DEMANd is a static product model of driver performance. It uses lookup tables and linear regression equations to relate particular design alternatives to declines in driving safety. Unlike DPM, DEMANd does not generate a time history of driver response to events; instead it adds the estimated cognitive demands of a set of tasks and subtasks. This approach does not attempt to describe the dynamic process that the driver goes through in interpreting and responding to an in-vehicle information system.

8. REAR-END COLLISION WARNING ASSESSMENT MODEL

ARCAM was developed to aid designers in evaluating candidate collision warning strategies. This model predicts driver response to warnings produced by various collision warning algorithms in different driving contexts (e.g., initial velocity, following distance, deceleration of the lead vehicle, initial velocity of the lead vehicle). With these predictions, designers can compare various algorithms of parameter choices for a wide range of roadway conditions. Currently, ARCAM predicts behavior of drivers only in imminent rear-end collision situations.

Figure 1 shows the major components of ARCAM. A central aspect of ARCAM is the focus of driver attention. A driver's attention to the roadway depends on the uncertainty about the state of the roadway. This uncertainty increases until it reaches an unacceptable level, at which time the driver returns attention to the road. The uncertainty grows as a function of information density of the road, vehicle velocity, rate of for-

getting, and time. The following equation describes the driver's uncertainty:

$$\text{Standard Deviation of Memory Position} = \alpha + \lambda \times t^{1.5}, \quad (1)$$

where t is the time since the last sample, α is the initial uncertainty associated with the driver's estimate of collision potential, and λ is the rate of uncertainty growth.

ARCAM is a detailed process model. It generates predictions of driver behavior based on algorithms that are tied to elements of human cognition that are relevant to drivers' response to imminent collision situations. These algorithms are based on a field theory of perception and a model of attention allocation that seems to capture the most critical cognitive processes associated with collision avoidance. As a process model, ARCAM produces a response to state changes that is updated at each time step of the simulation. This results in a time history of the driver state and vehicle position on the

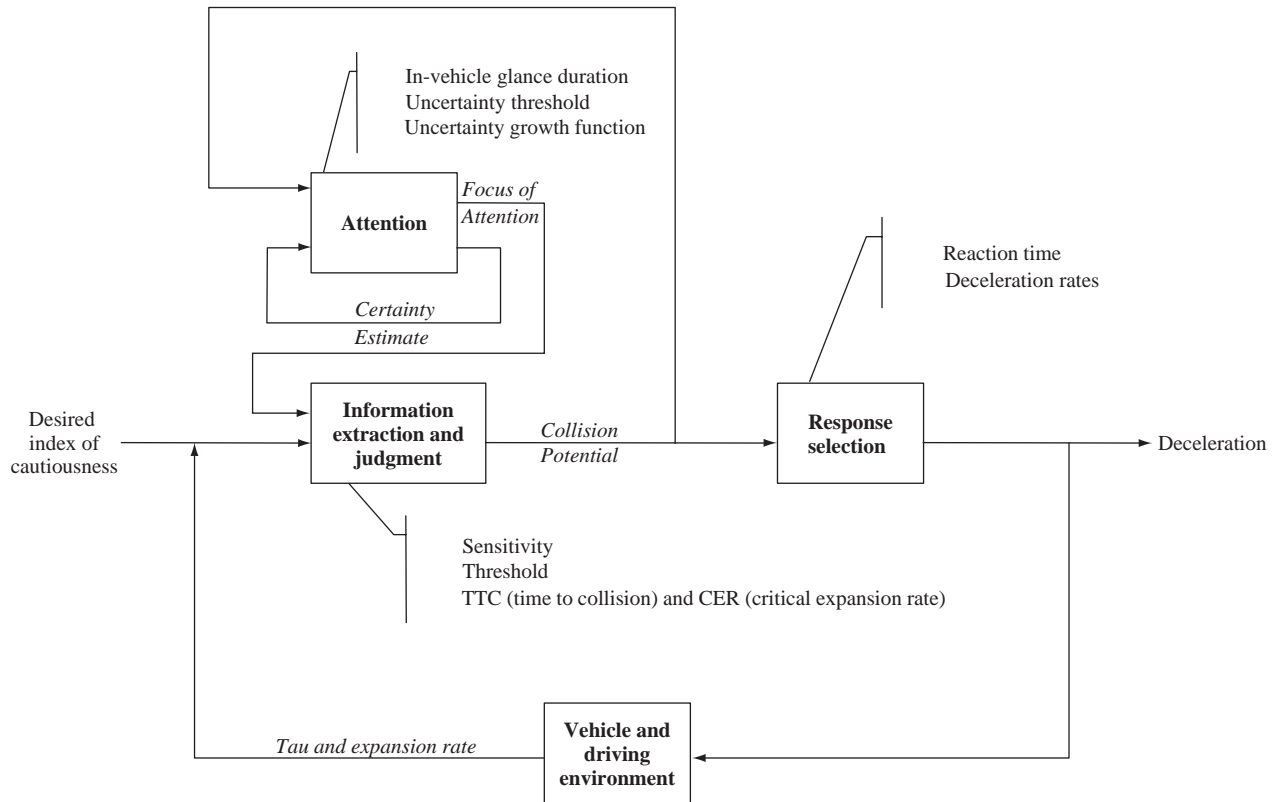

FIGURE 1 Major components of ARCAM. Reprinted from Brown and colleagues (2000).

road. This trajectory provides a basis for understanding how cognitive processes influence driver performance.

9. COGNITIVE ARCHITECTURES FOR MODELING DRIVER PERFORMANCE

In addition to models developed specifically to capture the demands of driving, several modeling tools or cognitive architectures could be used to model driving performance. These cognitive architectures include Adaptive Control of Thought (ACT-R), Soar, and Human Operator Simulation (HOS). A major benefit of these approaches is that they embody many of the cognitive limits and constraints of people. For example, ACT-R was developed to account for many elements of high-level cognition. ACT-R captures many aspects of how people learn and respond to problems. Using ACT-R or another cognitive architecture as a starting place for developing a driver model allows model developers to leverage many years of research as well as a validated approach to describing human behavior. Developing a model with ACT-R, Soar, or HOS can be much faster and provide results with greater validity than can an approach that develops the model without the benefit of an underlying cognitive architecture.

Although cognitive architectures offer important benefits, they also pose two substantial challenges. First, the level of detail assumed by many architectures might be more specific and detailed than many analyses need. Second, the cognitive architecture may make fundamental assumptions regarding human behavior that might conflict with how people drive. For example, ACT-R would describe driving in terms of discrete activities of symbol manipulation. Although this might be appropriate for some driving activities, many aspects of driving might best be described as continuous closed-loop control. Third, the tasks that many cognitive architectures have been designed to model are not necessarily those that comprise driving. Cognitive architectures act as a high-level programming language that can greatly enhance the efficiency of model development because they embody many of the cognitive constraints that govern driver performance. However, they have been developed to explain human performance in very different domains (e.g., human-computer interaction) and, thus, may make fundamental assumptions that conflict with the human performance capabilities and time-sharing strategies used for driving.

10. CONCLUSIONS

This brief overview of four modeling approaches demonstrates some of the trade-offs in developing models of driver performance. Comprehensive process models of driver performance, such as DPM, can be complicated to operate and resource intensive to create. However, they provide a powerful way in which to understand how design options affect driver cognition and performance. Outcome models, such as DEMAnD, can link large amounts of empirical data, using lookup tables and regression equations, to design parameters. They provide a powerful tool for designers, but they make many assumptions that might not be easily understood, and they might not be usable beyond the original purposes of the models. Focused process models, such as ARCAM, provide the benefits of the more comprehensive process models and are less resource intensive to build. Unfortunately, they might have such limited scope that they are useful only for only a very specialized application such as the evaluation of a rear-end collision warning algorithm. Cognitive architectures promise the generality of a comprehensive process model, such as DPM, without the demands of creating a complete modeling framework. The limitation of cognitive architectures such as ACT-R is that they have generally been developed for applications unrelated to driving, and the ability to adapt them to the driving domain has not been tested.

GLOSSARY

- contingency* Pairing or relationship between two events, behaviors, or thoughts; usually, the pairing or relationship is probabilistic (i.e., it does not always happen).
- intrinsic motivation* Behavior performed for its own sake and not for material or social rewards.
- justice* Perceptions of the fairness of the allocation of outcomes (i.e., distributive justice) or policies and procedures used to make the allocation decisions (i.e., procedural justice).

Motivating oneself or others in a work setting requires understanding many aspects of human thought and behavior. Several theories have emerged to facilitate understanding what people want and how they learn and process information to get what they want.

1. INTRODUCTION

Motivation has long been a topic of interest to applied psychologists. In work settings, motivational processes

are thought to relate to decisions of participation, such as joining or leaving an organization, and to performing well in an organization. Motivation is also implied in decisions and actions related to broader organizational concerns such as unionization, constructive behaviors (e.g., speaking well of one's employer), and destructive behaviors (e.g., workplace violence). An understanding of motivational constructs and processes can help employers to predict who will be motivated to join and work hard, why some are not so motivated, and what can be done to increase participation and performance generally and for specific individuals. From an employee's perspective, an understanding of motivation might help the individual to make participation decisions that lead to satisfying work experiences and techniques for motivating oneself to perform desired tasks promptly and well. To address these issues, the field of work motivation has generated a list of theories that speak to specific issues. This article describes some historically important and currently prominent theories in the field.

2. DEFINITIONS

Before reviewing the theories, it is useful to define the two concepts comprising the title of this article: motivation and taxonomy. Motivation is difficult to define. It is easier to understand in terms of what it is not: ability, knowledge, and skills. For example, a well-written essay requires knowledge of the topic, the ability to write, and the willingness to write. Only the willingness element is

motivation. More directly, motivation is often defined as that which determines the form, direction, intensity, and duration of one's actions. However, one must recognize that ability or other influences (e.g., situational constraints) might at least partially determine these results. Thus, separating motivational causes from nonmotivational ones represents a continual dilemma for motivational researchers.

Taxonomy represents a classification scheme in which elements are assigned to no more than one class and all of the elements are assigned; that is, it is mutually exclusive and exhaustive. Taxonomies are also often hierarchical; that is, within a class, subclasses are often identified. Here, content may be used as one higher order class and process as another class. Content theories deal with a particular property or set of properties thought to influence motivation. They address the question of what people want or need. Process theories focus on how individuals handle information or content. They address the question of how people learn to obtain or process information to obtain what they want and need. Process theories are content free; that is, they usually assume that people are hedonistic (i.e., seek pleasure and avoid pain), but they make no statements about what people inherently find to be pleasurable and painful. Content theories usually have some description of processes, but they also include descriptions (often taxonomies) of what might give people pleasure and pain.

3. CONTENT THEORIES

3.1. Needs Theories

One well-known taxonomy of human desires (or needs) was presented by Maslow, a clinical psychologist, based on a lifetime of interaction with patients. This taxonomy was arranged in a hierarchy designed to represent the order of precedence (Fig. 1). The bottom level (physiological needs) describes what individuals need to survive. Higher level needs describe what individuals need to thrive. A process element to Maslow's theory was that lower level needs had to be met to some extent before higher level needs became motivating. Maslow's hierarchy was important for work motivation because it included in the higher order needs more than just the material needs. Indeed, the highest need (self-actualization) describes the desire of individuals to be all that they can be. It represents a desire to strive, in both personal and work lives, to achieve new heights, to create, and to produce to the best of one's ability. This sentiment resonated with

FIGURE 1 Maslow's hierarchy of needs.

managers and executives because they believed that these kinds of desires motivated their behavior.

Unfortunately for Maslow's theory, the majority of empirical research did not support his hierarchy. Some suggested that the hierarchy be reduced to two or three levels with some processes added. Yet even these changes were not reconcilable with empirical and logical counterarguments (e.g., an individual can be eating a sandwich to meet a physiological need while writing his or her self-actualizing masterpiece). These issues led most motivational researchers to abandon the specific framework but to scavenge useful pieces from the hierarchy, including the general idea that people desire more than what money can buy.

3.2. Job Design

One area of motivational research that benefited from the needs approach was job design. If applied psychologists could understand what was intrinsically motivating about jobs, they might be able to redesign them so that workers were more motivated and more satisfied. Interviews with workers seemed to reveal that although lack of material rewards and/or poor working conditions (i.e., extrinsic elements) could make them unhappy, it was the opportunity to do a meaningful job well that was truly motivating and satisfying.

So, what makes a job meaningful? The most prominent theory in this area, called the job characteristics model, claims that it is the degree to which the job involves a variety of skills used to create a whole important thing (or service). In addition, the job should allow the individual (or team) to decide what, when, and how

to do the thing (or provide the service). Finally, the job should provide feedback regarding progress directly to the job holder. To the extent that these factors are present, an individual doing the job should be motivated because it allows the individual to demonstrate competence and an ability to affect his or her world. The theory also recognizes that if these needs in the individual are not strong, these job dimensions are not likely to be important and might even aggravate the individual.

Because job design theories are specific about what should be done, they are easier to test than are vague needs taxonomies. In this case, the empirical literature tends to be much more supportive of the recommendations within the theory, particularly in terms of job satisfaction. In terms of helping an organization's bottom line (i.e., profit and productivity), the findings are less clear. One issue is that recommendations from motivation-oriented job design techniques and engineering-oriented job design techniques often conflict. Engineering-oriented job designers tend to focus on efficiency, error reduction, and reliability. This approach emerged from Ford's assembly line formula that seemed to greatly improve the efficiency of production through work simplification, even as it substantially reduced the humanity of work. Some now suggest balancing all of the relevant criteria (e.g., reliability, intrinsic motivation) when designing and evaluating jobs.

3.3. Equity and Justice

A different class of theories focuses on what an individual does not want, that is, to be treated unjustly. Simply observing elementary school-aged children distributing a reward among themselves reveals the importance of this desire for fairness (and the difficulty in achieving it). The desire does not disappear with adulthood. Organizational members seem acutely aware of the fairness of distributions of outcomes and the policies used to make these distributions. The original theory focused solely on the distributions of outcomes (i.e., distributive justice). More recent work has focused on the fairness of distribution policies (i.e., procedural justice).

Actually, the original justice theory, called equity theory, was focused on a process, that is, the comparison between the outcomes that an individual receives and the outcomes that others receive. Moreover, these outcomes were appraised in relation to the inputs used to derive them. Hence, the theory predicted that if an individual received \$5 for a job and a friend received \$10, the former would perceive this as fair if the friend worked twice as long or twice as hard. On the other

hand, if the individual perceived that both he or she and the friend put equal work into the job, that person would see the pay as unfair and be motivated to rectify the situation. The individual might do that by working less hard in the future, finding some other form of compensation (e.g., pilfering office supplies), denigrating the friend's work to the boss, or coming to believe that he or she does not really put in the same quality of work as the friend. If none of these produced a sense of justice, the person might quit that job. Research has found that all of these things can happen. Meanwhile, the friend is likely to believe that his or her efforts are somehow worth more than the first person's efforts, relieving any sense of overpayment inequity. Researchers hoped that individuals would be motivated to work harder to overcome their sense of overpayment inequity, but the evidence seems to indicate this is rarely the case.

More recent research has focused on the perceived policies and procedures for making distribution decisions. Voice in the process, whether at the policy development stage, the policy implementation stage, or a follow-up stage (e.g., ability to appeal decisions), seems to be a central issue. In addition, thoughtful explanations for negative outcomes (e.g., layoffs) seem to reduce justice-restoring behaviors (e.g., sabotage). The procedural justice research seems to be summed up in the concept that one should treat people with respect.

4. PROCESS THEORIES

Process refers to how people meet (or strive for) their wants and needs. Three kinds of process theories have gained prominence in organizational psychology: learning theories, decision theories, and goal theories. Learning theories describe how people learn to achieve their desires. Decision theories describe how people process information such that they make choices leading them to meet their desires, including how they choose goals. Goal theories describe the properties of goals that most influence behavior and performance.

4.1. Learning Theories

Most learning theories claim that people make associations between responses and the consequences that follow those responses. If the consequences are what people want, people are more likely to make those responses in the future. Thus, if making a big sale earns the respect of bosses and colleagues, an individual is more likely to engage in the activities that led to the big sale in the

future. In addition, when stimuli (e.g., events) are frequently paired, people learn to associate the stimuli, allowing them to predict their environment to some extent. Thus, one might associate certain attributes of customers with sales. Observations of customers with such attributes indicate opportunities not otherwise present. The result might be the engagement of certain behaviors associated with sales directed at customers with certain attributes.

In organizational settings, the most common application of learning theories is behavior modification programs based on reinforcement theory. They involve determining the desired behaviors of employees and then setting up contingencies with rewards when the behaviors are observed. Well-designed studies of these programs have generally supported them, but several aspects of the approach make it onerous for organizations. First, it requires that one or a few specific behaviors are what all employees should be doing. For many jobs, this might not be the case. Second, it requires someone (or something) to look for the behaviors by the employees. Such extensive monitoring can be expensive and aversive to employees. Third, because the theory is content free (i.e., it does not state what people want), it requires figuring out what is rewarding for each employee. This generally is not a problem because most people want pay, which is a very flexible means to other ends. Unfortunately, employee pay is an organizational cost that organizations would like to minimize. Hence, some effort is made at finding less expensive rewards (e.g., praise). Fourth, theorists in this area advocate using the programs to encourage (i.e., reinforce) desired behaviors as opposed to discouraging unwanted behaviors. This can limit the approach's applicability. Finally, some motivation theorists argue that behavior modification programs undermine intrinsic motivation because they do not allow individuals to infer competence from their behavior.

In response, learning theorists point out that learning is constantly occurring in organizations. Organizations could simply hope that their work environments encourage the behaviors desired of employees, or they could attempt to construct environments that encourage the desired behaviors (i.e., behavior modification programs). Moreover, the intrinsic motivation issue does not seem to be a problem because individuals use the rewards to infer competence. Nonetheless, because of the difficulties associated with identifying an easily monitored set of specific behaviors, many researchers have sought to identify important properties of the work environment that might encourage or discourage the

desired behaviors. For example, the beliefs and desires of coworkers have been found to be significant sources of influence on learning and behavior.

4.2. Decision Theories

Decision theories have several advantages over other theories of motivation from the perspective of motivational researchers. First, as the key dependent variable, they can use self-report measures of choice rather than behavior, which can be hopelessly confounded with ability. Second, because decision theories assume the cognitive processing of information, researchers can also obtain reports from workers about the contingencies and associations they perceive in their environments. These theories focus on what individuals do with the associations learned as opposed to how they are formed. Hence, researchers can be less concerned with what the environments look like and can focus on how those environments are interpreted by the workers.

Several decision theories exist, but within organizational psychology, the expectancy-value models have received the most attention. Expectancy-value models reduce workers' interpretations of their environments to three key constructs. First, they are concerned with the contingencies that workers see between specific behaviors and performance; that is, individuals' belief in the probability that behaviors will lead to performance (although these theories consider more than performance). Second, expectancy-value theories claim that the associations that individuals form between performance and other outcomes are important. Finally, expectancy-value theorists want to know what anticipated value workers place on the outcomes associated with performance. Given this information, the theories predict that individuals will choose to engage in behaviors that will lead to performance (or choices) if the outcomes associated with performance (or choices) are positively valued. The amount of effort or persistence directed toward the behaviors will weaken to the extent that individuals believe the behaviors might not achieve performance or believe the performance might lead to negative or nonvalued outcomes.

The predictions from decision theories and learning theories are very similar. They both advocate the setting up of contingencies between performance and valued rewards. However, they are more likely to encourage training or the removal of performance barriers if behavior-to-performance expectancies are low instead of setting up specific behavior-based contingencies. This moves the monitoring to the level of performance and away from specific behaviors.

Research on decision theories is generally supportive. People do seem to use their beliefs regarding contingencies and value to make choices regarding what jobs to take and other work-related behaviors. Moreover, self-report methods of eliciting these beliefs can be useful as organizations seek to understand why performance levels are not up to standard or what might improve them. However, for more mundane issues, such as determining how much effort to exert toward performance, the theories are less impressive. Indeed, exceptions seem to be the rule, and decision researchers are attempting to explain why people deviate from doing what seems to be in their best interest as defined by an expectancy–value theory.

4.3. Goal Theories

One decision that seems to be critical to understanding, predicting, and influencing performance is the choice of a performance goal. Most current research focuses on goal theories, which continue the cognitive orientation found in the decision theories. That is, goals are defined as desired states internally represented within the mind. Properties of this representation, including its level (e.g., produce a little or a lot), its level of specificity (e.g., do one's best or do 20), and one's commitment to it seem to substantially affect goal-striving behavior. Specifically, difficult (i.e., high-level), well-specified goals with strong commitment will lead to higher performance than will easy vague goals with low commitment. Although the research has been somewhat ambiguous regarding the commitment concept, the level and specificity constructs are well supported within boundary conditions. For example, feedback regarding performance progress is required for goals to have an effect. Moreover, learning and complex tasks might be adversely affected by difficult performance goals, but learning goals or contexts where the goals encourage the development of appropriate strategies for performing complex tasks can enhance these outcomes. Also, it seems clear that through the integration of decision theories, beliefs about contingencies with valued outcomes can enhance commitment and the acceptance of difficult goals.

4.4. Integrative Efforts

Although controversy surrounds the value or potential of integrating the various motivational theories, several efforts have been made in that direction. One early attempt combined expectancy–value notions with a particular content, that is, need for achievement. According

to this theory, achieving difficult tasks (where expectancy was low) is more rewarding but may also lead to failure. Depending on each individual's desire for achievement, fear of failure, and expectancies, these factors predict choice and effort. Unfortunately, the evidence was not always supportive, and the theory has lost favor. However, the content (i.e., need for achievement) remains a candidate for being a measure of general work motivation.

More recently, social cognitive theory has emerged as an integrating theory of the process models of motivation. Social cognitive theory grew out of social learning theories that included concepts of learning from experience and from watching others as well as associations derived from people's history of experiences. Social cognitive theory, like expectancy–value theories, added the importance of how individuals perceive and interpret events and contingencies. For instance, individuals might use their feelings of physiological arousal to help them judge their ability to perform behaviors. According to the theory, a person's belief in his or her capacity to engage in a specific behavior, called self-efficacy, is key to understanding how the individual allocates resources to the task and how he or she reacts to frustrations and successes. For instance, individuals who are high in self-efficacy are likely to raise their goals when they achieve existing goals. Hence, goal processes are also included in social cognitive theory.

5. IMPLICATIONS FOR WORK SETTINGS

Several implications of specific theories have been described in this article. This section addresses some specific applied questions and what the theories do and do not have to say about them.

5.1. Who Should Be Hired?

One job of applied psychologists is to find individual differences that predict (i.e., correlate with) job performance. If measures of these predictors can be given during the application phase, organizations can use them to select individuals who will perform well. This strategy has proven to be fairly successful when it comes to measuring and predicting ability, knowledge, and skill. However, predicting who will be motivated has proven to be more difficult than predicting ability. This makes sense. Content theories (e.g., need for

achievement), which are most likely to provide explicit measures, have often suffered due to measurement problems. Even if the measures were reliable and valid, highly motivated individuals might direct their effort to nonwork endeavors (e.g., hobbies). Moreover, jobs often leave little leeway regarding what should be done or how to do it. For these reasons, research has tended to focus on more specific measures of motivation (e.g., work values) that indicate a fit with the organization where the job allows some autonomy or ambiguity.

5.2. Why Do Individuals Accept Job Offers and Stay?

Assuming that an organization likes what it sees in an applicant, the applicant has the next choice with regard to the organization (i.e., whether to join). Later, after being hired, the employee may decide to quit. Decision theories have much to say about these processes, and they have been used extensively to predict these outcomes. Particularly with regard to the decision to join an organization, factors such as pay and benefits play an important role. In regard to quitting, these factors and the working environment have an impact. Of particular importance for these decisions are perceptions of equity and fair treatment.

5.3. Why Do Individuals Work Hard (or Not)?

The motivational process theories argue for making pay and other rewards contingent on performance and providing specific difficult goals. Although the second recommendation is generally well received, the first one has created controversy. It seems to help motivate some employees, and some even like the system. However, in other situations, the measures of performance needed for contingency plans to work are considered suspect. If the measures (a) do not capture the behavior or performances that lead to organizational productivity or (b) are perceived to be a function of influences outside of an individual's control (e.g., the politics and idiosyncracies of supervisors), the measures are unlikely to work well and can lead to unwanted effects. Yet if individuals were informally surveyed about their performance appraisal systems, one would likely find few employees who believe that the systems capture all that they are supposed to capture and that they capture only what they are supposed to capture. Adding insult to injury is that in

jobs where performance is difficult to measure, it is also difficult to set fair performance goals. For instance, consider a high school teacher. How should performance for this job be measured? What goals could be set that do not rely on input from the students that is beyond the teacher's control?

Indeed, can the possibilities expressed in Maslow's view of people be realized? Can organizations and jobs be designed to be places where workers can derive meaning and satisfaction? Can policies and procedures that are perceived as just be developed? Can a fair wage be provided for work done without having to monitor the work done? These are challenging questions for which the motivational theories provide some reasons for optimism as well as some reasons for pessimism. This leads to the final, and perhaps most important, question: Can a better understanding of human motivation help to answer these questions? Among work motivation researchers, the answer is uniformly "yes."

personal investment theory A theory concerned with how persons choose to invest their energy, talent, and time in specific pursuits.

pseudo-etic research Research that assumes that research constructs and tools are etic when, in fact, they are emic; consequently, the validity of cross-cultural comparisons with pseudo-etic models is questionable.

social cognitive theory A theory that attributes learning to the cognitive processing of observed models of thought, action, and behavior.

GLOSSARY

achievement motivation The desire to excel, that is, the impetus to strive for excellence and success.

attribution- and cognitive-style models Theoretical conceptions that emphasize the causal role of thinking patterns in determining motivation.

ecological research Research that suggests that the experiential and performance dimensions of events and situations are essential in understanding the achievements, behaviors, responses, and scores of groups and individuals.

emic research Research that develops culture-specific constructs and tools that may limit cross-cultural comparability.

etic research Research that develops universally appropriate constructs and tools and that enhances cross-cultural comparability but may limit access to emic data.

goal theory A theory that posits that the purposes students have for learning, such as doing better than others and improving their personal performance, influence the nature and quality of their motivation and engagement in learning.

The potential impact of culture on the nature and functions of psychological variables has long been recognized. However, until relatively recently, it was often assumed that definitions, methodologies, data, and generalizations from psychological research could be readily transferred, more or less, across cultural boundaries. Typically, this meant that psychological theory and research that was based in (and on) American or Western European settings was considered readily transferable to other cultures with few, if any, modifications. In particular, the assumption of transferability applied to a range of psychological constructs of interest in applied (i.e., real-life) settings. These constructs included intelligence, anxiety, expectancies, motivation, perceptions of success and achievement, and self-concept. However, there is now a wide recognition that such constructs are not necessarily structured in the same way across cultures. Moreover, the relative importance of various constructs may differ greatly among

cultures. For example, it has been demonstrated that the ways in which students construct their understandings of achievement and success (i.e., what “counts” for achievement/success and how achievement/success is gained) may be very different across cultures. For this reason, there has been considerable impetus to reformulate important psychological constructs (and research methodologies) to make them more relevant and appropriate to the specific cultures to be studied. This, in turn, suggests the need for development of taxonomies, nomenclatures, and conceptualizations of affect, cognition, and behavior that are culturally specific. This article begins by discussing early studies in, and conceptualizations of, achievement and achievement motivation. It then discusses more recent theoretical and methodological approaches to the study of these constructs, with particular emphasis being given to their application in cross-cultural settings.

1. CROSS-CULTURAL APPROACHES TO ACHIEVEMENT AND ACHIEVEMENT MOTIVATION

1.1. Early Studies in Motivation and Achievement

The study of achievement motivation owes much to the work of McClelland and associates. They suggested that achievement motivation was a personality trait that developed in some people more than in others as a result of early socialization experiences and the emotional concomitants of these experiences. Because socialization practices were presumed to vary across cultures, McClelland and colleagues’ conceptualization provided a “ready-made” theoretical basis for the examination of achievement motivation in a range of groups, societies, and cultures. As a result, McClelland and colleagues’ work gave impetus to many research programs investigating a range of issues related to achievement motivation in cross-cultural settings.

Specifically, early cross-cultural studies inspired by McClelland and colleagues typically examined the antecedent-consequent variables associated with the development of achievement motivation among diverse social and cultural groups. Some of these studies were particularly concerned with relationships between achievement motivation and variables such as racial/cultural identity, self-esteem, and academic achievement. Other studies were concerned with the sociocultural antecedents of achievement motivation,

including independence training, social class, and acculturative stress.

1.2. Early Conceptualizations of Achievement and Achievement Motivation

McClelland and colleagues originally suggested that achievement behavior consisted of four distinct but related elements: competition with a standard of excellence, affective concern for goal attainment, an evaluation of performance, and some standard for the attainment of a long-term goal. These elements were typically identified in the projective responses to selected thematic apperception test (TAT) cards. In general, this approach categorized individuals as high or low in achievement motivation and determined those situations that would maximize their performance. Atkinson and colleagues introduced the concept of person (trait)/situation (state) interactions and explored the ways in which these interactions influence motivation and achievement. For example, Atkinson and colleagues’ research suggested that high-achievement need individuals are likely to be motivated by achievement situations that are moderately challenging, that is, where success is perceived to be possible but requires effort. Alternatively, low-achievement need individuals are likely to be motivated in situations that are minimally challenging and, hence, require little perceived effort for success. Moreover, low-achievement need individuals may also be attracted to maximally challenging situations where perceived effort is great but where a reasonable “excuse” for failure (i.e., situation difficulty) is inherent. Atkinson and colleagues’ research culminated in the formulation of expectancy-value theory, which systematically assessed the interaction between the value that individuals placed on perceived outcomes from achievement situations (value) and how likely they considered those outcomes to be (expectancies).

Overall, the research of McClelland and Atkinson and their colleagues suggested that achievement-oriented persons emphasized individual responsibility for their actions, were concerned with medium- to long-range goals, attributed success to their own abilities, were self-confident, and obtained most satisfaction from competitive situations where the outcomes were uncertain. Low achievement-oriented persons were characterized as being more motivated to avoid failure than to achieve success and as being most motivated by tasks that minimized the possibility of experiencing affect of failure.

This theme has been pursued up to, and including, studies by Bright in 1994 and Conchas in 2001 on student motivation and achievement.

Within its cultural context, the conceptualisation of McClelland and Atkinson and their colleagues was (and, to some extent, still is) quite an adequate interpretation of what constitutes achievement motivation. However, few studies questioned the basic premises of this conceptualization in terms of its cross-cultural validity. In contrast, most studies assumed that the conceptualization, its premises, and its associated methodologies were essentially etic (culturally transferable). Thus, when measures of differences between cultural groups on achievement and achievement motivation constructs were apparent, it was assumed that these reflected significant differences between groups on the constructs themselves rather than reflecting the applicability (e.g., appropriateness, salience) of the constructs across cultural groups. Interestingly, the non-Western cultural groups being examined often performed poorly with respect to given constructs. The conclusion drawn from such research was that “poor” performance reflected either (a) a deficiency in the group being examined (e.g., genetic inferiority, inadequate socialization for achievement) or (b) an incongruence and incompatibility between the values and norms held by the dominant cultural group and the assumptions, norms, values, and behaviors of the minority or culturally different group.

Perhaps more important, however, such studies often had the effect of “elevating” the goals, perceptions, and behaviors of Western cultural groups to the status of universal norms. In terms of cross-cultural work, this approach increasingly became recognized as both misguided and inadequate and has sometimes been termed “pseudo-etic.” For this reason, more recent cross-cultural studies have explicitly recognized the potential impact of a variety of specific cultural components on achievement and achievement motivation. This culture-specific research is often referred to as emic research. As a result of this research, a significant amount of evidence has accumulated, indicating that modes of expression, achievement, and achievement motivation are not culturally invariant but rather very much related to, and embedded in, cultural contexts. In particular, the emphasis placed on individual achievement and success in McClelland and colleagues’ theory is now questioned extensively. It is now argued that achievement must be analyzed in its total cultural context, including the various roles, both economic and noneconomic, through which achievement motivation may be directed. A wide range of studies in many different cultural settings

support this view. A common theme identified in these studies is that socialization patterns identified as important to developing achievement motivation in Western contexts (e.g., independence, self-reliance) are clearly not manifest (or, at least, not manifest in the same ways or for the same reasons) in other cultural contexts. From this style of research, researchers are able to extract common features that appear to have universal validity and then compare cultures on the basis of these features. This approach is often referred to as etic research.

2. TOWARD A BASIS FOR INVESTIGATING ACHIEVEMENT AND ACHIEVEMENT MOTIVATION ACROSS CULTURES

Quite early in the development of cross-cultural research into achievement and achievement motivation, Kornadt and colleagues in 1980, in accord with Maehr in 1974, suggested that, in spite of the many potential configurations of achievement and achievement motivation, some general characteristics of achievement in all cultures may be identified, thereby emphasizing the etic dimensions of achievement motivation. They suggested that these characteristics might serve as a potential basis for cross-cultural work on achievement motivation. These components include the following:

- The existence of a standard of excellence for an individual’s own goal-directed behavior
- The existence of affective reactions to success and failure (e.g., being proud and happy, being disappointed and sad)
- Individual feelings of responsibility for the outcome of achievement-related activity
- Personal incentives for achievement based on security or insecurity about an individual’s own capacity or ability to succeed

Kornadt and colleagues suggested in 1980 that the culture-bound experiences, cognitive structures, and values of each individual will determine the way in which these components are manifest in particular cultures but that the components themselves are relatively robust across cultures. Thus, achievement-motivated behavior will appear in all cultures—but in different forms, stimulated by different cues, and directed at different goals.

The preceding framework acted (and still acts) as a useful starting point for investigating achievement and

achievement motivation across cultures. However, this framework needed to be supported by more detailed conceptualizations of achievement and achievement motivation. In response to this need, many theoretical models that attempted to define such conceptualizations more explicitly emerged. Some of these models continue to be particularly useful for research in applied cross-cultural settings. Four of these are outlined briefly in the following subsections: personal investment (PI) theory, ecological theory, attribution theory, and goal theory.

2.1. Personal Investment Theory

Maehr and Braskamp's PI model of achievement motivation builds on and integrates various dimensions from earlier conceptualizations of the nature of motivation that are still considered to be important in any explanation and analysis of motivation, particularly in cross-cultural settings. PI theory is concerned with how persons choose to invest their energy, talent, and time. PI theory is particularly relevant for investigations into how individuals of various cultural backgrounds relate to different achievement situations. This is because it does not assume that people from a given culture will invest effort in the same achievement situations or, if they do, for the same reasons as will those from other cultures. PI theory addresses the apparent paradox between the low assessment of individuals from non-Western cultural groups on achievement tests and their obvious achievement and motivation across a range of activities as illustrated by persistence, level of activity, high performance, and continuing motivation in chosen areas of behavior.

PI theory also emphasizes the role played by social and cultural contexts in determining motivational patterns in performing achievement tasks. Moreover, it is phenomenologically based and emphasizes the subjective meanings of situations in light of individuals' culturally determined belief systems such as beliefs about self, perceptions of appropriate goals, and perceived alternatives available for pursuing these goals.

PI theory is a social cognitive theory in that it assumes that the primary antecedents of choice, persistence and variations in activity levels, are thoughts, perceptions, and beliefs that are embedded in cultural and social beliefs about self and situation. Specifically, PI theory designates three basic components of meaning as critical to determining PI in specific situations:

- Beliefs about self, referring to the more or less organized collections of perceptions, beliefs, and feelings related to who one is
- Perceived goals of behavior in given situations, referring to the motivational focus of activity, particularly what the person defines as success and failure in these situations (e.g., task, ego, social solidarity, extrinsic rewards)
- Perceived alternatives for pursuing these goals, referring to the behavioral alternatives that a person perceives to be available and appropriate (in terms of sociocultural norms that exist for the individual) in a given situation

Each of these components of PI theory may be influenced differentially by the structure of tasks and situations, personal experience, and access to information, as well as, importantly, the sociocultural context in which tasks, situations, and persons are embedded.

As a model, PI theory alleviates many of the problems inherent in monocultural research models. In particular, it conceptualizes achievement motivation in terms that recognize the possibility of diverse modes of achievement behavior across cultures. PI theory also strikes a balance between personality and situation while incorporating dimensions (e.g., locus of control) that have been found to be useful in analyzing levels of achievement motivation. Studies by McInerney and colleagues in 1995 and 1997 illustrated the use of PI theory in applied cross-cultural settings.

2.2. Ecological Theory

At about the same time as PI theory was being developed, Berry in 1980 attempted to redress the balance in cross-cultural research between laboratory-based programs and research set in naturalistic environments by proposing an ecological model for cross-cultural studies. This model (or at least its general approach) continues to be relevant for contemporary cross-cultural studies. Berry suggested that research that is based largely on experimentation, with little consideration of the wide range of variables operating in natural environments, holds little value. To make the task of effective naturalistic research easier, Berry proposed a multilevel model. This model describes research that moves from a naturalistic-holistic level to a controlled reductionistic level through (a) four environmental contexts (ecological, experiential, performance, and experimental) and (b) four effects (achievements, behaviors, responses, and scores).

The ecological context (also referred to as the natural-cultural habitat) refers to all of the relatively permanent characteristics that provide a context for human action. The experiential context is the pattern of recurrent experiences that provide a basis for learning. The performance context is the limited set of environmental circumstances, immediate in space and time, that may be observed to account for particular behaviors. The experimental context represents those environmental characteristics that are designed by the psychologist to elicit a particular response or test score. The experiential and performance contexts are always nested within the ecological context, whereas the experimental context may or may not be contained within the first three contexts. Berry suggested that the degree to which the experimental context is nested within the other three contexts represents the ecological validity of the experimental task.

Four effects parallel the four contexts just described: achievements, behaviors, responses, and scores. Achievements refer to the complex, long-standing behavior patterns that develop as an adaptive response to the ecological context and include established and shared patterns of behavior that can either be found in an individual or distributed in a cultural group. Behaviors are those acts that have been learned over time in the experiential context and include the skills, traits, and attitudes that have been acquired in particular roles or fostered by specific training or education. Responses, on the other hand, are those 'fleeting' performances that occur in response to immediate stimulation or experience. Finally, scores are those behaviors that are observed, measured, and recorded during a psychological experiment or testing. Berry argued that between each of the four environmental contexts and effects exists a relationship that should be considered in any effective cross-cultural research.

The complexity of Berry's model may have limited its usefulness to some researchers. However, the general ecological approach has proven to be very useful in recent research investigating motivation, achievement, and related constructs. Specifically, such research has arguably produced data with acceptable ecological validity and has specified a range of experiential, performance, and experimental variables that are associated with motivation and achievement across a range of "natural" habitats.

2.3. Attribution Theory

The problem of developing an attributional model that might form a more adequate basis for cross-cultural

research into achievement motivation has been a focus of older studies as well as more recent studies. These studies suggest that achievement motivation should be analyzed in terms of the subjective meaning of attributions (i.e., reasons given for success or failure) of a group or the persons who comprise that group. In other words, research into achievement motivation should be concerned with the phenomenology (i.e., definitions in context) of achievement attributions. This phenomenological approach to defining attributions cross-culturally requires that researchers elicit attributions of achievement behavior from people of different cultures rather than imposing inappropriate definitions on their achievement behavior.

In Western society, research indicates that assessments of achievement in terms of success and failure are best thought of as psychological reactions to outcomes and not as objective outcomes themselves. Thus, successes and failures are defined as much in terms of subjective feelings attached to given outcomes as in terms of the nature of the outcomes themselves. Moreover, attributions for success or failure that produce the greatest feelings of pleasure or regret are those related to ability (e.g., "I'm clever; therefore, I succeeded") and effort ("I tried hard; therefore, I succeeded"). More generally, attributions that enable a person to demonstrate to self or others that he or she possesses desirable qualities are considered to be important motivators. However, research concerned with examining the antecedents of success and failure across cultures suggests that ability and effort attributions are not necessarily salient to all groups. Hence, where research based on attribution theory emphasizes ability and effort as the most important perceived causes of perceived success and failure, it may be culture specific. For cross-cultural researchers, then, it is necessary to discover attributions that are salient to different cultural groups in eliciting feelings of success or failure.

2.4. Goal Theory

Goal theory developed by Ames, Dweck, Nicholls, Pintrich, and Midgley, provides a model that enables researchers to identify similar motives in diverse cultures, even if such behavior may vary in frequency and importance across cultures. Goal theory emphasizes the importance of goals and definitions of self in relationship to such goals. Goal theory differs from attribution theory in that attribution theory explores perceived reasons for success or failure while trying to succeed, whereas goal theory explores perceived reasons for trying to succeed

in the first place. These reasons for trying to succeed are labeled “goals” in the context of goal theory. Some important goals (or goal “orientations”) postulated by goal theory are the following:

- *Ability-oriented (performance) motivation.* This approach is characterized by striving to maintain a favorable perception of one’s ability to demonstrate competence. That is, the goal is to maximize the subjective probability of attributing high ability to oneself in culturally relevant areas. This approach, as with all goals in goal theory, focuses on the goal or function of behavior for the person rather than on the inevitably ambiguous external form of any given behavior itself.

- *Task-oriented (mastery) motivation.* This approach is characterized by behavior where the focus is on producing a product or solving a problem rather than on demonstrating one’s competence. In contrast to ability-oriented behavior, during task-oriented behavior, people are not attributing outcomes to ability or seeking to demonstrate ability. The completion of the task itself is its own reward, and the development of mastery is perceived as intrinsically satisfying.

- *Socially oriented (social) motivation.* This approach is characterized by behavior where the goal is to maximize the probability of attributing high effort to oneself (and to minimize the probability of attributing low effort to oneself) in conformity with perceptions of the probability of gaining social approval, respect, or recognition. This orientation, which is really a class of orientations, is based on the assumption that effort, unlike ability, is voluntary and is something that anyone can display. Therefore, it can indicate conformity to social norms or virtuous intent, and this in turn can lead to social approval, respect, or recognition. Conversely, lack of effort in conforming to social norms or virtues may result in reduced approval, respect, or recognition and, hence, is to be avoided.

Goal theory has provided, and continues to provide, a cogent and coherent platform for investigating cross-cultural issues in achievement and achievement motivation, especially where the purposes for achievement are the focus of investigation. This is because goal theory allows for a range of possible intents (e.g., purposes, reasons) for achievement and for the possibility that the range and salience of possible intents may vary considerably from group to group. As a result, significant cultural differences in goal orientations, and their impact on motivation and achievement, have been noted in a range of studies. However, there is also contrary evidence from studies by McInerney and others

suggesting that the goals that people espouse, and the effects of these goals on motivation and achievement, may be relatively stable across cultures.

3. APPLYING SOCIAL COGNITIVE CONCEPTUALIZATIONS OF MOTIVATION AND ACHIEVEMENT

In general, social cognitive theories of motivation, particularly goal theory and PI theory, have alerted researchers to the ways in which motivation and achievement may be differentially constructed across cultural (and other) contexts. However, a significant remaining question from this perspective is the following: Is there a single motivational environment that can be constructed in most applied settings (e.g., schools, hospitals, businesses, government organizations), especially when these settings are typically diverse in many ways with respect to individuals’ ages, genders, cultural backgrounds, and socioeconomic status? This is an important question because a range of different motivational environments cannot be easily generated in most applied settings. Theory and research have gone a considerable distance in demonstrating that mastery goals are preferable to ability performance goals in a wide range of situations. This is because mastery goals focus on an individual’s attention to the task(s) to be completed rather than on the individual’s perceived ability (or lack thereof) to complete the task(s). Psychologically, this appears to “free” individuals to perform at optimal levels, even in the face of difficulties. Indeed, it might also be that performance goals are dysfunctional in many applied settings, although not in all cases. More recently, social goals have also been shown to have adaptive effects on an individual’s engagement in a variety of achievement and social situations. These social goals may be particularly relevant in non-Western cultural settings, where the social dimensions of motivation and achievement may be more salient than in Western settings.

4. METHODOLOGICAL IMPROVEMENTS IN APPLIED SETTINGS

The preceding sections of this article have outlined (a) the need for a cross-cultural understanding of achievement and achievement motivation and (b) some relevant

conceptualizations and theories that may support research into achievement and achievement motivation from cross-cultural perspectives. This section deals with methods for researching these culturally variable constructs in appropriate ways in applied settings (e.g., schools, workplaces, sports settings).

It is obviously not acceptable to use “one size fits all” approaches when researching achievement and achievement motivation across cultures. Rather, culturally sensitive studies in achievement and achievement motivation are needed for the following purposes:

- To establish whether the behaviors and responses being examined across cultures are functionally, conceptually or metrically equivalent
- To establish that the constructs and tools used in research are culturally appropriate to all groups in the study
- To examine achievement and achievement motivation in “real life,” as opposed to laboratory or similar situations, whenever possible
- To consider in detail, at both theoretical and methodological levels, the potential mediating processes that might intervene among culture, achievement motivation, and achievement
- Not to conceptualize achievement orientation solely as an individual personality-based characteristic
- Not to use cultural deficit and deprivation models (or, at least, not without justification) to explain the differential performance of various cultural groups
- Not to define any culture too narrowly and fail to recognize the range of experiences, perceptions, and behaviors represented in any given culture

Following these steps should help to avoid pseudo-etic (e.g., Western individualist and competitive) ways in which to conceptualize achievement and achievement motivation in cultures where these values might not apply. At least these steps should contribute to a viable framework for examining achievement and achievement motivation cross-culturally in that they provide explicit procedures for developing culturally specific contents that may be applied in different cultural settings with comparable theoretical meanings.

4.1. Informal Assessment of Motivation in Applied Settings

Formal measurement of motivation (i.e., using psychometric instruments) occurs relatively rarely in applied settings such as schools and workplaces. However,

informal assessments are made regularly in applied settings, particularly by those responsible for “performance management” (e.g., managers, supervisors, teachers). Informal indicators of motivation typically include a demonstrated willingness to be involved in assigned activities, the selection of appropriate activities where choice is available, the level of intensity or involvement in given activities, and the quality of performance outcomes.

These informal indicators of motivation are assessed or determined, to a large extent, by the frame of reference of the individual (typically a superior) making a determination. In other words, teachers, managers, and supervisors consider their subordinates to be more or less motivated in terms of the superiors’ frames of reference. This process of evaluation, however, may cause problems in diverse settings (particularly in cross-cultural settings). For example, motivation in the workplace is often conceptualized by supervisors in terms of material or technical output (i.e., productivity). However, what happens when output is conceptualized (by subordinates) in “unconventional” ways, for example, by improving the relational climate of the workplace or classroom and by contributing to the work of others? In such cases, supervisors may consider subordinates to be “unmotivated” when the subordinates consider themselves to be highly motivated. A similar point could be made with respect to the balance between fulfilling social responsibilities (e.g., looking after family and friends) and fulfilling more conventional responsibilities (e.g., being on time for work, being available for after-work/after-school functions).

There are two major points being made here. First, motivation and the demonstration of motivated behavior may be conceptualized very differently by different cultural (or other) groups. Second, evaluations of motivation and motivated behavior are dependent on one’s frame of reference. This adds considerable complexity to the evaluation of motivation in applied settings and argues against defining motivated behavior too narrowly, especially as the cultural diversity or other diversity of any setting increases.

5. CONCLUSION

This article has reviewed basic approaches to cross-cultural studies of achievement and achievement motivation, especially in applied settings such as schools, classrooms, and workplaces. It did so by highlighting some major limitations of the concepts and methods used to guide early studies while still recognizing the

value of this early work. It also presented a range of theoretical and methodological options that are currently being developed to enhance cross-cultural research in general and cross-cultural research into achievement and achievement motivation in particular.

A perennial problem for cross-cultural research is generating data that are universally comparable while also being culturally valid. Recent studies have demonstrated much more sophisticated and sensitive approaches to the issues of achievement and achievement motivation in cross-cultural settings.

GLOSSARY

behavior therapy A field of psychology that provides information telling people how to change their individual habits; it involves self-control to make people's lives better.

motivation Term used to explain why people do, or do not do, certain behaviors.

obesity When an individual has a body mass index (BMI) of at least 30.

protection motivation theory Theory suggesting that people are motivated to protect themselves from harmful or stressful life events.

self-determination theory Viewpoint evaluating the relative importance of intrinsic and extrinsic rewards for human behavior.

self-efficacy Term referring to situation-specific self-confidence.

People are continually trying to exercise more and eat diets that are conducive to good health. The problem of childhood and adolescent obesity continues to be a major focus of concern for health care professionals in North America. This article describes the necessary

tools to make lifestyle changes with the potential to reverse this troublesome trend.

1. INTRODUCTION

The problems associated with obesity and chronic degenerative diseases, such as heart disease, arteriosclerosis, hypertension, osteoarthritis, and type 2 diabetes, are now reaching epidemic proportions. The prevalence of obesity, where an individual has a body mass index (BMI) of at least 30, is increasing worldwide. Currently, there are approximately 300 million obese individuals around the world. More alarmingly, in the United States, approximately 30% of all adults are categorized as obese. Despite this prevalence being somewhat lower in Canada, the rate has increased significantly there during recent years as well. In 2003, Bouchard reported that obesity costs the unregulated U.S. health care system approximately \$100 billion annually. Therefore, it is time to take a serious look at how to reverse this troublesome trend.

In 2000, data collected by the U.S. Department of Health revealed that nearly 30% of the population is physically inactive. It is interesting to note how this percentage corresponds exactly with the percentage of individuals who are considered to be obese. Also, an additional 40 to 50% of the U.S. population does not engage in the necessary amount of physical activity to achieve health benefits. Through a process known as tracking, these statistics are reported to have remained

relatively consistent for the past 10 years or so. This is unfortunate given that frequent physical activity has been shown to benefit every system of the human body. For example, exercise physiologists have documented several important changes in the body that accompany participation in an ongoing exercise program. These include a decreased chance of heart disease and stroke, an increase in good (HDL) cholesterol, a decrease in bad (LDL) cholesterol, a lowered risk of osteoporosis (i.e., brittle bones), a decreased percentage of body fat, an increased lean muscle mass, lower blood pressure, and an improved immune system. In addition, in 1998, Leith reported that regular participation in physical activity has been found to be associated with several psychological benefits such as lowered anxiety, lowered depression, improved self-concept, and better overall mood.

In 1996, Manley, the former U.S. surgeon general, made the following observation. Because physical activity is so effective in preventing diseases, preventing premature death, and promoting a high quality of life, it should be accorded the same level of attention that is given to other important health practices that affect the nation. This assertion suggests that there is absolutely no doubt that physical activity can be described as efficacious in the prevention and treatment of many medical conditions, including obesity. However, despite this and extant research highlighting the benefits of physical activity and a healthy diet, people remain inactive and eat poorly. Therefore, it is important to consider the “why” of this phenomenon. The next section summarizes contemporary motivational theories relating to these topics and examines their relevance for influencing the health behaviors of diet and exercise.

2. MOTIVATIONAL CONSIDERATIONS IN DIET AND EXERCISE

The term “motivation” is actually a derivative of the Latin word *movere*, meaning “to move.” It is the psychological term used to explain why people do, or do not do, certain things. For example, why do some individuals exercise regularly and eat healthy diets, whereas others choose the options of inactivity and eating junk foods? This is not an easy question to answer, but the bottom line is that people’s underlying motivation can be understood by looking at three characteristics of behavior. First, people’s selection of certain activities over others

indicates something about their motivation. To paraphrase, what is it that is important to people personally? Their answers to that question will indicate their likelihood or reluctance to engage in a specific behavior. Second, the effort that people put into any activity also reveals their underlying motivation. In other words, the more effort people put into any behavior, the more motivated they are to accomplish that goal. The harder people work toward accomplishing a task, the more they want it. Finally, the degree of persistence that people demonstrate in their pursuit of a goal also reveals their level of motivation. If they refuse to give up and really want it but still give up easily, they did not want it enough in the first place. Therefore, it is important that each and every individual is aware of these three benchmarks of motivational theory.

Now that we have examined the basic components of motivation, we look at theories of motivation that have specific relevance for dieting and exercise. It is far beyond the scope of this article to cover the whole range of motivational theories. In 2003, Carron and colleagues published a book summarizing a wide range of motivational theories. This section focuses only on self-efficacy theory, protection motivation theory, and self-determination theory. In each case, a summary of the theory is provided with specific implications for diet and exercise.

2.1. Self-Efficacy Theory

The term “self-efficacy” can be summarized with an individual asking himself or herself the following two questions: “Am I capable of doing this activity?” and “Will I be successful in achieving my goals if I engage in this behavior?” The internal question specific to this article would be “Am I capable of successfully participating in an ongoing diet and exercise program?” Self-efficacy can also be described as situation-specific self-confidence.

In 1997, Bandura reported that an individual’s concept of self-efficacy is molded by his or her past experiences, vicarious experiences, verbal persuasion, and physiological/emotional states. To summarize this theory in light of the article’s objectives, self-efficacy can be enhanced in a variety of ways. First, people should remember to take “baby steps.” In other words, they should start an exercise program slowly and try to improve their overall diet in small stages. Most people fail because they try to do too much too soon. Second, people should take advantage of watching demonstrations, television shows, and videos that show other people succeeding in their efforts. These options will improve people’s belief in their ability to succeed in

their quest. Third, people should learn everything they can about the exercise and diet topics. More information is always better. They should not be shy about soliciting support from their significant others; doing so can go a long way toward improving their chances of success. Finally, people should be aware of how their physiological/emotional states can influence their resolve to diet or exercise. It is only natural to question the increased heart rate associated with exercise and/or the effect of mood on exercise or diet compliance. People should become familiar with these outcomes and recognize them as harbingers of success in their future efforts.

2.2. Protection Motivation Theory

This theory suggests that people are motivated to protect themselves from harmful or stressful life events. It also considers coping strategies for these occurrences. To summarize, the protection motivation theory maintains that an individual's motivation to engage in a health-related behavior is influenced by two considerations. First, threat appraisal represents a conscious evaluation of a person's perceived vulnerability and the possible severity of a medical problem. The internal questions ask "Am I at risk, and how serious are the possible outcomes of not exercising and of eating a poor diet?" Second, coping appraisal reflects an individual's perception of whether he or she will be successful in implementing the appropriate behavior and, if so, whether these actions will remove the threat. The internal questions ask "Am I capable of engaging in regular exercise and maintaining a healthy diet and, if so, will I be less at risk for developing chronic degenerative diseases?" The answers to these questions will provide a good indication of the person's intention to improve exercise and diet habits. Intention remains a critical ingredient in predicting human behavior.

In 2000, Floyd and colleagues and Milne and colleagues published meta-analytic reviews suggesting the efficacy of the protection motivation theory in predicting health behaviors. The former study examined 65 published articles with 29,650 participants and concluded that increased threat severity, threat vulnerability, self-efficacy, and response efficacy resulted in facilitated health behaviors. The latter study reviewed 29 studies with 7700 participants and also concluded that the protection motivation theory is predictive of facilitated adaptive intentions and improved health behaviors. Therefore, it appears that an individual's perceived severity of threat and vulnerability from inaction, as well as the chances of being successful in changing

these health behaviors, will seriously affect the desire to exercise more and to maintain a healthy weight.

2.3. Self-Determination Theory

This theory evolved in an attempt to understand the relative importance of intrinsic and extrinsic rewards for human behavior. Originally, it was believed that if intrinsic rewards were present, extrinsic rewards would be absent, but empirical research disproved this hypothesis.

Deci's 1992 development of self-determination theory attempted to address the discrepancy. This approach maintains that extrinsic and intrinsic motivations exist on a continuum. At one end of the continuum is amotivation, indicating the complete absence of motivation toward engaging in a particular behavior such as exercising or losing weight. At this point on the continuum, the person has no desire to change his or her lifestyle. Extrinsic motivation lies in the middle of the continuum and is multidimensional in nature. It consists of three additional dimensions. Consider the scenario where a family doctor tells a patient that he or she must lose weight and start exercising to avoid serious medical problems. In this case, the patient may try to follow the doctor's advice simply to avoid illness. Slightly farther along the continuum, the patient may lose enough weight and exercise to no longer be considered a health risk, and the patient continues the program only because he or she believes that it must be done. Finally, the individual may continue to "count calories" and exercise three times per week, but only because doing so is necessary to avoid illness.

At the farthest point on the continuum lies intrinsic motivation, and it is also multidimensional. This type of motivation occurs when a person performs a behavior for the sole pleasure it provides. Intrinsic motivation is also a multidimensional construct. For example, acquiring the knowledge of how to count calories effectively, eat a more healthy diet, and perform a new exercise represents the first stage of intrinsic motivation. During the second stage, the satisfaction of losing weight and becoming a regular exerciser becomes more important. Finally, once an individual reaches the intrinsic motivation point on the continuum, he or she will continue to exercise solely for the pleasant sensations associated with the physical activity. Likewise, the person will continue to maintain a healthy weight simply because it feels good to do so.

Now that we have examined the theories of motivation most relevant to diet and exercise, it is time to learn how to apply this important knowledge. The next

section discusses the behavioral tools that people need to take control of their lifestyle choices.

3. INDIVIDUAL INTERVENTION STRATEGIES TO IMPROVE DIET AND EXERCISE

The field of behavior therapy provides important information concerning the making or breaking of individual habits. Practitioners who endorse this approach maintain that people often fail in their self-control efforts because they do not consider environmental factors or the “ABCs of behavior.” Environmental stimuli (i.e., cues) that affect people’s behavior represent the As. The behaviors themselves are termed the Bs, and the rewards or punishments that closely follow the behaviors are labeled the Cs. The following specific interventions use this ABCs approach to behavior change.

3.1. Strategy 1: Removing Potent Cues That Are Associated with a Problem Behavior

One serious handicap to the average weight control program is the typical pairing of eating and snacks that are readily visible. Not many people can walk by a bowl of chips or a box of chocolates without sampling these treasures. For this reason, if people are attempting to lose weight, they should not have the fattening snacks showcased in a well-traveled area of the house. In terms of exercise, many individuals report that televisions and computers are major impediments to being physically active. If this is a problem for people, they should make a deal with themselves not to walk by their televisions or computers until they have completed their exercise sessions. This will eliminate the automatic pairing of watching television or surfing the Internet with inactivity.

3.2. Strategy 2: Making the Problem Behavior Unlikely or Impossible

Following from the previous example, the simplest way not to indulge in high-calorie snacks is simply not to have them in the house. This way, if people feel that they are weakening, it takes a good deal of effort to make a special trip to the store, so they are less likely to do so. When people shop for groceries, they should not buy these fattening foods. Similarly, if people find that they fail to exercise on days when they go to a tavern or to a

friend’s place, they should make an agreement with themselves to avoid these venues on exercise days. People will still have many opportunities to enjoy these situations that are getting in the way of their exercise programs.

3.3. Strategy 3: Developing New Behaviors to Replace Maladaptive Ones

This intervention invites people to identify the existing connection between the usual cues to action and the problem behaviors. For example, if people find that they tend to overindulge in snacking when they are feeling angry or lonely, they should consider an alternative behavior. Many individuals report that writing down their thoughts or feelings on a pad of paper can be therapeutic. If people are trying to lose weight, this is a better option than snacking. Taking this example to the next level, people might want to consider going for a walk or going to a fitness facility to deal with their feelings. Exercise has been shown to improve mood, and exercising in a social setting can help to alleviate feelings of anger or loneliness.

3.4. Strategy 4: Developing Cues That Will Foster a Desired Behavior

People should think in terms of using environmental cues that can work for them in pursuit of their goals. Individuals who want to lose weight should consider taping pictures of their dream tropical island getaway destinations on the fronts of their refrigerators. This way, each time they are tempted to snack, they can visualize themselves looking good in their swimwear on the beach. This will give them the needed strength to resist temptation. People who want to exercise regularly should consider placing their walking/running shoes and/or sweat suit at the point of entry into their residences or on their bedposts. This way, the first thing that they see when they get home from work or wake up in the morning is exercise equipment. This will prove to be a strong reminder for them to walk and/or jog.

3.5. Strategy 5: Rewarding Oneself for Exhibiting a Good Behavior

The whole idea of whether or not people should reward themselves is contingent on the principle of their success in achieving the target behavior. In other words, if

people maintain their daily caloric intake or achieve their exercise goals, they need to give themselves a “pat on the back.” It is important that this reward closely follows the desired behavior. Effective self-control requires a reorientation of the way in which people reward themselves. If they limit themselves to a certain number of calories or engage in their exercise programs on any given day, they are entitled to a reward. People should take this reward sooner rather than later because they deserve it and it will lead to greater compliance.

3.6. Strategy 6: Rewarding Oneself with What One Really Wants to Do Anyway

If there is a behavior that people really like to do on any given day, such as watching television or surfing the Internet, they should use one or both of these activities as potential rewards for achieving their daily goal. So, if people like to watch a favorite television show or use their computers, they should allow themselves to do so only after they have gone for their walks or reduced their caloric intake for that day. This represents a way in which people can reward themselves with things they have already identified as important to them personally.

3.7. Strategy 7: Using a Point-Reward System to Motivate Oneself

Sometimes, achieving a goal can seem a long way off. For this reason, it is important for people to use a point-reward system so as to continue to motivate themselves. For example, if people’s goal is to lose 20 pounds or to be able to jog 2 miles, it is important to remember that these goals can be reached only with “baby steps.” This means that people should set smaller, short-term goals to achieve their desired results. Losing 1 pound per week or walking/jogging a certain distance during that week allows people to give themselves a “point” or “star” for their accomplishments. People should record these points or stars in diaries or on their monthly calendars as a form of self-monitoring. They should make a deal with themselves that once they have accumulated a certain number of points or stars, they can trade these in for something they really want such as a night on the town, a new video, or a CD that was recently advertised. They should continue to set new reward limits and to treat themselves every time they have achieved their short-term goals.

3.8. Strategy 8: Being Creative in Finding New Ways in Which to Reward Oneself

One of the most often overlooked sources of reinforcement is of a social nature, for example, people’s friends, families, and coworkers. People should not be shy about enlisting their families, friends, and coworkers for support. A pat on the back or a “thumbs up” from a significant other can go a long way toward helping people to achieve their behavioral goals of losing weight and exercising more.

3.9. Strategy 9: Using a Behavioral Contract to Help Achieve One’s Goals

Writing up an exercise and/or diet contract can be a very effective strategy. It requires people to put in writing their diet or exercise aspirations. For example, the number of days per week people are going to exercise and the number of daily calories they are going to consume are formalized with the written contract. It is also a good idea to include the mention of a reward that people will receive if successful as well as a response cost if they slack off in their mission. People sign the contract and have significant others also sign the document. This will increase the chances that they will be successful in their efforts.

4. CONCLUDING REMARKS

This article has examined the problems of increasing obesity trends and declining exercise habits in the North American population. Although these problems are indeed factual, it is important to put both topics into a healthy perspective. This article is not intended to suggest that everyone should become obsessive-compulsive about their diets and exercise patterns. The best approach is for people to find a happy medium where they exercise moderately and eat a healthy diet that is low in fats and includes lots of fruits and vegetables. If people buy into this philosophy, the intervention strategies outlined in the preceding section will provide them with the behavioral tools needed to achieve healthier lifestyles. Most experts would suggest that behavior can be changed within a matter of weeks using the behavior therapy approach.

GLOSSARY

competencies Capabilities needed by leaders for supporting goal setting, translating goals into action, committing to goals, and dealing with failure in managing human resources at work in a goal-directed way.

dealing with failure Dealing with not reaching a goal; failure can lead to strengthened approach tendencies with a higher motivation to reach the goal, but it can also result in withdrawal from the task.

goal acceptance When acting persons accept goals set by others; if such persons experience positive influence potentials, they have the chance of negotiating new goals.

goal commitment The commitment that keeps people persistent in striving for goals; the degree of goal commitment is dependent on changes in current motivation.

management system Instruments that are able to measure performance, offer feedback, and stimulate participative goal setting to help people reach organizational goals.

moderators Variables that moderate the translation of goals into actions; the most important ones are task complexity, goal commitment, and individual ability.

motivating potentials Opportunities in a situation to reach the goals of a motive; the interaction of motivating potentials with motives determines work motivation.

Motives and goals work together to control the intensity, direction, and persistence of behavior at work. Motives are defined as classes of goals that determine, in interaction with motivating potentials of the work situation, the kind of goals people use to control their actions. Goal characteristics, mechanisms, and moderators of the translating process are the determinants of behavioral outcomes. Motives also play a role during this action phase. They affect the degree of goal commitment that people show while performing. Especially interesting is the impact of motives on the way in which people deal with failure. People differ in their ways of reacting to failure. Some are better equipped to deal with failure because they tend to increase motivation, stay with their goal, and finally reach it. Others withdraw from the task.

1. INTRODUCTION

Goals are the basic concepts used to understand and describe the direction and persistence of behavior at

work. Goals are effective on various levels of abstractness, with very specific goals controlling specific behaviors (e.g., motor acts). For example, a person can have the goal to press a button 300 milliseconds after a signal appears on a screen. On a more abstract level, goals are aggregated and often are called motives. A motive is defined as a highly aggregated class of goals, with variants of a basic theme being common to all of them. For example, a set of social goals forms a social motive acting as a stable disposition in persons across situations and over long time periods. Examples of other motives when the focus is on the development of personal goals are provided later in this article. In this context, motives are introduced as central determinants of personal goal setting in concrete situational contexts.

Goals can be set by an acting person internally or can be set externally by others. In the following, the focus is on internally set goals. The acceptance of externally set goals is described later in the article. Next, several functional properties of goals and three phases of goal-oriented action processes are discussed, and how goals and motives interact during these phases of action is discussed throughout the article.

Setting goals for oneself means anticipating expected outcomes of action that the person wants to reach. Goals also function as motivational states, directing behavior, influencing commitment to those goals, and keeping action more or less persistent toward those goals. Moreover, goals serve as reference values in a feedback loop in that they are used as standards to

compare behavioral states in the course of actions with the intended goals. Finally, goals trigger the forming of emotions such as pride (in the case of reaching goals) and shame (in the case of failing to reach goals).

2. GOAL EFFECTS: MECHANISMS AND MODERATORS

According to Locke and Latham, goals determine the effort that people invest in their actions, goals direct behavioral acts toward the intended outcomes, and goals are responsible for the degree of persistence in keeping actions goal oriented. These are the mechanisms by which goals affect performance and outcomes. The effect of goals is moderated by a set of variables, and in this context the three most important variables are goal commitment, task complexity, and ability (Fig. 1).

Before going into details of the moderator effects, some characteristics of goals influencing their effect on performance should be noted. Hundreds of studies have shown that setting a specific difficult goal leads to higher performance than does a general intention to do one's best. This is true for individuals who have the ability necessary to perform a task. For people who do not have the necessary knowledge to perform a task effectively, setting a high outcome goal can have detrimental effects on performance.

In 2001, Seijts and Latham showed that in the case where people do not have the necessary knowledge to

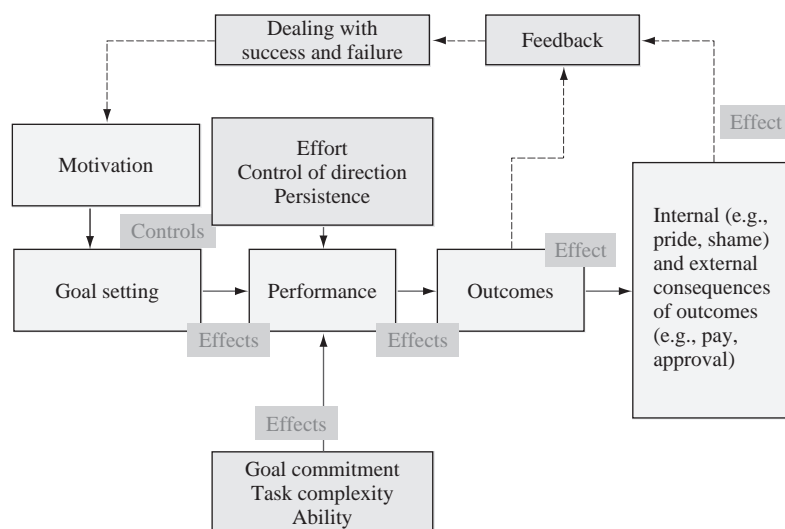

FIGURE 1 Concepts for understanding the translation of goals into action.

perform a task effectively, it is helpful to set a learning goal instead of an outcome goal. They defined a high learning goal as specific and difficult in terms of the number of strategies to be discovered to learn how to perform a task. In their study, they showed that a specific difficult learning goal leads to higher performance than does urging people to do their best on a task where they initially lack the requisite knowledge to perform it. Specific difficult outcome goals should be avoided because they appear to have a detrimental effect on performance during the learning process. The practical implication of these findings is that practitioners should focus on ways in which to increase workers' self-efficacy on tasks that the workers perceive as difficult and complex. This helps to avoid failure experiences with detrimental consequences for further goal setting and performance, and it also reduces negative effects on self-esteem.

Two additional variables in this model deserve some attention: goal commitment and the way in which actors deal with failure. Goal commitment is important to keep actions going so as to reach a goal. Highly committed persons stay with goals persistently, even when they encounter difficulties and hindrances along the way. They keep focused on the current task and resist temptations raised by other motivating potentials or motives.

Commitment to a goal actually controlling ongoing behavior directly depends on the motivation while pursuing the goal (Fig. 2). If there is no competitive motivational state, a persistent striving toward the original goal is not threatened at all. Although the strength of goal commitment for the ongoing action is affected by personal motives and situational

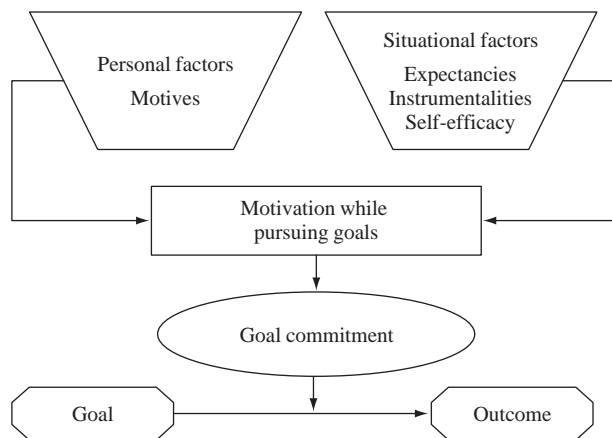

FIGURE 2 Determinants of goal commitment.

characteristics when starting the action, there may be changes in both groups of variables that are responsible for either a decrease in goal commitment or an increase in motivation for a different action. This could lead to an early change in activity (due to changing goals) before the originally intended goal has been reached. Other determinants of a high goal commitment are high self-efficacy, a high expectancy to reach the goal, and a high instrumentality of the outcome aimed for higher order outcomes in the future. A success-oriented achievement motive could also be helpful for keeping goal commitment high if the motivating potential of work is high with respect to the achievement motive system.

Setting high goals at work increases the probability of high performance. But high goals also carry the risk of failure. Although occasional failure should not be dangerous for successful work, it can be dangerous in the long run, especially when it has a negative influence on the self-esteem of acting persons. In the positive case, failure strengthens approach tendencies and goal commitment. The original goal stays as high as it was before the failure, or it is set even higher to invest more effort than before. This increases the chances of reaching the goal (Fig. 3). In the negative case, failure urges people to withdraw from the task, goal commitment goes down, and the acting persons give up on original goal. This leads to lower performance.

A large amount of research clearly shows the convincing effects of goals on behavior at work. Not only can performance be increased by high and specific

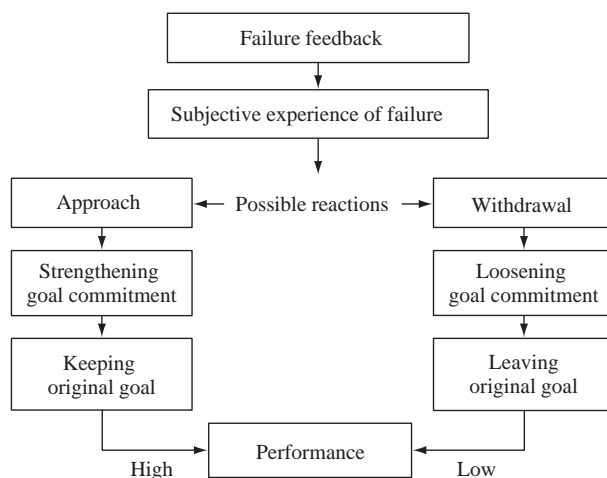

FIGURE 3 Possible reactions to failure: Approach or withdrawal.

outcome or learning goals, but withdrawal behaviors, such as absences and fluctuations, also can be influenced by goals. Important moderators are goal complexity, goal commitment, and the competence to deal with failure in an adequate mode. Motives are especially effective as central determinants of goal commitment. Of course, they unfold their influence on goal commitment in interactions with motivating potentials, changing with various situational aspects occurring in the course of an action.

3. DEVELOPING A PERSONAL GOAL

Whether a person sets high or low goals, whether the person directs his or her behavior in this or that direction, and whether the person persists more or less with one goal depend on the interaction of personal and situational factors. In motivational theory, these factors are called motives as personal factors and motivating potentials on the side of the situational factors. As stated previously, motives are highly aggregated classes of goals, and motivating potentials provide the occasions for realizing motive goals. Important motives in modern industrial and service-oriented societies include the following:

- Curiosity
- Achievement
- Affiliation
- Power
- Aggression
- Hunger, thirst, and sexual motives

For each motive, there are motivating potentials in the situation in which persons are acting. Motivating potentials for persons with a high curiosity motive are high when a situation enables them to increase their knowledge. For more information about motivating potentials related to various motives, see [Table I](#).

Motives and motivating potentials interact in determining goal direction and goal difficulty ([Fig. 4](#)). Empirical evidence has been reported for several motive domains. For purposes of illustration, the interaction of the achievement motive with the corresponding motivating potential of the work situation is described. The achievement motive is defined as striving for competing with a standard of excellence. Persons with a high achievement motivation like to know how efficient they are and how to improve their efficacy. To set high goals, these persons need challenging tasks that give them the opportunity to see for themselves how efficient they are and that allow them to

TABLE I
Important Motives and the Corresponding Motivating Potentials of Situations

Motive	<i>Motivating potentials offer an opportunity to:</i>
Curiosity	Get better knowledge of what is going on
Achievement	Enhance one's competence and feel pride about having reached a goal
Affiliation	Build a new social relation and keep it in a good state
Power	Influence the behavior of others
Aggression	Perform harmful acts toward others
Hunger, thirst, and sexual motives	Get food and water and get a sexual partner

find ways in which to increase their efficacy. Such tasks are characterized by a variety of task components. They are important, offer a certain amount of autonomy, and allow continuous feedback during task performance together with clear outcome feedback. In 1976, Hackman and Oldham referred to the combination of these factors as "motivating potential of tasks."

Outcome and performance feedback can be used by the acting person to calculate expectancies about the chances of reaching a goal. In the case of achievement motivation, expectancies are also important for the strength of motivating potentials because it makes sense for those with a high achievement motive to work with tasks that give them at least a moderate probability of success. In this way, it is possible for persons with a high achievement motive to learn as much as possible about their own efficacy.

4. ACCEPTANCE OF GOALS

Very often in their lives, especially at work, persons are asked to accept goals that have not been set by themselves. In such cases, the question arises as to whether they accept these external goals for controlling and regulating their own behavior. Reacting on externally set goals, a person has at least three choices: accepting the goals, internalizing the goals, or using the goals to control goal-oriented actions ([Fig. 5](#)). This happens, of course, when the externally set goals are not in conflict

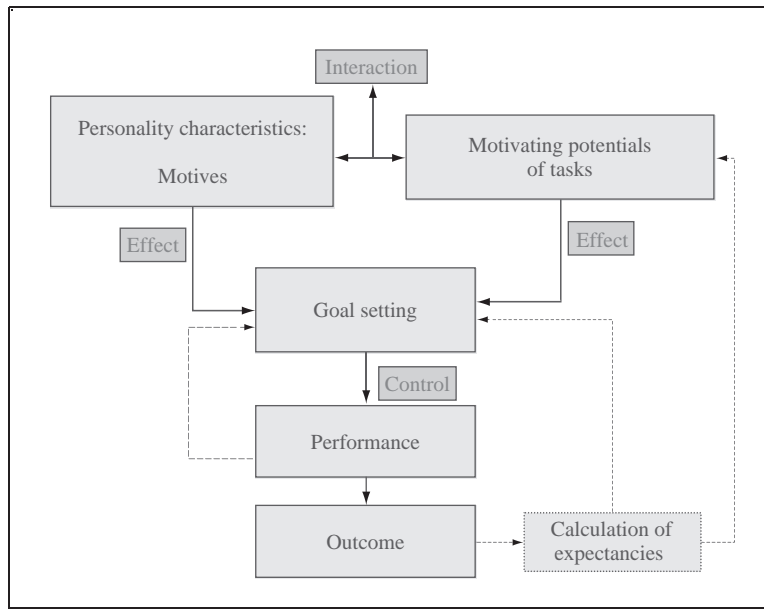

FIGURE 4 The formation of goals as the result of an interaction between personal and situational characteristics.

FIGURE 5 Concepts used to describe the process of accepting and internalizing or rejecting externally set goals. Adapted from Earley and Shalley (1991).

with personal goals, when they might even lead to outcomes with high personal valence, or when the costs of a conflict between personal and organizational goals is compensated by a stimulating reward.

On the other hand, one can reject goals directly when it appears clear from the beginning that there will be conflicts with personal goals and no compensation is in

sight. In this case, the person begins to think about the possibility of influencing the leader who set the goal. If influence appears to be possible, negotiation is started to change the original goal, possibly leading to a new goal. If the influence potential of the situation is negative, the person must decide either to comply and accept the goal or to withdraw from the situation.

These considerations have some practical implications for motivating people at work. When setting goals externally, it makes sense to be aware of the motives of workers and employees because these motives are of essential importance to their personal goals. If managers know these goals, they can calculate in advance what effects their externally set goals will have. If conflict between externally set goals and personal goals is expected, managers either can reformulate their goals to minimize conflict or can use other techniques that make clear how important it is to work on the goals set by them even if such goals are not in line with personal goals. One technique could be to introduce a participative goal-setting program, as discussed later in the article.

5. HOW TO PURSUE GOALS THAT ARE (STILL) UNKNOWN

Activities at work in general are goal oriented. Often, goals are specific and difficult, leading to high performance. Goal-setting theory offers evidence for understanding these effects. But nowadays, more and more work activities are no longer related to clear and specific goals because the specific goals are not yet known when the activities are started. One classic example is given with design tasks. They are characterized by the fact that outcomes are not at all clear for a long time during work on the tasks. They are similar to the learning tasks mentioned earlier in the article. In design tasks, people cannot do the following:

- Analyze the conditions of action necessary for reaching the goals exactly.
- Run trial actions.
- Form language terms to describe actions.
- Coordinate component goals toward ultimate goals.
- Compare outcomes with goals stored in memory.

Although these activities cannot be regulated by specific goals as anticipated outcomes, design actions are not without direction given that the outcomes must be developed first. During activities of this kind, people must do the following:

- Follow up more than one problem-solving alternative.
- Build up evaluation criteria to be used in iterative processes of error correction.
- Look for similar cases to be used as models for the current ones.

The practical consequences of these considerations are easy to describe. Although it is known that high specific and concrete outcome goals lead to high performance, it is not always possible to set such goals, especially when the outcome of work is not quite clear at the beginning. In such a case the chances for success will increase through setting learning goals such as the following:

- Discover a number of strategies to learn how to perform the task.
- Develop systematic testing of task-relevant strategies.
- Identify evaluation criteria.
- Use information from similar cases.

After having learned about strategies to solve the task, it could be helpful to again relate goals to outcomes.

6. MANAGING SUCCESSFUL GOAL-ORIENTED WORK BEHAVIOR: THE PARTICIPATORY PRODUCTIVITY MANAGEMENT

During the second half of the 20th century, many management systems that focused on goal setting were presented and used. The management by objectives system has been used successfully for five decades. Goal-oriented management systems help leaders to coordinate the goal-setting process continuously. The Balanced Scorecard (BSC) is well known for its ability to support successful management in this respect. Another powerful instrument with a more solid empirical foundation is the Participative Productivity Management (PPM), originally developed by Pritchard in 1990 as the Productivity Measurement and Enhancement System (ProMES). PPM is different from BSC in its very elaborate bottom-up approach that makes sure that workers accept the measurement and feedback system used to prepare adequate goal setting. So, it effectively helps to avoid goal conflicts between external or task-driven goals and personal goals set by the workers themselves.

In the framework of this management system, work group members develop their own measurement system coordinated with all responsible actors in the company, enabling them to participate as well-informed partners in the goal-setting process. In weekly or monthly systematic feedback sessions, group members and their leaders come together to discuss feedback delivered by the measurement

system that they had developed themselves. On the level of various performance indicators (e.g., amount of items produced, quality of work, customer satisfaction, scheduling effectiveness), group members use this system to describe the discrepancies between their previously set goals and their actual outcomes for each indicator. The system also helps the workers to weigh each indicator score with respect to its importance for the organization's productivity. On this basis, they discuss the reasons why they succeeded or failed to reach their goals. As a result of this discussion, they set new goals for the next measurement period. These procedures keep them in a continuous improvement process. The task of their leaders becomes more and more one of facilitators of a self-controlled productivity process. Meta-analyses show that using this management system has an enormous effect on productivity.

7. COMPETENCIES IN MANAGING GOAL-DIRECTED BEHAVIOR

Empirical data show that goal setting can be used as a technique to manage people effectively toward the goals of an organization. As was shown in the preceding section, the goal-setting process will profit from the support of a goal-oriented management system. For example,

PPM offers the structural systemic background for successful goal setting. It helps leaders to do the following:

- Set goals participatively so that acceptance of organizational goals can be expected.
- Delegate responsibilities to work group members.
- Clarify goal–outcome relations.
- Define clear criteria for success and failure.

But PPM does not replace leaders. The tasks of leaders will change, but leadership will still be necessary. Leaders using a management technique such as PPM should have some special competencies to support workers' goal setting and the effect of goals during various phases of the action process. During the first phase of the action process, when the goals are developed, special competencies are required to identify the personal goals (and motives) of workers and to take them into account while discussing the necessary goals for the next work and feedback period defined in the PPM measurement system (Fig. 6). Another competency is required to structure complex tasks and identify subtasks with corresponding subgoals. In the case of evaluating negative outcomes, leaders need some competencies as well. Dealing with failure can be dangerous for leaders because it is necessary to feed back failure without trying to make things seem better as they are. The danger is that feeding back such information about failure can be seen as an indicator of low ability by failing persons. This might be a reason for lowering

FIGURE 6 Competencies needed or leaders using goal setting in combination with a goal-oriented management system.

one's self-esteem, with further effects on goal setting. Goals will be set lower, or high external goals will not be accepted, due to fears of failing again. Although work motivation can be decreased by failure feedback, it does not make sense to hold back such information. Instead, leaders should be able to talk about failure as an opportunity to learn about new strategies to avoid failure and, as such, to increase their self-efficacy. These competencies help to strengthen goal commitment. Another set of competencies for successful leadership involves coordinating persons in groups as well as between groups and departments.

8. AN INTEGRATIVE MODEL FOR THE EFFECTS OF MOTIVES AND GOALS

Motives and goals work together to control the intensity, direction, and persistence of behavior at work. Figure 7 summarizes the effects of motives and goals during all phases of the action process. Motives are defined as classes of goals that determine, in interaction with motivating potentials of the work situation, the kinds of goals people use to control their actions. The way in which they do this is described by expectancy-value theories. One example of an empirically sound specific

theory of this kind is achievement motivation. It describes a motive (achievement motive) and a motivating potential (task difficulty) in explaining the development of individual goals in achievement situations. The translation of a goal into action and performance is the topic of goal-setting theory. Goal characteristics and mechanisms and moderators of the translating process are the determinants of outcomes. During this action phase, motives play a role as well. They affect the degree of goal commitment persons show while performing. Even the evaluative phase of an outcome motive can be seen at work. Motives influence the way in which causal attributions are used to explain the outcome. Especially interesting is the impact of motives on the way in which people deal with failure.

Failure delivers two kinds of information. First, it informs about the discrepancy between an outcome and the goal. Second, it says something about a person's efficiency. In case of failure, this second kind of information is dangerous for one's self-esteem. It tells a person that he or she is not able to succeed at this kind of task, especially if the failure repeats. Persons with a high achievement motive are better equipped to deal with failure because they tend to increase motivation, stay with their goals, and finally reach them. The integrated model helps to understand how goals are established, how they affect ongoing action, and how they influence the evaluation of outcomes of actions. It

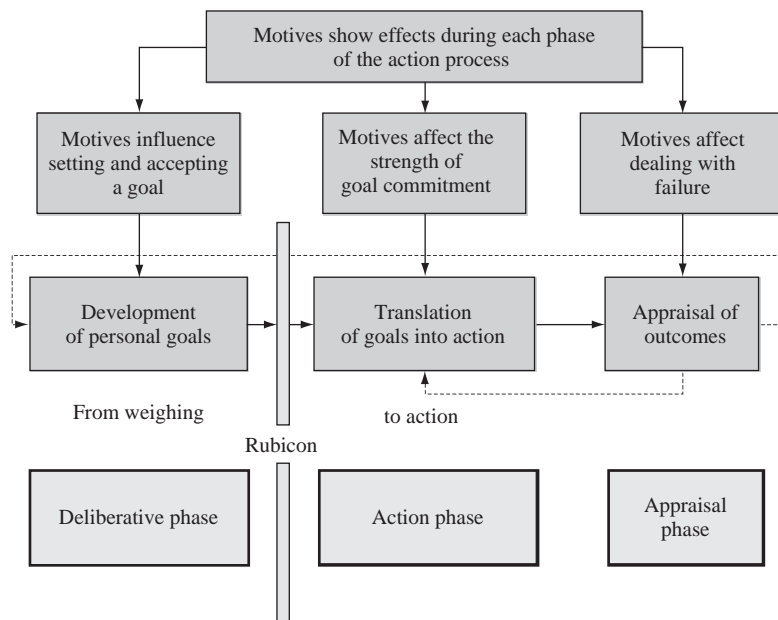

FIGURE 7 The role of motives in each phase of an action process.

summarizes a fundamental process that can be differentiated during all of its phases to describe the many facets of goal-directed behavior. Most of the concepts in the model have been tested empirically and have proven to be valid. On such an empirical ground, the model allows one to develop psychologically sound techniques to be used in applied psychology for increasing productivity and for adapting tasks and organizational contexts to the structure and functions of human resources at work.

GLOSSARY

pediatric neuropsychologist Uses standardized tests and observes behavior to define a child's pattern of cognitive development. The pediatric neuropsychologist uses knowledge of brain development, brain organization, and the effects of various forms of brain injury on development to guide this assessment and interpret results.

school neuropsychologist Integrates neuropsychological and educational principles in assessments and interventions with infants, children, and adolescents to facilitate learning and behavior within the school and family environments. School neuropsychologists also play an important role in curriculum development, classroom design, and the integration of differentiated instruction that is based on brain-behavior principles in order to provide an optimal learning environment for every child.

specific learning disabilities Disorder in one or more of the basic psychological processes involved in understanding

or using spoken or written language that may manifest itself in an imperfect ability to listen, think, speak, read, write, spell, or do mathematical calculations.

traumatic brain injury An acquired injury to the brain caused by an external physical force—resulting in total or partial functional disability, psychosocial impairment, or both—that adversely affects a child's educational performance. The term applies to open or closed head injuries resulting in impairments in one or more areas, such as cognition; language; memory; attention; reasoning; abstract thinking; judgment; problem solving; sensory, perceptual, and motor abilities; psychosocial behavior; physical functions; information processing; and speech. The term does not apply to brain injuries that are congenital or degenerative or to brain injuries induced by birth trauma.

Increasingly, school-aged children and adolescents have cognitive processing deficits (e.g., memory, learning, and attention) or behavioral/emotional deficits (e.g., autism, mood disorders, anxiety, and conduct problems) that are a result of known or suspected neurological conditions. Educational personnel, including school psychologists, are not always prepared to assess and intervene with these neurologically impaired populations; however, they can be trained. Traditionally, psychoeducational assessments measure estimates of overall intelligence and academic achievement but do not assess the underlying cognitive processes and sensory-motor

functions associated with learning and behavior. Neuropsychological assessments are designed to assess discrete cognitive processes (e.g., visual short-term memory, auditory short-term memory, and sustained attention) that help facilitate or inhibit the learning process. Ideally, a neuropsychological assessment of a school-aged child should link the assessment results with instructional and behavioral recommendations or interventions that improve the child's academic and/or social-emotional/behavioral functioning. This article presents several examples of children who would benefit from a neuropsychological evaluation, discusses several reasons why there is growing interest in integrating neuropsychological principles into psychoeducational assessment and intervention, discusses the current state of the art of school neuropsychological assessment, and presents a conceptual framework for school neuropsychological evaluations.

1. SCHOOL-BASED PROBLEMS THAT CAN BE ADDRESSED BY NEUROPSYCHOLOGICAL ASSESSMENT

1.1. Case Examples

Increasingly, children and adolescents are coming to school with known or suspected neurological conditions. Two examples are presented here that illustrate the types of cases being identified by educators and assessment specialists within the schools.

First, Mary is 17 years old and a junior in high school. While on a date with her boyfriend, a drunk driver struck the car in which they were riding head on. Her boyfriend escaped the accident with minor injuries, but Mary was not wearing her seat belt. She was thrown through the windshield. Mary suffered a severe head injury and was hospitalized. Several weeks later, after her medical needs had become stabilized, she was released from the hospital. Her medical insurance did not cover any cognitive rehabilitation so she was sent home. When Mary returned to school a month after the accident, her physical wounds had healed and she looked as if she had healed completely. She returned to her 11th-grade regular education classes. Prior to the accident, Mary was an "A" and "B" student. When Mary returned to school after the accident, her grades declined dramatically, she complained about having trouble focusing attention and concentrating for long periods

of time, she could not remember things, and she seemed to tire easily.

Second, Sam is in the fifth grade. He was diagnosed 3 years earlier with a specific learning disability in the areas of reading comprehension and written expression. Sam has average cognitive capabilities, but he has severe problems with understanding what he has read and putting his thoughts down on paper. Sam has made very little academic progress during the past 3 years. His teachers express frustration that they cannot seem to "find the right buttons to push" to help Sam make academic progress.

Sam and Mary represent two examples of children who have disabilities defined in federal legislation that are of particular interest to neuropsychologists: specific learning disability (SLD) and traumatic brain injury (TBI). In 1975, the U.S. Congress passed landmark legislation with the Education of All Handicapped Children Act (P.L. 94-142), designed to provide free and appropriate educational services to children. P.L. 94-142 was reauthorized in 1990 and became known as the Individuals with Disabilities Act (IDEA). IDEA was reauthorized in 1997 and is under revision with an expected adoption date in 2004.

1.2. Specific Learning Disabilities

SLD was included in the 1975 P.L. 94-142 as a student disability. SLD is a generic term that refers to a heterogeneous group of disorders due to identifiable or inferred central nervous system dysfunction. Such disorders may be manifested by delays in development and/or difficulties in one or more of the following areas: reading accuracy, reading comprehension, mathematical calculations, mathematical reasoning, written expression, listening comprehension, and oral expression. Since the inception of the concept of a SLD, educators have struggled with how to identify children who have these processing disorders caused by some type of central nervous system dysfunction. Commonly used methods of SLD identification, such as aptitude/achievement discrepancies, have failed to address the underlying brain processing disorder(s).

The revision of IDEA under consideration encourages states to deemphasize the use of discrepancy models in the identification of SLD and move toward a three-tiered intervention model. Tier 1 operates on the principles that high-quality instructional and behavioral supports are required for all students in general education. Tier 2 would require targeted, intensive prevention or remediation services for students whose performance and

rate of progress lag behind the norm for their grade and educational setting. Tier 3 would require a comprehensive evaluation by a multidisciplinary team to determine eligibility for special education and related services. Within the proposed third tier of the intervention model, neuropsychological assessments could provide valuable information about the child's cognitive strengths and weaknesses and the links to prescriptive interventions.

1.3. Traumatic Brain Injury

In the 1990 revision of IDEA, TBI was included for the first time as an identifiable student disability. TBI is an injury to the brain caused by the head being hit or shaken violently. When a head injury occurs in a child or adolescent, the brain has not fully developed. As a result, recovery from loss of function due to a head injury is often uneven and unpredictable. School-aged children who have sustained a head injury require organized, cooperative, and closely monitored special education services. As recently as 10 years ago, a child with a head injury would typically move from an acute care hospital setting, in which his or her physical needs were addressed, to an intermediate rehabilitation setting for a few months, in which cognitive rehabilitation took place. Today, it is typical for a child to be released from a hospital as soon as his or her medical condition is stabilized and to return to his or her regular classroom soon thereafter, without any cognitive rehabilitation. During the past 15 years, managed care within the insurance industry has led to a reduction of cognitive rehabilitation services offered to TBI victims. Educators have been faced with how to educate children with increasingly complicated learning and emotional needs.

Neuropsychological assessment can play an important role with TBI students by determining the mental and behavioral effects of the brain injury, identifying the functional assets and deficits for instructional planning, and establishing baseline data to evaluate subsequent change. Because of the rapid changes in recovery of function, it is often necessary to meet frequently as an individualized education plan team to review the TBI student's progress and to adjust the educational goals. Educational personnel, including school psychologists, speech and language pathologists, occupational therapists, physical therapists, adaptive physical education specialists, and regular and special education teachers, must all work collaboratively with the family to meet the educational needs of the student.

1.4. Other Disabilities That May Warrant a Neuropsychological Evaluation

Table I presents a list of other suspected or known disabilities or neurological impairments that would benefit from neuropsychological assessments. In the 1990 and subsequent IDEA definitions of TBI, only injuries to the brain as a result of trauma are classified as TBI. Acquired brain injuries as a result of infection, disease, chemotherapy, or high fever are not considered under the current definition as TBI. Children with acquired brain injuries are typically identified as "other health impaired" if there are significant academic and/or behavioral concerns that need to be addressed.

Research has shown that children born with neurodevelopmental risk factors, such as low birth weight, prenatal exposure to drugs or alcohol or both, or exposure to environmental toxins (e.g., lead), are likely to present with neurocognitive deficits (e.g., memory, attention, processing speed, and language skills). Children with medical conditions such as epilepsy or children undergoing chemotherapy due to cancer may also be at risk for neurocognitive deficits associated with their illnesses or treatments.

TABLE I
Suspected Handicaps and Neurological Conditions
for Which Neuropsychological Assessment
May Be Beneficial

Children and adolescents who are having academic or behavioral difficulties due to
Severe learning disabilities that have not responded to traditional intervention techniques
Processing discrepancies on psychoeducational measures (e.g., memory deficits, language processing deficits, attentional processing deficits, and processing speed deficits)
A documented rapid decline in academic achievement that cannot be explained by social, environmental, or psychological causes
Congenital or acquired brain damage
Neuromuscular diseases such as cerebral palsy
Chronic epilepsy
Neurodevelopmental risk factors such as low birth weight, prenatal exposure to drugs or alcohol or both, or exposure to environmental toxins (e.g., lead)
A treated or suspected brain tumor
An infection of the central nervous system
An unusually large scatter among test scores that cannot be explained

Unfortunately, many children who have known or suspected neurological conditions are misclassified [often as learning disabled (LD) or emotionally disturbed (ED)], which leads to planning that does not fully address their educational needs. For example, an undiagnosed TBI student can develop secondary emotional and behavioral problems due to the head injury and the associated cognitive deficits. Labeling this TBI student as emotionally disturbed and focusing the majority of the educational efforts on regulating the student's behavior will not address the underlying cognitive processing problems.

Traditional psychoeducational assessments conducted with school-aged children do not fully address the types of cognitive processing deficits associated with children having known or suspected neurological conditions. Neuropsychological assessments measure discrete cognitive processes (e.g., visual short-term memory) that help facilitate or inhibit the learning process. The results of a neuropsychological assessment can provide a profile of a child's functional strengths and weaknesses that will facilitate instructional planning.

2. STATE OF THE ART OF NEUROPSYCHOLOGICAL ASSESSMENT IN SCHOOLS

2.1. Neuropsychological Assessment in the Past and Present

From the 1940s to the 1970s, one of the main functions of a neuropsychological evaluation was to identify the source of a possible lesion or area of dysfunction within the brain. With the advent of modern neuroimaging (e.g., computerized axial tomography, magnetic resonance imaging, functional magnetic resonance imaging, and positron emission tomography), these specialized techniques are now used to directly assess the localization of lesions or tumors to millimeter precision. The goal of neuropsychological assessment should be to identify the functional strengths and weaknesses of the examinee and to translate those data into evidenced-based intervention strategies rather than to try to localize possible lesion sites within the brain. A lengthy neuropsychological report to the schools with the conclusion that "Johnny has a right parietal lobe lesion" will not facilitate educational planning. The neuropsychological report must summarize implementable prescriptive recommendations that address the student's functional strengths and weaknesses for parents and teachers.

Evaluators who wanted to administer neuropsychological measures to children prior to the 1990s were very limited in their assessment choices. The fixed batteries that were standardized 20–40 years ago (e.g., Halstead–Reitan Neuropsychological Batteries and Luria–Nebraska Neuropsychological Battery) were the principle measures available for neuropsychologists. Unfortunately, these test batteries were not designed for children but were downward extensions of adult measures. Also, the fixed batteries of the 1950s and 1960s had limited standardization samples for children and would not stand up to the scrutiny of test development today. In the 1990s, test authors and publishers provided school-based assessment specialists with a wide variety of new tests of memory and learning designed for and standardized on large numbers of children and adolescents (Table II).

Since the late 1990s, there has been an increased number of fixed battery tests developed specifically for school-aged children (Table III). Some of the tests, such as the NEPSY, are neuropsychological batteries based on modern theory and research and designed specifically for young children. Other fixed batteries are intelligence tests that have been reformulated to take into account advances in cognitive psychology, neuropsychology, and intelligence test theories [e.g., Woodcock–Johnson Revised Tests of Cognitive Abilities (WJIII) and the Wechsler Intelligence Scale for Children—Fourth Edition]. Tests such as the Delis–Kaplan Executive Functions System have revised and restandardized traditional tests (e.g., Trail Making and Stroop) and added to their interpretative depth.

TABLE II
Tests of Memory and Learning for School-Aged Children

Test	Age range (years)
Wide Range Assessment of Memory and Learning (WRAML; Sheslow & Adams, 1990; WRAML-2; Adams and Sheslow, 2003)	WRAML: 5–17 WRAML2: 5–90
Test of Memory and Learning (TOMAL; Bigler and Reynolds, 1994)	5–19
Children's Memory Scale (CMS; Cohen, 1997)	5–16
Wechsler Memory Scale—Third Edition (WMS-III; Wechsler, 1997)	16–89
California Verbal List Learning—Second Edition (CVLT-II; Delis <i>et al.</i> , 2000)	5–16

TABLE III
Selected Fixed Batteries for School-Aged Children and Adolescents

Test	Age range (years)
Cognitive Assessment System (CAS; Naglieri & Das, 1997)	5–17
NEPSY (Korkman <i>et al.</i> , 1997)	3–12
WISC-III as a Process Instrument (WISC-III PI; Kaplan <i>et al.</i> , 1999)	6–16
Delis–Kaplan Executive Functions System (D-KEFS; Delis <i>et al.</i> , 2001)	8–89
Woodcock–Johnson III Tests of Cognitive Ability and Achievement (WJIII; Woodcock <i>et al.</i> , 2000)	2–90+
Dean–Woodcock Neuropsychological Battery (DW; Dean and Woodcock, 2002)	4–90+
Diagnostic Supplement to the WJIII Tests of Cognitive Abilities (DS-WJIII; Woodcock <i>et al.</i> , 2003)	2–90+
Wechsler Pre-School and Primary Scale of Intelligence—Third Edition (WPPSI-III; Wechsler, 2002)	2–7
Wechsler Intelligence Scale for Children—Fourth Edition (WISC-IV; Wechsler, 2003)	6–16
Kaufmann Assessment Battery for Children—Second Edition (KABC-II; Kaufman and Kaufman, 2004)	3–18

There are three major trends in neuropsychological assessment. The first is a subtle shift toward providing the evaluator qualitative information about the cognitive processes a child used to obtain a score, in addition to the score itself. For example, publishers are providing base rates for each age range within the standardization sample for common qualitative behaviors (e.g., asking for repetitions and failure to comprehend). This “process approach” is important because the qualitative behaviors often provide valuable insight into how a child’s brain is processing information and assist in the diagnoses of neuropsychological conditions.

The second trend in neuropsychological assessment is ensuring the assessment is grounded in theory. Test authors and publishers are more consistently providing a theoretical foundation for their tests, which aids in test interpretation (e.g., NEPSY based on Lurian theory or the WJIII based on the Carroll–Horn–Cattell model). Finally, the third trend will be an added

emphasis during the next decade on linking assessment with evidenced-based interventions. Researchers and clinicians will need to establish and verify linkages between assessment and intervention.

2.2. Who Can Complete a Neuropsychological Assessment?

The most highly trained assessment specialists in schools are school psychologists. However, the majority of school psychologists are trained at the specialist level (master’s degree +30 hours) of training, which provides minimal training in the biological bases of behavior and rarely covers neuropsychological assessment techniques. School psychologists can only conduct neuropsychological assessments if they have expertise in neuropsychology. To ensure proper expertise, school psychologists must complete an organized competency-based, post-graduate training or a doctoral program in which they can specialize in school neuropsychology.

If a school district does not have a school neuropsychologist on staff, which is the norm, the district will often request a neuropsychological evaluation from a clinical neuropsychologist in private practice or working in a hospital setting. Clinical neuropsychologists are licensed psychologists who are trained at the doctoral level, typically with a degree in clinical psychology and a specialization in clinical neuropsychology. However, the majority of clinical neuropsychologists have expertise in completing adult assessments rather than school-based neuropsychological evaluations.

A pediatric neuropsychologist is a clinical neuropsychologist specifically trained to work with children. If school districts seek an outside neuropsychological assessment, it is best to contract a pediatric neuropsychologist. The downside to contracting with any specialist outside of schools is that the specialist may not be familiar with the IDEA rules and regulations that guide special education placements and may operate under a clinical model using clinical nomenclature (e.g., *Diagnostic and Statistical Manual of Mental Disorders*, fourth edition, diagnoses).

For neuropsychological principles to be best integrated into schools, there needs to be more cross-training. Many of the new cognitive ability tests and tests of memory and learning being administered by school psychologists have strong foundations in neuropsychological theory. School psychologists and educators need to improve their knowledge base about brain–behavior relationships if they are going to

appropriately interpret these newer tests. There are more than 25,000 school psychologists who have direct access to children in schools. Training to use and interpret neuropsychological assessments is important. At a minimum, school psychologists and educators should be taught to recognize the warning signs of neuropsychological conditions and know when to refer to another specialist for assistance.

As a general rule, pediatric neuropsychologists consulting with schools should learn to integrate their neuropsychological assessments within the context of IDEA eligibility and recommend realistic school-based interventions. A school neuropsychology specialist can write an insightful report about a child's cognitive strengths and weaknesses and make a set of educational recommendations that are evidence based and practical. It is possible that the neuropsychological assessment report may simply be filed away in a child's academic folder if the classroom teachers do not understand how to implement the educational recommendations. An essential role that a school neuropsychology specialist can play is to consult with classroom teachers regarding the integration of the neuropsychological assessment results into the instructional planning.

3. CONCEPTUAL FRAMEWORK FOR SCHOOL NEUROPSYCHOLOGICAL ASSESSMENT

A neuropsychological evaluation for a school-aged child should focus on answering the referral question. A conceptual framework for a school neuropsychological evaluation is outlined in Table IV. A sensory perceptual examination across the auditory, visual, and kinesthetic modalities should be a required baseline assessment in all evaluations. If the child is not able to adequately receive and process sensory perceptual information, then performance on higher order cognitive functions could be compromised. The next major component to be assessed is attentional processing skills. Attention serves an important baseline for the rest of the higher order processing. Attention is not a unitary construct. It is recommended that a school neuropsychological evaluation assess the following elements of attention for both the visual and auditory modalities: initiating, sustaining, inhibiting, shifting, and divided.

Assessment of executive functions is also a recommended component. For a thorough evaluation of executive functions, the assessment must include cognitive

TABLE IV
Suggested Components of a School Neuropsychological Assessment^a

Sensory perceptual
Auditory
Visual
Kinesthetic/tactile
Attention
Auditory (initiating, sustaining, inhibiting, shifting, and divided)
Visual (initiating, sustaining, inhibiting, shifting, and divided)
Executive functions
Cognitive (e.g., processing speed and efficiency, initiating and shifting cognitive sets, conceptual shift, planning, organizing, self-monitoring, and verbal/nonverbal retrieval fluency)
Motor programming
Behavioral/emotional regulation [e.g., interest, motivation, initiative, disinhibition (impulsivity), affect, judgment, insight, and activity level]
Memory
Auditory modality
Auditory, verbal
Explicit acquisition
Rote (word lists) (immediate and delayed)
Associative (paired learning) (immediate and delayed)
Discourse (words, sentences, paragraphs, and stories) (immediate and delayed)
Implicit acquisition
Incidental (passive)
Retrieval (recall—primacy and recency effects—and recognition)
Auditory, nonverbal
Explicit acquisition (immediate and delayed)
Implicit acquisition
Retrieval (recall—primacy and recency effects—and recognition)
Visual modality
Visual, verbal [letters, words, picture or shapes with verbal labels (rebus), etc.]
Acquisition (immediate and delayed)
Initial registration [sensory memory to short-term memory (immediate)]
Consolidation [short-term memory to long-term memory (delayed)]
Retrieval (recall and recognition)
Visual, spatial (e.g., Rey–Osterieth)
Acquisition (immediate and delayed)
Retrieval (recall and recognition)

Continues

Continued

Motor memory
Procedural [e.g., literal apraxias (imitation) and paragraphias (spelling)]
Complex motor tasks (e.g., riding a bicycle and tying shoes)
Ideomotor and ideational apraxias
Writing and typing
Language
Receptive (phonology, semantics, grammar/syntax, pragmatics, and listening comprehension)
Expressive [phonology, semantics, grammar/syntax, pragmatics, and discourse (e.g., articulation)]
Reading (phonology, semantics, grammar/syntax, pragmatics, decoding, and comprehension)
Written expression (not writing) (phonology–sequential processing, semantics, grammar/syntax, pragmatics, decoding, comprehension, and organization of thought and content)

Social–emotional
Personality characteristics
Temperament
Psychopathology

^aAdapted from a proposed model by Miller *et al.* (manuscript in preparation).

integrity, behavioral regulation, and motor programming components. Memory assessment is next in the conceptual framework. Memory is multifaceted as well. A comprehensive evaluation must include assessment of auditory and verbal memory and the associated subcomponents (immediate, delayed, recognition, recall, etc.).

Language assessment is next in the conceptual framework. Language assessment includes measures of receptive, expressive, reading, and written expression. An

evaluation of motor functions, if warranted, would include fine, gross, speed, and strength components. Mathematical skills are conceptualized as a separate area that includes verbal components (number knowledge, counting, computation, and reasoning) and nonverbal components (math notation, reasoning in time and space, and computation). Finally, a comprehensive school neuropsychological assessment should include assessment of the student's social–emotional functioning (e.g., personality characteristics, temperament, and psychopathology). This conceptual framework serves as a starting point when considering a comprehensive school neuropsychological evaluation. The component parts that are selected should vary from student to student based on the referral questions to be answered and the presenting behavioral and/or learning problems.

4. SUMMARY

Children and youth who have known or suspected neurological conditions are increasingly being identified in schools. Traditional psychoeducational measures do not fully address the underlying neurocognitive deficits associated with SLD, TBI, acquired brain injury, epilepsy, etc. However, neuropsychological assessments measure discrete neurocognitive functions (e.g., visual short-term memory, processing speed, and sustained attention) that provide valuable insight into the neurocognitive strengths and weaknesses of the child and guide prescriptive interventions to improve instruction or provide positive behavioral supports.

Neuropsychological assessments for school-aged children have changed dramatically in the past 60 years. The purpose of a neuropsychological evaluation has evolved from identifying potential brain lesions to identifying functional profiles of strengths and weaknesses that link to prescriptive interventions. There has been a tremendous increase in the number and quality of neuropsychological assessment measures available for use with school-aged children. The strengths of these measures are their theoretical foundations, reliance on empirical studies for construct development, broad standardization samples for children, inclusion of qualitative and quantitative data, and good psychometric properties.

Preferably, neuropsychological assessments should be completed by a pediatric neuropsychologist or a school neuropsychologist. There is an urgent need for more cross-training between specialists in neuropsychology and educators to ensure that the recommendations that are made in a neuropsychological assessment report can

be implemented by classroom teachers. A conceptual framework for a school-based neuropsychological evaluation was also presented in this article. The selected component parts should be based on the referral questions and the presenting behavioral and/or learning problems.

The application of neuropsychological assessments in schools is an emerging area within the broader field of psychology and school psychology. For neuropsychological principles to be fully integrated within schools, brain-based research needs to be more fully translated into practice. More specialists in neuropsychology need to be trained to be readily available to educators for consultation, assessment, and prescriptive intervention.

GLOSSARY

addiction A behavior pattern of drug use characterized by overwhelming involvement with the use of the drug, the securing of its supply, and a high tendency to relapse after withdrawal.

classical conditioning Learning in which the conditioned stimulus is paired with and precedes the unconditioned stimulus until the conditioned stimulus alone is sufficient to elicit the response.

dependence The highly controlled or compulsive use of a psychoactive drug that is reinforced by the effects of that drug and includes the occurrence of tolerance and withdrawal.

nicotine A chemical alkaloid ($C_{10}H_{14}N_2$) that is naturally present in tobacco.

operant conditioning Learning in which the desired behavior or increasingly closer approximations to it are followed by a rewarding or reinforcing stimulus.

tolerance The need for markedly increased amounts of a substance to achieve the desired effect or a markedly diminished effect of a drug with continued use of the same amount of the substance.

withdrawal The syndrome of often painful or uncomfortable physiological and psychological effects that result when the use of a drug is discontinued.

Tobacco use and cigarette smoking are widespread behaviors that involve the self-administration of the addictive drug nicotine. These behaviors directly contribute to premature morbidity and mortality from a variety of diseases, including cardiovascular diseases, cancers, and respiratory diseases. A great deal of information has accumulated relevant to the reasons people use tobacco products and the role of nicotine addiction. In addition, nicotine replacement therapies are used in conjunction with behavioral and cognitive therapies to help people abstain from tobacco use.

1. INTRODUCTION

Tobacco use and cigarette smoking are worldwide health problems. It is estimated that more than 1 billion adults, or one-third of the global adult population, smoke cigarettes. In the United States, approximately 46.5 million adults (23.3% of the adult population) are cigarette smokers and 7.6 million adults are smokeless tobacco users. Cigarette smoking is an especially difficult problem in the adolescent population. Although smoking among high school students is beginning to decline, more than 2000 people younger than age 18 begin smoking every day in the United States. In addition to

age, factors such as gender, race, and socioeconomic status affect the likelihood that an individual will use cigarettes or other tobacco-containing products.

The high prevalence of tobacco use results in significant costs to society. The medical consequences of smoking and tobacco use are extensive and result in 430,000 premature deaths per year in the United States and more than 5 million premature deaths per year worldwide, making tobacco use the leading preventable cause of death. Smoking is significantly related to an increased risk for stroke, heart attacks, vascular diseases, and aneurysms. It is estimated that approximately one-fifth of all heart disease deaths are smoking related. Tobacco use accounts for one-third of all cancers and has been associated with approximately 90% of all lung cancer cases, the leading source of cancer-related deaths in both men and women. In addition, smoking causes several other types of cancer and pulmonary diseases, and smoking increases overall morbidity rates. Smoking and tobacco use in the United States cost approximately \$80 billion per year in health care costs and \$138 billion per year when factors such as smoking-related fires, medical care for low-birth-weight infants born to smokers, and the medical effects of second-hand smoke are taken into account.

Psychological and biological processes contribute to the initiation, maintenance, and cessation of tobacco use. People begin to use tobacco as a result of peer pressure, role modeling, responses to advertising, and other social and psychological influences that expose them to the addictive drug nicotine, which is responsible for the development of tobacco dependence. Self-administration of nicotine via tobacco becomes interwoven with environmental stimuli. Principles of learning, including classical conditioning, operant conditioning, and paired associations, act in concert with pharmacological actions of nicotine to positively and negatively reinforce this self-administration. Treatment of tobacco use, therefore, involves pharmacological and psychological interventions that work together.

2. NICOTINE OVERVIEW

Nicotine is one of the 4000 chemical components of tobacco smoke and is also present in smokeless tobacco. It is an alkaloid that is derived from the leaves of several plants, most commonly tobacco. Nicotine's molecular formula is $C_{10}H_{14}N_2$, and structurally it is composed of a pyridine and a pyrrolidine ring. The fact that nicotine

is a relatively small molecule and composed of elements that are compatible with biological systems contributes to its distribution and actions in the body. The most common route of administration of nicotine is by smoking cured and processed tobacco leaves in the forms of cigarettes, cigars, or pipe tobacco. The pH of cigarette smoke is slightly acidic (5.5–6.5) and nicotine's dissociation constant (pK_a)—the pH at which the chemical is in its ionized versus deionized form—is 8.0. As a result, nicotine in cigarette smoke does not readily diffuse across the mucous membranes of the mouth or throat. The smoke must instead be inhaled into the lungs to be absorbed across the membranes of the pulmonary alveoli. Nicotine passes into the pulmonary vascular circuit and is transported directly to the brain within 5–10 seconds of inhalation. The nicotine acts in the brain and is carried in the bloodstream throughout the body, metabolized in the liver, passed to the kidneys, and then eliminated from the body.

Psychological and behavioral variables (including stress, diet, and activity) can alter the distribution of nicotine and its rate of elimination from the body, which helps explain why people smoke more in certain situations (e.g., when under stress). The pH of chewing tobacco, snuff, and cigar and pipe smoke differs from that of cigarette smoke; as a result, nicotine is absorbed across mucosal membranes from these noncigarette tobacco products. When nicotine is absorbed across membranes in the mouth, rather than in the lungs, it is slower to act on the brain.

In the brain, nicotine's effects are mediated by several subtypes of nicotinic acetyl cholinergic receptors. These receptors are pentameric (five-unit) peptides that are found in the brain and central nervous system. The stimulation of these receptors by nicotine results in cholinergic activation and an increased release of dopamine and norepinephrine. In addition, nicotine affects the release and availability of endogenous opioid peptides, serotonin, and a variety of other biochemicals. The effects of nicotine on dopamine and endogenous opioid peptides are particularly relevant to nicotine's rewarding effects and play a major role in the biological mechanisms underlying nicotine addiction. It is well established that dopamine is involved in reward pathways that reinforce the self-administration of drugs of addiction, including nicotine, cocaine, and opiates. In addition, the endogenous opioid peptides are the naturally occurring biochemicals that mimic effects of the opiates, including morphine and heroin.

3. ROLE OF NICOTINE IN TOBACCO USE

To understand the role of nicotine addiction in tobacco use and cigarette smoking, it is important to recognize and define the classical triad of drug addiction: dependence, tolerance, and withdrawal. The terms drug addiction and drug dependence are often used interchangeably. According to the 1988 U.S. Surgeon General's report on nicotine addiction, drug dependence refers to the highly controlled or compulsive use of a psychoactive drug that is reinforced by the effects of that drug. The American Psychiatric Association uses a similar definition for drug dependence but also includes the occurrence of tolerance and withdrawal as necessary to establish drug dependence. Tolerance is the need for markedly increased amounts of a substance to achieve the desired effect or a markedly diminished effect of a drug with continued use of the same amount of the substance. Withdrawal is the syndrome of often painful or uncomfortable physiological and psychological effects that result when the use of a drug is discontinued.

Nicotine fits the classic profile of an addictive drug resulting in dependence as characterized by the occurrence of controlled and compulsive use as well as tolerance and withdrawal in a variety of species of animals and humans. Nicotine has been identified as the addictive drug in tobacco that is largely responsible for development of chronic tobacco use and dependence. It is an addicting drug with multiple reinforcing actions that are relevant to the maintenance of cigarette smoking and tobacco use as well as relapse during quit attempts. Cigarette smokers report positive, rewarding effects of nicotine and negative effects following abstinence from nicotine self-administration. As a result, nicotine has positive and negative reinforcing actions. These reinforcing actions are mediated by neurochemical (including dopamine and opioid peptides), electrophysiological (including brain stimulation and muscular relaxation), and psychobiological mechanisms. Administration of nicotine to animals produces similar effects and alleviates symptoms of withdrawal. Psychological processes and principles (including classical conditioning, operant conditioning, and paired associations) contribute to the self-administration of nicotine. Nicotine's biobehavioral and psychobiological effects (including body weight control, attentional focusing, and stress management) also reinforce nicotine self-administration. In addition, nicotine has potential use as a treatment for a wide variety of medical conditions.

4. NICOTINE AS A TREATMENT FOR TOBACCO CESSATION

Although nicotine causes addiction, it does not cause most of the health risks associated with tobacco use. Nicotine replacement therapies (NRTs) are logical treatments to help people abstain from tobacco use because they help to relieve withdrawal symptoms associated with smoking cessation. In addition, the lower dosages of nicotine supplied by current NRTs do not produce the pleasurable effects associated with tobacco products and abuse potential is relatively low.

Nicotine polacrilex gum was the first pharmacological agent approved for smoking cessation treatment by the Food and Drug Administration (FDA). In 1984, it was only available by prescription. A higher dosage gum was introduced in 1992. In 1996, the FDA approved nicotine gum for over-the-counter sales. Nicotine patches that deliver nicotine transdermally were introduced in the United States in 1991. Two variations of these patches became available over-the-counter in 1996.

Today, there also are nicotine nasal sprays, inhalers, lozenges, and a variety of other nicotine-containing products, such as lollipops and water, that are marketed as NRTs. The FDA estimates that more than 1 million U.S. smokers have been successfully treated for nicotine addiction since the introduction of NRTs. The availability of over-the-counter NRTs and media campaigns to increase smoking cessation have produced an estimated 20% increase in successful cessation attempts each year. In addition, there are other nonnicotine pharmacological treatments to help people abstain from smoking. It is important to note that abstinence success is maximized when pharmacological treatments are used in conjunction with behavioral, cognitive, and psychosocial treatments.

5. DIRECTIONS IN NICOTINE ADDICTION RESEARCH AND APPLICATION

Psychologists, pharmacologists, neuroscientists, molecular biologists, epidemiologists, and other health care scientists and practitioners are actively studying nicotine addiction and tobacco use with the goal of developing additional and more effective ways to prevent and treat tobacco use. Ongoing research is examining various forms of NRT, novel nicotine analogs (i.e., drugs that

are similar to nicotine), and various pharmacological treatments that alter different mechanisms underlying nicotine's actions. In addition, psychosocial and cognitive-behavioral treatments are being coupled with pharmacotherapy to optimize tobacco cessation. Progress in understanding the mechanisms and treatment of nicotine addiction is constantly being made through innovative new research and techniques in the field. Many researchers are employing various methods of brain imaging to better understand how nicotine affects specific areas of the brain and how the sites and mechanisms of action might contribute to nicotine's addictive effects. At the molecular level, a variety of strains of genetically manipulated knockout mice provide information regarding the receptor biology associated with nicotine's effects.

In addition to pharmacological and psychological studies and strategies, immunopharmacotherapy is an active focus of inquiry for tobacco treatment. Substances are being developed and tested that can immunologically seek nicotine as it enters the body, complex with it, and prevent it from binding to its receptors. Of course, such treatment requires patient compliance, so psychological variables again become relevant and important for effective treatments.

The tailoring of treatments to people who are at the greatest risk of tobacco use is also an area of emphasis in nicotine research. People with mental health conditions, including depression, anxiety disorders, and thought disorders, are at high risk for tobacco use. In fact, approximately 50% of people with mental health conditions smoke. Therefore, it is important to determine why these high comorbidities exist and how to help these people quit smoking.

Nicotine has also been proposed as a potential treatment for disorders other than nicotine addiction.

Scientists are examining the use of nicotine to treat disorders such as Alzheimer's disease, dementias, attention deficit hyperactivity disorder, skeletal muscular diseases, Parkinson's disease, obesity, anxiety, affective disorders, and schizophrenia.

GLOSSARY

acculturation The process by which individuals from a different culture learn about and assimilate the values, beliefs, and attitudes of the mainstream culture in which they now live, as reflected by their knowledge of or participation in the new culture, including use of the dominant language. Acculturation is like any other developmental process and is largely a function of time and exposure to the mainstream culture so that individuals who have lived in the new cultural milieu longer tend to display higher levels of acculturation—that is, more knowledge of the culture and more proficiency and use of the dominant language of the culture.

assumption of comparability When tests are normed on particular populations, there is an assumption that all the individuals share similar or comparable, but not necessarily identical, background or acculturative experiences. This is the reason why 10-year-olds are compared to other 10-year-olds and not to 15-year-olds. If it can be assumed that there is comparability in the backgrounds of

the individuals on whom the test was normed (namely in terms of level of acculturation and language proficiency/development), then along with other controls for variation (age, grade, socioeconomic status, region, etc.), the norms can be said to establish an appropriate base for comparing performance of individuals against the group as a whole.

bilingual Refers to any individual with some experience or exposure to at least two different languages. Being bilingual is not an either/or proposition; rather, it is a continuum that ranges from people with very low levels of proficiency in both languages to people with very high levels of proficiency in two or more languages, or balanced bilinguals. Generally, bilingual individuals will have a “dominant” or preferred language and their proficiency is not often identical; being very proficient in one language and limited in another is quite common. Nonetheless, bilingual individuals do not share and do not have comparable backgrounds to individuals who have experience primarily with only one language.

culture The idiosyncratic values, beliefs, attitudes, customs, traditions, and language that belong to a circumscribed group of people and that are transmitted as part of the collective societal knowledge and behaviors from one generation to the next. Culture thus represents a powerful environment that shapes individuals in a unique way and differently from one group to the next. Culture is often equated with or confused with race or ethnicity, but it is neither. People of varying ethnorracial backgrounds can share the same culture. Likewise, people from the same ethnorracial background can come from markedly different cultures. It is culture, not race or ethnicity, that is

important because it is the force that defines and shapes an individual's behavior and cognition.

psychometrics Literally means "measurement of mental abilities" and refers to the field in psychology that is devoted to establishing statistical and mathematical procedures for quantifying a wide range of human cognitive abilities. Such abilities are latent; that is, they cannot be measured directly and their existence is inferred on the basis of manifest attributes that can be directly measured.

saturation This is similar to the concept of acculturation and refers specifically to the degree to which an individual's knowledge, experiences, and development closely align with expectations for individuals of the same age in the society. When an individual has acquired this knowledge or experience (become acculturated) to the degree that would be considered developmentally appropriate, his or her level of saturation can be said to be normal or comparable to that of other individuals of the same age or grade.

test validity The degree to which a test is valid is an indication of the degree to which it measures what it purports and is designed to measure. Validity is related to reliability, or the accuracy with which a test can measure something, because a test must first be reliable (or accurate) before it can be valid. No test that is unreliable or inaccurate can be reliable.

Although the need and rationale behind nondiscriminatory assessment have been clear from the outset of the development of psychometrics, the actual practice of providing fair and equitable assessment has yet to be fully embraced by practitioners in school psychology and other major areas of psychological practice. Indeed, many of the issues related to the use of standardized tests, particularly regarding individuals from diverse linguistic and cultural backgrounds, remain poorly or incompletely understood by school psychologists. There are many reasons for this gap, including lack of training standards and models of practice; a relative dearth of practitioners and academicians with expertise in the field; confusion regarding the nature of bias or discrimination in assessment; the lack of systematic guidelines for everyday practice; and the need to develop transdisciplinary, collaborative approaches that span other professional domains, such as speech-language and education. This article provides a brief overview of these issues including a historical perspective on nondiscriminatory assessment; the consequences of inequitable evaluations; the relationship between culture, language, cognition, and education; distinguishing definitions of bias in testing; and preassessment considerations. This article also specifies steps that can be taken

to conduct a comprehensive and systematic evaluation that is in keeping with best practices on nondiscriminatory assessment.

1. INTRODUCTION

In its simplest form, nondiscriminatory assessment refers to assessment that is conducted in a manner so as to ensure the validity of obtained results. Generally, the tests and procedures employed in assessment have been designed for use with a wide range of diverse individuals so that adherence to standardization and other guidelines effectively render the obtained results valid. However, the issues are not quite so straightforward. Even at the very early stages of psychometric development, psychologists were well aware of the potential problems with regard to testing diverse individuals. George Sanchez (as cited in Valdés and Figueroa, 1994), a Mexican American psychologist, noted with acute insight that "as long as tests do not at least sample in equal degree a state of saturation [assimilation of fundamental experiences and activities] that is equal for the 'norm children' and the particular bilingual child it cannot be assumed that the test is a valid one for the child" (p. 106).

The issue of validity is at the heart of nondiscriminatory assessment and the failure on the part of psychologists to fully understand and delineate this variable has led to far-ranging ramifications that may be widely recognized but are often misunderstood. Despite some attention to this issue, the effects of biased and discriminatory assessment (e.g., attribution of culture-specific behavior to various forms of psychopathology, overrepresentation of African American children in special education, and misdiagnosis of the normal process of second language acquisition as a disability) continue to be seen in virtually all aspects of psychological practice, particularly in schools. How and in what manner these variables have affected perspectives and practices in nondiscriminatory assessment will be discussed further in the following sections.

2. BRIEF HISTORY OF NONDISCRIMINATORY ASSESSMENT IN SCHOOLS

It is important to recognize that testing, evaluation, and assessment are not interchangeable terms. In the

school setting, testing represents the most narrow activity and refers to the actual use of tests to measure some trait or characteristic. Evaluation is the process of making inferences and judgments based on data collected during testing and generally takes the form of diagnosis, disability determination, and program eligibility consideration. The main focus of the activities that constitute evaluation is on “how much” a person exhibits some trait relative to same age or grade peers. Assessment is the broadest activity of all and is defined generally as the process of problem solving based on information gathered during testing, any evaluative inferences made regarding test data, as well as on other data, including observation, interviews, work samples, and review of existing records. Assessment activities ultimately lead to a corrective solution and nondiscriminatory assessment ensures that the solution is responsive to the particular individuals, elements, and systems that comprise the problematic situation.

One of the first legal battles regarding issues of potential test bias occurred in California in *Diana v. State Board of Education* (1970). The gist of the lawsuit by the plaintiffs was that the “educable mentally retarded” (EMR) placement and diagnosis were incorrect, particularly because the manner by which the latter was determined was invalid—an IQ test administered in English to children who were predominantly Spanish speakers. However, the case was settled out of court and never went to trial because the California State Board of Education agreed to adopt certain specific remedies to the satisfaction of the plaintiffs. The remedies were largely ineffective but set certain precedents regarding the testing of students with limited English proficiency, including testing in the primary language and in English, use of nonverbal IQ, reevaluation of children previously diagnosed as EMR with particular attention to nonverbal performance, development of an intelligence test appropriate for Mexican American children (never accomplished), and monitoring of the representation of EMR Hispanic students in special education throughout the state.

The remedies in the Diana case demonstrated the growing concern over linguistic issues and the potential discriminatory aspects and outcomes in assessment and education in schools. This sentiment was further reinforced by the U.S. Supreme Court in its *Lau v. Nichols* (1974) ruling that Chinese-speaking students were being discriminated against by having school instruction provided in English only—a language they could not understand—and thus were not

receiving an equal educational opportunity. Although the primary impact of the Lau decision was the implementation of a system for evaluating schoolchildren’s linguistic proficiency and need for equitable access to the curriculum, it also carried ramifications that extended to the assessment of students with limited English proficiency. Foremost among these implications is the appreciation of the potential bias inherent in evaluating students in a language they do not comprehend or comprehend fully as well as the possible consequences of failure to evaluate performance in the native language.

In 1975, P.L. 94-142 [known as the Education of Handicapped Children Act and reauthorized several times since then as the Individuals with Disabilities Education Act (IDEA)] contained specific wording that addressed issues in assessment in schools and whether in fact it was nondiscriminatory in nature. Several stipulations in IDEA make it clear that assessment has to account for possible areas of bias or discrimination, as evidenced by the following statement that remains in current versions: “Tests and other evaluation materials used to assess a child . . . are selected and administered so as not to be discriminatory on a racial or cultural basis; and are provided and administered in the child’s native language or other mode of communication” (IDEA §300.532, Evaluation Procedures). The emphasis in the law on fair and equitable assessment is quite clear, as is the notion that “tests” in particular may prove to be discriminatory if not properly used. Soon after the implementation of IDEA, the question of the fairness of IQ tests emerged prominently, as did concerns regarding the apparent negative consequences of their use, as evidenced most often by the overrepresentation of one cultural or ethnic group in special education.

The potential discriminatory aspects of psychological tests and testing in schools is exemplified in the landmark California case known as *Larry P. (Larry P. v. Riles, 1979)*. In this case, it was argued by the plaintiffs that the use of IQ tests with African Americans resulted in improper special education placements largely because the tests were biased. Judge Robert Peckham, the presiding jurist, provided an initial ruling that still stands today (in California) that prohibited the use of IQ tests for the purpose of determining placement in “dead-end” special education classes. In other words, IQ tests could not be used to establish the intelligence level of African American children in cases of suspected mental retardation because it had not been demonstrated that such tests had been validated for this purpose.

A later order by Judge Peckham banning the use of IQ tests altogether with African American children was rescinded on procedural grounds. However, the original order remains intact and the California Department of Education later adopted policy in keeping with the restriction of IQ tests for any special education purposes involving African American children.

At approximately the same time as the Larry P. case, the issue of IQ test bias and overrepresentation was also being considered in *Parents in Action for Special Education (PASE) v. Hannon* (1980). In this case, Judge John Grady limited the question of test bias to whether IQ tests were culturally biased against African American students and even examined for himself every item and correct answer from the Wechsler Intelligence Scale for Children (WISC), WISC-Revised (WISC-R), and the Stanford-Binet IQ tests. In rendering his judicial opinion, Judge Grady found only a handful of test questions (eight on the WISC and WISC-R and only one on the Binet) that he believed were biased and subsequently ruled in favor of the defendants, citing that the plaintiffs (PASE) failed to prove the question of bias in IQ tests. The more interesting aspect of the case, however, is that Judge Grady cited that in Chicago special education placement was not based primarily or exclusively on the IQ score but rather on a rigorous and careful placement process with well-trained and knowledgeable professionals, including sufficient numbers of African American school psychologists to manage the process fairly and equitably. Judge Grady's decision, although rather tenuous on the issue of test bias, reinforced the notion that nondiscriminatory assessment is a process and includes many aspects that may create or contribute to bias—all of which must be attended to in order to ensure fairness.

Criticism and concern regarding the discriminatory aspects of assessment in schools continues almost unabated primarily because of statistics that still indicate a disproportionate representation of African Americans (and other ethnic groups) in special education programs throughout the United States. Typically, African Americans are overrepresented in the Mentally Retarded and Emotionally Disturbed categories while conspicuously underrepresented in the Specific Learning Disabled and Speech-Language Impairment categories. The U.S. Office of Civil Rights has pointed to this overrepresentation as evidence of discriminatory assessment practices (which presumably include biased testing) and has routinely used its authority to enforce compliance with procedures and practices that

do not result in such inequitable outcomes. Nonetheless, overrepresentation continues to be a national problem in schools.

3. ISSUES AND DEFINITIONS OF TEST BIAS

The issue of bias in testing has revolved almost exclusively around statistical or psychometrically based definitions—that is, that bias exists as an inherent flaw within the test that results in a systematic but unintended pattern of results for a particular group of individuals. Thus, bias has been examined from various aspects of test construction, including as a function of such characteristics as (i) item content or novelty; (ii) item sequence, order, or difficulty; (iii) reliability in terms of measurement error or accuracy; (iv) stability of the underlying factorial structure; (v) examiner-examinee or atmosphere effects; and (vi) predictive ability, usually related to academic achievement or success.

Various types of studies, including correlation, multiple regression, factor analysis, prediction, and other types of analyses on test characteristics, have been conducted for decades and, by and large, evidence of bias along these lines has been rather meager. For example, items on tests with clear cultural connotations have been abandoned in favor of content that is more general and universal. Sophisticated techniques for creating scales and tests whereby the items show measurably progressive levels of difficulty (e.g., Rasch scaling) have been in use for more than a decade. Virtually all IQ tests have demonstrated more than adequate forms of reliability and their underlying factor structures have not been found to change as a function of cultural or ethnically based group differences. However, perhaps the most often cited type of research with respect to issues of bias (or lack thereof) revolves around studies that examine fairness via prediction methods. Generally, a test is considered to be fair when its use does not lead to different predictions for different groups as determined by comparison of the regression lines between a predictor test. Only when the characteristics of such regression lines differ across groups is it believed that a test may be unfair. Although this method of examining bias appears intuitive and appealing, it should be noted that even perfectly matched regression lines do not automatically imply that the construct or ability underlying the test used for prediction is in fact the construct or ability that

was actually measured. A test may well predict equally well for native English speakers as it does for limited English speakers, but the nature of exactly what ability was measured in each case can differ substantially.

Overall, these results are not surprising because the sophistication and psychometric rigor of modern-day tests virtually guarantee that bias in this form will not operate because careful attention has been paid to each of these issues in the development and construction of the test. Combined with norms that are stratified on the basis of age, grade, gender, geographical location, socioeconomic status, race/ethnicity, and other assorted variables, use and application of current assessment instruments would appear to carry little risk of bias defined as such. Indeed, when bias is viewed only as a function of the psychometric properties of a test (generally related to issues of reliability), it is unlikely to be found.

However, psychometric bias is by no means that simple a matter. Tests must not only be reliable but also be valid—that is, they must measure the very constructs they were designed to measure. By definition, a test that is valid must already be reliable, but a test that is reliable is not automatically valid. Hence, the expectation that a very reliable test will show evidence of psychometric bias related to its accuracy is essentially a straw man argument because the variables that might affect reliability have already been controlled or eliminated during test development. What has not been recognized, however, is that there are powerful variables that may not affect reliability but can indeed significantly affect validity. Inequity in assessment is most likely to occur in cases in which the obtained results no longer reflect the constructs that were purportedly measured but, rather, different constructs that were unintentionally measured. In its most simple form, this concept is illustrated in the administration of a test in English to an individual with no or an incomplete understanding of English. The test no longer provides an accurate measure of ability or achievement but, rather, reflects the individual's comprehension of and proficiency in the English language. Nondiscriminatory assessment demands recognition of the fact that variations in acculturation and language backgrounds and experiences can and do affect test validity—a historically underresearched area of test bias.

According to Scarr (1978), “intelligence tests are not tests of intelligence in some abstract, culture-free way. They are measures of the ability to function intellectually by virtue of knowledge and skills in the culture of which they are a sample” (p. 339). High-quality tests such as those currently available may indeed not be

“culturally biased” per se but they remain “culturally loaded”—that is, they have embedded content that is specific and often unique to the culture that gave rise to the test. For tests developed in the United States, this would encompass content and knowledge that is known as “mainstream” or popular—information that would be acquired either incidentally through exposure and contact with the culture or formally through instruction. The process by which an individual learns the common elements of a particular culture is known as acculturation, and it is a process that advances naturally and over time, as do all developmental processes. The more frequent, simple, and common elements of the culture are learned first and the more complex ones later.

Similarly, tests that rely on an individual's ability to comprehend English can be construed as being “linguistically demanding”—that is, they require certain expected levels of language proficiency or facility with the language in order to adequately or successfully understand directions for the task or even perform the task. Learning any language, particularly a second language, is also a developmental process. Usually, the process of learning a language begins at birth, but in many cases it may begin at some point after birth, putting the acquisition and learning of that language ostensibly “behind” that of native speakers. This means that the normal expectations for language proficiency (as well as those for acculturative knowledge acquisition) for a given age or grade may not yet have been attained by those who began learning the language at a point other than from birth or who were not indoctrinated into the mainstream culture from birth. Because neither language nor acculturation are finite, there is no point at which individuals who began at points other than birth will ever “catch up” or become equivalent to their mainstream, native speaking counterparts—except in cases in which individuals were well schooled and educated in their native language first, usually up to at least age 11 or the sixth grade.

In summary, both the level of acculturation and language proficiency (generally, English language proficiency) can significantly affect the process of assessment and can alter the psychometric properties of a test with regard to its validity even though the inherent reliability of the test remains intact. Tests in particular are constructed on an assumption of comparability, which presumes a relatively similar background and experiences for the individuals on whom the test was normed. Variations in background or experiences that violate this assumption therefore render test results

effectively invalid. This is most likely to occur in cases involving culturally or linguistically diverse individuals because the test may well degenerate into one that measures level of acculturation or English language proficiency more so than the intended or expected constructs. In such situations, the tests used may not be biased, but they are not likely valid either.

Apart from the more commonly defined areas of bias, there are other definitions that are important relative to nondiscriminatory assessment, albeit they are perhaps not as widely accepted. Bias in tests is often cited as a function of the fact that a test results in (i) mean differences (generally between different cultural or ethnic groups); (ii) variable selection ratios or disproportionate classification, usually in special education; and (iii) social consequences. Indeed, mean differences and disproportionate classification formed the basis of the arguments that prompted the advancement of the historical legal challenges to the use of IQ tests in schools discussed previously. Although the result may well be pernicious, it is important to note that bias definitions of this type reflect more the application and use of tests than any inherently discriminatory property of tests. This shift in the nature and definition of bias is particularly evident with respect to the issue of social consequences, or more accurately the negative social consequences of the use of IQ tests, which generally arises out of recognition of a more general failure on the part of special education to provide positive outcomes. Frequently, use of IQ tests leads to disability classification, which then leads to placement in special education organized around the disability label. When combined with the negative findings on attempts to match instruction to cognitive or neuropsychological strengths, the efficacy of labeling children via use of IQ tests results leads to decidedly negative and discriminatory social consequences.

4. ISSUES IN PSYCHOLOGICAL TESTING

Perhaps the area that psychologists tend to focus on most when considering nondiscriminatory assessment in general is that which pertains to what is the best test to use. This may be viewed as somewhat of a search for the Holy Grail. Sattler (1992) expressed this illusion best when he stated that “probably no test can be created that will entirely eliminate the influence of learning and cultural experiences. The test content

and materials, the language in which the questions are phrased, the test directions, the categories for classifying the responses, the scoring criteria, and the validity criteria are all culture bound” (p. 579).

As noted previously, there are no tests that have norms suitable for individuals who are either bilingual or bicultural (or, frequently, both). Level of acculturation and English language proficiency have yet to be stratified along with other variables in the construction of norm samples. This is problematic because in the United States, whenever an individual who does not speak English or is limited in English proficiency enters the public school system, he or she will invariably be required to learn English, or in a sense become a circumstantial bilingual. Even when such individuals become “English dominant” or “fully English proficiency,” they do not cease to be bilingual. Their dual-language backgrounds are not erased simply because they are now able to communicate at a conversational level and with no trace of accent. Even nonverbal tests, which reduce the inherent problems with communication and linguistic loading, do not address the issues of acculturation and the norms remain based primarily if not exclusively on monolingual English speakers. Native language tests also have the same problem. That is, although they tend to reduce bias that may be due to language comprehension or proficiency issues, they nevertheless are normed on monocultural, monolingual speakers of the native language—a group that is no more an appropriate standard for comparison than monocultural, monolingual English speakers when the examinee happens to be bilingual and bicultural.

The only practical recommendation that may be offered with respect to nondiscriminatory assessment is to first recognize that use of any test with diverse individuals will result in some form of bias but that the degree of bias can vary greatly. Initially, psychologists seemed intent on finding ways in which an actual IQ could be “adjusted” or modified so as to offer a better estimate of an individual’s true functioning, often by taking into account acculturation issues as well as norm sample issues in estimating the eventual IQ. However, such practices, as well as others that have utilized nonstandardized administrations, altered norms, and the like, have been met with harsh criticism and have failed to provide a viable framework for nondiscriminatory assessment. A more promising practical approach to dealing with the potential bias in the use of tests seems to rest in simply recognizing that all tests carry differing levels of expectations regarding language ability, embedded cultural content,

or both. By selecting tests that have less cultural loading and lower linguistic demands, more confidence can be placed in the fact that what is being measured is more a function of actual ability than lack of acculturation or English proficiency. This is not to say that the entire process of assessment has been rendered equitable but, rather, that the discriminatory aspects and potential in the use of tests have been considered and accommodated to a certain degree.

An example of a systematic framework for engaging in this type of selection and interpretive process is available via use of the CHC Culture–Language Matrix. Initially, the matrix provides a visual representation of cognitive ability tests as classified according to the degree of cultural loading and linguistic demand that allows practitioners to select tests that are lower along these dimensions and thus more likely to be equitable or fair. The matrix also provides a method for evaluating actual vs expected patterns of performance that draws upon research in order to guide interpretations regarding the validity of the results relative to the primary or contributory effects of cultural or linguistic differences.

By allowing practitioners to select tests that may provide fairer estimates of true ability as well as a practical way to gauge the extent to which cultural or linguistic factors may have played a role in influencing test performance, potential bias and discrimination in test use can be effectively reduced, albeit never eliminated entirely. Nonetheless, when it can be ascertained that cultural or linguistic factors did not play a primary role in determining the obtained pattern of test results, a significant portion of the potential inequity (related to validity) has been resolved and practitioners can exercise more confidence in the validity of their results. Ultimately, nondiscriminatory assessment is not dependent on so-called culture-free or nonverbal tests but rather on a process that recognizes the nature and source of possible invalidity and that seeks to reduce potential bias to the maximum extent possible.

5. NONDISCRIMINATORY ASSESSMENT

Several recommendations have been provided in the literature for engaging in various forms of nondiscriminatory assessment. Although many discrete methods for reducing bias in assessment have been described

throughout the years, much less attention has been paid to the development of a broad, comprehensive framework for nondiscriminatory assessment. Within the field of school psychology, Ortiz provided a framework that detailed a 10-step process for nondiscriminatory assessment. This process included guidelines and recommendations on how to assess and evaluate the learning ecology; assess and evaluate language proficiency; assess and evaluate opportunity for learning; assess and evaluate educationally relevant cultural and linguistic factors; evaluate, revise, and retest hypotheses; determine the need for and language(s) of assessment; reduce bias in traditional testing practices; utilize authentic and alternative assessment procedures; evaluate and interpret all data within the context of the learning ecology; and link assessment to intervention.

The framework delineated by Ortiz integrates salient and promising procedures and recommendations for nondiscriminatory assessment culled from research and practice. It is intended to be both a linear guide to assessment and a recursive model that allows a return to previous steps as may be necessary when newly collected data suggest alternative hypotheses. The framework can accommodate assessment activities at the individual and team levels and is particularly suited toward collaborative assessment in which members of an assessment team (including parents) can work together, sharing data and information and drawing conclusions or making decisions jointly. The need to consider multiple sources of information and multiple points of view in any assessment underlies the principles of nondiscriminatory assessment and serves to enhance the validity and ultimately the fairness and equity of the evaluation.

6. SUMMARY

Nondiscriminatory assessment should not be viewed as a single procedure, method, or test. Rather, fair and equitable assessment results from the integration of a wide range of approaches that together form the basis for drawing valid conclusions regarding the meaning of the collected data. Decisions regarding functioning and performance will likely prove to be less discriminatory in cases in which the sources of bias have been recognized a priori and systematic steps were taken to control their influence in both the collection and the interpretation of data. Nondiscriminatory assessment should not be seen merely as a search for nonbiased

tests—an impossibility—or a form of assessment that is applied only in cases of cultural or linguistic diversity. The provisions in IDEA and other guidelines for nondiscriminatory assessment do not assert that it is intended for select groups only but rather that it should be conducted in a way that ensures that all individuals are evaluated in the least discriminatory manner possible. As such, nondiscriminatory assessment is an approach to assessment that is equally applicable and appropriate to any individual and there is no reason it cannot be applied as such.

GLOSSARY

binge eating disorder (BED) Recurrent episodes of eating large quantities of food while feeling a loss of control without the use of compensatory purging behaviors.

body image A person's concept of his or her physical image.

body mass index (BMI) A common measurement to assess obesity; BMI is the relation between a person's height and weight, expressed by weight in kilograms per height in meters squared.

obesity An accumulation of excess adipose tissue in relation to lean body mass.

reasonable weight loss A 5 to 10% loss of current weight; losses of this magnitude are achievable for most people and will lower their risk of developing obesity-related diseases.

stigma Being viewed as different from normative expectations based on cultural and situational factors; obese individuals who are stigmatized are viewed as possessing certain undesirable characteristics that are not necessarily accurate of every obese person.

toxic environment An environment in which high-fat, high-calorie foods are advertised heavily, offered at low costs, and readily available.

weight cycling Recurring instances of weight loss and regain, also known as yo-yo dieting.

Obesity is chronic condition that has recently reached epidemic proportions worldwide. Obesity is associated with serious medical and social consequences. Although the psychological consequences of obesity are less consistent, body image disturbances and binge eating disorder are common. While there are efficacious medical and behavioral treatments, maintenance of weight loss continues to be a problem and is a direction for future research.

1. BASIC KNOWLEDGE OF OBESITY

1.1. Definition

Obesity is defined as possessing a body mass index (BMI) of at least 30 kilograms per square meter (kg/m^2), and morbid/extreme obesity is defined as possessing a BMI of at least 40 kg/m^2 . Besides using BMI, there are various ways in which to measure total body fat and classify obesity such as imaging techniques to assess localization of body fat, underwater weighing, skinfold thickness, and waist/hip circumference ratio. Obesity is often a chronic condition in which individuals who attempt to diet subsequently regain their lost weight, leading to "weight cycling."

1.2. Prevalence

Obesity is a health risk that has reached epidemic proportions worldwide, with more than 300 million adults

considered to be obese. Although prevalence estimates have differed due to various classification methods, recent statistics cite that nearly one-third of adult Americans are obese, a twofold increase over the past decade. Childhood obesity has also increased, with estimates suggesting that 15% of children and adolescents were obese in 2000, a 4% increase over the previous decade. In addition, there has been a marked increase in rates of morbid obesity; the prevalence rose threefold between 1990 and 2000.

1.3. Causes

Overall, obesity is the result of an individual consuming more calories than he or she expends, with an additional 3500 calories eaten leading to 1 pound gained. A complex interaction of environmental, genetic, and behavioral factors influences both consumption and expenditure. Factors related to consumption include food choices as well as food availability. For example, a diet high in fat will provide more energy than will carbohydrates or proteins and will produce fewer satiety signals, thereby disabling the individual's ability to suppress hunger cues. Currently, we live in a "toxic environment" such that the availability of unhealthy foods increases the likelihood that poor decisions are made. For example, there is an increasing number of commercials for calorie-dense foods, such as candy and high-sugar cereal geared toward children, and an abundance of easily accessible fast-food restaurants offering fatty foods at low costs.

Caloric expenditure is influenced by several factors, including resting metabolic rate and level of activity. Although a range of genetic factors most likely influences metabolism, the U.S. society is moving toward an increasingly sedentary lifestyle given that many Americans are engaging in less planned and lifestyle exercise. Fewer than one-third of Americans get the minimum recommended amount of exercise of light to moderate activity five times per week. Thus, as a society, Americans are consuming more and expending less, causing a rise in rates of obesity.

2. PROBLEMS ASSOCIATED WITH OBESITY

2.1. Medical Consequences

Obesity is strongly associated with diabetes mellitus; close to 50% of all individuals with type 2 diabetes have a BMI of at least 30 kg/m². This relation results from insulin's decreased ability to act at a cellular level

when there is an excess of fatty tissue in the body. Obesity is also a risk factor for the development of coronary heart disease (CHD). Obesity contributes to the development of CHD through increasing rates of risk factors such as hypertension and increased cholesterol. Recently, an association between obesity and cancer has also been found. Obesity is associated with increased risk for certain cancers, including colon, endometrial, and breast cancers, and is also related to increased mortality rates among cancer patients. The causal mechanisms linking obesity to cancer are currently unknown.

Obesity is also associated with other complications such as disruption of sleep, difficulties with daily activities (e.g., climbing stairs, walking, bending, kneeling), increased levels of lower back pain, shortness of breath, and fatigue. As a result, impairments in daily business, work productivity, and role functioning are significantly more common. Overall, obesity accounts for approximately 300,000 deaths nationwide each year, and treatment costs were as high as \$117 billion in 2000.

2.2. Social Stigma

Obese individuals are not only condemned for their appearance but also blamed for their condition. In a society that espouses a thin and lean body ideal, obese individuals are viewed as less attractive. Furthermore, body weight is viewed as controllable, leading obese individuals to be perceived as lacking the self-discipline necessary to maintain thinness. As a result, obese individuals are often thought to be lazy, gluttonous, and stupid. These assumptions have led to discrimination against the obese in areas such as employment, education, housing, and medical care.

2.3. Psychological and Behavioral Consequences

Efforts aimed at clarifying psychological consequences of obesity have provided inconsistent results. The obese population appears to be heterogeneous with respect to psychological functioning, with a subset of individuals experiencing psychological consequences of their weight and others exhibiting healthy mental functioning. To gain a more comprehensive understanding of the psychological correlates of obesity, researchers have suggested an approach focused on identifying risk factors that may explain the occurrence of negative

psychological consequences of obesity. Potential risk factors for psychological distress include being female, being adolescent, and being severely overweight. In addition, a subgroup of obese individuals who suffer more psychological distress are binge eaters. Binging refers to eating a large quantity of food (an amount larger than an individual would normally eat) in a discrete amount of time and feeling a loss of control. When individuals engage in binge eating more than twice a week and do not engage in compensatory purging behaviors (e.g., vomiting), they may be diagnosed with binge eating disorder (BED). Obese binge eaters tend to display higher levels of psychological distress and social dysfunction than do nonbinging obese individuals.

One area where obesity carries a more consistent risk for suffering is body image dissatisfaction. Body image concerns have been found to increase steadily with BMI, and body image disorders are thought to be present in approximately 10% of the obese population. Body image disorders often result in emotional distress due to preoccupation with appearance, negative self-worth, and social isolation.

3. TREATMENTS

3.1. Medical Approaches

There are two medical approaches currently available for the treatment of obesity: surgery and pharmacological treatments. Because of potentially life-threatening complications, surgery is recommended only for the morbidly obese (those with a BMI of at least 40 kg/m²) or for those with a BMI of at least 35 kg/m² and a comorbid physical illness. Bariatric surgery produces its effects through either limiting the stomach's capacity or interfering with the digestion of food. Gastric bypass is widely accepted as the surgery of choice due to its low mortality rate and the ability to produce losses of up to 70% of excess body fat. Surgical treatments have also been shown to effectively improve type 2 diabetes, cardiac conditions, and quality of life among obese individuals. Although the initial effects of the surgery are drastic, weight regain is likely without significant behavior modifications; the average regain is 15% of initial excess weight.

Pharmacological treatment may be appropriate for individuals with a BMI of 30 to 40 kg/m² and for the morbidly obese who do not opt for surgical treatment. Although weight loss drugs have proven to be unsafe in the past, significant advances have been made in this area. There are currently two weight loss drugs that

have been approved by the Food and Drug Administration: sibutramine and orlistat. Treatment with sibutramine increases satiety levels and produces average losses of approximately 5% of total body weight with a relatively low side effect profile. Orlistat blocks absorption of approximately 30% of dietary fat consumed daily and has weight loss effects approximately equal to those seen with sibutramine. Both drugs have been shown to be more efficacious when combined with dieting, and losses of more than 10% of original body weight are common. The long-term effects of pharmacological treatments are less promising. There is evidence that continued long-term use may lead to decreased efficacy, and discontinuation of the drugs is associated with weight regain.

3.2. Very Low-Calorie Diets

Very low-calorie diets (VLCDs) are defined as programs that allow fewer than 800 calories per day. The goal of such programs is to produce extremely rapid weight loss while maintaining muscle mass. This is generally accomplished through consuming small amounts of prepackaged foods and powdered supplements. VLCDS are appropriate only for those with a BMI of at least 30 kg/m² due to the muscle depletion that would occur in lower weight individuals. For the obese, VLCDS have been found to be effective in short-term weight loss and safe when used under medical supervision. Weight losses of approximately 20 to 25% of initial body weight typically occur within 16 weeks of treatment. However, individuals who use VLCDS find it difficult to maintain their losses over a 1-year period. When considering both the risk of malnutrition and the large level of weight regain following VLCDS treatment, there is substantial doubt as to whether VLCDS are preferable to more moderate diets.

3.3. Behavioral Approaches

Behavioral weight loss (BWL) approaches, also known as cognitive-behavioral treatments, are currently the psychological treatment of choice for obesity. BWL treatment for obesity is generally conducted in a group format and occurs once per week for 4 to 6 months. The primary goals of BWL treatments are to increase physical activity levels and decrease caloric restriction so as to create a negative energy balance. Patients are encouraged to set reasonable health goals and follow moderate dieting plans that provide sufficient nutrition and allow for flexibility. Some of the core components of

BWL for obesity include (a) self-monitoring, (b) identification of factors that influence eating, (c) stimulus control, and (d) cognitive restructuring. Self-monitoring is an essential component of behavior change. Patients record factors such as their food intake, emotions while eating, and daily exercise. These records allow patients to identify and work toward changing behavior patterns. Once eating cues are discovered, stimulus control is used to limit exposure to such cues. Finally, cognitive restructuring is used to reshape attitudes about dieting, weight, and body image.

The effects of BWL have been widely studied. BWL has been shown to produce average weight losses of 7 to 10% of total body weight and to significantly improve both the medical and psychological consequences of obesity. However, as with other treatments, maintaining initial losses has proven to be difficult for patients. Approximately one-third of the losses are typically regained within 1 year, and slow weight gain tends to continue until baseline levels are met. It appears as though patients are unable to continue with the behavioral changes over long periods of time. One possible reason is that the degree of weight loss that patients have experienced is not rewarding enough to continue with the challenging lifestyle modifications.

3.4. Binge Eating Disorder

During the short time that BED has been recognized as a distinct eating disorder, several effective treatments have emerged. Two specific psychological treatments for BED have been tested: cognitive-behavioral therapy (CBT) and interpersonal therapy (IPT). The focus of CBT for BED is similar to the focus of CBT (BWL) for the non-bingeing obese; however, an additional emphasis is placed on moderation of food intake so that the amount consumed is neither restrictive nor excessive. Initial studies of CBT for BED have shown that treatment cuts binge frequency in half and that approximately 60% of patients abstain from bingeing for 1 year. Self-help versions of CBT also show promising results, with abstinence rates approximately equal to those of group CBT treatments.

IPT for BED is a directive treatment that focuses on managing interpersonal difficulties that are thought to result in emotional states that trigger binge episodes and maintain problem behaviors. Specific eating behaviors are rarely discussed within treatment, and weight loss strategies are not included; eating and weight are addressed only as they relate to interpersonal issues. Controlled studies of the efficacy of IPT have revealed short-term and follow-up results approximately equal

to those of CBT. Finally, BWL strategies as used in the treatment of obesity have been shown to be as efficacious as CBT and IPT in reducing binge frequency. In addition, BWL programs show an added benefit of weight loss that is not seen in CBT or IPT. For this reason, BWL programs are considered by many to be the preferred treatment for BED.

3.5. Strategies for Weight Loss Maintenance

Effective weight loss treatments are available; however, the maintenance of losses continues to be a challenge. Three primary strategies aimed at increasing maintenance rates have been proposed recently. The first involves combining medical approaches with behavioral lifestyle modifications. It has been shown that combining surgery with psychological approaches aimed at healthy eating and exercise may be effective in maintaining initial losses. Also, the addition of lifestyle modification has been shown to more than double the effects of drugs alone and to prevent weight regain during the maintenance phase of treatment. Therefore, to provide optimal treatment, behavioral treatments need to be considered a standard adjunct to pharmacological interventions.

The second strategy is extending the length of existing CBT treatments. This has been shown to result in continued adherence to behavioral changes and, in turn, to improved rates of maintenance. The focus of the extended contact would be teaching problem-solving techniques that could be used in challenging situations and stressing the importance of maintaining behavioral changes. Although such strategies have been proven to be efficacious, attrition rates following initial weight loss are high; therefore, interventions aimed at increasing retention rates are necessary.

The third proposed strategy is to modify patients' expectations regarding the amount of weight loss that can be expected. For example, current CBT weight loss programs are typically able to produce losses of approximately 10% of initial body weight. Although a loss of 10% substantially improves health-related quality of life and medical complications related to obesity, patients typically expect greater weight losses and are disappointed by modest results. It has been proposed that the dissatisfaction experienced with modest losses, coupled with the effort required to maintain such losses, leads to an abandonment of behavioral changes and subsequent weight regain. Therefore, experts are

now suggesting that patients aim for modest losses rather than “ideal” losses. A new form of CBT for obesity that includes the modification of beliefs regarding the desired amount of weight loss and places an emphasis on acceptance of modest losses is currently being tested. Although realistic expectations regarding weight loss may increase maintenance rates, convincing obese individuals to engage in treatment for minimal losses will undoubtedly prove to be difficult.

4. FUTURE DIRECTIONS

Given the growing prevalence of obesity worldwide, the demand for effective treatments continues to increase. In response, researchers are continually working to improve existing treatments and develop new approaches. Medical breakthroughs will undoubtedly continue, and new psychological treatments are currently being developed and evaluated. However, obesity likely will remain a difficult disorder to treat. Brownell recently argued that a preventive approach, aimed at combating the toxic environment that supports obesity, is necessary to reverse the obesity epidemic. Brownell suggested that a public health approach with government initiatives, such as taxing fattening foods, removing unhealthy foods from public schools, and providing federal funding for nutrition programs, will be necessary to eliminate the environment that supports overeating and inactivity. Until such steps are taken, the ability of weight loss treatments to produce enduring change may remain limited. Public health policy might prove to be necessary in preventing obesity and maintaining long-term weight loss.

GLOSSARY

maxi-cycle A series of life stages characterized as a sequence of growth, exploration, establishment, maintenance, and disengagement.

satisfaction A perception of satisfaction from the perspective of the employee.

satisfactoriness A perception of satisfaction from the perspective of the employer.

Self-Directed Search A self-administered inventory that helps people to explore what occupations to follow and to estimate related abilities.

Strong Interest Inventory A self-report inventory that inquires about interests in a wide range of occupations, occupational activities, hobbies, leisure activities, school subjects, and types of people.

What makes people who are big lottery winners keep their jobs even if they are in low-paying positions? Of 16 women in a small town (population 736) in Minnesota who won \$95.5 million (approximately \$2 million each after taxes), 15 claimed that the

money was not reason enough to quit their morning jobs as school cafeteria workers or their second jobs driving school buses, cleaning houses, or milking cows. And what about the 16th woman? At 70 years of age, she already was considering retirement. Their story is not unusual. In 2004, Arvey and colleagues found that few lottery winners quit working completely, although some do take sabbaticals or change positions. These women certainly did not stay in their jobs due to the high wages they earned; their pay ranged from \$7.75 to \$10.68 per hour. Rather, research shows that a variety of internal and external factors keep people on the job—some grudgingly, of course, but others with passion and zeal for what they do. Obviously, people who are not big lottery winners do work for financial reasons—to meet basic needs or to be able to afford nonwork activities that cost money. But beyond income, work gives people a feeling of belonging and provides structure. It gives people a sense of satisfaction and productivity while satisfying their interests, promoting their self-esteem, and providing them with status and recognition. Work also provides a personal identity and a mechanism for describing oneself to others. Often, what people do is who they are. Most adults spend one-third to one-half of their waking hours at work. It follows, then, that work can have a tremendous impact on psychological and physiological well-being. It is little wonder that the process of making occupational choices can create anxiety as one searches for the perfect match.

1. CAREER THEORIES

Since the early 1900s, scholars have studied occupational choice and career decision making. They focused first on improving personal satisfaction, and later on increasing performance and lowering turnover, through informed occupational choices. Several theories have emerged that identify the variables important to the process of occupational choice and work adjustment. The theory of work adjustment focuses on the congruence between the abilities and needs of the individual and the requirements and rewards of the job, Super's life span theory focuses on the developmental process of occupational choice, and Holland's theory of vocational personality type focuses on prediction of the types of work that people will choose. These three theories complement one another and offer a framework for understanding occupational choice and adjustment. Career theories also provide a mechanism for conceptualizing career concerns and client goals. For example, the theory of work adjustment can guide conceptualizing clients with adjustment problems in the workplace, Super's theory can lend understanding to the influence of developmental stages in occupational choice, and Holland's theory can provide a model for describing the world of work.

1.1. Theory of Work Adjustment

The theory of work adjustment, stemming from the Work Adjustment Project at the University of Minnesota, first appeared during the mid-1960s and has subsequently been revised and extended a number of times. The theory describes the dynamic interaction between persons and their work environments that influences work adjustment and occupational choice.

According to Dawis and Lofquist, the architects of the theory of work adjustment, individuals "inherently seek to achieve and maintain correspondence with their environment," where correspondence is defined as a well-balanced relationship between the characteristics of the individual and the requirements of the environment. Indeed, much of the emphasis of the theory concerns the matching of the abilities and values of an employee with the abilities required by a job and the reinforcers provided by the job. Consequently, the theory provides a model for career counseling that is designed to help individuals achieve (a) a clear understanding of their own abilities, values, personalities, and interests; (b) a knowledge of the

requirements and conditions of success in a work environment; and (c) a true understanding of the interaction between these two groups.

Dawis and Lofquist maintained that abilities are general dimensions that underlie groupings of required skills, including general learning ability, verbal ability, numerical ability, spatial ability, form perception, clerical ability, eye-hand coordination, finger dexterity, and manual dexterity. Similarly, values are seen as representing a grouping of needs and are defined as achievement, comfort, status, altruism, safety, and autonomy. Two additional components to the prediction of work adjustment and occupational choice are satisfaction (i.e., a perception of satisfaction from the perspective of the employee) and satisfactoriness (i.e., a perception of satisfaction from the perspective of the employer). Put another way, satisfaction refers to the extent to which employees' needs are fulfilled by the work they do, whereas satisfactoriness concerns the appraisal by others, usually employers, of the extent to which the employees adequately complete the work that is assigned to them.

The theory of work adjustment is heavily based on the premise that individuals differ in their abilities, needs, values, and interests, among other variables. This principle views people as complex individuals who differ on a number of dimensions and suggests that counseling needs to be individualized to allow everyone to make a personalized occupational choice. Although the theory is broader than many career theories and has important implications for career adjustment and occupational choice, it focuses on only one point in time. Super's life span theory, on the other hand, focuses on the developmental process of occupational choice.

1.2. Super's Life Span Theory

Probably no one has written as extensively about career development or influenced the study of the topic as much as has Super. His earliest theoretical statements were influenced by researchers in various areas of psychology, sociology, and personality theory. In fact, Super described his theory of career development as a "segmental" theory or one that includes the work of many other theorists such as Freud, Maslow, and Rogers. From the works of these theorists, Super derived basic assumptions that allowed him to develop his own developmental process of occupational choice.

A hallmark of Super's theory is the view that occupational development is a process of making several decisions over time, culminating in occupational

choices that represent an implementation of the self-concept. Super viewed self-concept as a combination of biological characteristics, social roles people play, and evaluations of the reactions that others have toward the individual. For Super, self-concept served to organize roles that people play throughout their lifetimes.

An important idea throughout Super's career development theory is the concept of role. Super described six major roles—homemaker, worker, citizen, leisurite, student, and child—and stressed that these roles, as well as the importance of these roles, vary throughout one's life. For instance, he argued that during childhood, the roles of leisurite, student, and child are particularly important, while the roles of worker, citizen, and homemaker are minimal. During adolescence, citizen and worker may become more important roles, but work is not often directly related to one's eventual career. It is during adulthood that one has more occupational choices. Consequently, it is important that professionals understand the concept of life roles (in conjunction with developmental stages) when helping individuals to make occupational choices.

The notion of developmental stages is essential to Super's life span theory. Super proposed a series of stages or "maxi-cycles" over the life span, beginning with the growth stage during early childhood. During this stage, children become curious about life and begin to explore their environments. The information gained through this exploration will be an important component of the children's self-concept. The exploratory stage begins with adolescents' awareness that an occupation will be an aspect of life and ends with young adults choosing occupations that they believe are within reach and provide important opportunities. The establishment stage, as one would expect, relates to adults' early encounters within actual work experiences. During the maintenance stage, employees attempt to continue or improve their occupational situations. The final stage, disengagement, includes the preretirement period during which employees' emphasis on work is focused on retaining their positions rather than enhancing them. This period ends when older adults withdraw from the world of work.

Super proposed characteristic developmental tasks within each stage. Mastery of these tasks allows individuals to function effectively in their life roles within that stage and prepares them for the next task. Successful coping with the requirements of each stage is dependent on the individual's career maturity—a group of physical, psychological, and social characteristics that represent the individual's readiness and ability to deal with the

developmental problems and challenges that are faced. The person whose maturity is equal to the problem probably resolves it with minimal difficulty or concern. However, when the maturity is not sufficient for the task, responses of procrastination, ineptness, and/or indecision are likely to occur.

As was mentioned previously, a fundamental aspect of Super's theory is that occupational choice is an implementation of the self-concept. The implication for career counselors is that, in addition to providing clients with information about who they are, counselors need to integrate objective information about the self (e.g., interests, values, abilities). Holland's theory of vocational personality type focuses on this objective information.

1.3. Holland's Theory of Vocational Personality Types

Holland's theory continues to enjoy attention as it celebrates more than four decades of popularity. Holland's person–environment typology and theory of career choice clearly is the most widely studied career theory in history. In addition, the concepts that derive from this theory are integral to the vocabulary, tools, and processes of career counseling.

Holland's theory of occupational choice is based on several assumptions. One assumption is that persons and environments can be categorized according to six types: Realistic, Investigative, Artistic, Social, Enterprising, and Conventional.

1. Realistic individuals are likely to enjoy using tools or machines in their work and often approach problems in a practical or problem-solving manner. Likewise, a Realistic environment is one in which the work setting includes tools, machines, and/or animals that the individual manipulates and where the ability to work with "things" is more important than the ability to interact with others.

2. Investigative persons are likely to enjoy challenges that require the use of intellect and are apt to enjoy learning and feelings of confidence about their ability to solve mathematical and scientific problems. Similarly, an Investigative environment is one in which people search for solutions to problems through mathematical and scientific interests and competencies.

3. Artistic individuals like the opportunity to express themselves in a free and unsystematic way by creating music, art, and/or writing. Correspondingly, an Artistic environment is one that is free and open and is encouraging of creativity and personal expression.

4. Social persons are interested in helping people through teaching, helping with personal or vocational problems, and/or providing personal services. Similarly, a Social environment is one that encourages people to be flexible and understanding of each other and where people can work with others through helping with personal or career problems, teaching others, and being socially responsible.

5. Enterprising individuals enjoy being with others and like to use verbal skills to sell, persuade, and/or lead. Correspondingly, an Enterprising environment is one in which people manage and persuade others to attain organizational or personal gains.

6. Conventional persons are typically dependable and have the ability to follow rules and orders in unambiguous situations. Likewise, a Conventional environment is one in which organization, planning, and ability to follow directions (often in an office environment) are of utmost importance.

Another assumption, coined Holland's calculus hypothesis, describes the relationship among the six person-environment types. The calculus hypothesis states that the six types can be arranged around a hexagon, with the types most similar to each other (e.g., Social and Enterprising) falling next to each other and those most dissimilar (e.g., Social and Realistic) falling directly across the hexagon from one another.

Holland's theory has been applied extensively in career counseling, most notably using the six-category typology to categorize individuals in the interpretation of interest inventories such as the Self-Directed Search (SDS) and the Strong Interest Inventory (SII). In addition, Holland's typology has been used to classify occupational information and college majors in an attempt to facilitate individuals' success in making occupational decisions.

1.4. Summary of Theories

The theory of work adjustment, Super's life span theory, and Holland's theory of vocational personality types all have received a great deal of attention and empirical support over the years. Research on the theory of work adjustment has generated many promising findings; however, research specifically using constructs from this theory has proceeded at a slow pace. Super's life span theory is intuitively appealing and offers assistance in understanding the richness of an individual's career and life. Nevertheless, it remains to be seen whether it will maintain its position of preeminence

in the future. Finally, Holland's theory of vocational personality types stands as the most influential of the existing theories in both research and practice, and research supporting Holland's theory is very robust.

2. CAREER COUNSELING FOR OCCUPATIONAL CHOICE

Career theories suggest that people make their occupational decisions in an orderly and systematic fashion. Yet research shows that for most people, the path often is serpentine. On the one hand, barriers to occupational entry, such as stereotyping, prejudice, and family, economic, and educational constraints, thwart people's opportunity to follow their interests. On the other hand, roughly 60% of adults report that serendipity plays a role in helping them to make good career decisions. Career counseling is a process, facilitated by a counselor, designed to help people find their way through the decision-making process. The ultimate goal is to help people obtain satisfaction and effectiveness in their jobs, occupations, and careers.

Career counseling can be structured in several different delivery modes. In some cases, the intervention is one-on-one between the client and the counselor. In other instances, the intervention may be conducted for groups and may resemble an educational experience with assignments and "in-class" discussions and information sharing. Career counseling also can occur in a variety of settings. For example, it is not unusual for college students to seek career counseling to help them decide on majors or to help them focus their job searches at the time of graduation. Many high schools also offer students the opportunity to explore future careers either with their school counselors or in life studies courses. Some employers offer career exploration opportunities within the work setting or arrange referrals for clients to work with career counselors. In addition, community organizations (e.g., the YWCA/YMCA) and adult education centers offer career counseling. Many people also seek out career counselors (now sometimes called career coaches) who are in private practice or work for consulting firms.

The desire to learn more about oneself and to ponder career questions is not the privilege of only the young. Many adults turn to career counseling for a variety of reasons. Some people are genuinely unhappy in their jobs and seek career counseling with the goal of finding better matches for their interests,

personalities, and values. Some people are bored and believe that their abilities are underused or that they have reached career plateaus. Others, in spite of their achievements, may question whether they are making a difference. Still others believe that they drifted into their jobs and never made deliberate choices. Not all people will discover, even with the help of career counseling, that they have a passion for work. For some people, work is necessary simply to provide for their basic needs, and other aspects of their lives will give them more pleasure and satisfaction than will their work. However, career counseling can help even those not driven to career achievement to maximize the match between their personal characteristics and those of the jobs they choose.

Regardless of the format, setting, life stage, or goals and purposes, most career counseling approaches involve psychological assessment. The ideal situation allows assessment of interests, abilities, personality, values, and needs. However, time and financial constraints often limit testing to the administration of a vocational interest inventory such as the SII, the Campbell Interest and Skill Survey (CISS), the SDS, the Career Assessment Inventory (CAI), or the Sixteen Personality Factor Questionnaire (16PF) (Table 1).

The University of Minnesota's Vocational Assessment Clinic (VAC) offers one model for combining comprehensive assessment with career planning services during a time-limited intervention: intake, assessment, interpretation of inventories, and integration with plan of action. In addition to taking the SII to assess vocational interests, clients who use the VAC services take the Minnesota Ability Test Battery (MATB), the California Psychological Inventory (CPI), and the Minnesota Importance Questionnaire (MIQ). During the interpretive sessions, counselors use the test results to help structure career exploration, to stimulate new possibilities and directions, and generally to help clients develop an integrated whole of their self-knowledge. Interest inventories can provide clients with a wealth of information, and the number of possibilities to explore often can be overwhelming. Thus, additional information from the assessment of abilities, personality, values, and needs can be useful for focusing their exploration and for providing additional information to determine the extent to which their characteristics match those of various jobs and occupations. After exploring the assessment results, the counseling process moves to developing a plan of action, often in the form of outside assignments, for gathering more information to inform the career decisions.

TABLE 1
Comparison of Interest Inventories

<i>Vocational interest inventory</i>	<i>Focus</i>	<i>Usage setting(s)</i>	<i>Number of items</i>	<i>Scales</i>
Strong Interest Inventory	Professional populations Separate sex norms	High school/College	317	6 General Themes 25 Basic Interest 211 Occupational 4 Personal Style
Self-Directed Search	Student populations Self-administered Self-scored	High school/College	228	Daydreams Activities Competencies Occupations Self-Estimates
Campbell Interest and Skill Survey	Professional populations Combined sex norms Addresses self-estimated skills	Business	320	7 Orientation 29 Basic Interest 60 Occupational 2 Special
Career Assessment Inventory	Nonprofessional populations Combined sex norms	High school/College	370	6 RIASEC Themes 25 Basic Interest 111 Occupational 4 Nonoccupational
Sixteen Personality Factor Questionnaire	Professional populations Addresses personality	Business	185	16 Primary Factors 5 Global Factors 3 Response Styles

3. CONCLUSION

Research has been done to determine the effectiveness of career counseling. The results across several studies indicate that an average client has an outcome that is better than the outcomes of 80% of untreated control groups. Research has shown that congruence between a person's interests, abilities, personality, and values and the work environment—a desirable outcome of career counseling—leads to success and performance on the job and in school, life and work satisfaction, persistence on the job (i.e., tenure), and positive self-image and self-esteem. Conversely, poor correspondence (i.e., person–environment incongruence) is related to burnout, increased levels of anxiety, and somatic complaints. The implication of these outcome results is that whether people view their work as a job, a career, or a calling, career counseling can be a powerful aid in making occupational choices that lead to well-being.

GLOSSARY

contracts Employment and psychological contracts form the basis of the work relationship between employers and employees. Employment contracts tend to be in written form, stipulating legally binding terms and conditions of work. Psychological contracts are sets of shared understandings, obligations, and expectations of the work relationship.

job stress and burnout The negative psychological effects of workplace demands relative to the personal resources of the individual to cope with environmental stimuli. Stress is the interaction between job environment stimuli and individual responses in situations where the individual does not possess sufficient resources to cope. Burnout is characterized by feelings of emotional exhaustion, depersonalization, a lack of personal accomplishment, and a manifest inability to cope with even basic, ongoing demands in the work environment.

occupational psychology The scientific sub-discipline concerned with individual, work team, and organizational performance, psychological well-being, and human integration in the workplace.

occupation and gender Topics concerned with occupational choice, socialization, job performance, career choice, and

occupational choice as they relate to gender differences between males and females in the work environment.

personal initiative and innovation Topics concerned with idea generation, applied creativity, and innovation implementation in the workplace. Personal initiative involves work role changes that are self-initiated, that are proactive in orientation, and that demand persistence until change is implemented. Creativity is the generation of new ideas, whether eventually implemented or not. Innovation is the generation and implementation of new ideas, products, or processes at the individual, workgroup, or organizational levels of analysis.

personnel selection The attraction, recruitment, psychological assessment, and decision-making process involved in selecting newcomers for job vacancies in an organization in a valid, reliable, fair (i.e., legally defensible), and cost-effective manner.

work team A collective of two or more individuals that performs organizationally relevant tasks, shares one or more common goals, interacts, exhibits task interdependencies, manages boundaries, and is embedded in a broader organizational context.

Occupational psychology is a discipline related to industrial-organizational psychology that is concerned with individual, work team, and organizational performance, psychological well-being, and human integration in the workplace. Used especially in the United Kingdom, the term occupational psychology is used synonymously with that of industrial-organizational (I/O) psychology in the United States and Australia, and

with that of work and organizational (W/O) psychology in continental Europe. Due to its historic background in the United Kingdom, the subfield of occupational psychology developed somewhat specific foci, methods, and research concerns. Here, however, the term is used in its more general sense with acknowledgement to these historic precedents. Occupational psychology concerns work performance outcomes and health and well-being outcomes at three interrelated levels of analysis: (1) individual, (2) work group or team, and (3) organizational. Additionally, a few authors suggest a fourth level of analysis, that of interorganizational outcomes, although this has been more the concern of management scientists and organizational sociologists.

1. INTRODUCTION

1.1. Domain-Relevant Fields

The British Psychological Society (BPS) identifies eight major areas of knowledge and professional practice as constituting occupational psychology: (1) human-machine interaction, (2) design of environments and of work, (3) personnel selection and assessment, (4) performance appraisal and career development, (5) counseling and personal development, (6) training, (7) employee relations and motivation, and (8) organizational development. For individuals to become a chartered occupational psychologist (COP) under the BPS framework (essentially equivalent to licensing in other countries), they must have knowledge of all eight areas, supervised practice in five areas, and higher level independent practice over several years in at least two areas. Ongoing continuing professional development (CPD) workshops and seminars ensure that practitioners are kept updated on recent developments, but tensions between practice and research have risen under this framework. Researchers pursuing a Ph.D. and subsequent scientific career have found it difficult to gain the breadth of practical experience necessary to become COPs, as their work is usually specialized within one of the eight major areas. Recently, however, the Occupational Division of the BPS has issued tenders for project work to re-examine and possibly update this framework.

Arnold *et al.* stipulated 12 domains of occupational psychology, with some overlaps with the BPS professional society listing: (1) selection and assessment, (2) training, (3) performance appraisal, (4) organizational change and development, (5) ergonomics and equipment design, (6) career choice, development

and counseling, (7) interpersonal skills, (8) equal opportunities, (9) occupational safety and health, (10) work design, (11) attitude surveys, and (12) well-being and work. Again, the overlaps with the domain knowledge frameworks used to train I/O psychologists in the United States and Australia, and with European syllabi for W/O psychologists stipulated by the European Association of Work and Organizational Psychology (EAWOP) and the European Federation of Psychologists' Associations (EFPA), are self-evident. Occupational psychology, nevertheless, has several areas of interest and active research that are not widely represented in other countries. These include occupational choice and career guidance, gender studies, health and safety in the workplace, including accidents and errors, and historically, unemployment research, especially the negative psychological effects upon individuals of being jobless.

1.2. Brief History

Within the context of the United Kingdom, occupational psychology has a history of some 50–60 years. Industrial psychology, as it was called then, began during World Wars I and II as a highly focused effort to support the armed services and government departments. The inter-war years also saw the creation of the National Institute for Industrial Psychology (NIIP) and the Medical Research Council, which subsequently provided funding to several research programs in the United Kingdom, most notably the applied psychology unit at Cambridge University and the social and applied psychology unit at Sheffield University under Peter Warr (later, under Toby Wall). These all developed from war-time work and research studies into such topics as soldier selection and “shell shock” among soldier casualties, and demobilization studies into how best to return soldiers and commissioned officers to civilian and commercial careers in peacetime. This period also witnessed formative visits to Britain by U.S. and European applied psychologists, including, most influentially, Viteles in 1922.

The inter-war years brought with them troubles for occupational and applied psychologists. The economic depression and the heavy reliance of the NIIP upon industrial funding caused Elton Mayo to decline the position of its directorship upon C.S. Myers' retirement in 1938. His rationale for this decision is fascinating, describing the reliance for research funding upon industrial sources as being “made at the request of troubled firms” and resulting in “planlessness” of such

an unprogrammable approach to research. Exactly the same ills bedeviled occupational psychology and I/O psychology internationally in later periods of economic depression, when research funding was exclusively reliant upon business sources and commercially applied studies. Yet the NIIP was highly influential; the titles of some of its published reports closely resembled the domain areas noted above, which were to become the main foci of occupational psychology (e.g., *Industrial Accidents, Vocational Guidance and Selection, Methods of Work, Psychological Effects of Noise, Labour Turnover, and Hours of Work*). The NIIP and, later, the Tavistock Clinic formed the foundation of much commercial and applied psychology in Britain, but additionally the three armed services (Army, Navy, and Air Force) committed substantial resources, during World War II and after, toward research on occupational issues, including the development of soldier selection tests and exercises. Work by F.C. Bartlett at the Cambridge Psychological Laboratory (later named the Applied Psychology Unit) also contributed to these themes, again with a distinguishing feature being the synthesis between research on selection and psychological health outcomes. Post-war applications included the development of assessment centers for the British government (the so-called Civil Service Selection Board, or CSSB, which had close parallels to U.S. assessment center work at that time), pilot selection and error, naval officer selection and training, and pilot ergonomic studies.

The 30-year period between 1960 and 1990 witnessed substantial growth in both the numbers of registered occupational psychologists and the range of activities they were engaged in. The establishment of the Careers Service to guide school leavers in labor market entry, research work conducted at the Tavistock Institute (the so-called human relations movement), quality of working life (QWL) studies, and industrial training studies in the 1960s and 1970s culminated in the Socialist-Labour government of the time creating the Steering Group on Job Satisfaction, with representatives from trades unions and employers, and chaired personally by the Minister of State. The economic boom years of the 1980s led to a concomitant growth in occupational psychology, with COP numbers rising substantially. Consultancy firm growth was also a marked feature of this period, with firms such as SHL, Oxford Psychologists Press, and the Psychological Corporation expanding rapidly. International diversification by consultancies led several large U.S. firms to establish European subsidiaries, and also led SHL to set up offices in the United States.

Growth spurred a step-shift in the numbers of accredited occupational psychology masters degree programs in the United Kingdom from a mere handful at the start of the 1980s to almost 30 at the end of the 1990s; in fact, the accreditation procedure itself was introduced by the BPS Training Committee during this period. Health and human resource management (HRM) issues continued to be high on the agenda for research and consultancy, stimulated still further at the end of the century by legal precedent that allowed employees to sue their organizations for claimed negative psychological effects caused by allegedly negligent HRM practices.

1.3. Defining Occupational Psychology

Modern-day use of the term occupational psychology has come to be synonymous in the United Kingdom with the terms I/O psychology in the United States and W/O psychology in continental European countries. Several handbooks and textbooks offer useful overview definitions, for example, “The application of psychological principles, theory, and research to the work setting” (Landy and Conte, 2004, p. 6), and “Work psychology is about people’s behavior, thoughts and emotions related to their work. It can be used to improve our understanding and management of people” (Arnold *et al.*, 2004, p. 10).

1.4. Applications of Occupational Psychology

As psychology applied to the world of work, occupational psychology has generated a whole host of practical applications. This science–practice blend is both the essence of the discipline and cause for some periodic tensions. Porteous noted 13 main areas of application: (1) individual differences, (2) personality and work, (3) work design and measurement, (4) performance appraisal, (5) behavior and work performance, (6) humanistic values, (7) cross-cultural values, (8) counseling workers, (9) stress, (10) leadership, (11) human–computer interaction, (12) health and safety, and (13) new work. Occupational psychologists are employed in industry, government, and consultancies if functioning as practitioners, and by universities or research institutes if working as research scientists.

2. THEORETICAL PERSPECTIVES

As with other areas of applied psychology, occupational psychology has adopted a range of theoretical perspectives and approaches as it has developed over the decades. Distinct from other areas of psychology, however, occupational psychology has also been heavily influenced by theories originating from the management sciences and from the discipline of organization theory and behavior. It is possible to identify at least four main theoretical perspectives that have had a discernible impact upon occupational psychology: (1) individual differences, (2) applied social psychology, (3) applied cognitive psychology, and (4) management science. Table I summarizes these approaches and historic influences.

2.1. Individual Differences

The individual differences approach to personality traits, cognitive abilities, values and attitudes to work,

and workplace behavior has a long and illustrious history in occupational psychology. Much of the seminal work in trait differences was undertaken using correlational and factor analytic statistical techniques (including the work of Eysenck, Cattell, and later by commercial personality test developers). The structure of human intelligence was similarly informed by early, seminal research mostly in laboratory experimental studies by scholars such as Galton and Vernon. Debate still continues as to whether tests of GMA or measures of specific abilities best predict subsequent job performance. Current meta-analytic research internationally converges on the finding that GMA tests are highly valid stand-alone predictors of job performance and that measures of specific abilities do not add significant incremental validity. Other individual differences have also been investigated, including attitudes toward work, leadership beliefs, work-related values, and interpersonal attitudes and style. All of these strands have tended to adopt a trait perspective, presuming that these

TABLE I
Underlying Theoretical Approaches to Occupational Psychology

	<i>Individual differences</i>	<i>Applied social psychology</i>	<i>Cognitive psychology</i>	<i>Management theory</i>
Basic tenets	Individuals differ along stable, measurable dimensions that affect observable behaviors	Interpersonal and group processes affect group productivity and individual well-being	Individual cognitions, information processing capacities, and decision heuristics affect individual task performance	Organizing processes and leader behavior are critical determinants of organization success
Primary level(s) of analysis	Intra-individual Inter-individual	Inter-individual Intra-group Inter-group	Intra-individual	Organizational Inter-group
Illustrative topics of influence	Selection Personality at work Stress proneness	Group processes Attribution theory Innovation and creativity Conflict	Decision making Human-machine interface	Organization structure Authority relations Organization success
Key models and constructs	Five Factor model (FFM) of personality Type A, Type B General mental ability (GMA)	Group development models West's Four Factor model of team innovation	Information overload Heuristic biases Information Integration Theory (IIT)	Contingency theory HRM and human capital Organizational culture and climate

dimensions are stable, replicable over time, and causal of behavior across workplace situations, a perspective for which there has indeed been considerable research support.

2.2. Applied Social Psychology

As can be seen in Table I, the primary level of analysis for which applied social psychology research has been influential in occupational psychology is that of the workgroup or team in organizations. This has been a far more recent theoretical influence than individual differences research, however, and so there has been considerably less attention in the field paid to group-level issues than to individual-level issues. In more recent years, organizations internationally have moved more toward team-based structures of work organization, spurring considerable growth in research interest at this level of analysis. Much social psychological research into groups has been conducted in laboratory experimental conditions, leaving open to doubt whether their findings can be applied to real-life workplaces and business organizations. Recent occupational psychology research has been grounded upon earlier findings, models, and theories in applied social psychology but has examined phenomena in the workplace. Phenomena such as workgroup innovation, team performance and productivity, team decision-making among boards of directors, process losses in work teams, distributed cognition and decision-making, and conflict in workgroups have come to the fore. This research has irrevocably shifted the focus of occupational psychologists away from an exclusively individual level of analysis toward issues of interpersonal, group, and inter-group processes in organizations. Multilevel designs, that is, research measuring variables and effects across two or more levels of analysis (individual, workgroup, organizational), are becoming more common as a result.

2.3. Cognitive Psychology

Historic influences from cognitive psychology upon certain issues in occupational psychology are evident, as illustrated in Table I. Many of these influences concern individual-level issues of ergonomics, human-machine interface, and individual error in task functions. In certain countries (the United States and Germany, for instance), such applications were traditionally termed industrial psychology, with large-scale funding for often being provided by military research institutes or

in industries where error consequences are of particular concern (e.g., nuclear power generation).

2.4. Management Theory

Distinct from other areas of applied psychology, occupational and I/O psychology has been heavily influenced by more macro-analytic theories, approaches, and issues addressed generally in the management sciences. Table 1 suggests some key examples, but the field has been impacted by research from several sub-disciplines in management, principally organization behavior (OB), organization theory, HRM, and organization development (OD). Most of these approaches have adopted an organizational level of analysis in considering performance and processes across entire organizations or multiple subunits as part of a work organization. Thus, management research in occupational psychology has been highly pragmatic in orientation, almost always involving quantitative field studies or even qualitative case studies, and has examined practical problems and processes as they occur in work organizations. In essence, this fourth approach has considered the managerial implications of occupational psychology through major topics such as leadership, HRM processes and organizational performance, theories and models of organizational structure, organizational change and development, culture and climate as determinants of success, and so forth.

3. KEY TOPICS IN OCCUPATIONAL PSYCHOLOGY

This section of the encyclopedia is composed of seven separate articles covering key topics in occupational psychology. They are as follows:

1. Contracts
2. Job stress and burnout
3. Occupation and gender
4. Personal initiative and innovation
5. Personnel selection
6. Safety and risks
7. Work teams

These purposely concentrate on the individual and team levels of analysis, given the historic background and theoretical approaches to occupational psychology

delineated above. An overview of each of these topics is provided in the following sections.

3.1. Contracts

Employment contracts and psychological contracts form the basis of the employer–employee relationship. The exchange nature of what each gives relative to what is expected to be received from the other is crucial, and can be termed the “mutuality” of expectations and obligations. While employment contracts are usually written, formal, and legally enforceable, psychological contracts are sets of mutual expectations that may be differentially construed by individual employees and managers in the workplace.

Psychological contracts especially are changeable in nature, open to violation by either party, and may be open to negotiation and renegotiation over time. The relative power of each party to negotiate a favorable contract is therefore important. Perceived violations of the psychological contract by employees have been found to be frequent, but research into perceived violations on the employer’s side by underperforming employees is sparse.

3.2. Job Stress and Burnout

Stress and burnout at work represent major themes of research attention and concern within occupational and I/O psychology internationally. Stress is defined generally as the interaction between job environment stimuli and individual responses when the individual does not possess sufficient resources to cope, thus resulting in strain. So-called “interactional definitions” of stress emphasize the interaction between stimuli and individual responses as opposed to earlier, more limited, non-interactional conceptualizations of job stress. “Transactional definitions” imply that stress is a result of the transaction between the individual and his or her work environment.

Job stress and strain has been modeled in various ways, each guided by the definition of stress adopted by the researcher. Interactional and moderator models, which are more complex in their design and their inclusion of different types of variables, have become more prominent over recent years. A range of causal variables resulting in job stress has been identified, including work role demands, role conflict, role ambiguity, role overload, work complexity and multi-tasking, the home–work interface, the work–family balance, and financial and other non-work problems.

Wider causes include business travel demands, relocation, expatriate working, bullying and mobbing at work, harassment, job insecurity, and redundancy. Increasing attention has thus been devoted to stress coping mechanisms and individual differences in coping with stressful events and work environments. Organizations, concerned by the potential costs of absence caused by stress and burnout, have invested in Employee Assistance Programs (EAPs), which are designed to support individual employees in a confidential and constructive manner. “Burnout” has been defined as “a special form of strain” characterized by feelings of emotional exhaustion, depersonalization, a lack of personal accomplishment, and a manifest inability to cope with even basic, ongoing demands in the work environment.

3.3. Occupation and Gender

Gender differences in career prospects, earnings, seniority of job roles achieved, and occupational choice have concerned occupational psychologists for many years. Women have been found to earn less than men, be concentrated into certain industries, and be more likely to work in certain lower authority job roles, and may have imposed upon them a “glass ceiling” of how high up the organization they can progress in terms of promotion to higher grade managerial job roles. A greater proportion of women work in part-time jobs and in service industry job roles, largely due, it has been suggested, to family commitments and traditional stereotypes of the mothering role and the housewife. These differences, still present in several developed economies cross-nationally today, have been fundamentally influenced by historic trends and precedents.

The socialization of boys and girls into potential work roles in organizations is also thought to have an impact. Gendered job roles, that is, traditionally male- or female-dominated occupations, may be held up as desirable during child development. For boys these may include military roles, emergency services, senior management, technical and scientific careers, and executive functions. For girls, in addition to family being emphasized, helping roles such as nursing, the caring professions, and service roles may be held up as stereotypical examples. Occupational values and choice may thus differ between the genders, and this spills over into differences in leadership role choice and style between males and females. Anti-discriminatory legislation in several countries that makes it unlawful

to discriminate on the grounds of gender does not appear to have eliminated these problems. Organizational efforts to enhance and manage diversity have shown positive outcomes, but many inequalities remain, and further research and practical intervention is called for.

3.4. Personal Initiative and Innovation

As organizations have moved away from job specialization and Taylorian scientific management as methods of work organization, the importance of creativity, innovation, and personal initiative in the workplace has grown. The need for product or service flexibility, adaptability to changing business environments, matrix- and team-based organization structures, and more flexible forms of working have all heightened the importance of work role creativity and team-level innovation. Creativity has been defined as the generation of new ideas, whereas innovation involves both idea generation and solution implementation in the work setting. Personal initiative is a related construct, involving self-starting, proactivity, and persistence, the outcome of which may be deemed to be innovative by observers.

Innovations develop over time not in a neat, linear fashion or through discrete step-by-step phases, but generally as iterative, complex cycles of development–regression–further development. Factors associated with innovativeness at the three interrelated levels of analysis in occupational psychology have been identified. At the individual level, these include personality, motivation, cognitive ability, knowledge, and job characteristics. At the work group level, these incorporate team dynamics and structure, climate, processes, and leadership style. Organizational level variables include structure, climate and culture, size, resources, work processes, and physical environment. Linear, curvilinear, threshold effect, and indirect relationships between these variables and innovation have been suggested or found. More recently, multilevel designs, possibly using more robust meta-analytic techniques, have been called for to clarify this mass of individual study findings.

Applied occupational psychology findings have countered a predominant but fallacious pro-innovation bias common in management texts that suggests that all innovations are positive and that the more innovation, the better for organizational performance. Rather,

applied psychology research suggests that some types of innovations can be stressful for the initiator, problematic for the workgroup to assimilate, or conflict-provoking in the wider organization where other departments or subunits are affected.

3.5. Personnel Selection

Similar to stress and burnout, personnel selection has long been a major area of research and professional practice in occupational psychology. Based historically in individual differences theories and tenets, selection more recently has expanded its concentration of levels of analysis toward the team level and issues of person–work group fit. Applicant as well as organizational decision-making has also received considerably more research attention, but the traditional model of personnel selection is based upon fitting the person to the job through the administration of various prescreening and candidate assessment predictor methods.

Seminal usage and development of meta-analysis methods in selection have generated definitive research findings over the criterion-related validity of different predictors. The best stand-alone predictor of subsequent job performance across all complexities of jobs, and in different countries worldwide, is general mental ability. Other methods add to the prediction of the wider criterion space, including work sample tests, some dimensions of the “big five” personality framework, and integrity tests. Historically much maligned, interviews, particularly structured interviews, have been found in meta-analytical research to have far better predictive validities than previously thought. Other methods that demonstrate near-zero predictive validity include age, graphology, and other so-called alternative methods.

The dilemma that the most valid and reliable predictors are not necessarily the most popular with practicing recruiters continues to concern researchers in personnel selection. Other important research has investigated fairness issues (adverse impact or unfair discrimination) in selection in different countries. Driven by differing national legal frameworks, the stringent minority rights legislation in the United States has led to research there being far more developed than in other countries. The minority groups protected under legislation differ across countries, but usually depend upon the pattern and origins of immigrant workers to a host country.

Increasing research attention is being devoted to applicant reactions, so-called “banding” of minority

group scores to mitigate the effects of under-prediction, how best to combine the information gleaned from different predictors at different stages in a selection process, expatriate selection, selection for team-working, and new technology in the recruitment process.

3.6. Safety and Risks

Fay and Tissington proposed that unsafe behavior and errors lead to higher risks and therefore may cause accidents to happen on the work floor. Unsafe behavior is defined as “behaviors that are not in accordance with safety rules and procedures.” Error can be seen as “an intentional action which does not result in the attainment of the goal [whereby] prevention of the error must have been under the control of the person(s) [involved].” Research has adopted two different approaches toward safety and risks: the person-centered approach, focusing on the role of individual difference variables, and the engineering control solutions approach, seeking to design safety into the work system by acknowledging human factor variables. Three subsequent levels of prevention are central to this approach: the design of an error-proof system, engineering safeguards, and finally, installation of warning systems. Interventions striving to enhance safety aim at changing characteristics of the workforce, changing the work itself, and/or altering elements of the work context.

3.7. Work Teams

A work team is defined by Kozlowski and Bell as “a collective of two or more individuals that performs organizationally relevant tasks, shares one or more common goals, interacts, exhibits task interdependencies, manages boundaries, and is embedded in a broader organizational context.” As organizations have become flatter and delayed, team-working has become the predominant form of work organization in many post-industrial economies. In the past, Taylorism and the specialization of work dominated many large corporations’ mode of work organization, but organizations have become increasingly dependent upon team-level co-operative efforts for their success. Team effectiveness models of an input–process–output nature guided classical research into workgroup effectiveness, yet have become increasingly complicated by researchers’ attention to moderator and mediator variables and relationships.

Contingency models of team composition and structure emphasize the need to base team formation upon environmental and task demands, including such design issues as team size and diversity of members (i.e., homogeneity versus heterogeneity). Certain outcomes warrant a more diverse composition (e.g., idea generation, adaptability), whereas others suggest a more homogenous member composition (e.g., routine task performance, innovation implementation). Models of team development have also moved from a more prescriptive-descriptive stance to becoming more situation-dependent (i.e., contingent) as research has become more sophisticated. Fixed stage models have been supplanted by more recent punctuated equilibrium models.

Emerging research centers on cognitive and affective models of team motivation, the efficacy of team-building interventions, task interdependence and performance including knowledge structures, and highly pragmatically important issues of team creation, team-building, and performance improvement attempts. Little research appears to support the commercially driven consultancy market in this regard despite repeated calls by researchers for such evidence. Future research in occupational psychology into team-working in organizations is likely to reflect its increasing importance for organizational success, and the growth in research in this area is thus likely to continue apace.

GLOSSARY

diversity management Planned steps to increase the diversity of the workforce and to integrate minorities in organizations.

gender Social construction, based on sex.

gender-related interventions Interventions designed to equalize men and women with regard to the workplace.

gender-specific division of labor Different types of work for men and women.

gender stereotypes Generalized beliefs about men and women.

The gender-specific division of labor in society implies that men and women practice different occupations, and consequently differ with regard to income, status, power, influence, and career perspectives. This gender-specific division of labor is supported and kept strong by processes of socialization and assignments. In the past few years, a number of interventions have been designed to advance the developmental potential of both sexes.

1. THE GENDER-SPECIFIC EMPLOYMENT MARKET

In most industrialized nations, the percentage of working women has risen continuously during the past few years, whereas the percentage of working men has remained almost the same. Approximately 80% of all men and 60% of all women practice an occupation. Although women and men share an equal basis of knowledge, acquired in school, career perspectives differentiate in horizontal as well as vertical aspects of occupation. The horizontal aspects of occupation concern the type of occupation and trade; the vertical aspects of occupation concern inner structural hierarchies. More men than women are suitably employed after educational training. Women more often practice work characterized by low demands and low decision latitude. Employment uncertainty affects women more than men; women more often work part-time.

Even when men and women hold similar jobs, men are provided with higher salaries. Female managers earn less than their male counterparts. Women in Europe earn approximately 15% less than men, and women in the United States earn approximately 25% less than men. These differences in salaries affect not only the sexes but also families. Female-headed families are one of the most economically vulnerable segments of the population.

Men and women differ with regard to their career perspectives. In Europe, for example, men are twice as likely to be in managerial positions. Only 3% of top

management positions are occupied by women. Worldwide, men dominate executive functions.

Gender-specific working conditions are found within the psychology community as well. Male psychologists are more likely to be provided with higher salaries, secured positions, and more executive functions than their female colleagues. Another phenomenon of the employment market can be observed for the psychology job market as well: When an organization or profession becomes more “feminine”—female employees increasingly predominate—the public value and influence of its members decrease considerably.

The gender-specific division of labor is not limited to paid work: Beginning in early childhood, girls perform more household chores than boys. Numerous empirical studies show that women do chores more than men. These findings are not limited to housewives and part-time working women; they also hold for full-time working women.

Work tasks are gender specific as well. Twice as many women as men do volunteer work in the social field, and nearly three times as many men volunteer in the area of politics. Men nevertheless mainly hold executive functions and prominent posts in the volunteer segment.

Work is divided in a gender-specific way. Type of occupation and gender are therefore important. Industrial/organizational (I/O) psychology focuses on premises, conditions, and consequences of work and division of labor within society. Gender and occupation should also be integrated.

2. HISTORY OF I/O PSYCHOLOGY

In the early years of I/O psychology, researchers reported sex-related characteristics of work and noted gender differences. The following is an example:

Early Observations of Gender and Occupational Behavior

“Sex differences can be directly identified methodically, based on any profession tasking both sexes in a parallel manner. Female and male tailors are differing widely concerning the manual aspects of their occupation. A man treats and processes fabrics even on a subjective point of view, applying strength, energy, and a dominance that should be called systematic. A tailoress (female tailor) treats her fabrics somehow almost intuitional, playful, delicate, without any systematic, totally according to her own individual fittings.” (p. 922)

From Griese, F. (1928). *Psychologie der Arbeitshand*. Berlin: Urban & Schwarzenberg. Translated by E. B.

Differences between the sexes based on physiological aspects (e.g., muscular strength and operation of the cardiopulmonary system) and psychological aspects (e.g., intelligence, motivation, and commitment) were stated; specific sex-related aspects were noted.

The thesis of monotony resistance of women, developed in approximately 1920, stated that women engaged in repetitive work feel less bored and less monotony than men. Because repetitive work prevents struggling with constant decisions and allows daydreaming, women, who seek no satisfaction in their jobs, regard this kind of work to be convenient and desirable.

These statements are still made even today, but they have never been scientifically proven. A number of early studies by I/O psychologists integrated women (e.g., the Hawthorne study). However, no scientific discussion concerning the sexes of the test subjects and related consequences for the studies took place (and still do not take place). Other studies involved women only marginally in their samples. This has to be kept in mind especially regarding studies examining the consequences of working conditions and tasks on performance, health, and well-being. Until the 1980s, the issue of occupation and gender was almost totally ignored. Reacting to criticism about the neglect of women within industrial psychology research, a number of studies were performed that increasingly considered women and related results to gender-related topics. Kohn and Schooler, for instance, in their widely quoted study on occupation and personality, questioned men first and later their female partners, applying a longitudinal design.

Since the 1980s, an increasing number of studies have focused on women, resulting in increased research on gender-specific differences. Applying this new framework, research has focused on identifying and evaluating gender-specific differences (e.g., the degree of distinction in gender-specific values and interests and the degree of distinction in leadership behavior between men and women) and evaluating the differences in gender-related aspects within certain theoretical models (e.g., the connection between working conditions and personality).

3. CONCEPTS AND RESULTS

Common knowledge holds that gender-specific division of work is based on the differing work potential

of women and men. Applying this point of view, boys and men are mainly focused on career aspects, whereas women tend toward family aspects. Men are mainly interested in scientific/technical professions, which provide better career opportunities, whereas women focus on caring and nursing professions; men show materialistic interests, and women show social interests. Men are technically oriented and they impose their will; therefore, men succeed easier and are especially qualified for prominent positions of executive functions. Women are more cooperative. The following concept is regularly pointed out: Men and women differ according to the values related to the importance of work; therefore, consequences differ as well. For instance, for women unemployment is stated to be a minor problem because they have alternative roles.

How does common knowledge compare with scientific results? The following sections discuss three concepts of I/O psychology, focusing on occupation and gender.

3.1. Occupational Values and Goals

A number of studies have focused on whether occupational values and goals of men and women differ. Intrinsic values (social relations and job characteristics) and extrinsic values (salary, promotions, and occupational safety) are often separated. With regard to male and female frameworks of occupational values, there are only minor differences. Accordingly, intrinsic values are more important to women, and extrinsic values are more important to men.

The most prominent differences occur for young, married employees. The older the workers, the less prominent the differences become. This is due to the fact that men's focus on extrinsic values diminishes and their focus on intrinsic values increases with age.

A very striking connection was made by research examining the career orientation of students. The main sample showed only few differences between men and women. Focusing on the students' progression, the intrinsic career motivation of women is less prominent at the end of their scientific qualification period than at the beginning, whereas that of men is more prominent at the end of their scientific qualification period than at the beginning. Accordingly, there is a more prominent orientation on career aspects for men at the end of their scientific qualification period than for women.

Although the previously discussed results on occupational values show only few gender-related differ-

ences, these are found to be prominent by examining specific occupational plans and goals.

For many decades, research has elicited women's plans to reduce or discontinue occupational practice in favor of household matters. Correspondingly, especially women include housework in their future plans. This can be explained by the different social roles of men and women. Congruent to the gender-specific division of labor, men consider their future occupational practices to involve paid work. Their traditional responsibility is securing the family income. This injects special importance in career-related aspects, especially if entering the occupational market while simultaneously starting a family. Women view their working lives as involving paid employment as well as the family. Women have multiple roles. They are less likely to accept negative aspects or disadvantages of paid work than are men.

3.2. Leadership

Based on the previously mentioned gender-specific difference in employment within the management segment, leadership aspects have to be considered especially important. Here, the focus is on the occupational history and promotion of managers and on leadership behavior.

Studies have shown no significant difference between occupational values and motives of male and female managers. Compared to their male counterparts, female managers are more often single and have fewer offspring. Their occupational history can be compared to a "chimney," leaving space only for the paid work.

Mainly qualitative research indicates that men and women differ with regard to their identification of factors that enabled them to enter their career and gain promotion. Women refer more often to prejudices and systemic barriers—hindrances. Women in prominent positions with executive functions are more closely watched and they cannot use internal networks as effectively as men.

The prototype of the successful manager matches mostly male gender stereotypes and less often female gender stereotypes. The often validated phenomenon of think manager/think male is closely related to gender stereotypes, being the basis of judgments concerning leadership behavior. Despite major correspondences, these cause the difference in judgment of behavior of male and female managers. The position of female manager is considered as a token status. Women token workers experience a high degree

of visibility, isolation, and gender-stereotyped roles, causing discrimination.

Gender-related differences in leadership behavior have been the focus of many research projects in recent years. A more participative or personal-oriented style of leadership of women was noted especially by qualitative research. However, applied meta-analysis was unable to verify these findings. Research on leadership behavior only produced gender-related differences by applying laboratory-based methodologies. Field studies indicated only marginal gender-related differences. This could be due to the occupational socialization of the manager, corresponding with the development of specific skills. These skills build the central foundation of executive functions and are developed independently of being male or female.

3.3. Occupation and Health Issues

The average life expectancy of women is approximately 7 years longer than that of men. At first, this is not remarkable. Compared to women, men engage in behavior with significantly higher risks: Men smoke and consume alcohol more often than women, they abuse drugs more often, they less often have a healthy diet, they take advantage of health care programs less regularly, they are less sensitive toward signs of exhaustion, and they are involved in accidents at work more often. However, men are not more prone to sickness compared to women. Based on studies relying on self-reports, women suffer in a more intense way from psychological distress.

A number of explanations have been given for this finding. First is the more prominent emotional openness of women, which places women more at risk of psychological distress. This is more consistent with the female gender stereotype than the male, especially with regard to psychological distress and sickness. Another explanation is based on the differing vulnerability of men and women. The genetic, physiologic, and hormonal constitution of women is responsible for the inconsistency concerning stress, demonstrated by morbidity rates. The final explanation is the difference in working and living conditions between men and women, including stress related to paid work and housework.

The results provided by a meta-analysis on the significance of gender-related differences with regard to the relation of work and health are inconsistent with the second explanation presented previously. The second explanation states that there is a moderating function of gender within the relation of work and health. Due to the

contrariness of the presented findings related to working conditions and health, determining the most plausible explanation seems to be impossible. Such a determination would require significantly more information about gender-specific working and living conditions. Information on stress and resources is needed to gain deeper insight into working and living conditions. Information is needed that is unlimited to aspects of the practiced occupational matters alone. There is a lack of adaptable measuring instruments capable of analyzing the overall stress impact and resources.

4. EXPLANATIONS

In the past, gender research was primarily based on biological models. This frames the previously mentioned statements about I/O psychology and the differing vulnerability of men and women. Biological models are based on the assumption that genetic, physical, and hormonal factors establish (gender-specific) behavior. Current approaches are based on the assumption that in addition to biological aspects (sex), social aspects (gender) also have to be considered. According to socialization models, the difference between men and women and gender identity is established throughout human socialization based on processes of learning, such as model learning, imitation, differential enhancement, and gaining cognitive concepts.

Social structural-cultural models of gender highlight the specific division of labor applied by certain institutions (e.g., schools, businesses, and the military) in order to maintain their specific function. In addition to division of labor, especially gender-related division of labor, a distribution of status and power takes place. This sets the foundation for social structures, norms, rules, and behavioral standards accepted and executed by the participants. Current concepts of occupation and gender integrate the previously mentioned approaches.

Biologically determined sex implies socially determined gender: Men and women perform different tasks and different types of activities. This has effects for all types of work—housework, freelance work, voluntary work, and paid work—forming a horizontal and vertical division in the employment market that affects not only types of activities but also power and status.

By working within specific areas of work, men and women adapt different attitudes, actions, competencies, and abilities. Gender-specific attitudes or competencies are found whenever the types of activities differ between men and women.

Gender-typical conditions, the types of activities of men and women, affect gender-specific differences and gender-related characteristics and processes. This influences the common knowledge base about men and women and their occupational attributes considered typically male or female.

Regarding psychology, research has focused on gender stereotypes. Gender stereotypes are structured assumptions creating a connection between personality traits and social categorizations—constructions of manliness/womanliness.

As shown by research on gender stereotypes, adaptive-instrumental attribution (e.g., achievement oriented, logically oriented, and independent) particularly describes men, and integrative-expressive attribution (e.g., sensitive, warm-hearted, and emotional) particularly describes women. Gender stereotypes include more than attributes; they also include role-consistent behavior, occupational praxes, etc. Gender stereotypes contain statements about the basic way men and women are (sex trait stereotypes) and how they have to be (sex role stereotypes).

The gender-specific division of labor affects the way in which men and women are described, and it affects gender stereotypes (see *Three Schoolboy Essays*). Research has shown that gender stereotypes are more prominent in people whose professions can be classified as traditionally male/female.

Three Schoolboy Essays

1934: "I have often wondered what profession I would choose if I was a girl and was at the end of my school years. Since girls have not got so many options. Most of them become sales assistants. Since girls are frail other professions cannot be chosen for them" (p. 111).

1946: "If I was a girl, I would choose becoming a sales assistant for a bakery. I would like to do so because there would always be food for me in a bakery. Nowadays, girls are looking for apprenticeships at a grocery. The reason for this being, food can really be scarce" (p. 112).

1986: "Girls have fewer job perspectives than boys because there are mainly technical jobs left. Being a girl, I would take a job dealing with plants because I think that girls know more about plants. The job of a hairdresser is good for girls as well because they have more delicate hands than boys do. Myself being a girl, I would become a florist because boys are not tender enough to seed and care for plants" (p. 115).

From Bamberg, E. (1996). *Wenn ich ein Junge wär*. Göttingen, Germany: Hogrefe-Verlag. Translated by E. B.

Gender-related division of labor affects not only the way men and women are described but also the way

they describe themselves. A number of studies indicate that girls and women state they have expressive attributes, whereas boys and men state they have instrumental attributes. This can be mostly found in cases of similar experiences. In other words, whenever the job is considered typically male or female, generalized attributes of the job are adapted in the framework of the personal self. Research has shown that jobs considered typically female support the self-acquisition of female attributes, whereas jobs considered typically male support the self-acquisition of male attributes.

Based on the concepts presented here, a correlation between gender and occupation can be shown by applying two different perspectives. The individual or person-centered perspective focuses on acquisition of competencies, attitudes, and self-descriptions within socialization, including occupational socialization. Sex-related division of labor leads to the development of gender-specific attributes, which again support division of labor. Women who describe themselves as having expressive attributes will choose professions in which they can realize these expressive attributes.

The situational or context-related perspective focuses on valuation, furtherance, attachment, and hindrances set up by the actors and their frame of action. This again supports the gender-specific division of labor. Women working in typically male professions are often exposed to hindrances or systemic barriers that are not found in professions considered to be typically female.

5. CAREER ADVANCEMENT FOR WOMEN AND MANAGING DIVERSITY

In order to optimize manpower and minimize employee turnover, in the 1970s a number of businesses started to employ plans for career advancement for women. These plans employed a number of different starting points or target areas:

1. Ensuring personal safety: This includes guidelines to prevent discrimination and the creation of special safety areas for women, such as break rooms or reserved parking places.
2. Reduction of horizontal gender-specific segregation: This includes plans aimed at the facilitation of access to specific occupations, such as scientific/technical-oriented occupations.

3. Interventions focusing on changing vertical segregation: This includes mainly incentives aimed at increasing the percentage of female managers (e.g., mentoring).

4. Incentives aimed at increasing the compatibility between occupation and family life: This includes guidelines concerning work hours, maternity leave (the German *erziehungsurlaub* is an extended version of maternity leave for educational purposes), and implementation of part-time work.

As demonstrated by the latter target area, career advancement for women and the Equal Rights Amendment as well as family-support programs share overlapping components.

As mentioned previously, occupation and gender can be portrayed by two different perspectives: the individual or person-centered perspective and the condition-related perspective. Gender-related interventions are aimed at the implementation of individually oriented ways of development and at the creation of conditions necessary to advance development potential for both sexes. Therefore, both perspectives must be considered.

Nearly all interventions and measures for personal and organizational development can be implemented for gender-related interventions and measures as well. These include placing women in prominent positions, considering gender-related issues with regard to employment matters and recruiting, designing career advancement paths for women (e.g., offering training programs, mentoring models, and coaching), and implementing flexibility concerning workplace and working hours. Recently, the influence of gender-related measures on public opinion and ranking of organizations has been observed. Campaigns such as the family-friendly index, family audit, or the election of "house husband" of the year are part of this trend. In the United States, and in Europe as well, career advancement for women and the implementation of the Equal Rights Amendment are being replaced by the concept of managing diversity. The most prominent difference is that the concept of managing diversity does not just take women into consideration and does not focus only on forms of discrimination. The new approach centers on advancement of the developmental potential of all social groups within an organization (e.g., same-sex groups, age groups, and ethnic groups). Regarding multicultural organizations, employees are integrated not only structurally on all positional and hierarchical layers but also on the informal layer of networks. This decreases tension and discrimination based on employees belonging

to minority groups. Staff politics is based on the premise of equal opportunity. Norms, criteria, procedures, and methods are tested with regard to discrimination and equality and changed accordingly if necessary.

6. PRACTICAL AND SCIENTIFIC PERSPECTIVES

The central concept of occupation and gender is based on the type of work. Men and women acquire attitudes, competencies, and abilities based on their work activities. The processing of gender stereotypes and gender-typical self-adjustment depends on the type of work. Consequently, there are implications for the areas of practice and science. Practical measures aimed at changing attitudes or increasing competencies have to begin with job design. Classical interventions within organizations and firms, such as job design or organizational development, did not focus on gender-related issues explicitly. This implies the nonobservance of women-specific working conditions. Most measures concerning job design, for instance, are based on jobs held by male employees and not on jobs mostly held by women.

Therefore, future approaches should not focus on equal rights politics and management diversity alone. The development of methods and measures designed to implement conditions considered typically male or female, with regard to job design and personal and organizational development, is needed. Gender mainstreaming is becoming an increasingly more relevant intervention within organizations.

It is necessary for concrete working conditions to be considered in research. This approach implies the existence of theoretical models that enable work to be defined in diverse fields. It further implies the existence of measuring instruments that enable work to be analyzed in different contexts. Both the theoretical models and the instruments of measurement do not exist. As mentioned previously, I/O psychology's focus on paid work (and on specific forms of paid work) indicates the limitation of applied models and instruments of measurement. Further developmental work has to be undertaken.

Openness to Experience

Robert R. McCrae

National Institutes of Health, Baltimore, Maryland, USA

1. Conceptualizations of Openness
 2. Openness and Creativity
 3. Openness and Vocational Behavior
- Further Reading

GLOSSARY

absorption A trait characterized by intense concentration on an activity or experience.

divergent thinking The ability to generate many possible solutions instead of the single correct answer.

tolerance of ambiguity A willingness to deal with situations in which there is no clear-cut answer.

transformational leadership A leadership style required to make major changes in the direction or operation of an organization.

Openness to Experience is one of the dimensions of individual differences in the Five-Factor Model (FFM) of personality. Open individuals are characterized by an intrinsic interest in experience in a variety of areas and by a particularly fluid style of consciousness. Openness is strongly heritable and generally stable during adulthood. Open individuals are creative and adaptable, whereas closed people are pragmatic and down-to-earth. Recent research on Openness and vocational behavior shows that this factor is relevant to vocational interests, organizational change, and transformational leadership.

1. CONCEPTUALIZATIONS OF OPENNESS

Openness to Experience is the broadest of the five basic factors that comprise the Five-Factor Model (FFM), covering a wide range of loosely related traits. Among the relevant traits are tolerance of ambiguity, low dogmatism, need for variety, aesthetic sensitivity, absorption, unconventionality, intellectual curiosity, and intuition as measured by the Myers–Briggs Type Indicator. Perhaps because the links among such traits are not obvious, Openness is the least well understood of the five factors.

In studies of trait-descriptive adjectives, the fifth factor is usually called Intellect and is defined by terms such as perceptive, analytical, and reflective. Such words suggest intellectual ability, and Openness is sometimes confused with intelligence. In fact, intelligence (as measured by ability tests such as the Wechsler Adult Intelligence Scale) shows small correlations with Openness but forms a separate factor. Years of education is also modestly related to Openness; however, it is not clear whether education promotes Openness or whether open individuals pursue more education.

Perhaps the most widely used measure of this factor is the Openness scale of the Revised NEO Personality Inventory. In that instrument, Costa and McCrae provided subscales for six aspects of life to which individuals may be relatively more open or closed: fantasy, aesthetics, feelings, actions, ideas, and values. Thus, high scorers on the overall scale are imaginative,

responsive to art and beauty, attentive to their own feelings, willing to try new activities, intellectually curious, and unconventional. These traits appear to have both a motivational and a structural component. Motivationally, open people are receptive to new experience and to a deeper examination of their own thoughts, feelings, and values. Structurally, they have a permeable style of consciousness in which remote associations are easily made. In contrast, closed people are more comfortable with the world they know and tend to compartmentalize their ideas and feelings.

Although Openness appears to be an experiential style, it has pervasive social consequences. Open individuals tend to join liberal political parties and religious denominations. They seek friends who share their interests in the arts and tend to marry spouses who have similar open interests and values. Openness is also related to vocational interests and occupational behavior. Because Openness is so clearly expressed in attitudes and behaviors, there is generally strong agreement between self-reports and observer ratings on this factor.

In general, psychologists tend to be more open than closed, and many assume that Openness is a desirable trait. However, closed individuals prefer their own conservative and down-to-earth approach to life and would rate the desirability of Openness differently. Openness is associated with some negative outcomes, including nightmares, depression, and drug experimentation. Closedness is associated with authoritarianism and difficulty in adapting to change.

2. OPENNESS AND CREATIVITY

It is generally conceded that creativity is a complex phenomenon, depending on cognitive ability, training and experience, and the social context. However, creativity has also repeatedly been associated with personality traits and motives, and most of these (e.g., tolerance of ambiguity, preference for novelty, independence of judgment) can be considered aspects of Openness. Several features of open people predispose them to creative work. The fluid nature of their consciousness means that they can make unusual and remote (and sometimes creative) associations. The fact that they are low on the need for closure means that they can suspend judgment and seek alternative solutions instead of accepting the first that presents itself. The fact that they enjoy novelty means that they are motivated to seek new ways in which to accomplish tasks. Their love of beauty stimulates artistic creativity.

The aspect of intelligence thought to be most closely related to creativity is divergent thinking, assessed by tasks that require multiple answers to a single question. For example, a respondent may be asked to write as many sentences as possible with words beginning with a fixed set of letters or to list all of the possible uses for a brick. Tests of divergent thinking are moderately related to Openness, even after controlling for age, vocabulary, and years of education. Open individuals may be more interested in these tasks, or they may in fact possess this specific cognitive ability to a greater extent.

Openness has also been linked to creative performance in tasks such as writing stories, and it has been shown to predict real creative achievements. In 1999, Helson's pioneering studies of women's creativity over the life span demonstrated that those women who were to make substantial creative achievements had been characterized in college by traits related to Openness. Indeed, one easy way in which to understand the construct of Openness is by considering as case studies creative geniuses such as Jean-Jacques Rousseau and Leonardo da Vinci.

3. OPENNESS AND VOCATIONAL BEHAVIOR

During recent years, applied psychologists have begun to appreciate the importance of Openness for understanding vocational behavior. Openness is a major determinant of vocational interests. Open people prefer investigative and artistic occupations such as author, anthropologist, and research scientist, and they also endorse a wider range of interests. Closed people prefer conventional occupations such as banking and bookkeeping.

Open people welcome change, so it is not surprising that they are more likely than closed people to make mid-career shifts. Recent studies have also shown that they adapt more easily to organizational change. Part of that adaptability is tied to their willingness to seek information. Among new employees, more open individuals are more likely to seek out feedback about their performance from supervisors and coworkers, and they are more likely to regard learning a new job as a challenge. Meta-analyses have shown that open employees respond more favorably to training programs.

Because open men and women are creative and willing to seek new directions, they can become effective leaders of change, and studies have shown that Openness is associated with transformational leadership. Leaders, of course, also require other traits

(e.g., Conscientiousness) and skills, but for some leadership tasks, Openness may be a great asset.

It must be recalled that Openness is not inevitably superior to closedness. For many vocations and many roles within every organization, there are advantages to being conservative and conventional. Maintaining tradition can be as important as is creating innovation. Assessments of Openness can assist managers in assigning tasks and in understanding how employees are likely to perceive and react to organizational change.

have approached it under the rubrics of dispositional optimism, explanatory style, and hope. Regardless of how optimism is measured, researchers usually find that it is associated with desirable outcomes, with one notable exception: Optimistic individuals underestimate likelihood of future risks. More is known about the development of pessimism than of optimism, although deliberate interventions can nurture optimism among youth as well as adults.

GLOSSARY

agency Determination that goals can be achieved.

dispositional optimism Global expectation of optimism versus pessimism.

explanatory style Habitual style of explaining the causes of bad events, either with external, unstable, and specific causes (optimism) or with internal, stable, and global causes (pessimism).

hope Global belief that goals can be achieved (agency) by generating successful plans (pathways).

learned helplessness Passivity produced by learning that responses and outcomes are independent.

optimism Belief that the future holds more good events than bad events.

pathways Beliefs that successful plans can be generated to reach goals.

Optimism refers to the belief that the future holds more good events than bad events. Optimism is a popular topic of study among contemporary psychologists, who

1. INTRODUCTION

Optimism represents a cognitive, emotional, and motivational stance toward the future. Thinking about the future, expecting that desired events and outcomes will occur, acting in ways believed to make them more likely, and feeling confident that these will ensue given appropriate efforts sustain good cheer in the here-and-now and galvanize goal-directed actions.

The term optimism is a relatively recent arrival on the historical scene, as is its ostensible cousin pessimism. In the 1700s, Leibniz characterized optimism as a mode of thinking, and Voltaire popularized the term in his 1759 novel *Candide*, which was highly critical of the shallowness of an optimistic perspective. Interestingly, pessimism appeared fully a century later, when it was independently introduced by Schopenhauer and Coleridge.

At least in their original forms, optimism and pessimism were not symmetric. Optimism as discussed by Leibniz was cognitive in its emphasis, reflecting a

reasoned judgment that good would predominate over evil, even if goodness were sometimes associated with suffering. In contrast, pessimism as discussed by Schopenhauer had an emotional meaning: The pessimistic individual was one for whom suffering would outweigh happiness. Someone can be optimistic in the cognitive Leibniz sense yet pessimistic in the emotional Schopenhauer sense.

As these notions evolved in the language, optimism and pessimism became juxtaposed, and the connotations of each spilled over into one another. The resulting composite is what psychologists usually mean by these terms, a dimension anchored by optimism at one end and pessimism at the other. Accordingly, optimism refers to a belief—perhaps wish would be a better term or even motive—that in the future good events and associated positive feelings will outweigh or be more likely than bad events and associated negative feelings.

2. CONTEMPORARY APPROACHES TO OPTIMISM

Contemporary writers approach this family of strengths in two ways. Some—usually social philosophers—treat these as features of general human nature to be praised or decried depending on the writer's own biases, whereas others—usually research-minded psychologists in the personality or clinical tradition—regard optimism and pessimism as individual differences, characteristics that people possess to varying degrees.

There are three well-known approaches within psychology to this strength as an individual difference. Each line of work has an associated self-report measure, each usually has focused on the consequences of the individual difference as opposed to the antecedents, and each has spawned a large empirical literature demonstrating that hope and optimism (or at least the absence of their opposites) are associated with desirable outcomes—positive mood and good morale; perseverance and effective problem solving; academic, athletic, military, occupational, and political success; popularity; good health; and even long life and freedom from trauma.

2.1. Dispositional Optimism

Charles Carver and Michael Scheier pioneered the study of a personality variable they identify as dispositional optimism, which is the global expectation that good things will be plentiful in the future and bad

things scarce. Their overriding perspective is in terms of how people pursue goals, defined as desirable values. To them, virtually all realms of human activity can be cast in goal terms, and people's behavior entails the identification and adoption of goals and the regulation of actions vis-à-vis these goals. They therefore refer to their approach as a self-regulatory model. Optimism enters into self-regulation when people ask themselves about impediments to the achievement of the goals they have adopted. In the face of difficulties, do people nonetheless believe that goals will be achieved? If so, they are optimistic; if not, they are pessimistic. Optimism leads to continued efforts to attain the goal, whereas pessimism leads to giving up.

2.2. Explanatory Style

Martin Seligman and colleagues have approached optimism in terms of an individual's characteristic explanatory style. Those who explain bad events in a circumscribed way, with external, unstable, and specific causes, are described as optimistic, whereas those who favor internal, stable, and global causes are described as pessimistic. The notion of explanatory style emerged from the attributional reformulation of the learned helplessness model. Briefly, the original helplessness model proposed that following experience with uncontrollable aversive events, animals and people become helpless—passive and unresponsive—presumably because they have “learned” that there is no contingency between actions and outcomes. This learning is represented as a generalized expectancy that future outcomes will be unrelated to outcomes. It is this generalized expectation of response–outcome independence that produces later helplessness. However, the helplessness/explanatory style research tradition has infrequently examined expectations. Rather, researchers measure explanatory style and correlate it with outcomes thought to revolve around helplessness: depression, illness, and failure in academic, athletic, and vocational realms. In contrast to dispositional optimism, explanatory style is a construct concerning agency.

2.3. Hope

Rick Snyder's studies of hope in effect integrate these two visions of optimism—expectation and agency. Snyder traced the origins of his thinking to earlier work on expectations and goal achievement. According to Snyder's view, goal-directed expectations are composed of two separable components. The first is agency,

and it reflects someone's determination that goals can be achieved. The second is identified as pathways, which represent the individual's belief that successful plans can be generated to reach goals.

3. MEASURES OF OPTIMISM

Optimism (and/or pessimism) and hope (and/or hopelessness) have over the years inspired many measures. Most have been face-valid self-report questionnaires; other measures have relied on interviews, observer reports, or content analyses of written or spoken material.

Measures of optimism are usually based on what an individual says about what he or she usually believes. This strategy follows from the central role accorded expectations in the various definitions of these constructs; expectations are sensibly measured by self-report of beliefs. Each of the well-known contemporary research traditions has been facilitated by the existence of reliable and valid measures, such as the Life Orientation Test (LOT) to measure dispositional optimism, the Attributional Style Questionnaire to measure explanatory style, and the Hope Scale to measure agency and pathways. Each of these measures has been refined and revised several times to improve reliability and validity, and they are respected tools in the arsenal of research psychologists.

In the case of explanatory style and hope, there are separate self-report measures available for children and adults, as well as content analysis strategies for scoring these characteristics from written or spoken material. Ways to assess hope by observer report and from interviews also exist. Hope measures, and to some degree explanatory style measures, have spawned various domain-specific versions (e.g., hope concerning family life and explanatory style for academics). Dispositional optimism and pessimism have not been assessed among children and youth, although the straightforwardness of the LOT would presumably allow its use with early teens or even younger individuals.

A problem with respect to explanatory style is that questionnaire and content analysis measures do not impressively converge, although their correlates are usually identical. More generally, convergence among the different measures of optimism and hope has not been the subject of much research, although the typical study finds a modicum of agreement.

It matters whether measured expectations are about good events versus bad events. Therefore, the LOT has separate optimism and pessimism items, and these are

somewhat independent and occasionally have different correlates. Explanatory style for good events is independent of explanatory style for bad events; the correlates are usually opposite for "good" versus "bad" explanatory styles and more robust for the "bad" style. This latter finding may be an artifact of the tendency in the explanatory style tradition to study negative outcomes (depression, disease, and failure).

4. OUTCOMES

As noted previously, optimism and hope predict many desirable outcomes: achievement in all sorts of domains (academic, athletic, military, political, and vocational), freedom from anxiety and depression, good social relationships, and physical well-being. More specific correlates include active problem solving and attention to problem-relevant sources of information, as well as conscientiousness, diligence, and the ability to delay gratification. People who are optimistic make "to do" lists, use day planners, and wear wristwatches; they also balance their checkbooks. All of these activities imply an active orientation to the future.

The only well-documented downside of optimism is its link with biases in risk perception. Optimistic people exaggerate the widespread tendency of most individuals to see themselves as below average for such dire occurrences as cancer and heart disease, failure and heartbreak, and so on. This bias can be a problem when reality matters and optimism leads one to neglect preventive or remedial actions. However, if people acknowledge the possibility of risk, the more optimistic among them take the most appropriate coping steps.

5. DEVELOPMENT OF OPTIMISM

Most of the relevant research has examined the environmental influences on explanatory style, and here it is clear what makes explanatory style more pessimistic: trauma and failure of all sorts. Less is known about what fosters an optimistic style, although an inconsistent literature finds that the explanatory styles of children and parents sometimes converge. Perhaps modeling is implicated, but so too might be shared family environment or even indirect genetic influence, as already discussed. If explanatory style is modeled, one needs to consider not just parents but also teachers, coaches, peers, and the media. Along these lines, a neglected but

likely important influence on the development of optimism is adherence to orthodox religion.

6. DELIBERATE INTERVENTIONS

The Penn Prevention Program (the Penn Resiliency Project) is a deliberate intervention to foster optimism. Schoolchildren are taught basic cognitive-behavioral strategies, especially disputation and decatastrophizing, for thinking about the causes of events in more optimistic fashion. This intervention makes explanatory style more optimistic and prevents the later development of depression and anxiety. It has also been demonstrated that both hope and explanatory style change in the course of individual psychotherapy with adults, especially of the cognitive ilk.

Missing in any of these intervention projects is an explicit focus on the fulfillments that presumably accompany optimism and hope. Thus, we know that the Penn Prevention Program makes emotional distress and even physical illness less likely, but it is unknown whether it makes youth happy and healthy.

7. CONCLUSION

Optimism and hope have had a checkered reputation since their introduction centuries ago. To call someone a Pollyanna is an insult, and to speak of cockeyed optimism or false hope is to underscore the foolishness of an endeavor that is based on an unrealistic appraisal of future risks. However, the overall benefits of optimism are not diminished by these occasional excesses. The most practical implication of optimism and hope

research is to answer the question “Should one be optimistic?” by saying, “Yes, unless there is reason not to.” In other words, optimism and hope should be regarded as cognitive strategies under the person’s control—often useful but sometimes not—as opposed to immutable dispositions.

GLOSSARY

institution In classical institutional theory, explicit structures (e.g., nations, organizations) created by legal means that give the institutions explicitly delineated authority to control their members and to enter into agreements with other parties; in neo-institutional theory, institutions are sets of understandings, actions, and interactions that characterize an identifiable, but not necessarily sharply or explicitly bounded, entity.

Likert scale A method for measuring attitudes, beliefs, or values in which a respondent answers a short question using a quantitative response scale, typically ranging from 1 to 5 or from 1 to 7, with each quantitative response linked to a verbal anchor reflecting a continuum (e.g., from *strongly agree* to *strongly disagree*).

organizational climate A term used to refer to how sets of individuals perceive and come to describe their work environment, their job, and/or organizational practices, procedures, and behaviors that are rewarded and supported, often in relation to the implicit goal priorities of the organization such as a climate for service or a climate for trust.

organizational culture A term used to refer to the configuration of values, implicit assumptions, and understandings that are expressed in overt statements, patterns of behavior, and interpretations of symbols that distinguish one organization from others.

strong organizational culture An organizational culture that is understood to have particularly strong effects on the ways in which organization members think and behave; it is usually contrasted with competing influences on organization members other than culture, including direct supervisory oversight, rules such as job descriptions and budgets, and explicit contracts.

values Desired states of affairs variously used to reflect implicit or explicit preferences, sometimes ordered into means-ends chains such that some values are viewed as preferred only as a means to achieving other outcomes, applied at various social levels from individuals across societies.

Organizational climate and organizational culture are terms that are used to comprehensively represent the social quality of organizations. The term “organizational climate” reflects psychological and sociological thinking about organizations, whereas the term “organizational culture” includes an anthropological element. Organizational climate is typically analyzed by using work attitude questionnaires. The scholarly literature

about climate often has been devoted to technical survey design and data analysis problems. These include how to reliably and validly measure individuals' attitudes and combine the answers to represent characteristics of whole organizations. Organizational culture is sometimes represented by surveys about values but is more typically analyzed by using interviews to gather stories or accounts of organizations from their members or by directly observing organizations either as an outsider or as a participant. Both terms are applied by managers and consultants who are interested in promoting or evaluating large-scale organization change.

1. BASIC CONCEPTS

Organizational climate and organizational culture both began as terms for comprehensive overviews of what an organization as a whole is like. The term "organizational culture" has retained its meaning as a comprehensive representation, whereas some uses of the term "organizational climate" have drifted from the original use. Organizational culture is most often used for referring to values and understandings, broadly shared in an organization or in some part of an organization, that influence the thoughts and actions of organization members. The term "climate" is now used for three purposes: (a) as psychological climate to describe questionnaire surveys that provide a broad profile of attitudes and perceptions of an organization's members covering more specific topics (e.g., job satisfaction, leadership, group dynamics), (b) as organizational climate to describe shared perceptions of organization members about their work environment and organizational policies and procedures that are likely to affect their well-being, and (c) as facet-specific climate to represent the distinctive value focus or profile of value priorities in an organization such as a climate for service or a climate for innovation. Although the concepts of organizational climate and organizational culture have come to be differentiated to some degree, each also has a heritage that reflects an interest in a holistic view of organizations.

2. HISTORY OF ORGANIZATIONAL CLIMATE ANALYSIS

The concept of organizational climate has a longer history than does the concept of organizational culture. The former derives from analyses during the 1930s of

the qualities of a variety of social entities ranging in scope from a nation down to a group. Social climate was evoked to discuss the rise of fascism in Germany before World War II and the response of children's groups to adult leaders. The application of the social climate idea to organizations coincided with the development of the fields of organizational psychology and organizational behavior. Organizational climate was most often invoked when consultants and scholars working in these fields sought to provide a broad overview of the social side of an organization.

During the 1960s, climate surveys began to be used to ask organization members about what they experienced their organizational surroundings as being like. Employee responses were then combined to paint an overall picture of an organization that managers could use to evaluate the need for organization change and to plan and assess the effects of changes. Climate surveys included topics such as group dynamics, leadership, employee motivation, job characteristics, and management propensities to be supportive and fair. Many of these topics have become part of separate lines of research only loosely informed by climate research and are now most often encountered as distinctive literatures.

Likert, a social scientist and consultant with interests in attitude measurement, sociology, psychology, and organization change, inspired a great deal of the early organizational climate work. Most climate surveys use the now familiar Likert-type scale questions that ask people to rate work attitudes and perceptions. The typical scale for a climate item ranges from 5 to 7 points and includes verbal anchors ranging from "strongly agree" to "strongly disagree" (an agreement scale), from "to a very great extent" to "to a very small extent" (an extent scale), or from "very often" to "seldom or never" (a frequency scale). Climate surveys were one application to organizations of the questionnaire methods that began being designed for sociological and psychological research during the 1930s. Organizational climate surveys depended on emerging data analysis methods such as factor analysis during the early postwar years. The analysis of climate data became both more feasible and more complex as the field took advantage of developments in computer technology beginning in the 1970s. These methods made it increasingly practical to analyze data sets based on hundreds or thousands of respondents answering hundreds of questions.

The concept of organizational climate has evolved, in part, to sharpen its distinction from the concept of organizational culture. Three main perspectives have

been taken in the scholarly literature to distinguish it from organizational culture. First, climate has been conceptualized as individuals' representations or cognitive schema of their work environment. Individuals are thought to respond to situational variables in a manner that is psychologically meaningful to them. Therefore, this perspective focuses on the individual and is concerned with the psychological description of organizational conditions.

The second perspective focuses on shared perceptions of climate that can be used to describe either an entire organization or a work team. If individuals agree with each other about organizational policies, practices, or procedures that affect their well-being, these perceptions can be aggregated to the organizational level and used to describe the organization. Proponents of this approach have faced several methodological challenges. One is the difficulty of agreeing about appropriate ways in which to conceptualize and measure climate perceptions. Another is the establishment of statistical methods and cutoff criteria to determine that there is sufficient agreement or consensus among organizational members to believe that perceptions are sufficiently shared among organizational members to be used to describe the larger organization. This perspective is based on the argument that for shared perceptions to arise, it is necessary that (a) individuals interact at work, (b) individuals share a common goal or work toward an attainable outcome that predisposes them to collective action, and (c) individuals have sufficient task interdependence so that they develop a shared understanding of behavior. Because these conditions are more likely to be found in work teams than in the overall organization, proponents of this perspective argue that it is more likely that a shared climate develops at a group or team level rather than at an organizational level, especially if the organization is large, divisionalized, and multilayered. Consequently, this perspective on organizational climate has recently renewed the original social climate theme of group or team climates. Another offshoot of work treating climate as agreement or consensus has been the study of climate strength conceptualized as the level of agreement or consensus among organization members. Some argue that the effect of organizational climate on other variables, such as customer satisfaction, depends on how much members agree with each other, indicating a strong organizational climate.

Finally, climate has been used to represent a particular focus—a "climate for" something. Advocates of such facet-specific climates argue that using the term

"climate" requires a specific referent such as a climate for service, a climate for change, or a climate for innovation. This perspective has revived the interest in climate research and has provided a new perspective for studying organizational phenomena with a strong applied focus. This facet-specific approach to climate also has been argued to sharpen the distinction of climate from the broader construct of organizational culture.

3. HISTORY OF ORGANIZATIONAL CULTURE ANALYSIS

Organizational culture is the newer of the two terms in organizational analysis, although (paradoxically) the use of the agricultural idea of culture as a social metaphor has quite a long history. Organizational culture is linked to analyses of societal culture having their origins during late 19th-century cultural anthropology. The basis of the metaphor is that just as societies engage in the culture of animals and plants, they also actively engage in social culture.

The relevance of anthropological perspectives on culture for managing organizations came to the worldwide attention of managers during the 1980s, although occasional references to the culture of organizations appeared several decades earlier. During the 1980s, Japanese management techniques such as quality circles were being widely imitated throughout the world, and Japanese companies were making many acquisitions throughout the United States, Europe, Asia, and Latin America. These business activities initiated debates about whether the success of Japanese organizations was due more to management practices that could readily be transferred or to distinctive qualities of Japanese culture that were either hard or impossible to imitate. Scholars were also showing increased dissatisfaction with limitations in climate research, notably with whether climate surveys were really more suited to representing the attitudes of individuals than to representing the attitudes of whole organizations. In addition, an even more basic set of debates was fomenting in academic management theory about how adequate quantitative techniques were for representing the social aspects of organizations. Although explicit discussion of Japan now has fallen out of use in the organizational culture literature, many characteristics of culture analysis can be traced to issues in Japan's effects on the business world during the 1980s.

The organizational culture literature has drawn attention to a number of aspects of organizations that had been overlooked previously. For example, in 1985, Schein drew directly from a functional cultural anthropology theory to suggest that all organizations need to deal with basic problems such as whether people are basically good, evil, or some combination of the two. The culture of an organization, notably its approach to control, was understood to be linked to the often unstated assumptions about such matters that tended to prevail. Other culture authors drew attention to the symbolism of objects such as the physical facility and the ways in which employees dressed. The anthropological tradition of interpreting stories as culture indicators was reflected in interest in organization stories and myths and in the distinctive roles that influential organization members played in transmitting these stories.

The organizational culture literature has also sought to use the methods developed for analyzing organizational climate and to adapt them to the new themes brought out by organizational culture analysts. In particular, climate surveys have focused on employees' attitudes and perceptions, whereas culture surveys have focused on values. This quantitative side of the organizational culture literature has encountered controversies about whether it is "really" culture analysis or is instead a form of climate analysis. Value surveys had in fact existed and been used frequently in psychology since the 1970s, but until the appearance of organizational culture, they had rarely been part of organization analysis.

4. ORGANIZATIONAL CLIMATE CHANGE AND CONSULTANCY

Organizational climate occasionally appears as a topic in an academic journal article, but it is more significant now as a routine part of organization assessments by corporate human resources managers in large organizations and by management consultants. Beginning in the 1960s, organizational climate surveys became part of the process of diagnosing organizations to identify how they need to change and providing feedback to promote change. For example, first a climate consultant would conduct a questionnaire survey for people throughout an organization. Afterward, the consultant would provide summaries of the survey results to various groups in the organization so that they could

discuss what has produced the attitudes typical of their groups and what changes in the work system they might like to make. Alternatively, a consultant would provide managers with a summary report to inform their decisions about leadership training programs, improving the pay administration system, and/or implementing some other human resources change. Climate surveys are also used to assess the effects of either changes in an organization's competitive environment or new internal procedures initiated by management.

Following Likert, the types of organization improvements typically considered when climate surveys were first used were to increase employee participation in an organization's decision-making processes and to promote employees' satisfaction. These applications began during what is sometimes called the human relations period in organization analysis, that is, when management scholars and consultants typically had an egalitarian bias and accepted a view that employee satisfaction promotes employee performance. Although subsequent research has indicated that employee participation and satisfaction can contribute to organization performance under some circumstances, the consensus is that early advocates exaggerated their significance. More recent uses of climate surveys have retained the survey administration and feedback approach but have focused on identifying impediments that an organization is encountering toward achieving some particular goal such as service, trust, or innovation. Climate surveys remain one of the best ways in which to involve all organization members, regardless of their level, in diagnosing and assessing organizational changes.

5. ORGANIZATIONAL CULTURE CHANGE AND CONSULTANCY

The idea of organizational culture tended to come from consultancy-oriented approaches to organizations that appeared during the late 1970s and early 1980s and then were followed by scholarly assessments. Even more than organizational climate, organizational culture is now more firmly rooted in the management consultancy literature than in the academic management literature. One line of organizational culture consultancy advocates the virtues of establishing strong cultures. A second describes ways in which corporate leaders can show transformational leadership to effect cultural change. A third focuses more on diagnosing cultures using questionnaires in a way

that is reminiscent of organizational climate research. As detailed previously, organizational climate surveys focus on employee attitudes, beliefs, and perceptions about the people and groups around them, whereas organizational culture surveys focus on values. Some applications of culture surveys have been very similar to organizational climate applications, identifying values to the end of deciding whether and how to change them. Other applications have been to understanding and trying to promote effective work between groups that need to work together. These might be departments that traditionally have different values such as production and marketing, notably production efficiency versus customer responsiveness. They might also be parties in a merger or joint venture situation that are seeking to either interact more effectively or to anticipate and solve problems when combining into a single entity.

6. THE QUESTIONABLE VIRTUES OF STRONG ORGANIZATIONAL CULTURES

Many organizational culture consultants have recommended that organizations with strong cultures had advantages over those with weaker cultures. Specific views of what culture strength means vary, but most views have some common elements. These are that a strong culture includes understandings and assumptions that are broadly shared, as well as norms and values that are broadly accepted, throughout an organization.

Originally, there were two bases for advocating strong organizational cultures, both linked to presumed characteristics of Japanese society and the Japanese organizations that rose to world preeminence during the 1980s. One argument linked the advocacy of strong cultures to the idea of employee commitment. Theory and research related to organization commitment was developing at the same time as was culture research. It provided part of the explanation as to why Japanese culture promoted a generally more committed workforce than did most national cultures. Inspired by this belief, many scholars and consultants expected that a consistent link between commitment and performance could be documented despite the unsuccessful prior attempts to link satisfaction to performance. This hope was contradicted by research results that linked high commitment to low turnover but not to high levels of typically measured performance criteria.

A second argument was based on the idea of transaction cost economics that was being introduced to organization studies at about the same time. One category of transaction consists of those that occur between an organization and employees. Transaction cost thinking drew attention to the costs that organizations incurred in supervising people. One of the themes that linked anthropological understandings of culture to the economics of transaction costs was that cultural systems of norms and understandings could reduce the expense of monitoring employees. Japanese organizations were thought to economize on monitoring because employees knew how to behave appropriately due to a combination of general societal culture understandings and their socialization into an organization's culture. Some have argued that this understanding reduces the necessity of expensive ongoing performance evaluation and other monitoring systems. Based on both the expectation that employee commitment would have economic benefits and the view that the reduced need for monitoring would reduce monitoring costs, strong cultures came to be advocated. The virtue of strong organizational cultures continues to have its advocates, but the research base supporting the strong culture position has provided equivocal results.

7. ARE ORGANIZATIONAL CLIMATE AND ORGANIZATIONAL CULTURE ANALOGOUS TO CHARACTERISTICS OF LARGER SOCIETIES AND NATIONS?

The histories of climate and culture both are linked to analyses of larger societies. Culture theory was stimulated by questions about the business success of Japan, and climate research was influenced by attempts to understand how the social climate of Germany was transformed by fascism prior to World War II. The question of the relationship between nation characteristics and organization characteristics has continued. Part of the debate is about whether socialization into organization values has the same quality as does socialization into values while growing up as a child. Some would argue that the process is identical, whereas others would argue that organizations develop distinctive values either by selecting (or encouraging self-selection for) a particular type of value or by continually seeking to make salient a subset of those values developed during childhood.

8. INSTITUTIONAL ANALYSIS AS AN ALTERNATIVE TO CLIMATE AND CULTURE

The ideas of climate and culture have similarities to the idea of institution that is increasingly used in organization analysis. Institutions, like cultures, are viewed as patterns of understandings and actions that maintain stability in social systems and distinguish one system from another. Like organizational culture, institutions that appear as typical organizational practices, assumptions, and norms in one nation can be transferred to other nations, but the transfer requires adaptation to preexisting institutions. The term “culture” tends to be used in analyses that center on values, whereas institutions cover a broader range of phenomena that include established practices. The theory of institutions comes out of political science and is that field’s way of dealing with the type of issues and phenomena that climate covers in sociology and psychology and that culture covers in anthropology.

9. RECENT LITERATURE REVIEWS AND COMPILATIONS

Numerous books offer managers guidance about particular ways in which to understand and change organizational climates and cultures. The seminal book *Organizational Climate and Culture*, edited by Schneider in 1990, was the first to focus on organizational climate and culture simultaneously and still marks a milestone in this area of research. Four more recent books provide scholarly reviews that expand and deepen these discussions and provide careful evaluations of many perspectives on climate and culture change. Trice and Beyer, in their 1993 book, thoroughly reviewed how the organizational culture concept developed in a way that highlights its anthropological roots and its distinctness from organizational climate. Academic articles by Denison in 1996 and by Verbeke and colleagues in 1998 discussed the historical development and conceptual overlap between the two constructs. Handbooks edited by Ashkanasy and colleagues in 2000 and by Cooper and colleagues in 2000 compiled an eclectic mix of perspectives on topics related to organizational climate and culture. These recent reviews and integrations suggest a number of directions being taken in organizational climate and culture research and consultancy in

addition to those noted previously. In addition to covering many of the basic issues in climate and culture noted in the current review, some of the chapters in these handbooks linked organizational culture to other topics such as symbols, time, meaning, careers, individual attachment to organizations, and roles. In 2002, Martin provided a book-length review that frames the fields of climate and culture by using them as examples of struggles among competing basic conceptual perspectives on organization studies. Although organizational climate and culture are now less often the main focus of scholarly journal articles in management than they are in scholarly and applied books, some recent articles in the *Journal of Applied Psychology* and the *Journal of Organizational Behavior* show that academic interest continues. Furthermore, many topics that either first appeared or gained momentum through climate surveys and culture analyses are now studied separately.

GLOSSARY

climate and culture Important nonstructural organizational coordination mechanisms, representing an exemplary area for organizational diagnosis.

organizational diagnosis The systematic and scientifically based assessment, description, explanation, and prediction of regularly occurring experience, behavior, and performance of members of organizations and their interaction.

Organizational diagnosis is the systematic and scientifically based assessment, description, explanation, and prediction of regularly occurring experience, behavior, and performance of members of organizations and their interaction.

1. THE CONCEPT OF ORGANIZATIONAL DIAGNOSIS

Organizational diagnosis (OD) is a multistage process of assessment, analysis, description, explanation, and

[†]Deceased.

prediction. Features to be assessed are identified on the basis of theoretical considerations of relevant organizational characteristics and their relations (systematic). The diagnostic instruments have to comply with the standards of empirical research (scientific basis). The experience, behavior, and performance of organizational members, and also their interaction, are examined, setting aside individual differences in personality. The intention is not merely data gathering but also explanation and prediction.

Therefore, OD is connected to the understanding of organization and organizational psychology. Despite their diversity, organizational theories and models are based on the assumption that orders and rules exist in organizations and influence experience and behavior as well as performance of organizational members. The function of organizational psychology can be defined as the description, explanation, prediction, and modification of psychological phenomena in organizations. Its subject remains the organization with its multiple levels—individual and work task, group, unit, and organization—with the focus depending on the organizational theory being used. Consequently, the definition, goals, and tasks of OD are connected to organizational theories and models, and OD is always conducted from a certain position in organizational psychology.

There are several other definitions of OD; the majority date to the 1980s and do not originate from applied psychology but, rather, from management and organizational sociology. For example, Van de Ven and Ferry introduced a comprehensive approach to OD. Their framework of OD, which they called

organizational assessment, draws on psychology, sociology, and management and incorporates a high degree of integration of levels, perspectives, and interdisciplinarity. Harrison and Shirom present a pragmatic approach to OD, which they define as investigations, using models and methods of the behavioral sciences, to examine the state of organizations, solve problems, or enhance organizational effectiveness. Whereas the term OD in this article is reserved for a predominantly psychological approach, and approaches from business administration, management, and organizational sociology are referred to as organizational analysis, Harrison and Shirom's approach is in between. Addressing all organizational levels, including individuals and jobs, with a focus on the application and implementation of OD, they represent a management-oriented position, primarily responsive to the needs of managers and consultants.

2. GOALS AND TASKS

OD represents a methodological framework for assessing, describing, explaining, and predicting experience, behavior, performance, and interaction of organizational members. This general goal of OD can be realized concretely in a variety of specific topics. The diagnosis of climate and culture and the diagnosis of quality in organizations are examples of the wide range of practical applications of OD. Consequently, the tasks of OD comprise a broad spectrum. Lawler *et al.* identified three groups of stakeholders interested in data and results of OD: members of the organization (employees and management), external stakeholders (e.g., government, shareholders, and responsible public bodies), and researchers.

Accordingly, they distinguish three kinds of tasks and applications for data and results of OD. For decision makers (management) in organizations, these comprise

- Organizational diagnostic data to improve human resource management
- Organizational diagnostic data to support staffing decisions about internal transfers and job changes
- Organizational diagnoses to prepare for and support organizational changes (i.e., conducting systematic and continuous analyses of deficiencies) pertinent to implementing strategic changes
- Organizational diagnoses to evaluate organizational program activities—structural (e.g., decentralization via

team structures), psychological (e.g., quality circles), or clinical (e.g., addiction and rehabilitation programs)

- Organizational diagnoses to support decisions on the allocation of organizational resources (e.g., personnel, technology, and time)

The use of OD to provide decision makers outside the organization with important information is relatively rare. The following functions are the focus of OD for external decision makers:

- Organizational diagnostic data as the basis for investment decisions: There are no binding obligations for businesses or nonprofit organizations to provide external investors or controlling bodies—shareholders, governments, public advisory councils, or regulatory agencies—with decision-making information on the organization's state with regard to work and organizational psychological issues. However, findings of OD, such as information on qualification and knowledge, mobility, indicators of the quality of work life (e.g., satisfaction, commitment, and trust), can be highly relevant for decisions on technology, mergers, joint ventures, and strategic alliances.

- OD as a basis of a reporting system monitoring working conditions, health and safety, quality of work life, job attitudes, etc. to evaluate compliance with the criteria of humane work design: Similar to data on working accidents, absenteeism, or layoffs, these data could be considered in policy decisions regarding laws and regulations (e.g., tax, work, and social laws) and research programs. This application of OD will become more important as globalization and unification among countries (e.g., the European Union) increase.

The functions of OD for external stakeholders impose special requirements on the quality of data. This necessitates the authorization of independent external institutions, similar to auditing firms, to conduct OD because conflicting intraorganizational political interests make the validity of self-assessments questionable. Additionally, agreement on the applicable instruments is needed to allow for interorganizational comparability. These prerequisites illustrate that, to date, the application of OD in this context is more theory than practice.

The third domain for tasks and applications of OD is organizational research. OD can contribute to the development and testing of organizational theories. One criticism is the methodological one-sidedness of many organizational diagnostic approaches, primarily regarding measurement, which limits the comparability

of results and inhibits the advancement of organizational theory. To account for the diversity of organizational reality, Lawler *et al.* demand a renunciation of single methods in favor of multiple methods.

3. METHODS

OD incorporates methods of data gathering, data processing and analysis, formation of diagnostic judgment, and appraisal (i.e., the evaluation and presentation of results). In the following sections, the emphasis is on practical applications.

3.1. Instruments and Quality Criteria

Instruments from different disciplines, predominantly work and organizational psychology, economics, management, and organizational sociology, are used in OD. The choice of instruments largely depends on which aspects of experience, behavior, performance, and interaction of organizational members are relevant with regard to the focus and specific goals of the OD. Whereas, for example, for the diagnosis of organizational culture, the assessment of values and normative beliefs of organizational members is of particular relevance, for an OD focusing on quality, the perception and evaluation of internal and external customers are of vital importance. There are no comprehensive reviews on the instruments from the different disciplines; instruments are available from individual publications or books on certain groups of instruments. Table I lists seven ways of gathering data, for most of which a large number of instruments exists.

Frequently used are the analysis of documents and statistics; inquiries of organizational key persons, experts, and staff members; group discussions; and observations on the job of meetings, etc. Less common is the analysis of interactions in organizations by sociometry, network analysis, Bales' Interaction Process Analysis, or Kelly's relatively work-intensive Repertory Grid Technique. The choice of instruments from the variety of sometimes competing measures should be based on three aspects: focus (mainly if structures or processes are assessed), goal and purpose of the OD, and methodological strengths and weaknesses of the measures.

In practice, different methods and instruments are frequently combined, and often multiple methods are a response to specific strengths and weaknesses of the

TABLE I
Data Sources in Organizational Diagnosis

Analysis of documents: organization charts, records, regulations, job instructions, job descriptions, organizational handbooks, special handbooks (e.g., for malfunctions and irregularities)
Organizational and economic statistics: general human resource data, absenteeism, working accidents, fluctuation, and production and investment data
Inquiries of key persons and experts: oral or written questioning of persons who are assumed to have implemented and/or control organizational regulations or who are involved in the implementation and/or control in certain subareas
Inquiries of staff members: oral or, more often, written questioning of organizational members on different levels
Observations on the job: meetings, etc.
Group discussions
Analysis of interactions: sociometry, network analysis, and interaction-process analysis

instruments. A step-by-step organizational diagnostic approach includes the use of nonstandardized and standardized methods in different stages. Initially, observations and interviews are conducted, mainly in unfamiliar, complex organizational areas. Next, processes and relationships are assessed primarily through standardized methods, such as questionnaires, guided observation, and archival analyses.

The quality criteria of psychological test theory represent a fundamental issue regarding the strengths and weaknesses of organizational diagnostic instruments. Because perfect measurement typically is not possible, different kinds of measurement errors, depending on the design of the instrument, are caused by insufficient objectivity (objectivity in use, analysis, and interpretation), reliability (estimated as test-retest, parallel, split-half reliability, or internal consistency), or validity (estimated as construct or criterion validity).

In addition to the essential criteria of objectivity, reliability, and validity and their necessary standards for conducting empirical research, practical and economic requirements have to be considered in the choice of instruments. Organizational diagnoses necessitate various kinds of investments. Demands for time and manpower, structure, semantic and visual comprehensibility of manuals and instructions, and simplicity of use and interpretation are important determinants of investments and have to be taken into account in the decision to use an instrument.

Despite methodological concerns, a goal conflict, which is inherent to an applied discipline such as OD and consistently has to be solved anew, remains between methodological–scientific demands and the pragmatic–technical requirements of practice. If organizational goals are achieved, despite a weak foundation of diagnostic measures and interventions, theoretical and methodological considerations sometimes may appear secondary.

3.2. Data Analysis

The analysis of data is an integral part of the organizational diagnostic process. Analytic techniques of empirical social research and applied statistics and specific techniques of individual psychometric diagnostics or process diagnostics are used. The former include descriptive statistics and statistical inference, such as analysis of variance to conduct comparisons of organizational groups, cluster analysis to generate diagnostic types, and discriminant analysis to generate and apply multivariate statistical selection strategies. For process diagnostic assessments of changes, analyses of variance with multiple measurement points or, in the case of many measurement points, more appropriately time series analyses can be conducted. Although a wide range of statistical methods exist for analyzing data from standardized OD, there is a lack of work on strategies for analyzing qualitative organizational diagnostic data, be it content analysis or interpretative methods. In this case, the diagnostician is referred to the literature on qualitative empirical social research.

3.3. Conducting Organizational Diagnosis

Conducting OD involves the phases of introduction, exploration, planning, main investigation, data processing and analysis, interpretation, summary, and presentation of results. In the introduction phase, diagnosticians develop a preliminary understanding of the relevant variables and dependencies, usually through talks and negotiations with clients, management, and employee representatives. Important variables are goals, potential benefits of results, available resources, and possibilities for participation of organizational members. Additional information on methods and anticipated problems of the OD is exchanged. A clarification of interests in this phase is essential for the success of the

OD. An independent diagnostician has to take great care to avoid becoming biased toward one of the organizational groups (employee representatives and management). Both groups have to be completely informed during all stages. This also serves to prevent rumors and prejudices, which can result in misinterpretations of the OD as being part of a restructuring or downsizing program, which in turn can lead to low response rates, systematic biases, and the failure of measures.

In the exploratory phase, reconnaissance studies are conducted using largely nonstandardized interviewing methods, group discussions, and observations to consider and question issues and approaches and to prevent imbalances or restrictions in the diagnostic perspective. An evaluation of the sampling criteria for organizational units may also be indicated in this phase. Theoretical, methodological, and practical training may be necessary to align existing and required competencies and qualifications of investigators who are not experienced in conducting OD (e.g., freelancers and students).

The planning phase comprises the compilation, adaptation, and preliminary testing of the instruments, based on a model of the object of investigation, and considerations on their appropriateness regarding data processing and analysis. Additionally, various administrative issues of the investigation should be resolved in this phase (e.g., time, sampling, duration, location, information of participants, administration of instruments, and confidentiality of data).

In addition to these methodological, administrative, and concrete practical preparations, this phase can contain two higher level aspects of planning. First, cost–benefit analyses can be conducted for the purpose of the investigation and to help determine the diagnostic method (e.g., regarding requirements of time, personnel, materials, and sample size). Second, a meta-analysis of the scientific literature on methods and data collection can be performed if the reviews on certain issues of OD do not suffice for a reliable evaluation of the state of method development. The economy of the investigation should also be considered in the planning phase. Internet and corporate intranet offer good opportunities for its improvement. Currently, several sophisticated software packages for the social sciences facilitate online surveys and automated data processing (e.g., optical data scanning).

The planning phase takes on a central role in the OD. Not only does it set the course for the choice of methods but also a multitude of decisions are made during this phase that determine the organizational diagnostic process. The more accurate the planning,

the less fundamental problems will occur during the actual investigation. Despite careful planning, however, problems arise, at least in longer term organizational diagnostic projects. The four main problem areas involve the investigators conducting the OD, project controlling, changes in the examined organization, and unpredictable problems.

The lack of qualified personnel can cause staffing problems to become a crucial burden for any OD. Good leadership and human resource management are therefore imperative for success. Larger, longer term organizational diagnostic projects cannot be realized without regular feedback on compliance with schedule, budget, and quality standards. A systematic controlling of these aspects has to be incorporated into any project from the outset. Controlling time is usually less problematic than controlling costs and quality. This is caused, for instance, by the incalculable financial reserves needed to cover staffing gaps due to sickness or quitting of diagnosticians or the difficulties of controlling the quality of interviews, observations, etc. Changes in the diagnosed organization constitute a third problem area. Changes that interfere with the OD occur frequently in organizations but are difficult or impossible to predict (e.g., discontinuing of units due to market changes, changes in management, or unforeseen reactions of organizational members to the OD). Finally, there is always a residual category of unpredictable problems, ranging from unexpected method effects to the loss of data due to technical problems.

In the data-processing phase, compliance with predefined procedures for sampling and investigating and quality of data have to be assessed. This includes problems with methods (e.g., systematic nonresponse), data processing (e.g., errors in coding and screen forms for data input), or data management (e.g., confounding of variables and wrong recoding of items). Ensuring confidentiality of data is a major issue in the data-processing phase.

The actual phase of data analysis, carried out with statistical computer applications, should be preplanned, well specified, and hypotheses based, especially for larger data sets with numerous variables.

In the subsequent interpretation phase, results are evaluated with respect to the goal of the OD. Depending on the goal, results are used for inter- or intraorganizational comparisons (e.g., comparisons between units or divisions). Furthermore, results are interpreted with regard to hypotheses on relations (e.g., the perception of job insecurity is related to staff changes and a lack of cooperation/communication

with the supervisor) and assumptions about causes and consequences of symptoms and interrelations (e.g., the perception of job insecurity results in decreased flexibility and increased absenteeism).

The OD concludes with the summary, report, and oral presentation of results for clients and interested organizational groups. Summary, report, and presentation significantly determine the organization's ability and willingness to accept and implement the results. Considering their importance for the success of the OD, these aspects often do not receive sufficient attention.

Active involvement of organizational members should be considered for every stage of OD, not just a subsequent phase of organizational design or development. This participation of affected individuals refers to a direct involvement in decision-making processes, including participation in the introduction, planning, and interpretation phases. Participation not only realizes aspects of democratizing and humanizing work life but also can represent a valuable support for the ecological validity of the OD. After all, who could give a better account of practices, processes, etc. than the persons involved, especially at the unit and work group level?

4. AN EXAMPLE: ORGANIZATIONAL DIAGNOSIS OF CLIMATE AND CULTURE

As nonstructural coordination mechanisms, organizational culture and organizational climate play a special role in organizational psychology. Both culture and climate are theoretical constructs that possess observable correlatives but are not directly observable. Observable cultural correlates are the use of language (communication culture), work and production means (technological culture), goals and mission statements (progress culture), rituals (traditional culture), safety standards (safety culture), etc. As a fundamental part of the organizational identity, organizational culture forms the character of the organization and its members both by attracting and assimilating members and by excluding or selecting them.

Although knowledge on the cultural and climatic situation of an organization attains strategic importance, culture and climate as constructs are not easily accessible for OD. Additional complications arise because a variety of models and definition of culture and climate in organizations exist and because culture and climate are not unequivocally distinguishable. Culture and

climate have in common the fact that they both refer to organizational characteristics that are based on communication and cooperation. However, whereas organizational culture refers to characteristics that are taken for granted, unquestioned, implicit, and customary (e.g., norms, symbols, and rituals), aspects of organizational climate are more consciously perceived, reflected, and judged in their connection with changing conditions.

For the diagnosis of organizational culture, standardized questionnaires assessing traits of organizations and organizational units (group and team) exist. According to Neuberger and Kompa, instruments for the diagnosis of organizational culture can be classified by method (quantitative vs qualitative) and by the relevant aspects of culture (sociocultural configuration vs latent factors). Consequently, four classes of instruments can be distinguished: interviews with key persons using, for example, questionnaires on leadership behavior (quantitative, sociocultural configuration); structured questionnaires assessing norms, values, etc. (quantitative, latent factors); structured questionnaires assessing stories, jokes, slogans, etc. on customs, rituals, and traditions in organizations (qualitative, sociocultural configuration); and spontaneous self-interpretations of meaning and function of cultural practices (qualitative, latent factors). This classification illustrates the different methodological approaches of OD for the example of organizational culture.

In 1990, Rousseau reviewed several quantitative measures for assessing organizational culture, including the Organizational Culture Inventory by Cooke and Lafferty, which is a widely used instrument.

The Organizational Culture Inventory assesses normative beliefs regarding the extent to which specific behaviors help members fit in and meet the expectations of the organization. Twelve cultural styles, each assessed by 10 self-report items using a 5-point Likert scale, are distinguished and arrayed in the underlying circumplex model by their orientation on task vs people and security vs satisfaction:

Cultural styles and sample items

1. Humanistic–helpful (e.g., helping others to grow and develop)
2. Affiliative (e.g., sharing feelings and thoughts)
3. Approval (e.g., “going along” with others)
4. Conventional (e.g., always following policies and practices)
5. Dependent (e.g., pleasing those in positions of authority)
6. Avoidance (e.g., waiting for others to act first)
7. Oppositional (e.g., pointing out flaws)
8. Power (e.g., motivating others any way necessary)
9. Competitive (e.g., turning the job into a contest)
10. Competence/perfectionistic (e.g., doing things perfectly)
11. Achievement (e.g., pursuing a standard of excellence)
12. Self-actualization (e.g., thinking in unique and independent ways)

The instrument has been applied in a variety of settings and cultural contexts. In a study of fund-raising organizations, it was shown that team-oriented cultural styles (achievement, self-expression, humanistic–helpful, and affiliative) were positively related to desirable attitudes (e.g., role clarity, satisfaction, and propensity to stay), whereas security-oriented beliefs (approval, conventional, dependent, avoidance, oppositional, power competitive, and perfectionistic) were negatively related to these attitudes and to organizational fund-raising success.

OD is not an end in itself, and this holds true for the diagnosis of culture and climate. The interest in reliable knowledge on culture and climate is reinforced by the expectation that a positive climate and culture support organizational goals, that their implications can be actively shaped, and that their benefits are significant. Attitudes, motivation, and values of organizational members are affected by culture and climate. For example, the relation of a positive communication culture and a climate of trust with high job satisfaction has been empirically confirmed.

5. CONCLUSION

Due to rapid sociotechnical changes in organizations, assessing the state before an innovation, controlling its implementation, and evaluating its success comprise an important function of OD. Changes in experience and behavior of individuals, due to technological innovations, impose demands on OD that are not consistently met.

The diversity of sociotechnical processes involves the extent to which different organizational levels are affected by a change in the system (from the macro-organization to the individual) and the nature and quality of changes (from changes in organizational structure and technological processes to changes in the possibilities for interaction and communication on the job). This diversity represents challenges for

OD and necessitates the development of integrative approaches, incorporating multilevel theory and methods, and broadening the perspectives adopted in the investigation of sociotechnical processes.

The considerable practical benefits of OD have not received sufficient attention. With the notable exception of the seminal work of Van de Ven and Ferry, examples of methodologically sound and comprehensive OD projects are rare. This, however, may change if the practitioners in organizations and consulting firms become familiar with the possibilities and the cost-benefit relation of OD. To achieve this, the comprehensiveness of OD and its necessity and position in the process of organizational design and development have to be emphasized and illustrated by examples. The misperception of OD as an interesting methodological approach that is dispensable for the solution of time-sensitive practical problems can be easily disproven with concrete practical results.

In addition to the various general and specific benefits derived from information and knowledge on the state of organizations, an important argument for the value of a psychologically based OD for businesses, managers, and consultants is the financial aspect. Similar to other areas with regard to work and organizations (e.g., worker safety and health protection), cost reductions attributable to OD are hardly calculable in detail. The profitability of OD cannot be appropriately evaluated by the traditional economic calculation of the costs of isolated measures but, rather, includes the optimization and integration of the whole system with regard to functionality, safety, etc. Only a comprehensive economic resource accounting, including a human capital assessment and using data from controlling and comparisons of costs and benefits, has the potential to generate a sustainable effect by constantly providing feedback on the results of OD and thus stimulating and reinforcing the motivation of decision makers, managers, consultants, and other involved groups (e.g., work councils). A comprehensive economic evaluation can be provided by extended accounting systems, which incorporate both monetary and nonmonetary goals (i.e., goals of the company and goals of the employees) and capital value and human capital reflected, for example, in the level of qualification and motivation.

GLOSSARY

distributive justice The perception that what one receives in terms of outcomes is fair.

fairness heuristic theory An approach to making justice judgments that relies on cognitive shortcuts as guides in decision-making behavior.

fairness theory An approach to making justice judgments that considers whether other alternatives could and should have been used as well as the extent to which they would have led to more favorable outcomes (an extension of the earlier referent cognitions theory).

instrumental model A perspective arguing that justice is important to individuals because the voice provided them allows them some control over outcomes.

interactional justice The perception that the interpersonal treatment that is received from one's coworker, supervisor, etc. is fair.

organizational justice Individual's perceptions of the general level of fairness in a specific organizational context.

procedural justice The perception that the procedures or processes used in a particular situation such as the workplace are fair.

relational model A perspective arguing that justice is important to individuals because being treated fairly suggests that one is an important individual to others.

Organizational justice refers to perceptions of fairness in an organizational context. Justice research focuses on theoretical conceptualizations of justice, how justice decisions are made, and the dimensionality of justice, as well as its antecedents and consequences. Fair treatment is highly valued in the 21st century workplace, where justice perceptions tend to impact on employee attitudes and behaviors as well as the effectiveness of organizations.

1. WHAT IS ORGANIZATIONAL JUSTICE?

Organizational justice is the study of people's perceptions of fairness in organizational contexts. The term was coined by Jerry Greenberg in the 1980s to describe individuals' interest in and concern with fairness-related activities taking place in various organizations such as one's workplace. Organizational justice can be viewed as a class of motivated behavior that is engaged in by different individual and contextual characteristics. Perceptions of organizational justice then result in cognitive and affective responses that guide ensuing behaviors. It did not take long for the concept to capture the attention of both researchers and practitioners, and this interest has resulted in numerous books,

journal articles, and conferences that have been devoted to organizational justice. In addition, when consultants talk to managers, employees, and CEOs about the “hot” issues confronting their organizations and the people of those organizations, the consultants are deluged with examples, anecdotes, and stories that revolve around organizational justice and its impact on the organization and its members.

2. HISTORY OF JUSTICE IN ORGANIZATIONS

Adams' work on equity theory is the foundation for psychological work on fairness. The focus of this work was on the fairness of outcomes, or what has become known as distributive justice. Organizational researchers recognized the potential effect of distributive justice on organizational functioning and, thus, it has been a major focus of organization-based research since the 1980s. However, as it became clearer that employees' reactions to organizational events were not based solely on their perceived notions of outcome fairness or distributive justice, the direction of research followed from work in social psychology and process-related issues began to be examined. Thus, procedural justice, or the fairness of the processes used to determine outcomes, became a major research focus and this has continued into the 21st century. Procedural justice is enhanced by providing employees with opportunities for voice or input into the process and by following fair and consistent rules. In fact, Leventhal suggested a set of rules to follow to ensure procedural justice that included accuracy, ethicality, and representativeness.

In the mid- to late 1980s, Bies suggested a third dimension of organizational justice that he called interactional justice. Interactional justice is believed to be related to procedural justice, but in particular it describes how decisions are communicated to employees and focuses on interpersonal treatment. That is, whereas procedural justice focuses on the fairness of organizational procedures involved in decisions, interactional justice deals more with how these decisions are conveyed to employees.

There continues to be disagreements among researchers as to the number of independent dimensions of justice. Some believe only in the traditional distinctions between procedural and distributive, where interactional justice is subsumed under procedural justice. Others maintain interactional justice as a third independent dimension of

justice. It has also been suggested that interactional justice is composed of two dimensions: (i) interpersonal justice, which focuses on treating individuals with respect, dignity, and courtesy, and (ii) informational justice, which focuses on the explanations provided to individuals about the decision-making process.

3. THEORETICAL CONCEPTUALIZATIONS OF JUSTICE

Justice research has been driven by two main questions. First, why is justice important? Research has investigated the extent to which justice is critical to employees and why they value justice. Second, how do employees decide what is just? Researchers have developed theoretical models for examining and understanding this judgment process.

3.1. The Importance of Justice

Research has demonstrated that individuals value justice and behave, in part, based on their perceptions of fair treatment. One approach explaining why individuals value justice takes an instrumental perspective, arguing that individuals desire control over events and situations. Individuals perceive that they have control when they are provided the opportunity to voice their opinions, beliefs, and ideas. Ultimately, this instrumental model suggests that voice is used to exercise some control over situations, increasing the likelihood of favorable outcomes. A slightly different perspective is the relational model (formerly called the group-value model), which argues that individuals desire favorable relationships with others. Being treated fairly provides individuals with evidence or proof that they are valued by others, increasing their own sense of self-worth.

A recent perspective takes the position that justice is its own reward. The moral virtues model argues that justice is important to individuals based on an innate sense of right or wrong. In other words, individuals have a fundamental respect for the worth of human beings and, therefore, expect fair behaviors that are consistent with this respect. Finally, Cropanzano and colleagues attempted to integrate these various perspectives into what they call the multiple needs model, in which basic desires for control, belonging, positive self-regard, and meaning motivate a desire for justice.

3.2. Deciding What Is Just

Two major theories have been developed that purport to explain how individuals make justice decisions. Applied to organizations, these theories describe two different processes through which employees might evaluate work situations and draw conclusions about the fairness of treatment received. Referent cognitions theory, developed by Folger in the 1980s, posits that situations are perceived to be unfair when individuals can think of more favorable outcomes that *would* have occurred from alternative procedures that *could* have been used. If individuals cannot generate alternative procedures that would have led to more favorable outcomes, the situation is perceived as fair. In Folger's revision of this theory, fairness theory, a third requirement was added. Along with the *would* and *could* elements, he proposed that situations are only perceived as unfair if an alternative procedure *should* have been used according to a moral imperative. In sum, injustice is perceived when (i) unfavorable outcomes are experienced, (ii) alternative procedures could have been used, (iii) the alternative procedures would have led to more favorable outcomes, and (iv) these alternative procedures should have been used based on some ethical rationale.

Lind developed another perspective on the justice decision-making process in the 1990s that he termed fairness heuristic theory. In general, heuristics are shortcuts used to make decisions that free up cognitive resources for other purposes. With respect to justice decisions, Lind argues that individuals make fairness judgments and then use those judgments to regulate behavior. Research has shown that individuals' behaviors are more driven by early fairness information than later fairness information. In other words, once individuals make a fairness judgment based on available information, that judgment demonstrates stable properties and guides ensuing behavior.

4. ANTECEDENTS OF ORGANIZATIONAL JUSTICE

Now that justice has been defined and the prominent theories reviewed, it is necessary to consider variables that influence justice perceptions. These antecedents can be classified into three groups: individual differences, situational characteristics, and supervisory factors.

4.1. Individual Differences

Individual differences such as demographic variables, affectivity, and self-esteem have been investigated as potential antecedents of organizational justice perceptions. First, demographic variables such as age, gender, race, education, and organizational tenure seem largely unrelated to justice perceptions. This suggests that no particular category of individuals are more inclined to perceive injustice than any other category. Second, studies have found negative affectivity to be related to justice perceptions. Negative affectivity can be thought of as a personality disposition descriptive of individuals who have a generally pessimistic worldview. The findings suggest that those who have more negative affectivity tend to perceive more injustice in their organizations. In particular, this relationship is stronger for procedural and interactional justice than it is for distributive justice. Third, employees who have high self-esteem, manifested by self-confidence and positive perceptions of self-worth, tend to perceive more procedural justice in their organizations than do those who have low self-esteem.

4.2. Situational Characteristics

Organizational policies, procedures, and practices have been examined as predictors of justice perceptions. For instance, strong relationships have been demonstrated between the extent to which employees are provided with opportunities for voice and perceptions of procedural and distributive justice. This is consistent with the previous discussion about why justice is important to employees: Having input leads to perceptions of control, which is valued by the employee and results in impressions of justice. The degree to which organizations provide support and high-quality communication to their employees has also been linked to justice perceptions. For instance, employees who perceive more organizational support also view their organizations as being more procedurally just. Finally, one of the most consistent findings in the literature is that individuals react more strongly to unfavorable outcomes if those outcomes are accompanied by unfair procedures. In other words, fair procedures can partially overcome the negative effects that are usually associated with unfavorable outcomes. Individuals who experience unfavorable outcomes but who view the procedures as fair react more positively than do those who receive similar outcomes and view the procedures as unfair.

4.3. Supervisory Factors

The social context plays an intricate part in organizational functioning and it has been examined in terms of justice perceptions as well. In particular, leadership variables have been extensively studied with respect to justice perceptions. The relationship between leaders and subordinates has been the focus of a great deal of research in industrial/organizational psychology. This relationship is often operationalized as an exchange between leaders and subordinates. Leader-member exchange (LMX) theory has been developed to describe this social interaction. Research has found strong relationships between leader-member exchange and justice. In particular, more favorable leader-subordinate relationships are associated with higher perceptions of justice. Interestingly, consistent with the previous discussion of the interpersonal nature of interactional justice, the relationship between LMX and justice is strongest when justice is operationalized as interactional in nature.

In addition, transformational leadership—a leadership style in which the leader uses consideration and charisma to inspire employees—has been positively linked to procedural justice perceptions. Furthermore, transactional leadership—a leadership style in which the relationship between leader and supervisor is based on simple economic exchanges (i.e., meet these goals and receive this reward)—has been positively linked to distributive justice perceptions, as the theories would predict.

5. CONSEQUENCES OF ORGANIZATIONAL JUSTICE

One way to distinguish among the many consequences of organizational justice is to categorize them as attitudinal or behavioral in nature. When applied to organizational justice, this results in a variety of outcomes in each category.

5.1. Attitudes

One of the most studied variables in organizational psychology is job satisfaction or the emotional state resulting from the cognitive evaluation of what one's job provides to the employee in relation to one's expectations. It has been extensively studied with respect to justice, and strong consistent relationships have been demonstrated. The three major dimensions

of justice have been consistently linked, in a positive way, to job satisfaction such that employees who experience organizational justice also tend to report greater job satisfaction than those who do not experience organizational injustice. Furthermore, satisfaction with one's pay level has been strongly related to procedural justice, but as predicted by the theory, it has been even more strongly related to distributive justice. The most well-established conceptualization of organizational commitment is termed affective commitment, defined as the psychological attachment to the organization based on common goals and objectives. Research has found that the three dimensions of organizational justice are uniformly related to levels of affective commitment. Employees who perceive more fair experiences at work also tend to be more committed to the organization. Justice has also been found to be related in predictable ways to other attitudes, such as trust in the supervisor, trust in the organization, supervisor satisfaction, and management satisfaction.

Other attitudinal variables of interest focus on employee reactions to various organizational systems. First, considerable research has demonstrated that reactions to the performance appraisal process are affected by perceptions of organizational justice. Individuals perceiving the performance appraisal process as fair tend to be more satisfied with the appraisal system and session, view the appraisal as more accurate, view the appraisal as more useful, and are more motivated to use it for developmental purposes. Second, considerable research has investigated the relationship between justice perceptions about the employee selection system and reactions to that system. These studies have found that both rejected and selected applicants respond more favorably to selection systems that they perceive as fair and job relevant. These favorable applicant reactions include the tendency to recommend the company to other potential employees, satisfaction with the application experience, and work self-efficacy.

5.2. Behaviors

Research suggests that justice perceptions predict employee performance. In particular, procedural justice perceptions have been strongly related to work performance such that employees experiencing fair work procedures are better performers than those experiencing unfair work procedures. Performance has been expanded to include contextual performance, which consists of those behaviors focused on maintaining the social core of the work environment rather than

those task-related behaviors that make up the technical core of one's job. In other words, contextual performance maintains and supports the work environment but is not part of the main tasks of the job. Research has found consistent, significant relationships between justice perceptions and contextual performance, such as altruism, good sportsmanship, loyalty, and courtesy, but these relationships tend to be small.

Counterproductive behaviors in organizations include employee deviance, such as stealing, sabotage, and both physical and psychological aggression. In general, both distributive and procedural injustice have been shown to predict these behaviors, but interactional justice has yet to receive much research attention with regard to counterproductive behaviors. Employees experiencing unjust outcomes or procedures have been more apt to exhibit counterproductive behaviors than have those experiencing fair outcomes or procedures.

6. CONCLUSION

A plethora of organizational justice research has been conducted, mostly in the past 15 years. Much of what goes on in organizations is affected by perceptions of organizational justice. Employees and supervisors alike make judgments about what is fair and unfair in their organizations. These judgments, in part, affect

individuals' attitudes and behaviors and the interactions among individuals. Organizational functioning is indirectly affected via the processes involved in justice judgments and the ensuing behaviors. Be it in performance appraisal, selection, compensation systems, organizational change interventions, or the legal realities of organizational life, justice perceptions will continue to play an important role.

paper. This results in joint consensual responsibility. The process is slow, but implementation is quick.

semiautonomy Derived from research in the Tavistock Institute, it represents a delegation of a degree of influence and responsibility to an individual or group for a defined task. The definition of the prefix “semi” is critical.

GLOSSARY

codetermination Describes the German system, started by law in 1951 in the coal, iron, and steel industry, that gives workers 50% representation at the boardroom level. This was later extended, with lower worker representation, to other industries. Variations of this boardroom representation have been adopted in other European countries.

human resource management (HRM) A broader assessment of the role of employees than personnel management. The term indicates that employees are a resource (rather than a cost) in the way finance and capital are resources.

quality circle Japanese method of delegating quality responsibility to groups. It usually includes an intensive process of training. It has been adapted in various ways in other countries.

participative dialogue Derived from ideas developed by the German philosopher Jurgen Habermas and used particularly in Sweden to involve as many people as possible in organizational problem-solving processes.

ringo seido Japanese bottom-up decision making. The “ring” process starts at the lowest appropriate level and gradually moves up, with each person putting his or her “seal” on the

Organizational participation (OP) is about sharing influence and power in work organizations. This area of research has become important since World War II and has been called a number of names, such as employee involvement, high involvement management, participative decision making, partnership, joint consultation, industrial democracy, codetermination, and empowerment. Participation is still the most frequently used term and is often treated as a continuum. For instance, the research program at the University of Michigan used the terms system 1 (exploitative authoritative), system 2 (benevolent authoritative), system 3 (consultative), and system 4 (participative). In later research, particularly in Europe, the continuum was extended to include semiautonomy and delegation or complete control. In this extension, the term influence–power–continuum is sometimes used based on the assumption that participation can lead to degrees of autonomy or control and delegation of power in specified circumstances. There is a link with leadership and the decision-making process from the lowest level of organization to the boardroom and beyond to the national legal framework within which OP operates.

There is also a relationship between OP and the literature on industrial relations and organizational change. Collective bargaining, although part of the influence and power-sharing approach, is usually excluded from OP, as are cooperatives and share ownership; this article adheres to this tradition.

1. INTRODUCTION

Organizational participation (OP) can be treated from the micro perspective of the individual, the meso level of the organization, and the macro level of national policy. There are substantial differences between countries. The United States and Britain have voluntary schemes based on companies and sometimes on sections or divisions of companies. Most continental European countries have a legal underpinning for OP. For instance, the German codetermination scheme gives employees up to 50% representation at the supervisory board of their two-tier board structure. There are also elected representatives on works councils with legal rights to be consulted in defined circumstances. Similar legislation exists in most continental and Scandinavian countries.

However, formal representative participation does not require legislation. In Britain and the United States, such schemes are set up voluntarily by many companies sometimes related to collective bargaining. Formal schemes, sometimes called joint consultation or employee involvement, become part of company policy and frequently have a written constitution and elected representatives. Informal participation is quite different and can take many forms. It may be encouraged by top management, but it is not usually accepted boardroom policy. It is normally left to individual managers, departments, or divisions and can vary from ad hoc meetings to regular forums. Informal participation is an aspect of managerial leadership and changes as managers leave or retire. A particular department may acquire a tradition of OP, which then lasts beyond a particular manager's style of operating. In voluntary formal and informal OP, the content of deliberation and the amount of influence available to different groups vary considerably.

In Japan, tradition and culture, rather than legislation, have produced formally sanctioned schemes of bottom-

up management (*ringi seido*), the extensive use of quality circles, and the custom of lifelong employment in large companies. Some of these Japanese OP and human resources schemes have begun to weaken.

2. CONCEPTUAL SCHEMES

The goal of OP, whether formal or informal, is to achieve some organizational benefit, such as a more content workforce, more flexible work arrangements, less resistance to change, and increased productivity. Two theoretical models have emerged. First, the human relations model postulates a causal relationship between participation, work satisfaction and lower resistance to change, and increased organizational performance (productivity) (Fig. 1). As discussed later, evidence for this model is mixed. This model also lends itself to inauthenticity or pseudo-participation, often mentioned in the literature, since it may produce "a feeling of participation" through job satisfaction, without any real influence.

The second model is based on evidence that the positive outcome of OP seems to be due to the way in which participation allows existing experience and skill to be utilized. It is called the human resources model (Fig. 2). The assumed causality is participation → improved human resource utilization → improved organizational performance. Performance can take different forms, such as an increased propensity to innovate. The model does not exclude job satisfaction, although the direction of causality is not clear. The importance of this model is its emphasis on the utilization of competence, without which there can be no improvement of output. It follows that OP is not appropriate when employees do not have relevant experience and skill. It also virtually excludes inauthentic or pseudo-participation because the utilization of competence cannot be manipulated. The model suggests that any improvement in organizational performance is due to the utilization of existing experience and skill rather than to changes in attitudes.

Both models can be used in cross-sectional research with a single organizational level or department and therefore isolated from the total organization. Alternatively, they can be conceptualized as part of a systemic relationship within an integrated human

FIGURE 1 The human relations model. Possible feedback loops are not indicated.

FIGURE 2 The human resources model. Possible feedback loops are not indicated.

resources policy. Furthermore, it may be necessary to recognize the impact of the external environment within an open systems framework. The effectiveness of OP may be influenced by new technologies, external uncertainties, national policy, legal provisions, and macroeconomic events. An open systems framework may therefore be appropriate (Fig. 3).

3. BACKGROUND

As economic competition increased in the decades after World War II, OP was frequently advocated as a way to improve organizational efficiency. This justification for OP has continued. In the 1980s, when Japan had a very competitive economy, European and U.S. managers began using Japanese methods such as quality circles and similar employee involvement techniques. Toward the end of the 20th century, economic conditions changed and Japan started to dismantle some of its human resource policy, particularly lifetime employment security. Nevertheless, during these competitive changes in Japan and the rest of the world, some aspect of OP has remained an organizational objective in most countries.

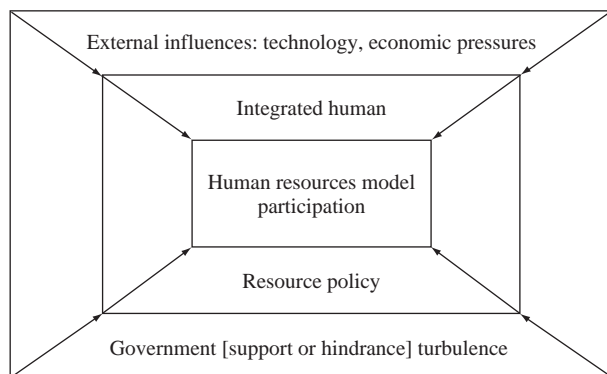

FIGURE 3 Open-system human resources model.

4. EXAMINATION OF THE EVIDENCE

4.1. Traditional Fieldwork

A considerable amount of the research literature concentrates on the lower levels of organization using a variety of quantitative methods and statistical designs. Much of this work, including meta-analyses, has been reviewed, for instance, by Locke and Schweiger, Cotton, and Strauss. The results do not present a uniform picture. OP frequently correlates with job satisfaction but much less often with improvements in organizational performance. Wagner reviewed 11 U.S. studies and concluded that even when there is a reliable statistical relationship between OP and performance, the correlations are so small that it is doubtful they have any practical significance and will tempt managers to adopt them on economic grounds alone. Other research, particularly if based on consultancy experience, such as that by Pfeffer, has found much more positive results; nevertheless, Pfeffer and others have been disappointed and surprised by the low uptake of OP work designs.

4.2. Cross-National Studies and Surveys

A number of large-scale cross-national studies on participative practices have been performed, especially in the United States and most European countries. Several studies cover the whole organization and use judgments from more than one level. Participative practices vary substantially between countries. One of the major reasons for this is the legal framework in which they are embedded (Fig. 3). When aspects of OP are mandatory, de facto influence sharing reaches the lowest levels of an organization.

The other consistent finding from large-scale national and cross-national studies is that the amount of distributed influence is very small. In a 12-country Industrial Democracy in Europe study, one of the scales asked people to describe their influence on a 5-point continuum from no influence (1) to very much influence (5). With regard to 14 decisions, the average low-level employee scored 2 (little influence). In relation to tactical and long-term decisions, their influence was much lower than 2.

4.3. Various Adaptations

The organizational function called personnel management has transmuted into human resource management

(HRM), which, as the name implies, gives greater weight to the role of human capital without diminishing the importance of economic and physical capital. Giving employees more voice plays a part in various HRM developments; for instance, semiautonomous work groups or teamwork have become popular and are often credited with improved efficiency as well as greater job satisfaction. As with other schemes, there are varying degrees of semiautonomy within teams. Sometimes, the power given to teams is minimal. In other cases, the team is able to reassign work sequences, layout, and task priorities and may be responsible for quality. Occasionally, more extensive power and responsibility are devolved to teams, such as choosing their own leader, setting targets and devising or distributing incentive schemes, agreeing on holiday rosters, job rotation, and job design, and communicating with management at a higher level. When teamwork is based on trust between management and employees and the group is assigned many of the tasks described previously, this is characteristic of a holistic system, which is discussed in the next section.

Quality circles have not always been successfully adapted to Western companies. They require skilled members, motivation, and incentives. In Japan, they were embedded in a nonadversarial industrial relations culture and could often call on the advice of outside experts.

The terms used to describe various HRM policies change frequently. Partnership is a term used to emphasize formal or informal influence-sharing arrangements between constituencies inside an organization or between an organization and an outside body (e.g., a private company and a public body). The development of virtual problem-solving organizations with people geographically dispersed, sometimes globally, has given rise to a form of interpersonal participation that can be said to create social capital.

As organizations and the environment in which they operate become increasingly complex, more emphasis is placed on a flexible workforce and the need for constant updating and learning. Among the characteristics required for an effective learning organization is a high level of motivation supported by a dispersal of influence to facilitate the acquisition of experience and skill. Equally important, but less frequently recognized, is the role of participation in reducing the underutilization of existing competence.

4.4. Systems-Oriented Research

Systems-oriented organization theory has been advocated since at least the 1960s through the writing of

Katz and Kahn and the Tavistock team, among others. However, until recently, it has had little impact on HRM policy. Most research on OP is designed and assessed within one part of an organization. It might be favored by a particular manager or consultant and does not survive when the manager leaves the organization. Even if OP applies to a whole organization, it is usually isolated vis-à-vis other HRM schemes.

Given the inconclusive results from traditional isolated projects, based on the human relations model (Fig. 1), more holistic OP designs have received attention. They are more like a human resources model operating within a systems perspective (Figs. 2 and 3). Several facets of an organization are clearly interdependent and are treated as a system, such as accounting. Managers at all levels work within the accepted set of interrelated accounting procedures. There is evidence that a systems design of HRM that includes OP can yield positive results. There are packages of HRM schemes, sometimes called high-involvement management (HIM), that include participation and a bundle of measures, such as teamwork, compensation-incentives, training, quality circles, broad job description, and similar work practices. Research suggests that such interrelated HIM-OP measures create synergy, leading to increased effectiveness, efficiency, and/or productivity.

Another relevant experience derives from Norway and Sweden. A number of individual sociotechnically designed OP projects were started in the 1960s but failed to grow and did not spread to other organizations. Gradually, later projects became more holistically designed. Several large-scale regional projects in a variety of industries were started in the 1980s and continue today. They are supported by employers and unions and oriented toward participative dialogue among as many employees as possible. The aim is to achieve a participative-communicative infrastructure to facilitate a continuous process of adaptive changes and improvements in organizational effectiveness. This systemic Scandinavian approach has been compared to the Japanese total quality management, and both appear to have achieved a measure of success.

There are substantial opportunities for further research. For instance, one can hypothesize that holistically organized participative organizations would increase work motivation, reduce boredom, facilitate conflict resolution, and increase a sense of responsibility as well as compliance with safety measures. It is reasonable to predict that OP will continue to play a useful role in applied psychology and related social science areas.

5. CONCLUSION

Organizational participation has several names and operates in a variety of contexts. It can be formal (i.e., representative) or informal and ad hoc. It can be isolated from other managerial and HRM schemes, or it can be coupled with them in a systemic arrangement. Improvement of organizational performance is usually the objective. In the human resources model (Fig. 2), this is achieved because OP, where appropriate, uses experience and skills that in the absence of OP would remain dormant. Although the case for OP has been widely advocated in management programs and the literature, employment of OP has been moderate or low. There are several explanations for this contrast between espousal and implementation. It has been argued that OP is not independent of positive or negative environmental influence (Fig. 3), but research design rarely allows for this. Another view suggests that when OP is seen as empowerment of lower levels of organization, it can be assumed to be a threat to the “managerial prerogative.” This interpretation is contested by those who argue that participation in the sense of contributing experience and skill does not abrogate the final responsibility of senior management to integrate the liberated competence in an effective decision-making process.

socialization tactics The ways in which organizations train and orient new employees.

This article reviews what socialization is, why it matters, and thoughts on how to ensure its success. Relevant research findings are reported.

GLOSSARY

accommodation The second stage of socialization, when newcomers learn how to fit into their new organization socially and task relatedly.

anticipatory socialization The first stage of socialization, when newcomers are thinking about joining the organization.

entry The point at which newcomers officially join the organization.

information seeking The process of new employees obtaining information, either overtly or covertly, about organizational life.

insiders Organizational members who are already established in the organization when a new employee joins.

longitudinal research Research that includes data collection at multiple points in time; this has typically occurred at 3, 6, 9, and/or 12 months postentry.

newcomers New employees who are undergoing the socialization process.

role management The third stage of socialization, when new employees become fully integrated into the organization.

1. INTRODUCTION

Organizational socialization refers to the “learning” of what it is to be an organizational insider. It has been referred to as the process of “learning the ropes” of organizational life. By definition, organizational socialization deals with changes for newcomers. Unsuccessful socialization means that newcomers have not learned to fit into the organization either socially or with regard to the work of the job. Lack of socialization can result in high turnover rates and employee dissatisfaction. On the other hand, successful socialization can help organizations to retain valuable employees and may result in considerable cost savings. When socialization is effective, newcomers understand and adopt the organization’s central values and norms. This guarantees better coordination among employees. Learning is key when looking at socialization. This article summarizes some of the important elements of organizational socialization and gives some practical implications for people in organizations.

2. STAGES OF SOCIALIZATION

Several scholars have proposed that socialization takes place in distinct stages. For example, the first stage is one of “anticipatory socialization.” This stage includes all of the ways in which newcomers prepare themselves for entry into the organization as well as interaction they have with the organization such as recruitment, interviews, the selection process, and paperwork. This is followed by the “accommodation” stage. During this second stage, organizationally entry begins and newcomers tackle the challenges associated with learning to deal with the people as well as the actual work of doing the job. The final stage of socialization, which has been referred to in a variety of ways such as “role management,” is when newcomers have mastered both the social and task-oriented portions of the job.

3. COMMON OUTCOMES OF SOCIALIZATION

Research on socialization has focused on newcomer adjustment and outcome variables. Adjustment variables include how much clarity newcomers have with their role, how accepted they feel, and how well they are adjusting to the organizational or career culture. Culture refers to the norms and operating guidelines within an organization, so these are not usually explicitly defined for new employees. Rather, they must discern them through interactions and questions. Other outcomes that have been studied include job attitudes, such as job satisfaction and organizational commitment, as well as performance and turnover. Research has shown that socialization is positively related to adjustment, job attitudes, job performance, and organizational culture and is negatively related to turnover.

4. WHAT DO ORGANIZATIONS DO TO FACILITATE SOCIALIZATION?

In Van Maanen and Schein’s seminal article on socialization in 1979, these authors delineated six tactics that vary from individualist to institutional: the level of interaction with other newcomers (formal vs informal), the number of newcomers within a given cohort (collective vs individual), the order in which socialization takes place (sequential vs random), whether or not there

is a specific time frame for socialization (fixed vs variable), how newcomers are trained (serial vs disjunctive), and whether or not newcomers are stripped of their old identity (investiture vs divestiture). All of these dimensions can be boiled down to a continuum with highly institutionalized approaches, where newcomers are socialized in a formal setting as a group and given clear information about the sequence and timing of the socialization process, and highly individualized approaches, where newcomers are socialized informally and given little explicit information about sequence or timing. Organizations vary in terms of these tactics. For example, in an extreme case, the military has very institutionalized formal tactics where individuals are brought in as large groups, the individuals go through formal training that is tied to specific goals and time lines, and individuality is not encouraged regarding how tasks are done.

5. HOW DO INSIDERS AID IN SOCIALIZATION?

Although a key focus on socialization research is newcomers, organizational insiders are important as well. Peers, supervisors, and mentors are often referred to as “agents” of socialization and are seen as playing an integral role in facilitating newcomer sense making. Insiders can facilitate socialization by providing newcomers with additional information, giving advice, clarifying job instructions, and giving social support.

Research has shown that the strength and nature of the newcomer–manager relationship relates to the success or failure of newcomer socialization. In general, research has also shown that job attitudes are positively related to the quality of newcomers’ relationships with peers and the frequency of their communication with peers and that performance is related to social support from coworkers.

A significant discovery in organizational socialization research is how important mentors are for successful socialization. Mentors can provide many benefits such as teaching newcomers about the organization, offering advice, helping with job instructions, and providing social support. Mentors are also important because they can be a sounding board for questions that employees are too intimidated to ask their managers, and mentors can also provide the support structure for new employees to help them fit in both socially and politically. It is important for an organization to

recognize the importance of mentors when bringing new members into the organization. This can help with many things such as meeting and managing expectations better. Mentors can help new employees to learn about the organization more efficiently. Events and practices of the organization can be relayed with mentors simply through interaction.

6. NEWCOMER PROACTION

It has been argued that newcomers' personalities can influence the ways in which they see their roles and the challenges facing them. Information seeking also seems to affect organizational socialization. Studies have also demonstrated predictable patterns in the relative frequency with which newcomers seek various types of information. For example, newcomers tend to seek more technical information than social information, believe that there are costs associated with seeking information, and believe that seeking technical and referent information is the safest form of information seeking.

A key form of learning that newcomers need to gain is how to fit into the organization. Research has shown that a variety of factors influence how well newcomers learn to fit over time.

7. SOCIALIZATION RESEARCH METHODS

Socialization researchers tend to conduct longitudinal studies, use actual newcomers to organizations, and (often) use 3-month intervals (i.e., 3, 6, 9, and 12 months) to measure socialization-related variables, especially outcome measures. However, little empirical evidence has been offered to support the selection of these measurement periods beyond the fact that other studies have used them and found significant results using them. Often, the samples studied are college graduates or specific professionals such as nurses or accountants. Thus, what we know about socialization must be inferred from a relatively narrow set of occupations or job types studied.

8. CONCLUSION

The overall conclusions include the need for organizations to be proactive when socializing newcomers and the need for them to be aware of the surrounding conditions. Learning efficiently comes from training programs that may include mentoring, internships, and other ongoing training programs that are extremely important for socialization given that learning is key during the early stages. There is a need to understand how to effectively manage the changing workforce and how it affects the socialization process because the workforce is a key factor in determining employee commitment, performance, and retention and affects how people view the organization's culture. It is also necessary to have different socialization processes for different types of employees, such as permanent versus temporary (e.g., contingent, internships), and to examine where the particular organization is with regard to the changing workforce.

specialization The diversity of operations within an organization as well as the number of departments and positions within departments in an organization.

work teams Groups of employees that work to complete a specific task within the organization.

GLOSSARY

alternative employment relationships The use of different employment contracting to vary the number of hours worked, the length of employment relationship, and the combination of the two rather than the “traditional” full-time, long-term employee–employer relationship.

centralization The extent to which power is concentrated in the upper levels of management.

formalization The extent to which rules, regulations, and policies are written and enforced.

globalization The extent to which organizations cross national boundaries in producing and marketing their goods and services.

matrix structure An organizational structure characterized by the use of project teams in which employees may be members of multiple project teams; teams include expertise from multiple functional areas and exist only until the projects are completed.

organizational learning The process of acquiring new knowledge and skills that can be applied in novel ways.

organizational structure Mechanisms that determine the interactions among organizational members within the social system.

Organizational structure refers to the processes by which individuals within an organization interact with one another and with individuals outside the organization. The design of the organization, based on various organizing principles such as centralization, formalization, specialization, team structures, matrix structures, organizational learning, globalization, and alternative employment relationships, shapes individuals’ behaviors and organizational functioning. These characteristics of the organization are interdependent, and contextual factors may moderate the effectiveness of organizational structure components in various environments both at the individual and organizational levels.

1. INTRODUCTION

The structure of an organization refers to mechanisms that control the interaction of organizational members in achieving organizational goals. The effects of organizing mechanisms on individual employees’ behaviors and attitudes have received considerable attention, as have the effects of organizing mechanisms on

organizations' stability, growth, and adaptability. This article provides a summary of this research. First, it focuses on three traditional characteristics of organizational structure: formalization, centralization, and specialization. Then, it discusses modern approaches to organizing with an emphasis on teams, matrix organizing, organizational learning, globalization, and alternative employment relationships.

2. TRADITIONAL DIMENSIONS

In 1961, Burns and Stalker suggested that organizations were structured on a continuum ranging from mechanistic to organic. Mechanistic organizations reflected those in which power was centralized and control was achieved through rigid hierarchical communication channels and formal procedures. Mechanistic organizations are considered hierarchical, or tall, with multiple levels of management. Decision-making power is concentrated at the higher levels. Organic organizations, on the other hand, are more flexible and decentralized with open communication among organizational members across levels and minimal use of formal procedures. Organic organizations are heterarchical, or flat, with relatively few levels of management. Decision-making power generally is distributed across all levels in the organizations.

2.1. Centralization

Centralization refers to the concentration of power within an organization to the upper levels of the hierarchy, suggesting that the organization does not trust the employees to make decisions that are consistent with organizational goals. This concentration of power also has the potential to make employees more dependent on upper level managers for resources and information. Thus, in the centralized organization, control over resources and information is retained by the top management team and power resides in formal authority. Lower level personnel generally do not participate in decisions, even those regarding their own tasks.

2.1.1. Individual Consequences of Centralization

Employees working in more centralized organizations experience less autonomy as a result of the increased control over resources and information by individuals at the upper levels in the organization. According to

Hackman and Oldham's Job Characteristics Model, reduced autonomy would be expected to result in lower motivational levels and ultimately in lower job performance. Also, the reduction in control resulting from lower levels of participation in the decision-making process can result in increased levels of stress. It would appear that decentralization is a more positive organizing mechanism from an individual perspective, although decentralization is not without some negative consequences. For example, in organizations where personnel decisions are decentralized, greater power is typically given to individuals' immediate supervisors in determining rewards and promotions. Because supervisors have greater power, there is an increased possibility that employees might feel as though they are being treated unfairly and might reduce their efforts. Depending on the quality of the relationship between an individual employee and his or her immediate supervisor, there might actually be a decline in job performance, especially discretionary aspects of job performance such as contextual performance and organizational citizenship behavior.

2.1.2. Organizational Consequences of Centralization

Centralization allows an organization, or at least the upper levels of the organization, to control lower level employees' behaviors so that they are consistent with organizational goals. Also, high degrees of centralization reduce the need for high levels of formal procedures because managers already directly monitor and advocate appropriate behaviors without needing written standards. However, as the organization increases its members and functions, the core group of top managers is less able to monitor all of the activities within the organization and more authority is shifted to departmental managers. Furthermore, centralization may constrain adoption of innovative ideas because lower levels in the organization have little decision-making power.

2.2. Formalization

Formalization refers to the extent to which there are formal rules, regulations, and policies in an organization. These formal rules and regulations control the behavior of employees, institutionalizing practices and procedures that have been successful in the past. If these procedures are followed, they provide consistency in decision making throughout the organization.

2.2.1. Individual Consequences of Formalization

The consistency of decision making provided by formal rules and procedures results in greater perceptions of organizational fairness and increased predictability within the work environment. This could result in increased job performance (especially contextual performance) and reduced job stress. In 2000, Schminke and colleagues suggested that the key to enhanced perceptions of fairness and predictability is not the extent of formalization but rather the extent to which the rules fit the organization's environment. For example, if the organization has a relatively stable and predictable environment, formalization matches the environment and is expected to have positive effects. However, if the environment is more fluid and dynamic, formalization might actually have negative consequences if the policies are perceived as unfair and/or too rigid. The gain in predictability from formalization can reduce job stress; however it can also lead to a sense of unnecessary red tape, a lack of control over the decision-making process, and a decreased sense of control, all of which can increase job stress.

2.3. Organizational Consequences of Formalization

Formalization results in standardization of processes and outputs, allowing an organization to maintain high levels of efficiency and productivity. For certain practices, such as selection and promotion, formalization helps the organization to avoid disparate treatment of applicants and candidates by standardizing procedures across all departments. This standardization of practices reduces the likelihood of legal actions against the organization. However, as Sitkin and Bies noted in 1993, promotion of a legalistic environment in an organization may actually undermine the social trust between managers and employees. Strict adherence to formal policies and procedures can limit the organization's adaptability and innovation much as in the case of high levels of centralization.

2.4. Specialization

Specialization refers to the diversity of operations performed within an organization. The organization may group similar areas of specialization into functional groups such as production, sales, and finance. Division of labor refers to the number of different job titles in the organization. In general, the greater the

number of departments within the organization and the more positions within each department, the higher the degree of specialization. A high degree of specialization creates a more complex organization with multiple types of expertise.

2.5. Individual Consequences of Specialization

Higher levels of specialization result in employees perceiving a greater level of autonomy in an organization. This autonomy reflects the increased power of possessing unique skills and knowledge. Performing work that is not duplicated by others in the organization also enhances individuals' control over their own work.

2.5.1. Organizational Consequences of Specialization

Greater specialization within an organization indicates more divergence among managerial perspectives and interests. This divergence can lead to greater innovation, flexibility, and adaptability if there is not too high a level of formalization and centralization. However, upper level managers will often attempt to enforce similar standards across specialized subunits. This generally results in an increase, rather than a decrease, in formalization.

3. MODERN APPROACH

Modern organizations are becoming more decentralized and specialized. There appears to have been a transition to what Moch called more pluralistic political systems rather than hierarchically coordinated social systems. Organizations have become more diversified and heterarchical. They are concerned with the process of organizing and directing personnel. This organizing approach is characterized by growth, flexibility, and adaptability. Organized power hierarchies have weakened, resulting in greater decentralization and increased specialization. There also has been a shift from control through formalization to greater self-management, with modern organizations using a combination of formalization and flexibility to obtain reliable results while enhancing opportunities for innovation. Organizational structures are still characterized by the traditional dimensions, but a shift toward organizing has resulted in the increasing significance of a variety of new structural components. This section discusses several structural dimensions that

have emerged with the modernization of organizations: work teams, matrix structure, organizational learning, globalization, and alternative employment relationships.

3.1. Work Teams

One of the major factors associated with organizations shifting from the traditional hierarchical organization to a more diversified heterarchical organizational structure is the increased use of work teams. The increasing complexity of the business environment makes the use of work teams increasingly appropriate where diverse skills can be applied to strategic decision making. The use of self-directed teams makes fewer hierarchical levels necessary.

3.1.1. Individual Consequences of Work Teams

In the traditional approach to organizations, larger organizations increase the likelihood that employees will feel less valued. Use of work teams can functionally reduce the sense of largeness by embedding individual employees within smaller organizational units or teams. It also is likely that individuals will have a greater sense of accomplishment in completion of these team tasks rather than the smaller tasks that individuals might have in a non-team environment. However, if a work team has more members than is necessary, members might reduce their individual efforts. If the team is understaffed, on the other hand, members might experience low group potency, reduced motivation, and greater job stress.

3.1.2. Organizational Consequences of Work Teams

Organizing based on a work team structure allows organizations to undertake more complex projects. However, it is more difficult for upper level management to monitor and control performance in a team-based structure. Therefore, a specialized manager for each team is more effective and economical than a hierarchy of executives. The use of work teams also requires an organizational culture that trusts teams to work toward organizational goals relatively independently. This suggests that implementation of a team-based structure requires investment in training and development of teams and individual team members.

3.2. Matrix Structure

A matrix structure is a complex organizational structure that is based on the use of project-driven teams,

generally requiring individuals with diverse functional expertise to be on the same teams. Project teams include multiple specialists, and each specialist may be part of multiple project teams. Members need to be highly skilled within their own discipline with strategic decision-making abilities and an ability to collaborate with others. Work teams, as described earlier, may work together indefinitely, but project teams in a matrix organization typically disband when the projects are completed. Matrix structures are intended to result in innovation, high task performance, and a collaborative shaping of organizational goals. Some automobile companies use a matrix structure during the development of new automobiles. Experts from a variety of functions, such as engineering, accounting, production, and marketing, all play a role in the success of new automobiles. Issues such as development, production, and sales are discussed, debated, and decided on by the team of experts, with each member bringing a unique and important perspective to the team.

3.2.1. Individual Consequences of Matrix Organization

The matrix organization involves considerable fluidity among organizational members, their assignments, and their social networks. Project team membership provides high levels of the core job characteristics. Thus, individuals would be expected to experience increased motivation and enhanced job performance. Furthermore, the social interaction among project team members has the potential to increase employees' social capital. However, working on multiple project teams with multiple managers can lead to role conflict and role ambiguity, both of which can result in job stress. Also, the relatively short duration of team membership and multiple team membership may reduce team members' identification with and commitment to each team.

3.2.2. Organizational Consequences of Matrix Organization

Project teams unite members with diverse skills and backgrounds that are expected to increase the quality of the projects and allow for innovative solutions if all members contribute. To some extent, they are the antithesis of stability in that they result in considerable movement within the organization by project team members. Matrix structures promote coordination across disciplines and functional areas within the organization, allowing a wide range of participation in

decision making and sharing of knowledge. However, communication across project teams is often not supported by the organization, and there may be power struggles among managers from different functional departments.

3.3. Organizational Learning

Adaptability requires learning, and as organizations are faced with competitive pressures, it is important that individual and organizational learning occur at a continual and rapid pace. Organizational learning is an active process in which knowledge is shared among organizational members, with information being shared across organizational subunits.

3.3.1. Individual Consequences of Organizational Learning

A structure that promotes individual learning promotes individual growth. If individuals are given opportunities to learn through training, they are likely to believe that the organization is supportive and committed to them as individuals and will reciprocate with increased organizational commitment and contextual performance. Also, when the organization provides an environment in which learning is valued and mistakes are tolerated, individuals will experience an increased sense of control over their work environment, thereby decreasing job stress and increasing well-being.

3.3.2. Organizational Consequences of Organizational Learning

The intended consequences of organizational learning are for the organization to be more innovative and adaptive to its environment. By acquiring and using new knowledge and skills, the organization is able to develop novel and more effective strategies for competing within the business environment. The effectiveness of organizational learning interventions varies across groups within an organization, depending on the interpersonal climate.

3.4. Globalization

Organizations have extended their domain from within a single country or region of the world to encompass multiple nations to reach a global market. There is no single standardized structure for multinational corporations. Their structures seem to reflect existing competitive environmental pressures and may vary across

locations. Strategic decision making may be tightly centralized around senior management in the home country; it may be decentralized to the national level, allowing for strategic planning to be tailored for each national market; or there may be more globally dispersed resources, although strategic decision making is still likely to be centralized with formal committees to facilitate communication and coordination among subunits. In 1989, Bartlett and Ghoshal categorized these different structures of multinational corporations as multinational, international, global, and transnational based on the degree of interdependence. The multinational model is decentralized and nationally self-sufficient, the international model has sources of core competencies centralized and all others decentralized, the global model is centralized and globally scaled, and the transnational model is dispersed, being the most interdependent and specialized model.

3.4.1. Individual Consequences of Globalization

As organizations become more global, individual employees are expected to travel more, including potential long-term assignments in countries other than their countries of origin. Adjustment to new cultures can be a powerful learning experience and a source of stress. This can affect individual employees as well as their families, and organizations frequently provide acculturation experiences for employees and their families before overseas assignments. It also has been shown that maintenance of social networks within organizations is important for expatriates' adjustment to the assignments and for the expatriates' successful return at the end of the assignments. Another aspect of globalization is communication across national boundaries on a regular basis. For example, coordination of telephone conferencing may involve individuals being available at hours outside of their regular working hours. This can create a sense of organizational injustice if it is not handled appropriately.

3.4.2. Organizational Consequences of Globalization

Multinational organizations vary in the degrees of complexity of their structures. The basis for interdependence in these organizations results from the flow of products, technologies, and people among subunits and between subunits and headquarters. The degree of interdependence can range from low in multinational models, to medium in international and global models, to high in

transnational models. Formalization may be able to handle the necessary coordination when there are relatively low levels of interdependence; however, as the level and complexity of interdependence increase, formalization generally is insufficient. There is a need for informal means of coordination and control.

3.5. Alternative Employment Relationships

Much of the literature on organizational behavior has focused on full-time employees. New employment relationships have emerged to include core part-time employees, peripheral part-time employees, independent contractors, guest workers, and temporary workers. These various work arrangements reflect alternative processes in organizing personnel.

3.5.1. Individual Consequences of Alternative Employment Relationships

The advantage of the increasing number of employment relationships is that they give individuals greater choice in the number of hours they work, in the length of commitments to particular employers, and in opportunities for developing skills across work environments. In general, these effects are considered to have a positive effect on individuals' well being. A caveat to this positive aspect must be mentioned. If individuals are not able to match their employment arrangements with their desired employment arrangements, they may experience underuse, underemployment, and other negative consequences to their well-being. The existence of multiple work arrangements within an organization also can lead to status differences among employees, even though employees are essentially doing the same work. This can lead to perceptions of unfairness and discrimination.

3.5.2. Organizational Consequences of Alternative Employment Relationships

Alternative employment relationships provide organizations with the flexibility of engaging the services of individuals as needed. Maintenance of core employees provides stability to organizations, whereas peripheral employees provide organizations with the ability to expand and contract the size of their labor forces based on production demands. Also, part-time, temporary, and short-term contracting allow organizations to expand

their labor pools to include individuals who might not be interested in full-time, long-term work arrangements. Thus, organizations can offer work arrangements that are consistent with their overall strategic decision making.

4. CONCLUSIONS

Organizational structures control social interactions within an organization. Centralization, formalization, and specialization have been shown to have effects on individuals' attitudes and behaviors as well as on organizations' stability, growth, and adaptability. Modern approaches to structure, such as the use of work teams, the adoption of a matrix structure, organizational learning, globalization, and the use of alternative employment relationships, reflect more of an organizing or process orientation to organizational structure, although they are not independent of centralization, formalization, and specialization. There are positive and negative aspects of all of these aspects of organizational structure, and context is important in understanding the choice of various aspects of organizational structure. It is recognized that structure should follow strategy so that the impact of the structure is consistent with the organization's strategy. However, as Burns and Wholey reported in 1993, adoption of a particular organizational structure may be explained somewhat by organizational characteristics, but it appears that what other organizations are doing in the local network influences the choice of a particular structure.

GLOSSARY

action research Collecting relevant information (data) about a given issue or problem (the research aspect) for the express purpose of providing ways to help resolve the issue or solve the problem (the action aspect).

appreciative inquiry Acts of exploration and discovery (asking many questions) for the purpose of recognizing the best in people (e.g., affirming strengths, potential, and successes).

cognitive map A thought process, mental exercise of establishing and tracing paths throughout an organization to help clarify and take corrective actions for organizational improvement and change.

development Growth, advancement, strengthen, and/or to bring an idea into action.

group unconscious A theory emanating from Freudian psychoanalysis that argues that a group of people has a collective unconscious analogous to an individual's unconscious.

information technology system The use of computers for transporting information throughout an organization; system, in this case, means that all organizational members are (or can be) connected electronically and therefore form a communicative whole.

interdependent multivariate systems Statistical term that is used to convey the notion that all organizational variables and components are interconnected and form a whole; the statistical method is a way of numerically demonstrating this idea.

intervention The act of intervening, coming between two or more parties in an organization—boss and subordinates, two or more departments, divisions, or business function/units, an individual and the larger group of which he or she is a part, or the organization and another organization (e.g., acquisition or merger)—for the purpose of initiating or furthering organizational change and development.

meta-analysis A statistical procedure for comparing the results of many studies of like content.

multirater feedback Based on specific behavioral ratings, a process of providing information about a person's leadership, management of others, or simply a range of individual behaviors, whereby a comparison is made of how one rates oneself with how others rate him or her on the same set of behaviors.

nonlinear complex systems theory Originating from chaos theory in the physical sciences; the proposition is that organizational behavior is affected by many variables that interact powerfully and interdependently but not in a single direction; cause and effect therefore is rarely as simple as it sounds (i.e., being a "one-way street").

norm A standard or rule of conduct to which people conform (e.g., a dress code).

open system framework A scheme or model usually in a two-dimensional arrangement that depicts an organization as having input (external environment), throughput (the operation of the organization), and output (performance) with a feedback loop connecting performance with the external environment; any organization is dependent on its external environment for survival, as in a living organism, yet through performance has an impact on and influences its external environment.

organization A sociotechnical system that has some purpose in society; sometimes it is only a social system such as a club.

refreezing Once organization change has occurred, a process of stabilizing and institutionalizing the new behavior that supports the change.

self-directed groups Organizational units that conduct their work without a leader or manager who has formal authority; group leadership occurs but usually in an informal and rotating fashion.

sensitivity training Based on interacting with and learning from others in a small group, a process of helping individuals to develop greater self-awareness and become more sensitive to how they affect and are affected by others.

sociotechnical system The principle that a work organization is both a technical system—the content or nature of the work itself—and a social system—the people involved and how they interact to get the work done; to overlook either system is to misunderstand the organization.

transactional That aspect of an organization involving daily operations, including transactions between organizational members and between them and those the organization serves.

transformational That aspect of an organization involving the larger system in the context of long time frames; its purpose, mission, strategy, culture, and senior leadership and how these organizational variables interact with the external environment and with one another.

unfreezing The act of changing (“melting away”) current employee and managerial behavior that no longer leads to optimum organizational efficiency and effectiveness, with the act being education and training, the introduction of new technology requiring different work habits, providing evidence from the external environment that a new strategy with different products and services is required to ensure long-term survival, or all of these.

Organization development (OD) is about changing an organization—an institution, a company, a government agency, a community service agency, a university, a school, or even a church, synagogue, or mosque. Organization therefore is broadly defined—that is, a sociotechnical system that has some purpose in society. Sometimes, however, it is only a social system

such as a club. The term development means growth, advancement, strengthen, or to bring an idea into action. By implication at least, development is about change. The change may be gradual or sudden but change nevertheless. Organization change can happen in a number of ways—by an election or appointment of a new leader; coercion via some civil disturbance; acquisition by a larger, more powerful organization; introduction of a new technology that immediately replaces the old; etc. For OD, organization change occurs by way of the application of behavioral science—that is, using knowledge from psychology, sociology, and cultural anthropology to develop and hence change the sociotechnical system.

1. AN ORGANIZATION DEVELOPMENT CASE

The organization development (OD) example described here began with the merger of two banks in a large metropolitan area of the United States. The two organizations were very similar with respect to number of employees, length of existence (both founded in the mid-19th century), and annual revenues, but they were highly dissimilar regarding their respective cultures. For example, one focused much more on cost-effectiveness as the way to a profitable bottom line, whereas the other emphasized revenue growth via developing new markets and services. The latter's motto seemed to be “you have to spend money to make money.” In other words, much work would be needed to successfully merge the two banks.

The CEO of the newly merged bank sought consultation—one for strategic planning and another for OD. The two consulting firms that were brought in worked in tandem but focused on different initiatives to facilitate the merger and to foster change. The OD firm's consultation began with three primary initiatives. The first initiative was to conduct interviews with the top 19 executives of the merged bank. These interviews consisted of broad, open-ended questions, such as “What is going well regarding the merger?” and “What is not?” The interviews served as a data-gathering source for the second initiative, which was an organizationwide survey. The survey was conducted 6 months into the merger to assess the general state of morale and, specifically, to determine the degree of understanding and opinions about the bank's strategy, its leadership, the newly merged culture,

organizational structure and systems, and the adequacy of management in general. The third initiative was to discard the two previous banks' mission statements and craft a new one for the merged bank. To accomplish this initiative, a task force of 16 employees was formed that represented a cross section of the bank. Working in pairs, the task force sought input from the various parts of the bank they represented, eventually involving several hundred employees. They used the input from the expanded group of employees to craft the initial draft of a company mission statement. After a number of revisions the task force presented its statement to senior management and later to the board of directors. A final version was unanimously agreed on by both senior management and the board. In fact, the task force received a standing ovation for their work from the board of directors.

Results from the organizationwide survey using a 5-point Likert scale showed that most employees were positive about the merger (example of survey question: "To what extent have mergers and acquisitions made the bank more efficient?") and their leadership, at least at the very top; clear about the new strategy (e.g., "To what extent are the bank's products and services competitive with the top tier of banks in our geographical region?"); and strongly supported the new mission statement (e.g., "To what extent does the bank's mission include valuing cultural differences?"). On the other hand, employees were somewhat confused about culture (e.g., "To what extent is it safe to say what you feel?") and structure, especially with respect to accountability; critical of the reward system, especially compensation and incentives (e.g., "To what extent does the bank have rewards and benefits necessary to attract and retain the very best people?"), information technology (e.g., "To what extent are the computer systems that you use advanced and efficient?"), and the budgeting process; and quite negative about leadership below the very top five or so executives and highly critical of management (e.g., "To what extent does your supervisor provide people with the information they need to do their jobs effectively?") overall.

The survey results led to further initiatives and interventions. The information technology system was strengthened, the reward system improved, and a major initiative was launched to address the deficiencies in leadership and management beginning with the top 125 executives and managers. These programs for leadership and management emphasized self-awareness for individual development via multirater

feedback, personality and leadership assessment, and coaching.

Approximately 1 year after the first organizational survey, a second survey was conducted. Responses to 125 questions resulted in two questionnaire items remaining the same as those from the first survey and all remaining items showed higher ratings. Although it cannot be scientifically proven that the desired changes for the bank did indeed occur, the bank's executives, managers, and employees believed that positive change had occurred. The results of the survey were interpreted within the framework of an overall organizational model of performance and change. The model included dimensions such as external environment, mission and strategy, culture, leadership, structure, systems, climate, motivation, and performance.

2. PRIMARY CHARACTERISTICS OF OD

The previous case helps to illustrate what constitutes an OD approach to organization change. The following characteristics, when applied to the case, help exemplify the essence of OD.

2.1. Relevance

OD must be relevant to the organization's purpose and to what its employees actually do every working day. In the bank case, the OD practitioner worked initially on the organization's mission and ensured that this work linked directly to the bank's business strategy.

2.2. Sequential

OD practice involves a sequence of activities. After entry and contracting (reaching an agreement about the consulting services to be provided and when), the OD practitioner then gathers data about the organization and its leadership/management, determines a diagnosis about what the data mean, provides feedback to the client organization, and facilitates collaboratively with the client several interventions (initiatives) that help to address issues and needs for change embedded in the data and the diagnosis. After the interventions are launched, the next step in the sequence is to gather data again in order to evaluate progress. In the case,

1. Contracting occurred with the CEO and his immediate direct-report executives.

2. Data gathering took the form of executive interviews, which in part set the agenda for further data gathering via the initial organizationwide survey.

3. Based on the initial interviews of the top 19 executives, feedback was provided to them that led to off-site meetings facilitated by the OD consultant to address issues highlighted from a summary of the 19 interviews. Further larger system feedback was later provided for all managers in the bank and subsequently to all employees from the organizationwide survey.

4. Interventions from the initial feedback consisted of top executive team building, changes in the information technology and reward systems, and the launching of leadership/management development workshops.

5. Further data gathering and evaluation of the change initiatives (interventions) up to that point were conducted using a second organizationwide survey.

2.3. Systemic

OD is a system approach to organization change. In the bank case, this was manifested in the construction and feedback of the data from the survey. The 125 items comprising the survey were arranged in 12 categories—that is, according to the 12 boxes in the Burke–Litwin causal model of organization performance and change. This model is an open-system framework (i.e., input-throughput-output with a feedback loop connecting output to input) and consists of the following categories: external environment, mission/strategy, leadership, culture, structure, management practices, systems, work-unit climate, job-person match, individual needs and values, motivation, and performance. The survey feedback in the bank case was in the form of these 12 categories with priorities for action steps according to the arrangement of the boxes in the model in Fig. 1.

2.4. Research Based

OD is steeped in the tradition of action research. This means that whatever action for change is taken, it is based on data, usually both qualitative and quantitative. OD interventions are “organic”—that is, based on what the data and the diagnosis reveal. Therefore, the action is based on the research (research loosely defined).

2.5. Humanistic

OD practice typically conforms to a set of values grounded in humanism and often takes the form of

- Involvement of organizational members in decisions that directly affect them
- Respect for differences among people
- Openness and honesty in communication
- A strong belief that the solution to organizational problems often lies within the knowledge and experience of people in the organization who have lived with the problem daily.

Usually this knowledge is either unspoken, perhaps due to an implicit norm not to disagree with the boss or with one another or the problem is a “sacred cow,” or the knowledge is tacit—that is, what may be known is not forbidden to discuss but, rather, is implicit and difficult to articulate. The OD practitioner’s role and function in these instances is to bring to the surface what organizational members are fearful of discussing or to help make explicit what is tacit, implicit. The previous four values are meant to be representative, not exhaustive.

3. ROOTS OF OD

Where did OD come from? Three primary streams of change methodologies and three institutions provide the basis for the emergence of OD.

3.1. Sensitivity Training

Evolving from the work of Kurt Lewin and colleagues during the 1940s, this form of training concerned the application of knowledge regarding group dynamics and interpersonal relations for individual learning. The learning occurred via feedback from others as to how one’s behavior affected these other group members. Learning also came from an analysis of interpersonal relations in small groups in which the primary source of information or data from which to learn was

the behavior and feelings of the group members. In the late 1950s and early 1960s, sensitivity training was employed in organizations to enhance interpersonal, managerial, and team effectiveness. These activities became the forerunner of what is a cornerstone of OD today—team building.

3.2. Sociotechnical Systems

Most any organization is at the same time a technical system and a social system, and to ignore either one during a change effort is to invite failure. Trist and Bamforth, both professional staff members of the Tavistock Institute, served as consultants to a coal mining company in the northern part of England. The company had made a technological change regarding the way coal was mined and instead of the change increasing productivity as management expected, morale of the workers plummeted and productivity declined. After studying the situation, Trist and Bamforth noted that the technological change had changed the social system. The miners could no longer work in small groups as before but were forced to work alone, resulting in a greater division of labor. The consultants explained to management what the real problem was and how to make another change that would not result in a return to the old method but modify the work process so that it would be more composite (i.e., less divided) and help to retain the social patterns that were so important to the miners. This way of thinking and changing organizations led to a number of interventions that are used by OD practitioners today, such as job redesign, self-directed work groups, and organizational redesign, especially in manufacturing companies.

3.3. Survey Feedback

Although not widespread, using a questionnaire to assess worker morale, attitudes, and perceptions in the 1950s was not new. What often occurred with the use of an organizational survey, however, was that management would retain the data and rarely report the results to those who responded to the questionnaire in the first place. Psychologists, particularly Rensis Likert and Floyd Mann at the University of Michigan’s Institute for Social Research, found that surveys did not work very well because of this lack of “reporting back.” Sometimes as a result of conducting a survey matters got worse. In other words, when asked to answer a questionnaire, employees thought that management

cared about what was on their minds. However, when nothing happened as a result of the survey, employees would become dissatisfied, even cynical, and productivity and morale would decline to levels lower than those before the survey was conducted. These Michigan psychologists believed that reporting the results to the people who answered the survey in the first place was a necessary step toward making the process a more positive experience. Necessary, they believed, but not sufficient for bringing about positive organization change. Mann, in particular, developed a way of stimulating action in an organization as a consequence of the survey. His procedure was to report the survey results to intact work and management teams—that is, to people who worked together. These work units would then analyze the results with respect to their own domain of work and responsibilities and then plan and subsequently take steps toward solving the problems identified in the survey. This procedure may not be groundbreaking today, but in the 1950s it was rare indeed. The procedure was called survey feedback simply because the results were “fed” back to managers, staff, and work units in a structured manner and the process set into motion action for resolving problems at the work unit level (i.e., where the knowledge resided about what to do). Survey feedback is common practice in OD today.

Although these three primary historical roots of OD differ, they all have in common the action research methodology and mode of thinking regarding organization change. It should also be recognized that theory, research, and methodology from industrial/organizational psychology have contributed significantly to the practice of OD.

4. RELATED THEORIES THAT UNDERLIE OD

There is no all-encompassing theory of OD. There are a number of “mini” theories that help to undergird the practice, however. The following sections provide a simple listing of these theories. They are grouped according to organizational level and emphasis of OD practice.

4.1. Individual Level

4.1.1. *Need Theory of Motivation*

Maslow’s theory concerns a hierarchy of human needs that begin with physiological or creature comfort

needs (air, water, safety, etc.), include security, belongingness, and ego status, and conclude at the top of the hierarchy with self-actualization. Herzberg’s theory is more about job satisfaction and dissatisfaction than about needs per se. Factors that reduce dissatisfaction he called “hygiene” or preventive, such as fringe benefits, good working conditions, and salary. Factors enhancing job satisfaction he called motivators and include recognition, challenging work, and autonomy. OD practice that relies on these theories includes job enrichment, quality-of-work-life projects, empowerment interventions, and career development.

4.1.2. *Expectancy Theory of Motivation*

This theory is cognitive in nature and consists of individuals’ expectations that (i) their efforts will lead to results, (ii) if enhanced these efforts will lead to rewards, and (iii) these rewards will be worth it to them. OD practice associated with this theory includes work redesign and modifying performance appraisal and/or systems.

4.1.3. *Job Satisfaction*

Related to Herzberg’s theory, this theory posits that there are three primary psychological states that affect job satisfaction: experienced meaningfulness of the work, experienced responsibility for the work and its outcomes, and knowledge of results (i.e., performance feedback). OD practice that relies on this theory includes primarily job redesign, job enrichment, and performance feedback procedures.

4.1.4. *Positive Reinforcement*

Although Skinner’s research and theory were more about individual animal and human behavior in the broad context of learning and change and not about organizational behavior per se, his principles can be applied to organizational reward systems. The primary emphasis is therefore on incentives and the belief that partial and variable reinforcement of behavior is more lasting and effective than continuous reinforcement. OD practice that relies on this theory includes modifying a reward system in general and putting into place some form of an incentive system.

4.2. Group Level

4.2.1. *The Group as the Focus of Change*

Applying concepts from the science of physics, Lewin analyzed human behavior in terms of “forces” impinging on an individual. These forces might be group norms to which the individual is expected to conform, supervisory pressure to exert more effort on the job, or deeply held beliefs and values emanating from the larger culture about what is the right thing to do. Changing norms and values is therefore tantamount to changing an organization’s culture. OD practice that relies on this theory includes team building, force field analysis, decision-making processes, and ultimately culture change (i.e., changing conformity patterns).

4.2.2. *Changing Values through the Group*

The work of Argyris is broad and thus difficult to reduce to one theory. Appropriate for OD are primarily ideas about change, particularly the motivation to change. The premise is that when individuals (think managers) are confronted with differences between what they espouse and what they actually do, they will be motivated to reduce the gap and as a result change their behavior. OD practice that relies on this theory includes “gap analysis”—that is, surfacing the incongruence between what managers say, the words they use (Argyris calls it espoused theory), and what their actions actually become (theory in action), especially decision making—and team building. Also, in collaboration with Schön, Argyris helped spawn another OD activity that is more at the larger system level—organizational learning.

4.2.3. *The Group Unconscious*

Steeped in psychoanalytic theory, Bion took Freud’s thinking one step further and argued that a group has a collective unconscious much like an individual’s. This collective unconscious revolves around the group leader, whether formal or informal, and the group’s motivation, albeit below conscious awareness, is to replace the leader irrespective of his or her performance. OD practice that relies on this theory includes group behavior diagnosis and team building, self-directed work groups, and sociotechnical systems interventions.

4.3. Larger System Level

4.3.1. *Participative Management—One Best Way*

A normative theory, Likert’s position was that any large organization could be considered as one of four possible systems. System 1 was authority centered, top-down, and unilateral; system 2 was a benevolent autocracy; system 3 was consultative (i.e., ask subordinates for their ideas and opinions but with the manager reserving the right to make the final decision); and system 4 was participative management with an emphasis on consensual decision making. Likert’s argument was that system 4 was the best way to manage an organization. OD practice that relies on this theory includes survey feedback and team consensus decision making (i.e., change to a participative form of management).

4.3.2. *It all Depends*

Opposite to a normative way of thinking, Lawrence and Lorsch stated that how an organization should be managed and designed depends on its relationship to its external environment (i.e., the organization should be as responsive as possible to external forces). Their key concept was interface—three of primary importance: the organization–external environment interface, intergroup interfaces within the organization, and the implicit relationship between the organization and the employee (the psychological contract). OD practice that relies on this theory includes organizational structure redesign, intergroup conflict resolution, and cross-functional groups for purposes of integration.

4.3.3. *The Organization as a Family*

Levinson considered top management as replicating the nuclear family, with the CEO being the father and the remaining executives acting as siblings, with rivalry among them being the dominant theme. Not surprisingly, Levinson’s work has been most applicable to family-owned businesses. OD practice that relies on this theory includes succession planning in a family-owned business, coaching the CEO, and team building for the top executive group.

Table I summarizes the minitheories discussed in the previous sections.

TABLE I
Summary of Primary OD Theorists According to Their Perspectives, Emphases, and Applications^a

<i>Perspective</i>	<i>Theorist</i>	<i>Emphasis</i>	<i>Application</i>
Individual	Maslow and Herzberg	Individual needs	Career development, job enrichment
	Vroom and Lawler	Individual expectancies and values	Reward system design, performance appraisal
	Hackman and Oldham	Job satisfaction	Job and work design, job enrichment
Group	Skinner	Individual performance	Incentive systems, reward system design
	Lewin	Norms and values	Changing conformity patterns
	Argyris	Interpersonal competence and values	Training and education
	Bion	Group unconscious, psychoanalytic basis	Group behavior diagnosis
System	Likert	Management style and approach	Change to participative management
	Lawrence and Lorsch	Organizational structure	Change contingent on organizational environment
	Levinson	Organization as a family, psychoanalytic basis	Diagnosis of organization according to familial patterns

5. OD AS A PROCESS OF CHANGE

As stated earlier, OD is based on action research as an approach (Fig. 2) and immersed in the Lewinian tradition exemplified by the following phrase: No action without research and no research without action.

5.1. Levin's Three-Step Change Procedure

Lewin provided a simple (although not easy to execute) three-step procedure for bringing about change. The following are the three steps:

1. Unfreeze the current level of behavior
2. Action that changes the system from its original state to a new level of behavior
3. Refreeze, meaning to secure the new behavior against further change or "slippage"

5.2. Schein's Elaboration on Levin's Three-Step Procedure

In 1987, Schein developed a useful elaboration of the three steps. He refers to them as stages rather than steps to emphasize the point that they overlap (i.e.,

they are not discrete). Schein's expansion of the three stages is presented in the following sections.

5.2.1. Stage 1: Unfreezing

Schein defined this stage as creating motivation and readiness to change. The following are his three ways of unfreezing:

1. Disconfirmation of the way things are, which leads to dissatisfaction and a need for change (e.g., costs are too high, morale is too low, and productivity is declining).
2. Induction of guilt or anxiety by establishing a gap between the current state and what would be much better. In the face of this kind of gap, most people become motivated to reduce it.
3. Creation of psychological safety to help deal with disconfirmation, guilt, and anxiety so that people can take the required action. The action needs to be associated with feelings of accomplishment and worthiness instead of humiliation or a loss of self-esteem.

5.2.2. Stage 2: Changing

Changing is the movement toward a new state that Schein believes can be accomplished via two processes. One process is the identification of organizational

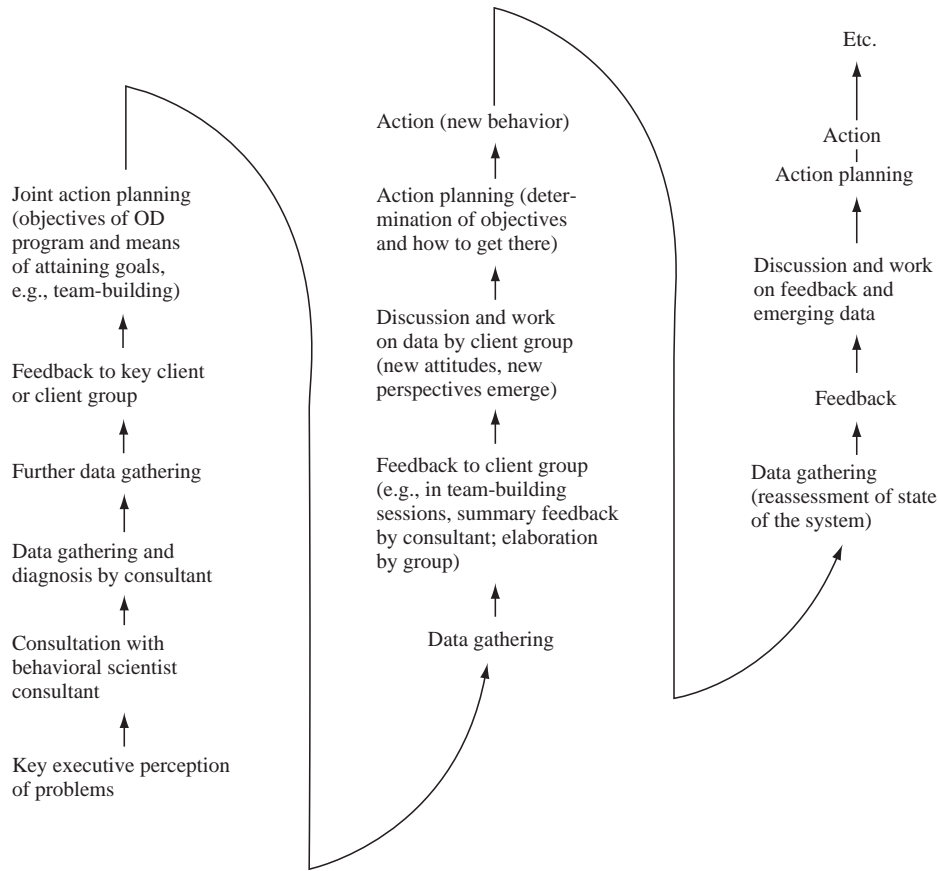

FIGURE 2 Action research model for organization development. From W. L. French, *Organization development: Objectives, assumptions, and strategies*, © 1969 by the Regents of the University of California. Reprinted from the *California Management Review*, 12(2), 26, by permission of the Regents.

members with a new role model, new leader, or perhaps the OD consultant to obtain a more attractive point of view and perspective. The second process is to scan the environment for new but relevant information that can facilitate the acquiring of a different perspective and point of view. This new information can come from a research project, outside expertise, or people in another organization who have gone through a similar organization change.

5.2.3. Stage 3: Refreezing

Schein conceptualizes this stage in two ways: the individual and relations with others. Refreezing with respect to the individual organizational member is a matter of feeling comfortable with the change—that it fits well with one’s self-concept, values, and new modes of behavior. Relations with others concerns also achieving a level of comfort. As one’s behavior

changes, the new behavior affects others differently than in the past. Will this be okay? Will others also change and work toward congruence of these new behaviors with one another? Reaching and maintaining these new levels is what Schein (and Lewin) means by refreezing.

5.3. Lippitt *et al.*’s Five-Step Elaboration

Another elaboration of Lewin’s three steps was developed in 1958 by Lippitt *et al.*, who expanded the three steps into five phases:

1. Development of a need for change (Lewin’s unfreezing)
2. Establishment of a change relationship between the client and the consultant(s)

3. Working toward change (Lewin's action movement step)
4. Generalization and stabilization of change (refreezing)
5. Achieving a terminal relationship between the client and consultant(s)

Lippitt and colleagues viewed an organizational change effort from the perspective of the consultant, which they referred to as the "change agent." To summarize, four models or approaches to organization development have been briefly described: action research, Lewin's three steps, Schein's elaboration of Lewin's steps, and Lippitt

et al.'s expansion. Figure 3 provides an overall summary and integration of these approaches.

Since these approaches overlap, they can be considered together in the form of an overall approach for OD that consists of the following elements:

- An outside consultant or change agent (the consultant may be an employee of the organization but would still be an "outsider" to the group in the organization being served)
- Data gathering from the client system (either the total system or some part that is relatively distinct—a

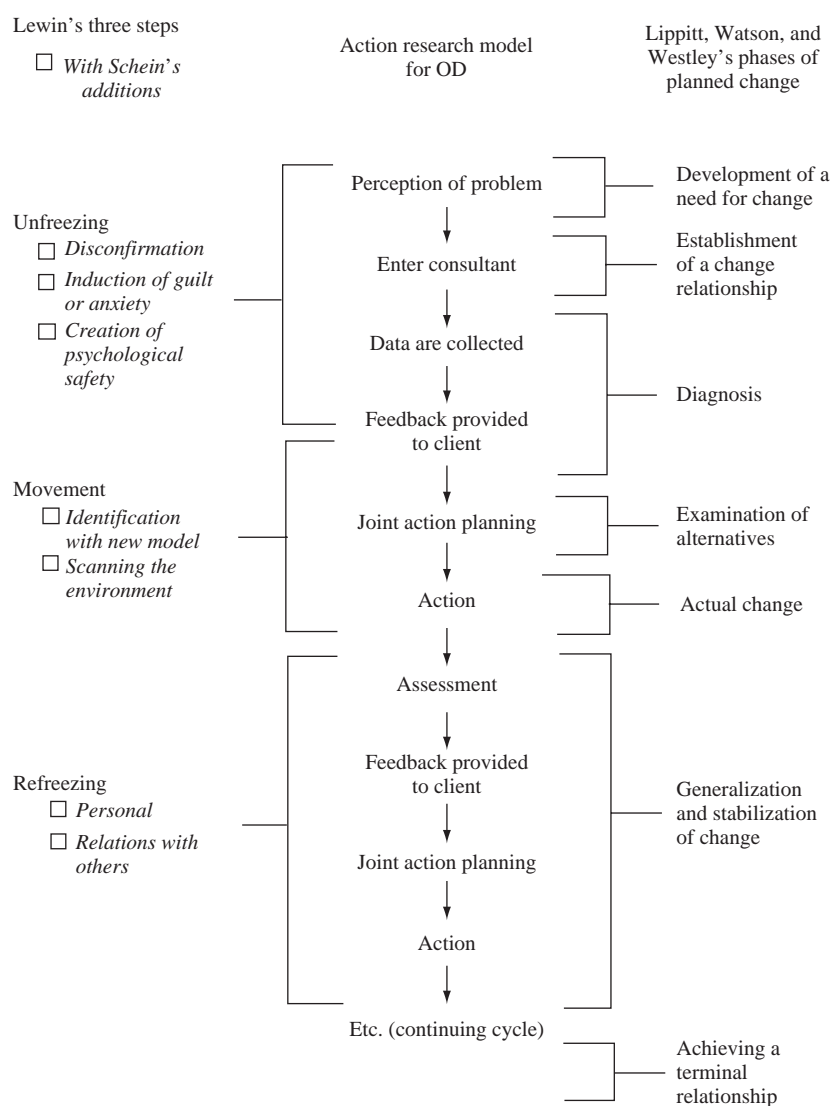

FIGURE 3 Comparison of the four models of change. From W. W. Burke, *Organization development: A process of learning and changing* (2nd ed.). © 1994 Addison-Wesley Publishing Co. Reprinted from p. 64 by permission.

division, a business unit, etc.) for the purpose of diagnosis (i.e., to understand in as much depth as possible the inherent nature of the system and its culture)

- Determine the major domains that need to be changed and problems to be solved
- Report this diagnosis to the client system so that appropriate action can be planned in a collaborative manner between the consultant (OD practitioner) and the client system
- Implementation of the planned change that is based on valid information in the form of interventions into the system that is usually conducted by the clients but with the continuing help of the consultant
- Institutionalization of the change

In short, the seven phases and processes of OD practice are as follows:

1. Entry: Establishing initial contact and a relationship with the client
2. Contracting: Agreement about the work to be done together (consultant and client); for example, who will do what and when
3. Diagnosis: Consists of data gathering and making sense of the information that has been collected (an organizational model helps with the latter process)
4. Feedback: Reporting to the client the summarized data and what the data mean
5. Planning change: Establishing action steps to accomplish the change
6. Intervention: Initiatives and actions that lead to change
7. Evaluation: Measures that help to determine if the change is taking effect

6. UNDERSTANDING ORGANIZATIONS: THE DIAGNOSTIC PROCESS

Methods for data gathering in the OD process consist of (i) structured interviews, (ii) questionnaires either to embellish interviews (or vice versa) or to collect data in the form of an organizationwide survey, (iii) archival information (e.g., statements of mission and strategy, annual reports, and planning documents), and (iv) observations by the OD practitioner (e.g., paying attention to artifacts in the organization, sitting in on key management meetings, and listening carefully to the language of organizational members).

Often, these forms of data gathering produce more information than either the consultant or the client can deal with. Moreover, these data in their “raw form” are not obvious with respect to meaning. After all, the data are more about symptoms than causes of problems and issues. Thus, a framework or organizational model for summarizing and understanding a large amount of data can be useful. To be useful, the data need to be treated in organizational terms. OD represents a systems approach to change and a model can help to translate raw data into systems language. Thus, a model needs to be an effective representation of an organization.

An early organizational model was developed by Harold Leavitt in 1965. His diamond-shaped framework consisted of the following four concepts positioned at the corners of the diamond with interconnecting lines: structure, technology, people, and task. His model helped to set the stage for thinking about organizations as interdependent multivariate systems. In fact, the popular McKinsey 7-S model was derived from Leavitt’s work.

As stated previously, an organizational model can be useful in a number of ways:

- It can help to categorize and summarize.
- It can help to enhance understanding. For example, finding that problems exist in four categories but not in six others helps to establish priorities for action.
- It can help to interpret data about the organization. In other words, how categories in the model are arranged vis-à-vis one another can aid in determining what action to take regarding change. For example, in Weisbord’s six-box model, the leadership box (category) is central, with the remaining five boxes surrounding leadership. For Weisbord, leadership serves as the coordinating mechanism for the other five categories, attempting to keep them in balance. In Weisbord’s thinking, for any action to be taken toward change, leadership will inevitably play a key role.
- It can help to provide a common, shorthand language. Simply using the category culture, for example, covers a lot of ground.
- It can help to guide action for change. In other words, it can serve as a “cognitive map.” If some of the categories are more important than others with regard to change, how the categories are situated in the model vis-à-vis one another can provide direction for change that is likely to be clearer than otherwise might be the case.

As previously mentioned, an organizational model can indeed be useful, but there are at least two important caveats:

Content is critical: A model is only as good as the components selected and the arrangement of these components—that is, how each part relates to the others. Organizations consist of many components. The myriad parts need to be categorized into a workable number and it must be determined which components are the most important.

Metaphors are paradoxical: In 1997, Gareth Morgan stated this caveat eloquently: “Metaphor [a model is a metaphor after all] is inherently paradoxical. It can create powerful insights that also become distortions as the way of seeing created through a metaphor becomes a way of not seeing” (p. 5).

7. FOUR MODELS COMMONLY USED BY OD PRACTITIONERS

7.1. Weisbord’s Six-Box Model

The six boxes are leadership (which is central) surrounded by purposes, structure, rewards, helpful mechanisms, and relationships. The six are arranged in a circle surrounded by environment as a seventh variable. The primary diagnostic question that Weisbord asks for each box helps to define that particular category. The questions are as follows:

- Leadership: Does someone keep the boxes in balance?
- Purposes: What business are we in?
- Structure: How do we divide the work?
- Rewards: Do all needed tasks have incentives?
- Helpful mechanisms: Do we have adequate coordinating technologies?
- Relationships: How do we manage conflict among people? With technologies?

Weisbord’s model is useful when time is limited (i.e., when a simple framework is needed for quick service) and/or when the client is not particularly sophisticated regarding systems thinking.

7.2. Nadler–Tushman Congruence Model

This is a more sophisticated model but it is based on the assumption that Weisbord *et al.* posit that an

organization is an open system influenced by its external environment. The primary inputs from the environment are environmental forces, such as competition, resources (e.g., raw materials and/or capital), and history (the organization’s past). Strategy then connects the inputs to the four throughputs: informal organization (e.g., culture), formal organizational arrangements (structure and accountability systems), individual (the people), and task (nature of the work). These throughputs lead to outputs, which amount to performance at three levels: organizational, group, and individual. The primary premise of the model is the importance of congruence, the concept of fit. Therefore, this model goes beyond mere description and takes the position that an organization’s effectiveness is a function of how well the components of the model fit together. For example, is strategy congruent (i.e., responding well) to forces in the external environment? Do employees’ skills and abilities match well with the tasks of the organization? In summary, the components of the Nadler–Tushman model are fairly comprehensive and have good face validity.

7.3. Tichy’s TPC Framework

This model is much more explicit about organization change and states that the nine components of the model are “change levers”: (i) external interface, or the organization’s external environment; (ii) mission; (iii) strategy; (iv) managing organizational mission/strategy processes (i.e., realistically engaging the relevant interest groups); (v) task—change often requires new tasks; (vi) prescribed networks—more or less, the formal organizational structure; (vii) organizational processes—communicating, problem solving, and decision making; (viii) people; and (ix) emergent networks—more or less, the informal organization.

TPC stands for technical, political, and cultural. These three “systems” overlay or cut across the nine levers, forming a matrix consisting of subcategories of, for example, the technical system with mission and strategy or the political system with people, etc. The technical system represents rationality and is strongly associated with empiricism and the scientific method. With the political system, Tichy argues that organizations have dominant groups with bargaining being the primary mode of change. The cultural system is the organization’s norms and values as well as shared symbols. Although Tichy also believes that congruence among all these elements is important, he prefers the term alignment. Data are collected and then

categorized within the matrix of the three systems with the nine levers.

7.4. Porras's Stream Analysis

Porras developed a framework rooted in open system theory, as are the previously discussed models. His input, of course, is the external environment and the output is defined as both organizational performance and individual development, a unique aspect not included in other models. The throughput consists of two broad categories: organizational members' behavior (individual cognitions and on-the-job behavior) and work setting or context. The work setting is composed of four components that Porras labels as streams: (i) organizing arrangements (goals, strategies, structure, and systems), (ii) social factors (culture, networks, and individual attributes), (iii) technology (equipment, machinery, job design, etc.), and (iv) physical settings (space, interior design, ambiance, etc.). In a sense, Porras's model also concerns congruence. His diagnostic process emphasizes a pictorial chart of how the four main streams flow vis-à-vis one another. His stream diagrams remind one of flowcharts designed by an engineer.

7.5. Burke-Litwin Causal Model of Organization Performance and Change

This model is also about theory. Litwin and Burke make the argument that certain organizational variables have more "weight" than others and therefore tend to have effects on less powerful organizational variables. However, the arrows in the model go in both directions and therefore causes and effects are bilateral. Nevertheless, some variables are more powerful than others in causing change. The model is intentionally arranged in a hierarchical manner, with the top boxes referred to as transformational factors (Fig. 4). When practitioners are working to change these categories—mission/strategy, leadership, and culture—the organizational effect is more revolutionary than evolutionary, more discontinuous and episodic than continuous. On the other hand, when practitioners are working to change the categories in the lower remaining part of the model, referred to as the transactional factors, the organizational effect is more continuous than episodic, etc. (Fig. 5).

FIGURE 4 The transformational factors. From the Burke-Litwin model of organizational performance and change. © 1987, 1992 by W. Warner Burke, Associates, Inc.

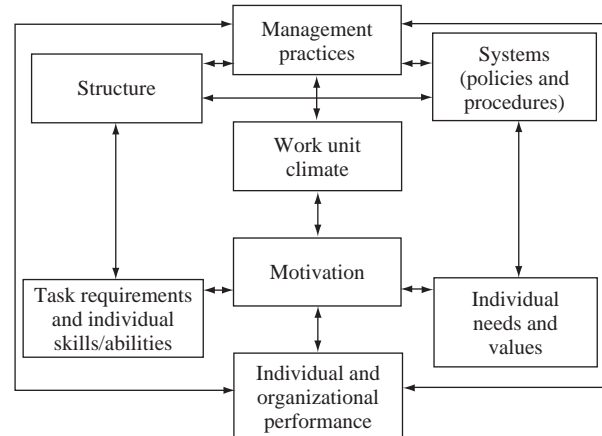

FIGURE 5 The transactional factors. From the Burke-Litwin model of organizational performance and change. © 1987, 1992 by W. Warner Burke, Associates, Inc.

When compared with the transformational categories, the transactional factors represent activities and organizational dimensions that are concerned more with daily operations, are more incremental with respect to change, and are more related to foreground (e.g., work unit climate) than to background (e.g., culture).

In summary, the five models discussed in the previous sections are the most prominent ones in the OD literature, but they may not be the ones used most. Many OD practitioners construct and develop their own models. Regardless of which model is used, more experienced OD practitioners rely on one that is grounded in open system theory and deployed in a manner consistent with action research.

8. PLANNING AND MANAGING THE CONSEQUENCES OF CHANGE

It is appropriate to plan change in terms of phases and steps, and it is appropriate to use models that help to frame data and to plan further. However, the actual process of organization change does not occur in the orderly way suggested in this article. This section addresses the realities of organization change.

The paradox of planned organization change is that the change is planned in a linear fashion—that is, phase 1 followed by phase 2, stage 1, 2, 3, etc., or steps 1–7; however, when the change is actually implemented, the process becomes nonlinear. As stated previously, the carrying out of change in an organization is messy: Things do not proceed exactly as planned; people do things their own way, not always according to the plan; some people resist or even sabotage the process; and some people who would be predicted to support or resist the plan actually behave in the opposite way. In short, unanticipated consequences occur. Leaders of change often say something like, “For every step forward we take, we seem to fall back two steps; something always needs fixing to get us back on track.”

Provided the change goals are clear and change leaders are willing to stay the course, over time the process may become somewhat linear, or at least a pattern may emerge. However, linearity is not what anyone experiences during the implementation process, which may seem chaotic, with people in the organization constantly asking “Who’s in charge here?”

With respect to managing the process, change leaders may be operating according to plan, especially with the change goal(s) clearly in mind, but the bulk of their time and energy is spent on dealing with issues and problems that were not planned for, were not anticipated, and must now be addressed and resolved. Otherwise, the change effort will become stymied, people will become frustrated if not disillusioned and eventually cynical, and ultimately true organization change will have failed. If planned and managed well, OD efforts can succeed.

9. DOES OD WORK?

This is the basic question that most managers in organizations ask when considering a proposal for getting involved in an OD effort. The answer to the question is “yes,” provided the principles and practices summarized in this article are applied.

With respect to research, some representative and key studies may be considered. In their study of 11 different types of OD initiatives employing a meta-analysis (a statistical procedure for comparing results of a number of studies that investigate related content) of 98 studies, Guzzo *et al.* concluded that “psychologically based organizational interventions,” as they called them, increased worker productivity. Some of the initiatives or interventions studied were job redesign, participative management, team building, and socio-technical systems methods. These interventions are common in OD practice. Also common in evaluating whether OD works are such measures of performance, broadly defined, as worker productivity, employee attitudes, job satisfaction, financial results (e.g., profits and/or cost reduction), customer satisfaction, turnover and absenteeism, quality of output, and degree of innovation.

In another study using a meta-analysis approach of 126 studies, Neuman *et al.* found that OD interventions had a significantly positive effect on worker attitudes and job satisfaction. In addition, their study showed that multiple OD interventions (e.g., intervening simultaneously with team building, leadership development, and an organizational redesign) had greater effect for positive change than relying solely on one OD intervention. In a less rigorous study of seven successful OD efforts, Burke found that the common denominator across all seven was the fact that multiple interventions were used in each case.

9.1. Evidence

There is evidence that OD works. However, there are problems concerning this body of work when matters of definition, purpose, and methodology are considered.

When discussing OD, what exactly are we talking about? An intervention or two or a total system change? Different OD interventions may result in different outcomes. With respect to purpose, is the study for knowledge generation or to evaluate the effectiveness of OD?

9.2. Methodology

It is not easy to conduct OD research using “normal” or traditional scientific methods. There are important considerations to be made when, for example, there is no control group and when it is not clear which variables of study are independent and which are dependent. Also, many studies have shown that the

researcher and methods used can have powerful consequences (biases) on outcomes.

Although there are complex issues to deal with regarding the determination of the effectiveness of OD, there seems to be cumulative evidence that, on the whole, OD works. Who makes it work? It is, of course, the managers and work unit members in the organization. The OD consultant plays a critical role as well.

9.3. The OD Consultant

Often, the term OD practitioner is used instead of OD consultant; in either case, the OD practitioner functions as a consultant. The OD consultant may be either internal (a full-time or part-time employee) or external (a member of a consulting firm, self-employed, or an academic who consults part-time). Although there are differences (e.g., it is difficult for an internal OD person to be a consultant to the CEO of his or her organization and to be as objective about issues in the organization as may be desirable, and the external consultant will never fully understand the culture of the client organization without living in it), the two still operate very similarly regarding the phases of OD practice (entry, contracting, diagnosis, etc.). Ideally, the internal consultant works in tandem with an external OD consultant.

With respect to the role of an OD consultant, Schein's distinctions are clarifying. He described three models or approaches: the purchase model, the doctor-patient model, and the OD model. The purchase model consists of expert services and information that a client organization may buy. For example, a client organization may want a market research study to be conducted and will purchase the services of a firm specializing in this form of expertise. The doctor-patient model means that the client organization calls in the consultant and describes a problem that needs attention, such as a recent loss of market share, an outdated information technology system, or the loss of too many talented people. The client then expects the consultant to provide a remedy. The OD consultant is more facilitative (i.e., helps the client organization to solve its own problems). Schein (1987) describes the process clearly:

It is a key assumption of change that the client must share in the process of diagnosing what may be wrong (or learn to see the problem for himself), and must be actively involved in the process of generating a remedy because only the client ultimately knows what is possible and what will work in his culture and situation. (p. 30)

The primary but not exclusive function of the OD consultant is therefore to help clients learn how to help themselves more effectively. The OD consultant may provide expertise, and even prescribe a remedy, but the role is most often one of being a facilitator (e.g., helping an individual manager to gain more self-insight about his or her impact on others, helping a work unit to operate more as a team, or helping the entire organization to understand the results of a systemwide survey).

9.4. Expert Facilitation

Expert facilitation requires certain individual skills and abilities. At least 10 are key:

1. Tolerance of ambiguity: Organizations are not neat and orderly and neither are the data that the OD consultant collects and has to analyze and report to the client.
2. Influence skills: The OD consultant's authority comes from knowledge, of course, but equally as important is the ability to impart that knowledge in a way that makes a difference but is not perceived as arbitrary.
3. Confronting difficult issues: Much of OD practice is bringing to the surface matters that clients are not eager to face.
4. Ability to support and nurture others: This skill is especially critical during times of conflict and stress.
5. Listening well and with empathy: This is particularly important for interviewing and when the client is under stress.
6. Being able to recognize one's feelings and intuitions quickly: This is especially important to discern between one's own perceptions and feelings and those of the client.
7. Conceptualization: This involves being able to express in clear language possible linkages in the organization, such as cause-effect and if-then combinations, and within a systems context.
8. Ability to discover and mobilize human energy: This includes within oneself and the client organization. One should remember that there is energy in resistance; channeling that energy is key.
9. Being a teacher: There are occasions when the OD consultant needs to give a "5-minute lecture" about knowledge that relates directly to the problem at hand.
10. Maintaining a sense of humor: The consultant and/or the client taking themselves too seriously deflects thoughts and energy that could otherwise be

applied more usefully. Also, humor can help to reduce tension when timed well.

This list is a compilation of highly important abilities and skills for the OD consultant. Other abilities could be itemized; this list is a starting point.

9.5. Becoming an OD Consultant

Becoming an OD consultant can be considered as a process of following three paths—apprentice, academic education, and professional development. First, there is no substitute for experience. Being an apprentice to someone with considerable OD experience is perhaps the most useful way to learn OD. After all, OD consultants are also known as practitioners, and the more practice the better. Practice alone is not enough, however. Thus, serving as an apprentice is valuable since one can receive feedback on his or her practice from a more experienced practitioner in the field.

Second, regarding academic education, many universities provide a curriculum in OD, some with master's or even doctoral degree programs in OD or in related fields. The following subjects are suggested as a guide for courses to take that would be the most useful:

- A basic, survey course in organizational psychology or organizational behavior
 - Group dynamics
 - Research methods that include both quantitative and qualitative skills—understanding and analyzing data are critical to effective OD practice
 - Adult learning, especially how to learn from experience
 - Career development
 - Counseling and coaching, including interviewing skills
 - Organization development and change—an overview course of the field
 - Training and development—designing programs and other learning activities
 - Action research
 - Human resource management—often the OD function in an organization is a part of the larger human resource or personnel function
 - Consulting skills with emphasis on process consultation
 - Organizational dynamics and theory—how organizations work (and do not work) and a comparison of different types of organizations
 - Functions of organization—learning the “business” of organizations (i.e., marketing, accounting

and finance, strategy, operations, information, technology, budgeting, etc.)

Third, regarding nonacademic training or professional development, the following are suggestions:

- Attend a laboratory, experiential training program to gain greater self-awareness.
- Attend workshops on how to consult; often these are activities that precede large conferences.
- Attend conferences that focus on OD or related practices (e.g., participating in the OD network's annual meeting and regional events).
- Attend specific professional development programs, such as the Principles and Practices of OD and the Advanced Program in OD and Human Resource Management sponsored by Teachers College, Columbia University, or the organization and systems development programs offered by the Gestalt Institute of Cleveland.

Finally, as noted previously, being an OD consultant means being a practitioner. Combining content learning from academic and professional development activities with practice and practice coupled with feedback on this practice are the necessary ingredients for learning and becoming an OD consultant.

10. OD VALUES AND CONSIDERATIONS FOR THE FUTURE OF THE FIELD

10.1. OD Values

Organization development emerged from beliefs that people in organizations had much of the knowledge required to make the system more effective. It was a matter of eliciting and applying this knowledge. This way of believing and acting was steeped in, if not dependent on, antecedent beliefs in and respect for human dignity, diversity, openness in communication, and the importance of empowering organizational members to take initiative and embrace change. Thus, OD grew from humanistic beliefs. However, there have always been the needs and demands of the organization. Thus, organizational requirements, particularly meeting budget demands and “bottom-line” pressures, are often seen as conflicting with humanistic values. Often, OD consultants spend more time and effort on the “D” and less on the “O,” but both are equally important. Weisbond (1977) addressed this potential conflict when he stated

OD's right goal—its central purpose—grows from its proper setting. If the proper setting is organizations, then there is only one right goal for OD: to confront an issue which most certainly predates the industrial revolution. That is the tension between freedom and constraint. OD's right purpose is to redress the balance between freedom and constraint. (p. 4)

There is always tension between the autonomy of the organizational member and the organization's requirements. The primary mission of the OD consultant, therefore, is to redress the balance whenever either one is out of kilter.

10.2. Considerations for the Future of OD

The field of organizational development originated during the late 1950s and early 1960s. OD today is well established. It now seems, however, that OD has reached a rather stagnant state. It is as if all that could be gleaned from the behavioral sciences to apply to organization change and development has been. Undoubtedly this is not true, but in any case, much of the creativity happened in the 1960s and early 1970s, with little innovation since then. Exceptions to this statement include the emergence of appreciative inquiry, self-directed groups, and large group interventions; otherwise, OD appears to be resting on precedence. New ways of thinking about organizations and changing them are needed. Within the field of OD, deeper understandings of the impact of the external environment on organizations and the difficulty of changing organizational culture, executive leadership, and organizational structure are needed. Perhaps of more importance is to infuse new ideas and theory from outside OD that are applicable and relevant nevertheless. An example is theory from the life sciences. The growing knowledge from chaos theory and non-linear complex systems theory may be nascent at present but brimming with ideas for how to think differently about organizational behavior and change. Finally, even from the more popular literature, a book such as that by Gladwell, titled *The Tipping Point*, is loaded with ideas directly applicable to OD.

For OD to survive and thrive in the future, an infusion of new and different thinking is required. The value of continuous or lifelong learning is absolutely necessary, and much of this learning needs to be done outside the behavioral sciences.

GLOSSARY

adaptability The capacity and motivation to adapt or change in response to changing task or environmental circumstances.

boundaryless career A career not bounded, not tied to a single organization, not represented by an orderly sequence, and marked by less vertical coordination and stability than an organizational career.

career In both the popular and behavioral science literature, there are four distinct meanings of the term career: career as advancement, career as profession, career as a lifelong sequence of jobs, and career as a lifelong sequence of role-related experiences. Based on all these different interpretations, career can be defined as the individually perceived sequence of attitudes and behaviors associated with work-related experiences and activities over the span of a person's life.

identity The person's awareness of his or her values, interests, abilities, and plans; the degree of integration between past, present, and future concepts of self; and the extent to which the person feels integrated over time.

organizational career A career conceived to unfold in a single employment setting.

protean career A career based on self-direction in the pursuit of psychological success in one's work.

psychological success The feeling of pride and personal accomplishment that comes from knowing that one has done one's "personal best."

This article discusses the general developmental stages that people pass through during the course of their working lives in organizations. The ways in which careers have changed since the mid-1970s are also discussed, with a focus on the changing career contract and the protean, or self-directed, career. It also examines what happens after a career choice has been made, particularly how the effectiveness of a career can be predicted. Performance, career attitudes, adaptability, and identity are discussed as the main dimensions of career effectiveness.

1. ORGANIZATIONAL CAREERS

1.1. Career and Life Stages

People go through a regular series of life experiences and tasks that constitute general phases of human development. Although in an era of rapid change and complexity the concept of regular and predictable stages or phases has diminished in significance, we have not lost completely the experience of regular, predictable changes in our roles, expectations, concerns, and self-images that are packaged as life and career stages. There are several life and career models that explain these regular stages or phases.

In Erik Erikson's 1963 theory of life stages, there are eight stages of development, each of which is characterized by a particular developmental task that the person must work through before advancing fully to the following stage. In the realm of vocational behavior, Donald Super and associates employed a model of five developmental stages: childhood, adolescence, young adulthood, maturity, and old age. According to their model, in childhood the main task is growth. In the adolescence stage, a person explores his or her interests and different specific career opportunities. In adulthood, a person may initially flounder a bit but eventually establish himself or herself in a particular field. In maturity, when the generativity concerns would probably be the most important, the person continues to hold his or her own in a sort of career plateau. Old age is a period of disengagement when ego integrity is achieved if the person has resolved all the earlier stages.

Psychologist Daniel Levinson and colleagues developed a theory of life stages and transitions based on in-depth clinical case studies of a sample of men and women. They utilized the concept of life structure, which is formed by the individual's sociocultural world, aspects of the self that are played out and those that are inhibited or neglected, and the person's participation in the world. In 1968, Hall and Nougaim identified organizational career stages by using a three-stage model of career development: establishment, advancement, and maintenance. At the establishment stage, people have strong concerns about safety, gaining recognition, and establishing themselves in the organization. The advancement stage is characterized by concerns for promotion and achievement. The maintenance stage represents the onset of a plateau, where the incumbent has cues that he or she is nearing the limit of his or her advancement.

1.2. Schein's Model of the Organizational Career

A model of career development in organizations needs to describe the career from two separate but related perspectives: the career as described by the characteristics and experiences of the person, who moves through the organization, and the career as defined by the organization, which involves policies and expectations. A useful approach for understanding this relationship was proposed by Edgar Schein in 1971, who viewed the organization as a three-

dimensional space like a cone, in which the three dimensions represent

- Vertical: Moving up or down, representing one's changing rank or level in the organization
- Radial: Moving more (or less) "inside" in the system, becoming more (or less) central, part of the "inner circle" acquiring increased (or decreased) influence in the system
- Circumferential: Transferring laterally to a different function, program, or product in the organization

1.3. Careers as Learning Cycles

One of the keys to understanding the new employment contract is the fact that the employees' needs and career concerns change during the course of the career in a much more dynamic way than in the past. Therefore, in Douglas Hall's 1996 concept of the flexible career or protean career, the career is not measured by age-linked life stages but, rather, by a series of short (3–5 year) learning cycles. Each learning cycle has the following phases: exploration, trial of new activity, mastery, and then exploration of some other new activity. Because the life cycle of technologies and products is short, so too are personal mastery cycles. As a result, people's careers will increasingly become a succession of "ministages" (or short-cycle learning stages) of exploration–trial–mastery–exit as they move in and out of various product areas, technologies, functions, organizations, and other work environments.

2. THE NEW CAREER CONTRACT: PROTEAN AND BOUNDARYLESS CAREERS

2.1. The Protean Career Contract

Another way to frame the changes in career patterns is in terms of the psychological contract between the employee and the organization. Ian MacNeil discussed two forms of what he called the social contract. The first was relational, which was based on assumptions of a long-term relationship and trust that the relationship would be a mutual one. In contrast, the other form was transactional, based on a shorter term exchange of benefits and contributions. MacNeil was discussing the role of an individual in a larger society, but his concepts seem applicable to organizations as well.

From the perspective of the individual, there is a shift from the organizational career to what Hall described as the protean career—a career based on self-direction in the pursuit of psychological success in one's work. The driving forces in the protean career are the person's core values and need for control of his or her life and career choices. In addition, the protean person has a strong learning or exploratory orientation that would predispose him or her to be quite comfortable in a career characterized by continuous learning cycles, as described previously.

The measure of success for the protean careerist is psychological success, or success as measured by the person's own goals and values. Thus, in Everett Hughes' terms, to understand the protean career, the observer must examine the subjective career, which is the way the individual experiences his or her career. In contrast, the more traditional organizational career was often assessed from the perspective of the objective career, which is the way career success would be judged by an external observer, usually in terms of outcomes such as money, power, or position.

2.2. The Boundaryless Career

In 1996, Michael Arthur and Denise Rousseau identified a related concept, the boundaryless career. They defined the boundaryless career as not bounded, not tied to a single organization, not represented by an orderly sequence, and marked by less vertical coordination and stability. In their words, "boundaryless careers are the opposite of 'organizational careers'—careers conceived to unfold in a single employment setting" (p. 5). In 1993, Defillipi and Arthur offered a congruent explanation of the boundaryless career that evolved around interfirm mobility. Peiperl and Baruch, in their discussion of the "post-corporate career," agreed that the emerging career clearly centered outside the organization—increasingly identifiable with professional and familial as opposed to organizational communities.

Thus, if the old contract was with the organization, in the protean career the contract is with the self and one's work. In a study comparing data collected in 1978 and 1989, Linda Stroh and colleagues found evidence of this shift from an organizational focus to an investment in one's own work; satisfaction with the company decreased from 1978 to 1989, but job involvement and job satisfaction increased. (They also reported that managers in 1989 were changing jobs and relocating more often than those in 1978.)

2.3. Mobility via Contingent Employment

One of the ways that career mobility and protean careers are currently manifest is in the rise of contingent employment. In the United States, the largest employer at the time of this writing is a temporary agency, Manpower, Inc. More than 90% of U.S. employers use temporary workers as part of their staffing mix, as identified by von Hippel *et al.* in 1997, and nearly 3 million people worked as temporary workers in a single year. It is clear that one of the major ways that careers have become boundaryless has been through the practice of temporary employment.

2.4. Life and Work Roles

Another way that change and flexibility manifest themselves in contemporary careers is in the interplay between the person's work role and the roles in his or her private life. There are three common forms of stress between work and home, and it is important to consider each one separately. (There is a huge literature on work-life issues, so this discussion is simplified by considering married couples.) The first and most common source is role overload. This is caused by the sheer number and intensity of demands on a couples' time. Overload pressure is especially high for young couples (at a career stage in which financial resources are tight) with children. The sheer number of demands on the partners exceeds the time and energy to do them.

The second type of work-life stress derives from role conflict, the incompatibility of different role expectations. One type of conflict is interrole conflict, in which one partner's different roles make mutually conflicting demands, such as when a person, as an employee, is expected to be out of town for a client meeting and is also expected, as a parent, to be at his or her child's school for the fifth-grade play. It is not possible to be in both places at the same time (although people may be tempted to do so electronically). There is also intersender conflict, within a role. An example is when a father is home taking care of his daughter and she wants him to let her stay up past her bedtime to watch a special TV show, even though the mother had left strict instructions that the daughter should be in bed on time.

A third type of conflict is intrapersonal conflict (within the person), in which a person feels torn between two valued activities (e.g., going to the son's band concert or to the daughter's all-star softball game). It could also be a conflict of unmet expectations, in which the person

feels that he or she is simply not measuring up to the standards set by other people he or she respects (“I could never be the father that he is” or “I’ll never be as successful as she is”).

The third source of stress is change. This is especially problematic for dual-career couples, who may be more likely to experience relocations more often than one-career families. A relocation can trigger all sorts of other changes—new jobs, new home, new friends, new schools, new community, new culture, often a more expensive house and the concomitant financial stress, etc. Again, synchronicity is an issue: The more roles that are changing simultaneously, the more the stress is compounded.

3. PREDICTING CAREER EFFECTIVENESS

In the research literature, career effectiveness has been defined in terms of performance and the popular symbols of success—money and position. However, there are other important measures of career effectiveness: career attitudes, adaptability, and identity. These four dimensions of career effectiveness can be considered as representing a 2×2 grid, as shown in Table I, where one axis involves the time span (short term vs long term) and the other involves the focus (task vs personal) aspect of career development.

3.1. Performance

The major category of performance effectiveness is related to typical financial indicators, such as current salary, average yearly salary increases, or salary in relation to that of other people with equivalent length of service or of similar age. The other major category involves the position, which has been employed as rank or level in an organizational hierarchy, number of promotions received over a given time period (i.e., rate of advancement), or, conversely, length of time in current position.

TABLE I
Four Types of Career Effectiveness^a

Focus	Time span	
	Short term	Long term
Task	Performance	Adaptability
Self	Attitudes	Identity

^aAdapted from Hall (2002).

3.2. Career Attitudes

The way the career is perceived and evaluated by the individual defines an individual’s attitudes toward his or her career. The major attitudes related to career are organizational identification and commitment, which tap the psychological involvement that the person feels with the organization and the extent to which his or her organizational membership is a significant aspect of his or her identity; the involvement and commitment to career and family and negative experiences related to involvement and commitment, such as burn-out; the psychological success, which is the feeling of pride and personal accomplishment that comes from knowing that one has done one’s personal best, as Hall and Mirvis discussed; and self-efficacy, which is the individual’s beliefs about his or her ability to perform successfully a given task, as identified by Bandura.

3.3. Adaptability

Morrison and Hall define adaptability as the capacity and motivation to adapt or change in response to changing task or environmental circumstances. Hall proposed adaptability as a higher order quality called metacompetency—the capacity to master many more specific skills when one masters this metacompetency.

3.4. Identity

An individual’s sense of identity can be defined as (i) the person’s awareness of his or her values, interests, abilities, and plans; (ii) the degree of integration between past, present, and future concepts of self; and (iii) the extent to which the person feels integrated over time. Role transitions, socialization, life stage, as well as race, culture, and history are critical factors that facilitate the growth of the person’s identity. There are two facets of the person’s overall sense of self. Personal identity refers to those qualities in the person’s self-perceptions that are unique to him or her. Social identity describes the portion of the overall identity that derives from the person’s membership in a particular social group, such as a gender group or a racial or ethnic group.

4. CONCLUSION

In the postindustrial era, individual career effectiveness entails more than traditional “objective” indicators of

success, such as money and position. In a knowledge economy, the rapid rate of change puts positive attitudes, identity growth, and adaptability at a premium. These are all qualities that are more “subjective,” or internal and unique to the person. The ultimate evaluation of these career outcomes (i.e., career success) can be assessed from the individual’s perspective. This individual or subjective definition of success is called psychological success.

All these personal career outcomes, including psychological success, are developable—that is, they can be influenced by the individual and the organization. Also, they tend to go together and to reinforce one another. For example, people with positive attitudes tend to make jobs into satisfying and developmental experiences; that is, they adapt effectively to frustrations in the work environment. Knowing oneself enables the person to make better choices that are in line with the person’s interests and values and to know whether it is better to make adaptations or to move on and select a new place to work. In turn, effective adaptation creates new skills and relationships, which in turn lead to a more positive and proactive self-identity.

GLOSSARY

burnout A psychological, physical, and emotional withdrawal from a formerly enjoyable and motivating activity resulting from prolonged or chronic stress.

long-term overtraining During long-term overtraining, lasting 3 weeks or more, athletes are on a chronic performance plateau that cannot be influenced positively by short amounts of rest and recovery periods.

overtraining This is due to a long-term imbalance between stress and recovery (i.e., too much stress combined with too little regeneration).

recovery An inter- and intraindividual multilevel (e.g., psychological, physiological, and social) process for the reestablishment of performance abilities. Recovery includes an action-oriented component, and self-initiated activities (proactive recovery) can be systematically used to optimize situational conditions to build up and to restore personal resources and buffers.

short-term overtraining Short-term overtraining, lasting less than 3 weeks, is a regular part of athletic training that leads to a state of overreaching in affected athletes. This state of overreaching is characterized by a transient

underperformance that is reversible within a short-term recovery period of 1 or 2 weeks and can be rewarded by an increase in performance ability.

This article addresses underrecovery as a key component in the development of overtraining and burnout. A constant lack of recovery or disturbed recovery results in overtraining or burnout, which frequently occur in sports. Even being slightly underrecovered over a longer period of time results in underperformance.

1. INTRODUCTION

At the 2002 Soccer World Championships in Japan and Korea, teams that were favored to win the World Cup, such as France and Portugal, did not survive the first round in the tournament. During and immediately after the World Cup, some journalists and the World Soccer Association (FIFA) started a discussion about why these teams were not able to perform at their expected level. A connection was quickly made to burnout, overtraining, and underrecovery due to the game schedule of the players during the season. Especially athletes from successful clubs playing in international competitions, such as the Champion League or the Uefa-Cup in Europe, have a very tight competition calendar. For example, Hertha BSC played more games than any of the other German professional soccer teams in the first half of the 1999/2000 season—29 games in 18 weeks, which is an

average of 1 game every 4.3 days, including travel time. By midseason, the players described themselves as physically and mentally drained. In addition to this schedule, some players are drafted to their national teams and have to play for them in addition to playing regular club games. Therefore, a common tendency seems to be that players purposely miss games of their national teams by claiming an injury to reduce the number of games they must play and to get more time off. Interestingly, often it is not the training and competition that are perceived to be stressful by the players but, rather, traveling and the continuous adaptation to new setting and surroundings. The schedules of professional sports teams in North America, such as basketball, baseball, and hockey teams, are similar to or even more intense than those of European soccer teams. In high-performance sports, especially professional sports, the drills performed in practice are often driven by the competition schedule so that there is only time for regenerative practice. For example, National Hockey League (NHL) teams played 82 games during the regular season in 2000/2001. According to the official game schedule, the Colorado Avalanche, like other NHL teams, played an average of 1 game every 2.3 days (including travel time), and reaching the playoffs added more games to the schedule. How much recovery time is left between games? When 2 or 3 games are played per week, physical and mental recovery is often incomplete. However, lack of recovery or underrecovery is not only due to the frequency of competitions. It can also be enforced by training mistakes, such as (i) having a monotonous training program, (ii) more than 3 hours of training per day, (iii) more than a 30% increase in training load each week, (iv) ignoring the training principle of alternating difficult and easy training days or by alternating 2 difficult days followed by an easy training day, (v) no training periodization and respective regeneration microcycles after 2 or 3 weeks of training, or (vi) no rest days.

2. RECOVERY

Often, recovery is defined as the compensation of deficit states of an organism (e.g., fatigue or decrease in performance) and, according to the homeostatic principle, a reestablishment of the initial state. In 2001, Kellmann and Kallus stated that recovery encompasses active processes of reestablishing psychological and physiological resources and states that allow one to tax these resources again. This more precisely describes the complex issue of recovery. However, it

is still not sufficient to define recovery as an elimination of fatigue or system restart. Kellmann und Kallus developed a more precise definition:

Recovery is an inter- and intraindividual multilevel (e.g., psychological, physiological, social) process in time for the reestablishment of performance abilities. Recovery includes an action-oriented component, and those self-initiated activities (proactive recovery) can be systematically used to optimize situational conditions to build up and to refill personal resources and buffers. (p. 22)

Recovery processes in competitive sports support the restoration of individual activity conditions and well-being following training and competition demands. Several studies have shown that recovery is faster when subjects exercise moderately instead of resting passively. Active recovery consists of cool-down activities, such as muscle relaxation and stretching, after practice and competition. The purpose of these exercises is to eliminate the effects of fatigue through physical activity. Passive recovery, on the other hand, includes treatments such as massages, hot and cold baths, steam baths, and sauna baths, which initiate physiological reactions through physiological stimuli (heat, cold, and pressure), affecting blood flow, respiration rate, and muscle tone. Optimal use of available recovery time is imperative for success in sports. Top performances can only be achieved by athletes who can recover quickly during competition and optimally carry out the changes between stress, recovery, and future stress.

3. OVERTRAINING

Kellmann summarized the literature and stated that 60% of females and 64% of males have been overtrained at least once during their running careers. Ninety-one percent of swimmers who were overtrained during their freshmen year in college also experienced overtraining during the following years, whereas only 30% of athletes who were not overtrained in their freshman year had problems later. In addition, overtraining was seen in 33% of Indian national-level basketball players during a 6-week training camp, in 21% of swimmers on the Australian National Team during a 6-month season, and in more than 50% of semiprofessional soccer players after a 5-month competitive season.

Gould and Dieffenbach pointed out the relevance of overtraining in high-performance sports and its importance as a performance-influencing factor identified in

several studies of high-performance athletes. They summarized a study on positive and negative factors influencing U.S. athletes and coaches at the Olympics in Atlanta in which 84 (28%) of 298 athletes reported that they had overtrained for the games and this overtraining had a negative impact on performance. Similarly, 35 of the athletes identified overtraining/not getting enough rest as the primary coaching action that negatively affected their performance. Ten percent of U.S. athletes who participated in the 1998 Nagano Winter Olympics reported that they were overtrained and that this had negative effects on their performance. The need to taper, rest, not to overtrain, travel less, and stay healthy were changes that they would employ if they could prepare again for the Olympics. Hence, these findings demonstrate that both summer and winter Olympic Games athletes identified overtraining as a concern. Gould and Dieffenbach note that the findings should not be assumed to result only from inappropriate physical training. Other factors, such as psychological stress, travel, personality, inadequate rest, type of recovery activity, and sociological issues must be examined in multifaceted models as well.

It is well accepted that overtraining is due to a long-term imbalance between stress and recovery (i.e., too much stress combined with too little regeneration). The term stress includes all training, competition, and additional nontraining stress factors. Social, educational, occupational, economical, nutritional, and travel aspects, time stress, and the monotony of training increase the risk of an overtraining syndrome.

The same training can have different effects on athletes depending on their personal situation, including emotional stressors (e.g., fights with friends or partners and also parents getting divorced), obligations at school, or difficulties in time management (e.g., practice/school/friends). Often, individuals can easily handle these situations, but when a heavy training load is added to an already high "personal package load," the total impact can be too high. Therefore, coaches should be aware of athletes' personal situations and design training accordingly. The most frequent causes of overtraining cited by athletes are (i) too much stress and pressure, (ii) too much practice and physical training, (iii) physical exhaustion and all-over soreness, (iv) boredom due to too much repetition, and (v) poor rest or lack of proper sleep. Therefore, training holism encompasses two ideas: Training must be balanced and varied, and non-training time has a major influence on training. It is therefore important that all factors outside the realm of the training session be evaluated with regard to their possible negative influence on total fatigue. Insufficient

and/or lack of recovery time between practices is the main cause of overtraining syndrome. Factors such as nutrition, sleep deficit, sickness, travel, and competitions increase the negative effect of insufficient recovery.

In 2002, Kellmann discussed the different uses of the term overtraining and related terms in the literature and concluded that the definition by Lehmann *et al.* provides the best integration and description of overtraining. Lehmann and colleagues distinguished between short-term overtraining, which lasts less than 3 weeks, and long-term overtraining that lasts 3 weeks or more. They noted that short-term overtraining (also called overreaching or supercompensation training) is a frequent part of athletic training, which leads to a state of overreaching in affected athletes. This state of overreaching is characterized by a transient underperformance that is reversible within a short-term recovery period of 1 or 2 weeks and can be rewarded by a state of supercompensation (increase in performance ability after 1 or 2 regeneration weeks after a short-term phase of overtraining). Therefore, short-term overtraining or overreaching is a regular part of athletic training and desired by coaches. When overreaching is done inappropriately or done for too long, short-term overtraining turns into long-term overtraining.

During long-term overtraining, athletes are on a chronic performance plateau that cannot be influenced positively by short periods of rest and recovery. Long-term overtraining can be characterized by an inability to train at the customary level. The symptoms include feelings of depression, general apathy, decreased self-esteem, emotional instability, irritability, impaired performance, lack of supercompensation, restlessness, disturbed sleep, weight loss, loss of appetite, increased resting heart rate, increased vulnerability to injuries, and hormonal changes. An important clinical feature of overtraining syndrome is the increased susceptibility to infections with corresponding symptoms, suggesting some kind of impaired immune response. Unfortunately, when athletes realize that performance has stagnated or declined, it is a common tendency to increase the training effort, which leads to an even deeper stage of long-term overtraining.

4. BURNOUT

Although there is no common definition for burnout, there is a consensus that burnout is a reaction to chronic stress. Smith defines burnout as a psychological, physical, and emotional withdrawal from a formerly

enjoyable and motivating activity resulting from prolonged or chronic stress. It is an exhaustive psychophysiological response exhibited as a result of frequent, sometimes extreme, and generally ineffective efforts to meet excessive physical training and psychological demands. It is also important to note that when athletes burnout of sport they do not always discontinue involvement altogether. Some athletes who experience burnout remain active. They believe that they cannot discontinue for various reasons (e.g., family pressure), and this entrapped participation is characterized by lower motivation, emotional detachment, less satisfaction, and poor performance. Burnout results in a decline in sport participation by an athlete as a result of chronic excess stress.

Maslach defines burnout as an individual syndrome including emotions, attitudes, motives, and expectancies. Burnout is a negative individual experience encompassing problems, distress, negative mood states, dysfunction, and negative consequences. Maslach and Jackson characterize the burnout syndrome through emotional exhaustion (i.e., loss of social interest) and reduced personal accomplishment and involvement. In addition to a lack of performance, burnout eventually results in the quitting of prior enjoyable activities. Research on burnout was originally performed in the area of social professions, and it was expanded to other professional groups, such as athletes and coaches. With an increasing level of burnout, the performance of athletes becomes inconsistent and eventually declines. The effect is supported by overtraining, routine, monotony, boredom, and a lack of diversity. This indicates that burnout is caused by a lack of recovery. In the case of an intense schedule during the season and intense training during the off season, a complete physical and psychological recovery seems to be impossible. Therefore, a long recovery phase or a temporary reduction in athletic activities are the only effective approaches to prevent athletes from dropping out of sport. Consequently, coaches and staff need to be sensitive to the recovery demands of athletes.

On the behavioral level, burned out athletes have less input with regard to training, fewer practice days, differences in motivation, poorer coping behavior, and a longer history within the sport. Gould *et al.* showed for tennis players that Smith's model well described the antecedents and consequences of burnout. Thus, one can view a model of chronic stress as a good basis for explaining burnout in athletes. Cohn identified too much practice or competition, lack of enjoyment, and too much pressure from self or others as the main sources of burnout. Furthermore, stress associated

with injuries and resumption of training can drastically increase the risk of dropout and burnout.

Burnout in coaches has also been examined. The work environment of coaches involves long hours, demands much mental and emotional energy, and exerts considerable subjective pressure due to standards set by the coaches or by fans and athletes. A survey by Vealey *et al.* demonstrated the importance of the coach's personality as a factor in the development of burnout. The results also supported the contribution of reward factors as buffers against burnout, which can be derived from Smith's model. Perceived rewards and perceived value of the social role, together with excitement, are the most important antiburnout buffers, as evidenced by research in organizations.

In 1996, Kallus *et al.* reported results from a study of 195 semiprofessional and professional coaches. They found (i) differences in the coping strategies of younger coaches as well as between coaches of team and individual sports; (ii) coaches of individual sports who used more cognitive reevaluation strategies, actively and positively coped with stress, and searched for self-affirmation pitied themselves more than coaches from team sports; and (iii) full-time coaches were more burned out and highly stressed, were experiencing less recovery, and were less fit than semiprofessional coaches. In addition, professional coaches showed deficits in coping strategies and therefore may possibly react less effectively in critical situations. It can be concluded that stress in addition to a recovery deficit and a coping deficit leads to a high risk of burnout. More research is needed to fully support the results of Kallus *et al.*; however, these results strongly indicate that recovery is a key variable in the development of burnout.

5. INTERRELATION OF STRESS STATES AND RECOVERY DEMANDS

The previous discussion has shown that recovery is the key factor in preventing overtraining and burnout. In this context, Kellmann proposed a general model that describes the interrelations of stress states and recovery demands (Fig. 1). The basic assumption of this model is that with increasing stress, increased recovery is necessary to remain at the same stress state. However, limited resources (e.g., time) initiate a vicious cycle: Under increased stress and due to the inability to meet increased recovery demands, a person experiences more stress. Recovery demands are defined as

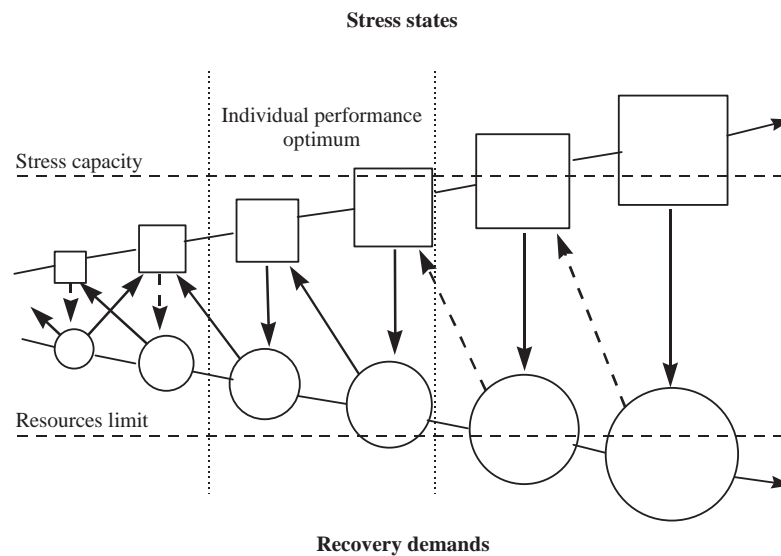

FIGURE 1 The “scissors model” of the interrelation of stress states and recovery demands. Reprinted, by permission, from K. W. Kallus & M. Kellmann, 2000, “Burnout in athletes and coaches” in *Emotions in sport*, edited by Y. L. Hanin (Champaign, IL: Human Kinetics), p. 212.

the quality and/or quantity of recovery activities required to level out the current recovery stress state. People may be stressed to the point that they fail to find or make time to recover adequately or to consider better ways of coping with the situation.

With intermediate levels of stress, one can find an area of optimal performance and thus an area of adequate recovery. Beyond this point, one cannot meet recovery demands without additional recovery activities. Stress will accumulate, and without intervention burnout symptoms are likely to develop. The state of balanced stress and recovery is related to optimal performance. In a state of adequate recovery, the individual can react appropriately and cope successfully with stress without additional recovery activities. A lack of recovery or underrecovery can trigger a process that leads to a state of elevated stress. Because increasing stress limits the possibility of recovery, the athlete must be given opportunities to recover in order to reestablish an optimal level of performance.

With regard to sports, the model may also explain how overtraining develops. The axis of the stress states can be seen as a continuum of an increasing training load, which can be labeled at the end points “no training” and “overtraining.” With extended training load, the organismic recovery demands increase proportionally. A short-term planned period of recovery enhances long-term performance effects (e.g., supercompensation). If the

training load and intensity increase over a longer time period without adequate or with merely inappropriate recovery, the individual experiences long-term underrecovery, which may result in the overtraining syndrome. To reach the optimal recovery stress state, athletes have to increase their self-initiated activities to fulfill their recovery demands. At each state of the model, recovery can work as a regulation mechanism, which is caused by an increasing distance between the two axes into a longer recovery period (days to weeks). The higher a person is on the stress states or the more extensive the overtraining syndrome, the more recovery efforts are needed to reach the individual optimal recovery stress state. The model interrelation of stress states and recovery demands implies that it is not necessarily bad to be highly stressed as long as a person knows how to recover.

6. TREATMENT OF OVERTRAINING AND BURNOUT

When performance plateaus or instability on performance occur, athletes and coaches have the tendency to increase their effort and the training load, which mostly leads to a vicious cycle. The best treatment for overtraining is rest and recovery phases from 2 to 6 weeks long (sometimes longer), depending on the degree of overtraining. In some cases of overtraining syndrome,

athletes may require months without any training and without any physical activity in order to recover completely. Changes in training can also positively affect the practice routine. A reduction of training load, a change in intensity, or a change in training technique can positively affect athletes. When a coach believes that an athlete is showing signs of overtraining, the athlete should consult a doctor to rule out injuries and damage due to overstrain. If overtraining syndrome is diagnosed, treatment with electrolytes can be considered. Active and proactive recovery is the best treatment for overtraining syndrome. Physical exercises, such as gymnastics, games, regenerative runs, or swimming, as well as a balanced and healthy diet play an important role in the recovery process. Environment and climate changes help athletes to recover both physically and mentally. Activities that were denied because of the rigid training regime can be important too, and psychoregulative techniques, such as progressive muscle relaxation or autogenic training, can accelerate the recovery process.

In the case of burnout, psychoregulative techniques also play an important role, enabling people to deal with chronic stress. Psychoregulative techniques enhance the ability of athletes to have appropriate reaction patterns when needed. Also, when someone is burned out, the setting of short-term and long-term goals is important to gain perspective on a new or formerly enjoyable activity. Setting short-term goals and providing rewards or incentives every time a goal is accomplished is motivating. In addition, having fun goals, especially during the end of a long season, is very beneficial. These goals should be set for competition as well as for practice, especially since practice often comprises more than 90% of the participation time in sports. Gould and colleagues' recommendations for dealing with and preventing burnout include playing for personal reasons, balancing sport with other activities such as school clubs or socializing with friends, stopping participation if the sport is no longer fun to play, focusing on making the sport fun, doing things to relax, and taking time off to recover.

GLOSSARY

biofeedback A procedure that combines voluntary control of autonomic nervous system activity with continuous recording and presentation of information ("feedback") regarding activity of (e.g., muscles) believed to be involved in various pain syndromes; the physiological information provided to the patient by means of electrical activity converted into signals, such as tones and lights, is used by the patient to help him or her learn how to control the autonomic activity being monitored.

cognitive-behavior therapy (applied to chronic pain) Involves multiple interventions that target behavioral contributors to pain and the maladaptive thoughts that can accompany adjustment to any chronic physical condition; the focus of therapy centers around four central components: (a) education to increase the patient's knowledge about his or her condition, reassurance, and reduction of fear; (b) behavioral exercises and activities designed to increase physical and functional activities such as pacing programs to enhance physical exercise and activity; (c) cognitive exercises and activities designed to help the patient alter responses to stressors and pain; and (d) skills training to help the patient

deal with problems created by a chronic disease and to modify the perception of pain using techniques such as relaxation, biofeedback, and other self-control strategies.

implantable drug delivery systems Consist of the implantation of a pump and reservoir containing analgesic medication (usually opioids); the pump provides a steady administration of the medication following a preprogrammed schedule directly into the spinal canal that may be more potent than oral administration.

interdisciplinary pain rehabilitation programs Comprehensive treatment programs that integrate physical and occupational therapy, medication management, vocational counseling, and psychological (e.g., operant conditioning, cognitive-behavior therapy) components, with an emphasis on self-management and functioning improvements despite residual pain rather than cure.

operant conditioning (applied to chronic pain) Has the main focus of modifying the frequency of a given behavior; if the consequence of the given behavior is rewarding, the likelihood of its occurrence increases, whereas if the consequence is aversive, the likelihood of its occurrence decreases.

spinal cord stimulation Involves surgical placement of electrodes along the spinal cord connected to an external device capable of generating a current along the electrodes, with the current designed to interrupt or mask the transmission of noxious sensations from the periphery to the brain.

Pain is an extremely common perceptual event that is essential for survival. However, when pain persists for extended periods of time, it no longer serves as a warning function, it affects all aspects of a person's functioning, and it can become a problem in its own

right. Despite advances in understanding of the anatomy and physiology of pain and the development of treatments based on sophisticated technology, chronic pain continues to be a prevalent and costly problem. Because chronic pain is a perceptual event, psychosocial and behavioral factors as well as physical ones contribute to the experience. Over time, cognitive, affective, and environmental factors play an increasingly greater role in the maintenance of pain, emotional distress, and functional disability. An understanding of the role of psychological factors has resulted in innovative treatment approaches that have been shown to have significant effects on pain intensity, associated physical symptoms, and physical functioning. These approaches are not cures; rather, they focus on functional restoration, alleviation of emotional distress, and reduction of disability. The effectiveness of psychological treatments for diverse chronic pain syndromes has been demonstrated in numerous studies. Moreover, psychological principles and techniques have been incorporated into successful interdisciplinary pain rehabilitation programs.

1. PAIN: MAGNITUDE OF THE PROBLEM

In 1998, Abbott and Fraser noted that pain is the single most frequent reason for physician consultation, with nearly one-half of those who seek treatment reporting pain as their primary symptom. Precise estimates of the prevalence of chronic pain syndromes are difficult to ascertain. In 1994, Joranson and Lietman indicated that there may be more than 30 million people with chronic or recurrent painful conditions in the United States. Based on a survey conducted by Marketdata Enterprises in 1995, an estimated 2.9 million Americans (1.1% of the population) are treated annually by health care professionals specializing in chronic pain.

The U.S. Bureau of the Census in 1996, as well as the National Research Council in 2001, estimated that the total annual costs of chronic pain (e.g., treatment, lost work days, disability payments, legal fees) in the United States range from \$150 billion to \$215 billion. In 1995, Cousins suggested that the costs of health care for patients with chronic pain might exceed the combined costs of treating patients with coronary artery disease, cancer, and acquired immune deficiency syndrome (AIDS).

2. PHARMACOLOGICAL AND SURGICAL TREATMENTS FOR PAIN

The first-line treatment for pain consists of a host of pharmacological agents. In 1998, Schappert noted that pain medications were the second most prescribed drugs (after cardiac-renal drugs) during visits to physicians' offices and emergency rooms, and the results of the National Ambulatory Care Medical Survey conducted in 1998 suggested that pain accounted for 12% of all medications prescribed during ambulatory office visits in the United States. Pharmaceutical industry data provided in a personal communication indicate that more than 312 million prescriptions for analgesic medications were written in the year 2000 in the United States, that is, more than one prescription for analgesics for every man, woman, and child.

The most frequently used medications to control pain in patients with chronic pain are nonsteroidal anti-inflammatory drugs, acetaminophen, opioid and nonopioid analgesics, low-dose tricyclics, and anti-convulsants. Despite their frequent use, currently available medications do not eliminate pain. For example, in 2002, Turk reviewed the available literature and concluded that the average pain reduction for patients placed on the most potent agents, opioids, is approximately 35%.

Persistence of some chronic pain syndromes (e.g., back pain) frequently leads to surgery. However, a number of studies, including those by North and colleagues in 1991 and Franklin and colleagues in 1994, reveal that significant pain may persist following surgery and that a significant percentage of chronic pain patients treated with surgery report that their pain is actually worse following surgery. Several studies of implantable devices (e.g., spinal cord stimulators, implantable drug administration systems) have reported impressive results in pain reduction, but only for carefully selected patients with pain of long duration.

3. FACTORS INFLUENCING THE PERCEPTION OF PAIN

There has been a growing recognition that pain is a complex perceptual experience influenced by a wide range of psychosocial factors, including emotions, social and environmental contexts, sociocultural background, the meaning of pain to the person, and beliefs, attitudes, and expectations, as well as by

biological factors. Biological factors may initiate, maintain, and modulate physical perturbations, but psychological factors influence the appraisal and perception of internal physiological signs and social factors shape the behavioral responses of patients to the perceptions of their physical perturbations and may have a direct effect on physiological processes associated with exacerbation and maintenance of symptoms.

Pain that persists for months or years, called chronic pain, will have an impact on all aspects of a person's functioning—emotional, interpersonal, avocational, and physical. Consequently, treating chronic pain patients successfully requires attention not only to the organic basis of the symptoms but also to the range of factors that modulate nociception and moderate the pain experience and related disability.

4. PSYCHOLOGICAL TREATMENT OF CHRONIC PAIN PATIENTS

A large volume of research exists demonstrating the efficacy of the psychological treatments for low back pain, fibromyalgia syndrome, noncardiac chest pain, arthritis, headaches, temporomandibular disorder (TMD), and whiplash-associated disorders, to name a few. Furthermore, cognitive-behavioral approaches appear to prevent the development of disability due to pain. Psychological modalities have been used in the treatment of chronic pain patients either on their own or, more typically, as an essential component of comprehensive interdisciplinary rehabilitation.

Table I lists the most common psychological approaches applied to chronic pain. The effectiveness of relaxation, biofeedback, and cognitive-behavior therapy (CBT) has been the most thoroughly evaluated. Electromyographic (EMG) biofeedback is a procedure that combines muscle relaxation with continuous recording and presentation of information (i.e., “feedback”) regarding activity of muscles believed to be involved in different pain syndromes. In 1979, Turk and colleagues noted that biofeedback is based on the idea that stress-induced hyperactivity is often an important component in muscular pain syndromes. Biofeedback makes use of surface records of muscle activity to provide patients with information about levels of muscle tension. Levels of muscular arousal are recorded and converted into signals (usually auditory or visual) that permit patients to observe their current levels of muscle tension. The signals provided indicate changes

TABLE I
Treatments for Chronic Pain

Pharmacological
Nonsteroidal anti-inflammatory agents
Acetaminophen
Opioids
Antidepressants
Anticonvulsants (e.g., gabapentin)
Topical agents (e.g., lidocaine)
Physical modalities (e.g., hot packs, ultrasound, exercise, transcutaneous nerve stimulation)
Surgery
Regional anesthesia (e.g., neural blockade, epidural steroid injections)
Spinal cord stimulators
Psychological
Relaxation
Electromyographic biofeedback
Hypnosis
Counseling (e.g., family, marital)
Behavior modification (e.g., exposure, desensitization, contingency contracting, operant conditioning)
Cognitive-behavior therapy
Complementary and alternative medicine (e.g., acupuncture, chiropractic, diet supplements, Tai chi)

in muscular activity resulting from patients' efforts to relax the muscles. Thus, the information about muscular activity is “fed back” to the patients and assists them in learning to alter high levels of muscular tension that may be contributing to the onset, maintenance, or exacerbation of pain.

The main focus of operant conditioning is modification of the frequency of a given behavior. If the consequence of the given behavior is rewarding, the likelihood of its occurrence increases; if the consequence is aversive, the likelihood of its occurrence decreases. Behaviors associated with pain, such as limping and moaning, are called “pain behaviors”—overt expressions of pain, distress, and suffering. When an individual is exposed to a stimulus that causes tissue damage, the immediate behavior is withdrawal in an attempt to escape from noxious sensations. Such pain behaviors are adaptive and appropriate. Over time, however, environmental contingencies of reinforcement may serve to maintain the pain behaviors long after the initial cause of the pain has been resolved (Table II). The behaviors are

TABLE II
Operant Conditioning: Modification of Behavior

Schedule	Consequences	Probability of the behavior recurring
Positive reinforcement	Reward the behavior	More likely
Negative reinforcement	Prevent or withdraw aversive results	More likely
Punishment	Punish the behavior	Less likely
Neglect	Prevent or withdraw positive results	Less likely

conditioned based on their consequences. Often, the consequences are provided by significant others, including health care providers, who may inadvertently reinforce the pain behaviors by providing attention, treatment, and/or avoidance of activities that are undesirable to the patient. The operant learning paradigm does not uncover the etiology of pain but rather focuses primarily on the maintenance of pain behaviors and on deficiency in well behaviors such as activity. Treatment focuses on extinction of pain behaviors and on increased well behaviors by changing the reinforcement contingencies—withdrawal of rewards for pain behaviors and increased rewards for well behaviors.

4.1. Cognitive–Behavior Therapy: Components

CBT programs usually involve multiple interventions that target behavioral contributors to pain and the maladaptive thoughts that can accompany adjustment to any chronic physical condition. In 1999, Turk and Okifuji found that these programs focus on four primary components: (a) education to increase patients' knowledge about their conditions, reassurance, and reduction of fear; (b) behavioral exercises and activities designed to increase physical and functional activities such as pacing programs to enhance physical exercise and activity; (c) cognitive exercises and activities designed to help patients alter their responses to stressors and pain; and (d) skills training to help patients deal with problems created by chronic diseases and to modify the perception of pain using techniques such as relaxation, biofeedback, and other self-control strategies (Table III).

TABLE III
Components of Cognitive–Behavior Therapy

- Provide education about pain and particular syndrome.
- Encourage acceptance.
- Foster a self-management perspective.
- Focus on function rather than cure.
- Assist in goal setting.
- Teach relaxation.
- Provide information and guidance about pacing and increasing activities.
- Provide guidance on ways in which to improve sleep.
- Emphasize identifying and eliminating maladaptive thoughts.
- Provide strategies to help cope with relapse.
- Provide skills and skills training for ways in which to cope with interpersonal problems.
- Discuss appropriate uses of medications, exercise, and physical modalities (e.g., heat, cold).

4.2. Cognitive–Behavior Therapy: Efficacy

In 1999, Morley and colleagues conducted a systematic review and meta-analysis of randomized controlled trials, comparing the effectiveness of CBT to waiting list controls and alternative treatment control conditions. They found that CBT produced significantly greater changes in pain experience, cognitive coping, and reduced behavioral expressions of pain. However, significant differences were not found for dysphoric mood, negative appraisals, and social role functioning.

5. INTERDISCIPLINARY PAIN REHABILITATION PROGRAMS

The large body of evidence demonstrating the importance of psychosocial and behavioral factors has led to the proliferation of interdisciplinary pain rehabilitation programs (IPRPs). In 2001, Loeser and Turk noted that these IPRPs typically include psychological (e.g., operant conditioning, CBT) components as integrated within comprehensive treatment plans that include physical and occupational therapy, medication management, and vocational counseling.

In 1992, Flor and colleagues concluded that IPRPs are more effective than no treatment, waiting list controls, and monodisciplinary treatments in terms of reductions of health care use and medication,

increased activity and return to work, closure of disability claims, and reductions of affective distress. The failure to find significant improvement in affective distress, noted by Morley and colleagues in 1999, is at variance with the results of this meta-analysis. The explanation for this inconsistency is unclear and may involve differences in the effects of psychological treatments on their own compared with when they are integrated within IPRPs. IPRPs are often referred to as being based on operant, behavioral, or cognitive-behavioral principles. The actual treatments are broadly defined and often include diverse ingredients. It is difficult to determine what the active components of the treatment packages actually are. Turk in 1990, as well as Kole-Snijders and colleagues in 1999, indicated that this is important because it is not cost-effective to provide comprehensive treatments with multiple components, some of which may be unnecessary. Patients with different characteristics may benefit from different treatments, and not all of the components included may be necessary for all patients.

The reduction of pain following treatment at IPRPs has been reported to be statistically significant in meta-analyses conducted by Flor and colleagues in 1992. Flor and colleagues reported the mean pain reduction for patients treated at IPRPs at 37%. However, the majority of patients continue to experience considerable pain. Interestingly, Flor and colleagues found that the pain reduction achieved at IPRPs, which is comparable to the pain reduction reported with opioids, is accompanied with a significant decrease (63%) in prescription pain medication. However, even when successful, people continue to experience significant levels of pain with which they must cope.

6. SUBGROUPS OF CHRONIC PAIN SUFFERERS

Although biobehavioral treatments appear to be important components of rehabilitation treatments for chronic pain patients, not all patients benefit equally. Focusing solely on group effects may mask important issues related to the characteristics of patients who respond successfully to a treatment. Chronic pain syndromes are made up of heterogeneous groups of people even if the individuals have the identical medical diagnosis. A common pitfall in clinical research and practice is the assumption of patient homogeneity. Inclusion of a diverse group of patients into the same

category simply because they present a common set of symptoms may result in inconsistent research results, as is commonly observed in the pain literature.

Several studies, including one by Kight and colleagues in 1999 and two by Turk and colleagues in 1998, have identified subgroups of patients based on psychosocial and behavioral characteristics. In 1997, Dahlstrom and colleagues found that when patients were classified into different subgroups based on their psychosocial and behavioral responses, they responded differentially to treatments. Similarly, Turk and colleagues noted differential responses to a common treatment for patients with distinctive psychological characteristics but identical physical diagnoses. The results of these studies could be used for developing treatments that are matched to patients' characteristics. Various studies comparing the subgroups have yielded evidence supporting differential responses to the same intervention.

7. CONCLUDING COMMENTS

Despite the advances in the knowledge of sensory physiology, anatomy, and biochemistry and of the prevalence of chronic pain, and despite the many treatments available to provide relief (see Table I), total elimination of pain is elusive for many pain sufferers. Pain and disability have not been eliminated as problems for a significant portion of the population and for society as a whole. Comprehensive biobehavioral treatments appear to have the best outcomes for patients with many chronic pain syndromes. Combining CBT with more traditional medical, surgical, and pharmacological modalities appears to be the most reasonable approach. Matching treatments with patient characteristics has the potential to improve outcomes and reduce costs.

Panic

Martin M. Antony

St. Joseph's Healthcare and McMaster University, Hamilton, Ontario, Canada

1. Introduction
 2. Definitions and Description
 3. Epidemiology of Panic Disorder
 4. Causes of Panic Disorder
 5. Treatment of Panic Disorder
- Further Reading

Panic is an emotional state associated with extreme fear and discomfort, a sense of dread or apprehension, and a number of intense physical sensations, such as racing heart, sweating, shaking, shortness of breath, and various other symptoms of arousal. It tends to begin suddenly, is often triggered by a feared situation or object, and may occur out of the blue, without any obvious trigger or cause.

GLOSSARY

agoraphobia A fear of situations in which escape might be difficult, or in which help might be unavailable, in the event of experiencing a panic attack or panic-like sensations.

anxiety sensitivity A fear of anxiety-related symptoms, such as dizziness, shortness of breath, and racing heart.

cognitive behavior therapy A form of psychotherapy used to change negative patterns of thinking and maladaptive behaviors using cognitive restructuring, exposure-based interventions, relaxation training, and other methods.

interoceptive exposure Exposing oneself to feared physical symptoms using exercises designed to trigger the sensations.

panic attack A rush of fear or discomfort that peaks quickly and that is associated with intense symptoms of physical arousal, including racing heart, shaking, and feeling lightheaded.

panic disorder An anxiety disorder in which an individual experiences recurrent unexpected panic attacks, accompanied by anxiety over having more attacks, worry about the consequences of the attacks, and changes in behavior aimed at preventing future attacks.

1. INTRODUCTION

The word panic has its origins in Greek mythology. It refers to Pan, the ancient Greek god of woods, fields, and flocks, who has a human torso and head, and the legs, horns, and ears of a goat. Pan was believed to be very mischievous, often inciting terror among travelers making their way through the forest by rustling trees and bushes. Pan's victims probably experienced many of the same sensations that people report during modern day panic attacks.

The experience of panic is often referred to as a "fight or flight" response, in which the body is mobilized to facilitate immediate escape from a perceived threat, or to meet the threat head-on with an aggressive response. During panic, the heart races to get blood to the large muscles that may be needed in the event of an escape. Breathing becomes more rapid in order to increase the flow of oxygen to the bodily tissues. Perspiration increases to cool off the body so it can perform more efficiently. In fact, almost all of the

symptoms that occur during a typical episode of panic can be explained in terms of their adaptive functions. In other words, the symptoms of panic serve to improve an individual's ability to escape from perceived danger.

However, panic is often not adaptive or helpful. In many cases, panic occurs in the absence of true danger or threat. Further, panic attacks may lead individuals to avoid feared situations, and may therefore cause considerable impairment in functioning. As a result, frequent panic attacks often lead an individual to seek treatment in one form or another.

2. DEFINITIONS AND DESCRIPTION

In the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders* (DSM-IV), a panic attack is described as a discrete period of intense fear or discomfort that peaks in 10 minutes or less, and is accompanied by at least four of the following 13 symptoms: (1) racing or pounding heart, (2) sweating, (3) trembling or shaking, (4) shortness of breath, (5) feeling of choking, (6) chest pain or discomfort, (7) nausea or abdominal distress, (8) feeling dizzy, unsteady, or faint, (9) feeling unreal or detached, (10) paresthesias (i.e., numbness or tingling sensations), (11), chills or hot flushes, (12) fear of dying, and (13) fear of going crazy or losing control.

Panic attacks are usually triggered by a feared object, situation, or thought. For example, a person who fears dogs may experience a panic attack each time he or she encounters a dog, or panic attacks may occur in anticipation of giving a speech for someone who is frightened of public speaking. Similarly, a person with obsessive compulsive disorder may experience panic attacks in response to obsessional thoughts (e.g., irrational thoughts about harming another individual).

Although panic attacks are often triggered, they can also appear unexpectedly or out of the blue. The presence of recurrent, unexpected panic attacks is the hallmark feature of panic disorder. In addition, people with panic disorder tend to be fearful of experiencing panic attacks and the symptoms that are associated with their attacks. They often anticipate the attacks, wondering when the next one will occur. They also are concerned about the possible consequences of the attacks, worrying about a physical catastrophe such as a heart attack, a stroke, dying, or fainting, or about an emotional or psychological catastrophe such as losing control, embarrassing oneself, or "going crazy."

Finally, people with panic disorder often change their behavior in response to the attacks. They may actively avoid situations where the attacks occur, and they may do things to protect themselves from experiencing further attacks (e.g., distraction, avoiding being alone, checking their body for panic symptoms, carrying medication). To receive a diagnosis of panic disorder, it must also be established that the attacks are not due to a medical illness (e.g., cardiac disease or hyperthyroidism) or a substance (e.g., cocaine use, caffeine overuse, alcohol withdrawal).

Most people with panic disorder also develop some degree of agoraphobia. Agoraphobia is a fear of situations in which escape might be difficult, or in which help might be unavailable, in the event of experiencing a panic attack or panic-like sensations. Typical situations avoided by people with agoraphobia include driving, flying, crowds, enclosed places, public transportation, malls, supermarkets, and traveling. In extreme cases, people with agoraphobia may avoid leaving the house altogether. Often, agoraphobic fear is milder when the individual is accompanied by a close friend, relative, or spouse.

3. EPIDEMIOLOGY OF PANIC DISORDER

Studies on the prevalence of panic disorder estimate that between 2 and 5% of individuals in the general population suffer from this problem, although up to one-third of individuals may experience a panic attack from time to time. Panic disorder occurs more frequently in women than in men. In addition, women with panic disorder tend to experience more severe symptoms (e.g., more intense and frequent attacks, more severe agoraphobic avoidance) than men with panic disorder. This condition most often begins in early adulthood (in a person's 20s or early 30s), though it can begin at any age, ranging from childhood to late in life. The onset often occurs following a period of stressful life events. Panic disorder occurs across ethnic and religious groups and does not appear to be significantly associated with intelligence, marital status, education, or socioeconomic status.

Panic disorder is often accompanied by significant functional impairment and leads to considerable costs to society in the form of increased healthcare utilization, inability to work, and decreased productivity at work. Without treatment, the course is usually

chronic, with up to 90% of individuals still experiencing panic attacks a year after their initial assessment. Panic disorder often occurs concurrently with other psychological problems, including other anxiety disorders and depression. The rate of substance use disorders is also higher in people with panic disorder than it is in the general population.

4. CAUSES OF PANIC DISORDER

There is evidence that both psychological and biological factors contribute to the development and maintenance of panic disorder. From a psychological perspective, cognitive factors seem to play an important role. A risk factor for the development of panic disorder is heightened anxiety sensitivity (i.e., a fear of experiencing symptoms of anxiety and arousal). In addition, people with panic disorder tend to misinterpret the meaning of their physical symptoms, and often assume that their symptoms are dangerous when in fact they are not. Panic disorder is also associated with a tendency to attend to threat-related information (e.g., to scan the body for uncomfortable symptoms) and to remember information that is consistent with anxiety-related beliefs and assumptions. It is believed that the tendency to pay attention to threat-related cues and to interpret benign physical symptoms as dangerous contributes to the development of panic disorder and to the chronic course of this condition.

From a biological perspective, a number of different factors have been studied and found to be relevant. Neurotransmitters in the brain (e.g., norepinephrine, serotonin, cholecystokinin) may play a role. For example, substances that increase levels of norepinephrine or cholecystokinin in the brain (including injections of cholecystokinin and inhalation of carbon dioxide-enriched air) have been found to trigger panic attacks, and medications that block the re-uptake of norepinephrine and serotonin are effective for preventing panic attacks. Genetics also influences the development of this condition. Panic disorder tends to run in families, and a portion of the transmission of panic disorder from generation to generation is directly attributable to the effects of genetics. Finally, brain imaging studies suggest that certain areas in the brain (e.g., the hippocampus) may be more or less active depending on whether someone has panic disorder. The nature of these differences is still not fully understood, and research findings are often inconsistent.

5. TREATMENT OF PANIC DISORDER

Evidence-based approaches to treating panic disorder include cognitive-behavior therapy (CBT), medications, or a combination of these approaches. On average, these options are about equally effective in the short term. However, any one individual may benefit more from one approach over another. In the long term, there is evidence favoring CBT. Rates of relapse and recurrence tend to be lower following the discontinuation of CBT than they are following the discontinuation of medication. Although most people benefit considerably from these treatments, fewer than half of individuals experience a nearly complete remission of their symptoms. Occasional panic attacks, anxiety, and avoidance are common following the end of treatment.

CBT is designed to help an individual to change the beliefs and behaviors that are thought to maintain the problem. The client is taught to replace anxious and unrealistic thoughts with more realistic beliefs, by critically examining the evidence for both anxious and non-anxious interpretations. Clients are also taught to confront feared situations by engaging in prolonged exposure on a regular basis (e.g., practicing driving for an hour each day) until the situations no longer trigger fear. They also learn to confront the fear of physical sensations through interoceptive exposure, that is, exposure to arousal symptoms (e.g., spinning to induce dizziness, aerobic exercise to increase one's heart rate). Finally, relaxation-based strategies (especially slow diaphragmatic breathing) are sometimes used to reduce the intensity of physical symptoms, although it is not clear that these strategies provide any benefit over and above the effects of the other CBT techniques. Usually, education about the nature and treatment of panic and anxiety is included throughout the treatment.

The most commonly used medications for panic disorder include certain antidepressants as well as a number of anxiolytics. Effective antidepressants include the selective serotonin re-uptake inhibitors (e.g., citalopram, fluoxetine, paroxetine, sertraline), certain tricyclic antidepressants (e.g., imipramine, clomipramine), as well as other medications (e.g., venlafaxine). Anxiolytics, such as the benzodiazepines (e.g., alprazolam, clonazepam) have also been shown to reduce the symptoms of panic disorder. Decisions regarding which medication to use should be based on the individual's past treatment history, medical history, possible interactions between the medication and other drugs

that person may be taking, potential side effects, and other factors.

Further Reading

silence The absence of vocal behavior for a period of time; often, it is misunderstood to refer to the absence of any and all communication.

tone of voice Pitch, loudness, and timbre of a spoken utterance.

turn taking The allocation of speaker and listener roles in a conversation; a person takes his or her turn when adopting the role of the speaker.

GLOSSARY

baby talk A voice and speech style used by adults, and even by children, when speaking to infants.

contact cultures Cultures from which people stand closer, face more directly, touch, and look more than do people from noncontact cultures.

distance between bodies Physical space between people in their conversations; there are wide cultural differences in what is considered appropriate distance.

facial expression Patterns of movements of brow, eye, and mouth regions.

paralinguistic behaviors Vocal and nonvocal phenomena that are either blended or associated with speech utterances but have no direct function according to linguistic rules; they include tone of voice, speech and conversation style, facial expressions, gestures, head and body movements, and distance between bodies.

Successful communication includes knowing when to speak and when to remain silent; which tone of voice, which facial expression, and which body position are appropriate in various contexts; what the routines for turn taking are in conversation; and how to exhibit the appropriate listener signals. These behaviors are referred to as "paralinguistic." Some of them may be common to all people, and some of them may vary from one culture to another. When communicating with persons who are culturally different, violations of the rules for paralinguistic behaviors often lead to misunderstandings, even if the words and grammar of the foreign language are appropriately mastered. The aim of the cross-cultural study of paralinguistic behaviors is to learn how the principles of paralinguistic behaviors vary from one culture to another and how universal principles must be qualified and adjusted on the basis of cultural differences. This understanding will help people to use communication effectively in intercultural encounters.

1. INTRODUCTION

One of the most striking differences among members of various cultures is that they speak different languages. Thus, it will obviously be useful to persons involved in international transactions to learn the languages of their interlocutors. However, successful communication involves knowing not only what to say to whom but also how to say it appropriately in any given situation. It includes knowing when to speak and when to remain silent; which tone of voice, which facial expression, and which body position are appropriate in various contexts; what the routines for turn taking are in conversation; how to request, how to offer, and how to decline assistance or cooperation; and how to exhibit the appropriate listener signals. These behaviors are not regarded by linguists as being an integral part of the verbal utterances with which they are associated; therefore, they are referred to as “paralinguistic.” Some of these behaviors may be universal (common to all people), and some of them may vary from one culture to another. As a person learns his or her “mother tongue” during childhood, that person usually acquires and reproduces the appropriate paralinguistic behaviors typical of speakers of that language because a first language is learned in the context of behavioral settings where the norms of the culture are acted and enunciated. However, these norms are less explicit and less under conscious control than are the rules of languages. Thus, learning a second language has traditionally stressed the acquisition of words and grammar while ignoring paralinguistic behaviors. When communicating with persons who are culturally different, violations of the rules for paralinguistic behaviors often lead to misunderstandings, even if the words and grammar of the foreign language are appropriately mastered. The aim of the cross-cultural study of paralinguistic behaviors is to learn how the principles of paralinguistic behaviors vary from one culture to another and how universal principles must be qualified and adjusted on the basis of cultural differences. This understanding will help people to use communication effectively in intercultural encounters.

2. THE NATURE OF PARALINGUISTIC BEHAVIORS

2.1. Description of Phenomena

Speech utterances not only convey information via spoken words and grammatical structure but also

include phenomena that, according to linguistic rules, have no direct function. These phenomena refer to the voice in which words are uttered and to their patterning in time. In face-to-face communication, speech utterances are accompanied by various body movements such as face and head movements, gestures, body postures, and body orientation. These vocal and nonvocal phenomena, which are either blended or associated with speech utterances, are called “paralinguistic behaviors.” Not all vocal modifications of spoken words are nonverbal; linguists distinguish between prosodic and paralinguistic features. Prosodic features, such as stress, tone, and juncture, follow the rules of language and affect the linguistic meaning of utterances. Paralinguistic features convey other kinds of information. They not only refer to the speech behavior of a single speaker but also comprise nonverbal aspects of a conversation between two or more speakers such as regulation of speaker roles and distance between bodies. Sometimes, the term “paralinguistic” is restricted to vocal features, excluding the nonvocal characteristics that are referred to as nonverbal behaviors or body language. This article uses the broader sense, comprising both vocal and nonvocal aspects of speech, although the focus is primarily on vocal aspects.

2.2. Measurement of Paralinguistic Behaviors

2.2.1. Levels of Analysis

Paralinguistic behaviors have been analyzed at four levels: at the motor–physiological level of the body organs that produce the signals, at the physical level using acoustic or spatial parameters, at the perceptual level of the various sensory (mainly auditory and visual) modalities, and at the functional level referring to “meaningful” voice or movement categories. Analysis techniques at the first three levels may be summarized as “microanalytic techniques,” whereas functional techniques may be referred to as “macroanalytic techniques.” Studies using direct recordings of muscle activities such as electromyography (EMG) are rare; most of the analyses carried out are based on audio or video recordings.

In many studies, human observers are used to assess paralinguistic behaviors. For some types of studies, the human assessment is indispensable because such studies focus on the perceptual properties of the utterances or on the inferences drawn by listeners. In other studies, the judgment of human observers is used as a

more readily available or more holistic measure as opposed to the rather analytically defined physical measures. The disadvantage might be that the human system is rarely able to isolate the various physical parameters from each other. The advantage might be that sometimes information is conveyed based on complex physical configurations that are more easily judged as holistic impressions than formalized in terms of physical parameters.

2.2.2. Vocal Behavior

Human vocal behavior is the joint product of the action of three muscle systems: the respiratory, phonatory, and articulatory systems. The action of these muscle systems leads to air pressure changes, which can be perceived by listeners and described in terms of acoustic parameters based on audio recordings.

Three major acoustic dimensions are distinguished: time, frequency, and amplitude. Time-based parameters are related to the number and length of sound and silence segments within the speech flow, to onset and offset parameters of speech passages, and to speaker switching. Amplitude-based parameters refer to the energy level of voice. Of the parameters based on frequency, the one used most often is fundamental frequency (F_0). It is defined as the number of repetitions of a complex wave per second, measured in hertz (Hz), and corresponds to the frequency at which the vocal cords open and close. Averaged over a speech utterance, it can be expressed as mean F_0 . Changes in F_0 may be measured in terms of F_0 variability or in terms of F_0 contour, referring to the course of consecutive F_0 values. Some important measures involve more than one dimension. For example, the voice spectrum refers to the frequency–amplitude pattern of a speech signal, showing the component frequencies of a complex waveform and their relative amplitudes.

At the perceptual level, the tone of voice, speech style, and conversation style are distinguished. Although there is no one-to-one relationship, the voice characteristics of pitch, loudness, and timbre are the perceptual counterparts of F_0 , energy level, and voice spectrum, respectively. Speech style can be assessed in terms of temporal properties, such as pauses and speech tempo, and in terms of speech disfluencies, such as “filled pauses” (i.e., interruptions of continuity filled by nonlinguistic vocalizations such as “ah,” “mhm,” and “er”) and slips of the tongue. The conversation style refers to features such as opening and ending a dialogue, speaker switching and

interruptions of the speaker by another person, turn-taking, and feedback signals.

At the functional level, voices may be characterized by holistic labels such as harsh, powerful, and pleasant, and speech styles may lead to impressions such as halting and hectic speaking. Feedback signals and interruptions in conversation may signal interest or attentiveness as well as criticism or disagreement.

Table I illustrates the common measures at the acoustic and perceptual levels and gives some examples of functional characterizations of voice, speech, and conversation style.

2.2.3. Nonvocal Behavior

Analysis of nonvocal paralinguistic behaviors sometimes relies on impressionistic descriptions of real-time behavior, but it is based mostly on video recordings. The most common microanalytic technique for the analysis of facial movements is the Facial Action Coding System (FACS) developed by Ekman and Friesen in 1978. It is an anatomically based system for identifying the muscular contractions (so-called action units) in the brow, eye, and mouth regions responsible for changes in facial movement that roughly correspond to functional descriptions such as various kinds of smiling and various emotions. The original manual coding system has been automated in terms of digital feature point tracking. A microanalytic technique for the study of gestures and body movement is provided by the Bernese System, which allows a quantitative description of body and gestural positions and movements. Functional characterizations of gestures distinguish emblems, illustrators, and adaptors. Emblems directly translate words or phrases, for example, the signs for “yes” and “no.” Illustrators accompany verbal utterances and clarify their verbal meanings, for example, upward movements that accompany the verbal expression “It’s up there.” Adaptors refer to movements that have no communicative function but serve some personal need, for example, scratching one’s head until the itch is eliminated.

2.3. Possible Functions of Paralinguistic Behaviors

On the one hand, paralinguistic behavior is a product of the speaker’s biological endowment as well as of the speaker’s cognitive and emotional state. Compared with language, information conveyed by paralinguistic cues is less controllable by the speaker. For example,

TABLE I
Acoustic, Perceptual, and Functional Characteristics of Vocal Behaviors

	<i>Acoustic level</i>	<i>Perceptual level</i>	<i>Functional level</i>
Voice	Frequency- and amplitude-based parameters Mean fundamental frequency (F_0) F_0 variability, F_0 range F_0 contour Energy level Measures of frequency spectrum	Tone of voice Pitch level Pitch variation, pitch range Intonation, speech melody Loudness Timbre, voice quality	Voice characteristics High voice Exaggerated intonation Soft voice, powerful voice Harsh voice, pleasant voice
Speech	Time-based parameters Duration of speech utterances Number and duration of silences Sound–silence ratio	Speech style Amount of speaking Number and length of pauses Speech rate, tempo Filled pauses Intrusions Disfluencies	Speech style Hectic speaking, halting speaking Hesitant speaking
Conversation	Time-based parameters Onset and offset of speech passages Speaker switching	Conversation style Opening and closing of conversation Speaker switching Turn-taking signals Interruptions Feedback signals	Conversation style Cooperative, intrusive Attentive, inattentive, criticizing

Note. F_0 , mean fundamental frequency.

the experience of stress often constricts the vocal cords, thereby creating an increase in vocal pitch. This unintentionally given information has been called “nonverbal leakage.” On the other hand, many aspects of voice, speech style, and face and body movement are managed and applied deliberately. For example, a speaker may increase loudness and raise pitch to prevent an interruption by the listener. In that sense, paralinguistic behavior may serve communicative purposes similar to those of verbal behavior. Yet there are some important differences. First, the information is less explicit because there is no unambiguous relationship between the cues emitted and their meanings. Second, compared with language, the relationship between cues and meanings is more iconic than arbitrary (i.e., the cues bear some intrinsic resemblance to the meanings that are expressed). For example, a loud voice by itself expresses a kind of potency. Third, compared with language, paralinguistic signals can be

encoded continuously instead of discretely; that is, modifications can be applied in a gradually varying manner without being subjected to fixed steps. For example, the voice can be raised in varying degrees, whereas a verbal appeal requires decisions about the use of specific terms. Implicitness and ambiguity sometimes may be an advantage for the speaker as well as for social interaction. For example, it might be more polite and less disruptive for social harmony to express anger toward the addressee through one’s voice or facial expressions rather than through words.

3. THE RELEVANCE OF CULTURE

Culture is not opposed to nature; rather, as a consequence of phylogenetic evolution, it is part of the natural endowment of humans. However, what can vary is

that there are specific forms of culture. In this sense, the term “culture” is used as a set of guidelines that individuals share as members of a particular society and that tell them how to view the world and how to behave in relation to other people. Cultural guidelines are transmitted from one generation to the next mainly by symbols. The most important system of symbols by which culture is transmitted is language. Although the general ability to use language must be viewed as species-specific, the specific language spoken by an individual is not. It is, as Hofstede stated, a “vehicle of culture.” In some sense, it is even a part of culture given that it has evolved simultaneously to the cultural tradition. Similar to the norms and rules of culture that are transmitted by language, language itself must be acquired by an individual during ontogenetic development. Therefore, because paralinguistic behavior occurs simultaneously with speech behavior, the question arises as to what extent it can be considered independent of the specific language that an individual uses. Whether such an abstraction is possible must be demonstrated by analyses showing equivalences in paralinguistic behaviors among users of various languages.

If cultural differences are to be investigated as antecedents of individual behavior, meaningful dimensions that differentiate cultures must be specified. The most important approach for doing so was used by Hofstede. Based on factor-analytic evaluation of questionnaires administered to members of more than 50 countries, he extracted four bipolar dimensions that he called “individualism–collectivism,” “power distance,” “masculinity–femininity,” and “avoidance of uncertainty.” The most investigated of these four dimensions is individualism–collectivism. Individualist cultures foster the needs, wishes, and desires of individuals; as such, they encourage autonomy, separateness, and uniqueness. Collectivist cultures foster the needs, wishes, and desires of in-groups over individuals; these cultures encourage values such as social harmony, cohesion, cooperation, and conformity. In individualist cultures, the self–other relationship is perceived as more independent, whereas in collectivist cultures, it is construed as more interdependent. Sometimes, collectivist cultures are also characterized as “high-context” cultures, as opposed to the “low-context” cultures typical of the individualist orientation. A high-context culture is one in which much of the information is implicitly inferred from the situational context and from shared experiences. A low-context culture is one in which most of the information is explicitly stated in the verbal message.

4. EVOLUTIONARY CONTINUITY IN COMMUNICATION

If human language communication is compared with primate vocal communication, some qualitative differences can be found. First, the relationship between sound and meaning is arbitrary and not iconic. Second, the minimal sound units (phonemes) have no meaning by themselves but distinguish different meanings (e.g., the phonemes [r] and [l] have no meaning in English but discriminate the meanings of the words “read” and “lead”). Third, the most dominant principle of sound production is articulation and not vocalization. Fourth, single units are not just repeated or intensified but are combined by rules at different hierarchical levels (i.e., phonological, morphological, lexical, syntactic, and semantic).

Although the symbol system of language must be considered a species-specific feature of humans, vocal communication has its precursors in nonhuman animal behavior. The qualitative differences between human language and nonhuman animal vocal communication do not rule out that there also exist evolutionary continuities of communication from animals to humans in forms and functions. As noted previously, paralinguistic behaviors show at least two properties similar to those of animal communication: iconic relationship to meaning and continuous encoding. Therefore, it makes good sense to study the evolutionary roots of language. The communication of sender identity, emotional states, and interpersonal relationships seems to be particularly well suited for study. For example, birds and mammals use harsh, relatively low-frequency sounds when they are hostile and use higher frequency, more tone-like sounds when they are frightened, appeasing, or approaching in a friendly manner. In 2002, Soltis and colleagues reported that certain responses of squirrel monkeys to audiotaped vocal calls reflect the affiliate relationship between sender and receiver. Although Darwin assumed that it serves the adaptation of an organism to communicate its state as precisely as possible to other organisms of the same species to allow cooperation and minimize the danger of lethal conflict, this assumption has been challenged by modern sociobiologists. According to their view, the basis for evolutionary adaptation is not cooperation but rather struggle between individuals, and natural selection favors individuals who successfully manipulate the behavior of other individuals. Applied to paralinguistic behavior, this means that expressive displays serve strategic purposes rather than simply mirroring emotional states and goals.

Based on those assumptions and results, it can be fruitful to look at similarities and continuities in animal and human communication. It is not impossible to find instances of communication that do not obey the rules of the system of language but reflect phylogenetic older layers of communication in humans. For example, some researchers have claimed that the vocalizations of infants are strikingly similar for humans, lions, polar bears, cats, and gorillas.

5. PARADIGMS FOR THE STUDY OF PARALINGUISTIC BEHAVIORS

5.1. A Functional Framework

Paralinguistic behaviors have been investigated in various disciplines. Among them are linguistics, psychotherapy, social psychology, evolution biology, and expression psychology. To evaluate results and hypotheses with respect to cross-cultural issues, a systematic framework is required. Research may be organized around a classification of material aspects (e.g., acoustic or perceptual properties) as well as around functional issues (e.g., questions closely related to social interaction processes). It seems more parsimonious to focus on the functional perspective because in that case the significance of results, in terms of human universals and cultural differences, can be evaluated easier. A basic assumption of the functional approach is that different patterns of behavior (in terms of material properties) may serve the same function in different cultures, and in turn the same pattern of behavior may serve different functions in different cultures. Starting from a functional classification, researchers must determine to what degree a given function is present in different cultures and by what material properties it is realized.

Two different functional paradigms are presented here: the communication model proposed by Schulz von Thun in 1999 and the Brunswikian lens model proposed by Scherer in 1982. The former is orientated toward verbal communication, whereas the latter was originally developed in the context of general perception and later adapted to social perception research.

5.2. The Communication Model of Schulz von Thun

Schulz von Thun's communication model represents an elaboration of Bühler's organon model, the speech act theory, and Watzlawick and colleagues' communication

theory. According to that model, the communication process consists of three distinct components: the sender, the message, and the receiver. The sender and receiver do not act completely independent of one another; they may change their roles. The receiver may give feedback signals that affect the sender. The message, which includes verbal as well as nonverbal properties, is emitted by the sender and decoded by the receiver. There is no one-to-one correspondence between what the sender emits and what the receiver decodes; the sender may emit more than the receiver can decode, and the receiver may perceive or infer other characteristics than those emitted by the sender. Concerning the message or, more specifically, the speech utterance, a distinction is drawn between what is said and how it is said. The former refers to the content of the message, whereas the latter refers to the relationship between the sender and the receiver. The relationship is subdivided into three functional aspects: expression of situational and habitual states of the sender, appeal to the receiver, and the kind of interpersonal relationship between the sender and the receiver.

The four functional aspects may be encoded by all material properties, although to different degrees. For example, an appeal to the receiver can be expressed through words underlining the urgency or legitimacy of a request or through characteristics of the voice signaling that the sender does not expect any resistance. Not all aspects are equally present in all messages; the relative weight of each aspect may vary in different situations. One can assume that cultural norms regulate which aspect is displayed to what degree as well as what verbal and nonverbal properties are to be used in which situation.

5.3. The Brunswikian Lens Model

Schulz von Thun's communication model focuses on products or outcomes of communication and does not give much attention to the processes leading to those products. To throw light on these processes, some investigators have adopted Brunswik's lens model as their research paradigm. Two kinds of processes are distinguished: (a) the externalization of the speaker's traits and states leading to objectively measurable or subjectively perceivable cues of a trait or state and (b) the listener's use of different cues to make judgments on the speaker's states or traits. Implementing the lens model involves three steps. One step is to investigate the process of externalization by measuring various physical qualities, perceptual qualities, or both and

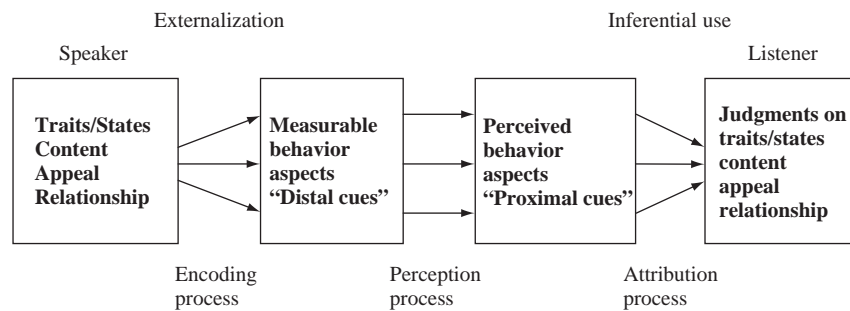

FIGURE 1 A modified version of the Brunswikian lens model.

determining which of these correlate with various speaker features that have been either manipulated or assessed by some objective index (e.g., test scores). This step serves to identify the ecological validity of various distal (i.e., objectively measurable) or proximal (i.e., perceivable) cues. A second step is to determine the accuracy with which listeners can identify the speaker's traits and states from paralinguistic cues. This is done by correlating listeners' judgments with the objective indexes of the speaker's traits and states. A third step is to investigate the specific kind of paralinguistic cues that listeners use to make their attributions. This is performed by correlating various physical or perceptual cues with listeners' judgments. This step identifies listeners' inferential use of cues.

A shortcoming of the lens model is that the communicative function of speech utterances is nearly completely ignored. In terms of Schulz von Thun's communication model, the expression function is stressed without taking into account the aspects of appeal, the kind of interpersonal relationship, and the content of the message. To overcome this weakness, a modified version of the lens model is presented (Fig. 1).

It is assumed that both externalization and use of cues are affected by cultural norms and rules. The model provides a guideline to examine these cultural variations.

6. EXTERNALIZATION OF PARALINGUISTIC BEHAVIORS

6.1. Gender and Age of the Speaker

There is little doubt that there are voice and speech characteristics that mark the personal identity, gender, age, and ethnic background of a speaker. Such

long-term speaker-characterizing features are of two different sorts. One type arises from physical characteristics of the vocal and respiratory apparatus and is, to a high degree, beyond volitional control. For example, men and boys usually have louder and lower pitched voices than do women and girls as a result of having a larger respiratory volume as well as longer and thicker vocal cords. Elderly individuals often experience changes in voice quality and loudness due to factors such as ossification of the vocal cords, diminished respiratory capacity, and reduced coordination within the central nervous system. The second type of characterizing features is the product of the way in which the speaker habitually sets his or her vocal apparatus for speaking. These features are under potential control, yet they are not usually deliberately managed by the speaker.

In all societies, age and gender are important social categories, and individuals of different genders and ages may be discernible on the basis of specific voice and speech characteristics. However, both the specific features and the magnitude of differences may be partly affected by cultural factors.

Usually, women and girls show higher pitch and greater pitch variability than do men and boys; however, the magnitude of female–male differences varies across cultures and even across social classes. It may be hypothesized that the magnitude of these differences relates to differences in the masculinity–femininity dimension. Because masculine countries stress gender role differences, voice differences should be more pronounced than in more feminine cultures. Consistent with this hypothesis is that in Japan, a country with a high masculinity index, the difference in pitch (as well as in verbal style) has been found to be higher than that in England and The Netherlands, two countries with a moderate masculinity index. However, the three

countries differ even more with respect to power distance, so that one cannot unambiguously attribute the voice and speech differences to differences in masculinity. It would be of interest to compare various countries of equal power distance differing exclusively in masculinity (e.g., with Japan as a masculine country and Thailand as a feminine country).

In a number of studies, F_0 has been investigated as a function of age. The average F_0 in babies has been found to be extremely high when they are crying (approximately 400–600 Hz) and somewhat lower when they are babbling (approximately 300–500 Hz). It decreases for both males and females with increasing age, at least until adulthood is attained. The changes during adulthood show a marked difference between the sexes, at least in Western societies. For women, no evidence of any systematic changes has been found. On the other hand, average F_0 in men appears to decrease slightly from young adulthood to middle adulthood and then to shift upward from approximately 65 years of age onward. One explanation relates the upward shift in old age to a weakening of the gonads in secreting hormones, a process comparable to puberty, a period when one generally finds a marked decrease in F_0 . However, it is also possible to explain this shift without recourse to biology. F_0 has been shown to be affected by both habitual and transitory stress; most people tend to respond to stress with an increase in mean F_0 . Thus, it seems reasonable to hypothesize that the upward shift reflects not only age-related physiological changes but also emotional tension caused by factors such as forced retirement, fewer social contacts, decreasing self-sufficiency, and low status associated with old age in Western societies. Cross-cultural comparisons might well shed some light on this issue, but there has been a lack of such studies so far. One may assume, for example, that factors such as the evaluation of old age, in terms of status and institutional support in a particular culture, do play an important role in mediating voice changes.

6.2. Personality Traits of the Speaker

Many attempts have been made to show that paralinguistic behaviors express long-term personality traits. In most of the studies, the central issue is the accuracy with which listeners can judge the speaker's personality on the basis of his or her voice. According to the

lens model, however, the first step must be to investigate whether or not personality traits are externalized in objectively measurable distal cues. This can be done by assessing the actual correlations between objectively measured characteristics and valid criteria of personality traits.

There is some evidence from research done in Western countries that personality traits such as extraversion and dominance are indicated by acoustical cues such as energy level and F_0 . However, the direction and magnitude of correlations, especially with respect to F_0 , turned out to depend on particular situations. In situations where competitive achievement is encouraged, dominant and extraverted people tend to speak in a higher pitched voice (i.e., with a higher mean F_0) than do submissive and introverted people. However, in neutral situations or in situations where communicative abilities are stressed, extraversion and dominance are associated with a lower pitch. Presumably, different facets of extraversion are addressed. Achievement-orientated situations favor ergotropic facets of energy, ascendance, and ambition, whereas neutral or interpersonal communication situations evoke a preponderance of trophotropic (rest) facets of warmth and gregariousness. Moreover, there are considerable cultural differences even within different Western countries. For example, the correlations are more pronounced in Americans than in Germans.

One may assume that in collectivist countries, the correlations between voice and personality are even smaller. When group conformity is stressed instead of individuality, personality traits as markers of the self should be externalized to a much lower degree than in individualist cultures, where the independent self is more likely exhibit cues that clearly mark individuality and serve self-presentation. Thus, it might not be surprising that the correlations between personality and voice obtained in Germany are smaller than those obtained in the United States given that Germany showed a lower index of individualism than did the United States.

6.3. Situational States of the Speaker

Often, the voice is considered to be a direct means of expression of perceived stress. Hence, there have been numerous attempts to find paralinguistic correlates of situational stress. The significance of acoustic cues has

been tested by comparing the differences against some baseline conditions such as neutral or positive situations. Stress has been experimentally induced by threatening movies, increased cognitive workload, and negative feedback.

Stress is often accompanied by increased muscle tension. Thus, it has been hypothesized that increased tension in the respiratory muscles leads to louder speech and that increased tension in laryngeal muscles leads to higher F_0 . Increased tension in the respiratory muscles increases subglottal pressure, thereby producing a slightly higher F_0 . Because of the increased muscle tension, the F_0 range of the voice should be narrowed and the number of harmonics should also decrease. Moreover, it has been hypothesized that the speech rate and the number of disfluencies increase with higher stress. In general, these hypotheses have been confirmed; most people respond to increased stress with an increase in F_0 relative to baseline, a decrease in the F_0 range, an increase in the speech rate, and an increase in the number of disfluencies. However, there also are considerable interindividual differences. Some people even show a reversed pattern, that is, a decrease in the mean F_0 and an increase in the F_0 range. There is some evidence that these interindividual differences mirror different coping styles such as repression-sensitization. Although they refer to personality differences in arousal control, there is no doubt that cultural norms strongly affect the expression of arousal by so-called display rules. With respect to facial expression of fear, it could be documented that the displays differ across cultures depending on the social situation. When alone, Japanese and American participants displayed exactly the same facial expressions of fear; however, when in the presence of another person, their expressions differed dramatically, with the Japanese invariably smiling rather than displaying their fear. Because articulatory and facial muscles are partially identical, one may expect some parallels to facial expression in the voice. Developmental studies suggest that the regulation of socially disruptive emotions is acquired at an early age. For example, Japanese preschool children respond to frustrating situations with less aggression and anger (as rated on the basis of voice, face, and body) than do U.S. children. To account for the differences, it is hard to determine whether they reflect differences in open expression or differences in experience of emotions due to different interpretations of frustrating events.

6.4. Emotional Content

A person would not be accepted as speaking a language properly if he or she did not deliver the utterances in the pitch pattern, stress pattern, and temporal pattern of grouping and pausing appropriate for that language. Although these prosodic features affect the linguistic meaning of a sentence, the emotional content of an utterance may be expressed independently. There is a long history of researchers trying to identify specific paralinguistic patterns associated with specific emotional contents, including the contributions of the German "expression psychology" and research by evolution biologists. It is a basic assumption that paralinguistic features exist and that they have an isomorphic relationship to their meaning. The validity of distal and proximal cues indicating a particular meaning can be tested by asking speakers to deliberately express a specific emotion, typically one of the six or seven basic emotions: anger, disgust, fear, happiness, sadness/grief, surprise, and (sometimes) contempt. If physically measurable or proximally perceivable correlates of the expressed meanings can be established, the validity may be ensured. Consistent correlations have been found only for anger and sadness/grief, two emotions that may be characterized as the poles of the dimension of activity. Anger seems to be indicated by high F_0 , high F_0 variability, high energy level, and high speech rate. The opposite characteristics seem to be associated with sadness/grief: low F_0 , narrow F_0 range, low energy level, and low speech rate. So far, there is little evidence for universal patterns discriminating between the poles of other emotional dimensions such as valence (positive vs negative). One reason might be that a particular emotion or emotional dimension is indicated by specific combinations of different cues (i.e., amplitude, frequency, and temporal patterns) that are difficult to quantify. Another reason might be that culture-specific display rules determine in which situations certain patterns may undergo a so-called ritualization, indicated by exaggeration and repetition of single-pattern elements.

6.5. Appeal to the Listener

Although speech behavior may occur without reference to listeners, in most natural speech situations the speaker addresses listeners with the purpose of exerting some influence on the listeners' thoughts, feelings, and behaviors. This function of speech behavior is often referred to as "appeal." It implies an adaptation

toward the specific addressees. The listener variables to which the speaker may adapt can be of different kinds. For example, the speaker may talk to persons of higher, lower, or equal status; to persons of the opposite sex; to familiar persons, or to strangers. Within empirical studies conducted in this field, the most salient feature of listeners that speakers adapt to is age. Thus, a speaker may talk in a loud voice and very slowly to older people, assuming that they are hard of hearing and have difficulty in comprehending. The best-known phenomenon in this area is so-called baby talk (*Ammensprache*, *Motherese*, or infant-directed speech), a voice and speech style used by adults, and even by children, when speaking to infants. Although the phenomenon has been found in a variety of cultures and so may assume the status of a universal, the extent of use and the upper limit of the addressee's age vary from culture to culture. Evidence from diverse linguistic and cultural backgrounds shows that infants prefer the baby talk to the adult speech style by showing more attention, more affective behavior, and more positive vocalizations. Infant-directed speech differs from adult-directed speech by phonetic, morphological, syntactic, and paralinguistic features. Most salient are the paralinguistic features. The most notable acoustic features of infant-directed speech, as compared with adult-directed speech, are its higher F_0 , wider F_0 range, slower tempo, and longer pauses. The differences in F_0 between infant-directed speech and adult-directed speech seem to be generally more exaggerated in Western cultures (e.g., United States, Australia, England, Italy, Germany) than in Eastern cultures (e.g., China, Japan, Thailand). This may be partly due to the differences between tonal and nontonal languages (e.g., Mandarin Chinese and Thai vs English, German, and Italian). For example, in tonal languages, overly exaggerated F_0 contours superimposed on a sentence may disrupt the lexical information conveyed by word tone. However, one cannot rule out the possibility that the differences also map onto cultural differences in the acceptability of open emotional expression. For example, in Japanese (a nontonal language), the exaggeration of F_0 contours in infant-directed speech, compared with that in adult-directed speech, is also less pronounced. There appear to be three main functions of infant-directed speech in that (a) it serves to initiate and maintain the child's attention, (b) it communicates empathy, and (c) it facilitates language acquisition. Because language-specific features, such as prosodic, lexical, and syntactic features, increase with increasing age of the child, it can be

concluded that facilitating infant socialization by engaging attention and empathy dominates at younger ages, whereas facilitating language acquisition prevails during later infancy.

A specific kind of appeal is used in the context of street traffic. For example, a pedestrian crossing a road must ensure that an approaching car will permit him or her to cross. In this case, eye contact and hand and body movements exchanged between the driver and the pedestrian have the function of emblems. Although these emblems may have evolved from universally valid iconic gestures, they have been culturally transformed and their situation-specific meanings must be learned. Eye contact between the driver and the pedestrian may universally signal "I see you," but in some cultures the action-relevant message is "Okay, cross the street," whereas in other cultures the appeal that is expressed is "Pay attention or it will be dangerous for you." Thus, merely decoding the literal meaning of the gesture will be misleading and may have severe consequences.

6.6. Interpersonal Relationship between Speaker and Listener

When two or more people are engaged in conversation, they take turns speaking. Usually, they manage to achieve a fairly smooth synchronization of utterances without too many interruptions and silences. The emerging "rhythms of dialogue" or "accommodation" patterns are highly dependent on the particular speech situation (e.g., formal vs informal, face-to-face vs telephone conversation) and especially on the kind of relationship between the speakers (e.g., mother-child, teacher-student, inferior-superior, like-dislike). Although considerable variations do exist within a culture due to interindividual differences (e.g., extraversion), cross-cultural differences appear to be even larger. For example, the physical duration of silence following an utterance by one of the communication partners that is experienced as appropriate, polite, or uncomfortable is highly regulated by cultural norms and conventions. Roughly speaking, utterances tend to be longer and interspeaker silences tend to be shorter in Western cultures than in Eastern cultures. This may reflect the difference between low-context cultures and high-context cultures. To a member of a high-context culture, what is omitted is an essential part of the communication. Therefore, silence is highly valued. To a member of a low-context culture, what is omitted

creates ambiguity that will be eliminated by explicit verbalizing.

The coordination between the speaker and the listener is perfect when the speaker sends the correct signals for a change of turn and the listener responds to these signals. Also, the listener may interrupt the speaker to take a turn. Interruptions imposed by the listener may signal positive feedback or act as a power device to get control of the conversation. In this vein, two main types of interruptions are distinguished: cooperative and intrusive. An example of the former is a vocalization signaling agreement, whereas an example of the latter is a loud voice abruptly interrupting the speaker. It has been hypothesized that in a collectivist culture that stresses social harmony, individuals send more cooperative interlocutor signals, whereas in an individualist culture that encourages self-assertion and competition, intrusive interlocutor signals dominate. In 2001, Li tested this hypothesis using simulated doctor–patient conversations between either Canadian or Chinese participants. The comparison of the two intracultural conversation conditions showed that Chinese participants engaged in significantly more cooperative interruptions than intrusive ones, regardless of their roles as doctors or patients. In contrast, the Canadian doctors performed significantly more intrusive interruptions than cooperative ones. Although the coding procedures did not differentiate between linguistic and paralinguistic cues, it can be assumed that the latter determined categorizing to a considerable extent. Researchers have observed similar differences in interruption patterns between members of other collectivist cultures (Japanese and Thai dyads) and members of another individualist culture (British dyads). These findings may be taken as providing strong support for Markus and Kitayama's theory that collectivists construe the self–other relationship interdependently, whereas individualists clearly mark their personal boundaries.

In addition to sending audible feedback signals, interlocutors coordinate their conversations through spatial behavior, eye contact, and touch. Cultures develop more or less explicit rules about the appropriate use of these behaviors. Those who stand or sit too far away are seen as cold, aloof, and withdrawn, whereas those who come too close are seen as embarrassingly intrusive and overly intimate. Anthropologists distinguish between contact cultures and noncontact cultures. People from contact cultures stand closer, face more directly, touch, and look more than do people from noncontact cultures. Contact cultures include

Arabs, Latin Americans, Southern Europeans (e.g., Greeks, Turks), and a number of African cultures, whereas noncontact cultures include Asians and Northern Europeans. Although it has generally been observed that U.S. Americans stand less close and touch less than do Arabs and South Americans, there are considerable differences within the United States: Hispanics stand closer than do Anglos, and most studies find that African Americans interact at greater distances, look less, and adopt a less direct orientation than do Whites. Moreover, these differences vary with age; African American children stand closer than do Whites, whereas adolescents and adults stand farther away from one another. Age differences have also been observed in Japan, which is generally regarded as a noncontact culture: in public situations, whereas adults show very little body contact, young Japanese women touch each other often.

7. ACCURACY OF LISTENERS' INFERENCES

7.1. Methodological Considerations

To study the accuracy with which listeners can infer traits or states of the speaker and emotional contents of the message on the basis of the speaking voice, listeners are presented with a voice sample and must make a judgment. The accuracy is assessed by correlating the judgments with some objective criteria of states, traits, or content. The voice samples used as stimuli may be, to a great extent, similar to those elicited in externalization studies. However, to prevent listeners from being biased by the linguistic content of the message, either the stimuli must consist of a standard text (spoken or read) or the linguistic content must be masked. Most masking techniques applied are low-pass filtering and random splicing. Low-pass filtering preserves pitch and loudness contours as well as temporal information, such as pauses and speech rate, but it removes most features of voice timbre due to the elimination of upper frequency parts of the voice spectrum. Random splicing is carried out by splitting the speech signal into short segments and then concatenating the segments in random order. It preserves the static voice characteristics of pitch, loudness, and timbre but eliminates the dynamic characteristics such as pitch contour and temporal properties. Judgments are obtained by having listeners either rate a particular trait, state,

or emotion on a rating scale or choose an item from a list of response alternatives.

7.2. Personality Judgments

In many of the earlier studies investigating the accuracy of personality judgments on the basis of voice, researchers have found that there is consensual agreement among the judges but that the validity of judgment is low. Based on these findings, it has been concluded that the judgments reflect “vocal stereotypes” rather than accurate inferences. This conclusion was challenged by arguing that invalid personality measures have been used and that the functional perspective of perceived personality traits has been neglected. In this vein, it has been suggested that people should be most attuned to those traits about which correct or incorrect identification has implications for actions relevant for survival and reproduction in the evolutionary past (e.g., social dominance, extraversion). More recent studies have shown that these traits can be inferred from voice with at least moderate accuracy. This does not necessarily contradict the situation specificity of distal cues indicating these traits given that judges may take into account the particular speech situation when making inferences. However, similar accuracy scores might not be obtained universally. Cultural differences may emerge due to several factors. First, real differences may exist in mean levels of personality traits such as extraversion and dominance. Second, the measurement of personality traits through questionnaires might not be equivalent across cultures due to various self-accessibility of personality traits and various response styles. Third, personality traits as markers of personality may be externalized to various extents due to cultural rules.

7.3. Judgment of Emotional Content

Considering that the emotional content of an utterance can be expressed independently of lexical and syntactic structure, a question arises as to whether listeners are able to accurately recognize the particular emotion the speaker has portrayed. The criterion for accuracy typically used is whether the judges correctly identify the emotion that the speaker has been asked to portray. Psychologists have often debated whether the recognition of emotions is universal or whether it varies by culture. Three competing hypotheses have been proposed. The strong universalist position follows Darwin and states that the expression and recognition of

emotions is biologically programmed and, hence, universal. The weak universalist hypothesis asserts that specific emotional categories are largely culturally specific but that broad dimensions, such as activity/arousal and valence, are universal. The interactionist position acknowledges that emotions are programmed biologically but claims that the process of learning to control both expression and perception is highly dependent on cultural factors.

Empirical studies have yielded the following results:

1. Emotions are recognized from voice and face at a better-than-chance level within and across cultures. In addition, accuracy differences among various emotions are highly similar within and across cultures.

2. Cross-culturally, some emotions are better recognized than others. Among the seven basic emotions, fear and disgust are the most poorly recognized, whereas happiness is the most accurately recognized.

3. Accuracy is higher when emotions were both portrayed and identified by members of the same national, ethnic, or regional group, suggesting a so-called in-group advantage.

4. Cross-cultural accuracy is different across channels. In general, the face seems to be the best source of information, although there are emotion-specific differences. Happiness is most accurately recognized from the face but least accurately recognized from the voice. In comparison, anger and sadness are most accurately recognized from the voice but relatively less accurately recognized from the face. Likewise, the in-group advantage seems to be smallest for happiness in the face and greatest for happiness in the voice. Fear shows a large in-group advantage in both the face and the voice, whereas anger shows a relatively small in-group advantage in both the face and the voice.

5. When emotions are expressed by speakers of a foreign language, accuracy is higher for judges whose mother tongue is close in linguistic structure to the language used by the speaker than for judges whose mother tongue is completely different.

6. The evidence for differences in culture per se is not clear-cut. Some results suggest that collectivists have difficulties in both expressing and recognizing emotions (e.g., anger, contempt) that might be potentially disruptive to social interaction. However, it is not clear to what extent the results can be attributed to a mismatch between the cultural background of the speaker and the listener.

Evaluating the three hypotheses formulated previously, it seems that the strong universalist position

cannot be held. There is some support for the second hypothesis in that the dimension of activity/arousal, but not the dimension of valence, seems to be present universally. The interactionist hypothesis fits the data best. Certain core components of emotions seem to be universal and are likely to be biological. However, the style of expression and recognition is governed by cultural conventions. Linguistic rules also appear to have a strong impact. Although linguistic content has been controlled experimentally, language-specific prosodic rules are likely to affect both expression and recognition. This parallels the results found in infant-directed speech, where language-specific and language-independent principles also seem to be intricately linked.

There has been some criticism concerning the studies of emotional recognition centered around the fact that both stimuli and elicitation of responses may lack ecological validity. Also, because responses are typically elicited as forced choices, the high accuracy scores obtained merely show that a particular emotion can be reliably discriminated from other emotions. They do not show that a particular emotion can be correctly identified in reality when no response alternatives are provided. In addition, some researchers have questioned the ecological validity of stimuli. Although deliberately portrayed emotions may exhibit stylized forms of paralinguistic behaviors intended to communicate, these might not be typical in the spontaneous expression of experienced emotions. Instead of mirroring actual emotional states, the latter may be influenced by subjective control mechanisms such as coping and interpersonal manipulation strategies. Moreover, the same emotion may produce different types of expression.

Finally, it has been argued that in face-to-face communication, the listener is presented with information from multiple channels. Thus, optical information may override acoustic information. Compared with judgments of the voice alone, the addition of video information—especially of the face—has been found to be associated with a large additional increase in cross-cultural accuracy. Moreover, in natural communication settings, judgments on voice and behavioral responses to voice usually are affected by the linguistic content of the message. In some cases, linguistic and paralinguistic sources of information may lead to similar inferences, but in others there may be discrepancies. The source of information on which the listener relies most may vary according to the particular speech situation, but it may also be affected by cultural factors.

8. USE OF PARALINGUISTIC CUES BY LISTENERS

8.1. Methodological Considerations

To investigate the kind of acoustic cues that listeners use, correlations between inferences and acoustic measures of the speech signal may be applied. However, results might not always be conclusive because one cannot be sure which of the many cues available have been used and to what extent important cues went unmeasured. Thus, it is useful (and eventually necessary) to manipulate the speech signal. Although speakers can be asked to deliberately vary the paralinguistic features, they may unintentionally vary other features as well. Therefore, experimenters must be able to manipulate features synthetically. This can be done either by systematically changing the digitized speech sample with a computer or by using a speech synthesizer. Typically, F_0 , energy level, and pauses have been manipulated.

The aim of some researchers is to identify proximal representations that lead to particular inferences. In that case, listeners are asked to judge the speech signal with respect to perceptual attributes such as soft voice, high voice, powerful voice, unpleasant voice, and halting or hectic speaking.

8.2. Cues to Personality Traits and Situational States

Results obtained in studies on acoustic cues leading to inferences of personality traits and situational states are not quite conclusive. Typically, mean energy level and energy variation are positively associated with dominance and extraversion judgments. With respect to F_0 and speech rate, the results are less consistent and seem to be both situation- and gender-specific. Some researchers have found that speech rate is positively correlated with extraversion and dominance, whereas other researchers have found a negative correlation. High mean F_0 seems to lead to the attribution of high dominance in male voices but not in female voices. Situational stress may be inferred from an increased F_0 relative to a baseline.

Results obtained in studies using perceptual cues indicate that extraversion and dominance are inferred from loud and powerful voices. This is consistent with the findings on acoustical cues. Results on inferences drawn from pitch are as inconsistent as those drawn from F_0 . High-pitched male voices are sometimes

judged as extraverted and dominant and, at the same time, as emotionally labile and disagreeable, although they are sometimes judged as less dominant and more agreeable. High-pitched female voices are usually judged as kind, humorous, immature, and agreeable.

Two reasons may account for the inconsistent results. The first is that judges rely more on configurations of multiple cues than on single cues. In addition, F_0 and energy level may be acoustically insufficient to describe relevant configurations. The spectral structure of speech, which determines how the voice sounds, may outweigh the importance of F_0 and energy level. For example, depending on the spectral structure, a high-pitched voice may sound childlike and be perceived as friendly, or it may sound shrill and be perceived as angry and aggressive.

The second reason is that judges are guided not only by vocal stereotypes but also by implicit personality theories. These are characterized by overgeneralizations and illusory correlations such as a negative correlation between dominance and emotional stability.

Although systematic cross-cultural studies on cues to attributions of traits and states are rare, there seems to be evidence of cultural differences. Because average loudness and tempo vary from culture to culture, misattributions from persons not familiar with the cultural standard may occur frequently. For example, Anglos who commonly speak in a softer voice and are not familiar with the Latin standard may erroneously attribute dominance and aggression to the louder voices of Latin people. Even familiarity with the general cultural standards does not prevent misattributions given that sometimes it is essential to analyze the situational demands in a culture-specific way. For example, in cultures stressing power distance, a higher ranked person will be judged as competent when speaking in a loud voice and a low tempo, whereas the same cues may lead to the attribution of boldness when exhibited by a subordinate person.

Cultural differences also seem to exist with respect to implicit personality theories. For example, the Chinese *shi gu*, which refers to “someone who is worldly, devoted to his or her family, socially skilful, and somewhat reserved,” is not an easily found stereotype in Western countries. On the other hand, the Western concept of an “artistic type” seems absent in Chinese. Thus, although it is easy for speakers of English or Chinese to refer to single personality traits (e.g., socially skilled, creative), each culture generates its own personality syndromes.

8.3. Cues to Emotional Content

Attempts to identify a set of vocal cues that reliably differentiate among the basic emotions have not yet been successful. In a classic experiment in 1972, Uldall presented listeners with a number of sentences on which 16 different F_0 contours had been imposed synthetically. The contours differed with respect to F_0 range, F_0 reached at end of contour, and shape. The listeners were asked to rate each sentence on several bipolar adjective scales representing the three dimensions of emotional meaning—valence, activity, and potency—defined by Osgood and colleagues in 1957. Both high activity and high potency were inferred from contours characterized by a wide F_0 range and a change of direction. A change of direction combined with a final rise led to the impression of a positive valence. The more smooth or monotonous a contour was, the more the judged meaning was dependent on the linguistic content of the utterance. The more lively a contour was, the more the judged meaning was stable and independent of linguistic content.

8.4. Selective Attention to Various Cues

In collectivist cultures, given that direct confrontation of another person is considered rude and undesirable and that paralinguistic information is less direct and less explicit than verbal information, one may assume that collectivist persons are more sensitive to paralinguistic cues than are individualists, who should be more attuned to linguistic information. In 2002, Kitayama and Ishii tested this hypothesis by using an interference paradigm similar to a Stroop task (i.e., a recognition task in which the print color interferes with the lexical meaning of a written word) to assess spontaneous attention to either linguistic or paralinguistic cues. In this modified Stroop task, lexical emotional content of a word interfered with vocal emotional content. Lexical and vocal meanings had previously been checked as equivalent in extremity in the two languages. Japanese participants (members of a collectivist culture) and English participants (members of an individualist culture) had to make a judgment of either vocal emotion or lexical meaning of an emotionally spoken evaluative word. As hypothesized, an interference effect by competing word evaluation in the vocal emotion judgment was significantly stronger in English than in Japanese. In contrast, an interference effect by competing vocal emotion in the word

evaluation judgment was stronger in Japanese than in English. This finding suggests that individualists are more attuned to direct communication of feelings involving words, whereas collectivists are more attuned to less explicit communication involving paralinguistic features. This does not contradict the notion that open expression of feelings is generally less acceptable in collectivist cultures than in individualist cultures; instead, it suggests that the communication of feelings in collectivist cultures involves paralinguistic behaviors rather than linguistic behaviors.

9. CONCLUSION

9.1. Universals and Cultural Differences

The aim of cross-cultural research on paralinguistic behaviors is to investigate to what extent such behaviors are used in a ubiquitously uniform manner and to what extent they are shaped by cultural factors. Addressing this issue, a modified version of the Brunswikian lens model may serve as a functional framework. Two kinds of processes are distinguished: externalization of paralinguistic behaviors by the speaker and use of paralinguistic cues by the listener. Both kinds of processes seem to be characterized by both universal and culture-specific principles.

The most uniform use of paralinguistic behaviors across cultures can be observed in adult speech directed toward infants. When speaking to an infant, adults accommodate their vocal behavior to the infant's cognitive ability and signal empathy, and the infant responds with attentive and affective signals. The paralinguistic features indicating infant-directed speech seem to be universal, although they are less pronounced in Eastern cultures than in Western cultures. The cultural differences cannot be attributed entirely to language differences (nontonal vs tonal languages). They also appear to map onto cultural differences in the social acceptability of open expression of emotion.

There is additional evidence for universality in decoding emotional meaning from paralinguistic behaviors. When emotions are intentionally portrayed, they are recognized quite accurately from voice and face both within and across cultures. This suggests that certain core components of emotional expression are not conventional and are probably biological. However, this does not imply that emotional experience is uniform across cultures or that specific emotions are

universally expressed in the same manner and with similar frequency. The wide variations observed in various cultures seem to reflect different display rules, that is, cultural rules that govern which paralinguistic behaviors are permissible and which are inappropriate in a social setting.

The most striking differences among cultures have been observed in paralinguistic behaviors that regulate the interpersonal relationship between speakers and listeners. It seems that members of individualist cultures send more signals that indicate self-focusing tendencies, whereas members of collectivist cultures exhibit more cues that stress harmony and cooperation. When giving feedback, listeners from individualist cultures tend to show their own feelings toward the utterance of the speaker, whereas in collectivistic cultures it is more important for listeners to signal a positive attitude even when they do not feel it.

Cultural differences have also been observed in the extent to which listeners use paralinguistic cues. Being presented with conflicting information from various channels, it seems that collectivists tend to be more sensitive to the less explicit information conveyed by the voice, whereas individualists rely more on the explicit information transmitted by the spoken words. This difference may reflect the difference between high-context cultures, in which the social meaning of situations is processed in a holistic mode, and low-context cultures, in which an analytic processing mode stressing the abstract meaning of words is preferred.

9.2. Applications to Intercultural Encounters

Cultural differences in paralinguistic behaviors have consequences with respect to intercultural encounters. The appropriate use of paralinguistic behaviors is needed to communicate effectively in a wide variety of intercultural situations. Success in business, teaching, politics, and private interpersonal relationships will depend in great part on the understanding and ability to display the culturally appropriate paralinguistic behavior when communicating with persons who are culturally different. Misunderstandings due to violations of cultural rules can result even if the words and grammar of the foreign language are appropriately mastered. In some cultures, the expectation is to mask, attenuate, or neutralize vocal and facial expressions of one's feelings. The listener must

recognize finer nuances of paralinguistic cues and pay more attention to the situational context in these cultures, as compared with cultures where feelings are openly expressed, to draw inferences about the feelings of persons from these cultures. Most notably, self-disclosure on the part of the speaker is likely to be interpreted as crude or even exhibitionistic in these cultures and may cause embarrassment.

On the other hand, in some cultures feelings are supposed to be dramatized, and so their withdrawal or suppression may lead to the impression of a cool and reserved person. However, as a practical maxim, one can assume that the lost benefit resulting from acting too reservedly in a culture stressing self-disclosure will be less than that resulting from acting too overtly in a culture where self-disclosure is taboo. The reason is that people generally pay more attention to behavior that is shown than to behavior that is not shown.

Lack of effectiveness in intercultural encounters may also result from inappropriate listening. The key to effective listening is participation. However, participation is inferred from different paralinguistic feedback cues in different cultures. In individualist cultures, feedback is expected to reflect the listener's comment on and "honest" attitude toward the content of the message conveyed by the speaker (e.g., feedback to the proposal of a business partner). In collectivist cultures, the listener will do better to just signal that he or she is actively attending to the speaker without giving his or her own comments.

GLOSSARY

contingent work Work done by part-time employees employed only temporarily (e.g., until a specific organizational goal is met or an operational subtask is finished).

core jobs Employment opportunities commonly viewed as permanent full-time contract positions.

peripheral work Any job in which the individual does not have an explicit or implicit contract for long-term employment or steady hours of employment.

Part-time work has generally been defined as whether an employee reports himself or herself as working part-time. Although the part-time workforce is acknowledged as being a heterogeneous group, most research has concentrated on comparing part-time employees with full-time employees across a range of criteria, most notably work attitudes and behaviors. Differences in work attitudes and behaviors are frequently found between part-time and full-time employees,

although the findings are inconclusive and very few theoretical frameworks have been put forward to understand or explain empirical differences. Likely explanations for different attitudes and behaviors across the two groups relate to theories of social exchange and motives for accepting employment.

1. INTRODUCTION

During the past 30 years or so, organizations have increasingly turned to part-time employees because they provide greater scheduling flexibility, meet market demands more efficiently, and reduce wage and benefit costs. For example, between 1971 and 1996 in Great Britain, the proportion of part-time employees nearly doubled from 15 to 29% of the workforce, increasing by 2.6 million. The proportion of part-time employees is similar in the United States, where part-time employees constituted 24% of the workforce and numbered more than 22 million employees in 2001, with the proportion doubling during the previous 40 years. Part-time employees also constitute the major proportion of the workforce for entire industries (e.g., service, retail), and part-time work is much more likely to be performed by certain demographic groups (e.g., women, older/younger workers).

Although this large part-time workforce is clearly important in terms of the increasing dependence on its productivity as well as its social implications, the part-time workforce is also interesting from a psychological

perspective. For example, some researchers have suggested that part-time workers view work differently than do full-time workers; thus, the way in which the jobs of part-time workers are designed, the human resource practices available to them, and the way in which they are managed all should differ from those of full-time employees.

Organizational researchers have largely neglected researching part-time employment. The majority of studies have simply compared part-time employees with full-time employees across a range of attitudinal outcomes. Too many of these studies have been atheoretical in design and simply documented empirical differences that are of limited lasting scientific value. Moreover, important areas of inquiry (e.g., differences among part-time workers) have been underresearched.

2. DEFINING PART-TIME WORK

There are two necessary components to a definition of part-time work. The first concerns the number of hours worked, and the second concerns comparisons with other forms of employment relationships. Fundamentally, part-time work has been defined by the number of hours worked per week. Government workforce data typically define part-time work as less than 30 to 35 hours per week. Part-time work has also been defined by whether the employee reports himself or herself as working part-time. In organizational research, the self-report definition of part-time work status (i.e., whether employed on a part-time or full-time basis) is used in the great majority of cases.

The second definitional issue is more complex and involves the distinction between part-time work and other forms of employment relationships. The key factor here is the extent to which part-time workers can be regarded as “contingent” or “peripheral” workers. Peripheral employment is equivalent, apart from minor differences, to the conceptual notion of contingent employment. These conceptualizations are rooted in core-periphery models of the workforce in which core jobs are commonly viewed as permanent full-time contract positions. Peripheral or contingent work has been defined as any job in which the individual does not have an explicit or implicit contract for long-term employment or one in which the minimum number of hours can vary in a nonsystematic way.

In early studies, part-time employees were synonymous with peripheral employees. However, there is

increasing support for the view that only certain types of part-time employees can be regarded as contingent employees. This view holds that permanent part-time employees are misclassified as contingent simply because they are not employed full-time and that permanent part-time employees are more likely to have contract conditions similar to those of core employees. For example, many permanent part-time positions permit long-term employment. Only certain types of part-time employees, such as part-time employees who are also employed on a temporary basis, are likely to fall within the definition of contingent workers. Distinguishing part-time work from other forms of employment is important because working part-time might not necessarily entail a subjective sense of being peripheral.

In conclusion, part-time work is typically defined by whether the employee reports himself or herself as working part-time. A further definitional issue is sensitivity to differences among part-time jobs, such as the permanence of the positions, because such characteristics are likely to be of substantive theoretical importance.

3. COMPARING THE WORK ATTITUDES AND BEHAVIORS OF PART-TIME AND FULL-TIME EMPLOYEES

Over the past 30 years or so, there has been a slow stream of studies examining part-time work where the dominant approach has been to compare the work attitudes and behaviors of part-time employees with those of full-time employees. Only the relationship between work status and job satisfaction and commitment have received any serious level of coverage, although some studies have considered other relationships such as work status and organizational climate, job involvement, and work characteristics.

Empirical research comparing part-time employees with full-time employees consistently finds differences on various work attitudes and behaviors. However, the findings are inconclusive. For example, across studies, part-time employees have been found to report higher, lower, and equivalent levels of job satisfaction compared with full-time employees. When facets of job satisfaction (e.g., satisfaction with pay, satisfaction with supervisor) have been considered, inconsistent findings remain. What these more in-depth studies have shown, however, is that ratings of satisfaction of part-time employees and those of full-time employees

might not act uniformly across facets of satisfaction. For example, part-time employees may report lower satisfaction with job content but higher satisfaction with social aspects of the work. These studies have drawn attention to the fact that nonsignificant differences in overall ratings of job satisfaction across work statuses may mask differences regarding facets of satisfaction.

Similarly, inconsistent findings have emerged from comparisons of the commitment levels of part-time employees and those of full-time employees. If one looks at the much smaller number of studies that have considered the relationship between work status and work-related behavior in the form of employee turnover, absenteeism, and job performance, the findings are again inconclusive.

A few studies have investigated work status as a moderator of the relationships among a range of job-related attitudes and behaviors. This is a potentially important issue because it may indicate whether predictors of attitudes for full-time employees, such as the psychological contract, are of equal utility to understanding part-time attitudes at work. From existing studies, there is little evidence of work status as a moderator, implying that part-time employees will respond in the same manner as will full-time employees in terms of human resource practices, rewards, and management strategies.

The main conclusion to be drawn from this brief review is that although attitudinal and behavioral differences are frequently observed between full-time and part-time employees, these empirical studies yield inconsistent results. Three further points are worth noting. First, findings on whether work status acts consistently across outcomes within the same study are mixed. Some studies have found that part-time employees report higher ratings of both job satisfaction and commitment, whereas other studies have found that part-time employees report higher ratings of job satisfaction but lower ratings of commitment. Collectively, these studies suggest that theories used to explain differences in job satisfaction between part-time and full-time employees might not be appropriate for organizational commitment. Second, some construct measures used in studies comparing part-time employees with full-time employees are designed with full-time employees in mind, raising the question of whether any differences found across work statuses on such measures can be considered as genuine differences on the underlying construct or instead should be deemed as artifacts of the method used. Finally, a narrow range of methods

has been used, with cross-sectional self-report questionnaire surveys being adopted nearly exclusively, where the limitations of such methods are well documented.

4. DIFFERENCES AMONG PART-TIME EMPLOYEES

Until the past decade or so, the heterogeneity among the part-time work group was rarely considered. For example, there were no clear theoretically based rationales for including demographic variables in research designs. Demographic variables were used to refer to age, sex, and marital status as well as to conditions such as organizational tenure and education. The control of demographic variables varied considerably across studies, with some studies not reporting the impact of any demographic variables and others using such unique sets of control variables that generalization was difficult.

In 1990, Feldman attempted to reconceptualize the research on part-time work. He argued that there were also major theoretical distinctions within the part-time work group and identified several key dimensions on which part-time work arrangements can vary, including the following:

- Whether the employee is employed on a permanent or temporary basis
- Whether the employee is recruited directly by the company or through an agency
- Whether the employment is year-round or seasonal
- Whether the job is the employee's main job or a second job
- Whether the individual accepted the part-time job voluntarily or involuntarily due to the unavailability of a full-time position

Feldman argued that these dimensions relate to attitudinal and behavioral outcomes. For example, part-time workers are hypothesized to be more likely to quit when they work part-time on an involuntary basis. Furthermore, there are three key demographic groups within the part-time workforce: students, married women with children, and retirees. These groups are indirectly related to attitudinal and behavioral outcomes in that certain demographic groups will gravitate to certain types of part-time work. For example, retirees are more likely to gravitate to voluntary part-time working arrangements as their main jobs, and these jobs are hypothesized as being more satisfying.

Feldman's research has drawn attention to some of the key dimensions of part-time work, but very few studies have explored whether these dimensions explain differences found in attitudes and behaviors within the part-time work group or, indeed, across part-time and full-time employees. In addition to highlighting important distinctions within the part-time work group, these categories draw attention to the need to control for confounding variables when comparing part-time employees with full-time employees. Researchers are now careful to locate their samples in terms of these categories.

Essentially, research in this area is concerned with what being "part-time" actually means. Some of the main dimensions of part-time work appear to have been identified, but these dimensions have received very little empirical attention and do not appear to be exhaustive.

5. THEORETICAL APPROACHES FOR UNDERSTANDING DIFFERENCES ACROSS PART-TIME AND FULL-TIME WORK

It should be noted that research comparing part-time employees with full-time employees has been largely atheoretical in design. When theories have been put forward to explain differences in attitudes and behaviors, mostly partial inclusion and/or frames of reference, they are applied post hoc to rationalize findings. The theories have received minimal attention and have tended to be applied in a rather cursory way.

5.1. "Part-Time" as a Proxy for Other Key Variables

The composition of the part-time workforce is known to differ from that of the full-time workforce in terms of various demographic (e.g., gender), organizational (e.g., tenure), and labor market (e.g., temporary/permanent) variables. Researchers have argued that these differences explain different attitudes and behaviors found across part-time and full-time employees and that once these differences are controlled for work status, they will no longer be associated with job attitudes and behaviors. In other words, differences in attitudes and behaviors between part-time and full-time employees are not due to the former's "part-timeness." Rather, they are due to the fact that part-time employees are more likely to come

from different demographic, organizational, and/or labor market groups; that is, "part-time" acts as a "proxy" for other key variables that are associated with working part-time.

A major problem with this argument is that proxy explanations constitute neither an adequate theoretical explanation nor an adequate psychological explanation for why there may be differences in attitudes and behaviors between part-time employees and full-time employees, and the use of proxy explanations may mask more meaningful theoretical explanations.

5.2. Partial Inclusion

Part-time employees are sometimes said to be "partially included" in the workplace. By spending less time in the workplace and being more involved in extra-organizational roles, they feel less included in organizations than do full-time employees. A number of limitations to this theory have been documented. The theory has been used in contradictory ways to explain attitudes where, for instance, feeling less included has been used to explain both higher and lower levels of job satisfaction. This theory has never been empirically tested, and it is not clear how the theory could be operationalized given that it is such a poorly elaborated concept.

This theory is perhaps better seen as a broad framework within which better understood theories can be placed. For instance, partial inclusion can be seen as embodying a number of ideas that could be explored separately in their own right, including the psychological contract, theories of the relationship between work and nonwork, and social identity theory.

5.3. Frames of Reference

It has been argued that part-time employees have a "frame of reference" that is different from that of full-timers, where the former evaluate characteristics of their work environment by considering how well they compare with those of another self-selected group. For example, part-time employees may be less satisfied with their pay if it compares unfavorably with that of their full-time counterparts.

This approach has been criticized in a similar way to partial inclusion in that it also has been used in contradictory ways to explain attitudes, is untested, and is too vague to operationalize. Furthermore, frame of reference comparisons can be used in an endless number of ways in terms of to whom, and over what, part-time employees choose to compare themselves.

5.4. Social Exchange and the Psychological Contract

The two exchange-based approaches of the psychological contract and social exchange theory have also been used to explain different attitudes and behaviors across work statuses. It has been argued that there are a number of factors that affect the exchange of contributions for inducements across part-time and full-time employees. For example, part-time employees receive fewer inducements such as benefits, task variety, and opportunities for advancement; part-time employees have lower expectations about what they should get from the organization; and part-time employees are more likely to be subject to “Theory X”-type management. These factors will have the effect of creating a perception of perceived inequity or psychological contract violation across work statuses, and they are more likely to lead to part-time employees developing economic relationships, rather than social exchange relationships, with employers. This, in turn, will affect outcome attitude and behaviors such as job satisfaction and organizational citizenship behavior.

Although some of the assumptions behind the social exchange-type approaches are questionable (e.g., that organizations treat part-time employees less favorably, that part-time employees expect less from their work), these approaches have been empirically tested and found to at least partially explain attitude and behavior differences across part-time and full-time employees.

5.5. Preferred Work Status/Schedule

Employees working their preferred work status (i.e., part-time vs full-time) or schedule (i.e., preferred number of hours per week) are often said to have more positive work attitudes. Previous research has found that a discrepancy between scheduled and preferred work hours for both full-time and part-time employees is related to work attitudes and that preferred work status matters more to part-time employees than to full-time employees.

What is not clear is the precise theoretical explanation for why such a discrepancy affects attitudes and behavior. One possible explanation is that employees involuntarily situated in their work arrangements have

lower levels of attachment. An alternative explanation drawn from social exchange theory is that employees working their preferred schedules achieve a better balance between contributions and inducements.

6. CONCLUSION

Despite a long history of comparing the work attitudes and behaviors of part-time employees with those of full-time employees, there have been relatively few studies conducted. Studies frequently find attitudinal and behavioral differences across part-time and full-time employees, but what emerges quite categorically is that findings are not consistent across studies. Many previous studies have been atheoretical in design and, thus, have contributed little to understanding the experience of part-time work. Since the 1990s, research on part-time work has been conducted under a stronger theoretical basis, and two particularly promising approaches to a better understanding of the experience of part-time work are social exchange and motives for accepting part-time employment.

GLOSSARY

adherence to medical treatment The complex interactions among patients, families, and health care providers in ensuring that treatment regimens are followed as intended.

assessment The evaluation process to describe domains related to physical, intellectual, cognitive, emotional, social, and family functioning.

bereavement The grief process following the loss (typically the death) of a loved one.

childhood chronic illness An ongoing medical condition requiring long-term medical care and follow-up (e.g., sickle cell disease, HIV/AIDS, asthma, cancer, juvenile diabetes); it often affects the life of the affected child and his or her family for an extended time period and can interfere with daily functioning.

cognitive-behavioral therapy (CBT) Psychological intervention that focuses on understanding how maladaptive thought patterns and beliefs lead to behavior that interferes with optimal social, emotional, and behavioral

functioning; CBT intervention concentrates on altering thoughts and beliefs so as to change behaviors and emotional states toward a more adaptive perspective.

evidence-based treatment An intervention for which there is empirical support.

interdisciplinary Involving two or more disciplines working toward a common goal; for example, an interdisciplinary team in pediatric oncology might include oncologists, nurses, nutritionists, social workers, physical therapists, occupational therapists, child life specialists, psychologists, and physicians from other medical disciplines.

intervention A systematic approach to facilitate change in a desired direction that may focus on individuals or families (e.g., cognitive-behavioral therapy, family therapy, pain management, consultation).

procedure A medical treatment (e.g., having blood drawn, undergoing a magnetic resonance imaging [MRI] scan).

psychosocial Involves the integration of psychological and social aspects of a person's well-being; sometimes, it is expanded as *biopsychosocial* to include the role of physical (biological) factors.

Pediatric psychology continues to grow and develop as an area of specialty and expertise within clinical psychology. This article highlights the interdisciplinary nature of the field. Research in pediatric psychology, including the emergence of evidence-based interventions, and their use in the clinical practice of pediatric psychology is described. Training requirements for pediatric psychologists are also discussed.

1. DEFINITIONS: PEDIATRIC PSYCHOLOGY AND PEDIATRIC PSYCHOLOGIST

As described by the Society of Pediatric Psychology, pediatric psychology “is dedicated to research and practice addressing the relationship between children’s physical, cognitive, social, and emotional functioning and their physical well-being, including maintenance of health, promotion of positive health behaviors, and treatment of chronic or serious medical conditions.” Pediatric psychologists are experts in the areas of developmental, emotional, behavioral, social, and family aspects of acute and chronic illness and injury. They work with children, adolescents, families, and health care teams around the areas of the physical, emotional, social, and cognitive aspects of illness or injury. Within interdisciplinary pediatric health care teams, pediatric psychologists evaluate and intervene to enhance the well-being of children and families.

2. PEDIATRIC PSYCHOLOGY: INTEGRATING PSYCHOLOGY AND PEDIATRICS

The importance of a close working relationship between psychology and pediatrics has long been viewed as essential to providing quality health care for children, adolescents, and their families. In 1965, Jerome Kagan spoke of the need for a “new marriage” between the fields of psychology and pediatrics to meet the needs of children in health care settings. In 1967, Logan Wright published a seminal article delineating the key elements of the field of pediatric psychology, including a call for empirical research supporting clinical practice.

3. EMERGENCE OF PEDIATRIC PSYCHOLOGY

Pediatric psychology is relatively new, having been founded in 1968 as the Society of Pediatric Psychology. Dortha Ross, Lee Salk, and Logan Wright were early leaders in the field. Interest in working with pediatric patients and their families within medical settings continued to grow during the 1970s. In 1973, the *Journal of Pediatric Psychology* was established and today remains the flagship journal in the field. This journal publishes

articles focused on original research, professional practice, and theory in pediatric psychology. Steady increases in membership and growing interest in working with pediatric patients and their families within medical settings occurred during the 1980s and 1990s, culminating in the Society of Pediatric Psychology gaining division status (Division 54) within the American Psychological Association in 1999.

4. GROWTH OF PEDIATRIC PSYCHOLOGY WITHIN MEDICAL SETTINGS

The numbers of pediatric psychologists are increasing within hospitals and other medical settings. Working together with interdisciplinary medical teams, pediatric psychologists serve as consultants and collaborators within inpatient and outpatient hospital settings, primary care and subspecialty clinics, and academic medical settings and schools.

5. MAJOR RESEARCH AREAS WITHIN PEDIATRIC PSYCHOLOGY

Scientific research is an essential part of pediatric psychology. Childhood chronic illness is a major focus of the field, although treatment of acute illness and attention to health promotion and prevention are also emphasized. Designing and evaluating evidence-based treatments and interventions is an important recent focus.

5.1. Chronic Illness

Frequently studied childhood chronic illnesses include (but are not limited to) asthma, cancer, cystic fibrosis, diabetes, HIV/AIDS, juvenile rheumatoid arthritis, organ transplantation, seizure disorders, pain syndromes, neuromuscular diseases, and sickle cell disease. Childhood chronic illness research focuses on how multiple aspects of diseases and treatments affect children, adolescents, and families, including adjustment to and coping with chronic illness, adherence to medical procedures and treatments, pain management, feeding and sleep disturbances, intellectual and cognitive development, social and emotional functioning with peers and family, family adjustment to chronic illness, and promotion of health and quality of life.

5.2. Assessment

Systematic assessment, using standardized psychological tests, can facilitate understanding of the intellectual, cognitive, social, and emotional impacts of illnesses or injuries. The assessment process provides essential information for developing effective treatments and necessary information to health care teams, families, and school personnel. For example, many diseases or illnesses adversely affect the child's central nervous system, causing physical, cognitive, and/or socio-emotional deficits that may influence the child's ability to perform competently at home, with peers, and in school.

5.3. Intervention: Evidence-Based Treatments

Carefully designed and controlled studies evaluating the effectiveness of manual-based interventions with children and their families have increasingly become a part of research and practice in the field of psychology. Beginning in 1999, the *Journal of Pediatric Psychology* published a series of reviews describing evidence-based treatments in pediatric psychology, including interventions for treating recurrent pediatric headache, recurrent abdominal pain, procedure-related pain, disease-related pain, pediatric obesity, severe feeding problems, disease-related symptoms, bedtime refusal and nighttime wakings, nocturnal enuresis, constipation and encopresis, and adherence to treatment regimens.

There are several effective treatments that may be used to treat children's pain. For example, cognitive-behavioral therapy (CBT) is an effective, well-established treatment for procedure-related pain, disease-related pain, and recurrent abdominal pain in children and adolescents. Examples of CBT techniques include teaching the child and family relaxation skills such as the use of deep breathing exercises, using guided imagery, and using distraction such as counting out loud or playing with toys. Active coaching by a caregiver and/or medical team member encourages the child to use self-soothing coping skills, which is another effective CBT intervention for pain. Relaxation and self-hypnosis are useful treatments for recurrent pediatric headaches. Biofeedback, whether alone or combined with relaxation or other CBT treatments such as those described previously, is also promising for headaches. In addition, guided imagery is an effective treatment for children with cancer who are undergoing chemotherapy.

Effective treatments for childhood obesity target several behavioral areas at one time, for example, promoting healthy eating patterns while also increasing physical exercise. For severe feeding problems, rewarding the child when he or she engages in desired behaviors (e.g., eating a particular food) and ignoring undesired responses (e.g., spitting out food) are useful interventions.

Evidence-based interventions for bedtime refusal and other childhood difficulties, including enuresis and encopresis, are promising. Educating parents about healthy sleep hygiene during the prenatal and newborn periods is helpful for bedtime refusal and night wakings in young children. Implementing a positive bedtime routine is another promising intervention. Extinction techniques, including parental ignoring of the child's cries so that the child learns to fall asleep on his or her own, is also effective but is often less feasible given that parents might not be willing to attempt this strategy. For nocturnal enuresis (i.e., repeated nighttime urination in places other than a toilet, e.g., in bed), addressing both the biological and behavioral aspects of the problem is most effective. Using a urine alarm combined with the medication desmopressin is a promising intervention. Fewer effective, evidence-based treatments for constipation and encopresis (i.e., repeated bowel movements in locations other than a toilet, e.g., in underwear) have been identified. The most promising treatments combine medical intervention (e.g., fiber, laxatives) with a behavioral component such as positive reinforcement.

Understanding the most effective ways in which to encourage adherence to medical regimens is an essential area of pediatric psychology research. Increased parental supervision and monitoring of medication use, coupled with increased attention and support from a health care team, improves adherence for children and adolescents with asthma. For individuals with juvenile rheumatoid arthritis, treatments using behavioral strategies (e.g., positive social attention, feedback from the child's family, token reward systems) are useful. Multicomponent treatments focused on teaching problem-solving, negotiation, and decision-making skills are promising for helping children, adolescents, and families to improve adherence to complex regimens for juvenile (type 1) diabetes.

5.4. Prevention

Often, the best therapeutic intervention is to prevent the occurrence of an illness or injury. Pediatric psychologists are actively involved in promoting healthy attitudes

and behaviors in children, adolescents, and families and in working to prevent disease, illness, and injury. Research targeting lifestyle choices and behaviors during childhood and adolescence, including healthy eating, exercise, drug avoidance, injury prevention, and safe sexual practices, encompasses the many prevention topics studied by pediatric psychologists.

5.5. Family Systems

Increasingly, the focus of pediatric psychology has transitioned from focusing exclusively on the child and adolescent to a more systems-focused perspective emphasizing the important roles that parents, caregivers, siblings, relatives, peers, teachers, the health care team, and other community contacts play in the child's functioning in relation to illness or injury. Families facing illness must balance medical management of the disease with feelings of fear, uncertainty, and grief. How successfully families are at navigating this challenge is influenced by the families' pre-illness functioning and adjustment, levels of support and resources, and the medical aspects of the illness. Families who demonstrate strength-based skills, such as effective communication, clear family boundaries, active coping, flexibility, and the ability to balance the demands of the illness with other family responsibilities, are more likely to demonstrate increased well-being throughout course of the illness.

6. CLINICAL PRACTICE OF PEDIATRIC PSYCHOLOGY

6.1. Settings in Which Pediatric Psychologists Work

Many pediatric psychologists are employed in, or have close affiliation with, hospitals. They work in emergency, inpatient, and/or outpatient facilities in freestanding children's hospitals, university-affiliated medical centers, community hospitals, and satellite clinics. A smaller percentage of pediatric psychologists are based in primary care, and others work in private practice serving children and families. Pediatric psychologists are also employed within schools and in other community settings.

6.2. Roles of Pediatric Psychologists

The professional roles of pediatric psychologists are as diverse as the environments in which they work.

Pediatric psychologists often serve as consultants to interdisciplinary medical teams within inpatient, outpatient, or primary care settings. Assessment of psychosocial, neuropsychological, and/or neurodevelopmental functioning of children with acute or chronic illness, injury, or developmental delay is another important activity. Pediatric psychologists often work directly with children and their families around the adjustment to acute or chronic illness or injury, including how the illness or injury will affect the children's cognitive, emotional, and social functioning. Adjustment to illness or injury may also include addressing adherence to medical regimens, coping with painful or stressful medical procedures, and exploring how the child's and family's beliefs about the adversity of the illness or injury are affecting their thoughts, feelings, and relationships with others. Bereavement work with children and families facing death due to illness or injury is another important activity.

7. PEDIATRIC PSYCHOLOGY TRAINING

Pediatric psychologists are typically licensed, doctoral-level psychologists. Many pediatric psychologists have backgrounds in clinical psychology, whereas others have training in areas such as developmental or health psychology. All have completed 4 to 5 years of graduate-level coursework and clinical training, a 1-year intensive clinical internship in a hospital or other setting related to health care, and 1 or more years of postdoctoral training.

In addition to didactic and experiential learning in basic psychological principles, pediatric psychologists receive specialized training and instruction in health care issues that affect children, adolescents, and their families. Focused training in pediatric psychology often includes instruction in the areas of adherence and health promotion, management of painful medical procedures, social and emotional aspects of pediatric medicine, and prevention of illness and injury. While training within diverse pediatric health care settings, pediatric psychologists gain advanced experience in working with children and adolescents with a broad range of medical illnesses.

Pediatric psychologists continue to use evidence-based research to inform clinical practice within interdisciplinary care environments. With the growth of this

relatively newly emerging field, the role for pediatric psychologists will clearly broaden and diversify as the needs of changing medical environments dictate.

GLOSSARY

- cross-cultural** An imprecise term used to describe comparisons between groups differing in culture but also often differing in other respects (e.g., gene pool, environment).
- eidolicity** Characteristic of flat figures responsible for perception of illusory depth.
- epitomy** Characteristic of flat figures responsible for their recognition as representing objects.
- horizontal-vertical illusion** Misperception of T-shaped and L-shaped figures.
- Kwengo calipers** A test in which individuals adjust a pair of calipers to an angle presented in perceptually flat or perceptually solid figures.
- Muller-Lyer illusion** Misperception of the length of lines bounded by arrowheads.

Cross-cultural studies of perception show differences among populations. They contribute more to the un-

derstanding of the perceptual processes than do analogous studies of nonhuman species. In spite of this, cross-cultural studies have not flourished greatly and have been concerned mostly with visual perception.

1. INTRODUCTION

Cross-cultural differences have long been the subject of travelers' reports. For example, it was reported that somewhere near the present-day Afghanistan, Alexander the Great's army encountered men who had one foot much larger than the other. These feet, in addition to their usual function, served as parasols when the men lay prone on their backs.

Systematic cross-cultural investigations are relatively recent, although not far temporally removed in time from the beginnings of scientific psychology. The first significant cross-cultural psychological study, the scope of which has never been exceeded, was carried out as part of the Cambridge Anthropological Expedition to the Torres Straits. Several psychologists, the most prominent of whom was W. H. R. Rivers, collected data on several perceptual functions such as olfactory and cutaneous sensations. However, much of the data collected, just like the data most ardently sought by research workers of more recent years, concerned visual perception. Later studies became even narrower in the scope of the phenomena investigated. With the notable exception of Reuning's investigations of the visual abilities of

the Bushmen, the studies are generally concerned with only one aspect of vision.

2. THE NOTION OF CULTURE

The term “cross-cultural” is vague because there is no definition of culture that would satisfy experimental psychologists, for example, by enabling them to decide whether two individuals come from different cultures with as great an aplomb as the psychologists can decide whether the individuals differ in terms of a perceptual skill or short-term memory. However, it is generally believed that the vectors of genetic endowment and the impact of the natural environment are insufficient to explain behavior and that the manmade components of the environment, such as language, architecture, customary rituals, and social organization, form a third vector, the “cultural” vector.

Therefore, there is a widespread conviction that the vectors that determine individuals’ responses are three-fold: genetic, environmental, and cultural. However, it is also generally accepted that the vectors are not mutually independent. For example, it is accepted that, when a “hunting and gathering” population changes its mode of life (a cultural change), takes to settled agriculture, and clears the land for this purpose (an environmental change), the following changes may follow. Agricultural activity and a settled population may offer an excellent breeding ground for malarial mosquitoes. Therefore, incidents of malaria will increase, as will the proportion of individuals suffering from sickle cell anemia. The latter individuals have certain physical disadvantages but are immune from malaria, and their immunity is genetically transmissible (a genetic change). Thus, culture, environment, and the genetic character of the population change together.

Although the vectors just described cannot be isolated in practice, they are heuristically desirable because they introduce a degree of tidiness into psychologists’ thinking. Such fine distinctions seldom intrude into psychologists’ experimental work. Most studies of perception are not concerned with the genetic vector at all; indeed, only a few attempts to separate the effects of the environment from the effects of culture have been made. This is not to say that results of such studies lack merit but rather to stress that they provide rather confounded data so far as the three vectors are concerned. However, such theoretically impure studies are of immediate practical use because they offer guidance, for example, for selection of personnel when the causes of particular

abilities are of no consequence but the presence or absence of such abilities is.

3. VISUAL ILLUSIONS

One of the phenomena investigated by Rivers in the course of the Torres Straits expedition was that of perception of visual illusions. It was a study intended to compare “Western” and “non-Western” populations on a number of illusion figures that, at the time, were thought to constitute a homogeneous category of stimuli. It was not driven by any clearly defined hypothesis. The same phenomena were investigated by Segall and colleagues more than 60 years later. However, their investigation was inspired by specific hypotheses concerning the extent to which environmental experience affects perception. Segall and colleagues sampled a number of distinct populations inhabiting distinct environments and having different cultural artifacts. The conclusions of the two studies were in agreement in that both suggested that common visual illusions do not form a homogeneous body of phenomena and that their effects differ among populations.

Segall and colleagues attributed the differences observed to the differences in visual experience, for example, to openness of vistas (i.e., the extent to which people can see open spaces—savannah dwellers can do so to a larger extent than can city dwellers) in the case of the horizontal–vertical illusion and to “carpentered environment” (i.e., the extent to which artifacts of a culture incorporate straight edges—Western artifacts do so to a larger extent than do those of, say, Zulus) in the case of the Muller–Lyer illusion. It should be noted that the cultural vector is explicitly involved in the latter case. Of course, it is not entirely absent in the former case.

4. PICTORIAL PERCEPTION

Surprising responses of individuals drawn from exotic populations to pictures have frequently been mentioned by travelers and anthropologists. These have ranged from reports of the complete inability of certain populations to perceive that pictures represented objects to reports of responses indicating that the depicted objects were seen as real (e.g., that the portrayed people were alive but asleep). These observations, which came from reputable observers, were casual and not based on data obtained in the course of properly conducted studies.

FIGURE 1 One of Hudson's items: A test of pictorial perception.

The problem was first tackled systematically when misperception of pictures was found to be an obstacle to working in industry. It was found that the difficulties experienced were those associated with the failure to perceive the third dimension in portrayals. This was detected by asking individuals to name distinct elements in the test picture, such as the man, the spear, and the duiker in Fig. 1 (taken from Hudson's test), and, if they named them correctly, asking for simple judgments of depicted depth. The questions put to the individuals were "Which animal is nearer to the hunter?" and "At which animal is the hunter aiming his spear?" The answer "elephant" to either of these questions was taken as showing difficulties in perception of pictorial depth.

Following this study, several other measures were developed. These measures did not rely on verbal responses but instead called for reconstructing the pictured scenes or for copying an "impossible figure," taking advantage of the fact that the impossible figure in question is seen as "impossible" only if it is seen as a depiction of a three-dimensional object.

Because pictures are such an important means of communication whenever linguistic communication is not possible, and because the population in such cases is illiterate or has a language that is not widely known, these findings aroused widespread interest. A number of investigations were carried out, intent on defining the phenomenon, identifying its causes, and determining the most efficacious portrayals. It was found that perception of pictorial depth is not an "either/or" phenomenon but rather is greatly affected by the nature of pictorial stimuli, so that certain geometrical figures (notably certain illusion figures) evoke

perception of depth even though they are not reminiscent of any objects and are not familiar to the observers. In contrast, certain other figures (e.g., silhouettes) may readily evoke recognition without evoking perception of depth. An example of the latter is the elephant in Fig. 1, which is recognized as an elephant (a three-dimensional entity) but is not seen as three-dimensional. Indeed, even so-called "pin men" or "stick men," consisting merely of a set of straight lines that depict arms, legs, and trunks, are readily recognized as depictions of men, although they contain no depth cues whatsoever. The term "epitemic" was proposed as a descriptor of such figures that portray objects but lack perceptual depth, whereas the term "eidolic" was proposed for those depictions that evoke perception of depth, although they do not portray anything recognizable (e.g., some illusions).

It was also found that formal schooling is associated with the ability to perceive pictorial depth. Therefore, it has been put forward that pictorial perception is a matter of skill. However, it was also found that otherwise very capable engineering students drawn from certain populations were markedly poor at engineering drawings and that unschooled illiterate Bushmen's performance on the Kwengo calipers test (in which individuals must set a pair of calipers to a depicted angle) varied with ethnic origin and, in the case of one Bushmen population, did not differ from the performance of urbanized and regularly schooled Zulus.

It is noteworthy that intercultural differences were reported on other visual tasks. Differences were obtained on measures of implicit shape constancy (i.e., shape constancy as perceived in pictures). African

individuals were less affected by this constancy than were European individuals. Kwengo Bushmen's children, Zulu children, and White South African children were found to differ greatly in their responses to incomplete figures. The Kwengo performed better than did the two other samples. It is highly probable that they did so because they were better at integrating the stimuli. However, the origin of this skill (if in fact it is a skill) is not apparent; Bentley, influenced by Berry, thought that it might be a facet of the skill of hunting. Therefore, it seems plausible that the difficulties of pictorial perception can arise from failure to integrate perceptual input in the manner intended by the artist. The ease with which young children copy "impossible" figures that contain mutually contradictory elements, and the fact that those individuals from relatively pictureless cultures who build well-integrated three-dimensional models find it difficult to copy drawings containing mutually contradictory cues, supports this view.

The reported investigations skipped over the most striking of pictorial failures, that is, the failure to recognize that a picture portrays an object. There are several anecdotal reports of this but only a paucity of systematic evidence. The evidence in hand suggests that such difficulties are rare and further suggests that an inexperienced pictorial perceiver may attach inordinate weight to the material used in making the picture. For example, if paper is not a common cultural artifact, the paper on which a picture is made, rather than the picture itself, may grasp the observer's attention. Therefore, the picture recognition difficulties may be reduced by substituting a familiar material for an unfamiliar one (e.g., substituting coarse cloth for paper).

The pragmatic implications of these findings are clearly those known to every advertiser: It is imperative that pictures be carefully evaluated on a sample of the population for which they are intended.

5. PERCEPTION OF PATTERNS

Another aspect of cross-cultural perception that attracted attention is that of reproduction of geometric patterns. It came to the fore when psychological tests such as Kohs blocks were used and scores attained by some populations were found to be so low that the effectiveness of the tests became questionable. In some instances, the tasks were modified to strengthen their interindividual discriminability. In Papua New Guinea, cubes used to reproduce patterns were replaced by flat plaques and trays that included appropriate recesses in

which the patterns were to be reproduced. In South Africa, a newly designed and interesting test required individuals to render symmetrical, by placement of a rectangular fiche, an arrangement of three identical rectangles. Both of these approaches were used for selection, the former in a scholastic setting and the second in an industrial setting.

Suppression of a recalcitrant variable, although justified by practical considerations, does not elucidate the theoretical problem. A number of investigations concerned factors such as the symmetry of the pattern and its apparent stability as well as individuals' tendency to leave the pattern in whatever orientation it was completed. A persistent reported tendency was to rotate the reproductions of patterns in such a way as to increase both their symmetry about the observers' median planes and their apparent stability. The question of whether the errors of orientation are errors of inattention to orientation (where the observers left the correctly reproduced pattern in whatever orientation they happened to complete it) or result from some lawful perceptual vector was addressed by Biesheuvel and Jahoda.

There are cultural groups, such as the Guugu Yimithirr of Northern Queensland, who judge orientations by referring to the geographical coordinates rather than to those of their own bodies (e.g., left and right). The implications of the two types of judgment are demonstrated in Fig. 2, which shows a stimulus viewed from the distinct stances. Those relying on the geographical notions see the orientation of the stimulus as the same from both stances (it is consistently pointing westward). Those relying on their body coordinates see the orientations as different; from Stance A, it points to the left, and from Stance B, it points to the

FIGURE 2 Graphical explanation of the effects of the two distinct frameworks on the object's reported orientation.

right. Two issues that ought to be noted here are (a) the justification of describing the phenomenon as perceptual and (b) that arising from the psycholinguistic gloss that would seek the roots of the phenomenon in linguistic use (i.e., “it is consistently pointing westward” vs “it is consistently pointing to the left”).

6. EIDETIC IMAGERY

Some people, notably children, experience a special kind of “photographic” imagery, pictorial in nature, that enables them to report with striking accuracy. This eidetic imagery was once believed to be more widespread in illiterate populations. However, empirical data do not support such a notion, and the very phenomenon remains one of the puzzles of psychology.

7. STUDIES OF PERCEPTION OF COLOR

Cross-cultural studies of perception of color have been dominated from their very beginning by the issue of the relationship of color vocabularies to perception of color. If the color spectrum can be conceived as a continuum resulting from steadily changing frequency of light waves, such a continuum can be arbitrarily divided in any manner and different languages may present different ways in which to divide it. Speakers of languages dividing the continuum differently will respond to colors differently. For example, speakers of a language that uses the same term for blue and green will respond to these two colors identically. On the other hand, if there is no such continuum, certain frequencies may be perceived as belonging together. That is, if observers, independent of the language, perceive pale green and dark green as mutually related and perhaps perceive a certain kind of green as the epitome of green (called focal green), the color spectrum obviously is not perceived as a uniformly changing continuum and perceived colors themselves impose certain differences in nomenclature. Neither of these polar positions has been sustained empirically, and the fact that pure colors can be blended to evoke percepts identical to those evoked by other pure colors erodes the notion of a perceptual continuum similar to that of, say, weight.

There is empirical evidence that linguistic groups tend to perceive colors differently in accordance with the categorization prevalent in their languages. For example, some Bantu languages use the same word

for green and blue, and speakers of these languages tend to treat these colors as if they were one; however, these effects are not as strong as rigorous application of the linguistic hypothesis would lead one to expect. There is also evidence that when focal colors are sought, these are identical in whatever language is used by the individuals. An additional complication arises because the same color may have quite different significances depending on the object of which it is a color. For example, the focal color detected when using Munsell chips may be quite different from that detected when using toy buffaloes. This effect is likely to be influenced by cultural differences in attention paid to color as opposed to shape of stimuli.

The notion that cross-cultural differences may arise due to differences in the structure of the eyes, namely in the pigmentation of the fundus oculi, has been put forward and investigated and has not yielded convincing data.

8. PERCEPTION OF TIME

Travelers' tales about surprising notions of time and of timekeeping are about as numerous as those about perception of pictures, yet the former have not attracted a comparable number of investigators, perhaps because the concepts involved are far more complex. Not only can a distinction be made between “social” time (e.g., as measured by punctiliousness, punctuality, or adherence to time schedules) and “physiological” time (e.g., as measured by the ability to judge and reproduce time intervals), but it also appears that attitude toward time and time-related concepts may vary between urban and rural groups and may affect the memorability of such concepts.

9. CONCLUDING REMARKS

It is apparent from this article that the dominant characteristic of cross-cultural studies in perception is their unevenness. Certain areas are pursued with vigor, whereas others are entirely neglected. For example, there are no extensive studies of basic perceptual processes. This is unfortunate because there are issues in relation to which only comparisons of distinct groups of individuals can define the extent of human capacities. For example, the surprising performance of the Bushmen on spatial tasks calls for a more fundamental explanation than does a statement that it may be associated with their hunting practices. These considerations extend beyond the here and now because

cross-cultural studies of perception also embrace studies of cultural artifacts of populations long vanished and sometimes known only by their artifacts. Such are the studies of Paleolithic art, that is, the studies of the early cognitive acts of humans.

It is noteworthy that none of the cultural differences demonstrated suggests that a population has unique perceptual attributes. The differences are in the intensity or frequency of attributes. When reflecting on such differences, one must bear in mind individual differences that are inevitably present in every population.

Probably the most important contribution that cross-cultural studies of perception can make is that of determining the range of human perceptual functions. Determination of the true range is essential both for a full understanding of such functions and for establishing a universal taxonomy of such functions.

GLOSSARY

attribution The perceived cause(s) of an event; these perceived causes have both emotional and motivational significance, so they can influence an athlete's behavior in response to performance difficulties.

choking Temporary unexpected decrements in performance that occur in situations where the perceived importance of good performance is high.

coping responses The specific cognitive and behavioral strategies that an individual uses to manage distress; these strategies are sometimes categorized in terms of their general approach or avoidance qualities.

motivational climate The psychosocial environment surrounding training and competition; rivalry, punishment, and recognition based on superiority to others are

generally viewed as elements of a counterproductive climate, whereas cooperative interaction and recognition based on improvement are generally viewed as elements of a productive climate.

performance profiling Systematic analysis of the essential ingredients for effective performance in a particular setting in combination with an assessment of strengths and weakness along these lines; this profiling can include physical, mental, and/or strategic aspects of performance and is useful for prioritizing skill development needs.

plateau Stabilization of performance at a given level, that is, a failure to improve.

process goals Specific and measurable objectives that relate to what one will do and how one will do it rather than the desired result or outcome; shooting 100 free throws at the end of practice every day for a month is an example of a process goal related to basketball.

relapse prevention A systematic attempt to reduce the probability that one occurrence of an undesirable behavior will lead to long-term debilitation or repeated occurrences; this framework emphasizes awareness of high-risk situations as well as the development of cognitive-behavioral strategies to maintain feelings of self-efficacy and control.

self-efficacy Situation-specific confidence in one's ability to accomplish something.

self-handicapping Generation of excuses or potential obstacles in advance of performance; although such actions may reduce the emotional impact of poor performances, they can also set in motion a self-fulfilling prophecy that makes good performance less likely.

Slumps are extended periods of below-average performance. The usual level of one's performance provides the frame of reference for defining a slump rather than some idealized or desired level of performance. The nature of one's sport involvement is also an important consideration. For a high-level athlete who trains daily and competes regularly, 2 or 3 weeks of below-average performance could constitute a slump. For a less committed performer with an irregular practice and competition schedule, a similar period of poor performance might not constitute a slump.

1. SLUMPS VERSUS CHOKING AND PLATEAUS

Individuals who participate in sport devote considerable time and effort to the development of physical skills, and they derive personal satisfaction from the public display of these skills. Consistency of physical performance is especially important for high-level amateur and professional athletes. Their scholarships or contracts may include performance-related contingency clauses, and their self-identity is often closely linked to physical prowess. Therefore, substandard performances are a source of concern for these individuals, and prolonged periods of poor performance can be highly stressful. Recreational athletes may also experience threats to their sense of self when, for no obvious reason, customary levels of performance are not attained for an extended period of time. The term "slump" is used to describe such a state of affairs.

Slumps can be distinguished from the related but qualitatively distinct phenomena of choking and plateaus. Choking refers to temporary unexpected decrements in performance that occur in situations where the perceived importance of good performance is high. Although choking can occur repeatedly, it is distinguishable from a performance slump because performance levels return to normal when the perceived importance of the event decreases. Factors associated with perceived importance include performance-contingent rewards or punishments and the ego relevance of the event. Performance plateaus are a longer term phenomenon than is choking, and the former are characterized by a failure to improve rather than by a decrement in performance. The athlete's performance improves to a point but then, despite diligent and conscientious training efforts, remains at a given level

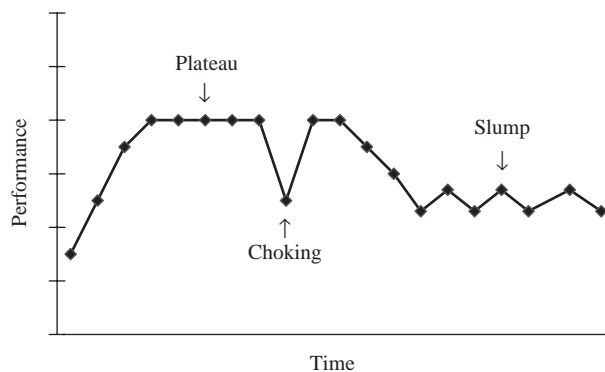

FIGURE 1 Illustration of the distinction among plateaus, choking, and slumps.

for an extended period of time. The distinction among plateaus, choking, and slumps is illustrated in Fig. 1.

2. CAUSES OF PERFORMANCE SLUMPS

The inability to pinpoint a specific cause for the extended period of poor performance is an important phenomenological aspect of performance slumps. Frequently (but not always), there is no apparent explanation for the performance deterioration, and this ambiguity creates frustration and a sense of helplessness for the athlete, who feels like he or she is working harder and harder but, despite this additional effort, is making little or no progress. However, from both theoretical and experiential perspectives, performance slumps are typically believed to originate from physical, psychological, behavioral, technical, and/or environmental causes. Table I summarizes these general categories of causal factors and provides examples of each of them. It is important to recognize that these categories are not mutually exclusive. In other words, performance slumps can have multiple causes, and it is entirely possible for factors within one category to have an influence on factors in another category.

Physical causes include lack of fitness, illness, injury, and/or general fatigue. With respect to fitness, it is important to recognize the distinctive purposes of general physiological fitness (e.g., strength, aerobic capacity) and of competition-specific fitness. Athletes sometimes have a tendency to place a heavy emphasis on general fitness and overlook the importance of match-specific fitness. This tendency is especially

TABLE I
Possible Causes of Performance Slumps

Category	Subcategories	Examples
Physical factors	Fitness	Training not specific to game conditions
	Illness or injury	Lingering cold or flu symptoms
	Fatigue	Suboptimal work-to-rest ratio
Psychological factors	Confidence	Uncertainty about style of play or role
	Concentration	Poor control of distractions and/or emotions
	Expectancies	Unrealistic demands from self/others
Behavioral factors	Routines	Inconsistent preperformance activities
	Self-handicapping	Precompetition behaviors that create obstacles
	Time management	Overcommitment and/or poor organization
Technical factors	Technique/Equipment	Minor changes that disrupt "system integrity"
	Coaching	Too much and/or confusing instruction
	Knowledge	Poor awareness of on-field contingencies
Environmental factors	Motivational climate	Excessive focus on outcomes or superiority
	Facilities	Substandard training/playing conditions
	Nonsport stressors	Family, work, or school problems

strong early in the competitive season when there is a need to make a transition from general off-season programs to performance-specific programs. Fatigue and illness/injury, on the other hand, can become problematic as the season unfolds. The cultural milieu within competitive sport is typically one of "hard work pays dividends," so athletes often push themselves to the brink of exhaustion in an effort to improve performance. A failure to recognize that optimal performance requires a balance between work and rest can produce decrements in performance that persist for an extended period of time.

From a psychological perspective, the ability to play with absorption and certainty of purpose is often viewed as the cornerstone of performance excellence. If athletes do not have a clear idea of their on-field or on-court roles, their performances can suffer due to hesitancy ("lack of conviction"). The heavy emphasis on results in competitive sport also makes it easy for athletes to lose sight of their performance objectives and become overly concerned with outcomes. This loss of focus can be both subtle and debilitating, and it is especially likely to occur when significant others (e.g., coaches, teammates, family) emphasize achievements when interacting with the athletes. Persistent decrements in performance can also occur if athletes allow themselves to become distracted by emotional overreactions and/or the behavior of teammates, opponents, fans, or officials. Tendencies along these lines

are sometimes rationalized as "competitive intensity" and so can persist despite being counterproductive.

Consistent performance in stressful competitive circumstances requires a consistent approach to training and performing. Schedules, plans, and routines help to provide this consistency, and performance disruptions can occur if these elements are missing, underdeveloped, or changed. Seemingly innocuous changes, such as alterations in training times, can sometimes interfere with performance by producing a cascade effect whereby many other activities and commitments must be rearranged to fit the new schedules. Similarly, inadvertent departures from standard precompetition or pre-execution routines can sometimes lead to persistent performance decrements. Self-handicapping behaviors can also interfere with performance and can infiltrate the athlete's preparatory activities in a subtle and seemingly defensible manner. Common self-handicapping acts include paying increased attention to sport-specific issues that are unrelated to performance, training excessively hard close in time to competition, and being preoccupied with minor injuries or illnesses. Failure to manage one's time effectively can also undermine performance by creating a general sense of urgency about whatever the athlete is doing at the time.

Technical factors that can contribute to performance slumps include changes to technique and/or equipment. Although sometimes such changes are not obvious, they can disrupt the integrity of the performance

system by altering finely tuned timing mechanisms. Attempts to execute skills in an ideal or prescribed manner can have a similar disruptive influence on performance that might take considerable time to overcome. Coaches sometimes contribute to this problem by offering too much input, providing overly technical input, and/or by showing a lack of flexibility with respect to methods. A lack of awareness regarding when and how to make on-field adjustments to strategy can also contribute to extended periods of subpar performance despite the presence of objectively good technique. Potential causes of slumps within the environment include substandard training or competition facilities, stressors related to nonsport roles, and a motivational climate that places a heavy emphasis on beating others and winning rather than on skill development.

3. PSYCHOLOGICAL CONSEQUENCES OF SLUMPS

At some level, athletes acknowledge performance slumps as an “occupational hazard.” At the same time, they admit to experiencing considerable distress when confronted with them. Prominent psychological reactions to slumps include feelings of frustration, anger, helplessness, self-doubt, and anxiety. Frustration is known to increase when there is proximity to a desired goal but attainment of the goal is blocked. For slumping athletes, the fact that they are accustomed to performing at a higher level serves as a continual reminder that the goal can be attained. On the other hand, their inability to reestablish these levels of performance despite diligent effort is a source of considerable frustration. This frustration is accompanied by increased emotionality, which may manifest itself in the form of impatience, irritability, and/or hostility. It may also manifest itself in feelings of helplessness, despair, and depression.

Loss of confidence, self-doubt, and anxiety are also experienced during a performance slump. It has been shown repeatedly that the strongest influence on situation-specific confidence (i.e., self-efficacy) is prior performance in similar situations. When the most recent prior performances have been consistently poor, confidence is eroded. At the same time, physical prowess is an important component of self-identity for most athletes, and there is no shortage of physically talented individuals waiting in the wings. Performing at less-

than-expected levels for an extended period can threaten the athlete’s sense of self and lead to pessimistic rumination on things such as “Do I still have what it takes?” and “Will I lose my spot [on the team, in the starting lineup, in the tournament, etc.]?” Such thoughts reflect self-doubt as well as anxiety about the future.

4. FACTORS INFLUENCING THE REACTION TO SLUMPS

Research findings indicate that the amount of stress experienced in response to a slump is related more to how the slump is appraised than to individual difference factors. More specifically, self-reports from athletes in a variety of sports indicate that slump-related stress is slightly lower for those with spouses or partners than for those without spouses or partners but that it is unrelated to age, sex, education level, or years of competitive experience. On the other hand, interpreting the slump as a loss or a threat substantially increases the level of perceived stress. Slumps are also perceived as stressful when they are interpreted as a challenge, but not to the same degree as when loss or threat interpretations are involved. Dimensional properties of causal interpretations also show some relationship to slump-related stress. Specifically, a lack of perceived control over the cause of a slump tends to increase the level of self-reported stress, whereas a high level of perceived control over the cause tends to decrease stress levels. This finding is, of course, consistent with the way in which perceptions of control are viewed within general theories of behavior change as well as within models of stress and coping.

5. COPING BEHAVIORS IN RESPONSE TO SLUMPS

Athletes tend to be concrete thinkers, and the sport environment is one that reinforces hard work and persistence. Therefore, it is not surprising to find that active, problem-focused coping strategies are cited most often when athletes are asked about their behavior in response to a slump. More specifically, findings from both qualitative and quantitative studies using various coping inventories indicate that athletes frequently employ increased effort or resolve, planned action, seeking of technical advice, seeking of social

support, and suppression of competing activities when they are confronted with an extended period of poor performance. Although emotion-focused strategies are used less often, they are sometimes employed. When that is the case, strategies related to conscious control of emotions, self-blame, and wishful thinking appear to be used most often. Avoidance-oriented strategies, such as denial and behavioral disengagement, are consistently the least frequently cited coping behaviors by athletes confronted with performance slumps.

Even though athletes have a general tendency to cope with performance slumps as outlined above, gender and personality influences are also evident in the literature. With respect to gender, it has been shown that female athletes seek emotional social support to a greater extent than do male athletes in response to a slump, but these differences tend to disappear when instrumental social support is examined (or when the two types of social support are considered together). Other studies have shown that male athletes report more use of the avoidance-oriented strategies of humor, denial, and behavioral disengagement than do female athletes. It must be emphasized that the overall frequency of citation for these strategies is low among athletes, but the

findings are interesting because they run counter to findings outside of sport that show a preference for active, approach-oriented coping strategies among males.

Personality factors that have been examined in connection with slump-related coping include dispositional optimism, trait sport confidence, perfectionism, self-consciousness, and achievement goal orientation. Table II summarizes the relationships that have emerged in this research. In general, athletes who are optimistic, possess high levels of domain-specific confidence, and adopt a mastery orientation to achievement tend to use active, problem-focused strategies in an effort to overcome performance difficulties. At the same time, these athletes are disinclined to rely on avoidance-based strategies, such as wishful thinking and behavioral disengagement, in response to a slump. Highly self-conscious athletes, on the other hand, have a tendency to fantasize, become preoccupied with their emotions, blame themselves for their difficulties, and/or disengage from the task. The impact of perfectionism on slump-related coping appears to depend on the particular subcomponent that predominates. More specifically, when perfectionist tendencies are driven by excessive concern about mistakes,

TABLE II
Personality Correlates of Slump-Related Coping among Athletes

<i>Personality construct</i>	<i>Coping strategies</i>	<i>Nature of relationship</i>
Dispositional optimism	Effort/Resolve	Positive
	Planned action	Positive
	Seeking social support	Positive
	Wishful thinking	Negative
	Behavioral disengagement	Negative
Trait sport confidence	Deliberate emotional control	Positive
	Behavioral disengagement	Negative
Mastery achievement goals	Planned action	Positive
	Behavioral disengagement	Negative
Self-consciousness	Wishful thinking	Positive
	Self-blame	Positive
	Emotional focus/venting	Positive
	Behavioral disengagement	Positive
Perfectionism		
	Concern over mistakes	
High personal standards	Denial	Positive
	Behavioral disengagement	Positive
	Suppress competing activities	Positive
	Planned action	Positive
	Self-blame	Positive
	Emotional focus/venting	Positive

avoidance-based coping strategies are employed. On the other hand, when concern over mistakes is accompanied by a focus on high personal standards, a potentially more productive mix of problem-focused and emotion-focused strategies tends to be used.

in connection with performance slumps. Figure 2 outlines a proposed structure for using the relapse prevention model in this way. Specific strategies for increasing awareness, maintaining confidence and emotional control, and facilitating a return to form are discussed next.

6. CAN SLUMPS BE PREVENTED?

In general, the answer to this question is no. Individuals who participate in competitive sport on a regular basis will, in all likelihood, be confronted by extended periods of below-average performance from time to time. Acknowledging this possibility from the outset has at least two beneficial consequences. First, it reinforces the need for athletes to understand why slumps occur and to approach their sport involvement in ways that will minimize the frequency of the occurrence of slumps. Second, it suggests that athletes also need to learn about the typical reactions that occur during a slump and need to develop behavioral strategies for “getting back on track” as quickly as possible. To put it somewhat more bluntly, athletes are probably going to be confronted with performance slumps from time to time, so they had better learn how to deal with them productively. In the area of substance addiction, this is the same philosophy that underlies relapse prevention training, and there is merit in using a similar approach

7. INCREASING AWARENESS AND MANAGING RISK

The first step toward increased awareness and effective risk management is to become knowledgeable about behaviors and circumstances that increase the potential for slumps to occur. The list of factors in Table 1, although not exhaustive, is helpful in this regard because it highlights some of the more common features of high-risk situations. These “red flags” include depleted physical reserves, information overload, inconsistent training and competition routines, a chaotic and disorganized lifestyle, and the presence of unusually strong nonsport stressors related to work, family, or educational duties. Specific interventions that address these issues are outlined in Fig. 3 and include self-monitoring of physical and mental state, systematic observation of coach–athlete interactions, establishment of regular daily and weekly schedules, rehearsal of preperformance routines, and development of time management skills.

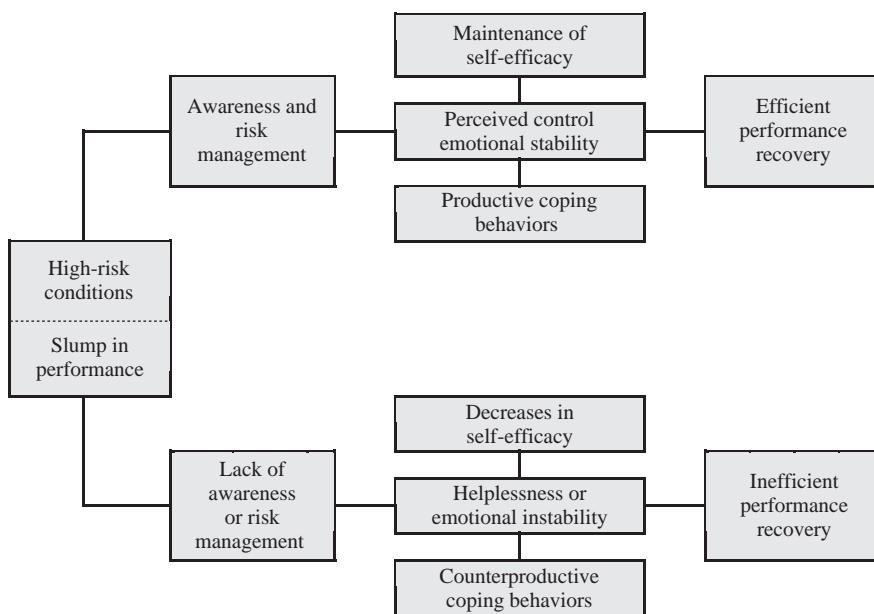

FIGURE 2 Application of the relapse prevention model to performance slumps in sport.

FIGURE 3 Intervention strategies for the management of performance slumps.

8. MAINTAINING CONFIDENCE AND EMOTIONAL STABILITY

When athletes are performing poorly, it is natural for them to lose confidence, feel somewhat helpless, and react with heightened emotionality. If not controlled, these negative thought patterns and emotional reactions can lead to a self-perpetuating cycle of counterproductive cognitive-behavioral reactions. To gain control over these reactions, it is sometimes necessary for athletes to remove themselves from the competitive environment for a period of time. This “time out” period, which might last from a few days to a few weeks depending on the level of involvement, gives them a chance to “clear their heads” and stabilize their emotions. There is certainly value in doing so, but it is sometimes difficult to convince committed sport performers that the best thing they can do for their game is to forget about sport for a while. An examination of Table II suggests that this might be especially problematic for highly optimistic/confident athletes with a strong mastery orientation.

Selected thought management strategies can be implemented to maintain feelings of self-efficacy and control as well as emotional stability. These strategies include affirmative self-talk, thought stoppage, and cognitive restructuring of attributions for the slump. Affirmations are simple, declarative, first-person

statements that reinforce positive personal qualities. As such, they are antithetical to the self-doubts that typically accompany performance difficulties. Examples of affirmations that might be relevant during a slump include “I deserve to be here,” “I’ve worked hard at my game,” “I can produce when I have to,” and “I enjoy showing what I can do.” A simple, three-part thought stoppage procedure can be used either by itself or in combination with affirmative self-talk to block negative thoughts and redirect attention in a constructive manner. This procedure consists of using covert verbal triggers (e.g., “Stop”) and/or physical triggers (e.g., snapping one’s fingers) to arrest negative thoughts. Attention is then redirected through a brief focus on the physical self (e.g., “Breathe . . .”) and/or the use of a cue word or phrase that captures a desired performance quality or orientation (e.g., “Let it rip,” “Play your game”). Affirmations can, of course, be used as the cue phrases in this procedure.

Attributions play an important role in the way in which athletes respond to performance difficulties both emotionally and motivationally. In general, it is emotionally comforting and motivationally productive to attribute poor performance to unstable specific factors (e.g., an unacceptably poor first serve percentage in tennis) rather than to stable global factors (e.g., a general inability to serve well). Doing so reduces the emotional impact of the negative outcomes and sets the

stage for continued striving toward improvement of the specific weakness. These explanations must be realistic, of course, because contrived excuse making will certainly not be advantageous. At the same time, consultants should be aware of the link between attributions and feelings of helplessness, and they should remain vigilant for potentially counterproductive attributional patterns when persistent performance difficulties arise.

Mental rehearsal and a variety of relaxation procedures may also be beneficial for maintaining confidence and emotional control. Two different types of mental rehearsal are relevant and can be used to one's advantage at different times. Mastery rehearsal involves visualization of effective performance and is good for maintaining self-confidence. It can be implemented by asking athletes to recall an excellent performance from the past and to reexperience it in as much detail as possible. After doing so, they can be asked to visualize an upcoming performance situation, see themselves performing in a similarly effective manner, and associate the prior feelings of success with the future performance. Coping rehearsal, on the other hand, involves visualization of potential difficulties that might be encountered in the future and the strategies that could be used to manage these difficulties effectively. This form of imagery aids in the recognition of behavioral alternatives and in the development of response flexibility. Relaxation exercises of various kinds can be used in isolation or in combination with mental rehearsal to alleviate some of the tension that typically accompanies a series of frustrating performances. Abdominal breathing exercises and abbreviated forms of progressive muscular relaxation are good choices for athletes because they focus attention on physical processes to produce a relaxation response. Sport performers are physically oriented people, and they are sometimes more accepting of physically oriented relaxation techniques than of cognitively oriented techniques.

9. PERFORMANCE RECOVERY STRATEGIES

On-field performance is the bottom line for sport performers, so taking steps to increase the probability of efficient performance recovery is an important element of slump-related coping. A variety of behavioral techniques are relevant here. For example, performance

profiling can be used to isolate key elements of the physical and/or mental game as well as to identify strengths and weaknesses in these key areas. Skill development prioritization follows quite naturally from such an exercise, so the stage is set for quality practice (as opposed to "mindless" practice). Such an approach to training has been documented as a core element of sporting excellence, and there is considerable merit in modeling performance recovery strategies on these same principles. A central feature of quality practice is the incorporation of daily process goals into the training regime so that athletes have a clear idea of what they will do on any given day, how long they will do it, and how they will evaluate what they have done. Verbal cueing can be used along with daily goal setting to remind athletes of their priorities and to direct attention toward processes rather than outcomes. Cueing can be done covertly by athletes through self-talk, overtly by athletes through written reminders, or overtly by informed others through verbal statements. Structured reviews of the extent to which process goals were attained can then take place following training sessions and/or competitive performances.

10. SUMMARY AND CONCLUSIONS

Slumps are an inherent and unavoidable phenomenon within physical performance settings. They are qualitatively distinct from the related phenomena of choking and plateaus, and they have predictable psychological consequences. These consequences include decreases in self-efficacy, feelings of helplessness and loss of control, and behavioral attempts to cope through approach or avoidance. Individual difference factors that have been shown to influence slump-related coping among athletes include gender and personality. Because it is likely that most sport performers will experience slumps at some points in time, it would be prudent for them to adopt a risk management perspective on the process. Such a perspective involves (a) increasing awareness of the potential causes of and common reactions to slumps, (b) becoming familiar with cognitive-behavioral strategies for the maintenance of confidence and emotional stability in the face of performance difficulties, and (c) adopting a process-focused approach to training and competition. Doing so will help to reduce the frequency of occurrence of slumps and will promote efficient restoration of typical performance levels when they do occur.

GLOSSARY

creativity The generation of new and original ideas.

exnovation When an organization actively discards existing practices associated with a previously implemented innovation, thereby allowing the adoption of a new innovation.

incremental innovation An innovation focusing on improvements of existing processes, products, or services to improve performance in an existing market.

innovation The process of generating and applying new ideas to benefit individuals, groups, organizations, or the wider society.

leader-member exchange (LMX) Where leaders develop relationships with all employees in their work groups; these can be high-quality or low-quality relationships in which a pattern of social exchange emerges.

path analysis A set of statistical procedures that allows the researcher to test hypothesized causal relationships among variables (sometimes called causal modeling).

personal initiative A class of active behaviors with three facets: self-starting, proactivity, and persistence.

radical innovation An innovation focusing on the development of processes, products, and services with unprecedented performance potential to create a dramatic change in existing markets.

role innovation Changes in task objectives, responsibilities, methods, materials, and interpersonal relationships.

Innovation is essential for organizational prosperity. It is an iterative process that involves idea generation and idea implementation. There are a variety of influences on the propensity for innovation at work that can be classified into three levels of analysis: individual, work group, and organizational.

1. INTRODUCTION

Over the past two decades, there has been an explosion of interest in innovation as organizations have recognized that creating new processes, products, and procedures is vital for productivity and growth in all sectors. With more dispersed and virtual working, role innovation is essential because clearly defined job descriptions no longer exist for many job roles. The research literature on creativity and innovation is immense, both in magnitude and in diversity. Until recently, there has been confusion in terminology regarding these two concepts, particularly in definitions and in criteria for assessment. Many have observed the lack of a cohesive theoretical

understanding of how creativity and innovation operate in organizations.

First, the concepts of creativity and innovation are defined. The various factors that influence innovation in organizations can be classified into three main levels of analysis: individual, work group, and organizational. Each of these levels of analysis is reviewed. Finally, a summary of the emerging issues is presented along with some implications for future research and practice.

2. DEFINING INNOVATION

The concepts of creativity and innovation are confused repeatedly, and these terms are often used interchangeably in the literature. Creativity and innovation are overlapping constructs, but the main distinction is with regard to novelty. Creativity is exclusively concerned with generating new and entirely original ideas. Innovation is a broader concept because it also encompasses the application and implementation of new ideas to produce something new and useful (in the context of groups, organizations, or societies). Innovation is often referred to as a process because implementing new ideas necessarily involves influencing others, whereas creativity could be achieved in isolation. Furthermore, an innovation could be the application of something familiar in one organization to another unfamiliar organization.

The most widely accepted definition of innovation is that of West and Farr, emphasizing the positive nature of innovation: "the intentional introduction and application within a role, group, or organization of ideas, processes, products, or procedures, new to the relevant unit of adoption, designed to significantly benefit the individual, the group, the organization, or wider society."

Nearly all authors recognize that innovation in organizations is a complex iterative process. Numerous approaches and process models have been proposed, but two main stages are common to all of them: a suggestion phase and an implementation phase. Innovation is not a linear process given that it involves several cycles of activities such as initiation, reappraisal, adaptation, implementation, and stabilization. In addition to person-level resources, there are various environmental factors that influence this process such as feedback, leadership style, resource availability, and organizational climate. [Table I](#) summarizes the factors that have been shown to influence innovation in orga-

nizations at the three levels of analysis: individual, work group, and organizational.

3. THE INNOVATION PROCESS

Early research involved stage model approaches to innovation, where authors attempted to identify the sequence of activities during the innovation process. Zaltman and colleagues' stage model of the innovation process in 1973 is perhaps the most widely cited. The model suggests two main phases, initiation and implementation, with various substages in each. The initiation stage involves the substages of knowledge awareness, formation of attitudes, and the decision to adopt or abandon. During the implementation stage, ideas are tested and eventually the innovation is sustained and routinized. Although this research emphasizes that the innovation process is multifaceted, King and Anderson criticized stage-based approaches because they often lack observable supporting evidence. Innovation processes may share some common features, but these are not easily identifiable as discrete stages occurring in a linear fashion.

During the 1990s, Van de Ven and colleagues studied the innovation process in-depth, using empirically grounded observations. Their studies comprised the Minnesota Innovation Research Program (MIRP), captured in detail in *The Innovation Journey* in 1999. This program encompassed several organization-based longitudinal studies of a diverse collection of innovations observed in real time. The research concluded that the innovation process is best characterized as a "nonlinear dynamic system." In this way, the system involves a complex cycle of divergent and convergent activities that may be repeated over time at various organizational levels and that are shaped by forces such as resource supply, leadership behaviors, and the organizational culture. Although the research concluded that innovation is a nonlinear process, by comparing case histories of various innovations, the MIRP studies identified patterns of commonality in innovation processes. These are the initiation, developmental, and implementation periods of the innovation. Each period is described in [Table II](#).

Research demonstrates that different types of innovation may have varying antecedent factors. Furthermore, the evidence suggests that not all of the elements of the innovation process are the same across different innovations. For example, in exploring differences in incremental and radical innovation processes

TABLE I
Factors That Influence Innovation at Work

<i>Level of analysis</i>	<i>Characteristic</i>	<i>Dimension</i>
Individual	Personality	Openness to experience, low conscientiousness, low agreeableness, originality, imaginative, self-confidence, tolerance of ambiguity, nonconforming, high energy, social rule independent, personal initiative (e.g., self-starting, proactive)
	Motivation	Intrinsic (vs extrinsic), personal initiative (e.g., persistent), determination to succeed, self-efficacy
	Cognitive ability	Above average intellect, creative cognitive style, ideational fluency
	Knowledge	Domain-specific knowledge
Work group	Job characteristics	Autonomy, control, support for innovation, job demands, job dissatisfaction
	Team dynamics and structure	Diversity, conflict, constructive controversy, minority influence, organic structure
	Team climate	Participation, shared vision, support for innovation (articulated and enacted), task orientation
	Team processes	Reflexivity, minority dissent, integration skills, decision-making style
Organizational	Leadership style	Transformational, participative, democratic style, delegating responsibility, autonomy, openness to idea proposals and challenges, constructive feedback, expected evaluation, leader-member exchange
	Structure	Centralization, formalization, complexity
	Climate and culture	Support for risk taking, tolerance of failure, organizational values, reward and recognition for innovation, participative management and decision making, flexible employment contracts
	Size	Number of employees, market share, alliances
	Resources	Economies of scale, slack resources
	Work processes	Collaborative idea flow across functions, idea champions, change agents, suggestion schemes
	Physical environment	Technology to support innovation, informal meeting places, stimulating physical environment

Source. Anderson, De Dreu, and Nijstad (2004).

Note. Factors cited represent a summary of variables, but this is not an exhaustive list. Some factors exert a positive influence, whereas others a negative influence. Some factors have a curvilinear association with innovation, whereas others have an indirect association with innovation.

in 1992, King showed that sequential linear models were most applicable for incremental innovations, whereas radical (revolutionary) innovations were characterized more by convoluted iterative patterns of development.

Innovation processes do not occur in a vacuum and can be shaped by current organizational practices, particularly during the implementation phase. To illustrate this perspective, King and Anderson highlighted the concept of “exnovation.” This concept was first introduced in 1981 by Kimberly, who described innovation as a series of processes that combine to define an “innovation life cycle.” The final process of the model is exnovation, where the organization must discard existing practice associated with a previously

implemented innovation, thereby allowing the adoption of a new innovation, where the life cycle starts again.

4. PERSON-LEVEL INFLUENCES

Innovation involves multiple components at the individual level. However, there has been little synthesis of the literature to build a framework within which to explore the many interrelated characteristics involved. During the past decade or so, there has been a shift in research toward more integrative approaches. For example, in 1999, Sternberg and Lubart proposed an “investment theory” suggesting that the propensity to innovate requires six distinct resources: intellectual

TABLE II
Common Elements in the Innovation Process Identified in the Minnesota Innovation Research Program

<i>Period</i>	<i>Observation</i>	<i>Examples</i>
<i>Initiation</i>		
Gestation	Initial events might not be intentionally directed at innovation, and gestation might last several years. Coincidental events can trigger a need for change.	Art Fry sang in a church choir for years. Art, like many choir members, put slips of paper in his hymn book to mark each selection. However, his technique was not foolproof, the slips of paper often fell out. Taking his dissatisfaction back to his job, he eventually developed what became 3M's Post-it note pads.
Triggering shocks	Efforts to initiate innovations can be triggered by shocks, whether driven internally or externally to the organization. Without shocks, new ideas might not be acted on.	While on vacation, Edwin Land took pictures of his daughter. When she showed her disappointment that she could not see the results immediately, he set his mind to the task of developing instant photography. In an organization, a shock could be new leadership, a recent product failure, or a change in legislation.
Plans, budgets and exposure	Realistic plans are developed to gain resource commitment (time and finance) to the innovation.	Cost-benefit plans are needed to convince resource controllers and venture capitalists that the risk is worth it. In the organizations studied by the MIRP, during this period, entrepreneurs acted to deflect attention away from the innovations' uncertainty and toward their potential value.
<i>Developmental</i>		
Proliferation	Initial ideas proliferate into diverse multiple pathways, making the process difficult to manage.	In the MIRP studies, most innovations did not consist of a single new product or procedure. Instead, families of related new products were developed in multiple pathways to reduce the risk of failure.
Setbacks	Setbacks can occur frequently because initial plans go wrong or there are unforeseen environmental events.	This period is characterized by budget overruns, unmet deadlines, unsuccessful product launches. Organizations may respond by adjusting plans and resources.
Shifting performance criteria	Criteria for innovation success and failure often change over time, reflecting differing stakeholder views.	Long-term goals could be expressed as return on investment, whereas short-term criteria may be obtaining resources, recruiting appropriate personnel, acquiring equipment, and so on.
Fluid participation of personnel	Personnel often do not work full-time on the innovation. In addition, specific expertise may be required.	There may be high turnover of personnel, or relevant technical expertise might not be available. Part-time involvement means that commitment may vary among personnel.
Investors/Top management involvement	Senior management and/or investors intervene in the process.	The roles of senior management may vary and might not have a unified perspective. Interventions could be to remove impediments or possibly to expand the innovation.
Relationships frequently change	Relationships shape the process, with many interest groups engaging in various transactions to move the innovation forward.	Relationships could be internal to the organization or between external parties through partnerships and joint ventures. With a complex network of interest groups involved, reaching a consensus to move innovations forward might be slow.
Community/ Industry infrastructure	Innovation stakeholders often work within an industry or community infrastructure that is needed to implement an innovation.	The infrastructure could include institutional norms or institutional standards. Organizations seek to establish a distinctive position through innovations but simultaneously must operate within an industrial infrastructure or community.

Continues

Continued

Implementation/Termination

Integrating the old and the new	The new is linked and integrated with the old rather than substituting or replacing what has gone before.	Because of limited resources and for political reasons, innovations are seldom substituted for existing organizational programs. Instead, the aim is to integrate existing arrangements.
When innovations stop	Innovations terminate when they are institutionalized or when resources expire.	Innovations become routinized and diffused into adopted practice. Reinvention may also occur here when adopters may modify innovations to fit their local circumstances.
Attributions are made	Stakeholders explain causes for the successes or failures of the innovation.	Whether correct or not, senior managers and investors make attributions for success or failure that can significantly affect the career development of the innovation champions and their future likelihood of gaining resources for innovations.

abilities, knowledge, styles of thinking, personality, motivation, and environment. This reflects the key areas of research at the person level where previous literature can be classified into that concerning associations between innovation and (1) intelligence, (2) knowledge, (3) personality, (4) motivation, and (5) personal initiative.

4.1. Intelligence

Numerous researchers have explored the association between innovation potential and intelligence. However, the findings are generally inconclusive. Much of the literature in this area can be classified into four categories conceiving of innovation as (1) a subset of general intelligence, (2) an aspect of genius, (3) a set of cognitive abilities and mental processes, and (4) associated with observer judgments of intelligence.

4.1.1. General Intelligence

Early research claimed that creativity was equivalent to high intelligence. The best-known researcher in this field is Guilford. In his theory of the structure of intellect published during the 1950s, he claimed that creative thinking was a mental ability involving divergent production as “thinking that goes off in different directions.” Many researchers followed Guilford’s work by producing evidence that ideational fluency (i.e., quantity of new ideas) underlies divergent thinking test scores. However, review studies show that such scores

often failed to correlate significantly with various indexes of innovation. Other investigations have tested the possibility of a curvilinear relationship between intelligence and innovation where intelligence would potentially become less influential as the level of intelligence increases beyond a certain point. However, tests have proven to be inconclusive, and some authors doubt whether divergent thinking tests measure abilities actually involved in creative thinking.

4.1.2. Aspect of Genius

Some have suggested that genius, as the most obvious manifestation of high intelligence, is closely tied to the propensity for innovation. However, there has been a lack of evidence to support a direct relationship between innovation and intelligence. Many have concluded that intelligence is a necessary, but not sufficient, condition for innovation. Recent studies conclude that intelligence and innovation potential are moderately related but that once intelligence quotient (IQ) scores surpass 115, the relationship is near zero. This finding has been described as “threshold theory,” where intelligence and innovation potential, instead of being twin or even sibling constructs, may be more like cousins.

4.1.3. Cognitive Abilities

In 1992, Finke and colleagues suggested that to understand the role of cognitive abilities in idea generation, one must draw on current models in cognitive

psychology and use experimentally based observations of the processes that underlie generative tasks. Their work followed a framework called the “geneplore model.” This model proposes that many creative activities can be described in terms of an initial generation of ideas or solutions followed by an extensive exploration of those ideas. Initial ideas are referred to as “preinventive” in the sense that they are incomplete solutions but offer promise in terms of originality and utility. The model assumes that one would alternate between generative and exploratory phases, refining the structures according to the demands or constraints of the specific task. This “creative cognition” approach emphasizes that generative capacity is a property of normative human cognition. Individual differences occur due to variations in the use and application of these generative processes together with the sophistication of an individual’s memory and knowledge in the relevant domain. In simple terms, the capacity for creative cognition is normally distributed. Highly creative people do not have minds that operate in any fundamentally different way from those of other individuals.

4.1.4. Observer Judgments of Intelligence

Innovative individuals are often perceived and rated by others as more intelligent than less innovative individuals. For example, in MacKinnon’s studies of architects during the 1960s, supervisors rated innovative architects as more “intelligent” than less innovative individuals. MacKinnon described the innovative architects as having high “effective intelligence”, and argued that traditional measures of intelligence (e.g., IQ) do not fully explain this “real-world” intelligence. In 2003, Feist and Barron showed that observer-rated intelligence at 27 years of age predicted lifetime innovation at 72 years of age. Similarly, tested intelligence had much weaker relationships with innovation over this time.

Historically, the literature on innovation and intelligence has lacked clarity. Part of the problem has been that intelligence, similar to innovation, is often viewed as a unitary concept. Previous theories of intelligence have tended to overemphasize cognitive abilities and downplay the role of knowledge-based intelligence.

4.2. Knowledge

Nearly all researchers in this field have assumed that knowledge is a key variable in both generative thinking and innovation. Immersion in domain-specific

knowledge is an essential prerequisite for innovation because an individual must have an accurate sense of domain (i.e., contextual relevance) before he or she can hope to change it for the better. However, the literature highlights that too much expertise in one area can also be a block to innovation within that domain. There is an “inverted U” relationship between knowledge and innovation, where too much or too little knowledge will not lead to new inventions. During the 1980s, Simonton studied the lives of more than 300 eminent people to explore life span development of innovation and found that both a lack of familiarity and an excess of familiarity within a subject domain can be detrimental to innovation. Domain knowledge, like intelligence, is necessary but not sufficient for innovation to occur.

4.3. Personality

From several decades of research on the association between innovation and personality, a consistent set of characteristics has emerged. These include imaginative, inquisitive, high energy, high desire for autonomy, social rule independence, and high self-confidence. The Five Factor Model (FFM) of personality has become a nearly universal template with which to understand the structure of personality. The FFM dimensions are Openness to Experience (e.g., ideas, aesthetics), Agreeableness (e.g., compliance, straightforwardness), Conscientiousness (e.g., order, dutifulness, competence), Extraversion (e.g., warmth, gregariousness, activity), and Neuroticism (e.g., anxiety, depression). Given that the FFM is an appropriate model for charting individual differences among adult populations, it provides a useful structure to review the literature exploring associations between personality and innovation.

4.3.1. Openness to Experience

There is good empirical evidence of a positive association between various characteristics associated with innovation and those used to depict openness (e.g., imaginative, original, flexible, unconventional). Research suggests that openness enhances an individual’s intrinsic motivation toward novelty and, therefore, works in a multiplicative way to produce innovation. Although there are some inconsistencies in the findings, openness is perhaps the most important personality dimension to predict the propensity for innovation.

4.3.2. Agreeableness

Several studies have demonstrated a negative association between agreeableness and innovation. Innovators have high social rule independence. During the 1990s, Eysenck emphasized the potentially negative characteristics of innovators, where innovators are often outspoken, uninhibited, quarrelsome, and/or asocial.

4.3.3. Conscientiousness

Research has demonstrated that lack of conscientiousness is associated with innovation. Defined by terms such as fastidious, ordered, neat, and methodical, the evidence shows that individuals high on conscientiousness are more resistant to changes at work and are more likely to comply with current organizational norms. Recent studies have shown that the facets of conscientiousness most closely associated with innovation are being methodical, being ordered, and being dutiful.

4.3.4. Extraversion

Meta-analytic studies (i.e., large-scale reviews of quantitative studies) suggest that, in general, introversion is positively associated with innovation. Similarly, many have argued that isolation and withdrawal are necessary conditions for generating new ideas. However, there is little evidence from organizational contexts, and some have suggested that extraversion is a positive predictor of innovation. In meta-analytic studies of occupational work performance in general, extraversion has been shown to be a positive predictor for many occupations. This is particularly the case in large organizations where interpersonal factors are likely to be important for effective job performance (e.g., sales, managers, other professional occupations). Further research is needed to explore the association between extraversion and innovation.

4.3.5. Neuroticism

There is relatively little research examining an association between neuroticism (i.e., low emotional stability) and innovation. Of what literature is available, there appear to be some inconsistencies depending on the domain of interest. For example, in a meta-analytic review, Feist observed that artists appear to be more anxious, emotionally labile, and impulsive than the scientists he studied. A more thorough investigation in this area is necessary, particularly in organizational

settings with a broader range of occupations. Some have suggested a curvilinear association between emotional stability and performance, where too much or too little anxiety is detrimental to innovation and where moderate levels of anxiety can enhance innovative potential.

There are various personality measures available that claim to assess the propensity to innovate, including Cattell and Eber's Sixteen Personality Factor (16-PF) Questionnaire and Patterson's Innovation Potential Indicator. Other approaches include cognitive-style instruments such as Kirton's Adaptation-Innovation Inventory.

4.4. Motivation

High levels of motivation are required for innovation, and innovators are viewed as displaying a devotion and total absorption in their work. During the 1980s, Amabile suggested a componential model of innovation that involves three components: intrinsic task motivation, domain-relevant skills (i.e., expertise), and innovation-relevant process skills (i.e., cognitive skills and work styles conducive to novelty). The model includes a five-stage description of the innovation process—task presentation, preparation, idea generation, idea validation, and outcome assessment—where the roles of the three components vary at each of the stages. Amabile's model suggests how and where individual skills and motivation affect the progress of the innovation process.

Intrinsic motivation is clearly a prerequisite for innovation, but the role of extrinsic motivators is less clear. In exploring environmental influences on motivation, the evidence suggests that constructive evaluation (e.g., informative, supportive, recognizes accomplishment) can enhance innovation. Amabile suggested that intrinsic motivation is particularly important in tasks that require novelty and that extrinsic motivators may be a distraction during the early stages of the innovation process. Later during the innovation process, when persistence and evaluation of ideas are required, synergistic extrinsic motivators may help innovators to persist in solving the problem within the domain. Any extrinsic motivator that enhances an employee's sense of competence without undermining self-determination should enhance intrinsic motivation and, thus, increase the propensity for innovation.

In related studies, results showed that individuals who received positive feedback given in an informational style, and who worked in a high-task autonomy environment, generated the most innovative solutions. Perceived competence (i.e., an individual's belief that

he or she is capable of doing the task) and self-determination (i.e., an individual's perception that he or she is the main influence behind successful performance of the task) are the two main antecedents of intrinsic motivation. When autonomy is high (in choosing work methods and work schedules) and when an individual receives positive informational feedback, this is likely to optimize innovative production.

4.5. Personal Initiative

Based on work by Frese and colleagues, the concept of personal initiative (PI) describes a class of behaviors that have been positively linked with innovation and entrepreneurial orientation. PI is defined by three main facets: self-starting, proactivity, and persistence. A self-starting approach is characterized by setting oneself context-specific goals and going beyond formal job requirements. Proactivity implies that one anticipates opportunities and problems rather than reacts and prepares to deal with them before they occur. PI also involves persistence because this will be required to overcome barriers in reaching one's goals. Frese suggested that these three facets of PI reinforce each other and tend to co-occur. Taking an action-based approach, each of the three facets of PI can be used to understand how individuals develop goals, collect information, and make plans for executing them as well as how individuals gather and use feedback.

In 2001, Frese and Fay proposed a complex model of distal and proximal factors that influence performance in organizations, whereby environmental supports (e.g., support for PI, control at work), knowledge, skills and abilities (e.g., cognitive ability), and personality influence individual orientations (e.g., self-efficacy, handling errors, active coping), which in turn influence PI. In this way, PI is conceptualized as a set of active behaviors and is directly linked to effective performance in organizations.

There is a growing body of research examining the association between PI and innovation. The relationship between PI and conservatism in the workplace has been studied. Results show that conservatives showed significantly less PI, were less orientated toward growth and challenge, and were less innovative compared with their less conservative counterparts. In exploring environmental influences on PI, research shows that increases in control and job complexity can help to enhance PI at work.

PI is particularly important during the idea implementation phase of the innovation process because it

involves overcoming barriers and persistence. In a study using path analysis, several predictors were examined, including individual-level variables (e.g., PI, self-efficacy, interest in innovation), work characteristics (e.g., control, complexity), motives (e.g., reward), and organizational system factors (e.g., supervisor support). Results showed that being proactive, being actively involved in one's work environment, and being confident that one is capable of thinking of good ideas were the most important predictors of innovation. Organizational factors were also important variables, and the results suggest that innovation is maximized when organizational climates promote an active approach toward work and interpersonal risk taking.

The concept of PI has been applied at an organizational level. Findings suggest that companies with pro-initiative climates are more innovative and profitable. Climates for initiative may improve organizations' ability to deal with innovation and change by encouraging self-starting, proactivity, and persistence in employees.

5. WORK GROUP INNOVATION

Until recently, there had been little literature available regarding innovation in work groups. Several factors enhance group innovation, and four key issues are considered: (1) operating principles in groups; (2) diversity, dissent, and minority group influence; (3) group development over time; and (4) group climate.

5.1. Operating Principles

In 2002, King and Anderson highlighted the differences between "organic" and "mechanistic" group structures in their discussion of operating principles. An organic group structure is characterized by loose boundaries of authority and responsibility and by a propensity to work as a group rather than breaking projects down into discrete tasks for individuals. Conversely, mechanistic groups are typified by being rule bound, hierarchical, and formal in operation. Organic group structures tend to be more innovative because autonomy and freedom are enhanced. Work group autonomy is an essential ingredient of innovation, and it is most effective when combined with unambiguous goals and objectives from management. Autonomy is important for idea generation, and mechanistic forms of organizing may have a role in coordinating the implementation of ideas. Research

suggests that “semi-autonomous” operating groups are optimal for innovation.

During the 1990s, West and colleagues described the process of “team reflexivity” as the extent to which team members collectively reflect on the team’s objectives, strategies, and processes, as well as the wider organization context, and adapt them accordingly. When teams regularly devote time to collective consideration of their objectives, plans, and actions, they are in a position to develop continuously and potentially to improve performance. Reflexivity enhances team learning and allows teams to refine shared goals, plans, and actions, all of which are likely to enhance the likelihood of innovation.

5.2. Diversity, Dissent, and Minority Group Influence

Groups consisting of people with a wide variety of backgrounds and perspectives are more likely to consider a wider variety of approaches to tasks. However, too much diversity will increase the likelihood of conflict within the group, and this could have negative consequences for productivity. During the 1980s, Tjosvold introduced the concept of “constructive controversy,” which indicates the value of social interaction, and specifically controversy, in decision making. Constructive controversy occurs when team members believe that they are in a cooperative environment (emphasizing mutually beneficial goals rather than a “win–lose” solution), when they believe that their personal competence is acknowledged, and when members use processes of mutual influence rather than attempted dominance. Accepting and encouraging the expression of minority views and dissent in groups and organizations is an important stimulus for creativity and innovation. Conversion to a minority view in groups is most likely to occur when the minority is consistent and confident in presenting arguments. A behavioral style of persistence is most likely to promote attitude change and influence over the majority. The minority group must reflect a visible commitment to the norms, values, and interests of the majority to gain influence.

5.3. Group Development over Time

In general, the longer groups are together, the less innovative they become as teams grow to be habit bound and more resistant to change. Work groups do not come together and develop over time in a vacuum. Initiating change in an organization might not be possible if this occurs at a peak time in an organization’s annual cycle of

activity. The concept of “entrainment” has been used to explain that cycles of activities are paced by the numerous other cycles. In applying this to organizations, this “entraining process” provides windows (or barriers) of opportunity for change to take shape and take root. In addition to longevity, the timing of the formation of a project group can be critical to its success.

5.4. Group Climate

During the 1990s, West and Anderson proposed a four-factor model of team climate. This model suggests that group innovation is related to (a) participative safety (members feel psychologically safe in proposing new and improved ways of doing things, and all participate in decision making), (b) vision (the team’s goals and objectives are clearly defined, shared, attainable, and valued), (c) support for innovation (there is expectation, approval, and practical support toward group members’ attempts to introduce new and improved ways of doing things in the work environment), and (d) task orientation (the team is committed to achieving the highest possible standard of task performance using constructive progress-monitoring procedures).

There is good evidence to support the existence of these four factors in relation to group climate. Groups with clearly defined and shared visions are more likely to develop new working methods because their efforts are focused and have direction. Participation in decision making is important because it increases the likelihood that group members commit to decision outcomes and will be willing to offer new ideas. In addition, innovation requires group commitment to achieve high task performance and requires members to offer articulated and enacted support for innovation attempts.

6. LEADERSHIP

Since the early 1980s, several independent studies have identified a range of leadership behaviors that enhance employee innovation. These behaviors include encouragement of risk taking, an open style of communication, a participative and collaborative style, provision of autonomy and freedom, support for innovation (verbal and enacted), constructive feedback, and optimism about the future. Most research has focused on one or two management behaviors resulting in a lack of integration of results. Furthermore, because many studies have focused solely on either idea generation or the implementation of ideas, clarity has been difficult to achieve.

King and Anderson proposed a contingency model to understand the role of leadership in relation to four phases of the innovation process: (a) initiation (the leader encourages ideas and is nurturing, supportive, open-minded, and nonjudgmental), (b) discussion (the leader obtains opinions, evaluates, and agrees on plans), (c) implementation (the leader sells the solution to all stakeholders, designs plans to include stakeholders, and gains commitment to plans), and (d) routinization (the leader checks effectiveness, modifies, and refines). Therefore, leaders must be flexible in their approaches and must employ different styles according to the different phases of the innovation process.

The quality of the leader–member exchange (LMX) predicts the propensity for innovation. Leaders develop relationships with all members in their work groups, and these can be characterized as high-quality or low-quality relationships, where a pattern of social exchange emerges. In 1999, Tierney and colleagues demonstrated that a high-quality LMX predicts employee innovation because employees who were engaged in more challenging tasks received more resources and rewards for innovation. In recent studies, job self-efficacy has been shown to be the strongest predictor of creative self-efficacy. This implies that if managers are to enhance employee innovation, they must provide the necessary training and feedback to enhance employee confidence and mastery. Recent theories of leadership describe two styles: a transformational style (inspiring and motivating others to achieve a shared vision) and a transactional style (influencing others through contingent rewards and punishments). Research demonstrates that a transformational leadership style enhances employee and group innovation.

7. ORGANIZATIONAL INNOVATION

Several factors facilitate or inhibit innovation at the organizational level of analysis: (1) climate and culture, (2) structure and size, (3) resources and work processes, and (4) external demands and environment.

7.1. Climate and Culture

Climate and culture are important antecedents to innovation to the extent that risk taking and idea generation are encouraged. Climate is the shared perceptions and attitudes that influence the social interaction behavior.

Culture is a set of commonly shared beliefs, values, and assumptions that form the basis for climate behavior. Supportive and challenging climates encourage innovation, whereas environments characterized by distrust, personal hostilities, limited autonomy, and unclear work goals inhibit the implementation of ideas. Organizational support for innovation is characterized by support for members pursuing new ideas and encouragement of innovation through both words and deeds. The espoused expectations and organizational values in relation to innovation (e.g., openness to change, willingness to experiment with ideas) are likely to have a major influence on employee behavior.

Amabile and colleagues noted that organizational encouragement is a vital aspect of a work environment for innovation and includes (a) encouragement of risk taking and a valuing of innovation from the highest level, (b) fair and supportive evaluation of ideas, (c) reward and recognition for innovation, (d) collaborative idea flow across the organization, and (d) participative management and decision making.

Research shows that an organizational climate can build a perceived need for innovation. Setting innovation goals at both the team and individual levels is one way in which to signal that innovation is valued and innovation can be incorporated in performance management systems. In 2001, Csikszentmihalyi argued that innovation must be considered within a complex system composed of the domain, field, and person. Thus, organizations have gatekeepers who can make decisions about which innovations are worth supporting without being too accepting or too conservative with regard to novelty. Organizational practices that positively influence innovation include flexible employment contracts and knowledge management systems, whereas practices that seek to control employees lower innovation supportive cultures.

7.2. Structure and Size

There are three main aspects regarding the influence of organizational structure on innovation: centralization, formalization, and complexity. Centralization refers to the extent to which authority and decision making lie at the top of a hierarchy. Centralization is believed to hinder innovation because it restricts information flow and communication. Decentralization also gives rise to greater participation by allowing more viewpoints to be considered during idea generation. However, decentralization has a negative impact on the adoption of innovation and idea implementation in that

decentralization is necessary for idea generation, whereas centralization is important for idea implementation.

Formalization is the degree of emphasis placed on rules and procedures. High formalization inhibits innovation because it prevents organizational decision makers from seeking new sources of information and from making changes at work. However, procedural guidelines and regulations can enhance the successful implementation of new ideas.

Complexity is the degree of occupational specialization in the organization and is believed to enhance idea generation and inhibit idea implementation. High complexity is likely to provide a diverse range of information sources during idea generation, but such diversity could accelerate the potential for conflict during the implementation phase.

Because innovation is a multifaceted process, some variables that are important to enhance idea generation may be counter to promoting idea implementation.

Some claim that increased organizational size enhances innovation because there is greater access to resources through economies of scale. However, organizational size does not directly predict innovation because it is related to several different variables such as resource availability (which promotes innovation) and integration of communication and knowledge sharing (work processes often become more fragmented as size increases and so innovation is hindered).

7.3. Resources and Work Processes

Availability of resources is positively related to innovation because resources are needed to develop ideas. Beyond a certain threshold, more available resources do not significantly increase the likelihood of innovation. Researchers have observed a concept of “escalation”; that is, there may come a point when there is so much invested that it is too costly to stop the implementation process.

Integration across functions and groups promotes innovation through establishing common goals, knowledge sharing, and communication. For example, mergers have been shown to reduce the potential for innovation because resources are focused on managing structural changes to enhance amalgamation. Conversely, alliances and joint ventures between competitors or between customers and suppliers promote innovation and product development where combining resources and knowledge is beneficial.

Some organizations create “idea champions” (i.e., formal job roles to enhance innovation) or “change

agents” (whose specific responsibility is to encourage and enhance innovation at work). Some organizations create an innovation resource fund specifically to encourage development and implementation of new ideas. Idea capture or suggestion schemes are beneficial to enhancing employee involvement in generating and implementing new ideas.

A stimulating physical environment can influence work processes to enhance innovation. Some organizations have innovation laboratories that make use of technologies such as electronic brainstorming software. Using this software in groups can significantly enhance the quantity of ideas produced because it reduces some of the negative social factors in paper-based group brainstorming such as evaluation apprehension (where members withhold ideas because they fear negative evaluation) and free riding (where members rely on others to accomplish the task).

7.4. External Demands and Environment

The context in which organizations operate influences the propensity for innovation. For example, environmental uncertainty predicts administrative innovation, and low market share predicts higher levels of product innovations in some sectors. In this way, uncertainty generated by external demands and potential threats can stimulate innovation. However, under extremely threatening conditions, some organizations tend to centralize control, conserve resources, restrict information flow, and rely on traditional work methods. As a result, the propensity for innovation may be reduced in the long term.

The information flow in and out of organizations will influence innovation to the degree that there is an active search of the environment for new ideas. The external reputations of organizations can influence innovation because innovative organizations may be more likely to attract individuals with a high innovation potential.

8. EMERGING ISSUES

Innovation is a process with a variety of situational- and individual-level determinants. Each determinant may be more or less important during the idea generation or idea implementation phase. Similarly, the role of the environment in shaping innovation is likely to have a differential impact on individuals. Future research should explore interaction effects where the

individual differences in personality or experience may influence the way in which a person interprets or reacts to extrinsic rewards or constraints. In general, there is a lack of theoretical integration of the variables involved at each level of analysis and relevant interaction effects. In 2004, Anderson and colleagues reviewed previous innovation research and argued for the development of multilevel theories and study designs and for the triangulation of research methods to address these issues. The need to measure negative predictors of innovation, such as job dissatisfaction, task conflict, and home/work strain, was emphasized. Future research could explore innovation as the independent variable.

Historically, there has been less research targeting group-level innovation, but this has expanded recently and there are now clear practical recommendations regarding enhancement of innovation in teams. Future studies on innovation should reflect the changing nature of work and the use of technology. The impact of dispersed and virtual teams (where members are geographically dispersed and in different global

time zones) on team dynamics and innovation has not been explored. Similarly, the impact of international and cultural differences on team working and innovation (where team selection may also be important) has yet to be explored. Future research could examine the impact of technology and the physical environment on innovation by evaluating innovation laboratories to enhance idea generation and implementation at work.

The role of leaders in enhancing innovation has been neglected. Leaders are the gatekeepers in the innovation process and have a significant impact on the organizational climate and culture. Although organizations recognize the need for innovation, some managers may be less equipped to recruit and develop innovative employees.

9. SUMMARY

Innovation is a multifaceted and multilevel process. Figure 1 summarizes the main elements of the innovation cycle and the various influences at different levels

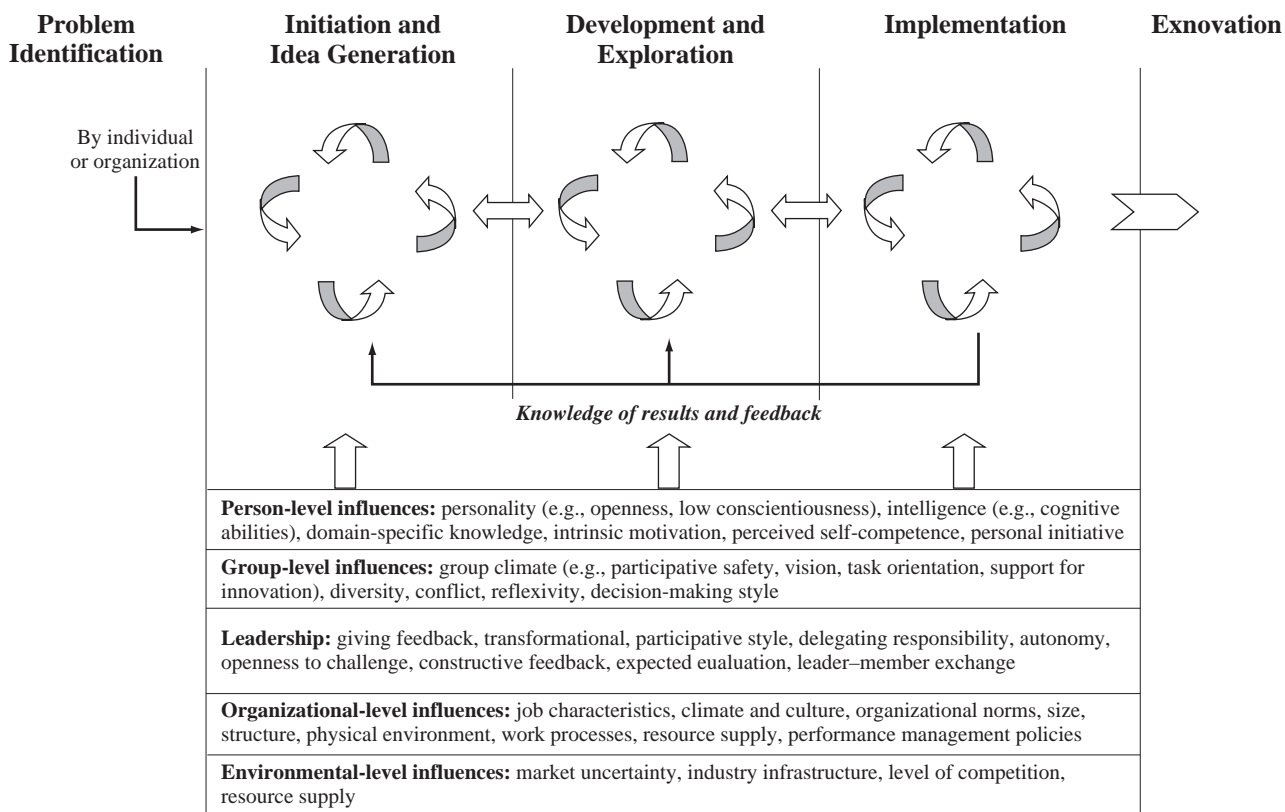

FIGURE 1 Phases in the innovation process and influencing variables.

of analysis. Innovative individuals have a creative cognitive style and are open to new experiences. Innovators are proactive, knowledgeable about the domains in which they are trying to implement their ideas, and persistent in the face of obstacles. A high level of diversity among employees enhances team innovation if there is integration of ideas among employees and team members. A positive team climate can have a significant influence on innovation and is characterized by participative safety, vision, support for innovation, and task orientation. Leaders can enhance innovation and may play different roles during different phases of the innovation process (e.g., encouraging ideas during idea generation, providing adequate resources and selling ideas to others during idea implementation). Many organizational factors influence innovation, including informal characteristics (e.g., climate and culture), formal policies (e.g., performance management systems), and factors external to the organization (e.g., market demand and uncertainty).

GLOSSARY

affect optimization Tendency to regulate emotional states toward more positive affective experiences and away from negative emotion.

cohort Group of people who are part of the same generation and, as a consequence, share similar life experiences and historical influences.

cohort-sequential design A study design that allows researchers to disentangle the effects of cohort and age as it tests different cohorts at the same ages across a period of time.

cross-sectional design A study design that allows researchers to draw conclusions about age differences by testing individuals of different ages at one point in time.

emotion regulation The ability to self-regulate or manage the internal experience and external expression of emotion.

emotions Short-lived negative or positive responses and reactions to events in the environment, or internal cognitions, that involve changes in body physiology, subjective experiences, and expressive behaviors.

life span development Development of individuals across the life span characterized by multidirectionality and multidimensionality; that is, developmental trajectories are assumed to include growth, stability, and decline within and across behavioral domains.

longitudinal design A study design that allows researchers to draw conclusions about age-related changes by examining the same group of individuals at different ages over a period of time.

personality Characteristics of an individual that are relatively stable and endure across time and settings.

primary emotions Set of emotions that are fundamental in organizing human thought and action across the life span, including happiness, fear, anger, sadness, surprise, disgust, and interest.

rank-order consistency The consistency of an individual's relative placement or rank within a group over time.

This article reviews the literature on personality development and emotional experience across the adult life span, with a particular emphasis on late life. It reviews theoretical developments and challenges, discusses methodological issues, and presents the major empirical findings about personality and emotion in late life. It concludes with a discussion of how future work that better integrates these two areas would be beneficial in advancing our understanding of well-being in late life.

1. INTRODUCTION

Advances in health care and public health practices have created a new culture of "old age." But what are old people like? Negative stereotypes suggest that older adults have certain personality characteristics, that is, that they are stubborn, set in their ways, and/or afraid

to take risks. Competing positive stereotypes suggest that older people are full of grace and dignity and are compassionate and wise. How do old people feel? Again, there are competing cultural conceptions. It is often believed that old people are lonely and depressed. On the other hand, old people are often viewed as carefree and satisfied. This article moves beyond cultural stereotypes of personality and emotion in later life to present the theories, methods, and findings gleaned from scholarly research.

Historically, many psychological characteristics (e.g., intelligence, learning ability) were characterized by decline in late life. More recently, however, psychologists have begun to focus on the positive experiences associated with aging. This dynamic tension between the positive and negative aspects of late-life functioning was elucidated in a 1987 article by Paul Baltes of the Max Planck Institute for Human Development in Berlin, Germany. He proposed the life-span approach and postulated that life span development is multidirectional and multidimensional. That is, different psychological characteristics show different developmental trajectories (e.g., growth, stability, decline) and different trajectories may coexist for behavioral functions within the same domain, making growth and positive development possible even into late life. Indeed, Smith's findings from the longitudinal Berlin Aging Study show that successful aging can be defined in terms of the ratio between gains and losses.

Personality and emotion have been at the forefront of research showing positive gains or maintenance of functioning in late life. As such, research on personality and emotion offers a window on facets of successful aging. This article reviews each area of work separately, focusing on major theories, methods, and empirical results.

2. PERSONALITY IN LATE LIFE

The term "personality" refers to the relatively stable characteristics of an individual that endure across time and settings. At first glance, this definition suggests that personality must be stable across adulthood; for example, an extraverted 30-year-old is expected to be extraverted when he or she is 65 years old. Evidence supports a good deal of continuity in adult personality, but there are also data showing that change occurs. Whether a researcher favors a view of stability or one of change depends mostly on his or her theoretical perspective.

2.1. Theoretical Issues

2.1.1. Personality Theories

Labouvie-Vief and Diehl, in a 1998 review of life span theories, pointed out that two major theoretical perspectives have led the area of personality development. The developmental-level approach is rooted in the psychodynamic tradition, with theorists such as Freud, Jung, and Erikson. This approach is categorized by developmental stages that emphasize qualitative changes in personality during different life periods. For example, Erikson theorized that each stage of development is characterized by a "psychosocial crisis" between opposing tendencies (e.g., generativity vs stagnation during midlife) that must be integrated for the self to fully develop. Although Freud's theory emphasized that personality was set at a fairly young age, later modifications (e.g., by Erikson and Loewinger) and extensions included lifelong processes of personality development.

The trait approach assumes that personality is composed of a number of basic behavioral tendencies (i.e., traits) and has focused on the measurement of these basic traits. McCrae and Costa's "Big Five" model of personality is one prominent example of this approach. According to this theory, there are five broad traits that make up human personality: Neuroticism, Extraversion, Openness to Experience, Agreeableness, and Conscientiousness. Trait theorists emphasize the stability of personality beginning in early adulthood.

A fairly recent addition to the personality literature is the contextual approach, which considers sociocultural and environmental influences that may affect how personality develops across the life span. Researchers such as Helson emphasize that people's environments and experiences influence who they become, at least in part. In contrast to the developmental-level and trait theories, the contextual approach argues for the malleability of personality across a lifetime. What are the mechanisms that lead to changes, or that sustain continuity, in personality?

2.1.2. Mechanisms of Continuity and Change

In a 1999 review, Caspi and Roberts summarized mechanisms that support continuity and those that facilitate change in personality across the adult life span. Genetics are thought to be a major mechanism leading to continuity. Data such as the MacArthur Longitudinal Twin Study suggest that approximately 80% of personality stability can be attributed to genetic

factors. Notable, however, is that genes seem to become less influential in late life. As twins age, they become less similar, suggesting that environmental influences play an increasingly stronger role as individuals age.

Environmental factors, such as differences in life experiences and socialization, are the mechanisms that are thought to produce changes in personality. For example, in a classic study, Helson and Moane showed that interpersonal dominance tends to increase in women who actively pursue a professional career, whereas raising children tends to heighten a woman's level of empathy. Thus, social roles that carry implicit and explicit demands can shape personality during adulthood. Individuals can also learn new behavioral patterns, at any age, by observing others or by getting feedback from others. This type of social learning refutes the old adage that "You can't teach an old dog new tricks." However, social and physical environments can also play a role in maintaining continuity. To the extent that people's environments remain stable, they foster stability in personality. Consistent environments tend to encourage consistency in personality across the life span. Thus, genetics and environment contribute to personality continuity and change in a complex integrated fashion. Researchers' theoretical perspectives, as well as their views of continuity and change, affect the questions they ask and the methods and measures they use.

2.2. Methods and Measures

Early theorists, such as Allport, Cattell, and Murray, suggested that personality should be studied over time. During more recent years, Block has advocated studying personality "the long way," that is, using longitudinal methods. Although the majority of personality research is still cross-sectional in nature, the number of longitudinal studies has risen considerably during recent years and invaluable information has been obtained regarding personality continuity and change in late life.

2.2.1. Types of Continuity in Longitudinal Research

Everyday conceptualizations of continuity and change in personality are typically thought of at the individual level, that is, involving intraindividual variability in personality (referred to as ipsative continuity). For example, has grandpa changed during the past 10 years, or is he the same person he used to be? Investigating personality

in this way has only recently received adequate attention because doing so requires complicated longitudinal designs of intraindividual change and advanced statistical analyses. Rather, researchers have focused their attention on two other types of continuity. Differential continuity refers to the consistency of an individual's relative placement within a group over time, that is, rank-order consistency. For example, in the case of high rank-order consistency, individuals are expected to preserve their rank over time, whereas low rank-order consistency is indicative of the fact that people are shifting around in terms of their rank. The second commonly studied continuity is absolute continuity, which refers to stability in the level of a particular personality characteristic over time. It is important to note that when most individuals change in the same direction, changes in mean level can occur over time without great changes in rank-order consistency. Thus, there can be various types of continuity, or lack thereof, observed in longitudinal assessments. There are also various factors that affect whether change or continuity is observed.

2.2.2. Factors Affecting Whether Continuity or Change Is Observed

Recent meta-analyses conducted independently by Ardel and by Roberts and DelVecchio identified similar factors affecting whether change or continuity in personality is observed in longitudinal studies. Three factors tend to bias results toward stability. The first factor is an individual's age at the initial time of testing. The older people are when personality is first assessed, the greater stability coefficients tend to be. Second, length of retest interval can affect findings. The closer together the times of testing, the more consistent personality appears. Third, the type of measurement instrument can also bias results. Self-report checklists of personality traits, the most commonly used instruments with older adults, tend to overestimate personality stability because individuals are usually biased in favor of reporting continuity. Behavioral observations get around the self-report bias in that they involve observations of how people behave across contexts. Given their contextual nature, behavioral observations are more sensitive to changes in personality, but they have rarely been used with older adults.

Other factors have an effect on whether change in personality is likely to be observed. Life events and transitions (e.g., retirement, widowhood) that individuals go through while participating in a longitudinal study may suggest change in personality. That is, as

individuals respond to new role demands, they may be learning new ways in which to cope. For example, financial strain that can accompany retirement may lead a person to become more worried (with “worrying” being part of the trait of Neuroticism) than they usually are due to the loss of income. This may be a new behavior that emerged as a result of the social transition, and it becomes incorporated into the individual’s personality if reinforced over time or may be a temporary way of dealing with a new life transition. Unknowingly, researchers would observe changes in personality.

Historical experiences and generational effects can also affect whether personality change is observed. In his classic work about the children of the Great Depression, Elder demonstrated how historical events affect people’s personalities in different ways depending on their life stages. Elder found personality change for middle-aged men in reaction to the Depression. Personality continuity was more often found for younger men because these men were able to seize newly emerging opportunities after the Depression. However, conclusions about personality development were confounded with individuals’ birth cohorts; thus, it was unknown whether the findings were a result of maturational change, the time of testing and historical influences, or the participants’ generations. Schaie developed the cohort-sequential design to tease apart the effects of these factors, yet this elaborate design is rarely used. In sum, longitudinal studies, although offering the most comprehensive picture of personality development, can be limited about personality continuity and change. Thus, when reviewing empirical results regarding personality across adulthood in the section that follows, one should pay close attention to the types of continuity found and the methods employed.

2.3. Major Findings

Table I summarizes the types of continuity and change evident in research on personality in late life,

the typical statistical methods used, and the general conclusions. This section reviews major empirical results supporting both continuity and change in personality.

2.3.1. Evidence for Continuity

There is quite a bit of evidence pointing toward continuity of personality during adulthood and late life. Costa and McCrae’s Baltimore Longitudinal Study began in 1980 and consists of approximately 1000 participants ages 20 to 96 years. Participants were given the NEO Personality Inventory, which measures the Big Five basic personality traits. In this and other work, they have found moderate to high rank-order consistency for personality traits across time intervals of 5 to 6 years. Costa and McCrae interpreted their results as indicating that personality does not change, except in trivial ways, after the age of 30.

Other researchers espousing the individual differences approach, such as Conley, have also found a great deal of stability in personality across adulthood. Using a different self-report personality measure as part of the Kelly Longitudinal Study, Conley and colleagues found that certain personality traits, such as neuroticism, social introversion–extraversion, and impulse control, demonstrated fairly stable patterns across 25- and even 40-year time intervals. Focusing on late life, Troll and Skaff found continuity in self-concept in the oldest old (85 years of age or over). Participants were asked how they thought they had changed over the years and how they had remained the same. These older adults reported that their core self-concept had remained stable over the years, and their self-descriptors were also relatively consistent. In sum, for different measures used to assess personality, there seems to be differential consistency of personality during adulthood and late life.

TABLE I
Summary of Personality in Late Life: Types of Continuity, Typical Methods, and Empirical Results

<i>Types of continuity</i>	<i>Typical methods</i>	<i>Empirical results</i>
Differential continuity	Rank-order consistency	Stability: ranks of personality characteristics relatively stable in late life
Absolute continuity	Mean levels	Change: decreases in neuroticism, increases in agreeableness, decreases and maintenance in extraversion in older adults
Ipsative continuity	Intraindividual differences and variability	Stability and change: growth, stability, and decreases in personality characteristics within individuals

2.3.2. Evidence for Change

Advocates of the contextual view, such as Helson, have argued that trait theorists seek to confirm hypotheses about the stability of personality rather than to explain why and how changes in personality occur when they do. In the Mills College Longitudinal Study, Helson found changes in adult women's personalities across a 30-year time period. For example, women became more assertive (i.e., mean-level increase on the masculinity scale) from 20 to 30 years of age, and they became more compassionate (i.e., mean-level increase on the femininity scale) as they approached late life (52 years of age). But what happens in very old age? Field and Millsap analyzed data from the Berkeley Older Generation Study and found consistent age-related trends for the mean level of some personality traits. For example, for this very old sample, they found increases in agreeableness and decreases in extraversion with age. Thus, there seem to be changes in mean levels of personality characteristics, even though rank-order consistency is fairly constant. Studies of intraindividual variability also suggest both change and continuity in personality across individuals' lives.

2.3.3. Intraindividual Variability: Evidence for Continuity and Change

Although few studies of intraindividual variability have been conducted, they provide a comprehensive picture of the variability of personality in late life. A classic study by Jones and Meredith examined individual patterns of personality development over a 30-year time span. For example, they found that some participants' self-confidence was stable until 30 years of age and then increased during middle age, others' self-confidence remained stable across the time period, and others' self-confidence declined with age. In a recent study, Mroczek and Spiro found variability in the rate and direction of change in personality among men ranging in age from 43 to 91 years. Although they found that many men showed declines in neuroticism and stability in extraversion, there were also many men who deviated from this overall pattern, thereby demonstrating individual variability even in old age.

In conclusion, personality in late life is undoubtedly characterized by both differential continuity and changes in mean levels of personality characteristics (i.e., absolute continuity). Studies of intraindividual variability reiterate that continuity and change in personality both occur in late life differentially for

individuals and that group means can be deceiving. However, mean-level changes that occur are relatively positive (e.g., decreases in neuroticism, maintenance in extraversion). Multiple dimensions and directions of change characterize personality in late life. Does a similar variable pattern exist for how people feel in late life?

3. EMOTION IN LATE LIFE

Emotions have been defined as short-lived responses to events in the environment that involve changes in body physiology, subjective experiences, and expressive behaviors. That is, emotions are transient and happen on multiple levels. Some emotions, such as happiness, do not endure over a lifetime but rather are dynamically and subtly tied to specific events and experiences—to cognitions, memories, and personalities. The important questions for emotion research have been whether older adults, given their unique life circumstances, cognitive abilities, and personalities, experience or feel emotions to the same degree as do younger adults, experience the same types of emotions as do younger adults, and regulate and express emotions in the same way as do younger adults. The following theories of emotion in late life address these central questions.

3.1. Theoretical Issues

3.1.1. Emotion Regulation and Affect Optimization

In 1989, Lawton proposed a theory of the regulation processes of emotion during adulthood, emphasizing positive gains in regulation with age. Furthermore, he postulated that in late life, adults regulate emotion toward "affect optimization," that is, a minimization of negative affect and a maximization of positive affect. He contended that better affect regulation in late life occurs as a function of positive changes in personality as well as changes in social contexts in late life. Examination of social context became a focal area for further theoretical expansion, as seen in the next theory.

3.1.2. Socioemotional Selectivity Theory

In 1992, Carstensen proposed the socioemotional selectivity theory, which situates emotion in the context of social goals associated with different life phases. This theory focuses on the salience of emotion in older adults' everyday lives. Carstensen, like Lawton, emphasized

regulating emotion toward obtaining positive affective experiences. The core of Carstensen's theory is that older adults show a selective narrowing of social networks to more emotionally close, gratifying social relationships. That is, the regulation of emotion is, in part, a function of social choices; maintaining a positively valenced emotional life is realized through selection of positive social relationships. Carstensen's theory ties emotion regulation to life phase-specific choices regarding social networks. The next theory also ties emotion to life phase, but largely through the relation of emotion to cognition and personality at different points during the life span.

3.1.3. Cognitive–Affective Developmental Theory

Labouvie-Vief proposed a cognitive–affective developmental theory of emotion that delineates the role of emotional functioning in conjunction with the development of cognitive and ego processes (the self) that occur across the life span. She argued that emotion is qualitatively different at various points in the life span. Specifically, with more complex ways of processing information and higher levels of ego development, emotional expression moves from being based on societal standards during adolescence to more sophisticated emotional functioning during adulthood. This includes increases in the complexity of experienced emotion, heightened emotional flexibility, and more tolerance for ambiguous emotions. Labouvie-Vief's theory clearly delineates the connection between emotion and personality, or self-development, as does the discrete emotions theory advocated by Magai.

3.1.4. Discrete Emotions Functionalist Theory

During the 1980s, Magai integrated emotion theory with personality theory by introducing the discrete emotions functionalist theory to research on adult development. Rooted in the differential emotions tradition, this theory emphasizes the functional nature of the primary emotions (e.g., happiness, fear, anger, sadness), focusing on how emotions are used to organize thought and behavior. Magai's work suggested that discrete emotions are hardwired from birth but serve similar functions across the life span. What changes with age is the ways in which emotions are expressed; that is, with increasing age, the complexity and elaboration of emotions increase. In addition, Magai delineated how emotion and personality are intertwined, particularly in late life. She suggested that discrete emotions experienced repeatedly early in

life become traitlike and integrated as “emotion traits” within an individual's personality.

These four theories make unique contributions to the literature regarding how emotion is regulated toward positive affect in late life, how social processes are used to regulate emotion in late life, how life span development of self and cognition encourages more sophisticated processing of emotion with age, and how emotions play a functional role in directing thought and behavior from early childhood but gain increasing complexity and elaboration across adulthood. Despite the differences among these four theories, each theory in some way addresses one of the central issues of how older adults experience emotion, regulate emotion, and express emotion.

3.2. Methods and Measures

Corresponding with the central questions of emotion research, most work has been cross-sectional rather than longitudinal. Emotion researchers use a rich array of methodological tools, including both objective and subjective measures.

3.2.1. Objective Measures

Objective assessments of emotion are psychophysiological measures tied to the basic neurology of emotion (e.g., autonomic nervous system activity, discrete musculature changes during facial expression). Studies assessing the psychophysiological aspects of emotion involve asking participants to look at emotional pictures (e.g., a child playing in a field) or to relive emotional experiences (e.g., a surprising event). Autonomic activity, such as changes in heart rate or breathing, is assessed online during these tasks. Similar stimuli are used when examining facial expressions of emotions. Ekman developed an elaborate system for coding universal, emotion-specific facial expressions. For example, people universally express sadness by pulling down the corners of their lips, and surprise is expressed by a widening of the eyes. These objective measures of emotion inform researchers about the underlying processes and universal nature of emotions.

3.2.2. Subjective Measures

Subjective measures of emotion are more commonly employed. They typically include self-report ratings and, more recently, behavioral observations (e.g., coding the types of emotion present during social exchanges) and

open-ended verbal narratives (e.g., coding emotional content of remembered narratives). Self-report measures (e.g., the Positive and Negative Affect Scale developed by Watson and colleagues) are undoubtedly the most common means of assessing emotion in late life. Adults answer questions about whether, and how intensely, they have felt several negative and positive emotions (e.g., sadness, happiness) over the past month or the past week. Self-reports are subject to response biases and, as Levine and Bluck demonstrated, have a memory component that may lead to greater biasing in older adults. For example, questions about general emotional experience (e.g., “How salient is emotion to you in your everyday life?”) probably require effortful processing if a person actually recalls everyday events to provide an estimate of the general emotional content. Thus, results using such scales are prone to memory error. More naturalistic and ecologically valid measures, such as observing emotional behaviors and collecting emotional memory narratives, may be better suited as subjective measures of emotion in late life. Bluck and Alea recently found that autobiographical narratives and scalar self-reports sometimes provide divergent information about the emotional lives of older adults.

In sum, both objective and subjective measures have been used to examine various aspects of emotion in late life. In terms of subjective measures, there are a number of tools that vary in level of reliability and ecological validity. The next section reviews major findings about emotional functioning during adulthood and late life, paying special attention to the type of measurement employed.

3.3. Major Findings

The major empirical findings mirror the chief theoretical concerns in this area: the overall experience of

emotion, the regulation of emotion, and the expression of emotion during adulthood and late life. Table II summarizes the major empirical findings by method of investigation.

3.3.1. Experience of Emotion

Research on the experience of emotion includes both physiological measures and the subjective experience of emotion in daily life. Levenson and colleagues have conducted a series of studies investigating whether older adults experience the same intensity of physiological reactions as do younger adults when they relive emotional experiences. Using online physiological assessments, these researchers have found that, for the most part, older adults exhibit the same physiological responses as do younger adults for discrete emotions. For example, both younger and older adults have increases in heart rate when experiencing fear. The magnitude or intensity of these responses, however, is often lower in late life.

The intensity of experienced emotion has also been examined using self-report measures. For example, Diener and colleagues conducted a large-scale study to assess age differences in the self-reported intensity of emotions in adolescents, younger, middle-aged, and older adults. They used the Affect Intensity Measure, which assesses how intensely individuals experience emotions in various situations (e.g., “I can remain calm even on the most trying days”). Older adults reported less intense emotional experiences than did younger adults. Thus, older adults tend to show the same pattern of physiological reaction as do younger adults, but emotions generally seem to be experienced with less intensity in late life. This holds for both physiological measures and self-reports. But what

TABLE II
Summary of Emotion in Late Life: Aspect of Emotion, Typical Methods, and Empirical Results

<i>Aspect of emotion</i>	<i>Typical methods</i>	<i>Empirical results</i>
Emotional experience	Psychophysiological	Mixed: no age difference for physiological experience of primary emotions; lower intensity with age
	Self-reports	Lower intensity with age
Emotion regulation	Self-reports	Increase in positive affect and decrease in negative affect with age; better emotion regulation with age
Emotional expression	Facial expression	Mixed: no age differences; more expressive with age; harder to decode expressions with age
	Verbal expression	Express more emotion with age
	Behavioral indicators	Fewer negative behaviors and more positive behaviors

happens if one looks at emotional valence? That is, do older adults experience both positive and negative affect with less intensity than do younger adults?

3.3.2. Emotion Regulation

Empirical work investigating the balance between positive and negative affect with age has often been conducted in the context of emotion regulation. Most (but not all) work on emotion regulation is congruent with existing theoretical accounts claiming that older adults tend to regulate their emotions toward affect optimization. Older adults self-report experiencing more positive and less negative affect than do younger age groups. For example, Mroczek and Kolarz analyzed data from more than 2000 adults ranging in age from 25 to 74 years. Using the Bradburn Affect Balance Scale, a self-report scale of positive and negative affect, they found an increase in positive affect after 45 years of age and a linear decrease in negative affect across age groups. Charles and colleagues found similar results concerning negative affect in a 14-year longitudinal study of self-reported positive and negative emotion. Furthermore, Gross and colleagues have demonstrated that increases in positive affect states and decreases in negative affect states also apply to discrete emotions such as happiness and anger. Thus, although researchers have found overall decreases in the intensity of emotion with age, it seems to depend on whether the emotion is positive or negative. In late life, negative emotion is often down-regulated, whereas positive emotion is often up-regulated.

In addition to examining the regulation of emotion through valence, researchers have explicitly asked adults about their ability to self-regulate emotions. In the study by Gross and colleagues, emotion regulation was investigated in a diverse sample (e.g., European Americans, African Americans). Participants were asked how well they could control both their inner and outer expressions of emotion (e.g., "Overall, how much control would you say you have over your emotions?"). They found that across age groups, there was an increase in self-reported ability to regulate emotion. Using a different technique, Labouvie-Vief and colleagues reported similar results as far back as 1989. They asked participants to recall emotional experiences and then conducted semistructured interviews about the types of emotional control or regulation strategies individuals used. They found age differences in emotion regulation, although the primary difference was between adolescents and the two

older age groups (middle-aged and older adults). Thus, using self-reports, there is reasonable evidence suggesting that older individuals are better at regulating emotions than are younger individuals and that older individuals tend to regulate their emotions toward positive affective states. Emotion regulation usually refers to internal experiences of emotion. Does emotional expression differ by age?

3.3.3. Expression of Emotion

Emotion can be expressed in three basic ways: facial expressions, verbal expressions, and specific behaviors. Levenson and colleagues examined the facial expressions of young and older adults while they were remembering and describing emotional experiences. The researchers failed to find age differences in how adults expressed the primary emotions of anger, disgust, fear, happiness, and surprise. In contrast, Magai found that older adults were at times more expressive than younger adults but that physical changes in their faces with age (e.g., wrinkles) can mask their expressivity.

Research examining the verbal expression of emotion has also found that older adults express greater emotion than do younger adults. In 1994, Carstensen and Turk-Charles conducted a study in which they asked younger and older adults to remember narrative passages. Compared with younger adults, older adults spontaneously focused more on the emotional aspects of the narratives than on the factual information. Alea and colleagues have found similar age results in their work using autobiographical narratives. Specifically, older adults remembered more emotional information about an autobiographical event than did younger adults.

Behavioral observations of emotional expression, common in the child development literature, have been less common in studies of adulthood. Emotionally expressive behaviors include gestures (e.g., banging one's fists when angry, crying when sad) and body movements (e.g., looking away from something in disgust, shifting when nervous). Carstensen and colleagues conducted one of the few studies examining such behaviors in older adults. These researchers videotaped older and middle-aged married couples discussing positive, negative, and neutral marital issues. They found that, after controlling for level of marital satisfaction, older couples showed less negative emotional behaviors during discussions of unpleasant topics and were more affectionate toward their partners than were middle-aged couples. Thus, work on emotional

expressivity suggests greater expressivity in older adults' verbalizations and behaviors, although the basic facial configurations used to express emotion do not appear to change with age.

In sum, empirical results regarding emotional functioning in late life are centered on the issues of experience, regulation, and expression of emotion with age. Using various measures has provided a rather complex yet comprehensive picture of emotion in late life. In general, emotions sometimes are experienced less intensely with age and at other times are experienced just as intensely in late life as in earlier life; however, for the most part, emotions are regulated toward positive affect and expressed in a variety of ways across the life span. Thus, the pattern of emotional functioning during adulthood is also mostly characterized by gains and maintenance of functioning in late life.

4. CONCLUDING REMARKS: LINKING PERSONALITY AND EMOTION

This article began with a discussion of the competing negative and positive cultural stereotypes about older adults' personalities and emotional lives. Does scholarly work support or refute these different pictures of late life? Theoretical and empirical work on personality development and emotional functioning suggests that although older adults certainly face losses (e.g., widowhood) and challenges (e.g., increases in physical ailments), they also have psychological resources available to compensate for, or moderate, losses in functioning. Personality is mostly stable in late life, and (on the whole) changes seem to be relatively positive. Changes in emotional functioning with age, such as better emotion regulation and decreases in the intensity of physiological arousal levels, may also help individuals to face challenges in late life. Thus, both personality development and emotional functioning represent areas of stability or growth that enhance the experience of growing old.

Consequently, a clear step toward better understanding well-being in late life is further delineating the integral relation between personality and emotion. Although the major personality theories imply that traits have an inherent emotional component, the assessment of personality and emotion linkages has

been rather sketchy so far. Emotion theories have been better at delineating the relation between personality and emotion. For example, Labouvie-Vief's work suggests that emotional development occurs during adulthood in part due to development of the self, and Magai's work postulates that emotions that are repeatedly experienced early in life become salient to an individual and integrated into his or her self-representations across the life span. Recently, with the publication of Block's book *Personality as an Affect-Processing System*, there is a growing awareness that the traditional distinct notions of personality and emotion may limit our understanding. Block suggested that these approaches can be fused in a creative way to examine both phenomena more comprehensively while including a life span developmental perspective relevant to the study of aging. The task for future researchers is to explore empirically how emotion and personality are interrelated and how they act together to influence quality of life in late life.

emphasis on psychoanalysis themes. Like the Rorschach test, the subjects' interpretations of the scenes are considered projections from their subconscious.

GLOSSARY

Big Five A set of personality dispositions (extroversion or energy, agreeableness or friendliness, conscientiousness, emotional stability or neuroticism, and openness to experience) considered by some to be present, to varying degrees, in every individual.

personality assessment Procedures designed to identify and evaluate enduring psychological qualities, including modes of thinking, feeling, and acting that characterize the individual and differentiate individuals from one another.

psychodynamic assessment Procedures, involving interviews and projective techniques, concerned with assessing the complexity of individual experience, including unconscious motives and conflicts among subsystems of personality.

Rorschach inkblot tests Cards with blots of ink (black, black/red, or multicolored) shown to subjects for interpretation. The subjects' interpretations of the abstract designs are considered projections indicative of their subconscious minds.

temperament Personality features evident early in life.

Thematic Apperception Test (TAT) Similar to a Rorschach inkblot test except that it is produced in shades of black and white and is somewhat more concrete, with an

Personality assessment refers to procedures designed to identify and evaluate enduring psychological qualities, including modes of thinking, feeling, and acting that characterize the individual and differentiate individuals from one another. Assessment techniques address the cognitive, affective, motivational, and moral components of individual functioning, including cognitive abilities and styles, temperament and mood, motives, attitudes and values, habitual behaviors, coping strategies, and self concepts and regulatory mechanisms. Through a great variety of quantitative and qualitative techniques, personality assessors serve both basic and applied research needs in settings in which descriptive, predictive, and explanatory information about people is required. Personality assessments may be conducted for a variety of purposes. One may aim to describe normal variations in any of the previously mentioned individual characteristics in the population at large, to diagnose psychopathology suffered by a small subset of the population, or to obtain a detailed portrait of the psychological structure and dynamics that characterize a particular individual. The existence of widely varying techniques also reflects the presence in the professional field of competing theoretical views that one may endorse when pursuing an assessment of personality.

I. MODERN APPROACHES AND CONTEMPORARY TRENDS

Modern approaches to personality assessment can be traced to late 19th- and early 20th-century efforts to assess intelligence, temperament, and vulnerability to mental illness. While Francis Galton was an advocate of measurement of both intellectual abilities and character, Alfred Binet set the premises for the long-lasting Intelligence Quotient tradition, and Emile Kraepelin and Carl Gustav Jung pointed to word association as a common technique to detect and analyze mental disorders and complexes. The Woodworth Personal Data Sheet, which appeared in 1918, represents the earliest model of a paper-and-pencil self-report inventory to assess personality, whereas the Rorschach inkblot test, which appeared 2 years later, remains the most famous exemplar of projective techniques, which were designed to circumvent the psychological defenses that, in principle, might invalidate responses to self-report paper-and-pencil test items.

Two main lines of inquiry set the stage for subsequent developments in personality assessment. One primarily focused on interindividual genetic differences, whereas the other was mostly focused on the internal dynamics of individuality. Investigators who assessed phenotypic individual differences, namely traits, motives, and attitudes, conceived personality as an architecture of tendencies and habits. In contrast, theorists focusing on internal personality dynamics perceived personality as a system in service of adaptation and pointed to internal forces, external pressures, and defense mechanism that underlie individual personality development and shape its distinctive features of functioning.

During the subsequent decades, self-report trait inventories were commonly used in a variety of contexts to describe and predict performance and adaptation. Projective techniques such as the Rorschach inkblot tests and the Thematic Apperception Test (TAT) were more frequently used in clinical settings. Both were largely endorsed by scientists and practitioners, regardless of their theoretical orientation. Although there was not yet a unique science of personality, most progress came from work in psychometrics, including the extension of factor analytic methods to study the components of personality.

Thus, by the mid-20th century, personality assessment could count on not only a large variety of instruments but also a consistent body of knowledge regarding sources of data and the quality of measures.

It was made clear that one should rely on different sources of data, such as behavioral observations, self-reports, psychophysiological indices, and narratives, to tap aspects of personality, and that alternative instruments may be differentially appropriate to capture general versus unique features of the individual, to assess different constructs, or to apply to different populations or in different settings. In this regard, the seminal contributions of Cattell to psychometrics and statistics and of Cronbach and Meehl to the quality of personality measures and to the various methods to ascertain their validity and reliability were long-lasting and influential.

However, sophistication of methods could not solve all disputes at the theoretical level. Today, although personality psychology is a well-established domain of scientific inquiry, the desirable idea of a unique science of personality in which multiple contributions from social, cognitive, psychodynamic, and dispositional orientations converge synthetically in the service of cumulative knowledge is far from being fully achieved. Instead, one finds a number of distinct broad trends in theory and assessment, each of which can claim to have made scientific progress.

One such trend addresses the subject as an active interpreter of his or her world. The cognitive and affective revolutions ultimately led to better appreciation of the role of the self system in granting unity, continuity, and coherence to individual experience. A new conception of personality as both an agent capable of making things happen according to its anticipations and standards and a social construct embedded in a network of interpersonal relationships has gained broad consensus. This widened the traditional view of personality as a mediated system, further highlighted the importance of continuous individual—environment interactions, reoriented the study of individual differences from global dispositions to contextualized behavioral strategies, and pointed to the systems that mostly account for the attribution of meanings and regulation of action as they operate and develop over the course of life.

Another area of advancement involves the assessment of personality features evident early in life. Research on temperament has begun to assess specific biological systems involved in the generation and regulation of affective experience. Much of this work has demonstrated that the assessment of temperament must consider not only the biology of personality but also the social contexts in which the person acts, especially because the nature and meaning of biological response measures may shift from one context to another.

Studies on emotional, social, and practical intelligence have brought closer the traditions of research on intelligence and personality that had often developed along separate pathways, the former focusing on cognitive abilities and problem solving and the latter on interpersonal relations and social behavior. The discovery of the cognitive unconscious, namely the variety of phenomena associated to automatic and implicit forms of knowledge, gave new impulse to the study of informational and motivational processes that operate beyond individual awareness.

The study of self systems has led to a focus on self-representations, self-beliefs, and self-regulatory mechanisms as they operate in concert to grant unity and coherence to individual experience and behavior. These changes in personality theorizing inevitably have carried new assessment aims, such as the assessment of skills and knowledge that underlie overt behavioral competencies, and have given impulse to the design of new procedures and instruments, including cognitive techniques to measure individual differences in knowledge accessibility and biopsychological techniques for tapping brain systems in personality functioning.

This progress has greatly benefited from major advances in the neurosciences that have yielded enhanced knowledge of brain functioning, as well as from the technological devices that allow closer access to the biological mechanisms underlying thought, affect, and action. In addition, access to large and diverse populations and computer-aided psychometrics further widened the scope of personality assessment process.

2. ISSUES AND STRATEGIES

Throughout much of its history a great part of personality psychology has been concerned with individual differences in observable variations in styles of behavior, affect, and cognition. Self-report and observer ratings have been the main methods to assess habitual behaviors, attitudes and beliefs, motives, and values.

A number of authors have posited traits to account for stable patterns of experience and action that people exhibit and that distinguish them one from another across tasks and situations. Within this line of thinking, personality has been conceptualized as a hierarchical organization with high-level traits (e.g., extroversion) that organize lower level tendencies (e.g., sociability), which in turn supervise lower level behavioral habits (e.g., talkative). Within this tradition, a broad consensus

has been achieved on a central question, namely, the number and content of the high-level traits. Five global dispositions are seen as necessary to individual-difference assessment: extroversion or energy, agreeableness or friendliness, conscientiousness, emotional stability or neuroticism, and openness to experience. These or similar individual-difference dimensions have been consistently identified across different cultural contexts. These dimensions have proven to subsume many previous taxonomies, with a variety of specific traits being shown to correspond to facets or variations of each main trait or combination of main traits. Among the most commonly employed instruments to assess the so-called Big Five traits are the Revised NEO Personality Inventory of Costa and McCrae and the Big Five Questionnaire of Caprara *et al.*

During the past 20 years, many studies have corroborated the concurrent and predictive validity of the Big Five in a variety of educational, organizational, and health settings. Yet this approach meets only part of what personality assessment should aim to achieve.

The Big Five provide a sufficiently comprehensive description of personality at the level of surface behavior tendencies. They may serve to tap interindividual differences by pointing to features that may significantly impact on others as well as predict performance in a variety of settings. However, it is beyond the reach of the Big Five to explain the underlying mechanisms that govern behavior and grant its continuity and coherence. The constructs and their associated assessments indicate little about essential characteristics of being a person, such as self-awareness and intentionality. They meet the need of the bystander psychologist, but they miss the perspective of self-reflective agent.

In contrast, psychodynamic theories have long been much more concerned with assessing the complexity of individual experience. In this tradition, interviews and projective techniques such as TAT or the Rorschach continue to be used by clinicians as well as by researchers. Unfortunately, work in this tradition has encountered numerous empirical obstacles since these instruments are hardly amenable to standard criteria. Reviews indicate that in many important applications, projective tests fail to display adequate predictive validity.

Other investigators have sought alternatives to trait and psychodynamic assessment approaches that are able to capitalize on both quantitative and qualitative methods and to meet the requirements of objective research seeking for general laws without sacrificing what is unique of individual experience. One

theoretical grounding for such efforts has been social cognitive theories. In conceiving of personality as an open, dynamic, unifying, and integrating system, social cognitive theorists point to the emerging properties of mind and focus on the processes and mechanisms conducive to knowledge and motivational structures that enable personality to function as a proactive self-regulatory system. Persons and socio-cultural environments are viewed as reciprocally interacting systems, with the core person variables being cognitive and affective mechanisms through which people interpret the world and regulate their own behavior. Thus, social cognitive theorists focus on the self-construction of personality as an integrative and coherent system as it takes place over the course of life, on the processes that enable the system to function proactively in continuous and reciprocal interaction with the environment, and on the self-structures that orchestrate these processes. Where assessment issues come to the fore, the primary targets are self-regulatory structures, including self-representations, self-efficacy beliefs, and personal goals and standards, namely the structures that are involved most centrally in the self-reflective and self-evaluative properties of mind that operate at the individual level to meet environmental opportunities and constraints and to maintain personally valued courses of action.

GLOSSARY

individual distance The amount of space between organisms and their conspecifics.

personal space The emotionally tinged zone around the human body that people feel is “their space.”

proxemics A term introduced by Edward Hall for the study of spatial relationships; Hall identified four interaction zones: intimate, personal, social, and public distance.

territory A fixed geographical space marked and defended by an organism and used for life-sustaining activities.

Because the concept of personal space originated in ethology, some of the most promising theories to explain why humans maintain predictable distances from one another employ a Darwinian (functional) framework. Researchers have investigated differences in interpersonal spacing associated with culture, gender, age, personality factors, and situation. Applications of the concept are found in design, communications, and legal cases.

1. PERSONAL SPACE CONCEPT

The term “personal space” was introduced into the social psychological literature to describe the emotionally tinged zone around the human body that people feel is “their space.” It has been described using analogies to a soap bubble, a snail shell, and an aura around the human body. The dimensions are not fixed but rather vary according to internal state, age, culture, and context. The concept has its roots in animal studies, particularly the work of ethologists and zoologists, because most animals in the wild maintain defined distances from conspecifics, and these distances are influenced by an animal’s age, size, gender, social rank, and other factors.

2. MEASUREMENT OF PERSONAL SPACE

Methods for measuring personal space in human interactions include both field studies and laboratory simulations (Figs. 1 and 2). A favorite laboratory technique is the invasion, which produces tension-reducing responses such as gaze aversion and withdrawal. In the stop distance technique, a researcher approaches the participant, who tells the researcher to stop when he or she comes uncomfortably close. In the approach distance technique, the participant is asked to move toward another person and to stop at a comfortable interaction distance. In figure placement tests, the participant places manikins, dolls, or other human

FIGURE 1 Field observation of seating in a college library.

FIGURE 2 Laboratory simulation of a space station environment.

surrogates in various social arrangements such as having a conversation. Other measurement techniques include questionnaires and physiological recording.

3. RESEARCH FINDINGS

Interpersonal distance is decreased by similarity between participants, acquaintanceship, attraction, cooperation, and cohesion. It is increased by threat, anxiety, stigma, smoking, and mental disorder. Children have smaller interaction distances than do adults, female pairs generally sit and stand closer than do male pairs, and people from Latin cultures use smaller interaction distances than do people from Anglo-Saxon backgrounds.

Environmental variables such as noise, crowding, and room size affect interaction distance.

4. APPLICATIONS

There is a flourishing research literature on interpersonal spacing in human services fields such as social work, nursing, counseling, and family therapy. Guidebooks and self-help books describe appropriate spacing in various interpersonal encounters. Some books dealing with sales, management, and dating specifically recommend the aggressive appropriation of space (i.e., standing excessively close) as a form of impression management.

As personal space enters the popular culture, airlines advertise more of it in their seating, residents of homeless shelters complain that they have too little of it, and corporate training manuals warn employees to respect each other's personal space to protect the company against lawsuits.

4.1. Design and Architecture

The personal space concept has been applied in the design of offices, stores, banks, and other building types, but its greatest applicability is in mass transit and institutional settings with fixed seating and little opportunity for personal mobility. The U.S. space agency, the National Aeronautical and Space Administration (NASA), used the results of personal space research to improve habitability in the space station.

4.2. Communication Skills

Diplomats and corporate executives being posted to different cultures are taught about the different ways in which people around the globe use space and time. These ideas have also been applied to interactions between salespeople and customers, police interrogations, nurse-patient and therapist-client relationships, and interactions among family members.

4.3. Legal Uses

In the United States, the concept has had nearly as much application in the courtroom as in design. It has figured prominently in lawsuits on prison crowding and became a pivotal issue in cases of sexual harassment as unwanted closeness was interpreted as a form of harassment toward individuals who lacked power. Judges have used the concept in establishing "no intrusion zones"

between protesters and their adversaries. In high-profile trials, space consultants advise lawyers during jury selection, a time when potential jurors are being screened by both the prosecution and the defense for signs of bias. Nonverbal behaviors such as posture, gesture, and interpersonal distance are observed as potential jurors respond to lawyers' questions.

person–job fit The extent to which an individual's skills and abilities match the skill and ability requirements of the job.

person–organization fit The extent to which an individual's attributes (e.g., goals, values, personality) are consistent with those of the culture or climate of the organization.

supplementary fit The extent to which an individual's attributes are congruent with or similar to those of the group or organization.

GLOSSARY

attraction–similarity–attrition (ASA) cycle Cycle whereby individuals are attracted to, selected by, and remain in organizational environments that have characteristics similar to their own.

complementary fit The extent to which an individual's attributes provide something that is needed or lacking in the environment (e.g., the group, the organization).

levels of analysis Delineation of organizations into interrelated levels of analysis—the individual, the group or unit, and the organization as a whole.

occupational fit The extent to which an individual's vocational interests and skills match the opportunities and requirements of the occupation.

person–environment fit The extent to which the characteristics of an individual (e.g., skills, abilities, goals, needs, personality, values) match the characteristics of the work environment (e.g., job requirements, work group climate, organizational goals, organizational culture).

person–group fit The extent to which an individual's attributes (e.g., skills, goals, values, personality) are similar to or complement those of others in the work group.

Person–environment fit theory addresses the extent to which the characteristics of an individual are similar to, or are complementary to, the characteristics of the work context, group, or organization. The degree of “fit” has implications for individual attitudes and behaviors in organizations, as well as for group and organizational effectiveness. Fit can be created through naturally occurring processes such as a cycle of being attracted to, selected by, and remaining in an organization, or through deliberate interventions such as socialization and training. Fit has a broad range of applications in organizations, including culture and climate, selection and socialization, and team composition and diversity.

1. OVERVIEW AND DEFINITIONS

Consider the hiring practices of two different organizations in the same manufacturing industry. In the first organization, the selection process entailed the

screening of each applicant's résumé to assess relevant background and work experience, a written test to assess job knowledge, and a short interview. This type of hiring process is not unusual in many manufacturing organizations. Now consider the hiring process used at Toyota when it opened a new plant in Kentucky. The process entailed a general knowledge test, a manufacturing exercise to provide a realistic job preview of the type of work to be performed, surveys of attitudes toward work, extensive interviews, and a physical exam. Each applicant spent at least 18 hours engaged in the selection process. Why would an organization devote so much time, money, and resources to hire employees from the lowest to highest job levels?

In the first case, the organization's primary concern was to achieve person-job (P-J) fit, that is, to hire employees with the relevant skills and abilities for specific jobs in the organization without specific consideration of the extent to which job applicants' characteristics are congruent or compatible with the characteristics of the organization in which the job is embedded. In the second case, the intensive selection process was geared toward hiring "whole" persons, that is, those who not only would fit the job but also would fit well into the organization's culture and the organization as a whole. Organizations that engage in such intensive hiring practices maintain that P-J fit alone is not sufficient to ensure that an employee will perform well in the organization. Rather, they advocate that employees who fit the job and the environment of their work group and the organization overall will be better performers, more satisfied employees, and less likely to leave the organization.

1.1. Definition: What Is Fit?

The fit or match between the characteristics of the individual, on the one hand, and the characteristics of the environment, on the other, is what is generally referred to as person-environment (P-E) fit. On the person (P) side, these characteristics may include skills, abilities, personality, personal needs, goals, and interests. On the environment (E) side, these characteristics may include specific job requirements, reward systems, goals, culture, climate, and resources of the unit or organization.

The underlying assumption is that a good fit between the characteristics of people and those of the environment will result in better performance, higher job satisfaction, enhanced loyalty to the organization, more positive attitudes, and a lesser desire to leave the

organization for another job. Furthermore, it is assumed that fit is a dynamic and developmental process such that a lack of fit will prompt a change in careers, jobs, groups, or organizations in the hope of achieving fit. Although this notion may appear to be intuitive, understanding how fit operates in organizational settings is complex. For example, what processes help to create fit? How can an organization best identify and attract those individuals who will better fit the organization? How can an organization assess which job applicants will ultimately be a good fit for the job, the work group, and the values and culture of the organization? Is fit always desirable? These types of questions represent the core of fit research and theory and are addressed in the following sections.

1.2. Brief History: From Interactional Psychology to Fit

Researchers in organizational behavior are concerned with understanding and predicting people's responses in organizational settings. Historically, researchers debated whether individuals' responses are primarily a function of their personal attributes (e.g., personalities, knowledge, past experiences) or the characteristics of the situation (e.g., organizational climate, rewards system, organizational structure). Interactional psychology theories assume that individuals and their situations are interdependent. The characteristics of the situations constrain and affect the responses of individuals, whereas individual responses simultaneously influence characteristics of their situations or organizations. In other words, people react to situations and also create or enact them.

Although the interactionist perspective emphasizes the importance of both personal and situational characteristics, little theoretical explanation as to how person and environment variables interact to affect behavior was provided. The principle of congruence or fit is one explanation that has gained considerable recognition, and it highlights that person and environment factors should combine through "matching." The optimal combination is one in which the personal and situational characteristics are matched or compatible. Conditions failing to reach this kind of match will lead to a state of incongruence that will have negative effects on outcomes such as performance and satisfaction.

This notion that a better fit between people and their environment results in more positive behaviors and responses has a long history in various fields of psychology, particularly social psychology, personality, group

dynamics, and educational psychology. For example, in social and personality psychology, laboratory experiments over the past 40 years or more have suggested that for each individual, there are environments that more or less match the characteristics of the individual's personality. In educational psychology, seminal studies beginning in the 1950s and 1960s demonstrated that larger discrepancies between self-ratings and ideal ratings of the college environment and between self-ratings and other students' ratings of the environment were related to greater dissatisfaction with college life. In vocational psychology, a substantial amount of research has been devoted to Holland's seminal theory of vocational choice, indicating that greater career success and satisfaction with work purportedly results from a match between individuals' interests and the tasks and activities associated with broad classes of occupations (as opposed to specific attributes of a particular job or a particular organization).

The early work in industrial and organizational psychology research domains addressed (implicitly if not explicitly) the notion of fit to job characteristics. In particular, a great deal of emphasis was placed on personnel selection, that is, devising selection procedures and tests to maximize the probability of an organization hiring individuals whose skills and abilities matched the skills and abilities required for the particular job. Through training, attempts were made to maximize fit by upgrading the skills of individuals to better match the job requirements. Furthermore, in the area of job design, emphasis was placed on redesigning jobs to fit the abilities and limitations of the people performing them. This early work focused largely on fit as it pertained to skills and abilities or the specific type of attributes and tasks inherent in the job itself. Surprisingly little attention was directed at understanding fit in the broader social, work group, and/or organizational contexts.

Starting in the 1980s, theory and research on fit in organizational psychology domains became more complex and integrative. There was a shift from a predominantly skill-oriented P-J fit perspective to a broader perspective of addressing fit between a wide range of individual attributes and a wide range of job, work group, and organizational characteristics across a wide range of organizational areas.

1.3. Fit to Different Levels of Analysis

The primary emphasis in organizational fit research has been on the extent to which individuals fit the attributes

of their job, their group, or their organization. As a result, three broad types of fit have been proposed. P-J fit focuses on congruence or fit between an individual's skills and abilities and the skills and abilities required to perform a specific job in the organization. Person-group (P-G) fit addresses the extent to which an individual's characteristics (e.g., personality, skills, values, goals) are congruent or aligned with the characteristics of other members of his or her work group or work unit. Fit to the broader organizational context is addressed through person-organization (P-O) fit focusing on the extent to which an individual's personality, goals, values, and attitudes fit in with the organization's broader context characteristics such as organizational climate, goals, values, policies, and systems.

Theory suggests, and some research has begun to illustrate, that aggregating across multiple types of fit (e.g., P-J and P-G together) is related to more positive responses (e.g., job satisfaction, reduced stress) than when fit is assessed by only a single type of congruence. On the other hand, some have argued that certain types of fit may be more important than others. For example, when evaluating the extent to which they fit, individuals tend to place a heavier emphasis on fit with salient environmental aspects than on fit with less salient environmental aspects. To date, little research has explored the relative importance of different types of fit.

1.4. Supplementary and Complementary Fit

The preceding conceptualizations define fit broadly as the congruence between individuals' characteristics and those of the job, group, and/or organization. However, compatibility or alignment is further delineated into supplementary and complementary fit. A situation in which an individual's attributes are similar to those of other individuals or to the characteristics inherent in the setting is referred to as supplementary fit. In contrast, when an individual's characteristics enhance or supply what is missing in the work environment, it is defined as complementary fit. For example, consider fit at the group level. Harmonious relations among group members might be achieved when supplementary fit on personality exists because each individual's personality is similar to the personalities of others in the work group. On the other hand, to function effectively in performing their task, a group might require a blend of people with different interpersonal strengths and personalities, for example, one

person with leadership qualities, one with skills at conflict resolution, and so forth. Thus, fit can exist when one entity provides what the other needs (i.e., complementary fit), when they share similar characteristics (i.e., supplementary fit), or both.

2. CREATION OF AND IMPORTANCE OF FIT

A number of theories explain how fit is achieved over time and why fit occurs. This section first addresses broad theories that explain the overall process that creates fit before considering current theories on why fit occurs and why it is important for both individuals and organizations.

2.1. Processes That Create Fit: The Attraction–Selection–Attrition Cycle and Socialization

Schneider's attraction–selection–attrition (ASA) cycle seeks to explain how persons and the organizational environment become naturally integrated over time. Individuals are attracted to and want to join organizations that have characteristics similar to their own, organizations restrict the range of the types of persons in them through the recruitment and selection of people who have the desired attributes and who are able to comprehend what the organization's context and goals should be, and, individuals who do not fit the organization leave, either voluntarily or involuntarily. At the same time, the kinds of persons in the organization determine the structures, processes, and general climate and culture of the organization.

The effects of the ASA cycle can be enhanced through socialization processes. Through mechanisms such as orientation programs, training, mentoring, and informal discussions, new employees learn the predominant values, attitudes, goals, social knowledge, and expected behaviors in the organization. Socializing new employees can lead to changes in their values or attitudes in the direction of the organization's values, or it can result in their leaving if the organizational characteristics continue to be incompatible with their personal attributes. Over time, through the ASA cycle and socialization, individuals within an organization tend to be homogenous and share many common personal attributes. Indeed, some research has shown that the personality characteristics of individuals within

organizations are more similar to each other than those between organizations. Furthermore, individuals with longer tenure in organizations tend to have personalities that are more consistent with the climates in the organizations.

2.2. How Fit Affects Responses in Organizations

A number of different theories have been proposed to explain why fit occurs and how it affects employees' responses and reactions. One perspective is "needs–supplies." Individuals have a variety of needs, desires, and preferences (e.g., achievement, safety, nice working conditions, affiliation, pay, growth and development). When these needs are met or satisfied by the job, group, and/or organizational contexts, individuals will perceive a good fit and are likely to feel fulfilled. As a result, they will be more motivated and satisfied and will perform better. A related perspective is based on "abilities–demand," which suggests that fit occurs when an individual has the abilities required to meet what the organization demands (e.g., time, effort, commitment, skills from employees). Here, when the demands of the organization are met, employees fit the requirements of the organization, allowing for more effective functioning.

Refinements and additional explications of these broad theories have been offered to further explain why fit occurs and how fit guides behavior, reduces stress, and reduces cognitive demands. First, the similarity–attraction paradigm proposes that the perception of similarity to others in background, attitudes, and lifestyles is the most important determinant for attraction dynamics. Individuals who perceive more similarity to others are more willing to pursue further interaction, work together, share knowledge, and form productive work relationships. Second, fit purportedly helps to guide behavior. The environment of the organization is satisfying and reinforcing when it is consistent with individuals' personalities. This consistency or congruence increases the stability of behavior because employees are reinforced for their behavior, whereas incongruence is not reinforced and stimulates a change in behavior. Third, when individuals' needs are met by the organization, or when ability–demand fit is achieved, stress and anxiety are reduced, thereby allowing for greater satisfaction, attitudes, and performance. Finally, when people fit the environment, cognitive demands on employees are reduced. They can more

readily interpret the work environment correctly and discern what is valued as important. Less learning, socialization, and adjustment are required on the part of employees, allowing them to adapt to the organization more quickly and to perform more easily. Internal conflict is also likely to be reduced due to employees having more similar or better alignment of values, competencies, and attributes.

2.3. Relationships between Fit and Outcomes

Fit has been shown to play a significant role in how job applicants choose organizations and how recruiters select applicants. A higher degree of fit has also been consistently related to higher job satisfaction, increased commitment to the organization, more citizenship or helping behaviors, greater career success, reduced stress, and less likelihood of leaving the organization. Although theory suggests that positive outcomes will emerge for the group and organization as a whole, very few studies have examined the impact of fit on group or organizational effectiveness. It is important to note, however, that some P-E fit theorists argue that fit can also have a negative impact on organizations. This potential paradox of fit is addressed in a later section.

3. ASSESSING AND MEASURING FIT

A variety of different techniques, methodologies, and analytical procedures have been used in studies of fit, although debate continues with respect to which conceptualizations and procedures are superior. This section highlights some of the fundamental conceptualization and measurement issues in conducting fit research.

3.1. Commensurate Dimensions

What classes of variables constitute the P and E factors? Although this list is not exhaustive, the key variables on the P side include values, personality, needs, desires, goals, values, interests, skills, abilities, and personal resources such as time and effort. On the E side, core variables include organizational culture, values, organizational climate, values, goals, norms, skill and ability requirements, pay and rewards, and job characteristics. In studying fit, it is recommended

that the P and E dimensions be commensurate or assessed in the same language and with the same classification scheme. For example, in examining P-O fit on cultural values, the P variables are often a list of 30 to 50 value statements, and individuals are asked to assess the personal importance of each value. The E variables contain the same list of 30 to 50 value statements, and assessments of how important these values are in the organization are made. Similarly, in examining the extent to which needs are met, the P factor represents a list of dimensions that individuals might desire (e.g., high pay, friendly coworkers, challenging work), whereas the E factor consists of the extent to which the work environment provides each of those same characteristics (e.g., employees receive high pay, work environment is friendly, jobs are challenging). In this way, direct comparisons of the degree of fit can be made on the same set of P and E variables or dimensions.

3.2. Direct Fit Versus Indirect Fit

Direct fit and indirect fit represent two different conceptual and operational approaches to fit. Direct fit focuses on individuals' own perceptions of the degree to which they fit into the work environment. It is derived by asking individuals the extent to which they believe they fit into the work environment, either generally (e.g., the extent to which they believe their skills fit the job) or for some particular dimension (e.g., the extent to which their values fit those of the organization). Here, for example, the focus is on how much individuals personally believe that their values fit those of the organization, but it is not known what the individuals' values or the organization's values actually are.

In contrast, indirect fit is based on separate measurements of the P and E factors, with fit being assessed statistically by jointly comparing the two P and E measures. For example, individuals' reports of their own values are compared with a separate assessment of the cultural values in the organization. In this case, the interest is in determining whether fit between individuals' values and organizational values is related to attitudes and behaviors, regardless of whether or not the individuals actually perceive this fit. Research is only beginning to address the relative importance of these different conceptualizations of fit. For example, some research has indicated that direct fit is more strongly related to individuals' behaviors and attitudes than is indirect fit.

3.3. Sources and Focus of Measurement

The source from which the P and E factors are derived can vary (e.g., individual, other employees, manager, independent assessor, objective data) depending on the purpose and research question. In many studies, both the P and E factors are measured from the same individuals. For example, individuals are asked to report on their desired characteristics of a work environment and then to report on their perceptions of their current organization's work characteristics. The degree of similarity or discrepancy between these two is taken as an index of fit. Same-source measurement is appropriate when the research question is to assess individuals' perceptions. However, the disadvantage is that relationships might be artificially inflated due to common method variance.

When attempting to address fit to the "actual" environment rather than to individuals' own perceptions of the environment, the E factors are typically derived from a separate source. For example, if the research question is to determine the extent to which an individual's values fit the cultural values of the work group, the individual might report his or her values while other members report on the values in their work group. Here, the individuals' values are compared with the aggregate of other employees' perceptions of the organization's values. Likewise, if the interest is in evaluating the effects of fit between individuals' goals and managers' goals, individuals' attributes would be compared with assessments from managers.

3.4. Analytical Issues

In testing fit, a number of different statistical indexes have been used, including difference scores (i.e., the algebraic or absolute difference between the score on the P measure and the score on the E measure), D^2 measures (i.e., the square root of the sum of squared differences between P and E across variables), and profile comparisons (i.e., the correlation between the profile of P dimensions and the profile of E dimensions). These indexes were criticized by Edwards for their conceptual and methodological shortcomings, and polynomial regression procedures have been touted as a more appropriate methodology for assessing congruence. Polynomial regression procedures allow for testing specific functional forms of congruence corresponding to a more specific conceptual model of interest. For example, one can assess

whether a lack of fit results in more negative outcomes when individual values are stronger than organizational values compared with the reverse, or one can assess whether congruence when both the individual and organization values are evaluated highly is related to more satisfaction than is congruence when both the individual and organizational values are rated low. Although polynomial regression procedures have increasingly gained acceptance in fit research, this technique is still the subject of some controversy because it requires very large sample sizes and is best for examining the dimensions of fit one at a time rather than simultaneously.

4. SELECTED APPLICATIONS OF FIT

Fit has been examined across a wide range of topic areas, including selection, training, job design, motivation, leadership, goals, diversity, and teams. This section focuses on three specific applications of the fit concept in the areas of organizational culture and organizational climate, selection and socialization, and team composition and diversity.

4.1. Organizational Culture and Climate

Organizational culture and organizational climate are two key attributes that differentiate organizations from one another. Furthermore, both culture and climate focus on how employees interpret, experience, and make sense of their organizations. As a result, both culture and climate have become important elements of P-O fit.

An organization's culture is composed of its fundamental ideologies underlying assumptions and core values. It is deeply embedded in the organization and is collectively held. Climate is based on the ways in which individuals experience and describe what is happening at work. Employees' perceptions of what the organization is like in terms of its practices, policies, procedures, and routines are the foundation of psychological climate (individuals' own perceptions) and organizational climate (shared perceptions of the situation across individuals). Culture and climate are aspects of the "supplies" side of the needs-supplies theory underlying P-O fit. To the extent that these organizational supplies are congruent with and

meeting employees' individual needs, supplementary P-O fit will exist.

In terms of fit to organizational culture, much research has assessed congruence between individuals' values and the cultural values espoused in the organization. Studies have been directed at understanding the implications of both direct and indirect fit for cultural values and have demonstrated that greater value congruence is related to greater satisfaction, commitment, adjustment, performance, career success, and tenure. Furthermore, fit between employees' preferred organizational culture and their employer's actual organizational culture has been shown to predict task performance as well as to enhance organizational citizenship behaviors such as helping other employees and volunteering for tasks. Similarly, with respect to climate, some work has indicated that congruence between individuals' needs, personalities, and work environment preferences, on the one hand, and the organization's climate, on the other, is related to higher individual satisfaction at work, commitment to the organization, involvement, performance, and adjustment to work as well as to lower levels of stress, turnover intent, and absenteeism.

Unfortunately, very little empirical research has been devoted to examining the impact of P-O fit to culture and climate on group or organizational outcomes. However, some research suggests that organizational effectiveness is greater to the extent that employees' personalities overall are congruent with certain dimensions of the climate of the organization. Likewise, although theory suggests that hiring employees whose personal values are consistent with future desired organizational values can be an effective tool to promote change in the organization, research is lacking in this area.

The implication of this body of work is that individuals' well-being and quality of work life are enhanced to the extent that individuals fit, or perceive that they fit, into their organization's climate and culture. Organizations desiring to maximize these employee attitudes can foster such P-O fit through practices such as management, rewards, mentoring, hiring, and socialization.

4.2. Selection and Socialization

Organizations traditionally focused on P-J fit in their selection tactics and training and development processes because high P-J fit (i.e., abilities-demands fit) has been demonstrated to positively affect task performance, tenure, and attitudes. More recently, attention

has been devoted to understanding the role of P-O fit in recruiting, selection, and socialization.

Values represent a starting point for P-O fit because an organization's cultural values affect what types of applicants are likely to seek, and find, employment there. Fit plays a significant role in how job applicants choose organizations and in how recruiters select applicants. Recruiters are more likely to make hiring recommendations to applicants who they perceive as having a stronger P-J fit, a stronger P-O fit, and values that are consistent with those of the organization. At the same time, job seekers' perceptions of value congruence are related to perceptions of their general P-O fit perceptions (i.e., how they would fit into the organization overall), which in turn positively affects attraction to the organization. Moreover, new hires whose values are more congruent with those of the organization are more likely to have higher job satisfaction and commitment to the organization and are more likely to remain in the organization 1 to 2 years later.

During socialization, new employees acquire an understanding of the attitudes, values, behavior, and knowledge required to participate as organizational members. Socialization practices, such as social activities that foster interaction, mentoring, and sets of formal and collective (group) learning experiences, can enhance alignment between newcomers' values and organizational values over time. The underlying assumption is that such tactics lead to a change in individuals' values. Although individuals' values are often thought to be relatively stable and difficult to change, there is also some evidence suggesting that employees' work-related values may be malleable if the organization's processes are strong.

4.3. Team Composition and Diversity

Fit in the group context has received the least amount of research attention to date. The distinction between supplementary fit and complementary fit appears to be particularly important when considering fit issues in teams or groups. Individuals' attitudes are likely to be more positive when the individuals fit well into the group and have attributes (e.g., skills, abilities, goals, values, personalities) that are similar to those of other group members (i.e., supplementary P-G fit). Likewise, in terms of the demographic composition of the group (e.g., age, race, sex, education), research has consistently demonstrated that individuals who are

more similar to others are more likely to have positive attitudes, better performances, and longer tenures.

However, it is also important to consider the composition of the group as a whole, that is, how the attributes of the group members complement one another to influence group functioning and group effectiveness. Effective group processes and performance may depend on supplementary fit, as in the case of a customer service team where all roles are shared by all group members and, hence, homogeneity in skills and interpersonal style may result in better team performance. Alternatively, a complement of more heterogeneous skills and styles might be needed, as in the case of retail teams dealing with diverse customers where a range of personality types may be linked to better team performance. Similarly, some research suggests that greater diversity in terms of demographic characteristics is also likely to have a positive impact on group creativity and performance. The underlying notion here is that some heterogeneity in characteristics and attributes is desirable. Complementary fit helps to ensure that all of the various skills and roles needed in the group are available.

The issue of achieving the appropriate balance between supplementary fit and complementary fit is a difficult one that has yet to be explored in detail. The understanding of the optimal profile or configuration of attributes across individuals for different types of work settings, tasks, and roles is in its infancy.

4.4. Implications

Although P-J fit can result in better task performance, research findings increasingly suggest that task performance alone is not sufficient for an organization's overall effectiveness. In particular, contextual performance or prosocial and organizational citizenship behaviors and commitment to the organization have been shown to contribute to organizational effectiveness. Furthermore, there is evidence that contextual performance and organizational commitment increase when P-O fit is high. As a result, all three types of fit should be attended to in making selection decisions and in designing practices such as training and socialization. More specifically, an organization should first consider (a) P-J fit as a match between the applicant's skills and abilities and the requirements and skill demands of the job to promote better job proficiency and performance; (b) P-O fit between the applicant's and organization's values, needs, and goals to enhance satisfaction, commitment, citizenship behaviors, and retention; and (c) interpersonal

attributes and broad proficiencies of the applicant to promote appropriate compatibility and alignment among group members to enhance group performance and intragroup relations. The relative emphasis placed on each will likely differ depending on the organization's overall goals and strategies.

Some researchers suggest that P-J fit may be more important for jobs with greater technical skill requirements, whereas P-O fit may be more important when the organization has a distinctive culture. Others suggest that a multiple-hurdle approach may be the most effective method for considering fit in the selection and recruiting process. For example, one suggestion is to first focus on identifying candidates with high P-J fit and then, from those candidates, to select individuals who are higher on P-G and P-O fit. Alternative sequences might be equally plausible. For example, when the organization provides a great deal of job training to new employees, it may be more appropriate to first identify those with high P-O fit and P-G fit and then, from these candidates, to select those with stronger P-J fit.

In terms of fit to groups, the needs that are most critical to team effectiveness should be identified and prioritized based on the various roles within the group. Supplementary fit on attributes such as values, goals, and personality can help to foster cooperation among team members. Yet members of the group also need to have complementary proficiencies so that the weakness of one group member can be offset by the strengths of another so as to enhance overall group performance. Thus, teams need to identify the unique attributes (e.g., specialized skills, interpersonal proficiency, problem-solving ability) that are not prevalent in current group members and that need to be brought into the group to enhance group performance and effectiveness. Once individuals are hired, additional socialization and group relations training is likely to be important due to the diversity in skills and other characteristics among group members.

The majority of fit research has been conducted on new hires, with the underlying assumption that newcomers who do not fit their job, their group, or the organization will adjust poorly and will be more likely to leave the organization. In turn, tenured employees are expected to have greater fit. However, employees who do not fit may remain in the organization for a variety of reasons such as a lack of market opportunities and personal reasons. Furthermore, given increased competition in the marketplace, the changing nature of jobs, and increased technology, job

demands often change after an individual has joined the organization. Likewise, group cultures are likely to change as managers and employees transition in and out of the work environment. This implies that an individual's fit may decrease over time even if fit was initially high, and as such, continued attention should be devoted to fit after the hiring and socialization period. For example, training can be used to foster greater fit as job demands change, formal and informal activities (e.g., information sharing, social activities, mentoring) can aid in enhancing P-O fit, and group development interventions (e.g., continual feedback, interpersonal skills training, leader training) can further enhance fit to the group and group relations.

Finally, targeted interventions can be implemented to help employees deal with conflicts and problems that arise from diversity. Although some research shows that greater diversity on demographic variables is related to higher levels of creativity and performance for the group, greater diversity has also been related to lowered attitudes, more turnover, and poorer perceptions of group relations. To offset the potential negative impact on individuals' responses and to capitalize on the diversity of viewpoints, interventions such as training targeted at interpersonal relationships, communication, and understanding diversity may be warranted. As a result, harmonious group relations can be achieved more quickly, and people may perceive a greater degree of fit sooner, thereby enhancing both individual satisfaction and group effectiveness. Furthermore, over time and with sustained contact, the negative impact of diversity tends to dissipate, allowing positive group-level outcomes to emerge.

5. A POTENTIAL PARADOX OF FIT

The majority of research studies have consistently shown that a greater degree of fit is related to more positive outcomes for individuals (e.g., greater attraction to organizations, higher satisfaction and commitment, better adjustment, less turnover). The ASA cycle and socialization processes can create a situation whereby those who remain with an organization are a more homogenous group than are those who were initially attracted to and selected by the organization. However, several authors have argued that too much homogeneity within an organization can lead to stultification. When individuals have similar personalities, values, goals, and perspectives, new ideas and innovation may be stifled. The conformity in outlook that

arises from a similarity of perspectives does not allow for alternative interpretations and makes it difficult for the organization to adapt to environmental changes. Information about the environment is incomplete, and the organization is unable to make appropriate and necessary changes to adapt to the environment.

Therefore, there is a potential paradox in fit. More positive attitudes and increased satisfaction of employees in an organization is a worthwhile goal because satisfaction is related to the quality of life for individuals as well as to greater productivity for the organization. Yet focusing on creating fit for individuals can lead to too much homogeneity in the organization, and this can stifle innovation, creativity, flexibility, and the ability to adapt, ultimately endangering the organization's competitiveness and long-term viability. How does one reconcile these conflicting findings on the relationship between fit and outcomes at different levels?

5.1. Possible Solutions

Although it is a topic of debate among fit theorists and researchers, there are several ways in which this paradox might be resolved. First, achieving a high degree of P-O fit among middle- and lower level employees can promote greater satisfaction and other outcomes for the majority of individuals within the organization. Achieving more diversity in perspectives, values, and skills among key decision makers or the top management team can foster problem analyses and consideration of alternatives so as to adapt to the environment and implement strategic initiatives as the organization moves forward.

Second, attention can be given to achieving similarity for core attributes that are critical for the organization while allowing variation for less critical attributes. Those attributes for which there should be similarity and those that may differ will vary from organization to organization depending on the organization's purpose, mission, strategy, and industry. Homogeneity in terms of the organization's key goals or most fundamental values is important so that employees perceive and understand the same goals and behave accordingly to promote the effective operating of the organization. Yet employees can vary in their attributes and perspectives around other less core goals and values. In such cases, there will be sufficient similarity to promote more positive attitudes and effective functioning but also sufficient diversity to allow new ideas and innovation to emerge.

Third, when the organization desires to change in some way (e.g., culture change, move to new markets), selection should focus on hiring people who have specific attributes that fit with the new goals. Both complementary fit (i.e., attributes that add what is needed) and supplementary fit (i.e., similarity) can be achieved simultaneously if the new attributes that are needed to effect the change are delineated and individuals with those attributes are selected while still ensuring that these individuals are similar to current employees on other attributes.

6. CONCLUSION

Insights from fit theory and research can be used to enhance organizational life at all levels: At the individual level, it can help to understand how to increase satisfaction, commitment to the organization, and task and contextual performance as well as how to raise individuals' quality of life at work by decreasing stress and anxiety. At the group level, fit can help to identify ideal team compositions based on both supplementary fit and complementary fit so as to enhance individual satisfaction as well as to promote harmonious group relations and effective functioning. Furthermore, fit can contribute to a better understanding of the processes and impact of demographic diversity, which in turn can lead to better, more effective diversity practices in organizations. Finally, at the organizational level, fit can be helpful in thinking about issues such as building a distinct culture and promoting change. It can also assist the organization in addressing issues such as turnover, absenteeism, and low productivity. In addition, P-O fit implies that organizations should shift away from the traditional focus on P-J fit in their

selection processes in favor of practices geared toward hiring "whole persons."

Further Reading

Personnel psychology is a subfield within industrial, work, and organizational psychology that is concerned with the application of psychological theories, methods, and research findings to the personnel functions in organizations. Primary functions include recruitment, selection, training, performance appraisal and feedback, and compensation. This article focuses on the research applications to these functions and outlines the current themes in personnel psychology.

GLOSSARY

compensation The entire process of designing and administering the package of returns that an organization provides to an employee in exchange for his or her work input.

performance appraisal The evaluation associated with a rater's evaluative judgment of the effectiveness of an employee's job performance.

performance feedback The information an employee receives concerning a rater's evaluative judgment of the employee's performance and the way in which the information is communicated.

recruitment The organizational activities and processes aimed at providing information to a pool of potential candidates to attract them to apply for job openings in the organization.

selection The process of testing and evaluating job applicants for the purpose of determining the subset of applicants to whom job offers will be made.

training The systematic and typically formal process of employee acquisition or learning of job competencies—knowledge, skills, abilities, and attitudes—that would enhance job performance.

1. RECRUITMENT

Recruitment refers to the organizational activities and processes aimed at providing information to a pool of potential candidates to attract them to apply for job openings in an organization. In the development of recruitment strategies, personnel practitioners must address important factors such as features of the relevant labor market for the job, the recruitment message and information to be communicated, and the specific recruitment methods to be used for the communication. The bulk of the recruitment research in personnel psychology is concerned with candidate perceptions of recruitment processes. These perceptions are of practical importance because candidates with negative perceptions may decide to withdraw from the application and selection process. Findings from previous studies suggest that although job attributes constitute the most important factor in affecting candidates' reactions and job choice behaviors, candidate perceptions of recruitment activities

and the recruiter may also affect reactions and associated behavioral intentions such as intent to apply for employment in the organization or to recommend it to others. There is some evidence that candidates tend to make inferences about the organization (e.g., leadership style) by extrapolating from perceived recruiter behaviors.

Another interest among personnel psychologists doing recruitment research is in the area of realistic job previews. The purpose of realistic job previews is to provide applicants with “true” information about the job and work environment (i.e., as the job incumbents actually experience them) rather than presenting the job and organization in “public relations” terms to maximize job and organizational attractiveness. The rationale is that the failure to present realistic job previews will lead to unrealistic, and hence subsequently unmet, expectations among newcomers (i.e., applicants who accepted the job offer) that, in turn, will have a negative impact on satisfaction, commitment, and motivation.

2. SELECTION

Personnel selection refers to the process of testing and evaluating job applicants for the purpose of determining the subset of applicants to whom job offers will be made. The majority of personnel selection research is concerned with the extent to which different selection predictors (i.e., instruments) can predict job performance and other job-relevant outcomes such as job satisfaction, organizational commitment, and intent to quit. The selection predictors that have been widely researched and used in practice include cognitive ability tests, personality measures, biodata measures, interviews, and assessment centers. Recently, there has been increasing interest in the research and use of situational judgment tests, which is one type of work simulation. Comprehensive reviews of the validity evidence of selection predictors in predicting job performance and other job-relevant outcomes were provided by Salgado and colleagues in 2001 and by Schmitt and Chan in 1998. The search for valid selection predictors needs to be driven by the nature of the criterion of interest. For example, with respect to job performance, the criterion space can be decomposed into specific areas of task requirements and specific knowledge/skill/ability requirements. In addition, the job performance criterion can be decomposed into distinct performance constructs such as typical versus maximum performance, task versus contextual performance, and routine versus adaptive performance. Each specific

performance construct can, in turn, be construed in terms of multiple dimensions; for example, contextual performance can be construed in terms of interpersonal facilitation and job dedication. The validity of a selection predictor is dependent on the specific performance criterion variable in question.

In making selection decisions, it is possible to use more than one predictor, that is, to use a battery of selection tests. One major issue that needs to be addressed when using selection predictors in a test battery concerns incremental validity, which refers to how much gain in prediction power is obtained by adding the new predictor to the existing predictor(s). Issues of incremental validity have focused on effects of predictor–criterion correlations and intercorrelations among predictors. All other things equal, incremental validity is increased when the new predictor is highly correlated with the criterion but is lowly correlated with the existing predictor(s). Another major issue concerns the joint effects of the combined use of predictors on subgroup differences in overall selection score. Research has shown that adding a new predictor with a small subgroup difference (or no difference) to an existing predictor with a large subgroup difference is unlikely to lead to any substantial reduction in subgroup difference on the composite selection score.

Special topics in personnel selection include test bias (e.g., whether a test predicts similarly for applicants from different demographic groups), applicant reactions (e.g., what characteristics of the selection system would influence the degree to which applicants perceive the selection as fair), selection for staffing teams (e.g., what competencies can be tested to predict how applicants would function when working in teams), and validity changes associated with dynamic criteria (e.g., how the validity of a selection test is affected when the components of effective job performance change over time). Many of these topics were summarized by Guion in 1998 and by Schmitt and Chan in 1998.

3. TRAINING

Training refers to the systematic and typically formal process of employee acquisition or learning of job competencies—knowledge, skills, abilities, and attitudes—that would enhance job performance. The training environment may range from artificial or contrived settings (e.g., classroom lectures, role-play exercises) to highly realistic settings (e.g., on-the-job training in which the learning environment is nearly identical to

the actual work environment). Regardless of the setting, the underlying assumption is that job competencies are malleable and alterable through training. The goal of training research is to identify appropriate interventions that can positively affect employees' target attitudes and behaviors so that the employees can meet the demands of the target job. Training research typically follows the framework provided by the instructional systems design (ISD) model that emphasizes three key interrelated components of the training process: training needs assessment, training design, and training evaluation. In training needs assessment, the primary goal is to provide information on what, where, when, and who. The information gathered also serves as input for the subsequent stages of the training process, that is, training design and evaluation. The strategies to gather information may include organizational analysis to determine where training is needed; job analysis to identify the nature of the job tasks, the underlying job competencies, and the performance standards required for successful task performance; and person analysis to determine performance gaps between potential trainees' performance and expected performance levels. Training design is concerned with specifying instructional objectives, sequencing training materials, incorporating learning principles, and identifying effective training methods. There is an increasing consensus among training researchers that a training program is more effective when trainees are given the opportunity to produce the capability, when the training environment enhances trainee self-efficacy and expectations that the training will be effective in leading to acquisition of valued learning outcomes, and when performance feedback given to trainees is credible, accurate, constructive, and timely. Training researchers also appear to agree that the effectiveness of training methods is a function of the properties of the method, the nature of the training content, and the person characteristics of the trainees. For example, declarative knowledge is better acquired through classroom instruction, whereas procedural knowledge is better acquired through work simulations. However, more empirical research is needed, and advances in training research are likely to be led by rigorous studies that establish empirical interactions linking training method, training content, and trainee characteristics. Training evaluation refers to the assessment of the degree to which trainees achieved the anticipated gains in job competencies from training and effectively applied these gains to the actual job. To measure these gains and conduct an adequate training evaluation, training objectives and the intended training

outcomes must be explicitly specified in ways that allow their valid measurement. An excellent overview of the typical problems in evaluating training and the alternative ways in which to assess gains was provided by Goldstein and Ford in 2002.

The ISD model, which is based on design principles derived from research findings on performance on simple tasks that require little complex cognitive processing, is somewhat deficient as a theoretical framework for training in jobs that are made up of ill-defined problems and cognitively complex tasks. Recently, several researchers have proposed more holistic approaches. These approaches involve applying cognitive constructs and principles to the training process and recognizing the multifaceted nature of the learning process by expanding the criterion space to include cognitive, skill-based, and affective learning outcomes. This cognitive-oriented and holistic context, grounded in the theory and empirical findings from cognitive psychology research, led to significant conceptual and measurement advances in training research. Many of these advances are related to the conceptualization of expertise and the measurement of metacognitive skills and knowledge structures.

4. PERFORMANCE APPRAISAL AND FEEDBACK

Performance appraisal refers to the evaluation associated with a rater's evaluative judgment of the effectiveness of an employee's job performance. Performance feedback refers to the information an employee receives concerning a rater's evaluative judgment of the employee's performance and the way in which the information is communicated.

In performance appraisal, the performance measure can be either objective or subjective. Examples of objective measures include dollars sold and number of units produced or contracts secured. Some objective measures, such as number of complaints received and days absent from work, are negatively scored. Examples of subjective measures include qualitative judgment of the creativity of work products and supervisor or peer ratings of overall job performance. The vast majority of early research on performance appraisal has focused on subjective measures and examined issues such as the various types of appraisal rating scales, rater accuracy, rater errors, and the cognitive processes underlying appraisal judgments made by raters. Despite the rater training implications of these findings, there is no clear evidence that rater

training based on these streams of research has in fact contributed to increased effectiveness of actual performance appraisal systems in organizations. One explanation for the apparent futility of early studies is that the researchers' focus on rating scales, rater accuracy and errors, and rater cognitive processes is somewhat misplaced because the researchers have neglected the central elements of the appraisal system, including the rater's motivational context and the employee's (i.e., ratee's) perspectives and reactions. This gap was filled by several subsequent streams of research focusing on motivational structures and rater–ratee relationships such as effects of rating purpose, accountability, and rater–ratee similarity on ratings and effects of organizational climate, perceived organizational support, and leader–member exchange relationships on appraisal reactions. One productive stream of research came from Greenberg's application of organizational justice research to performance appraisal in 1986. Studies by Greenberg and other researchers have identified a variety of aspects of the appraisal process and outcome (e.g., soliciting and using input prior to appraisal, ability to challenge appraisal) that affect justice perceptions about the appraisal. Most attention has been directed toward employee participation or voice in the appraisal and feedback process. In addition to identifying the antecedents of justice perceptions, researchers have examined the influence of justice perceptions on a number of attitudinal and behavioral outcomes (e.g., organizational commitment). Current research has adopted a broader perspective by locating the appraisal process in the larger context of the performance management system in an organization. This system refers to the interrelationships linking appraisal system development, appraisal processes, and feedback processes.

There has been increasing interest in “360-degree” assessment/feedback systems, where the central idea is to obtain appraisals on the same employee from multiple sources (typically supervisors, peers, and subordinates). Such systems have unique features involving multiple sources and perspectives that raise important research and practical questions regarding the impact of expanding the performance construct space on appraisal outcome and reactions. However, insofar as these systems consist of multiple rater–ratee relationships, many of the cognitive and motivational elements present in conventional appraisal are likely to remain applicable. For example, prior research findings on conventional appraisal that found that employees are more likely to react favorably to appraisal feedback when there is prior discussion on performance

expectations at the beginning of the performance period, opportunity for employees to provide input to the appraisal and discuss raters' rationales for the appraisal judgments, and consideration of employees' feelings.

Performance appraisal and performance feedback have the ultimate common goal of increasing job performance effectiveness. Important conceptual and practical relationships exist between performance appraisal and performance feedback. For example, accountability effects in performance appraisal are likely to be related to the type and specificity of performance feedback information, and justice perception effects in performance feedback are likely to be related to the accuracy and transparency of the performance appraisal process. Research findings with more theoretical value and higher external validity are likely to be obtained from studies that integrate performance appraisal and performance feedback.

5. COMPENSATION

Compensation refers to the entire process of designing and administering the package of returns that an organization provides to an employee in exchange for his or her work input. The package, which may include financial remuneration, services, and medical and other benefits, is typically divided into direct pay and indirect pay/benefits. Direct pay may consist of the fixed base pay, base pay supplements (e.g., market value adjustments, cost-of-living allowances, overtime pay), and performance-related pay (e.g., merit increments, performance bonuses, performance commissions). Indirect pay and benefits may consist of any services or benefits provided to the employee (e.g., vacations, medical benefits, discounts for goods and services).

In human resources management, most attention on compensation design and administration is focused on the strategic mix of the various components of returns to align the compensation system with the resources, constraints, priorities, and strategic goals of an organization within the labor market context of the need to attract and retain suitable employees. This typically revolves around issues of decisions concerning the value or grade level of the various jobs in the organization, the level of compensation relative to that of external referent organizations (which are typically competitors for the same employees), the design of the compensation package for individual employees, and the administration of the package. Compensation research in personnel psychology, on the other hand, is more concerned with the psychological relationships at

the individual level (although it may also involve team, organizational, or higher levels of analysis) linking compensation to employee performance and reactions. Specifically, these relationships are concerned with the motivations, perceptions, and attitudes of employees who are affected by the various types of compensation (and ways in which it is administered) and how these motivations, perceptions, and attitudes, in turn, affect employee performance and reactions.

Compared with issues of selection, training, and appraisal, compensation issues have largely been ignored by personnel psychologists, despite the fact that the idea of linking rewards to job performance has been central in empirically established theories of work motivation such as expectancy theory, goal setting theory, and equity and justice theories. Although compensation typically refers to a contractual (legal or semilegal) or formal package of returns, rewards is a more generic term used to refer to any positive reinforcement or inducement provided (explicitly or implicitly) by an organization to employees that is assumed to positively correlate with past, current, and/or future performance. During recent years, the rapidly changing nature of work has led to an increased use of new pay systems by employers. This has, in turn, activated research interest among some personnel psychologists. Not surprisingly, the majority of the recent personnel psychology research on compensation is on new forms of pay systems and has found considerable evidence that some of these new pay systems, such as variable pay and competency- and skill-based pay, are related to improved employee and organizational performance. However, it remains unclear why or how these new forms of pay lead to increased performance, although a number of conceptual models based on various psychological theories (e.g., social exchange theory, theory of planned behavior) have been proposed to account for the observed relationships. Instead of applying grand theories to commonalities across various new and effective pay systems, midrange theories that relate the specific form of pay system to the pay context, employee characteristics, and employee reactions are more likely to enhance our understanding and provide practical recommendations for specific compensation contexts.

6. CURRENT THEMES IN PERSONNEL PSYCHOLOGY

There are several discernible themes in current research in personnel psychology across the areas of recruitment,

selection, training, appraisal, feedback, and compensation. One theme concerns the importance of focusing on the multidimensional and dynamic nature of job performance. In early research, job performance was construed nearly solely in terms of core technical proficiency or task performance. Current research has expanded the performance construct space to include organizational citizenship behaviors, counterproductive behaviors, and adaptive behaviors. This expansion has implications for the various areas of personnel psychology (e.g., identifying and selecting candidates with dispositions toward citizenship behaviors and against counterproductive behaviors, appraising employees on these additional performance dimensions, designing training that enhances the ability to adapt to changing situations). Current research has also focused much attention on the dynamic nature of job performance with respect to changes in performance level over time and changes in performance dimensionality over time. These changes over time raise complex but important conceptual and measurement questions that provide a springboard to productive future research. Another theme concerns person–environment fit, where environment may refer to the job, the work group, or the organization. The basic idea is that maximizing person–environment fit often (but not always) leads to positive outcomes in recruitment, selection, training, appraisal, feedback, and compensation. Research in person–environment fit brings with it several challenging methodological and data-analytic issues such as the need to distinguish between subjective fit perceptions and objective fit assessments. Finally, running across virtually all current research in personnel psychology is the central theme that the changing nature of work has major implications for the conceptualizations and measurement of the various focal constructs as well as the relationships (conceptual and empirical) between constructs.

Personnel selection is concerned with identifying personal characteristics of applicants that relate to performance on jobs, measuring applicants on these characteristics, and hiring those who have the required characteristics.

GLOSSARY

adverse impact Disproportionate hiring of different groups; in the United States and the United Kingdom, adverse impact is said to occur when the selection ratio for a legally protected group is less than four-fifths that of the majority group.

criteria Measures of how well individuals behave or perform; these are the behaviors, performances, and outcomes that the organization is interested in predicting using a selection system.

criterion-related validity The association between the predictor and criterion scores; the criterion-related validity coefficient indicates the extent to which individual differences in a particular predictor are related to individual differences in a criterion (e.g., job performance).

predictive bias The systematic over- or underprediction of a criterion.

predictor Any measured applicant trait or characteristic that is used to predict performance and other behaviors on the job; a predictor assesses applicant characteristics deemed to be job relevant using a specific measurement method (e.g., test, application blank, interview).

selection ratio Proportion of job applicants hired to those who apply for a job.

1. INTRODUCTION

Personnel selection has been, and continues to be, one of the central functions of industrial, work, and organizational (IWO) psychology. Selecting the right people for the right jobs constitutes a source of competitive advantage for organizations. Individuals differ in various characteristics such as skills, abilities, personality traits, and interests. Similarly, jobs differ in what is required of the incumbents. The objective in personnel selection is to identify the personal characteristics that relate to performance on jobs, measure applicants on these characteristics, and hire those who have the required characteristics. When done properly, selection can enhance organizational productivity as well as provide individual benefits to workers themselves (e.g., increased satisfaction).

In personnel selection, one assesses the applicants on characteristics relevant to performance on the job and may want to select those who are likely to perform the best on the job. There are several characteristics on which individuals differ. Abilities, skills, personality traits, and physical abilities are some examples. These individual differences, which are relevant to

performance on the job under consideration, must be measured reliably and accurately before hiring decisions can be made. The method of such measurement could be an interview, a test, biographical information, or even physiological measurement.

A predictor can be any measured applicant trait or characteristic that is used to predict performance and other behaviors on the job. That is, a predictor assesses applicant characteristics deemed to be job relevant using a specific measurement method (e.g., test, application blank, interview). This article provides an overview of several commonly used and emerging predictors used for personnel selection.

Given several predictors, how should one choose the most desirable or optimal one for personnel selection in a particular situation? The answer to this question depends on the behaviors one wishes to predict. Such work behaviors can include both positive behaviors (e.g., job performance, task performance, teamwork) and negative behaviors (e.g., absenteeism, employee theft). Any work behavior that one is interested in predicting is referred to as the criterion.

Predictors assess variables on which individuals differ, and such differences are relevant only to the extent that they reflect individual differences in relevant criteria of interest (e.g., job performance, other work behaviors). Whether or not a predictor is a good prehire indicator of work behaviors that one is interested in can be determined by examining the relationship between a given predictor and work behaviors of interest. Criterion-related validity refers to the association between the predictor and criterion scores. The criterion-related validity coefficient indicates the extent to which individual differences in a particular predictor are related to individual differences in a criterion (e.g., job performance). Thus, the criterion-related validity coefficient can be used to evaluate the job relevance of a predictor for selection. Once the criterion one wishes to predict is identified, one can choose the predictor or combination of predictors with a high criterion-related validity coefficient for that criterion.

In addition to criterion-related validity, one may want to consider other factors that could affect the utility of the selection procedures. The utility of a selection system depends on the selection ratio and variability in job performance across individuals. The selection ratio is the percentage of applicants who are hired and can range from 0 to 1.0. When an organization hires all applicants (selection ratio = 1.0), the usefulness of a predictor is nonexistent because no "selection" takes place. The smaller the selection ratio, the greater the benefits obtained

from personnel selection. When there is no variability in job performance across individuals, the usefulness of a selection system is also nonexistent; it does not matter who gets selected. Thus, the exact utility (i.e., value and organizational benefits) of a predictor for personnel selection depends on the context in which it is used.

Another important consideration in evaluating the various predictors used for personnel selection is applicant reactions. For example, managerial applicants might not accept that scores on a verbal ability test reflect individual differences in managerial job performance. Undoubtedly, there are also cross-national differences. For example, personnel selection in the North American context is more reflective of the organizational perspective in that research and applications have emphasized the predictive validity of selection tools. In contrast, European research not only has been more eclectic in its assessment of the predictive validity of selection tools but also has taken a multilateral approach to evaluation, including evaluations from multiple stakeholders. It is more common in the European context to view selection as a negotiation among various parties such as the organization, unions or employee associations, and governmental agencies. Perhaps this broader focus is reflected in academic discussions of social constructivism in inferring meaning of organizational and individual acts. The study of applicant reactions, although in its incipient stages, has the potential to bridge this gap between the organizational perspective and multiple stakeholder perspectives.

Applicant reactions have important consequences for an organization. If top applicants turn down job offers, the utility of the selection effort is reduced. Furthermore, dissatisfied applicants are more likely to litigate against an organization and boycott its products. This article reviews research on the variables that affect applicant reactions and discusses different predictors used in personnel selection, both in terms of their criterion-related validity and in terms of applicant reactions.

Selection affects not only organizations and the individuals applying for jobs but also society. Society has a stake in promoting fair selection procedures, maximizing productivity, and ensuring opportunity to all individuals. The issues become complicated when there are discernible differences across demographic groups in predictor scores. Group differences result in greater proportions in hiring of the higher scoring group, and this could result in an adverse impact for the lower scoring group. Therefore, in discussing the different predictors used in personnel selection, this article also

reviews issues of fairness, bias, adverse impact, and group differences in predictor scores. Attempts made to reduce the impact of group differences (e.g., banding procedures) are also summarized. Finally, methods of using multiple measures in selection and research on emerging topics in personnel selection are presented.

2. PREDICTORS USED IN PERSONNEL SELECTION

Selection occurs after a pool of qualified applicants has been identified. Recruitment refers to the activities undertaken to attract a qualified pool of applicants, and several factors affect the effectiveness of recruitment. The content of the recruitment message, the characteristics of the recruiter, the medium used, and the like have been researched. Although this article does not elaborate on these topics, it is important to note that some prescreening (including self-selection) will have occurred in the normal flow of events in organizations prior to application of the selection methods discussed in what follows.

Several predictors are used in personnel selection. Some predictors assess whether individuals have the knowledge, skills, and abilities to perform a job task (i.e., “can do” predictors), whereas others assess whether individuals will typically perform well on the job (i.e., “will do” predictors primarily assessing motivation). In classifying predictors, it is possible to view them as determinants of declarative knowledge (i.e., knowledge of facts) needed to do the job (e.g., job knowledge tests), procedural knowledge (i.e., knowledge of how to get the job done), and motivation. A multitude of predictors have been used in personnel selection. This section

provides a summary of some of the most popular predictors used in personnel selection. It organizes the predictors into three main categories: (a) predictors based on individual differences (cognitive ability, physical ability, personality, and biographical information); (b) method-based predictors that can be used to assess various knowledge, ability, and trait combinations (job simulations and work samples, assessment centers, and interviews); and (c) predictors used primarily in the prediction of undesirable work behaviors (integrity tests and drug testing).

The coverage in this article is not comprehensive given space constraints, but it is intended to familiarize the reader with some of the popular selection tools. In fact, at times, popular predictors might not be the most valid ones. Table I summarizes the use and validity of the predictors discussed in this section. The data on predictor use vary across surveys; therefore, the table indicates a general categorization of use as high, medium, and low. The validity data are culled from meta-analyses and are also summarized into broad categories (high, medium, and low). The data in the table are suggestive and not definite in any sense because averaging percentages across surveys, where the numbers of respondents differ, is not indicative of any specific trend. The table is provided only as a heuristic to enable the reader to appreciate that some organizations may be employing less valid methods and incurring large utility losses. In a way, the table suggests that society may be incurring forgone opportunity costs to the extent that popularity and validity diverge.

2.1. Cognitive Ability Tests

There are more than a dozen definitions of what constitutes cognitive ability. Common threads across most

TABLE I
Summary Status of Personnel Selection Predictors

Predictor	Criterion-related validity	Extent of use	Applicant reactions
Cognitive ability	High	Medium	Moderate
Physical ability	Medium	Low	Positive
Personality tests	Medium	Medium (but increasing)	Moderate
Biodata	Can be high	High	Moderate
Job simulations	High	Low	High
Assessment centers	Can be high	Low	High
Interviews	Can be high	High	Moderate
Integrity tests	High	Low (except in the United States)	Moderate
Drug testing	Medium	Low (except in the United States)	Negative

of the definitions are the capacity to process information and learn. IWO psychologists have been using cognitive ability tests for more than 80 years. Furthermore, cognitive ability is one of the most widely researched traits in personnel selection. IWO psychologists have developed several tests of cognitive ability, and meta-analytic cumulation of the vast bodies of criterion-related validity studies have shown that cognitive ability is one of the best predictors of job performance. The relationship between cognitive ability test scores and job performance averages approximately .50. This is higher than what is found for other predictors. Furthermore, the validity of cognitive ability tests has been demonstrated in nearly all situations. This predictor is perhaps the best and most applicable one in personnel selection for nearly all jobs. All jobs require some cognitive ability to learn the jobs and perform effectively. The predictive validity of cognitive ability tests tends to be higher for high-complexity jobs (.58) than for low-complexity jobs (.23). A high-complexity job (e.g., nuclear physicist) involves more processing of information than does a low-complexity job (e.g., truck driver).

In addition to tests developed to assess general cognitive ability, there are ability tests tailored for specific purposes such as assessment of accounting ability and knowledge of mathematics. Tests have also been developed to assess perceptual ability and knowledge of mechanical principles. All of these tests measure general cognitive ability (*g*) to some extent, but they also have a specific ability component. It has been hypothesized that these specific abilities could be more predictive for specific jobs. For example, it has been argued that perceptual ability may be more important in clerical tasks. However, empirical research suggests that the predictive validity of specific abilities stems from their assessment of a general information-processing ability (i.e., the general cognitive ability). If the general cognitive ability is partialled out (i.e., held constant), most of the predictive power of specific ability tests vanishes. However, specific ability tests may have more face validity and may generate positive applicant reactions in a selection context.

2.2. Physical Ability Tests

Physical ability tests have also been used in personnel selection, especially in certain jobs such as firefighting and police work. Although there is a vast empirical literature on cognitive ability, the research on physical ability in selection contexts is more limited. Researchers have identified several dimensions of physical ability. One

classification conceptualizes physical ability as being composed of nine dimensions: static strength, explosive strength, dynamic strength, trunk strength, extent flexibility, dynamic flexibility, gross body coordination, gross body equilibrium, and stamina. Tests have been devised for these nine dimensions based on common physical tasks. Other researchers have categorized physical ability assessments into two major dimensions: endurance and maximum strength measures. The validity and usefulness of physical ability as a predictor of job performance has been empirically investigated. One study presented the validity of physical ability tests in personnel selection as .32 for predicting supervisory ratings.

2.3. Personality Tests

IWO psychologists have used personality variables for personnel selection since the beginning of the 20th century. Walter Dill Scott devised measures for selection of salespersons that assessed aspects of personality. The Woodworth personality datasheet was used to select or identify individuals who are likely to suffer from war neurosis. During early days, IWO psychologists hypothesized and assessed different variables that they considered to be promising. Variables such as reliability, dependability, sociability, and ego strength were assessed. Sometimes different names were given to the same trait, and at other times the same label was used to assess different traits. Given this state of affairs, the validity and usefulness of personality variables in personnel selection were questioned during the 1960s. Furthermore, the behaviorist revolution in psychology contributed to personality variables falling out of favor during this time.

Research conducted over the past decade has been more positive. Meta-analysis was used to cumulate the validity and usefulness of personality factors for personnel selection across studies. Results suggested that the dimension of conscientiousness is valid across jobs and situations, with a criterion-related validity of .23. Openness to experience was found to be correlated with the criterion of training performance, and extraversion was found to be correlated with performance in certain jobs such as sales. Emotional stability was found to be a good predictor of performance in security-related jobs (e.g., police work). Salgado summarized the validity evidence based on European samples and found that conscientiousness and emotional stability are useful predictors in Europe as well. Newly emerging research suggests that emotional stability may also be an important predictor in the United States. Although concerns have been raised that applicants could fake

their responses, the criterion-related validity is substantial for personality inventories despite the presence of any potential response distortion among job applicants.

Assessments of personality have employed structured paper-and-pencil inventories. The Hogan Personality Inventory (HPI), the California Psychological Inventory (CPI), the NEO Personality Inventory–Revised (NEO PI-R), and the Personal Characteristics Inventory (PCI) are some of the paper-and-pencil inventories. The Minnesota Multiphasic Personality Inventory (MMPI), although developed for clinical assessments of psychopathology, has also been used in personnel selection, especially in jobs where emotional stability is important for job performance (e.g., police work, firefighting).

2.4. Biographical Information (Biodata)

The use of application blanks is prevalent in personnel selection. The underlying principle in the use of application blanks is that past behavior is the best predictor of future performance. However, the question of what weights to assign to each response has been much debated. Weights reflect the relative importance assigned to each response. In general, larger weights should be assigned to responses that characterize individuals who perform better on the job. For example, if individuals with bachelor's degrees are likely to be better performers than those with high school diplomas, those applicants who check the bachelor's degree response in the application blank should receive higher scores than should those who check the high school diploma response. This is an example of how empirical scoring is done. Scoring of biodata items can be done either empirically or based on rational grounds.

In a weighted application blank (WAB), weights are assigned to several items and the scores are summed. Once a WAB has been developed, a score can be computed for each prospective applicant by weighting the response provided by that particular applicant. Sometimes a biographical information blank (BIB) could be employed. A BIB is similar to a WAB, but the former includes more experiential and personal information. An accomplishment record is a structured inventory of experiences that an individual considers to be a reflection of his or her talents.

Biodata items can be used to infer several individual differences characteristics. Decision makers can use education-related biodata items to make inferences about math and language abilities, sports-related items

to make inferences about physical ability, and items on social positions held to make inferences about personality characteristics. Research indicates that biodata instruments that are transportable across organizations can be developed. That is, scores developed in one organization can be used in another organization, so it is not essential to develop biodata items specifically for each organization. Validities of .48 have been reported for such biodata instruments. In general, applicant reactions have been favorable, especially when items have focused on events under the control of individuals. Applicant reactions are more negative when invasive items that raise privacy concerns for applicants are included on biodata measures.

2.5. Job Simulations and Work Samples

One of the major criticisms of the paper-and-pencil assessment method is that it does not capture the rich, complex, and subtle ways in which a trait is manifested in the real world, especially as performance on the job. Researchers have attempted to build realism into the assessment methods by simulating as much as possible the actual conditions under which individuals have to perform their work and testing how individuals perform in those simulations. Simulations differ in the degrees of realism captured. At one extreme are simulations that have very high psychological and physical fidelity to reality. At the other extreme are assessment methods in which the individuals are presented with paper descriptions of actual situations and asked to indicate how they would respond if they encountered the situations described.

Situational judgment tests are simulations of low fidelity. As the name indicates, individuals are presented with descriptions of situations and asked to indicate their likely responses. Situational judgment tests are typically high on face validity and have been found to display high levels of predictive validity. However, it has been difficult to ascertain the traits assessed in such simulations. Work sample tests have been employed to assess both job knowledge and procedural knowledge. Work sample tests have demonstrated high criterion-related validity (averaging .54). Work sample tests are relatively costly to develop. Also, in some instances where specialized knowledge is required or where tasks pose a danger to individuals assessed or to others, it is not possible to use work sample tests in personnel selection. Applicant reactions

tend to be favorable toward work samples, probably due to high face validity.

2.6. Assessment Centers

Related to simulations, but more comprehensive in coverage of the traits assessed, are assessment centers. Assessment centers typically involve multiple assessments of applicants using various tools and methods, including tests, interviews, and several types of exercises such as leaderless group discussion, in-basket exercises, and other problem-solving approaches. Assessment centers may also include role-playing and/or oral presentations. As such, the assessment center method of job candidate evaluation can span several days. A meta-analysis of the assessment center literature has found that the average validity of assessment center studies reported in the literature is .37 for predicting overall job performance. Recent research indicates that much of this validity is derived from traits such as cognitive ability and personality characteristics assessed. The use of assessment centers has also been found to elicit positive applicant reactions due to the apparent linkages between exercises and managerial work functions. Job applicants, especially for higher complexity jobs, consider assessment centers to be more acceptable predictors of job performance.

2.7. Interviews

Interviews are by far the most widely recognized personnel selection tools used. Interviews that are structured (i.e., the same set of questions and standardized scoring system is used for all applicants) have been found to have better validity than unstructured interviews. Another issue in the research on interviews is the use of multiple interviewers or panel interviews. Researchers have explored the composition of the interview panel in terms of demographic characteristics. The demographic characteristics (e.g., race, gender) of the interviewers and interviewees, and potential interactions between the two, have also been investigated. Typically, demographic variables do not influence the interview outcomes significantly.

During recent years, IWO psychologists have introduced two new types of interviews: the situational interview and the patterned behavior description interview. The basic rationale for the two types of interviews is that the questions asked of individuals should be reflective of actual situations that people face in the real world (where one wants to predict performance). Thus,

individuals are given examples of workplace situations and asked how they would respond if confronted with such situations. Validities of approximately .45 have been reported for structured interviews.

2.8. Integrity Tests

Employers have attempted to screen out applicants who are likely to engage in theft or related counterproductive behaviors. This is especially true in some industries such as retail, fast food, and banking. Physiological measures have been used to assess dependability. Since 1988, the use of polygraphs in preemployment testing has been limited to security-related jobs in the United States. Furthermore, most psychologists believe that the validity of polygraphs is doubtful. Another option is the use of paper-and-pencil tests designed to assess integrity of applicants. Some of these tests ask applicants about their thoughts about theft, their admissions of theft, and their estimations of theft prevalence rates. The rationale is that individuals who are likely to engage in theft are likely to rationalize their behaviors by reasoning that most people will engage in such behaviors. Thus, they are likely to overestimate the prevalence rates. The emphasis is on assessing applicants' attitudes toward theft. However, recent research indicates unequivocally that integrity tests assess primarily well-known personality traits of conscientiousness, agreeableness, and emotional stability. As for usefulness in prediction of work-related behaviors, meta-analytic findings suggest that integrity tests have a validity of .39 in predicting general counterproductive behaviors. The criterion-related validity for predicting actual detected theft is lower (.13), and the validity for predicting overall job performance is .41.

2.9. Drug Testing

Screening for substance abuse has increased over the years. Integrity tests can be used to screen applicants for potential theft and for counterproductive behaviors on the job, including substance abuse. However, many employers are skeptical that responses to a few items on a paper-and-pencil test will identify substance abuse. In fact, such personality assessment may be more useful for detecting proclivity for substance abuse, whereas physiological measures may be more applicable for detecting current use. Urinalysis, blood samples, and hair testing are some of the physiological measures that have been employed in testing for substance abuse. Many employers provide job offers to applicants

conditional on passing a drug-screening test. Some studies report substantial predictive validities for preemployment drug screening on a variety of job performance criteria. However, drug testing cannot distinguish between the casual or weekend user and the workplace abuser. A person who smokes one marijuana “joint” on Saturday night will have the same result as a person who is smoking marijuana continually on the job. This inability to discriminate is a major point of controversy in the drug-testing literature. Arguments have been made that personality tests, such as integrity tests, can assess the proclivity to use drugs and so can make the distinction between a casual user and a regular user.

3. FAIRNESS IN SELECTION

In discussing fairness in selection, one needs to clearly distinguish among culture-fair assessment, group differences, adverse impact, discrimination, bias, and fairness. These are related but distinct concepts. Any assessment is grounded in a cultural context to some extent. The degree to which responses are unique to a particular culture constitutes the culture-loadedness of the test. If one uses culture-loaded tests in selection, members of cultural groups for which the items were developed are likely to score better than are members of other cultural groups. However, there is a long history of test developers attempting to identify and delete such items from tests. The essential strategy is to equate individuals belonging to various cultural groups on the trait being measured and to test whether the difficulty level of items (i.e., percentage of individuals getting the items right) is significantly different across groups. If differences are found, a conclusion of differential item functioning is reached. Several statistical procedures have been developed to assess differential item functioning. However, empirical studies indicate that, at least for well-developed professional selection tests, there is no evidence of differential item functioning across racial groups.

Culture-fair assessment does not imply lack of group differences in traits. Just as there are discernible individual differences, there can be discernible group differences in traits. Groups can be defined based on race, gender, or age. When there are group differences, it is possible that there will be more members of the high-scoring group being selected. When the selection ratios (i.e., ratios of those who were selected to those who applied for a job) differ substantially across groups, adverse impact results. That is, the low-scoring group has been adversely affected by the selection procedures.

The issue of bias, in contrast to issues of fairness, is a statistical concept with a precise definition. Predictive bias is defined as the systematic over- or underprediction of a criterion. Two related concepts should be mentioned here: single-group validity and differential validity. Single-group criterion-related validity refers to the idea that the predictor is valid for one group but not for the other group. Differential validity indicates that the predictor is valid in both groups but that the magnitude of the validity differs. Finally, fairness depends on the value system of the individuals, and there are perhaps no right or wrong answers. Fairness perceptions are reflected in applicant reactions.

Applicant reactions to a personnel selection system are important for several reasons. First, applicants might not apply for jobs with an organization if they have negative reactions to the selection system implemented by that organization. Second, when applicants are offered jobs, those applicants with negative reactions might turn down the job offers. This may force the organization to offer the jobs to less qualified applicants and to increase testing and recruitment costs, all of which would lower the utility (i.e., overall value) of the selection system. Third, applicants who have negative reactions to selection procedures employed may be more likely to sue the organization for unfair discrimination. Finally, applicants who have negative experiences with an organization’s selection system may boycott the organization in the marketplace and influence others to do likewise.

Of course, it is not feasible to avoid every factor that someone, somewhere, and at some time will find offensive in a selection system. Individuals who score low on a cognitive ability test are likely to blame the test. IWO psychologists have studied various factors that affect applicant reactions based on theories of organizational justice. Research has shown that applicants have positive reactions when the selection system is based on a thorough job analysis, provides multiple opportunities for applicants to demonstrate their skills, is valid, and is administered in the same manner to all applicants. Applicants care about both the outcomes (i.e., the scores obtained whether they are selected or not) and the procedures used (e.g., whether the procedures and rules are applied consistently to all job candidates). Finally, there is evidence that applicant reactions are influenced by the extent to which all applicants were treated with dignity and respect.

Empirical data have been gathered about applicant perceptions of various predictors. In general, most commercially developed predictors have been shown to be

free of bias, although group differences may exist. Organizations must consider these issues before choosing the appropriate predictors to use. When faced with group differences (even if there is no predictive bias), an organization may have to confront the potential for adverse impact for the low-scoring group when that predictor is used in personnel selection. The extent of adverse impact will depend on factors such as the magnitude of existing group differences and how selective the organization is; that is, the lower the selection ratio, the more choosy the organization is and the greater the adverse impact will be on the low-scoring group.

Organizations have tried different strategies to address this potential for adverse impact. One strategy is to specify a low score above which all applicants are considered to be equally qualified. This strategy ignores the linear relation between predictor and criterion variables for most predictors and results in substantial loss of the utility of the selection system. Another option is to search for alternate predictors where there are fewer group differences. However, alternate predictors might not capture all of the individual differences initially identified as critical for successful job performance.

Another option is to consider the use of banding. Banding refers to a set of procedures that groups some scores as not being significantly different from one another. The rationale advanced for the use of banding is the well-known fact that there is a measurement error associated with each observed score. The idea is that scores within a band all are the same; differences among them are probably due to measurement error. Bands are usually formed using the top score in a group of applicants and the standard error of measurement (SEM). Selection can be at random within the bands, or some form of preferential hiring based on other variables can be employed. However, banding is controversial in personnel selection, and several criticisms of the technique question its scientific basis. For example, the SEM is dependent on the reliability of the test. If an organization uses an unreliable test, it can generate broad bands; that is, the SEM increases with unreliable tests. Thus, an organization intent on ensuring enough selected individuals belonging to a low-scoring group can achieve its political goals by using unreliable tests.

4. COMBINING PREDICTORS

Organizations rarely rely on a single predictor for personnel selection. When individuals are assessed on several traits, how should the scores be combined? There

are two options. The first is a compensatory system in which high scores on one predictor can make up (i.e., compensate) for low scores on another predictor. In a compensatory system, the scores from different predictors are combined in one of three ways. The scores may simply be added (i.e., unit weights given to predictors), different weights may be assigned to each predictor based on rational arguments, or (for optimal prediction) regression weights can be used.

The second option is a noncompensatory system in which applicants are expected to obtain a minimum score on each predictor. The minimum score is referred to as the "cut score," and extensive technical literature exists on how to set cut scores. Noncompensatory systems can be further classified as multiple-hurdle and multiple cutoff systems. In multiple-hurdle systems, applicants are assessed on the traits one trait at a time, and only those who meet the requirements on a trait are assessed on the subsequent trait. This procedure is useful when the costs of the various assessments vary. One can administer the least expensive assessments first, and the more costly assessments may be limited to only those who meet the minimum qualifications of the least costly assessments. In multiple cutoff systems, individuals are assessed on all of the traits, and those who meet the minimum cut score in all predictors are selected. Multiple cutoff systems are used when it is costly to bring in applicants for testing on each predictor.

5. EMERGING ISSUES IN SELECTION

An increased emphasis on teamwork has been witnessed during recent years. Some issues, such as whether teams should be staffed with individuals who are similar in trait levels or with individuals who complement one another in traits, need to be explored more comprehensively. The increasing globalization of business has raised the issue of expatriate selection. What variables should be considered in selecting individuals for overseas assignments? Finally, research is needed on whether organizations should select for particular jobs or for qualified applicants in general. This is important when the boundaries among jobs fade. However, such a strategy will raise a whole host of issues such as the definition of "qualified in general." The rapid advances in computer and other multimedia technology have definitely altered, if not revolutionized, how assessments are made. The role of technology is an important and evolving topic in personnel selection.

6. CONCLUSION

Personnel selection is one of the central functions of industrial–organizational psychology. This article has reviewed the various predictors used for personnel selection and how predictors are combined to form a selection system. It discussed the relationship between selection and society at large. It considered issues of fairness in selection and applicant reactions. The article underscored distinctions between compensatory and noncompensatory systems. It noted emerging issues of team selection, expatriate selection, and selection for an organization rather than for specific jobs. Personnel selection is a dynamic field in which research and practice go hand in hand in building a science around how to best select and hire individuals for jobs.

GLOSSARY

bibliotherapy Therapeutic intervention making use of books and reading.

catharsis Process by which unresolved emotional distress is relieved and resolved through expressive activity.

imaginal coping Coping through the use of imagination and play.

language play Play in which children transform and practice linguistic forms, including sounds, words, sentences, and narratives.

metacommunication Communication between players that serves to shape the play process rather than serving as the actual content of play; it serves to mutually negotiate and to maintain the play frame.

play frame Parameters for sociodramatic play, as negotiated between players; this includes which roles are to be played and which actions and objects will serve symbolic purposes in the play.

sociodramatic play Social pretend play in which children enact dramatic roles and fantasy scenarios.

zone of proximal development The gap between a child's independent ability and the ability gained when the child is helped by others who are more capable; this zone may

be manifested by adult assistance in enabling a child to function on a higher level as well as through interaction with more capable peers.

Play, an activity in which children apply nonliteral flexible behavior that is motivated by pleasure rather than external goals, has been theorized to have positive developmental advantages for children's cognitive, affective, and sociocultural growth. In Euro-American society, play has been exploited for therapeutic purposes. Children make use of play for self-healing, both in their own spontaneous play and when they are guided by a professional therapist in formal play therapy. Play entails the re-representation of experience, which enables a flexible remaking of experience that has both therapeutic and normal developmental advantages.

1. INTRODUCTION

Straightforward attempts to define play have been elusive. Play, which encompasses both human and animal behavior, evades obvious definition. The difficulty traces partly to the broad and varied forms of play, ranging from rule-governed games, to improvised role-play, to rough-and-tumble mock wrestling. Play, for definitional purposes, is recognized mainly by how

TABLE I
Four Criteria Defining Play

Criterion	Definition	Example
Nonliterality	Takes an “as if” stance toward reality, transforming actions and meanings	The child lifts and shakes his or her head, roaring as if he or she were a lion
Intrinsic motivation	Activity is done for its own sake rather than for external motivation	The child pulls a wagon for the fun of it rather than to take things somewhere
Positive affect	Pleasure or enjoyment	The child squeals with glee when riding a swing
Process flexibility	Actor flexibly makes use of an object rather than conforming to an action dictated by the object	The child uses a large box for many varied playful uses: turning it upside down as if it were a rock to hide under, turning the opening to the side as if it were a “store,” getting inside the box and rolling down a hill, and/or using it to build a pretend machine with fantasized powers

it contrasts with other dispositions or orientations. A workable approach for defining play involves assessing a behavior based on four criteria. The more the four criteria apply to the behavior, the more the behavior can be categorized as constituting play. These criteria, summarized and illustrated in Table I, are (a) nonliterality (a transformational “as if” stance such as riding on a stick as if it were a horse), (b) intrinsic motivation (an action pursued for its own sake rather than driven by external goals), (c) positive affect (pleasure), and (d) process flexibility (action taken in a free and flexible manner rather than constrained by an object). Activity that fits these criteria can be observed across the human life span.

In addition to occurring in many forms, play has ambiguous or paradoxical characteristics. For example, play is an activity set apart from ordinary reality, yet it often makes reference to ordinary social reality in its content and form. Play encompasses creative innovation by the individual, yet it concurrently is shaped by sociocultural norms. Play, an activity that is not explicitly goal directed, has also been used with therapeutic effect for problems ranging from support during hospitalization, to trauma intervention, to grief therapy among children. Despite (or perhaps in response to) the intriguing ambiguities of play, scholarly attention to play has blossomed over the transition into the 21st century.

This article discusses accumulated theories and findings about play among children, including the developmental trajectory, sociocultural context, and therapeutic application of play.

2. PLAY: DEVELOPMENTAL PROCESSES

Early in the 20th century, Groos offered the speculative theory that play served as practice for young organisms who used play to develop their survival skills. Modern-day observers of play have recognized Groos’s insight as appealing. For example, when a child and a playmate pretend to go shopping for groceries, they seem to be practicing social behaviors that prepare them for actual adult roles.

Contemporary theories of play share an underlying assumption that play is beneficial and contributes positively to children’s development. Influential theorists of play who wrote during the first half of the 20th century, including Freud, Piaget, and Vygotsky, all argued that play serves childhood mastery through the transformation of themes within a nonliteral domain. In other words, the representational symbolism of play helps children to master issues related to affect, cognition, language, and/or social understanding. Play is a way in which to advance children’s competence and mastery and has pronounced developmental significance.

In Freud’s book *Beyond the Pleasure Principle*, he argued that play is significant for children’s emotional mastery. Freud asserted that play could have a cathartic effect for children, facilitating the discharge of negative feelings. Building on Freud’s ideas, Erikson posited in his classic work, *Childhood and Society*, that play provides a domain in which children can find self-healing. As Erikson described, children use play to create a re-representation, that is, a model situation

flexibly manipulated to achieve emotional mastery. For example, a child who witnessed a violent crime may repeatedly reenact the scene in improvised play scenarios as if to reencounter affective issues precipitated by the violence. Play, according to Klein's *The Psychoanalysis of Children*, is a suitable medium for children to express complex ideas and feelings that they cannot yet verbalize. Therefore, for young individuals, play is a more appropriate vehicle for therapy than is conversational discourse.

Piaget focused on children's cognitive functioning in his work on play. Piaget conceived of learning as essentially a balancing of two complementary processes: assimilation (i.e., modifying reality to fit one's cognitive structures) and accommodation (i.e., changing one's cognitive structures to conform with reality). In Piaget's book *Play, Dreams, and Imitation*, he viewed play as an unbalanced state in which assimilation dominates over accommodation. Piaget believed that children achieve new learning not through play but rather through practiced and consolidated recently acquired cognitive abilities. In contrast, Vygotsky viewed play as having a more central role in cognitive development, for example, by furthering children's abstract representational thoughts through playful creation of imaginary scenarios. For example, substituting a banana for a telephone in a make-believe phone conversation would precipitate growth in children's ability to use meaning abstractly and symbolically. Vygotsky also referred to pretend play as constituting a zone of proximal development, a framed and imagined experience in which peers can perform activities together beyond a particular child's level of competence outside pretend play. Vygotsky also noted that play has affective components in that children act out desires that have not yet been fulfilled.

Much of the empirical work on children's play has focused on sociodramatic or pretend play in which children enact pretend roles and situations. Such play has been observed as early as the end of a child's 1st year of life, although true social pretend play normally emerges at around 3 years of age. In his *Play, Dreams, and Imitation*, Piaget reported an observation of his own daughter at 15 months of age where she treated a piece of cloth in the same manner as she usually treated her fringed pillow, that is, by laughing and pretending to close her eyes to signal her playful intent. Infants from varied cultures have been shown to produce pretend gestures from roughly 12 to 13 months of age. As sociodramatic play develops, children's activity gradually becomes separated from specific contexts

and outcomes, contains more references to others, and becomes less reliant on realistic props or materials. For example, early pretense might entail using a cup and pretending to drink, but later pretense could involve serving a pretend beverage to a menagerie of pretend animals from an imagined cup filled with a potion having fantastic effects.

Pretend play, as studied in middle-class Euro-American children from intact families, rises in incidence from the 3rd year of life to approximately 6 or 7 years of age. Sociodramatic play declines during the late kindergarten and elementary school years. During the grade school years, another form of play, games with rules, increases.

3. PLAY: SOCIOCULTURAL CONTEXTS

Established play theorists, including Piaget and Vygotsky, made presumptions that play, its forms, and its trajectory are universal such that social pretend play might, in theory, emerge at 3 years of age in all societies. Yet children's play is cultural activity and is subject to variation within distinctive cultural milieus distinguished by particular physical, economic, and social contexts.

Play is encouraged more in some cultural settings than in others. Play covaries with economic and social factors, which may affect the opportunity to play in the face of necessary work, as well as with the overall value placed on play by a community. Goncu, who examined cultural variations in children's play in his 1999 edited book *Children's Engagement in the World*, argued that in small villages with subsistence economies, parent-child play is rare due to the pressing demands of work. Children, who are expected to contribute to the economic well-being of families in these villages, might not have time to play. In the same volume, Gaskins described Mayan children as having access to few props for pretend play. Pretend play is not assumed to be a valued activity by Mayan adults; rather, it is tolerated at best. Playful use of language, or language play, is also less frequent among Mayan children than among American children. In another study, Carlson and colleagues found that in American Mennonite society, pretend play is rarely discussed or embellished and is sometimes actively discouraged. Play themes among Old Order Mennonite children during recess adhere closely to real-life roles.

If the amount and content of pretend play is subject to cultural variation, so too are the metacommunications by which play participants interact to maintain and transform play. Martini, in an ethnographic study of peer interactions among Polynesian Marquesan 2- to 5-year-olds, reported that these children avoided lengthy one-to-one negotiations about play activities, preferring to maintain consensus by playing in ways that were familiar to all players, that is, without much change or elaboration made to play events. Marquesan children similarly avoided leadership roles by engaging in games where all participants acted together in similar ways. In contrast, American children cooperated less often so as to negotiate and individually innovate during play. In Haight's study of caregiver-child pretending, she reported on naturalistic home observations of child-mother pretend play among 1- to 4-year-olds, tracing differences in the metacommunications about play between Chinese families and U.S. families. Although both Chinese and American caregivers sanctioned pretend play and initiated pretending for purposes of socialization, their metacommunications about play diverged. Chinese caregivers initiated pretend play in a more hierarchical and didactic manner, whereas American caregivers facilitated a more mutual engagement in which children were allowed to lead the interactions. Table II offers specific examples from Haight's research.

Although developmental scholars once viewed children in social groups who engaged in relatively little pretend play as if they were disadvantaged (by the so-called "play deficit"), this view has been dismissed by culturally sensitive researchers (e.g., Schwartzman). Variations in play reflect larger differences inherent to the particular cultures of children, representing sociocultural distinctions rather than deficits. Healthy functioning in play is best understood by keeping in mind the sociocultural context of a given time and place and by assessing play within the sociocultural confines of children's own environments.

It is important to note that culture is not an all-determining factor of the form or quantity of play. Individual differences occur within a culture in children's fantasy predispositions and play styles. When society has not provided materials explicitly meant for play, children have been known to use discarded items and places (e.g., abandoned buildings, construction sites) for play. Moreover, gender-related differences have great significance, both in the form of parental discouragement of cross-gender playthings and in the form of peer interactions that reflect and shape gender

TABLE II
Examples of Caregiver-Child Pretending: Girls and Mothers at Play

Taipei (Chinese)	<i>Caregiver:</i> Stand up, bow down. Teacher is going to deliver a lesson.
	<i>Child:</i> [Child smiles and moves closer to caregiver.]
	<i>Caregiver:</i> Teacher is coming to the classroom. What should the class monitor say?
	<i>Child:</i> Stand up! [Child stands and bows. Play continues as they read a story.]
Age of child: 2½ years	<i>Caregiver:</i> We have finished the story. [She claps her hands.] Before we dismiss the class, the class monitor should say 'Stand up! Bow! Sit down!' Stand up!
	<i>Child:</i> [Stands.]
	<i>Caregiver:</i> Bow!
	<i>Child:</i> [Bows.]
	<i>Caregiver:</i> Class is dismissed. Go play on the slide [She points to imagined slide.] Class is dismissed and you are happy.
Chicago (American)	<i>Child:</i> [Child gets toy, a plastic dashboard with steering wheel and seatbelt, and positions herself as if to drive.]
	<i>Caregiver:</i> Be sure to fasten your seat belt, right? Buckle up for safety!
	<i>Child:</i> [Child fastens seatbelt. Child turns to the steering wheel and pushes the horn.]
	<i>Caregiver:</i> Where are you going? Are you taking a trip?
Age of child: 3 years	<i>Child:</i> To Havana. [Child steers and pretends to drive.] You drive a car like this. Like this, okay? [Play continues as child explains that Havana is far and discusses with her mother how many stops will be needed en route and how old one must be to get a driver's license.]

differences. Thorne, in her book *Gender Play*, described how American school-age boys and girls mark boundaries on the playground (and elsewhere) between girls and boys—boundaries that are then crossed, undermined, and challenged through playful behavior. Play reflects not only individual differences and gender-related social behavior but also the distinctive cultural context.

4. THERAPEUTIC PLAY

Play has been regarded, both theoretically and practically, as a healing or coping activity to be engaged in when children are under stress or facing emotional challenges. A widely known application of therapeutic play takes place within the clinical modality of play therapy employed by social workers, psychologists, child life therapists, psychiatrists, and others working in counseling children. Less prominent in the scholarly literature is the fact that children also use play on their own, without explicit professional intervention, as a means of coping with adverse or stressful circumstances.

One example of child-initiated therapeutic play is the self-initiated use of stories or pretend play as a means of expression and resolution. Paley, in her well-known series of reports on young children's playful enactments, reported how children use role-playing to serve emotional ends by reworking details, for example, by eliminating the frightening big bad wolf when enacting the "Three Little Pigs," by resurrecting a dead grandfather during role-play, or by continually improvising threats to a baby (e.g., a baby-eating lion) in reflecting on the vulnerable infantile state.

Eisen, in his book *Children and Play in the Holocaust*, chronicled how children assimilated the horrors and traumas of Holocaust death camps through their own play. While waiting for deportation for internment, children pretended to comfort their dolls. Living in camps surrounded by death and cruelty, children constructed playful pastimes such as corpse tickling and pretend games of gravedigging, funerals, and gas chamber. Experiencing the most intense horrors, children found ways of playing that addressed the very traumas of their environment. Their play was a reaction to atrocity, yet it was also a buffered context in which children could creatively make meaning of a chaotic gruesome circumstance.

In Clark's book *In Sickness and in Play*, she described how American children with chronic illness used self-initiated play as a vehicle for coping with illness. Clark found that chronically ill children spontaneously, and without formal therapy, often employed play as a means of coping with the concerns and hardships of diabetes or asthma. Playfulness, such as pretending a superhero would protect the children from peril or making a game out of an onerous treatment, made space for children to examine and reframe illness-related dilemmas.

In short, play need not be guided by an adult (therapist, teacher, or child life specialist) to provide

meaningful transformative value to children confronting everyday stresses. Even without clinical intervention, play seems to be a child-manageable domain for raising and addressing emotional troubles. Play allows children to approach and express feelings that, if not masked in the "disguise" of play, might be inexpressible, whether through independent play or in therapy.

The development of formalized play therapy began during the 1920s, when Anna Freud advocated the use of toys and games as a way in which to build relationships with child patients. She claimed that this method was superior to the verbal adult method of free association. Her influential idea was that whereas adults "talk out" conflicted emotions, children are better suited to "play them out." Her techniques were further developed by Klein, Axline, Erikson, and others. Klein proposed that play was children's natural means of expression and could serve as a direct substitute for verbalizations, providing sustained symbolic expression to be interpreted by analysts. Axline, inspired by the client-centered therapy movement, proffered that in therapeutic play children should be given free rein to express feelings without judgment or direction by therapists. Erikson regarded play as a natural self-healing measure, that is, a given ability of childhood by which children could be helped to help themselves. Play therapy has developed in multiple directions during recent years, serving as an adjunct to other modes of treatment such as behavior modification and proliferating in forms such as art therapy, sand tray therapy, storytelling, music and dance therapy, puppet therapy, costume therapy, bibliotherapy, and numerous forms of symbolic and game play.

Play therapy has been used in individual therapy one child at a time, but it has also found wide application with groups of children who are facing or have experienced a shared trauma such as war. As an example of the latter approach, Simo-Algado and colleagues used therapeutic play to strengthen personal resources among children in Kosovo who were exposed to trauma during Serbian occupation and the ensuing 1999 NATO military campaign. The goal of the intervention was to preventively buffer against further effects of trauma among a child population that was impoverished, subject to injury from land mines, and dealing with difficult issues such as missing persons, the discovery of mass graves, and the memories of massacres, rapes, burnings, and shootings. Under circumstances of war, the play of Kosovo children had been narrowed to the play theme of reenacted war. Occupational therapists and aids worked with the children, engaging them in other activities that reflected their shared

cultural identity, for example, songs and poems in Albanian and games incorporating native cultural themes. Drawing, clay, narratives, and puppets were introduced as media through which children could vent, process, and discuss their feelings, including fear, anxiety, hatred, and despair. Play, which indigenous teachers were trained to facilitate, provided support, insight, external expression, and a sense of mastery. Following the therapeutic sessions, children took part in sports such as soccer, providing an opportunity for adults to observe the children at play (as well as those children who seem inhibited in free play) and to identify particular children who might benefit from additional individual attention. Through the play-based interventions, children gave expression to their war experiences and then gradually reflected new meanings about past trauma, in the words of Simo-Algado, “moving from victims to survivors.” The United Nations Children’s Fund (UNICEF) also used art and play in its psychosocial assistance program for children in the former Yugoslavia, through which children were encouraged to recall events from the past and express hope for the future. In crisis circumstances of mass trauma, play interventions can be taught to local professionals and volunteers, who in turn can help many children in need of healing.

Play therapy has also become a mainstream means of clinical intervention with children in individual therapy. For example, play is used as a means of helping pediatric patients by child life specialists who use play to provide child-relevant support in hospitals. Play is implemented as a means of instructing and preparing children for medical treatment procedures as well as a means of expressing or relieving emotional distress among ill youngsters.

Play serves multiple therapeutic purposes. First, it is an appropriate vehicle of communication between a professional and a child. Second, play can serve to relieve emotional tension by providing a means of expressing and reworking issues. Finally, play therapy can introduce children to new forms of beneficial play behavior, potentially to be extended into children’s lives outside of therapy.

Although play need not be guided by an adult (therapist, teacher, or child life specialist) to provide

meaningful transformative value to children confronting everyday stresses, adult support of therapeutic play is helpful when children face extraordinary circumstances. With or without clinical intervention, however, play seems to be a child-manageable domain for raising and addressing emotional troubles.

Nevertheless, the underlying process by which emotional resolution takes place in play is not completely understood. The therapeutic utility of play and the role of sociocultural contexts in shaping the trajectories of play are areas in need of additional investigation. Although play has come to be appreciated as a powerful human activity, its ambiguity and transformative dynamism continue to pose challenges for further scholarly understanding.

GLOSSARY

accessibility The ease with which information in long-term memory can be retrieved.

bias A systematic distortion in the processing of information.

entitativity The extent to which a social category is perceived as having real existence.

heuristic A simplified procedure or rule of thumb for making a decision or solving a problem without systematic processing of information.

ideology-based voting Voting choice based on ideology or values.

issue-based voting Voting choice based on parties' position on given political issues.

matching effect The different impact of persuasive messages as a function of authoritarianism and other characteristics of the target.

media agenda setting Decision process regarding the relative space and time to be devoted to different news by the media.

performance-based voting Voting choice based on evaluation of past performance of a party or a political leader.

political identity The part of the self-concept that derives from belonging to a political group.

salience Prominence, distinctiveness; any aspect of a stimulus that causes it to stand out and attract attention.

third person effect A tendency to overestimate media influence on others and underestimate media influence on oneself.

trait-based voting Voting choice based on personal characteristics of a political candidate that may have either a positive or a negative connotation.

voter's paradox A definition of voting as an apparently contradictory action, since costs implied by the act of voting are higher than the benefits the single citizen may expect from that act.

Political psychology investigates representations and actions of political actors, be they citizens, politicians, or members of groups characterized by collective and public goals. This overview begins with a definition of the area of interest of political psychology and of the main stages that have characterized the development of the discipline. We will then examine how citizens know and evaluate political reality, with a special focus on political candidates. Attention will also be devoted to the differences between experts and novices in the political domain, and superordinate principles (such as values and ideologies) around which political attitudes may be organized. In the third section of the article, political identity will be dealt with. Different groups one may identify with in the political context will be highlighted, with a particular stress on regional, national, and supranational identities, and on the roles they play in international conflicts. Media and various

forms of political communication, such as political interviews or discourses, influence most of our interpretations of political reality. These issues will be analyzed in the fourth section, with special emphasis on motivations and goals that underlie political messages, as well as their persuasive effects. Finally, we will consider psychological factors involved in voting behavior and in other forms of political participation.

1. SCOPE OF POLITICAL PSYCHOLOGY

1.1. Area of Interest

Let us consider millions of people in different countries all over the world gathering on the same day in main squares and streets of their towns and demonstrating in favor of peace, shouting slogans against terrorism and war. Let us consider other millions of people watching the event on television. If we zoom in on any of the demonstrators, politicians, bystanders, or the people simply watching this political event, we may investigate how they represent people struggling or not struggling for peace, what expectancies they have regarding possible success of peace movements, what plans they have regarding their future engagement in peace movements, and so on. We may also move beyond the specific event and investigate their political views, their political identities, or their voting intentions. All these issues fall within the area of interest of political psychology, which studies the representations and actions of all the people involved in political reality, from simple citizens to political leaders.

Most research in political psychology originates from the extension of “basic” psychological research to the political context, an extension that implies consideration of two main categories of context-specific factors: (1) rules and constraints that are present in the political context, and (2) motivations and goals of individuals and groups who act in the political context. For example, research on how citizens form an impression of political candidates takes into account the fact that in the political context, unlike other contexts, knowledge of a target person is often not direct, but is filtered by media. It also considers that motivations underlying the citizen’s perception of a political candidate may be different from those underlying perception of a target person in other contexts, and these differences may have an influence on perception accuracy or

on traits perceived as most relevant. The influence of the citizen’s ideological orientation on candidate perception is also taken into account—a variable that may not be as relevant in other contexts (see Section 2). These are examples of how research in political psychology may identify a series of factors that moderate or mediate effects already observed by basic psychological research, in some cases also highlighting previously neglected effects.

1.2. Historical Development

A short reference to the historical development of political psychology may offer an idea of the main issues dealt with by the discipline so far, as well as an idea of the psychological theories that have been most frequently assumed as frames of reference. Four main stages may be identified.

1. *1940s to 1950s: Politicians’ personality.* Studies of political psychology initially focused on the personality of political leaders, assuming psychoanalysis as their main frame of reference. Biographies of famous leaders (e.g., Alexander the Great, Hitler) were carefully reconstructed through historical and archival data, with a special stress on the educational environment that characterized the leaders’ development. Features of the adult personality, for example, a strong tendency to dominate over others or to be aggressive toward external enemies, were traced back to a series of psychological processes originating in childhood. Other studies, not focusing on political elites but on the wider category of political activists, adopted Maslow’s motivational model as a frame of reference. According to this model, people would perceive the need for engaging in political activity only when other, more basic needs have already been satisfied (e.g., health or social needs). As a consequence, politically active people would be characterized by high self-esteem and strong personal efficacy, that is, they would be deeply convinced of being able to engage successfully in political action.

2. *1960s to 1970s: Public opinion and voting behavior.* In this period, research focus changed dramatically from political elites to normal citizens and from personality to behavior. Surveys aimed at tapping political attitudes and voting intentions were being carried out on a regular basis, before or after national political elections. In 1960, Campbell et al. published a volume, *The American Voter*, in which they suggested that political attitudes would develop quite early, influenced by the individual’s family environment and, by adult age,

would become rather stable and resistant to change. Party choice would therefore be the consequence of a largely irrational process, defined as party identification, instead of being based on a thorough consideration of information regarding candidates, parties, and political issues. Although this approach evokes the image of an irrational voter, a very different, substantially opposite approach to voting behavior also developed in the same years, this one supporting the image of a rational voter. In *The Economic Theory of Democracy* (1957), Downs made reference to rational choice theory (RCT), according to which individuals, in this case voters, may effectively use all the information they have at their disposal so as to choose, from a series of possible alternatives, the one characterized by the maximum subjective expected utility. Decision-making would consist in an accurate evaluation of the pros and cons of each alternative in order to choose the one that is perceived as the potentially most useful for the individual, where utility is intended as functional to the personal, mainly economic, interest of the individual.

3. *1980s: Political cognition.* As compared to the previous stage of research in political psychology, in this stage attention shifted from political attitudes and behaviors per se to the cognitive processes that underlie and influence attitudes and behaviors. The 1980s were characterized by the extension of the “social cognition” approach to the political domain. Political psychology borrowed from social cognition a well-articulated corpus of theory and data regarding what happens in the different stages of human information processing, from initial coding of new information, to its organization in the individual’s mind, to its retrieval from memory. The citizen was seen as actively selecting and processing political information, attributing meaning to it through comparison with information already stored in memory, thus arriving at a personal interpretation of political reality. Information processing is constrained by the limits of human memory, mainly the capacity for dealing with only a limited amount of information at the same time. Because of these limits, citizens often do not thoroughly examine all the information they are exposed to. To save mental energy, they recur to simplified and rather superficial reasoning strategies, so-called heuristics. These strategies are functional to the everyday goal of making decisions and planning behaviors in a reasonably short time, but, being based on partial and approximate processing of available information, they may also lead to systematically distorted evaluations (biases). Thus, the political

cognition perspective offers an alternative to the above-mentioned opposition between the irrational and rational voter by suggesting that voters are characterized by a limited rationality.

4. *1990s to today: Social psychology of politics.* Although the synthesis of research developments that are still unfolding should be made with some caution, two main tendencies in contemporary political psychology may be singled out. The first one involves an enhanced attention to context-related factors (citizens’ motivations and goals, power relationships, normative and political constraints, etc.) and how these factors may influence both quality and quantity of political information processing. For example, cognitive theories of decision-making may be applied to voting decisions, taking into account the fact that context-related factors, such as the voting system of a given country or the dimensions and numbers of the opposing parties, may condition the way in which citizens make their decisions. The second tendency identifiable in contemporary political psychology is a gradual abandoning of a substantially individualistic perspective and the assumption of a more marked social perspective. Considering that one of the functions of politics is to regulate the relationships between individuals and groups, especially resources and power distribution, it is difficult to conceive of a psychology of politics that is completely detached from the social dimension. Social identity, social influence, intergroup relations: these are some of the factors that have been widely investigated by social psychology and are now also being taken into account by political psychology.

2. POLITICAL KNOWLEDGE AND POLITICAL ATTITUDES

In this section, we consider how political reality is perceived, felt, and reflected upon by the individual. As we have seen, studies of political psychology in the 1960s focused on public opinion: the substance of people’s political attitudes and how their attitudes on various political questions are interrelated. While these questions remain relevant, and indeed central to political psychology, in the following years there was greater recognition of the interdependence of attitudes and cognition, namely, how being in favor of or against a political candidate or issue is related to what we know (or believe we know) about them.

As compared to the past, contemporary society has developed an amazing number of ways through which information, including political information, can be transmitted and disseminated (TV, radio, Internet, mobile phones, etc.), and the potentiality of these media is still far from having been entirely explored. This means that, in principle, everybody has access to an incredibly large amount of information. However, such an access is filtered and regulated by a number of selection processes. Whereas some of these processes are independent from the individual, others depend (at least partly) on them.

1. *Media agenda setting.* This information selection process is operated by the media, that is, by those who decide the relative space and time to be devoted to each piece of information, as well as the language and images that convey information. These choices inevitably reflect a given way of reconstructing and interpreting reality, and are not under the control of the individual who receives information via the media.

2. *Non-voluntary media exposure.* This second source of selection is linked to the individual's life but at the same time is largely not dependent on the individual. Being born in a given place, living in a given family environment, attending a given school, these are all factors that inevitably influence the kind of media, and therefore the political information, to which the individual is exposed.

3. *Voluntary media exposure.* Although influenced by the individual's social and family sphere, media exposure is also voluntary, because individuals, once they have reached a certain developmental stage, start to choose the kind of media to which they want to be exposed.

4. *Selective attention.* Being exposed to a given piece of information does not necessarily mean paying attention to it. Social cognition studies have clearly shown that people engage in a process of selective attention, more or less consciously, that leads them to process only the information that, for various reasons, they perceive as salient or relevant in the given context.

In this section, we shall examine the latter type of selection process. We shall see what information is more likely to catch the individual's attention, with a special focus on information regarding political candidates. We will then consider how a well-established attitude regarding a political candidate or issue may influence or bias the processing of new information. Differences between experts and novices in political information processing will also be highlighted. Finally, we shall consider various theoretical proposals regarding

organizing principles (ideologies, values, etc.) of political knowledge and attitudes.

2.1. Candidate Perception and Evaluation

Citizens process information regarding political events, issues, programs, parties, candidates, or leaders. These various categories of information are obviously related to each other. However, the relative salience of each category may vary according to the goal pursued in processing that information and other context-related factors. In particular, when elections are upcoming, information regarding political candidates is especially likely to become salient. Actually, perception and evaluation of political candidates has been the most investigated area of political information processing so far, borrowing from the consistent body of results gathered by social cognition research regarding how people form descriptive and evaluative judgments about target persons.

2.1.1. Traits

When we form a judgment about a political candidate, we are likely to devote our attention to three main information categories: (1) the candidate's party, (2) the candidate's position on political issues, and (3) the candidate's traits, that is, personal characteristics that may have either a positive or a negative connotation. An analysis of the answers to an open question in a pre-electoral survey carried out on a regular basis in the United States (National Election Study) has shown that when people are asked to speak about candidates, they focus on their personal characteristics more than on their party or their position on political issues. This tendency is not significantly influenced by the individual's education level, suggesting that the stress on personal traits is not necessarily due to a lack of political competence, but may instead be due to the prevailing need for the individual to choose the right person to represent his or her own political needs and positions. Although some variation in the relative stress on personal traits has been found according to the political system and context in which individuals find themselves, recent years have witnessed an increasing personalization of politics, which is likely to make perception of the candidates' traits more and more important in citizens' political choices.

There is substantial consensus on what traits an individual focuses on when evaluating a political

candidate. These traits may be divided into five main categories: (1) competence (intelligence, ability in dealing with political issues); (2) integrity (being honest or, on the contrary, being prone to corruption); (3) reliability (being consistent, being able to keep one's word); (4) charisma (having capacity for leadership); and (5) image (being good-looking, attractive, photogenic). While the importance of the first two categories is generally more heavily stressed than the others, the relative weight attributed to each category may vary according to the context in which candidate evaluation takes place. For example, the salience of traits related to the candidate's integrity may be enhanced in a context characterized by a series of scandals involving corrupt politicians. These events usually get wide media coverage and may induce citizens to construct their evaluation of candidates around the dimension of integrity versus corruption. In these cases, a "figure-ground phenomenon" is likely to happen, in that the honesty of a given politician becomes especially salient because it is perceived as peculiar in a context of diffused corruption.

2.1.2. Emotions

The evaluation of candidates is influenced not only by their traits but also by the emotions (happiness, anger, etc.) they trigger. We may in fact wonder whether our judgment of a given candidate is based more on the traits we attribute to him or her (cognitive component of the attitude) or on the emotions we associate with him or her (affective component of the attitude). Research suggests that emotions, especially positive ones, are very good predictors of candidates' evaluation and voting intention. However, the relative weight of traits and emotions can vary according to the context. It has been suggested that emotions might become especially relevant in a changing context, when new candidates or new parties emerge in the political scene. The relative weight of positive versus negative emotions is also likely to depend on the context. Consistent with the figure-ground phenomenon described previously, higher relevance of positive emotions might be due to the fact that citizens are especially inclined to notice something positive when the context is mainly negative.

2.1.3. Influence of Ideological Orientation

So far, we have focused on traits and emotions that are generally perceived as relevant when evaluating a political candidate. However, some differences in perceived

relevance of traits and emotions have also been highlighted. In particular, citizens with opposite ideological orientations have been shown to differ in the positive traits they perceive as most relevant in political candidates. In a study by Caprara *et al.*, left-wing citizens asked to rate personality traits of candidates of different parties stressed the dimension of sincerity/reliability (sincere, loyal, reliable, accountable, authentic, etc.) in candidates of their own political side and the absence of the same traits in candidates of the opposite side. Right-wing citizens performing the same task have instead focused on the dimension of energy/innovativeness (dynamic, resourceful, resolute, energetic, creative, etc.), rating these traits as high in candidates of their own side and as low in candidates of the opposite side.

Interestingly, when evaluating their own personality, citizens tend to rate themselves as high in the same traits they perceive as typical of their favorite candidates. Can we therefore infer that citizens tend to choose candidates that are similar to them? Not necessarily. It may well be that an assimilation effect is taking place here, according to which we are inclined to perceive people we like as more similar to ourselves than they actually are.

2.2. Assimilation and Contrast Effects

As social cognition research has widely demonstrated, once a positive (or negative) attitude toward a given target has developed, processing of new information regarding that target may be biased, in the sense that we look for a confirmation of our own attitudes. This may happen in various ways, through discarding inconsistent information, devoting selective attention to consistent information, or reinterpreting neutral information in a way that is consistent with our attitudes. Attitude-consistent processing of new information is especially likely when the relevant attitude is strong and when information presents itself as somehow contradictory or ambiguous. Both conditions may be often found in the political domain. People typically develop strong attitudes in favor of or against political candidates, parties, or issues. At the same time, these attitude objects are not always stable over time, but may instead change, sometimes rather substantially. Let us consider a politician who argues about the opportunity for a country to restrict or enlarge its immigration policy. The politician's position on such an issue is not necessarily the same in different places and at

different times. With regard to place, the politician may present his or her stand on the issue with different tones and nuances according to the audience. Politicians know very well how to tailor their message, using all the possibilities offered by the richness of language and rhetorical strategies (see Section 4). Regarding time, politicians may change their position on a given issue due to several reasons, such as shifts in political alliances or changes in the national or international political situation. The more mutable and ambiguous a political position on an issue, the more strongly the citizen may be inclined to select, interpret, or even distort information in a way that is consistent with his or her consolidated attitude.

If we have a positive attitude toward a candidate, we are especially inclined to perceive the candidate's position on relevant political issues as being very similar to our own (assimilation effect). For example, we may ask people to rate their position on a restricted immigration policy on a 7-point scale, ranging from 1 (fully against) to 7 (fully in favor). Then we may ask them to use the same scale to rate the supposed position of political candidates on the same issue. Research results show the presence of a high and positive correlation between one's position and the one attributed to the preferred candidate: if one's position is rated with a 5, the candidate's position will also be rated with a 5, whereas if one's position is more extreme (i.e., rating 7), the same extreme rating will be attributed to the candidate. An opposite tendency to differentiate our position on a given issue from that of a candidate we do not like has also been observed (contrast effect). The contrast effect is weaker, however, than the corresponding assimilation effect. This asymmetry has been attributed to a positivity effect, according to which people prefer to focus their attention more on what they like than on what they dislike.

2.3. Expertise

So far, we have focused on how people know and evaluate political candidates and issues irrespective of the degree of competence these people have in the political domain. However, political information processing appears to vary according to people's level of expertise. Political expertise has been defined as the synthesis of different dimensions, such as political interest, political knowledge, and media use. Experts and novices in the political domain seem to process information very differently, and these differences affect all stages of information processing.

1. *Coding.* Experts understand new political information more quickly than novices do, and are quicker in expressing evaluations on political issues and candidates. Such evaluations are also more stable over time. These differences are due to the fact that frequent reasoning about politics makes a number of political concepts immediately accessible to the experts' minds and therefore easy to employ in the interpretation and evaluation of new information.

2. *Organization.* Experts' political attitudes are more consistent than those of novices, and experts experience a larger number of thoughts related to a political candidate or issue. This difference has been attributed to how concepts and their positive or negative connotations are organized in people's minds. Experts' conceptual networks are not only characterized by a larger number of concepts, but also by a larger number of links between concepts. Moreover, a hierarchical structure is often well developed in experts' mind, so that a series of concepts is organized around a limited number of more abstract concepts. This means that the activation of one concept easily leads to the activation of other related concepts at the same or a higher level of abstraction. Such an interrelated network increases the experts' consistency. Different political issues, such as unemployment subsidies, norms toward immigration, and the welfare state, may be linked to each other in the experts' mental network, and all of them may in turn be linked to a more abstract concept such as solidarity. If the experts' attitude toward applying the solidarity principle in politics is positive, related attitudes will also be positive. This may not be the case for novices, who may be more prone to express inconsistent attitudes. At the same time, novices are likely to be less sensitive to inconsistency in politicians' attitude.

3. *Retrieval.* Better organization of political information in experts' minds facilitates the process of retrieving information; this explains why the experts' recall of political information is better than that of novices.

2.4. Ideological Orientation and Values

As we have seen, specific political concepts and attitudes may be cogently linked to more abstract, unifying principles. But what are these principles? In his article in this encyclopedia entitled "Ideological Orientation and Values," Hans De Witte identifies them with values and ideologies, showing how research on this issue has developed over time. Research on values has focused

on single relevant value dimensions, such as conformity versus self-direction or materialism versus post-materialism, but it has also developed more encompassing models, including several value types (e.g., power, security, conformity, or universalism) and their compatibility relations. Prominence attributed by individuals to one or the other of these values has been shown to be a good predictor of political attitudes and voting. Research on ideology has especially focused on the notion of conservatism (as opposed to progressiveness) and has highlighted two different dimensions of it, economic conservatism and sociocultural conservatism. Like values, ideology dimensions are predictive of political attitudes and voting.

In his article “Human Rights,” Willem Doise also makes wide reference to values and ideology. The general relevance people attribute to human rights is related to values, and this reaches its highest level in people for whom the values of universalism and social harmony are very important. People may also differ in their representation of human rights according to their values and ideology. For example, for some people, the right to equality means that everybody has to be treated in the same way by the law or by public institutions, whereas for others, equality also implies that all should have equal access to a decent standard of living, education, and health care. Finally, people with different values and ideologies seem to differ in their opinions of the relative role individuals and institutions (e.g., governments) should play in safeguarding human rights.

3. POLITICAL IDENTITY AND CONFLICT

Campbell's early reference to the notion of party identification as a way of explaining people's voting behavior (see Section 1) undoubtedly had the merit of highlighting how through their vote people may express a feeling of belonging to a given party—a feeling made up of a mixture of cognitive and emotional components. However, the notion of identification as developed by Campbell had a limited heuristic validity. He saw strong party identification as a cause of a stable vote for a party, but envisaged no specific measure of identification. On the contrary, it was precisely the observed stability of voting that induced Campbell to infer the presence of identification. As such, his explanation of stable voting through identification amounts to little less than a tautology. In addition, Campbell's

view of identification as being deeply rooted in developmental age failed to explain possible shifts in voting preferences.

Research on identification processes in the political domain has gathered new strength in recent years. Thanks to the substantial progress made by psychosocial research on identity, we know a lot about how people define themselves as individuals or as members of meaningful groups, how they perceive members of other groups, and what processes characterize intergroup relations, leading to overt competition and conflict or, on the contrary, to peaceful coexistence and cooperation. While extension of this approach from the social to the political domain has proved to be fruitful, specific research in this field has also started to highlight some peculiarities of identification processes in the political domain.

3.1. Political Identity

In some circumstances of our lives, we tend to define ourselves as unique and different from anyone else (personal identity). In other circumstances, we define ourselves as members of a group: we perceive ourselves as similar to the other members of the group, sharing the same values and goals (social identity). One may identify with several groups (multiple identities); these may include groups that one cannot choose to belong to (e.g., gender or race) or groups chosen by the individual (e.g., a sports team, an association, a circle of friends). Moreover, some of these groups may be nested, with a more inclusive or superordinate group (e.g., the company one works for) including other less inclusive or subordinate groups (e.g., a specific sector of the company or a specific workgroup). According to the context, a given identity may be perceived as more salient than others. For example, party identity may become especially salient during the electoral period, when people discuss a politically sensitive issue, or when we confront ourselves with people who belong to different parties. Apart from the context, a given identity may also be more “chronically” salient to the individual; this means that a given identity may be especially relevant to the individual's self-definition. As compared to other kinds of identity, political identity seems to be especially characterized by the need for expressing the group's values in public and, more generally, for acting together in order to gain further consensus around these values. As Bert Klandermans highlights in his article “Collective Action,” a shared identity is one of the main antecedents of people's

involvement in collective action. At the same time, being involved in collective action leads to enhanced political identity.

An analysis of autobiographical accounts of political activists carried out by Catellani *et al.* has shown the presence of three main levels of political identity, characterized by a different degree of abstractedness and embedded within each other: ideological identity, party identity, and sub-party identity. These identity levels are likely to satisfy different needs, and, accordingly, the relative salience each of them assumes for the individual is likely to vary depending on circumstances. Ideological identity is characterized by the highest degree of abstractedness. When people identify themselves with left-wing or right-wing people, they state their inclusion within a social category that is difficult to visualize, with wide and ill-defined boundaries, including a large number of heterogeneous individuals. At the same time, such an abstract category of identification is likely to be perceived as more stable over time and less subject to transformations as compared to a more concrete category, such as a political party. In fact, ideological identity has been shown to be especially salient after a political schism, when a previous existing party splits into two or more new parties. In these changed circumstances, stressing one's ideological identity has the function of safeguarding a certain degree of continuity with the past, to keep a balance in one's own identity.

3.2. Regional, National, and Supranational Identity

Investigation of how multiple or nested identities may exist and coexist in the political domain may be usefully extended to the analysis of regional, national, and supranational identities. The issue has become of increasing relevance in a global world that is witnessing an ever-increasing close cohabitation of citizens of different nationalities as well as attempts to create solid supranational realities such as the European Union.

As already mentioned, a superordinate social category may be more difficult to visualize, because it is formed by a large number of people, possibly rather heterogeneous. Developing identification with a category of this type first requires developing a perception of its existence. Some studies by Castano *et al.* have investigated how a political institution such as the European Union may be perceived by people not so

much as an abstract and far-away entity but as a real community of citizens. These studies have referred to the notion of entitativity, the extent to which a social category is perceived as having a real existence. It is assumed that four factors especially contribute to enhance a social category's entitativity: common fate, similarity, proximity, and boundedness. If we ask people to read a journal article or to see a video stressing either common trends or differences in the economic development of European countries, we are manipulating the common fate factor. If we show people a map in which the boundaries of single European nations are thin lines but the external perimeter of the European Union is a thick line (or vice versa), we are manipulating the boundedness factor. Similarity and proximity may also be manipulated in various ways. Such manipulations have been shown to be effective in increasing people's degree of identification with the European Union. Their effect, however, seems to be felt mainly by people holding moderate attitudes toward the European Union and is not perceived by the so-called Euro-skeptics or Euro-enthusiasts.

Investigation of a higher order identity, such as supranational identity, usually focuses not only on its conditions of existence, but also on its conditions of coexistence with lower order identities. For example, can people strongly identify with Europe and at the same time strongly identify with their nation or region? Studies carried out in different countries have shown that citizens may show high identification with both the superordinate and the subordinate categories. These results suggest that regional, national, and supranational identities may indeed coexist in the citizens minds. This is more likely to happen when the frame of reference is one of integration between different identities, in particular when stressing the superordinate identity does not mean absorbing lower level identities and forcing homogeneity but, on the contrary, accepting a certain degree of internal heterogeneity. Ideally, diversity will become one of the core values of the superordinate identity. This means that belonging to a social category made up of different components that integrate with each other may become a core feature of, for example, North American or European identity. When, however, the frame of reference is one of competition between different identities, in particular when stressing the superordinate identity means absorbing lower order identities or threatening them, competition easily turns into open conflict, and fear of losing a given regional or national identity may hinder development of a supranational identity.

3.3. International Conflict

Analysis of what conditions may favor development of a new supranational identity starting from well-established national identities may be useful in highlighting strategies of international conflict resolution. In his article "International Conflict," Herbert Kelman describes psychosocial processes that underlie conflict insurgence and its escalation, as well as psychosocial processes that may instead favor a break in the spiral of conflict in the direction of conflict resolution. An essential step of an effective strategy of conflict resolution is the acknowledgement of each party's needs. An effective, long-term solution is unlikely to arise if either party has the feeling that its needs or its very existence is being denied or simply ignored by the other party. A similar premise may be found in the dual-identity model of conflict resolution, according to which a first essential step in negotiation between groups consists of creating conditions for the already existing group identities to be expressed and safeguarded. Although open expression of each group's identity and related needs may initially enhance intergroup conflict, it also has the advantage of enhancing each group member's perception of having a well-established identity. This is an ideal psychological premise for an effective interaction with the other party, in order to find solutions that address not only a single party's interests but also superordinate interests. If, however, the first step—expressing one's group identity—is lacking, members of each group may feel that their group's identity is threatened. The resulting uncertainty prevents the group from taking the next crucial step in the negotiation process, finding a solution that satisfies superordinate interests.

4. POLITICAL COMMUNICATION

When we think of politics, we are likely to think of a phenomenon encountered largely through the mass media. The link between politicians, events, and issues on the one hand and most citizens on the other is mediated through the complex web of information generated by newspapers, magazines, television, radio, and the Internet. While the mass media has significantly increased the opportunity for politicians to reach citizens, communicate, inform, and put forward persuasive messages, it has also offered citizens the means to scrutinize politics and politicians more closely while offering information on a previously

unthinkable scale. However, if the media multiply the opportunities for communication, it must also be recognized that the process of mediation is not neutral. Through the people who control them, the media select, classify, and shape political information, thus contributing to the creation of political reality.

The influence exerted by the media on political information processing and the degree to which citizens are aware of this influence will be the first issues dealt with in this section. Next, we will consider how political actors communicate and employ language and other communicative strategies in order to fulfill their goals. Our attention will be especially focused on two communicative contexts, political interviews and political discourses.

4.1. Mass Media and Politics

Studies on information processing have shown that a concept or an attitude that has been frequently retrieved in the past becomes more accessible to the individual's mind, that is, more likely to be retrieved again and to be perceived as relevant. Therefore, when media coverage of a given political issue is high, individuals are repeatedly exposed to it, and its accessibility is likely to become higher. Studying the cause-effect relationship between media coverage and accessibility or perceived relevance of a political issue is not an easy task. Is a political issue perceived as relevant because it is widely covered by media, or is it the other way round? Adopting a temporal series technique, some studies have measured perceived relevance of a number of political issues at different moments in time and have monitored media coverage of the same issues in between. Results suggest that media coverage significantly increases the relevance of political issues to which people already attribute a certain degree of relevance. In other words, media have the effect of amplifying the importance of a given issue and possibly of altering the hierarchy of the relevance of political issues. This may have not only generic consequences on the evaluation of political reality, but also more specific effects on the evaluation of a given politician. For example, before the Gulf War, U.S. citizens' evaluation of three main policy areas of President George Bush (foreign affairs, domestic affairs, and economic affairs) equally contributed to form the global judgment of Bush, whereas after the Gulf War, evaluation of Bush was based significantly more on his foreign affairs policy. Thus, media coverage of a political issue leads people to perceive that

issue as more important for the country than they thought before; consequently, that issue weighs more in their evaluation of political leaders.

Are we aware of media influence? Yes and no. We are inclined to think that the mass media influence “people” or “others,” but not ourselves. This is the so-called third person effect, according to which we overestimate media influence on others and underestimate media influence on ourselves. This tendency has been defined as a self-serving bias, in the sense that the perception of having full control on the surrounding reality and on one’s own choices contributes to raise the individual’s self-esteem. Thus, one’s capacity of resistance to media influence is enhanced if compared with others’ vulnerability to the same influence. The third person effect is more evident in those who perceive the media as untrustworthy and perceive target people as distant from themselves. In a post-electoral survey carried out in Australia by Duck *et al.*, people asked to evaluate the influence of a number of television programs (political debates, news, electoral spots, etc.) on voting choice declared themselves to be the least vulnerable to that influence, followed by voters of their party, voters of the opposing party, and voters in general.

4.2. Political Language

We may undoubtedly say that politics is made up of words. Politics deals not only with concrete, tangible objects, but also with abstract concepts or notions to which people attribute a shared meaning (e.g., democracy, liberalism, welfare state). Moreover, the planning of future events is an essential component of politics, which therefore often refers to something that does not necessarily exist now but that might become real in the future. Such referential elusiveness explains why political language has often been described as polysemous, many-faceted and, in the end, ambiguous. At the same time, such elusiveness makes it clear that political reality is mainly construed through language. Politicians propose a certain interpretation of political issues and events, which may be defined as successful when it becomes shared by a large number of people. Such interpretation often implies stressing similarities or differences between political groups, thus favoring or hindering citizens’ identification with these groups.

In studying political language, psychology focuses on the analysis of cognitive, motivational, and psychosocial factors that guide speakers and listeners in the political domain (politicians, activists, journalists, or

citizens). Special attention is devoted to the study of the various kinds of communicative contexts in which politicians find themselves. Although each context has peculiar characteristics, politicians’ communication is generally guided by three main goals that may be found across contexts: (1) presenting a positive image of themselves and their party, (2) presenting a negative image of opposing parties, and (3) trying to gain consensus. This means that on the one hand, politicians try to define themselves, to make clear what their political views are and how they differ from other politicians’ views. On the other hand, they aim to extend the boundaries of their party to include as many people as possible. Language helps politicians in the difficult and contradictory task of defining their group and at the same time trying to widen the boundaries of this group. In the communicative contexts we discuss below, we will consider how politicians defend their image when interviewed and how they use political discourse to define and depict social categories in order to gain consensus.

4.3. Interviewing Politicians

Thanks to the growing media-centered and spectacular character of politics, interviews have become one of the main channels through which politicians present themselves and their political positions. Psychosocial research on question–answer exchanges has shown many, often subtle, strategies employed by interviewer and interviewee to pursue their communicative goals. Extension of this approach to the analysis of political interviews started from two considerations that easily arise when listening to political interviews: (1) journalists’ questions are often not neutral and (2) politicians often do not reply to journalists’ questions. A systematic examination of interviews given by politicians has led to identifying an interesting typology of questions and answers as well as conditions that make non-replies more likely. As already mentioned, one of the politician’s main goals is to present a positive image of him- or herself. According to the so-called face model of political interviews, developed by Bull *et al.*, during interviews politicians tend to defend (1) their personal-political face; (2) their party face; and (3) the face of significant others. Journalists’ questions that are perceived as face-threatening are therefore more likely to get a non-reply. Questions may threaten a politician’s personal-political face in various ways, for example, by creating a negative impression of the politician (e.g., “Isn’t all this emphasis on personality a cover for the

fact that you haven't got a big idea?"), hinting at possible future difficulties, highlighting contradictions with past statements, or stressing difficulties in clarifying personal beliefs (e.g., "I wonder whether wavering voters aren't influenced by not quite knowing where you, Prime Minister, stand"). Similar threats may be found in questions regarding the politician's party (e.g., "Things aren't looking that good for your party, are they?"). Finally, questions may focus on other people or groups but still imply a threat to the politician's face. This is the case for questions implying that the politician does not care for the electorate or support a friendly country, and for questions luring the politician into awkward admissions regarding opposing parties (e.g., "Is there really a shift of opinion toward the Liberal Democrats or is it because they have run a better campaign than you have?", a situation in which confirming either alternative offered by the question would lead the interviewee to support an opposing party).

Although the interviewer has various ways to threaten the politician's face, the politician has various ways to avoid replying. Not replying does not mean being silent, but rather adopting communicative strategies aimed at avoiding a direct reply without necessarily appearing rude or not collaborative. The outcome will be a reply that may be defined as equivocal, because it is not consistent with the interviewer's communicative intention; it is, however, consistent with the politician's intention of presenting a positive face to the electorate. Equivocal replies may include ignoring the question, replying with another question, criticizing the question, or refusing to answer.

4.4. Political Discourse

In their discourses, the politicians' ultimate goal is gaining the widest possible consensus from their audience. They aim to create in their public a political identity that is consistent with their own and that of their party, so as to favor mobilization in their favor. To do so, politicians address not only single individuals but also significant groups to which their audiences belong and are likely to identify with. For example, they can explicitly address blue-collar workers, entrepreneurs, or housewives. They may also address wider social categories, such as the citizens of their country, or some vague social categories, such as all honest people: making these categories salient means addressing millions of potential voters. Whatever social category they are trying to make salient to their audience, politicians will use arguments that highlight the

fact that the values and goals of that category are consistent with the ones their party is ready to fight for (e.g., "Citizens want to be able to walk safely in their neighborhoods, and that's exactly what we're aiming for with our new bill on criminal offenses"). Very likely, they will also argue that the same values and goals are inconsistent with those of the opposing party. Whenever this is possible, politicians also try to present themselves as prototypical members of the salient category (e.g., "I am a father/mother myself" when speaking about school reform), thus implicitly stating that they are trustworthy and entitled to represent the category.

A confirmation of the relevance social categories have in politicians' discourses has been offered by some studies that compared how politicians of opposing parties interpret the same political event. Differences were observed regarding not only the description of facts, but also the definition of social categories involved in the event, as well as of the values and goals presented as typical of those categories.

An example may be found in Reicher and Hopkins' 1996 study on how a famous miners' strike in England was reconstructed from opposite perspectives by political leaders Margaret Thatcher (Conservative Party) and Neil Kinnock (Labour Party). In her interpretation of the events, Mrs. Thatcher created a picture in which miners that did not participate in the strike, as well as their relatives, were attributed personality traits such as courage and determination that were presented as typical of authentic English people. Mrs. Thatcher's definition of the category of strikers, on the other hand, identified them with violent people and even with terrorist groups. Thus, through her discourse Thatcher evoked a large ingroup of "no-strikers/authentic English people" on the one hand and a small outgroup of "strikers/terrorists" on the other. She consistently presented the Conservatives' reaction to the strike as a way of defending the nation at large against a minority of destabilizing forces. A similar though opposite argumentative strategy may be found in Mr. Kinnock's interpretation of the same event. He described the strikers as people who wanted to defend their rights against the repressive policy of Mrs. Thatcher. In doing so, Mr. Kinnock compared strikers to all Labour voters and more generally to all the people who were against Mrs. Thatcher, so that the initially small category of strikers ended up being redefined as the large ingroup of "strikers/liberals."

To conclude, the way in which both a political event and the people involved in it are defined is of crucial

relevance to increasing the public's feeling that the politician, the politician's party, and the public belong to the same wide ingroup and share the same goals and values. Politicians try to define the boundaries and the characteristics of social categories in order to mobilize people in a direction that is favorable to them and unfavorable to the political adversaries. Social and political categories are not stable and unchangeable; on the contrary, they are constantly being redefined, and political leaders contribute to their redefinitions through political discourse.

4.5. Political Persuasion

So far, we have focused our attention on how politicians present their political identity and try to shape the public's political identity. Research on political persuasion, however, has been more generally aimed at investigating how politicians' messages may have an impact on the target's (i.e., the public's) political attitudes. The typical research design of this kind of study implies a comparison of the target's attitude toward a given political issue (e.g., the tax system) before and after exposure to a persuasive message regarding that issue (e.g., a political discourse in favor of a reduction of the tax load on wages). Recent studies in the area have focused on the so-called matching effect, according to which the persuasive impact of different types of messages varies as a function of given characteristics of the target. For example, Lavine *et al.* investigated the different persuasive impact that threat-related and reward-related political messages may have on individuals characterized by different degrees of authoritarianism. The messages were intended to persuade young people to vote in presidential elections. While threat-related messages highlighted the possible negative consequences of non-voting (e.g., "Not voting allows others to take away your right to express your values"), reward-related messages highlighted the possible positive consequences of voting (e.g., "Voting enables one to bring about the kinds of public policies he or she believes in"). The change in attitudes toward voting after exposure to either type of message was then measured, comparing participants with high versus low degrees of authoritarianism. Threat-related messages had a high persuasive impact on authoritarian people and a low impact on non-authoritarian people, and the opposite was true of reward-related messages. Thus, the matching effect suggests that tailoring political messages with regard to the target's characteristics (e.g., authoritarianism) may help to increase the persuasive effect of those messages.

5. POLITICAL PARTICIPATION

For most people, voting is the only practical way to take part in political life. At the same time, in a democratic regime, it is also the most important one. In this section, we will focus on how voting behavior has been explained, by referring to motivational, cognitive, and social factors that may underlie political choice. Finally, we will briefly hint at more involved forms of political participation.

5.1. Voting Behavior

Since the pioneer work by Campbell *et al.* on party identification, that is, on voting as the stable result of an identification process that dates back to developmental age and to family influences, several other explanations have been proposed. As we have seen in Section 1, the extension of rational choice theory from mathematics and economics to politics has led to the view of voting behavior as the outcome of a rational process. In other words, people consider all the information they have regarding the various possible alternatives (parties or candidates), and choose the one that is characterized by the highest possible utility for them. However, ideas of human rationality and utilitarian goals implied by this approach have been seriously challenged by subsequent psychological and empirical research on voting behavior. The main acquisitions of this research are summarized here.

5.1.1. Cognitive Factors

When deciding how they will vote, people do not necessarily consider all the information they have acquired over time about the various parties or candidates. Given that the quantity of information they can pay attention to at a given moment is limited, they tend to focus only on information they perceive as salient and relevant at that very moment. Their decision-making process does not consider all pros and cons of each alternative. Instead, a series of heuristics or simplification strategies is adopted, which allow making a decision through a limited consumption of mental energy. Thus, people base their decision on a limited amount of information they perceive to be relevant at a given moment. Such information may be categorized into the following four main dimensions:

1. *Trait-based voting.* As we have already seen (see Section 2), candidate evaluation is a very good predictor

of voting behavior. The relevance of this dimension is likely to have increased in recent years, due to the growing personalization of politics favored by the media.

2. *Issue-based voting.* Voting choice may be based on parties' political programs or their positions on given political issues, such as social welfare, the tax system, or immigration rules, and people will choose the party or candidate whose positions on those issues are more consistent with their own. According to the so-called consumer model, recent years have been characterized by an increasing tendency for people to base their voting choice on their agreement with a party position on one or more relevant issues. This would lead to a party choice that is related to specific issues and consequently that is not stable over time.

3. *Ideology-based voting.* In contrast with the consumer model, the ideological model assumes that people choose parties or candidates with whom they share not so much a position on a given issue but general beliefs based on shared ideology or values. As the organization of political attitudes around abstract principles is typical of politically sophisticated people, ideology-based voting is likely to be more concentrated among this kind of people.

4. *Performance-based voting.* Voting choice may also be influenced by the evaluation of past performance of a party or a political leader. Actually, representation of the past is often the main source of information people use to make predictions about the future. Not only reference to the actual past, but also mental simulations of how things might have developed differently, significantly contribute to shape people's interpretation of political reality. For example, one may think that the armed intervention of the United States and their allies in Iraq in 2003 was appropriate if the most readily available alternative to the individual's mind was a course of events implying Saddam Hussein's alliance with Al Qaeda and a rise of terrorist attacks in Western countries. On the other hand, one may evaluate the same intervention as inappropriate if to the individual's mind the available alternative was a successful mediation process handled by the United Nations. A negative evaluation of past action of politicians may sometimes lead to strong disenchantment with politics and increase the possibility of success for new emerging or extremist political parties.

While each of the preceding factors has been shown to play a significant role in people's choices, recent research has been developing more complex predictive models of voting behavior aimed at assessing the

relative weight of each factor on voting. Through application of these models, one may be able to assess how much the electoral success of a given party may be attributable to the party leader, to party ideology, to past performance of either the party or the leader, and so on.

5.1.2. *Personal Interest*

According to rational choice theory, utility pursued in voting decision corresponds to self-interest, intended as material, economic interest. Recent empirical research in political cognition has reconsidered this issue in a different perspective, focusing attention on political attitudes that are perceived by people as personally important. Issues of domestic policy, such as welfare or taxation, are usually perceived as more personally important than other issues. When asked to express their attitudes regarding issues considered personally important, people reply more readily than regarding other issues. This suggests that attitudes toward domestic policy issues are more immediately accessible to the individual's mind and therefore are more likely to influence voting behavior. The same does not hold for attitudes toward issues of foreign policy, such as defense expenses or non-intervention in war. Though these issues are perceived as more important than domestic issues at a national level, related attitudes are less easily accessible to the individual's mind and therefore are less predictive of voting behavior. Meta-analysis of a number of survey data sets in the United States has confirmed that attitudes on policy issues that are personally important are more stable over time and are more predictive of candidate preferences and voting.

Analysis of what factors may be at the origin of a political attitude's personal importance has shown that self-interest, as defined by rational choice theory, is just one of these factors. Another factor that significantly contributes to raise the personal importance of a political attitude is its relation with one or more core values, values that hold a high position in the individual's hierarchy. This means that, for example, some people may perceive having an efficient public health system as important not only because of the personal advantage implied by such a system but also because solidarity is one of their core values.

5.1.3. *Social Factors*

In addition to self-interest and core values, a third factor that has been shown to underlie the personal

importance of political attitudes is social identification with reference groups. As we have seen in Section 3, social identity is that part of an individual's self-concept that derives from awareness of belonging to one or more groups. If voting for a given party is a shared and relevant characteristic of a group one identifies with, voting for that party may become a way of expressing and reinforcing one's group identity. A confirmation of this can be found in research that has investigated psychological antecedents of the so-called regional vote, that is, the prevalence of a given party in a given region or area of a country. For example, Scottish people are traditionally more in favor of the Labour Party: research results by Abrams and Emler show that Scottish people who vote for the Labour Party have a higher Scottish identity than Scottish people who vote for the conservatives. Although people with higher Scottish identity feel they have fewer economic opportunities as compared to people living in England, these people are also more willing to remain in Scotland. These data suggest that voting may be a way of expressing one's social identity, in this case, regional identity. Even more, they suggest that in voting behavior, expression of group identity may challenge, if not overcome, the pursuit of economic self-interest.

In conclusion, empirical research on voting behavior has shown that vote is not the outcome of fully rational thinking aimed at maximizing personal benefits and minimizing personal costs. It is a more complex process that implies selective information processing, reference to values or other abstract principles, and the expression of one's own identification with one or more social groups. All these factors allows one to overcome the so-called voter's paradox described by rational choice theorists, which portrays voting as an apparently contradictory action: The costs implied by the act of voting (e.g., acquiring knowledge of the issue, renouncing a day's leisure) are higher than the benefits the single citizen may expect from that act, since one single vote cannot decide the outcome of the election. Thus, if voting were based on a mere cost–benefit ratio, no single citizen would vote. As we have seen, however, voting decision is not the outcome of a simple cost–benefit ratio but rather of a range of cognitive and psychosocial factors that must be taken into account if satisfactory predictive models of voting behavior are to be developed.

5.2. Collective Action

When we shift our attention from voting as the basic level of political participation to more involved forms

of participation, such as demonstrations, sit-ins, or strikes, finding satisfactory explanations of why people get involved in such actions becomes even more challenging. On the one hand, the cost of similar actions may be very high for the individual, in terms of time, money, and energy spent in participation, but also, in extreme cases, in terms of stigmatization or physical damage suffered because of participation. On the other hand, possible benefits deriving from the success of collective action may be enjoyed just as much by people who did not actively participate in that action, which may be one further reason to not undertake the risk of participation. In his article “Collective Action,” Bert Klandermans deals with this issue in detail, focusing on three main motivations that lead people to get involved in collective action: instrumentality, identity, and ideology. Klandermans also offers an articulate definition of collective action, distinguishing it from other types of group actions. Finally, he analyzes a number of factors that play a role in transforming potential participation into actual participation.

enlightenment Characteristics of psychological knowledge, producing changes on studied objects that have created this knowledge.

postmodernism Movement or set of ideas that implies an epistemological and social change with respect to the basic principles of the modern rationality.

social construction Idea that human and nonhuman objects do not exist independently of human actions and their linguistic practices.

Postmodernism can be understood as the critique of modern scientific rationality. It may be thought as a loss of belief in truth, in universalistic ideas of historical progress, in unitary subjects, and in objective scientific method. This also means incredulity regarding the great narratives of legitimacy. Postmodern thought contains diverse interpretations and proposals that replace a positivist method of knowing the “real world,” by local and engaged accounts of reality with focus on social and linguistic construction. The influence of these ideas can be found in psychology, as in any other discipline. Here, it reflects, among others things, shifting conceptions in the main epistemological and methodological topics that comprise the field of psychology. Postmodernism can be found overall in the social constructionist approach (Gergen, Ibáñez, etc.), but also in others’ approaches. This article introduces the general themes in postmodern thought, and its bases in French poststructuralist philosophy, feminist studies, and postcolonial studies. All these have had their effects on psychology and we shall see

GLOSSARY

critical psychology Psychological theories that try to substitute the study of psychological processes used in positivist psychology for a study based on language and social practices.

cyberpsychology An approach that allows thinking about technoscience, cultural theory, and political effects.

deconstruction Action to disassemble structures that are supposed to be well known in order to know the non-explicit way in which they have been organized and the premises that construct them.

discourse analysis Variety of forms developed by linguistics, philosophy, and psychology to analyze both social linguistic practices that produce social meaning and the effects of the discourse.

how its principal topics of study such as emotion, attitudes, memory, self, and gender have all been challenged.

1. INTRODUCTION

During the 1970s, a “crisis” in psychology reflected a more general crisis in the social sciences: the crisis of the paradigm of positivist modern rationality as a privileged form of knowledge of the human being. This debate was inspired by French poststructuralist philosophy (Foucault, Derrida, etc.), feminist studies (Kristeva, De Lauretis, etc.), and postcolonial studies (Gayatri-Spivak, Bhabha, etc.). The postmodern thought was represented by Lyotard, Baudrillard, Haraway, Bauman, and Butler, among other thinkers.

This crisis emerged from the recognition that a general openness to change had, by the 1970s, precipitated transformations in both the academic and the personal spheres under the influence of social movements such as feminism, ethnic movements, and the political, social, and cultural transformations that drove the new technologies.

Events of the 20th century have prompted several questions about truth, science, reason, and the concept of reality. Within the social sciences, a critique has been developed, based on the questioning of the basic dichotomies of Western modern thought such as reality–fiction, nature–culture, emotion–reason, objective–subjective, and mind–world.

Mainstream psychology, until the end of the 1970s and the beginning of the 1980s, had followed the dominant paradigm of the natural sciences. It put its faith in the hypothetical-deductive method, a methodology for human research that separates science, on the one hand, from “the world” on the other. The fundamental ideas that constitute this form of knowledge are objectivity and neutrality. These are supposed to produce knowledge that is both universal and predictive. Nevertheless, in different fields of psychology, doubts have arisen as to whether objectivity and neutrality can handle complex reality. These reframings suggest that we see psychological knowledge as impregnated of values and “experimental emptiness.” In psychology, this is signaled, for example, in the emphasis on the Western cultural, gender, and sexual values as individualism, ethnocentrism, logocentrism, and androcentrism that are inherent to psychological practice and research. Psychology is challenged in its claims to objectivity and neutrality and in its belief that the world and the subject are independent from each other.

The aim of change can be seen clearly in the works of Gergen, in his treatment of psychology as history, in the socioconstructionist paradigm, and in the analytic critiques of experimental psychology. Challenges to traditional psychology also exist in Latin America with the development of a more reflexive and engaged communitarian psychology. It is important to emphasize that of the several ways aimed at changing the traditional psychological form of thinking and doing research, only some are directly acknowledged as postmodern. Other are recognized as “critical psychology” (among other terminologies).

General topics that are often taken for granted in psychology have begun nowadays to be deconstructed. In other words, this postmodern turn shows how the system of representation of the world is not free of values and can operate by promoting or oppressing certain forms of life or personhood, within the hierarchy of power relationships.

2. CONTEXTUALIZATION: ISSUES OF POSTMODERN THOUGHT AS A CRITIQUE OF MODERN RATIONALITY

2.1. Postmodernity and the “Postmodern Condition”

Postmodernity is a controversial term. The French philosopher Lyotard claimed that it neither defines nor identifies a period or a historical time. Postmodern rather serves to indicate that something is in decay in modernity, in the universality of the philosophical discourse of the enlightenment. Terms and their opposites begin to lose their sense and enter the play of auto-reflexivity, namely, the differences between fact and fiction, language and its objects, art and “kitsch,” as well as the limits between styles, disciplines, genres, etc.

How can postmodernity be understood? Postmodernity can be found in the goal, common to literary theory, philosophy, and the social sciences, to reveal how it is that positivist dominant discourses are able to create “illusions” of theoretical coherence and empirical credibility from certain institutional conditions and with consequent effects of power.

The post-structuralist, feminist, and post-colonial contributions constitute a source of inspiration for the “postmodern turn” as well as the new sociology of science and neopragmatism. The philosophical base of the modernity–postmodernity debate is found in

French poststructuralist thought in its various forms. In particular, the work of Foucault on matters such as power, madness, sexuality, prisons, and subjectivity develops the thesis of the relationship between power-knowledge-truth and the political, historical, and rhetorical character of psychological sciences.

One of the key methods of postmodernity is the deconstruction of Derrida and one of his main ideas: that language does not have any sense or truth, directly or literal, and its relation with social institutions and hierarchical and power relations. A continuous self-reflexivity is proposed. One consequence is to consider scientific knowledge as a form of knowing the world that is not beyond any other human activity.

What is the postmodern condition? According to Lyotard, it is understood as the generalized acknowledgement of the exhaustion of reason and is based in the crisis of “representation.” That is, it includes the crisis of the social and political movements and discourses, as they are constructed from modern rationality, as well as the transformations in social relations, changes of production, and the global culture of new technologies.

2.2. Three Main Ideas from Postmodern Thought

To be precise, the postmodern critique of modern scientific rationality involves the following three ideas.

1. The critique of great narratives that legitimize a multitude of social actions, erected as discourses of “truth,” and of the linear and evolutionary ideas of progress and history inherent to the modern project. Instead, a local and committed knowledge is proposed.

2. The critique of the concept of representation that entails the dissolution of the border between the language and its object and of the idea of mind as the location of knowledge. A socially constructed reality is proposed.

3. The critique of the subject of Western knowledge and the vindication of “differences,” and the death of the subject as the center of representation and history, and the recognition of its universalism and androcentrism. The consequences for emancipatory social movements appear controversial. The proposal is to avoid essentialism and universalism and to consider using identity categories of a more temporary and local dimension.

With these three critiques, statements of “objective truths” become constructions of communities with

particular values; interest moves towards the forms in which the world “is represented” and what consequences these representations carry. This will bring about a change in the traditional assumption of the way in which language operates. It will no longer be seen as an instrument for the expression of internal representation of external reality, but rather something that obtains its meaning from its use in social life. What is in play, then, is the notion of objectivity as a legitimacy of the truth about how the world and what people are like.

3. POSTMODERNISM COMES TO PSYCHOLOGY: THE CRISIS OF MODERN PSYCHOLOGY AND ITS DIFFERENT THEORETICAL AND PRACTICAL PROPOSALS

3.1. Modern Psychology and the Analysis of Its Own Discourse

With the postmodern turn, psychology, from the reflexivity and the deconstruction point of view, analyzes its own discourse. It tries to understand the way in which it opts to produce certain knowledge and what relations of power are produced. Social constructionism in psychology requires that we put aside the basic presupposition of modern rationality that, as objectivity, had led psychology to constitute itself, as Tomás Ibáñez indicates, as an extraordinarily authoritarian system. Psychological entities were naturalized as corollaries of the human condition, pressuring it to adapt itself to them and freeing the psychologist from the responsibility of the effects of power over the individual. Thus, the productive character of psychology has made a vocabulary and new knowledge of the individuals possible. But simultaneously, its commitment to a rhetoric of truth has entailed effects of social regulation. An individual’s motivations or attitudes, satisfaction, self-esteem, etc., are the elements that are used in deciding who gets a job, who may look after their children, etc.

To consider, then, that psychology is not an objective science like the natural sciences entails a series of changes. Is the conduct of human beings really predictable and not altered by people’s knowledge of themselves, or by the continuous transformations of the world around them? Kenneth Gergen calls this effect enlightenment.

3.2. The New Conception of Psychology: The Postmodern Psychology

Due to its symbolic character, situated in a concrete society, culture, and history, psychology's theories, from a postmodern point of view, are to be understood as a practice, and its concepts are to be understood in a dialogical form. For example, if a complex, a frustration, a motivation, an attitude, or a phobia exists, it is because psychology segments, differentiates, and compartmentalizes certain phenomena and gives them a name. It divides populations and their actions into normal and pathological, or normal and abnormal. The possibility of decoding an interview or an observation of a child in a daycare center depends on training that has separated out different behaviors, compared them, named them, and classified them. In other words, it has made available to the people trained in this discipline the authority to carry out the actions that correspond to this domain.

An important change is to stop conceiving the concepts developed by psychology as individualized and as the result of cognitive or cerebral operations. Rather, they should be thought of as relational and evaluative, or in other words, as ways to understand the world and to agree or disagree with it, or to act on it or cause reactions in it. In addition, this way of thinking about psychology totally changes the form of acting and producing personal and social transformations. In the field of psychotherapy, as in educational or social psychology, it leads to specification of from where and why the psychologist wants to intervene, not from an aseptic and neutral form, but rather from an engaged and participative position.

Postmodern psychology replaces a concern for the subject of investigation and the adequacy of theories with an interest in the procedures and instruments used for the study of the socially constructed subject and the way in which we relate to it. And, above all, it is interested in the social conditions that give rise to such a subject and its relations. The concepts inherited from positivist psychology are reanalyzed, and the "great narrative" of psychology is replaced with local knowledge. The attempt to find universal laws is dropped in favor of circumscribing knowledge to certain socio-historical conditions of production, susceptible to change. It has been suggested that the professional practice of psychology may get along well with postmodern thought, since it focuses on "situated" knowledge of human activity, the everyday world, and validation through practice; dynamic, dependent on context, and fragmentary.

4. IMPLICATIONS FOR TRADITIONAL PSYCHOLOGICAL TOPICS SUCH AS EMOTION, ATTITUDES, AND MEMORY

From postmodern psychology's point of view, our conception of self, science, representation, and language influences the way that the human being has been studied. This implies a deconstruction of the typical themes of the discipline. Identity, emotions, gender, attitudes, and memory are some of the subjects that have been reconsidered along the lines previously mentioned.

4.1. Bases for Reconsidering the Main Topics of Psychology

1. Proposing a less individualistic and more collective or relational conception;
2. introducing a dialogical perspective, a more contextual and a non-universalistic or essentialist analysis;
3. being conscious of one's own prejudices of interpretation;
4. recovering the role of language not as a simple transmitter but as constructivist;
5. introducing the creative, resistant, and transforming aspects of subjects; and
6. introducing a dimension that defines the moral, evaluative, political, and functional character that must lie in any object of analysis within a certain social order and intersubjective relation.

4.2. Examples: The Study of Emotions, Attitudes, and Memory

In the study of emotions, they are not seen as responses or reactions, but as a part of a contextual representation, not in the intentional sense, but rather as significant in each different situation. In this sense, the emotions are considered as having performativity and pragmatic meaning, showing how the individual understands their context and how they express moral valuations.

Another example is the study of attitudes, almost always considered to be prior to performance, and locatable. But they become understandable as dilemmatic and challengeable constructions, dialogical in character, and as possible *a posteriori* elaborations of our behavior. This way, when we try to understand an event, we relate it to others or to ourselves, resorting to

this cause–effect relation in which we have been socialized. Thus, perhaps we looked for motives and reasons that were not always there before, and which are perhaps reconstructed in some cases *a posteriori*, and that are more applicable to current circumstances than an expression of a previous reason or idea.

In the study of memory, individual memory is not considered as an individual cognitive property, but rather in relation to its function and its use in a certain context. In the production of a particular memory, what is more important than its activation or configuration is the moment and the other people involved. This way, the details, the precision, or the changes in narration are not established by the ability of memory to reproduce reliable truth, but in its relative performativity at the time of production. That is to say, it serves to say something about the individual or to obtain something of the others, and obeys a system of expression of values, beliefs, and functions. Something similar happens in the case of collective memory that is considered in relation to its historic and political role in a concrete socio-economical and political context, with a sense only within a political, economic, institutional and communicative relationship. The implications, for example, in individual or family therapy's ability to solve conflict or trauma are clear, as are the implications in situations of intergroup conflicts and in institutions.

5. IMPLICATIONS FOR PSYCHOLOGICAL FIELDS AND THE NEW ROLE OF THE PSYCHOLOGIST

5.1. Implications of the Postmodern Turn for Psychological Fields

What does this postmodern movement imply for treatment and therapy, for educational, environmental, psycho-social, and organizational intervention, or for the resolution of problems, mediation, and so on? That is to say, what does it imply for applications other than psychology? Since, as we have commented, from the postmodern psychology point of view, any type of individual or group psychological intervention is not considered merely an “application” of the theory, the psychologist cannot be placed in an external relation—as could happen with other sciences—and the values that guide an application and the directions of the transformation need to be specified.

As examples of methods, even if they do not have their origins in postmodern thought but are developed

or used by postmodern psychology, we have discourse analysis, with a variety of schools and developments, which is centered on identifying the discursive practices in relation to their functions and pragmatic effects, and conversational analysis, with its emphasis on the interpretation and meaning of the participants in a concrete context and in its institutional background. Both constitute bases for the study of daily interactions and institutional contexts in research, therapy, education, racism, etc., to transform concepts and methods of work into the day-to-day practice of the psychologist.

An example is the communitarian psychology in Latin America, based on the Action-Research of Lewin and ethnographies that have developed the theology of liberation or the socioconstructionist movement. Its basic characteristic is to obtain a more dialogical relation of a horizontal nature. Another example is in psychotherapy, with the reflective teams, inspired by Andersen and White, in which interdisciplinary teams of psychologists and relatives use these developments to jointly find formulas of dissolution or changes of problematic aspects or in work on the psychologist-client dialogue developed by socioconstructionist therapy. In family therapy, counseling, and individual psychotherapy, the emphasis moves away from the individualized problem and is related to cultural and institutional practices, opening therapeutic work to social justice and to larger sociopolitical and relational contexts. Works is also done on what is defined as “problematic,” to reconstruct it from alternative forms or, even, deconstructing diagnoses to make possible different solutions.

5.2. Implications for the New Role of the Psychologist

To summarize, some of the proposals of postmodern psychology to equip psychology with a less authoritarian and more democratic, plural, and participative position are related to the new role of the psychologist.

1. The role of the psychologist is understood to be that of an agent who facilitates personal transformation and social change, while being aware of the values and interests of professional performance.

2. The activity of the psychologist depends on the participation of the people involved in the investigation or the intervention, co-producing the obtained knowledge and not holding a privileged position as expert. The procedure should include, for example, the people involved in the decision making and the

evaluations before, during, and after treatments and interventions.

3. The psychologist should be sensitive to diversity and differences as well as the plurality of opinions, situations, etc.

4. A role is developed to commit with its ideas by its professional action, which makes explicit and does not hide under neutrality or aloofness.

5. The psychologist develops a less authoritarian intervention in respect to the status that psychology has in our society, beyond the pursuit of the deontological codes of the professional practice.

6. The psychologist incorporates the personal or communitarian explanation of what happens.

7. The psychologist should incorporate a constant reflexivity in all actions and professional practices in order to question and to query the methods of investigation or intervention.

8. The psychologist should develop and apply methods and techniques that incorporate parts of this program.

6. AN EXAMPLE: IMPLICATIONS OF THE POSTMODERN TURN ON THE STUDY AND CONCEPTION OF IDENTITY AND GENDER

6.1. The Deconstruction of the Subject in the Postmodern Perspective and the Changes with Regard to Identity

In fact, this critique of psychology has been made by a great number of psychologists influenced by symbolic interactionism, ethnomethodology, poststructuralism, and deconstruction, who have questioned the individual/society dualism, the idea of the mature, autonomous, and independent person who is seen as an agent planning his or her life, and who has values in virtue of which he or she makes choices (the self-sufficient individual). Consequently, the idea of evolution or development of modern rationality that impregnates a great part of evolutionary theories of personality or child development is replaced by more relational options and different understandings. The works of Foucault on the technologies of the self, developed by Rose, Walkerdine, Sampson, etc., show that the knowledge of our individuality (for example the search for “our own identity” or the wished-for social objectives, such as well-being,

happiness, efficiency, etc.) has been constructed in relation with the use of the capacities of citizens and also for its regulation. The idea of a “saturated self,” as Gergen proposed, as the result of a social saturation process, with the new technologies and the variety of human relationships, leads to a condition in which doubts are instilled about who and what we are. This is not the result of our personal essence: real feelings, deep beliefs, etc., but of how we are constructed.

In particular, these developments imply that we should consider a more relational and dialogical “self” and the replacement of individualized theories of identity with more relational theories. A consequence is a work with a symbolic plurality of meanings with its respective positions in networks of power, shared or constructed between different people, present or not. When constituting intersubjectivity in the interaction, “self” can be understood discursively as a “text,” constructed by a multiplicity of narratives, about how we relate ourselves, full of other stories that we receive explicitly and implicitly throughout our life, among which it is possible to register not only those of human actors, but also those of nonhuman (nature, for example), as proposed by “actor-network theory.” The metaphor of the text is used to talk about the identities in a continuous process, in an intimate relationship with the social institutions and practices. One works with the change from applying different techniques to narrate in another form the events, and thus to transform them.

6.2. Cyberpsychology and the Deconstruction of Gender

The idea of biotechnological self, grounded in the cyborg, an organism that the anthropologist Donna Haraway developed in her study on primates, is an organism made up of technology, biology, culture, and politics, and is used to destabilize the essential differences between body and mind, body and machine, and masculine and feminine. Also, it brings closer another form of new identities that start from, for example, the use of prostheses. Additionally, we can find changes for the gender relations as in cyberpsychology. Cyberpsychology allows us to work with technology and subjectivity, and in politics, feminism, and technoscience with transgressive identities. In fact, a postmodern feminism, as psychologists Raquel Hare-Mustin and Jeanne Marecek suggest, is brought about through a deconstruction of the polarity of sex and

gender, to go beyond the different previous totalitarian theories while maintaining a feminist critique on the effects of how psychology has constructed sexual and gender difference.

GLOSSARY

adjustment Psychological processes and behaviors that people use to manage or cope with the demands and stressors of everyday life.

anxiety Feelings of excessive apprehension and worry often accompanied by physical disturbances such as racing heart and sweating.

attention deficit/hyperactivity disorder (AD/HD) A mental disorder characterized by difficulties in maintaining attention with or without hyperactive behaviors.

bipolar disorder A mental and physical disorder characterized by very low mood with intermittent high mood swings; it was previously called manic-depressive disorder.

depression A mental and physical disorder characterized by mood disturbances such as persistent feelings of sadness and despair with a lack of energy.

Diagnostic and Statistical Manual of Mental Disorders (DSM-IV) The classification manual used by health professionals to identify people's mental disorders.

stress Environmental demands made on individuals that may exceed or tax their ability to adapt, cope, or adjust.

Students engaged in postsecondary education often are confronted with stressful situations. Although many students adjust well to the college situation and have the coping mechanisms in their repertoires to successfully negotiate/navigate the stressful events on their own, some students do not. Postsecondary institutions recognize the potential for students' problems that may interfere with institutions' and students' educational endeavors by offering assistance, primarily in the form of counseling. This article reviews normal development and stressors usually encountered by college-age or older adults. It also recognizes many problems with which students present when seeking counseling.

1. OVERVIEW: THE NEED FOR COUNSELING

The majority of high school students planning to continue their education tend to enter a university, community college, junior college, or technical school during the fall immediately following their high school graduation. However, there is also a growing population of high school graduates who enter a postsecondary institution after being employed for a number of years. This article focuses on students seeking postsecondary education at a university or 4-year college, the

problems that interfere with students reaching their goals, and counseling services offered on campus.

1.1. The Role of Stress and Adjustment

Students who begin immediately after high school graduation and those who resume their studies after a hiatus from formal education naturally will encounter various sources of stress. Stress may be experienced in relation to external events (positive and/or negative) or to internal psychological and developmental issues. During the late 1960s, Holmes and Rahe developed a list of traumatic life events that tend to cause stress in most people. The list of events included things such as changes in schools, living conditions, social groups, and work hours or conditions. Many of these events occur when students begin or are engaged in their postsecondary education. Students who move away from home or lose their support groups in other ways must adjust daily to new situations, including different people (e.g., roommates, various campus groups). Some must split their time between work and school. All experience pressures to succeed in the academic environment. These pressures may be self-imposed or a result of parental expectations. Additional pressure to maintain high grades is placed on scholarship recipients. Many students must reevaluate their view of self in regard to their strengths and skills. Individuals who were identified as extremely successful, academically, politically, and/or athletically, might now be among hundreds of students with similar skills, achievements, and abilities. For someone who has been successful in the world of work and “the one in charge,” there now is a need to make conceptual adjustments to being in the student role that often requires more passive behaviors. These changes in environment often induce stress in many individuals. Therefore, in response, students must make adjustments and learn new coping behaviors.

Developmental theorists, such as Erikson and Marcia, suggest that identity concerns are very prominent and normal during late adolescence (i.e., college age). This period is one of questioning and exploring personal values. Values may be examined within the context of areas such as religion, gender, sexual orientation, and potential careers. In addition, as college students enter early adulthood, the quest for intimate relationships becomes paramount. The search for identity and intimate relationships is potentially stressful and anxiety producing, but it is part of the normal developmental process.

Although these stressors are to be expected, individuals often need assistance in learning to adjust or cope with the external and psychological stressors associated with college. There are many ways in which people respond to stressors. How individuals adjust or fail to cope with stressors is dependent on how they appraise and what meaning they attach to the demands and pressures associated with the potential stressors. The perceived degree of threat to one’s well-being and coping abilities is related to each individual’s previous successful or unsuccessful coping behaviors and experiences. For example, two people may assess attendance at a social event differently. One may be excited and look forward to a wonderful evening, whereas the other may view an evening interacting with others with trepidation. In general, individuals tend to respond to stressful events by developing preferred coping methods or various degrees of maladaptive reactions. It is important that students recognize when they can benefit from assistance in dealing with academic, relationship, and/or personal stressors. Students may seek counseling as a means of learning new ways of dealing with new situations or in recognition of their own inability to adjust effectively to this developmental period and the college experience. Counseling can be preventive, developmental, or remedial.

Prevention or outreach activities of counseling psychologists may entail services such as making a presentation to a dormitory, fraternity, or sorority on the identification and avoidance of date rape or eating disorders. Examples of developmental activities include offering support groups on improving social skills and on learning methods for time management. Training others (e.g., resident hall personnel) on communication skills and peer counseling may be preventive as well as developmental. When a student or others close to the student believe that a problem exists, remediation is usually the typical intervention.

1.2. Influence of Diversity

In addition to the stress and adjustments with which college students must deal, students also bring a diversity of experiences and backgrounds to this new setting. Increasingly large numbers of students are not in the traditional 18- to 22-year-old age range; are from diverse ethnic, racial, and cultural backgrounds; and bring backgrounds of widely varying experiences to the college classroom. Their family systems may range from close and supportive to demanding and

abusive. Their cultural backgrounds may or may not be supportive of higher education. They may have lived on their own or never left home. They may have worked in significant jobs or had careers before going back to school. These students bring new expectations, new goals, and new issues. As a result, campuses are no longer islands of simple intellectual pursuit and career development (if they ever really were); instead, they are dynamic and demanding social structures that must be negotiated on a daily basis.

2. PROBLEMS THAT INTERFERE WITH COLLEGE GOALS

The issues of stress and adaptation appear to have been increasing in intensity over the past decade or so and have been the subject of considerable discussion among higher education mental health professionals. This section briefly examines some of the major problem areas resulting from this increase.

2.1. Academic Problems

Academic problems are common among students. This is the area involving the job of students, that is, to learn new information, new concepts, and new skills. This is also the area for which there is constant evaluation of success or failure. Most students go on to postsecondary education because they did well in prior academic settings. However, being successful in secondary education can happen for a number of reasons, not all of which are useful at the next level. Being academically successful due to easy classes, special privileges, extracurricular renown, or any other basis that resulted in background deficits is a major detriment to college success. Following are some of the most common academic problems and the application of psychology to their resolution.

2.1.1. Study Skills

Many students have not learned how to study. They are usually very intelligent and have used their ability to memorize quickly and/or to write convincingly to succeed in high school. When faced with increasingly difficult material at a college level and competing against equally intelligent classmates, they discover that the tasks of taking good notes, writing college-level papers, and studying for difficult exams is very

different from what they were used to doing in high school. Classes and workshops in study skills are offered at most schools using information and techniques developed as a result of psychological studies in human learning. Some of these include overlearning, multichannel information acquisition, and note-taking organization.

2.1.2. Time Management

Many people are very poor time managers, and students are no exception. Choosing what to do and when to do it is a constant decision-making process and is a skill that many students do not have. Students begin to feel overwhelmed and out of control of their lives as academic demands increase in the context of everything else in their lives. Many schools offer training in time management using psychological techniques for values clarification, task organization, and assertiveness training.

2.1.3. Student Role Conflicts

As mentioned previously, the role of students is to learn. This role can be especially difficult for returning students who may have spent years working in jobs, directing other people, and/or being experts in their fields. Although the return to school may be the fulfillment of their dreams, the return to the role of students may be much more difficult. They quickly discover that students are not in charge of the curriculum, do not get to choose their professors' teaching styles, are not experts in every field, and do not get to decide the merits of their own writing styles. In addition, they learn quickly that the way in which they learned to do something on their jobs might not be acceptable in their academic programs. This readjustment of roles may require individual or group counseling focusing on issues of self-identity, motivation, and role flexibility.

2.2. Career Decision Problems

For much of human history, there was not a lot of choice in careers. Usually, an individual's occupation was determined by what his or her parents did as an occupation. Although this process did not provide much freedom of choice, it also eliminated the stress of decision making. When a different occupation was chosen, it was usually based on community need. That is no longer the case in our current society. Each year, there are new

possibilities for careers and old careers may disappear. The result is that decision making about one's career has become difficult and stressful. Following are two types of career decision-making problems.

2.2.1. Undecided Students

There are students who come to school knowing what they want to do for careers and who then continue on into those careers. These are a minority of all students. Many students come to school with no idea of what they eventually want as careers. Others come with ideas or even clear goals and then change their minds. Most students change their intended majors several times over their college careers. Some of these decisions are a result of developmental changes that redirect their interest, whereas others are pragmatic decisions based on classes that they discover they really enjoy, do not like, or cannot pass. There are a number of career development theories about how people make these important life decisions, and counselors will often spend time with students using psychological tests to assess their strengths and interests, provide them with information about employment opportunities and forecasts, and help them to evaluate their past successes as indicators of future possibilities.

2.2.2. Indecisive Students

There are many students whose problems with career choices stem from difficulties with decision making of any kind. Because their career choices are such significant decisions, their indecisiveness may completely stop their progress, eliminate their motivation, increase stress, and cause them to change their majors whenever something new attracts their attention. Counselors are able to make use of knowledge about the fear of failure, the fear of disappointing loved ones, and other unreasonable expectations that may stop students from making decisions. The principles of cognitive-behavioral psychology have very direct application to this problem.

2.3. Personal Problems

All individuals bring their own histories, their own traits, and their own problems with them wherever they go. College is a place where stress can amplify these issues to such a degree that they can interfere with life, sometimes in a serious way. Following are

some of the typical problem areas and the application of psychology in their amelioration.

2.3.1. Relationship Problems

Problems with relationships are perennially one of the major concerns for college students. Most students are involved in, or at least concerned about, their search for life partners. Consequently, social relationships are a significant part of their world. They may be dealing with roommates for the first time in their lives and working out the day-to-day adjustments of living with other people who are not family members. They may be in intimate relationships where they must make decisions, set boundaries, and take risks all on their own for the first time. They often hold memberships in various groups such as classroom teams, social organizations, and athletic teams. Here, they must negotiate the more complex social politics of group dynamics. There are also relationships with authority figures that are unmediated by parents or other hometown supporters. Professors have a wide range of personal styles, pedagogical practices, and worldviews. Residence hall personnel bring their own customs and communication styles. Offices of deans and other college administrators have their own agendas and rules. Through this often confusing maze of people, students must successfully negotiate a variety of relationships. It is not surprising that they run into difficulties. This is an area where it is critical to have counselors who are well versed in the application of group dynamics and interpersonal relationships.

2.3.2. Family Problems

Most students are still a part of family units. These special relationships are very powerful, and students' advancement to postsecondary education does not guarantee that these relationships will be trouble free. Some of these family relationships are problematic from the beginning. Many students come to college with histories of abuse. These childhood experiences usually result in long-term damage to self-esteem, interpersonal relationships, and general psychological health. Students with abuse histories may discover their learned wariness of others creates relationship difficulties in many areas of their lives. These problems often require extensive individual or group therapy to explore and work out new patterns of thinking, feeling, and behaving.

Family relationships that have not been problematic might still create considerable stress for students.

Parents do not receive training in how to let go of the more directive role that they have played in their children's lives for many years; however, abandonment of all control is not a healthy solution either. Thus, a new version of old relationships must be developed, often without the mutual agreement of both parties. This is very stressful for both parents and students. It is a developmental issue that everyone must face. Students want more freedom than they had previously (especially those students who are now used to living on their own), whereas parents are often concerned about, or even frightened by, the lack of experience or appropriate behavior exhibited by their sons and daughters. Issues of independence, control, acceptance in a new role, and responsibility for their own lives are very important to resolve as students mature and take their place in adult society. Counseling must be readily available for short-term interventions, with attentive listening mixed with appropriate support, confrontation, and reality testing. Most students survive this stage without the help of professionals, but some outside help at this point can often make the passage smoother and quicker.

2.3.3. Alcohol Use and Abuse

The use of alcohol among students in postsecondary education settings is both a time-honored tradition and a serious mental health problem. Many students use this freedom from parental oversight to increase their drinking behavior. Usually, students do not seek help for problems in this area of their own volition but rather are forced into counseling by concerned others. This may be problematic behavior for only a small percentage of people, but it is a problem that may cost them their academic careers and considerable legal and relationship problems. Although the application of behavioral techniques may be useful here, often more intensive inpatient rehabilitation is needed.

2.3.4. Depression

Perhaps the most prevalent issue in any higher education counseling service is depression. During recent years, this has even exceeded the traditional number one issue of relationship problems. Depression is identified by the fourth edition of the *Diagnostic and Statistical Manual of Mental Disorders* (DSM-IV) as having a number of the following symptoms: depressed mood much of the time, diminished interest or pleasure in nearly all activities most of the time, significant change in appetite, significant change in weight, insomnia or hypersomnia,

psychomotor agitation or retardation, fatigue, feelings of worthlessness or excessive guilt, diminished ability to think or concentrate, and recurrent thoughts of death or suicide.

Although there is considerable discussion in the professional community about the prevalence of biochemical depression, it is clear that depression may have either or both a psychological basis and a biochemical basis. The evaluation of a student with symptoms of depression will often include an exploration of current and past stressors, a personal and family history of depression or other psychological issues such as alcoholism, and the current or past use of medication. Depression may have a range of impacts on college students, from simple lack of energy to complete withdrawal from interaction with anyone and serious contemplation of suicide. This can result in academic dysfunction, with concomitant course failures, academic dismissal, and financial repercussions. In addition, interpersonal relationships may deteriorate, social and organizational obligations may be ignored, and physical health may be compromised. Suicide is the most dangerous outcome of depressive behavior; therefore, considerable attention must be devoted to students with depressive symptomatology. Although college students typically commit suicide at a lesser rate than do non-college students of a similar age, it is still a major concern for college mental health professionals. It is important to differentially diagnose depression from bipolar disorder as well as from a fairly large number of potential physical problems. During recent years, there has been an increased use of consultations with medical colleagues as this vital physical/psychological link has become more understood. Many mental health professionals now see that the prescription of psychotropic medication is an effective way in which to quickly handle the crisis experienced by severely depressed students. Usually, the medicating of depression is done in conjunction with psychological interventions, a strategy that appears to have the greatest ameliorative effect. The goal is to keep these students alive, to return them to an acceptable level of functioning, to help them learn more effective ways of handling stress (if it is more than simply biochemical), and to enable them to continue their educational pursuits.

2.3.5. Anxiety

An area of concern that often coexists with depression is anxiety. This may range from minor apprehensions about performance, appearance, and social acceptability

to panic attacks, phobias, and obsessive–compulsive disorders. Although not as life-threatening as depression, anxiety can still become life-disabling. Unfortunately, students with anxiety problems are often overlooked. Because everyone is anxious about something—especially in school—its very commonality means that it can be an invisible plague, damaging performance and interfering with students' quality of life. Evaluation of anxious students involves an exploration of current and past stressors, a personal and family history of anxiety or other psychological issues such as depression, and the current or past use of medication. Anxious students may present themselves with a variety of symptoms such as inability to concentrate while studying or sitting in class, difficulty in sleeping, avoidance of social situations, and compulsive performance of repetitive behaviors. Again, as with depression, coordination of treatment with medical professionals can be the most effective intervention.

2.3.6. Attention Deficit/Hyperactivity Disorder

Attention deficit disorders are relatively new areas of concern for college counselors. Although these issues have been around for as long as there have been learners, only recently have there been concerted efforts to respond appropriately to these problems. These are clearly dysfunctions in the neurophysiology and biochemistry of the individuals concerned. Unfortunately, these problems have been very difficult to measure and document, leaving sufferers with significant deficits and very little remediation. Adult attention deficit/hyperactivity disorder (ADHD) has only recently been clearly recognized, diagnosed, and medicated. Some of the signs include making careless mistakes, being unable to concentrate, not seeming to listen, often losing things, being easily distracted by external stimuli, and being forgetful. Many students who are evaluated as having ADHD have at least one parent who had the same problems and so they thought it was normal. Others have had ADHD identified all the way through school but have parents who have been reluctant to use medication due to side effects, stigma, or disbelief that their children had anything wrong with them. For many of those who have ADHD, the use of medication can literally change their lives, enabling them to concentrate and to actually enjoy learning for the first time.

2.4. Environmental Problems

External events may affect and interfere with students' academic progress. The accidental or intentional deaths

of fellow students can cause distress among a large number of students, even if they are not acquainted with those who have died. Special counseling services dealing with bereavement issues may be necessary for a large number of students at one time. Fear resulting from a series of physical assaults and/or robberies on campuses is a realistic response, yet it is one that affects students' mental functioning.

Rejection of individuals due to their lifestyles (e.g., gay, lesbian, bisexual, transgender), religion, race, or native countries on the part of a large number of students, faculty members, and/or administrators often causes disruptions in students' efficiency. Students facing the decision to “come out”—and to whom—are often conflicted about the best course of action. Recently, the invasion of Iraq caused many Muslim students to fear for their safety on campus. Racial tension on campus often is the result of one group being perceived as receiving more support from the university. Individual or group counseling can be an important resource during these times.

3. COUNSELING RESOURCES

Recognizing the large number of adjustment demands on students, a variety of counseling services are supported by postsecondary institutions. Sources of counseling include individuals, agencies, and organizations. Colleges often employ academic advisers, psychologists, and psychiatrists. In addition, campus ministries have people trained in pastoral counseling, and they are a wonderful source for personal and religious counseling. Resident hall assistants who, like the residents, are also students are a source of peer counseling. Many counseling centers hire counseling psychologists to work with college-age students in the development of more appropriate adjustment strategies and in the alleviation of stress-related symptoms. Agencies such as career service centers, ombudsperson's offices, and student health centers offer specialized counseling that may be preventive and/or remedial in nature. Postsecondary institutions recognize the need for, and their responsibilities in offering, counseling services to their students.

GLOSSARY

acute stress disorder (ASD) A psychiatric disorder that develops in some people following a trauma; symptoms include dissociation, reexperiencing of the trauma, avoidance of trauma-related cues, and increased arousal.

arousal The tendency for individuals who have experienced a trauma to have elevated levels of physiological and emotional tension; this may be manifest as increased agitation, irritability, and/or startle as well as difficulty in concentrating or sleeping and in a sense of hypervigilance.

avoidance The tendency for individuals who have experienced a trauma to stay away from reminders of the trauma.

numbing A sense of diminished emotional responding commonly seen in trauma survivors; it is sometimes described as an empty or blank feeling.

posttraumatic stress disorder (PTSD) A psychiatric disorder that develops in some people following a trauma; symptoms must persist for at least 1 month and include reexperiencing of the trauma, avoidance of trauma-related cues, and increased arousal.

psychological trauma The emotional impact of a traumatic event on the person who experienced it.

reexperiencing The tendency for memories, thoughts, feelings, and/or images related to a past trauma to intrude into the current day; manifestations of reexperiencing symptoms include intrusive thoughts or images, nightmares, and extreme emotional and physiological distress when reminded of the trauma.

traumatic event An event that involves actual or threatened death or injury or a threat to the physical integrity of oneself or others.

traumatized people People who have experienced a traumatic event that resulted in psychological trauma.

The psychological aftereffects of traumatic events can be dramatic, and in some cases they can be prolonged. There are a group of common psychological reactions to traumatic events that reflect the overwhelming nature of the trauma. These reactions, when severe or prolonged, may develop into the psychological disorders of posttraumatic stress disorder (PTSD) and acute stress disorder (ASD). This article describes common reactions to trauma, trauma-related psychiatric disorders, common issues in the assessment of trauma and posttrauma symptoms, and treatments for posttraumatic stress disorders.

Psychological reactions following traumatic events have been recognized for hundreds (or perhaps thousands) of years in literary descriptions and for more than 100 years in the psychiatric field. Terms such as war neurosis, shell shock, and battle fatigue reflect the fact that these reactions were largely associated with war. More recently, researchers and

clinicians have begun to examine the psychological impact of a wide range of traumatic events, including rape, physical assault, natural and manmade disasters, motor vehicle accidents, and chronic abuse in various populations such as child abuse, domestic violence, and political imprisonment. This research clearly demonstrates that traumatic events can have devastating and long-lasting effects on the psychological well-being of survivors. At the same time, this research also indicates that humans are remarkably resilient and that, with time, most trauma survivors recover on their own.

1. DEFINITION OF TRAUMA

Individuals will label many different events as traumatic. The formal definition of a traumatic event adopted by the American Psychiatric Association in the fourth edition of the *Diagnostic and Statistical Manual of Mental Disorders* (DSM-IV) consists of two distinct aspects. The first describes the characteristics of the event itself, and the second describes the subjective emotional responses of the individual who experiences the event:

1. The person has experienced, witnessed, or been confronted by an event that involved actual or threatened death or injury or a threat to the physical integrity of oneself or others.
2. The person responds to this event with intense feelings of fear, horror, or helplessness.

The definition allows different types of events to be identified as traumatic and recognizes that some people will experience psychological trauma from a particular event, whereas others will not. Although experiencing traumatic events was once thought to be rare, it is now known that most people are exposed to at least one traumatic event over the course of their lifetimes.

2. COMMON REACTIONS TO TRAUMA

The psychological impact of a traumatic event differs across types of events and individuals. Some events (e.g., rape, combat) are more likely to result in long-lasting psychological problems than are others (e.g., motor vehicle accidents, natural disasters). Also, individuals who experience the same event may differ

greatly in their reactions to it. Despite this variation, there is a cluster of reactions that commonly occur following a trauma. Table I presents a group of reactions that many trauma survivors experience. Research on recently traumatized people suggests that nearly all trauma survivors will experience at least some of these reactions. These include symptoms that reflect elevated levels of emotional distress, such as increased feelings of fear and anger and general increased arousal, as well as feelings of guilt, shame, and grief. In addition, shortly after a traumatic event, people often find themselves replaying or reliving the event in their minds. These intrusive thoughts are usually accompanied by feelings similar to those experienced at the time of the traumatic event. The distress associated with the traumatic memories often leads trauma survivors to avoid people or situations that remind them of the traumatic event.

3. COURSE OF RECOVERY FROM TRAUMA

Shortly after a traumatic event, most traumatized people experience significant emotional distress that, in the majority of cases, diminishes over time. Although there are individual differences in patterns of emotional recovery from a traumatic event, most people recover within the first few weeks or months after the event. However, a substantial minority experience persistent chronic psychological problems related to the trauma. In some cases, individuals appear to recover relatively well from the trauma, only to have trauma-related problems surface months or years later.

Several factors have been found to distinguish people at most risk for persistent trauma-related problems, particularly those people who develop chronic posttraumatic stress disorder (PTSD). The factors that appear to be related to persistent posttraumatic problems can be loosely divided into (a) characteristics of the traumatic event, (b) characteristics of the individual exposed to the trauma, and (c) characteristics of the environment in which the individual is attempting to recover.

Among the characteristics of the traumatic event that are associated with persistent posttrauma problems is the type of trauma, with sexual assaults and combat being more likely to result in prolonged problems than nonsexual assaults and motor vehicle accidents. Exposure to a more severe traumatic event

TABLE I
Common Psychological Reactions to Traumatic Events

<i>Reaction</i>	<i>Examples</i>
Fear and anxiety	Fear of a repetition of the trauma Fear in response to environmental cues reminiscent of the trauma such as people, places, times of day, smells, and noises Anxiety attacks that feel as though they come out of the blue General sense of dread or anxious arousal
Reexperiencing of the trauma	Unwanted thoughts of the trauma Unwanted mental images of the trauma Flashbacks in which the person feels the trauma is occurring again Bad dreams or nightmares
Increased arousal	Feels jumpy, jittery, or shaky Feels irritable or angry Has difficulty in concentrating Has difficulty in sleeping
Avoidance	Attempts to suppress trauma-related thoughts and feelings Avoids trauma-related conversations Avoids situations or activities that are reminiscent of the trauma
Numbing	Sense of emotional numbness or emptiness Detachment from surroundings and other people Depersonalization or derealization
Guilt and shame	Blames self for things he or she did or did not do Is ashamed of what happened during the trauma or by the nature of the traumatic event Is ashamed or guilty about the emotional or behavioral reactions the person experienced during and after the trauma
Grief and depression	Feels down, sad, hopeless, or despairing Has loss of interest in, and decreased enjoyment from, normal activities
Altered image of self and the world	Sees the world as generally or uniformly dangerous Views the self as incompetent or bad in some way Views others more negatively and less trustworthy Is concerned that the person's reactions to the trauma mean that he or she is losing control or "losing my mind"
Disrupted relationships	Has difficulties with intimate relationships Feels distanced or cut off from friends and family
Alcohol and substance use	Increased use of alcohol and drugs to "self-medicate" reactions to the trauma

is also more likely to produce persistent problems. Markers for a severe trauma include physical injuries and the duration of the event. Individual characteristics that are associated with persistent problems include prior exposure to traumatic events and the presence of diagnosable depression or anxiety prior to the event. Among posttrauma factors, the absence of a supportive social environment appears to be associated with persistent problems following a trauma.

Additional markers that predict persistent emotional distress reflect the interaction of trauma and

individual characteristics. For example, the perception that one is likely to die during the trauma, which reflects both the severity of the trauma and the individual's interpretation of the events of the trauma, is associated with persistent posttrauma problems. Similarly, intense emotional reactions (e.g., fear, helplessness, shame, anger) during and shortly after the trauma, as well as severe initial posttrauma reactions (e.g., intrusive memories, increased arousal, dissociation), are associated with more persistent problems.

4. PSYCHOLOGICAL DISORDERS FOLLOWING TRAUMA

4.1. Posttraumatic Stress Disorder

PTSD was first introduced into the diagnostic nomenclature in the third edition of the *Diagnostic and Statistical Manual of Mental Disorders* (DSM-III) in 1980. PTSD is classified as an anxiety disorder, but it incorporates three distinct groups or clusters of symptoms: reexperiencing, avoidance, and increased arousal. The reexperiencing cluster consists of five symptoms that reflect distressing spontaneous or cued recollections of the traumatic event such as intrusive memories, nightmares, and emotional distress in response to trauma-related cues. The seven avoidance symptoms reflect attempts at avoiding memories or reminders of the event as well as disruptions in emotional/interpersonal experience such as a numbing of emotional reactivity and a sense of detachment from other people. The increased arousal cluster consists of five symptoms that reflect an elevated level of alertness (e.g., hypervigilance, increased startle) and a high level of general arousal (e.g., sleep disturbance, irritability). To be diagnosed with PTSD, an individual exposed to a traumatic event (as defined by the DSM-IV) must experience symptoms in each of these clusters. Specifically, the person must manifest at least one reexperiencing, three avoidance, and two increased arousal symptoms for at least 1 month after the traumatic event. If the symptoms persist for more than 3 months, the condition is considered chronic.

4.2. Acute Stress Disorder

Acute stress disorder (ASD) was introduced as a distinct disorder in the DSM-IV. ASD is characterized as an anxiety disorder and shares many symptoms in common with PTSD. One important difference between the two disorders is the time frame of the symptoms. The diagnosis of ASD requires that the symptoms occur within the first 4 weeks after a traumatic event, whereas PTSD requires that the symptoms persist for at least 1 month after the traumatic event. The other feature that distinguishes the two disorders is a greater emphasis on dissociative symptoms in ASD than in PTSD.

To be diagnosed with ASD, a person must be exposed to a traumatic event and develop symptoms in each of four categories: dissociation, reexperiencing,

avoidance, and arousal. In contrast to PTSD, the avoidance cluster of ASD symptoms consists of only effortful avoidance of trauma reminders. Symptoms of emotional numbing and amnesia are included in the dissociation cluster, and other symptoms (e.g., anhedonia, foreshortened future) are not included. In contrast to the diagnosis of PTSD, ASD requires only one symptom in each of the reexperiencing, avoidance, and arousal clusters.

Initially, it was thought that the presence of ASD would identify people who would go on to develop chronic PTSD. However, recent research suggests that the relationship between acute reactions to trauma and more chronic problems is not so straightforward. ASD does appear to serve as a risk marker for PTSD with many people who develop chronic PTSD meeting criteria for ASD shortly after a trauma. However, some survivors with ASD do not go on to develop PTSD, and some traumatized people who do not have ASD may develop PTSD later. The imperfect relationship between the diagnoses of ASD and PTSD probably reflects the fact that the initial severity (not simply the presence or absence) of symptoms following a traumatic event is related to their persistence. Also, relating the presence of ASD directly to a PTSD diagnosis ignores factors that augment or impair recovery during the first month following a traumatic event. Regardless of its utility as a precursor to PTSD, the ASD diagnosis does capture the significant distress that some people experience shortly after trauma—distress that cannot be diagnosed as PTSD because the symptoms have not yet persisted for more than 1 month (Table II).

5. ASSESSMENT IN THE WAKE OF TRAUMA

Assessments of posttrauma pathology focus on three areas: (a) exposure to traumatic events, (b) trauma-related symptoms, and (c) establishment of the link between the traumatic event and the symptoms. Establishing the link between the event and the symptoms is particularly difficult in cases of chronic PTSD where the traumatic event may have occurred years or even decades in the past and in cases where the patient has experienced multiple traumas. Establishing this link is typically less complicated when assessing ASD where the traumatic event must have occurred recently.

TABLE II
Symptoms of Posttraumatic Stress Disorder and Acute Stress Disorder

<i>Posttraumatic Stress Disorder</i>	<i>Acute Stress Disorder</i>
<i>Reexperiencing symptoms (need at least one)</i>	<i>Dissociation (need at least three)</i>
1. Intrusive thoughts or memories of the trauma	1. Subjective sense of emotion numbing or detachment
2. Recurrent dreams related to the trauma	2. Reduced awareness of surroundings
3. Flashbacks of the trauma	3. Derealization
4. Emotional distress to trauma reminders	4. Depersonalization
5. Physiological reactivity to trauma reminders	5. Unable to recall important aspect of the trauma
<i>Avoidance (need at least three)</i>	<i>Reexperiencing (need at least one)</i>
6. Efforts to avoid thoughts or feelings of trauma	6. Recurrent trauma-related images, thoughts, dreams, or flashbacks
7. Efforts to avoid trauma reminders	7. Emotional distress to trauma reminders
8. Unable to recall important aspect of the trauma	<i>Avoidance (need at least one)</i>
9. Diminished interest in activities	8. Marked avoidance of trauma-related thoughts, feelings, or reminders
10. Detachment from others	<i>Arousal (need at least one)</i>
11. Restricted range of affect	9. Marked symptoms of arousal such as sleep problems, irritability, difficulty in concentrating, hypervigilance, exaggerated startle, restlessness
12. Foreshortened sense of the future	
<i>Arousal (need at least two)</i>	
13. Sleep disturbance	
14. Irritability or angry outbursts	
15. Difficulty in concentrating	
16. Hypervigilance	
17. Increased startle response	

5.1. Assessing Exposure to Trauma

The specific guidelines for assessing exposure to traumatic events depend on the goals of the assessment. This being said, five aspects of traumatic exposure are typically assessed during the evaluation: (a) establishing the presence of trauma in the life of the client, (b) identifying the nature of the traumatic exposure, (c) estimating the severity of the trauma, and (d) establishing the timing of the traumatic exposure.

5.1.1. Establishing the Presence of Trauma

Typically, the assessment of traumatic exposure includes an evaluation of traumatic events across the life span. In some cases, the primary focus may be on a single event, but understanding the prior trauma history of the person who experienced the trauma is important.

The presence of traumatic exposure is typically determined by presenting the person with a list of traumatic events and having the person indicate those events to which he or she has been exposed. The specific events included on the list will vary across settings, situations, and clinicians. The most

commonly evaluated traumas include motor vehicle accidents, physical and sexual assaults, physical and sexual abuse (childhood or adult), fires, natural disasters, and combat. It is better to use structured questions that describe each event in detail rather than a single question such as “Have you experienced a trauma?” This helps to ensure that the person’s response does not rely on his or her understanding of a single word such as “trauma.” Similarly, the wording of each item should be designed to reduce the likelihood of misunderstanding or misinterpretation. For example, it is better to ask “Has anyone ever used physical force or threats of force to make you do something sexual that you didn’t want to do?” instead of “Have you ever been raped?” There are many times when a person reports having experienced forced sexual contact but will not view it as rape.

In addition to determining what types of traumatic experiences a person has experienced, assessments should inquire about the number of times various types of events have occurred. For example, the assessor will want to know how many earthquakes the person has experienced or how many times the person has been assaulted.

5.1.2. Identifying the Nature of the Traumatic Exposure

Although traumatic events are thought to share certain characteristics, it is clear that they are not the same in their emotional impact. A more complete understanding of the traumatic event and its potential impact on a person requires a thorough understanding of the specific characteristics of the event and the nature of the person's exposure to that event. The definition of trauma included in the diagnostic criteria for PTSD and ASD allows for three types of exposure to the event: (a) directly experiencing the event, (b) witnessing the event, and (c) being confronted with the event. In general, but not always, directly experiencing a trauma is more likely to produce lasting effects on the person than is witnessing the event or being confronted by it.

Often, a distinction is made between interpersonal traumas (e.g., criminal assaults, child abuse) and other types of traumas (e.g., fires, natural disasters). Research suggests that interpersonal traumas are more likely to produce persistent reactions than are other types of traumatic events. However, this might not be true in all cases.

Traumas have also been differentiated by whether the event happened to a particular individual or to a group of people. Events such as criminal assault, child abuse, and life-threatening illnesses typically happen to only one person. In contrast, events such as natural disasters, wars, and the terrorist attacks of September 11, 2001, affect entire communities simultaneously. Although individual reactions may be quite varied, there is some suggestion that individual traumas are more likely to result in chronic problems than are community traumas. However, the distinction between individual traumas and community traumas is far from perfect. For example, a violent crime may typically be perpetrated against an individual, but the cumulative effect of crime can affect an entire community. Similarly, although a hurricane or another natural disaster may affect an entire community, the specific experiences of individuals within that community may be quite varied.

5.1.3. Assessing the Severity of the Traumatic Event

Two aspects of trauma severity are typically assessed: objective severity and subjective severity. These map loosely onto the two aspects of the DSM-IV definition of trauma in the diagnostic criteria for PTSD and ASD. Measures of objective dangerousness will depend on the specific type of traumatic event, but they reflect

characteristics of the event such as whether someone was killed, whether and how badly the person was injured, and whether an assailant used a weapon during the assault. Other objective measures of trauma severity might include the duration of the event and the amount of monetary or property loss.

Subjective severity of the trauma refers to the person's evaluation of the event and overlaps considerably with the second part of the trauma definition mentioned previously. Therefore, these estimates of severity tend to focus largely on feelings of fear, horror, and helplessness. Typically, survivors are asked to what degree they felt each of these emotions during the traumatic event. For diagnostic purposes, all that the assessment needs to establish is that the person experienced the emotion, and simple questions such as "Did you fear that you would be killed during the trauma?" are sufficient. In other cases, one may wish to establish the subjective severity relative to other events. In these cases, it is often helpful to have the person rate the intensity of the feeling on an arbitrary scale.

The objective and subjective ratings of trauma severity may be quite different. Seemingly minor (based on objective ratings) events are rated as subjectively very severe and vice versa. Therefore, it is important and informative to assess both the objective severity and subjective severity of traumatic events.

5.1.4. Assessing the Timing of the Traumatic Event

Timing of the trauma refers to both the developmental level (i.e., age at which the event occurred) and the duration over which the event occurred. In this case, duration usually refers to whether the event occurred a single time (e.g., assault by a stranger on the street) or was repeated over time (e.g., physical abuse by a parent over years). There is some indication that exposure to a traumatic event at an early age or repeated exposure to a traumatic event over a period of time is more likely to lead to psychological problems than is a single traumatic event during adulthood. Some have argued that these problems extend beyond those captured by the PTSD diagnosis and include disrupted sense of self and relationships.

5.2. Assessing Early Emotional Reactions to the Traumatic Event

As described earlier, it is common for people who have experienced a traumatic event to report reactions such

as intrusive memories, emotional distress, and increased arousal. In most situations, there will be little formal assessment of these reactions unless the person is being seen by a mental health professional. Informal assessment of these reactions might consist of a review of the common reactions listed in Table I. Such informal assessments respect the survivor's wish to limit what he or she discusses, and the presence of the common reactions discussed previously should be normalized and validated. Because these reactions will diminish over time naturally, it is recommended that a recently traumatized person be encouraged to use his or her naturally occurring support system and to follow his or her natural inclination with regard to how much to say and to whom to talk. However, an individual who experiences very severe emotional reactions or who shows high levels of dissociative symptoms should be referred for further evaluation and possible treatment.

5.3. Assessment of Symptoms

Two areas are typically evaluated in a comprehensive assessment of trauma-related symptoms. The first is the specific symptoms included in the PTSD or ASD diagnostic criteria. The second involves the assessment of associated symptoms and problems. As with the assessment of trauma exposure, the specific questions or instruments included in the assessment battery will depend largely on the purpose of the assessment and the specific trauma history of the person being evaluated.

5.3.1. Assessing the Symptoms of PTSD or ASD

Both self-report and interview-based instruments have been developed to assess the symptoms of PTSD and ASD. In some cases, only the presence or absence of each symptom is assessed, but most instruments also call for rating the severity of the symptoms. The specific metric on which the severity of the symptoms is measured varies across instruments, but usually the measurement incorporates an evaluation of the frequency with which each symptom has occurred and the intensity or severity of each symptom when it is experienced. Typically, PTSD symptoms are assessed over a 1-month time frame, reflecting the criteria that symptoms must be experienced for at least 1 month to be diagnosed with the disorder, but symptoms have been assessed over periods as short as 1 week when necessary. Because ASD can occur only within the month immediately following a trauma, these

symptoms are generally evaluated relative to a time frame of 1 week or even a few days.

When assessing symptoms of PTSD or ASD, it is important to relate the symptoms to a specific traumatic event and to determine whether the current presentation reflects a shift from prior functioning. In the case of some of the symptoms, this is relatively straightforward because the symptoms are directly tied to the event (e.g., intrusive thoughts or memories of the event, efforts to avoid reminders of the event). In the case of other symptoms, however, the association with the specific traumatic event in question is not necessarily clear (e.g., sleep disturbance, sense of detachment from other people). In the latter case, the evaluator will generally find it necessary to use the "change from prior functioning" criteria to link the symptoms to a particular trauma. As noted earlier, this task is easiest when the traumatic event in question is relatively recent and discrete. When the trauma occurred a long time ago (particularly when it occurred during childhood) or over a long period of time (as in the case of domestic violence), it is much more difficult to establish the link to a particular event or a shift from prior functioning.

5.3.2. Assessing Broader Difficulties Associated with Trauma

Beyond the symptoms of PTSD and ASD, trauma survivors can experience a wide range of problems, including (a) mental health problems such as depression, anxiety, and substance abuse/dependence; (b) problems in functioning such as disrupted relationships, difficulty in working, and physical health problems; and (c) cognitive and emotional difficulties such as intense feelings of guilt or shame, anger control problems, and problem-solving deficits. Some instruments have been developed to assess these broader difficulties associated with trauma, but for the most part, evaluators have used established instruments for assessing each of these areas of interest.

6. PSYCHOLOGICAL TREATMENT OF POSTTRAUMATIC DISORDERS

Psychological treatments for trauma survivors can be divided into those designed to be implemented in the immediate aftermath of the traumatic event (often termed "debriefing"), those aimed at treating ASD,

and those aimed at treating chronic PTSD. Treatments aimed at alleviating PTSD have been studied much more extensively than have those used for ASD or debriefing.

6.1. Treatment of Chronic PTSD

The most well-studied and empirically validated treatments for PTSD are based on behavioral and cognitive-behavioral approaches to therapy. Three major categories of treatments have been tested and found to be somewhat effective for patients with PTSD: (a) exposure therapy in which patients are encouraged to systematically confront reminders of the traumatic event that elicit anxiety, (b) cognitive techniques in which patients are taught to challenge cognitive distortions thought to underlie the symptoms of PTSD, and (c) anxiety management techniques in which patients are taught methods for managing their trauma-related anxiety. In addition, various combinations of these treatments have been examined and found to be useful in treating chronic PTSD.

Of the treatments used for chronic PTSD, exposure therapy has been the most widely validated. Two forms of exposure are typically included in these programs: imaginal and in vivo. Imaginal exposure refers to patients intentionally confronting specific memories of the traumatic event in their imaginations either by verbally describing the traumatic event or by writing a description of the trauma. Typically, this is done for a prolonged period of time (i.e., 30–60 minutes) and is repeated over the course of treatment. The second type of exposure, in vivo exposure, refers to real-life confrontation with situations that are objectively safe but elicit intense anxiety or with situations that elicit memories of the trauma itself. The most effective therapies for chronic PTSD include these two exposure techniques or combine one or both of these techniques with cognitive therapy techniques aimed at altering PTSD-related dysfunctional cognitions.

6.2. Treatments for ASD

Treatments for ASD have been studied much less extensively than have treatments for chronic PTSD. The available studies suggest that the cognitive-behavioral techniques found to be useful with cases of chronic PTSD are also helpful in the more immediate aftermath of trauma. These interventions are typically brief (four or five sessions, with each session lasting 90–120 minutes) and are conducted during the first

2 to 4 weeks after the trauma. Despite the early promise of these interventions, it is premature to conclude that treatment targeting ASD symptoms during the first month after a traumatic event are effective in reducing long-term difficulties associated with trauma.

6.3. Debriefing: Treatment in the Wake of Trauma

Although debriefing interventions (typically administered in a single session during the first several days after a trauma) have become widely used, they have been poorly studied. These interventions aim to reduce long-term mental health problems associated with the trauma, but there is little evidence to support their efficacy in achieving this goal. Indeed, there is growing evidence that debriefing does not substantially reduce the rates of PTSD among trauma survivors. Of more concern are recent findings suggesting that debriefing might actually be detrimental to some trauma survivors, leading to more long-term emotional disturbance than would have occurred with no intervention at all.

GLOSSARY

authority The institutionalized power between a superior and a subordinate that ensures compliance with the superior's wishes because he or she is the boss.

empowerment A motivational process involving feelings of self-efficacy among organizational members; to enhance the perception of self-efficacy, members use a set of strategies to influence and improve their behavior, taking responsibility for their own lives rather than depending on a leader to direct and motivate them.

influence A force that one person (the leader) exerts on others (followers) to induce a change in the latter, including changes in behaviors, attitudes, and values.

leadership Power relationships and influence processes between a leader and followers in which the leader exercises greater influence over the followers to accomplish group or organizational objectives.

power The potential ability of a person to influence others; thus, influence is "power in action," just as power is "potential influence."

Leadership involves power relationships and influence processes between a leader and followers in which the leader exercises greater influence over the followers to

accomplish group or organizational objectives. Thus, power is essential to leadership and processes of influencing members of a group or an organization. However, although power is necessary for leadership, it is insufficient by itself for leadership. The same person could be described as having influence, being persuasive, and/or being a leader. As a result, social scientists have attempted to discover how leaders use power to influence followers, looking at the difference between exercising formal authority and leadership and followers' responses to these influence attempts. It should be noted that there is a clear difference between yielding to social pressure from an individual and being genuinely persuaded. This article first examines the various bases and sources of power that are used to influence people and the responses they elicit in followers as well as the difference between management and leadership. Then, it focuses on three fundamental features that are critical to leadership: traits or personal characteristics, behaviors, and situations. Finally, it describes some integrative approaches represented mainly by charismatic and transformational leadership.

1. POWER AND INFLUENCE

In trying to understand how people influence each other when they interact, social psychologists have used the concepts of social power and influence tactics. The two terms have sometimes been interchanged, but a clear distinction needs to be made between them.

Social power reflects the repertoire of tools available to a person to influence the environment or the other party. Influence tactics refer to the actual use of a certain tool in a specific situation. The definition of the two concepts helps to clarify the differences between them. Following Lewin's initial conceptualization in 1941, French and Raven in 1959 defined influence as a force that one person (the leader) exerts on others (followers) to induce a change in the latter, including changes in behaviors, attitudes, and values. Social power was subsequently defined as the potential ability of a person to influence others. Thus, influence is "power in action," just as power is "potential influence."

The conceptualization of power highlights two important characteristics of power. The first reflects that power is potential and, as a result, that a person can have power without using it. The availability of tools does not mean that the tools must be used. The second characteristic refers to the relational aspect of power in that it does not reside in the person but rather resides in the relationship between people in a given situation. In general, power is derived from the situation in which the person operates, and in the event of the situation changing, the person's power also changes.

1.1. Social Influence Dynamic

In studies examining people's responses to leaders' influence attempts, there is a clear difference between yielding to direct or indirect social pressure from a leader and being genuinely persuaded. For example, the leader's influence may be strong enough to wield control over the followers' behavior, ensuring public agreement, regardless of whether the followers are privately convinced. On other occasions, the influence process may change followers' private attitudes or opinions and make them committed to the leader's request. Therefore, social psychologists have proposed various types of influence processes, the most important of which was Kelman's traditional distinction, made in 1958, among compliance, internalization, and identification. Compliance refers to a surface change in behavior and expressed attitudes, often as a consequence of coercion or the followers' desire to obtain a reward. Because compliance does not reflect internal change, it usually persists only while behavior is under surveillance. In contrast to compliance, internalization means subjective acceptance that produces true internal change that persists in the absence of surveillance. The norm becomes an internalized

standard for behavior. There is genuine support for the leader's proposals because they appear to be intrinsically desirable and are suited to the followers' values and beliefs. Identification is based on the leader's attractiveness to the followers, who imitate the leader's behavior and attitudes to gain his or her approval. The maintenance of close relationships with the leader involves the followers' need for acceptance and esteem.

The outcomes of these various forms of social influence in terms of compliance, internalization, and identification may occur at the same time. For example, a person who works in a nongovernmental organization (NGO) with exploited children in the Third World may accept a proposal from a superior to design a new program because he or she will obtain tangible rewards for carrying it out (compliance) and believes in the necessity and effectiveness of the program (internalization). At the same time, the person is proud of working with his or her superior on this project, and this will increase the level of satisfaction in the relationship with the superior (identification).

1.2. Bases and Sources of Power

To understand the different ways in which power can be exercised, it is best to look at the various bases and sources of power. In 1959, French and Raven proposed a well-known taxonomy of power that considered five bases of power: reward, coercion, legitimacy, reference, and expertise (a sixth base of power, information, was added a little later). A leader possesses these resources and can use them to change the beliefs, attitudes, and/or behaviors of followers. Reward and coercive power rely on others believing that the leader can provide them with the desired rewards or can punish them, respectively. Using either of these bases will induce only a superficial change in the followers. In other words, none of the followers' privately held beliefs, attitudes, or values is changed. Only compliance is obtained, and the continuation of this compliance depends on successful surveillance of the followers by the leader. A person possesses legitimate power when others believe that he or she has a legitimate right to exert influence over them and they are obliged to accept this influence. It cuts across all three types of influence processes and, as a result, may share elements of each of them. Referent power refers to followers' identification with the leader. It leads to private acceptance by followers by enabling them to maintain a satisfactory relationship with the leader and to see themselves as similar to the leader in certain

important areas. Expert power depends on followers' perception of having expertise or knowledge in a specific domain. If the followers perceive the leader as an expert, this will result in private acceptance on the part of the followers. Finally, informational power leads to internalized and lasting changes in the followers' beliefs, attitudes, and/or values. Compared with other social power bases, the changed behavior resulting from information is maintained without continued social dependence on the leader and is instead based on the perceived importance and validity of the information. Only informational power leads to cognitive change in followers because it immediately becomes independent of the leader.

Another related dimension of power refers to sources of power. When dealing with the bases of power, the focus was the repertoire of tools available to a person to influence the other party or the environment. In terms of sources of power, the focus points toward the way in which a person comes to control these tools. Two different sources of power have been identified: position and personal power. Position power arises from the formal position held in a group or an organization, whereas personal power arises from personal attributes and the kind of relationship established with the other party. In position power, potential control is derived from legitimate authority. In personal power, it stems from task expertise or the opportunity to access certain information that is important for other members of the group or organization.

So far, this article has identified two sources of power, six bases of power, and three influence processes. Figure 1 illustrates the relationships among these aspects of power.

1.3. Influence Tactics

As was explained earlier, literature on social power takes power to be the capacity to exert influence. However, power can be used in different ways, and the specific ways in which power is enacted involve influence behavior. With the publication of *The Powerholders* in 1976, Kipnis approached influence behaviors from the perspective of the agent of influence. He stated that the choice of a means of influence depends mainly on the resources at the agent's disposal (i.e., on the power bases that the target possesses), on the target's inhibition to invoke a power base (as determined by the target's estimate of the costs of using a power base, the target's subjective values and attitudes, individual differences, and social norms),

FIGURE 1 Relationships of sources, bases, and types of social influence elicited in followers.

and on the resistance that one expects from the target toward the influence attempt. Subsequent developments by Kipnis and colleagues in 1980 identified the specific behaviors that people have at their disposal for influencing others in organizations. The various categories of proactive influence behaviors that were proposed were referred to as "influence tactics."

Building on and extending the previous work, Yukl and colleagues developed a classification with nine proactive influence tactics: rational persuasion, inspirational appeals, consultation, ingratiation, personal appeals, exchange, coalition tactics, legitimating tactics, and pressure. In general, effective leaders use a combination of influence tactics that they select depending on their judgment of what is most appropriate for a given situation. As Yukl pointed out in his recent book titled *Leadership in Organizations*, a leader prefers to use tactics that are socially acceptable, feasible in terms of the leader's power in relation to the followers, likely to be effective for a particular objective, and unlikely to require much time, effort, or cost to the leader.

2. FORMAL AUTHORITY AND LEADERSHIP

As noted in the previous section, power that stems from a person's formal position in a hierarchical structure is sometimes called formal authority or legitimate power. Authority represents the institutionalized power between a superior and subordinates that ensures compliance with the superior's wishes because he or she is the boss. Thus, authority involves a

person's right to exercise control over other people or the environment. For example, a manager usually has the legitimate right to make a job-related request to subordinates, who in turn have the legitimate right to request job-related information and assistance from the manager. However, a manager may have a great deal of legitimate power due to his or her position but may have little, if any, expert power. As a result, followers may think that the manager does not understand the problem they must deal with but that they must do the work because they have been told to do so by the boss.

2.1. Management and Leadership

Although nobody has argued that managing and leading are equivalent, it has sometimes been assumed that managers' control over some important resources involves leadership processes. In fact, the exercise of power that stems from a person's hierarchical position may facilitate the emergence of leadership. But hierarchical position is simply a context from which leadership may or may not emerge. Leadership does not arise by virtue of occupying hierarchical roles. There are differences between formal role designations (which deal with formal aspects of the relationship) and the emergence of leadership (which deals with informal aspects of the relationship). Thus, the emergence of leadership involves more than subordination and is related to the kind, or depth, of social influence elicited from followers. People who achieve acceptable influence, such as internalization or identification, are the ones who are defined as leaders. Therefore, leaders can be identified because they demonstrate leadership. Countless presidents, kings, generals, and military figures who were chosen or appointed (bottom-up vs top-down), and who have power and authority, give few examples of behaviors that could be associated with actual leadership. If a person with formal authority (i.e., a manager) is able to induce internalization or identification, he or she would have managed to exercise leadership. If this person is not able to do so, he or she would have exercised authority. In turn, a person who develops a relation that induces internalization or identification despite not holding a hierarchical role (i.e., a nonmanager), is exercising leadership. In other words, a person can be a leader without managing, and a person can be a manager without leading. From this perspective, leading and managing are viewed as different processes, although leaders and managers are not considered to be different types of people.

TABLE I

Authority and Leadership as Results of Social Influence

<i>Social influence</i>	<i>Type of power</i>
Compliance	Formal authority (management)
Internalization	Leadership (transactional)
Identification	Leadership (transformational)

Nevertheless, it must be emphasized that some overlap does exist among the various types of social influence and that more than one influence process may occur at the same time, as stated previously. It may also be the case that the same type of influence attempts may produce different individual responses. As a result, not all theoretical perspectives share the same conceptualization on the exercise of power, authority, leadership, and management. In fact, the relationship among these concepts has been the subject of extensive debate. Table I presents a summary of the conceptualization developed in this article.

2.2. Empowerment

Leaders and managers often share power with followers or subordinates for a period of time to accomplish a variety of organizational tasks and objectives. This process is known as power delegation. In 1988, Conger and Kanungo proposed that empowerment differs from delegation in that the former is a motivational process involving feelings of self-efficacy among organizational members and is not temporally limited by the leader. To enhance the perception of self-efficacy, members use a set of strategies to influence and improve their behavior, taking responsibility for their own lives rather than depending on a leader to direct and motivate them. In conventional terms of social influence, empowerment can be understood as a process of identification focused toward the development of a shared vision among organizational members. The aim of the empowerment process, by strengthening individual and/or collective efficacy, is to enable organizational members to solve organizational problems arising from the turbulent environment and diversification of the workforce.

3. MODELS OF LEADERSHIP

As stated previously, a person cannot lead unless there are power relationships between the leader and the

followers. However, power by itself is not a sufficient condition for leadership. Various perspectives and models have approached the question of the variables that need to be considered to achieve the exercise of leadership. The conventional perspective emphasized the personal attributes and acquired behaviors that leaders bring to the situation as well as the situational forces that shape and determine effective leadership. Some new perspectives emphasize that leadership is not only a transactional relationship between the leader and the followers but also produces important effects in followers' value systems.

3.1. Traits, Behaviors, and Situational Models

Some of the earliest research to approach the subject of leadership consisted of trait or dispositional studies. Trait models focus on what a person brings to leadership activities. This approach emphasizes the personal attributes of a leader that are treated as innate and unique. Accordingly, attention has focused on certain combinations of personality traits (e.g., tolerance of stress, emotional maturity, self-efficacy), motives (e.g., power orientation, relatively strong motivation to achieve, need for affiliation), and skills (e.g., technical, conceptual, interpersonal) because these might be reflected in the achievement of leader status and as possible predictors of a leader's effectiveness in promoting group or organizational performance. However, the studies aimed at uncovering the characteristics constantly linked to leadership have been inconclusive, and no definitive predictors of effective leadership have been established.

Researchers became discouraged with the trait approach, and around 1950 they began to look at what leaders or managers do in their jobs. The behavioral models of leadership analyze what leaders or managers do with whatever personal traits, skills, or motivational capacities. The primary concern of behavioral models focused on developing methods to determine what leaders do and measure relevant dimensions of their behavior that might be linked to group effectiveness and subordinate satisfaction. Two main dimensions that reflected how subordinates perceived a manager's behaviors were identified. Consideration (or relationship-oriented) behaviors reflect the extent to which a leader shows concern for subordinates' satisfaction and well-being. Initiating structure (or task-oriented) behaviors reflect the degree to which a leader explains and

defines the roles of a task, assigns subordinates to various task roles, controls subordinates' performance, and provides feedback to subordinates. Because these are two independent dimensions, the behavior of a leader may be described as a combination of both. According to this perspective, the ideal leader would be someone with high scores on both dimensions.

Both the trait and behavioral models focus on personal attributes and acquired behaviors that leaders bring to the situation and provide a framework for identifying and cultivating leaders in organizations. However, an important difference between the models lies in the fact that traits are considered innate in a person—a person either does or does not have the gift—whereas specific behaviors may be learned. A difference in the practical implications of the two models is that if the trait proposals were correct, leaders could be selected to hold formal posts in groups and organizations. However, if the behavioral models were correct, it would be possible to teach leaders, such that programs could be designed to train people to become effective leaders. The interesting aspect of this last perspective is that it could increase the number of available leaders.

During the 1960s, situational models supplanted universalistic approaches. Situational models focus on situational variables that moderate the relationship between the leader's attributes and behaviors and his or her effectiveness. Researchers became convinced that predicting the success of leadership was more than just a case of signaling certain preferable traits or behaviors. The impossibility of obtaining congruent empirical results gave rise to a new emphasis on situational factors. The relation between leadership style and efficacy indicated that Style X would be appropriate for Condition A, whereas Style Y would be appropriate for Condition B. However, it was one thing to assert that the efficacy of leadership depended on the situation, but managing to identify those situational conditions was something completely different. Attempts to isolate those conditions gave rise to a wide variety of situational models of leadership, all of which focused on explaining how aspects of the situation moderate the relationship between leaders' traits, behaviors, or both and the outcomes arising from a particular situation. A representative sample of these models is next described briefly.

The least preferred coworker (LPC) contingency model introduced by Fiedler in 1967 considered two types of leadership styles that were regarded as fixed or immutable dispositional traits: directive or task-oriented

style and nondirective or relationship-oriented style. The effectiveness of both styles depended on three situational variables that were identified as the leader-member relationship (e.g., the degree of confidence and commitment between the leader and the followers), task structure (e.g., the extent to which procedures for performing the task are established), and position power (e.g., control of resources such as money or information). Thus, when selecting leaders, this model suggests matching a person's leadership style with the situations. For example, if there is a group or situation in which the leader is trusted, the task is highly structured, and position power is good, it would be more appropriate to assign a task-oriented leader than to assign a relationship-oriented leader.

The popular life cycle model proposed by Hersey and Blanchard in 1977 identified four leadership styles—telling, selling, participating, and delegating—each of which is basically a mixture of task behavior and relationship behavior styles. The model viewed the “maturity” of followers—defined in terms of ability, motivation, and self-confidence—as the chief contingency variable to which one of these leadership styles had to be matched. Thus, followers with low maturity, as is often the case with new employees, would be most responsive to a telling leadership style (characterized as relatively high on task behaviors and low on relationship behaviors), whereas a delegating style (low in both task and relationship behaviors) would be more appropriate for followers with high maturity, as is usually the case with experienced employees. Therefore, the model states that the leader should adapt his or her leadership style to the maturity of the followers. The life cycle model was widely marketed and used in many leader training and development programs in organizations during the 1980s despite having received only partial support from empirical research.

According to the path-goal model developed by House in 1971, the leader's main role is to help his or her followers achieve goals and to provide sufficient leadership and support to guarantee that their goals are compatible with the overall objectives of the group or organization. To achieve these objectives, the leader must identify two critical situational variables (follower needs and task demands) and then choose an appropriate leadership style (consideration style or initiating structure style). The behavior of the leader is motivating for his or her followers in that, first, the satisfaction of the requirements of these followers depends on a good performance and that, second,

these followers need to receive the leadership, support, and rewards that are vital for achieving a good performance.

The normative decision model built by Vroom and Yetton in 1973, and developed by Vroom and Jago in 1988, considers that decision making is the critical leadership activity with groups. The model went further than did previous proposals on decision procedures by specifying which procedure will be the most effective in each of several specific situations. Two intervening variables for measuring decision effectiveness were suggested: decision quality and decision implementation or acceptance by the parties involved in the decision. In turn, these variables are affected by the decision-making procedure used by the leader: two varieties of autocratic decision (AI and AII), two varieties of consultation (CI and CII), and one variety of joint decision making as a group (GII). Depending on seven key situational variables, such as the amount of relevant information possessed by the leader and followers and the likelihood that followers will accept an autocratic decision, the model provides a set of rules for identifying the best decision procedure in terms of decision quality, parties' acceptance, and costs of decision making. Vroom and Yetton developed a decision process flow chart, known as a decision tree, to help leaders identify the optimal decision procedure for each situation.

A more recent situational model is the cognitive resource model, introduced by Fiedler and Garcia in 1987, which focuses on the cognitive resources of the leader (intelligence and experience), leader behavior (directive leadership), and two aspects of the leadership situation (interpersonal stress and the nature of the group's task). Basically, the theory points out that leader intelligence contributes to group performance only when the leader is directive and the followers require guidance to perform the task effectively. However, perceived stress moderates the relation between intelligence and decision quality. Finally, perceived stress moderates the relationship between leader experience and performance. The general idea is that leader effectiveness is predicted by intelligence in low-stress conditions and by experience in high-stress conditions.

The final situational model of leadership considered here is the tridimensional leadership theory developed in 2003 by Yukl, who considered that leadership behavior can be described in terms of three broad categories: task oriented (primary effect on efficiency and reliability), relations oriented (primary effect on

innovation and human resources), and change oriented (primary effect on innovation and adaptation to the environment). The theory states that effective leaders integrate behaviors in a way that is consistent with the situation and that the primary situational variables are the type of organization or unit and the amount of environmental volatility and uncertainty.

In general, situational models of leadership have received only moderate support from empirical studies. However, most of them have the advantage of providing detailed prescriptions for practitioners that are theoretically rooted in the emphasis of leaders' needs to interpret situations and to bring specific traits and acquired behaviors to these situations so as to exercise effective leadership.

3.2. Charismatic and Transformational Leadership

During the 1980s, the previous leadership models began to come under criticism due in large part to their dependence on the methodology used that gave rise to what is known as the "performance-cue" effect. This effect refers to the fact that groups with knowledge of their performance levels reported "objective" leadership behaviors that were consistent with performance levels (e.g., good leadership behavior was reported when performance was good, whereas poor performance led to less flattering ratings), regardless of the actual behavior of the leader. During these years, conventional leadership wisdom came under heavy attack, and this led to a "leadership gap" or "leadership crisis." Nevertheless, this gap was soon filled with a new kind of leadership whose characteristics were connected to one of the oldest traditions in leadership studies, that is, charisma. This Greek word meaning "special or divine gift" was already prominent in Weber's analysis of organizational authority in 1921. The charismatic leadership theory developed by Conger and Kanungo in 1988 relies on its effect on followers and society in general and stemmed from their radical vision of a new world, the exhibition of their own behavior for followers to imitate, and the confidence expressed in the followers' capacity to achieve challenging goals.

Therefore, this new perspective of charismatic leadership differs from the conventional line on leadership studies. To this point, this article has analyzed various aspects of leadership that have been grouped under the term "transactional leadership" because a type of

transaction is established between a leader and followers in all of them. The members of the group or organization recognize the leader as such and accept his or her authority, but in turn the leader must provide the followers with valuable resources. As we have seen, these resources may occasionally refer to the cognitive skills and knowledge that enable objectives to be obtained, whereas other times they may be rewards such as pay increases and recognition of jobs well done. However, if one examines social reality and history itself, one finds that there is another type of leadership that produces important effects in followers in particular but also in society in general. This type of leadership has been labeled "transformational leadership" and refers basically to charismatic leadership.

The differences between transactional leadership and transformational leadership, as defended by Bass in 1985, are significant in terms of followers' commitment to challenging group or organizational goals. In transformational leadership, these goals are presented as a compelling vision and are expressed in ideological and inspirational language (e.g., "what we are able to achieve by challenging ourselves continuously"). In fact, transformational leadership is most likely to emerge when there is a group or organizational crisis or when followers are disenchanted with the current state of affairs. In other words, transformational leadership affects, first of all, followers' value systems and ambition levels. Its ultimate effect is that followers will appreciate projects and options that they would not appreciate unreservedly on their own. It transforms the value systems of followers in such a way that they start pursuing new ideals. Thus, the role of the transformational leader is to attempt to bring about followers' acceptance of a bold vision by inciting positive feelings toward desired behaviors. Change, then, comes about through an induced reevaluation of behavioral options by followers.

In contrast to transformational leadership, transactional leadership does not intervene in followers' value systems. Leaving these systems untouched, it tries to perceptually or materially model the contents of influence attempts to fit the existing values of followers. Followers become committed to supporting and implementing the proposals espoused by the leader because these proposals are intrinsically desirable and match their values and beliefs. The leader achieves this by clarifying or guaranteeing the profitability of requested efforts.

By the 1990s, issues of transformational leadership and charisma had become the dominant themes in leadership studies, and there was a proliferation of

models and perspectives on charismatic and transformational leadership. They emphasized, for instance, the connection between charisma and culture as well as between charisma and affective communication.

3.3. Individual Differences and Cognitive Processing Models

As theories on transformational leadership developed, new models in the domain of transactional leadership appeared, featuring a renewed interest in long since discredited trait-based models. Although trait approach research has been out of favor for a long time, recent work has once again suggested that stable individual differences in leader behavior do exist. Studies have become increasingly interested in the special endowments of leaders, and new models have focused on the intellectual and creative abilities of leaders. One good example of this development is the role motivation theory of organizational leadership that was introduced by Miner at the beginning of the 1970s and has been developing constantly ever since. The theory states that different leader attributes fit different types or roles in the organization and that leadership is a function of the larger organizational form within which it operates. Using a projective test, Miner described the type of motivational traits required for success in most leadership (management) positions in hierarchical organizations. Leader role requirements and the matching motive patterns are derived from the form of the organization. This person-organization fit model involves individual differences, strategy, organizational structure, and environment.

The individual differences research domain was strongly influenced by the information-processing concepts applied to the study of leadership perceptions. Cognitive research generally emphasizes the role of followers as well as leaders in leadership perception. Extensive research using an information-processing approach shows that individuals can be recognized as leaders based on their fit with leadership prototypes or that leadership can be inferred from favorable outcomes. Lord and colleagues' categorization theory and Mitchell and colleagues' attributional model represent that trend. The general idea is that leadership resides (at least in part) in the minds of the followers and that individual differences are important perceiver frameworks for assessing emergent leadership. This approach emphasized the role of individual differences in defining implicit theories or leader prototypes. The categorization theory assumes that relatively fixed

prototypes, which are learned through extensive experience by followers, are the basis for leadership categorization. Followers appear to share (within a context) a set of general beliefs about the characteristics related to leadership (e.g., decisive, determined, intelligent) in diverse situations and tend to use their implicit theories and leader prototypes to decide whether or not an individual is judged to be an emergent leader. Specifically, if an individual is perceived to match followers' leader prototype, the person is likely to be viewed as an emergent leader and rated accordingly. From Lord and Maher's theoretical perspective, although leader qualities are clearly important for understanding leadership, followers' social-cognitive process is also important. Attributional notions are also introduced into the leadership cognitive approach, and the mutual influence of a superior's behavior and subordinates' behavior on one another is considered, inserting each person's causal attributions into the loop as mediational variables. As for future developments using the cognitive perspective, Lord and Emrich suggested in 2000 that one promising area covers the effect of self-concepts and self-regulatory processes such as self-efficacy. Although much of the research in the cognitive domain has focused on the relationship between a leader's behavior or traits and subordinates' satisfaction, behavior, and performance, increasing attention is being devoted to understanding the intervening mechanisms, such as values and self-concept, with which leaders influence followers.

As for conclusions on leadership research, Sternberg and Vroom provided a clear summary about theoretical leadership approaches in 2002: "The persons, the situation, and the interaction of the person with the situation . . . all matter for leadership effectiveness." Other recent reviews of leadership literature have called for increased attention on leadership context (e.g., Lowe and Gardner in 2000) as well as a greater focus on personal attributes, especially in the area of executive leadership (e.g., Hooijberg and Schneider in 2001). Similarly, Lord and Emrich suggested, in their review of cognitive leadership research in 2000, that "information processing research has established . . . that leadership factors reside not only in the minds of followers, but also in the minds of leaders, in leaders' behavior and attitudes, and in the social context in which leaders and their followers interact."

Prejudice toward and discrimination against members of other groups can take a variety of forms and are caused by a number of factors. Their consequences for target group members are extensive and can potentially pervade all aspects of life. Several strategies for reducing prejudice and discrimination have been suggested, based on an understanding of the processes that serve to maintain negative intergroup relations. These strategies have led to the development of programs for use in educational and employment settings.

GLOSSARY

discrimination Negative behavior toward members of a social group based on group membership.

group identification The degree to which a person associates himself or herself with a group in terms of identity, shared interests, and outcomes.

group identity A person's view of, or sense of, himself or herself as a member of a social group.

illusory correlation Falsely perceiving a relationship between two variables where none exists.

in-group A group with which a person identifies or feels a sense of belonging.

minimal group paradigm Arbitrary assignment of individuals to different groups, with minimal information other than group membership provided.

out-group A group other than those to which a person belongs.

prejudice A negative prejudgment about or attitude toward members of a social group.

stereotypes Beliefs about the specific characteristics possessed by members of a social group.

1. STEREOTYPES, PREJUDICE, AND DISCRIMINATION

People are judged and treated not only based on who they are as individuals, but based on the various groups to which they belong. For example, almost universally, members of the national group within a country are viewed more positively and receive better treatment than immigrant groups. Traditionally, men and women have been seen as possessing different characteristics, and women have frequently been viewed as inferior to men, with consequences for their treatment in society. Thus, relations among individual members of social groups can be strongly influenced by stereotypes, prejudice, and discrimination.

Although stereotypes, prejudice, and discrimination are conceptually related, they are not necessarily highly correlated. People may hold similar attitudes toward a variety of out-groups, whereas their stereotypes of these groups

may differ considerably. For example, although people may hold similarly negative overall evaluations of two groups, they may perceive one group as lazy and unintelligent and the other as conniving and cutthroat. In such cases, the stereotypes differ but the overall attitude toward the two groups is the same. Of importance, prejudice is not always related to discrimination. One major reason for this lack of association is that people do not necessarily act on their attitudes, particularly when such behavior may be prohibited by society. For example, even though an individual may hold a negative attitude toward members of a particular ethnic group, that individual might not be able to overtly express this attitude or blatantly discriminate against a member of the group due to societal constraints.

Some people claim that prejudice and discrimination are things of the past and that they no longer influence individuals in society. Although it is the case that overt, blatant prejudice has decreased considerably in recent years, it seems to have been replaced by a more subtle, covert prejudice. This subtle prejudice may be the result of unconscious negative emotions toward a group (of which prejudiced individuals are not even aware). It may be expressed in situations in which appropriate behavior is not clear-cut and where a variety of explanations for the negative behavior are available. For example, an individual might not hire an immigrant job candidate based on claims about the candidate's lack of local experience, rather than expressing negative attitudes toward the candidate's group.

Prejudice and discrimination may operate at different levels of society. At an individual level, a single person may hold prejudicial attitudes and discriminate against members of other groups. At an institutional level, prejudice and discrimination may operate through the practices and policies built into the institutional framework, which may prevent the full participation of members of certain groups. At a societal or cultural level, prejudice and discrimination may operate through the beliefs and values of the society that encourage and justify discrimination against particular groups. In all cases, the consequence is that certain groups receive negative outcomes and are not able to enjoy the benefits of full participation in society.

2. CAUSES OF PREJUDICE AND DISCRIMINATION

Prejudice and discrimination may be caused by a variety of factors. Chief among these are several factors

that can be described as involving competition and threat. Realistic Group Conflict Theory and the more recent Instrument Model of Group Conflict propose that intergroup attitudes and behavior reflect group interests and are based, at least in part, on the nature of and the compatibility of group goals. When group goals are compatible, positive relations are likely to result. Conversely, when group goals are incompatible and groups are seen as competing for resources, conflict and negative intergroup relations are likely to result. Intergroup conflict, in turn, promotes hostility toward the competitive out-group. This hostility may be manifested in the expression of negative attitudes toward members of the other group and in attempts to prevent the other group from succeeding. For example, it has been demonstrated that when immigrants are seen as doing well and thriving in a difficult job market, members of the host population perceive increased competition with immigrants for resources and, therefore, are more likely to express negative attitudes toward immigrants and immigration. Relatedly, Social Dominance Theory suggests that threats to the in-group's power and dominance in society can lead to discrimination and willingness to aggress against less dominant out-groups. In such cases, prejudice may be driven by a fear of loss of social status or power rather than by a fear of loss of resources.

According to Social Identity Theory, for prejudice and discrimination to arise, it is not necessary to believe that a group is threatening tangible resources. Rather, the mere categorization of people into out-groups and an in-group stimulates a motivation to maintain or achieve a sense of positive group distinctiveness. As demonstrated in numerous studies using the minimal group paradigm, strategies for doing so include biases in evaluations that favor the in-group over out-groups and discrimination in resource allocations. In such cases, the motivation for a positive group identity may lead to processes that result in prejudice toward and discrimination against members of other groups.

Similarly, a number of recent theories have suggested that prejudice and discrimination may result from threats to values. For example, Symbolic Racism Theory proposes that prejudice against African Americans in the United States is partly attributable to a belief that African Americans threaten core American values, particularly those embodied in the Protestant work ethic (e.g., value of hard work, reward based on personal merit). Similarly, research on prejudice toward homosexuals has demonstrated that

perceived threats to religious and family values may form the basis of, and are used to justify, prejudicial attitudes.

Certain types of individuals are especially likely to perceive these types of threats and, thus, are particularly likely to hold negative attitudes toward other groups. Two personality variables that have been studied extensively in this context are right-wing authoritarianism and social dominance orientation. Right-wing authoritarianism involves submission to authority, belief in traditional values, and willingness to aggress against those who do not follow traditional ways. High right-wing authoritarians tend to be threatened by a variety of out-groups, particularly those that are seen as holding nontraditional values, and to hold negative attitudes toward these groups. In contrast, social dominance orientation involves a belief in inequality and preference for hierarchically structured social systems. Individuals who are high in social dominance orientation believe that unequal social outcomes and social hierarchies are appropriate, and they are especially likely to perceive threats to their group's status, power, and resources from other groups. As a result, they are especially likely to hold negative attitudes toward, and to discriminate against, other groups.

Group conflict and perceived threat, whether tangible or intangible, are not the only factors that can lead to prejudice and discrimination. There is a large body of research to suggest that people naturally categorize individuals into groups, particularly based on salient features such as sex, race, and age. Once people do so, a number of cognitive processes serve to promote stereotypes and prejudice toward members of other groups. For example, it has been demonstrated that the operation of an illusory correlation between a distinctive out-group (e.g., Asians) and a distinctive behavior (e.g., erratic driving) can result in an unfounded negative stereotype about members of the group (e.g., belief that Asians are bad drivers). Once formed, stereotypes are difficult to change due to selective attention to, interpretation of, and memory for stereotype-consistent information. In addition, once people categorize others into groups, they tend to exaggerate the similarities within groups and the differences between groups. Thus, members of an out-group are seen as all alike and as very different from members of the in-group.

In sum, the perception that a group is threatening the in-group's way of life and competing with the in-group for resources, power, status, and positive

identity can lead to prejudice toward and discrimination against members of that group. Individuals who are high in right-wing authoritarianism and social dominance orientation are particularly likely to perceive such threats. Cognitive factors related to the categorization of individuals into groups can also promote and perpetuate negative stereotypes and prejudice.

3. THE EXPERIENCE OF BEING A TARGET OF PREJUDICE AND DISCRIMINATION

Individuals belonging to groups that are negatively stereotyped in society are potential targets of prejudice and discrimination. How do members of such groups experience and navigate the social world with these added concerns? Central to this experience is identity. Although considerable variation in identification exists, individuals belonging to devalued groups (e.g., ethnic minorities, physically handicapped individuals, homosexuals) tend to identify strongly with these groups. This heightened identity is the result of a combination of factors such as awareness of the devalued identity and availability of social support from group members. For many members of devalued groups, then a significant portion of self-image and identity is tied to that group membership.

Even before members of devalued groups become victims of prejudice and discrimination, the knowledge of their devalued group identity can have adverse consequences. One example of these consequences is evident in research on "stereotype threat." Stereotype threat occurs in situations in which members of negatively stereotyped groups perceive the possibility of confirming a negative group stereotype through their behavior. For example, the stereotype of African Americans as less intelligent than European Americans creates anxiety for them in academic domains. In these domains, performing poorly would serve to confirm the negative stereotype of low African American intelligence. When faced with the threat of confirming a negative stereotype, performance is impaired and, over time, disidentification with the academic domain can occur. As a classic demonstration of the stereotype threat effect, when a test is described as a measure of academic ability and race is made salient, the performance of African American students is impaired. That is, African American students perform worse

than European American students taking an identical test and also worse than African American students who are not told that the test is a measure of academic ability or for whom race is not made salient. Ironically, this is particularly the case for African American students who identify strongly with academic achievement. Extensive research has demonstrated the potential for such impaired performance related to the stereotypes of a variety of groups (e.g., women and math performance).

Because of the awareness of the potential for prejudice and discrimination, individuals belonging to devalued groups may exist in a state of attributional ambiguity. This term is used to describe a state in which members of devalued groups cannot make clear explanations for the causes of negative or positive events that occur in their lives. For example, if an African American individual receives poor service in a restaurant, it might not be clear whether this occurred due to the prejudice of a server or to the fact that the restaurant was busy at the time. This ambiguity can exist even when positive events occur. For example, if an African American student receives a high grade in a course, it might not be clear to the individual whether this grade was due to his or her ability or to the fact that the professor was concerned with appearing nonprejudiced.

This ambiguity surrounding the causes of positive and negative events can have positive or negative implications for the self. Making attributions to discrimination can protect self-esteem by allowing individuals to maintain positive self-beliefs in the face of failure in desired domains. However, making constant attributions to stable, external, and/or uncontrollable factors has been shown to be related to poor self-esteem, feelings of helplessness, and depression. Research shows that devalued group members at times will make attributions to bias, whereas in other situations they are reluctant to attribute events to prejudice. There is a tension that devalued group members must negotiate between making accurate assessments of prejudice and protecting perceptions of efficacy and control. Although the state of attributional ambiguity is described as pervasive, not all members of devalued groups will perceive and react to attributional ambiguity in the same way. Assessing the antecedents and consequences of attributional ambiguity is important in understanding the experience of being a target of prejudice and discrimination, as well as in promoting the overall well-being of these individuals.

There are other costs associated with making attributions to prejudice and discrimination, including

social isolation, physical threat, financial loss, and emotional disturbance. Not surprisingly, individuals who belong to devalued groups are not always willing to perceive or admit prejudice and discrimination. One phenomenon that captures this is called the personal/group discrimination discrepancy. Researchers have found that individuals are willing to admit discrimination against their group in society, but are much less willing to admit that they personally have experienced discrimination. One factor that consistently affects the size of the personal/group discrimination discrepancy is individuals' identification with the group in question. Researchers have found that those higher in group identification are less likely to show the discrepancy; that is, they report more similar levels of personal and group discrimination than do those who are low in group identification. Perceiving or not perceiving discrimination has implications for numerous group processes such as identification and the willingness to engage in behavior that will help to improve the position of one's group in society.

In sum, the consequences of being a target of prejudice and discrimination are pervasive and begin even before observable negative behavior from others has occurred. However, individuals who belong to devalued groups are not passive recipients of biased treatment. They actively construct their world and experiences to protect and promote well-being and overall life success.

4. PSYCHOLOGICAL STRATEGIES FOR REDUCING PREJUDICE AND DISCRIMINATION

By being aware of the processes that lead to prejudice and discrimination, we can develop strategies for promoting more positive attitudes and behavior toward members of other groups. The contact hypothesis represents one of the most prominent approaches to prejudice reduction. In general, people are afraid of the unknown, which includes groups of people with whom they are fairly unfamiliar. However, the more knowledge about, understanding for, and experience with other groups that people obtain, the less negative and hostile people are likely to be. The underlying reasoning of the contact hypothesis is that if people are exposed to members of other groups in a variety of ways, they will become more positive toward members

of those groups and less likely to display prejudicial behavior. Nevertheless, it is not sufficient just to expose people to a minimal amount of information about another group or to live next door to someone who is of a different background. Several specific conditions must be met for the contact strategy to improve attitudes and behavior toward members of other groups.

Actual cooperation among members of the different groups is essential. In other words, people from the distinct groups should not be competing against each other for jobs, status, living space, money, and so forth. Cooperation between groups can be achieved by developing a common goal that can be achieved only if members of the different groups work together. Such cooperation will also help to develop a common identity that further decreases negative intergroup attitudes and discrimination. Equal status between the groups represents another important factor that underlies the contact strategy. In other words, it is critical that members of one group do not see themselves as superior to the members of the other group. Cooperative interdependence has been found to be helpful in superseding the presence of unequal status between two groups. In cooperative interdependence, each individual, regardless of group membership, is equally important for the task accomplishment.

Frequency, duration, and meaningfulness of interactions among the members of the different groups represent a set of factors that contribute to the effectiveness of the contact strategy. Specifically, the interaction among the members of the distinct groups should be frequent, long, and significant rather than occasional, short, and irrelevant. As a result, people will gain meaningful personal information about members of the other group. Social and institutional support is the final essential condition of the contact hypothesis. Contact between groups in the manner outlined here should be strongly supported by various levels of society such as the government, educational organizations, and employers. Overall, the contact approach provides a general framework consisting of several important factors that have been shown to contribute to decreasing prejudice and discrimination among members of different groups.

The second major approach to reducing prejudice and discrimination consists of categorization strategies. Two main strategies for restructuring people's mental representations of members of other groups have been suggested. Recategorization proposes the development of one common identity (i.e., us) rather

than distinct in-group–out-group identities (i.e., us vs them). The existence of a shared identity will decrease the salience of the differences that often exist between two groups and will highlight the commonalities that the members of the two groups share. As a result, this focus on the shared aspects of a common identity will decrease the negative attitudes and discrimination between the two groups.

Decategorization offers a different approach to restructuring the perception of “us versus them.” Rather than recategorizing separate identities by developing one shared identity, decategorizing signifies the elimination of group categorization. In other words, the removal of group-based typing will lead to the individualization of the members of the other group. As a result, they will be perceived as unique persons without the negative stereotypes that are traditionally associated with that specific group. This perception of people as unique individuals will further decrease the prejudice and discrimination that were brought about by intergroup differentiation.

It is also important to address the role of individual differences in the effectiveness of strategies for the reduction of prejudice and discrimination. For example, to decrease prejudice and discrimination, it is important to develop strategies that will counter right-wing authoritarian tendencies. One strategy that has received support is the personal value confrontation technique. With this technique, the discrepancy between people's ratings of the importance of freedom versus equality and their simultaneous support for discriminatory treatment of a minority group is highlighted. When the attention of high right-wing authoritarians is drawn to this incongruity, they tend to show improved attitudes toward the minority group.

In sum, based on knowledge of the processes that underlie prejudice and discrimination, strategies to counteract these influences can be suggested.

5. PROGRAMS FOR REDUCING PREJUDICE AND DISCRIMINATION IN EDUCATIONAL AND EMPLOYMENT SETTINGS

Several programs for reducing prejudice and discrimination in educational and employment settings have been implemented. As shown in [Table I](#), one way of thinking about these programs is to categorize them

TABLE 1
Programs for Reducing Prejudice and Discrimination
in Educational and Employment Settings

Enlightenment-based programs

- *Multicultural education*: Provide information on the history and cultural practices of a wide variety of groups and emphasize standards of acceptance and inclusiveness
- *Cultural diversity training*: Attempt to promote value of group differences and understanding of how behavior is influenced by people's culture and background
- *Moral development training*: Emphasize standards of behavior and values of social justice, fairness, and equality

Interaction-based programs

- *Intergroup dialogues*: Allow members of different groups to address areas of contention through discussion and recognition of different perspectives
 - *Cooperative learning and cooperative work groups*: Encourage cooperative interdependence among members of different groups working toward a common goal
-

as enlightenment-based programs or interaction-based programs.

The enlightenment-based programs generally involve increasing the knowledge that people have of other groups and altering people's perceptions of their relationships with others. These programs focus on changing the representation of members of other groups (e.g., reducing stereotypes, personalizing others, developing more inclusive representations) and on highlighting values relevant to tolerance and equality. For example, cultural diversity training programs are brought into industrial settings to teach managers and employees to value group differences and to develop increased understanding of other groups. Through this process, it is hoped that individuals will become committed to identifying and preventing the operation of stereotypes and prejudice in the workplace.

Interaction-based programs focus on bringing members of different groups together to provide direct interaction among members of the groups. They exert their influence through processes associated with intergroup contact. For example, cooperative work groups bring members of different groups together to work on a common task and emphasize cooperative interdependence whereby each person is dependent on the others for successful completion of the task. In the process, it is hoped that members of the different

groups will come to appreciate the contributions of all others, come to see each other as members of the same "team," and learn about the individual characteristics of others so that they are personalized.

Despite the plethora of programs to reduce prejudice and discrimination in educational and employment settings, the effectiveness of many of these programs has not been fully evaluated. Indeed, assessment of effectiveness depends critically on the specific outcomes desired. For example, is the goal to reduce stereotypes, change group representations, or reduce tension among members of different groups? Depending on the context and on the rationale for implementing a program in a new setting, one or another of these goals may be paramount. As a result, in choosing which program to introduce in an educational or employment setting, one must first identify the specific goals desired. Once an appropriate program is implemented, a continuing process of evaluation of effectiveness can be put into place.

GLOSSARY

crowding Perception that there are too many people in a situation.

privacy as a cultural universal The notion that all societies have developed mechanisms for regulating openness and closedness.

privacy mechanism Behaviors used to change the amount of openness or closedness in an interaction.

privacy regulation Selective control of access to the self or to one's group, that is, control over the degree of openness or closedness.

Privacy regulation refers to how individuals and groups control interactions with others, especially about confidential or intimate information or with respect to physical contact or access. All societies have developed mechanisms for regulating privacy, and effective use of these mechanisms is related to individual and group viability.

1. BACKGROUND AND DEFINITION

1.1. Definition

According to Altman in 1975, privacy regulation is defined as the “selective control of access to the self or to one’s group.” Although standard dictionary definitions equate privacy with seclusion and withdrawal, psychologists study privacy regulation processes as a dialectic wherein people ebb and flow between seeking and avoiding social contact. There are many applications of privacy theory, including privacy policies in hospitals and other businesses, privacy policies on Web sites, security screening, and planning for privacy regulation in the design and use of home and community settings. All of these applications must accommodate people’s needs to be open as well as closed or else they will be inadequate. Creating information management systems or designing settings that only allow people to close themselves off makes it difficult, if not impossible, for people to share information and/or connect with others, whereas systems and designs that encourage openness, sharing, and accessibility run the risk of preventing people from guarding their own secrets and/or screening out unwanted information from others.

“Selective control” means that people aim to manage whether, when, and with whom to be open or closed. They actively negotiate how accessible they want to be about themselves and their personal information. Decisions about openness/closedness, as well as

abilities to control degrees of openness, vary with time and circumstances. For example, among friends and acquaintances, there are some people to whom an individual is almost always available (regardless of his or her other desires, obligations, and activities), some people the individual talks to unless he or she is busy, and other people the individual avoids most of the time. With respect to strangers, the individual may ignore them completely or may be open in civil and polite ways. In some situations, the individual may eagerly seek interactions with strangers and view them as opportunities to form new friendships, interact across cultures, and/or create a more civilized community (e.g., pleasantries in a park or at sporting events). At the same time, it is important for the individual to maintain reserve with strangers until safety is ensured. The general principle is that people constantly and selectively choose how open or closed they desire to be. People often act in ways that help to achieve their goals, creating blends of openness and closedness for short or long periods of time.

“Access” refers to a two-way process of both receiving information from others and giving information to others. People monitor both what comes in and what is given out, and they decide whether to allow the information to pass. Information includes physical stimuli such as sounds, odors, visual information, and even the presence of someone at the door or on the telephone. Other information that people aim to control is economic and financial such as social security numbers, credit card numbers, and banking information. Information can also be more psychological in nature such as intimate and confidential information about people’s criminal or sexual histories, health problems, grades, and incomes. People try to maintain control over what they learn about others and what others learn about them. The importance of controlling information varies with the nature of the information, individual preferences, time, and circumstances, and people put more or less effort into privacy regulation for different reasons.

“Self or group” is included in the definition to emphasize that sometimes individuals are the focus of analysis and sometimes dyads and groups are the focus. That is, individuals regulate interaction with other individuals or groups, and dyads and groups often act in coordination to regulate interaction with outsiders. For example, privacy regulation within a marriage involves regulation between the spouses, between the spouses and their respective in-laws, and between the spouses and their friends or outsiders.

In sum, according to Altman,

Privacy is an interpersonal boundary-control process, which paces and regulates interaction with others. Privacy regulation by persons and groups is somewhat like the shifting permeability of a cell membrane. Sometimes the person or group is receptive to outside inputs, and sometimes the person or group closes off contact with the outside environment.

Thus, privacy regulation is dynamic, and people constantly monitor their needs and opportunities and then decide what levels of openness and closedness to seek or accept.

1.2. Privacy Mechanisms

People use many “mechanisms” or strategies for achieving their desired levels of openness and closedness. Some mechanisms are verbal or paraverbal (e.g., intonations of words), whereas others are nonverbal (e.g., interpersonal distance, eye contact). Many mechanisms involve the physical environment; examples include opening or closing doors, choosing more sociable or more secluded settings, and creating territories by claiming and defining places and their boundaries. Many mechanisms are technological; examples include answering machines and caller ID that allow an individual to selectively answer or ignore telephone calls, filters on e-mail that allow blacklisting of “spam,” and home-centered filters on television channels and Web sites to control what information children can access. Mechanisms that facilitate openness include instant messaging, videoconferencing, and the ready availability of cell phones.

Individuals can use privacy mechanisms alone or in combination to seek out or exclude others and information about others. With respect to the intimacy level in an interaction, sometimes a subtle facial expression is sufficient and sometimes a facial expression, physical distance, and changing the topic all are needed to achieve the desired level of intimacy. Similarly, with respect to physical contact, sometimes a single mechanism is sufficient and sometimes additional mechanisms are needed. Some individuals who are very skilled at privacy regulation can achieve contact with a telephone call and/or can achieve needed solitude without offending others, thereby leaving open future opportunities for interaction. As an example of the latter, consider the difference between “Sorry, I’m busy right now” and “Sorry, I’m busy right now but I’ll call you when I’m free.” The second version achieves

short-term solitude while maintaining opportunities for future openness.

2. IMPORTANCE OF PRIVACY REGULATION

2.1. Importance

Privacy regulation serves critical individual and interpersonal functions. Individuals need to be able to regulate how much stimulation they receive and how much information others have about them. They need to control their physical environment and keep control over resources such as food, time, and space. Individuals and groups that can be easily intruded on, stolen from, forced to disclose secrets, and/or violated in other ways can lose a sense of self. Similarly, individuals and groups that cannot connect with others for personal or professional goals are isolated and unable to participate in interpersonal activities that are essential for functioning effectively in society. Individual and group viability is an important consequence of effective privacy regulation.

2.2. Privacy Regulation as a “Cultural Universal”

Because of its importance to effective functioning, privacy regulation is acknowledged as a “cultural universal,” meaning that every society has developed mechanisms so that individuals and groups can regulate interactions with others. Particular privacy mechanisms vary from one group to another, and use of privacy regulation mechanisms is usually guided by cultural norms, customs, and styles of behavior. Examination of societies around the globe shows that they vary in their preference for being relatively open or closed, but even the most open societies have mechanisms for closing themselves to others and even the most closed ones have ways of opening themselves up to others.

Most societies treat homes as places where individuals can withdraw, knowing that they can develop selected relationships and will rarely experience unwanted visitors. Visitors are expected to call ahead or announce themselves in other ways and then wait to be invited inside. In some situations, residents signal their availability to guests. For example, in traditional Egyptian Nubian homes, decorative plates are mounted on the homes’ exteriors but are removed

when the families are in mourning. The presence or absence of the plates signals to visitors whether they would be welcome. The Navajo in the southwestern United States have a custom that gives control over visitors to residents: Visitors do not knock, but they make themselves visible and wait for residents to invite them in. In some societies or for some groups of people, it is acceptable to use “keep out” mechanisms if people so choose, and no offense is taken when people leave the room, go on extended trips, or simply ignore visitors. In other groups, these and other “keep out” mechanisms are acceptable if people are busy working but are less acceptable if people are involved in other activities such as entertainment and loafing. The statement that someone “needs space” affirms the idea that people can legitimately vary between degrees of openness and closedness.

There are many privacy regulation mechanisms for the control of confidential information, and their use depends on many factors. Interpersonal distance controls access to some personal information (e.g., odors such as alcohol on the breath, physical details about age such as gray hair and wrinkles). Controlling verbal information is quite common as people choose to disclose or not disclose confidential information. In some groups or for some people, not only refusing to disclose but also actively lying is acceptable as a privacy strategy. Although people may use evasion or lying to control information, in many societies (e.g., the Javanese in Indonesia) lying is rarely needed because confidentiality is respected and it is considered rude to inquire too much about other people’s business.

In 2002, Petronio suggested that privacy rules and mechanisms often change and evolve so that they work most effectively for each group. She noted that many groups negotiate both general and specific privacy regulation rules. An example would be a group that shares confidential information and understands that the information should not be disclosed to the general public but negotiates specific details such as whether spouses or particular friends could be told some part of the story. Thus, the group co-owns the information, agrees to cooperate in protecting it, but negotiates particular boundaries around different parts of the information.

As computers make sharing of confidential information easier, mechanisms are being developed to control who has access and for what reasons. Privacy policies on Web sites promise that credit card information is protected from theft, that one can choose whether to be contacted, and that one’s contact information is not shared without permission. An important difference

between U.S. and European Union rules lies in the “opt-in” versus “opt-out” wording of these policies. In the United States, a company assumes that it can use or even share contact information for promotional purposes unless consumers explicitly notify the company to keep their identities confidential. In contrast, in the European Union, the opposite is assumed, and consumers must notify the company of their willingness to share identity information.

3. LONELINESS, CROWDING, AND CRIME: CONSEQUENCES OF ADEQUATE AND INADEQUATE PRIVACY REGULATION

3.1. Dynamics of Privacy Regulation

As illustrated in Fig. 1, privacy regulation is a dynamic and ongoing process. People develop a desired level of contact with others, compare that desired level with their actually achieved level, and activate privacy regulation mechanisms (if needed and possible) designed to reach their desired levels of contact. When people desire more contact than they are experiencing, they feel lonely and select mechanisms that will bring them into contact with others. When people desire less contact than they have achieved, they describe themselves as crowded or overwhelmed and select mechanisms that will reduce their levels of contact.

Judgments about crowding and loneliness are very subjective and can be based on interaction partners, topics of conversation, and whatever alternative activities might be available. An individual can feel lonely in a crowd of people if the particular people the individual wants to be with are absent. The process can be very fluid. An individual can join a group and feel that his or her social contact is optimal, spend some time with that group but then begin to feel crowded or lonely, and then move to a different group and feel that social contact is optimal again. Problems with privacy regulation can occur when individuals or groups lack the behavioral and interpersonal skills needed to seek out or avoid contact with others or when the physical or social environment makes privacy regulation difficult.

3.2. Viability

The ability to manage privacy is related to viability, that is, the ability to thrive, achieve goals, grow, and adapt to a changing environment. Research suggests that individuals and groups that do a better job of regulating interactions are more viable. Measures that tap viability have varied and include psychological variables such as satisfaction with the environment, satisfaction with social relations, improved task performance, greater task persistence, less stress, and other evidence that people are successful in achieving their short- and long-term goals. Several lines of research

FIGURE 1 The process of privacy regulation.

have addressed relationships between privacy regulation and indexes of viability. These include loneliness, crowding, family and community relations, burglary and crime, and interaction stress in offices, prisons, hospitals, and other public settings. Typically, a combination of intrapersonal and sociophysical factors contribute to viability. For example, in one study, when pairs of naval recruits began an isolation mission by clearly establishing and maintaining separate territories that gave order to and allowed control over daily activities, they were more likely to complete the mission successfully. In contrast, pairs who did not create separate spaces did not perform as well on daily assignments and were more likely to abort the mission before the completion date. Thus, viability was related to successful management of privacy.

Another study asked dormitory residents what strategies they used for privacy regulation, that is, what they did when they wanted to make contact with others and what they did when they wanted to avoid contact. These strategies were related to one index of viability: whether the students chose to return to school the following year (excluding academic expulsions). Again, viability was related to effective strategy use. Students who remained in college were more likely to use both opening and closing mechanisms and to state that the mechanisms were successful. Students who dropped out reported using fewer of the successful mechanisms and also reported using other mechanisms that did not help them to achieve their desired levels of contact.

3.3. Loneliness and Privacy Regulation

Loneliness is usually considered to be a problem stemming from a lack of individual skills, but solutions include both skills training and restructuring of the physical environment. Clinical and counseling psychologists have developed training programs designed to help people learn how to make and maintain friendships, and some of these programs have been quite successful. Equally important is research suggesting that physical and social environments play a role in supporting or discouraging contact. For example, one university study found that foreign students could regulate interactions with family members inside their apartments but had difficulty in making friends with residents in the courtyard. One explanation is that the foreign students had difficulty because the customs

and strategies for making contact in the United States were different from those in their countries of origin; for example, the Asian students did not feel comfortable in making casual “small talk,” whereas that was how U.S. students tended to initiate interactions. The housing director began to provide additional settings in which U.S. and foreign students could interact. Another study found differences in friendship patterns in inner-city public housing developments to be related to the physical environment. These researchers found that having green spaces close to residents’ apartments was related to increased informal contact among neighbors, larger social networks among adults, and higher rates of child–adult contact and interaction in the outdoors. In essence, residents were drawn to green spaces, and this increased proximity led to informal contacts that then led to deeper friendships.

The importance of the physical environment in providing opportunities for friendship formation is well known from research on proximity in housing developments as well as from research on public gardens as a context for friendship formation. A growing trend in community development is to use design features that invite people to spend time in community settings. These include streets that invite walking (e.g., storefronts at the sidewalk instead of behind parking lots, safe tree-shaded streets with attractive architecture, few cars or low speed limits, things to look at along the way, proximity to shopping and other services) and the availability of parks and green spaces where children and adults can congregate. These studies combine to suggest that coupling social skills training with supportive physical and social environments is all important for helping people to avoid loneliness.

3.4. Crowding and Privacy Regulation

One of the most well-researched areas in privacy regulation is crowding. Unlike being “cramped,” where one person has too little space to accomplish tasks, crowding always involves more people than one desires or too little space for those people in a setting. Crowding occurs when an individual or group feels too accessible to others. For example, the phrase “two’s company, three’s a crowd” captures the idea that it is not the sheer number of people but rather one’s goals in an interaction that determines whether one experiences crowding. Similarly, being part of a crowd at a football game not only is not crowding but actually part of

the fun of being a fan is the presence of numerous others.

Theories and research on crowding have focused on “control” and the lack of control that accompanies the experience of crowding. Loss of control is an important construct because it connects the work on privacy regulation—and the theory’s central idea of selective control—with research on stress and stressors. Stressful events are often characterized by a loss or lack of perceived control. Sometimes, people experience crowding stress because they cannot control the amount or type of stimulation they receive from others such as crowd noises that overwhelm them. Related to this is crowding stress that occurs from uncontrolled interaction with others such as too many people at a party and too many neighbors in a housing complex. Sometimes, stress occurs because people interfere with or frustrate each other’s goal attainment, as might occur when too many people try to get on a subway or freeway, when a third person thwarts dyadic intimacy, or when there is no space to sit at the park or on the beach. Another common basis of crowding stress is resource based and occurs when there are too many people for the available food, water, and space. All of these bases of crowding are subtle variations on the idea that other people can undermine people’s sense of control over their own goals as well as over their interactions with others.

Studies conducted among college and university dormitory residents revealed that crowding was related to negative effects on friendship formation, lower satisfaction with and commitment to their academic institution, and lower grades. Housing three people in a room resulted in unexpected social dynamics. Male students tended to withdraw from the situation and leave the room to study at the library or spend time with friends. Female students tended to form “two against one” coalitions that left one student feeling alone and rejected. These problems were reversed when students were housed two to a room.

Social dynamics are also a problem in large dormitories (i.e., 32–40 residents) compared with both dormitories providing differentiated spaces and smaller dormitories (i.e., 6–20 residents). Sharing a dormitory with large numbers of residents makes it difficult to learn individual names and differentiate one student from another. It also makes it difficult to avoid social contacts when walking down the hall or using the shower. Initially, students in large residence halls may try to assert control and regulate their interactions, but eventually they stop trying as much to do

so. In one experiment, students in large dormitories reported a variety of social and educational consequences. They spent less time socializing, began to ignore other residents, complained about greater difficulty in controlling interactions, and said that they had more unwanted interactions. They also reported evidence of learned helplessness such as putting less effort into trying to control interactions with others and finding quiet places to study.

Research also shows that although people can tolerate high density for short periods of time, sustained high density for several weeks is stressful by itself and can exaggerate other stressors, including the stress of daily hassles. To add to these problems, friendships often deteriorate under the stress of high-density living, and people lose opportunities for social support that would ordinarily help to buffer them against stress.

In addition to helping to understand relationships between density and stress, these studies have been valuable in showing design features that give more control to residents and reduce crowding stress. For example, dormitories are now designed as suites or apartments to create smaller subgroups of residents. Breaking up long hallways into separate areas and providing kitchens, bathrooms, and social areas for each group gives residents manageable numbers of interactions, gives more control over who uses their spaces, reduces competition for resources, and restores order to interactions. Suite or apartment designs house six or more students together, with central common areas surrounded by separate sleeping areas. The common living room and bathroom encourage residents to function as a group, whereas the separate sleeping rooms each house two students, allowing them to withdraw from the group as needed but also allowing them to form closer relationships with a smaller number of residents. In theory, each cluster or pod then becomes a viable social unit that can interact with other similar clusters in the larger dormitory building.

Research has also examined how to optimize functioning in homes and apartments, regardless of whether residents are related, involved, or living together as roommates. Some groups develop effective rules that allow individuals to regulate interactions with others. People can use open and closed doors and verbal messages (e.g., “I need to study now”) to signal their accessibility and inaccessibility. In many cases, design features can support such regulation. People can withdraw to their bedrooms, can study, or can use the bathroom if they desire to be alone.

Research indicates that homes and apartments with highly differentiated spaces (i.e., more small rooms with separate access via hallways) give residents more control over their interactions (i.e., allow them to decide whether to be open or closed to others) and reduce crowding stress. The ability to avoid contact must be complemented by opportunities for making contact. In most apartments and homes, people can gather in common areas, such as living rooms and family rooms, when interaction is desired. Often, people are attracted to rooms with activity opportunities such as television sets, games, and stereos. These areas become “behavioral focal points,” that is, spaces whose design, location, and function invite people to gather together.

Another design feature that supports privacy regulation is the “privacy gradient,” that is, the idea that places in homes vary in their physical accessibility to outsiders. This physical accessibility should parallel residents’ desired accessibility. Some rooms and spaces are close to the entrance, whereas others are deeper in the home’s interior and so are less accessible to outsiders. The front yard, main entrance, and entryway all are fairly accessible to anyone who desires contact. Living rooms, dining rooms, and guest bathrooms tend to be formal areas where strangers and visitors might be invited. Places such as the kitchen, family room, bedrooms, and family bathrooms are typically used exclusively by residents. Managing interactions may be facilitated when the physical layout of the home or apartment puts public areas closer to the entrance and private areas far from the entrance and less accessible to visitors.

3.5. Privacy Regulation in Other Settings

Research on residential crowding has been paralleled in prisons, homeless shelters, hospitals, and similar settings, and the results have generally been similar. Living in undifferentiated spaces with numerous others is stressful. Aggression and crime can be high, and residents feel vulnerable and unable to control interactions. For example, in dormitory-style prisons, there were high aggression rates as well as high stress-related illness rates. Redesigning these spaces with simple barriers that gave each inmate a separate area around a bed reduced stress levels considerably. Consistent with the idea that privacy regulation involves openness and closedness, the prisons did not completely enclose each prisoner. Walls were low enough and entryways

had no doors, so that guards could ensure safety for each prisoner and monitor for illegal activities.

3.6. Crime and Defensible Design

Public housing in the United States has become notorious for its physical unattractiveness, lack of upkeep by residents and staff, and high crime rates that include drug abuse, minor and major property crimes, gang warfare, and even murders and drive-by shootings. For more than 50 years, social scientists have tried to understand the bases of this disorder so as to correct it. A central issue is the extent to which the housing developments themselves undermine positive social relationships. Comparisons of different configurations indicate that developments with more “defensible designs” yielded more viable communities. Design elements allow residents to differentiate legitimate users from outsiders, encourage residents to use outdoor spaces and become protective of their own territory, and allow residents to use passive surveillance to monitor legal and illegal activities. In this way, defensible design can be viewed as a privacy regulation mechanism. There is no simple panacea to problems associated with many housing developments, but some essential design features include limiting the numbers of residents so that they can recognize one another and distinguish residents from outsiders (this is often accomplished with relatively low numbers of floors and limited numbers of apartments on each floor and with separate entrances and separate elevators), windows that allow surveillance of the outside area, outside gathering areas that provide activities and seating for multiple age groups, attractive settings to increase pride in place, and clear differentiation of the private setting from the public street.

Most of the research on defensible design has been done in public housing developments. These ideas have been replicated in middle-class suburban neighborhoods, where homes and neighborhoods with more defensible space are less likely to be burglarized. Neighborhoods are less likely to attract burglars when they appear to have stronger territorial claims, that is, when the homes are personalized and the homes and neighborhood convey the impression that residents feel a sense of ownership over the space and would react to the presence of suspicious strangers. The roads appear to be less public (i.e., fewer traffic signs of all types), sites allow surveillance from one home to another, residents appear to spend time on the block, and intruders are often challenged by residents or reported

to the police. Sense of territorial control is also apparent at each home site. The home and yard are personalized with names and house numbers, and there is often evidence that someone is at home (e.g., toys and tools are in the yard, mail and garbage are picked up). Surveillance is clearly possible because shrubs do not obscure the entrance or the windows, and homes are sited so that neighbors can observe each other's homes. When burglars are asked to indicate which homes they are not likely to target, they usually indicate the homes where they would expect the resident or a neighbor to challenge them if they tried to enter.

In sum, the physical environment serves important privacy regulation functions. Environments that provide clear differentiation between public and private areas are less likely to be intruded. Neighborhoods and housing developments whose designs support neighborly friendships also support creation of neighborhood territories and defensible spaces. These spaces also contribute to enhanced control over who can enter and who cannot as well as to what people can do in these spaces.

4. TECHNOLOGY AND PRIVACY REGULATION

4.1. Communication Technology and Privacy

As people increasingly use technology to connect them to the world, people are also developing technological mechanisms that allow them to control their accessibility and inaccessibility to others. People use cell phones, telephones, fax machines, e-mail, and the World Wide Web 24 hours a day to contact friends and business associates. They can meet new people, learn new ideas and philosophies, try on new personas, and even fall in love using Web-based exchanges. They can also send pictures through their telephones and the Web. Television is expected to allow Web access that will expand the ability to select programs, movies, sports events, and so on. Sophisticated cameras provide surveillance to increase safety in parking garages, on university campuses, and elsewhere, and cameras are used to cite motorists for speeding and other violations.

Each of these opportunities comes laced with issues essentially involving tensions between openness and closedness. How and when do people control their accessibility to others? How can people trust the honesty of others they meet online? If people have cell

phones, should they be available 24 hours a day? Does owning a telephone and having telephone service mean that telephone solicitors can contact people, or can people decide who can call them and who cannot? Do Web and television access mean that children can view material that is intended for adults? How can children be protected from Web-based crime, including adults who use chat rooms as a base for contacting and harming children? When does surveillance become intrusive?

Extensive discussions of these and related issues have begun to lead to a variety of solutions. This article addresses proposals in the United States, although other countries are dealing with similar issues. Efforts are ongoing to find ways of modifying and improving these control systems so that they provide opportunities for openness while protecting people from serious harm as well as minor inconveniences. Just as different but effective privacy mechanisms have evolved in different cultures, privacy mechanisms are continuing to evolve as new technologies open the world to people. Some strategies that allow selective access already exist such as caller ID on telephones, unlisted telephone numbers, listed numbers that omit home addresses, and Web search engines that screen children from pornography but allow adults wider access.

At the same time, marketers selectively target particular consumers using information gathered on the Web, grocery store "preferred customer" spending patterns, and credit card files and other sources. Advertisers seek to use this personal information to target marketing to the most appropriate and receptive consumers. They emphasize the importance of free and open access to consumers as a way of maintaining a vital economy. Knowing individuals' family sizes and configurations, buying habits, business and recreation preferences, annual incomes, and other information allows companies to target consumers with promotional materials. Some consumers enjoy receiving this material, regardless of whether it comes through the Internet, telephone, or mail, whereas others consider these contacts to be intrusions and seeking ways of preventing such marketing. Privacy regulation strategies include state and federal legislation as well as commercially available screening systems and personal controls.

Faxes and telephone calls are regulated by the Telephone Consumer Protection Act of 1991. When fax machines first became widely available, marketers sent unsolicited promotional materials. Because consumers could show evidence of harm—the recipient had to pay for paper and ink, and incoming offers tied up their fax machines—federal rules supported

recipients over senders. Faxes could not be sent without permission or an existing relationship (e.g., organizations could fax conference announcements to members). A more restrictive rule, requiring recipients' written permission before faxes can be sent, was under review at the time of this writing.

Similarly, telephone solicitors created sufficient problems (e.g., calling at dinnertime; taking financial advantage of people) that federal policies and supportive legislation have been put into place to allow people to put their names and telephone numbers on "do not call" lists, with no charge to consumers but with hefty penalties to marketers for violations. The policy was challenged in court and was on appeal at the time of this writing. This list is for interstate commerce, and each state must enact its own "do not call" list to regulate local marketing calls. Some states want consumers and marketers to share the cost of this service, indicating their belief that telephone solicitors have a right to make calls and that consumers should pay to assert their right not to be called.

E-mailed solicitations (derisively called "spam") have been more difficult to stop, in part because there is less apparent harm to consumers and marketers claim that unsolicited e-mails could be seen as a necessary nuisance. Also, many senders immediately change their e-mail addresses or otherwise conceal their identities, making it difficult to screen future mailings or locate the senders if the behavior is declared illegal. Evidence of harm has been claimed by Web administrators whose server equipment must handle large numbers of unsolicited and unwanted e-mails daily. These administrators are pressuring the federal government to stop spam.

4.2. Health Care Privacy

The appropriate blending of openness and closedness is also a central issue in health care privacy. Patients may wish to be accessible by sharing test results among several doctors or by receiving information about new medications and medical procedures for their particular conditions, they may need an efficient way in which to get billing information to their insurance company, they may wish to receive test results on the telephone, and so on. Therefore, delimited openness of medical information can be beneficial. On the other hand, patients may wish to disseminate only information about particular medical conditions, may be uninterested in hearing from marketers, may want to withhold some information from insurance companies (even to the point of paying privately for some tests so that

insurance companies will not perceive them to be risky clients), may want to receive test results only on a confidential telephone line (rather than having a coworker take a message), and so on. A major concern has been that patients' fears about control over information might make them unwilling to be open and honest with their doctors, thereby putting their health at risk. Patients might not disclose illegal or embarrassing behaviors, past health problems, health problems of relatives, and other private concerns, lest this information be widely disseminated without their explicit permission. People may opt out of genetic tests that can yield important information because they fear that employers might get the information and use it for insurance coverage or employment decisions.

Federal legislation begun during the Clinton administration and modified during the Bush administration has addressed some of these issues. The Health Insurance Portability and Accountability Act of 1996 (HIPAA, modified in 2002) requires a single signed consent to allow access in three domains: "treatment" (provision of health care and related services), "payment" (submitting insurance claims and determining eligibility), and "health care operations" (broadly defined sharing of information). The bill has been criticized for being coercive (people in health plans often must sign to receive treatment) and for the vague and broad scope of the third provision. Others have commended the plan for bringing a national uniform rule to these issues and for increasing access as well as control. For example, it is now easier for doctors to share patients' medical records, and there are fewer insurance approvals to sign (due to the single signature requirement). Control over information is more specific under this rule. Psychological and psychiatric records cannot be shared without a separate signature specifically for that information. With respect to test results, doctors must now ask how to contact the patient and whether leaving a message is acceptable. Also, without explicit permission, hospitals cannot even disclose whether someone is a patient, let alone disclose health status.

It has taken many years and much discussion to develop and enact HIPPA. Balancing access with confidentiality is a difficult task, especially when widespread use of computerized databases makes it easy to share confidential information and easy to inadvertently or deliberately share information that should be protected. Some patient advocates consider HIPPA to favor the medical system over individuals' rights to privacy, and reform efforts are under way. This is an issue that will receive ongoing attention as people seek

to achieve desired openness and closedness under changing circumstances.

5. SUMMARY AND CONCLUSIONS

5.1. Overview of Importance of Privacy Regulation

Privacy regulation is the selective control of access to the self or group. All societies have developed strategies through which their members can regulate interactions with others, although each society sets different standards of openness and closedness and has evolved different mechanisms for regulating privacy.

Privacy regulation involves many different kinds of events—from people standing too close in subways to burglaries being committed in neighborhoods, from concealing information about one's test scores to lying about medical conditions to obtain insurance. Privacy regulation also involves managing relationships to achieve a desired level of intimacy, perhaps by disclosing secrets to deepen a relationship or by avoiding listening to disclosures to maintain the relationship at a less intimate level. Privacy regulation involves choosing the levels of openness and closedness that one desires and then trying to achieve those levels by activating various privacy regulation mechanisms. Individuals and groups that can regulate their privacy are more viable and more likely to achieve their goals. When desired privacy is not achieved, people often complain of stress.

5.2. Prospects for the Future

Privacy regulation has been practiced and refined for centuries, yet people still have difficulty in managing interactions. This is due in part to differences between individuals in expectations about how open people should be and how to convey this through privacy regulation mechanisms. These problems occur in part due to cultural differences. As people immigrate to new countries, residents and new immigrants must recognize differences in privacy goals and strategies. Possibly, once people are aware of these differences, they can work on accommodating each other's preferences or on recognizing the cues used to signal whether the other wishes to be more open or more closed. In a changing situation, privacy regulation mechanisms and desires can also be changed.

Another source of problems is the rapidly changing technological environment and pressures to use

technology for more openness. Psychological research on privacy suggests the following principles for guiding the use of these technologies:

1. *People should have reasonable control over others' access to them and people's access to others.* People should be able to proactively and reactively open and close themselves to others as they desire and see fit. This principle highlights privacy as a dialectic process of opening and closing rather than closing alone. It also emphasizes the importance of both a proactive and a reactive control capability. People should be able to proactively initiate openness or closedness rather than just react passively to the world.

2. *People may need a new or enhanced repertoire of regulatory mechanisms to control openness and closedness during the technological era.* Traditional face-to-face communication uses particular verbal, paraverbal, environmental, and cultural mechanisms. Although some of these mechanisms may apply during the technological arena, additional mechanisms—unique to new modes of communication—might be necessary.

3. *A dynamic privacy regulation system, with the ability to shift desired openness and closedness as circumstances change, will continue to be necessary and may require innovative applications of technology.* For example, some people like the anonymity of chat rooms, whereas others fear being lied to and deceived. To address this, some Web chat rooms may continue to be wide open and allow people to adopt personas and play out fantasies. In other chat rooms, participants may insist on knowing background information on each other and may agree to post authenticated vitae as the price for participating.

4. *Awareness of the importance of privacy regulation must be at the forefront of technological innovations.* Mechanisms that allow flexibility in achieving openness and closedness will be most successful.

GLOSSARY

effectiveness A measure of outputs compared with goals or standards; examples of effectiveness measures would include actual billable hours divided by the standard or expected amount of billable hours and actual percentage of returning customers compared with the goal of returning customers.

efficiency A measure of outputs divided by inputs; outputs are the products or services of the organization such as radios produced, customers satisfied, and/or clients seen, whereas inputs can be all inputs needed to produce the outputs such as labor, equipment, supplies, energy, and buildings.

feedback Information provided about employee behavior and outputs; it can be in many forms, including providing information on the amount or quality of work completed, subjective ratings of performance by managers, information provided informally by peers and subordinates, and a person's own perceptions about his or her work done.

goal setting A process whereby the subordinate and his or her supervisor jointly agree on a specific quantitative level of output that the subordinate will produce during the next work period (e.g., increasing revenues by 4% in the next quarter); less formal goal setting might be plans to make improvements or general intentions to perform better in the future.

incentives Outcomes of value that are provided to employees based on their levels of performance; most common are monetary outcomes (e.g., bonuses, incentive pay) and outcomes that have monetary value (e.g., vacations, sports equipment).

performance A general term that can refer to the amount or quality of the outputs produced, an evaluation of the outputs produced, or some combination thereof; it can be applied to an individual or to a much larger unit such as the total organization.

performance appraisal A process whereby one's supervisor, and sometimes one's peers and subordinates, evaluate the performance of an individual and provide this evaluation as feedback to that person; it is typically done with a series of ratings on various dimensions of performance such as technical knowledge and oral communications skills, but it can also include objective data on the quantity or quality of work done by the individual.

performance management A general term that includes all techniques used to influence and improve the performance of employees in organizations; such techniques include training, feedback, control systems, goal setting, and incentive systems.

productivity A term that can be defined in multiple ways, with the most traditional being outputs divided by inputs, usually expressed in monetary terms; it is also commonly defined as efficiency (outputs over inputs) plus effectiveness (outputs relative to a standard or goal).

productivity improvement Improvement in productivity measures over time.

role clarification Techniques used to make the expectations of the organization clear to the individual; examples include discussions about expectations with one's supervisor, formal systems that identify the relative importance of different parts of the work, and information systems that indicate what the priorities are for making performance improvements.

Productivity is an important topic, and the field of psychology has made many contributions to understanding and improving productivity in organizations. Productivity, especially improving productivity, has important benefits ranging from global effects to effects on individuals' quality of life. There are a number of different definitions of productivity, and it is important for communicating with others to be clear on what definition is being used. Psychologists focus on improving productivity by influencing people's behavior, especially through techniques such as feedback, motivation, goal setting, incentives, and role clarity. Measuring productivity is complex, and this article describes both the purpose of the measurement and the criteria for good measurement. Once measured, productivity is normally used as feedback, so the article summarizes criteria for optimal feedback design. Finally, the article notes specific approaches to measuring and improving productivity.

1. INTRODUCTION

1.1. History

Labor economists originally used productivity as a formal term during the early 1900s. During the 1950s and 1960s, the United States was the most productive country in the world, and there was little doubt that this state of affairs would continue. However, by the 1970s, American superiority in productivity was being threatened by productivity in other countries, and this was seen as a major concern that would lead to serious long-range economic problems. For example, the success of the Japanese in U.S. automobile and steel markets led to plant closings and lost jobs, major U.S. companies were in severe financial difficulties, and what had historically been a trade surplus became a trade deficit that was increasing.

1.2. Productivity as a National Issue

Although many causes were responsible for these problems, loss of clear U.S. superiority in productivity was seen as one of the major ones. Because of this, productivity and productivity improvement became issues of great social and political importance, not only in the United States but in all industrialized nations. This led many other disciplines, besides economics, to focus on productivity issues, and one such discipline was psychology.

2. DEFINING PRODUCTIVITY

Defining productivity is a difficult task. Since the 1970s, behavioral scientists of many types have worked in the area of productivity, resulting in a proliferation of definitions of productivity. However, the vast majority of definitions fall into one of three categories.

2.1. Efficiency

The first category defines productivity as an efficiency measure where outputs are divided by inputs. Thus, the number of outputs generated, such as refrigerators, potatoes, or university graduates, is divided by the inputs used. Such inputs usually include raw materials, labor, energy, and so forth. Typically, both outputs and inputs are measured in terms of cost, so that the two can be divided to form a ratio that is interpretable across different settings. This definition is used by most economists and by some behavioral scientists.

2.2. Combinations of Efficiency and Effectiveness

The second definition of productivity is a combination of efficiency and effectiveness. Efficiency is the output/input measure used in the first definition. Effectiveness is the ratio of outputs relative to some standard or objective. For example, the number of trucks produced relative to a specific quantitative goal is an effectiveness measure. Those taking the approach that productivity should include both efficiency and effectiveness argue that both are necessary for a complete definition of productivity. One such definition is that productivity refers to how well an organization uses its resources to achieve its objectives.

2.3. Broader Definitions

The third type of definition is the most broad one and essentially includes as productivity any characteristic that makes the organization function better. This approach includes efficiency and effectiveness but also includes factors such as quality of output, work disruptions, absenteeism, turnover, and customer satisfaction.

2.4. Definitions and Clear Communications

It is important for anyone working in the area of productivity to be aware that these different definitions exist. Some researchers and practitioners are very rigid in their choice of definition and do not accept that the other definitions are “productivity.” Thus, for effective communication, the same definition of productivity should be used by all.

3. THE IMPORTANCE OF PRODUCTIVITY

Productivity and productivity improvement are important because they influence many aspects of our lives. They have effects that range from global effects to those on specific individuals.

3.1. Global and National Benefits

Increased productivity means generating the same goods and services with less inputs. Thus, it is a way in which to conserve societal or global resources ranging from trees to human labor. Increased productivity also allows for more outputs to be available for the same inputs. Thus, we can be closer to a global society of plenty while using less of our global resources. At the national level, there are clear ties between productivity and important economic outcomes such as controlling inflation. For example, the real cost of goods is influenced by productivity because productivity improvement results in producing the same goods for lower costs. Assuming a roughly constant profit margin, the real cost of goods decreases as productivity increases.

3.2. Benefits for Industries and Specific Organizations

Productivity and productivity improvement are also important at the levels of the industry and the individual

firm. If productivity improvement of an industry or a firm is higher than that of its competitors, that industry or firm will more likely survive and prosper. Costs and prices are lower, thereby making those products and services more competitive in the marketplace. This leads to higher sales, greater profits, and more jobs.

3.3. Benefits for Individuals

Productivity improvement can also increase the quality of our lives. Productivity gains will lead to efficient use of our time and more leisure time, and high productivity is a key to advancement in organizations. Equally important, people like to be productive. It is a central aspect of self-fulfillment and self-respect.

4. IMPROVING PRODUCTIVITY

The major reason why people focus on productivity is to improve productivity. It is by improving productivity that the gains from the global level to the individual level can occur.

5. APPROACHES TO PRODUCTIVITY IMPROVEMENT

There have been two major approaches to improving productivity. The first is through a change in technology. Some economists argue that most or all major improvements in productivity can be traced to technological improvements. The other approach is behavioral. Behavioral scientists argue that new technology can improve productivity only if organizational personnel use it effectively; thus, technological improvements also require a behavioral component. Furthermore, behavioral scientists argue for the importance of issues such as performance measurement, motivation, feedback, goal setting, incentives, and role clarity. It is here that the field of psychology has made the greatest contributions.

6. MEASURING PRODUCTIVITY

To improve productivity, it is important not only to measure it but to measure it well. However, productivity measurement is very complex, and a number of issues must be considered in designing a productivity measurement system.

7. PURPOSE OF MEASUREMENT

The first step is to decide on the purpose of the measurement because that decision will affect how the measurement is done. One purpose in measuring productivity is to compare large aggregations of organizations with each other. Examples of this purpose include comparing the United Kingdom's economy with Japan's economy and comparing the electronics industry with the automobile industry. Another purpose is to evaluate the overall productivity of individual organizations for comparison with each other or with some standard. A third purpose is as a management information system or control system. Here the focus is on a single organization, and the measurement deals with the functioning of the human/technological system. Finally, productivity could be measured for use as a motivational tool. This is the typical purpose of the organizational psychologist. The assumption is that if individuals change their behavior appropriately, productivity will increase.

7.1. Criteria for a Good Productivity Measurement System

There are many specific issues that must be considered in measuring productivity by the psychologist or organizational behavior specialist. These include ensuring that all important aspects of the work are measured, having reliable and valid measures that are cost-effective to collect, using measures that are understood by all, using measures over which the personnel have control, ensuring that the measurement system will be accepted by both the managers and the people doing the actual work, and ensuring that measures for each unit are aligned with the strategic objectives of the broader organization.

In most approaches to productivity improvement, the productivity measurement system is used for feedback to the personnel doing the work. The assumption is that such feedback will help to produce the behaviors that will increase productivity. However, to be most effective, the feedback system must meet an additional series of criteria beyond those for the productivity measurement system. Feedback must be given in a timely manner, be understood by those receiving the feedback, contain both descriptive information (e.g., the unit finished 15 orders) and evaluative information (e.g., 15 orders is very high performance), give information on all important aspects of the work, account

for the varying importance of different aspects of the work, provide an overall productivity score, identify improvement priorities, and allow for unit personnel to plan new strategies for doing the work.

Research has indicated that such feedback can be very effective in improving productivity. For example, one approach developed by Pritchard and associates measures productivity and uses these measures for feedback. It is called the Productivity Measurement and Enhancement System or ProMES. Figure 1 shows the effects of feedback due to ProMES as shown from field studies on 55 organizational units located in seven different countries. The nature of the organizations varied, and the research was conducted by nine different research groups. The horizontal axis represents time beginning with baseline (prior to the use of feedback) and continuing through the implementation of feedback. The vertical axis represents the overall effectiveness score, which is an index of overall productivity. Once feedback was introduced, there were large increases in productivity.

FIGURE 1 Effects of ProMES feedback on productivity. Reprinted from Pritchard and colleagues (2002).

8. SPECIFIC APPROACHES TO MEASURING AND IMPROVING PRODUCTIVITY

Psychologists and other organizational specialists have proposed a number of other specific techniques for measuring productivity that focus on using productivity measures as feedback to help personnel improve their productivity. The best-known examples are the Balanced Scorecard and Six Sigma.

The Balanced Scorecard was originally designed as an aid to top management. It stressed that other measures besides financial measures are important to overall organizational effectiveness and that including these nonfinancial measures would result in a more “balanced” evaluation. It has since been broadened and is now used for all levels of the organization. Six Sigma was originally developed for feedback and productivity improvement in manufacturing settings. The central idea is that processes with multiple steps, such as assembling cars and refining petroleum, require that each step be done with extremely high reliability for the final product to meet required specifications. Measures of each step in the process are taken, and efforts are made to increase the reliability of each step.

Finally, there is a class of practices that are designed to improve performance and thereby productivity. These practices, which have come to be called “performance management,” include performance appraisal, other forms of feedback, goal setting, incentives, and role clarification.

GLOSSARY

attitude The general evaluation of an object; in the theories described in this article, it refers to the general evaluation of a behavior.

intervention technique A method to change behavior in a certain direction; in this article, it refers to a method to change anti-environmental behavior to pro-environmental behavior.

pro-environmental behavior Behavior that is relatively favorable for the environment in comparison with behavior that serves the same primary function (e.g., using public transportation instead of driving a car).

social dilemma The tension between individual interests and collective interests.

To understand pro-environmental behavior and be able to influence it, it is essential to apply knowledge

from attitude-behavior theories. However, the central characteristic of pro-environmental behavior can be understood only if knowledge from social dilemma theory is applied simultaneously.

1. INTRODUCTION

Large-scale environmental problems have been on the political agenda for more than 30 years but continue to threaten the earth's inhabitants. Clearly, some of the problems are particularly stubborn and defy easy solutions. Basic to an understanding of environmental problems is the fact that they are ultimately phenomena created by human behavior and, thus, are to be solved by human behavior. Gradually, this has become recognized in a field that was traditionally dominated by experts from the physical sciences such as chemists, biologists, and ecologists.

This article gives an overview of contributions from social/environmental psychology that deepen insights into the human dimension of environmental problems and that are helpful in designing interventions that change behavior in a pro-environmental direction. First, the article describes a number of research traditions that are highly relevant for understanding behavior that affects the environment. These deal with attitude-behavior relations, moral considerations, and

habits. Overarching these perspectives is the conceptual framework of social dilemmas, a paradigm that is essential for understanding the nature of environmental problems. The article then describes what psychology has to contribute when considering ways of changing behavior in a pro-environmental direction.

2. ENVIRONMENTAL PROBLEMS AS SOCIAL DILEMMAS

Essential in thinking about the origin of many environmental problems is their social nature, originating from a fundamental tension between acting in the service of direct individual interests and acting in the service of long-term community interests. Many societal issues have this structure, and it is almost essential to an organized collective that individuals sacrifice, to some degree, their individual interests in favor of the interests of the community. Consider, for example, the principle of paying tax to finance collective institutions and services such as police, health care, and infrastructure for transportation. From an individual perspective, it would be profitable to evade the obligation of paying taxes. But when everyone would succeed in doing this, no public good would become available and everybody would be worse off. This is the core of the social dilemma that lies at the heart of many environmental problems. It was described in 1968 by Hardin as “The Tragedy of the Commons.” That publication has become emblematic for the analysis of environmental problems.

Different in comparison with the taxpayers’ dilemma is that environmental problems are often delayed in time and that effects are not necessarily manifest at the place where the problem is created. Consider the greenhouse effect, one of the most serious environmental problems of our time. One reason why the greenhouse effect is difficult to solve is that effects are expected to be delayed some 50 years. Also, it will become most threatening in parts of the world that have hardly contributed to the problem but that will be most vulnerable to the expected rise in sea level.

The social dilemma paradigm has proven to be a fruitful area of social-psychological experimental research, providing information about which factors are likely to influence the trade-off between choosing for the private interest and choosing for the collective. Important factors include the payoff structure (i.e., how much the individual loses by acting in the

collective’s interest), communication about the decision among group members, expectations about the others’ cooperation, perceived efficacy (i.e., how important the individual contribution is in determining the outcome of the group), and identifiability (i.e., the degree to which a person is known to have decided in favor of individual interests vs collective interests).

3. THE RELATION BETWEEN ATTITUDES AND BEHAVIOR

The social dilemma framework helps one to understand how behavior can be differentially driven toward individually valued outcomes or collectively valued outcomes such as the quality of the environment. However, it gives only a limited account of how behavior results from cognitive and motivational processes. Three theories are specifically important in the context of environmental behavior.

3.1. Theory of Reasoned Action

One of the most influential models in the social-psychological literature is the theory of reasoned action (TRA) developed by Fishbein and Ajzen. The TRA postulates that behavior is the result of three main factors: attitude toward behavior, subjective norm, and behavioral intention. Attitude and subjective norm are postulated to cause behavioral intention, which in turn causes behavior.

In the TRA, Fishbein and Ajzen confined the attitude concept to the general evaluation of a behavior. Other theories have no restrictions as to the nature of the attitude object and, thus, may consider ideas, persons, things, issues, ideas, or other entities. However, these more general theories have fared less well when it was important to understand and predict behavior. Therefore, at the time, Fishbein and Ajzen’s theory came as a much-needed innovation in the domain of attitude theories.

The attitude is measured with a number of adjectives (e.g., good–bad, pleasant–unpleasant, positive–negative) that are generally statistically combined to obtain a general judgment of the performance of a certain act.

Subjective norm is the perception of the individual that, in general, other people who are important to the individual want him or her to perform, or not to perform, that behavior. Who is important may vary across behaviors, but often this will include family, friends,

and neighbors. Other influences may stem from a religious institution to which a person feels attached, a political party, and the environmental movement. It is the individual's overall impression of how to behave, according to this collective of reference persons and groups, that is defined as the subjective norm.

The third concept is behavioral intention, that is, the deliberate plan to perform the behavior. According to the theory, the intention is the result of a decision process based on the attitude and the subjective norm, and it is the best predictor of behavior.

Finally, behavior is the performance of a certain act. In the TRA, behavior is usually confined to acts that are observable by others such as separating garbage and buying ecological food.

3.1.1. The Backgrounds of Attitude and Subjective Norm

In the TRA, the concepts of attitude and subjective norm both are explained by a combination of two elementary concepts. The attitude toward a behavior is caused by beliefs about the likelihood of salient outcomes of performing a behavior, weighted by the evaluation of each of those outcomes. Salient outcomes are the outcomes that immediately come to the mind of the individual when thinking of the behavior. This combination of belief strength and evaluation of each outcome was formalized by Fishbein and Ajzen in the following formula: $A_{act} = \sum B \times E$. The formula states that the attitude toward a certain behavior (A_{act}) is the sum of the products of beliefs (subjective estimate of likelihood of occurrence) and evaluations (valence) of all the behavioral outcomes that are considered by the individual.

Subjective norm, like the attitude concept, is composed of two subconcepts that explain which persons and groups are responsible for the normative pressure to perform, or not to perform, a certain behavior. The first concept is that of normative belief. A normative belief indicates the extent to which a person thinks that a specific referent person or group wants him or her to perform a behavior. Usually, with each behavior, the individual holds a number of normative beliefs. Referent persons will be family members (e.g., spouse, children, parents) who are important for many behaviors, whereas the influence of other persons or groups may vary more strongly with the behavior. For some behaviors, such as recycling of organic waste, the opinion of an environmental organization may be quite influential, whereas the opinion attributed to this

group will be irrelevant when deciding whether to make a visit to one's parents' house over the weekend. Each normative belief (NB) is weighted for the so-called motivation to comply (MC), that is, the degree to which an individual allows this referent person or group to exert influence on him or her. Subjective norm (SN) is the sum of the products of all normative beliefs and the corresponding motivation to comply. Expressed as a formula, $SN = \sum NB \times MC$.

3.1.2. Correspondence: A Major Condition for Application of the TRA

Correspondence entails that all of the components of the model are measured at the same level of specificity. Correspondence must exist on four criteria: action, target, context, and time. Action refers to the behavior itself. For example, if the behavior that is being investigated is recycling, all concepts of the theory must be specified as recycling and not as recycling in the measure of behavioral intention and as pro-environmental behavior in the measurement of the attitude. Similarly, one should specify the target (also called object sometimes) consistently. If one is interested in predicting the recycling of organic waste and not of used paper, aluminum cans, or glass, one should specify each component of the model as pertaining to the recycling of organic waste. And again, concerning context, one should decide whether one wants to investigate people's recycling behavior of organic waste in their homes, in their workplaces, or perhaps in all of the places where they spend time. Finally, concerning time, one must decide whether one wants to investigate people's recycling of organic waste next week (e.g., because there will be a special organic waste recycling drive organized by an environmental organization), the coming year, or forever from now on. Note that it is a matter of choice by the investigator at which level of specificity all of the components of the model are measured. Note also that the often used concept of environmental concern can be considered to be a very general attitude that is not correspondent with specific behavioral measures. Therefore, relationships between environmental concern and specific behaviors will necessarily be weak.

3.2. The Theory of Planned Behavior

The TRA assumes that the behavior under investigation is under volitional control, that is, that people believe that they can execute the behavior whenever they are

willing to do so. Gradually, the TRA was used more often for the study of behaviors for which control was a variable factor. For that purpose, the TRA was complemented by a component that was named perceived behavioral control. This concept represents the extent to which people believe they are able to perform the behavior because they have adequate capabilities and/or opportunities or are lacking in these. It is very easy to see that this factor can substantially improve the generality of application of the model because there are many behaviors that need specific skills or external facilities. For example, recycling is virtually impossible if no collection system is available, and abandoning private cars is often impractical, at the least, when public transportation functions poorly.

The successor of the TRA that incorporates volitional control is the theory of planned behavior (TPB). Similar to attitude and subjective norm, the joint effects of two subconcepts determine behavioral control. The first subconcept consists of so-called control beliefs, that is, the estimated likelihood that each of a number of specific factors will facilitate or impede execution of the behavior. An example might be the following control belief: "I can go to my office by bus given the distance from the bus stop to my home." The second factor is called perceived power, that is, a judgment of the degree of facilitation or impediment that each specific control belief represents. An example might be the following: "The distance from the bus stop to my home makes it very easy/very difficult to go to my office by bus." The formula combining the two subconcepts of likelihood of control and perceived power is identical to that of the attitude and subjective norm concepts: $PBC = \Sigma C \times P$.

Both the TRA and the TPB have been used repeatedly for investigating specific environmental behaviors such as changing travel mode, water conservation, recycling, and green consumerism. In general, the models have proven to be useful in understanding the behavior, with important contributions of perceived behavioral control.

3.3. Norm Activation Theory

The attitude concept, as used in the TPB, is meant to be a general evaluation of a behavior. This implies that all of the specific evaluative criteria that guide a decision to adopt, or not to adopt, that behavior should determine the attitude score. This does not seem to be the case given that research has shown repeatedly that

moral considerations are not effectively covered by the attitude concept. Environmental behavior, because of its social dilemma character, clearly has a moral dimension in that acting in favor of the environment/community is generally perceived as morally superior to acting out of self-interest. The development of moral considerations and their relation to behavior is described in Schwartz's norm activation theory (NAT). The central concept is personal norm, defined as intrinsically motivated self-expectations regarding morally appropriate behaviors. Norm activation generates a feeling of personal obligation to perform a specific behavior. According to the NAT, norm activation occurs under the influence of four situational activators and two personality trait activators. Norm activation starts with the awareness of need. It involves the extent to which a person's attention is focused on the existence of a person or a more abstract entity (e.g., the environment) in need. Apart from being aware of need, the potential actor must define the situation at hand as one in which he or she feels some responsibility for the consequences of the needy party's welfare. Norm activation is further enhanced by efficacy, that is, the extent to which a person recognizes actions that might alleviate the need. The actions that are recognized as such determine which specific norms are activated. Finally, ability refers to the actor's perception about whether he or she possesses the resources or capabilities needed to perform the focal behavior.

In addition, the NAT proposes that two personality traits influence activation of personal norm: awareness of consequences and denial of responsibility. Awareness of consequences refers to a person's receptivity to situational cues of need. Denial of responsibility refers to a person's inclination to deny responsibility for the consequences of his or her behavioral choices for the welfare of others. The four situational activators and the two personality traits determine whether or not a behaviorally specific personal norm becomes activated. Specific behaviors, such as burning garden waste, recycling, buying lead-free gasoline, using off-road vehicles in the environment, energy conservation, and littering, have been studied by means of the NAT. In general, just parts of the whole model have been used. Most studies show that personal norms significantly influence pro-environmental behavior, whereas there is less agreement about the predictors of personal norms and the exact process through which personal norms become activated.

3.4. Habits

All of the approaches to understanding environmental behavior described in this section assume that people process relevant information to decide to perform an environmentally relevant behavior in a pro- or anti-environmental manner. However, people often rely on behavioral routines or habits. Habits are especially likely to develop when behaviors are displayed frequently and in a stable context. Habitual behavior is defined as behavior that is displayed automatically on the presence of a goal, that is, a direct goal-action link that is not preceded by consciously developed intentions. Automatically executed behavior has three main characteristics in that (a) it can be executed fast, (b) its execution cannot be controlled, and (c) it is very efficient (i.e., it allows other cognitive processes to be executed simultaneously). Care should be taken not to equate habitually performed behavior with all behaviors that are performed in the past, even when the conditions of high frequency and context stability are met. Behavior executed in the past can influence future behavior through its effect on intentions, and in that case it is unlikely that the behavior is a habit. However, some studies have shown that the strength of intentions to influence behavior depends on the degree to which behavior has been performed in the past. When behavior has been frequently performed in the past, the effect of intentions on behavior is smaller. In such cases, where past behavior changes the intention-behavior relationship, it is very likely that past behavior indicates that habits play a role.

Clearly, the automatic execution of behavior has important advantages. But it has drawbacks as well in that people who have established habits pay less attention to information that might be important for changing behavior. For example, the information that is issued by a railway company about improved services is likely to be ignored by people with strong car travel habits, even though it might be very advantageous for them. Given that people with strong habits cannot easily be influenced by information, an important question then becomes how to change habitual anti-environmental behavior.

4. HOW TO EFFECT PRO-ENVIRONMENTAL BEHAVIOR CHANGE: THE ROLE OF PSYCHOLOGY

Applied psychology can play a role in establishing more environmentally sound living patterns. This

section gives a summary of the potential contribution of psychology for the development of intervention methods. The methods range from obligatory to voluntary systems, but all need the application of psychological knowledge to understand and optimize effects.

4.1. Laws, Rules, and Regulations

It seems to be a straightforward solution to communal problems to implement rules, regulations, or laws that prohibit the actions that cause the problem. However, from a psychological perspective, there are several issues that need mentioning. First, regulations will fail when the targeted population is not convinced of the necessity of the policy measure. In that case, strict enforcement will be necessary and costly. If strict enforcement is not applied, the targeted population will not adhere to the regulation. In both cases, the measure will not have the favorable effects that are desired. Second, a policy measure will be accepted according to its perceived fairness. Fairness means that people will realize that the policy measure targets the right actions and punishes offenders according to the severity of their offenses. Third, from these characteristics and based on laboratory research on social dilemmas, it can be predicted that people will be most willing to endorse policy measures when they are in favor of the proposed measure but are very uncertain what other people's attitudes and behavior will be. These psychological effects of perceptions, attitudes, and uncertainties and their relationships were formalized in the structural goal expectation theory developed by Yamagishi in 1986. Fourth, implementation of policy measures, even if they are successful, is not an easy way out of the social dilemma. To develop legislation, political support for measures protecting the environment is necessary. To create political support, environmental awareness and concern among voters, and willingness to sacrifice personal advantages for long-term collective benefits are necessary.

4.2. Changes in the Physical Environment

Measures that are generally less dependent on political approval are changes in the physical environment that facilitate pro-environmental behavior or impede anti-environmental behavior. These kinds of measures can work in three different ways.

4.2.1. Direct Influence on Behavior

Changing the layout of a road (e.g., by creating additional curves or narrowing lanes) will reduce automobile speed and emissions directly.

4.2.2. Influence on Habits That Control Behavior

Many environmental behaviors are habitually performed. Changing the physical context of the behavior means that these habits no longer apply and information must be sought about how to achieve the behavior's goal in these changed circumstances. This renewed need for information creates possibilities for pro-environmental behavior change, for example, by showing that the daily commute to work can now be completed faster by public transportation than was the case during the period when the car commute habit was developed.

4.2.3. Influence on the Convenience of Performing Pro-environmental Behavior

In many cases, pro-environmental behavior is impeded not by negative attitudes but rather by weak positive attitudes combined with a lack of perceived behavioral control. For example, most people are in favor of recycling garbage but are discouraged by the time and effort it takes to bring their recyclable garbage to a recycling station. Creating drop-off facilities for recycling paper, bottles, and other recyclables at close range from home may strongly increase the volume of recyclable materials.

4.3. Monetary Incentives

It might seem as though the most straightforward way in which to solve environmental problems is to let polluters pay for the damage they do to the environment. In general, this may be an effective strategy that eliminates the social dilemma structure of environmental problems. Research has shown that people are indeed sensitive to changes in the payoffs and that the number of egoistic choices (as compared with choices for the collectivity) is reduced when egoistic choices are less profitable. However, the following subsections review a number of complicating factors pertaining to the psychology of justice, the perception of monetary changes, and the dependence of monetary incentives on information to accomplish the desired effect.

Moreover, financial measures run the risk of weakening intrinsic motivation, that is, the motivation to act in a pro-environmental manner out of deeply felt concern for the state of the environment.

4.3.1. Policy Measures

Financial measures, in particular, can be evaluated differently depending on the fairness principle that is considered appropriate. Three principles are applied: those of equity, equality, and need. Equity implies that the damage is compensated by the actor in proportion to the damage that he or she causes. Equality implies that people contribute to the same extent, for example, that they pay the same amount for having their houses connected to the city's sewer system regardless of the amount of polluted water they produce. Need implies that people with more financial resources assume a larger share of the financial burden. It is not always clear which principle should apply in a specific situation. This political disagreement constitutes a reason for the absence or delay of appropriate measures.

4.3.2. Price Perception

Price perception is subject to many different influences that can substantially change the relation between actual costs and willingness to take pro-environmental action. A finding that is at the core of Tversky and Kahneman's prospect theory is that people are more sensitive to potential losses than to potential gains. For that reason, it is advised to frame financial consequences of anti-environmental behavior as a potential loss instead of framing financial consequences of pro-environmental behavior as a potential gain. The complexity of consequences of financial measures may cause the use of heuristics. For example, the calculations necessary to decide whether it is cost-efficient to install double-glazing are difficult because it is necessary to simultaneously consider changing consumption, changing energy prices, costs of a loan, and/or lack of profit from a different investment. Consumers, and even entrepreneurs, are rarely able to take all of the relevant factors into account and may simply evaluate a decision on the basis of nominal costs before and after installment.

4.3.3. Financial Measures

Measures such as subsidies, loans, discounts, and other price changes do not automatically lead to changes in

behavior. Being aware of those price changes is crucial, and this implies the importance of informational interventions that precede or accompany the introduction of financial measures. Several experiments have demonstrated that attractive financial propositions are successfully implemented only when sufficient attention is given to making the programs known. To increase participation, it is often more prudent to spend money on information campaigns than to further increase the financial attractiveness of propositions.

4.3.4. Target Recurring Behavior

When preparing financial measures that target recurring behavior, one should bear in mind that the motivation to perform pro-environmental behavior is changed from intrinsic (out of concern for the environment) to extrinsic (for the monetary advantage). For one-time decisions, this might not be an issue. However, for recurring behavior, a relapse to anti-environmental behavior might occur once the financial gain from acting in a pro-environmental manner is removed. Pro-environmental behavioral maintenance then becomes problematic. Another unwanted effect that may stem from financially favorable energy-saving devices is the rebound effect. The knowledge that energy, or water, is so sparsely used due to new efficient devices might invite people to be less careful in their use of these devices. Having lights on throughout the night and showering longer might be invited by the installment of energy-saving lamps and water-saving showerheads, respectively. This phenomenon helps to explain why reductions in energy use through new efficient devices are generally not as favorable as foreseen in the calculations of technicians.

4.4. Information Strategies

As has now become clear, information is indispensable for implementing other interventions. It is helpful in increasing acceptance for policy measures, in announcing that physical changes in the environment are forthcoming, in announcing that financial support can be received for the implementation of energy-saving measures, and so on. Apart from supporting other measures, information can be used on its own for a large number of purposes, all ultimately intended to change behavior in a pro-environmental direction. Prominent functions of information include the following:

1. Information may create insight into the structure of the dilemma of environmental behavior. Laboratory research on social dilemmas has pointed out that people are more willing to cooperate when they are made aware of the dilemma structure of environmental problems.

2. Information may increase problem awareness and emotional concern. Both are important, but they are important to different degrees for different target groups. Groups of people who are motivated and capable of processing information thoroughly are better served by more factual information. Knowledge about the environmental problem—its nature, causes, and consequences—is an important condition to induce pro-environmental behavior, according to Schwarz's norm activation theory. For people who are relatively lacking in ability and motivation to process information, messages that stress the affective consequences of environmental degradation may be more influential.

3. Information can teach people relevant skills that facilitate the performance of pro-environmental behavior. People should learn how to dispose of chemical waste and how to compost organic waste before such pro-environmental behavior is applied. Many studies point out that the relative ease of performance is a crucial factor in pro-environmental behavior.

4. Information may tackle anti-environmental habits by reminding people of their pro-environmental attitudes. Using prompts to remind people not to drive fast, to lower thermostat settings well before going to bed, and so on can be successful in that these prompts encourage behaviors with which people agree.

5. Information may be used to address possible personal benefits of pro-environmental behavior. Sometimes, wrong estimates are made regarding the costs and benefits of pro-environmental behavior. This may occur, for example, when someone estimates the financial consequences of home insulation. Wrong estimates can be caused by outdated information (among other reasons), and this is especially likely in the case of habitual behavior when less attention is given to new information. This neglect of information may, for example, impede a choice for public transport even though travel conditions have improved greatly compared with the past when the choice to drive private automobiles was made.

6. Communication can reduce social uncertainty. Knowing that others are also willing to incur the costs of pro-environmental behavior convinces people that their efforts will not be in vain. This confidence in the efficacy of shared efforts will increase people's

willingness to behave in a pro-environmental manner. It should be noted, of course, that this mechanism works only when others (are willing to) behave pro-environmentally. If this is not the case, communication strategies should focus on other determinants such as knowledge, concern, and ability.

5. CONSIDERATIONS REGARDING THE EFFECTIVENESS OF INTERVENTIONS FOR PRO-ENVIRONMENTAL BEHAVIOR CHANGE

Changing behavior is sometimes a difficult task, and this certainly applies to changing environmental behavior in a pro-environmental direction. The social dilemma nature of environmental problems makes personal benefits of change, and thus of pro-environmental change, less likely. Nevertheless, people are willing to change to some extent. The categories of instruments described in the previous section may be effective in inducing change. But what does effectiveness actually mean? Contrary to what one would think intuitively, effectiveness is not a unitary concept. In what follows, this section adheres to the evaluation system proposed by De Young in 1993. According to De Young, effectiveness must be broken down into five dimensions:

- *Reliability*. Is an intervention able to effect the desired change in the target group? Moreover, is it able to do this every time? This criterion comes closest to what one would ask of an intervention program. However, an answer may be subtler than the questions imply. For example, the technique may be able to change individual behavior to some extent and may be more successful with some individuals than with others. The question about repeated use implies that the technique is not expected to create a lasting change that is exhibited each time the behavior can be displayed.

- *Speed of change*. How fast are changes in behavior accomplished? Of course, the sooner, the more impact (aggregated over time). However, some interventions can be expected to have their effect only after some time. The installation of expensive energy-saving equipment, such as a new central heating furnace, will usually be done when the old equipment is worn out. For research on effectiveness of intervention programs, it constitutes a challenge to be able to discover

changes initiated by the program but effected over a longer term. However, this would be desirable to know so as to be able to give a good estimate of the value of an intervention program.

- *Particularism*. This is the degree to which an intervention must be tailored to the characteristics of a target group. This ranges from an intervention that is universally applicable to an intervention that is uniquely designed for an individual. Money is an example of a motivator that is considered to be generally applicable because it retains its value regardless of the person intervening, whereas personal attention seems to be at the other extreme because it clearly matters who is giving personal attention. An intervention that is universally applicable and effective is, of course, a great tool because it can be administered much more efficiently. However, in general, a degree of tailoring to characteristics of the target group is necessary to increase the effect of an intervention. Favorable in that respect is a recent development that allows messages to be tailored to the target person or group in an automated process by which personalized information is sent to individuals whose characteristics have been inventoried earlier by means of a questionnaire and stored in an electronic database. Based on this information, a computer program automatically compiles an informative message that is closely tuned to the receiver. This technique combines the reach of mass media with the advantages of personalized advice; therefore, it seems promising.

- *Generality*. To what extent does an intervention technique influence behaviors that are not directly targeted but are conceptually related? And how closely related should they be to be influenced by the intervention? In general, it has proven to be difficult to create a degree of transfer from one behavior to the next. This is considered one of the two main challenges for an environmental psychology that aims to contribute to substantial changes in environmental behavior.

- *Durability*. To what degree are effects of intervention techniques lasting? Achieving durability of pro-environmental change constitutes the second main challenge. Especially with intervention techniques that focus on voluntary participation, it has been difficult to create substantial effects that last beyond the period when the intervention is executed. Examples of long-lasting changes are scarce. However, it seems that some techniques are more promising in this respect than are others. Especially explicit commitment (e.g., by a pledge done in public to

adhere to the goals of the intervention) seems to offer possibilities of behavioral maintenance after the intervention has expired.

6. CONCLUSIONS

Environmental problems are essentially problems of human behavior. Psychology can help one to understand behavior and propose ways of changing behavior. These are the main tenets of environmental psychology. This article has given a brief overview of influential theoretical perspectives and of the way in which psychology can help to create or improve pro-environmental behavior. It seems that a considerable knowledge base has been built over the past 30 years but that much more scientific attention, creativity, and persistence are needed, especially in developing interventions that change behavior. The rate of pro-environmental changes, and especially the durability of changes, is problematic. This is very understandable when considered from the perspective of social dilemmas. Given the existing structures in society, it is difficult to forgo individual interests for environmental improvements that are uncertain, may take a long time to come about, and may even be mainly beneficial to others. Possibly, psychology must dedicate more attention to the key actors in society—politicians, managers, and people who lead and represent large organizations. To this point, most attention has been on understanding and influencing people as consumers and citizens. For the most part, interventions have aimed at influencing people in their homes and sometimes in the workplace. In general, no attempts have been made to influence decisions made at city halls, in the boardrooms of multinational companies, or in the courts. Nevertheless, the bottom-up strategy of influencing people as consumers and citizens may profitably be complemented by attempts to understand people in specific, rare, and influential roles. This might help to bring about structural changes in society that would make it easier for everyone to behave in accordance with the needs and demands of the environment.

prosocial behavior, and prosocial actions are affected by contextual factors as well as by individual differences in temperament or personality. Prosocial tendencies are likely due to genetic factors as well as to socialization both within the family and in the child's larger social world.

GLOSSARY

altruism Prosocial behavior that is motivated by sympathy or moral values/concerns rather than by egoistic factors (e.g., concrete rewards, social approval, elimination of vicarious distress to make oneself feel better).

empathy An affective response based on another person's emotion or condition that is similar to what the other person is experiencing or would be expected to experience.

meta-analysis A procedure that statistically combines the findings from a number of different studies to determine whether a general finding holds across various empirical studies.

prosocial behavior Voluntary behavior that is intended to benefit another person.

sympathy Other-oriented concern that is often based on empathy.

Prosocial behavior starts to develop early in life and plays an important role in moral development. There are cultural and gender differences in some types of

1. INTRODUCTION

Prosocial behavior, or voluntary behavior intended to benefit another person, is of obvious importance for enhancing human relationships and for the smooth functioning of society. Of particular importance is altruism, which sometimes is defined as prosocial behavior that is motivated by sympathy or moral values/concerns rather than by egoistic factors (e.g., concrete rewards, social approval, elimination of vicarious distress to make oneself feel better). Unfortunately, it is often difficult to differentiate the two; indeed, some psychologists (and philosophers) claim that real altruism does not exist. Thus, most of the existing empirical work involves the study of prosocial behaviors that may or may not be altruistically motivated.

Some theorists, such as Batson, believe that altruism usually stems from an individual experiencing another's emotional state (i.e., empathy) or other-oriented concern (i.e., sympathy). Other theorists, such as Eisenberg, believe that prosocial behaviors (especially altruistic ones) can be engendered by internalized moral values

as well as by sympathy. Still others, such as Cialdini, believe that prosocial behavior is motivated by hedonism; for example, people help to improve their own moods. Empirical studies have demonstrated that there are associations between prosocial behaviors and both sympathy and measures of individuals' moral reasoning and values. Empathy and sympathy are also believed to inhibit cruelty toward others, although it is not clear whether prosocial behavior and aggression are highly negatively related (although both likely are affected by empathy and sympathy).

2. THE DEVELOPMENT OF PROSOCIAL BEHAVIOR

Even infants can experience concern for others and have the capacity to perform prosocial behaviors. By 10 to 14 months of age, infants frequently express agitation when viewing others in distress. Self-distressed reactions when viewing others in distress decrease in frequency during the second year of life, and by 18 months of age infants sometimes make efforts to comfort (e.g., by patting a person) or help other people who are upset or sad, especially their parents. In addition, even toddlers frequently try to assist adults with household chores.

According to Hoffman, toddlers do not fully distinguish between their own inner states and other people's inner states; consequently, their attempts to help are often egocentric (e.g., a toddler may bring a distressed peer to his or her own mother rather than the peer's mother). With age, children's prosocial actions become more situationally appropriate and sensitive to others' specific needs.

Meta-analytic reviews have shown that the frequency of children's prosocial behavior, including sharing, comforting, and instrumental helping, tends to increase with age across childhood, although there is little difference in the frequencies of prosocial behavior between younger and older adolescents. Age differences tend to be greater in studies with experimental/structured designs than in those with naturalistic or correlational designs, and they also tend to be greater when prosocial behavior is measured with self- or other-reports than when it is measured with observations. Moreover, although the consistency of prosocial behavior across contexts is low during the early years of life, it becomes more consistent with age and there are relatively clear individual differences in prosocial tendencies by late childhood and adolescence. However, there is some

consistency of prosocial tendencies over time, even from the preschool years. For example, preschool children who spontaneously engage in sharing behaviors that involve some cost (e.g., giving up a toy) are more sympathetic and prosocial as adolescents and adults.

Younger and older children also differ in the reasons they report for their prosocial actions. Older children are more likely to say that they assist for apparently altruistic or other-oriented motives, whereas younger children are more likely to assist to obtain material or social rewards. Furthermore, with development, children are more likely to resolve hypothetical moral dilemmas regarding assisting others at a cost to themselves by referring to higher level moral justifications. For example, preschoolers tend to verbalize primarily hedonistic reasoning and some needs-oriented (primitive empathic) reasoning. By school age, some children begin to express concern about gaining approval, enhancing interpersonal relationships, and behaving in stereotypically "good" ways. During late elementary school or thereafter, children start to verbalize reasoning reflecting abstract principles, internalized affective reactions (e.g., guilt or positive affect about the consequences of their behavior for others, living up to internalized principles), self-reflective sympathy, and perspective taking. From childhood into early adolescence, children's needs-oriented reasoning increases, whereas hedonistic reasoning decreases. For most children, reasoning concerning role taking, internalized norms/rules/values, generalized reciprocity across members of society, internalized affective reactions based on concern about the consequences of their behavior for others, and positive affect related to internalized values and living up to those values is uncommon during elementary school and increases with age from adolescence into early adulthood. Nonetheless, people of all ages sometimes express low-level, hedonistic moral reasoning. Age-related changes in children's prosocial moral reasoning are of interest because higher level reasoning likely reflects developmental changes in the goals and motives underlying children's prosocial behavior and has been correlated with the tendency to engage in prosocial behavior.

3. GENDER DIFFERENCES

Gender stereotypes regarding sex differences in prosocial behavior are common in American culture and probably in numerous other cultures. In general, girls and women are expected to be more caring and to

engage in more prosocial behaviors than are boys and men. Consistent with the stereotype, in meta-analytic analyses, effect sizes indicate that girls reliably display greater prosocial tendencies than do boys. For example, in 1998, Eisenberg and Fabes found that girls evidenced considerably greater kindness and consideration for others than did boys ($d = .42$). Likewise, girls shared and donated more than did boys, although not to such a marked extent ($d = .13$), and also provided somewhat more instrumental help ($d = .14$). In additional meta-analyses, investigators found that girls exhibited greater empathy and sympathy than did boys, at least on some types of measures (e.g., self-reports, some observed behavioral measures). In 1999, Fabes and colleagues noted that these sex differences in prosocial tendencies become stronger during adolescence as compared with early and middle childhood. Thus, there is support for a developmental change in the expression of prosocial behaviors.

In contrast, examination of sex differences in adults' prosocial behaviors has provided mixed results. In 1986, Eagly and Crowley found that men, but not women, generally exhibited considerably greater helping ($d = .34$). However, many of the studies with adults involved helping strangers and performing instrumental tasks (e.g., changing a tire). These authors suggested that men's greater helping likely reflects the conventional gender role-rooted expectation for men to enact agentic behaviors or to "rescue" others (i.e., behave chivalrously) and that the findings likely differed for prosocial behaviors involving both caring and recipients who are known.

Consistent with Eagly and Crowley's speculations, women have been found to display greater prosocial tendencies than have men with regard to other indexes of prosociality. For example, women deliver messages containing greater emotional support and report more sympathy and empathy than do men, both on questionnaires and after being exposed to empathy-inducing stimuli, although they generally do not differ on physiological or facial measures of empathy. Furthermore, adolescent girls and adult women generally score higher on caring and other-oriented moral reasoning.

It is important to emphasize that the strength of sex differences fluctuated greatly across studies included in the aforementioned meta-analyses. Myriad factors, such as the design of the study, account for some degree of the difference between women and men. Nonetheless, the data do support the legitimacy of the stereotypes regarding sex differences in prosocial

behaviors, at least when taking into account the type of helping behavior. However, the finding that sex differences in empathy and sympathy are stronger for self-reports than for other methods of assessment is consistent with the notion that people likely perceive a greater gender difference in prosocial tendencies than actually exists and respond accordingly.

4. CULTURAL DIFFERENCES

Prosocial tendencies appear to differ considerably across cultures. For example, in some traditional cultures such as the Ik in Africa, aggression and cruelty are commonplace, whereas in some other cultures, caring, helping, and supportive behaviors are fairly commonplace. Anthropologists have found that children in traditional cultures tend to assist family members and neighbors more than do children in industrial communities. Even in industrialized societies, children from collectivist cultures that emphasize the well-being of the larger social group (e.g., China) appear to be more prosocial with peers than do children from individualist cultures (e.g., the United States). However, it is not known whether these cross-cultural differences hold when unfamiliar people, rather than family members, neighbors, and friends, are the targets of aid.

The reasons for observed cross-cultural and subcultural differences in prosocial and cooperative behavior are probably multiple and complex. Clearly, the value placed on the well-being of others and on prosocial behavior varies across societies and likely is taught to children by parents and teachers as well as communicated through social norms. Some evidence suggests that these expectations are communicated in everyday life. For example, in cultures where children are expected to be cooperative and help others, often as part of their chores (e.g., when caring for siblings), children tend to be relatively prosocial. Moreover, prosocial actions tend to be viewed as more obligatory in collectivist societies than in individualist societies. Also in collectivist societies, privileges and social acknowledgment in the classroom are dependent on group accomplishments rather than individual accomplishments, so that children are reinforced for helping one another.

5. CONTEXTUAL FACTORS

Children's and adults' prosocial behaviors vary considerably as a function of the specific context. For

example, people are more likely to help if they see someone else—even a stranger—modeling prosocial behavior. Moreover, there is evidence that children and adults help more when they are in a good mood and help less when they are sad or depressed (especially in the case of older children and adults). Furthermore, factors such as the clarity of cues related to the other person's need, the cost and benefits associated with a particular prosocial action, and the salience of social norms regarding prosocial behavior appear to influence whether people choose to help or share with others.

6. DISPOSITIONAL FACTORS

Some people are more prosocial than others. Individual differences in prosocial behavior have been linked to a variety of aspects of personality or other dispositional characteristics. For example, as already noted, people who are prosocial are relatively prone to experience empathy and sympathy for others. In addition, prosocial individuals tend to feel a sense of responsibility for their actions and for others and also feel competent to assist. During childhood, prosocial tendencies also have been linked to being well regulated, socially competent, emotionally positive, and sociable, although nonassertive and less sociable children may be especially likely to perform compliant prosocial behaviors that are requested by their peers (in part because they have difficulty in asserting their own will). Thus, even within cultures and across the sexes, characteristics of individuals seem to contribute to their willingness and ability to assist others.

7. THE ORIGINS OF PROSOCIAL BEHAVIOR

Findings in twin studies support the common assumption that there is a genetic component to prosocial behavior and the tendency to empathize with others. Nonetheless, individual differences in children's socialization experiences in the home, school, and community are linked to individual differences in their prosocial behavior.

Prosocial children (and adults) tend to be those with parents who model and value prosocial actions and who apply ethical principles (especially those related to caring and helping) to a broad spectrum of

humanity. Parents of prosocial children also tend to use reasoning (inductions) when they discipline their children (e.g., pointing out the consequences of children's behavior for others) and seldom resort to physical punishment or threats of punishment. In addition, these parents tend to be authoritative and democratic in their parenting style (i.e., are supportive and use inductions while also clearly communicating their expectations for appropriate behavior) and provide opportunities for their children to assist others. In general, parents of prosocial children also appear to promote the development of children's sympathy, and sympathy appears to motivate altruistic caring behavior.

Similarly, prosocial and cooperative behavior also can be fostered in school-based programs that emphasize rational discipline, cooperation, and prosocial values and that include activities designed to heighten children's sympathy and understanding of others and their feelings. In addition, a positive relationship between children and their teachers is associated with children's consideration for others and children's empathy with unfamiliar peers. Finally, there is a modest positive relation between children's viewing of prosocial television programming and their prosocial behavior. Thus, it appears that individual differences in prosocial behavior are due to a variety of influences in the home, media, and community.

Psychological Assessment, Standards and Guidelines for

Dave Bartram

SHL Group, Surrey, United Kingdom

1. Introduction
 2. International Standards and Guidelines
 3. National Standards and Guidelines
 4. Conclusion
- Further Reading

Standards and guidelines in assessment cover three related areas: the people who use tests, the tests the people use, and the process of assessment within which tests are used. Both nationally and internationally, all three of these issues have been addressed in various ways.

GLOSSARY

psychological assessment Any assessment of an individual's psychological characteristics carried out using procedures that are standardized and repeatable; this can include structured interviews and standardized work sample assessment exercises as well as more traditional psychological tests.

psychological testing Standardized procedures whereby quantitative measures of psychological attributes or characteristics are obtained.

psychological tests Instruments with known psychometric properties designed to measure one or more psychological characteristics; the psychometric properties will include measures of reliability and validity as well as data to aid interpretation.

standards and guidelines Two kinds of criteria that differ in that standards are generally more prescriptive than guidelines, whereas guidelines tend to be advisory and informative.

test user Anyone who is responsible for the use of a psychological test in an assessment process.

1. INTRODUCTION

Standards and guidelines have been developed to cover all aspects of test design, development, and use. In many countries, test publishers or distributors were the first to develop qualification criteria, guidelines, and standards to regulate, advise, and control test users. National psychological associations and international bodies concerned with testing and test use (e.g., European Federation of Psychologists Associations [EFPA], International Test Commission [ITC]) have also played a major role in developing and promulgating standards and guidelines. These standards and guidelines have addressed issues associated with test development, the qualification of test users and test distribution, proper test use and best practice, and test taker rights and responsibilities.

Standards and guidelines cover all sorts of psychological testing and assessment methods—from tests of ability and aptitude to tests of personality and motivation, from paper-and-pencil tests to computer-based

and Internet-delivered tests, from single instruments to complex 2- or 3-day “assessment centers.”

A survey of 48 countries, carried out jointly in 1996 by the ITC and EFPA, suggested the following:

- Approximately 79% of test users operate in the educational field, 12% in the clinical field, 9% in work and organizational settings, and less than 1% in the forensic area.
- The majority (86%) of test users are nonpsychologists.
- The clinical and forensic areas are the only ones where nonpsychologists do not outnumber psychologists as test users.
- Only 41% of all users have received any specific training in test use, with the lowest rates of training in the educational area and the highest rates in the clinical area.
- Psychologists have only slightly higher rates of training than do nonpsychologists.

Overall, the survey showed the need for more training for all test users and revealed marked differences in patterns of response among different countries. Of particular interest were the big differences among countries in the power and role of the professional psychological associations in relation to setting and enforcing standards.

2. INTERNATIONAL STANDARDS AND GUIDELINES

In the relatively recent past, it was possible to think of individual countries as “closed systems.” Changes could be made in terms of best practice, procedures, and laws affecting the use of tests in one country without there being any real impact on practice or laws in other countries. People tended to confine their practice of assessment to one country, and test suppliers tended to operate within local markets by adapting prices and supply conditions to the local professional and commercial environments.

This situation has changed. Individual countries are no longer closed systems. Psychological testing and assessment is an international business. Many test publishers are international organizations that sell their tests in a large number of countries. Many of the organizations using tests for selection and assessment at work are multinationals. In each country, test suppliers and test users are likely to find differences in practices related to access, user qualification, legal constraints on test use, and so on.

2.1. The International Test Commission

The ITC is an association of national psychological associations, test commissions, publishers, and other organizations committed to promoting effective testing and assessment policies and to ensuring the proper development, evaluation, and use of educational and psychological instruments. The ITC has been responsible for a number of guideline development projects. In each case, the process has been one of ensuring widespread international agreement on the content of the guidelines.

2.1.1. ITC Guidelines on Adapting Tests

These provide 22 guidelines for adapting psychological and educational tests for use in various different linguistic and cultural contexts. These guidelines fall into four main categories: the cultural context, the technicalities of instrument development and adaptation, test administration, and documentation and interpretation. Adaptation is an area of major importance as tests become used in more and more countries and as tests developed in one country get translated or adapted for use in another country. Adaptation needs to consider the whole cultural context within which a test is to be used.

2.1.2. ITC Guidelines on Test Use

These guidelines were published in 2000 and have been widely adopted by countries around the world as the basis for their own local standards. They focus on good test use and cover both ethical issues and best practice process. They provide a common international framework from which specific standards, codes of practice, qualifications, user registration criteria, and so on can be developed to meet local needs. By 2004, these guidelines were available in 14 different languages.

The competencies defined by the guidelines are specified in terms of assessable performance criteria. These competencies cover the following:

- Professional and ethical standards in testing
- Choice and evaluation of alternative tests
- Test administration, scoring, and interpretation
- Report writing and feedback
- Rights of the test candidate and other parties involved in the testing process

2.1.3. ITC Guidelines for Computer-Based and Internet-Delivered Testing

Work is in progress on the development of international guidelines in this area. These were scheduled for publication in 2004.

2.2. European Initiatives

2.2.1. The EFPA Test Review Criteria

The EFPA represents 30 European countries. Its Committee on Tests and Testing published the EFPA standards for the review of psychological tests in 2001. These standards, developed from British and Dutch work on test reviewing, are now being used as the basis for test reviewing across Europe and provide the basis for a test registration procedure.

Within Europe, new legislation on data privacy has had a major impact on testing and the use of tests. This has resulted in good practice in assessment becoming embodied in law and has led to the development of guidance to support this within European countries. Increasingly, it is being recognized that there is a need for standards and guidelines to be considered at a European level to match the demands arising from European Union directives, especially those that relate to fairness and equity issues in the employment area and to the transferability of professional qualifications among countries.

2.2.2. Other European Initiatives

The European Association of Psychological Assessment (EAPA) has published a set of Guidelines for the Assessment Process. The European Association of Work and Organizational Psychologists (EAWOP) has established a working group to focus on Europe-wide issues relating to testing and assessment in the area of work and employment. Work has started on the development of European standards for the certification of competence in the use of tests for assessment in the work and organizational field. This work is being carried out by a joint EFPA–EAWOP task force and could lead to a European qualification of competence in testing.

2.2.3. Other International Initiatives

International standards and guidelines have been developed in some other areas that relate to psychological testing and assessment. For example, an international

task force of leading practitioners in the field developed Guidelines and Ethical Considerations for Assessment Center Operations. These guidelines have been updated a number of times.

3. NATIONAL STANDARDS AND GUIDELINES

International guidelines and standards have both influenced national initiatives and been influenced by them.

3.1. The United States

There are a large number of organizations and committees involved in work that relates to testing and assessment practice in the United States. It is not possible to mention all of these here. However, some key ones are described in what follows.

3.1.1. The “Joint Standards”

The Standards for Educational and Psychological Testing (the 1985 version of the standards issued jointly by the American Educational Research Association [AERA], the American Psychological Association [APA], and the National Council on Measurement in Education [NCME]) have been widely adopted around the world as the authoritative definition of technical test standards. After a lengthy revision and consultation process, a new version of these influential standards was published in 1999. Many countries' psychological associations were expected to adopt these as the successor to the earlier edition.

3.1.2. Test User Qualification

Over the past few years, there has been some progress in the United States on the issue of test user qualification. In 2000, the APA Task Force on Test User Qualifications (TFTUQ) produced guidelines that inform test users and the general public of the qualifications that the APA considers to be important for the competent and responsible use of psychological tests. In this context, the term “test user qualification” is being used to indicate a desired level of competence rather than the award of some certificate or license or the outcome of a credentialing process (as is the case in the United Kingdom). The report suggests that the old three-level APA system (A, B, C) for classifying test user qualifications that was first defined in 1950 is now

obsolete and needs to be replaced by one where the competences required are defined in relation to the context, instrument, and use to which it will be put.

3.1.3. Computer-Based Testing

The Association of Test Publishers (ATP) has produced technology-based guidelines for the testing industry. The goal of the proposed guidelines is the international adoption by companies involved in technology-based testing. The guidelines are for use as an aid in the development, delivery, and use of computer-based certification examinations as well as psychological testing in general. The guidelines cover applications for use on the Internet and various multimedia computer strategies used to deliver, administer, and score tests.

3.1.4. Internet-Delivered Tests

In 2001, the APA set up a task force on psychological testing and the Internet to assess the extent and range of testing on the Internet and to review current practices. It aims to define and outline the issues raised by Internet testing, including test validity, administration, confidentiality of test taker and test results, test taker authenticity, ethical interpretations of test results (e.g., feedback), psychological dynamics of Internet testing (e.g., proclivity of being more revealing when taking Internet-based tests), copyright infringement, psychometric equivalence (e.g., comparability of tests results), license issue of the psychologist (e.g., crossing state lines), and interpretations based on limited assessment information.

3.2. European Countries

There is a great deal of work going on in Europe in relation to the development and encouragement of best practice in psychological assessment. Some major examples are described in what follows.

3.2.1. The United Kingdom

The United Kingdom was the first country to establish a test user certification procedure accredited by the national psychological association, the British Psychological Society (BPS). Both psychologists and nonpsychologists can obtain certificates in test use from the BPS. These qualifications are subject to stringent quality control or “verification” procedures and currently provide recognition of qualification in test use relating to occupational assessment. Similar

qualifications for educational testing became available in 2004. All of these qualifications are based on a set of performance standards defining the competence required of a test user and a set of guidelines defining how this competence should be assessed.

The BPS has a standardized process for the review of tests and has published a number of volumes of test reviews focused on assessment in the work and organizational assessment area. These are designed as “consumer” reviews for test users rather than being for a more academic audience.

All of the BPS procedures and services relating to testing and test use are now managed within a single organization, the Psychological Testing Center. This organization manages the delivery of test user certification and test reviewing and operates a Web site that provides information, advice, and guidance for test developers, test users, and test takers.

The BPS has produced a set of guidelines for assessment centers and standards for computer-based testing. The BPS has also produced guidelines on 360-degree feedback in collaboration with the Chartered Institute for Personnel and Development, the University of Surrey at Roehampton, the SHL Group, and the Department for Trade and Industry.

The British Standards Institute has issued a standard (BS7988) covering technology-based assessment. This standard focuses on many of the technical issues involved in the delivery of assessments by computer and over the Internet and is concerned mainly with educational testing and tests for licensing and certification. Unlike the ATP guidelines, this standard currently excludes areas of psychological testing (e.g., personality assessment).

3.2.2. Germany

In Germany, the national standards institute has published a “norm” setting out standards for assessment for job selection (DIN33430). These standards set out good practice for the process of assessment and include requirements relating to test quality and test user competence.

3.2.3. Finland

Guidance on good practice in assessment has been produced in Finland as a consequence of recent legislation relating to the European Union Directive on Data Privacy. This directive has had implications for all European countries on how test data can be used, the rights of test takers over their data, and what is done with the data.

Like the German standard, the Finnish guidance describes best practice for assessment process as a whole (in employment settings) rather than just for psychological testing. Recently, the Finnish Psychological Association developed test user certification procedures for psychologists and nonpsychologists based on this guidance.

3.2.4. Sweden, Norway, and Denmark

In Sweden, an institute, Stiftelsen för Tillämpad Psykologi (STP), was set up in 1996 to provide test user qualification certification, test reviewing, the quality audit of organizational testing policies, and an ombudsman function to which test takers may appeal. Test and test use quality assurance procedures build on the ITC Guidelines on Test Use and on the BPS test review and test user certification models. The STP also accredits organizational test policies and testing processes. Guidelines for organizational policies on test use are based on the model provided in the ITC Guidelines on Test Use.

More recently, Det Norske Veritas (DNV) has initiated a project to establish test user certification procedures in Norway, Sweden, and Denmark. DNV, one of the leading worldwide registrars for certification of ISO 9000 and related standards, is working in conjunction with the Norwegian Psychological Association, the STP, and representation from Denmark.

3.2.5. The Netherlands

In the Netherlands, Commissie Testaangelegenheden Nederland (CoTAN), a committee of the Dutch Psychological Association, has a long history of producing reviews of tests covering all areas of assessment.

More recently, the Institute for Best Test Practice (4TP) was set up with a set of aims and objectives very similar to those of the Swedish STP. The Dutch institute aims to improve the quality of test use in occupational and workplace assessment. It is making use of the ITC guidelines and the experience of both the BPS and the STP in setting standards with which users, instruments, and practices must confirm. The institute has developed procedures for examining the competence of test users, for reviewing tests (using the EFPA criteria), and for auditing organizations.

A guiding principle of 4TP is the need for transparency. First, the standards adopted must be open and

available for all to see. Second, all of the results of examinations carried out by the institute will be published on the Internet—registers of certified test users, reviewed tests, and quality audited organizations. Therefore, everybody interested in the quality of people, instruments, and practices will be able to access this information. In this way, it is hoped that the institute will provide a practical way of implementing quality and transparency.

4. CONCLUSION

The challenge for the future is to bring together the various standards and guidelines from different countries and organizations and to secure international agreement on the key issues. Work by bodies such as the ITC, EFPA, and EAWOP has made considerable progress during the past few years in moving this forward.

and/or self-sufficiency have been partially or extensively compromised temporarily or long term; interventions are aimed at restoring or improving level of independence or self-sufficiency, enhancing personal functioning and quality of life, or addressing the physical, architectural, social, cognitive, communicative, and/or other barriers to everyday life.

GLOSSARY

acquired disability A loss, impairment, or decline from the previous level of functioning or bodily integrity, sustained due to illness, trauma, or injury.

brain dysfunction A brain disturbance that can be caused by illness or injury and that results in disruption to life-sustaining autonomic functions or to motor, sensory, appetitive, affective/emotional, and/or cognitive functions subserved by the brain areas involved.

cognitive remediation Provision of treatment strategies geared to improve cognitive abilities directly or to teach compensation strategies for cognitive skills weakened by brain dysfunction and help people deal with changes in cognitive functions.

congenital disability A functional or physical impairment originating from a developmental event or deviation during or prior to birth of nonhereditary origin.

rehabilitation An interdisciplinary treatment approach, devoted to the optimization of physical and psychological functioning, where independence, personal autonomy,

Psychotherapy has among its goals establishing a new, or restoring a prior, sense of identity to patients whose sense of self has been deeply threatened by mental or physical trauma. Along with decreasing emotional suffering, the restoration of identity may be a key outcome of psychotherapeutic treatment in rehabilitation. Patients' losses include not only the physical aspects of disability but also the symbolic and psychological losses that ensue. Cognitive deficits may develop as a result of brain dysfunction, and these may also be targets of remediation techniques designed to compensate for, or directly strengthen, those functions that were weakened. Emotional sequelae, including depression, anxiety, terror, anger, blunting, constriction, instability, lability, and agitation, may also be foci of treatment. Broader issues involving psychosocial and interpersonal needs, physical dependence, personal care routines, medical comorbidities, vocational disruptions, and financial losses all can have impact. All that forms the fabric of quality of life may need to be

considered in treating patients with disabling loss in rehabilitation.

1. HISTORY

Among the early developments in the field of rehabilitation were concerns for the holistic treatment of people with physical disabilities. Dr. Howard Rusk, the pioneer of rehabilitation medicine as a specialty within medical practice, was dedicated to the notion that persons served were best viewed as people within a complex of not only physical but also psychological and social facets. The latter would include a focus on the emotional effects of disability and the social implications as well as on the vocational and avocational concerns that need to be considered.

The field of rehabilitation psychology was an outgrowth of the field of rehabilitation medicine in the sense that psychologists devoted themselves to the study and treatment of persons with acquired or congenital disabilities. Psychological treatment and psychotherapeutic treatment of persons with disabilities are now considered to be an integral part of rehabilitation medicine and behavioral medicine programs. Psychological rehabilitation draws heavily from fields such as rehabilitation, clinical psychology, neuropsychology, health psychology, behavioral medicine, counseling psychology, and developmental psychology. Practitioners come to the field from one of these areas and gain the specialized training necessary to confront the unique challenges encountered with rehabilitation of patients in psychological treatment.

2. POPULATIONS SERVED

Psychologists serve in adult and pediatric settings that include all ages of the life span—pediatric, adolescent, general adult, and geriatric. The populations served in rehabilitation and medical settings involve a great diversity of conditions. These include traumatic injuries of all kinds and illness-related disabilities such as neurological disorders, neuromuscular disorders, cancers, debility due to deconditioning from prolonged illnesses, amputations, spinal cord injuries, brain dysfunction, head traumas, and orthopedic conditions—in short, any conditions that may result in physical limitations or disabilities. Patients may have sustained multiple injuries in ski accidents or falls or may have been involved in car or diving accidents, resulting in spinal

cord or head injuries. They may have been victims of natural disasters or terrorist attacks, collapsed buildings, gunshot injuries, burns due to fires or explosions, or other tragic events. Patients may have undergone back surgery for spinal conditions such as stenosis or may have undergone hip replacement surgery due to osteoarthritis or degenerative joint disease. Others may have more chronic conditions such as Parkinson's disease, lupus, and multiple sclerosis.

Onset may be sudden such as in stroke, myocardial infarction, and Guillain–Barre syndrome. Alternatively, sudden onset (e.g., lower extremity amputation) can sometimes follow a prolonged period of declining function/disability and pain or even progressive surgeries. Time factors may play a role in patients' experience of disability, including chronicity and duration of condition, age at onset, and congenital versus acquired disability. For some patients, the longer the condition has existed, the more time they have had to adjust; for others, the pain or disability may have persisted for a long time, so that the stress can be additive or cumulative. Other factors to be considered include the nature of onset (e.g., traumatic vs nontraumatic, accident vs illness related), risk-to-life factors (e.g., initial brush with death, terminal nature of condition), and prognostic descriptors (e.g., progressive, stable, remitting, expected to improve). Also, the treating clinician must consider the question of awareness, that is, what the patient has been told, whether the patient knows the condition, and the patient's ability to be aware of implications based on emotional factors such as denial.

Psychological treatment in rehabilitation often deals not only with the stresses imposed by disability and altered life circumstances but also with issues of hospitalization and medical tests and procedures. Posttraumatic stress disorder may be an aspect of patients' emotional responses as they relive the accidents or traumas, sometimes in the form of flashbacks or nightmares. Naturally in the course of continuing treatment, psychologists may deal with a broad range of evolving and changing responses to the whole spectrum of effects of disability and its life-altering impact.

3. TREATMENT CONSIDERATIONS

3.1. Assessment

Psychological intervention often follows an assessment that can range from 1 hour to several hours and

generally taps all pertinent aspects of emotional response to the loss, change, or trauma. Emotional reactions may include anger, anxiety, depression, agitation, emotional lability, emotional stability, and even apparent indifference. Signs of affective blunting or constriction may be noted and need to be distinguished from illness-specific features such as the mask-like face (i.e., masked facies) often associated with Parkinson's disease and prosodic deficits (i.e., aprosodia) often associated with right hemisphere brain dysfunction. Included in this assessment is a focus on psychosocial history, vocational history, health habits (e.g., dietary, exercise, smoking, alcohol, recreational drugs), medical history, premorbid psychological functioning and history of treatment, suicide risk, ability to communicate emotional needs based on affective constriction and defensive styles, awareness of losses, emotional denial, cognitive ability to understand and appreciate the losses, prior risk-taking behaviors, educational history, and living arrangements. Also tapped are features of mental status and cognitive function as indicated through cognitive or neuropsychological testing during the process of psychological assessment.

3.2. Setting

The setting in which the patient is treated is also meaningful. Early phases of rehabilitation, which are often acute care or hospital based, may engender needs that are centered around medical or nursing needs, personal care routines, bodily functions, and/or food intake. Treatment often involves psychoeducation along with cognitive-behavioral or psychodynamic approaches to help educate a frightened patient who is unfamiliar with medical/hospital routines and terminology. Issues of dependence on caregivers—often strangers—for basic personal needs can engender feelings of helplessness, shame, anger, and/or depression as the patient grapples with losses to dignity, self-esteem, and sense of control over bodily functions. The treating psychologist must be familiar with the physical status and needs of the patient. By conveying knowledge of the medical/physical needs and a sense of competence, the experience becomes more normalized for the patient, and expectations are addressed from both educational and psychological perspectives.

3.3. Nature of Stressors

Disability itself produces stressors that are cumulative or interactive. Physical losses, including motor deficits

and sensory losses, affect all aspects of mobility, elimination functions, and activities of daily living. Speech or swallowing deficits may ensue, affecting quality of life in terms of communication and basic appetitive pleasure. Personality changes or cognitive losses may have far-reaching effects on sense of self, interactions with family and others, and ability to resume prior activities such as work and leisure activities. The Americans with Disabilities Act of 1990 offers guidelines and legal protection to people with disabilities regarding access to public services, transportation, employment, and so forth. Yet the modifications and the special equipment needs, as well as their visibility, may also be stressful. The fact is that a physical disability can involve disruption not only to the body and its functions but also to more psychological entities. In fact, among the most devastating losses experienced by the patient may be losses to aspects of the self. The role of cultural factors and attitudes is also critical in shaping the individual's responses to a disability and the responses of others in that subculture. Nonetheless, familial and individual differences are many and may have even more meaning to the patient than to the subculture alone.

3.4. Developmental Considerations

For congenital conditions producing physical or cognitive disabilities, there are complex issues pertaining to the development of sense of self involving body image and sense of mastery. These may be particularly salient for the child who is growing up with a physical disability. Patients may grapple with guilt regarding the impact of their disabilities on their families. In some instances, especially if there are genetic components to a disabling illness, there may be added stress on the parents' marriage and concerns for genetic transmission. Some adults with lifelong disabilities have come to develop special skills that help them to adapt in the world, including social skills, navigational skills, and personality features. These skills, which are highly prized for their adaptive value, may form a core part of the identity in a very positive way. Identification with disability may then be very strong and complex. Patients with exacerbation of long-standing disabilities (e.g., postpolio syndrome) often find it difficult to take advice from less seasoned staff members who might not know their conditions as intimately as do the patients.

Other developmental considerations pertain to stage of life, such as when the disability occurred during the

life span, prior experience with illness or disability in oneself or others, and the availability of supports. The latter is crucial in working with an aged population where many family members, who could be of support, may have already died or become disabled themselves.

4. PSYCHOLOGICAL ISSUES

The issues that are confronted by the patient and psychotherapist are many and include mortality, mutilation, loss of limb, helplessness, loss of body functions, alterations in sexual functioning, loss of psychological entities such as sense of competence and mastery, loss of personal identity and ways of knowing oneself that may be shattered or threatened by physical injury, loss of job, loss of one's sense of manhood or womanhood, and role alteration within the family or with friends. Patients are frequently frightened of repeating trauma and may have flashbacks or dreams of impending disaster anticipated with devastating illness. In end-stage illness, pain management is a concern, as is worry about losing one's mental faculties, whether due to the illness or due to medication. Sometimes, there are issues of unawareness, and these are among the most challenging ones because the patient might not even realize the severity of the situation. This unawareness is often due to cognitive dysfunction itself but is sometimes due to significant emotional denial that blocks the awareness and the ability to make sound judgments regarding care or planning needs. There may be overestimation of abilities that can pose ethical challenges to the treating therapist with regard to issues of competence. These often do not require legal/judicial intervention because there might also be the possibility of improvement in the patient's status.

Psychological treatment of the patient in rehabilitation is aimed at the emotional sequelae of the event onset or ongoing situation of loss. Reactions such as depression, anxiety, anger, agitation, emotional lability, and instability of mood are very common. The supportive normalization of certain reactions is a key aspect of forming the therapeutic bond and educating patients, particularly less medically sophisticated patients, about what to expect. For many others, a more aggressive approach to treatment of the significant psychic distress and emotional disorders is indicated. The notion of losing control not only over physical functions and body parts but also over the emotional response system can be very threatening

for patients who previously took pride in emotional coolness. Patients who used denial or avoidance as defensive styles prior to the onset of their illnesses/disabilities will continue to use these defenses in dealing with the disabilities. Denial, as a response to disability, poses a significant challenge to treatment not only by psychotherapists but also by other treatment providers such as physicians, rehabilitation staff, and family members or caregiving aides.

The degree to which there is distress and suffering is crucial to consider in any psychological treatment. A depressive reaction may be chronic whereby the disability and its privations persist over years or decades. Facilitating adaptation to disability may then be a realistic goal for the psychologist. Adaptation, unlike "acceptance," means that an individual is coping with and dealing with the situation to the best of his or her abilities. Adaptation does not imply that the person has accepted a notion of permanence or resignation, and it certainly does not imply that the person has lost hope of improvement (although he or she might very well have). Restoring identity to the patient whose physical or cognitive losses have compromised his or her identity is an integral part of rehabilitation and therapy.

5. THERAPEUTIC APPROACHES

Psychological treatment may evolve from crisis intervention to approaches that address deeper issues as the patient emerges from the acute phase of shock or traumatic stress. In time, therapies using more depth or psychodynamic models may be chosen to work on emotional issues, or cognitive behavioral approaches may be used to deal with depression, anxiety, or other emotional responses. Stress management techniques are employed to help relieve anxiety, tension, and posttraumatic stress. Other models, such as existential explorations of meaning of loss and life, can be selected for use by the therapist as indicated.

Once adapted to the needs of the setting and the patient, traditional psychodynamic approaches are helpful to the patient in dealing with new or unresolved needs and conflicts that may pertain directly to the disability. Issues regarding dependence and care, having developmental roots, or reflecting challenges to the personality structure will often surface as the patient grapples with unwelcome changes in physical functioning. The impact on well-established patterns of interactions and roles within family and other social structures assume primary importance to the

patient. Thus, psychodynamic approaches can be very useful in helping patients, as well as staff and family, to understand the basic emotional features that are threatened by the disability (e.g., the need for self-reliance or control) or are exacerbated by the disability (e.g., fears about abandonment or loss of love). Historical roots of needs or conflicts that have remained dormant prior to the onset of disability may be more amenable to exploration since the onset and may allow for unexpected resolution. Support, empathy, and genuine caring can be integral parts of the healing process in adjusting to the trauma of loss and disability and of the conflict/need resolution process in using the psychodynamic approach to treat the patient in rehabilitation.

Stress management and relaxation techniques, alone or in conjunction with the other forms of psychological treatments offered, are very useful in the treatment of the medical or rehabilitation patient.

Other psychological treatments may involve behavioral management strategies employed when behavioral disruptions occur. These disruptions can be induced by a stress reaction in the context of usually more limited coping skills. Alternatively, they can occur as a result of restricted access to the patient's previously used coping skills due to the limitations of disability itself. There may also be underlying psychiatric disturbance that is exacerbated or aggravated by the psychic trauma of disabling losses, leading to psychic regression or decompensation. Sometimes, there may be primary effects of brain dysfunction on behavior (e.g., initiation, sexual disinhibition, problem-solving skills, memory, attention/concentration, impulsivity, agitation, aggressive responses, adynamia, apathy). These effects may disrupt behavior to a greater or lesser degree, and when they are seen in the social sphere or with family, they can be very disturbing. Often, the psychologist treats the patient's behavior through a combination of psychotherapy and behavioral conditioning principles. Behavioral management meetings may be organized to help staff implement individualized approaches to behavioral management issues, whether due to significant cognitive dysfunction or the patient acting out under stress.

Because some patients might not even realize a need for psychological treatment, they may appear to be uncooperative, defensive, unmotivated, and/or agitated. Judgment and safety may be affected by lack of awareness or by impulsive behavior. Patients might not even fully realize the implications of their condition, or may not yet realize the extent of the change in their behavior or emotional responses. These are challenges

to treatment and may put the burden of goal setting on the treating therapist until these patients can better acknowledge changes and appropriate treatment goals.

With regard to the cognitive impairments that may accompany certain disabilities, specifically those involving brain function of various etiologies, there is a tradition of cognitive remediation treatments. Such treatments are frequently adjunctive to treatments offered by other disciplines, such as occupational therapy and speech therapy, and are often integrated into the patient's physical therapy program. Therapy is tailored to the nature of the deficit, so the patient may be treated for basic disturbances. Deficits are measured by using neuropsychological assessment tools if possible. If deficits are too severe, they are measured by observational assessment and by comparison with scales of recovery after brain injury. Neuropsychological deficits may involve arousal level (i.e., hyperaroused or hypoaroused), attention and concentration, orientation, thought coherence, visual perception, visuospatial skills and visual attention, reasoning, coherence, judgment, planning, initiation, response latency, organization, inhibition of response and problem solving, all aspects and types of memory, and language functions (with the latter being treated primarily by speech and language pathologists), among others. Basic functions, such as reading, writing, copying, and arithmetical skills, may be affected by any of these deficits.

For brain dysfunction, model systems have been designed to integrate the cognitive-behavioral treatments within the entire rehabilitation treatment program throughout the day. Various brain injury facilities have established treatment programs that integrate the conceptualizations of neuropsychological recovery after brain injury. These programs may exist ideally within a dedicated unit, but they also may be effective in "units without walls." These are designed to have the complete treating staff integrate the recommended cognitive approaches within their disciplines, tailored to the individual cognitive, behavioral, physical, and emotional losses of the patient with diffuse or traumatic brain injury.

Cognitive remediation treatment may target skills lost or weakened by brain dysfunction and may involve either direct remediation of the weakened skill or compensatory strategies that help the patient deal with and compensate for the losses (e.g., training in the proper use and organization of a log/notebook for the patient with memory storage/retrieval difficulties). There is some debate in the literature regarding the

efficacy of compensatory versus direct remediation strategies. Both individual remediation and group remediation have been used in different settings. Psychological treatments have also been used in novel ways to enhance physical functioning (e.g., biofeedback techniques to improve aspects of motor control in certain patients).

Treatment of comorbid psychiatric or substance abuse issues may pose a challenge in the medical rehabilitation setting. However, these issues may arise with a patient who has a preexisting personality disorder (with aggressive anger, impulsivity, risk-taking, and/or acting-out behaviors). In fact, the personality trait may perhaps be expressed in more exaggerated form due to the emotional stress of loss or to the direct or secondary effects of brain injury. Sometimes, particularly in the aftercare or outpatient setting, the patient may even be referred to the psychologist specifically for treatment of these disturbances (e.g., impulsivity, anger/aggression management). The impact on significant others and family may be profound, especially if there is a change or worsening of a preexisting problem or a new emergence of a disturbing behavioral symptom. Family members may feel at a loss to deal with these disruptions, and counseling may be beneficial.

6. CONCLUSION

Depending on the setting, training, and need, therapists may take a more active or directive role. Some may become involved in coordination on behalf of patients for social services and/or vocational needs; with agencies, the challenge is to help the patients rebuild their lives. Others may be more involved in the team approach. The key is realization that the patients' needs may be complex and interdependent. Often, treatment is not offered in a vacuum and ideally is offered within a coordinated system, however tightly or loosely defined, because patients might not be able to negotiate through other aspects of life planning due to devastating change and loss or to the cognitive disruptions (if any). The specific approach and training of the therapist may dictate whether psychodynamic, cognitive-behavioral, stress management, cognitive remediation, or more counseling/educational-type approaches are used, or are useful, for the needs of patients.

Rarely are the challenges of identification more apparent than in working with persons who may be of similar age, background, and/or vocation and who are

reasonably healthy until some catastrophic loss occurs. Psychologists might need to use the identification process in a manner that does not cloud patients' individuality and uniqueness of response, so that the therapists maintain the therapeutic stance needed to work effectively while retaining subjective understanding. The task of simultaneous subjectivity and objectivity is, of course, not unique to the practice of psychotherapy in a rehabilitation setting. In the work of psychological rehabilitation, however, there is a constant and humbling realization of one's own humanity and vulnerability. This sense of personal vulnerability may tug at the heartstrings. With time, experience, supervision, and self-awareness, this task is made easier for psychotherapists. Of course, the remarkable ability to adapt may be a humbling experience for clinicians working with patients rallying against all odds to cope with tasks of daily life that have become monumental. The inspiration derived can fuel professional growth, enhance therapeutic work, and enrich personal meaningfulness of the many values that form part of therapists' identity.

GLOSSARY

anxiety An experience characterized by fear, doubt, or worry; at a physical level, it is often felt as a racing heart, a nervous stomach, jitteriness, or jumpiness.

arousal A physiological state characterized by heightened activity of the sympathetic division of the autonomic nervous system; it prepares an organism for action and is a common, if not necessary, component of most athletic experiences.

efficacy expectations The belief that one is capable of performing a given behavior in such a way as to bring about a desired outcome; experienced athletes may hold higher efficacy expectations about their abilities to perform various skills and tasks in sport.

flow A state of consciousness in which one's attention and concentration are focused on an activity with precision and clarity; the performance of the activity is experienced as effortless and pleasurable and is often superior by objective standards.

individual zone of optimal functioning (IZOF) The intensity magnitude of a given biopsychosocial state in which an individual athlete performs best; IZOFs exist for the behavioral, cognitive, affective, motivational, bodily, operational, and communicative domains.

imagery The internal experience of sensory stimuli that are not externally present; for instance, visualization involves seeing something through "the mind's eye" and is a skill often used by athletes to calm anxiety, focus form, and facilitate performance.

mastery experiences Episodes of behavior in which a desired outcome is achieved through the actor's own effort; they lead to a sense of accomplishment, and when they accumulate, they facilitate a sense of competence and encourage efficacy expectations.

mental rehearsal A set of activities wherein an athlete imagines himself or herself performing some skill or task or behaving in a desired fashion; although this may involve imagery, elite athletes may mentally rehearse other components of an experience such as what it will feel, sound, and even smell like to perform an action.

psychological skills A set of techniques and strategies used to optimize athletic performance; they are largely nonphysical in nature.

self-instruction A process that encompasses internal reminders, reassurance, and self-talk; it may be used as a self-regulatory tool and is often effective in the remediation of some of the negative emotional states that athletes commonly experience.

self-monitoring The process of attending internally to one's ongoing cognitive and emotional processes as well as externally to one's behavior and performance.

self-regulation A process that is dependent on self-monitoring and involves evaluating one's degree of success in achieving desired goals as well as implementing both internal and external feedback to make necessary corrections; self-monitoring and self-regulation in sport performance appear to be skills associated with athletic success.

Psychological skills in sport constitute a set of techniques and strategies used to optimize athletic performance. Psychological skills have traditionally been neglected in favor of physical skills in assessing athletic performance. However, increasing evidence suggests that psychological skills may be just as important as their physical counterparts, particularly in elite-level athletes. Psychological skills in sport comprise different practices and strategies across the realms of behavior, cognition, emotion, motivation, and interpersonal functioning. Some techniques may facilitate the enhancement or development of various skills in athletes; however, much of what is known about psychological skills has been gleaned from studies of elite athletes, and research on skills training is not yet extensive. Therefore, caution is recommended in attempting to train psychological skills in a "one size fits all" fashion. However, interventions may be more confidently "targeted" to a specific group or, better yet, can be "tailored" to a specific individual.

1. INTRODUCTION

Andrea shakes out the tightness in her arms and shoulders while she waits in the shadows outside the gym's side entrance. She peeks around the corner and is hit by a gusty winter breeze from the open doors across the floor. The murmuring crowd looks like a tidal wave, rising high up into the rafters, waiting to crash down on her. She has competed in the championships before, but never in front of this many people.

Suddenly, the loudspeaker crackles, and the master of ceremonies announces a 5-minute break to check equipment before Andrea is due to compete. Her heart surges, and suddenly her limbs feel stiff and her skin feels clammy. She had been all ready, psyched up, and in the perfect rhythm. Now, she will get cold and go

out there and make a fool of herself in her biggest meet ever.

Andrea thinks of her coach. He is not there, but she knows what he would say. She takes a deep breath to slow down her heart, remembering how well she has done in big meets before. Her practices have been going better than ever lately. Didn't she tell her friend just last night that her confidence was at an all-time high? Andrea closes her eyes and imagines what she will be doing in 5 minutes, what her body will feel like as it goes through the motions that are by now second nature to her. Her heart begins to slow, but at the same time, she bounces on the balls of her feet, does pushups off the wall, shakes her legs out. Blood returns to her limbs, replacing the clammy, paralyzed feeling. She takes another deep breath.

Andrea's name buzzes over the loudspeaker, but it seems distant, just loud enough to reach her. She walks into the gym, concentrating only on the equipment and imagining what her performance will feel like. The crowd begins to disappear; she hears only the rhythm of her own breathing and sees only the equipment. With a calm mind, she steps into the competition area, her body feeling like a compressed spring that is warm and ready for action.

In a minute, it is all over. Andrea steps back and looks up. The judges nod approvals, but she already knows that her performance was a personal best. The crowd's cheers spill down on her now like fresh air, no longer a suffocating tidal wave. She thinks of her coach and smiles.

This scenario is one example of many performance situations that confront athletes. Naturally, the situational demands of athletics vary largely depending on the sport. Is it an "open" sport, where the challenges and demands are constantly changing, or is it a "closed" sport, where the tasks are performed against a relatively stable backdrop (e.g., the green on that troublesome fourth hole does not suddenly change its size or slope, despite the frustrated impressions of golfers)? Is the athletic endeavor an individual one, such as wrestling or weightlifting, or a team game, such as soccer or basketball?

Research on elite athletes has always studied the psychological dimensions of athletic performance. What makes an athlete a good athlete? Given equal physical capabilities, what makes one athlete better than another? What makes a good athlete an extraordinary one? Contemporary sport psychology emphasizes a variety of factors that may influence performance differently across individuals and situations. For a

time, however, the presumably stable personality traits of athletes were thought to play the largest role in their success at sport.

1.1. The Athletic Personality

During the 1960s and 1970s, research examined personality differences between athletes and nonathletes as well as between successful athletes and unsuccessful athletes. Was there a general “athletic personality”? Were athletes more extraverted than their nonathletic peers? Were elite athletes a “different breed” from their less successful counterparts—more disciplined and aggressive? To explain the personality type associated with good athletes, Morgan proposed a “mental health” model suggesting that athletic success is inversely related to psychopathology. Other evidence gathered through the use of conventional personality inventories suggested that successful athletes tended to be more assertive, dominant, aggressive, self-sufficient, and vigorous; to have a higher need for achievement; and to be less anxious than less successful athletes.

Although such personality factors seemed to explain some of the differences between more successful athletes and less successful athletes, research of this sort fell out of favor by the mid 1970s. Sport psychologists grew more interested in differences between individuals rather than group commonalities. Successful athletes vary widely in characteristics such as pain tolerance, optimal arousal levels, and anxiety, and these factors interact in different ways across different athletes in different situations. So, if there is no general “athletic personality” solely responsible for one’s performance in sport, what accounts for athletic success?

1.2. Psychological Skills in Sport

The answer appears to lie in the broad array of psychological skills reported by successful athletes. Surveys of elite athletes and studies of peak performance reveal a variety of mental, emotional, and motivational techniques that appear to account for a large part of success in sport. Evidence indicates that elite athletes employ mental imagery and bodily feedback, generate and maintain motivation, handle performance anxiety, concentrate, and retain self-confidence more effectively than do their less successful counterparts. Furthermore, such skills may be at least partly modifiable.

This article considers psychological skills in five broad categories: those skills that are primarily bodily

and behavioral, those that are cognitive, those that involve primarily emotions, those that concern motivational states, and those that encompass interpersonal functions in sport. Bodily and behavioral skills relate to controlling one’s physiological functions and actions such as regulating one’s bodily state and readiness and acquiring and polishing motoric routines that are necessary for successful performance. Cognitive skills encompass a broad class of activities such as using mental imagery, monitoring one’s thoughts and cultivating effective self-talk, and attending and concentrating in optimal ways. Emotional skills typically involve the regulation and optimization of affective states, including the ability to control anxiety and foster positive mood and feelings about oneself. Motivational skills provide athletes with inducement or impetus to excel and may involve things such as goal setting and responding to social facilitation. Finally, interpersonal skills relate to one’s smooth interaction with others in sport and include communication abilities and the regulation of emotion in a team environment. Many skills function across several of these domains. The current classification scheme is intended only for ease of presentation and description and not as a discrete taxonomy.

1.3. Bodily and Behavioral Control Skills

Behavioral and bodily control skills operate at the physical level to enhance athletic success. Two primary skills involve regulating one’s level of arousal and practicing or physically rehearsing motor skills.

1.3.1. Physiological Arousal Regulation

Physiological arousal refers to a state of heightened activity within the autonomic nervous system. High levels of arousal bring on the so-called “fight or flight” response, a reaction to threat and stress inherited from humans’ distant mammalian forebears. Athletes may experience physiological arousal through the distinctive “charged-up” feel of adrenaline, increased flow of blood to skeletal muscles, increases in heart rate and respiration, and so forth.

It is important to note that such physical sensations often accompany the emotional experience of panic or anxiety. Although anxiety usually involves a strong component of physiological arousal, the two phenomena are not identical. An athlete may be in a state

of high physiological arousal but not be anxious; for instance, he or she may be angry. Similarly, an anxious athlete may experience low levels of physiological arousal, particularly if he or she is exhausted but still worried.

Some have suggested that, at an optimal level, arousal may actually diminish anxiety and/or serve to focus selective attention. For these reasons, different athletes often prefer different levels of arousal. One useful way in which to understand this relationship is from the perspective of an individual zone of optimal functioning (IZOF), an idea proposed by Hanin.

An IZOF corresponds to the intensity magnitude of a biopsychosocial state within which a given athlete feels most capable of executing the skills that are necessary for success in his or her sport. Examining autonomic arousal from this perspective, athletes must discern the levels of arousal at which they perform best. This may vary across behaviors, skills, and situations. Athletes who are aware of their somatic IZOF are able to detect when they are over- or under-aroused and then can take corrective measures to regulate their arousal.

The ability to self-regulate arousal levels is critical for athletic success. This may take the form of last-minute mental or physical rituals to increase or decrease arousal, as discussed previously, or may be a more gradual process drawn out for hours (or even days) prior to a competition. In fact, the regulation of arousal can be important even during practice sessions. The ability to “turn on” or “turn off” the autonomic nervous response is largely a learned skill that is discussed later in the article.

Finally, different sports require different levels of physiological arousal. Games that are dependent on fine motor skills—archery, golf, shuffleboard, billiards, and so forth—clearly require a relative degree of calmness for effective skill execution. Sports that require strength, gross or explosive motor movements, and combative maneuvers—football, wrestling, sprinting, boxing, and so forth—generally necessitate higher levels of physiological arousal, although again optimal zones vary by individual athlete. It is also possible to be overaroused even in such sports; for instance, a soccer player may lose what is called “touch” in his or her passes and shots, instead kicking the ball into the stands.

1.3.2. Behavioral Practice

Motor learning of sport-specific skills requires physical repetition. Different degrees and types of repetition

increase different skills at different rates in different athletes. But whether skill acquisition is sudden or gradual, the adherence to some sort of practice regimen is nearly always necessary for the learning, maintenance, and continued development of athletic skill.

One consideration is the amount of practice. Early research on the amount of practice in motor performance suggested that plateaus or ceilings sometimes may be reached, but modern work on deliberate (i.e., effortful) practice suggests that sustained practice generally leads to continued improvement, even over long periods of time. The relationship between practice and skill acquisition may or may not be linear and is usually a function of the athlete, the skill, and the degree of learning that has already taken place.

The variability or breadth of practice is also an important consideration. To learn a complete repertoire of sport-specific motor skills, an individual must practice the complement of skills that the sport requires. Sometimes, it is also beneficial to practice under a variety of conditions, particularly if the conditions of competition vary (as in changing weather patterns or variable lighting). Thus, varying the motor behaviors themselves and the conditions under which they are executed may lead to greater degrees of overall skill acquisition.

Finally, performance on complex motor tasks may be improved by decomposing them into simpler component movements. An athlete practicing a partial movement may focus attention and effort more thoroughly. Thus, proficiency acquired at these task parts may then translate into greater proficiency at the whole task. Part task practice typically works best for behaviors in which component parts are not highly interdependent; complex behaviors in which components are more highly organized and coordinated may benefit less from decomposition into separated constituents.

2. COGNITIVE SKILLS

Cognitive skills are those that primarily involve mental processing. This section discusses three categories: attention and concentration, mental rehearsal and imagery, and self-monitoring.

2.1. Attention and Concentration

Within the realm of sport, attention and concentration are important in many ways. Athletes need selective

attention to extract relevant features from the field of activity. Likewise, divided attention may be called on to follow diverse streams of action, particularly in open sports. In the earlier example, Andrea must monitor processes inside herself, such as her bodily feelings and sensations, as well as the events in the competition area. Without good divided attention skills, she might have missed her name when it was called over the loudspeaker.

Attention and concentration skills involve focusing mental effort on task-relevant cues and filtering out distractors. Some evidence has linked attention to optimal levels of arousal, and it has been suggested that the superior attention skills of elite athletes are related to their ability to regulate their own arousal levels. Optimal levels of arousal may narrow or focus attention on task-relevant details in the environment. Conversely, under- or overaroused athletes may find themselves to be distractible. But attention may also be focused too narrowly, with less successful athletes overfocusing on minute details of competition and not seeing “the big picture.” In addition, less successful athletes may tend to allow their attention to focus on negative perceptions of themselves or their performance.

In this vein, Moran has classified challenges to attention and concentration as arising from either external distractors or internal distractors. External distractors arise from the environment and generally involve things such as crowd noise, equipment and playing conditions, verbalizations and strategic interference from opponents, and visual distractions. Internal distractors involve things such as misplaced or excessive thoughts about the past or future, waning motivation and fatigue, and anxiety. Attention and concentration skills permit athletes to screen these distractors and focus on relevant cues and situations developing during a practice session or competition.

Also relevant is Nideffer’s model of attention, which proposes that attention may be either internally directed or externally directed and be either broad or narrow in scope. Different athletes may have preferred attention styles, and different sports may have different attentional demands. For instance, in soccer, an individual must direct attention largely externally and in a broad fashion to teammates, opponents, and other outside task demands. Optimal attention is a function of how well the individual’s preferred attention mode fits that demanded by the sport. From a psychological skills perspective, successful attention during sport may be contingent on an athlete’s ability to detect and implement the sort of attention required.

Some research has also found that elite athletes tend to use associative, as opposed to dissociative, attentional strategies. Associative strategies involve an active comparing of task demands with one’s physical capacities—a continual comparison of external and internal perceptions. Dissociative strategies, on the other hand, involve separating external task performance from kinesthetic and somatic feedback, that is, “shutting out the pain” or distracting oneself from unpleasant bodily sensations. For instance, the fact that elite distance runners report using associative attention (whereas mediocre runners report using dissociative strategies) suggests that superior performance may in part be a function of matching athletes’ physical abilities to external task demands—a process that is difficult, if not impossible, if athletes have “tuned out” their bodily signals.

The ultimate form of concentration occurs during episodes of peak performance labeled as flow. Peak performances are episodes in which athletes report complete engagement with their immediate tasks, sometimes yielding results of an incredible nature. Several features of peak performance episodes appear to be noteworthy. Athletes in flow report that all things irrelevant to the immediate task tend to recede from awareness. The spectators, distracting thoughts, and indeed even pain may disappear from athletes’ perceptions. All available resources are focused unswervingly on the athletic performance. Episodes of peak performance are characterized by such supreme concentration that even an awareness of time may be diminished or lost. Finally, athletes reporting flow experiences often say that they feel as though their performance is executed with an automated ease.

2.2. Mental Rehearsal and Imagery

Another skill that clearly contributes to athletic success is mental rehearsal. Mental rehearsal refers to the practiced imaging of successful athletic performance. Imagery refers to the specific thoughts, sounds, smells, visual array, and sensations that an individual experiences when he or she conjures up a mental experience of something. Mental rehearsal and imagery, particularly of specific skills, may facilitate motor learning. Repeatedly imagining successful athletic execution may enhance an individual’s certainty that he or she is capable of performing a given skill. In contrast, evidence suggests that although successful imagery is related to better performance, imagining unsuccessful outcomes tends to be a detriment to performance. Elite athletes

also report that the images they employ are extraordinarily clear, vivid, and multisensory—nearly lifelike.

Imagery is not confined to visualization. Many elite athletes report using a holistic form of imagery in which they imagine the sounds, feels, and even smells of a situation. Elite athletes also report using “first-person” imagery, that is, imagining successful outcomes from their own perspectives. Less skilled athletes may be more apt to use external imagery in which they view themselves performing some action from the outside as if they are watching a video of themselves.

2.3. Self-Monitoring

The execution of physical skills is only the beginning of athletic performance. Success in sport also involves monitoring one’s performance, evaluating it accurately against expectations and task demands, and then changing or maintaining it accordingly. Also required is the awareness and regulation of thoughts, feelings, and even physiological arousal. Self-monitoring is the ability to accurately perceive and evaluate performance (or internal experience) against task demands, whereas self-regulation is the ability to manipulate one’s behavior (or internal states) accordingly.

Some evidence suggests that elite athletes are better able to self-monitor and self-regulate than are their less successful peers. In evaluating performance against demands, individuals with high mastery of the tasks at hand (i.e., more successful athletes) seem to notice and use feedback from both positive and negative aspects of performance. In contrast, individuals who are low in task mastery (i.e., less successful athletes) seem to benefit only from focusing on the successful dimension of their performance. This does not imply that to become a better athlete, one must immediately begin focusing on performance failures in addition to successes. On the contrary, such a focus may be counterproductive to self-confidence and inappropriate in less advanced athletes.

In addition to evaluating one’s behavioral outcomes against those called for in a sporting situation, self-monitoring often involves tracking thoughts. Negative thoughts often exert deleterious effects on performance. In the earlier example, Andrea experiences doubt about her ability to deal with the unexpected delay in the form of a sudden thought. The awareness of such thoughts, called negative self-statements, is extremely important in athletic performance, particularly because many people are not immediately conscious of them.

3. EMOTION SELF-REGULATION SKILLS

This section focuses on two areas that are closely related to functions of emotion: the relationship of anxiety to athletic performance and the nature of self-confidence and self-efficacy.

3.1. Anxiety and Personal Meaning

For many years, performance anxiety in sport was considered to be debilitating, that is, to be avoided at all costs. More recent perspectives suggest that such blanket conclusions are somewhat oversimplified. The nature and effects of anxiety vary highly across individuals and situations. To be sure, performance anxiety often hampers otherwise talented athletes, and some athletes manage it better than do others. The worried emotions that are characteristic of anxiety often have cognitive and physiological counterparts that may be controllable through self-talk or relaxation. But perhaps most important in the management of anxiety is the meaning that athletes attach to it.

For some athletes, anxiety represents a fundamental fear of failure that has deep personal ramifications. Many athletes attach their identity or self-worth to their athletic abilities and performance. In this case, failure in sport is tantamount to failure as persons, a shortcoming that is much more profound and fundamental than merely losing a game or performing poorly during a competition. Poor performance, from this perspective, is a destructive event to be feared and guarded against at all costs, yet its mere potential is so threatening that athletes can never ignore or forget it. In instances such as this, anxiety is debilitating precisely due to the meanings attached to it.

Although most athletes report that high levels of anxiety are not pleasant, anxiety may be facilitative as well. Research with some elite athletes suggests that they view their anxiety as an ally or a companion. For them, insufficient anxiety may be disconcerting because it signals a lack of interest or engagement in the task at hand. For these athletes, management of anxiety involves “pacing”—allowing a slow buildup of anxiety, beginning days or even weeks before a competition, that spurs them to maximal performance. Rather than eliminating anxiety entirely, athletes may be aided by developing an understanding of the function that anxiety plays for them. Once this has been achieved, it will be easier to know how to regulate anxiety so that it

may be kept at levels that are facilitative, but not inhibitory, of performance.

3.2. Self-Confidence and Self-Efficacy

Self-confidence is a general feeling of competence or certainty in one's ability to succeed. Self-efficacy refers to the belief that one can successfully perform a specific action. Both are critical to athletic performance. Because self-confidence is so vague and general, the descriptions in this section note the components that recent research suggests constitute self-confidence in sport as well as a general framework for understanding the role of self-confidence in athletes.

Vealey proposed a model in which self-confidence in sport may be seen as a product of nine dimensions: mastery, demonstration of ability, physical/mental preparation, physical self-presentation, social support, coaches' leadership, vicarious experience, environmental comfort, and situational favorableness. These nine areas can be grouped into three domains: Achievement (involving mastery of sport skills and the demonstration of an athlete's ability), Self-Regulation (encompassing an athlete's degree of physical/mental preparation and feelings about physical self-presentation), and Climate (including an athlete's sense of social support, perceptions of coaches' leadership, favorable vicarious experiences, and comfort with the environment and degree of situational favorableness). To the extent that these factors arise or are arranged in a more advantageous way, an athlete will feel more confident in sport.

At a broader level, self-confidence is not merely the absence of doubt or the rational certainty of success. Like anxiety, self-confidence may be deeply tied to athletes' personal meaning systems. Relative to their less skilled peers, elite athletes may experience a more flexible connection between their self-worth and their sport performance. The result may be a decrease in felt performance pressure because their value as persons is not totally invested in any particular performance. In other words, elite athletes may have more ability to remain "faithful to themselves" (as suggest by *confidere*, the Latin root of "confidence") regardless of the outcome of their sport performance.

Successful athletes also generally hold high efficacy expectations. Efficacy expectations are anticipations of achieving desired outcomes or goal states. Efficacy expectations may be increased through the praise and

assurance of others as well as through techniques such as mental rehearsal and imagery. But efficacy expectations are usually developed through repeatedly performing a graduated series of tasks more and more successfully. This process is called mastery.

When an individual performs some action successfully, it serves as a mastery experience. A mastery experience involves executing a behavior that leads to a desired goal state, with the result being an increase in the athlete's confidence that he or she can perform the action successfully in the future. Practice in sport allows athletes to build self-efficacy through potential mastery experiences—but in a safe environment where failure does not result in the loss of competitions. Successful performances in prior competitions may be even better mastery experiences because they involve achieving goal states under conditions similar to future competitions. In the earlier example, although Andrea has never performed before such a large crowd, she has competed previously under conditions that were similar in other ways.

4. MOTIVATIONAL SKILLS

This section discusses two types of motivation common in athletics: goal setting and social facilitation. Goal setting usually serves long-term purposes, whereas social facilitation is generally an external motivator on which some athletes capitalize.

4.1. Goal Setting

Goal setting marshals and directs an athlete's energies and efforts either in the short term, as in Andrea's intention to win her immediate competition, or in the longer term, as in her plans to increase her conditioning during the off-season. Successful athletes generally report using personally meaningful goals. Choosing goals with little personal relevance is likely to produce diminished effort. In pursuing their goals, elite athletes also tend to report a healthy balance between their athletic pursuits and other dimensions of their lives. Athletes who drive themselves single-mindedly may generate momentum in the short term but often tend to ultimately lose balance in their lives. Because of this, they may be more susceptible to slumps in motivation and performance.

In general, research suggests that performance benefits more from specific and/or realistic goals than from vague and/or unrealistic goals. Likewise, some evidence suggests that intrinsically motivated athletes

may improve when allowed to set their own goals, whereas extrinsically motivated athletes may improve when others set their goals. Another area of research has examined the effectiveness of goals aimed at task mastery versus goals aimed more externally at competitive superiority. Individuals motivated by task mastery challenge themselves in ways that develop their skills, whereas individuals motivated primarily by outcomes may choose goals or activities that are easily accomplished to avoid threats to self-esteem. It is unclear whether task mastery goals lead to better performance than do outcome-oriented goals, but athletes who employ task mastery goals do seem to experience greater increases in self-efficacy than do those who use outcome-oriented goals.

4.2. Social Facilitation

Another motivational source in athletics lies in social facilitation. Social facilitation is a process whereby performance is increased due to the presence of others. It is one of the oldest areas of sport psychological research. Better performance in the presence of competitors or spectators has been explained by classical psychological concepts such as drive theory. Spectators tend to increase arousal, and drive theory proposes that arousal increases the performance of dominant responses. This is a desirable state of affairs when dominant responses are correct and well learned, as in familiar tasks. But the presence of spectators may hamper performance when dominant responses are incorrect or underlearned, as in novel or unfamiliar tasks. Therefore, the presence of others may or may not facilitate performance. Not surprisingly, research on drive theory and social facilitation in sport has produced some inconsistent results. Social facilitation effects appear to vary across real-life sports, where motor behaviors are more complex than those studied in laboratories.

Interviews with elite athletes suggest that the ability to draw inspiration from a crowd or the presence of opponents may be highly individualized. For some, the attention may be energizing. Such individuals generally benefit from some level of awareness that others are present and watching. In this case, the crowd may become a task-relevant cue in competition, and athletes may develop the ability to capitalize on social facilitation by attending to the crowd. Performing in front of individuals in practice may help to develop the skill of drawing energy from a crowd as well as provide practice in partitioning attention among motor

performance, internal cues, and the external importance of the crowd. For other athletes, knowledge that they are the center of attention becomes anxiety provoking. Such athletes may benefit more from skills training that minimizes the scrutiny felt from the presence of others.

5. SOCIAL AND INTERPERSONAL SKILLS

A broad array of social and interpersonal skills may be brought to bear in athletics. Smooth and effective interactions with others—not just teammates but also coaches, officials, and even opponents—may facilitate higher degrees of performance. This section considers two areas that are relevant to interpersonal skills: communication and interpersonal and intragroup anxiety in a team context.

5.1. Communication

Being able to communicate in sport is often critical to success. This is true even in the case of individual sports, where an individual must still interact with officials, coaches, and opponents. In general, performance will be maximized to the extent that an individual can effectively encode and deliver feedback and messages to teammates, coaches, and officials as well as decode and incorporate received information.

In team sports, delivering encouragement and technical feedback to teammates is often essential. Sending understandable messages at appropriate times permits teammates to correct deficiencies or other performance impediments, facilitating better team play. Being able to communicate openly and effectively with coaches during training and practice also permits the ready flow and interchange of necessary (and often vital) information about an athlete's functioning across biopsychosocial states. Finally, communicating appropriately with officials during the heat of competition is a particularly difficult, but nonetheless indispensable, skill.

Communication also involves receiving messages. Often, feedback may be delivered from teammates, coaches, opponents, or officials in an emotional or insulting manner. The ability to evaluate feedback for its truthfulness and usefulness, and then to glean helpful elements while rejecting unhelpful parts, is often critical to improving sport performance. Athletes who "can't take criticism," or who incorporate all critiques

of their performance without discrimination, may be missing out on valuable opportunities to benefit from appropriate guidance.

In addition to articulating thoughts clearly, communication patterns also affect the emotional climate. Belittling a sensitive or anger-prone teammate might not be an effective performance enhancer for the team, and communicating with a high level of tension in an already pressurized competition might serve only to increase the anxiety of some teammates. In some instances, the contagious effect of high-level emotions may have an overall positive impact on team play. In other cases, it may be disastrous, as in the case of raising individuals' anxiety levels.

5.2. Interpersonal and Intragroup Anxiety

The uniquely social nature of sport may serve to heighten anxiety. Although individual traits or dispositions contribute to anxiety, Hanin described two types of anxiety that are also partially created by the team or interpersonal environment: interpersonal and intragroup anxiety. The two are related and, whether operating alone or in conjunction, may exert deleterious effects on individual and team performance.

In interacting with a training partner, a coach, or some other individual, interpersonal anxiety may arise. Interpersonal anxiety is typically a state in which an athlete fears negative evaluation from, is distrustful of, or is uncomfortable with the partner of an interaction. This may occur commonly with an unfamiliar or new coach or in communicating with a higher status team member. There is some indication that an athlete may feel less or no interpersonal anxiety in interacting with a cohort of equal or lower status because social comparison works favorably for the athlete in such cases.

A related form of anxiety, intragroup anxiety, may also exist in team contexts. In intragroup anxiety, the broader social milieu of the team itself affects an athlete's subjective anxiety. Intragroup anxiety may arise as a result of things such as rejection or poor treatment by teammates, a lack of group cohesiveness or poor team atmosphere, a lack of experience, and poor self-confidence. Athletes who are naturally more anxious possess greater degrees of negative emotionality and are more concerned with maintaining socially desirable appearances and behaviors. They may be more prone to intragroup anxiety. Lower status group members may be particularly susceptible to this type of anxiety.

The anxiety management skills discussed in the next section apply to interpersonal and intragroup anxiety. But in addition, trainers, teammates, and coaches may play important roles in regulating the interpersonal and intragroup anxiety of individual athletes. To the extent that familiarity and comfort can be enhanced between the members of a dyad, interpersonal anxiety may decrease and performance may increase. In a broader team setting, a mature group climate and healthy group dynamics may be encouraged by perceptive and effective coaches.

6. TRAINING PSYCHOLOGICAL SKILLS

Some evidence suggests that arousal regulation, behavioral practice strategies, attention and concentration, mental rehearsal, self-instruction, appropriate goal setting, and communication skills can be trained. However, in contrast to conventional psychotherapy where accountability has long been an issue, research on psychological skills training in sport is still in its infancy. Much of what is known about psychological skills has also been gleaned from studies on elite athletes, and the techniques and strategies observed in elite athletes may or may not be effective in less skilled athletes. Thus, the consequences of attempting to teach a general canon of psychological skills in a "one size fits all" approach may range from success for some athletes, to wasted effort for other athletes, to perhaps even detrimental effects for some individuals. Therefore, overzealous or indiscriminate training of all skills with all individuals is discouraged in favor of interventions that take into account an individual athlete's personal characteristics, needs, sport, and levels of physical, cognitive, and emotional development. With this caveat in mind, this section reviews some commonly used protocols and techniques for developing psychological skills.

6.1. Arousal and Anxiety Regulation

Because a large component of anxiety is physiological overarousal, the following considerations are relevant to the training of both anxiety and physiological arousal regulation. For anxious and overaroused individuals, various forms of relaxation training are the interventions of choice.

One form of relaxation training is called progressive muscle relaxation. Progressive muscle relaxation involves systematic decrements in the tension of the body's skeletal muscles. Typically, an individual flexes and then relaxes one muscle group at a time, often using visual imagery to facilitate the effect. Breathing becomes a focus, with special attention paid to a slow and steady rate of breath and deep inhalations and exhalations. When executed properly, these processes slow heart rate and decrease neuronal firing in the skeletal muscles, with parallel arousal decrements in the sympathetic division of the autonomic nervous system.

The gist of progressive muscle relaxation may be learned in a single session with a skilled facilitator, but mastery requires regular practice. A script or tape-recording may be employed to guide the progressive muscle relaxation, often beginning with arm and shoulder muscles and proceeding downward (although other variations are common). Employing tapes enables coaches, trainers, and athletes to institute relaxation practice without the presence of a trained facilitator, allowing relaxation sessions at any time or location and at less expense than bringing in a consultant. A variety of relaxation tapes are commercially available.

Another training mechanism for arousal regulation is biofeedback. Biofeedback involves electronic monitoring of an athlete's physiological signs, especially heart rate, pulse, galvanic skin response, and muscle tension. This information is subsequently used to guide progressive relaxation. With biofeedback data, problem areas in the relaxation process can be pinpointed and targeted with precision. After biofeedback training, an athlete often gains control over physiological processes that were previously beyond his or her ability to regulate. This permits an athlete to relax with greater ease and efficiency.

Biofeedback training generally occurs over multiple sessions. Initially, an athlete is introduced to the equipment and basic principles of biofeedback. He or she is shown, in visual terms, the effect of small bodily changes on heart rate and other indicators of arousal. Initially, an athlete may find it difficult to exert control over bodily processes that occur automatically. However, over successive practice sessions in a biofeedback laboratory, he or she learns how the manipulation of subtle and previously ignored physiological operations may affect levels of arousal and felt anxiety. Eventually, the biofeedback equipment is no longer needed, and an athlete can effect the necessary alterations to his or her arousal level in other contexts.

Meditation training may also reduce arousal and anxiety. Meditation involves relaxation techniques such as deep breathing but adds an element of mental focus, usually in the form of a thought or an image that is repeated or on which attention is focused. In this way, meditation may also serve to train mental imagery abilities and attention and concentration processes while also regulating physiological arousal. In learning meditation, an individual focuses on relaxing physically through deep breathing and gently releases competing thoughts, mental chatter, and worries while constantly returning to a "centering" image. This is best learned from either an experienced meditator or the use of tapes.

In developing meditation skills, regular practice is imperative, and patience and gentleness are critical, because it is extremely difficult to detach from "mental chatter." Finding a regular time and place for meditation practice often augments the process, but it is important that an athlete experience the setting for meditation as comfortable and peaceful. The duration of meditation practice is often specific to individual tolerance levels, but early practice sessions generally should be kept to shorter lengths (10–20 minutes for most beginners).

Other interventions permitting arousal and anxiety regulation may include prayer and hypnosis. Although one does not typically think of prayer as a sport performance skill, prayer may facilitate relaxation and focus attention. It may also provide an athlete with a calming reassurance that a divine force is operating on his or her behalf. Similarly, hypnotic states are defined by nearly total physical relaxation. However, not all individuals are easily hypnotizable, and trained hypnotists are not always available. Thus, unless an individual has access to a certified instructor, it is a less practical form of intervention and not an easily acquirable skill, although some individuals are able to learn to hypnotize themselves.

Finally, arousal regulation also involves "psyching up." Athletes may be trained to drastically increase arousal levels over a short time. This type of arousal regulation training has been less researched, but control may be exerted through physical channels (e.g., slapping oneself, shaking, jumping up and down) or through cognitive mechanisms (e.g., imagining anger-producing things, planning and anticipating challenges during competition, focusing on context cues such as the crowd, engaging in final rituals that have been repeatedly paired with high-arousal states in the past). Habitually underaroused athletes must explore

a variety of last-minute psyching strategies and must retain and practice those that seem to be most advantageous.

6.2. Part Practice

Behavioral practice skills and motor learning can be facilitated through part practice. In part practice, an athlete can focus greater attention and concentration resources on simpler components until they become automatized, thereby freeing up resources for execution of the whole task. This discussion considers three forms of part practice: segmentation, fractionation, and oversimplification.

In segmentation, a complex task is divided into a number of constituent dimensions, which are then trained separately. For instance, a gymnast training a routine on the balance beam may separately train the mount, actions performed on the beam, and the dismount. Often, repetition of task segments may involve graduated acquisition to more complex combinations of segments. In this way, task parts can be “chained” together, usually from the beginning pieces of a complex behavior to the end (forward chaining) or from the end pieces of a complex sequence to the beginning (backward chaining). The degree to which facility in task segments transfers to the whole task may be determined by whether the segmented practice involves integrated control of the “links” in the behavior chain. If an athlete does not learn necessary transitions between segments, the whole movement might not improve substantially even in the face of dramatic improvements in the segments.

In fractionation, an athlete trains separate pieces of a complex action that normally occur at the same time. Results regarding the effectiveness of this technique have been somewhat mixed, but it seems that for tasks in which component behaviors are highly integrated because they occur simultaneously, practicing various parts in isolation often fails to develop coordination among them. Research investigating fractionation does suggest that it may be useful for complex tasks where subcomponents must be randomly combined, that is, where there is not a single template or control/coordination process for the task. For instance, in a video game, multiple fractionated skills (e.g., making a figure run, jump, or fire a gun) may be called on, but in random combinations.

A final form of part practice is simplification. Simplification generally takes the form of training easy versions of complex motor behaviors as

precursors and building blocks. A juggler may first learn to juggle two scarves, then progress to three baseballs, and then finally to five or more torches or knives. In this example, the degree of difficulty (as well as the danger of potential mistakes) increases incrementally. Again, research on simplification has been somewhat mixed. Although it seems to be an effective teaching technique, there may be a point at which simplification of a complex motor behavior alters the essential nature of a task. At this point, it is unlikely that skill acquired at the simplified task would generalize to the more complex task. However, if the fundamental control processes of the complex task are not altered to a great degree, simplification may facilitate motor skill acquisition in some athletes.

6.3. Improving Attention and Concentration

Attention and concentration skills are malleable and can be learned and improved through repeated practice. Several exercises have been proposed, including scanning number tables and staring intently at a sport-related object. However, the merit of such training techniques lacks systematic substantiation. Nonetheless, one technique that has gained some credence is adversity training.

In adversity training, the specific alterations to practice sessions are less important than their general effect: to create a training atmosphere in which distractors, unconventional circumstances, situations, and/or environmental interferences exist. By training in the presence of such potential disruptions, athletes develop a more robust ability to focus their attention and resources on task-relevant cues and screen out potential impediments that arise randomly in the competition environment. By treating practice sessions of this sort “like the real thing,” athletes learn to screen out intrusive and novel stimuli as a matter of course so that if such nuisances appear in actual competition, they will be less disruptive. Although little systematic research has investigated adversity training, it is a manifestation of the well-established principle of state-dependent learning and anecdotal support is plentiful.

Another way in which divided attention skills may be developed is through dual-task practice. In sport, athletes are often required to perform multiple tasks simultaneously, and this requires switching skills to allocate attention between the different tasks.

Training multiple tasks simultaneously can help athletes to develop attention allocation strategies and increase attentional resources. For instance, a basketball player's dribbling skills may be improved by practicing dribbling two balls at once while looking ahead. In this way, dual-task practice facilitates automatization of component movements, thereby freeing an athlete's attention resources for allocation elsewhere.

However, it is important that dual-task practice be conducted with sport-specific tasks. Developing divided attention on an unrelated array of activities might not generalize to the idiosyncratic demands of a particular sport. Training attention skills through dual-task practice should also take into account an individual athlete's attention resources and skills. Individuals vary widely in their reservoir of attentional resources and in their skills at allocating them. But even for expert performers, continued overload of attentional resources through graduated dual-task or multitask practice may permit ongoing increases in attention skills.

Finally, a variety of other strategies have been proposed for improving attention and concentration skills. Preperformance routines, which generally consist of a series of motoric movements and/or accompanying thought and self-instruction, may serve to focus concentration. Centering exercises and mental imagery may also facilitate concentration on external task demands indirectly through augmenting internal focusing skills. Regulating arousal to optimal levels has salutary effects on attention or concentration. And although the ability to enter flow voluntarily seems to vary across individuals, certain strategies may help individuals to induce flow states. Setting miniature goals in practice sessions, such as executing a tennis serve with perfect form five times in a row, have been helpful at inducing flow in athletes. Transforming practice sessions into "games" may also help. For instance, soccer players practicing "juggling" the ball with their feet may elect to play a juggling game in which the player who can juggle the longest gets to skip a mandatory conditioning run.

6.4. Self-Monitoring and Self-Instruction Training

Self-monitoring may be facilitated through recording successful and unsuccessful behaviors in practice and competition. These records may then be reviewed either individually or with a teammate, coach, or trainer to examine patterns in an athlete's performance. With a

log of successes and failures (and the assistance of another pair of eyes), athletes may begin to see performance patterns that can help them to pinpoint specific areas that need closer attention. Videotaping and reviewing performance may also facilitate self-monitoring skills. For instance, an athlete may realize that a particular type of performance mistake is always preceded by a motoric or kinesthetic flaw that can then be expunged during subsequent practice sessions.

Self-instruction may be taught through the use of verbal scripts. Scripts serve the purpose of providing a format, or template, of helpful statements and important reminders that an athlete can implement before, during, and after competitions. Self-instruction scripts ideally provide the athlete with a ready storehouse of important reminders and encouragers that, with practice, will become automatic. When well practiced, self-instruction may provide instantaneous correction, redirection, and reassurance in the midst of competition.

Cue words also may assist in self-instruction. Salient cue words, when implemented regularly, will serve to convey immediate corrective feedback to athletes when performance errors occur or are in danger of occurring. Cue words should be personally selected by an athlete but should be relevant and bear some important meaning about the activity being performed. For instance, a cricket bowler may employ the phrase "follow through" to increase the accuracy of his or her pitches. Common cue words may also be shared with teammates or coaches, who may assist athletes in acquiring and regularly implementing instructive words during performance.

6.5. Mental Imagery and Mental Rehearsal Training

Mental imagery is often conducted in states of relaxation, although it may be practiced anywhere. In general, however, the absence of distractions in relaxed or meditative states permits more efficacious use of mental imagery. Guided imagery is best learned with the help of another knowledgeable coach, trainer, or sport psychologist. Usually conducted during a state of relaxation, a series of relevant sensations are described in detail, invoking mental representations of sights, sounds, smells, and so forth. The images may proceed from an external perspective (i.e., a "camera reel" of a performer in action) or from an internal perspective (i.e., from the performer's view). Again, the content and use of imagery should be dictated by the individual athlete's needs. For an athlete who has trouble "getting

in the zone” prior to a competition, bodily sensations of tension and anticipation may be invoked during guided imagery practice, along with a “tour” of the precompetition environment and preparations, ending with an image of the athlete fully aroused, attentive, and eager to execute the actions that are necessary for competition.

Mental rehearsal of athletic performance may be conducted in nearly limitless ways. Some sport psychologists have developed structured training programs to help athletes improve mental rehearsal. Researchers have recently proposed a model that may be useful in the training and practice of imagery. Athletes are encouraged to consider where (e.g., during practice, before a competition) and why (e.g., trying to build general confidence, trying to improve a specific skill) they employ imagery. Athletes are trained not only to select places and times to use imagery that is consistent with what they are trying to achieve but also to use different types of imagery for general or specific goals. Imagery may be either specific (e.g., imagining the successful performance of a particular skill) or general (e.g., imagining oneself competing with confidence). The bulk of research suggests that imagery practice enhances specific skills and, like physical practice, should be distributed across time.

Visualization may be trained by using photos or videos as guides. Because real-life visual stimuli tend to be detailed and vivid, using them as models may facilitate visualization in beginners. Training may proceed from looking at sport-specific pictures or films, concentrating and noticing every detail, to engaging in mental practice wherein the model is recalled with as much vividness and detail as possible. If visual models of an athlete’s own top performances are available, these may facilitate transition into personal visualization in practice. The content of visualization practice should match an athlete’s goals. At a generic level, an athlete might visualize himself or herself preparing for, engaged in, and winning a competition. But at an individually specific level, an athlete might train visualization skills around a particularly difficult maneuver or motor sequence in performance. If motivation or confidence is an issue, visualization of goal states, successful outcomes, and mistake recovery may be helpful.

6.6. Acquiring Emotion Regulation Skills

Some techniques for reducing anxiety were addressed previously in the discussion of arousal and anxiety

regulation. However, in addition to relaxation exercises, a variety of other strategies and interventions exist for regulating distressing emotions. These can often be developed using techniques found in most conventional psychotherapies. Although space constraints prohibit extensive coverage of these methods here, a variety of general self-help books provide thorough and accessible discussions of emotional regulation strategies.

One way in which emotional distress may be remediated involves examining and challenging the thoughts associated with negative emotions. This requires that an athlete first develop an awareness of the sort of thinking that accompanies negative emotions. For instance, in the introductory example, Andrea experiences a surge of anxiety. Such a rush of nervous feelings may very well be accompanied by the thought, “If I don’t perform well here, my career will be ruined.” Naturally, this sort of absolutistic thinking serves only to heighten feelings of anxiety.

Identifying the self-defeating, irrational, catastrophic, and/or distorted thoughts behind negative emotions can often be difficult and frustrating for athletes learning emotional regulation because such thoughts may be so automatic that they are hard to detect. The use of logs, in which athletes track emotionally distressing moments and the thoughts beneath them, often helps to illustrate the connection between thinking and emotion and illuminates patterns. When athletes develop such awareness, they know where to intervene when emotions turn problematic.

Once the thoughts driving negative emotional responses have been reliably identified, the next step in emotional regulation is to begin systematically challenging such thoughts. Athletes can learn to “act as their own defense attorneys” in response to self-derogating thoughts or self-anger and to question the likelihood of fictional finalisms or the validity of hidden assumptions. However, this process is often effortful and requires extensive practice because negativistic thinking patterns tend to be quite entrenched. It is important to note that identifying and challenging self-defeating thoughts is likely to be an unfamiliar experience to an athlete learning emotional regulation. For this reason, the athlete might wish to enlist the aid of a personal therapist, counselor, or trained sport psychologist.

Self-confidence may also be trained through techniques such as imagery and mental rehearsal of confident performance, monitoring and replacement of self-defeating thoughts, seeking out mastery experiences,

and validation and encouragement from others. However, self-confidence in athletics may also be rooted to deeper feelings of personal inadequacy. When this is the case, personal counseling or psychotherapy is likely to be useful. In fact, for athletes experiencing emotion regulation problems at a deeper level and/or extending outside of competition, personal counseling or psychotherapy is highly recommended not just to improve sport performance but also to improve overall happiness and quality of life in general.

6.7. Training Appropriate Goal Setting

The consequences of inappropriate goal setting can be more deleterious to an athlete's motivation than training bereft of goals because the wrong type or set of goals can set up an athlete for failure. Research suggests various parameters that are most conducive to goal attainment, although goal setting should also be considered from an individualized perspective due to the wide variation in individual abilities.

In general, athletes should be encouraged to select a series of easy proximal goals early on (e.g., accomplishing small things that are close and immediate). Easy proximal goals offer the possibility of quick feedback and mastery experiences, which serve to enhance motivation. The arrangement of proximal goals may also form a chain toward some ultimate goal. For instance, a team may institute night-by-night goals during the regular season to reach the league championship. However, it is important to avoid an overly rapid or unrealistic series of proximal goals. Individuals or teams may be prone to set less realistic goals after successful achievement of early easy goals.

Athletes learning to set goals should also be encouraged to select specific goals. Specific goals permit achievement in precise areas relevant to success. For instance, rather than setting a goal to improve one's overall strength, a weightlifter may set a specific goal of improving his or her maximum clean and jerk by 2 kilograms and his or her maximal snatch by 1 kilogram. If the weightlifter also invokes the principle of proximal goal setting, he or she may resolve to achieve this at the end of 4 weeks of training sessions. Specific goals render large tasks (e.g., winning a competition) less imposing or intimidating by breaking down a desired end state into components.

Goal-setting skills are best developed by encouraging athletes to use mastery goals as well. Athletes

should be encouraged at first to "compete against themselves" by improving past performance or meeting specific competence levels independent of competition. Developing athletes who set competitive goals may rob themselves of a sense of personal control in pursuit of their desired ends because competitive goals tend to be at least partly contingent on other individuals. The achievement of mastery goals, in contrast, is generally more within the direct control of the athlete himself or herself. Mastery goals, in turn, promote the development of self-efficacy more readily than do competitive goals.

An athlete may also wish to begin with individually chosen goals. In cases where the athlete is uncertain of his or her abilities or appropriate first goals, it may be helpful to develop goals initially with a coach, trainer, or sport psychologist in a collaborative fashion. In such instances, goals that are personally meaningful to a given athlete may serve as the foundation for early development. The mastery experiences attached to maintaining individually salient goals may be more motivating than the sense of accomplishment felt at meeting institutional or external goals, although an athlete who is extrinsically oriented may also benefit from external goals.

Finally, it is important to note that these considerations apply primarily to the training of goal-setting skills in inexperienced athletes. Elite athletes may benefit just as much, or in some cases more, from distal and competitive goals. But the use of proximate, specific, mastery, and individual principles can be highly recommended to less advanced athletes wishing to develop goal-setting skills.

6.8. Enhancing Communication

Hanin recommended three general strategies for enhancing communication skills in a team environment. First, if communication problems are a function of the specific subset of individuals involved, such as having an aggressive or belligerent athlete in the starting lineup, one may alter the composition of the unit. Communication patterns among players are likely to change accordingly. However, this is only a temporary solution and does not remediate the root of communication problems if it resides in one or more particular individuals.

If certain activities, tasks, or situations tend to produce communication difficulties, one may redefine, alter, or substitute tasks that do not evoke such difficulties. For instance, if one teammate always has trouble performing

in a certain drill and this leads to negative interactions with other players, an alternative drill that accomplishes the same thing may be instituted. Naturally in some situations, such as rehearsing a particular play that is indispensable to team performance, one cannot alter the situation or group task without compromising the integrity of practice. In such instances, communication problems may be dealt with by managing players' communication at a behavioral level.

At the level of communication behaviors, athletes may be taught to monitor and regulate the content, delivery, and even frequency of their messages. Through observation, instruction, and discussion, they may develop specific styles of communication for specific teammates. Negative feedback may be sandwiched between positive comments, accusing or derogatory content can be unlearned in favor of appropriate and task-relevant comments, and athletes can be taught active listening skills so that teammates feel that they are heard.

At both the individual and team levels, communication skills may be practiced through role-plays outside of practice. As new communication patterns are acquired, athletes should be encouraged to implement them during practice and to observe their own and others' reactions to these changes. The ability of an athlete or a team to transfer new communication skills to competition should then be monitored closely, with appropriate discussion of both positive and negative exchanges and necessary adjustments.

Whether communication deficits are a function of skill deficits or situations, facilitating communication skills in athletes requires close observation of problematic communication patterns, including their antecedents and effects. With such knowledge, coaches and/or other helpers may meet with individual team members, as well as the team itself, to discuss specific problems. It is also important to provide feedback on instances of effective communication as well so that appropriate interaction patterns can be reinforced.

7. CONCLUSIONS

Research on elite athletes reveals that rather than a general "athletic personality," psychological skills are more important determiners of athletic success. These skills are mostly acquired rather than innate, and they span the bodily/behavioral, cognitive, emotional, motivational, and interpersonal domains. Bodily/Behavioral control skills encompass arousal regulation and behavioral practice of motor skills. Within the cognitive realm,

mental rehearsal, attention and concentration, and self-monitoring and self-instruction skills are critical to athletic success. Emotional balance, controlling anxiety, and maintaining self-confidence are necessary. Motivational skills involve setting appropriate goals and capitalizing on social facilitation. Finally, interpersonal skills involve effective communication patterns and management of emotions within a team or group context.

These skills are trainable, and although research on skills training is still in its infancy, a variety of strategies and techniques exist to facilitate skill acquisition. Training of skills should proceed in a supervised environment and in a manner that is appropriate to an athlete's developmental level. Typically, developing skills requires investment and practice as well. Some techniques, particularly unfamiliar ones such as relaxation and meditation, may appear to be quite foreign and may frustrate beginners. But with repeated practice, they can be nurtured, with resulting improvement in performance.

Finally, although training of skills may be undertaken in a group or team format, the effective inculcation of psychological skills proceeds best at an individual level. Although some skill sets may be necessary for a class of athletes or team in general, individuals will often vary in the style or degree to which they implement a skill. In the end, efforts should be made to match skills training programs to individual athletes' strengths, weaknesses, desires, and capabilities. Attention to each athlete's uniqueness is ultimately the most important factor in enhancing his or her performance.

GLOSSARY

adjudicative competence Functional legal abilities that a criminal defendant must have in sufficient degree in order for the adjudicatory process to go forward. Also called competence to stand trial, competence to proceed, and fitness to proceed.

best interests of the child doctrine The philosophy, now incorporated into law in all 50 states, that in making decisions concerning custodial placement and parenting plans, the interests of the children should supersede those of the parents and/or others involved in the dispute.

blank lineup (target absent lineup) A lineup in which all the members are known to be innocent.

cognitive interview Forensic tool that comprises a series of memory retrieval techniques designed to increase the amount of information that can be obtained from a witness.

direct questions Yes/no or short-answer questions that probe for particular details about an experienced or witnessed event; questions can range from nonleading to suggestive, depending on how the question is phrased and the type of information included in the question.

effective size The number of plausible members in a lineup.

encoding specificity principle States that if cues that were present at encoding are also present at retrieval, recall of stored information is more likely.

estimator variables Factors in eyewitness situations whose influence can only be estimated and are not under the control of the justice system.

ethical interviewing A police interview technique, based upon three principles, designed to encourage suspects to tell their side of the story. The use of deceit is forbidden, and psychological pressure is not used.

evaluation of comparative custodial suitability A forensic psychological evaluation in which the primary focus is the relative strengths and deficiencies in the ability of parents to parent the specific children whose custodial placement is at issue.

evidence-driven deliberation Deliberation in which jurors engage in general discussion of evidence in the case prior to voting, in contrast to verdict-driven deliberation, in which voting typically precedes evidence discussion.

forensic assessment instrument (FAI) An assessment test, tool, or device designed to measure or to inform a clinical judgment about specific functional legal abilities required in a given legal context.

forensic mental health assessment The evaluation of defendants or litigants, usually conducted by mental health professionals such as psychologists, psychiatrists, or social workers, that is performed to assist the court in making better-informed decisions or to help the attorney present evidence relevant to his or her case.

free-recall questions Vague, general prompts requesting for a narrative description of a prior events; prompts provide minimal cues or information about what should be recalled.

lineup bias A lineup constructed in a manner that leads the suspect to stand out from the other lineup members.

mental state at the time of an offense (MSO) A general term inclusive of various legally recognized mental states

- (e.g., insanity, diminished capacity, automatism) that provide the bases for a defense to culpability for criminal behavior.
- mock witness** A person who is not a witness to a crime but who is asked to identify a perpetrator from a lineup based on another source of information, such as a verbal description.
- post-event (mis)information** Events that occur after a crime that influence eyewitness memories of the crime.
- Reid technique** A police interrogation technique, consisting of nine steps, designed to encourage reluctant suspects to talk during police interviews. The technique allows interrogators to use deceit and to build up psychological pressure.
- restorative justice** Legal proceedings that aim to make the victim and community whole following an offender's conduct, and to reintegrate the offender into the community, if appropriate.
- scientific jury selection** The use of scientific techniques by jury consultants to determine the individual demographic and attitudinal characteristics that are linked to views of a case. Techniques include community surveys, mock trials, focus groups, and in-court selection.
- script** A general knowledge structure that represents information from a class of similar events; a description of the typical, common features of repeated events.
- showup** The presentation of a single suspect to a witness in order to determine if that suspect is the perpetrator.
- source amnesia** The inability to recall the origin of the information that comes to mind when attempting to recall an event.
- story model** Theory of juror decision making in which jurors arrange evidence in the form of a narrative or story, and match the story to the closest verdict alternative.
- structured interviews** Scripted interview prompts and questions that are designed to obtain as much narrative information from children and be as minimally leading as possible.
- suggestibility** The act or process of impressing something (an idea, attitude, or desired action) on the mind of another.
- system variables** Factors that may influence eyewitness memory and that are under the control of the criminal justice system.
- therapeutic jurisprudence** Legal practices intended as therapeutic interventions for the benefit of the litigant.
- therapeutic role** Within the context of custody evaluations, perspective and actions that are consistent with one's obligation to assist those with whom one is professionally interacting.
- verbal overshadowing effect** When the act of verbally describing a perpetrator decreases the witness's ability to accurately identify a perpetrator from a lineup.
- voir dire** Questioning process during jury selection.

Psychology and law, or forensic psychology, is a branch of applied psychology, with three primary dimensions: research, practice, and policy implications. Major accomplishments in psychology and law are reviewed in this article, drawing on empirical research by

experimental and clinical psychologists with several distinct forensic populations, e.g., juveniles, offenders, witnesses, and jurors. Experimental psychological contributions on detection of deception, eyewitness memory, and jury decision making are outlined. Clinical research and practices regarding forensic mental health assessments are described, e.g., of legal competency in criminal, civil, and family law cases. Roles of psychologists in therapeutic versus forensic settings are distinguished, and standards for providing relevant and reliable expert evidence are described.

1. INTRODUCTION

If experimental psychology is to enter into its period of practical service, it cannot be a question of simply using the ready-made results for ends which were not in view during the experiments. What is needed is to adjust research to the practical problems themselves and thus, for instance, when education is in question, to start psychological experiments directly from educational problems. Applied Psychology will then become an independent experimental science which stands related to the ordinary experimental psychology as engineering to physics.

The time for such Applied Psychology is surely near, and work has been started from most various sides. Those fields of practical life which come first in question may be said to be education, medicine, art, economics and law.

This bit of advocacy was written by Hugo Muensterberg in 1907, and makes clear that both the vision and the empirical research program on which the field is founded were present a century ago. Research at the time, and much of the work since, has taken place in the areas of perception and memory, as well as abilities, intellectual performance and social relations, areas in the list of problems related by Muensterberg. All of these areas are treated in the present section of this encyclopedia, and while they would all be recognized by turn-of-the-19th-century psychologists, their elaboration since that time has been considerable. Legal psychology has grown in many ways, and has multiple foci.

2. IMPORTANT ATTRIBUTES OF THE FIELD

There are certain attributes of psychology that set it apart from other fields with relationships with law

(e.g., social work, psychiatry). These attributes form common themes across the articles in this section. The field of psychology and law displays an interesting diversity of approaches to its application, which reflects the full diversity of the underlying field. Its approach is at base scientific, and in the analysis of policy, practice, and evaluation, the goals are theoretical and empirical clarity. The orientation is, for the most part, one of engaging problems at a practical level, using available theory and new research to develop pragmatic responses tailored to the demands of situation and context—just as Muensterberg foresaw.

The field of psychology and law exhibits a distinctive scientific character. The field is committed to testing standards that are based in measurement theory and developed according to scientific standards that distinguish this professional enterprise from that of others, e.g., social workers, psychiatrists. Validated measures and tests exist for some topics (e.g., competence to stand trial and competence to consent to treatment), but are not yet developed for others. The cutting-edge developments in the field are precisely the formation of new tests and measures, new empirically validated techniques and procedures, and policies founded in empirical research.

The potential contributions of psychology to the various demands of law are by no means fully realized. As psychologists embark on analysis of many domains in the psychology and law interface, alternative approaches and explanatory hypotheses are framed and tested using multiple data sources—a part of the fields of history of philosophy of science and methodology.

Psychology has a special role of assisting courts in making retrospective assessments of what occurred and in identifying lies and distortions (i.e., in serving justice). The contexts in which these needs appear are vast. Witnesses to events of all kinds, from bank robberies to traffic accidents, are relied upon to provide accurate information for legal processes. Those alleging the occurrence of a crime, either as a witness or as a victim, are evaluated for accuracy and for incentives to distort. Report of memory for events is a large part of many fact-finding activities in law. Psychology's special role emerges from the fact that records of events and the accounts of them come from human memory and the perceptual and cognitive processes that both record and report them—both selectively. The report of a police officer, for example, comes from memory, and even when it is written contemporarily with the event, the selectivity typical

of human attention requires understanding and interpretation, especially if the officer's report conflicts with the reports of others. Psychology is uniquely positioned to address memory for events and other forms of experience, as well as intentional distortion and deception. No other field of study is so focused on these processes.

Memory for narrative integration of information, making judgments, and studying the effects of personal history, attitudes, and belief systems are all aspects of legal processes. Some take a central role and assume great importance. Jury decision making is a strong traditional area of psychology and law. The integration of new information into existing attitude and belief systems in the context of whatever constraints are placed on judgment by the court is an important area of understanding for scholars to pursue. Research in this area has the potential for important contributions to our understanding of why long-term trends of injustice (e.g., racial discrimination in all areas of opportunity and legal protection, gender inequality in ownership and employment) were able to continue and how and why change occurs.

Criminal suspects and litigants have incentives to fabricate, mislead, exaggerate, and confabulate. These incentives and the difficulties they present to fact finders extend through many areas, including forensic mental health assessment. As noted by Heilbrun and Landers in their article on assessment in this section,

Some individuals evaluated through FMHA respond to questions openly and honestly. Others exaggerate or fabricate symptoms and problems. Yet others minimize or deny symptoms that are genuinely experienced. Response style is a term used to describe how an individual reports his or her own symptoms, behaviors, and problems, and is used to classify an individual's responding as (1) reliable, (2) exaggerated/malingering, (3) defensive, or (4) uncooperative. Self-reported information from an individual who is not reliable will have significant inaccuracies. This principle emphasizes the value of third party information (records and interviews of collateral observers) in both detecting and correcting these inaccuracies.

The role of psychologists in a legal context is often structured very differently from that of psychologists in other contexts. For example, there is an important distinction between therapeutic and forensic roles. Ten differences elaborated by Heilbrun include (1) the purpose for which the evaluation is conducted, (2) the nature of the relationship between the evaluator and the individual being evaluated, (3) the need for a

formal notification of purpose, (4) who is being served, (5) the nature of the standard(s) applied in the evaluation, (6) the sources of data considered, (7) the response style of the individual being evaluated, (8) the need to clarify the reasoning and limits of knowledge, (9) the nature of the written report, and (10) the expectation of expert testimony.

Heilbrun and Lander remind us that it is only in the past 50 years that courts have been using psychologists as opposed to other mental health professionals to provide information on assessments. Recognition of the role of psychology is still lagging in some communities, and many courts still require a medical degree from the professionals whose opinions they seek. It is only in the last 25 years that expert testimony by experimental psychologists has been widely used in court in matters involving memory and eyewitness identification.

The role of expert witness is quite different from the role of researcher and teacher. An important example is ultimate opinion testimony. A researcher specializing in eyewitness identification will rarely speak with the witness(s) who made the identification, and so is sometimes asked how he or she can talk about the accuracy of the eyewitness identification without examining the witness. The answer is straightforward and contains an important constraint on the role of an expert in contrast to the fact finders in the legal system (e.g., juries, judges). The important factors influencing eyewitness identification are either facts elicited in depositions, hearings, or in trial or facts about the construction and administration of the eyewitness identification materials and process. These are all external to the witness him- or herself. It is a misconception (and maybe a stereotype) that experimental psychologists testifying as expert witnesses on eyewitness testimony make psychological assessments of the witness. The question also contains a trap and another misconception. Eyewitness experts do not offer conclusions about the accuracy of the eyewitness identification. On the contrary, they discuss the events and conditions that are known to influence the accuracy of identification. It remains the province of the jury (or other fact finder) to consider these factors in their own consideration and judgment about the probable accuracy of the identification. Offering an opinion about the accuracy of the identification is known as ultimate opinion testimony, in that it offers an ultimate opinion about an issue that is to be decided in the trial process. The role of the expert in this instance is to inform the jury so that in their evaluation of the evidence they can consider the expert's information—a kind of teaching

role for the expert. It is important to keep the decision making in the hands of those placed in that role by the legal process; this clearly structures the role of experts in court and related proceedings.

3. ARTICLES IN THIS SECTION

Nowadays, forensic psychologists are frequently consulted by courts or lawyers to provide information about a party's mental state or a party's decision-making ability or capacity, although some judges and other court personnel remain confused about the differences in training and expertise offered by a psychologist, a psychiatrist, a social worker, or other mental health professionals. The articles by Poythress, Heilbrun and Lander, and Martindale and Gould serve to clarify the nature and scope of empirically based contributions that psychologists can make by providing forensic mental health evaluations in civil and criminal cases.

The extent to which an individual is personally responsible for his or her conduct is critical in many situations involving both criminal and civil legal issues. For example, a defendant who engages in behavior that is illegal, but who is unaware of what he or she is doing, or who does not appreciate the significance or consequences of these actions may be entitled to a defense against criminal charges on this basis. Similarly, someone who is easily influenced because of a learning disability or some other psychological impairment can not be expected to take charge of his or her own affairs to the same degree as someone without any mental impairment, and once his or her disability is established, may require assistance in the form of a legal representative or guardian. Expert testimony or a report from a mental health professional such as a psychologist may assist the courts in understanding the cognitive limitations of any impairment, temporary or permanent, as it bears on a legal issue. Psychologists who are trained in forensic assessment and evaluation can help courts to resolve such legal issues.

Defenses to criminal charges premised on a mental disease or disorder are often unpopular in the community because of common erroneous assumptions about the frequency and consequences of such a plea. Research by Silver *et al.* on the public perception of the number of defendants who plead not guilty by reason of insanity shows the number is often exaggerated, and moreover, that the public wrongfully assumes that defendants who enter such a plea are released into the community. In fact, the insanity defense, which applies

only to the defendant's state of mind at the time the alleged offense was committed, is used in fewer than 1% of all criminal cases, and when proposed it is unsuccessful 74% of the time. As Perlin points out, the consequence of entering a plea of insanity is often a period of incarceration in a psychiatric hospital longer than the offender would spend in prison if convicted of the crime charged.

Other defenses proffered on grounds of diminished capacity or limited mental responsibility are similarly unpopular and controversial, as they, too, are often thought to permit culpable offenders to circumvent punishment for their transgressions. Expert assessment and expert testimony is common in these cases to explain how varied mental or neurological conditions may produce situations in which the conduct of the accused is unintended, e.g., because it was involuntary, perhaps a form of automatism, caused by events such as a head injury or a condition such as sleepwalking, hypoglycemia, epilepsy, consumption of alcohol or drugs, or dissociation. Certain mental conditions or disabilities may exonerate a defendant from criminal responsibility if the offender lacks the capacity to form the necessary criminal intent, e.g., defenses that the offender was suffering from battered woman syndrome, post-partum depression, sexual addiction, urban survival syndrome, false memory syndrome, post-traumatic stress syndrome, multiple personality disorder, or schizophrenia.

3.1. Legal Competency

The article on legal competency by Poythress delineates the types of decision-making abilities or competencies at discrete moments in the civil and criminal legal process about which courts most frequently seek advice from psychologists trained in forensic assessment and evaluation. The accompanying tables and charts succinctly illustrate the legal standards or issues in the cases and the related psychological competencies that bear on them. Three elements that must be addressed by a forensic psychologist in each case involving an assessment of fitness or competency are (1) the presence of a mental condition that causes an impairment, (2) specifications of the functional impairment, and (3) the distinct legal abilities key to the case that are affected.

The article begins by orienting practitioners to the context of the task by outlining a framework within the law that psychologists are well advised to understand in order to offer more useful information to the courts. A helpful conceptual tool for practitioners and

psycholegal researchers is a table listing the five aspects of legal competencies identified by Grisso, as it sets forth those aspects of the task most clearly within the province of the forensic psychologist, and those aspects most clearly within the province of the fact finder (judge or jury). In particular, it is important to note that the legal standards or tests for fitness vary from one circumstance to the next. Accordingly, the psychologist must appropriately tailor the information critical to the fact finders in applying the legal standard appropriate to a given case. Many of the competence tests and standards pertinent to civil cases have received less research attention than those pertinent in criminal cases, i.e., criteria relevant to determinations of fitness to make decisions about guardianship, treatment, research participation, and testamentary capacity.

A point of significance is the limited utility of a diagnosis in many legal proceedings. Although the goal or end point of many clinical mental health inquiries is a diagnosis, legally, the diagnosis itself is of little value to a court charged with determining whether someone meets the criteria for a defense of insanity or otherwise lacks fitness to proceed to trial. The fact finder seeks a functional description or understanding of the nature and scope of an individual's impairment from the consulting expert. A diagnosis by a mental health professional of a mentally disabling condition or disorder does not guarantee that the applicable legal test will be met, but the diagnosis may be of some relevance. Severe mental disturbance or lack of a diagnosis neither guarantees nor is fatal to a claim of incompetence or insanity.

The terms insanity and incompetence are legal, not psychological, concepts. The legal test for insanity varies from one jurisdiction or community to another, although most tests incorporate the offender's cognitive awareness of the consequences of the conduct at issue. Tests that address some of the "irresistible impulse" standards have in some cases devolved into a question as to whether the accused would engage in the same conduct were there a policeman present. In some states or countries, the standard of "guilty but mentally ill" has been adopted as a variant of "not guilty by reason of insanity." In other communities, legal policy reforms have established that voluntary conduct that produces diminished capacities, such as drinking alcohol or taking drugs, obviates resort to this defense. Finkel points out that policies along these lines conform with the results of studies of juror decision making in insanity cases, which revealed that jurors often take into account the offender's capacity

to make responsible choices and whether the offender was negligent or reckless in bringing about his or her mental disability.

In his article, Poythress adroitly sets controversial topics such as the insanity defense in context by pointing out the infrequency of its use and its low success rate. He also emphasizes the importance of and demand for many other fitness determinations by psychologists, such as fitness to stand trial, or when the death penalty applies, fitness to be executed. Although it is difficult to obtain precise figures of the number of evaluations prepared annually on issues of fitness or competence, Costanzo shows that approximately 5% of all criminal defendants are assessed for competence to stand trial. Thus, Zapf and Roesch provide estimates that between 25,000 and 39,000 psychological evaluations for competence to stand trial are performed annually in the United States, making this one of the most frequently requested psychological services. Of the group of offenders evaluated for this purpose, Melton *et al.* indicate that a relatively small proportion, 12%, is found incompetent.

This article provides an excellent overview of methodological issues facing professionals who are bound to offer evidence-based conclusions to the court. The article includes practical advice to practitioners, such as avoiding controversy as an expert by refusing to prepare a report that addresses more than one type of fitness. Similarly, psychologists are advised to avoid making any statement about the "ultimate legal issue." As Poythress points out, to do so mixes moral and professional standards.

Poythress also illustrates the significance of a clear understanding of the relevant comparative group in interpreting the test outcomes of standardized test instruments. Over the past decade, more test instruments designed to address legal competence and fitness have been developed and studied, thus the dearth of available forensic tests is decreasing. One of the drawbacks in developing evidence-based instruments is finding appropriate control groups and obtaining permission to conduct randomized trials on relevant forensic populations to produce comparative data and appropriate test norms.

3.2. Forensic Mental Health Assessment in Legal Contexts

The article by Heilbrun and Lander on forensic mental health in legal contexts complements the work of

Poythress by providing a more hands-on, practically oriented discussion. Heilbrun and Lander include step-by-step guidance on how to conduct a forensic mental health assessment, including advice on how to structure a report intended for use by the court. Heilbrun and Lander guide the forensic practitioner through 29 steps for conducting a forensic mental health assessment, starting with the initial consultation and ending with expert testimony. This article leads practitioners through substantive considerations at each of three major steps in conducting forensic assessment, namely, preparation, data collection, and data interpretation. For each step, the authors itemize the standards or guidelines that provide parameters for sound practice. Thus, this article is of value in outlining the various pertinent authorities: legal, ethical, scientific, and practical or clinical.

One of the vital themes developed for sound forensic practice is the importance of gathering information from multiple sources to permit more extensive scrutiny of the reliability of the information gathered in the context of litigation. Heilbrun and Lander state the following:

A single source of information is usually less accurate than multiple sources considered together. This is particularly applicable in forensic mental health assessment, as some of the information sources can be particularly distorted. A defendant might be inclined to exaggerate or minimize symptoms or capacities, depending on the possible implications of each in litigation.

Others exaggerate or fabricate symptoms and problems. Yet others minimize or deny symptoms that are genuinely experienced. Response style is a term used to describe how an individual reports his or her own symptoms, behaviors, and problems, and is used to classify an individual's responding as (1) reliable, (2) exaggerated/malingering, (3) defensive, or (4) uncooperative. Self-reported information from an individual who is not reliable will have significant inaccuracies. This principle emphasizes the value of third party information (records and interviews of collateral observers) in both detecting and correcting these inaccuracies.

Other researchers, such as Rogers, have developed forensic instruments to assist practitioners in discerning distorted responses from litigants who seek to appear better or worse than they are in reality.

A second major theme of forensic mental health assessment in legal contexts, developed by Poythress, Heilbrun, and Lander, is acknowledgement of the

distinction between psychologists who are retained to perform a therapeutic role, e.g., by treating offenders, and those who are retained to perform an evaluative forensic role. The full nature of the distinction is appreciated when one considers the ten differences between these roles elaborated by Heilbrun, outlined previously in this article.

Psychologists are often consulted to assess parental competence in the context of a marital dissolution, where decisions about the placement of children in the custody of one, both, or neither of the parents must be made by a court. One parent may be mentally ill, or there may be allegations of physical or emotional abuse or neglect by a parent; in such cases, the courts must determine whether that parent is unfit to raise the children. More frequently, courts must grapple with the question of which type of custodial arrangement will promote the child's best interests.

Psychologists who are well versed in the research on psychological effects on children of divorce and custodial arrangements can play a significant role in assisting courts with determinations about parental fitness. Family life has traditionally held a sacrosanct position within most legal systems. Over time, social and cultural factors regarding who has worked outside of the home and who has been a primary caregiver for a child have shifted the status and rights of children, women, mothers, and fathers. As Krauss and Sales point out, definitions of the family have undergone a dramatic change, particularly regarding the nature of nuclear and extended families. Hetherington *et al.* show that about one-half of all Australian and North American children born in the 1990s will be raised by a solo parent, and many children have no siblings. The rise of "no fault" divorce laws has contributed to these changes and has removed much of the stigma previously associated with marital dissolution. However, in certain cultures, remaining married to a spouse who takes on a new partner provides more benefits and social advantages to the ousted wife and children than does the option of divorce.

Along with changes to the definition of family, the concept of the psychological parent has developed. Accordingly, the rights of grandparents, step-parents, gay parents, and other domestic partnerships have influenced trends in custodial determinations. The extent to which children are consulted regarding their preferences, and the age at which this occurs, varies from one community to another.

The contributions of and participation of psychologists as researchers and practitioners in issues relating

to marriage, divorce, and child custody have been welcomed by legal practitioners. Bausermann demonstrates how research has contributed to our understanding of circumstances that promote healthy adjustment in children, and can assist in assessing custodial options such as sole versus joint custody. Eight studies that compared children's adjustment in intact families versus joint custodial arrangements showed no adjustment differences in the children. Data from 33 studies indicated that (1) no causal relationship has emerged between the type of custodial arrangements and children's adjustment; (2) when the parents are in extreme conflict, children experience adjustment difficulties no matter what the custodial arrangement; (3) more parental conflict ensues between ex-partners when one parent retains sole custody than when custody is joint legal and physical; and (4) the ongoing involvement of the father with the child is predicted by the relationship between the parents, not by the relationship between the father and the child.

3.3. Child Custody

The article on child custody by Martinson and Gould traces the four major doctrines relied upon by courts in making custody decisions: (1) the "tender years" doctrine for children under the age of 7, favoring maternal custody; (2) the "psychological parent" rule, favoring the primary caregiver; (3) the "least detrimental alternative," favoring the stability and ongoing relationships in the child's life; and (4) the "best interests of the child." Although the latter is the prevailing standard, it has repeatedly been criticized as too vague, e.g., regarding the time frame to take into consideration when it is applied.

This article also outlines the key features of ethical practice standards, such as the American Psychological Association Guidelines on Custody Evaluations. These guidelines assume the legal criterion is the best interests of the child. In line with the distinction between functional and diagnostic criteria noted earlier, the guidelines emphasize that evaluators must avoid focusing on the psychopathology of parents except to the extent that it affects parenting skills and fitness. The guidelines echo the need to use multiple methods of data gathering, such as observations, interviews, contacting third parties or collaterals courses, obtaining school reports and records, as well as formal psychological assessments, in order to offer a more reliable recommendation to the courts.

Because the stakes are high in custody disputes, practitioners are advised to take steps to uncover efforts by the parties undergoing evaluation to exaggerate positive information or minimize negative information. The principle of substantiating one's opinion with evidence to back it up is critical to avoid recourse to clinical opinions that are more susceptible to attack. Many of the recommendations for successful forensic consultation in child custody cases can be applied to other areas of forensic practice.

Commentators have pointed out that one consequence of the implementation of no fault divorce laws is the greater likelihood of resorting to mediation to resolve issues of custody. In many jurisdictions, parties litigating in family court must participate in mandatory mediation or family conferences prior to attending any court hearing, and in other jurisdictions, referral to mediation is routine. More custody cases are resolved via mediation than by trial. Research on uses of mediation in family cases is more extensive than in other areas of the law. Sales and Beck argue that mediation may produce more losses for mothers and gains for fathers and can have both positive and negative effects. Success of mediation has more to do with the readiness of the parties for the procedure. The best candidates for mediation are those who are cooperative in resolving conflicts. There is no evidence that the psychological functioning of parents enmeshed in conflict can be enhanced by mediation, or that mediation can change the relationship patterns of parents who are angry, volatile, disengaged, or withdrawn. Researchers also caution against generalizing from measures of satisfaction with mediation.

The approaches to evaluation and assessment outlined by Poythress, Heilbrun, Lander and Martindale and Gould establish core principles that can be applied to all forms of forensic assessment. Greenberg and Brodsky discuss their application to civil damages and assessment of the nature and scope of injuries following an accident, and Foote and Goodman-Delahunty discuss their application following a statutory violation, such as employment discrimination.

Just as children have been given greater and more careful attention in many legal processes than in the past, more recently their testimony has achieved greater acceptance. They have been seen more frequently as victims of crimes and therefore as witnesses. Many nations have experienced an increased focus on children and their welfare in a wide range of legal contexts. As divorce rates have increased, the question of how to provide for the children has come more into focus. In

that context alone, there has been an increased concern for the abilities of children to know their own minds, to give accurate testimony, to withstand the pressures of family members, and to participate in the legal process. Although many of these concerns focused on protecting children from becoming victims of their situation, many children do indeed become victims, often within the family. Various kinds of abuse are observed, from neglect, to beating, to sexual abuse. Abuse that in the past would not have come to light in public or in legal proceedings came to the attention of professionals working for public agencies charged with overseeing (among other things) child welfare. As these events are reported, questions inevitably arise regarding the abilities of children to remember the important events, report their memory, differentiate between what they experience directly from what they have been told, and withstand the pressures of testimony and cross-examination in the presence of strangers and the imposing atmosphere of the courtroom. There are also concerns about the appropriate means of interviewing children to get the most reliable information with the least cost to the child.

3.4. Children's Testimony

Quas and Beck divide the research questions that have been asked in this area into three major categories: characteristics of the child, characteristics of the to-be-remembered event, and characteristics of the interview. Age is a rough way of indexing the cognitive and social changes that occur with psychological development. Many changes occur as children grow and age: their general knowledge, sense of what is important, and ability to interpret and remember events all change in important ways. Other factors (e.g., intelligence, temperament, emotional reactivity) are also important influences on the child's memory and ability to provide reliable testimony. The authors point out that it is difficult to apply knowledge of these factors to make judgments about the validity of a given child's report. However, such information can assist in deciding how best to interview the child, and how to protect the child during the process. The recent move by the Home Office in the United Kingdom to identify and moderate treatment of vulnerable witnesses is of particular interest in this connection.

Event characteristics are of interest here just as they are in other areas of eyewitness memory. Quas and Beck review the major findings from research with children. Emotional events, for example, are remembered better than neutral events, although peripheral

aspects of an emotional event may not be well remembered. But again, applying this knowledge is not always straightforward. What is central to a child may not be what is central to an adult, and as with adults, children vary with regard to what aspects of an event they consider central or peripheral. Like adults, children learn generalized accounts of common, repeated events. But more so than adults, they fail to differentiate between the common characteristics of an event and the unique ones, often failing to report unique events and common, expected events that did not occur in the instance of interest.

The characteristics of both interviews that lead to erroneous reports and those that lead to more accurate and complete reports have been the subject of a very large portion of research on children's testimony. To some degree this was driven by the nature of the court cases that were very much in the public eye in both North America and Europe. The conclusions reached for children are very similar to those developed by Vrij for interviewing adults. Free recall questions are fairly accurate (although they may be incomplete), and suggestive questions lead to errors, in the direction of adopting the suggested information.

3.5. Interviewing and Interrogation

Obtaining information from persons associated with a criminal event (and certain other events such as food poisoning, accidents, and workplace events) is a process that is both important and fraught with possibilities for error. Some errors are intentional—e.g., withholding self-incriminating information—while others are mired in the complexities of retrieving precisely accurate memories. The difference between these cases is the difference between interrogations and interviews. This and the related topic of detecting deceitful testimony are treated in the article by Vrij on interviewing and interrogation.

Posing suggestive questions to victims and other witnesses risks the integrity of the resulting information. When witnesses are asked leading questions containing one possible answer to the question, e.g., “Was the car red?”, when the answer is “Yes” it is not clear whether it is because the car was in fact red or because the witness has no memory of this fact but answers “Yes” because of a judgment that the questioner probably knows the right answer and is looking for confirmation. Alternatively, the suggestion may actually modify the witness's memory. On subsequent occasions, the witness may confidently and spontaneously

answer “Red” and experience the attribute of “red” associated with that object and event, firmly believing it was red.

One alternative to asking leading questions is to ask questions containing multiple choices, but these are still limiting and leading, albeit in a broader sense. The best practice is the use of open questions, often a number of open questions, sequentially. For example, “Tell me everything you can remember about the car,” followed by “What was the color of the car?” if color is not mentioned. In general, it is better to begin with the more open questions, probing with more open questions, and ending with specific questions (leading, in the end) to elicit specific responses. However, if the witness cannot come up with “Red” in response to “What color was the car?”, asking “Was it red?” yields interpretable information only if the answer is “No.” These topics are discussed in more detail by Vrij.

For more than 20 years, techniques based on context reinstatement have been known to enhance the recall of information, even after significant time delays. The most commonly used of these techniques is the cognitive interview (CI), as developed by Fisher. CI techniques are based on the premise that the witness has the information wanted by the interviewer, that the information is organized by the witness according to meaningful criteria applied by the witness at the time of encoding or organizing the information for retention, and that the retrieval of this information must be organized by the witness (not the interviewer) in ways that fit the organizational criteria imposed on it by the witness in the first place. This set of assumptions requires that much of the social interaction—as well as the cognitive interaction—about the recall process be in the hands of the witness. Witnesses are therefore encouraged to take an active part in the interview, to recall and report everything, and to return to previously discussed topics if additional details have been recalled. Witnesses are also encouraged to report the events under investigation from the perspective of other actors present during the events. Research indicates that context reinstatement techniques greatly increase the gross amount of memory reports. The ratio of correct to incorrect items recalled does not change, however, so while the amount of material produced is greatly increased, its efficiency at differentiating correct from false reports is unchanged. Nevertheless, having much more to work with is a great advantage to investigators.

The Reid technique is the single most popular approach to the interrogation of uncooperative suspects. It is

used to obtain confessions from people whom investigators believe are guilty. Of course, the detection of guilt or innocence is well known to be a judgment prone to error, and the confession is meant to establish guilt, so the technique is to some degree circular. Its adherents defend it as being nearly perfect, producing confessions from the guilty but not from the innocent. However, there is an increasing catalog of cases in which Reid-like techniques are associated with false confessions and wrongful conviction. The technique has achieved a negative reputation in psychological research circles because of certain components of the technique, such as altering the suspect's decision-making environment by lying about the nature and strength of the evidence against him, by painting the picture of his situation as hopeless, and creating a (false) understanding that confession is the only way he can obtain any leniency (something usually outside the investigators control). Vrij's article reviews the Reid technique and provides an extended analysis of its difficulties.

Vrij offers as an alternative a technique used increasingly in the United Kingdom as a response to a series of notorious British miscarriages of justice involving false confessions. The technique involves the extensive use of detailed knowledge of the crime by the investigating officers and the skillful use of questioning techniques.

False confessions have received a great deal of attention in the popular press in the last few years, and many nations have their own catalog of prominent cases. Vrij distinguishes three types of false confessions: voluntary, coerced-compliant, and coerced-internalized. Voluntary false confessions are given with no special effort from investigators. The famous case of Henry Lee Lucas, who is estimated to have confessed to more than 600 murders is offered as an example by Gudjonson. Coerced-compliant confessions are those that result from the pressures and incentives of an interrogation. Coerced-internalized false confessions occur when people become convinced that they actually did commit the crime even though they have no memory of the event. Analysis of these forms of confession is provided, and means of detecting false confessions are discussed.

Law enforcement personnel often display great confidence in their ability to detect deceit in suspects they are interviewing. The bad news is that in controlled studies, people are able to detect truthfulness a bit above the level of chance expectation but detect lies somewhat below the level of chance expectation. Studies using law enforcement personnel, as compared with college students, find similar accuracy rates. Some

professionals (e.g., U.S. Secret Service officers and others with a special interest in deception) perform better than chance levels. Vrij reviews a number of common pitfalls in the deceit detection process, discusses cultural differences in social interaction norms that interfere in the process, and debunks some popular beliefs about the behavior of liars. Techniques for improving deceit detection are reviewed, e.g., attention to the content of a witness's speech leads to more effective assessments of deceit than does attention to non-verbal behavior.

Another form of error, although rarely intentional, is that made by eyewitnesses when they are asked if the perpetrator is among the persons shown to them in a "lineup." The prevalence rate of such errors is not altogether clear. However, the problem has persistently attracted attention for more than 100 years and is not easy to dismiss. The most recent incarnation of attention to this problem is found in the work of the Innocence Project, which as of April 2004 has documented 143 exonerations of wrongfully convicted persons. Eyewitness identification errors are the single most important contributor to these wrongful convictions. The malleability of memory is an important contributor. New information can be incorporated into old memories, and the source of memories is often forgotten. It is often not possible to tease out the origins of what appear to be intact and accurate memories. In addition, it is not uncommon for aspects of a typical event to be incorporated into memory for a specific event in which certain of the typical elements were not present.

3.6. Eyewitness Testimony

The misinformation effect, discussed by Levine and Loftus in their article on eyewitness testimony, is an important example. They show how the wording of a question can lead to the intrusion of non-existent elements into reports of memory. Similarly, the strength of the verb used to characterize and event (e.g., "How fast were the cars going when they smashed/collided/bumped/contacted . . . ?") affects the answer. Not surprisingly, the effects are stronger when the actual memory is weaker. And the passage of time only fosters integration of the new or modified elements into an altered but apparently unitary memory.

The authors review the relatively new and somewhat surprising findings on the subject of creation of new memories of personal events that in fact never

happened. Suggestions made by trusted others are important ways in which non-existent events can be created in memory. But imagining an event oneself can also result in the creation of memories, as the fact that the event was only imagined is itself a memory that may be forgotten.

The spurious relationship between confidence in the accuracy of a memory and its actual accuracy is briefly discussed. Belief in the validity of a confidence accuracy relationship is strong on the part of many people, some of whom will serve as jurors or fact finders in legal contexts. Even though confidently given accounts of events may be convincing, the confident manner of reporting is in itself no indication of the validity of the recollection. Only a very small relationship is found between confidence and accuracy. And to make matters worse, confidence is easily manipulated independently of accuracy, making it an even less useful factor.

The role of emotion in memory is an interesting area of study. Emotional events appear to be well remembered, but it appears that this is primarily for central events, or those that have important meaning for the observer. Peripheral events appear to be more poorly remembered. Studies of activation of brain areas and their relation to memories of emotional events can help to clarify our interpretation of the memory–emotion relationship.

The confrontation of a criminal by victims and other witnesses captures interest and imagination; when the accusing finger points at the perpetrator of a crime, it is the moment of justice. However, this is no simple imposition of justice at a personal level. Everything about the identification process has meaning for the outcome, and eyewitness identification is notoriously fallible. Because the identification and the preparations for it have a central role in a significant proportion of criminal cases, concern for identification procedures has attracted the attention of law enforcement agencies, non-governmental organizations concerned with justice, and the research community.

3.7. Eyewitness Identification

Tredoux, Meissner, Malpass, and Zimmerman introduce the topic of eyewitness identification and set forth some of the complexities of this area of applied research. The authors distinguish three stages in the eyewitness process: perceiving an event, storing and assimilating the information obtained, and remembering and acting upon the event. They review and discuss

the ways in which factors related to these stages affect the result of the identification process.

Any identification is dependent on the amount and quality of the information obtained from the original event. This is affected by the amount of time the witness had to view the event and the perpetrator, distance from the event, and its visibility, including lighting and conditions that obscure vision. Apart from external conditions, aspects of the witness are also important at the initial stage: stress, fear, and the presence of a weapon all influence the information-gathering process.

Certain enduring characteristics of witnesses are related to their performance. Their age (at least at the extremes) has some influence. Alcohol and other drugs also have effects. The “race,” sex, and occupation of witnesses have also been studied. While there is no general advantage of males or females in identification performance, there are some differences in memory for events that appear to be matters of attention rather than memory per se. While it is a popular belief that law enforcement officers will be better in facial identification, the small research literature on this topic does not support this idea. However, experience as a officer does relate to the quality of the descriptions they provide, both of persons and events. However, they also tend to misperceive innocent events as being criminal in nature. The race of the witness is unrelated to facial or event memory of reporting performance.

Attributes of the perpetrator also contribute to accuracy of identification, in interesting ways. First, disguises are effective, especially those that cover the most informative areas of the face. There are also distinctive patterns of facial appearance. Typical faces are more difficult to distinguish from each other, while non-typical faces are more distinctive and easier to remember. Some faces can be characterized as having specific characteristics (such as “criminality”); observers agree on this, even though it is unrelated to actual criminality. The race of the perpetrator alone does not contribute to accuracy of identification, but the combination of the race of the perpetrator and the witness does. “Cross-race” identifications are more frequently in error than “own-race” identifications.

An important part of the investigative process is getting information from witnesses, about both the event and the appearance of persons taking part in the event. Verbal descriptions of perpetrators are notoriously sparse, but there are techniques that assist first responders in obtaining more useful descriptions and information; some of these are described. Consequences

of asking witnesses to describe the faces of perpetrators include short-term reduction in the ability to recognize the face described.

The technology of pursuing the identification of suspects by eyewitnesses includes such procedures as searching mug shot collections, constructing composite portraits, and constructing and administering lineup and other identification procedures. These topics are all discussed in this article. More detailed attention is given to the construction, evaluation, and administration of lineups.

It is important for law enforcement organizations to keep collections of facial images so that fair lineups can be constructed for criminal investigation. The authors point out that these collections and the means of perusing them are behind the available technology. Examining mug shots is a facial recognition process. Facial recall, however, externalizes a facial image in memory to a representation that can be shared. Verbal descriptions are a form of face recall; another is the construction of a composite portrait. Of course, if the portrait is constructed by another person through the witness's verbal descriptions and then approval by recognition, it is not exactly facial recall. But when the witness uses composite construction computer programs, the work of the eyewitness is more constructive. These are moot points, however. There is no evidence that composite construction is a reliable means of producing high-quality likenesses from memory. There are other dangers in their use: first, many investigators believe in their usefulness, and second, many times a witness is given a copy of their composite to keep with them. Evidence suggests that repeated viewing of a composite changes memory for the original face.

Lineups should be constructed to be fair in two respects: the suspect should not stand out from the other members of the lineup, and the fillers—the five other members of a six-person lineup—should be meaningful alternatives to the suspect. Quantitative methods for measuring the fairness of a lineup have been developed and can readily be applied by law enforcement personnel who create them. The authors describe these techniques and show their importance for effective use of identification evidence in an investigation and prosecution.

Many law enforcement agencies have policies governing the admonitions that are read to eyewitnesses during the identification process. The authors argue that one of the more important problems in eyewitness identification is the tendency for eyewitnesses to believe that they must choose someone from the lineup

they are shown. Admonitions of various kinds have been developed in an attempt to correct this tendency, and to orient the eyewitness to the important nature of the identification decision.

Alternative forms of lineup procedures have been proposed and researched in the last decade. The authors describe and evaluate a series of these, and describe what is known about the use of lineups involving other modes than visual sensory ones. Finally, the authors consider the beliefs and knowledge held by prospective jurors about eyewitness identification. This is information that feeds into the evaluation of the use of expert testimony in the evaluation of eyewitness identification. The balance between informing the jury and influencing the jury is an important one, and so it is important to know whether juries can benefit from expert assistance. Research indicates that lay jurors lack the requisite knowledge to appropriately evaluate eyewitness identification evidence.

3.8. Jury Decision Making

Opportunities for laypersons to participate in legal decision making exist in many jurisdictions, most commonly provided through some form of jury service, although there is considerable variability in jury systems and the scope of the jury role and the types of cases in which the public participate around the world. Albertson, Farley, and Hans report on developments in the jury decision making area. Jury behavior is one feature of the legal system that has been the subject of extensive psychological research for several decades, starting with the University of Chicago Jury Project. The research database on jury studies is so vast that gaining an overview is challenging. A recent meta-analysis of jury research published in an 18-year period (1977–1994) revealed that studies of criminal cases far outstripped those about civil jury decision making (89 vs 11%). Thus study also provided some insight into the most frequently studied topics of jury behavior: the impact of litigation strategies, the influence of different types of witnesses, and the effects of juror or litigant characteristics. Distinctive subtopics addressed most often by researchers emerged: criminal defense strategies, capital punishment and sentencing, characteristics of individual jurors, judicial instructions to jurors, general litigation strategies, witness performance, evaluation of evidence by jurors, and characteristics of offenders or parties.

Jury researchers have employed a diverse array of methods and approaches to gain insight into factors

that influence jury performance. These include archival studies of jury verdicts in actual cases, case analyses, community attitude surveys (e.g., via telephone), observations of trials and interviews of actual jurors, experimental simulations, and experimental or quasi-experimental designs using real juries.

One of the limiting factors in studying jury decision making is that the deliberations that take place among jurors at the conclusion of the trial are typically confidential, and the observation or recording of jury deliberations in many jurisdictions is prohibited. This policy has impeded researchers from gathering much information about the scope of jury-initiated misconduct in actual trials. Researchers who rely on post-trial interviews can not accurately gauge the extent to which juror recall is accurate and reliable. At times, researchers have employed “shadow jurors” who attend courtroom trials and then are interviewed about their observations to infer what the actual jurors might think of the evidence. Occasionally, extra alternate jurors have been empanelled and their deliberations have been videotaped and analyzed to gain insight into how the information they heard and witnessed is used in reaching a verdict.

Research involving real jurors in actual cases, including archival studies of jury verdicts, is relatively rare, accounting for approximately 10% of the jury studies conducted over an 18-year period. Because this method is not very informative about the decision-making process of the jury, many researchers have adopted a mock trial paradigm in which simulated juries receive information akin to that presented in an actual case. The materials may range in realism from brief written descriptions or case summaries to extensive videotaped trials in which attorneys present opening and closing arguments and question witnesses via direct and cross-examination, and jury instructions on the law are provided to the mock jurors. A benefit of this approach is the more extensive empirical control gained by the researcher, permitting causal inferences to be drawn. When mock jurors are used, the extent to which they are similar to actual or potential jurors is an issue. Although much of this research has been conducted with psychology undergraduates, the use of jury-eligible participants has steadily increased, enhancing the generalizability of these results.

The unit of analysis studies by jury researchers has varied. In some cases, individual jurors are the target of the studies, while in others, group deliberations are included, and the unit of analysis is the jury. The article by Albertson, Farley, and Hans carefully outlines the

major findings to emerge from both types of studies, i.e., those that have focused on individual jurors and those that have addressed the jury as a group. Studies of the deliberation process have increased in the past 30 years, and they have examined the influence of features such as the size of the jury, the way in which differences of opinion between majority and minority groups are resolved, the influence of majority versus unanimity rules, and so forth.

The significance of distinctions between external validity and ecological validity have been highlighted by Bornstein and Vidmar, specifically in discussing whether research conditions in simulation studies include sufficient features of real trials to render them adequately representative of actual trials, permitting researchers to draw on research findings to make policy recommendations regarding reforms to enhance jury performance. Questions of normative criteria against which jury performance should be assessed have also been raised, particularly since research has shown that many judges are susceptible to the same biases or weaknesses as are many jurors. The authors suggested that profitable future avenues of research might include the influence of juror and jury anonymity, options for jurors to become more active during the trial, and comparative jury studies.

Before his death in 1916, at age 53, Hugo Muensterberg conducted research on several of the topics discussed in this section, namely, assessment, detection of deception, bystander and witness accuracy, and jury persuasion. At that time, concern was widespread that he was pushing the state of scientific knowledge beyond its limits. Each of the forensic topics explored by Muensterberg has been the subject of extensive inquiry and refinement by psychologists in the ensuing century. As noted previously, concerns that forensic psychologists must work within the limits of scientific knowledge, in particular by scrutinizing the external and ecological validity of their findings, have remained constant. Many forensic topics that Muensterberg presaged through his interest in environmental influences on individual differences have since been added to the repertoire of psychology and law studies, for instance, interventions to treat violent and sex offenders and the identification of individual and environmental factors that lead to offending behavior. Contemporary events have stimulated advances on topics such as the psychology of law enforcement and of terrorism. Newly emerging topics, such as restorative justice and therapeutic jurisprudence, with more emphasis on contextual factors and community involvement derive

from closer interdisciplinary collaboration between scholars trained in law and psychology than was typical in the field in the past. Research, practice, and policy development borne of collaborative endeavours by those trained in psychology and law may meet with less resistance than did Muensterberg's early work in this field.

GLOSSARY

measurement principles and scales Psychological scaling methods for scoring tests.

objective scoring Procedures that yield the same exact score regardless of who or what conducts the scoring of tests.

projective techniques Measurement instruments and devices in which the stimulus items are unstructured and/or ambiguous.

psychological testing A procedure that involves the use of tests to measure psychological constructs of individual persons.

psychometrics The formal study and practice of test construction principles and evaluation of numerical test results and the interpretation of protocols.

psychophysics The study and determination of sensory thresholds.

subjective scoring Procedures in the scoring of tests that involve intuition, bias, and other subjective judgments that yield different test scores depending on who or what does the scoring.

technical manual Booklet accompanying tests that provides technical information relating to sound psychometric properties of the tests.

testing standards Standards prepared periodically by professional associations with expertise in psychological testing and made available to test constructors and users by the American Psychological Association.

1. PSYCHOMETRIC TESTS DEFINED

The term “psychometric” is defined in *Webster’s* dictionary as “the measurement of the duration, force, interrelations, or other aspects of mental processes, as by psychological tests.” However, not all psychological tests are psychometric tests. Cronbach, an early prominent psychometrician and author of books and journal articles in the field of psychological testing, identified psychometric tests as those that obtain numerical estimates of human behavior and performance, in accordance with Thorndike’s dictum that “if a thing exists, it exists in some amount.” Cronbach went on to distinguish psychometric testing from impressionistic testing. Within Cronbach’s framework and classification of tests in the former category are tests of general intelligence, ability achievement, performance, personality, and the like. In the latter category are the projective devices and techniques as well as rating scales and interview measures based on subjective judgments. An even earlier distinction between these classifications of tests was formally made by the American Psychological Association (APA) in its first publication of *Ethical Standards of Psychologists* and citing incidents of reported ethical problems of psychologists. In Section 5.4,

“Publishing and Using Psychological Tests and Diagnostic Aids,” it was inferred that the former are psychometric tests and the latter are not. (Incidentally, it was in this section that the three-tier (i.e., A, B, C) hierarchy in classifying tests and diagnostic aids was established and first published.)

1.1. Characteristics of Psychometric Tests

Paramount among the features of psychometric tests is objectivity of scores obtained through standardized testing procedures. This means that whatever or whoever produces the scores, they are always the same; subjective judgment never enters into the process of scoring. The numerical scores of psychometric tests yield continuous or discrete frequency distributions that may legitimately be analyzed statistically. Furthermore, for a test, a scale, or an inventory to qualify as being a psychometric one, there must be evidence that the instrument possesses sound psychometric properties. Finally, the instrument should be shown to measure psychological constructs, particularly those consistent with well-known psychological theory.

1.2. Characteristics of Nonpsychometric Tests

A distinguishing feature, particularly of projective techniques, is the unstructured tasks that are presented to respondents and the ambiguous stimulus items. The principal contrasting feature between psychometric and nonpsychometric tests is the objectivity versus subjectivity of scoring. In the vernacular of psychometricians and measurement specialists, the scoring of nonpsychometric tests involves, in the main, what are referred to as “subjective–intuitive procedures.” However, in spite of these differences, instruments in this category are required by national testing standards to be in compliance with those published by national professional societies. Table 1 provides examples of both psychometric and nonpsychometric tests.

2. EARLY HISTORY OF PSYCHOMETRICS

In the social sciences, particularly education, psychology, and sociology, psychometrics as an academic field of study is of relatively recent origin. It is barely 50

TABLE 1

Examples of Psychometric and Nonpsychometric Tests	
Psychometric tests	Nonpsychometric tests
California Personality Inventory (CPI)	Children’s Apperception Test (CAT)
Differential Aptitude Tests (DAT)	Machover Draw-A-Person Test (D-A-P)
Scholastic Assessment Test (SAT)	Rorshach Inkblots (RI) ^a
State–Trait Anxiety Inventory (STAI)	Rosenzweig Picture Frustration Study (RPFS)
Wechsler Intelligence Scale For Children (WISC)	Thematic Apperception Test (TAT)

^aTo be distinguished from the Holtzman Inkblot Technique, for which a genuine attempt has been made by the author, Wayne Holtzman, to meet standards of psychometric tests.

years old. The first formal programs to train psychometricians in graduate schools in the United States were established shortly after the end of World War II. They were the programs at the University of Chicago (headed by Palmer O. Johnson) and at Harvard University (headed by Phillip J. Rulon). However, the underlying roots can be traced to the 19th century, even prior to the establishment of psychology as a discipline by Wundt in 1879.

2.1. Derivation From Psychophysics

Historically, psychometrics can be viewed as an outgrowth of psychophysics during the latter part of the 19th century. In Germany, Fechner and his colleague Weber, who in 1834 had postulated the famous Weber’s Law of just noticeable differences, were the founders of psychophysics. Both were early physiologists and were credited with founding psychophysiology. It was these original works by Fechner and Weber that led to the postulation of the measurement model in the United States by Stevens in 1946. But because Fechner’s works laid the early foundation to the basic principles of measurement, Fechner is often referred to as the first psychometrician.

2.2. The Measurement Model

At Harvard University, Stevens was the psychologist who provided the social sciences with a taxonomy of measurement scales that form the base for the scoring

of psychometric tests. Stevens had been greatly influenced by the earlier work of Fechner and Weber with physical scales. Besides Stevens, other psychologists in the United States, such as Thurstone and Likert, had already begun to extend Fechner's work to measure psychological constructs. Later, fundamental advances to furthering work in psychometrics beyond psychophysical theory and methods were the measurement models based on true score theory and item response theory.

3. PSYCHOMETRIC THEORY AND PRINCIPLES

Commensurate with and preceding the existence of formal academic graduate courses and programs in psychometrics, as well as the publication and distribution of national testing standards and ethical principles governing the rise of tests operationally and in research, a number of textbooks explaining psychometric theory began to be published. Prominent among these early texts were those of Guilford in 1936 and 1954, Gulliksen in 1950, Lord and Novick in 1968, and Nunnally in 1967. All of these books are still in print and available to students, professors, and researchers. The Lord and Novick book was supplemented by that of Wainer and Braun in 1988. In 1978, Nunnally revised the first edition of *Psychometric Theory*, and several years after his untimely death, a third edition by Nunnally and Bernstein appeared on the scene in 1994.

3.1. Test and Testing Standards

The first test and testing standards were published by APA in 1954, that is, 1 year after its publication of the *Ethical Standards of Psychologists*. These testing standards were the *Technical Recommendations for Psychological Tests and Diagnostic Techniques*. They were published as a supplement to the *Psychological Bulletin*. Subsequently, the American Educational Research Association (AERA) and the National Council on Measurement in Education (NCME) collaborated with APA in producing the *Standards for Educational and Psychological Tests* in 1966, 1974, 1985, and 1999. The documents are published and distributed by APA. They set forth the principles of sound psychometric properties to be met by all psychometric tests as well as all nonpsychometric tests.

3.2. Ethical Principles Governing Use of Tests and Testing Practices

Following the first publication of the *Ethical Standards of Psychologists* in 1953, APA has periodically revised and updated these principles. In each case, a section has been included that relates to the proper use of tests and testing practices. On June 1, 2003, an expanded *Ethical Principles of Psychologists and Code of Ethics* took effect.

3.3. Principal Psychometric Properties of Tests

The current testing *Standards* publication is the most comprehensive single documentation of tests and testing practices ever published and circulated by APA. There are 15 sections of standards that cover 194 pages (including the glossary and index). Foremost among the standards with which all psychometric (and other measurement) instruments must comply are Standards 1 to 6:

1. Validity
2. Reliability and errors of measurement
3. Test development and revision
4. Scales, norms, and score comparability
5. Test administration, scoring, and reporting
6. Supporting documentation for tests

Adhering to the principles espoused by the *Standards* for testing and mandated by the *Ethical Principles* leads to the assurance that measurement instruments and the scores they yield possess the required psychometric properties. Only in this way can it be established that the assessments measure the psychological constructs that are purported to be measured by the instruments. Equally important is evidence that adherence leads to a determination that the scores produced are internally consistent and stable over time (i.e., reliability) and that the purposes for which the tests were developed are being fulfilled. Compliance also ensures that the properties of the tests demonstrate evidence of and support for the meaningfulness and usefulness of the interpretation of the scores yielded by the tests and are consistent with psychological theory (i.e., validity).

4. REQUIREMENT OF TECHNICAL MANUAL FOR ALL PSYCHOMETRIC TESTS

In *Section 6* of the *Standards*, authors and test publishers are advised to provide test users with empirical

documentation that the tests in question possess the required sound psychometric properties. Standard 6.1 states, "Test documents (e.g., test manuals, technical manuals, user's guides, and supplemental materials) should be made available to prospective test users and other qualified persons at the time a test is published or released for use." Until recently, many psychometricians and measurement specialists who were requested to review and critique tests for the *Mental Measurement Yearbooks*, including the current author, would decline to review tests that were not accompanied by technical manuals and other supporting documentation. The 2001 edition of the yearbook contains an appendix titled "Tests Lacking Sufficient Technical Documentation for Review" listing 94 such tests that had been submitted for review to the Buros Institute of Mental Measurements.

5. CONSEQUENCES OF USING TESTS THAT DO NOT COMPLY WITH TESTING STANDARDS AND ETHICAL PRINCIPLES

Prior to the publication by APA of the first ethical codes of psychologists in 1953 and the first testing standards in 1954, there were no national regulations in the United States governing the use of tests, whether psychometric or otherwise. However, the current author began to testify in the federal courts as an expert witness (a psychometrician) to support the sound psychometric properties of tests in 1952. Over the subsequent 50 years, he continued to testify in favor of the proper use of psychometric tests and in opposition to the misuse of tests. Much of the misuse has involved violations of the testing standards and the ethical codes of psychologists. These violations have included failure to accompany tests with technical manuals and further documentation, improper application of tests, improper interpretation of test scores, and "stealing" of materials and systems copyrighted by legitimate test authors.

The consequences of violations of the *Standards* and *Ethical Principles* may fall into moral or legal categories. Moral violations may be those on the part of psychologists who are APA members and/or American Psychological Society members. Violations in this category usually result in dismissal of membership in either or both professional associations as well as loss of license for psychologists in private practice. (The same is true for members of other professional associations

and societies.) The consequences in the legal category are much more severe and costly, especially in court decisions in class-action suits. As an example of the latter, a summary of a class-action suit in which the current author was the principal expert witness (as a psychometrician) for the plaintiffs is presented next.

A 1991 case, *Soroka, et al. v. Dayton-Hudson Corporation*, was settled by an out-of-court agreement between the parties. The consent decree was ordered by the trial court judge and was signed by both parties on September 23, 1993. The general terms of the agreement provided for payment of \$1.3 million to an estimated 2500 job applicants who were administered the test at issue between 1988 and 1991, payment of an additional \$60,000 for four plaintiffs legal fees, and payment of an additional \$35,000 for services to the plaintiffs' legal staff in administering the claims procedure and the settlement funds.

The case was filed by applicants for the position of store security officer at Target Stores in California. Target Stores is owned and operated by Dayton-Hudson, with headquarters in Minneapolis, Minnesota. The applicants claimed that they were required to take the 704-item Rodgers Condensed California Personality Inventory-Minnesota Multiphasic Personality Inventory (CPI-MMPI) and alleged that the test was not psychometrically sound, that it violated California's fair employment laws, and that it constituted an unlawful invasion of privacy protected by the constitution of the State of California.

Four expert witnesses for the plaintiffs (three psychometricians and one industrial-organizational psychologist) were successful in convincing the court of the merits of the complaints and charges filed against Dayton-Hudson. It was the experts' respective testimonies, based primarily on alleged violations by the defendant, that led Dayton-Hudson to seek the out-of-court agreement. On October 25, 1991, the court granted the plaintiffs a preliminary injunction on further testing in concluding that the plaintiffs had in fact convinced the court of the merits of the claims that had been filed. The defendant had considered appealing the ruling to the California Supreme Court but then decided against following through on the appeal.

6. CONCLUSIONS

Psychometrics has enjoyed a history about as long as that of psychology itself. It has been viewed as an outgrowth of the earlier psychophysics. Many

psychometricians and measurement specialists recognize Fechner, the early German psychophysicist, as the Father of Psychometrics.

Psychological tests are classified into two major categories: psychometric and nonpsychometric. The principal distinctions between the two rest mainly with (a) the nature of the scoring of test items and (b) the nature of the items themselves. To qualify as a psychometric test, the scoring procedures must be purely objective, whereas in the scoring procedures for nonpsychometric tests, subjective judgment on the part of the scorers enters into the process of scoring the items. Relating to the items themselves, those for psychometric tests are structured, whereas those for nonpsychometric tests are unstructured and generally ambiguous. However, both types of psychological tests are required by national regulations to comply with the *Ethical Standards of Psychologists* and with the *Ethical Principles of Psychologists and Code of Conduct*. The publication and dissemination of these testing standards and ethical principles and codes for test constructors and test users dates back more than 50 years. Violation of these regulatory standards and principles may result in dire consequences to the violators so as to protect the test takers.

GLOSSARY

cytokines Proteins created by cells that influence the behavior of other cells; they often act as messenger molecules that enable communication between cells, particularly immune cells.

endocrinology The study of internal secretions of the body, particularly hormonal secretions, and activities involved in such secretions.

granulocytes White blood cells containing granules that themselves contain substances that can be used to combat invaders (e.g., oxygen radicals).

hormone A substance secreted by the body that affects distant target cells.

immune system A system of organs and cells that protects the body from intruding organisms and, in some cases, malfunctioning cells.

interventions Attempts to modify behavior, cognition, or emotions so as to improve psychological and physical well-being.

leukocytes White blood cells, including granulocytes, monocytes, and lymphocytes.

lymphocytes White blood cells that have specific abilities to kill particular invaders (e.g., a given cell recognizes and responds to only one stimulus) through cytotoxic action or antibody production; lymphocytes include B and T cells and natural killer (NK) cells, which are a type of nonspecific lymphocyte.

monocytes Mononuclear cells that can migrate into tissue (where they are called macrophages), induce inflammation, and phagocytose (i.e., engulf or eat) invaders.

neuroendocrine Relationships between the nervous and endocrine systems as well as cells that release hormones into the blood in response to a neural stimulus.

psychoneuroimmunology The study of interactions among the mind, the nervous system, and the immune system.

psychosocial Having to do with an individual's psychological or social state.

Psychoneuroimmunology (PNI) is the study of interactions among the mind, the nervous system, and the immune system. The mind, or psyche, involves thoughts, emotions, experiences, and ideas; the nervous system involves the brain, the spinal cord, and nerves throughout the body; and the immune system consists of organs and cells that defend the body against invaders. The mind and the immune system communicate through the peripheral nervous system, hormones, and cytokines. This communication allows the immune system to be responsive to psychosocial factors and allows the immune system to signal the brain (e.g., about infection). The field of PNI is interdisciplinary and

connects knowledge from endocrinology, immunology, psychology, neurology, and other areas. There is increasing interest in the applied aspects of PNI, specifically whether psychosocial interventions can affect diseases such as human immunodeficiency virus (HIV) and cancer.

1. ABOUT THE IMMUNE SYSTEM

The main function of the immune system is to protect the body from infections. When foreign substances or pathogens (e.g., bacteria, viruses, parasites, fungi) attack the body, the immune system detects and destroys these invaders. In addition, the immune system can repair and heal tissue damage from injury as well as destroy and eliminate otherwise normal cells that have been altered by infections or, in some cases, malignancies.

The immune system consists of white blood cells that develop in the bone marrow and the thymus; congregate in the spleen, the lymph nodes, the lungs, the gastrointestinal (GI) tract, and the skin; and circulate through the blood and lymph. These cells include granulocytes and macrophages, which act nonspecifically in processes such as inflammation. They also include lymphocytes, such as B, T, and natural killer (NK) cells, which act specifically on targeted invaders to kill infected cells (i.e., cytotoxicity) and produce proteins that attack invaders (i.e., antibodies). A critical element of the immune response is the production of molecules that amplify and direct the immune response (i.e., cytokines). Different cytokines promote inflammation, cytotoxicity, antibody production, or some combination thereof.

2. PATHWAYS BETWEEN THE BRAIN AND THE IMMUNE SYSTEM

Historically, the immune system was thought to be an independent system. However, during the 1960s and 1970s, evidence that the immune system could be influenced by psychological phenomena began to accumulate. In 1964, Solomon and Moos proposed that the development of rheumatoid arthritis was related to personality factors, advancing the possibility of psychoneuroimmunological phenomena. In 1975, Ader and Cohen demonstrated that conditioning could affect the immune response by pairing taste with an immunosuppressive drug. Animals that were

conditioned in this way showed evidence of immunosuppression when the taste was later presented alone. Evidence of anatomical pathways between the brain and the immune system began with the discovery of sympathetic nervous system innervation of immune organs and has accumulated rapidly to include numerous neurological, hormonal, and cytokine pathways.

2.1. Autonomic Nervous System

Bidirectional neurological pathways exist between the central nervous system (CNS) and the immune system. The most direct pathway from the CNS to the immune system is through the autonomic nervous system (ANS) as sympathetic nerve fibers innervate lymphoid organs such as the thymus, the bone marrow, and the spleen. The influence on the immune system depends on the specific cells and receptors involved and can be inhibitory or stimulatory. Recent evidence suggests that the immune system can also signal the brain through the ANS, specifically the subdiaphragmatic vagus nerve.

2.2. Endocrine System

The endocrine system consists of a variety of glands that secrete hormones. Hormones are chemical substances that are released into the bloodstream, stimulate receptors in target cells, and alter the behavior of those cells. Ample evidence exists that neuroendocrine substances influence immune cells. For example, immune cells react to many hormones, including cortisol, substance P, vasoactive intestinal peptide, prolactin, and growth hormone. Many of the cells involved in the immune response carry surface receptors for a number of hormones, allowing them to respond to signals from the brain as well as from other organ systems.

2.3. Immune-to-Brain Communication

Cytokines, particularly proinflammatory cytokines, can affect both neuroendocrine and brain function in an endocrine fashion. When an immune response occurs, cytokines signal a state of disease to the CNS. Proinflammatory cytokines raise body temperature (fever), and this retards the growth of some bacteria but does so at a cost: Fever increases the host's metabolic rate by 13% for each 1 degree Celsius. As a result, behavior changes to preserve metabolic resources for fighting the infection. "Sickness behavior," which

accompanies fever, includes feeling tired and weak, loss of interest in surroundings, loss of appetite, and loss of concentration. These behavioral changes are consistent with centrally mediated change in priorities away from activity and pursuit of goals to conservation of energy.

3. STRESS, HORMONES, AND IMMUNITY

The idea that stressor exposure might influence the immune response was an early topic of interest in psychoneuroimmunology (PNI), and evidence clearly indicates that psychological and physical stressor exposure can affect the immune system. Both the type of stress and the person involved may affect the influence of stress on the immune system. Stress can be physical or psychological, controllable or uncontrollable, and acute or chronic. Furthermore, different people may handle stressor exposure in different ways.

When a situation is perceived as threatening, the sympathetic nervous system responds by releasing epinephrine and norepinephrine. Consequences of this response include increased heart rate, increased blood pressure, and peripheral vasoconstriction. Stressor exposure also influences the endocrine response, changing levels of hormones such as cortisol, a steroid hormone produced by the hypothalamic–pituitary–adrenal (HPA) axis. These responses can, in turn, affect the immune system.

There are more than 300 studies that have linked stress and stressors to immune parameters. In a meta-analysis of these studies, both acute stressors (lasting minutes) and chronic stressors (lasting days to years) were reliably associated with changes in the immune system. The effects of stressors and stress hormones depend critically on characteristics of the stressor, particularly time course. In general, the changes associated with acute stressors could be adaptive as part of the “fight or flight” response; acute stressors (lasting minutes) are associated with large increases of non-specific defenders (e.g., neutrophils, NK cells) in the bloodstream, release of antibody into saliva, and increased production of cytokines that stimulate non-specific immunity. Mechanistic investigations have shown that many of these changes are due to sympathetic signaling through β_2 -adrenergic receptors on lymphocytes.

However, longer term stressors had less potentially beneficial effects. The shortest “chronic” stressors, such as academic examinations, were associated with decreases in the function of cytotoxic lymphocytes (e.g., NK cells, T cells), but antibody-producing functions were generally unchanged. Chronic stressors that were long-lasting, such as having a spouse with dementia, decreased both cytotoxic and antibody-producing functions of immune cells.

4. PSYCHOLOGICAL AND BEHAVIORAL INTERVENTIONS

PNI is mainly a basic science. However, the number of studies investigating the impact of psychosocial interventions on the immune system is increasing. In particular, the hypothesis and evidence that psychosocial stress can affect the immune system has generated the secondary hypothesis that psychosocial interventions to alleviate stress could have the opposite effect on the immune system. Such interventions commonly involve stress management, relaxation, and hypnosis. A recent meta-analysis found that there were few effects of interventions on the immune system but also that most stress management and relaxation interventions failed to enroll stressed participants. In those that did, there was some evidence that the interventions could alleviate stressor-related immune change.

4.1. Stress Management

In stress management interventions, participants are taught to recognize situations they experience as stressful and to identify the reactions they have in these situations. The participants are then trained to avoid unnecessary stressor exposure and to cope better with stressors. Stress management interventions have mostly been targeted to patients with chronic medical illnesses such as cancer and HIV. Such interventions usually include information and education about the illness, access to psychological support, help in changing cognition about the disease, and training to improve coping skills. Studies involving stress management interventions have yielded mixed results, but some such interventions have been found to reduce negative emotions and have been associated with positive changes in immune function, including increases in CD4+ T lymphocyte numbers, NK cell numbers, and NK cell activity.

4.2. Disclosure and Health

Some data indicate that undisclosed traumatic cognitions or emotions might lead to serious physiological consequences. In intervention studies on this topic, participants are asked to write or talk about stressful or traumatic situations that they have experienced. The cognitive processing and emotional expression during this activity are thought to lead to better regulation of physiological systems. Research in this area has found associations between disclosure and reduced negative affect, reduced activity in the sympathetic nervous system, and reduced health center visits. Immunological consequences have included better response to vaccination and better immune control of latent viruses.

4.3. Relaxation

A relaxed state can be induced in several ways, including progressive muscle relaxation, relaxation response, biofeedback, imagery, hypnosis, and meditation. In general, all of these forms of relaxation have been related to decreased negative mood, decreased hormone levels, and decreased activity in the sympathetic nervous system. However, the results of relaxation techniques are inconsistent with regard to immune responses. Relaxation exercises are associated with increased levels of antibody in saliva and may increase levels of CD4 helper T cells in the blood as well as NK cell activity.

4.4. Hypnosis

Hypnosis involves the induction of an altered state of consciousness, including focused attention and high suggestibility. In research studies, the application of hypnosis to influence the immune system is often through hypnotic suggestion to affect an allergic response. The participant first has an allergen injected under the skin. A hypnotic state is then induced, and the hypnotized participant is instructed to either enhance or suppress his or her response to the allergen. In most hypnosis interventions, the direction of effect is specified. Following such interventions, hypnosis has successfully suppressed, but not enhanced, the immune response. Studies have also shown that hypnotic suggestions can lead to changes in the ANS such as alterations in heart rate and blood pressure. In medical contexts, hypnosis has been used to manage chronic pain and to enhance adjustment to physical conditions and illnesses. There are great differences in people's susceptibility to hypnosis, and highly

hypnotizable individuals have the strongest immune changes.

5. PNI AND INTERVENTIONS FOR CHRONIC DISEASE

5.1. Interventions in HIV

The clinical course of HIV infection varies greatly, and although some people can live with HIV infection for years without developing acquired immune deficiency syndrome (AIDS), others progress more quickly after being infected. A number of factors, such as viral strain, genetic immune factors, presence of other infections, nutrition, and drug abuse, are thought to influence progression. In addition, a host of psychosocial stressors related to the diagnosis and stigma of the illness may contribute to differences. A person infected with HIV may face social, medical, legal, professional, and mental problems on diagnosis, and coping with these stressors may make a difference in how the illness progresses.

HIV infection develops into AIDS when the immune system is too weak to fight infections. HIV infection has been associated with physical and psychological stressor exposure and distress, and because stressor exposure and distress have been associated with suppression of immune functions, the progression of HIV infection may be influenced by interventions that can affect responses to stress. In intervention studies, HIV-infected patients in cognitive-behavioral stress management programs had decreased distress levels and higher NK cell and CD4+ levels than did HIV-infected controls. HIV-infected patients in cognitive-behavioral stress management programs also had decreases in depression and anxiety, and both cognitive-behavioral training and relaxation training appear to have positive impact on immune function among patients. However, findings from other studies have yielded contradictory results, and although relationships among behavior, psychosocial stressors, immune status, and HIV progression apparently exist, these relationships are not completely understood.

5.2. Interventions in Cancer

PNI may have implications for cancer. One possibility is that psychosocial factors influence the onset and especially the advancement of cancer through psychological impact on the immune system. This is the most

traditional view, and psychological influences on the immune system are often assumed to be the connection between psychosocial factors and cancer. However, controversy surrounds this topic because few studies have been able to detect clear associations between psychological effects on the immune function and cancer outcomes. Some of this confusion may arise from the heterogeneity among various types of cancer that have different molecular mechanisms and different immunological vulnerabilities.

PNI may also be of importance to oncology in that psychological influences on the immune system may affect the risk of infectious disease. Infectious disease is a major source of concern in oncology because the immune suppression often seen in patients due to cancer treatments and psychological distress may render patients' immune systems incapable of fighting off intruding viruses and bacteria, leaving patients more susceptible to infectious disease. However, there is not yet much research in this area.

Associations have been found between support group interventions and longevity in people with cancer. However, other studies have found no association. Some interventions have demonstrated an immune benefit for people with cancer. In cognitive-behavioral stress management interventions, breast cancer and malignant melanoma patients received health education, stress management training, problem-solving skills training, and social support. Participants had decreased depression and anxiety as well as increased immune parameters. However, such effects remain to be replicated, and the consequences of these changes for patient health remain unclear.

6. CONCLUSION

Clear connections exist between the nervous and neuroendocrine systems and the immune system, and compelling evidence points to the influence of psychosocial factors on immune function as well as vice versa. Interventions to reduce potentially deleterious effects of stress and depression on the immune system are in their infancy, but there are encouraging examples of how applied PNI may contribute to better immune function and, potentially, to better health.

GLOSSARY

- cardiovascular activity** Functional activity of the heart and vessels controlled by the autonomic nervous system.
- electrodermal activity** Electrical activity of the skin due to activation of the sweat glands by the sympathetic nervous system.
- electromyography** Electrical activity of the striated muscle controlled by the somatosensory nervous system.
- event-related potential** Specific change in the electroencephalogram (EEG) due to the presentation of a stimulus or in anticipation of a response; it is recorded after averaging the EEG signals produced by a number of repeated events.
- functional magnetic resonance imaging** Neuroimaging technique based on the magnetic properties of the spinning protons; the greater the magnetic signal in a brain area, the greater the blood flow and neural activity in that area.
- neuropsychological disorder** Psychological disorder due to brain lesion.
- psychopathological disorder** Psychological disorder not due to brain lesion or other organic disorder.
- psychophysiological disorder** Physiological disorder due to psychological factors.

psychophysiology The scientific study of psychological processes through noninvasive recording of physiological responses.

Psychophysiology is the scientific discipline devoted to the study of the relationships between the physiological and psychological aspects of behavior. Although such relationships have been studied from different perspectives, the psychophysiological perspective emphasizes the use of noninvasive physiological measures—both peripheral and central—to assess the psychological processes underlying human behavior.

1. INTRODUCTION

The scientific study of human behavior becomes enriched when it is done in close relationship with the biological body that sustains behavior. To study the activity of the organisms from this perspective means to examine what people do, think, and feel while simultaneously taking into account the physiological and psychological mechanisms that control human behavior.

The relationships between physiology and psychology have preoccupied philosophers and scientists throughout history. The different debates about the soul–body, spirit–matter, and mind–brain relationships all are variations on a single theme: the connection between the behavior—people’s acts, thoughts, and feelings—and its sustaining biological body.

2. HISTORICAL ANTECEDENTS

Nearly all physiological recording methods are based on the bioelectrical nature of the living tissue activity. Since the discovery of electricity by the end of the 18th century and throughout the electronic and computer revolution of the 20th century, it is not surprising that the history of the psychophysiological approach to assessment evolved in parallel with technological evolution.

The first psychophysiological instruments were based on the galvanometer, that is, a moving coil suspended in the magnetic field of a permanent magnet that rotates when an electric current flows through the coil. A galvanometer-type device used with a writing system mounted on the moving coil is the basis of the traditional polygraphs.

The electronic and computer revolution during the 20th century influenced psychophysiological instruments in three basic aspects: (a) increased precision and reduced size and weight of the amplifiers; (b) improvements in the traditional recording systems using digital computers to represent, store, and analyze the psychophysiological signals, and (c) allowing the discovery of new psychophysiological variables only available after complex computerized systems have been used to detect and extract the biological signals.

Psychophysiological equipment must take into account the physiological recording and the psychological manipulation. Figure 1 illustrates the basic elements of current equipment. On the left, the

FIGURE 1 Diagram representing the basic elements of a psychophysiological laboratory: (a) the physiological recording system; (b) the connection box; (c) the analog-to-digital and digital-to-analog card; (d) the computer central processing unit where the card is inserted; (e) the computer monitor where the physiological recording is being displayed; and (f) the slide projector, controlled by the computer, to present the psychological stimuli.

participant has the sensors placed on the surface of the body while the psychological task is being performed. On the right, in the experimenter's room, are the physiological recording system, the connection box, the analog-to-digital and digital-to-analog card, the computer central processing unit where the card is inserted, the computer monitor where the physiological recording is being displayed, and the slide projector, controlled by the computer, to present the psychological stimuli.

3. PERIPHERAL PSYCHOPHYSIOLOGICAL MEASURES

Psychophysiological techniques are classified into peripheral and central techniques. Peripheral techniques include those variables directly controlled by the somatosensory nervous system and the autonomic nervous system (e.g., surface electromyography, eye movements, respiration, cardiovascular activity, electrodermal activity). Central techniques include those variables directly controlled by the central nervous system (e.g., event-related potentials [ERPs], functional magnetic resonance imaging [fMRI], positron emission tomography [PET]). Table I summarizes the various psychophysiological techniques following this classification. This section describes one psychophysiological technique belonging to the peripheral somatosensory system (surface electromyography) and two techniques belonging to the peripheral autonomic nervous system (cardiovascular activity and electrodermal activity).

3.1. Surface Electromyography

The biological basis of electromyography is the electrical activity of the striated muscle, that is, that type of muscle responsible for motor activity and made up of a large number of parallel fibers. Such activity is triggered by the activation of the motoneuron that innervates the fiber. This functional physiological entity, made up of a single motoneuron and the individual muscle fibers innervated by the motoneuron, is called the motor unit. Recording of the electrical activity of the striated muscles from the surface of the skin is referred to as surface electromyography (EMG). This EMG signal represents the ensemble of action potentials produced by the muscle at a given moment. The

TABLE I
Classification of Psychophysiological Techniques

<i>Neurophysiological mechanism</i>	<i>Psychophysiological techniques</i>
Somatic nervous system	Surface electromyography Direct electromyography Integrated electromyography Eye movements Respiration
Autonomic nervous system	Cardiovascular activity Electrocardiogram Impedance cardiography Photoplethysmography Blood pressure recording Electrodermal activity Pupillary activity Gastrointestinal activity Others
Central nervous system	Electromagnetic techniques Electroencephalogram Event-related potentials Brain electrical activity mapping Magnetoencephalography Metabolic techniques Positron emission tomography Functional magnetic resonance imaging

aggregate signal is characterized by a frequency range between 20 and 1000 hertz and an amplitude range between 2 and 2000 microvolts, displaying a direct relationship between frequency and amplitude; the greater the frequency, the greater the amplitude. In psychophysiological assessment, it is common to transform the direct surface EMG into integrated EMG. The integration procedure implies, first, rectification of the signal (i.e., elimination of the negative mirror part of the signal) and, second, smoothing of the remaining signal by a low-pass filter. This produces a contour following integration, that is, a varying voltage proportional to the envelope of the direct EMG signal.

3.2. Cardiovascular Activity

The cardiovascular system consists of the heart and a network of vessels for distribution, exchange, and return of the blood throughout the body. The

cardiovascular system reacts quickly to physical and psychological demands, with such activity being controlled by neural and humoral pathways. The neural pathway to the heart involves the two branches of the autonomic nervous system: the sympathetic and parasympathetic branches. When the sympathetic nerves are activated, the heart rate accelerates and heart contractions become stronger. When the parasympathetic nerves are activated, the heart decelerates. The neural pathway to the vessels involve mainly the sympathetic nerves, and its activation produces either vasoconstriction (in skin and viscera) or vasodilation (in motor muscles). The humoral pathway involves the neural sympathetic activation of the endocrine system, resulting in the secretion by the adrenal glands of various hormones into the bloodstream (e.g., adrenaline, cortisol). The impact of psychological processes on cardiovascular activity is assessed through noninvasive measurements of the various components of cardiovascular activity; heart rate (the number of ventricular contractions per minute), blood pressure (the force of the circulating blood in the arteries, and blood flow (the amount of circulating blood in a particular area). In psychophysiological studies, heart rate is the main index to assess cardiac function. Heart rate is measured in terms of beat-by-beat heart rate values derived from the electrocardiogram (R-R interval).

3.3. Electrodermal Activity

Known since the end of 19th century, electrodermal activity is one of the peripheral measures most frequently used in psychophysiological assessment, with its biological basis being the activity of the eccrine sweat glands. Sweat glands are distributed along the surface of the body with a greater density in the inner parts of the hands and feet. The activities of the glands are controlled by the sympathetic branch of the autonomic nervous system, and when the glands are activated, there is a hydration of the skin accompanied by an electrical signal. The electrical signal can be detected on the surface (called skin potential), and there is an increase in conductivity to the passage of an external current (called skin conductance). This activity responds to thermal and psychological stimuli. The psychological significance of the electrodermal activity is predominant when the temperature is below 25 degrees Celsius. The recording of electrodermal activity can be done using two general procedures. First, the endogenous procedure records the electrical potential produced in the skin without passing any external

current. Second, the exogenous procedure records the change in conductivity to the passage of an external current. Depending on the type of external current (DC or AC) and whether the current maintains a constant voltage or constant intensity, the recording procedure is called skin conductance (DC and constant voltage), skin resistance (DC and constant intensity), skin admittance (AC and constant voltage), or skin impedance (AC and constant intensity).

4. CENTRAL PSYCHOPHYSIOLOGICAL MEASURES

The techniques to measure central nervous system activity are classified into two categories: electromagnetic and metabolic techniques. The electromagnetic techniques are based on the electrical activity of the brain tissue, that is, the neurons' action potentials. The metabolic techniques are based on the differential distribution of blood elements (mainly oxygen and hydrogen) in the brain.

4.1. Electromagnetic Techniques

Electroencephalography (EEG) was the first electromagnetic technique developed. Like all psychophysiological techniques, it requires careful attention to electrode location, choice of electrode reference, grounding, proper filtering and artifact control. A good EEG recording is characterized by changes in voltage as a function of time with two inversely related parameters: frequency and amplitude. The lowest frequency band (0–4 hertz, called the delta range) has the greatest amplitude (20–200 microvolts), and the highest frequency band (36–44 hertz, called the gamma range) has the lowest amplitude (2–20 microvolts). The intermediate frequency bands, called the theta (5–7 hertz), alpha (8–12 hertz), and beta (13–30 hertz) ranges, have a progressively decreasing amplitude. An important technological development based on the EEG occurred during the 1960s with the advent of digital computers. Digital computers allowed the event-related brain activity to be extracted from the background EEG by applying the averaging procedure, that is, repeating a particular event and averaging the digital samples of the EEG that are time-locked to that event. The resulting signal, the ERP, contains a number of positive and negative peaks identified by the letters P and N, respectively, each with a numeric

subscript (1/2/3/4 or 100/200/300/400) indicating the order or time in milliseconds of the peak, respectively. Examples of ERPs include the N₁₀₀, P₃₀₀, and N₄₀₀. Once extracted, ERPs are interpreted as manifestations of the specific psychological processes activated by the event.

4.2. Metabolic Techniques

The metabolic techniques are similar to traditional radiological techniques (e.g., X ray, computerized tomography). The neuroimage is elaborated from the recording of radiological signals emitted by moving blood particles in the brain (oxygen and hydrogen) necessary for neuronal activity. The first metabolic neuroimaging techniques developed were the radiotracer techniques. PET is one of them. The radiotracer commonly used in PET is a pharmacological compound labeled with a positron-emitting radioisotope (O_{15}) of short life (approximately 4–10 minutes). Once administered to the participant either intravenously or by inhalation, the radiotracer is distributed through the blood to all parts of the body, including the brain. The number of emitted positrons detected from outside the head reflects the amount of oxygen demand in the various brain areas.

The most promising metabolic technique, as an alternative to radiotracers, is fMRI. The physical foundations of fMRI are the magnetic properties of the spinning protons within the nucleus of certain atoms. These subatomic particles behave like small magnetic needles. When the body is placed within the magnetic field of a potent external magnet, all hydrogen and oxygen protons line up along the axis of the external magnet. The orientated spinning protons rotate, or precess, about the axis of the external magnetic field with a rotating frequency that is within the range of radio frequency waves. Using a transmit–receive coil, the MRI technique then applies a momentary external radio frequency wave perpendicular to the magnet axis and identical to the precessional frequency of the spinning protons to produce the resonance phenomenon, that is, a momentary electromagnetic signal detected by the receive coil and used to create the image.

5. THE PSYCHOLOGICAL CONTEXT

The physiological recording becomes psychophysiological only when the environmental context and the activity of the participant during the recording are well controlled. The task of the participant during the

recording is the critical aspect providing psychological meaning to the physiology. Control of the context implies paying attention to three items: the place, the participant, and the task.

5.1. The Place

The place refers to the physical and social environment of the recording. There are numerous physical and social environmental variables that may affect the physiological recording. The main physical variables are noise, light, temperature, and humidity. The main social variables are the presence of people during the recording (including the experimenter). To control these variables, specific rooms in which such variables could be eliminated or maintained constant should be used. The optimal place is the psychophysiological laboratory, with a participant's room independent of the experimenter's room (Fig. 1).

5.2. The Participant

The participant always introduces a set of variables that affect the physiological recording. Some of these variables are characteristics of the participant such as age, gender, menstrual cycle (in women), whether or not the participant smokes, and whether or not the participant has any physical disease or psychological condition. Other variables affect the participant indirectly such as physical activity done just before the recording, hour of the day, and food, medication, or drinks taken before the recording. All of these variables should be included within the information protocol obtained at the beginning of the assessment session. When possible, they should be controlled either by exclusion of participants with characteristics that saliently affect the recording or by elimination or matching of the conditions affecting the recording.

5.3. The Task

The tasks that should be used depend on the aim of the assessment. Each research area of psychology has developed its own assessment paradigms and tasks. Therefore, assessment must be linked to the theoretical contexts in which the different tasks have been developed. Tasks developed to assess attention are different from tasks developed to assess emotion, memory, language, thinking, motor control, or learning. However, all psychophysiological tasks share a common structure: a period of recording with no stimulation (resting period)

used to stabilize the physiological measures and a period of recording with stimulation (the specific task).

6. ASSESSMENT OF BASIC PSYCHOLOGICAL PROCESSES

Interest in psychophysiological assessment has existed since the early years of scientific psychology. Examples of psychophysiological applications for the study of basic processes can be found in the work of James (emotion), Pavlov (learning), and Cannon (motivation). This section presents some examples of current basic applications.

6.1. Electromyography

Electromyography has been used to study arousal, facial expressions, somatic correlates of thought and mental imagery, motor reflexes, motor skill learning, and so forth. An example of current application of EMG to the assessment of emotional and attentional processes is the startle probe paradigm. In humans, the first and most reliable component of startle is eyeblink. Eyeblink is measured using integrated EMG of the orbicularis oculi (i.e., the muscle around the eye). Startle is typically elicited by a brief sudden noise. Emotional modulation of startle is observed when the reflex is elicited while the participant views affective pictures presented for 6 seconds. Compared with neutral pictures, unpleasant pictures increase the reflex and pleasant pictures inhibit it. Attentional modulation of startle is observed when another stimulus precedes the eliciting stimulus by less than 500 milliseconds. Under these conditions, the reflex is inhibited (i.e., prepulse inhibition) independently of the affective content. Normal and pathological emotional and attentional processes can be assessed using this paradigm.

6.2. Heart Rate

Cardiovascular activity has been used in numerous research contexts, including unconditioned reflexes (i.e., orienting and defense), habituation, sensitization, Pavlovian conditioning, instrumental learning, motivation, emotion, memory, and mental workload. Heart rate has been the cardiovascular measure most frequently used in these contexts.

The psychological meaning of heart rate has been a subject of debate in the past. Two major interpretations

can be identified: the cognitive and motivational interpretations. The cognitive interpretation assumes that cardiac changes in response to external or internal stimuli reflect attentional and perceptual mechanisms aimed at facilitating (heart rate deceleration) or inhibiting (heart rate acceleration) sensory processing. On the other hand, the motivational interpretation assumes that cardiac changes reflect metabolic mechanisms aimed at providing energy to adaptive behaviors. If the appropriate behavior is to be passive, the cardiac response will be a heart rate deceleration. If the appropriate behavior is to be active either physically or psychologically, the cardiac response will be a heart rate acceleration.

6.3. Skin Conductance

Skin conductance is one of the most sensitive measures of mental activity. It has been used extensively to study attention, habituation, and conditioning. A skin conductance response to stimuli of moderate or low intensity is interpreted as an attentional response indicative that a novel stimulus has been detected and processed. Habituation of the response (when the same stimulus is repeated) and dishabituation (when the repeated stimulus changes in some parameter) is also indicative that the system is correctly processing the environmental information. In the context of conditioning studies, the skin conductance response is interpreted as indicative that a neutral stimulus has acquired the signal value of the unconditioned stimulus, allowing assessment of the degree of learning or unlearning.

Skin conductance has also proved to be sensitive to unconscious presentation of threat stimuli. Using masked stimuli (visual pictures presented for 30 milliseconds followed by a mask), Öhman and colleagues showed that fear-relevant stimuli (pictures of snakes, spiders, and fear–angry faces), as compared with irrelevant stimuli (pictures of flowers, mushrooms, and neutral–happy faces), can be processed without awareness.

6.4. Central Electromagnetic Measures

Among the central electromagnetic measures, the ERPs are the most frequently used to assess cognitive functions. The N_{100} , P_{300} , N_{400} , and mismatch negativity all are ERPs that are studied extensively in relation to attentional and linguistic processing. Each ERP

requires, in addition to the EEG recording, the use of specific tasks.

One of the tasks to obtain the N_{100} and the P_{300} is the oddball task. It consists of a large series of presentations of two stimuli with different degrees of probability, for example, a tone of 1000 hertz presented 160 times (80% probability) and a tone of 1500 hertz presented 40 times (20% probability) in random order. The task of the participant is to pay attention only to the tone with lower probability. Under these conditions, the N_{100} reflects the nonspecific attention paid to both stimuli, whereas the P_{300} reflects the specific attention paid only to the low-probability stimulus.

6.5. Central Metabolic Measures

PET and fMRI are the latest techniques used in psychophysiological assessment. Identification of the brain areas involved in the psychological functions activated by the task requires application of the subtraction method. It consists of obtaining images at different stages of the task. For example, in a semantic processing task in which a participant is asked to think of the meaning of a word, the task is divided into several stages: to hear the word, to hear the word and repeat it, and to hear the word and generate a verb representing a use of the word (e.g., hammer: to hit). By subtracting the images from the different stages, the specific brain areas involved in the act of thinking can be identified.

7. CLINICAL APPLICATIONS

Psychophysiological assessment has been used in many applied areas, including ergonomics, sport, lie detection, and clinical psychology. This section presents some examples of applications within clinical psychology.

7.1. Psychopathological Disorders

Psychopathological disorders are characterized by symptoms of psychological dysfunction with no diagnosable brain lesion or physical disease. Psychophysiological assessment of psychopathology has focused on identification of psychophysiological markers, that is, deviation in one physiological variable that is reliably associated with a specific disorder. For example, research on schizophrenia has suggested several markers, including reduced P_{300} , reduced skin conductance orienting response, reduced prepulse

inhibition of startle, and abnormal eye movements. Similar suggestions have been made in relation to other disorders such as psychopathy, depression, and anxiety, although more research is needed before useful clinical protocols can be developed for these disorders.

7.2. Psychophysiological Disorders

Psychophysiological disorders are characterized by symptoms of physiological dysfunction in specific organs such as the heart, lungs, stomach, muscles, and neural tissues. Such dysfunction is caused or aggravated by psychological factors such as emotions, stress, personality, and lifestyle.

Therefore, psychophysiological assessment is a key procedure for reliable diagnosis of these disorders. Psychophysiological disorders in which an etiological role played by psychological factors has been demonstrated include cardiovascular disorders (e.g., essential hypertension, cardiac arrhythmias, migraine), respiratory disorders (e.g., asthma, hyperventilation), gastrointestinal disorders (e.g., ulcer, irritable colon, colitis, chronic constipation), neuromuscular disorders (e.g., tics, tremblers, tension headache), dermatological disorders (e.g., eczema, acne, psoriasis), sexual disorders (e.g., dysfunction of sexual desire, excitation, and orgasm), and neurological disorders (e.g., sleep disturbances, epilepsy).

7.3. Neuropsychological Disorders

Neuropsychological disorders are characterized by symptoms of psychological dysfunction caused by a diagnosable brain lesion. The psychological dysfunction is usually a cognitive one such as altered perception (agnosias), memory (amnesias), language (aphasias), or motor coordination (apraxias). The neural lesion is usually a stroke, a traumatic brain lesion, a tumor, or a degenerative neural disease.

Although neuropsychological assessment does not normally use psychophysiological methods, recent attempts to combine both methods are promising. For example, ERPs are being used to assess cognitive deficits in Alzheimer's disease, epilepsy, alcoholism, and mental retardation. Similar applications of functional

neuroimaging techniques are helping to better understand the specific brain dysfunctions produced by different lesions.

GLOSSARY

cohort based A focus on generational groups rather than age groups; examples include the World War II generation, the baby-boomer generation, and Generation X.

contextual The idea that changes in therapy often relate to the social–environmental context within which older adults reside rather than their developmental stage; this is especially apparent in settings such as hospitals and nursing homes.

contextual, cohort-based, maturity, specific challenge (CCMSC) model Model that proposes that older adults are more mature than younger adults in certain important ways and yet are concurrently facing some of life's most difficult challenges; the model also asserts that the current social context and past sociocultural circumstances experienced as members of earlier born cohorts must be considered when conceptualizing psychotherapy with older adults.

loss–deficit model A negative conceptual model of aging that portrays late life development as the accumulation of deficits and a series of losses as the normative experience of older adults; the result is characterized by negative mental health outcomes.

maturity The developmental maturation that occurs during normal aging; although this maturation includes changes such as cognitive slowing and use of simpler language, it also includes greater emotional complexity and a greater source of expertise from which to draw.

specific challenges The idea that the high prevalence of chronic medical problems and neurological disorders among older adults will result in the frequent presentation of these problems in assessment and therapy; grief for deceased loved ones and caregiving for other older adults (e.g., spouses, parents) are also specific challenges faced by older clients.

This article integrates discussion of psychotherapy with current research and clinical observations in the field of gerontology. It briefly summarizes past and current research on aging in several areas of practical interest to psychotherapists seeking to apply various psychotherapy treatment techniques in working with older adult clients. The framework for this discussion is the contextual, cohort-based, maturity, specific challenge (CCMSC) model, which grew from the application of gerontology to the practice of psychotherapy with older adults. This model is intended to be nonspecific with regard to system and modality of therapy and, thus, affords a wide utility. The article discusses common presenting problems, issues of assessment and diagnosis, and prevalence rates relevant to psychotherapy with older adults. It reviews the literature concerning effective psychotherapeutic interventions across systems and

modalities in an effort to report the state of the art. It also addresses issues of diversity and the importance of cultural competence among psychotherapists who treat older adults.

1. PRESENTING PROBLEMS

Older adults seeking therapy often are dealing with problems that would threaten psychological well-being at any age in the life span. These problems include dealing with chronic illness and disability, grieving the loss of loved ones, and caregiving for loved ones with cognitive or physical disability. Although these problems are not unique to later life, they are more likely during this period. Additional problems seen earlier in the life span, such as interpersonal relationship difficulties and personal failures, appear later in the life span as well. Finally, many people who have struggled with depression and anxiety in earlier life continue to struggle with these problems in later life.

Working with distressed older adults often means working with those who are struggling to adjust to the problems associated with being chronically ill or physically disabled. Thus, therapists must acquaint themselves with chronic illnesses and their psychological impact, pain control, adherence to medical treatment, strategies of rehabilitation, and assessment of behavioral signs of medication reactions. The increased presence of chronic illness and disability with each decade of life makes it necessary for therapists working with older adults to develop the ability to discuss physical problems and to discuss when a problem may have physical causes.

Similarly, working with older adults often involves grief work. Although the death of loved ones can be experienced at any point in the life span, this experience is more common in later life. Older adults presenting with depression often have experienced the death of loved ones during recent months or years. In addition, many older adults do not experience the death of loved ones as normal or expected. This is the case even when their loved ones have been ill for some time. These losses are still experienced as surprising and tragic, and they may be experienced more deeply due to the length of their relationships. As a result, psychotherapy with older adults may often require grief work.

Finally, older adults often find themselves in the role of caregivers for physically or cognitively impaired spouses or parents. The course of these physical and

cognitive disorders is frequently progressive and debilitating. As such, older adult caregivers are forced to adapt to increasingly difficult caregiving tasks and, consequently, may begin to appraise caregiving as a burden. Thus, therapists working with older adult caregivers must be prepared to treat the stress resulting from this burden.

2. ASSESSMENT, DIAGNOSIS, AND PREVALENCE

Prevalence studies of depression in older adults who are chronically ill or physically disabled have reported rates up to 59%. Further examination of the relationship between depression and physical illness finds that the disability often accompanying physical illness, rather than the illness itself, is a risk factor for depression in older adults. Conversely, depression can be seen as a serious physical and psychological health problem because it has been found to be associated with increases in disability, poorer rehabilitation from physical health problems, and greater risk of mortality. Physicians frequently do not detect symptoms of depression in their older adult clients, and symptoms of depression in older adults often go untreated. This problem is exacerbated by the fact that older adults often present symptoms of depression to their primary care physicians rather than attempting to seek out mental health professionals.

Depression can also be a problem for older adults suffering from Alzheimer's disease or other forms of dementia. Thus, the issue of screening clients with depression for dementia is an important one when working with older adults. Conversely, because depression and dementia may present similar symptoms, clients suspected of having dementia should be screened for depression. In addition, clinicians should be aware of possible cognitive impairment and should include a brief screening instrument, such as the Folstein Mini-Mental State Exam, as a matter of routine when assessing older adult clients. Signs of cognitive impairment on initial screening indicate the need for more extensive cognitive assessment and may necessitate adjustment of treatment goals and intervention style.

Although depression is prevalent in older adults who experience chronic illness with disability, overall research contradicts the stereotype of the older adult as frequently depressed. In reality, depression is less

prevalent in older adults than in younger adults. However, it is important to note that although prevalence of major depressive disorder appears to be low among older adults, studies of self-reported depressive symptoms show increases among older adults. As such, care should be taken to assess both clinical and subclinical depression in older adults. Similarly, multiple symptoms of anxiety may exist among older adults even in cases where a constellation of symptoms meeting diagnostic criteria for anxiety disorders is not present. Regarding older adults who do indeed meet diagnostic criteria, the combined prevalence of all anxiety disorders in adults over 65 years of age is approximately 5.5%.

Although prevalence rates of alcoholism for older adults are lower than those for younger adults, there remain many serious concerns involving alcohol and older adults. In addition to the myriad of psychosocial ramifications of alcohol addiction, other problems include increased risk of falling, potential liver damage, adverse medication interactions, and decreased cognitive functioning. Although some older adult alcoholics have been addicted since younger adulthood, others develop problems with alcohol in older adulthood in response to inadequate social support, depression, and loneliness. This occurs at higher rates for older adults than for younger adults.

Finally, insomnia should be noted as a common problem among older adults. Studies have found that 10 to 25% of adults over 65 years of age report experiencing chronic sleep difficulties. Sleep disturbances may influence daily functioning and, thus, should be included as part of standard assessment practice with older adults.

3. INTERVENTIONS

3.1. Cognitive–Behavioral Therapy

Empirical evidence regarding the effectiveness of psychological interventions with older adults has been collected over the past two to three decades. In a 1994 meta-analysis by Scogin and McElreath of mainly cognitive–behavioral psychological interventions in the treatment of depression in older adults, an aggregate effect size was shown to be roughly equal to that found in another 1994 meta-analysis by Schneider for the efficacy of antidepressant medications.

The factors affecting outcomes with older adults were explored in a 2001 meta-analysis by Pinquart and

Sörensen. These include psychotherapy as superior to psychosocial interventions, more than nine sessions of therapy, and specialized training of the therapist. Older adults with clinical depression improved more than those considered to be at risk for depression. It was found that individually based interventions for both depression and caregiver distress were generally more efficacious than group-based interventions. A 2003 study by Wetherell and colleagues of treatment of generalized anxiety disorder found that brief cognitive–behavioral therapy (CBT) had large beneficial effects, and a discussion group treatment had medium beneficial effects, among older adults with generalized anxiety disorder. These results support the effectiveness with older adults of professional therapy by well-trained providers.

In an effort to establish a set of standards for evaluation of therapy effectiveness, the American Psychological Association's Division 12 has developed guidelines to identify empirically supported treatments for specific psychological problems. In 1998, Gatz and colleagues used the then current guidelines in their evaluation of the literature on psychological treatments with older adults. They reported that efficacious treatments for older adults included CBT for sleep disorders and cognitive and behavioral treatments for clinical depression. Gatz and colleagues also found strong support for the effectiveness of behavioral interventions and environmental modifications for persons with dementia.

With regard to subclinical problems in later life, Gatz and colleagues also found that CBT had above-average effects on self-ratings of subjective well-being. In support of these findings, Pinquart and Sörensen's meta-analysis of psychotherapeutic interventions with older adults found that CBT had above-average effects on depression and other self-ratings of subjective well-being. In addition, Gatz and colleagues reported that for nonsyndromal problems of aging, cognitive training is often efficacious in slowing cognitive decline. Therefore, there is considerable evidence for the effectiveness of CBT with older adults.

3.2. Other Individual Therapies

The use of a short-term manualized form of psychodynamic psychotherapy (PDP) has also been studied among older adults. In a 1982 study comparing CBT with PDP among depressed older adults, Gallagher and Thompson found that PDP and CBT were equally effective at posttest. However, this effect did not hold up

for PDP at follow-up. Findings from Schneider's study support the use of a PDP variation, interpersonal counseling (IPC), with older adults. Gatz and colleagues' review of empirically validated treatments examined several studies that included brief psychodynamic therapy as a treatment condition for depression among older adults and found it to be equally as efficacious as CBT. As such, brief psychodynamic therapy can be considered an often efficacious treatment for depression in late life. In addition, Gatz and colleagues concluded that the technique of structured life review or reminiscence is often efficacious for treating depressive symptoms among older adults. However, it is noted that several studies suggest that when life review is compared with other methods of treatment, the alternative methods are more efficacious.

3.3. Family and Caregiving Interventions

Some of the most salient issues in psychotherapy with older adults appear within the family context. Older adults often depend on family members for both emotional and instrumental support. In the event that these family relationships become strained, disruption of support can ensue, resulting in distress for older adults. Exploration of older adults' family histories and interpersonal relationships can often inform the therapeutic process in such cases. In 2000, Qualls argued that although few empirical studies examining the efficacy of family therapy for older adults have been conducted, a solid rationale for its use with this population exists. Prominent in this rationale is the assertion that the lives of many older adults are essentially embedded within the functional context of family. Similarly, the contextual, cohort-based, maturity, specific challenge (CCMSC) model can be applied to the adaptation of family therapy for older adults. This adaptation includes the examination of specific challenges facing older relatives and the family system, the integration of cross-cohort views when working across a multiple-generation family structure, and the influence of age-related social context on older adult family members.

Sørensen and colleagues' meta-analysis of interventions with caregivers of older adult family members with physical or dementing illnesses found that these interventions were generally effective in reducing burden and depression, increasing subjective well-being, and increasing caregiver mastery. It is important to

note that although these results were significant, the effect sizes were, on average, small to moderate. These appear to be lower than the previously mentioned effect sizes for the treatment of depression among older adults. In that study, psychoeducational and psychotherapeutic interventions consistently produced short-term effects on outcomes. The majority of these effects remained intact after an average of 7 months postintervention. It was also found that intervention effects were smaller for dementia caregivers than for caregivers of family members with other illnesses.

4. DIVERSITY

4.1. Ethnicity

The CCMSC model asserts that the majority of diversity issues in psychotherapy with older adults can be considered as cohort and contextual differences among clients. These differences are apparent when ethnicity, gender, and sexual identity are considered. Cohort differences are particularly salient in relation to ethnicity. Ethnic minorities belonging to earlier born cohorts have had to contend with especially difficult experiences of racism and economic hardship. In addition, social context may vary by ethnicity. In some ethnic groups, the use of large intergenerational family structures and an increased emphasis on familism is prominent. It is important for clinicians to become sensitive to potential ethnicity-related contextual or cohort differences. Some of these differences may include verbal and nonverbal behavior and communication styles that differ according to the level of acculturation. Thus, rather than making assumptions about clients, it is incumbent on clinicians to respectfully encourage clients to openly define for themselves the salience of their ethnicity to their issues in therapy.

4.2. Gender

In addition to contextual and cohort differences related to ethnicity, gender-related differences should be considered. The majority of older adults are women, and women tend to be overrepresented among therapy clients. Earlier born cohorts of women have seen the metamorphosis of women's roles in society over time, yet many may find that their personal experiences differ from those of later born cohorts. Many of these women may approach therapy with perceptions that are unique to their cohorts. In addition, because many

women find themselves surviving their husbands in later life, they may suddenly be faced with role transitions that are presenting themselves for the first time. Therefore, clinicians must be sensitive to the unique challenges faced by women in later life.

4.3. Sexual Identity

Finally, differences related to sexual minority status should be considered. Cohort differences among lesbian, gay, bisexual, and transgender (LGBT) older adults reveal differences between earlier born cohorts coming of age prior to the 1969 Stonewall riots (and the gay rights movement that followed) and those cohorts whose members matured later. However, some of these LGBT older adults may have been involved in earlier smaller movements that supported rights for sexual minorities. Thus, although many of these earlier born cohorts may have experienced a large portion of their lives under the weight of secrecy and shame, others may have experienced a more publicly expressed identity. Nevertheless, a range of LGBT older adults have endured the tremendous stress of both personally and socially experienced stigmatization. As with ethnicity, it is important for clinicians to refrain from developing assumptions regarding LGBT older adult clients. Instead, clinicians should allow these clients to define for themselves the salience of their sexual minority status to issues in therapy.

5. CONCLUSIONS

The CCMSC model proposes that older adults are more mature than younger adults in certain important ways and yet are concurrently facing some of life's most difficult challenges, including adjusting to chronic illness and disability in addition to frequently grieving the loss of others. The model also asserts that the current social context and past sociocultural circumstances experienced as members of earlier born cohorts must be considered when conceptualizing psychotherapy with older adults. Older adults seeking therapy often are dealing with problems that include coping with chronic illness and disability, grieving the loss of loved ones, and caregiving for loved ones with cognitive or physical disability. Although these problems are not unique to later life, they are more frequent during this period. Prevalence studies indicate the presence of depression and anxiety disorders among older adults, albeit at lower rates than those among younger adults.

Nevertheless, it is important to note that although rates of clinical depression decline in later life, rates of self-reported symptoms of depression increase. Thus, clinicians should attend to the possible presence of subclinical depression among older adults. In addition, issues of alcoholism and sleep disorders appear during older adulthood.

Research on empirically validated treatments has shown that efficacious interventions among older adults include (a) CBT, IPT, brief psychodynamic therapy, and life review for depression; (b) CBT for increases in subjective well-being; (c) CBT for sleep disorders; (d) cognitive treatment to slow nonsyndromal cognitive decline; and (e) psychoeducational and psychotherapeutic interventions for caregiver distress.

Finally, in keeping with the CCMSC model, contextual and cohort-based issues should be considered regarding the diverse experiences of ethnicity, gender, and sexual identity among older adults. Clinicians must be sensitive to this diversity by setting aside assumptions and encouraging the expression of diversity throughout clients' therapeutic process.

race A group of humans identified as distinctive by physical characteristics such as skin color.

racial identity The view one has about the role of race in dictating social group membership.

racism Fear, hatred, and oppression solely based on the perceived racial or ethnic characteristics; may be intentional or unintentional.

GLOSSARY

acculturation A process of attitudinal and behavior change experienced by individuals who have come in contact with a different and dominant culture.

competence The ability to predetermine and then to attain the desired outcomes of one's profession or vocation by coordinating and integrating relevant skills and microskills.

counseling The purposeful development and structuring of a professional relationship of which the intention is to facilitate meaningful changes in the lives of its recipients. The focus is typically on normal and developmental aspects of functioning as opposed to psychopathology.

culture The ideals, beliefs, skills, customs, values, and social behavior of a particular group of people.

ethnicity A group of humans identified as distinctive by cultural practices and/or beliefs.

multicultural Relative to two or more groups or cultures.

Counseling racial and ethnic minorities entails the provision of counseling services (including individual and group therapy, consultation, and research) to members of racial and ethnic minorities in the United States. In response to societal and demographic changes, as well as a growing ethical awareness, the need to address completely the unique needs of racial and ethnic minorities has been a powerful influence in counseling psychology. Of particular importance are the relationship of acculturation to counseling, the influence of unintentional or aversive racism in counseling, racial identity in regard to counseling, and especially the overarching issue of what constitutes multicultural counseling competence.

1. INTRODUCTION

Historically, the field of applied psychology has been negligent in its delivery of services to racial and ethnic

minorities. The assumptions that have guided practice throughout the history of psychology have relied on White (English-speaking, European-descended, heterosexual) males as the standard for normalcy. Persons from other backgrounds (i.e., race, ethnicity, socioeconomic status, and sexual orientation) were conceptualized, regarded, and treated as deviants; systematically denied access to quality services; and often discounted and ignored by psychology professionals. As the United States entered the Civil Rights era in the 1950s, the injustice of ignoring race and culture in counseling psychology became apparent. In 1962, Wrenn coined the phrase “cultural encapsulation” to describe counselors who defined a client’s reality according to their own cultural assumptions and stereotypes, minimized cultural differences in favor of universal explanations, disregarded their own cultural biases, conceptualized other cultures in terms of pathology, and used a technique-oriented model of the counseling process.

Gradually, partially in response to the Civil Rights movement, applied psychology grew more reflective as a specialty. Practitioners, researchers, and scholars began to recognize the extensive harm caused by the profession’s racial and ethnic biases and prejudices. Professionals began to observe and identify biases in their own approach to minority clients. It was clear that applied psychology was far from being a value-neutral profession.

In what has commonly been referred to as psychology’s “fourth force,” multiculturalism has assumed a position of significant impact in the past two decades, prompting psychologists to revisit and repair their damaging beliefs and practices as well as to make a concerted effort to ensure that counseling services are accessible and amenable to racial and ethnic minority clients. Concurrent with the new awareness has come a growing commitment to training members of racial and ethnic minority populations as counselors.

Progress in the field has been hampered by unclear definitions of the constructs of race and ethnicity and vague descriptions of who constitutes a minority. Race and ethnicity have been criticized as being unscientific and socially constructed categories that are inadequately defined and operationalized. Often, issues of race and ethnicity are confounded by other factors, such as socioeconomic status. In addition, the term multicultural has been criticized as too general and serving to obscure unresolved racial issues.

2. MOTIVATION FOR COUNSELING RACIAL AND ETHNIC MINORITIES

In addition to the historical and societal forces identified previously, two main motivations for the competent counseling of racial and ethnic minorities have been identified: demographic change and ethical concerns. In terms of demographics, the United States has seen a steady increase in some minority populations. The U.S. Census has documented the changing demographic composition of the United States. Census predictions suggest that by 2050 Whites will no longer represent a majority of the U.S. population; in some states, such as California, this change is already a demographic reality. The increase of racial and ethnic minorities, however, does not automatically yield economic success, access to education, or political empowerment. On the contrary, although in some areas people of color are no longer a statistical minority, true economic, educational, and political equality for them remains an ideal to which many aspire rather than a reality that is practiced.

Both psychology’s and counseling’s ethical guidelines have reflected the evolution toward a more culturally sensitive applied profession, reflecting the theme of social justice. The most recent version of each set of guidelines takes culture—defined broadly to include age, gender, race, ethnicity, national origin, religion, sexual orientation, disability, language, and socioeconomic status—into account. The guidelines impart the expectations that counselors and psychologists be adequately prepared to treat clients from diverse backgrounds, that they do not practice unfair discrimination, and that they consider culture in the practice of applied psychology. However, professional ethics codes and standards of conduct—believed by many to be an improvement over the earliest versions, in which consideration of culture was absent—still meet with criticism by many scholars. Critiques tend to focus on the underpinnings of the codes, which are individualistic, based on principle ethics, and therefore problematic when viewed through a collectivistic lens; on the vagueness of the standards and practices, which fail to give practitioners sufficient direction; and on the absolutist assumption, which fails to give culture satisfactory emphasis. Considerable work must be done before the profession can ensure that racial and ethnic minority clients receive ethically appropriate treatment from culturally sensitive, competent practitioners.

3. ACCULTURATION AND COUNSELING

Acculturation can be defined as a process of attitudinal and behavioral change experienced by individuals who live in multicultural societies or who have come in contact with a different culture due to colonization, invasion, political change, globalization, and the increased mobility of society due to technological advances. Acculturation refers to the balance between changing attitudes and behaviors as a result of contact with a dominant group and retention of existing cultural values, beliefs, and traditions. In the United States, institutions such as the educational system and the media are a part of the acculturation process. Another component of the acculturation process may include the acceptance of the need for counseling. The degree of acculturation to a dominant culture may also play a role in preference for the ethnicity of one's counselor or the client's willingness to discuss racial, ethnic, or cultural issues. For example, a client who has low levels of acculturation may not view counseling as an option and instead prefer to rely on family or other culturally sanctioned sources of support. On the other hand, a highly acculturated individual may be very receptive to counseling and may even prefer to work with a White counselor.

4. UNINTENTIONAL RACISM/ AVERSIVE RACISM

In a cultural zeitgeist of increased awareness about the damaging effects of racial and ethnic prejudice and discrimination, overt acts of racism have abated to some extent. It would be erroneous to conclude, however, that decreased incidents of blatant racism indicate an absence of racial and ethnic prejudice. Instead, as public and professional awareness about racism increases, more covert examples of racism are evident. These have been termed aversive and unintentional racism.

Aversive racism occurs when individuals who identify themselves and others as egalitarian and unprejudiced subtly discriminate against racial and ethnic minorities in their beliefs and feelings. This may occur when such prejudice can be rationalized or when information the individual has received is ambiguous. In 1995, Ridley identified eight methods of unintentional but pervasive racist defenses that occur

in counseling. Color blindness is the tendency for counselors to disregard the race of their clients, assuming that all clients are similar. They may minimize or deny the harm inherent in racism, prejudice, and discrimination. Color consciousness, on the other hand, occurs when counselors place too much emphasis on race, ignoring pathology or attributing all presenting problems to culture. Cultural transference can occur when racial and ethnic minority clients project their feelings about the majority culture onto their counselor, whereas cultural countertransference indicates the counselor's projection of emotional reactions toward a minority group onto a particular minority client. Cultural ambivalence can occur when counselors use the therapy arena to act out their own feelings about race and ethnicity, either by dominating and controlling or by seeking approval and acceptance from the client. Pseudo-transference refers to the tendency for counselors to discount their clients' perceptions of them as racist and prejudiced; the clients' reactions to their counselors may be casually dismissed as transference when actually rooted in reality. Overidentification occurs when minority counselors relate significantly with their minority clients and may unwittingly focus on racial issues to the neglect of other important presenting problems. Finally, identification with the oppressor refers to the tendency for some racial and ethnic minority counselors to deny their experiences as minorities and overidentify instead with the majority culture. Ridley offered counselors a variety of ways to combat unintentional racism.

5. RACIAL IDENTITY

The ways individuals perceive themselves as racial beings form the processes by which people acquire their racial identity, and thereby influence both the counseling process and the selection of counselors. Researchers have proposed several different models that outline the distinctive processes that formulate racial identity.

Phinney based her 1993 model of ethnic identity development primarily on her work with adolescents. She proposed a three-stage model to capture the process by which adolescents formulate their ethnic identity. The first stage, unexamined ethnic identity, represents a relatively static condition in which individuals are not in the process of exploring themselves as

ethnic individuals. In the second stage, ethnic identity search/moratorium, individuals are involved in actively exploring themselves ethnically and trying to make meaning of their ethnicity. In the third stage, achieved ethnic identity, individuals have a clear understanding of themselves in terms of their ethnic identity.

Updating Cross's earlier work on Black identity, Cross and Vandiver in 2001 proposed a four-stage model to elucidate racial identity formulation, referred to as the expanded nigrescence model. In stage 1, preencounter, individuals have not yet begun to explore themselves as racial beings and may even denigrate their own culture. Eventually, individuals encounter an experience that prompts them to begin to explore themselves as racial people; this experience is referred to as an encounter experience. This can include an incident involving racism that is experienced personally or having a powerful response to a cultural event, historical incident, or other racial experience. In stage 2, immersion–emersion, individuals experience the most pronounced period of transition. As they continue to concretize their racial identity, they may embrace all things affiliated with their racial or ethnic group and they may eschew those things affiliated with the dominant culture. In stage 3, internalization, individuals have worked through a significant portion of the transition period and may embrace their racial identities as one facet of themselves while simultaneously considering multiple salient roles. In stage 4, internalization–commitment, individuals sustain their interest in their racial identity and may choose to devote themselves to promoting the needs and interests of their particular ethnic group. Cross and Vandiver note that there are cluster identities within each stage, and these cluster identities acknowledge that within stages individuals will experience identity development differently.

Therefore, according to the stage of their racial identity development, racial minority clients may have different views about the purpose of counseling, the preferred race of their therapist, and what they want to work on in counseling. For example, a client in the preencounter stage may deny the salience of race and endorse “color-blind” views of the United States. A client in the immersion–emersion stage may need to explore actively the meaning of race and struggle to make sense of an encounter experience. However, it is not only the client who undergoes racial identity development; the counselor also has a racial identity and undergoes development. The interaction of the two identities can be a powerful dynamic in therapy.

Cross and Vandiver's model may also be generalized beyond Black racial identity and serve as an exemplar of the racial or ethnic identity process.

Janet Helms has utilized her models both on White racial identity and on people of color racial identity to create an interpersonal process model that may be particularly useful for counselors seeking a greater understanding of the dynamics that occur in cross-racial dyads. Helms posited that it is the expressed racial identity of the individuals involved in a particular dialogue that is most critical. In parallel interactions, individuals share similar attitudes and assumptions and generally try to maintain accord. In regressive interactions, the person afforded the most power socially functions from a less evolved status than the person with less power. In progressive interactions, the individual with more social power responds from a relatively more evolved status than the person with less social power. Finally, in crossed interactions, participants interact from places that are diametrically opposite in terms of responding to racial matters.

6. MULTICULTURAL COUNSELING COMPETENCE

During the past two decades, significant attention has been focused on the notion of multicultural counseling competence. The profession of applied psychology has particularly endorsed the need for practitioners who are multiculturally competent.

One such approach originally proposed by Sue and colleagues in 1992 consisted of creating guidelines for multiculturally competent practitioners. This entailed specific directives based on a tripartite model of knowledge, skills, and attitudes. The focus is on the acquisition and endorsement of those facets of competence endorsed by the authors and supported by the profession at large. In this view, multicultural counseling competence consists of professionals who are actively open to examining and adjusting their own assumptions and worldviews, who work toward nonjudgmentally understanding their clients' viewpoints, and who practice appropriate and sensitive strategies with clients from diverse racial and ethnic backgrounds. Many instruments have been created in response to the tripartite considerations of knowledge, skills, and attitudes.

Another approach by Ridley and Mollen recognizes the importance of the aforementioned competencies model and endorses a model that embraces an

integrative deep structure as well—a structure that involves such facets of practice as purposeful application, motivation, selection, sequencing, and timing. This approach posits that multicultural counseling competence consists not only of the building blocks of therapy called microskills and competencies but also of the purposeful, committed intention of the counselors to create an environment suitable for meaningful and relevant client change in consideration of racial, ethnic, and cultural variables.

GLOSSARY

rape Oral, anal, or vaginal penetration through threat or use of force or intentional incapacitation.

rape myth acceptance Tendency to accept as true statements about rape and rape victims that imply victim blame and are not supported by data (e.g., “Every woman has the secret desire to be raped”).

rape prevention beliefs Perceptions of personal risk and of the effectiveness of different preventive strategies.

rape shield laws Legal restrictions limiting the admission of evidence about complainant sexual history.

rape trauma syndrome A distinct pattern of psychological and physical symptoms characteristic of victims of sexual assault.

real rape stereotype Idea that the genuine rape is a surprise attack in a dark alleyway by an assailant who is a stranger to the victim and uses force during the assault.

Rape is a pervasive problem in societies around the world and causes severe suffering and trauma to victims. The vast majority of rapes are committed by men against women, but male-on-male rape and female sexual aggression against men have also been recognized

during recent years, as reflected in changes in legal definitions as well as in research attention. Therefore, interventions designed to reduce the rate of rape are of paramount significance. Most interventions are directed at individuals, targeting either men as potential perpetrators or women as potential victims. Systematic evaluations of these programs show that their success is limited. In addition, measures are implemented at the societal level to enforce more rigorous legal prosecution of sexual offenses and to challenge traditional gender stereotypes that are conducive to rape.

1. RAPE: DEFINITION AND PREVALENCE

In a worldwide survey of sexual violence published in 2002, the World Health Organization defined rape as physically forced or otherwise coerced penetration—even if slight—of the vulva or anus, using a penis, another body part, or an object. Although this definition provides a common basis for documenting the prevalence of rape across a range of countries, legal definitions of the offense show some variations in the key elements in the definition of rape. In the United States, for example, the Federal Bureau of Investigation (FBI) adopts a definition of rape that is restricted to forcible vaginal intercourse with a woman without her consent by force or threat of force. In contrast, most federal states have adopted legislation in which rape is defined more broadly in terms of oral, anal, or vaginal

penetration through threat or use of force or intentional incapacitation. There is no longer a restriction of legal definitions to extramarital acts of sexual aggression, thereby instituting “marital rape” as a criminal offense. Similar legal definitions can be found in other Western countries. In Britain, rape is legally defined as sexual intercourse (i.e., vaginal or anal penetration with the penis) without the other person’s consent and where the defendant knows that the other person does not consent or is reckless as to whether that person is consenting or not. In Germany, the current legal definition includes the use or threat of violence or the exploitation of the victim’s incapacitated state to force another person into sexual activities. Forced sexual activities qualify as rape if the act involves penetration of the victim’s body, and this is no longer restricted to penile–vaginal intercourse.

Official crime statistics record only those incidents of rape that are reported to the police, and there is a general consensus that they severely underestimate the true scale of rape. Nonetheless, these sources show that rape is a widespread problem. For 2001, the Uniform Crime Reports reveal that 62.2 per 100,000 women in the United States were victims of forcible rape and that a rape was committed every 5.8 minutes. In terms of lifetime prevalence, it is estimated that 15% of women in the United States become the victims of rape at some point in their lives. Figures in other Western countries are lower but still substantial, for example, a rate of 13.6 per 100,000 female citizens in Germany in 2000 (including both use/threat of force and exploitation of incapacitation).

Evidence based on community surveys is able to detect at least a proportion of cases not reported to the police and, therefore, typically yields higher prevalence rates. In 1987, Koss and colleagues published a groundbreaking survey of college students from 32 higher education institutions in the United States that found that 15.4% of all women reported they had been raped since 14 years of age. In 1999, Spitzberg integrated evidence from 120 studies with a total of more than 100,000 women and arrived at a similar figure of 12.9%. Evidence compiled in the World Health Organization report of 2002 from a range of samples in Africa, Latin American, Asia, and Eastern Europe reflect prevalence rates between 0.3% (The Philippines) and 8.0% (Brazil), but these figures include only incidents from 16 years of age onward.

The majority of rapes are committed by perpetrators known to the victims either as acquaintances or as dating partners. Despite the persistence of the “real

rape stereotype” picturing rape as a surprise attack in a dark alleyway by an assailant who uses force during the assault, sexual assaults by strangers are the exception rather than the rule. This fact has important implications for rape prevention efforts. Such efforts can be broadly classified into two groups: (a) prevention efforts targeting individuals as potential perpetrators or victims and (b) measures at the societal level designed to discourage sexual violence.

2. PREVENTION MEASURES TARGETING INDIVIDUALS

The majority of rape prevention efforts are directed at individuals, aiming to make men less likely to engage in sexual violence and to prepare women to anticipate and avoid sexual assault. The specific aims and contents of such measures vary depending on the target audience. Three main types of programs have been implemented and evaluated in systematic research: (a) programs directed at men only, (b) programs directed at women only, and (c) programs directed at mixed-sex audiences.

2.1. Programs Directed at All-Male Audiences

The purpose of these programs is to address men’s cognitive and affective predispositions toward sexual aggression. Several studies have demonstrated that greater knowledge about rape, particularly about the rape trauma syndrome, is associated with men’s lower likelihood of committing sexually aggressive acts. Measures in this category are directed at changing men’s rape-supportive attitudes, such as rape myth acceptance, and promoting information about the adverse effects of sexual assault on the victims. They typically consist of one or two sessions lasting up to 2 hours each. In terms of success, meta-analytic evidence shows that human sexuality courses, workshops, video interventions, and other formats have short-term success in reducing rape myth acceptance. However, to prevent men from acting out rape myths in sexually aggressive behavior, such intervention effects need to persist over a longer period. In addition to preventing first-time sexual assault through supplementing rape-supportive attitudes by greater victim empathy, programs need to focus on sexually aggressive men to prevent them from reoffending. This is particularly

important given the high proportion of multiple offenders among sexually aggressive men. One approach is to train men to discriminate between their arousal by consensual sexual stimuli and that by nonconsensual sexual stimuli and to teach them to activate inhibitory self-persuasion with regard to nonconsensual sexual cues. However, programs directed specifically at men with histories of sexual aggression show that this group responds less well to rape prevention efforts, even in the short term, than do unselected male audiences.

2.2. Programs Directed at All-Female Audiences

This category includes measures directed at women as the most likely victims of sexual assault. Measures are designed to reduce the risk of sexual victimization by alerting women to potentially dangerous situations and behaviors and by enabling them to resist sexual assaults more successfully. Despite the fact that the ultimate responsibility for avoiding rape lies with the perpetrators, there is now a broad consensus that women should be empowered to take a more active self-protective role. This includes both provision of information about the risk factors of sexual victimization and specific advice and training on how to fight off an attack.

High levels of sexual activity, alcohol consumption in the context of sexual encounters, and the ambiguous communication of sexual intentions have been linked to an increased risk of sexual victimization across a range of studies. Women must be informed about the risks involved in these behaviors to give them the opportunity to adjust themselves to the threat of rape. Programs teaching self-defense skills and strengthening women's assertiveness are aimed at reducing women's feelings of vulnerability and increasing their self-confidence when faced with a potentially dangerous situation. However, systematic evaluations of rape prevention programs suggest that their success is limited. In particular, there is evidence showing that rape prevention programs may lead to a small reduction in the incidence of first-time assaults on women but are ineffective in reducing the risk of revictimization in women who had experienced prior sexual assault. In addition, some programs were found to increase participants' knowledge about rape but failed to affect the incidence of sexual victimization compared with a control group.

Whether or not women are willing to take behavioral precautions against the risk of sexual assault depends, to a large extent, on their "rape prevention beliefs," that is,

their perceptions of personal risk and of the effectiveness of various preventive strategies. The rape prevention beliefs of most women are restricted to the stranger rape scenario and fail to acknowledge the risk of acquaintance rape. Moreover, rape prevention beliefs are primarily concerned with responding to a sexual attack once it has occurred so as to minimize harm rather than with avoiding an assault in the first place. Women generally perceive a low personal risk of acquaintance rape and, therefore, are less likely to see a need to adopt protective behaviors against this form of threat.

An important component of rape prevention efforts directed at women is to promote women's reflection about potential protective responses in an assault situation. There is conclusive evidence suggesting that fighting back is more likely to succeed in avoiding rape than to lead to greater injury. Therefore, most researchers advise that active self-defense is a prudent response to a sexual attack. However, it is important to bear in mind that the positive evaluation of active resistance is based on probability estimates for samples of assault victims and does not guarantee that resistance is the best strategy in any single case. Therefore, authors are careful to stress that the decision for or against physically fighting back in an attack must be based, in the final instance, on an assessment of the particular circumstances of the attack.

However, it has been noted that empowering women to fight back when they are sexually assaulted involves more than providing self-defense skills. It requires a fundamental challenge of traditional gender stereotypes that portray active physical resistance as unfeminine and, therefore, as inappropriate for women. This applies in particular to rape resistance in assaults by acquaintances or dates where women may be reluctant to acknowledge men's behavior as dangerous and take protective action for fear of appearing to be rude or even paranoid. Prevention programs concerned specifically with date or acquaintance rape are scarce, and the few studies available do not reveal a substantive impact on subsequent victimization rates compared with nonintervention controls.

2.3. Programs Directed at Mixed-Sex Audiences

In terms of their contents, programs directed at mixed-sexed target groups largely address the same aspects as single-sex programs, with a strong emphasis on providing information about the traumatic effects of rape

and on changing men's rape-supportive attitudes. Programs are also similar in terms of their short duration, rarely lasting more than 2 to 3 hours. If such programs are at all successful, their impact is short-lived and generally disappears within a few weeks. Although there may be practical advantages of combining male and female participants in a rape prevention program, this is outweighed by significant disadvantages. One is that men, particularly those with previous histories of sexual aggression, may be unwilling to approach their rape-supportive attitudes and coercive behaviors in an open way in the presence of women. In addition, the message—directed at female participants—that rape is prevalent and that the probability of prosecution for rapists is low may send the message to men that they can expect to get away with rape. Therefore, rape prevention experts recommend that rape prevention programs be directed at men and women separately.

2.4. Problems of Evaluation

Studies implementing and evaluating rape prevention programs are fraught with a number of conceptual and methodological problems that limit their significance. First, participation is voluntary, leading to self-selected samples of participants. In the case of men, this may lead to samples whose members are more open-minded and willing to learn and not representing men with strong rape-supportive attitudes and/or previous sexual aggression. In the case of women, self-selection may lead to the systematic underrepresentation of women who have previous histories of sexual victimization and who might find it too painful to approach the issue in a group setting. As a result, little is known about the success of rape prevention efforts in those target groups that are particularly in need of intervention. A second methodological problem concerns the operation of social desirability biases in the assessment of program success. Reports of greater victim empathy or lower support for rape myths may reflect respondents' tendencies to present themselves in a socially desirable way as much as they may indicate genuine change.

At the conceptual level, a major problem is the selection of criteria by which the success of an intervention is assessed. In the majority of programs, post-intervention measures of success are restricted to changes in cognition and affect such as reductions in rape-supportive attitudes and the promotion of victim empathy. As noted previously, significant but small

changes are typically found on these variables immediately following the intervention. Far more important from an applied perspective is (a) whether cognitive and affective changes are of a sufficient magnitude and persistence over time to be able to exert an influence on behavior and (b) whether a program is successful in reducing the rates of sexual aggression. The evidence available suggests that the answer to the first question is no. Program effects on attitudes and victim empathy typically dissipate within 2 to 4 weeks after the intervention. The answer to the second question is hampered by the fact that there are few longitudinal studies that relate program participation to subsequent reports of sexual aggression in male participants or sexual victimization in female participants. However, the limited evidence that is available suggests that rape prevention programs so far have been largely unsuccessful in reducing the incidence of rape.

3. PREVENTION MEASURES AT THE SOCIETAL LEVEL

As a necessary complement to programs targeting individuals, measures in this category aim to change the sociocultural context in which sexual violence occurs. Their purpose is to increase the costs of rape for the perpetrators and to reduce opportunities for sexual assault in a society. Essential components of this approach are challenging gender stereotypes condoning aggressive behavior in men, reducing opportunities for sexual assault through policies designed to increase women's safety, and reforming the legal treatment of rape to raise the likelihood of conviction for rape offenders and improve the treatment of victims. Rape reflects a power differential between men and women that is part-and-parcel of a wider imbalance of power in society in Western culture and in most other parts of the world. Therefore, addressing this imbalance by promoting equal rights and equal participation of men and women in society will affect the perception of men's entitlement to women to gratify their sexual needs. In addition, gender stereotypes and sexual scripts placing men in the role of initiators and women in the role of gatekeepers of sexual interaction must be challenged and replaced by a more egalitarian view of how sexual intimacy should be negotiated.

Drawing on evidence that links sexual aggression to exposure to violent pornography, some have called for stricter control of accessibility of such material.

Moreover, education campaigns are needed to inform the public about the negative aspects of violent pornography with regard to promoting aggressive behavior.

3.1. Reducing Opportunities for Sexual Assault

This approach includes policy decisions designed to increase women's safety at the local community level. They include practical measures such as providing free late-night transport for women, designating safe spaces for women in public automobile parking lots, installing security cameras in public places, and ensuring that public pathways are well lit at night. These measures reduce opportunities for stranger sexual assault by making it harder for potential assailants to reach their targets without the risk of being caught and arrested. They can also serve to reduce women's fear of rape and to give women a greater sense of security. However, such measures are more likely to lead to a shift of sexual assaults to less well-protected locations than to a genuine reduction in sexual violence. In addition, their effectiveness is taken at face value and has not been subjected to systematic evaluation.

Different measures are required to reduce the incidence of date and acquaintance rape. Given a conclusive database that links both the perpetration of sexual assault and the risk of sexual victimization to alcohol consumption, legal regulations prohibiting the sale of alcohol to adolescents must be enforced. Because alcohol abuse on university campuses is widespread, particularly in fraternity cultures, special campaigns directed at curbing student drinking can also be instrumental in reducing sexual violence in this group.

3.2. Rape Prevention through Legal Reform

Among the most important objectives of rape prevention efforts at the sociostructural level is to increase the number of rapes reported to the police as well as the number of court cases that lead to convictions. There is no doubt that rape is a vastly underreported crime, as evidenced not least in the fact that victim surveys produce much higher incidence rates than do official crime reports. It is estimated that no more than 10 to 15% of all rapes are reported to the police. Victims' reluctance to report rapes has been attributed in large part to insensitive treatment of victims by the police.

Many victims who report their rapes perceive police response as a "second assault," particularly if their cases depart from the real rape stereotype of a stranger assault. To encourage victims of rape to come forward, confidence must be established in the treatment that victims expect to receive from police, medical professionals, and legal institutions. To address this aim, police authorities have implemented procedures designed to ensure more sympathetic treatment of victims such as assigning female officers to the job of recording victims' statements. They have also developed training programs attacking derogatory attitudes toward rape victims and providing information about the traumatizing impact of rape. Despite these efforts, the reporting rate remains low compared with evidence based on large-scale crime surveys of the general population. Even if a rape is reported to the police, the likelihood of the case going to court is low and the probability of a conviction is even lower. Fewer than 10% of reported rapes end with convictions of the defendants. One reason for the low conviction rate in rape trials, particularly for date and acquaintance rape, lies in the tendency by defense lawyers to undermine victims' credibility by referring to the women's past sexual behavior or moral conduct. Rape shield legislation has been introduced to restrict the admissibility of past sexual history evidence. However, the law allows for exceptions to the rape shield provisions that open up the possibility of victim blame and reduce the likelihood of defendants being found guilty.

4. CONCLUSION

Rape prevention is a challenge that requires a multilevel approach, integrating measures directed at individuals as potential perpetrators and victims of sexual assault with macro-level approaches designed to change the sociocultural climate that is conducive to rape. The evidence reviewed in this article makes it clear that rape prevention efforts have had only limited success so far. Ultimately, a reduction in the prevalence of sexual aggression is the criterion by which the effectiveness of prevention efforts must be measured. To date, however, there is no substantive database that demonstrates the success of rape prevention programs in reducing incidence rates of sexual assault. For the time being, most prevention measures are judged on the basis of whether or not they are successful in changing the cognitive and affective antecedents of sexually aggressive behavior rather than in changing the behavior

itself. The restricted time span of most programs targeting individuals is undoubtedly a major limiting condition of their success. Given the deep-rooted attitudes and stereotypes underpinning sexual violence, it seems unrealistic to expect sustainable effects of an intervention lasting just a few hours. Moreover, the large-scale underreporting of sexual victimization is a major problem. So long as the true scale of the problem of sexual assault can neither be accurately measured nor reliably estimated, the ultimate success of rape reduction measures will remain hard to assess.

presented with a printed word, he or she may undergo a process of making letter–sound associations and matching the printed word to the spoken form of the word.

phonology Understanding the variety of possible sounds found in a language.

Reading interventions are necessary for children who struggle to acquire reading skills. There are several reading interventions for various types of reading problems, including word-level and comprehension problems. Reading interventions that are implemented should be tested on a continuous basis to determine their effectiveness and whether they need to be modified for individual children.

GLOSSARY

alphabetic principle Knowing that there are 26 letters in the standard English alphabet and that each letter is represented by a sound; knowing the symbols and corresponding sounds of one's own alphabetic collection (e.g. Cyrillic, Greek, and English).

morphemes The meaning units of words—roots, prefixes, and suffixes. With an understanding of morphological rules, a student may be able to find the root of an unfamiliar word and/or redeploy the term with alternative suffixes or prefixes.

orthography Conventionalized rules of letter patterns and spelling strategies (e.g., “I before E . . .”).

phonemic awareness The alertness to and operation of discrete sounds in spoken language, including rhyme, rhyme production, sound blending, sound deletion and substitution, and sound segmentation.

phonological recoding The combining of phonological with orthographic knowledge about words. When a student is

1. INTRODUCTION

Reading is a complex act. It is complex because written language is an abstract representational system of communication. Becoming literate is not a natural process but rather one that needs to be cultivated through various experiences. Children who are reared in families in which many rich verbal interactions occur are more likely to grasp the skills necessary to become literate. A rich language experience may include verbal dialogues between parents and children that consist of extending upon statements made by children. These types of dialogues facilitate vocabulary development as well as verbal reasoning skills. Before real reading takes

place, joint storybook reading with pictures provides children with rich language experiences. Parents can engage children in a discussion about the story by asking them to retell the story, explain why certain events might have occurred, and predict what might happen next as well as other types of comprehension questions. In 1991, Sulzby and Teal found that children progress from a spontaneous storybook telling phase (i.e., looking at pictures and telling a story about the pictures in an unconventional manner) to looking at pictures and telling a story about the pictures in a conventional manner as if they were reading the printed words. Finally, they actually read the printed words on a page without relying on the pictures. Rich language activities are necessary but not sufficient to becoming literate.

There are certainly other critical skills of emergent literacy, such as concepts about print, phonemic awareness, the alphabetic principle, orthographic processing, phonological recoding, morphological understandings, and reading fluency. Acquisition of these skills may serve to prevent future reading problems in children. A description of these critical reading skills is provided.

1.1. Concepts about Print

Before many children enter school, they begin to obtain concepts about print and this continues as children progress in school. Concepts about print involve skills in differentiating print from pictures, knowing that a book has a front and a back, and knowing that reading (in most Western languages) is a left-to-right and top-to-bottom process. At more advanced stages, children grasp that words written on a page can be spoken, and children know when a word and a sentence begin and end (i.e., spatial relationships between words and sentences).

1.2. Phonemic Awareness

Phonemic awareness is the alertness to and operation of discrete sounds in spoken language. It is one of the most important precursor skills to acquiring word recognition. Phonemic awareness activities include rhyme, rhyme production, sound blending, sound deletion and substitution, and sound segmentation. An example of a sound blending exercise is saying the individual sounds in a word such as /c-a-t/ and having children blend the sounds together to form a whole word. Sound segmentation involves saying a word as a whole, such

as /ran/, and having children break the word apart and say each sound sequentially, such as /r-a-n/. These phonemic awareness activities should be explicitly taught to children in kindergarten and first grade according to a synthesis of research presented in the National Reading Panel Report. Among the phonemic awareness exercises, phonemic segmentation and blending were found to be the best predictors of word recognition performance in first grade.

1.3. Alphabetic Principle

In 1990, Adams asserted that children enter into the alphabetic system easily if they have acquired phonemic awareness. The alphabetic principle is knowing that there are 26 letters in the standard English alphabet and that each letter is represented by a sound. The use of alphabet books helps children grasp making letter–sound correspondences, particularly beginning letter–sound association of words.

1.4. Orthographic Processing

Orthographic processing consists of noting letter sequences in words or spelling patterns of words. Therefore, it involves examining the graphic structural properties of words.

1.5. Phonological Recoding

Phonological recoding involves combining phonological with orthographic knowledge about words. It is a process by which children examine graphic representations of a printed word and recode them back into its spoken language form. When children encounter a printed word, they go through a process of sounding out the word and then check to determine if the word matches a word stored in their memory and in their speaking vocabularies. Children initially make sequential one-to-one correspondences with letters and sounds. At more advanced stages in this process, they hierarchically decode words by using some letters in a word to cue the sounds of other letters (e.g., the e at the end of “came” cues the reader to say the /a/ as a long vowel sound).

1.6. Morphological Understandings

Conceptual knowledge about spoken words is critical for beginning readers. Morphemes represent the meaning units of words. Vocabulary development plays a

role in gaining morphological structures (meaning units) of spoken and written language, which is particularly critical when children, for instance, learn to read words that contain prefixes and suffixes as well as compound words.

1.7. Reading Fluency

The goal of basic reading instruction is to read words automatically or fluently. This is accomplished by acquiring a repertoire of word identification strategies as well as engaging in repeated readings of words in and out of context under timed conditions. Children are considered to be reading within grade level if they are reading between 75 and 100 words per minute correct on a grade-level passage with three to five errors.

2. CHARACTERISTICS OF INDIVIDUALS WITH READING PROBLEMS

Individuals with reading problems are generally characterized as having difficulties in obtaining word recognition skills and gaining meaning from text. These individuals are typically referred to psychologists for evaluation due to these general characteristics. Upon evaluation of several individuals with reading problems, the psychologist may discover that some children display delays across various areas, such as exhibiting low average cognitive ability (i.e., not in mental retardation range) and low average language, reading, math, and written language skills. These individuals are considered to be delayed types of readers, meaning that they tend to be delayed across cognitive and several academic learning domains.

Some individuals with reading problems have a central nervous system condition. These individuals are often classified as dyslexic and have average or higher intellectual abilities but severe reading problems coupled with speech production, rapid naming, phonological processing, and orthographic processing deficits. However, these individuals may not be delayed in math and other academic subject areas. Whether children are classified as dyslexic or the low average type, many children classified as having severe reading delays have deficits in phonological processing. Generally, students identified with learning disabilities in reading due to a central nervous system condition and a discrepancy between intellectual ability and achievement

are not functionally different in their development of reading skills than those who are low average across several cognitive and academic domains. The diagnostic label is less important than the identification of the specific skills for which children experience difficulty. In fact, many researchers have found that low average readers and individuals diagnosed with central nervous system conditions or dyslexia exhibit similar underlying literacy deficits, particularly deficits in phonological awareness.

Other individuals' reading difficulties are due to poor instruction, which often leads to acquisition and fluency problems. Some students recognize and comprehend words accurately but not at a sufficient rate. Other students do not recognize and comprehend words accurately. The most efficient readers are those who recognize and comprehend words accurately and at a sufficient rate (i.e., reading 100 words per minute in the students' grade-level text).

3. PHONIC INTERVENTIONS

Phonics is the system by which children learn to make letter–sound correspondences. According to many prominent reading scholars, good phonics instruction does not dominate literacy instruction; it is brisk, lasting 20–30 minutes per day; and it includes phonemic awareness and spelling instruction. There are a variety of approaches to phonics instruction. Synthetic phonics instruction involves breaking words into their constituent sounds and blending the sounds together to form a whole word. An example of synthetic phonics instruction is Englemann and Bruner's Reading Mastery (formerly known as DISTAR). Analytic phonics involves the application of rules to identify words. Analogic phonics approaches involve word study methods of identifying unknown words by making analogies to known words. The research is inconclusive regarding the best approach to teaching phonics; however, some researchers suggest that synthetic approaches are more effective than analytic approaches. A synthesis of the research concluded that systematic direct instruction of phonics is more effective for achieving word recognition and spelling skills than indirect methods.

A number of contemporary phonic techniques involve studying phonological and orthographic features of words. Many of these approaches are not discussed here. However, some are provided as examples of techniques that can be employed to help children examine words. Word sorts are an analogic phonic approach for

helping children categorize words according to shared phonological, spelling, and meaning components. They can be in the form of closed sorts, in which the teacher establishes the categories, or open sorts, in which children induce the categories based on an examination of subsets of given words. Words are printed on index cards, and three or more words are designated as the category words. A stack of words is shuffled and then children are asked to sort the words into one of the categories according to common sound or spelling patterns. Bear *et al.* provide a comprehensive guide to creating various types of word sort lessons and other word study phonic activities. For instance, children can complete phonemic awareness sorts by sorting pictured objects according to beginning and ending sounds. This type of sorting has been found to be especially beneficial and appropriate for preschool and kindergarten children. Children can also spell words in respective categories as the teacher orally presents words. Howard Street and Early Steps, two effective tutoring programs for low achievers, incorporate word sort techniques rather extensively. Word sorts are also being used for children identified with mental retardation, and these exercises have been found to be helpful in improving these children's spelling performance.

Word boxes, a synthetic phonic approach, help children segment sounds of spoken language. This approach has been effective for helping children with learning disabilities identify and spell words and has helped first graders and preschool children achieve phoneme awareness skills. Typically, word boxes have been used in Clay's comprehensive reading recovery program. A word box consists of a drawn rectangle that has been divided into sections (boxes) according to individual phonemes in a word. Initially, children place tokens in respective sections as each sound in a word is articulated slowly. Eventually, children place letters (either magnetic or tile) in respective sections as each sound in a word is articulated. During advanced phases, children are asked to write letters in the respective divided sections of the box.

4. WHOLE WORD INTERVENTIONS

Whole word recognition or "look-say" approaches are effective especially for teaching words with irregular sound and spelling patterns. In look-say approaches, children practice reading words as a whole until they achieve fluency and the words become a part of their sight vocabularies. For instance, words that are printed

on index cards can be read as a whole within a specified time period. Research has shown that whole word methods may produce immediate word recognition achievement effects, whereas phonic approaches may produce more long-term generalized effects, especially when students encounter words unknown to them.

5. REPEATED READINGS

Repeated readings are a very effective whole word recognition strategy for building fluency. Essentially, children read the same passage several times for 1 minute until mastery of the passage has been achieved. Mastery usually means reading the passage fluently—that is, reading all the words accurately and quickly. Reading fluency is highly correlated with reading comprehension.

6. VOCABULARY DEVELOPMENT AND READING COMPREHENSION STRATEGIES

According to McCormick, instruction aimed at developing vocabulary should consist of (i) teaching a small number of words intensively in any given lesson; (ii) exposing the student to the same word in various contexts and in a systematic and continuous fashion; (iii) including gamelike activities to stimulate interest in learning concepts, teaching morphological units (e.g., prefixes and suffixes); and (iv) explicitly, teaching derivations of words through exercises using the dictionary. Categorization activities help children group words that share similar meanings and help students make distinctions about words that are not similar. Cloze procedure exercises involving a passage with every "nth" word missing can be used to help children determine where words are placed contextually within a passage.

Learning strategies instruction approaches were found to be effective for helping children with learning problems attain concepts and improve their reading comprehension performance. Effective learning strategies instruction approaches consist of self-questioning, constructing mental representations to integrate information from text, and identifying text consistencies. Examples of these approaches include semantic mapping, PQ4R (preview, question, read, reflect, recite, and review), and reciprocal teaching.

Semantic mapping typically involves developing word webs that reflect students' understanding of

concepts and constructing a diagram connecting events of a story or connecting facts taken from content area textbooks. Students who struggle to grasp conceptual relationships may find diagrams to be helpful visual aids. Semantic maps can be either process oriented or product oriented. Process-oriented maps are usually completed before students read assigned material to help them establish some background knowledge. This type of mapping requires teacher facilitation of student responses. For example, a teacher may write a concept (e.g., satire) in a drawn box and ask the class members to give examples of when they experience it. As the class members respond, the teacher writes their comments below the concept. The teacher may then ask the class members how they feels when they witness the concept and to write their responses, drawing connecting lines to the other comments, and so on. Product-oriented maps, on the other hand, are produced by students as an outcome activity after they have read material. Students generally work independently or with other peers and construct a map connecting ideas presented in text.

The PQ4R method of comprehending reading material is an extension of SQ3R (survey, question, read, recite, and review). This method involves previewing the reading material, questioning the reading, reading to answer the questions, reflecting on the reading, reciting the reading, and reviewing the material. Previewing the material means surveying the chapter titles, main topics, and subheadings of the text. Students can turn the headings and subheadings into questions. Questions that were developed can be answered by reading the text. Reflections about the content can occur as the material is being read if the students pause to form connections and create images. Reciting is retelling what was read from memory. This form of retelling helps students monitor the information they are obtaining from the reading. If some information is not being retained, students may need to read sections of the text again. Lastly, students review the material by answering questions and referring back to the text for clarification of mistaken responses to questions. This method appears to be most appropriate for older students because it encompasses the application of higher level metacognitive processes. Although PQ4R is not a new method, it continues to be considered an effective technique for helping students organize and retain information from texts.

Reciprocal teaching is a reading comprehension approach that has helped delayed readers catch up to and even exceed the level of typically developing readers.

This approach places heavy emphasis on teacher–student interactions in a rather cognitive apprenticeship fashion. After students and teacher read from common text, they dialogue with each other about the reading material. Initially, the teacher leads the dialogue by modeling strategies of predicting, question generating, summarizing, and clarifying text. The students are then asked to lead the discussions and apply the strategies that were demonstrated by the teacher. Guided practice is provided until students can use the strategies effectively. The goal of these reciprocal teaching interactions is to construct meaning from texts.

7. PRINCIPLES OF TEACHING AND LEARNING READING

The principles of teaching and learning word recognition and comprehension strategies include connecting to and building schema, demonstration and modeling, providing opportunities to learn and practice skills, and shaping reading behaviors through corrective feedback and reinforcement.

7.1. Connecting to and Building on Schema

Word recognition and comprehension skills are acquired more easily if the context from which these skills are presented is personally meaningful. This is especially important for children, who have limited conceptual knowledge. It is important for educators to become aware of children’s prior knowledge and experiences so they can help children associate new information presented in text to their already existing schemas.

7.2. Shaping Reading Behaviors

Shaping behavior refers to modeling/demonstrating, providing corrective feedback, and eliciting reinforcers for successive approximations toward completing a task. Reading behavior is not acquired as naturally as language. In other words, we are not biologically predetermined to acquire reading skills but are biologically wired to acquire language. Therefore, reading behaviors need to be explicitly demonstrated and then modeled. It is important for parents or caregivers to provide opportunities for joint book reading early in children’s development. Joint book reading activities should consist of the parent demonstrating reading

print on a page and looking at the pictures. When parents are not engaged in shared book reading with their children, they should model reading behaviors by reading, for example, a newspaper, magazine, letter, or novel. When children enter school, educators need to explicitly demonstrate prereading and reading skills, such as phonemic awareness, letter naming, and letter-sound correspondences, and whole word reading skills. They also need to model these skills while they are engaged in their own reading activities.

Children need corrective feedback on inaccurate responses made during reading activities. When children mispronounce a word, they should be provided with corrective feedback or prompted to supply the accurate pronunciation of the word. When children identify words incorrectly, they may be corrected through whole word correction procedures or phonic analysis procedures. Whole word correction procedures consist of saying a word correctly when children read a word incorrectly. Phonic analysis correction procedures may involve helping the child break the word apart by sounding out each letter or letter combinations and then blending the sounds to form a whole word.

Delivering reinforcers for efforts made toward achieving a goal can be considered as a way of supporting children through the reading process. Children with reading problems will struggle and become frustrated as they proceed through a trial-and-error process of learning how to read. Reinforcers need to be delivered for efforts made toward reading words accurately and comprehending text and not just for accurate performance. For many older children with reading problems, reinforcers may not have been a systematic part of their instructional histories. In other words, consequences for reading behaviors may have not been emitted or delivered haphazardly rather than in successive approximations to desired reading performance.

7.3. Providing Opportunities to Learn

It is important for children to be provided with sufficient time to engage in reading activities. However, allotted time for reading is not sufficient to ensure active engagement in reading tasks. Instead, children need to be provided with many opportunities to be engaged in tasks during the allotted time for reading exercises. During oral and silent reading activities, children need plenty of opportunities to make responses. This can be achieved if

lessons are structured so as to increase the number of responses children can make. For instance, choral reading of passages rather than round-robin reading increases all children's opportunities for being engaged in reading orally. Children also need many opportunities to practice skills that are learned. This is especially the case for children with learning disabilities and children with mental retardation. Overlearning leads to the ability to generalize skills to other contexts more easily.

7.4. Scaffolding

Scaffolding means providing necessary support and gradually reducing that support as an individual begins to function more independently. Educators need to employ scaffolds or necessary supports for children until they are able to complete tasks independently. Scaffolds include teacher facilitation and feedback as well as appropriate instructional materials that serve to make problems solvable. Examples of scaffolds used during reading activities are verbal prompts, context clues, and manipulative materials. Educators who use scaffolds often view themselves and the materials they design or select as mediators of the learner's development.

7.5. Motivating

Attribution retraining (training students to attribute their performance to the amount of effort rather than other factors) coupled with learning strategy instruction has been found to be effective for helping low achieving students to increase the amount of effort put forth on their reading through use of reading strategies. Children in kindergarten and first grade are more likely to expend effort toward reading even if they do not experience success, whereas older children, especially those with learning disabilities, are less likely to put forth effort if they do not experience immediate success with reading. This is because young children are likely to attribute their failures and successes to the amount of effort they expend, whereas older students are likely to attribute their successes and failures to other factors, such as teacher perceptions or task difficulty level. Likewise, many children lack an awareness of various strategies that would aid their reading skills, which makes it easy for these children to attribute their performance to other factors that may have no or a limited relationship to their performance.

8. TARGETING AND CONTINUOUS IMPROVEMENT OF READING SKILLS THROUGH PROCESSES OF LINKING ASSESSMENT TO INTERVENTION

The best approach to targeting specific reading skill problems is to conduct direct systematic assessment of reading performance. This can be accomplished through direct observations of students' oral reading behaviors in the classroom and through the use of curriculum-based reading measures. Curriculum-based reading measures consist of grade-level timed reading passages to assess fluency (accuracy and time) and also may consist of phonemic awareness, letter naming, and reading words out of context. Informal reading inventories and miscue analysis inventories are also helpful assessment measures for targeting specific reading performance. Evaluators should also observe the strategies students do and do not use while attempting to identify words and comprehend reading material. After specific skills and performance levels are assessed and noted, appropriate interventions can be targeted. Interventions should be implemented in a systematic manner and skills should be assessed during intervention periods to monitor student progress on a continuous basis as a function of the intervention. This process helps determine the effectiveness of the intervention. If a student does not demonstrate progress over time, then another intervention needs to be implemented and evaluated. This process of assessing and intervening is cyclical as students progress from performance level to another and from one skill to another.

GLOSSARY

alphabetic principle Set of correspondences between a phoneme and the alternative one- or two-letter spelling units that represent it in the writing system.

automaticity Nonstrategic, effortless, direct retrieval and production of a word.

decoding Converting letters to phonemes and synthesizing the phonemes into a pronounceable word or covert phonological representation of a word.

fluency Fast, smooth, coordinated oral reading that reflects the intonation (melody) of the spoken language or rapid, efficient silent reading.

morphemes Word parts that, alone or attached to other word parts, convey meaning.

morphological awareness Conscious reflection about and manipulation of morphemes, including prefixes, roots or bases (roots plus affixes), and suffixes (inflectional ones that mark number, tense, and comparison as well as

derivational ones that mark grammatical speech part) in short-term and working memory.

nature–nurture interactions The notion that reading (and other) behavior is the result of biological and environmental influences.

orthographic awareness Consciously reflecting about and manipulating letter units in written words in short-term memory and working memory.

phoneme Smallest unit of sound that (a) has no meaning of its own but makes a difference in meaning and (b) corresponds to one or more spelling units.

phonological awareness Consciously reflecting about and manipulating sound patterns in spoken words (syllables, phonemes, and remaining parts of syllables after initial phonemes are removed) in short-term and working memory.

reading comprehension Text interpretation derived from vocabulary meaning, syntactic awareness, and discourse structures in text and from language and cognitive processes that go beyond what is stated in text.

rule-governed knowledge versus word-specific knowledge Abstracted patterns and relationships that can be applied across cases (single exemplars or multi-item constructions) versus learned representations in multiple formats (orthographic, phonological, and morphological codes) used in case (exemplar or instance) learning.

spelling unit or grapheme One or two letters that correspond to a phoneme.

strategies Nonautomatic reflective approaches applied to reading goals.

syntactic awareness Consciously reflecting about and manipulating the structures in sentences or conversational utterances in short-term and working memory.

Teaching reading is a teacher-led process of explicitly guiding students who actively participate in developing and coordinating (a) orthographic, phonological, and morphological awareness of words and their parts that results in accurate and automatic reading of words from the Anglo-Saxon, Latinate, and Greek layers of the language; (b) vocabulary meaning, syntactic awareness, and discourse structures that contribute to accurate and fluent reading and reading comprehension; and (c) interrelationships of reading with listening, speaking, and writing. Effective reading instruction also shows students how to apply the emergent knowledge and procedural skills to a wide variety of goals, including (a) learning from and thinking about written texts, (b) enjoying reading, and (c) using reading for pragmatic functions at school, home, and work as well as in everyday living.

1. HISTORICAL BACKGROUND

1.1. Writing Systems and Teaching Methods

Reading became possible when humans discovered three ways in which to represent the meaning or sounds of words in writing: ideograms/pictographs portraying concepts with line drawings, visual syllabaries standing for spoken syllables, and alphabets representing phonemes in spoken words with one- or two-letter spelling units. Three instructional methods corresponding to each of these writing systems were developed: whole word method (also referred to as look-say or sight words), syllable method and related word family method (syllable without its initial sound), and phonics (correspondences between phonemes and alphabet letters), respectively.

1.2. Debates

During the 20th century, scientific research resolved the debate about phonics versus the whole word. The conclusion was that phonics is the most effective, at least for the primary grades when basic word decoding skills are typically mastered. Research also showed that decodable text is effective in beginning reading instruction but that other methods, such as repeatedly reading the same whole words and teaching word families, are effective supplements to phonics. During the 20th century, scientific research also resolved another debate about whole language versus phonics that was about the optimal unit of instruction and instructional goal.

Advocates of whole language argued for the whole text (based on good children's literature) as the unit and meaning as the goal, whereas proponents of the phonological method argued for the phoneme in spoken words as the unit and phonological decoding as the goal so that students can read independently. Scientific research supported the conclusions that (a) the phonological method is more effective for beginning reading instruction, (b) meaning is motivating to beginning readers who benefit from listening to and discussing good children's literature rather than reading it independently, (c) children exhibit individual differences in the amount and intensity of phonological instruction they require, (d) phonological instruction may be necessary but it is not sufficient, and (e) a balanced approach focused on both decoding and meaning is the most effective. Because language has multiple dimensions, effective instruction directs children's attention not only to phonology and orthography but also to the morphology, syntax, and discourse structure of spoken and written language.

The debate about direct instruction (which is teacher controlled with rote student responding) versus constructivism (which has minimal direct teacher input and relies on student construction of personal written language knowledge) is also being resolved with scientific research. Both teacher-led explicit instruction and strategy instruction for self-regulated learning benefit struggling readers, who learn from (a) direct explanations about the structure and rules underlying language and (b) teacher-led questions, prompts, or activities that encourage students to engage in active hypothesis testing in applying those explanations to their own reading. At the beginning of the 21st century, there is an increasing recognition that instructional methods for teaching reading should be grounded in scientific research rather than in philosophical belief.

2. RELATIONSHIP BETWEEN TEACHING AND LEARNING

Teaching has three instructional components: pedagogy (instructional behaviors of the teacher), curriculum (instructional goals and plans to reach those goals), and instructional materials (text and other instructional resources for achieving those goals). Teaching is related to learning but not in a simple one-to-one fashion. Teachers cannot program students' minds/brains through instruction the same way in which a

programmer can program a computer through input. Ultimately, students create their own learning (mental representations and organization) from the instructional cues they receive from pedagogy, curriculum, and instructional materials. Teacher knowledge of the developing brain, cognitive psychology, linguistics, and child development can influence the quality and appropriateness of the instructional cues provided. These instructional cues, in turn, are influenced by multiple biological (e.g., genes, neural architecture, maturation) and environmental (e.g., home literacy, school instruction, cultural, linguistic, socioeconomic) factors. Hence, learning is the by-product of nature–nurture interactions, and internal cognitive, affective, and motivational processes in the learner’s mind/brain mediate the instructional cues and constrain but do not determine learning independent of environmental input.

3. DEVELOPMENTAL FRAMEWORK FOR CREATING A FUNCTIONAL READING SYSTEM

The functional reading system, which supports independent reading for a variety of purposes, is constructed over a long course of development from multiple language and nonlanguage systems in the brain and their interactions with the instructional environment. Although research has established correlations between beginning reading and subsequent reading skill, this relationship is not causal; developmentally and instructionally appropriate intervention at any time in reading development may improve the functioning of the reading system. In designing and implementing developmentally appropriate intervention, it is important not to confuse the novice and expert stages. Effective reading instruction aims just above the current instructional level to promote further growth along the developmental path to literacy. Children may follow different developmental paths to literacy. Some begin the journey at home during the preschool years, with parents using the lap method (reading storybooks to their children on a regular basis). Others do not begin the journey until school entry, but instructional methods have been developed to simulate the lap method in school settings (e.g., big books and little books with teacher-led finger point reading). However, federal programs are providing home literacy programs and incentives for explicit literacy instruction in preschools for those children who, heretofore, came to

TABLE I
Developmental Framework with Partially Overlapping, Cascading Stages

First stage: Learning to read words and understand text
1. Subword level: alphabetic principle, syllables, and morphemes
2. Word level: rule-governed decoding, word-specific representations, automatic word recognition
3. Text level: fluent oral reading, fluent silent reading, reading comprehension
4. Integration of reading with listening, speaking, and writing
Second stage: Reading to learn, enjoy, and work in school and nonschool settings
1. Domain-specific content areas in school curriculum
2. Leisure time activities in and out of school
3. Everyday reading for functioning in society
4. Vocation-specific reading for functioning at work
Third stage: Executive coordination of reading and high-level functions
1. Integration with technology (e.g., word processing systems, Web-based information systems)
2. Integration with thinking (e.g., critical thinking), mental world building (e.g., creative thinking), and problem solving

school unprepared for reading. *Table I* provides an overview of partially overlapping, cascading developmental stages and their instructional components.

4. LEARNING TO READ

Basic decoding skills are typically taught during the first three grades. Fourth grade is an important transition time. Written text changes from mostly one- and two-syllable words of Anglo-Saxon origin that characterize primary grade reading material (and conversation) to a high density of words of more than two syllables and mostly of Latin (and Greek) origin that characterize reading material in the upper grades—when students continue to benefit from explicit instruction in decoding longer, more complex words. Also, the nature of the reading vocabulary, syntax in written text, and discourse structures changes. High-frequency vocabulary gives way to low-frequency complex vocabulary. Syntax in written material becomes more complex. Discourse structure changes from primarily narrative to primarily expository. Oral reading gives way to silent reading as the primary mode of instruction.

4.1. Teaching Word Reading Skills

Table II lists the instructional goals and associated instructional activities organized in the developmental progression from initial to mastery phases in learning word reading skills. In general, English word reading is predictable but not completely regular on the basis of alphabetic principle alone. Alphabetic principle can be applied to decoding both structure words (high-frequency words such as prepositions, conjunctions, pronouns, and articles that contribute to sentence meaning but have no meaning by themselves and are not always perfectly decodable) and content words (nouns, verbs, adjectives, and adverbs that tend to be more decodable). In English, a word might not be governed by regular rules of word identification at one level of analysis (e.g., single letter and associated phoneme) but might be when larger units (multiletter word families) or a different level of analysis (morphological) is taken into account. Although alphabetic principle benefits beginning word decoding, subsequent reading of polysyllabic

words requires attention to additional linguistic cues (e.g., morphological) in word structure as well.

4.2. Teaching Reading Comprehension

In 2002, Carlisle and Rice provided an overview of teaching reading comprehension (see also Table III). Because lack of word automaticity (Table II) or text fluency (Table III) can interfere with normal reading comprehension, instructional activities aimed at developing oral and silent reading fluency are important components of reading comprehension instruction. From fourth grade onward, reading vocabulary instruction is necessary because many of the words are not part of students' speaking vocabulary as was the case with beginning reading texts. Effective vocabulary instruction requires far more than teaching the meaning of each word in the language. Both morphological awareness and syntactic awareness contribute to oral

TABLE II
Teaching Word Reading

<i>Reading instructional goal</i>	<i>Instructional activities</i>
Phonological awareness	Rhyming, syllable and phoneme analysis with spoken words
Orthographic awareness	Letter naming and letter writing; looking games requiring careful attention to (and memory for) all letters in a written word
Alphabetic principle	Producing the phoneme corresponding to a spelling unit containing one or two letters
Decoding monosyllabic Anglo-Saxon words (structure and content words)	Finding letters or spelling units that correspond to phonemes (applying alphabetic principle) and synthesizing the phonemes to pronounce the word
Decoding two-syllable Anglo-Saxon words (structure and content words)	Identifying type (e.g., closed, open, silent e, vowel team, r-controlled, -le) of each syllable in word and then decoding each syllable using alphabetic principle
Morphological awareness	Differentiating initial common spelling patterns that do or do not correspond to prefixes and final common spelling patterns that do or do not correspond to suffixes marking tense, number, or comparison or derivational suffixes marking grammatical part of speech; analyzing words into roots, affixes, or bases (affixed roots)
Decoding polysyllabic words from the Latinate and Greek layers of the language of Latinate and Greek origin	Introducing correspondences between spelling units and phonemes, syllable patterns (e.g., schwa), and morpheme patterns specific to the Latinate or Greek layers; practice applying multiple strategies based on alphabetic principle, syllable types, and morphemes to words
Automaticity	Practice reading monosyllabic and polysyllabic words from Anglo-Saxon, Latinate, and Greek word origin out of sentence context (on lists or flash cards) with and without rate criteria

TABLE III
Teaching Reading Comprehension

<i>Reading instructional goal</i>	<i>Instructional activities</i>
Oral reading fluency	Encourage children to attend to units larger than single words and to reflect the musical melody of the spoken language when reading aloud. Compute and record rate of accurate reading of repeated readings of same passages on which children can identify at least 90% of running words.
Silent reading fluency	Transition to silent prereading before oral reading, and follow same procedures as for oral reading fluency. Eventually transition to silent reading and wide reading of many passages. Record time for silent wide reading as a function of comprehension criteria (answering factual and inferential questions with 90% accuracy and story recall with main idea and supporting details).
Vocabulary	Guide students in inferring word meaning from sentence context. Define new vocabulary and use each word in a sentence to illustrate its meaning in context. Provide morphological patterns for generating new vocabulary items.
Sentence interpretation	Draw students' attention to the importance of word order by rearranging scrambled words into grammatically acceptable sentences. Discuss how meaning changes by reordering words slightly in a sentence. Help students paraphrase sentences to communicate the same idea.
Discourse understanding	Relate students' background (world) knowledge to content of the text to be read. Ask questions that prompt students to think about both information stated in text and information inferred from text. Teach strategies for self-regulating and monitoring the comprehension process, including prediction, summarization, clarification, and elaboration. Show how discourse structure can be used to build a mental representation of text. Describe the discourse structures of different genres: narrative (setting, characters, plot, and outcome) and expository (informational: lists, descriptions, comparisons, cause and effect, problem-solution; persuasive: one argument with evidence and conclusion with reasons, counterarguments with evidence, point-counterpoint, conclusions with reasons). Call attention to the different kinds of paragraph organization within the different genres (e.g., events for narrative, main idea and supporting detail for expository, mix of more than one genre).

vocabulary development as well as reading comprehension. Prior focus on question asking to assess comprehension has given way to pedagogy for explicit instruction in cognitive strategies for self-regulating and monitoring the reading comprehension process and for increasing active engagement of the reader in processing written text.

4.3. Integration of Reading with Other Language Skills

4.3.1. Listening

Students learn about reading by listening to the teacher's instructional language. Compared with conversational speech that is highly contextualized (embedded in social routines that support turn taking and communication repair), instructional language is decontextualized, with the focus redirected from language as a means of achieving an end (social communication) to language as an end in itself (language as the object of attention and

reflection). Listening to the teacher read good children's literature stimulates linguistic development (vocabulary meaning, syntactic awareness, and discourse understanding) and cognitive development, and this in turn benefits reading development.

4.3.2. Speaking

Oral discussions about what has been read promote elaboration and deeper understanding of a text. Pedagogical methods for encouraging talk about reading material range from teacher-guided, collaborative, whole group discussions; to reciprocal teaching in which students assume teaching roles with some teacher guidance; to book clubs in which discussion is totally under student control.

4.3.3. Writing

Writing alphabet letters increases orthographic awareness, which in turn may facilitate learning to decode

words. Word spelling may exert reciprocal, mutually enhancing influences on the development of word reading. Written composition develops as children write about the material they read for various assignments.

5. READING TO LEARN

5.1. Teaching Domain-Specific Reading Skills in Content Areas

Although many middle school and high school teachers view their role as merely transmitting content matter, students learn more in content subjects when teachers also teach the vocabulary terms, textbook genre, and study strategies unique to the discipline.

5.2. Teaching Positive Affect Toward Reading

Unless children are successful in reading and enjoy reading, they are unlikely to engage in sufficient sustained practice of reading to become skilled readers. Therefore, reading instruction must create opportunities for children to learn to derive pleasure from reading. Some effective techniques for developing a reading habit and positive affect toward reading are including reading choice time at school and including leisure reading time at home. Children enjoy keeping reading logs of what they have read (e.g., books, magazines, newspapers) and competitions to see who can read the most books.

5.3. Teaching Everyday Reading Skills

Reading skills might not transfer automatically from the classroom to the real world without explicit instruction in specific reading tasks such as reading labels on food and household products, medicine labels and pharmacy instructions, menus, newspapers, magazines, advertisements, and the like.

5.4. Teaching Vocation-Specific Reading Skills

Vocation-specific and job setting-specific reading requirements vary considerably. High schools and colleges cannot prepare students fully for every kind of job-related reading goal (e.g., reading and applying

information in highly technical manuals for operating heavy equipment or high-tech instruments). Job-related reading goals require not only decoding skills but also considerable domain-specific content knowledge. Some on-the-job reading comprehension strategies might be necessary.

6. COORDINATING READING AND HIGH-LEVEL SKILLS

6.1. Teaching Literacy for Technology Users

Although most elementary schools have computer laboratories, few have fully integrated technology into their literacy programs. By middle school, many students use word processing programs to complete written assignments based on reading source material but without explicit instruction in how to do so. As word processing and voice activation programs become more widely available and integrated with the instructional program, the need for explicit instruction in keyboarding, dictation, and integrated reading-writing systems for word processing will increase. During the information age, students also need explicit instruction in using Web-based information systems.

6.2. Teaching Critical and Creative Thinking and Problem Solving

Reading instruction should prompt readers to go beyond understanding a text at an initial level of analysis. For example, instruction may challenge readers to take a critical stance toward the text (e.g., its arguments, the author's intent), create new ideas that extend those in the text, and/or solve problems posed in writing assignments using reading source material. Many believe that teaching reading as a thinking skill is critical to the survival of democracy as a form of government.

7. INDIVIDUALIZING INSTRUCTION FOR STUDENTS WITH READING DISABILITIES

Effective strategies for teaching students with reading disabilities have been developed. However, many challenges remain in implementing individually tailored, appropriate instruction for all students with learning disabilities.

8. OPTIMIZING READING INSTRUCTION FOR ALL STUDENTS

At the beginning of the 21st century, expectations are rising for the educational achievement of all students. Considering the enormous normal variation among students at the same grade level, the expectation that all students will be readers and meet high-stakes standards will require reading instruction to become increasingly sophisticated.

GLOSSARY

adaptation level The standard of adjustment to a pattern of experience that a person has become used to.

comparison level A standard against which a person judges the attractiveness of a relationship with regard to whether he or she receives what is deserved, relative to his or her costs.

comparison level for alternatives The reference point employed in deciding whether to remain in an interaction. It can be considered as the lowest level of reward that an individual will accept in order to continue in the relationship. It also relates to the concept of adaptation level, with respect to what one has come to expect.

distributive justice A concern for whether an individual's investments in an ongoing relationship are or are not balanced by rewards.

egoism A self-centered basis for judging experience as good or bad in terms of one's benefits.

injustice A perceived negative outcome between actual rewards and expected rewards.

reference group A group that an individual takes as a standard for attitudes and actions, whether or not he or she belongs to it.

Social interaction between individuals involves an exchange of benefits, the most distinctive feature of which is the "give and take" of reciprocal behavior. This norm of reciprocity has been summarized by Gouldner as a universal norm stating that a benefit should be returned and, above all, that one who gives a benefit should not be harmed. These are often captured in everyday speech by such statements as "do unto others as you would have them do unto you" and "don't bite the hand that feeds you." Gouldner states that reciprocity fulfills two basic functions: to stabilize relationships and to serve as a check on egoism. These show concern for interdependence in relationships and the need to consider more than one's self-interest.

1. BACKGROUND

The rewards exchanged in relationships need not be of the same kind or of equal amount. Also, the anticipation of receiving a reward can account for such things as sacrifices, where goods are given to "appease the gods," which occur in many societies.

Another example is the distinction between a leader's election or appointment. An election has been found to give followers a great sense of responsibility and higher expectations for the leader's performance. In effect, the group gives the leader a benefit in advance by electing him or her to a position of higher status, and then the group feels a claim on the leader to return the benefit by producing favorable outcomes to the group.

2. MUTUAL INTEREST

When there is mutual interest, in most social settings one can assume that the other person understands the relevance of the reciprocity norm. This makes for a smoothing of relationships, if commonly understood. However, this need not always be the case, even with the need for interdependence. Most often, however, the concept of community of interest requires that reciprocity prevail, although it is conditional. There are variations among individuals and groups in the way in which it is applied. Although the broad culture may support the norm, its application still depends on the particular people in a given interaction.

3. INTERDEPENDENCE

Group support is closely tied to the motivation to take part in the task of a group. Whenever individuals come together to do things, they rely on one another for suitable performance. To the extent that members are rewarded by their attempts to achieve group goals, they will help work toward the goal and will be supported by the others. From a psychological standpoint, it is crucial that the individual care about what the group seeks to attain. Therefore, in joining groups, individuals are often attracted by the group's activity. Then they play a role that is rewarded by others' approval, which brings task and affiliation motives together.

Not just any source of support will influence a person's actions, however. The favorable effects of group support require two conditions: The individual must be positively motivated toward the activity, and he or she must be favorable about identification with the group members as relevant others. They must be people whose standards and support are desired—that is, a “reference group.”

It is possible for an individual to do something he or she finds personally distasteful because others whose approval is sought are doing it. However, where a choice exists, the usual inclination is to be associated with those who support activities that the individual finds satisfying.

4. SOCIAL EXCHANGE

Although stated mainly in economic terms, social exchange goes beyond the simple notion of straight profit.

Two early contributions to an understanding of social exchange derive from the 1961 work of Homans and the 1959 work of Thibaut and Kelley. Both involve certain concepts associated with a rewards–costs relationship.

Homans views social exchange as the underlying factor accounting for certain features of face-to-face interaction. He states that the rules for social interaction apply in various settings and can be understood primarily in terms of reinforcement, where the quantity and the value of an activity or a sentiment can affect the behavior of another individual. His propositions for what he calls elementary social behavior can be simply stated as follows: The more a person's activity is rewarded, the more likely the activity is performed; the more similar a present activity is to one rewarded in the past, the more it is performed; the greater the value of an activity, the more it is performed; the more rewarded an activity, the less any further unit of reward is valued; and the failure to receive an expected reward for an activity results in anger, which makes the results of aggressive behavior rewarding. In addition, he explains that a lack of reward leads to apathy, whereas too much of that reward decreases its value. Profit is defined as total rewards minus costs, with costs including values given up or forgone.

Thibaut and Kelley proposed that rewards for the parties involved are needed to maintain the interaction. In ongoing relationships, there is a trading off of rewards and costs for both parties. Thibaut and Kelley define rewards as

The pleasures, satisfactions, and gratifications the person enjoys. The provision of a means whereby a drive is reduced or a need fulfilled constitutes a reward. We assume that the amount of reward provided by any such experience can be measured and that the reward values of different modalities of gratification are reducible to a single psychological scale. (p. 12)

They define costs as

Any factors that operate to inhibit or deter the performance of a sequence of behavior. The greater the deterrence to performing a given act—the greater the inhibition the individual has to overcome—the greater the cost of the act. Thus cost is high when great physical or mental effort is required, when embarrassment or anxiety accompany the action, or when there are conflicting forces or competing response tendencies of any sort. (pp. 12–13)

In line with Homans' idea of profit as rewards minus costs, Thibaut and Kelley use the concept of comparison level. This is a standard against which the person judges

the attractiveness of the relationship with regard to whether he or she receives what is deserved, relative to his or her costs. Related to this concept is the comparison level for alternatives. It represents the reference point employed in deciding whether to remain in the interaction. It can be considered as the lowest level of reward that the individual will accept in order to continue in the relationship. It also relates to the concept of adaptation level, with respect to what one has come to expect.

The relationship of comparison level and the comparison level for alternatives can be stated simply: In general, an individual will be highly satisfied with outcomes if his or her comparison level and the comparison level for alternatives are both exceeded by actual outcomes. The opposite holds true with regard to dissatisfaction.

An injustice can also be thought of as an imbalance between an individual's rewards and costs in an activity. This is the fundamental point in Homans' concept of distributive justice. It deals with the condition in which an individual's investments are either balanced or not by his or her rewards. As previously noted, he considers profit to be rewards minus costs. Among these costs may be the investments of the individual—that is, what the individual brings to the situation from his or her background. This includes status, education, and experience, in addition to capability.

5. EQUITY AND INEQUITY

Equity is another term for fairness. An inequity is more likely to be perceived as an unfavorable comparison between one's own and others' rewards relative to costs. In the latter case, individuals will compare their rewards with others and take account of their own and the others' investments. In the workplace, these include such factors as seniority, responsibility, and productivity. Compensation is not the only element in assessing equity in the workplace. In 1983, Greenberg and Ornstein found that other variables, such as promotions, interesting work, pleasant co-workers, and increased status, contribute to the sense of equity. In 1987, Bandura more broadly asserted that goal accomplishment is a major feature of equity as well.

An earlier conception presented by Adams in 1965 defines equity as a function of the balance effected between a person's inputs and outcomes on the job. Inputs include qualifications and how hard one works

$$\frac{\text{Outcomes}_P \text{ (gains)}}{\text{Inputs}_P \text{ (costs)}} \qquad \frac{\text{Outcomes}_O \text{ (gains)}}{\text{Inputs}_O \text{ (costs)}}$$

FIGURE 1 Comparison of a person's (P) own ratio of outcomes to inputs with an other's (O) ratio. Adapted from Adams (1965).

at the job, whereas outcomes include pay, fringe benefits, status, and the intrinsic interest of the job.

In his equity theory, Adams contends that the major expectancy is that an equitable input–outcome ratio will prevail. Inequity exists for a person (P) whenever he or she perceives that the ratio of his or her own outcomes to inputs and the ratio of other's (O) outcomes to inputs are unequal. This comparison of ratios can occur when P and O are in a direct exchange relationship or when both are in an exchange relationship with a third party, such as working in the same group or organization (Fig. 1).

In any consideration of justice or injustice, and equity or inequity, there is likely to be a difference of view. It is to be expected that P's perception of his or her own investments, costs, and rewards may not be the same as O's perceptions of them. However, it is not the actual fact nor the other person's perception that matter most in determining action. It is the individual's own definition of the situation. Therefore, inequities may be perceived by individuals despite the fact that others see no inequity in their version of social reality.

6. BARGAINING AND NEGOTIATION

Fundamentally, the process of interaction has a bargaining component. Even as they compete to gain desired outcomes, there are advantages to be achieved as P and O cooperate to trade rewards. Cooperation within competition is facilitated by negotiation. It remains the one method most widely used, and it is seen routinely in labor management relations, in which there may be awkwardness associated with power differences. To be effective, rules are necessary for an agreed procedural structure that depersonalizes the conflict. These help to avoid pitfalls such as perceiving the conflict as a zero-sum game, in which there must be a winner and a loser. Instead of accommodation, there may be an adherence to fixed positions, which may make both parties losers.

There is also the prospect of misunderstandings that derail progress. A basic feature of successful negotiation is to understand the opponent's position, which is helped by having open communication with the mediation of an outsider. A mediator can be useful for encouraging such things as limits on hostile language. This risk occurs when leaders desire to solidify their support base, with costs to the resolution of the conflict. Osgood's 1962 GRIT (Graduated Reciprocation in Tension-Reduction) grew out of his concern with the threat posed by the arms buildup in the Cold War between the United States and the Soviet Union. The strategy involves making concessions, usually small at first, to set in motion a process of reciprocation by the other side, ultimately leading to tension reduction of wider scope. At the negative extreme, in 1962 Tuchman described the misunderstandings and downward spiral that led to the arms buildup, always said to be "defensive," prior to the onset of World War I.

7. IMPLICATIONS

Running through these points is the norm of reciprocating, whether positively or negatively. The strategy utilized is dependent on the circumstances and the goals sought, including power relationships. If there are not mutual benefits in a solution, then the likelihood of a successful outcome is remote. Therefore, the norm is important, but it is sometimes not as important as the attitudes and motives of the parties involved.

recruiting methods Approaches such as job fairs and mailing lists used by employers to reach potential applicants for the purpose of informing them of job openings.

Research has shown that various recruitment decisions can have a significant impact on such factors as the diversity of job applicants and whether they accept job offers and remain on the job for a reasonable period of time. This article addresses such important topics as deciding on recruitment objectives, choosing a recruitment method, selecting recruiters, deciding on a recruitment message, and evaluating a recruitment campaign.

GLOSSARY

applicant population The type of job candidates (e.g., retirees and former employees) an organization hopes to reach by its recruiting efforts.

applicant self-insight Refers to the extent to which a job candidate has an accurate understanding of his or her abilities, interests, etc.

employee referrals A recruitment method that involves current employees of an organization referring people they know as candidates for open positions. Frequently, an employer will offer incentives to motivate such referrals.

realistic job preview (RJP) An attempt by an employer to convey accurate information concerning a position (e.g., job duties and work hours) to job candidates. RJPs can involve a variety of different approaches (e.g., a video, a brochure, and a visit to the work site) and are designed to improve the accuracy of recruits' job expectations.

1. PROBLEMS RESULTING FROM INEFFECTIVE EMPLOYEE RECRUITMENT

The importance of effective employee recruitment has become increasingly recognized by organizations. This recognition at least partly stems from the fact that ineffective recruitment efforts (e.g., using unprofessional recruiters and presenting an overly positive view of an open position) have been linked to a number of serious problems that employers commonly face. For example, ineffective recruitment activities have been linked to (i) desirable job applicants turning down job offers; (ii) firms' Web sites being inundated

with resumes from unqualified job seekers; (iii) job advertisements resulting in applicant pools that do not reflect the demographic diversity desired; and (iv) newly hired workers, who had unrealistic job expectations, resigning after spending only a few weeks on the job. In order to understand how organizational recruitment activities are linked to these and other outcomes, several issues need to be considered, including what applicant population to target, how to reach these individuals, what recruitment message to convey, and whom to use as recruiters.

2. DECIDING ON RECRUITMENT OBJECTIVES

Prior to undertaking recruitment activities such as drafting a job advertisement or selecting individuals to serve as recruiters, it is important that an organization carefully considers its recruitment objectives. Although Breaugh reviewed numerous objectives that could be important to a given organization, this article focuses on four key questions that should be addressed in establishing recruitment objectives, and it shows how decisions concerning these objectives should guide subsequent recruitment actions. The first question an organization needs to answer is whether its focus is on filling a given position or on recruiting individuals who will progress through a series of positions over the course of a career with the organization. If the focus is on successfully filling a given position, then the employer does not need to be concerned with whether job applicants possess the talent and the motivation that would enable them to successfully perform higher level jobs.

A second important question is whether an employer prefers to fill jobs internally or externally. If the employer's focus is on recruiting from within its current workforce, it will not be difficult for the organization to reach the targeted population of potential recruits, nor is it likely that the firm will need to communicate information concerning organizationwide characteristics such as its values. In contrast, if an organization seeks to target applicants who do not currently work for it, more consideration will need to be given to how to reach desirable job candidates and what information to convey about the organization.

A third question meriting consideration in establishing recruitment objectives is whether an employer wants to attract a large number of applications or

fewer applications from a select group of individuals who possess certain job-related attributes. If the former is the case, then posting a job advertisement that lists few applicant requirements for hiring on a well-known job board may be an appropriate strategy. In contrast, if an employer only wants to attract applications from a limited number of individuals who meet restrictive requirements such as expertise in SAS programming, then a different recruitment approach (e.g., a direct mail campaign) may be appropriate.

A fourth question that merits consideration is whether demographic diversity is important. To the extent that it is, an employer would be wise to incorporate certain steps into its recruitment plan. Such steps might include recruiting at colleges with diverse student bodies, having a diverse group of recruiters, and including pictures of minorities and women in recruitment brochures. Having given serious consideration to these four questions should enable an employer to more precisely define the applicant population it is interested in reaching.

3. RECRUITMENT STRATEGY DEVELOPMENT

Having established the types of individuals it seeks to attract (e.g., persons with experience working in a team or retirees who may be interested in working part-time), an organization needs to consider what method(s) to use to reach them. If an employer decides to target individuals who currently work for it, the organization may decide to post job announcements on the company's Web site. Alternatively, in order to limit the number of applications received, some employers rely on supervisors to nominate subordinates who are seen as both qualified and interested in a job opening.

To reach individuals who do not work for an organization, organizations have utilized several different recruitment methods, including newspaper advertisements, employment agencies, school placement offices, job boards, employee referrals, radio ads, direct mail campaigns, and job fairs. Although research has not been entirely consistent, research reviewed by Barber showed that employee referrals are frequently among the best recruitment methods. The benefits associated with employee referrals may be due to current employees (i) providing potential referrals with a realistic preview of what a job involves, (ii) prescreening potential referrals so that only individuals who are seen as

qualified and motivated are referred, and (iii) helping the referred person succeed once on the job. A potential drawback of using an employee referral program is that it may not result in a diverse pool of applicants if the current workforce lacks diversity.

Some employers are able to generate job candidates without any formal recruitment activities. For example, some individuals apply for jobs (i.e., mail a resume) without knowing whether a job opening exists. As noted by Breaugh and Starke, such direct applicants are more likely if an organization is highly visible and has a positive reputation. A number of highly visible organizations, such as Southwest Airlines, have relied heavily on their Web sites to generate job applications. Little research exists on whether Web sites generate more desirable applicants than more traditional recruitment methods.

A number of recruitment methods, such as job fairs and the use of college placement offices, involve the use of corporate recruiters. As discussed by Rynes and Cable, recruiters play an important role because they convey information concerning a job opening, they prescreen job candidates, and they answer questions from prospective employees. The selection and training of recruiters are also important because job candidates may interpret how recruiters treat them as a signal of how the organization treats its employees. Given the significance of their role, it is not surprising that considerable research on recruiters has been conducted. Although results are not consistent, in general, job candidates rate recruiters as being more effective to the extent that they are interpersonally skilled and informative. Research has shown that although training can have a modest effect on the performance of recruiters, the selection of recruiters is likely to have a greater impact. In particular, an employer should give consideration to whether a staff recruiter is used as opposed to using someone from the department with the job opening. The advantage of using a staff recruiter is that the person may be better able to answer questions about such issues as employee benefits and may be less likely to ask a candidate inappropriate questions. However, utilizing someone from the department in which the job opening exists (e.g., the supervisor to whom the person would report or a prospective coworker) offers important advantages. For example, in general, someone from the department will be seen as more informative concerning job duties, work group climate, etc. In addition, someone from the department, especially a potential coworker, is likely to be seen as a credible source of information. Given that many job seekers are

cautious about accepting at face value all the information presented during the recruitment process, such credibility is important. Given their relative strengths and weaknesses, during the course of the recruitment process many employers use a team of recruiters composed of both line and staff recruiters. Regardless of the type of recruiter chosen, this decision should not be made lightly. Research by Rynes *et al.* showed that unprofessional treatment by a recruiter, such as failing to return phone calls or condescending behavior, can cause job candidates to withdraw as candidates.

After deciding on one or more recruitment methods to use to reach prospective employees, an organization needs to consider the information it wants to communicate to these individuals. In considering its message, one question an employer must address is whether it is interested in presenting a realistic view of a position or an overly positive one. A quick scan of the help wanted advertisements in a newspaper shows that many organizations convey an exaggerated view (e.g., can the pay for every job be competitive?). An employer should provide a realistic view of what a job involves. Presenting an exaggerated view of a position is unethical. Furthermore, it is likely to result in individuals accepting jobs that they quickly come to dislike. Wanous showed that such dissatisfaction is associated with a high rate of turnover for new employees. Such turnover can be quite expensive, especially if an employer has invested considerable training in the new employees or has reimbursed them for relocation expenses.

In phrasing a recruitment message, an employer should consider other factors in addition to realism. A key concern should be whether recruitment communications convey information that is considered important by recruits for making job choice decisions. Research has shown that most job candidates perceive information concerning the job (e.g., job duties and remuneration), the work group (e.g., coworker competence and whether interactions are cooperative or competitive), the supervisor (e.g., managerial style and technical competence), and the organization (e.g., corporate culture and economic conditions) as being particularly important. In addressing such topics, research has shown that recruits desire information that is sufficiently specific to allow for an informed job choice to be made. Thus, it is not sufficient for an organization to transmit information concerning how supervisors in general act or how coworkers in general relate. Instead, such information needs to be tied to a given job opening. Unfortunately, the recruitment messages sent by many organizations

fail to include the level of information specificity sought by many job candidates.

4. CONSIDERING THE JOB APPLICANT'S PERSPECTIVE

Filling an open position requires the agreement of both the hiring organization and the job candidate. Therefore, it is important that an organization consider the job applicant's perspective in planning the recruitment process. Because the types of information that many job applicants desire were discussed previously, it suffices to state here that an organization should do whatever it can to present such information in a credible manner. Off-the-record conversations with co-workers can be a particularly effective vehicle for conveying information that may be sensitive in nature (Does this organization truly have a merit-based reward system? Does the supervisor really involve employees in decision-making?). Such conversations are also effective for addressing the unique information needs of some job applicants, such as how easily a position will accommodate the observance of religious holidays.

If an organization seeks to hire new employees for whom there is good person–job fit, it is not sufficient for the organization to provide realistic and detailed information about important aspects of the position being filled. It also needs to be concerned with whether the job candidate can make sense of the information it conveys. For example, new employees may have been told that a job requires 60-hour workweeks or dealing with angry customers. However, if they lack relevant experience, some new hires may not be capable of fully grasping the meaning of the information conveyed by the organization. If an organization believes that inexperienced individuals will not be able to fully comprehend what a job involves, it may want to target individuals who can better appreciate what the job being filled demands. For example, individuals with prior experience working long hours should be better able to comprehend how a long workweek can interfere with family responsibilities. In order to maximize person–job fit, organizations should consider recruiting former employees whose prior performance with them was viewed favorably. If successfully recruited, former employees should have an excellent understanding of job and organizational attributes and thus have realistic job expectations.

5. ASSESSING RECRUITMENT RESULTS

After an organization has completed its recruitment activities for filling one or more job openings, it is important for it to evaluate the effectiveness of these activities. For example, an employer could compare recruiters, colleges visited, or advertising outlets (e.g., newspaper versus radio) in terms of the number of job applicants generated, the number of individuals hired, the cost per hire, the diversity of those hired, and/or the first-year performance of those hired. Unless an assessment of recruitment activities is conducted, an organization may not discover that certain activities have more value than others. For example, although employers frequently rely on job advertisements as a method for generating job candidates, research has shown that the use of employee referrals is a better method for generating employees who perform well and who remain on the job for a longer period of time. A particularly important source of information for assessing the effectiveness of recruitment actions can be newly hired employees and job applicants who were not hired. These individuals can provide insight into how they were treated during various stages of the recruitment process (e.g., whether phone calls were returned in a timely manner and whether a site visit was professionally conducted). Such information should provide those responsible for recruitment decision making with valuable ideas for improving the effectiveness of future recruitment efforts.

6. CONCLUSION

In staffing an organization, attention is frequently given to the soundness of a firm's selection system. Although using valid selection devices is clearly important, it is increasingly being recognized that poor recruitment activities can result in a pool of job applicants who lack the ability and/or motivation to successfully fill job openings. Such an applicant pool can restrict the value of even the best selection system. This article addressed a number of issues that can have a major impact on the overall success of a recruitment campaign. Specifically, it discussed key issues that an organization should consider in deciding whom to target for recruitment, how to reach them, what recruitment message to convey, and whom to use as recruiters. Thoughtful consideration

of these issues is likely to result in a more desirable applicant pool (e.g., more diverse, more qualified, and more interested) and in a more desirable group of new employees (e.g., higher job satisfaction and longer tenure).

 7. Summary
- Further Reading

Rehabilitation counseling is a counseling profession noted for its emphasis on serving persons with various physical, intellectual, behavioral, sensory, and developmental disabilities. The profession has been characterized by its counseling model and its responsiveness to state and federal mandates to coordinate the delivery of services to eligible individuals with disabling conditions to promote their employability and independence.

GLOSSARY

vocational evaluation A systematic and comprehensive assessment process to identify an individual's vocational potential; the evaluation may include, but is not limited to, self-report and observational assessment of a person's vocational and career interests, values, temperaments, work-related behaviors, aptitudes, skills, physical capacities, learning style, and training needs.

vocational rehabilitation The provision of services to enhance the employability and functional independence of a person who has been adversely impaired in these roles by a physical, intellectual, sensory, behavioral, intellectual, or developmental disability.

work adjustment The degree of congruence and correspondence between an individual's values and behavior and the behavior that is valued, accepted, and expected in a work environment.

1. INTRODUCTION

Rehabilitation counseling is a relatively young profession. In contrast to most human service professions, the birth and development of rehabilitation counseling are rooted in federal legislation. The genesis of the profession can be traced to the early 20th century in the United States. The establishment of the profession was precipitated by a number of social factors, the most fundamental of which was the need to provide rehabilitation services for an increasing number of people who were unable to work due to physical disabilities that were often incurred in the rapidly changing workplace. Although there was a need to provide services for these persons, there was no existing professional field available. Thus, the federal government mandated that the profession provide expert coordination and

administration of necessary services to citizens who were eligible for assistance.

2. DEFINING ROLES AND FUNCTIONS

Rehabilitation counseling initially focused on helping clients to become employable so that they could return to the workforce. This goal has expanded over the years to subsume a systematic process that assists persons with various disabilities to achieve their personal, career, and independent living goals in the most integrated settings possible. The rehabilitation counseling process involves communication, goal setting, and beneficial growth or change through self-advocacy, psychological, vocational, social, and behavioral interventions. The specific techniques and competencies used in rehabilitation counseling may include, but are not limited to, the following:

- Assessment, vocational evaluation, and appraisal
- Diagnosis and treatment planning
- Career (vocational) counseling
- Individual and group counseling treatment interventions focused on facilitating adjustment to the medical and psychosocial impacts of disability
- Case management, referral, and service coordination
- Program evaluation and research
- Interventions to remove environmental, employment, and attitudinal barriers as well as to enhance work adjustment
- Knowledge of disability-related legislation and regulations and of community resources
- Consultation services among multiple parties and regulatory systems
- Expert witness testimony
- Job analysis and modification, job development, and placement services, including assistance with employment and job accommodations
- The provision of consultation about access to relevant rehabilitation technologies

Currently, most rehabilitation counselors possess a master's degree in rehabilitation counseling (or in a related field) and are credentialed. The types of professional credentials available to a rehabilitation counselor fall into three general categories:

- Registration
- Licensure
- Certification

3. HISTORY AND EVOLUTION

Vocational rehabilitation (VR) emerged during the early years of the 20th century as federal policy-makers wrestled with the consequences of an increasingly industrialized and urban economy as well as the ravages of international conflict. The Smith–Hughes Act of 1917 provided money to states on a matching basis to establish vocational education programs and also created the Federal Board of Vocational Education to administer VR programs. Relevant training and rehabilitation programs were provided under this legislation to meet current workforce demands. Parenthetically, this act established the first rehabilitation education programs within colleges of education in universities; rehabilitation counseling traditionally has been housed within this academic environment. The Soldier's Act of 1918 created VR programs for returning soldiers with disabilities, and the Federal Board of Vocational Education administered these programs.

Training programs were established in academic institutions, and considerable debate concerning the appropriate “intellectual home” for rehabilitation counseling ensued. One contingent viewed rehabilitation counseling within the larger domain of counseling psychology because rehabilitation counseling was perceived as a logical extension of the field's emphasis on vocational counseling, career development, and recognition of everyday people experiencing transitional stress in personal and social roles. Over time, however, critics expressed disapproval of “psychologized” coursework in graduate programs and argued that esoteric theories were of little use in the work setting. In addition, the multidisciplinary nature of VR, generally had little tolerance for theories that could not be easily conveyed or understood across disciplines. A greater emphasis on labor market issues, job assessment, work adjustment, and job placement was encouraged. The premium on practitioner competencies and issues permeates graduate training in rehabilitation counseling. Although coursework in areas considered “core” to psychology training may be offered, these are usually confined to areas of applied interest (e.g., assessment) and others may be permitted as electives (e.g., personality, abnormal behavior). In some institutions, rehabilitation counseling students may require the permission of the psychology department to enroll in any graduate psychology course.

4. CRITICAL LEGISLATION

Subsequent legislation increased the role of the federal government in preparing persons with disabilities for employment. For example, the Smith–Fess Act of 1920 increased the amount of money provided to state programs, and the 1935 Federal Social Security Act made the federal–state VR programs permanent. Other legislation extended VR services to blind individuals (the Randolph–Shepard Act of 1936) and to persons with mental retardation or psychiatric disabilities (the Barden–Lafollette Act of 1943).

The Vocational Rehabilitation Act of 1954 ushered in the “golden age” of rehabilitation and essentially created the rehabilitation counseling profession. It also dictated the model for systematically providing VR services and provided money to expand facilities. Services were also expanded to persons with substance abuse problems, public offenders, and the socially disadvantaged. The Rehabilitation Act of 1973 made services to persons with the most severe disabilities a top priority for state programs. It instituted the use of individualized written plans for clients and welcomed consumer input into the VR process. It also advanced a civil rights agenda for persons with disabilities by promoting access, prohibiting architectural barriers, and prohibiting discrimination in educational institutions and in the workplace.

Contemporary legislation has had a dramatic impact on rehabilitation counseling in terms of training and opportunities. The passage of the Americans with Disabilities Act in 1990 expanded the civil rights of persons with disabilities and reinforced the consultative role of rehabilitation counselors. However, a series of legislative acts appear to blur the support and role of rehabilitation counseling and its traditional role in the VR process. Specifically, the Workforce Investment Act in 1998 and the Ticket-to-Work/Work Incentive Improvement Act in 1999 were passed in part to circumvent perceived “red tape” that was associated with the traditional VR process as well as to encourage greater client input and options for rehabilitative services. These policies provide incentives for other entities in the private sector to offer and provide competitive rehabilitation services to consumers.

5. SETTINGS

From its inception, rehabilitation counseling has been virtually synonymous with state VR agencies, as

originally mandated by federal legislation. This association continues to the current time. Traditionally, rehabilitation counselors have also found employment with Veterans Administration agencies, state employment agencies, state health departments, hospitals, mental health centers, prisons and correctional facilities, independent living centers, educational institutions (and training programs for students with disabilities), job training centers, social security offices, and workers’ compensation programs. For decades, rehabilitation counselors were considered among the chief advocates for persons with disabilities and were seen as experts concerning these persons’ rehabilitation and integration into society. Many rehabilitation counselors actively participated in the independent living movement for persons with disabilities.

However, changes in legislation and increases in the incidence of chronic disease and disability over the past three decades opened new opportunities in private business, substance abuse treatment programs, and employee assistance programs. Many rehabilitation counselors obtained positions in health care management programs, with insurance companies, and with third-party payers as case management specialists. Those in private practice often provide expert testimony, consultation, life planning services (for workers who incur lifelong severe disabilities), and vocational evaluation for legal firms, health care systems, businesses, and other agencies.

Individuals who possess a master’s degree in rehabilitation counseling may pursue licensure as licensed professional counselors. With this licensure, they may be able to provide a wide range of mental health services for reimbursement. Most doctoral-level rehabilitation counselors retain their status as certified rehabilitation counselors. Others may qualify for psychological licensure in some states (depending on the graduate program content and the accreditation status of the department conferring the doctorate). These individuals may identify with rehabilitation psychology and pursue the diplomate in rehabilitation psychology offered under the auspices of the American Board of Professional Psychology. Doctoral-level rehabilitation counselors also assume academic positions where they are distinguished by their research, service, and training programs. Most rehabilitation counseling training programs are housed in colleges of education, a few are found in colleges associated with allied health professions, and some are found in psychology departments.

6. RESEARCH BASE

As a multidisciplinary enterprise that is constantly responsive and sensitive to the vagaries of federal legislation, fluctuating state budgets, and labor market trends, the VR literature has been criticized in academic circles for lacking theory-driven research (undermining its scholarly relevance to other fields) and an archival base (in which current knowledge builds on, advances, and refines prior knowledge). In a seminal text, Wright argued in 1980 that rehabilitation counseling has an established literature base that has steadily advanced the knowledge and sophistication of the profession. The peer-reviewed outlets associated with the field showcase a great diversity of topics, methodological rigor, and practitioner concerns. The *Journal of Rehabilitation* and the *Journal of Applied Rehabilitation Counseling* (both affiliated with the National Rehabilitation Association) have a clear emphasis on practitioner interests. The *Rehabilitation Counseling Bulletin* (affiliated with the American Rehabilitation Counseling Association) publishes studies of theoretical and practical interest and has a reputation for high standards in research design and methodology. The *Vocational Evaluation and Work Adjustment Bulletin* historically has focused on psychometric and practice issues germane to vocational assessment. *Rehabilitation Psychology* (affiliated with the American Psychological Association) publishes some work relevant to rehabilitation counseling. *Disability and Society* features work germane to rehabilitation counselors from a perspective associated with academic programs in disability studies and proponents of independent living programs for persons with disabilities. Other relevant outlets include the *Journal of Vocational Rehabilitation*, *Journal of Rehabilitation Administration*, and *Rehabilitation Education*.

The rehabilitation counseling literature has attended to the competencies and issues that face the field, including training, credentialing, and roles and functions. In addition, this literature has valued studies that address practice concerns associated with measurement, program evaluation, specific techniques and their application, and studies of psychosocial adjustment and vocational outcomes of clients with specific disability conditions. Rehabilitation counseling research often scrutinizes vocational evaluation practices and effectiveness as well as program and outcome evaluations of state VR programs. Recent research has

attended to multicultural issues and practice implications of recent legislation. Many rehabilitation counselor researchers have considerable expertise in psychometric theory because the field has systematically evaluated the psychometric properties and appropriateness of psychological measures for use with persons with various physical, sensory, and intellectual disabilities.

A perusal of citation behaviors in available search engines suggests that research published in the outlets traditionally associated with rehabilitation counseling is somewhat insular because relatively few outlets outside of the field cite work published in these journals. A notable exception can be found in the contributions that rehabilitation counseling has made in the area of job placement. The practice of supported employment, which developed as a placement technique for persons with severe disabilities, has emerged as an effective placement strategy in several published clinical trials. The approach requires job specialists to observe and correct problematic client behaviors in the workplace over staggered and intermittent periods of time to promote work adjustment and model appropriate work behaviors. The practice has demonstrated efficacy in studies of persons with traumatic brain injuries, mental retardation, severe mental disorders, and sensory disabilities. Clinical trials supporting this technique have been published in mainstream (and influential) psychology and psychiatric journals.

7. SUMMARY

Rehabilitation counseling has evolved in response to federal legislation and labor market trends. Rehabilitation counselors in state agencies have been mandated to prioritize services for eligible clients with the most severe disabilities. During the time frame in which this mandate has been active, available data indicate that competitive employment placements increased substantially despite declining state budgets and increased expense for these clients. The profession will likely face competition from other professions that respond to recent legislation and provide VR services and placement to persons with disabilities, but it is probable that the field will continue its association with state agencies and thrive in case management roles in the private sector. Rehabilitation counseling has imbued its practitioners with unique skills in case management, job placement, and vocational evaluation,

and these skills serve the profession well in the public and private sector. Those with advanced training will also provide invaluable service in the program evaluation, training, and consultation that ensure the future of the profession.

GLOSSARY

caregiver A person who takes care of patients with end-stage cancer or Alzheimer's disease; often a relative.

positive psychology Psychological research on positive emotions, such as joy, wonder, happiness, satisfaction, meaning, purpose, and hope.

In the past, the predominant view was that religion is inherently unhealthy. Recent research has begun to convincingly challenge this assumption. In hundreds of studies, religion has been associated with positive mental and physical health outcomes and with positive emotions. Although most studies have been cross-sectional, some have been longitudinal and several randomized clinical trials have also been completed. Despite these provocative associations, it is important to keep in mind several caveats. There may be significant scientific and theological concerns surrounding the

prescription of religion and the empirical investigation of religion's effects on health. Moreover, not all religions may relate to health in the same ways, and in some cases religion may have decidedly negative consequences for health. Psychiatric and psychological training is beginning to emphasize a need to address religious and spiritual issues as part of clinical practice.

I. INTRODUCTION

For quite some time, many influential mental health professionals conceptualized religion and mental health as being diametrically opposed, and only within the past 10 years have such notions been challenged. Religion and spirituality have many components that are of potential relevance to mental health, including religious attendance, private religious activities (e.g., prayer and reading of holy scriptures), a feeling of connection or relationship with God or a higher power, religious beliefs, and religious coping. In addition, religion and spirituality may cause mental health via healthy lifestyles and behaviors and the promotion of social support. Some writers distinguish religion from spirituality by claiming religion is more organized, whereas spirituality has more to do with one's personal relationship with God or a higher power.

In 2001, Koenig *et al.* performed a comprehensive, systematic review of research on religion and mental health and identified 724 quantitative studies that

examined this association. Many different populations—from young to old, from sick to healthy—have been examined. Studies have been conducted in almost every area of the world, including the United States, Canada, England, continental Europe, Australia, China, Malaysia, Egypt, India, and Israel. The majority of studies (478; 66%) reported statistically significant relationships between religious involvement and better mental health, greater social support, or less substance abuse. Most of the studies were cross-sectional, but a number have been longitudinal and there are several clinical trials that have examined the effects of religious interventions on mental health. Longitudinal studies have also shown faster recovery from depression in community samples and more rapid adaptation to stressful life circumstances in religious caregivers. Several clinical trials examining the effects of a religious-based psychotherapy on treatment outcomes in depression, bereavement, and anxiety have likewise documented benefits for both Christian and Muslim patients.

2. BENEFITS TO MENTAL HEALTH

Mental health involves not only the freedom from mental disorders, such as depression, anxiety, psychotic conditions, or personality problems, but also the regular experience of positive emotions, such as joy, wonder, happiness, satisfaction, meaning, purpose, and hope. Relatively little research has been done on positive emotions and mental states. This is changing with the growth in “positive psychology,” which has been led by Martin Seligman, former president of the American Psychological Association. Religiousness appears to be related to positive emotions, where the relationships may be even stronger and may have implications for the prevention of mental disorder. Of the approximately 100 studies conducted during the past century on religiousness and well-being, hope, and optimism, nearly 80% have found that religious persons experience significantly more positive emotions compared to those who are less religious. Similarly, in a recent study, measures of religious belief, coping, and spirituality were associated even more strongly than was social support with measures of life satisfaction among Protestants and Catholics, which is consistent with a role of religion-influenced positive emotion in well-being.

3. APPLICATIONS OF RELIGION

It is important to emphasize that clinical applications of religion must be theologically and ethically informed. For example, it is not only impractical but also may be theologically and ethically inadvisable to prescribe religious behaviors on the part of patients, for a clinician to impose his or her religious beliefs onto patients, or to create an atmosphere of intolerance for patients of diverse faith communities.

4. CAVEATS TO RESEARCHERS

From a research perspective, it is crucial to be theologically savvy. One aspect of this is to recognize that not all religions are the same, and that people from different faith communities may differ in psychologically relevant ways. One example is the salience of certain mental states (e.g., faith) to Jews and Protestants. For example, in the religion/well-being studies mentioned previously, social support from religious sources correlated modestly with well-being for Jews, Protestants, and Catholics. However, religious belief, spirituality, and religious coping were much more related to well-being among Catholics and Protestants than among Jews.

5. TESTING PRAYER?

Another aspect of being theologically informed in examining religion and mental health connections has been raised in the context of research on the effects on health of distant intercessory prayer. Chibnall *et al.* argued that such research may border on heresy because it tests or challenges God, that operational definitions of prayer may fly in the face of theological definitions, and that results are incredibly difficult to interpret. For example, do positive effects of prayer on health prove the existence of God? What do negative effects indicate? What if prayers by members of one faith community turn out to be more efficacious than prayers by those of another faith community?

6. NEGATIVE IMPLICATIONS OF RELIGION

Religious beliefs or activities may sometimes be associated with worse mental health or neurotic behavior.

Most clinicians today know from experience that religion may be utilized in an unhealthy manner or manipulated to serve defensive functions that ultimately impair mental health and prevent healthy growth. For example, religious concerns are common among people with obsessive–compulsive disorders and even people in nonclinical samples, including fears of sin, fears of God, and viewing the moral status of thoughts to be equal to that of actions. Vivid examples can be seen when individual cases are examined: the rigid fundamentalist; the obsessive–compulsive who attends church daily and prays 10 or 20 times per day; the psychotic patient who believes he is God, Jesus, or the devil; and the severely depressed person who is overwhelmed with guilt, believing that she has committed the unpardonable sin. This does not necessarily mean that religion promotes mental ill health, since ill people often turn to religion for comfort.

7. TRAINING COUNSELORS AND CONSULTANTS

Training programs in both psychiatry and psychology are beginning to emphasize the need for mental health professionals to address religious or spiritual issues as part of routine mental health care. This is now a requirement for accreditation of psychiatric residency programs by the American College for Graduate Medical Education (1994), which has mandated that training programs include didactic training in the “presentation of the biological, psychological, sociocultural, economic, ethnic, gender, religious/spiritual, sexual orientation and family factors that significantly influence physical and psychological development in infancy, childhood, adolescence, and adulthood” (pp. 11–12). Training programs in psychology are also required to ensure that the curriculum “includes exposure to theoretical and empirical knowledge bases relevant to the role of cultural and individual diversity,” and religion is included in the definition of cultural and individual diversity.

As a result of increased training and exposure to research on the relationship between religion and health, there appears to be more widespread integration of religion into clinical practice, with therapists now utilizing patients’ religious beliefs and social connections within the faith community to facilitate healing and recovery. Not only is the area of pastoral counseling growing rapidly but also there are indications that

secular therapists are beginning to address spiritual issues when treating patients. Unfortunately, systematic research documenting when, where, and how frequent such integration is taking place has not been done.

8. CONCLUSION

Religion and mental health appear to be related—either for better or for worse. Clinicians need to be aware of the research that has been done in this area and understand how to both sensibly and sensitively apply this knowledge to clinical practice.

GLOSSARY

actual–aspirational gap theory A model that postulates that people perceive salient attributes of their physical environment and evaluate them based on certain standards of comparison, especially standards defined by what people believe they may reasonably aspire to.

appropriation of place The process by which people become more closely associated with or involved in places through taking possession, sharing and communicating social meanings, and manipulating and personalizing the environment.

cognitive dissonance A state of tension or discomfort resulting from inconsistency among beliefs or between one's beliefs and one's actions.

housing bundle The set of physical (e.g., dwelling size, building type, and neighborhood facilities) and nonphysical attributes (e.g., tenure) defining a housing alternative.

life values Desirable end states that the individual strives to attain in his or her life.

person–environment fit theory A model that assumes that congruence between personal preferences or needs and environmental press fosters environmental satisfaction and psychological well-being.

place attachment An affective bond between an individual and a particular place not interchangeable with another with the same functional quality.

place identity All aspects of self-identity having place-related implications.

proactive behavior Acting in advance to prevent potential stressors and to promote personal growth.

settlement identity Pattern of cognitions, feelings, behavioral tendencies, and skills that relate the identity of a person to a type of settlement and provide dispositions for future engagement with that type of settlement.

To what extent do places where people live meet their needs and desires? Family life and social life are changing dramatically in many areas of the world. How are these changes reflected in the meaning people attribute to their residence and the way they assess it? During the past few decades, researchers from different disciplines have addressed these issues from different perspectives, sharing the assumption that the quality of residential environment plays a central role in the global quality of life.

1. THEORIES AND CONCEPTS

What is the residential environment? As an environmental domain, the residential environment is usually

defined in contrast to other environmental domains, such as the working environment and the public environment. In both cases, the reference is to a concept of residence that is private, based on the model that has evolved in Western societies since the industrial revolution.

However, the home/work contrast has been questioned in the Western world both from a feminist perspective and in relation to the advent of telework, which has focused attention on a phenomenon—home-based work—that has in fact always existed but is currently growing.

Regarding the public/private contrast, cross-cultural research has revealed that the boundaries between the two spheres can be very fluid and do not necessarily coincide with the domestic confines. Institutional residences, such as student dormitories or nursing homes, can hardly be considered private environments.

Finally, it should be kept in mind that the residential environment has no definable spatial boundaries. One can approach residential preference at the level of room and dwelling unit or include the immediate surroundings, the neighborhood, or even the larger community. The term housing bundle, used to indicate the pattern of attributes defining a housing alternative, includes items pertaining to different scale units (i.e., from both the micro- and the macroenvironment). Research has shown that for different groups of people, salient environmental units may be different; furthermore, when assessing housing bundles, including both the dwelling unit and the neighborhood dimension, people modify the importance assigned to the attributes of housing or neighborhood when evaluated in isolation.

This article focuses on the domestic environment. Aspects related to neighborhood satisfaction and preferences are reviewed elsewhere in this encyclopedia and will only be mentioned here in reference to the location of the dwelling unit.

1.1. The Meaning of Residential Environment and Home Attachment

In the study of residential environment, a distinction is regularly made between house and home. A house (or apartment) is defined by its physical structure, and a home is defined by a set of meanings. Research on housing is focused on the spatial and behavioral aspects of living, whereas that on the home deals with the symbolic and emotional meaning of the living

experience. The term dwelling has been put forward as a link between house and home: Dwelling means the process by which a physical entity takes on psychological, symbolic, and social meaning, transforming it into a home.

Many psychological and sociocultural dimensions have been identified to distinguish between home and nonhome and to grasp personal differences in the home meaning: security and control, reflection of one's ideas and values, acting upon and modifying, permanence and continuity, place for relationships with family and friends, center of activity, refuge from the outside world, indicator of personal status, material or physical structure, and a place to own.

A comparison of home and nonhome reveals that the meanings attributed to the former generally have a positive connotation, whereas those associated with the latter are generally negative in physical as well as social or personal terms. Recently, there has been an increasing focus on the negative aspects of home experience, viewed, for example, as a constraint (for the old or the unemployed) or as a place of possible violence or oppression, particularly for women and children. In addition, extending analysis of the meaning of home to different cultures, other meanings emerge, such as religious meanings as evidenced, for example, by the beliefs of Hindu and Muslim women.

To characterize the variety of representations and use of space in homes in different cultures, and also the changes that occur in the same culture over time, Altman and colleagues adopted a dialectic approach in which the sociopsychological meaning of the home is given by a limited number of bipolar dimensions that characterize the individual's relationship with society, such as identity/communality and accessibility/inaccessibility (or openness/closedness). In relation to preferences, it can therefore be said that cultural and individual differences are represented by the changing balance in the relative strength of the oppositional poles that define each dimension.

Many researchers have argued that what defines the very nature and essence of home, as distinguished from house, is the emotional relationship with the place. Based on earlier theoretical work on place and home by phenomenologists and humanistic geographers, a growing body of psychological literature has been devoted to the study of affective bonds that people develop with places. The concept used in this context is place attachment. Although it is argued that people may develop feelings of attachment to places of different spatial scale—residence, neighborhood, city,

region, country, etc.—and to a variety of types of setting, from the work environment to natural settings, empirical research in this area has focused on residential settings. Although from a spatial standpoint environmental units are “nested” within each other, to be attached to one’s city does not necessarily imply being attached to one’s neighborhood, house, or apartment: The degree of attachment to different environmental units varies in relation to sociocultural and demographic variables, such as social position, age, and gender.

Attachment has been considered in relation to residential satisfaction—even though the direction of the relationship is not clear (e.g., is one more satisfied because one is more attached, or is one more attached because one is more satisfied?)—to residential mobility, and to residential choices. With respect to satisfaction, attachment represents a comprehensive measure, including even behavioral and emotional aspects that go beyond a mere affective response. In fact, what qualifies attachment is not the positive valence of affects but the fact that it is perceived as a bond, with an enduring quality, directed toward a specific target, not interchangeable with any other with the same functional quality. Consequences of attachment have been postulated at the level of social involvement and mobility and at the level of well-being and mental health.

Moreover, attachment is not necessarily positive; it can represent a source of individual hardship or be the result of conformist attitudes or social rejection. It has also been suggested that place attachment develops and supports place identity; that even in mobile countries such as the United States, the majority of people form affective bonds with places; and that changes of place consistent with changes occurring in their needs and identity during their lifetime may actually favor rather than hinder the formation of affective bonds.

1.2. Preferences, Satisfaction, and Housing Choices

What kind of residential environment is good for what kind of person? Environmental psychologists have tried to answer this fundamental question by studying residential satisfaction and preferences. Although the terms satisfaction and preferences are often used interchangeably to indicate what people like, they are two distinct concepts. Both have to do with an assessment, but in the former case the fulfillment of needs is evaluated, whereas in the latter case the fulfillment of

desires is evaluated. Furthermore, although satisfaction is generally measured in relation to the actual environment, preferences can also refer to an ideal environment (i.e., not bound by the limitations of the individual or the constraints of the market). Finally, strictly speaking, preferences imply a choice among alternatives.

Preferences and satisfaction have been put in direct relation in different models of residential satisfaction, such as the actual–aspirational gap theory or the person–environment fit theory. Both models postulate that satisfaction derives from the perceived congruence between personal preferences or aspirations (which are in turn influenced by the personal characteristics of residents) and the objective and subjective characteristics of a place. Satisfaction has therefore often been used as an indirect indicator of preference. Moreover, both preferences and satisfaction have been considered to be predictive of behavioral intentions and actual behavior. However, various studies have shown a low correlation both between choices and preferences and between satisfaction and preferences. Although the explanation in the first case refers especially to external factors (e.g., market restrictions) and only to a lesser degree to other factors, such as the negotiating process with other members of the household, the discrepancy between satisfaction and preference is generally explained by psychological factors, such as processes of adaptation and assimilation or mechanisms of cognitive dissonance. Highly positive responses often reflect or even conceal an adjustment to inevitable inadequacies.

How is the meaning attributed to the environment related to the preferences toward the objective attributes of the housing? The subject has not been investigated systematically. Most research on housing preferences has simply been aimed at identifying correlations between objective environmental attributes and subjective evaluation (satisfaction and preferences) and/or personal and social influences on subjective evaluation. The two lines of research on subjective evaluation and the psychological meaning of the residential environment have largely remained separate.

A more general question is whether residential preferences and choices can be predicted from subjective beliefs about the effect of different housing alternatives on the attainment of life values (e.g., comfort, family, freedom, security, togetherness, and money). Unfortunately, limited attention has been devoted to this issue. Results provide evidence that beliefs determine the evaluations. In addition, they suggest

important differences between residential preferences and simulated choices, particularly that preferences do not completely explain choices and that choices, unlike preferences, are better explained by the overall evaluation of all attributes than the evaluation of single attributes.

1.3. Evaluative Perspectives and Aesthetic Preferences

Asking someone to express his or her preference for a residential environment is like asking whether that person would like to live in a certain place. However, preferences can be different depending on whether the place would be a permanent residence or a vacation home, a place to live alone or with the family, etc. Furthermore, as already mentioned, a residence has to satisfy a multiplicity of needs, not the least of which is aesthetic. Satisfaction of aesthetic needs is a salient component of housing satisfaction with regard to the inside, the outside, and the neighborhood, and the aesthetic qualities of the living environment are given high importance across all age and social groups. However, empirical research on preferences for interior decoration and furnishing has shown that aesthetic preferences can enter into conflict with other needs, such as comfort, practicality, or upkeep, and that some persons will change their preferences depending on whether they are asked to evaluate a house for living purposes or merely from an aesthetic standpoint.

The explanatory models adopted in environmental psychology are classified into two different traditions: (i) the experimental and motivational aesthetics of Berlyne, who traces aesthetic preferences to the physiological arousal response elicited by the "collative properties" of the objects, which include structural properties (e.g., complexity and coherence) and aspects of experience (e.g., novelty and the ability to surprise), and (ii) the sociopsychological tradition that derives preferences from the social meaning of the objects (i.e., their ability to express social identity in terms of belonging and distinction). Other theories have emphasized the cognitive components of aesthetic preference: For example, according to the schema theory, preferences relate to the discrepancy between the perceived example and the abstract schema, or prototype, representing the appropriate category. Increases in discrepancy evoke arousal and interest, but preference is highest for moderate to low discrepancies. Considerable empirical work has been carried out to study the physical and symbolic

properties of a building and what individual variables affect preferences.

1.4. Methods for Assessing Preferences

In studying preferences, a distinction widely made is that between revealed and expressed preferences: Revealed preferences are inferred from actual behavior, whereas expressed preferences are directly derived from the answers people give to questions about what they like or dislike. Although revealed preferences are used considerably in the sociological and economic domains, in psychology the second technique is preferred. Persons may be asked to provide preferential judgments that record their personal likes or dislikes concerning the places to be assessed (e.g., through adjective checklists and rating scales), or they may be asked to record comparative appraisals (i.e., evaluations made with regard to some implicit or explicit standard of comparison). Preferences can also be surveyed indirectly by measuring residential satisfaction, although attention must be paid to possible discrepancies between the two measures, as previously mentioned.

One useful approach is based on various forms of trade-off games that allow for priorities for competing interests to be identified. For example, answers to the question of how persons would change their home if they had one room more or less provide a good ranking of priorities.

Variety in methods and techniques is also determined by the presentation of the stimulus to be evaluated: verbal descriptions, drawings, photographs, scale or life-size simulations, or direct observation. There is a lack of data concerning the relative validity of different methods and measurement procedures, even though it has been shown that observers' perceptions of room size and crowding vary significantly in three different modes of environmental display (actual room, video tape, and scale model).

Finally, there is a major methodological difference between asking for the evaluation of separate housing attributes and asking for a global evaluation of different housing alternatives. Adoption of one or the other method is of considerable theoretical importance. In the former case, it is assumed that the preference for a particular housing alternative is determined by the sum of the evaluations of its attributes, whereas in the latter case emphasis is placed on the holistic

dimension of the evaluation, hence the preference for a single attribute depends on the other attributes with which it is associated.

2. HOUSING ATTRIBUTES AND PREFERENCES

What are the objective qualities that make one residence preferable over another? The question has been dealt with in a variety of ways, by a number of disciplines, and in the theoretical and applied spheres, ranging from market research to public agencies responsible for housing policies. Considered here are selected aspects that best exemplify the psychological approach at three environmental levels: domestic interior, architectural style, and housing location.

2.1. Interior Arrangement and Decoration

A house becomes a home through a process of “appropriation,” which largely consists of choosing and changing the functional organization of space, furniture, and decoration—in other words, by personalizing it. A place that can be personalized becomes a symbolic mirror of certain aspects of the personality of the person residing in that place. It has been shown that people can derive hypotheses regarding the social and personal aspects of the inhabitants from photographs of their living rooms, and that observers’ inferences on the personality and lifestyle of the homeowners correspond significantly to their self-concept.

In a survey of all members of 80 families in Chicago, valued and cherished objects in the home were found to have different meanings based on age and gender. Women and older adults tended to value them as symbols of personal relationships and family ties. Younger people and men, on the other hand, were more utilitarian.

Studies carried out in Italy and France to identify the descriptive dimensions of the physical environment that best differentiate interior decorating choices found that in addition to the kind and style of furniture (modern vs old-fashioned, rich vs plain, etc.), the arrangement of the furniture plays an important role. The items characterized by particular complexity and richness (e.g., antique and large or highly decorated furniture) are generally associated with a symmetrical or central position, whereas more sober items are

associated with a more elaborate and unconventional composition. The close correspondence between preferences for interior design and furnishings and cultural background and social status suggest that individual taste is largely shaped by cultural ideologies.

If interior decorating choices largely reflect the sociocultural context, this holds true even more for the internal organization of space, over which individuals can exercise less control. Anthropological studies have shown that division of the domestic space and the functional restrictions by gender, age, or activity are congruent with the social and political organization of a culture. In addition, architectural and organizational characteristics have a precise psychological meaning. For example, by asking participants to construct models of houses that would promote in turn privacy, security, and social interaction for the occupants, researchers found that privacy houses had significantly more rooms and corridors, security houses were smaller, and social interaction houses had greater visibility between rooms.
