A final topic to consider within team measurement should be noted. That is the idea of team mental models or the “shared cognition” of a team. The idea that shared mental models allow team members to coordinate by anticipating and predicting each other’s needs through common expectations of performance was discussed previously. However, the ability to measure these expectations as an external observer has proven to be more difficult than have other team processes. Currently, indirect measures of shared cognitions measure individual mental models of the team and task and aggregate the individuals’ mental models to assess the degree of overlap between the cognitions used. Further research is needed to develop tools that can directly address team shared cognition. The diversification of techniques such as automated measures, or measures that are embedded in the task (e.g., simulations), also provides avenues for future research endeavors.

7. CONCLUSION

Experience has shown that teamwork and cooperation can substantially affect organizational effectiveness. However, organizations, managers, executives, and leaders need to know what develops and fosters teamwork as well as what derails it. This article has discussed why teamwork is important.

The article also discussed the nature of teamwork, indicating that it consists of the KSAs that are displayed in support of one’s teammates, objectives, and mission. Ways in which cooperation and teamwork can be derailed were examined as well. Similarly, a presentation of teamwork facilitators was provided. For example, very often it is the responsibility of the leader to create a shared understanding of the vision and goals of those who report to him or her. Furthermore, it is the leader who is usually able to obtain resources and distribute them appropriately, whether through reward systems, work tools, personnel, or training opportunities. At the group level, many factors contribute to the level of cooperation that occurs among individuals. Not only do shared vision, the task itself, and the organizational culture play a part, but factors such as the level of diversity, familiarity, and the number of individuals working together also affect cooperation.

The article also presented a discussion of how training is used to promote cooperation and teamwork. Training opportunities are especially important from a cooperation perspective in that training teamwork skills is imperative to effective cooperation. Training

allows members to gain knowledge about their teammates' skills, abilities, roles, and responsibilities, and this allows them to better anticipate each other's needs and to adapt to the changing organizational environment and tasks. Training can also assist in the creation of a shared vision through goal setting and interpersonal relations.

The article then examined the measurement requirements for team effectiveness research. The fact that teamwork and training effectiveness must be measured should not be lost on the reader. Without effective description, evaluation, and diagnosis of team effectiveness, we would not know where to begin to correct performance deficiencies.

From an organizational perspective, teams and the social system in which they are embedded are interdependent, such that a change in one will affect the other. Thus, organizations that encourage cooperative behaviors through their leadership and organizational systems (i.e., reward systems) will facilitate and encourage cooperation among employees. There is clear evidence that cooperative work arrangements improve overall organizational performance. Individuals also have a role in the effectiveness of cooperation and teamwork as an organizational tool. Evidence indicates that attitudinal factors such as team identity, orientation, commitment, and trust are important. Commitment to the group will increase the willingness of the individual to expend effort and have higher involvement in the group task that is required for cooperation.

Understanding the nature of teamwork and how its interrelated components manifest themselves in terms of cognitions, behaviors, and feelings is critical to promoting coordinated adaptive team performance in increasingly complex and dynamic environments.

Thus, actions taken to improve cooperation and teamwork can have a substantial impact on the organizational bottom line.

GLOSSARY

adaptive defense mechanisms Coping behaviors, including humor and altruism, that help to alleviate anxiety; also called mature defense mechanisms.

coping strategies Consciously chosen, intentional behaviors and cognitions that can flexibly respond to environmental demands.

coping styles Consistent methods of dealing with stress that focus on information accessing as well as emotions.

defense mechanisms Unconscious dispositional behaviors (e.g., defensive styles) associated with pathology.

depersonalization The act of separating one's identity or sense of reality from a situation.

emotion-focused coping A wide range of strategies (e.g. avoidance, withdrawal, expressing emotion, and the use of substances such as alcohol or food) that are directed toward managing one's emotional response to a problem.

meaning making A coping strategy that involves trying to see the positive or meaningful aspects of the stressful situation, especially with severe or chronic stressors. It is sometimes referred to as cognitive reappraisal.

problem-focused coping Behaviors and cognitions aimed at solving a problem that is generating anxiety. It is also called instrumental action.

psychotic defense mechanisms Individual distortions of a situation that may involve outright denial of reality, neurotic defense mechanisms, or may consist of denial of the

significance of an event, such as intellectualization. They are sometimes called immature defense mechanisms.

religious coping A multifaceted coping strategy including elements of social support coping, problem-focused coping, and emotion-focused coping, that aims to conserve or transform meaning in the face of adversity.

sequelae Pathological condition and/or a secondary consequence, in this case resulting from trauma.

social support coping Seeking advice, emotional aid, and/or concrete aid from others.

In the past 25 years, more than 30,000 articles have been published on coping. This is not only a testament to the popularity of this construct but also reflects the enormous interest in the psychological and physical effects of stress. Theoretically, at least part of the reason for differential vulnerability and resilience to stress lies in how individuals cope with stress. Testing this hypothesis has led to the growing understanding of the complexity of the adaptation process. There is simply no "silver bullet" that will magically solve all problems but, rather, the effects of coping vary by how coping strategies are assessed, the type of problem, and a variety of situational factors, as well as the skill and resources of the individual facing the problem.

1. TYPES OF COPING

There are three major approaches to the study of coping: psychoanalytic approaches, coping styles, and coping

processes. These approaches to coping differ as to whether they focus on unconscious mechanisms, personality or information processing styles, or environmental influences.

1.1. Psychoanalytic Approaches

Psychoanalytic approaches focus on the use of defense mechanisms, which are unconscious ways of fending off anxiety. Defense mechanisms differ from coping strategies in that they are unconscious, dispositional (e.g., defensive styles), and are associated with pathology, whereas coping strategies are consciously chosen, intentional, and can flexibly respond to environmental demands. However, defense mechanisms vary in the degree to which they distort reality and may be hierarchically arranged from psychotic to adaptive or “mature.” Psychotic defense mechanisms may involve outright denial of reality, whereas “immature” or neurotic mechanisms may consist of denial of the significance of an event, such as intellectualization. The most adaptive or mature defense mechanisms include humor and altruism.

Because they are believed to act on an unconscious level, defense mechanisms are difficult to study and they are usually assessed using in-depth interviews and case studies. Thus, there have been few large-scale studies of their effectiveness. However, they did provide the initial impetus for the study of how individuals cope with stress.

1.2. Coping Styles

Coping styles differ from defense mechanisms in that they focus on how people deal with information as well as emotions, and are thought to be consistent across time and situation. As such, they typically take the form of dichotomies such as repression–sensitization, blunting–monitoring, and approach–avoidance. Research studies have typically found that approach styles are associated with better outcomes than avoidance styles. However, this does not hold true across all circumstances, such as with uncontrollable stressors. Furthermore, studies that empirically test consistency in coping across time or situations are rare, and the ones that do include such tests generally find that individuals are not very consistent in how they cope with different types of problems.

1.3. Coping Processes

In contrast to the two previous views, the coping process approach argues that coping is responsive to both environmental demands and personal factors such as values

and beliefs. As such, coping strategies are flexible and unfold over time, either in response to changing appraisals or as a function of developmental processes. Coping strategies are proactive and are not simply responses to environmental contingencies. One can appraise a situation as benign, in which case no coping is needed, or as involving threat, harm, or loss or as a challenge, all of which may evoke various coping strategies. Because this approach emphasizes the flexible nature of coping, the focus is on how individuals cope with particular situations and, as mentioned earlier, several studies have shown that coping strategies do vary across situations.

There are many different conceptualizations of coping strategies, but the five general types of coping strategies are problem-focused coping, emotion-focused coping, social support, religious coping, and meaning making. Problem-focused coping, also called instrumental action, encompasses behaviors and cognitions aimed at solving the problem, such as seeking information, taking direct action, or breaking the problem down into more manageable pieces, a strategy referred to as “chunking.” Sometimes, delaying or suppressing action can be a useful problem-focused strategy. For example, purposefully delaying a direct confrontation with someone may lead to a more rapid solution to a problem than acting in anger.

Emotion-focused coping includes a wide range of strategies that are directed toward managing one’s emotional response to the problem. Some examples are avoidance, withdrawal, expressing emotion, and the use of substances such as alcohol or food. As might be expected, avoidance strategies are often associated with poor outcomes, but other emotion-focused strategies, such as expressing emotion through journals or writing, may be associated with positive outcomes.

Social support involves seeking both emotional and concrete aid from others or advice. The outcome of these types of coping strategies often depends on the social context. For example, confiding in others after a trauma is generally associated with better outcomes, but if the confidant responds negatively, emotional distress may be increased.

The study of religious coping is relatively new. It can contain elements of social support or problem-focused and emotion-focused coping, and it seeks to conserve or transform meaning in the face of adversity. In general, religious coping is associated with positive outcomes, but it does have negative guises. Belief in a punitive God, or feeling that one has been treated unfairly or been deserted, may be associated with much poorer outcomes.

The final category, meaning making, is the least well understood. It is sometimes referred to as “cognitive reappraisal” and involves trying to see the positive or meaningful aspects of the situation, especially with severe or chronic stressors. As with religious coping, how one goes about making meaning may affect its association with outcomes. Simply asking “Why me?” may be associated with poorer outcomes, but coming to realize how a problem fits into the larger pattern of one’s life may be a painful process but in the end may be one way in which individuals grow from stressful or traumatic experiences.

1.4. Measurement Issues

Coping style measures ask individuals how they typically cope with problems. The dichotomized nature of coping styles lends itself well to psychometric assessment. The factor structures of coping style inventories are generally stable, and the factors correlate well with psychological outcomes. Given that coping may not be very stable, however, their ecological validity is somewhat questionable.

Process measures ask individuals to select a recent problem and indicate how they coped with that type of problem. Unfortunately, process measures typically have somewhat “messy” psychometrics, and their factor structures may be unstable. This makes comparison across situations or over time problematic.

Sometimes a more accurate picture can be obtained using multiple assessments, either through daily diaries or through event sampling throughout the day. Although some scholars have criticized the psychometric properties of these measures (often consisting of only one item per strategy), these types of procedures may be especially useful in the context of coping with chronic stressors because they permit within-subject analyses that may yield strong relationships between coping and outcomes.

2. COPING AND HEALTH OUTCOMES

2.1. Mental Health Outcomes

In many ways, being able to successfully cope with problems can be considered a hallmark of psychological health. Difficulties in coping may be associated with emotional distress, including depression and anxiety. However, the relationship is neither simple nor straightforward. Because there may be differences

between how people cope with trauma and with more everyday stressors, these two different types of problems are addressed separately.

2.1.1. Coping with Stressors

The relationship between coping and psychological symptoms is characterized by complexity along a number of different dimensions. First, coping strategies have situation-specific effects. Many studies have demonstrated that the effectiveness of coping strategies rests on the controllability of the stressor. Controllable stressors, such as problems at work, are more effectively managed with problem-focused coping, whereas uncontrollable stressors, such as the death of a loved one, are more effectively managed with emotion-focused coping.

Second, there may also be a confound between stress, distress, and coping. Higher levels of stress may evoke more coping strategies and also create more distress; thus, all coping strategies will correlate with higher levels of distress in particularly difficult circumstances. Only by controlling for the stressfulness of the problem can the true relationship between coping and mental health be revealed.

Third, there is a difference between short- and long-term outcomes. Avoidance coping strategies, for example, may decrease psychological distress in the short term but cause great distress in the long term if the underlying problem remains unresolved. Brief periods of respite, however, can allow individuals to “recharge their batteries” and promote better problem-focused coping in the long term.

Fourth, the causal directionality of coping may not be clear. Rather than coping resulting in depressive symptoms, individuals who are depressed may cope in different ways than nondepressed people.

Fifth, people may employ the same coping strategies with different levels of skill. Thus, it makes sense to determine the efficacy of the strategy—that is, whether it “worked” for that person in that particular situation.

Finally, most research has focused only on coping as a means of reducing symptoms. However, effective coping may lead to more positive outcomes, such as increases in mastery, self-knowledge, and better social relationships. Thus, it is not surprising that the literature on coping and mental health is rich but somewhat contradictory.

2.1.2. Coping with Trauma

Traumatic stressors are ones that either threaten or expose individuals to loss of life and major physical damage to

themselves, loved ones, or large numbers of individuals. Surprisingly, the trauma literature is much clearer in demonstrating the efficacy of coping strategies. In general, how individuals cope with trauma and its sequelae are better predictors of the development of posttraumatic stress disorder (PTSD) than simply exposure to trauma.

There are four ways in which coping with trauma differs from coping with less severe stressors. First, traumatic circumstances are often uncontrollable and many people fall back on the use of unconscious defense mechanisms, such as denial and repression. For example, depersonalization may be the only possible response to being tortured. Second, disclosure and seeking support from others appear to be especially important in traumatic situations. However, if the disclosure evokes negative responses from others, PTSD symptoms may become worse. Some individuals are relatively successful at “partitioning off” their trauma experience and rebuilding their lives.

Third, the process of coping with traumatic events and their sequelae is much longer and may take years. Finally, the coping strategy of meaning making is particularly important in dealing with trauma. Whether an individual is able to make some sense out of traumatic events can determine whether those events lead to positive or negative mental health outcomes.

2.2. Physical Health Outcomes

The evidence for the effect of coping on physical health outcomes such as pain, blood pressure, catecholamines, lipids, and immune system function is much weaker, in part because studies are relatively rare and may focus on special populations, such as heart disease patients or AIDS victims.

We identified four models by which coping may affect health outcomes. The direct effects model examines a simple correlation between coping and health outcomes, regardless of the situation or type of stressor. For example, instrumental action may be associated with better lipid or immune system profiles whether the stressor is major or minor. Second, coping may moderate or buffer the effects of stress on health outcomes. That is, there are no direct effects, but individuals under high levels of stress who use instrumental action may have lower blood pressure levels. The mediated effects models suggest that the effects of coping depend on a variable or variables intervening between coping and physical health outcomes. For example, many of the physiological effects

of coping on health might be explained through its effect on psychological distress. If an individual's coping strategies decrease negative affect, then it may be associated with better immune system profiles. The fourth model is the contextual effects model, which states that the effect of coping on health might depend on environmental context. For example, Zautra and colleagues showed that seeking social support may be effective in reducing pain for diseases such as osteoarthritis but less effective for rheumatoid arthritis, in part because the symptoms in the latter illness are less clear and thus may be more difficult for others to understand.

There is evidence for each of these models; however, none of them has received overwhelming empirical support. Clearly, much research is needed to illuminate the pathways by which coping influences physical health outcomes.

global context, whether that perspective is held in the Western or Eastern geographic hemisphere.

Counseling is a product of Western cultures whose values have continued to dominate the counseling profession through the imposition of cultural assumptions as counseling services have spread to other cultures, demonstrating the generic centrality of culture to achieve competence in the counseling process.

GLOSSARY

cultural encapsulation The tendency of people to build walls or capsules around themselves by simplifying or minimizing the importance of other people's culture's.

cultural grid A framework combining personal factors (e.g., behavior, expectation, values) on one dimension and the cultural contexts in which those personal factors were learned on the other dimension.

culture-centered perspective A perspective that makes the cultural context central to an understanding of every situation.

fourth force The view of multiculturalism as a "fourth dimension" of counseling to supplement the psychodynamic, humanistic, and behavioral dimensions.

multicultural competencies A list of 34 specific competencies describing how an understanding of culture is basic to the counseling process; this list has been evolving since 1962.

Western culture A dominant culture sociopolitical perspective favoring individualism and linear thinking in the

1. INTRODUCTION

Because all behaviors are learned and displayed in a cultural context, accurate assessment, meaningful understanding, and appropriate intervention require consideration of the cultural context when providing counseling services. Making the consumer's cultural context central rather than marginal when providing psychodynamic, behavioral, and humanistic services strengthens those traditional counseling perspectives. However, because counseling first developed as a field in a Euro-American cultural context, counseling typically reflects Euro-American assumptions in textbooks, theories, tests, ethical guidelines, methods, and other services. The purpose of this article is to discuss the generic importance of making cultural context central rather than marginal to the counseling process.

2. CULTURAL BIAS IN COUNSELING

In 1996, a report by the Basic Behavioral Science Task Force of the National Advisory Mental Health Council (NAMHC) documented the extent of cultural encapsulation of mental health services. First, anthropological and cross-cultural research has demonstrated that cultural beliefs influence the diagnosis and treatment of mental illness. Second, the diagnosis of mental illness differs across cultures. Third, research has revealed differences in how individuals express symptoms in different cultural contexts. Fourth, culturally biased variations in diagnosis vary according to the diagnostic categories relevant to the majority population. Fifth, most providers come from a majority culture, whereas most clients are members of minority cultures. If the standard practices of mental health services are themselves encapsulated, as suggested by the NAMHC report, these cultural biases will certainly influence the practical applications of psychology through counseling and therapy.

Counseling has typically assumed that there is a fixed state of mind that is obscured by cultural distortions and that relate behaviors across cultures to some universal definition of normative behavior described in textbooks. A contrasting anthropological perspective assumes that cultural differences are clues to divergent attitudes, values, or perspectives that differentiate one culture from another based on a culture-specific viewpoint. Anthropologists have tended to take a relativistic position when classifying and interpreting behavior across cultures. Psychologists, in contrast, have linked social characteristics and psychological phenomena with minimal attention to cultural differences. When counselors have assumed the same interpretation of similar behaviors regardless of the cultural context, cultural bias has been the consequence. The influence of cultural bias has led to the encapsulation of counselors by dominant culture perspectives regardless of the cultural context.

3. CULTURAL ENCAPSULATION OF COUNSELORS

In 2001, Ponterotto and colleagues described how counseling has a reputation among many minorities as protecting the status quo of the dominant culture by requiring minority clients to fit the dominant culture system even when that system is acknowledged to be unjust. In 1999, Sue and Sue described how these

attitudes have resulted in documented examples of scientific racism.

In 1962, Wrenn first introduced the concept of cultural encapsulation. This perspective assumes five basic identifying features. First, reality is defined according to one set of cultural assumptions. Second, people become insensitive to cultural variations among individuals and assume that their own view is the only right one. Third, assumptions are not dependent on reasonable proof or rational consistency but are believed to be true regardless of evidence to the contrary. Fourth, solutions are sought in technique-oriented strategies and quick or simple remedies. Fifth, everyone is judged from the viewpoint of one's self-reference criteria without regard for the other person's separate cultural context. The encapsulation has not diminished over time. There is evidence that the profession of counseling is even more encapsulated now than it was when Wrenn wrote his original article.

In 1994, Albee described how completely psychology—and counseling as based on a psychological foundation—in the United States has been encapsulated during the past 100 years:

Most of the early leaders in psychology embraced ideological views that stressed the natural superiority of a white male patriarchy, the acceptance of social Darwinism, [and] the inferiority of women and of the brunette races. Calvinism stressed economic success as the hallmark of salvation, and psychology concurred. Anti-semitism and homophobia were standard. Eugenics spokesmen urged the elimination of the unfit and inferior and opposed welfare programs, decent wages, and safe working conditions.

These views continue to be held today, although sometimes in more subtle forms. The encapsulation of counselors is most evident in the way in which counselors are trained and educated.

4. CULTURALLY LEARNED ASSUMPTIONS IN COUNSELOR EDUCATION

The training of counselors has been characterized by conventional assumptions that reflect the values and priorities of the Euro-American cultural context. [Table 1](#) describes 10 examples of these assumptions that Pedersen used in 2002 to demonstrate their pervasive influence in applications of counseling.

TABLE I
Western Cultural Assumptions in Counseling

<i>Euro-American cultural assumption</i>	<i>Comments</i>
Counselors all share the same unimodal measure of what is normal behavior.	There is a frequent assumption that describing a person's behavior as "normal" reflects a judgment that is both meaningful and representative of a desired pattern of culture-specific behaviors across social, economic, political, and cultural contexts, that is, represents the dominant culture perspective of culture-specific behavior.
Individuals are the basic building blocks of society.	This individualistic presumption is reflected in psychological terms such as personality and self-awareness. Conventional counseling is focused primarily on the development of individuals rather than collectivities or groups such as the family, the organization, or society itself.
Only problems defined within the framework of the counselor's specialized expertise or academic discipline are of proper professional concern to the counselor.	There is a tendency to isolate the professional identity of the counselor from that of other professionals even though multicultural problems wander across these boundaries freely.
There is a superior quality judgment attached to psychological abstractions.	In the counselor's use of professional jargon, he or she assumes that the same words have the same meaning across cultural contexts. Although this assumption is typical of a "low-context" culture where the context is less relevant, it would not apply to "high-context" cultures where all meaning is contextually mediated.
Independence is usually desirable, and dependence is usually not desirable.	As part of the Western emphasis on individualism, there is a belief that individuals should not be dependent on others or allow others to become dependent on them. This is not the case in a more collectivist culture.
Clients are helped more by formal and professional counseling than by their natural support systems.	Family and peer support are the primary resources in many cultures where professional counseling is less available or is inappropriate. In some non-Western cultures, counseling is a last resort only when everything else has failed.
Everyone thinks the same way, moving linearly from cause to effect.	It is not just the content of one's thinking that is culturally mediated but also the very process of thinking itself. Nonlinear thinking, typical of many non-Western cultures, will seem illogical to linear thinkers.
Counselors need to change clients to fit the system and not change the system to fit the clients.	Advocacy by counselors is frequently considered unethical and unprofessional. Much of the counseling literature relates to client adjustment, sometimes even when the system is wrong and the client is right.
History is not relevant for a proper understanding of here-and-now problems.	Counselors are more likely to focus on the immediate here-and-now events that created a crisis and to consider historical background as a distraction at best and as a defensive evasion at worst.
We already know all of our culturally learned assumptions.	Each time counselors discover one of their cultural biases, they disprove this assumption. As they increase their contact with persons and groups from other cultures, this process of self-discovery is accelerated.

One way in which to challenge the universal application of dominant culture perspectives, regardless of the cultural context, is to separate behaviors from expectations in counseling. This will demonstrate how shared positive expectations (e.g., safety, respect, fairness) might be expressed by very different behaviors and how similar behaviors (e.g., direct/indirect, loud/quiet) across cultures might be linked to very different expectations in a two-dimensional “cultural grid.”

5. THE CULTURAL GRID LINKING COUNSELING AND CULTURE

The connection between counseling and culture can be described visually in a cultural grid that includes individual behavior, expectations, and values on one dimension and the “culture teachers” of those individual characteristics on the other dimension. The cultural grid, as described by Pedersen in 2000, is an attempt to demonstrate the personal–cultural orientation of the individual in relationship to the many different cultures to which that individual belongs. The cultural grid shows an “inside-the-person” or intrapersonal cultural framework for demonstrating how cultural and personal factors interact. Through the cultural grid, each individual behavior can be linked to the culturally learned expectation on which that behavior is based, and each expectation can be linked to the culture teachers from whom those expectations were learned.

The cultural grid provides a systematic framework for the counselor to interpret each client behavior in the context where that behavior was learned and is displayed. The cultural grid demonstrates that there are many different culture teachers present in the counseling interview, with some belonging to the counselor and some belonging to the client. The cultural grid further provides a framework for comprehending the client’s culturally learned behavior from his or her point of view.

Pedersen pointed out that each cultural context is complicated and dynamic, influenced by many culture teachers who take turns being salient according to every time and place. An awareness of one’s cultural identity requires the ability to identify how each behavior is an expression of specific culturally learned expectations and how each expectation was learned from specific culture teachers. The culture teachers might come from family relationships, power relationships, or other memberships. Judging other people’s behavior out of

context or without regard to why they engaged in the behavior or where they learned the behavior is likely to be misleading at best and totally wrong at worst. It is not easy to discover why people do what they do, but that does not excuse the counselor from the obligation to try. Unless each client behavior is understood in context, that behavior is very likely to be misunderstood by the counselor (Fig. 1).

The culturally learned assumptions on which current theories of counseling are based, such as those favoring individualism over collectivism, need to be reassessed so that the theories of counseling can be applied across cultures more accurately and meaningfully.

6. MULTICULTURAL THEORIES OF COUNSELING

One culture-centered perspective that applies cultural theories to the counseling process is found in a 1996 book on multicultural counseling theory (MCT) by Sue and colleagues. This approach is based on six propositions that demonstrate the fundamental importance of a culture-centered perspective:

1. Each Western or non-Western theory represents a different worldview.
2. The complex totality of interrelationships in the client–counselor experiences and the dynamic changing context must be the focus of counseling, however inconvenient that might become.
3. A counselor’s or a client’s racial/cultural identity will influence how problems are defined and will dictate or define appropriate counseling goals or processes.
4. The ultimate goal of a culture-centered approach is to expand the repertoire of helping responses available to counselors.
5. Conventional roles of counseling are only some of the many alternative helping roles available from a variety of cultural contexts.
6. MCT emphasizes the importance of expanding personal, family, group, and organizational consciousness in a contextual orientation.

As these MCT propositions are tested in practice, they will raise new questions about competencies of multicultural awareness, knowledge, and skill in combining cultural factors with psychological process. How does one know that a particular psychological test or theory provides valid explanations for behavior in a particular cultural context? What are the cultural

boundaries that prevent generalization of psychological theories and methods? Which psychological theories, tests, and methods can best be used across cultures? Which psychological theories, tests, and methods require specific cultural conditions? MCT assumes multicultural competencies.

Multicultural competencies have been developed by Sue and colleagues over the past 40 years or so. In a comprehensive description of these 34 competencies in 1998, Sue reviewed these multicultural competencies. A summary of those competencies in three dimensions, emphasizing multicultural awareness, knowledge, and skill, can be described in three developmental dimensions:

- *Dimension 1.* Counselors' awareness of their own assumptions, values, and biases includes (a) awareness of cultural heritage comfortable with differences but aware of limits; (b) knowledge about oppression,

racism, and discrimination; and (c) skills in self-improvement toward a nonracist identity.

- *Dimension 2.* Understanding the worldview of the culturally different client includes (a) awareness of emotional reactions toward other racial/ethnic groups, (b) knowledge about the culture of the client population and its influence on counseling and society, and (c) skills in mental health issues of other cultures and active involvement with ethnic minority groups.

- *Dimension 3.* Developing appropriate intervention strategies and techniques includes (a) awareness of religious and spiritual indigenous mental health resources; (b) knowledge about how counseling fits with other cultures, institutions, and assessments; and (c) skills in culturally appropriate counseling of indigenous people.

These three dimensions of multicultural competency have tended to be described as abstractions, and much

more work is needed to link these abstract competencies to individual cases and situations. Ponterotto and colleagues did an excellent job of reviewing the literature already in print to apply the multicultural competencies in practice. As of this writing, Constantine and Sue are working on an even more comprehensive demonstration of how the multicultural competencies can be applied in practice. Applying these competencies in practice will reduce the number of racist incidents in the counseling profession generally.

The lack of trust in people who provide counseling services and the belief that the status quo was being held are documented in “scientific racism” and “Euro-American ethnocentrism.” According to Sue and Sue’s 1999 book, cultural differences were explained by some through a “genetic deficiency” model that promoted the superiority of dominant White cultures. The genetic deficiency approach was matched to a “cultural deficit” model that described minorities as deprived or disadvantaged by their culture. Minorities in the United States were underrepresented among professional counselors and therapists, the topic of culture was trivialized at professional meetings, and minority views were underrepresented populations in the research literature. Consequently, the counseling profession was discredited among minority populations because they viewed counseling as a tool to maintain the differences between those who had power and access to resources and those who did not. Making the cultural context central to counseling is in no way intended to diminish the importance of established counseling theory. In fact, making culture central as a “fourth dimension” will serve to increase the accuracy and importance of established theory.

7. MULTICULTURALISM AS A FOURTH FORCE

In 1998, Pedersen examined some of the issues involved in declaring multiculturalism as a fourth force in psychology:

1. Significant changes are taking place, even though there is disagreement about the nature of those changes.
2. Multiculturalism has become a significant domestic force in most cultures, even though it may not yet provide a coordinated global perspective.
3. Multiculturalism has sometimes been used to rationalize oppression in countries such as South Africa; consequently, it has a bad reputation in those countries.

4. It may be premature to describe multiculturalism as a fourth force, although it has had a more powerful impact in the more applied areas of psychology such as counseling.

5. The U.S. version of multiculturalism is grounded in the individualist values of that cultural context more than in a non-Western collectivist perspective.

6. Within-group differences of ethnocultural groups, such as demographics, status, and affiliation, function “like” cultures regarding issues of age, disability, gender, and other special interests.

7. Cultural similarities (e.g., among youth-age strata) probably exceed similarities across generations in each separate ethnocultural group.

8. Multiculturalism will change not only the content of our thinking but also the very process of thinking itself.

9. Making culture central enhances the meaningful usefulness of traditional psychological theories in ways that might lead us to call this new perspective a fourth dimension rather than a fourth force.

Adding a fourth dimension of multiculturalism to counseling theory is not an easy task but remains a very important aspect of making the cultural context central to counseling.

8. RESISTANCE TO MULTICULTURALISM AS A FOURTH FORCE

In 1998, Sue identified sources of resistance to the term “multiculturalism as a fourth force”:

1. Some view multiculturalism as competing with already established theories of psychological explanation in ways that threaten the professions of counseling and psychology.

2. The terms “multiculturalism” and “diversity” are loosely associated with affirmative action, quotas, civil rights, discrimination, reverse discrimination, racism, sexism, political correctness, and other highly emotional terms.

3. To the extent that multiculturalism is connected with postmodernism, the arguments against postmodernism as a valid theory are also applied to multiculturalism.

4. Those favoring a universalistic perspective contend that the same practice of counseling and therapy applies equally to all populations without regard to cultural differences.

5. Others contend that there are no accepted standards for describing multiculturalism as a theory in practice and that it is too loosely defined to be taken seriously.

6. There are no measurable competencies for multicultural applications of counseling or adequate standards of practice.

7. Multiculturalism is too complicated, and it would be unrealistic to expect counselors to attend to such a range of factors simultaneously.

8. More research is needed on multicultural competencies, standards, methods, and approaches.

9. Multicultural standards cannot be incorporated into the counseling profession until all groups have been included.

10. Multiculturalism represents reverse racism, quotas, and is anti-White.

In discussing these sources of resistance, Sue pointed out the tendency to misrepresent or misunderstand the notion of multiculturalism and the dangers of that misunderstanding.

Although the task of reducing cultural bias in counseling is extremely difficult, it remains an “aspirational goal” of the profession.

9. CONCLUSION

In 1999, Sue and colleagues summarized what needs to happen for psychology programs to facilitate positive multicultural initiatives so as to include (a) faculty and student preparation in the development of cultural competence; (b) a multicultural curriculum in all aspects of education and training; (c) minority representation among students, staff, faculty, and administration; (d) an inclusive and positive campus climate; (e) recognition of culturally biased teaching and learning styles; (f) people providing a social support network and services that understand the minority experience; and (g) recognition that current programs, policies, and practices negating multicultural development must be changed.

Multiculturalism is not just a trend or fad; rather, it is a permanent phenomenon of social functioning that reflects the advanced technology of a world where international boundaries have been replaced by close interactions among people around the globe. As the primary support systems of the village and family are diminished in authority around the world, more and more societies are looking for alternatives to provide the necessary social support in their communities. The field of counseling is a promising alternative for many of the world's

cultures provided that counseling can be modified to fit with a variety of cultures and not merely impose Western or dominant culture values.

GLOSSARY

catharsis The expression of feelings and emotions by a client or patient during a clinical interview.

clinical interview A relationship between a psychiatrist, a psychologist, a social worker, or other types of professionals with a client or patient, the focus of which is the facilitation of the growth and development of the client or patient.

confidentiality A client's or patient's trust that the counselor will not reveal to others the information given to him or her.

contract An agreement between a counselor and client or patient about the goals of the treatment process and the means that will be used to achieve them.

counseling A generic term that refers to a relationship between two or more people in which one person facilitates the growth and development of others in order to help them deal with their problems more effectively.

counseling interview A dyadic relationship between a counselor and a client or patient in which the former facilitates the growth and development of the latter in order to help him or her deal more effectively with his or her problems.

intake interview The first interview by a counselor in which an assessment of the client or patient is made and an agreement is reached by both parties about what the goals of the counseling process will be and how these goals will be achieved.

presenting problem A problem the client or patient is experiencing or, when dealing with an involuntary client, the problem the referring agency defines.

privileged communication Laws that give the counselor the right to hear almost anything a client or patient says with the responsibility of not repeating it to others.

psychiatric interview A dyadic relationship between a psychiatrist and a patient for the purpose of diagnosis and treatment of a patient who has problems in interpersonal functioning and/or internal psychological and emotional difficulties and that includes the assessment and treatment of any physiological sources of the patient's distress.

trust The client or patient's belief that whatever the counselor does is in his or her best interest.

The purpose of the counseling interview is to help a client or patient with a problem he or she is experiencing or a problem the referring agency defines. This is known as the presenting problem. The counselor must be in control of the interview and respond to the client in a professional way that is different from that of friends and neighbors. The rhythm and cadence of the interview requires that the counselor allow the client to lead, focus on his or her feelings, be open and honest in response to the client, and be reflective so that the client learns that this is his or her problem. Basic to the

counseling process is that the client must learn to trust the counselor so that he or she will be open to seeing the problem differently and dealing with it more effectively. The variety of methods and techniques the counselor uses to achieve this end are described in detail in this article.

1. PURPOSE AND GOALS

The purpose of the counseling interview is to help the client with a problem he or she is experiencing or, when dealing with an involuntary client (e.g., a criminal or delinquent or a parent accused of abuse or neglect), the problem the referring agency defines. This is often called the presenting problem. Although it is imperative that the counselor deal with the problem as the client or referring agency sees it, this does not mean that the counselor always perceives the problem in the same way. For example, a wife may come to the counselor because she believes her husband does not love her anymore, but it soon becomes apparent that her interpersonal response to her husband is at least partially responsible for his negative reactions to her. However, it may take a number of sessions before the counselor believes it is possible for the client to understand the problem in a way that is different from his initial presentation. [Although both counselors and clients may be men or women, for purposes of style we refer to counselors in the feminine and to clients in the masculine.]

Early in the interviewing process, it is important to set goals for counseling and to discuss the means that will be used to achieve these ends. Agreement is reached with the client that must reflect both an understanding of the problem by the client and counselor and a way of dealing with the problem that is likely to be effective and agreeable to the client. This agreement about means and ends is called the contract. In some counseling situations, the contract is implicit in the setting. For example, the employment counselor is there to help the client find a job, or the academic counselor sees her purpose is to help the student find the best college for him. In other situations, the contract may be much more complicated; for example, the father accused of abusing his child who believes “spare the rod, spoil the child” may need to agree to consider alternative approaches to child rearing. In the latter situation, considerable discussion between the client and the counselor, sometimes over a series of interviews, may be necessary before a contract can be established.

2. DYNAMICS OF COUNSELOR-CLIENT INTERACTION

There is a rhythm and cadence in the counseling process that often needs to be established in the early interviews. First, the counselor allows the client to lead. It is the client who is asking for help and he must do so in the way that makes the most sense to him. This does not mean that the client will present material in the most logical way. Rather, he will present the “story” in his own way, which in itself should have meaning to the counselor who is listening. The organization of the material presented may have as much meaning as the content. The counselor will make note of what is not said as well as what is said. She will notice any changes in speech patterns and times of silence as the narrative flows. By allowing the client to lead, the counselor is beginning to establish the trust that the client needs to continue.

Second, the focus, particularly in the early interviews, should be on feelings. Clients come to each new counseling session, even those that seem to deal with relatively unemotional situations, with feelings— anxiety or fear, grief or despair, rage or betrayal. The student may be afraid that he will not get into the college of his choice or that he may disappoint his parents, the teenager may be furious at her parents for limiting her activities, or the husband may be overwhelmed with grief after the death of his wife. In each case, before the client can move on he must have the opportunity to express these feelings. The expression of such feelings is called catharsis. The counselor can help the client by putting an accurate name to these feelings and describing their effect, intensity, and magnitude, which helps the client to control them and then move on to deal with the problem that causes them.

A third issue is the quality of the counselor’s communication. She must be open to what is heard and open and honest in her response. It means accepting the client’s statements, not arguing or debating with the client about what has been said or what the client feels and not using the word “but” to rebut what the client is feeling or saying. It means being nonjudgmental even when the client expresses values incompatible with those of the counselor or that seem morally reprehensible. This does not mean that the counselor will never disagree with the client or that she approves of the client’s antisocial behavior. It does mean the counselor will not do so until she has begun to establish a relationship of trust with the client, and that the

counselor will not confront the client with his unacceptable behavior until the client has sufficient positive feelings about the counselor that he can accept such confrontation with understanding and insight.

There are three therapeutic-type responses that are very useful in allowing the counseling interpersonal relationship to develop. The first we call minimal encourager. This is nothing more than nodding, murmuring “uh huh,” or using simple statements such as “Tell me more” or “Please go on.” Such statements are minimal and do not intrude on the client’s flow of material.

The second type of response is summation of content. By summarizing or paraphrasing the client’s content in her own words, the client can confirm or modify the counselor’s perceptions. This allows the client to continue to control the interview situation while at the same time the counselor confirms an understanding of what is being said.

The third technique is to reflect the client’s feelings about the situation or person he is describing. This is a powerful response because this teaches the client at least three things: (i) that it is okay to have feelings, no matter what they are; (ii) that the counselor is not afraid of any of his feelings, no matter how intense they are; and (iii) that naming these feelings is the first step in getting them under control. This will sometimes be followed by the client expressing a great sense of relief: “Someone finally understands.” The counselor’s silence after that will allow the client to think about what he said and this will often be followed by some of the most significant statements that will be made in the interview.

Finally it should be noted that the counselor’s reflective responses should be such that the client learns that he owns the problem. This is particularly important if the client blames others for the problem. “My child does such terrible things I have no alternative but to physically punish him.” The counselor’s appropriate response is not to suggest alternative punishments at this point but rather to reflect on the client’s feelings: “He must make you very angry.” Thus, the mother may begin to see that it is her anger that led to her being accused of being abusive and not the child’s behavior.

3. ISSUES, DILEMMAS, AND CONTRADICTIONS IN THE COUNSELING PROCESS

The counseling process is a complex one. What makes it different from other forms of interpersonal interaction is

that the counselor responds differently from the typical relative, friend, or neighbor to the person who comes for help. This means she must be particularly alert to her own responses to what the client tells her. This leads to dilemmas and contradictions in the helping process that must be carefully thought through in order to maintain the integrity of the process. Some of these issues, dilemmas, and contradictions are discussed here.

3.1. Values and Ethics

Each of us has our own sense of what is right and wrong and our own preferences about what is important to us. Our ethics and values to a great extent determine who we are and how others see us. Furthermore, we tend to choose friends whose values and ethics are similar to our own. Some of us believe it is legitimate to use the loopholes in the law to reduce our taxes; others think this is cheating. Some of us prefer to spend our money on a house and car; others prefer to use our funds to give to charity or for political action. However, in most circumstances we are not in a position to influence others about what they think and what they value. Counselors, though, may be confronted with clients whose thinking about these and many other issues is quite different from their own.

What do they do about this? In most situations, if these values and ethics are unrelated to the problems the client brings to them, they do nothing. They have no right or obligation to attempt to change a client’s values or ethics, even if they find them repulsive. If this makes it difficult for the counselor to work with the client, she must refer him to another counselor.

Sometimes these values are related to the client’s problem. Then what? The use of argument or logic hardly ever works to change values, beliefs, or attitudes. Often, the only alternative for the counselor is to help the client see how these values are dysfunctional—how they may get him into trouble. Only when the client can make this connection is he likely to change. However, this can occur only if the counselor has established a relationship of trust with the client. One of the fundamentals of such trust is confidentiality.

We have noted that referral to another counselor may be necessary if the client’s values and ethics are so different from those of the counselor that she finds it difficult to work with him. This may occur when there are major differences in culture and/or socioeconomic class between the client and the counselor. There are two other circumstances in which such a referral may be wise: when the counselor feels hostile to the client

and cannot figure out why and when the counselor believes that she does not have the expertise to be helpful to the client.

3.2. Confidentiality

Basic to a client's trust in the counselor is that she will not reveal to others the information given to her. Many helping professionals have what is known as privileged communication, which by law gives the counselor the right to hear almost anything the client says with the responsibility of not repeating it to others. A violation of confidentiality is likely to destroy the helping relationship and may even make it difficult for the client to seek help from any other counselor. Yet, if the client trusts the counselor, he may say things that seem outrageous to relatives and friends. He may tell the counselor that he hates his mother, that he wishes a child was dead, or that he is having an extramarital affair. Again, what makes the counselor special and helpful is that she reacts differently from friends and relatives. Above all, the information remains with the counselor except in the circumstances described next.

There are times when it is not only both ethical and legal to disclose information but also may be required. When a child or elderly person has been abused or neglected, the counselor is required to report this to the local protective service agency. When a client threatens another person with violence, the law requires that the counselor protect the potential victim by hospitalizing the possible perpetrator or informing the potential victim of the danger. Sometimes, it is a good idea for the counselor to discuss the case with a supervisor or to consult with another professional in deciding the legal, moral, and professional dimensions of her actions. Finally, the counselor may be required by the client's insurance company to provide certain information in order for the client to be reimbursed for her fees. However, in each of these instances, before confidentiality is violated, it is essential that the counselor get the client's permission, preferably in writing. This also provides her with the opportunity to discuss the issues related to the disclosure of information with the client and may open up new avenues for helping the client.

3.3. Trust

As implied previously, central to a successful or helpful counselor–client relationship is trust. However, this in

itself is a dilemma. Often underlying the problem with which the client comes to the counselor is a lack of trust in those people with whom he has contact. Thus, one of the first and most important tasks of the counselor is to enable the client to learn to trust her.

What is the meaning of trust? In this context, trust means that the client believes that whatever the counselor does is in the client's best interest. Trust means that the client feels that no matter what he says it will not be used against him. Trust means that when the client is angry at the counselor, disagrees with the counselor's attitudes and values, or is ambivalent or indecisive, the counselor will not respond with anger or rejection, belittle, or badger him. Trust means that when the counselor confronts the client about his thoughts, feelings, and intentions, the client knows that the intent is to help him face up to the problems he is experiencing and that the counselor will provide support and encouragement as well. Trust means that the client understands that change is painful but that any pain the counselor inflicts on the client has as its purpose the reduction of the problem for which the client came into counseling.

However, if trust is so important, how does the counselor build it, especially since clients are unlikely to trust the counselor at the beginning of the counseling process? First, the counselor must be open and honest. The counselor must not evade the client's questions or respond with platitudes or try to give false hope. In her own way, she must convey to the client that although her attitudes and values may be different from his, each has a right to what each thinks and believes. The counselor respects the client for whom he is despite any differences there may be between them.

Second, the counselor encourages the client to lead and she is willing to follow, especially at the beginning of the counseling process. She allows the client to tell his "story" in his own way.

Third, the counselor encourages catharsis in order to relieve some of the client's anxiety, while at the same time she provides empathy and support. She listens with sensitivity and compassion, demonstrating by eye contact, body position, facial expression, and occasional words of reassurance that she is listening. However, this too can be a dilemma for the counselor, especially at the beginning of the counseling process. If too much anxiety is relieved through catharsis, the client is likely not to be motivated to return. On the other hand, if there is little or no relief of anxiety, the client is likely to think that the counseling process

is not helpful and again may not return. It is through experience that the counselor learns how to balance this issue in work with clients.

Thus, anxiety is a two-way process that has both negative and positive consequences. Most clients come to us because they have so much anxiety that they need to do something to reduce it. This is the motivation for change. On the other hand, many involuntary clients present a different type of dilemma. Many of them are not likely to be anxious. Many psychopaths and sociopaths do not experience anxiety in the same way most of us do. Without anxiety, there is no motivation for change, and without such motivation change is very difficult if not impossible. Thus, our job as counselors is to increase this type of client's anxiety level. One prominent way to achieve this is to point out the consequences of the client's behavior (e.g., loss of freedom by going to jail for dealing drugs or loss of life by overdosing on drugs). Nonetheless, this is a very difficult process.

Fourth, in order to establish trust, the counselor makes use of the client's priorities. That which the client sees as his most important or immediate problem must be dealt with. This is so even if the counselor believes that there are other problems that the client is experiencing that are more acute or may underlie the problem he brings to the interviewing session. The counselor must respect what the client believes is important.

A fifth method of gaining the client's trust is known as joining. This involves identifying with the client by following some of his behavior and speech patterns. Sometimes, it means mirroring the client's movements (leaning forward when the client does) or matching the client's timing (slowing down one's speech to be in harmony with the client's pace).

Sixth, if the counselor can provide immediate relief for one of the client's problems, trust is likely to occur. We have discussed how catharsis is one way of achieving this, but there are other ways as well. Sometimes, information can be very helpful. An explanation of unemployment or Social Security eligibility requirements can be very helpful with some clients. Explaining what is expected in college application materials to graduating high school students can relieve much anxiety. Referral to another agency or resource, such as a local tenants council or a store that sells reasonable clothing, can be seen as very helpful.

The "a-ha" response is another technique to establish trust. This occurs when the client arrives at a special understanding of his own situation that he did not have

before. It happens when the counselor is able to ask just the right question at the right time or make a crucial observation just when the client is ready to accept this about himself.

Finally, trust can and should be built by giving the client a sense of hope by assuring him that it is possible to change, to give up even the most painful feeling. However, for this to occur, the counselor must have the sense that she can be successful with this client. If the client does not have hope, the counselor must try to understand why and sometimes consult with a supervisor or colleague if this feeling persists. Without this sense of hope, it is highly unlikely that the counseling process can be helpful.

3.4. Diversity

Despite the counselor's good will, and her wish to be helpful to others, there are some clients who at first seem to reject the counselor's efforts and seem unwilling to trust her. These are people who are different from the counselor. They may be of a different race, may come from a different ethnic background or culture, or may be of a different gender or belong to a socioeconomic group different from that of the counselor's. They may have a difficult time understanding her, and she may have a difficult time understanding them. Her behavior may seem strange to them, and their behavior may seem strange to her. How can they trust someone who is so different from themselves?

Furthermore, if clients are from an oppressed group they may not only be anxious about the counselor's differences but also angry. Their experiences with "people like us" may have been very negative. The wheelchair-bound professional was denied employment despite his training and experience because of his disability. The black welfare mother was accused of child abuse when the teacher saw a bruise on the child even though it was caused by a fall. The gay or lesbian couple was denied health benefits because they were not legally married, although they have been living together for more than 20 years. The woman earns considerably less than her colleagues despite equal years of experience because of her gender. All of these people have reason to be angry, although the counselor is probably not the source of the anger.

How does the counselor deal with such differences? She must start by being a learner as well as a teacher. When the counselor does not understand the reasons for a client's behavior, it is her responsibility to figure out what is going on. She must not only teach the client

but also be open to learning from him. If the counselor is working primarily with a certain type of client—Puerto Ricans, the blind, or low-income women—it is useful for the counselor to read as much as she can about this group. However, this is not a substitute for asking the client about his behavior because not all clients fit the stereotypes described in the literature. By asking, the counselor not only learns about the client and his special differences but also shows respect for these differences.

However, what about the client who is angry? He may show that anger in a variety of ways; he may have a temper tantrum in the counselor's office, miss appointments, be unresponsive, give superficial answers to questions, or even lie. First, the counselor must remember that his anger is unlikely to be personally against her as an individual but rather who she represents. If she returns the anger, she will lose the client's trust. Rather, she needs to focus on the client's feelings, trying to determine the source of his rage. The counselor must let the client know that she understands that it may take him considerable time to trust her but that she is patient. She must try not to be defensive, such as by reassuring the client that she is not like other people. Although none of this may work for awhile, client anger has a way of wearing down, leaving the counselor a way of reaching the client.

3.5. Listening

The heart of the counseling process is the ability of the counselor to listen. She not only listens to the content of what the client is saying but also listens to how it is said. Is the client's speech a monotone or emotional, fast or slow, loud or quiet? Does it change depending on the topic being discussed? Does the tone of voice convey the image of a child, a seductive woman, an angry parent, or a sense of hopelessness or helplessness? Listening includes observation of the client as he speaks. Is there eye contact? Are there changes in facial expression or body position? All of these are clues about what is going on in the client's mind, and the client's thought processes provide the counselor with some understanding of the sources of the client's problem. The counselor must put all of this information together to assess the client's strengths and weaknesses and to plan with the client how she can best be of help to him. As she listens, the counselor must decide what response may be helpful to the client.

The counselor's responses are often different from those that might be expected from friends, neighbors,

and relatives. The counselor raises questions that the client had not thought about before. The counselor makes statements that challenge the client's way of thinking. The counselor confronts the client's assumptions about himself and others. The counselor remains silent when the client expects a vigorous rebuttal. These are the responses that make the counseling relationship unique, and these are the behaviors that build trust between the client and counselor.

3.6. Silence

As unusual as it may seem, silence is an important part of the counseling process. Silence by the client has meaning that the counselor must try to understand. Silence by the counselor can be used to help the client in a variety of ways.

The client may be silent just because something he said or the counselor said has led him to think in new ways, to see new meaning or make connections he did not make before. He may be sorting out thoughts and feelings. This is a time when the counselor should also remain silent, as difficult as this may seem. When the client speaks again, a significant breakthrough in his thinking may occur.

The client may be silent because he is feeling deep emotion. The counselor lets the client experience this but not drown in it. She may ask, "What are you feeling right now?" The client may also be silent because he is confused. The counselor can interrupt the silence by indicating that what she said may be confusing and then try to clarify what has happened in the conversation.

The client may be silent because he is resisting the counselor's probing and/or rejecting the counselor's authority. There is tension in the air. The counselor's response might well be that both of them seem to be uncomfortable and maybe they should talk about what is causing the tension between them.

Thus, silence is not to be feared in the counseling process. Rather, it is to be understood and used by the counselor as a way of moving the helping process forward.

4. CONCLUSION

The counseling interview is a complex process that requires considerable training and experience by the counselor to be effective. Although the previous sections discussed the importance of listening and

silence by the counselor, it must not be forgotten that she must be in control of the interview to be effective. It is the counselor's ability to respond—and sometimes not respond—in ways that are not expected by the client that enables her to see the problem differently and deal with it more effectively. When successful, the counseling process can not only be of great aid to the client but also provide much satisfaction to the counselor.

GLOSSARY

cross-cultural psychology The systematic study of behavior and experience as it occurs in different cultures, is influenced by culture, or results in changes in existing cultures.

cultural psychology The intensive study of psychological processes in one culture, which identifies how features of the culture affect these psychological processes.

indigenous psychology The systematic study of the culturally unique concepts and processes found in a given culture.

All human behavior is influenced by the culture in which a person develops. Thus, there can be no complete account of psychological phenomena without taking the cultural context into account. This claim applies not only to the findings of psychological researchers, but also to practitioners, who must

consider the cultural settings of their applications as well as the cultural roots of the behavior.

1. DEFINITION OF CROSS-CULTURAL PSYCHOLOGY

According to Triandis and Lambert (1980), "Cross-cultural psychology is the systematic study of behavior and experience as it occurs in different cultures, is influenced by culture, or results in changes in existing cultures." And per Berry *et al.* (1997), "The field is diverse: some psychologists work intensively within one culture, some work comparatively across cultures, and some work with ethnic groups within culturally plural societies."

Some think of culture as an independent variable that influences psychological processes, and some emphasize that culture and psychological processes are mutually constituted, i.e., "make each other up." Berry argued that culture is both outside and inside the individual. It is independent of the individuals who arrive into a culture and become incorporated into a culture through the process of enculturation; but individuals also incorporate the culture through the same process, so that it also becomes an organismic variable, ready to be transmitted anew to other arrivals. In 2000, a special issue of the *Asian Journal of Social Psychology* discussed the

similarities and differences between indigenous, cultural, and cross-cultural psychology, which reflect these differences in point of view.

2. DEFINITION OF CULTURE

The conceptualization of culture is by no means a simple matter. One possible way to think about culture is that “culture is to society what memory is to individuals,” as per Kluckhohn (1954). It includes what has worked in the experience of a society, so that is what was worth transmitting to future generations. It includes both objective elements, such as tools, bridges, chairs, and tables, and subjective elements such as norms, roles, laws, religions, and values.

Sperber used the analogy of an epidemic. A useful idea (e.g., how to make a tool) is adopted by more and more people and becomes an element of culture. Barkow, Cosmides, and Tooby (1992) distinguished three kinds of culture: metaculture, evoked culture, and epidemiological culture. They argued that “psychology underlies culture and society, and biological evolution underlies psychology” (p. 635). The biology that has been common to all humans, as a species distinguishable from other species, results in a metaculture that corresponds to panhuman mental contents and organization. Biology in different ecologies results in “evoked culture” (e.g., hot climate leads to light clothing), which reflects domain-specific mechanisms that are triggered by local circumstances and leads to within group similarities and between groups differences. What Sperber describes Barkow *et al.* call “epidemiological culture.”

Elements of culture are shared standard operating procedures, unstated assumptions, tools, norms, values, habits about sampling the environment, and the like. Because perception and cognition depend on the information that is sampled from the environment and are fundamental psychological processes, this culturally influenced sampling of information is of particular interest to psychologists. Cultures develop conventions for sampling information from the environment and for how much to weigh the sampled elements. For example, people in hierarchical cultures are more likely to sample clues about hierarchy than clues about aesthetics. Triandis argued that people in individualist cultures, such as those of most cultures of North and Western Europe and North America, sample elements of the personal self (e.g., “I am busy, I am kind”) with high probability. People from collectivist cultures, such as those of most cultures of Asia, Africa, and South America, tend to

sample mostly elements of the collective self (e.g., “my family thinks I am too busy, my co-workers think I am kind”).

Just as individuals are incorporated into their primary culture through the process of enculturation, people may also become members of more than one culture through the process of acculturation, depending on life experiences.

2.1. Relationships with Other Perspectives

Cross-cultural psychology derives from both anthropology and psychology, taking various concepts, theories, and methods from each discipline. Because of this, the field is not unitary, but is composed of various perspectives. In our view, cross-cultural psychology combines two broad traditions. First, we use the comparative method (the “cross”), making assumptions about the comparability of behavior (see below) and employing research and statistical methods drawn primarily from individual psychology. Second, the field is concerned with the unique sociocultural contexts in which people develop and act (the “cultural”), employing observational and narrative methods drawn primarily from cultural anthropology. The “cultural psychology” and “indigenous psychology” schools of thought emphasize this second perspective. However, in practice, both perspectives employ individual data, contextual data, and the comparative method in their work.

3. HISTORY OF CROSS-CULTURAL PSYCHOLOGY

The first person to write anything relevant about this topic was probably Herodotus, during the 5th century BC. There are three histories of the field that start with Herodotus, who had the insight that all humans are ethnocentric. This is necessarily an aspect of the human condition, because most humans are limited to knowing only their own culture and thus are bound to use it as the standard for comparing their culture with other cultures. It is unfortunate that this is necessarily the human condition, because it makes people think that their norms and values are universally valid, and any deviations from them is seen as not only wrong but also immoral. Much human conflict can be traced to ethnocentrism. It is only when humans have experienced several other cultures that they

become sufficiently sophisticated to see both the strengths and weaknesses of every culture and thus to become less ethnocentric.

Jahoda provided a detailed history of the field in which he discussed the work of Vico in the early 19th century, Wundt in the early 20th century, Tylor, Rivers, Boas, Luria, Bartlett, Benedict, Vygotsky, and others. These writings were not central to the activities of most psychologists until the late 1980s and early 1990s, when many of the findings of cross-cultural psychology began challenging some of the theories of mainstream psychology.

The field became a distinct field of psychology in the early 1970s, when awareness of the need to stop being ethnocentric in research, and the need to develop measurements of psychological constructs that are both culturally sensitive and equivalent across cultures, became acute. Avoiding intellectual colonialism, such as the exploitation of data from other cultures without giving credit to local psychologists, resulted in an effort to develop a code of ethics for cross-cultural research. However, this code was not adopted by any association of psychologists because it was felt that it was overly strict and unrealistic and would inhibit research.

In the 1970s, most psychologists used an absolutist viewpoint. That is, it was assumed that all psychological discoveries were valid everywhere, and culture provided only minor modifications of these discoveries. In the 1980s, however, a number of researchers assumed more relativistic positions, in some cases even denying the psychic unity of humankind. Nowadays, a universalistic perspective is taken by many cross-cultural psychologists.

Journal publications with a cross-cultural psychology focus started in 1966. Leonard Doob, editor of the *Journal of Social Psychology*, and Germaine de Montmollin, editor of the *International Journal of Psychology*, announced that they would favor cross-cultural articles. The Human Relations Area Files started a journal that year that eventually became *Cross-Cultural Research*. It is now the official organ of the Society for Cross-Cultural Research. The *Cross-Cultural Newsletter* (first edited by Triandis) was launched in 1967. It eventually became the *Cross-Cultural Bulletin of the International Association for Cross-Cultural Psychology*. A directory of cross-cultural psychologists was first published by Berry in 1968. The *Journal of Cross-Cultural Psychology* (Walter Lonner, editor) started in 1970 and became the official organ of the International Association for Cross-Cultural Psychology. The Association pour la Recherche Interculturelle was established in 1984, and included

French speaking cross-cultural psychologists. The Annual Review of Psychology introduced chapters reviewing cross-cultural work in 1973. The first edition of the *Handbook of Cross-Cultural Psychology* (Triandis, editor) appeared in six volumes in 1980–1981. The second edition (J.W. Berry, editor) appeared in three volumes in 1997.

3.1. Theory

The term absolutist was used to refer to a theoretical position that assumes that psychological findings are valid for all people everywhere; culture is thought to play little or no role in the development or expression of human behavior. Two other theoretical perspectives have been differentiated from absolutism. Relativism is essentially the opposite point of view: culture is so important in understanding human behavior that no psychological research or application can be done without knowing, and taking into account, the cultural context. An intermediate position (universalism) takes the position that human psychological processes are common, species-shared qualities; culture plays important variations on these basic processes during behavioral development and expression. In addition, absolutism tends to make comparisons freely; relativism generally avoids them; and universalism makes judicious comparisons (based on the underlying commonality) while taking care to understand the influence of culture. In a sense, the basic commonality makes comparisons possible (see discussion of equivalence, below), while the cultural variation in expression makes them interesting and worthwhile. In terms of the other perspectives or schools discussed previously, the cultural and indigenous approaches tend to be relativist, while the cross-cultural approach tends to be universalist. (But few psychologists who read this article are likely to be absolutist!)

4. METHODOLOGY

4.1. Levels of Analysis

Cross-cultural psychologists often work at different levels of analysis. For example, Hofstede has collected data from over 100,000 participants in more than 40 countries. By 2001, the data set was expanded to 50 countries. Responses to a sample of 40 and later 14 goals/value items were collected. He summed the responses to each goal/value item by the participants from each country. Then he factor-analyzed the 40 by

40 (or 14 by 14) matrix, based on 40 or 50 means. This is an ecological analysis and is very different from a within-culture analysis, in which the matrix of correlations is based on the number of participants from that culture.

Readers may need an illustration of the fact that results at the cultural (or group) and individual levels of analysis can be different. Lincoln and Zeitz studied 500 employees divided among 20 social service agencies. They found that supervisory duties were positively correlated with professional qualifications across individuals but negatively correlated across agencies. The latter correlation was due to the fact that the members of the more professional agencies did not need much supervision.

4.2. Comparability and Equivalence

As was noted above, there are different viewpoints regarding whether comparisons are legitimate: relativists tend to object to them, absolutists tend to make them without restriction, and universalists employ them with caution, once certain conditions are met.

All acts of comparison (whether they be of cultures, institutions, or behaviors) require some common dimension along which phenomena can be judged. Apples and oranges can indeed be compared: on sugar content, juiciness, or price. The presence of such commonalities is a prerequisite for making a comparison; however, it is not enough. Cross-cultural psychologists seek to establish the comparability of two (or more) phenomena, using a number of ideas and techniques. One of these is equivalence, in which conceptual meaning and psychometric properties can be demonstrated to be sufficiently similar between two sets of data to be compared. It is no longer accepted practice to simply use an instrument, obtain a score, and apply a test of significance to the difference. While this has been known for a long time, it is still ignored by some writers who submit papers to the editors of psychological journals.

4.3. Emics and Etics

One approach to better controlling cross-cultural comparison is with the use of the concepts of emics and etics. All cultures categorize, but the categories that are used are culture specific. For instance, our eye is capable of discriminating 7,500,000 million colors, but we get along with a couple of dozen color names. Through the use of Munsell color chips, which provide an objective domain to which we can compare the way people in different cultures categorize colors, we can

determine that the categories are not identical. The stimuli at the core of major color categories such as “red” are the same, but the periphery is not. So, even when we deal with something as simple as the identification of colors we must take cultural specificity into account. All categories are culture specific. We call these emic, from Pike’s use of phonemics and phonetics. But while most categories are emic, there are elements that are universal, which we call etic. In short, if we stick only to the core of each color range (the etic part) we can use the word “red” and its translations across cultures with reasonable equivalence. But there are regions of the category that are not equivalent across cultures.

Furthermore, there are languages that have very few color names. Some languages have only two words that are relevant to color that are more or less equivalent to white and black. When a language has three color names, it adds a word for red. If it has four or five names, then it also has words that are more or less equivalent to yellow and green. Languages that have progressively richer color vocabularies have a word for blue, then for brown, finally for purple, pink, orange, and gray.

People who do not distinguish between green and blue have difficulties in discussing differences in color between grass and the sky. If we study this domain and assume that they see color the way we do, we are likely to obtain distorted results. To avoid this problem, when we do a study we should talk to many people from each language to see how they cut the pie of experience. This would identify their emics for dealing with the particular topic. When we do that, some of their categories may also appear in other languages. Then, they may in fact be etics.

When we construct instruments such as tests or interview questions, or scales, we need to incorporate both emics and etics. The emics allows us to measure a phenomenon with cultural sensitivity, “the way the natives see it.” The etics allows us to compare the cultures. For example, a scale of social distance was constructed for Greeks and Americans in 1962. The scale values were standardized separately for each culture, and were made equal to zero for “I would marry this person” and 100 for “As soon as I have a chance I am going to kill this person.” The item “I would accept this person as a roommate” made sense only in the United States and had a scale value of 29.5. The item “I would accept this person in my *parea*” was a Greek emic, and had a value of 31.1. A *parea* is an intimate group of friends that meets almost daily to enjoy things together. “I would rent a room from this person” had a scale value

of 57.5 in the United States and 42.8 in Greece, suggesting that in Greece it was a more intimate activity. In a culture such as India, where touching is a very important issue, one would use emic items such as “I would allow this person to touch my earthenware.” In a culture that has residential segregation, an item such as “I would allow this person to live in my neighborhood” would be a useful item to measure social distance.

We also need to consider the fact that often a construct used in the West has very different meanings in other parts of the world. For example, when people in the West use the concept of “intelligence,” they include the ideas of speed, successful adaptation, and effective completion of tasks. In parts of Africa, people think that to be intelligent means to be slow, sure, and not make mistakes. In other parts it includes the ideas “knows our traditions” and “does what the elders expect.” Among the Cree, a Native American tribe, “lives like a white” is conceptually close to “stupid.”

4.4. Translation

In the construction of instruments that can be used equivalently across cultures, researchers need to use translation. This is a complex process.

5. DIMENSIONS OF CULTURAL VARIATION

As has just been noted, comparisons require common dimensions on which they can be made. Beyond this simple dictum is a complex reality: there are many possible dimensions that could be employed in comparing cultures, institutions, and behaviors.

When we think of the relationship between culture and psychology, it is useful to use a metaphor from geography. We can discuss continents by describing mountain ranges, rivers, bays, etc. We can discuss countries by describing similar features, cities, villages, roads, etc. We can describe cities by describing roads, buildings, etc. We can describe villages by specifying the location of every building in relation to every other building. We can describe neighborhoods by discussing the economic, social relationships, religions, and political organizations of the residents, etc. Finally, we can discuss households by giving the biography of each member of the household, etc.

Note that as we move to lower levels of abstraction, we need more dimensions, details, specifications.

Psychologists deal with phenomena that are based on the common biology of humans, as it adapts to different environments (continents). Social psychologists also examine different environments (ecologies), for instance, social relationships in which people influence each other a great deal, as one finds in agricultural societies, or relatively little, as one finds among hunters and gatherers. Then, different behaviors can be identified. For example, there is more conformity in agricultural than in hunting environments. The societies that are agricultural have more inequality than the societies that engage in hunting and gathering.

Different disciplines focus on different levels of analysis. For example, literary productions describe events at the level of households. Anthropologists describe neighborhoods. Sociologists tend to describe cities and villages. We believe that all this work is valuable. All the information is necessary for a balanced understanding of the culture and psychology relationships.

In this section we focus on some of the dimensions of cultural variation that correspond to the level of continents. The data are obtained from different countries, though this is a very rough procedure because each country contains hundreds of cultures. Yet because regions of the world (e.g., Europe versus East Asia) have something in common, we can discuss the ways in which they are similar and different. Other work that we have no space to discuss is done at the other levels of analysis and is also valuable. The dimensions of cultural comparison are also called “cultural syndromes.”

5.1. Complexity

We mentioned previously the contrast between hunters and gatherers and agricultural societies. Agricultural societies are more complex in the sense that they have more types of roles than hunting and gathering societies. As we move to modern information societies we find even more complexity, for instance, many more roles than in more simple cultures. If we consider all forms of specialization, e.g., the difference between medical specializations, in complex societies there are more than a quarter of a million roles.

5.2. Tightness and Looseness

Societies differ in the number of norms concerning correct behavior. Some have many norms, e.g., how to bow and how to smile, and others have few norms. Furthermore, some cultures punish severely those who deviate from norms whereas others are lenient. In tight

cultures, there are many norms, and those who do not follow the norms are criticized or even killed. In loose societies, there are not many norms, and people who do not behave according to the norms are not punished. People are very likely to say “It does not matter” when they see a deviation from a norm. An example of a tight culture was the Taliban in Afghanistan. They killed people in large numbers for relatively minor deviations from arbitrary norms that they imposed on the basis of supposedly religious guidance. Some of these norms, such as not listening to music and not watching Western television, had nothing to do with religion. An example of a loose society, on the other hand, is Thailand, where people tend to smile even when employees do not show up for work as expected. The imposition on norms depends of the domain or the situation. For example, in the United States there is tightness concerning how to deal with banks, your checkbook, loans, mortgages, and the like. But now there is considerable looseness concerning who you can live with. Of course, there are also major individual differences. Some people are compulsive about their own and others’ behavior, while others are very lenient (e.g., any behavior is okay; it’s none of my business to criticize this behavior).

Hofstede identified a dimension he called uncertainty avoidance, which is related to tightness. Countries high on this dimension were Greece, Portugal, and Guatemala; low were Denmark, Jamaica, and Singapore. Subjective well-being was negatively correlated with this dimension, presumably because people in tight cultures are anxious about being criticized or punished for behavior that is not perfectly “correct.”

5.3. Collectivism and Individualism

Societies that are both simple and tight tend to be collectivist. Societies that are both complex and loose tend to be individualist. Collectivism is a cultural pattern found especially in East Asia, Latin America, and Africa. It is usually contrasted with individualism found in the West, e.g., in Western and Northern Europe, the United States, Canada, Australia, and New Zealand. Note, however, that any typology is an oversimplification; societies are not purely individualist or collectivist but some mixture of the two. The construct has been widely used in the study of cultural differences. Unfortunately, however, most of the research compared samples from North America versus East Asia. Thus, in the description of the attributes of the construct and its antecedents and consequents we rely too heavily on the differences between the United States and Canada on

the one hand and China, Korea, and Japan on the other hand. We do not know if the information we present below applies equally to Africa and Latin America, though we suspect that much of it does. Much more research is needed on this topic.

Among the most important characteristics of the collectivist cultural pattern are the following:

1. Individuals define themselves as aspects of a collective, interdependent with some ingroup, such as one’s family, tribe, co-workers, or nation, or a religious, political, ideological, economic, or aesthetic group.
2. They give priority to the goals of that collective rather than to their personal ones.
3. Their behavior is determined more often by the norms, roles, and goals of their collective than by their personal attitudes, perceived rights, or likes and dislikes.
4. They stay in relationships even when the costs of staying exceed the advantages of remaining.

These are the defining attributes of collectivism. There are as many kinds of collectivism as there are collectivist cultures. To distinguish among collectivist cultures additional attributes are necessary.

Triandis summarized the literature that used that construct in social psychology, and Kagitcibasi provided a critical evaluation of the construct. Hofstede found that the United States, Australia, and Britain were highest in individualism and Panama, Ecuador, and Guatemala were highest in collectivism. Most Western countries are individualist and most East Asian countries are collectivist. However, gross national product per capita is correlated with individualism; thus, wealthy East Asian countries such as Japan are not as collectivist as one would expect from their geographic location.

Within any society there are individuals who behave like persons in collectivist cultures, called allocentrics. They contrast with those who behave like persons in individualist cultures, who are called idiocentrics. There are both allocentrics and idiocentrics in every society, but their distributions are different, with more allocentrics found in collectivist cultures.

Collectivism is maximal in relatively homogeneous societies, such as theocracies and monasteries, while individualism is maximal in heterogeneous societies that are very affluent. Thus, there will be few idiocentrics in monasteries and few allocentrics among Hollywood stars.

All individuals have access to cognitive systems that include both allocentric and idiocentric cognitions, but they sample them with different probabilities, depending on the situation. For example, if the ingroup is under

attack, most individuals become allocentric. In the company of other allocentrics, the norms for allocentric behavior become salient, and individuals are more likely to sample allocentric cognitions. Some situations provide very clear norms about appropriate behavior (e.g., in a house of worship), while other situations do not (e.g., at a party). Individuals will be more allocentric in the former than in the latter situations. When the ingroup can supervise an individual's behavior, norms are more likely to be observed, and the individual will be more allocentric. In one study, allocentrics and idiocentrics were randomly assigned to simulated organizations that were individualist or collectivist, and the degree of cooperation exhibited by the individuals was studied. It was found that cooperation was high when allocentrics were in a collectivist organization. In the other three cells of the experiment, there was very little cooperation. In short, both the personality and the situation were required to predict the behavior.

Collectivism can appear in all or none of the domains of social life. For example, it can be found in politics, religion, aesthetics, social life, economics, or philosophy, as was the case in China during the Mao period, or in none of these domains, as among Hollywood stars.

5.3.1. Antecedents of Collectivism

Some of the antecedents of collectivism are listed in Table I and are discussed below:

Homogeneity of the collective. If people disagree about the norms of proper behavior, or the goals that people should have, it is difficult for people to behave according to the norms of the group.

TABLE I
Some Antecedents of Collectivism

-
- Homogeneity of the collective
 - Low exposure to other cultures
 - Interdependence is adaptive to ecology
 - Population density
 - Social stability
 - Low economic status
 - Large families
 - One large ingroup rather than many ingroups
 - Salient common fate
 - Collective mobility is advantageous
 - Strict religious upbringing
 - Little exposure to modern mass media
-

Low exposure to other cultures. People who know only one culture tend to be maximally ethnocentric, authoritarian, and submissive to ingroup authorities. Those who are more educated, traveled, and have lived with more than one cultural group develop idiocentric tendencies.

Interdependence is adaptive to ecology. People are more interdependent in agricultural societies than in information societies. For example, when the goal is to complete large projects such as irrigation canals or defensive walls, collectivism is more likely. In societies where people are financially interdependent, collectivism is high. People who can do their job when they are alone are more likely to be idiocentric.

Population density. In dense social environments, many rules that are designed to reduce conflict and ensure the smooth functioning of the group develop.

Social stability. When the collective is stable, it is more likely to develop agreements about norms, and to make sure that the norms are observed. There is evidence that the older members of all societies are more allocentric than the younger members.

Low economic status. The lower social classes tend to be more conforming to social norms than members of the upper classes. When resources are limited, one often depends on group members for assistance, especially in emergencies. These factors increase collectivism. On the other hand, in all cultures, those in positions of leadership tend to be idiocentric.

Large families. In large families it is not practical to allow each child to follow idiosyncratic schedules or to have much privacy. Many rules are enforced, and that creates collectivism.

One large ingroup rather than many ingroups. Those who only have one ingroup can channel all their energy into that group. Also, they cannot afford to develop poor relationships with members of that group, so they are more likely to observe its norms.

Salient common fate. Common fate with members of the ingroup (e.g., when the ingroup is under attack) increases collectivism. Time pressure for decisions has similar consequences.

Collective mobility is advantageous. If individual upward social mobility is not possible, then collective mobility may be used. Thus, individuals invest their energy in promoting the status of their ingroup.

Strict religious upbringing. Most religions require observance of a large number of norms and threaten to punish those who ignore these norms. That increases collectivism.

Little exposure to modern mass media. U.S.-made television is widely available throughout the world.

Content analyses show that the themes used are highly individualistic (e.g., emphasis on pleasure, doing what the individual wishes to do even if that is inconsistent with the wishes of authorities). Countries where people have little exposure to Western mass media are more collectivist.

5.3.2. Consequences Of Collectivism for Cognition, Emotion, and Motivation

Marcus and Kitayama have reviewed much evidence showing the influence of collectivism on cognition, emotion, and motivation (see Table II).

Thinking. Nisbett, Peng, Choi, and Norenzayan examined a broad range of literature concerning thought patterns in ancient Greece and China, two cultures that correspond to the individualism–collectivism contrast. They argued that the Greeks thought analytically and the Chinese holistically. The Greek traditions influenced the West, which now uses logic, rules, and categories and sees the world as a collection of discrete objects, while the East sees the world as a collection of overlapping and interpenetrating substances. They reviewed much empirical work that contrasted Western and Eastern cultures, and found that the West focuses on objects and their attributes, while the East focuses on the context of objects and the relationships of objects and events to each other. Western thought

is linear, concerned with abstract analysis, and pays much attention to contradictions. Eastern thought is dialectical, experience-based, and pays little attention to contradiction. The West is more field independent; the East more field dependent. Explanations of events in the West focus on the attributes of the object, e.g., the attitudes, beliefs, and values of individuals as determinants of behavior; in the East, the focus is on the context of the object, e.g., group memberships, norms, and social pressures that influence the behavior of individuals. Numerous other cognitive patterns contrast these two kinds of cultures and show not only quantitative but also qualitative differences in thinking.

Attributions. Allocentrics make external attributions in explaining events, whereas idiocentrics show the opposite pattern. Thus, the idiocentrics make the fundamental attribution error (i.e., seeing internal rather than external causes for the behavior of other people, while the actors themselves see external causes as explanations of their own behavior more often than internal causes) more frequently than do allocentrics. Also, allocentrics attribute their successes to the help they have received from others and their failures to personal shortcomings (e.g., I did not try hard enough). Allocentrics tend to think that social environments are stable and individuals are easy to change so that they can fit into the environment; idiocentrics think that individuals are stable and social environments are easy to change.

Emotions. Members of collectivist cultures get angry when something unpleasant happens to ingroup members more often than when something unpleasant happens to themselves. They do not express negative emotions as often as do members of individualist cultures.

Description of self. When asked to complete 20 statements that begin with “I am . . .” members of collectivist cultures provide sentence completions that have more social content (e.g., I am a brother, I am a member of the Communist party) than do members of individualist cultures.

Socialization. In collectivist cultures, children are socialized to be obedient, be reliable, follow traditions, do their duties, sacrifice for the ingroup, and be conforming. An important value is self-control.

Low well-being. While members of all cultures are satisfied with their life, members of collectivist cultures are less satisfied than members of individualist cultures. Well-being tends to be correlated with individualism. This relationship persists even when statistically controlling for income.

TABLE
Consequences of Collectivism

-
- Thinking
 - Attributions
 - Emotions
 - Describe the self by using roles, groups
 - Consequences of socialization
 - Low well-being
 - Social behavior
 - Receive much social support if they conform
 - Have poor skills for entering new groups
 - Are easy to mobilize for confrontations with outgroups
 - Have the ideal of fitting-in rather than shining
 - Show little social loafing
 - Recreation occurs in stable groups
 - Communication
 - Conflict resolution
 - Conformity
 - Apologize more for transgressions of the ingroup
-

Social behavior. Collectivists are extremely concerned with “saving face,” and even attempt to save the face of the persons with whom they are interacting. Preserving harmony within the ingroup and being pleasant in relationships with ingroup members are often important values. On the other hand, collectivists do not care much about their relationships with outgroups. They usually behave quite differently toward ingroup versus outgroup members, showing sacrifice and extreme cooperation with ingroup members and suspicion and hostility toward outgroup members.

Social support. Allocentrics report that they receive more social support and a better quality of social support than do idiocentrics. However, those who do not conform to ingroup norms are rejected, and may even be killed.

Poor skills for entering new groups. Members of collectivist cultures do not have good skills for entering new groups, because they are not socialized to do this. They are comfortable as members of their ingroups, thus they do not need to enter other groups.

Easy to mobilize for confrontations with outgroups. When ingroups are in conflict it is easier to arouse members of collectivist cultures to fight for the ingroup than it is to do so with members of individualist cultures. Ethnic cleansing is more often found in collectivist than in individualist cultures.

Have the ideal of fitting-in rather than shining. Allocentrics prefer to fit in and be like most others in their ingroup rather than shining and sticking out. Idiocentrics tend to be high in self-enhancement (i.e., report that they are better than most other people on most desirable attributes). Allocentrics tend to be modest when they compare themselves to others.

Show little social loafing. Allocentrics show little evidence of social loafing (i.e., the tendency to produce less when working in a group versus when working alone, if their output is not identifiable). They usually produce as much as possible when they work with ingroup members, but they do show social loafing if their co-workers are outgroup members.

Recreation. Members of collectivist cultures seek recreation in groups to a greater extent than members of individualist cultures (e.g., bowling rather than skiing).

Communication. Members of collectivist cultures rely on the context (e.g., distance between and position of bodies, eye contact, gestures, tone of voice) more than on the content of communications. For example, rather than saying “no,” they may serve incongruous foods in order to put across their negative message without

causing the other person to lose face. When they describe a person they are likely to use context, e.g., “He is intelligent in the marketplace,” rather than decontextualized statements, such as “He is intelligent.” Silence is used more in collectivist than in individualist cultures. Compliments are not used as frequently as in individualist cultures. The languages of collectivist cultures do not require the use of “I” or “you.” Collectivists use more action verbs (e.g., he asked for help) rather than state verbs (e.g., he is helpful), which suggests that they use communications that make greater use of context, are more concrete, and place less emphasis on the internal attributes of the person.

Conflict resolution. Members of collectivist cultures avoid conflict with ingroup members, and in the case of disagreement they prefer silence to argument. They prefer mediation to confrontation.

Conformity. Members of collectivist cultures show more conformity than members of individualist cultures in experiments that measure conformity.

Apologize more for transgressions of the ingroup. Members of collectivist cultures apologize more when an ingroup member commits a crime than is common in individualist cultures.

5.3.3. Evaluation of the Construct

While people in collectivist countries indicate that they are less happy than people in individualist countries, individualism has been found to be associated with poor marital adjustment, thus high divorce rates, and more delinquency, crime, drug abuse, suicide, experimenting with early sex, and stress.

Naroll has reviewed much evidence that indicates that tight social groups are needed for social control and the good life. Diener and Suh suggest that “real happiness” depends on having many small positive experiences rather than having a few very intensive positive experiences. Thus, while people in collectivist countries may feel unable to do “their own thing” and thus report low levels of happiness at the moment they are asked if they are happy by the researcher, they may be happier in the long run. Thus, each cultural pattern has both positive and negative aspects.

5.4. Power Distance

Hofstede identified a dimension of cultural variation he called power distance. Cultures high on this dimension have members who see a large distance between those

who have power and those who do not. Thus, for instance, people in such cultures fear disagreement with their superiors. Countries high on this dimension were Malaysia, Guatemala, and Panama. Countries low were Denmark, Israel, and Austria. This dimension was highly correlated with collectivism. It was also correlated with the level of corruption of the country.

5.5. Sex Differentiation

Hofstede has identified a dimension he calls masculinity–femininity. In feminine cultures, members of the culture attach more importance to relationships, to helping others, and to the physical environment than people in masculine cultures. In masculine cultures, people emphasize careers and money. The goals of men and women are more differentiated in masculine than in feminine cultures. National samples that emphasized male goals were found in Japan, Austria, and Venezuela, whereas the Scandinavian countries and the Netherlands emphasized female goals. In the countries that were high in masculinity, men and women gave very different responses to Hofstede's value questions, while in the countries that emphasized female goals, the answers obtained from men and women were the same. Similar differences were observed across occupations, with engineers giving masculine and secretaries giving feminine answers. The consequences of this cultural difference included such matters as people in masculine countries wanting brilliant teachers versus people in feminine countries wanting friendly teachers. Differences in politics were also identified. In masculine countries people supported tough policies toward poor people and immigrants. Economic growth was given priority over preservation of the environment in masculine countries. In feminine countries, compassionate policies toward the weak and the environment were given high priorities.

5.6. Dealing with Time

There are cultural differences in the way time is viewed and in the speed of life. People in countries that are rich, individualistic, and in cold climates move fast and arrive for appointments at the correct time. Those in poor, collectivist countries located in hot climates tend to move slowly and arrive for appointments late. For example, because in collectivist cultures interpersonal relations are very important, if a person who is on her way to an appointment meets a friend, the chances are that she will spend much time with the friend and be very late for the appointment. But it will not be

necessary for her to apologize for being late, as most likely the other people at the appointment will also arrive late.

In all countries, cities are faster than rural environments. Levine devised a number of methods that objectively measured speed; for example, how fast do people walk in the street, how long does it take to mail a letter, how accurate are the clocks in public places. These measures were intercorrelated, showing concurrent validity. He took several samples on each measure in 31 countries. Switzerland, Ireland, and Germany were the fastest and Brazil, Indonesia, and Mexico the slowest countries.

Hofstede introduced a measure of long- versus short-term orientation. A long-term orientation was found in East Asia, among countries with a Confucian tradition, while a short-term orientation was found in the Philippines, Nigeria, and Pakistan.

5.7. Missing Topics

The relationship between culture and psychology is so extensive and complex that in this article we were able to present only an introduction. Cultural differences in trust, although not discussed here, are especially important because in countries that are low in trust it is difficult to have economic development. Low trust is frequently found in collectivist cultures where outgroups are often seen as enemies. Because most people belong to outgroups, people in low-trust countries feel surrounded by enemies. A study by Bond, Leung, and 60 other researchers identified a factor that is related to distrust. Countries such as Pakistan and Thailand were high on this factor whereas most of the European countries were low. It is not clear at this time if economic development results in high trust or if high trust leads to economic development. It is likely that the relationship is reciprocal.

6. EVALUATION OF FINDINGS AND APPLICATIONS

Approximately 20 years ago, the World Health Organization (WHO) approached the International Association for Cross-Cultural Psychology with what appeared to be a rather simple question: "What do you know, as cross-cultural psychologists, that can help the WHO to achieve its goal of Health for All by 2000?" A number of meetings were held to discuss, and to try to answer, this question. The result was a volume of topical appraisals and an evaluative overview of them. Dasen

et al. concluded that there was considerable research-based knowledge, but little that was readily applicable. Two reasons were advanced to explain this discrepancy. First, most knowledge acquisition is driven by a research orientation more than (even rather than) a view to eventual application: at the end of a project, there is often the question, “What do we do with all this?” Second, most research, even research that is explicitly cross-cultural, is rooted in one dominant psychological perspective (e.g., WASP, Western academic scientific psychology) that smacks of ethnocentrism, even if that is inadvertent.

A later approach was made to a broader range of questions that went beyond health to other domains of human activity. Once again we concluded that there was great potential but little actual achievement: a substantial knowledge base had not yet been applied. More recently, a number of authors addressed this question for a limited number of behavioral domains, and found that while progress had again been made, the gap between knowledge and practice remained wide. This state of affairs is not unique to cross-cultural psychology, but it is made more salient by the urgent need to use psychological knowledge in many parts of the world. Critical projects are needed in societies other than those in which the knowledge was generated.

One way to assist in the process of application is to present the knowledge base for findings that may qualify as “universals,” and hence that may be applicable across cultures. In such cases, the problem of cultural irrelevance or incompatibility may be reduced, even though the science–application gap may remain. Following the sequence in this article, we can first make use of the knowledge provided by our cognate disciplines of cultural anthropology, linguistics, and sociology. These disciplines have established universals in sociocultural systems and institutions, ones that can be found in all societies. Some of these have been portrayed in Section 5. What we take from these is not that the variation hinders application, but that the common dimensions provide a basis for the cross-cultural use of various research findings.

From these other disciplines, we have also adopted theoretical perspectives (especially relativism and universalism) and concepts that provide foundations for our methodological tools (emics, etics, equivalence); other applications include cultural similarities and differences in organizational behavior. Finally, an important application is training people to learn how to interact successfully with those from other cultures.

GLOSSARY

individualism–collectivism Continuous dimension of cultural variation emphasizing an orientation toward personal goals, independent self-construal, and individual autonomy, at the one end, and group goals, interdependent self-construal, and emphasis on long-standing close relationships within in-groups, at the other.

looseness–tightness Continuous dimension of cultural variation describing the degree to which a culture endorses multiple and pluralistic standards of behavior, at the one end, and uniform, socially prescribed behaviors, at the other; loose cultures tolerate deviance from norms, whereas tight cultures emphasize sanctions for violating norms.

multilineal cultural evolution Dominant perspective on the evolution of cultural complexity; although it emphasizes some universal patterns in culture change from family level to state societies, it acknowledges multiple causal variables and trajectories in cultural evolution.

power distance Continuous dimension of cultural variation describing how relationships between high-ranking and low-ranking persons are conducted, with a high degree

of deference to superiors and social distance between superiors and subordinates, at the one end, and egalitarianism, at the other.

social power The means by which a social actor can influence, motivate, or control other individuals; it can be developed through interwoven networks of economic, military, ideological, and political sources of power and control.

standard cross-cultural sample (SCCS) A coded sample of worldwide cultures compiled by anthropologists for the purposes of cross-cultural studies.

unilineal cultural evolution Popular theoretical perspective during the late 19th century that cultures evolve along a single lineal dimension through set stages, usually based on technological or economic development; it has been long discredited by cultural anthropology and archaeology as simplistic and ethnocentric.

Cultural complexity entails the presence of a multitude of social networks, social groups, hierarchies, power structures, roles, positions, and/or divisions. Whereas kinship is the primary organizational concept in simpler societies, complex societies have multiple levels of crosscutting ties, affiliations, responsibilities, membership, values, norms, and rights. Individuals pursue their own particular goals through social networks, and no two people have the exact same network or objectives. Perhaps the key difference between simple societies and complex societies is the presence of social power, that is, the means by which human actors can manipulate others in the pursuit of social goals.

1. CULTURAL COMPLEXITY: A RECENT PHENOMENON

Cultural complexity is a recent phenomenon of human society. Paleoanthropology and the fossil record reveal a record of at least 5 million to 6 million years of hominid evolution. Hominids with large brain cases, the genus *Homo*, date back to circa 2 million years ago. Archaic *Homo sapiens*, including the Neanderthals, stretch back to perhaps 400,000 years ago. Our own species, *Homo sapiens*, can trace its origin to Africa some 150,000 to 200,000 years ago.

Yet even after the appearance of physically modern humans (with brains apparently as large and complex as our own), human culture and society remained relatively simple for tens of thousands of years. Despite having the same mental “hardware” as we do today, humans showed no flashes of art, complex organization, ethnicity, or other indications of significant change until the Upper Paleolithic period in the Old World circa 40,000 years ago. Even so, this early florescence of art, religion, technology, ethnicity, identity, and other human cultural hallmarks was still characterized by small and mobile populations, the lack of institutionalized leadership, extremely limited social power, and fairly simple social networks.

It is not until the first appearance of dense population, food surpluses, and settled villages roughly 10,000 years ago (the Neolithic period in the Old World and somewhat later during the Formative period of the New World) that cultural complexity can first be discerned in the human record. Since that point, there has been a drastic trend toward fewer and more complex societies. Eventually, chiefdoms, archaic states, and early empires in turn gave rise to modern nation-states during the 19th century. The 20th century witnessed the rise of economic, political, and cultural globalization. Clearly, there has been a breakneck rush toward ever higher levels of cultural complexity over the past few centuries. Perhaps as a consequence of this pattern of historical evolution, cultural complexity has been used primarily to characterize premodern societies rather than to differentiate between modern nation-states.

Social scientists interested in the relationship between human culture and biology should keep this point clearly in focus: The modern complex human brain was in place far earlier than were the complex cultural and social manifestations that it permits. Evolutionary psychologists should be cognizant of this when inferring connections between current human social behavior and the biological apparatus of the mind.

2. CULTURAL COMPLEXITY DEFINED

Given that it is a central theoretical concept in the social sciences, especially anthropology, an explicit definition of cultural complexity is surprisingly hard to pin down. Carneiro provided one influential perspective, arguing that complexity focuses on society as a structural end product, whereas evolution focuses on the processes that gave rise to this. Following Spencer, Carneiro defined evolution as “a change from a state of relatively indefinite, incoherent homogeneity to a state of relatively definite, coherent heterogeneity, through continuous differentiations and integrations.” Hence, cultural complexity would be characterized by coherent heterogeneity—a state of organized differentiation. Such a definition is necessarily vague in that cultural complexity is used primarily as a relative term to rank order various cultures and societies (and this can be done reliably) rather than standing alone in terms of essential meaning according to necessary traits or attributes.

Cultural complexity entails the presence of a multitude of social networks, social groups, hierarchies, power structures, roles, positions, and/or divisions. Whereas kinship is the primary organizational concept in simpler societies, complex societies have multiple levels of cross-cutting ties, affiliations, responsibilities, membership, values, norms, and rights. Individuals pursue their own particular goals through social networks, and no two people have the exact same network or objectives. Perhaps the key difference between simple societies and complex societies is the presence of social power by which human actors manipulate others in pursuit of social goals. With social power comes the potential for social inequality, ranking, hierarchy, and social stratification. It is also possible, however, to have multiple divisions of horizontal rather than vertical power, that is, heterarchy rather than hierarchy. In such cases, there is a different but equal distribution of power.

3. THEORIES ON THE ORIGINS OF CULTURAL COMPLEXITY

A wide range of theoretical perspectives has been employed to understand how and why human cultures become complex. Progressivists such as Locke first opened the door to explaining differences in human societies without recourse to religious or mythological causes. By the mid-19th century, naturalists and social

scientists alike were profoundly influenced by Darwin's theory of natural selection. Social Darwinists such as Spencer and early anthropologists such as Tylor applied evolutionary concepts to the development of human society. Morgan and other unilineal cultural evolutionists believed simplistically that human societies naturally progressed through a series of stages usually tied to economic or technological patterns. Such thinkers, unfortunately, tended to invoke racial arguments to explain differences in cultures and their level of attainment. Nevertheless, such thinking had a strong influence on Marx in his theories of social evolution and economic materialism. Similarly, Freud was heavily influenced by unilineal evolution as he outlined the development of human societies from simple to complex through universal psychological patterns.

The early and mid-20th century saw two major perspectives on cultural complexity struggle for supremacy in both American and European social sciences. "Multilinear evolutionists" favored materialist explanations focused on economics, technology, energy, ecology, and the like. Unlike their 19th-century predecessors, however, these theories recognized numerous causal factors and possible cultural trajectories. Evolutionists rarely gave credence to ideology, symbolism, or the role of the individual. Cultural relativists, on the other hand, avoided generalizations and focused instead on the diffusion of cultural traits or functional descriptions of culture and social structure. The most prominent example in American cultural relativism is Boas. In Europe, social theory was led by schools of sociology (e.g., Durkheim, Mauss, Weber), structuralism (e.g., Levi-Strauss), and functionalism (e.g., Malinowski, Radcliffe-Brown, Evans-Pritchard). These perspectives often downplayed materialism and instead employed ideology, symbolism, and deep cognitive structures as causal factors. Some of these perspectives also attached great importance to the role of the individual as a cultural actor with agency.

The social sciences, however, did develop a synthesis view of cultural evolution and cultural complexity by the end of the 20th century. It recognizes that extreme views are unlikely to derive a parsimonious explanation for all cases. Mann has been a leading figure of the synthesis through his multidimensional social power theory, which stresses that individuals are agents that pursue their goals through overlapping networks of economic, military, political, and economic power. Social power is the means by which individuals acquire and manipulate the flow of information, energy, social status, wealth, and other resources.

Social scientists during the past few decades have had a more sophisticated view of cultural complexity, one that takes account of a variety of overlapping factors.

4. MEASURING CULTURAL COMPLEXITY

A recent review by Chick outlined three major approaches to the measurement of cultural complexity (a broader review of seven specific measures was developed earlier by Levinson and Malone). The three types of measures are highly correlated, and each has specific strengths and weaknesses. The approaches are (a) attribute counting procedures, (b) development scores based on the Standard Cross-Cultural Sample (SCCS), and (c) maximum settlement size.

The first measure is termed "culture by accretion." In this method, cultural complexity is assessed by an attribute checklist; the greater the number of attributes possessed, the greater the complexity score. As few as 50 and as many as 618 attributes have been used. The greater the number used, the more accurate the score and the greater the ability to differentiate between cultures at similar levels of complexity. If only a limited number is chosen (e.g., 50), items conforming optimally to Guttman scaling procedures are required.

Domains for the attributes (or traits) used by Carneiro in 1970 were economics, social organizations and stratification, political organization, law and judicial process, warfare, religion, art, tools–utensils–textiles, metalworking, watercraft and navigation, and special knowledge and practices. Sample items included the presence or absence of markets, military conscription, special religious practitioners, and temples. Most of the items were related to technological and organizational elements of culture rather than expressive ones, but the breadth of the attributes nonetheless allows researchers to empirically assess the level of cultural complexity.

Although comprehensive, reliable, and accurate, such measures have fallen out of fashion due to the difficulty in obtaining scores for such a large number of attributes and because the attributes chosen seem to be specific to cultures at certain stages of development. They measure increases in structure rather than growth in the size of a structure (e.g., a society with 7 judges is of equal complexity to a society with 7000 judges in this system). Because the most complex society studied by Carneiro was the Roman Empire, such domains as information technology or energy sources were not assessed in his scoring system.

The second approach, perhaps the best known among the approaches, is based on 10 indicators of development from the SCSS, with each being rated from 0 to 4 and largely focused on technology: writing and records, fixity of residence, agriculture, urbanization, technological specialization, land transport, money, population density, political integration, and social stratification. In 1973, Murdock and Provost reported a correlation of .95 between their scale and Carneiro's scale using a sample of 45 societies common to both studies.

Because this measure depends on rating the degree of sophistication of a few indicators rather than counting the presence or absence of many attributes, Chick called it "complexity by elaboration." The measure factors into two dimensions: social and technological complexity and the complexity of human ecology. Like Carneiro's measure, the sample of the SCSS has few complex modern societies, and so the top end of the scale might not differentiate well. Chick argued that the scale does not adequately assess expressive elements of culture such as arts and dance. But in 1972, Lomax and Berkowitz provided evidence that cultures synchronize activity in productive efforts and expressive performance.

Finally, and most succinctly, there is a measure of complexity by magnitude. Drawing from previous work showing a .97 correlation between Carneiro's scale and the logarithm of maximum settlement population, Naroll and Divale argued in 1976 that maximum settlement population is the single best measure of cultural complexity. The reason for this can be found in Carneiro's 1987 study of single-community societies (i.e., autonomous bands and villages). He reported that the organizational complexity of a village increases as the two-thirds power of its population. Villages that do not increase in organizational complexity as their population increases tend to fall apart. Extrapolating from this, it follows that in larger societies there should also be a mathematical relationship between maximum settlement size and the amount of organizational and technological complexity required to provide for and hold together these populations.

It would be difficult to apply this measure to non-sedentary populations, and it does not capture the types of cultural complexity afforded by globe-spanning mass communication and information technologies. It would also imply that Japan, with more than 30 million people living in agglomeration around metropolitan Tokyo, is the most complex society in the world today.

To summarize, despite difficulty in providing a precise conceptual definition of cultural complexity, and despite limitations in its operationalization, there is consistent evidence of the convergent validity for this concept. However cultural complexity is operationalized, its disparate measures are highly intercorrelated. This suggests that there is a common theoretical construct underlying these measures, however difficult it may be to articulate succinctly.

5. CULTURAL COMPLEXITY AND DIMENSIONS OF CULTURAL VARIATION

In relating cultural complexity to the dimensions of cultural variation typically used by psychologists, it is important to remember that the concept originates in anthropology. Most of the societies and cultures used by Carneiro or Murdock and Provost to establish their measures of cultural complexity either cannot or are unlikely to be represented in the corpus of data associated with psychology. This is not to say that the concept of cultural complexity is not useful to psychologists, but it does sound a warning that there is a severe restriction in range among the peoples studied by psychology, including cross-cultural psychology. Established measures of complexity are not especially sensitive to differences at the high end of complexity, which is the range drawn on by most psychologists.

On the other end, it is unclear how less complex societies would score on the dimensions of variation in subjective culture cherished by psychologists. Would hunters and gatherers tend toward individualism or collectivism? Hunters and gatherers certainly relied on kin groups for survival, but these tended to be loose coalitions that could change with the availability of resources or with social conditions. Although interdependence was a basic condition of survival, there were fewer social norms governing behavior and less enforcement of these norms than in more complex societies. In 1994, Triandis argued that complexity is related to affluence and to the existence of multiple subgroups with different norms (hence promoting individualism), but another view is that it is difficult to establish a clear linear relationship.

Lomax and Berkowitz, using both the Ethnographic Atlas and cantometric measures of song, provided evidence that the relationship is curvilinear, with group cohesiveness, group organization, and division

of labor being highest among cultures at middle levels of complexity. A similar argument could be applied to looseness–tightness. Data from an ecocultural approach found that only in the range from moderate (i.e., irrigated agriculture) to highly complex (i.e., industrial) societies is increased complexity associated with more looseness and less social conformity. In the range from hunter-gathers to the onset of agriculture, Berry found in 2001 that increased complexity, as operationalized by societal size, is actually associated with more social conformity (less looseness). At the high end, both the United States and Japan are incredibly complex but are currently used as instances of individualism, on the one hand, and collectivism, on the other.

There appears to be a more clear-cut relationship between cultural complexity and the second most frequently used dimension of cultural variation in psychology, that is, power distance. Put simply, cultural complexity affords power distance. By definition, the amount of differentiation of statuses, roles, affluence, and power with a society increases with its complexity. However, there is considerable latitude in how this differentiation is managed and perceived. For example, Americans aspire toward informality based on egalitarian ideals, whereas Japanese adopt more role-based formality in dealing with different statuses and roles. Although the real difference in incomes between people in upper and lower classes is greater in the United States, the psychological distance between the upper and lower parts of society is perceived to be lower among Americans than among Japanese. But over the broad range of human societies, given the tendency of individuals to exploit structural differences in power to their advantage, the perception of power distance should increase with increases in cultural complexity.

The measurement of cultural complexity is a reminder to psychologists that subjective culture is not the only viable definition of culture. The technological, material, organizational, and political–economic features of society taken by anthropologists to be indicators of cultural complexity may provide preconditions for the emergence of dimensions of variation in subjective culture found in cross-cultural psychology. From the other end, it may be extremely dangerous to assume that dimensions of cultural variation emerging from the analysis of samples from modern nation-states provide an adequate description of the full range of variability in subjective culture possible in human society.

6. GLOBALIZATION AND CULTURAL COMPLEXITY

The historical and archaeological record over the past 10,000 years can be read as a steady movement toward increasing levels of cultural complexity, with a massive acceleration during the past 200 years. Concurrent with increases in complexity has been a decrease in the number of independent polities in the world. There were more than 100,000 world polities circa 500 AD compared with the approximately 200 sovereign states represented in the United Nations today. With the onset of globalization, where information technology, high-speed travel, trade, and mass media have reduced geographic boundaries between societies, representing dimensions of cultural variation as dichotomies (e.g., individualism vs collectivism) is becoming increasingly problematic. It is now possible to speak of a global system and the cultural complexity of this system, with hybridity and contact zones between cultures being just as important as core values and practices within cultures.

In such a global system, it may be interesting to speculate about the ramifications of increased complexity. In the developing world, traditional cultures will continue to struggle with the onset of modernity. Collectivism and tightness in these cultures will give way before or hybridize with individualism and looseness. In the system as a whole, power distance will continue to increase, with immense concentrations of power and wealth being in the hands of global elites. In such an emerging system, words such as “individualism” and “looseness” might be inadequate to describe the values and roles of people at the top end of human society. The influence of economic elites—whatever their nationality—on the evolution of global cultural complexity will be immense and largely unprecedented in human history.

Of course, social scientists are aware that cultural evolution is not a one-way street. Cultural devolution, or the reduction of complexity, has also been documented and is usually caused by political or ecological catastrophes. This is not an unforeseen possibility for observers of the global system. Whereas the conceptualization and measurement of cultural complexity has been focused on simpler societies, future research might undertake to describe cultural evolution at the high end of complexity as social scientists seek to describe the interaction between a global supersystem and its constituent parts.

GLOSSARY

apprenticeship The interactive process by which cultural experts help novices acquire knowledge in a particular domain.

coconstruction Creation of shared meanings or shared activities through an interactive communication process.

community of practice A group that regularly comes together to participate in shared activities.

cross-cultural psychology The study of similarities and differences across cultures in human behavior, cognition, and emotion, with culture usually being an independent variable. It differentiates etic and emic approaches. Etic approaches imply the transfer of concepts and methodologies from one culture to other cultures; emic approaches imply the development of culturally sensitive concepts and methodologies that are derived from within each culture to be studied. Cross-cultural psychology was first linked to cognitive psychology and cognitive development and later to social psychology and social development.

ethnography An anthropological method of field research through participant observation. The researcher utilizes a participatory role as a position from which he or she can

make observations in a particular cultural context. Ethnography is generally carried out by researchers who do not belong to the ethnic community under study but who spend a considerable amount of time within the ethnic community and usually speak the local language. Ethnography covers observational methods, interviews with cultural informants, and focus group discussions.

ethnotheory A folk or lay theory of some part of the everyday world.

expert An expert has acquired advanced cultural knowledge in a particular domain.

independence The self-construal prevailing in large-scale, urban industrialized cultural communities, such as the United States or Western Europe. It denotes a cultural deep structure of a self-contained and bounded self that is separate from and competes with social others. The deep structure becomes instantiated in locally appropriate phenotypical expressions.

indigenous psychology The study of local conceptions of humans, their development, and their psychology. Indigenous approaches express dissatisfaction with the ethnocentric Euro-American view of psychology, with its claims of universality. There are two conceptual approaches, one aimed at describing variability within a universal framework (the unity of mankind) and the other aimed at establishing diverse psychologies.

interdependence The self-construal prevailing in small-scale, rural, subsistence cultural communities in Asia, Africa, and Latin America. It denotes a cultural deep structure of an interrelated self that maintains harmonious and hierarchically structured relationships with social others. The deep structure becomes instantiated in locally appropriate phenotypical expressions. Historical transitions and multicultural societies may support expressions of both

independence and interdependence in the definition of the self.

macrodevelopment Directed change over a relatively long timescale, such as years.

microdevelopment Directed change over a relatively short timescale, such as hours or days.

novice A novice is at the beginning stages of acquiring cultural knowledge in a particular domain.

parental ethnotheories The social cognitions that humans hold with respect to the concept of a child, the concept of a parent, and the developmental process. They are organized as belief systems that pertain to different domains. Parental ethnotheories are shared among members of cultural communities. They have intuitive, nonconscious components and serve as frameworks for parental behaviors and actions.

Social interaction among beings biologically primed for culture creates culture for the group and for the individuals in it. Culture is viewed as a socially interactive process with two main component processes: the creation of shared activity (cultural practices) and the creation of shared meaning (cultural interpretation). Shared cultural knowledge and modes of cognition are the result of processes of coconstruction. The creation, acquisition, transmission, and use of culture are psychological and interactional processes. It is the study of these processes that is the paradigmatic subject of cultural psychology.

1. INTRODUCTION

Shared activities are adapted to survival in a particular environment; they are the material side of culture. A key aspect of shared activity is that it involves goal-directed action; this point is particularly emphasized in the German tradition of cultural psychology. Shared meaning is the symbolic side of culture. A key aspect of shared meaning is interpretation, the notion that culture provides a lens through which we see and interpret (evaluate) the world. Empirical study in cultural psychology focuses on these two components of cultural process—shared meaning and shared activity.

Both components are cumulative in nature because culture is created by processes that occur between, as well as within, generations. Meanings and activities not only accumulate but also transform over time. This cumulative and temporal characteristic of culture creates the necessity for historical methods of studying culture as psychological process. It also creates the

necessity for developmental methods for studying the transmission and transformation of culture from the older to the younger generation. Equally important (albeit understudied) are developmental transitions from being a novice socialized by experts to being an expert socializing novices. Cultural psychology does not conceptualize the adult as a static entity with set cultural characteristics but rather attempts to study the diachronic processes of socialization and development that constitute cultural learning and apprenticeship.

As a species, humans are biologically primed to create, acquire, and transmit culture; culture is the primary mode of human adaptation. Because of the centrality of adaptation as a concept, cultural psychology aims to study meanings and activities in context rather than in the more decontextualized setting of the laboratory experiment. Cultural psychology is an interdisciplinary specialty that integrates psychology and anthropology.

2. THE CONCEPTION OF CULTURE IN CULTURAL PSYCHOLOGY: CONCEPTUAL AND METHODOLOGICAL ISSUES

Cultural psychology can be understood by contrast with two other approaches to the relationship between psychology and culture—cross-cultural psychology and indigenous psychology. Although all three are fuzzy concepts with partially overlapping exemplars, the paradigmatic instances of the three approaches are quite distinctive; these paradigms are central to the descriptions that follow.

2.1. Cultural Psychology Compared with Cross-Cultural Psychology

The goal of cross-cultural psychology is to separate the universal from the culture specific in human behavior. Cross-cultural psychology has a universalistic bias: Culture can be decomposed, its different layers can be peeled off, until the existential and universal human nature remains. In cross-cultural psychology, culture is generally operationalized as an antecedent or independent variable to behavior. Often, the independent variable is the label of a particular national group (e.g., a comparison of Chinese and U.S. participants). Occasionally, as in Harry Triandis's 1980 definition, culture is also conceived as a dependent variable, with

behavior or experience as the independent variables. Whether an independent or a dependent variable, culture is implicitly viewed as being outside of and apart from the individual.

In cultural psychology (original terminology from Price-Williams), culture is, in contrast, seen as inside the individual. Culture is “a way of knowing, of constructing the world and others” (Bruner, 1993, p. 516). Through processes of interaction and communication, these construals acquire a certain degree of intersubjectivity or shared meaning. Shared knowledge and shared meanings generate a set of everyday practices that also define culture in terms of shared activities. Thus, as Jahoda points out, culture and behavior, culture and mind are viewed as indistinguishable.

Accordingly, cultural psychology derives its problems and procedures from an analysis of the nature of culture, with an important focus on everyday life. Whereas the methodological ideal of the cross-cultural psychologist is to carry a procedure established in one culture, with known psychometric properties, to one or more other cultures, to make a cross-cultural comparison, the methodological ideal of the cultural psychologist is for problems and procedures to flow from the nature of culture, both in general and in specific. For example, in their 1981 book, Scribner and Cole focused on literacy as an important cultural element, a way of interpreting and representing the world (the nature of culture in general). They proceeded to find out what each of three different literacies meant to the Vai people of Liberia (the nature of culture in specific) and to study the cognitive consequences of these literacy practices.

The cultural psychology of Scribner and Cole traces its intellectual roots to the work of Russian psychologists Vygotsky and Luria. In the early 1930s, soon after the Russian revolution, Vygotsky and Luria studied the logical processes of collectivized and noncollectivized central Asian peasants. Their stimuli were two kinds of syllogism: “The contents of some were taken from the concrete, practical experience of the villagers; the contents of others bore no relation to familiar, practical life” (Cole & Scribner, 1974, p. 161). The point of their study was the cognitive difference in the way the two groups of peasants handled the two kinds of syllogism. Again, syllogisms are an aspect of human logic (culture in general), whereas the everyday life of the peasants (culture in specific) was a key source of problems to solve. These examples from Scribner and Cole and Vygotsky and Luria not only illustrate the methods of cultural

psychology but also illustrate the importance of cognition in the origins of cultural psychology.

Thus, cultural psychologists study cultural processes directly—for example, literacy or syllogisms as cultural forms and products. In comparison with cross-cultural psychologists, their research designs rely much less on what the anthropologist Beatrice Whiting called “packaged” variables. A packaged variable is an index of culture as an antecedent or independent variable. An example of a packaged variable is the labels “Japanese” or “German.” In principle, each of these labels “packages” a whole suite of shared cultural characteristics and processes. When cultural psychologists make comparisons, they do not use packaged variables. Instead, they use much narrower groupings, such as collectivized vs uncollectivized peasants in Luria and Vygotsky’s work.

Some research falls on the border between cultural and cross-cultural psychology. In the 1960s, for example, Greenfield brought Piagetian cognitive tasks to the Wolof of Senegal, an approach belonging to cross-cultural psychology. However, she did not compare Senegalese to North Americans, which would have been a cross-cultural approach. Instead, she looked at developmental trajectories within each culture, as well as compared children from different ecologies within the Wolof world: urban vs rural and schooled vs unschooled. She also examined the Whorfian hypothesis by doing a semantic analysis of various domains in Wolof and French. This was another way in which research procedures flowed from the nature of the culture—in this case, the linguistic aspects of culture.

The cultural psychological perspective implies that research is conceptualized as a communication process. Communication with the people of the study community in their own language is a prerequisite for cultural analyses of shared activities and shared meanings. The anthropological notion of ethnography as a methodological concept is a necessary first step in order to bring the importance of lived experience in a cultural place from ground to figure. In order to study cultural processes from the participants’ own points of view, cultural psychology has, as Greenfield pointed out in 1997, developed its own tool kit of methods. Some, like ethnography and discourse analysis, have been adapted from anthropology. With other methods, such as the use of video, cultural psychology has followed the leadership of developmental psychology as a discipline. (Later, exemplars of different research programs are introduced, noting different cultural methodologies for different research problems.)

2.2. Cultural Psychology Compared with Indigenous Psychology

Although indigenous psychology and cultural psychology clearly have independent origins, they share the notion that the prime subject of study is the subject's creation of meaning systems, particularly systems that are shared or normative within a defined cultural group. In different ways, both traditions have recognized that psychological theories are important aspects of shared cultural meaning. Millers, writing from the vantage point of a cultural psychologist, has, on a theoretical level, asserted the cultural grounding of all psychological theory. This cultural grounding of theory has been a strong motive, if not an explicit metatheoretical statement, for indigenous psychology.

The unique contribution of indigenous psychology is the notion that psychological concepts and psychological theory, not just data-collection techniques, should be developed within each culture. Unlike indigenous psychology, the empirical research tradition of cultural psychology has not been based on formal psychological theories with culture-specific origins. Nevertheless, cultural psychology has increasingly in recent years made ethnotheories (i.e., folk theories) of psychological functioning and development a subject for empirical investigation—for example, in the collaborations of Shweder and Bourne and Harkness and Super.

Indigenous psychology, however, aims to go one step further: The goal of indigenous psychology is to take informal folk theories of psychological functioning and formalize them into psychological theories. Cultural psychology arrived at the empirical study of folk theories, including folk theories of psychological development. Indigenous psychology has, in turn, moved ethnopsychology from an object of empirical study to a source of formal psychological models. In other words, indigenous psychologists have taken steps to translate ethnotheories of psychology into formal theories of psychology and, from these theories, to conduct empirical psychological studies. This goal is incredibly important for psychology as a whole, on both a metatheoretical and a metamethodological level.

However, cultural and indigenous psychology also differ in some respects. Unlike indigenous psychology, which, as Sinha points out, was born as an attempt to decolonize the mind—in fact, many of its pioneers and proponents inhabit former British colonies—cultural psychology still constitutes a “crossing over” into someone else's culture by the investigator. Also, unlike indigenous psychology, its connection to

cross-cultural psychology has tended to be erratic and ambivalent.

On the other hand, because of its own origins with an emerging scientific elite in developing nations, indigenous psychology, especially in East Asia, tends, on the whole, to privilege elite populations (university students) as subjects of study and culture change as a research topic. Cultural psychology, in contrast, tends to give a great deal of attention to relatively stable subsistence village cultures; for example, well-known studies have been done on subsistence groups in Liberia, Morocco, Guatemala, India, and Mexico.

2.3. Comparing Indigenous, Cross-Cultural Psychology, and Cultural Psychology

Although indigenous psychology shares the spirit of cultural psychology, its methods (in practice, although not in principle) tend to resemble those of cross-cultural psychology. That is, indigenous psychology most often utilizes standard psychological methodology such as questionnaire formats and tends to study variables rather than processes. For example, Yang and Bond used rating scales and adjective lists in their 1990 study of indigenous Chinese personality constructs.

There are some notable exceptions. For example, Enriquez, the founder of indigenous psychology in the Philippines, has utilized an indigenous (and group-oriented) method of social interaction as a means for data collection. However, by and large, indigenous psychology, unlike cultural psychology, has not experienced the influence of method and theory from anthropology and developmental psychology.

Why has cultural psychology developed in the way that it has? To answer this question, we turn to a study of its sociopolitical roots.

3. SOCIOPOLITICAL ROOTS OF CULTURAL PSYCHOLOGY

Cultural psychology has a long tradition and a rather young history in psychology. In the context of defining the place of psychology in the systematics of sciences, in 1920 Erich Stern presented a view that could not be more modern. For him, psychology is inevitably a cultural science since any attempt to understand any psychological phenomena needs to take into account the social cultural environment, ontogenetic history,

and ancestral heritage. Culture represents the legacy of preceding generations as expressed in the dispositions, the consciousness, and the psychology of each living individual whose plasticity allows change in order to adapt to changing surroundings. His thoughtful and comprehensive treatise also disqualified experiments as a tool to understand psychological processes.

The modern conception of cultural psychology developed without connection to such ancestors. It grew out of liberal policy in a world increasingly dominated by the Cold War after World War II. The notion was to help the Third World develop in order to make sure that, on the political level, Third World countries did not fall to Communism. Thus, John Gay and Michael Cole, funded by the Ford Foundation, began their cultural psychological research in Liberia as part of the African Education Program of Educational Services, Inc. of Watertown, Massachusetts. Daniel Wagner originally went to Morocco with the U.S. Peace Corps. Patricia Greenfield's dissertation research in Senegal in 1963 was funded by a grant (awarded to Jerome Bruner at Harvard University) from the U.S.-based Ford Foundation to develop the Institute of Pedagogical Studies at the University of Dakar in Senegal.

Initially independent from this U.S. branch of cultural psychology, a German school of cultural psychology emerged in Saarbruecken. It was founded by Ernest Boesch and further developed by Lutz Eckensberger. These scholars also went to so-called Third World cultures on the basis of politically motivated developmental aid programs. Ernest Boesch went to Thailand using grants from the UNESCO in order to set up an institute; Lutz Eckensberger went to Afghanistan using grants from the former German Ministry of Developmental Aid in order to train teachers in vocational schools. The initial contact with other and very different cultures thus became a major factor in conceptualizing cultural psychologies.

On the institutional level, the Department of Social Relations at Harvard, with its integration of psychological, sociological, and anthropological methods and theories, provided the educational foundation of modern cultural psychology and was particularly crucial in the merger of psychology and anthropology. The actual term cultural psychology seems to date from 1969, when two anthropologists, DeVos and Hippler, wrote an article titled "Cultural Psychology: Comparative Studies of Human Behavior" for the second edition of Lindzey and Aronson's *Handbook of Social Psychology*. A second use of the term cultural psychology emerged in 1980 when Douglass Price-Williams, a psychologist

serving as a member of an anthropology department, wrote an article titled "Toward the Idea of Cultural Psychology: A Superordinate Theme for Study." Hence, cultural psychology has from the beginning represented the meeting of psychology and anthropology.

On the intellectual level, cultural psychology has grown out of dissatisfaction with the universalism and decontextualized methodology of psychology in general and cross-cultural psychology in particular. On the other hand, it has also grown out of anthropology's wish to deal with the person, not merely the culture as a supraindividual envelope. These motivations, from Cole, Shweder, and Bourne in the United States, contrast with that of German cultural psychology. The latter has, in reaction to the Nazi Terror, been driven by a strong desire for a humanistic psychology or even a more human world. These qualities seemed lacking in behavioristic approaches that became mainstream during that time.

4. EXEMPLARS OF RESEARCH PROGRAMS

4.1. Parental Ethnotheories: An Example of Shared Meaning

The analysis of parental ethnotheories about development has become a vital area of research. Parental ethnotheories are shared beliefs about the goals of child development and the socialization practices that will achieve these goals. According to Harkness and Super, they specify how to become a competent adult in a particular environment. Parents throughout the world hold specific beliefs about proper care and handling of small children. These parental ethnotheories express conceptions of the nature of children, parenting, and development. In this way, ideas about child care practices are related to developmental goals, as defined by the cultural environment. Parental ethnotheories thus link socialization practices to cultural values. They also link the socialization agendas of one generation to the next. Parental ethnotheories generate child-rearing practices that, in turn, create the cultural adult. This cultural adult, in turn, participates in the socialization processes of the next generation.

Although interindividual differences are prevalent with respect to parenting goals and practices in every culture, members of cultural communities can be viewed as groups of individuals who coconstruct a shared reality in different domains of life. According

to Markus and Kitayama, two basic contrasting realities are the value systems that define independent and interdependent construals of the self. These, in turn, as Greenfield and Cocking have shown, generate corresponding developmental goals. These goals are actualized through different socialization practices and parenting styles during different stages of development. Parental ethnotheories can thus be conceived of as the mediating links between these cultural metamodels and behavioral contexts and practices.

Keller and collaborators analyzed parental ethnotheories in cultural communities found to differ in their orientations toward independent and interdependent construals of the selves: West African Nso farmers (interdependent orientation) and middle-class northern Germans (independent orientation). Parental ethnotheories were assessed as reactions to videotaped prototypical interactional situations from these different cultural communities. (This procedure has also proved revealing of cultural patterns in research on teacher and classroom evaluation.) Particularly because these reactions were assessed in a group setting, in which consensus was generally negotiated, it can be assumed that the respondents use their shared cultural framework with all the cultural standard operating procedures and unstated cultural assumptions. Because of the use of actual interactions as stimuli, this procedure further allows one to address the issue of the belief-behavior dissonance. Comments concerning deviations from normative practices reveal the valued practices and beliefs.

These analyses revealed results that are in line with the expectations of different cultural orientations with respect to independence and interdependence. The Nso women comment on parental behaviors that can be related to interdependent developmental goals such as primary care and body contact and subscribe to a physical stimulation model of infancy, in which their special technique of motor stimulation is supposed to foster growth and development. The German women, through their cultural lenses, value face-to-face communication, exclusive attention toward the baby, object play, and language. They subscribe to a communication model of infancy, in which communication occurs between two bodies that are physically separate and the flow of the interactional exchange is supposed to be shared by (quasi) equal partners, thus supporting independent socialization goals.

The evaluations of the German and the Nso women are independent of the origin of the videotapes. That is, the Nso cultural lens interprets physical stimulation practices positively when participants see them on

videos from either culture. In contrast, the Nso cultural lens provides a negative evaluation when these stimulation practices are missing in the videos of either culture. Similarly, German mothers positively evaluate instances of the communication model and negatively criticize their absence on both the Nso and German tapes. However, physical stimulation behaviors are more prevalent in the Nso videos, whereas communication behaviors are more prevalent in the German videos. Thus, the cultural values manifest in the ethnotheories are reflected in socialization practices favored by each cultural group.

Ethnotheories link to socialization practices, which then link to children's behavioral development (e.g., the timing of mastering developmental tasks). Having experienced distinct and frequent body stimulation, the Nso babies develop the gross motor milestones of sitting, standing, and walking significantly earlier than the German babies. On the other hand, the experience of a rich language environment, face-to-face interactions with nonverbal and verbal contingencies, and object play instigate an earlier onset of language in German babies compared to Nso babies. The fact that the Nso community does not value the early onset of language as much as the German cultural community is expressed in a statement of a Nso woman, commenting on the language use of a German mother interacting with her baby: "For them, every child needs to be intelligent." The cultural timing of developmental milestones organizes subsequent developmental pathways in coherent and systematic ways so as to achieve the developmental goals valued in each cultural environment. The mothers who engage in these child-rearing practices were themselves the object of the corresponding socialization practices when they were children. It is believed that childhood socialization is perhaps the most conservative or persistent part of any culture. On the other hand, with changing sociocultural and especially socioeconomic environments, cultural practices also change. However, research shows that practices change long before attitudes and beliefs.

4.2. Apprenticeship: The Historical Transformation of Shared Practice

As Barbara Rogoff and Jean Lave note, apprenticeship is the participatory structure by which more expert members of a culture induct less expert members into the normative activities and practices of a culture. Corresponding to the two basic types of ethnotheory,

one idealizing the independent individual and one idealizing the interdependent individual, are two basic styles of apprenticeship. The independent style of apprenticeship utilizes more trial-and-error strategies, learner initiative, and division of labor. The interdependent style utilizes more teacher guidance, observational learning, and interdependent problem solving. The former is well adapted to a traditional agrarian setting in which information and resources flow from the older to the younger generation with relatively little change. The latter is well adapted to a commercial economy in which innovation and novelty are valued and the younger generation is more independent of the older.

However, the styles of apprenticeship are not constant; they are socially constructed in response to environmental conditions. Therefore, changes in economic conditions should induce a shift in mode of cultural transmission. This notion was tested by Greenfield, Maynard, and Childs in a video study of weaving apprenticeship in a Maya community at two points in time; the two waves of data collection were separated by two decades. At the second point of data collection, the weaving learners from the first wave had grown up and become mothers whose daughters were now learning to weave.

In both cohorts, researchers microanalyzed weaving videos to understand the interaction between learner and teacher as apprenticeship progressed. The first generation of weaving teachers, mainly mothers, utilized the interdependent style of apprenticeship as their daughters learned to weave. Two decades later, after a period in which the economy moved away from subsistence and toward commerce, the mode of apprenticeship had indeed shifted. Microanalysis of the videos revealed the appearance of a new, more independent style of apprenticeship. Weaving learners were displaying more initiative in the apprenticeship process, peer teachers (compared with teachers from the older generation) had become more prevalent, and there was less cooperative weaving between learner and teacher. This shift was concentrated, moreover, in just those girls who, with their mothers, were most involved in textile commerce.

This historical transition in the apprenticeship process was reflected in changes in resulting weaving practices. What girls and women wove had also changed. The concept of community creativity, in which a few fairly uniform designs identified members of a cultural community, was joined by a concept of individual creativity. Design innovation and individuation were now apparent throughout the woven textiles. Shared practices had changed in the direction of a new cultural model.

The dimension of shift was that dimension most basic in the cultural differentiation of ethnotheories of development discussed previously. This parallel suggests a close conceptual relationship between the analysis of cultural meanings and the analysis of cultural practices.

4.3. Connecting Shared Practice to Shared Meaning

Although development and the analysis of developmental processes are an integral part of cultural psychology, not all research programs address ontogenetic, intergenerational, or historic development directly. Adult cultural experience is also a focus of cultural psychology. An important theoretical issue is the extent to which shared practice results in shared cultural meaning. In the German tradition of cultural psychology, Lutz Eckensberger and colleagues used different microcommunities of practice to explore this issue with adults. The researchers interviewed different samples of people who had different views on a coal plant that was supposed to be built. The groups included people living in the area, experts on coal plants, environmental activists, and politicians. Each group could be considered to share activities and practices in relation to coal plants in general and this plant in particular.

The investigators used interviews to assess the moral meanings constructed by the different groups concerning the coal plant. Their interest was in the structure (e.g., complexity) of the reasoning rather than in its content. Findings revealed that each group had a typical pattern of moral reasoning about the coal plant. Thus, there was a link between activities common to each group in relationship to the plant and level of moral reasoning. The pattern of results indicates a connection between shared activities and the construction of shared structures of moral meaning.

5. APPLICATION OF CULTURAL PSYCHOLOGY

As these examples show, cultural psychology can be applied to analyzing the everyday realities of members of different cultures and subcultures. However, there is another level of application that is also possible: applying findings to social interventions. We present one example. An implication of the modern-day multicultural reality in countries such as the United States or Germany is seen at

school. Multicultural immigration opens up the possibility of different cultural values among students, between students and teachers, and between home and school. An applied project, "Bridging Cultures," began with basic research by Greenfield, Quiroz, and Raeff documenting cross-cultural value conflict between Latino immigrant families and schools. Immigrant parents were generally much more collectivistic in their orientation to child socialization than were their children's teachers. In collaboration with a group of teachers, Greenfield, Trumbull, Rothstein-Fisch, and Quiroz utilized this research to help teachers and schools understand home culture and school culture in order to create educational "bridges" between them. The result of this intervention was greater home-school harmony in educational practices and classroom management. Shared practices and meanings were created between home and school.

6. CONCLUSIONS: AN EXAMPLE OF CULTURAL PROCESS

Both shared activities and shared meanings are intrinsic to the human mode of adaptation for survival. They are two facets of shared cultural knowledge and the primary subject matter of cultural psychology. An example will elucidate how shared activities and shared meanings are coconstructed in communities of practice; such coconstruction is the paradigmatic cultural process. The example illustrates that both material culture and symbolic culture result from processes of cultural coconstruction.

Following the Los Angeles earthquake of 1994, many of the material supports of everyday life, such as water, electricity, and roads, were destroyed. In small groups and through the media, people developed new shared knowledge concerning survival activities, such as where to get water, how to circumvent damaged roads to get from point A to point B, and methods for detecting leaking gas. Expertise was shared with novices, such as when a contractor showed his neighbors how to turn off their gas or a ham radio operator provided news of the location and magnitude of the earthquake in the absence of electricity. The nature of culture as a tool for organizing everyday life, a notion developed by anthropologist Thomas Weisner, was quite apparent.

Symbolic communication, through both language and visual media, is a critical means by which social sharing takes place; communication processes were quite intense during this period of adapting to the physical conditions created by the earthquake. As a result, new

shared activities that enhanced physical survival were created through cultural processes of social interaction.

Simultaneously, shared meanings were also created to rationalize and understand the events that had taken place. Like shared activities, shared meanings arose through communication processes. One shared meaning that developed was the custom of asking people how they fared in the earthquake; the normative reply was, "I was fortunate." The search to create shared meaning for a stunning physical event was particularly apparent when, a few days after the earthquake, a local public affairs radio show host convened clergy from many religions to ask them about the larger meaning of the earthquake. His question was, "Did God send the earthquake to punish Los Angeles?" Clearly, adaptation to the aftermath of the earthquake could not be reduced to a process of adapting to physical conditions; the interpretation of these conditions—that is, processes of creating meaning—were part and parcel for the shared culture that developed in response to the earthquake.

This example provides a model of processes that are assumed to occur whenever a new member of society is born: the creation of shared knowledge, activities, conventions, and meanings through communication and social interaction. This microdevelopmental example of culture re-creation by adults occurs in each generation in the macrodevelopmental processes of children. The example is also a model and metaphor of culture change provoked by new ecological conditions. Finally, this example illustrates the potential for cultural variability as a response to different ecological conditions. This is the stuff of cultural psychology.

GLOSSARY

collectivism A cultural pattern where the importance of the in-group is paramount; people think of themselves as aspects of groups, give priority to in-group goals, behave according to the norms of the in-group, and do not leave the in-group even if they are dissatisfied with it.

cultural complexity The contrast between simple cultures (e.g., hunters and gatherers) and information societies.

cultural tightness Cultures that have a very large number of rules and norms about social behavior and in which people are severely punished when they do not follow these rules and norms.

cultures high in diffusion Cultures that tend to think holistically, not differentiating among various aspects of situations.

cultures high in specificity Cultures in which people think analytically, distinguishing among various aspects of situations.

egalitarian cultures Cultures that emphasize equality.

hierarchical cultures Cultures that are organized according to status levels, where the dictates of those at the top of the social structure are given much weight and the opinions of those at the bottom of the social structure are not given much importance.

individualism A cultural pattern where the importance of the individual is paramount; people think of themselves as independent of groups, give priority to their personal goals, behave according to their attitudes, and easily leave groups with which they are dissatisfied.

masculine cultures Cultures that emphasize the differences between men and women and in which men rarely do the jobs that women do.

outcome cultures Cultures that emphasize the outcomes of action.

particularism Cultures in which behavior depends on the attributes of the person with whom one is interacting.

process cultures Cultures that emphasize how things are done.

universalism Cultures in which behavior is based on general principles rather than on the specific attributes of the person with whom one is interacting.

A cultural syndrome is a pattern of shared attitudes, beliefs, categorizations, self-definitions, standard operating procedures, unstated assumptions, norms, roles, and values that is organized around a theme. The theme is shared among those who speak a particular language, during a specific historical period, and in a definable geographical region. Cultural syndromes provide information about cultural differences. The number of existing cultural syndromes is unknown. However, some examples of cultural syndromes that have been identified are provided in this article.

1. EXAMPLES OF CULTURAL SYNDROMES

The following subsections describe five cultural syndromes that have been studied better than other cultural syndromes.

1.1. Cultural Complexity

The contrast between hunters and gatherers and information societies is vast. Simple cultures have few members, whereas complex cultures have many members. The number of people who constitute a cultural group is only one clue. Hunters and gatherers usually consist of bands of approximately 50 individuals who are related to each other through marriage or some other ceremonies. Information societies consist of millions of individuals who are sometimes related to each other through the Internet. In between, there is a very large number of levels of complexity such as “slash and burn” agriculture, regular agriculture, and industrial cultures.

Complexity is associated with the presence of writing systems, the presence of records, fixity of residence, agriculture, urban settlements, technical specializations, modes of transportation other than walking, money, high population density, many levels of political integration, many levels of social stratification, and the presence of different ways in which to make a living. For example, the number of occupations in simple cultures is small, whereas approximately 250,000 occupations have been identified in complex cultures. The number of choices available to individuals in simple societies is small, whereas it is vast (e.g., dozens of kinds of mustard) in complex societies. The number of standards for judging religious, economic, political, educational, social, and aesthetic phenomena is small in simple societies, whereas it is very large in complex societies. Thus, the organizing theme of this cultural syndrome is complexity.

1.2. Tightness

In tight cultures, there are many norms, standards, and rules for behavior. Those who do not do what is specified by these norms are criticized, punished, or even killed. In loose cultures, there are few norms, and people tolerate deviations from these norms. When a person does not do what is expected, people simply smile and say that it does not matter. Again, in between

these two extremes, there are thousands of levels of tightness. The organizing theme is doing what is specified by in-group norms.

Conformity is high in tight cultures. Extreme examples of tight cultures are the Taliban in Afghanistan and North Korea. Tight cultures emerge in societies that are relatively homogenous, so that people can agree concerning what norms are to be used as guides for behavior. They also emerge when there is much interdependence required to make a living. For instance, to get a crop, one might need an irrigation system, but an individual cannot construct such a system without help. In addition, when there is enough density in the population to make it likely that deviations from norms will be observed and punished, there is more cultural tightness. The organizing theme is the importance of norms.

Loose cultures are usually exposed to several normative systems, so that people must develop tolerance for behavior that does not follow a single set of norms. Thailand is a culture that has been influenced by both the Indian and Chinese cultures, so it is understandable that it is loose. The organizing theme is the unimportance of norms.

1.3. Collectivism

This cultural pattern occurs in most of the traditional cultures of the world, including East Asia, Latin America, and Africa, as well as among Asian Americans. In collectivist cultures, the self is defined as an aspect of a group such as the family or tribe. In addition, religious, political, occupational, aesthetic, educational, and athletic groups can function as in-groups. In these cultures, the self has much social content (e.g., “I am a member of this family,” “I am a member of this religious group”) and is interdependent with one or more in-groups. When there is a difference between personal and in-group goals, in-group goals have priority. Behavior is a function of both attitudes (what one would like to do) and norms (what one should do). Group-based relationships endure even if the individual would like to get away from them. The organizing theme is the importance of the in-group.

1.4. Individualism

This cultural pattern occurs primarily in Northern and Western Europe as well as among European Americans, Australians, New Zealanders, and others influenced by Western culture. In this case, the self is

defined as autonomous, is independent of groups, and has little social context (e.g., “I am busy,” “I am proud”). When there is a difference between personal and in-group goals, personal goals have priority. Behavior depends much more on attitudes than on norms. Group-based relationships are subjected to a cost–benefit analysis (e.g., “Do I get out of this relationship more than I have to put in?” [if so, stay in the relationship; if not, leave it]). The organizing theme is the importance of the individual.

Within any culture there is considerable variability concerning the presence of behaviors that correspond to collectivism or individualism. There are countercultural personalities in all cultures. People who tend toward individualism find collectivist cultures to be oppressive and so try to leave them. People who tend toward collectivism find individualist cultures to be cold and so join many groups (e.g., gangs, unions, communes).

1.4.1. Some Contrasts between Individualism and Collectivism

People in individualist cultures tend to see the self as stable and the environment as changeable (e.g., “If I do not like my job, I change jobs”). Conversely, people in collectivist cultures tend to see the environment as stable and themselves as changeable or ready to “fit in.”

In individualist cultures, people are most likely to sample cues about events “inside” other people (e.g., beliefs, attitudes, values), whereas in collectivist cultures, they are most likely to sample cues about external events and social entities (e.g., norms, roles, situations, social structures, agreements, intergroup conflict).

In 1999, Norenzayan and colleagues reviewed evidence showing that when East Asians make dispositional attributions, they see traits as quite malleable, whereas when Western individualist samples make dispositional attributions, they see them as fixed. The authors reviewed a wide range of information, from laboratory studies to ethnographies, and concluded that probably all cultures make dispositional attributions but that cultural differences occur because people from East Asia make situational attributions much more frequently, and to a greater extent, than do people from the West.

When people communicate in individualist cultures, they sample the content most heavily, whereas when people communicate in collectivist cultures, they sample the context of the communication (e.g., level of voice, eye contact, gestures, emotional expression) most heavily.

Antecedents of individualism include affluence, migration (leaving the in-group), leadership roles, education, and living in heterogeneous environments (e.g., large cities). Antecedents of collectivism include poverty (survival depends on the help of the in-group), stable residence, low social class roles, and living in homogeneous environments (e.g., rural or simpler societies).

1.4.2. Kinds of Individualism and Collectivism

These cultural patterns take different forms in different cultures. Specifically, there are horizontal and vertical individualist and collectivist cultures. Horizontal individualist cultures, such as Sweden, emphasize that the individual is independent from groups and is self-reliant but also that people do not wish to “stick out.” Modesty is a virtue. People wanting to be “the best” characterize vertical individualist cultures such as the corporate and academic cultures in the United States. Competition is high and modesty is not a virtue in such cultures.

Horizontal collectivist cultures, such as the Israeli kibbutz, emphasize interdependence of the individual and the group, but there is little hierarchy. In theory, every member does all of the jobs, whether the jobs are prestigious or not. In vertical collectivist cultures, such as China and India, sacrifice for the group is virtuous. The individual is not important, and the group is all-important.

Another variety of collectivism is the one that stresses the relationship of children to all of the women in the extended family, as occurs in India, where there is no particular emphasis on the mother–child relationship. This pattern contrasts with the Japanese pattern, where the mother–child relationship is all-important and the relationship of the child to the women of the extended family is not important.

1.5. Hierarchy Versus Equality

This pattern is the same as the vertical–horizontal pattern just discussed, but it is useful to categorize it as a separate syndrome because it is very important and can be conceived independently from individualism–collectivism. In hierarchical cultures, people pay a lot of attention to the status of individuals when organizing their social behavior. In cultures that stress equality, people espouse many ideas, such as “one person/one vote,” that stress the importance of equality. The organizing themes are the importance or unimportance of status.

The syndromes that follow have not been studied well but are included here to suggest future research.

1.6. Masculinity Versus Femininity

In masculine cultures, men rarely do the jobs that women typically do. In feminine cultures, both men and women tend to do most of the tasks of the society (e.g., child rearing). The organizing theme is the importance or unimportance of being male.

1.7. Pragmatic Induction Versus Ideological Authoritarianism

This syndrome contrasts cultures in which people make most judgments based on information that comes from experience with cultures in which people make most judgments based on information obtained from ideological sources such as leaders, tribal chiefs, and gods. The organizing theme is empiricism versus ideology.

1.8. Short Versus Long Time Perspective

In cultures with a short time perspective, the emphasis is on the “here and now,” whereas in cultures with a long time perspective, the emphasis can be on the past or future. The organizing theme is the present versus the past or future.

1.9. Valuing Planning Versus Spontaneity

In cultures that value planning, much effort is expended in planning, whereas in cultures that value spontaneity, planning is considered to be an imposition on one’s freedom of action. The organizing themes are planning versus spontaneity.

1.10. Universalism Versus Particularism

In universalistic cultures, one uses general principles such as “to each according to his or her contribution,” whereas in particularistic cultures, one takes into account who the other person is, such as in-group membership, previous accomplishments, sex, age, and social class, and one gives what is appropriate for a person who has those particular qualities. For example, in waiting for food at a cafeteria, universalistic

cultures use the principle of “first come/first served,” whereas particularistic cultures unquestionably allow high-status persons to go to the front of the line. The organizing principle is the use of universalistic criteria (one behaves in a certain way no matter who it is) versus particularistic criteria (behavior depends on who the other person is).

1.11. Specificity Versus Diffusion

Specific cultures tend to be analytical, paying attention to each element of information such as who said what, when, where, and why, whereas diffuse cultures tend to be holistic, assuming that if a positive (or negative) element is present in one element, it is also present in all of the other elements. The organizing principle is specificity of the stimuli versus the diffuse reaction to the stimuli.

1.12. Process Versus Outcome

In some cultures, people emphasize the process (e.g., “This is the way we do things”), whereas in other cultures, people pay little attention to the process but instead emphasize the outcome (e.g., “We must win”). Thus, in the former kind of culture, one pays attention to how something is done, whereas in the latter kind of culture, the emphasis is on what happens as a result of the action. The organizing principle is emphasis on process versus emphasis on outcomes.

1.13. Additional Syndromes

In addition to the syndromes just listed, there are many narrow syndromes. There is a literature, for instance, that describes syndromes whose organizing principles are honor, achievement, competition, and so on.

2. RELATIONSHIPS AMONG THE CULTURAL SYNDROMES

There is some evidence that syndromes are not unrelated to each other. For example, cultures that are tight tend to be collectivist. In general, collectivist cultures tend to be simpler and tighter, whereas individualist cultures tend to be more complex and looser. But there are many exceptions to these patterns. One usually finds more masculinity in collectivist cultures and more emphasis on pragmatic induction in individualist

cultures. Planning is more likely in individualist cultures. Particularism is more common in collectivist cultures. It is best to measure each cultural syndrome independently of the measurement of the other syndromes.

3. PRACTICAL SIGNIFICANCE

There is a correlation between some of the cultural syndromes and specific patterns of behavior. For example, industrial organizations in collectivist cultures are more likely to hire individuals who are in-group members regardless of their level of competence. In collectivist cultures, people tend to think of individuals as being easy to change and ready to adapt to different groups. Thus, it is understandable that they think that any in-group member can become a good employee. Loyalty to the organization, and especially to its authorities, is valued more in collectivist cultures than in individualist cultures. Thus, hiring loyal in-group members is more likely in collectivist cultures than in individualist cultures.

Collectivist managers are more likely to promote on the basis of tenure in the organization than on the basis of individual achievement. Also, collectivist employees prefer to be paid based on the achievement of the group rather than on the basis of individual achievement. But other things being equal, there is more organizational commitment and more training offered to employees in collectivist cultures than in individualist cultures.

Although on average members of a culture may have a particular attribute, there is very high variability within each culture. Thus, one can find employees who are behaving in highly individualistic ways in collectivist cultures and can find employees who are behaving in collectivist ways (e.g., joining unions) in individualist cultures. There are organizations that are individualist (e.g., academia) and organizations that are collectivist (e.g., the military) in all cultures.

When distributing resources such as bonuses, collectivists are likely to take into account the needs of employees (e.g., they have many children) or distribute equal amounts to each employee. In individualist cultures, bonuses go to those who have contributed more to their organizations.

The ideal leader is a benevolent father figure in collectivist cultures. The ideal leader is warm and supportive, but he or she also emphasizes production. Paternalism is a desirable leadership pattern in many collectivist cultures but not in individualist

cultures. In fact, top management is much more aware of the private lives of employees in collectivist cultures than in individualist cultures. For example, top management in collectivist cultures likely will send condolences to an employee who had a death in the family (e.g., when an employee's parent dies), whereas top management in individualist cultures might not even be aware of the death of an employee's parent. Also, management in collectivist cultures likely will send congratulations when an employee's child graduates from high school or is accepted by a college.

Cultural differences in tightness also have implications. For example, people follow rules and specifications in manufacturing much more rigidly in tight cultures than in loose cultures. Improvisation and exploration of different ways in which to do the job are more common in loose cultures.

Differences in the way in which time is used provide a major difficulty in getting along with people from other cultures. Some cultures use monochronic time (e.g., holding one conversation at a time), whereas other cultures use polychronic time (e.g., holding several conversations with different people at the same time). When people from the former cultures are not aware of this cultural difference, they are easily offended by people from the latter cultures. Another contrast is between work time (i.e., time to work and not socialize) and social time. The definitions of what are work time and social time are culture bound. In some cultures, all of the farmers work together on the plot of one farmer and then go together to work on the farm of another farmer, and so on, and all the time they mix work time and social time. Still another contrast is between doing time (i.e., when one is supposed to do things) and not doing time. The desirability of "doing nothing" is very culture bound. In some cultures, it is the ultimate goal, whereas in other cultures, it is associated with utter boredom. Finally, the contrast between clock time (e.g., meetings end at a certain time) and event time (e.g., meetings end when the purpose of the meeting has been accomplished) can be the source of many misunderstandings.

GLOSSARY

cybernetics A discipline devoted to the study of information processing and communication systems as well as the functioning of control systems when applied to machines, animals, and organizations.

cyberpsychology A new realm of psychological research and action that uses cyberspace as an instrumental means toward an end, analyzes and identifies the underlying dimensions that structure and make sense in cyberspace, studies the cognitive and social processes that facilitate or impede the involvement of cyberspace, discloses pragmatically designed principles leading to success in cyberspace, pays attention to personality disorders or social conflict arising in cyberspace, and introduces quality filters for searching and evaluating Internet resources.

cyberpunk A person who knows how to use computers as a means of self-expression and as a tool for producing virtual worlds in which reality and fantasy are intertwined and the individual person becomes a character in a scenario.

cyberspace An imaginary and multidimensional space in which people can absorb sensory experiences, enjoy intellectual creations, and interact cognitively and emotionally. It is also an economic survival kit for the information society.

cyborgs Initially, fusions of machine and organism, animate and inanimate at the same time. Later, new-age chimeras

blurring mythic hybrids such as man/machine, male/female, white/black, and homosexual/heterosexual, created for pleasure by fine artists and graphic designers; fabulous creatures amalgamating over-elaborate features rooted in science fiction and social reality.

digital game-based learning A type of learning through use of a fusion of computer games and video games in which the game player is an actor exploiting the interactive possibilities, the climate of incertitude, and the curiosity appeal of a given game to attain learning goals.

e-learning The use of Internet and digital TV technologies to make available a broad array of information and databases that must be transformed in the learning process to produce sound and reliable knowledge and to facilitate human performance in real-life settings.

homepage Opening page of a Web presentation that provides links to other documents and that becomes the starting page to which secondary documents are linked. It is often the basic platform of a given Web-based or Web-linked organization.

hypertext Basic unit of associated sections within and outside a text connected to each other nonlinearly. Hypertext was invented by Douglas Engelbert in the mid-1960s, and it has become the underlying podium for the availability of documents in cyberspace.

knowledge management Active and systematic process of managing information to transform it into sound knowledge by capturing, creating, codifying, distributing, and filtering among networked users. Sometimes it is a substitute for the concept of learning.

telematics An English transposition of the French expression *telematique*, derived from the expression *teleinformatique*, that may be translated as “networked computers” or “wired computers.”

virtual reality The computerized simulation of an entire three-dimensional surrounding in which a person can perform actions or manipulate objects by clicking on the mouse. Visually the degree of realism is very high but kinetically leaves a lot to be desired.

World Wide Web (Web) A hypertext-based information network rooted in internationally accepted standards. It was developed in 1990 at the European Centre for Particle Physics by Tim Berners Lee.

This article has been divided into three sections. The first analyzes the emergence of cyberspace as a counter culture, emphasizing distinctive backgrounds. The second analyzes how cyberpsychology is a brand new name in the phase of increasing its visibility within the domain of applied psychology. The third pays attention to six different strategies used by applied psychologists when they deal with Internet and multimedia databases and hyperdocuments.

1. CYBERSPACE: A TECHNOCULTURAL REALM

There is a hidden nexus between the basic unit of electric current, known as the ampere, and “cyber,” a multifaceted root present in a large variety of domains within the umbrella of new information and communication technologies (NICT). The term ampere expresses homage to André Marie Ampère (1775–1836), a French physicist, mathematician, and philosopher. He coined the term cybernetics in 1834 for a prospective new science devoted to the overseeing and control of governments. In classic Greek, *κυβερνάω* means to lead or to pilot, and so the derived noun, *κυβερνητικός* means the pilot. Norbert Wiener (1894–1964) recaptured the word cybernetics in 1948 as a title for his book on “the science of control and communication in the animal and the machine.” Later, in 1950, he emphasized that cybernetics should ultimately be regarded as a matter of “the human use of human beings,” highlighting the nexus between learning and feedback as both technological and cultural frameworks in the functioning of control and governing systems.

During the 1950s and 1960s, cybernetics became a widely accepted label for studying (1) the processing of information and communication systems, (2) the flow of information within a system, and (3) the use of feedback to get intended impacts on goal-directed

activities cropping up in technological artifacts as well as in living organisms and organizational settings. Soon cybernetics lent its name and the new root “cyber” started to circulate, becoming used by computer-literate university graduates in a large variety of disciplines.

In 1970, Alvin Toffler coined the term “cyborgs” in his book *Future Shock*, which devoted several pages to analyzing the possibilities of human–machine integration and the interaction of human brains and databases through networked communication. Initially, a cyborg was described as a fusion of machine and organism, animate and inanimate at the same time. Mechanical or electronic devices built into the body allowed its physiological functioning to extend some abilities beyond normal or to compensate for some disabilities. Psychological expertise was demanded during the design process to optimize performance levels or to smooth training processes and after the surgical implant of devices to facilitate the psychological adjustment of ongoing interactions.

During the 1980s, the conception of cyborgs transformed classical dichotomies into mythic hybrids by blurring binary pairs such as man/machine, male/female, white/black, and homosexual/heterosexual. At first glance, it was a change of focus: cyborgs started to be created for pleasure. Fine artists and graphic designers crossed the line of gender representations and pushed their art into the awareness of the sexual impact of cyberbodies. So, cyborgs became sexy, and a diversified fauna of new-age chimeras emerged. “A cyborg is a cybernetic organism, a creature of science fiction and a creature of social reality,” highlighted Haraway (1991) in her seminal essay “Cyborg Manifesto” published in 1985. From a psychological perspective, these utopian cyberbodies induced morbid fascination and were ready for scrutiny as the latest taste in projective techniques. A cyborg is a cybernetic organism, a creature of science fiction and a creature of social reality.

The term “cyberpunk” started to be used as an argot among writers in counter-cultural circles in the mid-1970s, for example, by John Brunner in his novel *Shockwave Rider* and by William Gibson in several science fiction stories collected in *Neuromancer*. Soon, some creative writers began to call themselves “cyberpunks,” stressing that they used computers and video games as a means of self-expression, personal pleasure, net profit, and out of a sense of duty. In fact, they ascribed the roles of main or secondary characters to “first-generation cyborgs,” that is, microsurgically reworked characters, showing a disembodied

intelligence, bringing to the fore an anarchist cultural background melting away into a high-tech mood and open-minded attitude. In cyberpunk stories, the narrative usually took place in postindustrial and information-governed settings populated by urban misfits, dead reconstructions of people previously alive or artificially smart beings ready to think for themselves and question authority. Cyberpunks were often depicted as skillful people with expertise in knowing how to take advantage of NICT to attain goals that were often malevolent.

During the 1980s, fiction writers realized that they had developed a set of beliefs about the existence of some kind of actual space behind the screen, “a place that you cannot see but you know is there.” This world of lucid dreaming beyond a television or a computer screen came to be known as cyberspace, an imaginary and fictional universe in which sensory experiences take place, the mind is absorbed, and the person feels as one with the set of stimuli, challenges, and performances elicited. It generates a trancelike experience, actual and genuine, known as “consensual hallucination,” the assertion coined by cyberpunk writers. Cyberspace was a place where individuals were welcome if they knew how to stroll along boundless passageways, entering and exiting large intellectual creations made available online. It was a “World III” structure in the terminology launched by Sir Karl Popper (1902–1994).

Cybersex was a term introduced during the 1990s to identify the existence of sensual and hedonistic waterways irrigating the digital underground of cyberspace. It is the domain of a large variety of incorporeal intercourses, sometimes known as “robotoculation” or “onanism for two,” that make the most of computer-generated hyperrealism as well as mind-to-mind networked but yet dreamed scenarios. As Dery put it, “sex with machines, together with dalliances conducted in virtual worlds, seems a seductive alternative in an age of AIDS, unwanted pregnancies and sexually transmitted diseases” (1996, p. 199). It is a kind of online sex play, X-rated and interactive computer programs adapted for the stage by similarly equipped participants recurring to an array of sensor-effectors ready to generate a realistic sense of tactile presence.

Bell and Kennedy and Spiller have compiled large sets of difficult-to-find articles on cyber-cultural challenges and dilemmas, published over several decades during the second half of the 20th century, that otherwise would be rather inaccessible.

2. CYBERPSYCHOLOGY: AN INCREASINGLY GROUNDED BRAND NAME

The term cyberpsychology started to circulate in cyberspace in 1994 when Prof. Leon James at the University of Hawaii wrote a pioneering paper, “Cyberpsychology: Principles of Creating Virtual Presence,” which was expanded over a decade and made available online. As a result, some post-modern views on psychology and Jungian connotations were launched: an ineffable continuity of an online communal mind exists and grows in cyberspace as a self-ruling collective unconscious. The existence of a critical mass in interactions and transactions “in any topical zone and the type of ongoing activity” suggest the emergence of a communal mind in the Internet. “Topics and activities in cyberspace create their own virtual zones that become accessible to others across time and space” and give the impression of omnipresence in such a communal mind. The overlap between cyberspace and the mind was asserted under the umbrella of cognitive psychology. Computers were appraised as “convenient and powerful extensions of the human mind” and the consequence was that “every characteristic of the mind can be expected to show up as a property of the cyberspace.” The basic argument justified a new denomination such as cyberpsychology based on the certitude that “cyberspace, like mind, is not in physical space, but in virtual space, without extension, distance, or mass.”

In 1994, José M. Prieto at the University of Madrid set up the homepage of the International Association of Applied Psychology (<http://www.iaapsy.org>), which included the online proceedings of the 23rd International Congress of Applied Psychology. Nielsen, the leading expert in usability challenges, advances, and dilemmas in the production of multimedia and hypertext documents, mentioned this initiative as an illustration of navigating large information spaces. Soon afterward, Prieto began to focus on cyberspace as a setting where psychological teaching, learning, and research programs may take place and where spatial orientation and time management skills play a very significant role in online performance. The initial focus was outlined in the paper “Psychology and Telematics” (a new term derived from the combination of “tele” and “informatics”), and the next step was the interface between literacy in NICT and the involvement of work and organizational psychologists in knowledge management programs. In 1997, it became an e-learning space

nicknamed *prietolandia* by psychology students: an online learning experience for university graduates in psychology from 1995 to 2003, when the program came to an end.

In 1996, Prof. John Suler at Rider University started to write an electronic book, *The Basic Psychological Qualities of Cyberspace*, made available online, another project in a course of continuous expansion. The point of departure was an intensive case study carried out on the psychological and social interactions held by members of a very vivid and evolving community who used to meet in a quiet notorious virtual space known as "The Palace" (<http://www.thepalace.com>) that closed by the end of the 1990s but was again active by 2004. In 1995–1996 it was a visual, auditory, and chat environment where visitors adopted and role-played a large variety of characters by using graphical representations in the realm of pure fantasy and fiction. Suler used the participant observation technique to study cyberspace as "a psychological space" and as "a dream world." The psychoanalytic as well as field theory perspectives shaped the theoretical and operational background, making sense of what emerged in this research project. Internet users felt comfortable because somehow cyberspace was "an extension of their mind and personality—a 'space' that reflects their tastes, attitudes, and interests." Following a psychoanalytical vein, cyberspace was interpreted as a "transitional space" between the self and the other.

A peer-reviewed journal entitled *Cyberpsychology and Behavior* was launched in 1998 (<http://www.liebertpub.com>) and made public during the 24th International Congress of Applied Psychology and the 106th Annual APA Convention, both held in San Francisco in August 1998. Since the year 2000, the electronic and the printed version have been accessible at the same time; subscribers have access to each online issue via a password.

Gackenbach compiled 13 contributions written by 20 authors from Australia, Canada, Israel, the United Kingdom, and the United States focusing on the psychology of Internet use. Special attention was paid to the normal and deviant aspects of the self when staying online, lively relationships maintained during close and distant interactions, and transpersonal issues such as the development of consciousness and collective unconscious. Through surveys and case studies, the incidence of Internet addiction was examined and its presence was restricted to "an exceedingly tiny minority" (p. 71). This is a typical example of research findings that refute comments in the mass

media occasionally introduced by practitioners expressing opinions without reliable data on the subject.

Wallace approached the Internet within a psychological perspective; the outcome was a book titled *The Psychology of the Internet*. It focused on the "online persona" and the way Internet users generate impressions, use masks as ID during interactions, and become involved in group dynamics through conformity and cooperation as well as conflicts and aggressions. She studied how liking and loving take place on the net, calling attention to how interpersonal attractions arise when people try to find out who is next door on the net.

Fink is the lead author of a book devoted to analyzing how to use computers and cyberspace in the clinical practice and psychotherapy. There are 10 separate contributions that each highlight specific topics. Together, they scrutinize the challenges faced by professional psychologists determined to transmute the conventional couch into an online couch, to explore the self by inviting the patient to produce a personal Web page, to go after the consequences of a disembodied gender in cyberspace, and to go along with the consequences of virtual health-care programs. A catalogue of Internet resources for clinical psychologists was added as a bonus.

Gordo-López and Parker, in a book entitled *Cyberpsychology*, brought together a set of 14 articles written by 16 psychologists and social science scholars from Europe, the United States, and Latin America, bringing into focus the relationships between psychology and cybernetics. The prevailing approach is rather theoretical, rooting psychology into the technological background of cyberspace without endorsing fantasies of liberation that surround NICT in the mass media and the popular culture regarding the Internet. The approach is rather interpretative: "Cyberpsychology needs to embed within itself a self-annihilating device, a certain kind of critical and self-critical narrative"; "We want to insist that it is only in its ephemeral use that the potential of cyberpsychological critique can function" (p. 16).

Birnbaum compiled 12 contributions produced by 23 authors from Canada, Germany, Italy, Switzerland, the United Kingdom, and the United States. Studies carried out in the Internet were compared to similar studies carried out in laboratories or in field studies, stressing methodological aspects to be taken into consideration when deciding which is the appropriate medium to use. The role of individual differences and cross-cultural differences as identified through

online research was also examined. Potential uses of advanced computer techniques or pondering the appropriateness of server-side solutions reveal weak points in design as well as the adequacy of server-client relationships. This is an Achilles heel rarely assessed in papers.

Wolfe compiled 12 contributions written by 19 authors from Europe and the United States that examine cost-effective advances and achievements attained by the use of learning technologies placing the development of Web resources on a consistent psychological foundation. It combines theoretical advances and empirical findings and moves from the frame of reference of the individual learner to that of learning communities in university campuses. One out of two college courses list Web resources in the syllabus, and one out of four college courses have their own Web pages, thus producing a gap between those making an offer of online and offline handouts or practical exercises, for instance.

Prensky has emphasized the importance of computerized games as educational and training tools that meet the needs and learning styles of people wishing to improve their expertise by using simulations and theatrical scenarios. There is in fact a generational gap between educators belonging to a pre-digital cohort and students raised in an audiovisual and digitalized cultural background. Digital game-based strategies allow the acquisition of very specific skills on demand for specialized jobs and risky situations. Findings and developments founded on studies derived from the psychology of play provide the background for the cognitive and emotional involvement of students galvanized as players.

Reips and Bosnjak compiled 20 contributions written by 40 authors from Europe and the United States. These papers obtained expert advice and commentaries from two rounds of double peer review from 32 independent reviewers, evidencing high standards in standard publication procedures. They examine the Internet both as an instrument for, and an object of, scientific research, and approach issues such as psychological Web experiments, Web questionnaire studies, studying perception on the net, net-based surveys, and communication research as well as knowledge acquisition and learning throughout cyberspace.

Stein has written an essential Baedeker for students and scholars, a traveler's guide to the topography of cyberpsychology. His book is a comprehensive and accessible overview of what resources are

available, how to track down subject-specific materials and use them efficiently, and how to compile Internet references for term papers, reports, and dissertations. The author has also provided an online catalogue of appropriate hyperlinks mentioned in the book.

3. CYBERPSYCHOLOGY: SIX PERSPECTIVES AS OPERATIONAL TOOLS

It is possible to distinguish six quite different strategic approaches followed by applied psychologists when they use the Internet and multimedia hyperdocuments in daily professional activities. Private life approaches are not considered here, but they are always embedded as background. The six professional strategies advanced are (1) instrumental, (2) dimensional, (3) process-based, (4) pragmatic, (5) psychopathologically biased, and (6) knowledge management-based.

3.1. A Tool for Psychologists

The first strategy approaches online computer-based resources and support facilities as a tool for conducting a large number of activities that psychologists carry out regularly in university campuses as well as in professional practice. It is an instrumental way of understanding psychology within the cyberspace, the nexus "means to an end." Cyberspace is viewed as a means to (1) communicate via email or transmit documents, (2) participate in discussions via interactive groups and Web-based conferences, (3) exchange or supply files and programs, (4) carry out transactions with customers, and (5) increase visibility across borders. Thus, cyberspace is valued as a useful territory that facilitates the achievement of certain ad hoc aims, rooted in psychological action and effective performance. Psychology students and graduates typically learn to handle only a few of the tools available, those they become comfortable with and use for certain purposes. Newer tools are often avoided because they demand too much time and imply too much uncertainty: only members of younger cohorts are open minded enough to try them. This attitude contrasts with the hedonistic ways of understanding cyberspace: a stage for playfulness and inventiveness, a joyful scenario for divergent thinking among advance expert

knowledge-based groups ready to fix acceptable standards in 5 or 10 years.

3.2. Alternate Dimensions of Experience

The second strategy deals with psychological dimensions of computer-based settings, online environments, and personal and professional grounds of performance instigated by the involvement in computer networks. It is the realm of magnitudes and measurements present in online phenomena and online users. It brings to the forefront the psychological analysis of personality questionnaires, for instance, producing comparisons between factor structures obtained through offline and online versions of the same instrument. Present evidence suggests equivalence regarding what they measure and how well they serve the intended purpose. Similar approaches have been tried in the study of abilities, skills, interests, and values underlying online tasks and activities examined by researchers to obtain the factors or clusters underlying effective or ineffective performance. It allows the identification of multifaceted features such as experience requirements, cyber-users' characteristics and requirements, and communalities and specificities among members of relevant virtual communities. Follow-up studies of observable response patterns obtained through Web-based surveys favor the reconstruction of response undertakings and the identification of specific typological profiles different from those obtained via offline surveys. For example, controlling the display of questions and answering actions allows the number of questions displayed and the number of answers marked to be taken into consideration. Findings support the distinction between "performers" and "explorers" as basic typology. Performers answer all questions displayed, whereas explorers read initial set of instructions and preliminary items and quit suddenly, read the full set of questions screen by screen but never answer, or answer a few or even many questions but do not conclude the protocol. The psychological study of group structures in cyberspace also follows a dimensional approach, since it allows comparisons within and between communities to identify overt or hidden fraternities in communication networks, leadership styles in online chats, and prevailing norms and roles among users when they are on stage in a Web conference room, for example. Psychological dimensions are

also the basis for the study of human diversity in cyberspace.

3.3. Psychological Processes and Human Performance

The third strategy addresses the issue of the psychological processes associated with human performance in networked computers and hypermedia. This process-based notion of cyberpsychology stresses that analysis may be carried out at the individual or at the group level and that it requires follow-up controls and strategies. The distinction between text-based and hypertext-based handouts used in online seminars has served to analyze operational and cognitive interactions concerning navigation, information scrutiny, and knowledge acquisition. Feelings of getting lost while navigating hypertext documents have been detected, and organization and presentation schemes have been suggested and validated to provide reliable frameworks for interested readers. For instance, the use of frames that include a contents index or a graphic map synchronized to sequential actions seems to facilitate the orientation of individual readers. Generational gaps have been remarked upon, and the presence or absence of dynamic icons accentuates the impression of "cool" versus "puerile" settings and thus acceptance or rebuff, by cohorts, of information presented. Eye movement screenings allow the analysis of how much time readers stay absorbed in a given text paying or not paying attention to navigation bar as compared to readers looking through a hypertext document. The navigation process seems to distract persons who are not experts in the subject from the actual text; they retrieve more information compared to those who are expert in the subject who can skim the text with hypertext advantages. Sensation, perception, attention, memory, knowledge acquisition, conscious experience, tacit learning and so on play an active role in the way people behave in cyberspace and have been examined, capitalizing on models and procedures developed in cognitive psychology. The study of group processes in cyberspace enables the discernment of formation, commitment, and identity within a given virtual community, as well as the understanding of influences pervading each community, of decision-making patterns and the value of minority dissent, of conscious and unconscious phenomena, and of autonomy and effectiveness.

3.4. Optimizing the Cyberspace Experience

The fourth strategy tackles the understanding of useful principles and guidelines based on psychological grounds that may improve the success of a home page, a portal, or an online e-business or e-commerce action plan. It is a pragmatic notion of cyberpsychology that looks for psychological theories, models, or findings that may refine communication patterns, learning strategies, and the intended presence and visibility of individuals and groups in cyberspace. The focus of attention is the identification of how cyberspace can be used to isolate and advance a psychological elucidation of behaviors and actions and the way of influencing its appearance or withdrawal. For instance, Gestalt psychology principles, formulated at the turn of the 20th century, are still an adequate framework in which to ameliorate the design of multimedia pages and navigation tools. Tacit learning theories have been implemented to reduce the number of procedural steps in online commercial or stock market transactions. Heuristic techniques have been used to optimize the testing of complex hypermedia documents to identify missing links, errors, intended loops, or unfortunate paths, before producing the final version. The pragmatic approach favors a focus on online behavior as natural, on online inventiveness in problem-solving strategies as natural, and on accepting a continuous flow of new online standards and norms as natural.

3.5. Cyber Pathology

The fifth strategy focuses on online psychological disorders; online overuse is the recurring example. In fact, it is the consequence of a parody written in 1995 by Ivan Goldberg, a psychiatrist who is quite active online, that made fun of the pathological gambling criteria described in DSM-IV. This resulted in a psychopathologically biased notion of cyberpsychology pivoting on reported cases of pornography, interpersonal or sexual attraction, disembodied gender, marital problems, neglect of children, and so on, as broadcast by the mass media. The high visibility of this perspective resulted in focus on antisocial and manipulative behavior online. However, it must be stated that cyberspace just mirrors a person's regular social behavior and is simply a new scenario for interrelating with others. There is no evidence suggesting that cyberspace may be the direct cause of new mental or emotional problems. It is more a matter of inappropriate virtual behaviors such as (1) spam, invasive, unsolicited, and

superabundant email, (2) "spoof," a message sent with the sender's identity concealed, and (3) "flaming," communication that is perceived as an insult, a direct attack, abuse, insolence, or rudeness. The large majority of cyberspace dwellers understand the consequence of spamming or spoofing because their email inboxes regularly receive a large number of unwanted or forged email messages. These behaviors have highly detrimental consequences, since many derived costs are borne by the person receiving the messages instead of the sender. Paradoxically, these inappropriate behaviors can shock online users, but usually are not considered scandalous or outrageous by offline users such as investigative journalists or psychologists in the field. This is just one example of double standards regarding criminal behavior in cyberspace versus in "real life."

3.6. Information and Knowledge Management

The sixth strategy views cyberspace as a huge virtual library that facilitates access to information in accounts, advertisements, books, brochures, databases, discussion groups, documents, journals, manuals, newsgroups, papers, journals, newsgroups, proceedings, software, surveys, syllabi, and so on. At first glance, cyberspace can be viewed as a storehouse ready to grasp the interest of psychologists interested in keeping an open mind to a large variety of old and new subjects, theoretical, technical, or practical. However, the use of filters is required to separate the wheat from the chaff. The same criteria that are useful in the analysis of scientific papers can be used to identify helpful online resources: (1) intended audience, (2) authority on the subject, (3) amount and type of coverage (e.g., in-depth versus superficial), (4) milieu in which the information is accessible, (5) objectivity versus subjectivity in distinguishing facts from values or opinions, (6) precision according to reliable sources, (7) topicality (i.e., high or low profile subjects) and, (8) the ease of use of the interface.

GLOSSARY

biases Systematic judgmental tendencies that violate the rules of probability.

bounded rationality Decision making within the limits of human cognitive capacities.

choice The selection of an option from a set of options.

decision The commitment to a course of action.

heuristics Mental rules-of-thumb used for the judgment of probabilities.

image theory A theory that includes the maximizing strategy as a special case but focuses on a strategy that works on the compatibility of options with the decision maker's goals and plans.

prospect theory The currently dominant theory of individual decision making, developed by Kahneman and Tversky, that keeps the core components of the classical rational model but takes the findings of empirical research into account.

rationality Decision making consistent with the axioms of the normative model that assumes the use of all available

information, stable preferences, and a maximizing strategy.

uncertainty/probability The uncertainty that people associate with the occurrence of the potential outcomes of their decisions.

value/utility The value that people attach to outcomes resulting from their decisions.

Decision making is a mental or behavioral commitment to a course of action. In a broader sense, the term "decision making" denotes an information-processing activity of a single decision maker, or of multiple decision makers, that begins with the recognition of a choice situation and ends with the implementation of the choice and the monitoring of its effects.

1. INTRODUCTION

More than many other behaviors, individual decision making is a subject not only of psychological research in the laboratory but also of interest in a number of "real-world" domains where significant decisions are actually made and where psychological knowledge has been applied successfully. The study of decision making has its roots in economics and statistics, and this is still the most active field for decision researchers. Topics include how people choose among consumption goods, investment options, and/or retirement plans as well as how managers make production and

marketing decisions and how they make organizational and employment decisions. Another important field involves health-related and medical decisions of both patients and physicians. For patients, topics include how people make their personal decisions about smoking, drinking, taking drugs, and/or sexual behaviors as well as how patients choose among treatment options (e.g., surgery or radiation) and how they can be helped in making such decisions. For physicians, topics include how they choose among diagnostic and treatment alternatives and how their individual or collective decision processes can be supported. A very different field is aviation, where the interest focuses on the decisions that pilots must make—often under extreme time pressure. Closely related are decision situations in high-risk facilities such as nuclear power and chemical plants. Knowledge about people's decision-making behavior has also been used for designing counseling and advice-giving procedures. Examples include when patients are asked for their informed consent, when parents come to a genetic counselor, when people seek investment advice, and when adolescents need behavioral strategies against sexual assault.

2. KEY CONCEPTS

A decision is a mental or behavioral commitment to a course of action. An option to change the status quo may be brought to the attention of a person and is accepted or rejected, or one of several given options is preferred over the others. A decision can be expressed by verbal judgment (e.g., "Option X is the best one") or by behavioral choice (e.g., Option X is chosen). In a narrow sense, the term "decision" denotes only the moment in which the commitment is made. In a broader sense, the term denotes an information-processing activity, usually beginning with the recognition of a choice situation and ending with the monitoring of the outcomes of the chosen option. Research has looked at all phases of a decision-making process—how people identify, generate, screen, and modify options; how they mentally simulate courses of action; how they match actions to situations; how they frame, compare, and evaluate all or a subset of options; and how they process information after a choice has been made. Decisions can require different amounts of cognitive effort and be made on different levels of awareness, depending largely on the significance of the problem, the familiarity of the situation,

and the experience of the decision maker. When people drive from their home to their office, or when surgeons perform appendectomies, their decision making is often nearly automatic and is experienced as performed routinely or intuitively. On the other hand, when people in a restaurant choose from a menu, they realize that they must make decisions and often ponder about the options and consider the various pros and cons. Typically, substantial cognitive effort is invested only if the problem is important, complex, or unfamiliar such as in the purchase of a house by a family, the choice of a cancer treatment by a patient, or the development of a new product by a company. Economists tend to consider a decision maker—the homo economicus—as a rational decision maker if he or she uses all available information, if preferences and beliefs are stable and consistent, and if a maximizing strategy is applied. Psychologists (and behavioral economists) favor the assumption that decision makers usually operate with bounded rationality (i.e., within the limits of their cognitive capacity) and that they apply the strategy that best matches their situational assessment and motivation.

3. FEATURES AND DISTINCTIONS

The dominant view is that people make their decisions as a result of anticipating and evaluating the potential outcomes and the uncertainties associated with them. This is called a consequentialist perspective. The major part of this article focuses on research that takes this perspective, but nonconsequentialist approaches are also presented later. From the consequentialist perspective, decision problems differ formally in the following ways. First, the consequences of the decision are certain (e.g., the consequences of choosing Apartment A or Apartment B) or uncertain (e.g., the consequences of choosing chemical therapy or surgery). Second, the consequences are unidimensional (e.g., the consequences of gambling in a casino as either a gain or a loss of money) or multidimensional (e.g., the consequences of choosing a job in a company or at a university). Third, the decision process may have one stage (e.g., the decision to hire a person) or several stages (e.g., the decision to develop a new drug). Fourth, the decision may be unique (e.g., decisions among cancer treatments) or may be made repeatedly (e.g., decisions between job applicants). Fifth, another important distinction must be made between individual decision situations and social

ones. In the former case, decisions are made by individuals, and individuals primarily must bear the consequences. This situation is the topic of cognitive psychology. In the latter case, decisions are also made by individuals, but the decisions are made in direct or indirect interaction among these individuals. This situation is the topic of social and organizational psychology.

4. VALUE/UTILITY

People are assumed to make their decisions depending on their preferences for the potential consequences (i.e., states or events) of the given options. Implicitly or explicitly, people evaluate these consequences, and the subjective values, called utilities, determine their decisions. However, the utility of outcomes is not simply a linear function of their quantity. In general, one finds a logarithmic function well known from psychophysics. In economics, this is called the decreasing marginal utility function: The second million causes less pleasure than the first million. The same holds for the negative part of the function: A dessert for \$5 appears to be less expensive after a \$70 dinner than after a \$7 pizza. Advertising and marketing use the knowledge about the psychophysics of spending in many ways.

Evaluations are influenced by a number of factors, including the following prominent ones. First, people value an object more highly when they believe to have achieved it by their performance rather than by luck (i.e., source dependency). Second, people value an object more highly when they consider selling it than when they consider buying the same object (i.e., endowment effect); that is, a person would want a higher price for a painting he or she owns than the person would pay for the same painting. Third, the evaluation of an option is sometimes influenced by investment of money, time, or effort in the past (i.e., sunk cost effect); that is, a person does not leave a boring movie because he or she has paid for the admission ticket. Fourth, the evaluation also depends on the moment in time when the object will be received or when the state will occur (i.e., time preferences); that is, a person prefers to receive \$100 sooner rather than later, and the person probably prefers to see the dentist later rather than sooner (unless he or she has pain).

Multiattribute options (e.g., consumption goods, job applicants) require trade-offs between attributes. Consumer reports provide the relevant attributes of the goods and the values of the goods on these attributes. But consumers must make the trade-offs themselves.

Numerous studies have examined which attributes people use in such situations, how they weigh them, and how they integrate the information about the goods on all attributes. Sometimes, people use noncompensatory rules; that is, they eliminate all options that do not exceed certain cutoff points on one or several attributes or that do not share certain features, independent on their values on other attributes. For instance, a person looking for an apartment may first screen out those apartments that do not have a minimum size, then those whose rents exceed a certain limit, then those whose distance to the beach exceeds a certain distance, and so on until finally one acceptable apartment is left. Alternatively, people may use compensatory rules; that is, they accept that each value on an attribute, however low, can be compensated by high values on other attributes. For the person looking for an apartment, the small size of an apartment might not lead to its elimination because it can be compensated by a low rent. Consumer research has used the theoretical concepts, the research methods, and the empirical findings extensively.

5. UNCERTAINTY/PROBABILITY

Decisions are always made under uncertainty because their consequences occur in the future and, thus, depend not only on the decision makers' choice but also on events and states not under the decision makers' control. In some situations, the consequences can be considered as nearly certain or the fundamental uncertainty is irrelevant for the choice. However, in most decision situations, the uncertainty cannot be ignored; therefore, research on how people deal with uncertainty is an important field of decision research.

For mathematicians, probability is the language of uncertainty; for decision researchers, subjective probability is the language of uncertainty. The subjective probability for an event may be based on the known or assumed relative frequency of that event (e.g., the subjective probability of rain tomorrow, the subjective probability of having a car accident), but in many situations the event is unique and there are no relative frequencies (e.g., the subjective probability of Brazil winning the soccer world championship, the subjective probability of an increase of the gold price by the end of the year). Research has studied the psychological variants of uncertainty, their cognitive characteristics and determinants, the ways in which people express uncertainty (e.g., numerically, verbally), and the ways

in which people understand expressions of uncertainty (e.g., probabilities, percentages, frequencies). Intuitive judgments of probabilities have been shown, under certain conditions, to deviate considerably from our statistical knowledge and to violate the rules of probability theory systematically. These observations led Tversky and Kahneman to develop their heuristics and biases research program. The key assumption is that people intuitively apply mental heuristics rather than statistical algorithms, and although these heuristics are generally useful and efficient, they can produce judgmental errors, fallacies, or biases. Two heuristics are particularly important: representativeness and availability. Representativeness is when events are unique (e.g., the guilt of a defendant) or set in the future (e.g., the outcome of the next election) and people draw on their knowledge about the case and judge the probability by the closeness of the match between the event and the prediction derived from their knowledge. Availability is when events are grouped in categories or by features (e.g., percentages of road accidents in a year) and people judge the probability by the number of examples that come to mind or by the ease with which they come to mind. Many judgmental biases can be explained by the assumption that people use these heuristics, for instance, the base rate fallacy, sample size neglect, regression neglect, the unpacking effect, and the conjunction fallacy. Other prominent biases in subjective probability judgments, not directly related to the use of heuristics, are the hindsight effect, the overconfidence effect, conversion errors, the illusion of control, and unrealistic optimism.

6. MODELS AND MODES OF DECISION MAKING

Prescriptive theories of decision making say how decisions should be made if the decision maker wants to follow certain principles of rationality (e.g., the principle of transitivity). These theories are part of management science. They provide formal rules and procedures for structuring and processing the relevant information and, thus, provide support in complex decision situations. Descriptive theories aim to show how people actually make decisions. Because the cognitive capacity is limited, or at least is not always used efficiently, actual decisions are often suboptimal compared with the decisions prescribed by formal theories.

The first descriptive model of decision making under uncertainty was proposed by Edwards in 1954. The

subjective equivalent utility (SEU) model assumes that people try to maximize their subjectively expected utility. The SEU of an option is the sum of the utilities of its consequences, weighted by the subjective probabilities of their occurrence. The decision maker is assumed to choose the option with the highest SEU value. In 1979, Kahneman and Tversky proposed prospect theory (PT) as an updated version of the SEU model. The theory sticks to the assumption that decisions are determined by the values and probabilities of their consequences but takes into account the many observations of decision-making behaviors that do not concur with the SEU model. PT has become very influential, particularly in the economic and medical domain. In 2002, Kahneman was awarded the Nobel Prize in economics, primarily for this theory (Tversky had died in 1996). The essential elements of PT are the value function and the decision weight function. With respect to the value factor, PT assumes that people mentally code the potential outcomes of options in relation to a reference point, that is, the status quo or the aspiration level. Outcomes above the reference point are coded as gains and outcomes below the reference point are coded as losses. Gains and losses are evaluated according to a value function that has two properties. First, the function is concave over gains and convex over losses; that is, additional gains please less, and additional losses hurt less. Second, the function is steeper over losses than over gains; that is, a loss of \$100 hurts more than a gain of \$100 pleases. With respect to the probability factor, PT assumes that subjective probabilities of outcomes are transformed into weights that represent the significance of the occurrence of the outcome. For instance, many people weigh the transition from a 0.99 probability to certainty (1.00) as heavier than a transition from a 0.41 probability to a 0.42 probability. PT provides explanations for a number of empirical phenomena that often are considered as irrationalities or anomalies, particularly in economics. Examples include the finding that preferences are not invariant with respect to their verbal description (i.e., framing effect) and the finding that investors sell winner stocks too fast and hold loser stocks too long (i.e., disposition effect).

An alternative theory, image theory, was proposed in 1990 by Beach. Image theory has become very popular in management and business schools. Beach assumed that people apply an optimizing strategy like the one proposed in PT, only under very special conditions. More often, people examine whether a new option is compatible with their goals and plans (called images)

and accept and implement the option if that is the case. If the option is not compatible and violates important features, other options are searched and explored. When people are confronted with a number of options, they first screen out the ones that are incompatible with goals and plans, and only if more than one option remains do they try to identify the optimal one.

Other researchers have also pointed out that in real life, optimizing decision making is the exception rather than the rule. Features of the problem and the situation are often more important than the potential consequences of a decision. For instance, the behavior of managers in organizations is strongly determined by rules. The decisions of consumers are often determined by affects. In ethical conflicts, decisions are primarily determined by basic values, such as honesty and “do not harm,” irrespective of the consequences.

Still another approach focuses on what is called naturalistic decision making, denoting the process by which people use their experience to make decisions in complex and dynamic environments, often under time pressure and involving high risks (e.g., pilot decisions on the flight deck). For such situations, in 1993, Klein proposed a recognition primed decision model that involves recognition of cue patterns that leads to retrieval of a response option. Serial evaluation of single options is considered typical, and the first option that matches the decision maker’s goals and the situational constraints is chosen.

Models of organizational decision making describe decision making by both single and multiple actors in an organizational context. The normative rational (classical) model assumes that the organization follows a computational value-maximizing decision-making strategy. The model’s usefulness is limited to a small set of situations with specific characteristics (e.g., goals can be described in quantitative terms); consequently, alternative models were developed based more on the actual behavior of decision makers in organizations. For instance, the (behavioral) organizational model focuses on the limited information-processing capacity of decision makers and postulates an outcome-satisfying strategy. In addition, the garbage can model conceives of organizations as “organized anarchies” (e.g., having inconsistent goals). Universities are considered the prototype of such organizations that do not follow one specific decision-making strategy. Outcomes result from the variable participation of their various members and groups in continually changing tasks. All of these models differ in their capacity to cope with different degrees of uncertainty and conflict among interests.

7. METHODS

Decision researchers use a variety of quantitative and qualitative methods to examine how people make decisions. Experimental studies in the lab usually ask participants to make judgments about values and importance as well as about uncertainties and risks, to make choices among given options, and to evaluate options, search for information about options, or distribute goods. Reaction times, eye movements, and other behavioral data (including verbal reports) are also used as measures of the information-processing activity of participants. Outside of the lab, the questionnaire is the dominant method, where either decision problems are presented by the researcher, and participants provide the required responses (e.g., students in a lecture) or decision situations arise and the researcher observes and records participants’ behavior (e.g., pilots in a cockpit).

8. AREAS OF APPLICATION

The examples provided in this article for illustrative purposes have indicated some of the areas where decision making has been studied and where concepts and findings of decision research have been applied. More systematically, one may distinguish the following major domains: (a) behavioral economics and finance (e.g., investment and savings decisions); (b) business, administration, and management (e.g., employment, organizational, and product decisions; strategic planning with scenarios; communication of decisions; distributed decision making; cultural differences in decision making); (c) marketing and consumer behavior (e.g., product advertising, labeling, and pricing decisions; consumers’ allocation of their scarce means over various commodities and services; consumers’ decisions to acquire, consume, and dispose of products, services, and time); (d) health and medicine (e.g., addictive behaviors such as smoking, drugs, and alcohol; cancer screening campaigns; physicians’ use of probabilistic information; diagnostic and treatment decisions; informed consent; shared decision making); (e) aviation, military command, and firefighting (e.g., pilot crew decisions and decision-aiding systems; battle commander decisions; general aviation safety decisions); (f) high-risk facilities (e.g., operator decisions in nuclear power and chemical plants; emergency and general safety-related organizational decisions); (g) environmental issues (e.g., individuals’ benign attitudes and destructive behaviors;

governmental decisions and their implementation; communication between the public and the experts); (h) ethical and justice issues (e.g., organ transplantation decisions; business ethics; conflicts between self-interest and the other; dilemmas in risk communication); (i) advice, consulting, and counseling (e.g., decision advice in medical and financial problems; decision consulting for companies and agencies; genetic or abortion counseling for potential parents).

9. CONCLUSION

Approximately 50 years ago, the study of decision making started with lab experiments examining how people make choices among monetary gambles. Since then, the scope of studies has been extended immensely, reflecting the increasing importance of understanding and improving decision making in our society as well as the progress of methodology and model construction within the research community. However, the extension of the field has also eroded the idea of a general theory of decision making in favor of situation- and domain-specific models and empirical research on the conditions under which the various modes and strategies are being applied.

GLOSSARY

anticipation A mental operation that allows the athlete to predict upcoming events based on the elaboration between the current available visual-spatial information and knowledge stored in long-term memory.

coping strategies and self-regulation Active or passive emotion-focused or problem-focused methods used by athletes to appraise the environmental pressure that enable appropriate processing of information and decision making.

decision making A process by which an individual or a group of athletes select one course of action or actions from several alternative actions to be performed during precompetition or during a competition. It enables the athlete or the group to function under physically, emotionally, and mentally stressful conditions.

decision-making self-efficacy The belief that an athlete holds in his or her ability to make the right decision at the right time under competitive pressure.

perceived stress The perception of cognitive and somatic stimuli in the competitive environment that evoke feelings of anxiety and other emotions. It is linked to the degree with which one can adjust to the conditions to allow efficient decision-making processing.

visual-spatial attention The location in space in which the visual attention is focused, which enables a selection and elimination of environmental cues essential for decision making.

Jake plays in a central-midfield role on his soccer team. He plays at the very heart of the field and all moves, both offensive and defensive, bypass Jake. He has a multitude of decisions to make. Jake is young and prone to overarousal and constant errors. He pays equal attention to all the features of the soccer field and is limited in his capacity to process the most relevant information; thus, he often makes the wrong decisions. Coaches, parents, and teammates are upset with Jake; he is physically talented, but under time and event pressure he consistently chooses the wrong course of action. This article addresses the main issues related to Jack's limited cognitive capacity, which prevents him from making the right moves at the right time. The article addresses the required cognitive skills for proficient decision making and action execution. Several examples from different sports are provided to illustrate the research and theoretical issues.

1. INTRODUCTION

Decision making (DM) is a process by which an individual, a group, or an organization selects one preferred action from among two or more possible

actions within a specific situation. This article focuses mainly, but not conclusively, on the procedures involved in an individual athlete's DM processes. In sport, the DM process depends largely on the environmental and temporal conditions and rules under which a decision maker operates. These conditions vary with the nature of the sport. For example, in open-type sports such as basketball and soccer the environment is dynamic and consistently changing. The DM process in such sports requires the athlete to make a response selection (RS) based on past, present, and anticipated actions that may change through the course of time. Under such variable environmental conditions, the decision pertains to (i) which type of response/action to choose and (ii) at which time to execute the selected motor response. In contrast, closed skills, such as shooting and archery, which are performed within predetermined environmental constraints, require the decision maker to attend to his or her own proprioceptive sensory signals and decide when in the course of time to implement the decision.

In all sport environments, the DM process consists of three sequential phases: a preparation phase (i.e., visual search, selective attention, and anticipation); DM and RS through information processing (i.e., working long-term memory elaboration); and an action evaluation phase, in which DM and RS may be altered if new information is available at this stage. These stages are illustrated in Fig. 1. This information-processing model assumes that DM occurs under cognitive control. In cases in which the sport environment triggers a response under severe time constraints (i.e., less than 150 ms, which is the required reaction time under cognitive control), DM may occur under

self-organized rules. In such circumstances, decisions may come "naturally, without thinking." Generally, this self-organized DM process is more likely to occur among highly skilled and experienced athletes.

RS is typical to all sports, although the number of internal and environmental stimuli varies. The RS is more challenging when the number of stimuli increases, the temporal conditions shorten, and the athlete's affective state (i.e., anxiety) becomes less tolerable. The prevailing viewpoint in DM research in sport is that the process occurs within the context of both cognitive and affective systems, which operate simultaneously. The multifaceted perspective of DM in sport situations is presented in this article.

2. NONSPORT PERSPECTIVES ON DM

The traditional approach to DM was developed in the economics/statistics domain. The prescriptive approach viewed the person as an "outcome" seeker who pursues a desired goal. Accordingly, decision makers attempt to maximize a certain "expected value" and they process information in a manner that is targeted toward this ultimate end. The process is governed by comparing one's alternatives to an ideal solution that in many cases is unknown and speculative. One application of this approach accounted for gambling behaviors, where the unknown product necessitated a probabilistic estimation of utility. Despite their appeal, the prescriptive theoretical normative models were largely unsuccessful because they had limited ecological validity. Since human beings often make decisions that incorporate more considerations than just the expected value of their choice, these components needed to be identified and taken into account.

Cognitive-oriented researchers have examined the capabilities necessary for DM under certain environmental constraints. Also, cognitive capacity was believed to be a major constraint. Studies by DeGroot, Simon, Chase, and others in the early 1970s demonstrated that repeated exposure, experience, and skill level are associated with task-specific capabilities that enable the decision maker to use strategies and integrate information beyond the previously believed cognitive constraints. For example, expert chess players were able to recognize patterns in situations specific to chess in order to overcome limitations in working

FIGURE 1 Stages of information processing and decision making in sport.

memory, although their overall cognitive capacities were not superior to those of nonexperts.

The naturalistic/descriptive approaches to DM assume that the DM process involves both rational and irrational processes and incorporates personal values, morals, motivation, and emotional level in the DM process. From a naturalistic standpoint, DM consists of defining the problem, seeking alternative solutions (some of which may not be available at a given moment), and then choosing an alternative. According to these approaches, the DM process can be compromised under various conditions, such as those imposing psychological pressure. Several theoretical models, such as image theory, explanation-based theory, recognition-primed DM, and cue retrieval of action, were introduced to account for the human DM process.

Contemporary models within the naturalistic/descriptive approach concentrate on how people make decisions rather than on how they should make decisions. Mechanisms in the form of heuristics are offered to account for the quality of decisions as well as the processes by which decisions are made. These models, which consider the real-world conditions under which decisions are made, have largely replaced the more mechanistic prescriptive models.

The recognition-primed model (RPD) developed by Klein assumed that past experience in similar situations governs the DM process. Klein suggested that DM consists of cue identification, situational goals, alternative action generations, and expectations for possible alterations, all of which can be enhanced with increased experience. The complexity of the situation generates more adjustments or alterations, when time permits. Mental representations, which are established through experience and repetitions, guide the DM process. RPD was found to be valid in chess playing, and this approach is closely related to current concepts and models in sport-related DM processes.

The naturalistic method is a knowledge-driven discourse (i.e., domain-specific declarative and procedural information processes) that according to Lipshitz has not been given its deserved attention. Recent studies emphasize the role that domain- and content-specific features play in utilizing decision strategies under varying environmental conditions. In sport, however, knowledge base in the form of expertise and deliberate practice is well documented, thus advancing the naturalistic conceptualization of DM in simple and complex conditions.

3. DM IN SPORT: THE DYNAMICS AND MECHANISMS

DM in sport constitutes a set of adaptive behaviors that enable an athlete to operate effectively within the competitive environment under conditions that vary with regard to emotional, mental, and temporal demands. The efficiency of this capacity is influenced by the richness and the variety of perceptions, as well as one's ability to process information, at a given time. Sport-related tasks are unique in nature and, therefore, encoding relevant information for further processing requires specific perceptual and attentional resources and mechanisms. Depending on the situation at any given moment, a shift between serial and parallel processing of environmental stimuli is required to allow an efficient RS process. Under unconstrained time conditions, information is fed forward for further processing, responses in the form of neural codes are selected and maintained "on alert," and a preferred action is selected at a given time while others remain activated to some degree until decayed. For example, a golfer may consider the weather and the terrain when selecting a particular club while awaiting his next shot. In contrast, under restricted time constraints the DM process operates under direct perception-action rules, which depend on knowledge structure and schemas stored in long-term memory (LTM). A "fast break" in basketball is a common example of this type of condition.

DM in sport can be viewed as a sequence of decisional processes rather than one RS. This sequence starts at an early stage when the athlete observes his or her opponents on a video film or uses his or her visualization skills. While watching the rival athlete's or athletes' style, weaknesses, strengths, and so on, the athlete plans potential actions, which are stored in memory in the form of representations that can be retrieved easily when required. The more the player is aware of the context, the more he or she can anticipate and alter his or her opponent's action even before stepping into the playing court. While competing, however, the first decision is related to the selection of relevant (and elimination of irrelevant) cues in the environment through the use of different visual strategies. A sequence of events in the performing environment is similar to a "mental chronometry" introduced by Posner, Nissen, and Odgen in which warning signals draw attention until an imperative signal triggers a response. During the preparation period, the athlete attends to the visual field and anticipates upcoming

events through the elaboration between working and long-term memory systems. The decisions at the anticipatory stage pertain to what actions the opponent intends to perform and with what probability (e.g., a tennis player anticipates the location of her opponent's serve). The next decision in the sequence regards what response to select from several alternative responses and when to execute it (where and when to move on the court). This decision has both quality and timing components. Last in the sequence is the decision about response alteration when conditions require or impose a change. This decision relies on a quick modification process, which controls the system's adaptation level to the changing and dynamic environment (how the player might recover if the serve goes in an unanticipated direction). The success rate of DM depends to a large extent on different mechanisms operating simultaneously and in mutual interaction. To clarify these processes, the main mechanisms affecting DM in sport are introduced next.

3.1. Visual–Spatial Attention

An athlete uses visual–spatial attention to select and discriminate among cues in the playing environment. In many sport settings, a vast array of stimuli, some relevant and some irrelevant, are available to the athlete, and a major aim here is to minimize environmental uncertainty and to enable smooth detection, recognition, recall, and selection of relevant stimuli for higher level processing necessary for RS. The visual system has two main characteristics: fixation, the target toward which visual attention is directed, and duration, the time lag between two shifts in fixation. Scientific evidence indicates that among athletes who play fast ball games, with increases in experience and skill level, the number of eye fixations decreases, whereas fixation duration increases. In other words, more experienced players tend to have fewer shifts in visual–spatial attention.

Visual scanning operates via two possible strategies: the target control strategy, which consists of scanning individual targets in a sequence until one is located that is compatible with a representation stored in LTM, and the context control strategy, which is initiated by memory representations not sensitive to individual objects but rather to a pattern in the visual display. Scanning the environmental stimuli under context control is of greater advantage in open and dynamic settings because it reduces the information-processing load, increases visual attention efficiency,

and simplifies the elaboration between working and long-term memory.

Novice players for whom the environment is not fully familiar adopt a target control strategy, whereas with increased experience and skill level a context control strategy becomes more prominent. With the shift from a target to context visual control strategy comes a reduction in eye fixations and an increase in the duration of fixations. In fast ball games, eye fixation location depends on the visual scan sequence. One first fixates on the large features in the display, such as the entire court in racket sports, then moves to the racket (tennis, badminton, and squash) during the later sequence before a RS is made. Such a synthetic strategy enables the player to integrate information from the core sources of reference at once instead of relying on serially analytic chronological order scan, which is time-consuming and inefficient.

Cueing and priming are also key features in the sport realm that are integral in visual attention. When an athlete anticipates that a move will occur with high certainty, his or her response is faster as a consequence of this “priming a response.” When the environment causes greater uncertainty, response time is slower. While visually scanning the stimuli display, late cuing experiments in sport have shown faster reaction times to cue-primed locations than to unusual and unanticipated ones. However, sport-specific studies have shown that the cueing effect depends on the time interval between the warning and imperative stimuli. Reaction times increased with the time delay between the warning and imperative stimuli. However, in dynamic and fast-changing environments, perceptual-motor integration works differently from that reported for naive subjects in laboratory situations. As Cave and Bichot claim, the visual system is powerful in detecting and selecting objects in parallel to guide a response, and an object's location in the display is another criteria for DM. However, once extensively practiced, the probabilities assigned to upcoming events become the knowledge base of the athletes in the form of neural codes, from which they anticipate that events will occur. They thus become better equipped to prepare an appropriate action regardless of the time and space constraints of the environment. An example of this process is a batter in baseball who, through experience in detecting specific cues, learns which particular pitch (e.g., curve ball or fast ball) is most likely to be thrown in a certain situation.

An extensive knowledge base enables the athlete to minimize the costs associated with shifting attention

from narrow to large areas. When distracters in the space are cued, they interfere with the identification of a designated target and lead to an increase in reaction time. It is argued that when skilled athletes are exposed to several sources of information at one time, each carries with it a “probability value” for upcoming moves. When an anticipated action carries with it a high probability value, it enables the athlete to process the information efficiently and effortlessly and to subsequently make an adequate decision at the time. In contrast, an athlete who lacks such a capability pays the costs in the form of increased time for processing as well as less appropriate responses.

Finally, despite early beliefs that attention cannot be allocated or split among various sources simultaneously, recent research showed that attention could be divided when two targets were discriminated from each other by a given property or when all stimuli were suddenly presented. In open and dynamic environments such as ball games, anticipatory processes simplify the selection process by allocating visual attention to the more expected location and, at the same time, by using a context control strategy, which leaves other attention channels on alert for possible unexpected imperative stimuli to arrive. In such a manner, the skilled player secures a response with higher probability for success and at the same time leaves room for modification and refinement if circumstances require. These mechanisms help to explain how, for example, an elite basketball player can prepare to shoot a layup and, at the last moment, notice a defender’s position, alter his decision, and pass the ball to a teammate.

3.2. Priming, Attentional Flexibility, and Dimensions of Attention

In the typical sport environment, cues are assigned a probability value in terms of response priming. That is, based on the visual information received, one response is given a higher probability of selection than the others. Responses are primed when their associated stimuli are detected. The primed response provides a “benefit” in terms of the reduced time required to process and select it, whereas the “cost” is that it then takes longer to process and prepare an alternative response for unexpected stimuli. The cost–benefit ratio determines the flexibility of the attention process.

Research using the expert–novice paradigm in sport has shown that the higher the skill level of the athlete, the more one is able to optimize this effect (i.e., to

decrease the cost and increase the benefit of the stimuli-associated information processing). Precueing has a positive effect on the RS process because priming increases an athlete’s awareness of upcoming events as well as response readiness. Scientific evidence also suggests that athletes can use automatic and voluntary signal detection modes and can shift between the two when required. With increasing expertise, the athlete acquires both a “smoother” shift and more pronounced flexibility process. In sport, the type and intensity of priming are essential for RS. In competitive situations, athletes choose the priming options that have the highest utility value; that is, they select those that ensure the best chances of triggering the appropriate responses at the proper times.

Because different sports require different attentional processes, no single strategy is ideal for all situations. Some sports (e.g., archery and golf) consist largely of stationary positions, requiring the athlete to focus attention on both internal and external signals. Sports that are more open and dynamic (e.g., basketball and football) require a wider and more flexible attentional style. Moreover, some sports include conditions that require a wide, external attention (e.g., a playmaker in basketball) but others that require a narrow internal attention focus (e.g., shooting a free throw). In these sports, attentional flexibility, which is the ability to alter one’s focus, is a major asset. Neidefer’s model of attentional style accounts for the requirements and shifts of attention needed in various sport contexts. Accordingly, he recognizes two dimensions of attention: (i) width, from wide to narrow, and (ii) direction, from internal to external. Athletes must acquire the skill of adopting the appropriate attentional width and direction that enables them to make effective decisions. Failure to shift attention increases the probability of missing the relevant information needed for optimal DM.

3.3. Anticipatory Mechanisms

The attentional system, which detects the most salient environmental cues, enables the athlete to anticipate events in advance. Repeated responses to game maneuvers enhance the athlete’s perceptual anticipatory capability, which allows for a quick elaboration with the stored program representations in LTM. Fast access to one’s knowledge base becomes possible with only partial information. Because practice in the form of task-specific skill develops ready-access scenarios, these preexisting schemes are available for access even when a limited amount of the information contained in

the game situations “yet to be” is captured by the visual system. This anticipatory capability becomes automated and effortless with the development of expertise. For example, an elite volleyball player may notice the movement of just one of six players on the opposing team. However, since she has a complex set of stored schema developed through experience, she is able to predict or anticipate the movements of the remaining players.

Scientific studies of fast ball games have demonstrated the advantage of expert athletes over their novice counterparts in anticipatory decisions. Advanced anticipatory capability reduced the time required for a response, particularly when temporal conditions were extremely short. Anticipatory capability stems from both knowledge structure and advanced visual attention strategies. During the initial stages of scanning the environment for relevant stimuli, anticipatory decisions alter depending on the events taking place at the time. In expert athletes, visual attention is directed to pattern recognition through enduring eye fixations, and fast eye movements occur only under certain environmental constraints. At this stage, attention is simultaneously diverted to several sources of information, including the opponent’s moves, teammates’ locations, and time left on the play clock. Lack of experience and target types of visual scan result in impaired anticipatory capability. At the final stages of the anticipatory process, the novice athlete is engaged in decisions about what and where moves and actions will be performed, whereas the expert makes decisions about what action to perform in response to the opponent’s moves and/or situational demands. A novice wrestler, for example, decides where his opponent might step, whereas the expert selects the move he will use to score a takedown because he “knows” where the opponent’s leg will be. Finally, RS appropriateness depends not only on the cognitive process but also on the proficiency of the motor system and the confidence one has in his or her ability to carry out the response. In the example cited previously, the wrestler must possess sufficient strength, quickness, and confidence for the decision to be effective.

3.4. Memory Representations, Information Delivery, and Knowledge Structure

When an athlete’s knowledge base is rich, environmental distracters have limited impact on the DM process. A limited knowledge base considers these distracters as

relevant information, resulting in slowed DM via inhibition of the athlete’s information processing. The seminal studies of DeGroot and Chase and Simon on chess players in the 1960s and 1970s, and follow-up studies on a variety of sports since then, demonstrated how information is encoded, processed, and retrieved as a function of skill level and duration of visual exposure. It was assumed in these studies that recall accuracy following a short exposure to structured and unstructured situations would be a reliable indicator of both the visual attention strategy and the knowledge structure of the participants. Differences were consistent in that more skilled athletes could more accurately recall structured/logical/meaningful positions presented in a relatively short time than could unskilled athletes. The “chunking hypothesis” emerged as an explanation for this advantage in memory representation. This hypothesis rests on the premise that experience in the form of knowledge base and structure enables the player both to capture larger chunks of information in the form of logical patterns and to use these patterns as retrieval paths in a later stage. The chunking hypothesis was used to account for many research results, although recent scientific evidence from dancers and musicians has demonstrated significant memory superiority of skilled performers not only in meaningful information structures but also for memorizing random pieces of information. Thus, the chunking hypothesis has been called into question. In 1995, Ericsson and Kintsch proposed the existence of long-term working memory (LTWM), which may account for unusual memory capability in experts that is task-specific and cannot be generalized to other domains.

Short-term memory appears to have limited influence on experts’ memory capabilities, and working memory was considered a constraining factor because only small amounts of information could be temporarily stored while other information was processed. The concept of LTWM overcomes the notion that memory storage capacity is limited and decays immediately after stimulus onset. The constraint of a limited capacity working memory system seems to be irrelevant in expert memory performance, wherein concurrent activity seems to present limited interference. The new LTWM conceptualizes that when one becomes an expert in a given domain, such as sport, he or she can utilize LTM as a means for expanding short-term working memory.

LTWM develops through the creation of a domain-specific retrieval structure that is used to enhance storage and to maintain information in a more accessible

and less interference-prone state. A specific knowledge base is developed through practice, which enables task-specific memory traces to be rapidly and efficiently retrieved. The advantage of LTWM is that it relies on fast encoding and storing processes in a ready retrieved form from LTM. Domain-specific stored information in LTM is used as a retrieval cue that allows one to “unpack” the requested retrieval structure. Although decisions in sport are required, these same memory traces are used to retrieve a response and keep another response alternative on alert for possible and immediate alteration, refinement, or modification. When the stored information is richer and readily accessible, the DM process is smoother and of higher quality.

For a RS process to be efficient, task-specific declarative and procedural knowledge should be structured in a form that allows for easy and fast access. French and McPherson explored the network of conceptual knowledge required to make and execute tactical decisions in the dynamic and changing environments of ball games. The knowledge base consists of memory representations for action profiles, game situation prototypes, competitive scripts, and sport-specific strategies. The knowledge base is structured hierarchically and consists of macro- and microlevel routes. The microlevel is managed by the working memory and enables the athlete to attend to ongoing events in the sport environment. Advanced environmental visual scanning and anticipatory capabilities enhance the flow of information for further processing. The macro knowledge level refers to action plan profiles and specific event profiles, which enable the athlete to control and regulate the sensory systems and efficiently select and execute a response.

3.5. Decision Alteration

Several studies incorporating overt (e.g., reaction time, choice reaction time, and accuracy) and covert behaviors (e.g., evoked potentials) simultaneously have indicated that correct and incorrect decisions can be detected in brain activity and described in neural codes. Although not examined in actual competitive situations, these results can be extrapolated into the sport realm. It is suggested that with practice and experience, the athlete incorporates a decision strategy so that he or she can successfully replace one response by another response when the conditions necessitate such an endeavor (i.e., decision alteration). The psychophysiological research clearly indicates that beyond a given neural activation threshold, response alteration is almost impossible. Nevertheless, to reduce the probability of

error, the expert athlete holds alternative decisions “on alert” and activates them when an alternative decision is required. Thus, expert athletes, unlike their nonelite counterparts, activate alternative pathways that allow an “effortless” alteration process, which occurs mainly in complex and time-limited conditions.

An explication of decision alteration among experts was presented in Shallice’s “selection process” theory. According to this explanation, two attentional mechanisms control DM and action: contention scheduling (CS) and supervisory attentional system (SAS). The CS is automatic in nature and selects responses for action. The multiple schematic responses are activated and are in mutually inhibitory competition for selection. The final selection of a response is made when one of the alternative decisions is activated beyond a given threshold. The SAS mechanism can access the neural representations in the form of an intention for execution. When the selected response by the CS is proved to be inadequate during the time sequence, SAS modifies, stops, or, if not too late, alters the RS. Research shows conclusively that despite the advanced anticipatory capabilities of the expert athlete, RS is taking place only in the last stage of the process when uncertainty is minimized so that decision alteration can be made without tremendous processing costs. When an alternative response is ready and required, the alteration takes place.

4. DM IN TEAMS

One key advantage that a team has over an individual is a greater supply of human resources available for DM. For example, teams have an advantage over individuals on some measures of information processing (e.g., storage) owing to the extra information processing capabilities provided by multiple team members. Accordingly, in teams, the cognitive labor associated with DM tasks can be distributed over team members. Thus, the team can be considered as a cognitive system in itself. However, the cognitive properties of a team are more than just the sum of the cognitive properties of the team’s constituent members; information processing is affected by the way the team communicates and is coordinated and organized. Consequently, DM efficacy increases to the extent that a team invests effort into establishing strategies for efficient communication, coordination, and organization.

Evidence supports the notion that the more a DM task requires intramember information exchange between team members, the more important are effective

communication strategies for performance. However, studies have revealed a tendency for teams that are under time pressure or that are newly formed to discuss only information shared by all team members and not information unique to individual team members. Teams may be subject to DM biases under these conditions. Similarly, studies on crew communication during ship navigation and subsequent use of computer simulations of communication have shown how confirmation bias, a phenomena known to affect DM in individuals, can be accentuated in teams. In 1991, Hutchins showed that even while holding the cognitive properties of individuals constant, groups may display quite different cognitive properties depending on how communication is organized within the group and over time. In summary, DM benefits from the extra resources a team can provide only to the extent that teams factors such as coordination, organization, and communication are taken into account.

5. AFFECTIVE STATES AND DM

DM in practice or competitive situations often occurs in the presence of psychological pressure and under conditions that elicit physiological arousal. Therefore, the cognitive process that leads to RS depends on the (i) perceived stress experienced at the time, (ii) coping strategies and self-regulations used to cope with the emotional and physical stress, and (iii) confidence the athlete has in successfully anticipating and selecting a response.

5.1. Perceived Stress and DM

DM is strongly affected by the perceptions of stress (i.e., anxiety) the athlete experiences during competition. Both somatic and cognitive anxieties affect the attention processes, which are vital for the DM to be effective. Under an excessively low-anxiety state, attention is directed internally, which may result in the athlete ignoring or avoiding crucial cues that, under an ideal state, would trigger a response. Under a high-anxiety state, attention narrows to a level at which important environmental cues are missed. The detrimental effects of an elevated anxiety level are most prominent in complex, open, and dynamic situations in which a plethora of environmental stimuli are required for effective DM. In closed and explosive-type sports, such as Olympic weight lifting, high levels

of perceived anxiety are less harmful and, indeed, can even be beneficial.

In line with major theories of cue utilization and attention narrowing under conditions of high perceived anxiety, various studies have shown that DM under low anxiety relies on processing relevant and irrelevant cues alike. Under such conditions, the most important cue is not always primed to trigger a response. Thus, selectivity under such a condition is unfocused and unlimited. Under high-arousal conditions, the opposite is true. That is, an athlete's attention is narrowed, and DM occurs with too few cues. Under moderate levels of anxiety, attention processes are optimal in that only the most relevant cues are primed for processing and DM. Highly anxious athletes more frequently conduct "false alarm" DM errors, (i.e., make unnecessary decisions), whereas athletes with low arousal levels conduct both false alarms and correct RS. Moderate anxiety levels also limit the problems that many athletes have concerning sustained alertness (i.e., vigilance). Optimal anxiety levels are associated with "alertness preservation" (i.e., high concentration) over a given period of time. Thus, when mental alertness is optimal, it enables one to process the environmental stimuli so that no major stimulus is missed.

A concern arises when "choking" under pressure is evident even in the expert athlete. Two theories account for DM and performance decrements under psychological pressure conditions. Distraction theory claims that once under pressure, shifting attention to task-irrelevant cues results in a move from automatic to conscious attention control, resulting in poor DM. Alternatively, self-focus theory or explicit monitoring theory proposes that pressure causes the performer to pay attention to and control the automaticity of the skill. When a skill is learned and is best executed under automatic control, a shift to intentional control negatively affects DM and motor response processing, resulting in choking. In short, the athlete "thinks too much." Increased arousal levels result in a narrowing and self-focused attention that shifts away from the relevant cues and ultimately affects the DM process. Furthermore, choking seems to be most evident in tasks that require procedural knowledge and less so in tasks that primarily consists of an explicit knowledge base.

A recent development with regard to the emotions–performance linkage indicates that RS depends on a larger range of emotions than merely cognitive and somatic anxiety. It is the individual's perceptions of the intensity, pleasantness, and functionality of emotions that determine the specific resources recruited,

which generate energy required for optimal DM. When such an emotional state is not experienced, DM, and subsequently performance, may decline. Thus, each individual has a unique emotional-related performance zone within which the probability of making sound decisions and implementing them is highest. In other words, optimal, moderate, and distracted decisions are more probable under different emotion zones for each athlete. These performance zones may overlap to some degree and may change with experience and skill level.

5.2. Coping Strategies and Self-Regulation

When emotions are elevated, coping strategies are used automatically as part of the process of protecting the self. Thus, different emotions produce different hormonal reactions, which trigger certain responses to cope efficiently with current conditions.

The methods athletes use to regulate themselves through the use, misuse, or avoidance of coping strategies determine how emotions are appraised and, by extension, the effectiveness and efficiency of the DM process. Repeated exposure to similar physically and emotionally stressful situations enables an athlete to better tolerate and monitor processes of attention and DM under pressure. Successful self-regulation can be attained and has been proven through the measurement of electroencephalographs, heart rate/pulse, and other physiological responses of the autonomic nervous system. Sustained alertness has been enhanced by avoidance of sleep deprivation; supplementation with nutritional ingredients; elevated physical conditioning; task-related strategies, such as breathing control, relaxation, imagery, and stress inoculation techniques; and conscious control over one's actions.

Coping has two basic forms: emotion-focused and problem-focused. Both strategies are aimed at changing the individual's appraisal of the current situation. An appraisal change results in a new meaning given to the situation, and attentional processes change as a result. Therefore, strategies such as avoidance, denial, and distancing imply one's intention to disengage from interfering stimuli to promote efficient use of visual attention, information processing, and other components necessary for effective DM. In other cases, when emotions are extremely elevated, such strategies may detract from information processing efficiency. Instead, approach strategies may be more

helpful through the use of mental techniques such as relaxation, imagery visualization, and the setting of process and outcome goals. Research has consistently shown that the approach coping strategies are more helpful in monitoring the appraisal process under high perceived pressure, enabling the cognitive system to make decisions more efficiently. The more complex and dynamic the situation, the more beneficial their effect.

5.3. Self-Efficacy and DM

The social cognitive theory, particularly Bandura's self-efficacy theory, has important implications in sport DM. The beliefs athletes hold in their ability to make the right decision at the right time can be viewed as a coping strategy for handling decisions under competitive conditions. Self-efficacy in the context of sport DM has two dimensions: (i) the confidence one has in successfully anticipating and selecting the right response and (ii) the efficacy one has in executing the selected response. The limited research in this area leaves much to speculation. Current research indicates that self-efficacy in anticipatory decisions differs among novice, intermediate, and expert athletes. In fast ball games, experts display moderate levels of self-efficacy in their anticipatory decisions at early stages of response preparation. After the racquetball contact, anticipatory self-efficacy increases sharply. In novice and intermediate players, anticipatory self-efficacy remains moderate throughout the full duration of the task. These findings appear to support the notion that highly skilled athletes hold several alternative anticipatory decisions on alert under extremely short visual exposure frames, although this alters with the course of time—a pattern not typical of less skilled athletes.

6. SUMMARY: A HOLISTIC VIEW OF DM IN SPORT

DM in sport is a process of information processing in natural environments that impose unique constraints on the decision makers. When temporal conditions allow, the athlete relies on his or her experience and practice-related knowledge base to locate cues in the environment that are used for anticipatory DM. With experience and skill development, athletes shift from serial to parallel processing and from target to context visual strategies. These processes enable an athlete to

identify patterns of essential stimuli, elaborate on them efficiently via stored motor programs, and retrieve a response while keeping other responses on alert for possible decision alteration when needed. This process is efficient when the appropriate attentional style is employed throughout variable environmental constraints. The process of DM is more efficient when the athlete perceives the pressure of the sport environment as facilitative and less efficient when debilitating pressure is perceived. Being in the optimal emotional performance zone and feeling a high sense of efficacy for anticipating decisions and selecting responses increase the probability of making the correct decision. To secure an efficient DM process, the successful athlete employs the appropriate methods and mechanisms that underlie a skillful performance.

GLOSSARY

cognitive function Intellectual abilities such as the dimensions of attention, language, memory, problem solving, orientation, visual-spatial abilities, judgment, and psychomotor skills.

cognitive impairment A general term referring to alterations in cognitive functioning that occur in some elders and that affect behavior and impair the ability to function in usual activities such as activities of daily living (ADLs); such alterations may or may not be reversible, depending on the causative factors.

dementia The permanent and progressive deterioration of intellectual function caused by changes in the brain that results in impaired thinking and altered behavioral impulses.

memory disorders A general term referring to the wide variety of structural and functional changes in the aging brain as well as a range of symptoms of memory impairments.

normal changes in aging cognition The normative changes in cognitive functioning as assessed from a population-based

research perspective; there is a wide individual variability, with some individuals showing no changes at all.

Parkinsonism A chronic progressive disease of the nervous system characterized by a slowly spreading tremor, muscle weakness, and (during the later stages) dementia.

Pick's disease A brain disorder involving atrophy of the cerebral cortex and resulting in asthenia (i.e., loss of strength), loss of speech, and progressive dementia.

senescence A general term referring to the process of growing old.

senile dementia (or Alzheimer's disease) A progressive disease characterized by neuritic plaques and neurofibrillary tangles that leads to cognitive decline; it is most common during older adulthood.

senile plaques Extracellular brain tissue changes described by Alzheimer in 1907 and found in the brains of persons with Alzheimer's disease and, to a lesser extent, in normal-aged brains.

senility A term referring to a generalized deterioration in mental or cognitive skills, leading to a decline in the ability to perform social or occupational activities.

vascular dementia The second most common dementia, caused by an interruption in cerebral blood flow due to stroke.

This article deals with the concept of senility using a broad frame of reference. Cognitive effectiveness and age-related cognitive decline or impairment have been the subject of much research, especially during the past decade or so. At this time, there is not a consensus regarding all ideas about screening for dementia and preventive treatment to delay progression of the

disease. During the coming decade, more research findings will help to answer questions about the most reliable screening methods and the efficacy and ethics of using them. Controlled longitudinal studies will help to determine the value of pharmacological and nonpharmacological interventions. This article explores the meaning of senility, what it is and what it is not, who is at risk, prevention, early and late recognition, comorbidities and misdiagnoses, interventions, and future prospects.

1. SENILITY: WHAT IT IS AND WHAT IT ISN'T

1.1. History

Senile dementia was mentioned in the writings of Hippocrates and Pythagoras during the Greco-Roman era. It was recognized by Bacon in 1290, by dePratis during the 1500s, and by Pinel during the 1800s when he reformed the treatment of the mentally ill. At the turn of the 20th century, Alzheimer defined clinical and physiological brain lesions of senile dementia, now referred to as Alzheimer's disease.

1.2. Definition of Normal and Impaired Cognitive Functioning

It is important to differentiate between normal changes in aging cognition and senility or dementia. In normal aging, cognitive processes are slower and less accurate for more effortful or novel tasks than they are during younger years. Therefore, the older person may take longer to absorb the communication message, retrieve a thought, and respond. Memory is a special problem in aging because the older person takes longer to store information so that it may be recalled. Some have likened the aging brain to an overworked computer. The processor of the older computer is slow and the hard drive is overloaded with stored data, thereby making retrieval a more complex and longer process. Sometimes the files get disorganized, particularly when the computer is tired and overused. The new computer has a fast processor and little data stored in it so that retrieval is rapid. In terms of memory retrieval and learning new information, the older person processes information more slowly than does the younger person. The older person's cognition may be likened to the old computer's processor.

Working memory becomes less efficient in the older person. Working memory may be thought of as the ability to retain or temporarily store some information while at the same time accessing or using other information to perform a task. A complex environment, such as a loud and busy room, may interfere with working memory performance in the elderly. Working memory is needed in problem solving.

In terms of problem solving, the older person has more experiences to draw on, so decision making may be more effective in the older person than in the younger and less experienced person. Some refer to this as judgment or wisdom.

In dementia, there is a breakdown in several dimensions of cognition. Judgment is impaired and memory function is disrupted in terms of storage retrieval and planning for future conversations or decisions. Communication breaks down because the person is unable to problem solve or think ahead about the flow of words to use. Confusion and frustration may result, leading to behavioral and emotional changes.

In 1994, the American Psychological Association defined dementia as having the following deficits: memory impairment, cognitive disturbances (e.g., aphasia, apraxia, agnosia), and disturbances in executive functioning (i.e., goal setting) that result in significant impairment in social or occupational functioning and represent a significant decline from a previous level of functioning. According to this widely accepted definition, senility or dementia becomes a disability when social or occupational functioning is impaired.

2. MYTHS AND STEREOTYPING

Unfortunately, "ageism" or labeling sometimes can cause an older person to be called senile or demented when perhaps he or she is only hard of hearing or has received a large volume of information rapidly so that there is not time to encode it for memory retention and recall. Such stereotypes are common and permeate our society.

Consider the example of an 85-year-old and a 35-year-old talking with a group about a party they had attended the previous night. Both met a number of new acquaintances, but each could recall only one or two new names. The older person was quickly labeled senile, whereas the 35-year-old was viewed as just not having paid attention.

3. EXTENT OF THE PROBLEM

There is a clear association between cognitive decline and aging. This association is confirmed with cross-national prevalence data. Because of longevity, an increased percentage of the population is seen as having cognitive decline compared with earlier generations when the life expectancy was shorter. In 1996, Sloog and colleagues reported that 1% of 65- to 70-year-olds are diagnosed with moderate to severe memory disorders, whereas that number increases to 21% in 85-year-olds. Danish studies published in 2001 reported that among centenarians, 21% show no dementia symptoms, whereas 40 to 63% have mild to severe dementia.

3.1. Positive Risk Factors

There is much discussion that keeping an active mind deters memory and other cognitive function decline, although these approaches have yet to be tested longitudinally with large samples. Prevalence studies do indicate that a higher educational level, high occupational status and workplace complexity for older ages, an intact marriage to a well-educated spouse, a stimulating environment, and engagement in cultural and educational activities are associated with higher intellectual functioning into old age.

3.2. Negative Risk Factors

A number of disease conditions increase the risk of cognitive decline in individuals. Conditions such as a previous head injury, Parkinsonism, and multiple small brain infarcts or hemorrhages are common conditions that are likely to progress to cognitive impairment.

Major risks for dementia or cognitive decline are chronic diseases. Longer life expectancies are accompanied by increased prevalence of chronic conditions, resulting in more dementia in old age today than was the case during earlier decades when life spans were shorter.

Withdrawal from intellectual engagement, such as retirement from an intellectually challenging and complex job, can be a negative risk factor. These and other associations with cognitive functioning provide positive arguments for continued intellectual activity into old age as a deterrent or delay strategy for dementia.

There is some disagreement in the literature as to whether a busier and more complex life can lead to

fatigue that interferes with cognition or, if kept in balance, can provide intellectual stimulation. A lifestyle that allows for self-pacing provides more time for reflection and provides an opportunity to encode new information and retrieve old information without hurrying.

4. PREVENTIVE MEASURES

The research literature is clear in that there are no absolute preventive measures for senility or age-related dementia. If genetic predisposition occurs, preventive measures might only delay symptoms. However, studies have shown repeatedly that prevalence rates of dementia are lower in cases where certain associations have occurred. Some of these are discussed in this section.

4.1. Nutrition and Nutritional Supplements

Various studies have shown associations between the prevalence of Alzheimer's disease and the content of food intake. Vitamins that fall into the antioxidant category are considered to be beneficial in preventing dementia due to their ability to repair or replace molecules that are damaged by free radicals. The National Institute on Aging currently supports several large clinical trials that look at the effects of Vitamins A and C, selenium, betacarotene, folate, and multivitamins on cognitive decline and on the prevalence of Alzheimer's disease. The outcome of these large trials will provide additional empirical basis for evaluating the effect of vitamins and food supplements on aging cognition.

Reduced intake of saturated fat and maintenance of a low cholesterol level are believed to lower the risk of the onset of dementia and Alzheimer's disease. Studies have shown some association of lowered prevalence of cognitive decline among elders who eat a diet that is high in fish and other unsaturated fats. Fish oils taken in large amounts are reported to have a positive effect on the retention of cognitive function. These and other food substances have not been well tested with controlled and longitudinal studies on large samples.

4.2. Pharmacological Effects

Repeated studies have also shown some positive association between cognitive functioning and long-term use of nonsteroidal anti-inflammatory drugs such as

the regime that an individual with arthritis might take. People on prednisone, a steroidal drug, have not shown protection against dementia.

There have been a number of studies on estrogen showing mixed results regarding its effect on protecting cognitive functioning in women. The pattern seems to be that the larger trials, such as the Women's Health Study, show that there is no protective effect of hormone replacement therapy in older women on the prevalence of dementia and Alzheimer's disease.

4.3. Physical and Mental Activity

The concept of neuroplasticity applies to the ability of the adult brain to remodel pathways as occurs in the rehabilitation process in persons with stroke or brain injury. Magnetic resonance imaging has helped researchers to visualize brain mapping and to observe the reconfiguration of active pathways. Although confirming research trials have not been conducted to show the brain's ability to remap cognitive and memory function, the concept of "use it or lose it" has gained strength during recent years. Studies showing associations of cognitive function with higher education levels, as well as greater intellectual and social activity, have provided incentives that encourage people to engage in cognitive activities throughout their lifetimes so as to prevent age-related dementia. Although more longitudinal studies are needed, recommendations to engage in lifelong learning, even into old age, are widespread. However, the lasting effects of such behavior are not known.

5. EARLY AND LATE RECOGNITION

Ethicists have discussed the efficacy of screening for dementia. Who decides to screen? What is done with the information? Who decides to share the results of dementia testing? What are the implications for labeling a person with the Alzheimer's disease diagnosis? Who has the right to refuse screening? Does screening make a person disability eligible, or do the results of screening disqualify a person for the workplace or even for health insurance? Before screening for dementia, clinicians should ask themselves these and other questions and discuss the implications of screening with their colleagues and patients.

5.1. Early Recognition and Intervention

In looking for signs of the onset of dementia, it is important to differentiate between normal changes in memory that occur with aging and changes that may be associated with dementia such as Alzheimer's disease. In normal aging, the older person takes longer to learn new information, and the encoding process requires more time for new material to be retained, than is the case in younger persons. Therefore, an apparent inability to learn or to remember what was just heard is not necessarily a sign of early dementia; rather, it may be a sign of slowed cognition that occurs in all aged persons.

Changes with dementia, on the other hand, emerge with difficulty in learning new information. The person often gives up trying to learn. Difficulty in learning subsequently affects the ability to recall, that is, memory. This applies to verbal information as well as spatial information such as remembering directions.

5.2. Clinical Picture

The person with early age-related dementia may be unable to initiate new ideas into conversation, appears to be repetitive in speech, engages mainly in familiar routines to minimize stress, and shows behavior changes such as impatience, frustration, and withdrawal or depression. The person may encounter difficulty in concentrating as well. Complex skills, such as language planning and problem solving, may be shunned if the person with early impairment is aware of his or her own difficulty in cognitive functioning. Later stages show more memory impairment and language skill deterioration. The advanced stage of dementia will show impairment of all mental functions, including changes in personality and emotions exhibited by changes in behavior.

5.3. Screening and Diagnostic Tools

It is important that an assessment of an individual's cognitive functioning not be based on one instrument or tool. A multifaceted assessment of cognition will require an interdisciplinary team approach because special training is necessary to administer these and other approaches to evaluation. Where teams are absent, the use of a variety of assessment tools is

important. A basic assessment regime might include the following procedures:

- History and physical examination
- Neuroimaging and electroencephalography (EEG)
- Blood and spinal fluid laboratory tests
- Social history from a close family member
- Pharmacological and food supplement history
- Evaluation of activities of daily living (ADLs) and instrumental activities of daily living (IADLs)
- One or more of the following cognition data collection instruments:

1. *Mini-Mental Status Examination.* The Mini-Mental Status Examination (MMSE) is a common screening test that is used because of its reliability and validity in evaluating dementia, although it may show some bias for education and socioeconomic status. The 30-item instrument covers orientation, registration, attention, calculation, short-term recall, language, and construction. The test is not sensitive to early dementia.

2. *Clock Drawing Test.* In the Clock Drawing Test, the patient is provided an examiner-drawn circle and asked to put numbers in it and then to draw the clock hands at a given time (e.g., 11:10, 2:45). The properly administered test requires abstraction. Although it is sensitive, it should not be used alone as the sole screen or measure of cognition.

3. *Depression scales.* Although a number of depression scales are available, two seem to have common applicability for the elderly. The Geriatric Depression Scale (GDS) has several versions (5–15 items per version) and is a self-report of how the individual has felt during the past week. The Beck Depression Inventory (BDI) is a 21-item self-report scale that includes some somatic symptoms that may also be found in other chronic conditions. A depression assessment is important when determining dementia in older persons due to the frequency with which depression occurs in the elderly and concern that signs of depression may mimic or cloud those of dementia.

4. *Activities of daily living.* An important part of the dementia assessment is an evaluation of the individual's ability to carry out routine ADLs such as bathing or showering, dressing, eating, transferring, and toileting. Each item is rated as minimal assistance, moderate assistance, maximal assistance, or total assistance. This information may be gained from direct observation, interview of the caregiver or close relative, or self-report. A measure of ADLs can be used to rate the severity of the psychomotor or behavioral accompaniments of dementia.

5. *Instrumental activities of daily living.* The IADL tool provides higher level functions than does the ADL tool. IADLs include food preparation, home maintenance, laundry, financial management, communication (including use of a telephone), use of transportation, and medication administration. The IADL tool has been criticized for having a gender bias due to the food preparation and household items.

6. MISDIAGNOSES AND COMORBIDITIES

Careful screening and diagnosis is important in determining the presence of dementia, particularly during the early stages when signs and symptoms might not be obvious. Vision or hearing problems can interfere with verbal or spatial input and can impair the individual's ability to communicate accurately, thereby obscuring some cognitive functions such as the date and time. Sorting out such conditions is facilitated by multidisciplinary evaluation and repeated assessments over time to ensure an accurate diagnosis.

Frequently with the onset of multiple chronic conditions and diseases, it is difficult to determine whether comorbidities precede or follow the onset of dementia. This is particularly true in the case of senility or dementia. There are some frequently observed conditions that are strongly associated with dementia or are known to predispose to cognitive dysfunction. A number of common ones are mentioned in this section.

6.1. Head Injury

Depending on the location and severity of a head injury, or in repeated head injuries such as those that boxers may experience, dementia can occur.

6.2. Stroke, Atherosclerosis of Cerebral Arteries, High Cholesterol, and Hypertension

Vascular dementia is an outcome of some strokes or advanced atherosclerosis of cerebral arteries causing cerebral emboli. Persons with advanced diabetes can experience vascular dementia.

6.3. Oxygen Depletion of Cardiovascular or Respiratory Origin

Decreased cerebral oxygenation can lower brain metabolism and, over time, can lead to cognitive impairment.

6.4. Parkinsonism

During the advanced stages of Parkinsonism, this neurodegenerative disease can exhibit cognitive impairment, particularly in working memory.

6.5. Chronic Mental Illness

Some long-term mental health problems may show a slow emergence of dementia that may be due to the mental condition or to the effects of long-term therapy.

6.6. Drugs or Other Toxic Substances

Long-term exposure to certain toxic substances can affect cognition. Short-term drug toxicity can cause the person to exhibit changes in cognitive function, particularly orientation, that can be reversible in many instances.

6.7. Other Conditions Such as Dehydration, Fatigue, and Relocation

A fair amount of research points to the effects on working memory and orientation when the older person experiences unusual physical or mental stressors such as those that may occur with dehydration, extreme fatigue, and sudden relocation of the living environment. Research has demonstrated that older people have times of peak functioning during the day, usually the morning hours. Careful assessment of the entire person is essential before applying the label of senility or dementia.

7. INTERVENTIONS AND CARING

There is a great deal of literature on interventions for individuals with moderate and advanced dementia. This article deals with some early interventions and

concerns for the care of persons with cognitive impairment.

7.1. Dietary Supplements and Medications

Aricept (other trade names include Cognex and Exelon) is the most widely used drug to alleviate the symptoms of Alzheimer's disease. It does this by prolonging the effects of acetylcholine release events, thereby raising neurotransmission and increasing neurotransmission effectiveness. Its use is thought to delay the advancement of symptoms rather than to provide a cure, although side effects may interfere with use of the drug.

7.2. Memory Aids and Other Nonpharmacological Treatments

The use of memory cues, such as written notes, is thought to help prolong independence in people who have progressive age-related dementia. Some literature indicates that people with mild or even moderate dementia retain reading skills longer than they do oral skills. There is also evidence that the use of written language becomes less complex in terms of sentence structure and vocabulary as the dementia progresses.

If familiar routines are retained in persons with mild to moderate dementia, independent living can be extended. Conversely, learning new routines can trigger undesirable or stressful behavior. Community-based group programs are often available through a day care format and use a variety of activity approaches to enable the individual to retain a desirable quality of life and to provide respite for the family caregiver.

7.3. Management Concerns

As the dementia condition progresses from mild to moderate levels of impairment, a number of concerns that need to be addressed may arise. Because dementia emerges in very different ways for each individual, not everyone with moderate or advanced dementia will experience these problems. However, an awareness of possible concerns will enable the practitioner to aid the family caregiver in planning ahead to prevent unsafe or disturbing behaviors.

Driving is an activity that is closely identified with a person's sense of autonomy and independence. Yet as the individual's judgment and problem solving become impaired, it is not unusual for the person with

dementia to become lost or to make wrong decisions that can result in an auto accident. Determining when it is no longer safe for the individual to drive is a problem that family members face and that often requires their intervention.

Wandering is another concern for the ambulatory person with moderate or advanced dementia. Assistive devices, such as radio and identifier tags, can help to quickly locate the individual who has the potential for wandering. Failure to locate the person who has wandered may lead to dehydration, hunger, hypothermia, and even death.

When the person with moderate dementia is unable to carry out two or more ADLs, additional support for the family might need to be considered. Such support may be provided by adding additional assistance in the home. If the behavior is unmanageable, a time may come when the family decides to move the individual to a protective environment such as an assisted living facility for persons with dementia. Measures of family coping may assist in determining the amount of caregiving burden that the caring family members are experiencing and may serve as a useful tool in assisting the family with making decisions about care.

Repetitive forgetfulness can pose problems for caregiving. Forgetfulness can include leaving a stove on, leaving a cigarette lit, and not being able to locate familiar objects such as keys.

These are just a few of the concerns that can arise in providing care for the person with moderate dementia. The caregiver can gain many tips on how to deal with caring for the family member with dementia by joining a support group and sharing concerns with others who face similar experiences.

8. FUTURE PROSPECTS

Many call the decade of the 1990s as the “decade of the brain.” Although much knowledge has been gained about brain function, there is much more to learn. Further advancements in maintaining cognitive effectiveness are certain to be made, although a cure for age-related dementia is not anticipated. Whether new approaches, such as brain stimulation from electrical or pharmaceutical products, are developed and are effective in lessening the progression of dementia is another area for empirical study.

Recent brain research, summarized in the September 2003 issue of *Scientific American*, indicates that there is evidence that brain pathways for motor control have

the capacity to change. This phenomenon is referred to as plasticity. Future research will demonstrate whether repatterning can occur in intellectual functioning as it has with physical activity.

Impending demographics in terms of increased life expectancy and population aging means that there will be increasing numbers of elders throughout developed and newly industrialized nations. Greater numbers of people living longer will mean that increases in the prevalence of degenerative diseases, including dementia, will be experienced throughout the world. If preventive approaches and proposed therapies are found to be effective, much will be saved in terms of human and economic resources, and the quality of life of large numbers of elders will benefit.

GLOSSARY

age-related changes Normal physical and psychological changes from young adulthood through old age.

comorbidity The co-occurrence of two disorders or syndromes.

late-onset depression Depression with an onset at age 65 or older.

major depression Major depressive disorder as defined in the *Diagnostic and Statistical Manual of Mental Disorders*. It is characterized by depressed mood for at least 2 weeks and at least four additional symptoms of depression.

minor depression Minor depressive disorder as defined in the *Diagnostic and Statistical Manual of Mental Disorders*. It is characterized by depressed mood for at least 2 weeks but with few symptoms and less impairment than in major depressive disorder.

reminiscence therapy Involves recall of events in a person's life and is usually done in groups in which participants are encouraged to talk about past events, sometimes with such aids as photos, music, and personal objects.

somatic symptoms Fatigue, changes in appetite, changes in sexual activity, and changes in sleep duration.

subsyndromal symptoms Symptoms of depression that are not of sufficient frequency, duration, or intensity to meet the formal criteria for an affective disorder.

The 1999 Surgeon General's Report on Mental Health revealed that almost 20% of older adults experience mental disorders. Depression, although not the most prevalent mental disorder among older adults, is a very significant source of suffering. From a clinical perspective, it is a particularly complex and challenging phenomenon, due in part to age-related differences in the experience and presentation of depressive symptoms, risk factors, and the many potential causes of depressive symptoms (e.g., medications, comorbid diseases, and stroke).

1. EPIDEMIOLOGY OF LATE-LIFE DEPRESSION

Depression in older adults is often overestimated and underrecognized, and it is not the most prevalent psychiatric disorder among older adults, as many believe. Indeed, the prevalence of depression is lowest among adults aged 65 or older. Prevalence rates for major depressive disorder among community-dwelling older adults (65+ years) range from 1 to 4%. The North Carolina Epidemiologic Catchment Area Study estimated a prevalence of 0.8% for major depression, 2% for dysthymia, and 4% for minor depression. Incidence

estimates of depression in long-term care facilities have ranged from 12.4 to 14%. If one considers clinically significant depressive symptoms that do not meet diagnostic criteria (subsyndromal symptoms), the rate of depression ranges from 8 to 15% for community-dwelling older adults, 25 to 33% for hospitalized older adults, 10 to 15% for nonpsychiatric outpatients, and 30 to 40% for long-term care residents. The Epidemiological Catchment Area Studies reported bipolar I and bipolar II prevalence rates of approximately 0.1% among older adults.

2. CONCEPTUAL AND DIAGNOSTIC ISSUES

There is increasing evidence that depression among older adults differs from that of younger adults along several dimensions (e.g., etiology, presentation, and phenomenology). In 1988, Alexopoulos *et al.* suggested that the etiology of depression among older adults appears to be somewhat related to the age of onset. Gatz and Fiske noted that among depressed older adults, approximately 50% are cases of late-onset depression. The etiology of late-onset depression may be quite different from that of depression occurring in earlier years. The experience and presentation of depression among many older adults appears to be different than that of younger adults. For example, depressed older adults are less likely to report dysphoria than younger adults with the same level of overall depression. Gatz and Hurqitz revealed that older adults are also more likely than younger individuals to endorse test items suggesting a lack of positive feelings, whereas younger adults are more likely to endorse test items suggesting depressed mood. Older adults are also less likely to report ideational symptoms (e.g., guilt) than younger adults and more likely to report somatic symptoms. These somatic symptoms, such as fatigue and changes in appetite and sexual activity, may be related to coexisting medical conditions or normal age-related changes. Reports of lack of interest, sleep disturbance, and lowered energy level, however, may be useful in differentiating depressed and nondepressed older adults.

In addition to the content of age-related symptoms of depression, there is evidence that symptom levels and patterns that would not currently meet *Diagnostic and Statistical Manual of Mental Disorders*, fourth edition (DSM-IV), criteria for major disorders are nevertheless

problematic for older adults. Many older individuals present with somatic complaints and experience symptoms of depression that do not meet the criteria for depressive disorders. The effects of these subsyndromal conditions may be just as consequential as those of the disorders that do meet diagnostic criteria.

In summary, depression among older adults appears to be different in a number of ways from that encountered in younger adults. The etiology of depression among older adults appears to vary depending on the age of onset. Moreover, the nature and pattern of depressive symptoms of older adults appear to deviate from those one would expect based on depression criteria found in the *DSM-IV*.

3. RELATIONS AMONG DEPRESSION, PHYSICAL DISEASES, AND MEDICATIONS

One of the complicating factors faced by clinicians and depression researchers regarding the nature and etiology of depression among older adults is that older adults have a higher incidence of medical disorders than younger adults. Approximately 80% of older adults suffer from at least one chronic health problem. Consequently, it is relatively common for depressed older adults to have comorbid medical disorders; that is, they exhibit the co-occurrence of two disorders or syndromes.

Although the relations between depression and comorbid disorders can be rather complex, they are generally well established. Depression can precede, follow, or simply co-occur with unknown directional relations. Depression is a risk factor for physical disease (e.g., cardiovascular disease) and diminished cell-mediated immunity. Symptoms of depression can also arise directly from various physical diseases (e.g., hypothyroidism, stroke, Parkinson's disease, and pancreatic cancer) and from the psychological reaction to a disease (e.g., Alzheimer's disease). Depressive symptoms may also follow a disease process (e.g., myocardial infarction). Similarly, depression is very common among cancer patients, with rates varying from 25 to 50%; there is a greater prevalence among individuals experiencing higher levels of pain, physical disability, and illness. When considering the relations between physical disease and depression, it is important to understand that one need not meet criteria for depression for the symptoms of depression to affect physical health.

The complexity of the relations between depression and physical diseases is often amplified by the adverse effects of medications used to treat medical diseases (e.g., parkinsonism, pain, cancer, arthritis, and hypertension) because many of these medications can produce symptoms of depression. Older adults consume more medications than any other age group and are at higher risk of adverse drug reactions than any other age groups because of age-related changes in physiology and increased use of multiple medications.

4. ASSESSMENT OF DEPRESSION

The assessment of depression among older adults can be quite challenging, particularly in light of the issues discussed previously. Age-related differences in the presentation of depression as well as the potential for coexisting physical ailments, medication side effects, and natural age-related changes increase the complexity of diagnosing depression when assessing older adults.

Methods of assessment for depression include self-report, clinical interview, report by others, physical examination, and direct observation. Given the intricacy of identifying depression in older adults, there may be no single best method for assessing depression. Each method has its own relative strengths and weaknesses; however, combining methods during the assessment process can enable a clinician to obtain a more complete understanding of depressive symptomatology in older adults. Here, discussion is limited to the most commonly used self-report and clinician-rated instruments.

5. INSTRUMENTS FOR THE ASSESSMENT OF DEPRESSION

The most widely used instruments for assessing depression use the self-report method due to the relative ease of administration and brevity. Clinician rating scales, although often taking slightly longer to administer, offer the advantage of objective observation of the depressive symptoms, which can be particularly useful with cognitively impaired older adults.

5.1. Self-Report Instruments

5.1.1. Beck Depression Inventory

The Beck Depression Inventory (BDI) is a 21-item, multiple-choice inventory. Respondents are asked to

rate each item based on four response choices according to the severity of the symptoms, ranging from the absence of a symptom to an intense level, during the past week. A 13-item version of the BDI is also available. Both the original and short forms have reasonable internal consistency for normal and depressed older adults and adequate test-retest reliability in older adult patient and nonpatient populations.

A second version of the BDI (BDI-II) was published in 1996 so that items would be consistent with the revised criteria for depressive disorders in the *DSM-IV*. The number of items on the BDI-II is the same as that for the original version. Edelman *et al.* suggest that the BDI-II be used with caution with older adults given the lack of empirical support for its use with this population.

5.1.2. Center for Epidemiological Studies-Depression Scale

The Center for Epidemiological Studies-Depression Scale (CES-D) is a 20-item instrument with good psychometric properties. A 10-item version of the CES-D also has adequate psychometric properties and appears to be a good instrument for screening for depression in community-dwelling older adults.

5.1.3. Geriatric Depression Scale

The Geriatric Depression Scale (GDS) is a 30-item scale designed specifically for use with older adults. The scale uses a yes-no format and has well-established psychometric properties with community-dwelling older adults, outpatient and hospitalized older adults, and geriatric stroke patients. A 15-item form of the GDS yields scores that are strongly correlated with those of the long version. Overall, the GDS appears to be a useful instrument for assessing depression in older adults.

5.1.4. Zung Self-Rating Depression Scale

The Zung Self-Rating Depression Scale contains 20 items that are rated on a 4-point scale by the patient according to the amount of time he or she currently experiences the symptom. Psychometric properties with older adults are less than desirable.

5.2. Clinician Rating Scales

5.2.1. Hamilton Rating Scale for Depression

The Hamilton Rating Scale for Depression (HRSD) is used to quantify the severity of symptoms of depression and is one of the most widely used and accepted instruments for assessing depression. The standard version of the HRSD is designed to be administered by a trained clinician, and it contains 17 items rated on either a 3- or 5-point scale, with the sum of all items making up the total score. The HRSD may be a useful scale for cognitively impaired patients who have difficulty with self-report instruments.

5.2.2. Geriatric Depression Rating Scale

The 35-item Geriatric Depression Rating Scale (GDRS) combines the severity rating format of the HRSD with the content of the GDS. The GDRS probably requires less experience and training to administer than the HRSD and has good psychometric properties with hospitalized, outpatient, and community-dwelling older adults.

5.3. Instruments for Assessing Depression with Coexisting Dementia

Individuals with dementia pose a particular challenge when assessing for depression due in large part to the overlap of symptoms of depression and dementia as well as the effects of cognitive impairments and memory deficits. Several instruments have been developed to address the complicated nature of assessing depression with coexisting dementia, including the Cornell Scale for Depression in Dementia (CS) and the Dementia Mood Assessment Scale (DMAS).

5.3.1. Cornell Scale for Depression in Dementia

The CS contains 19 items that assess for the severity of depression based on a 3-point scale with content similar to the that of the HRSD. Psychometric properties of the CS are adequate. The CS appears to be a useful measure for assessing severity of depressive symptoms in older adults with dementia or cognitive impairments.

5.3.2. Dementia Mood Assessment Scale

The 17-item DMAS is a brief measure of mood in patients with dementia that includes a semistructured

interview and direct observation of the individual over time. The psychometric properties of the DMAS are not strong. Its advantage lies in the combination of interview and direct observation.

In summary, there are a wide range of assessment instruments available for the assessment of depression among older adults, with each having strengths and weaknesses. Although many of the instruments were developed for use with younger adults, they have proven reliable and valid with older adults with a wide range of clinical characteristics.

6. TREATMENT OF LATE-LIFE DEPRESSION

Despite the availability of treatments for depressed older adults, only a few older adults utilize such treatments. Depressed older adults are most frequently first seen by a primary care physician, usually for somatic symptoms and complaints of low energy. Unfortunately, many older adults and their physicians attribute these symptoms to “normal aging” or a physical ailment and fail to make a mental health referral.

Although presentation and diagnostic considerations for depression appear to differ in older adults when compared to their younger counterparts, Karel and Hinrichsen’s review of the literature suggests that treatment interventions effective for younger adults are also efficacious for older adults. This section focuses on psychosocial interventions, with an emphasis on evidence-based treatments for older adult depression.

6.1. Evidence-Based Psychosocial Treatments

A number of psychosocial interventions have proven effective for treatment of older adult depression. These treatments include psychodynamic, cognitive, behavioral, cognitive-behavioral, and interpersonal therapies. Although the rationale for each form of therapy is derived from varying conceptualizations, a number of studies have demonstrated the effectiveness of each of these therapies for treatment of depressed older adults.

6.1.1. Psychodynamic Therapies

Psychodynamic therapies focus on intrapsychic conflicts that may be affecting the individual’s coping and adjustment. Emotional insight, gained through the therapeutic

process, is the goal of treatment for resolution of these conflicts and establishment of more effective coping styles. In addition, this form of therapy focuses on resolution and acceptance of social and physical losses that are characteristic of old age and addresses unresolved issues from various stages of development that may be contributing to the person's distress. Psychodynamic therapies also frequently incorporate a focus on the "self" and maintaining self-esteem through the trials and tribulations of the aging process.

6.1.2. Behavior Therapy

Behavior therapy relies on the premise that overt activity and mood are closely linked. In 1974, Lewinsohn, who offered one of the principal behavioral theories of depression, demonstrated that the lack of sufficient positive reinforcement from one's environment can negatively affect one's mood state. Zeiss and Lewinsohn adapted Lewinsohn's behavioral approach for older adults. This form of therapy typically involves behavioral activation, scheduling of pleasant events into the person's life, decreasing one's participation in aversive activities, and problem solving and social skills training. In addition, "homework" assignments are frequently given to facilitate the achievement of clearly developed goals and skills and activate the person for change.

6.1.3. Cognitive Therapy

Cognitive therapy, as developed by Beck *et al.* in 1979, assumes that maladaptive and irrational cognitions are contributing to, if not causing, the depressed mood. This therapy focuses on identifying distorted or irrational thoughts and beliefs that may be contributing to the mood state. During therapy, the person is encouraged to monitor, challenge, and eventually replace negativistic and irrational thoughts with realistic, more positive ones. Practice through completion of homework assignments is integral to this form of therapy, and clients are encouraged to monitor and challenge irrational or negativistic cognitions in their daily lives once they have practiced in a therapeutic setting.

6.1.4. Cognitive–Behavior Therapy

Gallagher-Thompson and Thompson combined behavioral and cognitive therapies, which they termed cognitive–behavior therapy, for the treatment of depression in older adults. This form of therapy is

based on the rationale that irrational cognitions and/or maladaptive behaviors contribute to and maintain a depressed mood state. It is assumed that negative cognitions or thoughts, especially about one's self, future, and experiences, create a negative lens through which one sees the world. In addition, the depressed older adult is not engaging in enough positive mood-enhancing activities, which tend to exacerbate the negative cognitions. This form of therapy is generally psychoeducational, goal-directed, structured, and brief, designed to give the depressed older adult the cognitive and behavioral skills (e.g., relaxation techniques, assertiveness training, and problem-solving skills) he or she is lacking.

6.1.5. Interpersonal Psychotherapy

Finally, interpersonal psychotherapy (IPT), developed by Klerman *et al.* in 1984, is a time-limited form of therapy that emphasizes interpersonally relevant issues that may have preceded or resulted from depression. Specifically, this therapy stresses the importance of family relations in older adults' lives and, as such, emphasizes the nature of important relationships and focuses on one of four potential interpersonal problems: grief, interpersonal dispute, role transition, and interpersonal deficits. Treatment strategies are then implemented to address each of these problems and reach identified treatment goals. In a review of the use of IPT with older adults, Hinrichsen found several studies that demonstrated the effectiveness of this therapy for older depressed adults.

6.1.6. Other Psychosocial Treatments

Although the previously described therapies have been well established as effective for use with older adults, a number of other therapeutic approaches are used, although little empirical evidence is available for their efficacy in this population. It should be noted, however, that simply because an intervention has not been empirically studied does not indicate that it is not useful or effective in the treatment of older adult depression. Several of these forms of treatment have been examined through preliminary studies that have rendered promising results.

6.1.6.1. Life Review Therapy Life review therapy, a form of reminiscence therapy, encourages the older adult to reflect on his or her life and is thought to facilitate his or her progress through Erikson's final developmental task and emerge with a sense of integrity

or despair. Although it is used for the treatment of depression in older adults, some caution its use with this population because it could prove more harmful than helpful, especially for older adults for whom a life review would not be a positive experience. Researchers continue to debate the efficacy of this form of therapy.

6.1.6.2. Group Therapy Group therapy, especially psychoeducational group therapy, is another form of treatment for older adult depression. Group therapy captures the interpersonal or social component not seen in other forms of therapy and thus allows for older adults to share with and learn from each other while acquiring behavioral and cognitive coping skills. This form of therapy can be quite effective with depressed older adult family caregivers.

6.1.6.3. Less Common Forms of Treatment Less common forms of treatment for older adult depression include bibliotherapy and self-help therapy, both of which emphasize the individual's role in treatment and overcoming depression without a great deal of intervention from a therapist. Typically, in both of these forms of therapy, the older adult is educating himself or herself through readings. In 1989, Scogin *et al.* conducted one of the few studies on the efficacy of bibliotherapy and found promising and generally positive results.

A number of treatments or therapies for older adult depression have been described briefly in this section. Although there are several well-established, effective treatments for depression in this population, there is a need for additional research to empirically examine some of the other less common but potentially advantageous forms of therapy. There is also a need to make treatments more available and acceptable to older adults so that when referred by physicians, depressed older adults will seek treatment.

 3. Collaborative Relationships
 4. Guiding Principles for Developmental Counseling Processes
 5. Appraisal in Developmental Counseling
 6. Developmental Counseling Interventions for Resolving Current Developmental Problems
 7. Developmental Counseling Interventions for Preventing or Reducing Developmental Problems
- Further Reading

interventions for prevention Interventions designed to prevent problems from either becoming more serious or expanding to other areas of functioning.

life cycle Differences in a person's activities across time.

life structure Differences in a person's activity pattern or configuration at a particular point in time.

Developmental counseling is a collaborative and catalytic relationship formed between a professional counselor, who is trained in both counseling and human development, and a client, who is currently experiencing or is expected to experience problems that impede progress toward mastering personally and/or culturally valued functions for the purpose of co-constructing new meanings of current actions and/or new possibilities for future actions.

GLOSSARY

appraisal Collecting and synthesizing data to construct a description of a client's life history and current problems.

collaborative relationship A counselor and client working together jointly toward agreed-on goals.

developmental change Relatively enduring irreversible differences over time in a person's activity pattern judged as movement toward mastery of culturally valued functions and social competencies.

developmental problem A "gap" between present experiences and experiences desired by the developing person or by people who have a stake in the person's development.

interventions Counselor-initiated acts that literally "go between" events sequenced along a client's life span, between the client's problem-saturated activity and future growth/movement toward resolving problems and addressing new challenges.

1. INTRODUCTION

Most people experience problems while growing up, that is, problems that impede their progress toward mastering personally and/or culturally valued functions. Most contemporary cultures value successful functioning as a friend, a learner, a producer/worker, a spouse or partner, and a citizen. Furthermore, the specific cultural group with which a person identifies—not necessarily the dominant culture—sets a "timetable" for growing up that specifies the period in life during which the person's attentions to these functions should begin, peak,

and diminish. Problems arise when people perceive a “gap” between their current experiences and the experiences desired by themselves, by important others in their lives, and/or by cultural standards. People may experience developmental problems such as making and keeping friends, finding and sustaining meaningful work, achieving intimacy, and defining and implementing a sense of unique personal identity.

Described in another way, a person’s development is problematic when his or her activity is not organized effectively to perform major life functions that the person’s culture considers to be fundamental to the human condition. Although most cultures seem to agree on some essential human functions, they differ on others. For example, achieving a sense of personal identity is more prominent in cultures that emphasize individualism and autonomy than in those that emphasize community and belonging. Cultures also differ in their prescribed cultural pathways to achieving competence. For example, some cultures promote pathways of personal independence, whereas others promote pathways of social interdependence.

Over the past 50 years or so, several writers have advocated an approach to counseling that addresses developmental problems. The aggregate scholarship on developmental counseling remains somewhat informal and eclectic. Perhaps the most systematic treatment has been developmental counseling and therapy (DCT) advanced by Ivey and colleagues. Given such wide-ranging ideas and practices, this article represents a composite definition amalgamated from many sources.

Developmental counseling represents a broad counseling approach designed to help a wide range of people who are experiencing problems of growing up across the life span. Because few counselors can master all of the skills and knowledge necessary to serve all people with developmental problems, developmental counselors usually specialize in working with clients from a particular age group (e.g., counselors for children), address a particular cultural function (e.g., career counselors), or identify with a particular subculture (e.g., counselors for women).

The delivery of developmental counseling can be distinguished from other counseling approaches. Most notably, developmental counselors work with people to activate their movement toward developmental change rather than to remediate pathology. Developmental counselor–client contacts usually are for a limited number of meetings and may be intermittent over longer periods of time, similar to the relationships that many adults maintain with their dentists or accountants.

Developmental counselors serve as catalysts, rather than as the sole providers or vehicles, for clients to change and mobilize every helping resource in their environment—sometimes called activating a network of resources—so as to stimulate and support developmental changes. Client growth is expected to occur both outside and within the counseling relationship.

Developmental maturation or growing up is given meaning both from the perspective of the person who is experiencing it and from the perspective of external observers. If the person who is experiencing developmental problems seeks the help of an expert “external observer” called a professional counselor, that collaboration is called developmental counseling. Sometimes, developmental counselors will work with groups of people who are about to experience common developmental problems in an effort to prevent more serious problems. Professional counselors provide, among other initiatives, a fresh perspective on developmental problems experienced by clients, a perspective that is informed by knowledge of human development and cultural standards. Although developmental counselors employ many of the same ideas and techniques as do counselors with other theoretical preferences, the former are most clearly set apart by subscribing to a developmental viewpoint.

2. THE DEVELOPMENTAL VIEWPOINT

Development generally refers to changes in patterns of overt and covert activity as people grow up or mature in their capacity to perform several culturally valued life functions. Individual development involves multiple changes as the person strives to master many life functions simultaneously. When such changes are judged as movement toward cultural ideals of maturity or healthiness, there is general agreement that the person made developmental changes. Developmental change is progressive and incremental, usually involving movement away from simple, dependent, self-centered activity patterns that are typical of younger members of a society and movement toward complex, independent, society-centered activity patterns that are typical of mature members of a society. The metaphor for developmental change is usually a spiral rather than an inclined plane, thereby representing back-and-forth movement that is predominantly forward. By contrast, development is not construed as change in traits (e.g., becoming less

introverted or more intelligent), as change in states (e.g., becoming less anxious or more expressive), or as change in specific isolated behaviors (e.g., eliminating socially disruptive behaviors, increasing frequency of approaching peers).

Developmental counselors conceptualize differences in individual clients' activity along two dimensions: the time across the life cycle and the activities within a contemporary life structure. The life cycle traces differences in a person's activities across time, and the life structure specifies differences in a person's activity pattern or configuration at a particular point in time. Development usually connotes quantitative changes (e.g., frequency, intensity, duration) in age-graded normative activity that is typical, rather than unusual, for the age group. For example, the duration of friendships tends to lengthen during late childhood and adolescence. Development also refers to qualitative changes in action patterns (e.g., complexity, coherence) that serve the same broad, culturally valued life functions. For example, patterns of values expressed as reasons for moral or career choices are generally more complex and coherent during adolescence than during childhood. Developmental change is also reflected in the transformation of the organization of activity—the life structure—as well as in the activity content.

Life span simply denotes the sequence of activities across the whole of life from birth to death. In contrast, the developmental life cycle denotes changes that meet three conditions:

- A sequence of changes over the life span that are undergone as people master progressively more complex life functions
- Changes over time through segments of the life span, called life stages, that are characterized by distinctly different activities and expectations
- Stages of change that replicate the progressive mastery experienced by preceding generations

An essential idea in development is the life stage, an age-graded segment of the life cycle that is demarcated by changes in the physical body, in social expectations, and (consequently) in the psychological activity responding to these changes. Each life stage includes a set of developmental tasks that must be mastered, or normative problems that must be solved, within an age range as expected by the culture and, therefore, must follow the culturally imposed timetable. These tasks can be carried out well or poorly. Mastery of tasks within an early stage is essential to mastering other tasks within that stage and as a precursor to mastering tasks within later stages.

Failure to resolve tasks from an earlier stage often is experienced as unfinished business and is likely to produce recurrent problems later in life, sometimes called delays in development. Developmental counselors often encounter young adult clients who are experiencing developmental problems because they did not master the tasks during childhood and adolescence.

In contrast to developmental tasks are developmental marker events that occur at various ages/stages and that require the person to make adaptations in activities and roles. Such events often result from circumstances beyond the person's control (e.g., illness, death of a loved one, accident, job loss, military conscription, natural disaster). Other marker events are likely to be anticipated (e.g., marriage, childbirth, job changes, retirement).

Developmental life structure denotes the contemporary pattern or configuration of activities organized to fulfill culturally valued functions and to achieve age-appropriate developmental tasks. Activity patterns are often distinguished as social roles (e.g., friend, student, jobholder, citizen), each of which represents aggregate responses to cultural expectations and developmental tasks. The multiple social roles that one person plays often introduce problems such as conflicting demands from two or more roles. For example, a worker may be expected to meet production goals that require time and energy usually devoted to family. As people age and developmental tasks change, the activity that is considered appropriate for the age and role also changes; therefore, life structures are reorganized into new activity patterns. For example, when high school or college graduates move to different communities, start new jobs, and start families, their activity patterns become reorganized. The transition from one life structure to another presents a person with an opportunity to address new developmental tasks and problems.

3. COLLABORATIVE RELATIONSHIPS

The developmental counselor and client develop a working relationship, sometimes called a working alliance, that represents a collaboration between two perspectives on the client's experiences, the client's internal subjective perspective, and the counselor's external "objective" perspective. The collaboration recognizes that the counselor is influenced by the client and also exercises influence on the client; the client tends to talk and act in the manner in which the counselor

listens and responds. Their shared goal is to accelerate movement toward achieving mastery of developmental changes (e.g., expanding action possibilities within the current structures, reorganizing structures). Co-constructing a developmental goal is often a first step in the developmental counseling process. Developmental counseling goals emphasize constructing and not repairing, working toward new client successes in mastering life functions and not recovering the functions—or, in short, promoting healthy development rather than treating psychopathology.

4. GUIDING PRINCIPLES FOR DEVELOPMENTAL COUNSELING PROCESSES

Three principles guide the counseling processes selected by developmental counselors. A paramount principle is that counselors adapt their processes to fit clients' current developmental stages and structures. For example, developmental counselors who work with children will adapt their manner of communication as well as the content of their language to fit the children's cognitive developmental levels. Because people under extreme stress often regress to forms of communication appropriate for earlier stages (e.g., they cry or scream like children), counselors must be careful to initiate responses that are appropriate matches regardless of clients' chronological ages or current social standing.

Such counselor adaptation is sometimes called the "problem of the match" in developmental counseling or instruction. The principle was probably derived from education (rather than from psychology or medicine), where the phrase "developmentally appropriate practice" is frequently invoked to describe instructor selection of learning climates and pedagogical methods that match the students' cognitive developmental level. Some counselors are very specific in matching cognitive developmental structures (e.g., assessing for client Piagetian stages), whereas others match on the broad dimension of conceptual complexity. Developmental counselors believe that their effectiveness is linked to their ability to adapt counseling processes to match their clients' developmental levels.

A second principle guiding developmental counseling processes is that counselors' stances toward their clients cycle between support and challenge. Counselors begin by supporting their clients' full expression of problem-filled stories. Then, counselors

challenge—without confronting—their clients to move toward actions that promote developmental growth. Later, counselors support their clients' efforts to think or act in new ways that will contribute to growth. Some developmental counselors attempt to challenge their clients at "one-half step" beyond the clients' current positions on a theoretical developmental continuum. The rationale is, in part, to present the next steps in solving the developmental problem as a way in which to encourage client changes.

Third, most developmental counselors adhere to a principle captured by the following phrase: "the symbiotic nature of appraisal and intervention." The principle holds that both processes are ongoing within the counseling process and that each contributes to and profits from the other. For example, appraisal data are the material for counselor or client interpretive interventions, and client responses to interpretations become data integrated into client portraits constructed from appraisal data.

5. APPRAISAL IN DEVELOPMENTAL COUNSELING

Appraisal in developmental counseling is the conjoint collecting and synthesizing of data about the client's life structure and life cycle. The data are used to construct a descriptive portrait of the client's development and current problems. The assumption is that current developmental problems are best understood when the person's contemporary activity patterns and the sequence of past events are fully examined. Appraisal of a client's life structure involves identifying patterns or configurations of contemporary roles, relationships, and/or activities. For example, adult clients are usually asked to describe the work, family, and community roles that they play, whereas young clients are often asked to describe their family roles and family compositions, sometimes in the form of a family tree. Specifically, the client and counselor review the life structure for incidents of both the support and stressors.

Life cycle appraisal involves describing the sequence of events that the client deems to be critical in his or her development. In addition, the developmental counselor inquires about how the client has experienced developmental tasks within past and current life stages. Life cycle appraisal processes may involve, for example, a life history questionnaire or a life review interview. The client's history is assumed to affect current experiencing.

Therefore, developmental counseling appraisal techniques emphasize the person's assets and coping strategies as well as his or her limitations and barriers.

When making an appraisal, the developmental counselor gives careful attention to the context or surroundings of the client's activity. This attention often yields important observations about person-environment interactions that are critical to understanding the client's development. Questions about social and physical surroundings are frequently included in early discussions with the client. Parents, teachers, and/or friends may also be consulted for independent observations of the client's surroundings. Attention is paid to the hierarchical organization of social systems, especially the differential exercise of authority and power, and to the horizontal structure for opportunities for peer relationships. Specifically, the contextual barriers to action and opportunities for actions are identified.

6. DEVELOPMENTAL COUNSELING INTERVENTIONS FOR RESOLVING CURRENT DEVELOPMENTAL PROBLEMS

Interventions are counselor-initiated events that literally "go between" events sequenced along the life span, that is, between the client's current problem-saturated activity and his or her future growth or movement toward resolving problems and addressing new developmental tasks. Developmental interventions usually focus on the client's cognitions or behaviors and use techniques similar to other counseling approaches such as interpretations, teaching, and role-playing.

The developmental counselor frequently constructs interpretations and invites the client to construct interpretations that stimulate new client insights. These interpretations emphasize explanations derived inductively from descriptions rather than derived deductively from classification systems. The developmental counselor may also teach the client a new action sequence that is derived from the counselor's knowledge about the action sequences, called developmental pathways, which are common to people who have mastered a developmental task. Role-playing is another example of how the counselor teaches the client a new pattern of activity. The counselor demonstrates the activity, and the client imitates it, practices it, rehearses it, and finally implements it under real-life conditions. The developmental counselor also encourages the client to engage in

self-directed activities (e.g., self-help books, computer-assisted programs) or to take advantage of learning opportunities outside the counseling sessions.

7. DEVELOPMENTAL COUNSELING INTERVENTIONS FOR PREVENTING OR REDUCING DEVELOPMENTAL PROBLEMS

The developmental counselor often engages in interventions to prevent people's problems either from becoming acute or from expanding to interfere with more life functions. Primary prevention occurs when the counselor engages in educating groups of people who are addressing a common developmental task. For example, the counselor may instruct groups of people who are preparing for retirement or, in developmental terms, are preparing to cope with the task of assigning meaning to their lifetimes of productive activity. The instructional goal is to reduce acute problems associated with the loss of work. By learning coping strategies and constructing action plans, these people may avoid persistent regrets or sadness about retiring.

Secondary prevention occurs when the developmental counselor works with a small group of people selected because the members have a common developmental problem. The goal is to prevent the spread or further complication of problematic actions or situations. For example, the developmental counselor may work with young adults who have few friends and are considered to be "shy" in an effort to enrich their current friendships and possibly increase the number of friends or acquaintances, thereby forestalling more serious relationship problems.

GLOSSARY

- axis** A reference line in a coordinate system.
- category** Each division in a system of classification.
- classification** Grouping of elements according to classes.
- code** Number for identification of disorders.
- mental disorder** A clinically behavioral or psychological syndrome associated with stress or disability or with increased risk of suffering death, pain, or an important loss of freedom.
- syndrome** A group of associated disease symptoms.

The *Diagnostic and Statistical Manual of Mental Disorders* (DSM) classification system for mental disorders, developed by the American Psychiatric Association and now employed worldwide, has its historical roots in previous systems dating back over several centuries, from the Greek Hippocrates in the fourth-century BC to the nineteenth-century German psychiatrist Emil

Kraepelin. This article traces the development of the DSM, describing successive changes and improvements over the course of its six editions, as well as its relationship with the other main system, the European-based *International Classification of Diseases*.

1. ANTECEDENTS

Classification is both the process and the result of arranging individuals into groups formed on the basis of common characteristics. It is important in any science, but it is usually a difficult task that raises a variety of problems for experts to deal with, including mixture (heterogeneity or homogeneity of a group), discrimination (between-group differences), and identification (assignment of an individual to a group).

Historically, the first attempt to put the variety of psychological disorders into some kind of order was made by the Greek physician Hippocrates (4th century BC); he coined the terms *phrenesis*, *mania*, and *melancholia*, which were maintained by Galen in Rome (1st century AD). Much later, during the Renaissance, Barrough (1583) divided mental disorders into mania, melancholia, and dementia. The work was continued in Europe by the German philosopher Immanuel Kant in his *Anthropologie* and by the Frenchman F. Pinel in his *Nosologie Philosophique* (1789), which divided mental

disorders into mania with and without delirium, melancholia, dementia, and idiocy. The Swede, K. Linnaeus, better known for his classifications of plants and animals, also extended his work to the field of the human mind, employing such categories as *Ideales* (delirium, amentia, mania, melancholia, and vesania), *Imaginnarii* (hypochondria, phobia, somnambulism, and vertigo), and *Patheci* (bulimia polydipsia, satyriasis, and erotomania).

At the end of the 19th century, the German, Emil Kraepelin—often considered the founder of modern scientific psychiatry—in his *Lehrbuch der Psychiatrie* [*Handbook of Psychiatry*] (1899) included a highly influential classification. He aimed to identify groups of patients through symptom clusters that would define different syndromes, and he attributed disorders to four organic roots: heredity, metabolic, endocrine, and brain disease. His categorization laid the bases for systems such as the first official American Psychiatric Association (APA) classification, which included mental disorders by brain traumatism, mental disorders by encephalopathy, mental disorders by drugs, mental disorders by infectious agents, syphilis, arteriosclerosis, epilepsy, schizophrenia, manic-depressive psychosis, psychopathy, psychic reaction, paranoia, oligophrenia, and other cases.

In the 1960s, neo-Kraepelinian psychiatrists called for improvements to the old classification, and men such as Spitzer, Endicott, and Feighner began to prepare the construction of a new American psychiatric classification.

Although the roots of modern American classification are in Europe, the first official classification was a census of mental disorders drawn up in the United States in 1840, with just two categories: idiocy and madness. Another important antecedent of the *Diagnostic and Statistical Manual of Mental Disorders* (DSM) was the work of the Committee on Statistics of the American Psychiatric Association (1917), led by Dr. T. Salmon, which recorded mental disease statistics from the psychiatric services of hospitals. Its result was the *Statistical Manual for the Use of Hospitals for Mental Disease*. A few years later, the New York Academy of Medicine organized the National Conference on Disease Nomenclature (1928) to unify the terminology and nosology used by practitioners; its *Standard Classified Nomenclature of Diseases* (1932; rev. ed., 1934) originally referred only to physical diseases, but a section on Diseases of the Psychobiological Unit was included later, and the 1951 edition was published for use in mental hospitals. All of these classifications owed a debt to Kraepelin's system.

World War II brought so many diagnostic problems to military psychiatrists that they urged the construction of a *Classification of Mental Problems*. The psychological nomenclature was introduced in 1944 by the Navy and a year later by the Army. However, the existing *Standard Nomenclature* (1932) proved inadequate for many situations, and the Armed Forces asked for a revision of the three systems in use. The result was the creation of the DSMs.

In Europe, a parallel movement, that of mental hygiene, held its first meeting in Paris in 1932. A European classification would unify psychiatric nomenclature, with the following categories: congenital mental disorders, endogenous psychosis, reaction psychosis, symptomatic psychosis, encephalopathies, epilepsy, toxicomania, and non-alienated mental disorders. However, this proposal was not well accepted by the mental health community.

Today, the two most well-known categorical classifications of mental disorders are the *International Classification of Diseases* (ICD) and the DSM. The ICD, created in Europe, has been promoted by the World Health Organization (WHO) since 1900, but its original version included only physical diseases; the DSM, published by the APA since 1952, has always focused on mental disorders. The two classifications attempt to deal with the same behaviors and coincide to a large extent, but there are some important differences.

The first ICD versions included only physical disorders (Table 1), but the ICD-6 (1948) saw the incorporation of mental diseases, bringing it closer to the DSM-I. The ICD-8 (1967) and DSM-II (1968) also coincided in many aspects, but the APA's decision to develop the DSM-III generated new tensions. Much of this divergence was resolved through better communication, and the DSM-IV and ICD-10 reestablished the close relationship between the WHO and the APA.

2. DSM-I (1952)

The DSM was first published in 1952 (DSM-I). Influenced by its European antecedents, and by the views of A. Meyer (a biologically oriented psychiatrist) and K. Menninger (who was psychoanalytically oriented), it took into account not only biological but also social and psychological elements, and it offered a multidimensional consideration of disorders. The process of developing the manual involved the collaboration of the National Institute of Mental Health and different psychiatrists and military professionals.

TABLE I
Relationship over Time between the DSM and the ICD

Year	DSM (APA), United States	ICD (WHO), Europe
1900		ICD-1 ^a
1910		ICD-2 ^a
1920		ICD-3 ^a
1929		ICD-4 ^a
1938		ICD-5 ^a
1948		ICD-6
1952	DSM-I	
1955		ICD-7
1966		
1967		ICD-8
1968	DSM-II	
1975		ICD-9
1978		ICD-9-CM
1980	DSM-III	
1987	DSM-III-R	
1992		ICD-10
1994	DSM-IV	
1996		ICD-10 Children
1998	DSM-IV-R	
2000	DSM-IV-TR	

^aICD with only physical diseases.

Its impact was quite limited. Smith and Fonda, in a study using the *DSM-I* criteria, found interrater agreement to be high for organic psychosis, melancholia, and schizophrenia but quite low in many other categories.

Other studies were also critical. For example, the omission of criteria was criticized by H. J. Eysenck and R. B. Cattell; in their view, common nomenclature in itself would not improve clinical diagnosis, as clinicians would understand different things from the same labels. Furthermore, P. E. Meehl questioned the reliability of clinical judgment, whereas L. Cronbach and Meehl drew attention to the urgent need for accuracy in diagnostic identification.

With the publication of the *ICD-7*, some of the differences between the WHO and APA classifications were highlighted. The *DSM-I* categories were also adopted for a computer program designed for assessment tasks (DIAGNO), but this presented some problems of application. The need to improve the system was evident, and it was Endicott, Guze, Klein, Robins, and Winokur who assumed the task of reviewing and improving the manual.

3. DSM-II (1968)

This was published as the *American National Glossary* to the *ICD-8*. An APA committee, with the help of some experts, carried out an in-depth revision of its first version. Meyer's previous influence was drastically reduced, whereas more room was given to psychoanalytical and Kraepelinian ideas in order to improve its acceptance by clinicians. It was based on the medical illness model of different syndromes made up of clinical symptom clusters.

Many unsuccessful attempts were made to coordinate the *DSM* and *ICD* systems, but the differences eventually increased, both in diagnoses and in terminology. For instance, the *DSM-II* had 39 more diagnoses than the *ICD-8 10/3*, and regarding terminology, terms associated with certain theoretical frameworks (such as "schizophrenic reaction" for schizophrenia) were avoided but others, such as "neuroses" or "psychophysiological disorders," remained.

The *DSM-II* has frequently been referred to as "old wine in a new bottle" since the influences of Meyer and Kraepelin were still present but many of the new research perspectives were absent. One year after its publication, Jackson described it as "a hotchpotch of different bases of classification." However, studies on schizophrenia diagnosis in various countries greatly stimulated the task of revision, and efforts were redoubled to clarify basic diagnostic criteria, paving the way for the construction of the *DSM-III*.

4. DSM-III (1980)

Criticism of the previous editions had noted the lack of an organizing criterion and the overlapping of categories. Efforts to improve the instrument culminated in the publication of the *DSM-III*.

A task force chaired by R. Spitzer, with international cooperation and the participation of N. Andreasen, J. Endicott, D. F. Klein, M. Kramer, Th. Millon, H. Pinsky, G. Saslow, and R. Woodruff, prepared the work. New members were added subsequently, and a draft was prepared at the important St. Louis conference in 1976. Collaborators were recruited from many institutions, including the Academy of Psychiatry and the Law, the American Academy of Child Psychiatry, the American Academy of Psychoanalysis, the American Association of Chairmen of Departments of Psychiatry, the American College Health Association, the American

Orthopsychiatry Association, and the American Psychological Association. Misunderstandings arose between the American Psychological Association and the American Psychoanalytical Association, but all were eventually solved.

The goals of these teams were (i) to expand the classification, maximizing its utility for the outpatient population; (ii) to differentiate levels of severity and cause within syndromes; (iii) to maintain compatibility with the *ICD-9*; (iv) to establish diagnostic criteria on empirical bases; and (v) to evaluate concerns and criticisms submitted by professional and patient representatives. Subsequently (1977–1979), drafts were sent to experts and practitioners for study and suggestions before the definitive modifications were made. The major characteristics of the *DSM-III* are (i) operational or explicit criteria for assigning patients to diagnostic categories and (ii) the implementation of a multiaxial framework.

4.1. Explicit Diagnostic Operational Criteria

Diagnostic criteria make explicit the signs and symptoms required for a diagnosis on the basis of empirically validated rules, and they are not only descriptive but also phenomenological and behavioral. They would permit greater effectiveness and reliability in diagnoses. Also included for each disorder was its description, the usual age at which it begins, mean duration, prognosis, rates by sex, and risk factors. Criteria for Axes I and II are basically the same as the Feighner Criteria, based only on disorder definitions, as in the *DSM-I* and *DSM-II*.

Such criteria were used when creating the *Research Diagnostic Criteria*, which included 23 disorders (schizophrenia, schizoaffective disorder–manic, schizoaffective disorder–depressed, depressive syndrome superimposed on residual schizophrenia, manic disorder, hypomanic disorder, bipolar with mania, bipolar with hypomania, major depressive disorder, minor depressive disorder, intermittent depressive disorder, panic disorder, generalized anxiety disorder, cyclothymic personality, labile personality, Briquet's disorder, antisocial personality, alcoholism, drug-use disorder, obsessive–compulsive disorder, phobic disorder, unspecified functional psychosis, and other psychiatric disorders).

An operative description of clinical disorders was included, employed in Axes I and II of the *DSM-III* to differentiate between syndromes. Unlike those of the

biological classifications, *DSM-III* criteria are polythetic (patients do not need to have all the characteristics in order to be included in a category) and intentional (patient's characteristics are listed).

4.2. Inclusion of Five Diagnostic Axes

A new feature in the *DSM-III* was the inclusion of five diagnostic axes in order to obtain greater sensitivity and accuracy in diagnoses and treatments and permit the consideration of psychosocial aspects. The idea of such axes was introduced by Essen, Möller, and Wohlfahrt (in Sweden in 1947). They proposed separating the syndromes from all etiological conceptions, creating two principal axes (“phenomenological” and “etiological”) plus three others (“temporality,” “social functioning,” and “others”). In 1969, Rutter *et al.* in the United Kingdom constructed a multiaxial classification system for children (with axes for clinical syndromes, delay of development, mental retardation, medical condition, and psychosocial situation), and other multiaxial systems were proposed in the United Kingdom by Wing in 1970, in Germany by Helmchen in 1975, and in the United States by Strauss. Apart from the *DSM-III*, the multiaxial formula was applied to the *ICD* in 1992.

Axes were assigned as follows: Axis I to clinical syndromes; Axis II (with two sections) to child maturational problems and adult personality disorders; Axis III to physically rooted problems; Axis IV to the intensity and severity of psychological stressors; and Axis V to the patient's level of adaptive functioning in the past year, objectively evaluated. Axes II, IV, and V link the syndromes with environmental determinants and reflect a shift toward more psychological conceptions.

DSM-III constitutes an authentic work of description on psychopathology (including differential diagnosis, etiology, treatment, prognosis, and management). The *DSM-III*, although atheoretical in principle, maintained a biological interpretation of the field. Although praised for its achievements, it was also criticized for including inessential characteristics of disorders and for employing too many diagnostic categories (265); psychoanalysts also criticized the lack of an axis that took into account defense mechanisms and ego functions, and they complained that the replacement of the term neuroses by anxiety disorders situated them at a greater distance.

In sum, the *DSM-III* represents a key stage in the evolution of the *DSM* classification. This change was both quantitative (from 104 syndromes to 395, and

from 132 pages to 500) and qualitative. Since 1980, with the adoption of the axes system, the corpus of categories has remained practically constant. Moreover, *DSM-III* made important progress in relation to aspects such as reliability, intracategory coherence and differentiation, validity, and behavioral data. It also favored the construction of new assessment instruments based on its criteria (self-rating questionnaires, semistructured interviews, and so on). Despite all these innovations and improvements, further revision was necessary, and this arrived in the form of the *DSM-III-R*.

5. DSM-III-R (1987)

This appeared in 1987 as the final result of revisions carried out by a work group headed by Spitzer. Innovations included the reorganization of categories; some improvements in Axes IV (on psychosocial stress) and V [inclusion of the Global Assessment of Relational Functioning (GARF) scale]; and the incorporation of aspects related to drug abuse, homosexuality (now included in unspecified sexual disorders), and hyperactivity. Classification of affective disorders was reorganized. This version had a dramatic impact worldwide and became more commonly used than the *ICD*, even in Europe.

6. DSM-IV (1994)

A task force led by Allen Frances working with experts and scientific groups from all over the world prepared this version. The goal was to improve its cultural sensitivity and to improve compatibility with the *ICD*.

Features of the new instrument included (i) brevity of criteria set, (ii) clarity of language, (iii) explicit statements of its constructs, (iv) it was based on up-to-date empirical data, and (v) better coordination with the *ICD-10*. The *DSM-IV* also presented a series of changes with respect to its predecessor. Categories such as organic mental disorders disappeared, whereas others such as eating disorders, delirium, dementia, and amnesic and other cognitive disorders, and some severe developmental disorders (Rett's syndrome and Asperger's syndrome), were incorporated; the categories of child and sexual disorders were restructured.

In the multiaxial system, the changes occurred in Axis IV, which includes more stress-generating events, and Axis V, in which other scales were added for determining level of adaptation—the Social and

Occupational Functioning Assessment Scale and the GARF scale.

Criticism of the *DSM-IV* has not been lacking, especially with regard to its focus on consensus more than on data. However (and despite claims that there would never be a *DSM-V*), remodeling of the *DSM-IV* is currently in progress.

7. CATEGORICAL DEVELOPMENT OF THE DSM

7.1. Important Changes

Over time, the *DSM* categories have undergone significant changes. Whereas in 1952 there were two main categories, in 2000 there were 17. This increasing complexity is even more evident in the case of subcategories (Table II).

Each diagnostic category is identified by a numerical code. The current *DSM* codes the different disorders with its own code and also with that of the *ICD*, making it possible to compare and contrast diagnoses made with these two different categorical systems, thus facilitating communication between them.

7.2. Critical Positions

The *DSM* classification system has attracted criticism from various theoretical points of view. Those from the antipsychiatry current have always been against the use of classifications in psychiatry since they consider labeling a dangerous procedure. Another notable critic was Eysenck, who spoke of the fundamental weakness of any scheme “based on democratic voting procedures rather than on scientific evidence.”

Further criticisms of the *DSM* refer to (i) the cultural biases of all classification systems; (ii) its extreme individualism—only individual diagnosis is taken into account; (iii) the influence on it of old-fashioned medical classifications, despite modern developments in psychology and psychiatry; and (iv) the “softness” of the categories, which are based more on description than explanation, despite the crucial importance of the latter.

However, despite such criticisms, categorical classifications have made possible comparisons and inferences that have helped to advance clinical knowledge. They may have their imperfections, but they have made an enormous contribution to diagnostic reliability and to understanding among mental health professionals. They have also helped to promote the creation of more

race A social construct that attempts to divide human groups based on physical characteristics.

racism A belief that people can be validly grouped on the basis of biological traits and that some groups have superior traits, whereas others have inferior ones.

structural assimilation A process that occurs when one group can access and experience full participation within majority group organizations such as country clubs and private clubs.

GLOSSARY

cultural assimilation A process that occurs when one group assumes the values, behaviors, and beliefs of another group, often the majority culture.

culture The beliefs, values, traditions, behavior patterns, and social and political relationships that are shared by a group of people who are bound together by things such as common history, language, social class, and religion.

discrimination Often based on prejudice, a process consisting of differential treatment directed toward certain groups.

ethnicity An individual's sense of identification that provides him or her with a sense of belonging to a group.

power An important concept when entering into a discussion about diversity given that the struggle for power, and the dominant group having power, has played an integral part in the continued oppression of marginalized groups.

prejudice Attitudes and beliefs toward a particular group that are often negative and formed in disregard of the facts.

Working with culturally different children and families requires psychologists to have an understanding of cultural differences and, in the best of circumstances, to become cross-culturally competent.

1. INTRODUCTION

It is fairly well known that there has been a dramatic demographic shift in the United States population during the past decade or so. Based on the 2000 census, people of color make up approximately 29% of the U.S. population. By the year 2050, they are expected to account for 47% of the U.S. population. The demographic changes have major implications for many institutions, including schools and the workforce. The change in the ethnic composition of the population is viewed as both an opportunity and a challenge. There is the opportunity

to enrich society with multiple and diverse cultural elements. The challenge is to find effective ways in which to incorporate and respect the multiple diversities that exist while at the same time recognizing that there is an American culture. Historically, White ethnic groups have been “forced” to abandon their cultures and blend into the American culture. Ethnic minorities, on the other hand, have not been so successful. The reason why has not been for lack of trying; rather, they have not fared as well due to the racism and prejudice that exists in the United States. Ethnic minorities are often received and treated as marginalized groups. As marginalized groups, they have not always had full access to the “American dream.” Although the civil rights movement and subsequent civil rights laws in the United States improved opportunities in education and employment for many ethnic minorities and women, people continue to be marginalized and discriminated against.

While many ethnic minorities have been successful in culturally assimilating, they still struggle to experience full structural assimilation in the United States. There has been a growing acceptance and recognition that, as a society, there has not been an appreciation of the rich diversity that exists; instead, there has been an attitude that one must fit in or assimilate to be successful. Exploring how variables such as class, race, ethnicity, and gender interact and intersect to influence behavior has been critical to researchers understanding life in America for marginalized groups. The United States is a pluralistic nation made up of many different ethnic groups whose members desire to retain their cultural identities. Understanding these different cultural identities is beneficial in working effectively with diverse populations. Identity development research has contributed to this knowledge base.

2. RACIAL AND ETHNIC IDENTITY

Identity is complex and influenced by a number of factors. Erickson was instrumental in helping people to understand that individual identity is embedded in social, cultural, and historical contexts. Race and ethnic identity adds to this complexity. The development of racial and ethnic identity for people of color often begins to occur during late adolescence. It is generally this period of time when adolescents start to explore the questions of “Who am I?” and “Who will I become?” Searching for racial and ethnic identity can be a lifelong journey. A focus on certain aspects of people’s identities may vary at different times in their lives, depending on

the circumstances. For example, high school is a time when most adolescents begin to start to develop their identities separate from their families as they self-reflect on who they are. Individuals are faced with attempting to integrate these different components of identity to form who they are. Many aspects of society influence how people view themselves and, consequently, how they develop their identities.

Cross and Helms have researched Black identity and White identity, respectively. They have demonstrated that racial and ethnic identity develops in stages. Most important, these stages are fluid, with people moving back and forth between stages. It should also be noted that not all people move through these stages. Black adolescents and other adolescents of color tend to begin to develop racial identities earlier than do White adolescents because their self-perceptions can be influenced by how society views them. The aspect of people’s identity that others notice and make them most aware of is one that can potentially loom large in their lives. Thus, adolescents of color are subjected to questions and stereotypes about their race and/or ethnicity more often than are White adolescents. Even though some adolescents begin to explore their racial and ethnic identities, research has shown that the movement through the stages most often occurs during late adolescence and early adulthood. For Whites, identity development involves the abandonment of entitlement or White privilege. The key challenge for people of color is the development of a positive identity. Research continues on the development of racial and ethnic identity.

3. UNDERSTANDING CULTURE AS A CONTINUUM

When working with culturally diverse children and families, it is important to understand that culture occurs on a continuum and is influenced by the process of dual socialization, which is the process by which individuals learn how to function in two distinct socio-cultural environments. Most ethnic minorities in the United States are able to function in their own cultures but also learn how to navigate the waters of the majority culture. Individuals who navigate these two different cultures successfully are said to be bicultural. This concept is important and is related to assimilation. In the United States, the dominant group controls most of the social, economic, and political institutions. Thus, the dominant group determines these institutions’

norms, values, and beliefs, which are often referred to as culture capital. Having knowledge of culture capital allows easier movement through mainstream culture. Members of ethnic minority groups often must acquire the necessary cultural traits of the majority group to move up the social and economic ladders. It is often necessary for working-class people and people of color to learn the cultural norms, or to be told explicitly the rules of the culture of the dominant group, for them to acquire power.

However, when working with culturally different people, it is important to remember that individuals will vary along the cultural continuum. Individuals may choose to remain isolated from the mainstream, on one end of the continuum, or choose to relate to both cultures, never quite integrating them into one. Many ethnic minorities find themselves straddling two cultures. The challenge for these individuals is to develop strong self-concepts and positive self-esteem without compromising who they are. Understanding issues of identity and cultural continuum provides a better understanding of culturally different people. Thus, with the acknowledgment that diversity exists, a body of knowledge that encourages people to learn to respect, value, and understand diverse groups has evolved. This has occurred primarily through educational channels such as ensuring that disciplines require a diversity course for graduation and the development of multicultural competencies.

4. CROSS-CULTURAL COMPETENCE

As with so many disciplines, the demographics of education and psychology do not match those of the U.S. population. In psychology and education literature, there is increasing emphasis placed on training individuals to become cross-culturally competent. Cross-cultural competence means that individuals possess attitudes, abilities, and understandings that allow them to function not only in American culture but also within and across various ethnic, cultural, and linguistic groups. Three common elements of cross-cultural competence are personal awareness, knowledge, and skills. Although different disciplines may advocate diverse ways of attaining cross-cultural competence, these three elements appear to be universal aspects of that process. In education and psychology, having cross-culturally competent individuals is seen as critical to being able to deliver services that are sensitive and effective in meeting the needs of culturally different individuals. Developing cross-cultural competence is a

process. It is generally recognized that becoming cross-culturally competent will not occur by simply studying groups of people. It is necessary to have personal experiences with culturally different groups as well.

Self-awareness consists of individuals engaging in self-exploration that requires them to examine their own culture and socialization process that influences how they view and interact with majority and minority people. Understanding their own culture and its influence on their socialization is the first step in awareness. To understand another culture, individuals must first explore their own culture and its impact on their development. This often requires them to become aware of their biases and prejudices. Knowledge is the second component of cross-cultural competence. This is usually accomplished by studying the concept of diversity as well as racial and ethnic groups. This can be accomplished in a number of different ways, including reading books, talking with individuals from the cultural groups, and interacting with culturally different people. Skills are the final component. Skills involve the ability to work effectively with culturally diverse populations, understanding the influence that issues of diversity may have on people as well as one's ability to interact effectively with them.

Cross-cultural competence also means that individuals are aware of their own cultural limitations. Learning about other cultures requires them to take risks and have a willingness to be open, appreciative, and respectful of cultural differences. Intercultural interactions should be viewed as learning opportunities, recognizing that there is integrity and value in every culture one encounters.

5. CROSS-CULTURAL COMMUNICATION

One of the most difficult tasks that people face is communicating across differences. There is always the fear that what people intend to say will not be interpreted the way in which they meant it to be interpreted. It is generally recognized that there are high-context cultures and low-context cultures, and there are differences in how individuals from these cultures engage in communication. High-context cultures tend to communicate with fewer words and less emphasis placed on verbal interactions. As a result, individuals from these cultures are better at reading nonverbal cues. Situational and nonverbal cues convey primary meaning. For example, it is not unusual to hear an African American say, "All

my mother needed to give us was that “look.” She didn’t have to say anything. We knew we were in trouble.” Individuals from high-context cultures also place a great deal of emphasis on establishing trust first. Thus, before revealing personal information, individuals from these cultures will want to first establish a relationship. Examples of high-context cultures include Asians, Native Americans, Arabs, Latinos, and African Americans. Low-context cultures, in contrast, tend to exhibit precise and direct verbal communication. They often do not notice, or are not attuned to, nonverbal communication. Meaning in low-context cultures is conveyed primarily through written and spoken words. Communication is often linear. Individuals from these cultures become particularly frustrated with high-context cultures that communicate in a circular fashion. Content of communication in low-context cultures can be best described as “cutting to the chase.” Examples of low-context cultures include European Americans, Swiss, and Germans.

Cultures also differ in other aspects of communication, including proximity and touching. Groups differ in the amount of social distance they tolerate in social situations. For example, European Americans tend to keep a distance of 3 feet when talking to people with whom they are unfamiliar. Latinos and African Americans tend to feel comfortable with less social distance between themselves and others. Touching also varies greatly between groups. For example, handshaking takes on different meanings across cultures. Americans use handshaking as an introduction, whereas other cultures may be reluctant to engage in handshaking.

It is important to recognize that communication can be culturally loaded. Understanding communication differences across cultures and learning to adjust one’s communication style to minimize misinterpretation is the key. Effective cross-cultural communication consists of individuals being willing to learn and understand cultural differences.

6. DIVERSITY IN EDUCATION

Schools are reflective of the larger society in its diversity. The changing face of society and schools was predicted as early as the 1980s. Much of the past 20 years has focused on how to best serve an increasingly diverse population in the schools. An increasing achievement gap between White students and students of color continues to be problematic. Overrepresentation of certain ethnic minority groups in special education categories

continues despite efforts to remedy the situation with a requirement for nondiscriminatory assessment as part of a multifaceted evaluation for special education placement. Overrepresentation of African American males for suspensions and expulsions has been well documented. Students of color are overwhelmingly tracked in lower level classes, are underrepresented in gifted and talented classes, have lower expectations placed on them by educational personnel, and have access to fewer resources than do their more affluent peers. Finally, the limited English-proficient (LEP) population is increasing. All of these issues, as well as others, make it imperative that clinicians have a solid understanding of issues of diversity and their influence and impact in educational settings.

Having cross-culturally competent personnel in education is a must. Understanding the lives of children and their families enables the provision of services that will make positive changes in their academic and personal lives. It is well known that involved parents are important to children’s education. Unfortunately, parents from lower socioeconomic status and minorities have a lower level of contact with the educational systems. The challenge for professionals is to find opportunities to bridge the cultural gap between themselves and parents. Lack of contact does not equate with lack of interest. Epstein has engaged in considerable research that has been informative regarding best practice in how to work with parents. Like other areas of diversity, issues around the distribution of power, resources, and knowledge may prohibit meaningful engagement of parents in the schools. Understanding the influence of the parents’ experiences with schooling may also help to explain their reluctance to become involved. This is especially important with immigrant children whose parents’ ideas of involvement may mirror what they experienced in their native lands and may be inconsistent with beliefs in the United States. In addition, a large percentage of parents in the inner city are young parents who never finished school, or were unsuccessful in school, and who view schools as negative places. These parents often did not have good role models for participation and may be struggling to understand the need for parent involvement in their children’s schooling.

Finding effective ways in which to connect with parents and help them to become full partners in their children’s education and mental health development can be far-reaching. To do that, psychologists need to understand the social and cultural differences that may exist between the home and the school. This understanding alone could prevent miscommunication

between parents and the school. One goal should be to establish two-way communication between the school and families. It could be quite enlightening to know parents' perceptions of the school and how they believe they are (or are not) welcomed. Clinicians are often trained to "cut to the chase" and attack the "problem" when, in fact, what may be most important is to build rapport and the relationship with parents. Instead of telling parents what they should be doing, clinicians could instead ask them, "How can we assist you?" Parents who feel truly invited into the school, have a sense of self-efficacy, and perceive that they play a critical role in their children's educations are more likely to be involved in their children's schooling. It is important to acknowledge parents as important contributors to the lives of their children.

As clinicians seek to close the achievement gap between Whites and ethnic minorities and to improve the overall educational experience, they must also understand and acknowledge conditions that may be barriers to learning. Poverty is one such variable that has far-reaching implications. Children in poverty (of which ethnic minorities are disproportionately represented) experience more problems with physical health, lower cognitive ability, poor school achievement, and the like. Despite the odds against these children being successful, there is evidence that many of these children actually do succeed. Research on resiliency identifies many factors, which are termed "protective," that enable children to beat the odds. It is important for clinicians to be familiar with this literature so that they are skilled at identifying and promoting those protective factors that are present in children's lives. Research has identified the following as protective factors: social skills (e.g., empathy, communication), problem-solving skills, a sense of control, a sense of purpose, caring relationships with adults, high expectations for doing well, and opportunities for meaningful participation in clubs, teams, and/or organizations. For many culturally diverse children and families who are also in poverty, having available resources that include human resources can make an incredible difference in their lives.

7. IMPLICATIONS FOR PRACTICE

Most disciplines acknowledge the importance of having their personnel become cross-culturally competent. Although nearly everyone in the United States shares the American culture at some level, there are many who

also have subcultures that are very much a part of their lives. Recognizing the similarities as well as the differences helps to bring clinicians one step closer to providing effective services to a culturally different population. Although it may seem like a daunting task, especially if clinicians are in an area with many different cultural groups, there are some ways in which clinicians can increase their skills in being effective psychologists with culturally different groups. First, they should be open to new ideas and experiences. Too often, clinicians look at the world through their own lenses. They should take time to learn about other groups and attempt to understand the world from their perspective. This does not mean that clinicians need to agree with them so long as they at least understand these other groups' perspectives. Second, clinicians should find a cultural mediator who can guide their understanding about the beliefs and practices of a particular culture with which they may be unfamiliar. This is often done through open discussions and interpersonal sharing. Clinicians should always remember that even though they do not represent everyone from that culture, members of that culture can provide them with some insight. Third, clinicians should see diversity as something to be celebrated rather than as something that is a deficit. Fourth, clinicians should view their learning experience as a journey. There is so much to know. They will not "get it" in one course. Instead, they will continually explore, learn, and explore some more. Fifth, clinicians should explore their own cultural or ethnic identities and examine their socialization with respect to majority and minority people. Until they can understand the impact of their culture and socialization on their attitudes, beliefs, and behaviors, clinicians cannot fully appreciate the cultures of others. Finally, clinicians should always remember to strive to engage in culturally responsive practices that will ultimately benefit clients in a positive way.

The United States is a pluralistic country that is rich in diversity. This is not a phenomenon but rather a reality. Understanding the cultural differences in this country, and how they may influence behavior and aspects of society, is critical. Clinicians should embrace diversity and view it as an opportunity rather than as a challenge.

GLOSSARY

burnout A gradual process of loss during which the mismatch between the needs of the person and the demands of the job grows ever greater.

distributive justice The fairness of the outcomes of decisions, for example, in the allocation of bonuses or merit pay or in making decisions about who goes and who stays in a layoff situation.

downsizing Planned changes in a firm's organizational structure that affect its use of people; in a broader sense, downsizing refers to reductions in a firm's use of assets (e.g., financial, physical, human, information), so when referring to reductions in the numbers of people in an organization, it is appropriate to use the term "employment downsizing."

knowledge-based organizations Collections of networks in which interrelationships among individuals (i.e., social networks) generate learning and knowledge.

organizational citizenship behaviors Discretionary behaviors performed outside of one's formal role that help other employees to perform their jobs or that show support for and conscientiousness toward the organization.

organizational decline An environmental or organizational phenomenon that occurs involuntarily and results in erosion of an organization's resource base.

organizational support The extent to which an organization values employees' general contributions and cares for their well-being.

outplacement As an extension of the termination process that typically includes two elements: (a) counseling employees who have lost their jobs for emotional stress resulting from the trauma of termination, and (b) assistance with job search.

procedural justice The fairness of the procedures used to make decisions; procedures are fair to the extent that they are consistent across persons and over time, free from bias, based on accurate information, correctable, and based on prevailing moral and ethical standards.

Employment downsizing is synonymous with layoffs, but it differs from organizational decline. Its extent and scope are global, and it is an ongoing feature of many organizations. Downsizing has led to a redefinition of the concept of loyalty and has led organizations to think in terms of 3- to 5-year relationships with employees. Evidence indicates that downsizing does not lead to better long-term performance of organizations, but that it may have negative effects on victims and survivors, particularly if they perceive procedural injustice in the process. Outplacement, which provides counseling for those who have lost jobs as well as assistance in job search, can help to speed the reemployment and readjustment process.

1. DOWNSIZING DEFINED

In everyday conversation, the term “downsizing” is often used as a synonym for “layoffs” of employees from their jobs. Downsizing is commonly the result of a broader process of organizational restructuring that refers to planned changes in a firm’s organizational structure that affect its use of people. Such restructuring often results in workforce reductions that may be accomplished through mechanisms such as attrition, early retirements, voluntary severance agreements, and layoffs. Layoffs are a form of downsizing, but it is important to note that downsizing is a broad term that may include any number of combinations of reductions in a firm’s use of assets—financial, physical, human, and information assets. Therefore, when referring to reductions in the numbers of people in an organization, it is appropriate to use the term “employment downsizing.”

1.1. Downsizing and Organizational Decline

Employment downsizing is not the same thing as organizational decline. Downsizing is an intentional, proactive management strategy, whereas decline is an environmental or organizational phenomenon that occurs involuntarily and results in erosion of an organization’s resource base. For example, the advent of digital photography, disposable cameras, and other imaging products signaled a steep decline in the demand for the kind of instant photographic cameras and films that Polaroid had pioneered during the 1940s. On October 12, 2001, Polaroid was forced to declare bankruptcy.

1.2. Extent and Scope of Employment Downsizing

According to the U.S. Department of Labor, approximately 2 million people have been affected by employment downsizing each year since 1996. In 2001, for example, companies announced nearly 1 million job cuts during the 3 months after the terrorist attacks of September 11. Many firms conduct multiple rounds of employment downsizing during the same year as ongoing staff reductions become etched into the corporate culture. On average, two-thirds of firms that lay off employees during a given year do so again the following year.

The phenomenon of layoffs is not limited to the United States. They occur often in Asia, Australia, and Europe as well. Japan’s chip and electronics

conglomerates shed tens of thousands of jobs during the first few years of the 21st century as the worldwide information technology slump and fierce competition from foreign rivals battered their bottom lines. In Mainland China, more than 25.5 million people were laid off from state-owned firms between 1998 and 2001. Another 20 million were expected to be laid off from traditional state-owned firms by 2006.

The incidence of layoffs varies among countries in Western Europe. Labor laws in countries such as Italy, France, Germany, and Spain make it difficult and expensive to dismiss workers. For example, in Germany, all “redundancies” must by law be negotiated in detail by a workers’ council, which is a compulsory part of any big German company and often has a say in which workers can be fired. Moreover, setting the terms of severance is tricky because the law is vague and German courts often award compensation if workers claim that they received inadequate settlements. In France, layoffs are rare. Even if companies offer generous severance settlements to French workers, as both Michelin and Marks & Spencer did, the very announcement of layoffs triggers a political firestorm.

2. MERGERS, ACQUISITIONS, AND THE DEMISE OF LOYALTY

Worldwide, tens of thousands of mergers and acquisitions take place each year among both large and small companies. In general, after a buyout, the merged company eliminates staff duplications and unprofitable divisions. Employment downsizing is part of that restructuring process. Such restructuring often leads to similar effects—diminished loyalty from employees. Following takeovers, mergers, acquisitions, and downsizings, thousands of workers have discovered that years of service mean little to struggling managers or a new corporate parent. This leads to a rise in stress and a decrease in satisfaction, commitment, intention to stay, and perceptions of an organization’s trustworthiness, honesty, and caring about its employees.

Companies counter that today’s competitive business environment makes it difficult to protect workers. Understandably, organizations are streamlining to become more competitive by cutting labor costs and to become more flexible in their response to the demands of the marketplace. But the rising disaffection of workers at all levels has profound implications for employers. Perhaps one of the most fundamental issues to consider

is the new meaning of loyalty. Today, workers and managers are less loyal to their organizations than ever before. As Reichheld has shown, U.S. companies on average now lose half of their employees in 4 years, half of their customers in 5 years, and half of their investors in fewer than 12 months.

So, what is the new meaning of loyalty? Employees at all levels are still loyal, but instead of being blindly loyal to their organizations, they are loyal to a vision or to a mission. They are loyal to mentors, protégés, or team members. As a result, more and more organizations are now thinking in terms of 3- to 5-year employment relationships. Some are even adopting a strategy long used in the sports world, that is, fixed contracts with options for renegotiation and extension.

3. CORPORATE FINANCIAL PERFORMANCE BEFORE AND AFTER DOWNSIZING

In a series of studies that included data from 1982–1994, 1995–2000, and 1982–2000, Cascio and colleagues examined financial and employment data from companies in the Standard & Poor's (S&P) 500. The S&P 500 is one of the most widely used benchmarks of the performance of U.S. equities. It represents leading companies in leading industries and consists of 500 stocks chosen for their market size, liquidity, and industry-group representation. Cascio and colleagues' purpose was to examine the relationships between changes in employment and financial performance. Each year, they assigned companies to one of seven mutually exclusive categories based on each company's level of change in employment and its level of change in plant and equipment (assets). Then, they observed the companies' financial performance (profitability and total return on common stock) from 1 year before to 2 years after the employment change events. They examined results for firms in each category on an independent basis as well as on an industry-adjusted basis.

In Cascio and colleagues' most recent study, they observed a total of 6418 occurrences of changes in employment for S&P 500 companies over the 18-year period from 1982 to 2000. As in their earlier studies, they found no significant, consistent evidence that employment downsizing led to improved financial performance, as measured by return on assets or industry-adjusted return on assets. Downsizing strategies—either employment downsizing or asset downsizing—did not yield long-term payoffs that were significantly

larger than those generated by “stable employers,” that is, those companies in which the complement of employees did not fluctuate by more than $\pm 5\%$.

Thus, it was not possible for firms to “save” or “shrink” their way to prosperity. Rather, it was only by growing their businesses that firms outperformed stable employers as well as their own industries in terms of profitability and total returns on common stock.

3.1. Is Downsizing Always Wrong?

Sometimes, downsizing is necessary. In fact, many firms have downsized and restructured successfully to improve their productivity. They have done so by using layoffs as part of a broader business plan. In the aggregate, the productivity and competitiveness of many firms have increased during recent years. However, the lesson from the research described previously is that firms cannot simply assume that layoffs are a “quick fix” that will necessarily lead to productivity improvements and increased financial performance. The fact is that layoffs alone will not fix a business strategy that is fundamentally flawed.

Employment downsizing might not necessarily generate the benefits sought by management. Managers must be very cautious in implementing a strategy that can impose such traumatic costs on employees—on those who leave as well as on those who stay. Management needs to be sure about the sources of future savings and carefully weigh those against all of the costs, including the increased costs associated with subsequent employment expansions when economic conditions improve. [Table I](#) shows direct and indirect costs of downsizing.

4. EFFECTS OF DOWNSIZING ON KNOWLEDGE-BASED ORGANIZATIONS

Knowledge-based organizations, from high-technology firms to the financial services industry, depend heavily on their employees—their stock of human capital—to innovate and grow. Knowledge-based organizations are collections of networks in which interrelationships among individuals (i.e., social networks) generate learning and knowledge. This knowledge base constitutes a firm's “memory.” Because a single individual has multiple relationships in such an organization, indiscriminate, nonselective downsizing has the potential to inflict considerable damage on the learning and

TABLE I
Direct and Indirect Costs of Employment Downsizing

<i>Direct costs</i>	<i>Indirect costs</i>
Severance pay in lieu of notice	Recruiting and employment costs of new hires
Accrued vacation and sick pay	Low morale; risk-averse survivors
Supplemental unemployment benefits	Increase in unemployment tax rate
Outplacement	Lack of staff when economy rebounds; training and retraining
Pension and benefit payouts	Potential lawsuits from aggrieved employees
Administrative processing costs	Heightened insecurity; reduced productivity
Costs of rehiring former employees	Loss of institutional memory and trust in management

memory capacity of the organization. Empirical evidence indicates that the damage is far greater than might be implied by a simple tally of individuals.

When one considers the multiple relationships generated by one individual, it is clear that downsizing that involves significant reductions in employees creates the loss of significant “chunks” of organizational memory. Such a loss damages ongoing processes and operations, forfeits current contacts, and may lead to forgone business opportunities. Organizations that are at greatest risk include those that operate in rapidly evolving industries, such as biotechnology, pharmaceuticals, and software, where survival depends on a firm’s ability to innovate constantly.

5. THE PSYCHOLOGICAL IMPACT OF DOWNSIZING ON VICTIMS AND SURVIVORS

Downsizing exacts a devastating toll on workers and communities. Lives are shattered, people become bitter and angry, and the added emotional and financial pressure can create family problems. “Survivors,” or workers who remain on the job, can be left without loyalty or motivation. A common experience is that employee morale is the first casualty in downsizing. Workplaces tend to be more stressful, political, and cutthroat than before the downsizing. Local economies

and services (e.g., human services agencies, charitable organizations) become strained under the impact on the community. Survivors often experience “burnout,” that is, a gradual process of loss during which the mismatch between the needs of the employees and the demands of the job grows ever greater. Research indicates that each person expresses burnout in a unique way but that the basic themes are the same:

- *An erosion of engagement with the job.* What started out as important, meaningful, and fascinating work becomes unpleasant, unfulfilling, and meaningless.
- *An erosion of emotions.* The positive feelings of enthusiasm, dedication, security, and enjoyment fade away and are replaced by anger, anxiety, and depression.
- *A problem of fit between the person and the job.* Individuals see this imbalance as a personal crisis, but it is really the workplace that is in trouble.

Violence and sabotage are possible among victims of the downsizing. In fact, the most common precipitator of workplace violence is a layoff or firing. Sabotage, especially cyber-sabotage, has emerged as a new threat among disgruntled ex-employees. Recently terminated workers have posted a company’s payroll on its intranet, planted data-destroying bugs, and handed over valuable intellectual property to competitors. Although exact numbers are hard to ascertain, computer security experts say that this is fast becoming the top technical concern at many companies.

5.1. Roles of Procedural and Distributive Justice in Employment Downsizing

Procedural justice focuses on the fairness of the procedures used to make decisions. Procedures are fair to the extent that they are consistent across persons and over time, free from bias, based on accurate information, correctable, and based on prevailing moral and ethical standards.

Distributive justice focuses on the fairness of the outcomes of decisions, for example, in allocating bonuses or merit pay or in making decisions about who goes and who stays in a layoff situation. In simple terms, it is the belief that all employees should “get what they deserve.”

In the wake of decisions that affect employees, such as those involving pay, promotions, and layoffs, employees often ask, “Was that fair?” Judgments about the fairness or equity of procedures used to make decisions (i.e.,

procedural justice) are rooted in the perceptions of employees. Strong research evidence indicates that such perceptions lead to important consequences such as employee behavior and attitudes. As noted previously, when employees believe that they have not been treated fairly, they may retaliate in the form of theft, sabotage, or even violence. In short, the judgments of employees about procedural justice matter.

Procedurally fair treatment has been demonstrated to result in reduced stress and increased performance, job satisfaction, commitment to an organization, and trust. It also encourages organizational citizenship behaviors, that is, discretionary behaviors performed outside of one's formal role that help other employees to perform their jobs or that show support for and conscientiousness toward the organization. These include behaviors such as the following:

- Volunteering to carry out activities that are not formally a part of one's job
- Persisting with extra enthusiasm or effort when necessary to complete one's own tasks successfully
- Helping and cooperating with others
- Following organizational rules and procedures, even when they are personally inconvenient
- Endorsing, supporting, and defending organizational objectives

Procedural justice affects citizenship behaviors by influencing employees' perceptions of organizational support, that is, the extent to which the organization values employees' general contributions and cares for their well-being. In turn, this prompts employees to reciprocate with organizational citizenship behaviors. These effects have been demonstrated to occur at the level of the work group as well as at the level of the individual. In general, perceptions of procedural justice are most relevant and important to employees during times of significant organizational change. When employees experience change, their perceptions of fairness become especially potent factors that determine their attitudes and behaviors. Employment downsizing is a major change for people, whether victims or survivors. Thus, considerations of procedural justice will always be relevant.

6. OUTPLACEMENT: EASING THE CAREER TRANSITION PROCESS

Outplacement is an extension of the termination process. It typically includes two elements: (a) counseling

the employee who has lost his or her job for emotional stress resulting from the trauma of termination, and (b) assisting with job search. Its premise is that the sooner the terminated employee is reemployed, the less time he or she has to become disgruntled, to file a lawsuit, and/or to cause problems for those who remain, particularly through violence or sabotage.

Employment downsizing often creates anxiety or resentment among remaining employees. Some workers might feel that the departing employee received unjust treatment. Others may doubt their own job security and resent the upheaval and additional workload caused by a coworker's departure.

Outplacement can help to address these issues. It provides firing managers with training and procedures to minimize trauma to the workers affected and disruption within the affected department. It helps survivors to see their organization as a fair and considerate employer. Among those downsized, outplacement can mitigate the damaging effects of unemployment on family life by including the terminated employee's spouse in counseling sessions. Subsequent career assessment and job-search assistance may include activities such as an interest inventory as well as "how to" advice on building a résumé and doing well in a job interview. These activities focus on helping the terminated employee to identify his or her strongest skills and career preferences, to negotiate job offers, and to select the best placement.

increase his or her chances of being in a crash or becoming severely injured in a crash.

sensation seeking The behavior associated with a psychological need to seek out and engage in activities for the purpose of stimulation.

GLOSSARY

countermeasures Programs or other activities designed to solve or alleviate a problem.

graduated licensing A legislative countermeasure designed to reduce risky driving and crashes among young, beginning drivers.

mobile phones Wireless communication devices that are also known as cellular telephones or cell phones. A mobile phone is either hand-held, requiring the driver to handle the phone while engaging in a conversation, or hands-free, allowing the driver to have a conversation without physically holding the phone.

occupant crash protection devices Devices that are designed to reduce the severity of injury incurred by a motor vehicle occupant during a crash. The two most common devices are safety belts and airbags.

perceived risk A driver's perception of the probability of a negative outcome for a certain driving behavior. The two most important negative outcomes for traffic safety are crashes and citations.

risky driving behaviors Actions that increase, above a particular threshold, the objective likelihood of a crash or the severity of injury should a crash occur. A driver may not consider his or her actions to be risky even though they

The automobile provides unprecedented personal mobility. The costs of this convenience, however, are traffic crashes and the deaths and injuries caused by these crashes. In the United States, for example, there were 6,394,000 police-reported traffic crashes, resulting in non-fatal injury to 3,189,000 people and fatal injury to 41,821 people, in the year 2000. In fact, motor vehicle crashes are the leading cause of death for people aged 4 to 33 years.

For decades, traffic safety professionals have worked to reduce the frequency of motor vehicle crashes and the severity of resulting injury without compromising personal mobility. While this problem has been approached from several perspectives, such as designing safer roads and developing occupant crash protection devices for cars, perhaps the most important viewpoint comes from behavioral scientists. Regardless of the safety features present in cars or on the roads on which they travel, cars are operated by people whose behaviors are influenced by a multitude of psychological factors. Therefore, an important component of the traffic safety problem is understanding, predicting, and modifying the behaviors of drivers.

Because of its clear influence on crashes, much research has focused on risky driving behavior. Estimates suggest that risky driving behavior causes or contributes to at least 40% of crashes. Risky driving behaviors are those actions that increase, above some threshold, the objective likelihood of a crash or the severity of injury should a crash occur. As such, a driver may not consider his or her action to be a risky one even though it increases his or her chances of being in a crash or becoming severely injured in a crash. This definition of risky driving behavior assumes a threshold from which to assess the increase in risk or crash severity. This objective threshold is set by societal standards. In the case of speeding, for example, the threshold may be the speed limit, the speed of traffic flow, or the speed that is safe for the current road or weather conditions. Thus, drunk driving, speeding, running red lights, talking on a mobile phone, and lack of safety belt use are all examples of risky driving behaviors.

1. FACTORS RELATED TO RISKY DRIVING BEHAVIOR

Certain groups of people seem to engage in risky driving more often than others. Reviewed here are four of the most common demographic and personality factors associated with risky driving.

1.1. Age

Observational and self-reported studies of driver behavior show that young people, more frequently than others, speed, travel with shorter headways, run traffic lights, use hand-held mobile phones, and fail to use safety belts. Drinking and driving is also common among young drivers, peaking between 21 and 35 years of age. These empirical studies mirror U.S. crash statistics that show that the number of motor vehicle crashes per licensed driver is highest for young drivers and declines with age, suggesting that the frequency of risky driving decreases with age.

1.2. Gender

It is well established that men, more often than women, drive after consuming alcohol, tailgate, speed, and fail to use safety belts. Interestingly, however, use of hand-held mobile phones while driving is more common among women than men, although data on the contribution of

mobile phone use to crash involvement have not yet been routinely or accurately collected. Crashes involving alcohol, speeding, and lack of safety belt use are more common for men than women. Collectively, these data show that risky driving behavior, in general, is more common among men than women.

1.3. Sensation Seeking

A large body of work has documented the fact that certain people, referred to as sensation seekers, have a psychological need for a higher level of arousal than others, leading to negative traffic safety consequences. Sensation seekers engage in new, complicated, or emotionally intense activities, such as taking risks, because of the resulting increased arousal. Thus, a sensation seeker might engage in risky driving behavior simply to experience a situation in which physiological arousal will be elevated. Sensation seeking can be measured with a test, the Sensation Seeking Scale (SSS), in which behaviors related to sensation seeking are self reported. Several studies have shown that men score higher on the total SSS than women. Studies have also documented that SSS scores tend to increase with age up to about 19 years and then decline gradually through the life span. SSS scores also correlate significantly with frequency of motor vehicle crashes, traffic citations, and many observed and self-reported risky driving behaviors such as drinking and driving, speeding, and lack of safety belt use. Thus, there appears to be a link between risky driving behaviors and the biological need to seek arousal.

1.4. Attention Deficit/Hyperactivity Disorder (ADHD)

There is some evidence that people diagnosed with ADHD may engage in risky driving behavior more often than others. Although few studies have investigated the role of ADHD in risky driving behavior, those that have reported that people with ADHD were more likely than control subjects to speed, disregard traffic control devices, drive without a license, have multiple crashes, and have multiple moving and nonmoving violations on their record. They were also more likely to have records of failure to appear in court and failure to pay fines, suggesting that people with ADHD tend to not follow through on the consequence of their violations. Because of methodological weaknesses of these studies, these results should be considered as preliminary. In

addition, the relationship between risky driving behavior and successfully treated ADHD is unknown.

2. THEORIES OF RISKY DRIVING BEHAVIOR

The last two decades have seen a profusion of theories on risky driving behavior, with no single one emerging as clearly superior. Collectively, however, these theories show various perspectives on how risk is conceptualized and its influence on driving. In addition, there are many commonalities among the theories that can help practitioners develop countermeasures for risky driving behaviors. The following sections briefly describe a sample of theories chosen to illustrate the breadth of thinking about risky driving behavior.

2.1. Zero Risk

The theory of zero risk assumes that driving behaviors result from motives, a primary one being the need to be mobile. As people drive, they experience subjectively risky situations, which over time they learn to avoid. In addition, as drivers gain experience, previously threatening situations that cannot be avoided begin to be perceived as less risky the more they encounter these situations without adverse consequences. The theory posits that people both learn to avoid risk and adapt to risky situations they encounter by a reduction in perceived risk, to the point of experiencing zero risk while driving. Risky driving behaviors, therefore, occur either because of inexperience or because of inappropriate amount of perceived risk for certain behaviors.

2.2. Risk Homeostasis

The theory of risk homeostasis maintains that people in a population have a preferred level of risk for a given activity. Rather than attempting to minimize risk while driving, people change their driving to reach the preferred level of risk. If the perceived risk of crash or citation is reduced, through roadway improvements or reductions in police presence, for example, drivers will simply increase their risky driving behaviors to compensate.

2.3. Utility Maximization

Theories of utility maximization posit that people choose driving behaviors based upon the outcome of

a cost–benefit analysis, in which the cost is the perceived risk associated with certain driving behaviors. People engage in the behavior that maximizes their benefit, or utility, at the present time. Therefore, risky driving behaviors could arise from (1) assigning a low cost to the risky outcome, such as a crash, (2) perceiving a low risk for the behavior, or (3) believing that the benefits of the risky behaviors, such as saving time, outweigh the costs of the behavior.

2.4. Problem Behavior

The theory of problem behavior posits that all risky behaviors of adolescents and young adults, not just driving, are interrelated. The theory suggests that risky behaviors result from the combination of influences from three general components of an individual's life: the psychological, social, and behavioral characteristics of the individual; the social environment; and the specific situation for the risky behavior. Each of these components has influences that make risky behavior more likely and less likely. These components interact and result in a tendency to engage in or not engage in risky behaviors. An important aspect of this theory is that behavior is motivational in nature; individuals may wish to engage in risky behaviors because they fulfill certain developmental needs, such as the need for peer approval. According to the theory, risky driving behavior results from both a motivation to engage in the behavior and a lack of inhibiting influences in the personal, social, or situational contexts to prevent the behavior.

2.5. Decision Making

Decision making theories conceptualize risky driving behaviors as resulting from a decision-making process in which risk is just one of several factors that may be considered. Therefore, the cognitive abilities of people, such as the speed at which they can process information, their memory capacity, and their general knowledge of the world, influence the selection of a given behavior. Various components of the decision, including the perceived risk, are combined to determine a subjective worth for the behavior among the set of behaviors available for a given situation. In these theories, risky driving behaviors can occur for the following reasons: (1) the risky driving behavior is selected over a less-risky behavior because it affords the person greater perceived benefit, or (2) the person, relative to others, is lacking cognitive skills or abilities for good decision making.

3. COUNTERMEASURES FOR REDUCING RISKY DRIVING BEHAVIORS

In general, traffic safety countermeasures are not based on theory. However, designing psychology-based countermeasures that are effective in reducing the incidence of risky driving behavior is of great interest to traffic safety professionals. These countermeasures fall into three general classes: legislation/enforcement, licensing, and educational programs.

3.1. Legislation/Enforcement

Most traffic safety legislation is designed to prevent risky driving behavior by making it illegal to engage in these behaviors. We are all familiar with the fact that it is illegal to drive over the speed limit, fail to stop at a stop sign, or not use a safety belt. This legislation, however, cannot be effective without enforcement. Legislation and enforcement countermeasures work on the principle of using punishment, or the threat of punishment, to reduce the likelihood of risky driving behaviors. The effectiveness of such programs has been shown in studies of drinking and driving, safety belt use, bicycle helmet use, and motorcycle helmet use. Although not commonly used, positive reinforcement has also been shown to be effective in reducing risky driving behavior. At least one study has shown the effectiveness of a variable reinforcement schedule in increasing safety belt use. In this study, police randomly pulled over drivers and rewarded them with prizes for wearing safety belts. Legislation coupled with enforcement is the most effective way to combat risky driving behavior.

3.2. Licensing

Countermeasures based on driver licensing are designed to legally restrict driving privileges until the driver meets certain criteria. Because of the high crash rate and high incidence of risky driving among young people, for example, many states have implemented a graduated licensing system. With graduated licensing, young drivers gradually gain skills, experience, and knowledge over a period of time under controlled, less risky conditions. Generally, there are three phases to graduated licensing. In the first phase, the young driver can operate a vehicle only under adult supervision. In the second phase, the young person can drive without an adult present, but his or her unsupervised driving is subject

to restrictions, such as daytime driving only. In the third phase, the driver is given full driving privileges. Usually, these programs incorporate motivation for safe driving behavior by requiring the driver to be citation- and/or crash-free for a period of time before graduating to the next phase. These programs also occasionally include educational components in which the driver attends and passes a class and/or demonstrates driving proficiency via a driving test. In summary, graduated licensing is designed to reduce risky driving among young people by rewarding safe driving behaviors and giving young drivers the opportunity to gain experience, acquire knowledge, and mature under conditions in which risky driving behavior is less likely. Evidence suggests that graduated licensing does reduce young driver crashes by as much as 25%, probably by reducing the incidence of risky driving among young people.

Suspended licensing is also used as a sanction following a conviction for certain driving violations, usually drunk driving. The removal of a person's driving privileges is intended to both separate the person from his or her vehicle so that the undesirable driving behaviors cannot occur for some period of time, and to punish the person by taking away a privilege. This sanction has been found to be modestly effective for reducing the incidence of drunk driving, both during the sanction period and after.

3.3. Educational Programs

Educational countermeasures attempt to reduce the incidence of risky driving behaviors and crashes by presenting drivers with information relevant to traffic safety. The topics of these programs vary widely. Probably the most familiar program is the driver education course that is required in most jurisdictions for beginning drivers. The effectiveness of these programs has been extensively researched and the unfortunate conclusion is that these programs do not reduce crashes or risky driving; they do, however, teach people the rules of the road and how to operate a car. Similar findings are reported for motorcycle training programs. Other programs have attempted to teach young drivers advanced skills, such as controlling a vehicle during a skid. It has been found that when compared to a control group, young drivers completing the course actually had more crashes, although the difference was not statistically meaningful. Educational programs have attempted to teach people about the negative consequences of risky driving. The most common of these programs are victim impact panels, in which a convicted drunk driver is required to listen to

statements from the family of the victim impacted by that driver's behavior. Again, evaluations of these programs have shown that they do not reduce drunk driving behavior or crashes. As a final example, another common countermeasure involves public information and education about the presence and enforcement of a particular traffic safety law. These programs are designed to inform or remind the public about specific traffic safety legislation, such as a mandatory safety belt law, and tell the public that police are making a special effort to enforce the law, that is, to create an increase in the perceived threat of enforcement. These programs have been found to be effective, when coupled with actual enforcement, in increasing safety belt use, decreasing drunk driving, and decreasing aggressive driving.

The disappointing conclusion from these examples is that, to date, few educational programs positively impact risky driving behaviors, except those coupled with legislation and enforcement. One should not, however, draw the conclusion that educational programs cannot be effective, but rather that more research is needed in order to develop effective programs. As discussed earlier, there is no unifying or even leading theory of risky driving behavior. Lacking such theory, program development is forced to proceed in an *ad hoc* fashion. Another challenge is developing programs that use cognitively appropriate language for the target group. As recently recognized by the National Highway Traffic Safety Administration (NHTSA), traffic safety programs targeted toward young people may not accommodate their cognitive abilities. Consequently, NHTSA has begun a program to apply the principles of cognitive development in the construction of young driver programs. Finally, it should be noted that measurement of the effectiveness of an educational program has several inherent difficulties. The typical outcome measures are either infrequent (crashes), requiring several years of follow-up data, or difficult to measure on the road (risky driving behaviors). Furthermore, many programs may not reach the proper audience or may suffer from a self-selection bias, compromising the validity of evaluations.

4. CONCLUSION

Advances in our understanding and prevention of risky driving behaviors lie ahead. Many of these advances will undoubtedly result from the application of psychological theory and principles. Further research is needed to develop and test theories of risky driving behaviors and continued efforts are needed to integrate these theories

into effective countermeasures. Success in these areas will greatly enhance the prevention of the death and injury toll caused by motor vehicle crashes.

This article describes behavioral targets and strategies to improve driving safety. Speeding, alcohol-impaired driving, and safety belt use behaviors are discussed, as are unsafe driving behaviors among young (age 14–18 years) and older drivers (age 70+ years). For each behavior or set of behaviors, those factors that support safe driving or reduce poor driving and those that undermine safe behaviors or support unsafe driving behaviors are discussed.

GLOSSARY

alcohol-impaired driving Instances in which at least one driver involved in a crash was impaired by alcohol.

alcohol-involved crash A crash in which at least one involved driver had been drinking prior to the crash, but the level of impairment is unknown.

crash severity Measured in terms of the extent of the damage sustained by the vehicle involved in a crash and the severity of the injuries sustained by the people involved in the crash.

deterrence Describes avoidance behaviors of drivers that are formed by perceptions of enforcement levels as well as punishment likelihood and severity.

graduated licensing A licensing procedure by which young drivers are permitted driving privileges incrementally based on the successful completion of each licensing phase, allowing young drivers to experience more complex driving situations gradually.

speed-related crashes Crashes in which a driver was traveling in excess of the posted speed limit or the speed was higher than the safe driving speed for the conditions.

1. DRIVING SAFETY AS A BEHAVIORAL TARGET

Driving safety is measured objectively by the presence or absence of motor vehicle crashes and/or the severity of motor vehicle crash outcomes. Crash severity is typically measured in terms of the damage sustained by the vehicle involved in the crash and the severity of the injuries sustained by the people involved in the crash. Driving safety is also assessed by the presence or absence of precursor behaviors demonstrated to be related to crash involvement and/or severity.

According to the National Highway Traffic Safety Administration (NHTSA), in 2001 there were 6,323,000 traffic crashes in the United States resulting in nearly 40,000 deaths and an additional 2,003,000 injuries. Annually, there are approximately 20 persons killed and an additional 1585 persons injured for every 100,000 licensed drivers. The NHTSA estimates that

the total economic cost of traffic crashes in 2000 was \$230.6 billion.

Although improvements in vehicle and road design have contributed much to improving driving safety, perhaps the most significant advances in driving safety in the past 15 years are behavior change programs designed to reduce the likelihood of drivers engaging in unsafe behaviors and programs designed to increase the likelihood of safe driving behaviors. Specifically, most efforts in behavior change to improve driving safety have focused on five target areas: speeding, alcohol-impaired driving, safety belt use, and driving behaviors of older drivers (age 70+ years) and young drivers (age 14–18 years).

2. SPEEDING

The NHTSA estimates that speeding (traveling in excess of the posted limit or traveling too fast for conditions) is a contributing factor in 30% of fatal crashes, resulting in approximately 12,000 lives lost in speeding-related crashes per year. Speeding reduces a driver's ability to steer around curves or objects in the roadway, extends the distance that is needed to stop a vehicle, and increases the distance a vehicle travels as a driver reacts to a situation. Moreover, the dynamic forces generated in a crash increase exponentially with the speed of the vehicle.

Speeding behaviors are motivated and reinforced by a wide array of conditions. Speeding behaviors can result from consciously accepting risks inherent in the behavior or unconsciously by misinterpreting speed cues and subsequent risks. Drivers often speed to achieve their goal of reaching a given location at a given time. Some speed because they are not attending to available speed cues. A speedometer serves as an objective and reliable cue of vehicle speed. However, subjective cues in the driving environment (e.g., the rate at which trees on the roadside pass by as one is driving) may or may not be perceived by a driver. Even if perceived, a driver may not understand the meaning of these objective and subjective speed cues, the risks associated with the cues, and what the safe driving speed may be for a given situation. Variations in risk perceptions and acceptance among drivers compound these relationships.

Expectancies play a significant role in a person's perception and acceptance of speed. For example, drivers turning into a traffic stream on a road with a 30 mph limit would not generally expect to have a vehicle

approaching at 100 mph. A misperception of closing speed in this case could easily cause a traffic crash when the turning vehicle crosses into the path of the oncoming car that should have been farther away when the turn began. Another expectancy that many drivers have is that any given driver will get to his or her destination much sooner by passing traffic traveling slowly in a cue, like one would find when two lanes of a highway are merged into one because of road construction. Although there can be a measurable time savings from speeding, the gains are minimal. A vehicle traveling in an open lane at 50 mph passing a 3-mile-long line of traffic traveling at 10 mph will gain less than 2.5 min (and no doubt anger a number of people). In fact, the faster car has to pass approximately 700 vehicles to save the 2.5 min. Passing slower vehicles may create a perception of getting to the destination faster than is warranted by objective information.

The primary means applied to limit speeding behavior has been traffic law enforcement. The theoretical roots for this approach are found in learning theory. Enforcement strategies to control speeding behaviors target change in a driver's perception of the likelihood of arrest, prosecution, conviction, and the severity of the subsequent sanction. That is, the programs change the perceived reinforcing and punitive qualities of the behavioral consequences. These perceptions serve as antecedent conditions signaling a heightened probability of negative consequences resulting from speeding. That is, speed can be regulated by decreasing the perceived utility/reinforcing properties of speeding. For example, perhaps drivers would perceive fewer benefits associated with driving on an adjoining lane of slowly moving traffic if they were made aware of the small gain made. On the other hand, if drivers perceive the environment as being too dangerous to speed, they will try to avoid the negative consequences by traveling at safe, legal speeds.

When the level of enforcement activity and its concomitant publicity decrease, changes in drivers' perceptions of the risks and rewards of speeding will result in a return to the speed behaviors that were reinforced (or at least not punished) prior to the special enforcement program. These changes may occur quickly, as is the case among drivers using two-way radios to alert other drivers to the threat of enforcement. These informed drivers will slow while in the enforcement zone and resume speed once the threat has passed. These changes may also occur slowly, as is the case when enforcement patrols target an area using an intermittent enforcement schedule.

3. ALCOHOL-IMPAIRED DRIVING

According to the NHTSA, 41% of persons killed in traffic crashes in the United States in 2001 were killed in crashes involving alcohol. That is, 17,448 persons were killed in alcohol-involved crashes in 2001. This seemingly dangerous activity is motivated by the desire to travel from point A to point B and is in part controlled by the extent to which drivers perceive risk in the behavior or reward in alternate behaviors. Behavior change programs to reduce the likelihood of alcohol-impaired driving have taken the forms of reducing the response cost for alternate behaviors, programs to reduce the social acceptability of drinking and driving, interventions to reduce alcohol dependency, and enforcement campaigns to increase the perceived threat of drinking and driving behavior.

Some of the most innovative and successful programs to reduce alcohol-impaired driving have been those that reduce the response cost and even reward alternate behaviors incompatible with alcohol-impaired driving. Incentives in the form of free food and nonalcoholic beverages for persons who serve as the designated driver for a group have proven to be successful. An interesting program that prevents a person from driving while impaired is the "tipsy taxi" program. In this program, a patron who has had too much to drink is given a ride home by a volunteer. The patron or a friend then picks up the car from where it was parked at a later time.

The primary challenge to these programs is that the response cost for the desired behaviors can be perceived to be quite high. A designated driver may resent not being able to drink or become angry at boisterous drinking friends. The designated driver may feel uncomfortable to the extent that he or she can be identified and treated poorly by others in an establishment because he or she is the designated driver. In addition to the embarrassment of having to have someone else drive one home, the tipsy taxi has a significant response cost obstacle to overcome: People do not like to leave their cars on the street or in a parking lot near a bar.

Perhaps the most common programs to reduce impaired driving are those intended to persuade people that alcohol-impaired driving is an unacceptable behavior. The foci of these persuasion programs are attitudes, perceptions, and social norms associated with drinking and driving. These programs use mass media distribution of materials to educate and persuade readers to adopt the desired set of values and to engage in the desired behaviors. Although these types of

information and persuasion strategies are an effective, almost necessary, adjunct to other types of programs, persuasion programs are not in themselves an effective means to change driving behavior.

As is the case for speeding behaviors, policies, laws, and their enforcement are significant components of alcohol-impaired driving reduction programs. Strengthening laws and increasing sanctions may increase their deterrent value in two ways. First, a law may serve to discourage a group of persons from engaging in the illegal act (general deterrence). Second, a law may serve to affect the behavior specifically of persons who have had a previous experience with violating the law (specific deterrence). For example, a new law that affects only repeat offenders may have a general effect (a reduction in drinking and driving among persons without a conviction) in addition to its desired effect on the target group of repeat offenders (specific deterrence).

Behavior change programs targeting a reduction in alcohol-impaired driving also include interventions designed to reduce alcohol dependency. The most significant problem faced by treatment-based programs to reduce alcohol-impaired driving is the fact that often participants are ordered by the court to attend the treatment sessions that the court prescribes. The result is a client who has little motivation to participate actively in the change program imposed by the court and is being asked to make a major life change using a strategy that may well be inappropriate for that client.

4. SAFETY BELT NONUSE

When used, lap/shoulder belts reduce the chance of death or serious injury from a traffic crash by 45–60%. The NHTSA estimates that in 2001, use of safety belts prevented more than 12,000 fatalities that would have otherwise been caused by traffic crashes. Despite the demonstrated effectiveness of safety belts for preventing death and reducing injury, a substantial proportion of people do not use safety belts. Although NHTSA observation studies have shown that safety belt use has increased considerably from its 1994 level of 58% to its 2002 level of 75%, one out of four vehicle passengers still travel without this proven life-saving device.

Programs to promote safety belt use have focused primarily on managing short-term consequences of safety belt use. The most significant consequence, loss of life, is an extremely rare event when considered on a

trip-by-trip basis. Because of its infrequency, this consequence does little to promote belt use. In fact, prior to the implementation of laws mandating safety belt use, the national rate of belt use was approximately 14%. This rate shows that other, short-term consequences are necessary to increase belt use. Perhaps the most underused programs for promoting safety belt use are incentive programs in which a person or group of persons are rewarded for belt use.

Incentive programs have proven to be effective in achieving belt use in the 90–100% range at industrial sites and within communities. At the heart of the programs is the delivery of rewards for belt use rather than punishments for belt nonuse. Some jurisdictions have used police patrols to pull vehicles out of the stream of traffic to reward drivers, similar to the manner in which drivers are given tickets. These programs often create resentment toward police because the circumstances surrounding the delivery of the reward are perceived to be more punitive than the value of the reward. Strategies in which the delivery of rewards is concurrent with another activity in which belt use can be assessed easily by observation (e.g., fast-food drive-throughs) are highly successful.

The regularity and generalization of belt use can be accomplished with contingency management. Delaying the reward for belt use until multiple examples of the behavior are observed or using an intermittent reinforcement schedule can serve to extend the effects of the program past the time the program has ended. An example of delayed reward is a program in which persons who are observed wearing their belts receive a single bingo letter each time they order from the drive-through. The completed card may be redeemed for a product from the participating store. An intermittent schedule is achieved when belt users select a card randomly from a set of cards in which there are winning and losing cards.

Using a mixed cognitive and behavioral approach provides another strategy for promoting belt use. In this type of program, persons visiting participating stores may be given an opportunity to complete a form that pledges them to use their safety belt on every trip they take. The form is divided to create a raffle ticket that is entered in a weekly drawing for nominal prizes and a rear-mirror tag displaying their commitment to belt use. The mirror tag serves two purposes. First, it serves as a cue to the driver to put on the safety belt. Second, volunteers observe belt use on streets in the area and record the plate number of every person with a mirror tag who is using a belt. This is done throughout the program period, after which a

small number of desirable prizes are awarded to persons with the highest number of observed belt use. This mixed strategy is most effective at sites where the number of observations that can be made of all participants is approximately the same (e.g., parking lots).

The effectiveness of incentive programs is often improved by using group contingencies. When group contingencies are applied, the reward is earned only when each member of the group achieves the target level of the desired behavior. In this type of program, motivation is not derived from desire to obtain the reward alone. There are additional motivations resulting from the group asserting its influence on a person who may be preventing the group from receiving its reward.

There are also a variety of belt promotion strategies that employ punishment or the threat thereof to achieve program goals. Changes in enforcement policy mandated by laws requiring belt use have resulted in the most dramatic increases in belt use among the general population. Many, if not most, who begin to use their belt after this type of law change do so because they obey laws generally. Others respond to the fact that being pulled over is unpleasant and buckle up to avoid the stress of getting a ticket. The group of nonusers consists of persons who believe it is a personal decision; those who derive satisfaction merely from “tweaking the system”; and those who, for personal reason (e.g., fear of entrapment and discomfort), choose not to use belts.

Efforts to increase belt use through the exclusive use of mass media strategies have proven to be universally ineffective. These programs are based on increasing knowledge and shaping attitudes conducive to belt use. Although ineffective when used in isolation, media strategies can be highly effective and essential components to promoting an incentive- or disincentive-based safety belt promotion program.

5. DRIVING SAFETY AMONG OLDER DRIVERS

Achieving and maintaining safe driving behaviors among older drivers is going to be a growing challenge in the future. The NHTSA reports that in the United States there were 18.9 million licensed drivers age 70 or older in 2000, a 36% percent increase since 1990. During the same time period, the general population of older persons increased 6%, whereas the number of older drivers involved in fatal crashes increased at three times this rate (18%).

The basic motivations for driving at age 70 do not differ from those of younger drivers. One drives to get from one point to another. However, driving allows older persons the mobility required to maintain their physical and mental health. Without independent transportation, older persons may feel isolated and depressed because they cannot get together with family or friends without help; their access to medical treatment and fresh foods is reduced, further increasing their risk of an early death; and often they lose feelings of maturity and value as their driving abilities restrict their driving. The privilege to drive is often an important rite of passage from youth to adulthood in the United States. In order to avoid these negative consequences, many older persons drive in situations they have difficulty managing and may not freely admit to family members or others that they have difficulty driving in these situations.

Changes in vision, reduced range of motion, and slowed reflex and reaction times are among the effects age has on the body. Cognitively, there is a reduction in attention resources required for effective perception and decision making. Moreover, as people age, the ability to divide attention between several tasks and to identify and ignore irrelevant information decreases. As drivers age, they tend to perceive a given situation as being more threatening and their ability to respond lower than is actually the case. Older persons often take a variety of medications that may affect their ability to perceive or act in a manner consistent with safe driving. These changes affect the number, cause, and severity of crashes experienced by older drivers.

Compared to younger drivers, older drivers have a lower rate of alcohol involvement in fatal crashes but are increasingly under the influence of multiple prescription drugs that may affect driving in ways that have not yet been determined. Older drivers have a crash profile similar to that of younger drivers, but the causes of these profiles are different. As drivers age, their perceptions and assessment of risk are greater than they are in reality, and their perceived skill at meeting these challenges is lower than it is objectively. Comparing crash configurations for older and younger drivers, the NHTSA has shown that vehicles with drivers age 70 or older are three times more likely to be the vehicles struck in fatal collisions and six times more likely to crash while turning left than is the case for younger drivers.

Worsening vision and flexibility caused by aging may make assessments of an oncoming vehicle's approach speed more difficult, thus requiring more time to scan the environment. This reduces the time available for decision making. Also, age-related deficits

in decision-making processes may result in drivers making decisions too slowly to maneuver to avoid a collision. Finally, once the decision is made cognitively, the ability of older persons to act on that decision behaviorally is also impaired by age.

The gradual degradation of abilities necessary for safe driving creates a significant challenge. Some programs have attempted to address problems associated with age by using training sessions to increase skeletal flexibility and mental dexterity. Although these programs have had limited success, it may be useful to consider a licensing system that allows drivers to exit the driving population gracefully and in a manner consistent with their condition. However, one must keep in mind that alternatives to driving oneself from point A to point B may be extremely limited. This is especially true outside large metropolitan areas. Because there are few opportunities for traveling locally for day-to-day necessities, states are reluctant to modify licensing laws that may further restrict an elderly person's ability to be independently mobile and drive.

6. DRIVING SAFETY AMONG YOUNGER DRIVERS

According to the NHTSA, motor vehicle crashes are the leading cause of death for persons age 15–20 in the United States. In 2001, 3608 drivers in this age group were killed in fatal crashes and traffic crashes injured an additional 337,000. More disturbing is the fact that although drivers age 15–20 constitute only 7% of the driving population, they are involved in 14% of all fatal crashes and approximately 20% of all reported crashes. Research has shown that teens are three or four times more likely to be involved in a crash during their first 2 or 3 years of driving compared to the general driving population.

For drivers age 15–20 involved in traffic crashes, police recorded the cause of the crash to be driver error or other factors related to the driver's behavior in 75% of cases. Compared to drivers older than age 20, young drivers are more likely to exceed posted speed limits, drive too fast for conditions, follow too closely, cross traffic lanes, pass other vehicles, and approach signals at higher speeds. Young drivers are also less likely to use their safety belts and are affected by lower levels of alcohol than are older drivers. One of the central causes of these problems is the fact that younger drivers perceive a given situation to be less

risky and their ability to handle a given situation to be greater than is actually the case.

Until recently, driver education classes were the primary means by which young drivers were trained to drive. These programs are excellent at teaching basic skills, such as accelerating, stopping, and steering, but do little to improve the necessary perceptual and decision-making skills required for safe driving. Research has shown that driver education may at best result in a small and short-lived improvement in driving safety but appears to have no effect on crash involvement in the long term. Recently, states have begun to implement a driver licensing protocol called graduated licensing.

Young drivers are involved in a higher rate of crashes because of their lack of experience driving and their heightened levels of risk taking. Graduated licensing is a licensing procedure by which young drivers are given driving privileges incrementally based on the successful completion of each licensing phase. This allows young drivers to experience more complex driving situations gradually, reducing the chance that drivers will encounter situations beyond their skill levels. Because graduated licensing practices restrict young people from driving at hazardous times, there is an additional safety benefit associated with reduced exposure.

Differences in laws from state to state make it difficult to specify each stage of graduated licensing, but the process is generally the same for all states. The process generally starts with a highly restricted learner permit that permits driving only in daylight with an adult in the car. In the second stage, drivers earn an intermediate license that limits driving without a guardian to daylight hours and still requires supervision at night. The final stage is full licensure, which occurs when a person is age 17 or older, has completed at least 6 months of the intermediate license condition, and has remained violation and crash free for the prior 3 months. Research has shown that the implementation of a graduated licensing system results in approximately 25% fewer crashes involving young drivers compared to the number of crashes before the institution of a graduated license system.

7. CONCLUSION

Safe driving requires that appropriate behaviors take place in the correct manner at the correct time. Risky driving behaviors, such as speeding, alcohol-impaired driving, and safety belt nonuse, have been proven to be best controlled by the application of learning theory models. The most successful intervention models have

been those that managed relationships between the behavioral antecedents, the desired/undesired behavior, and the consequences associated with the behavior. By restricting driving to relatively safe conditions and extending driving experience over a long period of time prior to full licensure, the crash risk of young, novice drivers can be reduced significantly.

GLOSSARY

pharmacology The study of the effects of chemical substances on living systems.

psychoactive The ability of a drug to induce subjective effects on mood and feeling.

psychosocial Reflecting the combined influences of psychological and social factors.

relapse Resumption of drug use following a period of abstinence.

withdrawal A maladaptive behavior change that occurs when blood or tissue concentrations of a drug decline in an individual.

Drug abuse, also referred to as substance or chemical abuse, is the recurrent use of a drug despite the experience of problems caused by the drug use. Difficulties arising in certain areas of a user's life are of more importance to researchers and treatment professionals than other areas for identification of a drug abuse problem. The following are types of problems that signify drug abuse: impairment meeting

major responsibilities in life, such as those regarding school, work, or home; difficulties with the law and social behavior; and aggravation of physical/medical conditions due to drug use. Drug abuse is to be contrasted with drug (chemical/substance) dependence. With drug dependence, use is considered compulsive and beyond the willful control of the user. That is, someone who is drug dependent is addicted; this is thought to be a more severe condition than drug abuse. Treatment of drug abuse is accomplished primarily using a variety of counseling and psychotherapeutic techniques employed to assist the abuser to stop using the drug, to develop new behavioral and mental coping skills, and to rehabilitate his or her life from the damage caused by the substance abuse.

1. INTRODUCTION

In the discussion of drug abuse, it would be easy but inaccurate to label any regular use of a substance as abusive. Drug use in the United States is commonplace. Many people are capable of consuming drugs without developing problems. Drugs such as caffeine and alcohol, as well as prescription pharmaceutical products such as pain killing agents or antianxiety medication, are routinely and openly consumed every day in the United States (and in other countries as well). The various drugs affect the body differently and are used for specific purposes. For example, caffeine is used to remain alert and to enhance concentration, and

tranquilizers are used to quell anxiety and for relaxation. However, drugs of abuse all have in common the property that they are psychoactive. For the sake of discussion, drugs may be classified with respect to different properties; one commonly employed system is in terms of the effect of the drug on the central nervous system (CNS). The following is one such classification system, with examples of drugs in each category:

1. CNS stimulants: Cocaine, amphetamine, and caffeine
2. CNS depressants: Alcohol, barbiturates, benzodiazepines, and solvent inhalants
3. Psychotomimetics (also known as psychedelics or hallucinogens): Marijuana, LSD, and mescaline
4. Narcotics/Opioids: Opium, heroin, codeine, morphine, and methadone

Substance use typically begins in adolescence. Adolescent substance use does not appear to be random; that is, it follows a fairly predictable pattern. Adolescents tend to start using substances that are legal and widely available to adults: alcohol and tobacco. Due to the fact that these drugs are the starting point for substance use, they are referred to as “gateway drugs.” In 1975, Kandel developed a stage model of progression of drug use that has since been revised:

1. Beer or wine use
2. Hard liquor or cigarette use
3. Marijuana experimentation
4. Alcohol abuse
5. Prescription drug use
6. Opiates and other illegal drugs

The vast majority of adolescents experiment with the gateway drugs at least one time. However, although most individuals try alcohol and tobacco, only for a minority of adolescents does use advance to abusive levels. As the stages advance, progressively fewer adolescents are found in each category. For example, alcohol will be tried by approximately 9 out of 10 students by their senior year in high school and cigarettes by approximately 6 out of 10 students by senior year. Opiates, at the last stage of the model, will be tried by only 1 out of 100 students by senior year.

Due to the high prevalence of substance use in the United States, it should be no surprise that substance-related problems are often encountered by mental health clinicians. The relatively high frequency with which substance-related problems are encountered by mental health professionals reflects the influence of the following factors: (i) Drug abuse has the potential to

create or worsen all psychological symptoms, such as anxiety, depression, impulsive behavior, and antisocial behavior; and (ii) people seeking mental health services also tend to be at elevated risk for substance abuse problems. In other words, drug abuse harms people and contributes to psychiatric symptoms, and people experiencing psychological problems are apt to use drugs abusively.

2. RISK FACTORS AND CAUSES OF DRUG ABUSE

With any medical or mental health condition, it is desirable to determine the cause or causes of the affliction. Identifying the cause(s) helps to develop prevention strategies to limit or eliminate future cases and treatment strategies for those already affected by the condition. For example, after the discovery that an absence of insulin was responsible for type 1 diabetes, effective treatment of diabetes with externally supplied insulin became possible. In addition, research is under way to develop early identification tests for intervention strategies to prevent later development of diabetes. This research has led to the isolation of faulty antibodies believed to attack the insulin-producing cells of the pancreas. The antibodies can be detected before the person is symptomatic for diabetes; experimental treatments are being used in an attempt to prevent the development of diabetes in these high-risk individuals.

Human behavior is complex and defies easy explanation. Unlike certain physical characteristics (e.g., eye color) or physical disorders that can be traced to single genes, a disorder such as drug abuse likely represents the interaction of multiple genetic and environmental influences. Complicating things further, ethics prevents us from conducting experimental studies (involving environmental or genetic manipulation) that might help us to tease apart various possible influences. One way to attempt to identify possible causes of substance abuse is to study risk factors. Risk factors are those variables associated with increased likelihood of developing a substance use disorder. Classes of risk factors are listed here with examples in each class:

1. Peer: Peer substance use, strong attachment to peers, and positive peer attitudes about substance use
2. Parent/family: Parent substance use, positive attitude about substance use, parent tolerance of adolescent substance use, and family disruption (e.g., divorce)

3. Personal: Early (childhood) behavior problems, poor academic performance, anxiety/depression, and low self-esteem

4. Biological: Genetic predisposition to substance use (e.g., a parent is a substance abuser)

5. Community/social: Low socioeconomic status, high availability of substances, and deviant norms that encourage use of substances

Risk factors help us to understand influences to use substances, but we know many more people use them than become abusers. Therefore, the question as to who will progress beyond experimentation and casual use to the level of abuse is not answered by risk factors alone. It appears that use of substances is more a function of external risk factors, such as peer, social, and family factors; abuse of substances appears to be more a function of personal factors, such as psychiatric, behavioral, and emotional problems.

The biopsychosocial disease model is the most widely accepted model of substance abuse and addiction. It should be clear after reviewing the list of risk factors that biological, psychological, and social factors contribute to substance abuse. The biopsychosocial model is sufficiently comprehensive to include all known contributors to substance abuse.

3. COURSE OF DRUG ABUSE

Disease conditions are defined by several common factors, such as having identifiable causes, characteristic symptoms, and established treatments. In addition, diseases have an observable course. It is important to describe the course of an illness in part so that the condition can be identified (i.e., for diagnostic purposes). Also, if the untreated progression of an illness was not known, there would be no way to judge the effectiveness of treatment. Treatment interventions endeavor, essentially, to change the course of a disease. Initial attempts to describe and classify the course of alcohol abuse depicted an ever-worsening condition that eventuated in death, unless the drinking was stopped altogether. As it turns out, the long-term outcome of regular alcohol use is not certain death. Some people who use alcohol never develop problems, some who develop problems (alcohol abusers) never become addicted, and a minority of alcohol abusers (approximately one-third) exhibit the progressive deteriorative pattern of drinking. The same overall trends may be expected with other substances of abuse as with

alcohol. In 1995, Shaffer and Robbins developed a general model to describe the typical course of an addiction, consisting of the following stages:

1. Initiation: Experimentation with a drug is begun.

2. Positive consequences: At this point in the use process, only the pleasurable pharmacological and social effects of the substance are experienced.

3. Negative consequences: For those individuals who continue to regularly use the substance, eventually negative consequences are experienced in terms of health, relationships, work, school, finances, or the law.

4. Turning point: For abusers who continue despite negative consequences, there is some recognition of the damage the substance is causing in their lives and ambivalence ensues.

5. Active quitting: For some abusers, ambivalence is resolved in the direction of stopping use.

6. Relapse prevention: For those who have quit, behavior changes are maintained over time to prevent resumption of drug use.

4. ASSESSMENT OF DRUG ABUSE

In order to treat a condition, it must first be determined that a given individual has the condition; in other words, the diagnosis of drug abuse must be made. In medicine, objective tests via technologically advanced equipment (e.g., x-ray and magnetic resonance imagery) are often used to assist the doctor in the diagnostic process. In the evaluation of drug abuse, modern technology is hardly relevant. Biological testing, in the forms of urinalysis and evaluation of saliva and blood samples, may be used but are not the mainstay of assessment. Biological testing can determine if a specific drug or drug metabolite is present in a sample but cannot indicate anything about patterns of use, withdrawal symptoms, compulsive behavior, or consequences of use, all of which are important aspects to assess. Therefore, biological testing is confined to the role of confirming recent abstinence; this information is especially important in certain settings (e.g., criminal justice system and workplace) but of limited use in a drug abuse assessment. Since we are more interested in determining whether a pattern of abusive drug use is present or not, relevant information needs to be gathered. Therefore, the interview is the primary method by which information is acquired to make the diagnosis of drug abuse. Typically, the diagnostic interview is conducted with the person in question as well as with

others in a position to observe relevant behaviors (most often family members and/or close friends). In addition to the interview, information is sometimes acquired via self-report, paper-and-pencil tests. The following information is typically obtained during a drug abuse assessment:

1. List all substances ever used
2. Age of first use of all substances
3. How used each substance (e.g., smoke, drink, snort, etc.)
4. Age of peak use, and amount used, for each substance
5. Number of days use substance per week, for each substance
6. Amount of substance used on a typical day of use
7. Date of last use of each substance
8. List all negative consequences resulting from use of substances

Diagnosing a drug abuse disorder is only one element of the assessment process. It is also necessary to determine as part of the evaluation the most appropriate setting in which treatment should take place (e.g., outpatient, halfway house, or inpatient); the proper intensity of treatment (e.g., daily treatment or monthly treatment); whether other treatment needs exist (e.g., medical and/or psychological disorders); and specific, individual treatment goals for a given person.

5. TREATMENT OF DRUG ABUSE

There is no one treatment for drug abuse. This fact is a reflection of the complexity of the condition and its diverse manifestations, and it highlights the importance of the assessment process, which is critical in helping determine the best treatment for a given individual. The treatment of drug abuse may occur in different settings, with varying degrees of professional assistance (e.g., self-help/12-step and professional help) and different modalities of professional services (e.g., individual therapy, group therapy, family therapy, and pharmacological treatment). Drug abuse treatment may be characterized as specialized treatment with one main goal: to stop the use of the substance. Treatment is primarily talking therapy—counseling and psychotherapy; in addition, medications may be employed to manage detoxification from some drugs and/or to treat coexisting psychological or medical conditions. However, regardless of the setting of treatment, the intensity of the contact schedule, or who

renders the treatment, it is ultimately talking therapy that takes place. Especially early in treatment, the focus of discussion is on behavior directly related to drug use and stopping the use of the drug. Most programs and professionals recommend complete abstinence from drugs; some have the goal of harm reduction (allowing use to continue while attempting to reduce drug use to less harmful levels), but they are in the minority. As treatment progresses, and abstinence is achieved and maintained, the emphasis usually broadens to other areas of the person's life that may need repair, such as their decision-making skills, coping skills, emotional state, and relationships. In other words, the individual suffers psychological and social damage from drug abuse and may even have had significant deficits in these areas prior to his or her drug abuse; treatment is designed to improve the psychosocial functioning of the individual once he or she is drug-free.

6. RELAPSE PREVENTION

Drug abuse has been described as a chronic, relapsing disorder. Like all chronic conditions, long-term effort must be applied for the individual to maintain abstinence from drug use. Nobody would expect the blood sugar levels of someone with diabetes to be in a healthy range if the person only complied with the prescribed care regimen for 1 month after a visit to the physician. Likewise, if a drug abuser only applies the principles of treatment for a limited period of time, resumption of abusive habits would be expected. One way to attempt to guard against a backslide into prior behavior is to extend treatment as long as possible. In addition, teaching relapse prevention skills that an abuser may use going forward in time is an integral part of drug abuse treatment. Some common elements of relapse prevention programs include identification of high-risk situations that are likely to lead to relapse, development and practice of skills to effectively cope with risky situations, enhancement of self-confidence to be able to apply coping skills when needed, learning to limit a slip to an isolated incident rather than allow it to be the beginning of a process of abuse, drug/alcohol monitoring for abstinence verification, and developing positive behaviors (e.g., working and physical exercise).

GLOSSARY

drug tolerance The physiological buildup of a drug in the body's metabolic system generating a constant urgency for more of the drug to avoid withdrawal symptoms. Drug abusers "tolerate" more of an ingested chemical as the body habituates to its effects.

drug-dependent behavioral patterns The functional and topographical sequence of responses conditioned as a by-product of repeated episodes of drug consumption. The sequence of "behavioral patterns" consists of orderly connected responses overtly and covertly occurring from the onset of cravings to the offset of pleasure gratification. Intravenous heroin users, for example, may (i) search for a syringe (or other paraphernalia), (ii) secure an isolated place for drug preparation, and (iii) go through ritualistic steps to penetrate the vein (tighten a large rubber band around the vein site; hit the vein with two fingers to draw blood flow; insert the needle inside the vein; and compress the plunger, forcing the liquid through the syringe).

drug dependence-induced disorders Medical and psychological complications result from chronic drug dependence producing a cluster of symptoms otherwise not present in the addict's life. Common disorders include mood, dementia, Korsakoff's, anxiety, depression, psychosis, and sexual.

polysubstance addiction Progression of one drug dependence to another drug dependence so that both drugs produce similar effects, opposing effects, or complementary effects. Cross-addicted users who drink alcohol (depressant) may also enjoy sedative effects of cannabis or contrast alcohol with cocaine (stimulant-euphoric); they may also find that alcohol's calming effects take the edge off of painful crack-cocaine withdrawal.

recidivism The gradual relapse of drug addiction after a substantive period of abstinence. Recurrence of drug-dependent behavioral patterns starts the spiral of habits, followed by small amounts of the drug being ingested. As drug-intake levels increase to pretreatment amounts, self-control erodes into compulsive fulfillment of cravings.

remission Period of drug treatment when addictive habits and behavioral patterns disappear but are not extinct. Medical or social stressors may force rapid detoxification and drug-free behaviors atypical in the addict's normal life. Incarceration for drug possession and intent to deliver (drug sales), for example, may last several months, dramatically eliminating drug use. Abstinence occurs, but only artificially and temporarily since the addict restores drug dependence once released from jail.

routes of administration Entry routes of drug use include major sensory receptors such as inhaling or "snorting" through the nose (smell, olfactory), swallowing through the mouth (taste, gustatory), rubbing on skin (topical, tactile), injecting needles through skin (intravenous, intramuscular, or subdermal), or forceful anal insertion (suppository).

setting events Environmental, physiological, and psychological variables mediating the relationship between drug-dependent behaviors and their consequences. Location of drug use (e.g., home and bars), people around whom use occurs (e.g., friends and relatives), time of day, light or

darkness in room (media of contact), nervousness or indigestion (e.g., irritable bowel), migraine headaches, chronic back pain, spousal arguments, and persistent sexual deprivation are all examples of the endless continuum of drug-causing antecedents.

substitutive effects Spontaneous regeneration of drug cravings or even pretreatment use levels may result from addicts either consuming what they think are benign compounds or engaging in benign activities, all of which restore the body's climax of pleasure previously evoked by the drug. Recovering cocaine addicts who increase daily numbers of cigarettes smoked or drink more cups of caffeine-loaded coffee may unknowingly reactivate the body's tolerance for stimulation similar to using cocaine.

titration Prescribed or self-induced weaning off of one drug while simultaneously ingesting a new drug. The replacement drug may generate milder or controlled effects, such as when highly regulated methadone doses replace opioids (e.g., heroin). Titration from medication dependence may involve a gradual reduction schedule of thinning the dose or altering the frequency of intake.

withdrawal syndrome Deliberate or accidental cessation of continuous drug use causing the body to crave replenishment of the drug. Substances taken in greater amounts over a long period of time and then sharply reduced or stopped continue in the bloodstream until slowly diffused; this is also called detoxification.

Drug dependence is a pathological condition marked by biological tolerance and withdrawal symptoms resulting from consuming large amounts of a particular drug through various routes of administration (e.g., oral and intramuscular). Essential features of biological tolerance include intense and compulsive cravings for substances to reach a desired peak effect. This is due to two reasons. First, attainment of effect level, after repeated use, requires higher amounts of the same drug, whereas less amounts produced pleasure during earlier stages of use. Second, pleasurable effects diminish after repeated use of a drug, fooling the user into ingesting higher doses to restore a prior peak effect. Chronic, uncontrolled use may be triggered by life stressors that impede social, financial, occupational, and interpersonal functioning, typically impacting nuclear family members. Life stressors are cues or "setting events" evoking unwanted emotional, behavioral, or cognitive states eliminated through drug use. The second defining feature of drug dependence, withdrawal syndrome, involves physiological reactions upon immediate cessation of the drug. General symptoms observed include restlessness, anxiety, insomnia, and nausea, although severity of body complications depends on the type of

drug discontinued. For example, acute withdrawal symptoms of cocaine, such as fatigue, dysphoric mood, increased appetite, and psychomotor retardation, markedly differ from cannabis withdrawal symptoms, of which there are few except for excessive sedation or appetite stimulation. Abatement of withdrawal symptoms occurs when either abusers reuse the drug in small or large doses or titrate to another drug expected to produce commensurate effects. Users under court order to "drop urine samples" (urinalysis), for example, may cease cocaine use but increase their intake of alcohol for its stimulant properties. In this way, body cravings for peak effects remain the same when satisfied by an equivalent-acting drug.

1. CONCEPT OF DRUG DEPENDENCE

Drug dependence is a clinical term denoting significant distress or impairment in cognitive, behavioral, and physiological symptoms of users consuming large amounts of legal or illegal compounds. "Impairment," conceptually, considers the abuser to persist habitual drug ingestion despite realization of the untoward physical or psychological effects produced. Adverse effects are manifold but functionally are uniform. First, abusive use increases in quantity and frequency to match the gratifying or intoxicating effects desired. Mathematically, multiple daily routines build rapid metabolic adjustment or "tolerance" to the substance. The demand for more substance is higher to compensate for the body's adjustment (tolerance) and ensure euphoric or intoxicating sensations. Tolerance develops into dependence in two ways: physically and psychologically.

A physical dependence defines when substance intake levels greatly increase to maintain a desirable, sensory peak effect and prevent withdrawal symptoms. A psychological dependence is not biochemical in origin but contains a learning cycle of achieving optimal levels of functioning while intoxicated. Stimulant properties of high alcohol consumption, for example, may enable socially heroic, gregarious, or flirtatious behaviors in people who are introverts when sober. Withdrawal effects occur due to abrupt cessation of either physical or psychological dependence. Discontinuation causes adverse cognitive, behavioral, and physiological changes due to the decline of blood and tissue concentrations and musculoskeletal constrictions and dilations.

Withdrawal symptoms for alcohol, in particular, are classified as delirium tremens (DTs) because characteristic signs of delirium (e.g., hallucinations, delusions, and autonomic hyperactivity) are present.

1.1. Dependence versus Abuse

Drug dependence differs from drug abuse in three ways. First, drug dependence consists of clearly measurable periods of tolerance and withdrawal, whereas drug abuse sets the occasion for tolerance and withdrawal. Abuse means there exist early warning signs of life impairment predictive of physical and psychological dependence. Adults arrested for driving under the influence of alcohol, for instance, often face fears that their uncontrolled drinking may result in fatal vehicular accidents. Second, drug-dependent users show marked cognitive, behavioral, and psychomotor retardation in their daily activities. Drug abusers, however, may or may not suffer apparent cognitive, behavioral, or psychomotor malfunctioning; they may mask intoxication symptoms by performing their jobs and vehicular operations adequately and interacting normally with their families. Third, the phenomenon of withdrawal syndrome applies only to drug dependence. Drug abusers are episodic and not routine users, and their consumptive rates are variable; intermittent and lesser quantity users build resistance to adverse cognitive and visceral repercussions and only suffer mild or no side effects after abrupt cessation of desired substances.

1.2. Primary Types of Drug Dependence

The *Diagnostic and Statistical Manual of Mental Disorders* (fourth edition, text revision) nosology of drug dependence cites 11 subclassifications of substances: cannabis, opioids, nicotine, phencyclidine, sedative-hypnotics, alcohol, amphetamines, caffeine, cocaine, hallucinogens, and inhalants. Ingested routes of administration vary for each substance type, as do the dependent and withdrawal symptoms. For cannabis, oral or inhalant routes of intake of the psychoactive component tetrahydrocannabinol (THC) produce sedation, mild euphoria, and altered perception of time and sensations. Effects arise as the drug attacks the nerve cells in the brain and alters their function. Physical withdrawal effects are significant, despite the popular opinion that there are none, and include irritability, anger, depressed mood, headaches, and

restlessness. Similarly, psychological effects include anxiety, paranoia, hypersensitivity, and overeating.

Opioids, whether synthetics (e.g., Vicadon), semisynthetics (e.g., heroin), or synthetics with morphine-like action (e.g., codeine), are orally, inhalantly, and intramuscularly infused. Effects include analgesic, anesthetic, and suppressive changes, whereas withdrawal signs include psychomotor agitation, impaired judgment, drowsiness, and, in severe cases, respiratory depression. Nicotine is absorbed orally (smoking or “chewing”) due to the rapidity of intake and high nicotine content of the substance. Stimulant and nausea-inhibitive properties of dependence counter unpleasant withdrawal effects of insomnia, irritability, anxiety, concentration erosion, agitation, and appetite suppression. Phencyclidine (PCP or angel dust) grew from medical anesthetics in the 1950s to one of today’s street drugs, producing sedative and disinhibitive effects when taken orally or intravenously. Withdrawal effects are uncertain, but stages of dependence result in rage, violence, and bizarre personality defects. Sedative-hypnotics similarly alter mood, judgment, and sexual functioning. Short-acting sedative-hypnotics (e.g., diazepam) may incur weak withdrawal effects, whereas longer acting agents cause autonomic hyperactivity, hand tremors, insomnia, anxiety, and often nausea.

Alcohol dependence depresses the central nervous system (CNS). However, to many, mild sedation under low doses is perceived as excitatory, not inhibitory. At advanced or chronic stages, there is damage to the neural pathways associated with liver failure, pneumonia, hallucinations, delusions, or head trauma. One collateral disease, Korsakoff’s syndrome, arises from a thiamin deficiency from injury to the thalamus. In withdrawal, sudden termination of high alcohol intake levels can be devastating, producing an acute state of depression, convulsive seizures, nausea, agitation, and DTs.

Amphetamine dependence is bioequivalent to cocaine dependence. Both activate the CNS and generate intense but temporary anxiety, paranoia, and hypermania concurrent with aggressive, violent, or psychotic behaviors. Reversal of neuralgic arousal occurs in withdrawal phases, including lassitude, depression, weight loss, nightmares, and psychomotor retardation. Similarly, caffeine—the central ingredient in coffee, tea, colas, and most over-the-counter analgesics—ubiquitously tempts physical and psychological dependence. Substance-induced effects range from autonomic arousal and appetite suppression to inexhaustibility. Heavy doses of caffeine in excess of two or three cups of coffee daily result in restlessness, anxiety, insomnia, diuresis,

rambling speech, agitation, and possibly gastrointestinal disturbance. Eliminating caffeine “cold turkey” initiates symptoms of fatigue, anxiety, depression, or even nausea.

Unlike caffeine, hallucinogens atypically develop into physical dependence, whereas users may psychologically depend on hallucinogens for euphoric and psychedelic effects; consequently, cross-tolerance frequently exists with LSD, psilocybin, and mescaline. After stopping use, the long-acting effects of hallucinogens produce residual cravings and even persistent perception disorders or “flashbacks,” a symptom commonly found during overuse or intoxication. Inhalants, too, are mood-altering, psychoactive compounds. These volatile substances, which contain esters, ketones, glycols, and halogenated hydrocarbons (found, for example, in spray-can propellants and cleaner solutions), produce inhalable vapors absorbed orally or by olfaction, reaching the lungs, bloodstream, and neural sites very quickly. Opposite effects manifest during withdrawal, including irritability, sleep disturbances, tremors, and diaphoresis.

1.3. Medication Mismanagement

Drug dependence is not always a result of teen or adult street-addictive habits. Medicines prescribed by family physicians and psychiatrists for mental health illnesses, and used appropriately at first by consumers, may be mismanaged accidentally. For example, the cerebral stimulant Ritalin, given to children with attention deficit hyperactivity disorder, requires parents to be regimen conscience. Self-administering of pain killers (Darvocet and Vicodin) also requires adherence to a rigid timetable to prevent lethal intoxication. Despite copious compliance, mistakes do occur in caretaker-administered or self-administered doses, which cause physical tolerance. The five common medication mistakes observed in clients are overuse, underuse, erratic use, contraindicated use, and abuse. Overuse is mistakenly taking several doses of a medication or taking the medication when it is not needed. Underuse includes both failures to fill prescriptions and forgetting to take the medication. Signs of underuse are the clients taking fewer doses than instructed to make the medication last longer or discontinuing use earlier than directed. Erratic use refers to the failure to follow physician or pharmacy instructions. This includes missing doses, taking double doses, taking doses at the wrong time, and confusion regarding which drug to take at which interval. Contraindicated use

occurs due to incorrect storage of medications, using outdated drugs, or not monitoring side effects. Errors in judgment pose higher physiological risks when clients unknowingly mix psychotropics with nonpsychotropic medicaments, such as anti-inflammatories, antihypertensives, or diuretics. The last maljudgment, that of abuse, is the intentional misuse of a drug for its secondary or tertiary properties either to hurt or help oneself. Suicidal patients overusing Tylenol with codeine may exceed the recommended dose and abuse the purpose of its analgesic properties.

1.4. Routes of Administration Accelerating Addiction

Substances ingested into the body pass through three stages before they are excreted: absorption, transmission, and metabolism. All these stages enable drugs to accelerate or decelerate through the bloodstream to the site of action. The speed with which drugs reach the site of action, called the fate of drugs, depends on how drugs enter the body or the route of administration. The three routes pertinent to drug dependence are oral, inhalation (nasal), and intramuscular. Orally taken drugs dissolve in the stomach and pass into the bloodstream through the stomach or small intestine. Solid drugs (pills and capsules) diffuse slower than liquid drugs but trigger desired effects rapidly. Inhaled drugs such as (powdered) cocaine enter the bloodstream through membranes lining the nose. The magnitude of peak effect is very fast but short in duration before excretion occurs. Consequently, abusers quickly establish a high tolerance, vigorously trying to replicate euphoric sensations they had during their first inhalant experience. By far the most accelerated drug passage to the bloodstream is intramuscularly (intravenously). Despite the obvious perils of unsanitary needles, abusers prefer injection because it bypasses the filtering process through different organs, which could retard onset of effect. Instead, the stimulated site of action is powerfully immediate, and equally brief, triggering higher and repeated injection doses for sustained pleasure.

2. CONTINGENCIES OF DEPENDENCE

The genesis of drug dependence is only partly physiological. Although drug tolerance builds body

resistance, tempting larger doses for desired effects, abusers shape their ritual habits through predictable phases of environment–behavior interactions. These phases, called contingencies, describe a unique learning relationship that the drug-using person has with his or her surroundings. Early teenage recreational use of alcohol or drugs, for example, may occur alone or with friends; this is called the setting. The teenager's disposition during these occasions is known as the set. Set and setting qualify abstractly as the place and individual emotions predisposing mild, moderate, or heavy substance use.

However, in every setting lies events. Events describe more operationally the context of settings, such as who is present, what they are doing, the time of day, and whether they are influential on the abuser. Events also name behaviors endemic to the abuser, such as deprivation and satiation levels (e.g., thirsty, hungry, full, high, and fatigued), sensory status (aroused, depressed, in pain, angry, and happy), and thoughts or expectations about the setting (plans to drink, abuse drugs, and sell drugs). Connections between setting events and behaviors create a special interdependence whereby as setting events change, they covary with changes in behaviors. In this way, settings events function like stimuli triggering not just one response but many responses in a response class. For example, meta-amphetamine (crystal) abusers may buy and use the drug at a nightclub and dance with friends who also use. Drug use and dancing with friends constitute the response class. However, setting events also demarcate drug use from drug nonuse behaviors. The crystal abuser may only engage in the drug when dancing but not when he or she is alone at home and not dancing.

2.1. Types of Drug Response Classes Conditioned

Differentially learning drug habits under different settings is the result of conditioning. Conditioning means that the outcome of drug use under one setting is reinforcing and under another setting is either neutral or aversive. Simply stated, crystal abusers enjoy themselves more when they are dancing at bars rather than getting high at home. At home, the effects of crystal are benign or stagnant (neutral), or withdrawal effects may cause depression (punishment). Condition outcomes vary by another property—the response class. Responses from buying the drug or alcohol to multiple consumptions of it span a series of separate

response units held together in one of two ways. Think of a constellation of stars strung together by a common link. As one star changes, it produces specific or broad effects on surrounding stars. First, response units can be concurrent. This means two or more response units occur simultaneously rather than in a linear fashion. Crystal use may accompany respiratory elevation, muscular contractions, glandular secretions, heightened sexual arousal, speech amplification, and accelerated dancing movements. Second, response units may be sequential. Here, responses occur logically in a row like a domino effect. As one response appears, it predictably evokes the serialization of several more responses coordinated in order. After using crystal, abusers know they will perform better dance steps or feel heroically uninhibitive to flirt with the opposite sex. Response classes, either sequential or concurrent, are powerful in building drug dependence when they produce outcomes or “consequences” immediately reinforcing the final (terminal) response in a response class. When terminal responses produce aversive consequences, such as when the crystal abuser vomits violently or is robbed, drug dependence may diminish only for a short time. Drug habits regenerate rapidly because the physical cravings for the drug reactivate the same response class or a variation of the response class.

2.2. Topography and Function of Drug Response Classes

Response classes include the topography and function of behaviors. These indices measure behavior, purpose, and configurations predictive of whether drug abusers will increase or decrease consumption rates. Topography describes (i) how often the person abuses drugs (frequency), (ii) the response class (simultaneous, concurrent, etc.), (iii) how long the response class occurs (duration), and (iv) how the effects of the responses on others (magnitude). Function describes the consequences produced by the response class (reinforcing, punishing, or neutral) and whether other setting event variables interact with the response class to accelerate or decelerate occurrences. For example, topography indicates that a crystal abuser goes to a bar twice weekly, stays there for 4 h, dances with five partners, and gets irritable and aggressive toward uncooperative partners later in the evening. A functional explanation of the response class indicates that the crystal abuser dances elegantly by midevening, receives countless praise from admirers including the

partners toward whom he later makes sexual advances, and usually generates business from those wanting to learn to dance from him. In other words, functionally, drug dependence for this crystal abuser recurs partly from physical tolerance and largely from conditioned reinforcement outcomes of his drug response class.

2.3. Avoidance and Escape Effects of Drug Response Classes

Reinforcement contingencies may increase a response class by enhancing the pleasure for drug abusers, as in the case of the crystal user described previously. Reinforcement contingencies may also be effective by removing displeasure (aversive consequences) for the user. Nicotine-dependent users, for example, may smoke cigarettes both to prevent or delay fatigue onset when staying up late and to eliminate anxiety produced by daily stressors. In the first case, nicotine functionally serves to avoid aversive consequences, whereas in the second case nicotine acts as a catalyst to remove, terminate, or escape from aversive consequences. Avoidance and escape patterns become viciously intertwined in the matrix of drug response classes and account for exacerbation of physical tolerance and resistance to withdrawal effects. For example, a three-pack-a-day cigarette smoker quit (escaped) a smoking-cessation program because the withdrawal effects reminded him of the chronic anxiety suffered during his traumatic, physically abusive childhood. He used to feel nervous when battered by his mother, and the same body sensations reemerged (without him being battered) during nicotine withdrawal. Another smoker sharply increased the number of cigarettes used from 10 to 20 per day to delay (avoid) confronting his spouse about divorce. In both cases, elevated nicotine consumption proportionally correlated with avoidance and escape patterns.

2.4. Susceptibility to Drug-Dependent Response Patterns

Response classes are like an immune system. Tightly connected or interdependent responses are resilient against delays of desired drug effects, withdrawal effects, or disruptions in the response class, such as when an alcoholic runs out of beer or cannot buy more because the local stores are closed. Response classes resist extinction and the drug abuser can freely adapt without suffering withdrawal effects. In contrast, weak

responses that are poorly interlinked become vulnerable to deterioration, which puts the abuser at risk of suffering withdrawal effects. Two properties of behavior causing susceptibility to degenerative drug response classes are deficits and excesses. Deficits consist of underdeveloped and immature responses falling below the social norm for adults or children and forcing abusers to expend extra effort to keep up with other people. Adults paralyzed by interpersonal deficits may be unassertive, shy, introverted, and awkward in social situations. They may drink several beers or smoke several joints (cannabis) to overcome their psychosocial deficits. However, deficiencies masked by polydrug dependence remain detrimental to abusers because their response class cannot withstand even the slightest disruptions. Two missed days of not smoking marijuana or one less beer consumed than normal may damage the response class and trigger physiological withdrawal. With excesses, the abuser overdoes responses. Excesses consist of abundant and obsessive behaviors aberrantly beyond the social norm and causing repulsion for onlookers. Compulsive exercisers, competitive athletes, academic overachievers, and perfectionists arouse constant excitement in their bodies. Excesses may be intensified or deintensified by drug dependence, but in either case the response class is fragile and susceptible to penetration. The mildest interruption of excessive behaviors (e.g., brought on by delayed access to the drug) can throw the drug abuser into a panic.

2.5. Effects of Titration on Drug Response Class

One way that drug abusers with excessive and deficient response classes protract against involuntary detoxification is by a process called titration. Titration can be controlled through medical prescription or haphazardly induced by desperate abusers. Titration consists of phasing out one drug while replacing it systematically with another drug, bioequivalently calculated to avoid withdrawal effects. Heroin (opiate synthetic) addicts traditionally taper off addictive levels through a regulated dose of a physician-prescribed drug called methadone, which is also a synthetic opiate but chemically purified to ease the abuser through stages of drug reduction. Nonprescriptive practices of titration are dangerous but common. Cocaine-dependent users may consume alcohol to offset adverse side effects of “coming down from cocaine.” Consequently, the

ethanol supplement builds a tolerance in the abuser's body, eventually replacing the cocaine when cocaine supply becomes too costly or is inaccessible. Alcohol, functionally, offers risk-reduction effects for the cocaine abuser, but it does not replace the desired effects of cocaine.

When titration serves to transition one desired-effect drug to another desired-effect drug, similar to replacing heroin with methadone, the result is a substitutive effect. Substitutes occur intentionally and unintentionally. Intentional substitutes describe the cannabis abuser who abstains from marijuana to avoid THC detection on job-related random urinalyses; instead, he or she begins regular intake of two or three glasses of vodka per night to remain calm. Unintentional substitute abusers may overestimate their recovery confidence once they abstain from "bad" drugs for a period of time. Sober alcoholics, for example ("dry drunks"), may innocently consume 5–10 cups of coffee (caffeine elevation) per day, oblivious to the outcome. They may spontaneously regenerate the climax of sensory arousal previously achieved through alcohol. Renewal of these accelerated sensations (through coffee) rapidly restores body tolerance levels and makes the abuser unknowingly prone to alcohol relapse. Another common substitute misused by nondrinking alcoholics is ingestion of sweets (e.g., candy and pastries). Here, the sugar compound in sweets is bioequivalent to the sugar composition of ethanol, the deadliest antagonist to the body, causing cirrhosis. Reemergence of physical dependence on sugar, the powerful ingredient in ethanol, can swiftly sabotage sobriety by tempting nondrinkers to reconsume alcohol for satisfaction of the sugar craving.

3. FAMILY REASONS FOR RECIDIVISM

Erosion of recovery from drug dependence occurs for many reasons. The causes of recidivism range from cue-induced cravings triggered by drug substitutes and drug-using settings to unsupportive family members. The latter represents an unusual paradox in substance abuse rehabilitation because, in the spirit of change, therapists assume the victimized family welcomes abstinent members. After all, strategic planning and confrontation of the drug-abusing member by key family members probably precipitated treatment. With disunity of the family threatened, abusers are told they

must receive therapy, submit to medication blockers (disulfiram, CB-1, naltrexone, methadone, etc.), or, if they refuse either of these choices, be legally or morally expelled from the family system. Ironically, compliant abusers who undergo the treatment and return to family members as caring, loving, and sober are greeted with consternation and resistance. Family members are unfamiliar with the reformed abuser's strangely alien personality and become dubious that the recovery will last. Healthy nondrug members also threaten the family equilibrium; a recovering member invokes positive and negative changes on other family members, challenging routines, rituals, traditions, and habits sanctioned for years and possibly underlying the main reason why the target member began abusing drugs. Uncertainty, skepticism, and fear become destructive agents in slowly unraveling the abstainer's confidence. Consequently, families become instigators of drug relapse in four ways, as discussed in the following sections.

3.1. Family Distrust

Distrust guards against repeated emotional and even physical injury in an unforgiving family environment. Family members who are uncertain when they will witness the next mood swing, aggressive outburst, or odd behavior of the abstainer are suspicious of every unexplained reaction. Self-defensively, family members such as children, a partner, or a spouse discredit proof of sobriety and question signs of progress. This interrogatory phase controls chaos in the family by preventing ignorance and blind faith—both of which were betrayed by abusers. Family members believe that by policing the abuser, they can monitor stability and instability of behavior and emotions and be alert to problems causing relapse. Abusers, however, object to this surveillance. They regard the distrusting family as coercive, suffocating, aggressive, and deliberately undermining their therapeutic program for recovery.

3.2. Family Protectiveness

Overtrusting may also produce untoward effects during recovery. As cohesion grows by abstainer and family members mending their wounds, the family supply of compassion goes into overdrive. Members feel compelled to help the abstainer reach recovery goals and be a productive contributor within the family. The intensity of help doubles when members fear drug recidivism and its intolerable effects on the family. They may spare the abstainer of major decision

making, financial responsibilities, and household chores and compare the drug recovery period to recuperation from surgery. Just as stitches may reopen, so it is that emotional stitches sewn together by a loose thread are perceived as fragile. The family caters to the abstainer's needs and places the recovery process on a pedestal. Caretaking, the term frequently applied to this altruism, mistakenly signals love and respect for the abstainer. The drawback of caretaking involves treating the abstainer as inactive. However, the abstainers must be active participants in altering family interactions using techniques that replace their drug abusive or dysfunctional behaviors. When families shower abstainers with unconditional nurturance, preventing natural opportunities for change, abstainers feel defeated, ineffective, and regress to pretreatment patterns.

3.3. Newly Surfaced Resentment

Family member anger kept repressed during years of the abstainer's drug dependence may surface unexpectedly when the abstainer first returns from inpatient rehabilitation or enters outpatient treatment. Previously inhibitive children, for example, may declare their resentment as victims of the abstainer's long-standing reign of terror. Embittered spouses may confess their infidelities, express thoughts of divorce, and lambaste abstainers for ruining precious years of their lives. Catharsis explodes by unloading a Pandora's box full of hatred against the abstainer with the hope of inciting debilitating guilt. Instead of shame, abstainers perceive this emotional release as a terrorist attack aimed intentionally at detonating aggression and inducing drug relapse. Two other effects on abstainers are equally disastrous. First, abstainers disenfranchise from the accusatory family harboring anger and fear. They attach onto family surrogate friends—many who abuse drugs—for emotional refuge. Second, the inescapable onslaught of allegations and criticism can result in abstainers spiraling into depression. Learned helplessness develops from suppression of their motivation and skill efforts.

3.4. Recovery as Threat to Family

Observed changes in the abstainer's behavior signal a necessary family adjustment in ways that are uncomfortable and thus avoided. Spouses, for example, are not accustomed to communicating with a healthy, sober spouse and thus resist talking. Children who never received verbal or nonverbal affection now rebuff hugs, kisses, money, or gifts given unconditionally by

abstainers. Displays of love and family involvement frighten members away from the abstainer, causing the family to aggressively resent this improvement. Resistance arises when the family must engage in behaviors about which they are ignorant, have deficits, or have incompatible behaviors.

Consider affection. Instructions of therapy may inspire a wife who is a drug recoverer to be more sensual and receptive to sex. Surfacely, her romantic advances toward her husband may be what her husband always wanted. However, after years of sexual denials, emasculative teasing, and erectile inhibitions, he finds his wife's sexual overtures repulsive. He also developed alternative sexual relief outlets, such as frequent masturbation, cybersex with chat-session partners, visitation to topless bars, and flirtation at work. Consequently, his ritual of incompatible sexual behaviors is so reinforcing that the husband refuses his abstainer wife's passion and enrages her into feeling rejected and abandoned. Angered abstainers surmising their efforts are in vein may rebel against the uncooperative family members and gradually cease the recovery goals.

4. CONCLUSION

Conceptually, drug dependence is higher on the physiological and psychological continuum of pathology than drug abuse. Tolerance forms when continuous drug ingestion increases body absorption, digestion, and excretion, all directly connected to body weight, age, set and setting, gender, race, body disease, diet, personality, and history of cross-addiction. Abrupt cessation of the drug causes immediate cognitive, emotional, and biochemical changes in the body defining withdrawal symptoms. Because drug use and nonuse habits are muticausal, variables influencing high-rate or low-rate use include routes of administration and the unique relationship drug behavior shares with the environment. Under reinforcing environments, for example, drug consumption rates increase depending on the pattern or response class of drug habits. Topographically, patterns composed of sequential or concurrent responses bond together tightly and resist extinction even when the drug abuser stops misusing the drug. Patterns of eating, sleeping, avoidance (and escape) rituals, and social routines that persist can still trigger cues inducing cravings, especially if the abuser replaces the drug with substitute compounds or titration or returns to settings that were conducive to drug use. Altering this response class thus represents the first goal of therapy, combined

with controlling the withdrawal symptoms. Moreover, conscientious therapists recognize that abuser recovery is not unilateral, wherein only the abstainer gets healthy. Instead, abuser recovery is bilateral, affecting a two-way exchange between family and abstainer. For this reason, barriers of family resistance against a reformed abuser, including distrust, protectiveness, resentment, and change, all must be addressed early in treatment to prevent hazards of drug recidivism.

GLOSSARY

basal metabolic rate The daily energy requirements for the body to perform its basic functions, expressed in terms of number of calories.

body mass index (BMI) An estimate of body fat or degree of obesity ($BMI = kg/m^2$).

dieting The attempt to limit food intake in terms of amount or type of food for the purpose of weight control or restrained eating.

food neophobia A fear of trying new or novel foods.

satiety The feeling of fullness after eating.

set point An internal sensor of body fat to which metabolic processes will respond to achieve a balance of energy input and expenditure so as to defend a specific weight range for an individual.

Eating is a complex human behavior that is influenced by cultural, social, personality, and biological factors. Dieting, obesity, and overeating all are important social and health problems within applied psychology. The

absence of demonstrably successful weight loss programs, as well as controversy over the supposed health benefits of weight loss in the long term, casts doubt on the popular notion that dieting makes people healthier.

1. INTRODUCTION

One might think that a behavior so essential to our survival as eating would be fully explained through biology. It might seem that, like other essential behaviors such as sleeping and breathing, one could neatly explain the physiological mechanisms at work just before we put food into our mouths. However, decades of research into the biological mechanisms involved in eating have produced rather disappointing results. It seems that humans just do not do a very good job of eating in accordance with verifiable hunger and satiety cues. The biological perspective of eating posits that we should eat when our metabolic energy fuels are expended. However, one problem with this explanation of eating behavior is that humans often report feeling "hunger" despite ample energy stores in the form of body fat. Furthermore, most of us eat much more food than we require to remain alive. Another problem with the biological explanation of eating is that overall blood glucose levels (another index of metabolic energy) do not correspond well with reported hunger or (again) eating behavior. Finally, the hormone and neurotransmitter involvement in

hunger and eating is especially complex and not yet completely understood, with several hormones potentially involved (e.g., leptin, insulin, ghrelin, cholecystokinin). Rather than being determined by iatrogenic biological markers, humans' eating behavior seems to be largely determined by factors outside the individual. This article examines the psychology of eating and attempts to answer the question of why we generally tend not to eat according to hunger and fullness. Culture and environment, sensory factors, social factors, and even personality can influence food choice and eating behavior, and all of these factors take us further away from eating according to our internal hunger and satiety cues. The article also examines the problems of eating too much and obesity as well as what applied psychology can tell us about the solutions to these complex health problems.

2. CULTURAL AND ENVIRONMENTAL INFLUENCES ON FOOD SELECTION

In general, our diets are made up of what is readily available for us to eat. To a large extent, our culture decides for us the type of food we can eat as well as the portion sizes we consider to be normative. In brief, we tend to eat what is put in front of us. For instance, the North American diet, replete with an overabundance of saturated fats and larger portion sizes as compared with its international counterparts, can at least partially explain North America's relatively high obesity rates. Experimental studies have confirmed that the more we are served, the more we eat.

Humans and animals alike experience food neophobia, that is, an intrinsic fear of trying new or novel foods. This fear is believed to serve a protective function in that it dissuades us from eating foods with which we are not familiar and that might not be safe. Factors that have been shown to increase food neophobia include knowledge that the food is of animal origin as well as trait and state anxiety. Factors that decrease our unwillingness to try new foods include modeling by others trying the new food, information about the nutritional value of the food, information about the good taste of the food, and mere exposure to the food.

In addition to the role of culture in determining our diets, personal learning experience dictates which foods we will and will not tend to include in our diets. Negative food associations are formed quite

readily. For example, a single episode of upper gastrointestinal illness (i.e., vomiting) after eating a particular food can be enough to produce a strong and resilient conditioned taste aversion. Presumably, this aversion has a protective function by keeping us away from a food that may make us sick again and endanger our health. Interestingly, illness after ingesting foods of animal origin is more likely to lead to the development of a conditioned taste aversion than is illness after eating fruits, grains, or vegetables.

Sensory qualities of foods themselves may override our bodies' hunger and satiety cues, resulting in our eating either more or less of the foods. For instance, we generally eat more as a function of the variety of foods we are offered, with total food intake increasing with greater variety. Even variety in the texture of a single type of food we are offered (e.g., different pasta shapes, ice cream vs milkshake) can increase our total food intake as compared with the presentation of a single texture of that food alone. The taste of a food also moderates our desire to eat more or less of it. Foods that are high in sugar and fat are intrinsically more appealing to the human palate, so it is not surprising that we are more likely to consume more of these foods when we are given the opportunity. According to the evolutionary perspective, this preference for sweet and fatty foods is due to those foods' scarcity during the hunting-and-gathering phase of human evolution and their energy content per gram of food as compared with foods high in protein. We can also lose our appetite for eating a specific food, a phenomenon known as sensory specific satiety, but then begin eating again when a new food is introduced. Most of us have experienced a resurgence of appetite for dessert, despite feeling full after finishing dinner. It is as though our bodies "get bored" of a particular food or taste after a while, prompting us to seek out more variety in our diets. This effect would presumably have a positive impact on our health by increasing the number of nutrients in our system.

Despite the cultural variations in cuisine and food selection, research has shown that humans are generally good at self-selecting a nutritionally balanced diet—at least they are as children. In a classic series of studies by Davis, human toddlers were offered a "buffet-style" meal plan and were allowed to choose the type and amount of food they ate. Her results showed that the toddlers self-selected foods that together made up a nutritionally balanced diet and resulted in a normal and stable pattern of weight regulation.

3. SOCIAL INFLUENCES ON EATING BEHAVIOR

Although we may start out with an intrinsic appetite for foods that will maximize our chances of being healthy as well as a general reliance on internal hunger and fullness cues, as we grow, our eating is more likely to be influenced by non-nutrient-related variables. One social factor affecting how much we eat is the number of people who are present in a given situation. We generally eat more as a power function of the number of people present. One proposed explanation for this social facilitation of eating behavior is related to competition for food resources; that is, we do not want to lose out on the opportunity to eat by letting our companions get to the food first. Another explanation is that the mere presence of people may provide distraction from our satiety cues. Of course, in real life, the presence of eating companions is often confounded by other factors that stimulate eating such as the variety and quantity of foods available (e.g., the “dinner party” effect). There is some evidence that the relationship between people who are eating together also moderates this social facilitation effect; that is, we are more likely to eat dessert when our eating companions are friends than when they are strangers. This suggests that the presence of others, particularly others with whom we are socially close, reduces inhibitions around eating. Interestingly, the idea that we eat more with more people present does not appear to hold true for obese and dieting individuals, who actually eat less when eating with others and are prone to splurge when eating alone. Presumably, for these individuals, an impression management motive—the desire to present themselves to others as being small eaters—overrides the effect of social facilitation of eating.

In addition to the mere presence of other individuals, the eating behavior of those individuals affects our own eating behavior. Modeling by others has a strong influence on eating behavior in that individuals tend to match the amount eaten by those with whom they are eating. For instance, even when we are very hungry, we will tend to match a small amount eaten by our companions.

4. THE ROLE OF PERSONALITY IN EATING BEHAVIOR

Personality also influences diet and eating behavior. The goal of weight loss or weight maintenance is the most common reason for efforts to control one’s eating.

Herman and Polivy’s “restraint theory” of eating behavior emphasizes the importance of chronic attempts at dieting as a predictor of food intake and has been very influential in the study of eating behavior. In research studies, restrained eaters (or chronic dieters) have been shown to demonstrate several differences with respect to their eating as compared with their unrestrained eating counterparts. Psychologically, restrained eaters exhibit higher body dissatisfaction, lower self-esteem, and a higher drive for thinness. Although dieters’ eating can be characterized essentially as an attempt to reduce energy intake (calories, fat, and/or portion size), they are especially prone to overeating. Laboratory studies of eating often employ a taste test methodology to demonstrate this effect. Participants are allowed to ad lib eat as part of an ostensible taste test during which they rate the different taste properties of the food (e.g., sweetness, saltiness). Their total food intake is measured by subtracting the weight of the plate(s) (or, in some cases, counting the number of food items eaten such as candies) after the experiment from the preexperiment weight. Sometimes, participants are given a “preload” or snack to eat before the taste test, and they are typically exposed to an independent variable of interest before the eating task. Disinhibited eating or overeating among dieters has been demonstrated to occur in response to ingestion of a high-calorie preload (e.g., milkshake, chocolate bar), stress, perceived weight gain, food cues, lowered mood, positive mood, exposure to thin media images, and even anticipated future overeating. With all of these and more potentially disinhibiting factors, it is not surprising that studies have shown that dieters tend to eat more overall, and also weigh more, than do nondieters. As noted previously, humans are inclined to select foods based on their sensory qualities. Obese and dieting individuals are particularly dependent on external and sensory cues in deciding how much of a food to eat, showing a heightened preference for good-tasting food over that of their normal-weight or nondieting counterparts.

Herman and Polivy’s “boundary model” of overeating posits that restrained eaters have a cognitively determined “diet boundary” that exists before the experience of satiety. This boundary represents what a dieter believes he or she should eat. Under normal conditions, food intake is expected to remain within the limits set by the diet boundary. However, once eating has surpassed the boundary limit (e.g., by ingesting a high-calorie preload such as a milkshake), eating will continue until eventual fullness is achieved. Herman

and Polivy labeled this event the “what the hell” effect; given that the dieter’s self-imposed diet boundary has already been surpassed, the dieter continues to eat until satiety and sometimes even beyond. Therefore, intended eating behavior for restrained eaters is cognitively determined by perceptions of what should be eaten in terms of type or quantity of food. In contrast, unrestrained eating is relatively more determined by an awareness of hunger or satiety cues.

5. SET POINT MODEL OF WEIGHT REGULATION

There is solid evidence for a genetic factor in body weight determination. In terms of weight, adopted children tend to resemble their biological parents more than they do their adoptive parents. Identical twins, even when reared apart, are more similar in terms of weight than are fraternal twins or siblings. These examples suggest that genetics plays a role in determining one’s “set point,” that is, a type of internal sensor around which weight is regulated. When fat levels fall below this set point, the body responds by slowing metabolic processes so as to require fewer calories, thereby making the body more efficient in its energy expenditures and fighting against the depletion of fat stores. Keys and colleagues demonstrated this scenario in an experimental study of human semistarvation during World War II. Participants in the study were young men who agreed to lose 25% of their body weights for the study for the purpose of determining the best way in which to refeed starving people in war-torn Europe. On rations of 50% of their original daily caloric intake, the men initially lost weight quickly. However, over the 6-month starvation phase of the experiment, the men’s rate of weight loss reached a plateau, with many participants’ rations needing to be cut even further to achieve the desired weight loss. Keys’s starving participants exhibited a number of symptoms characteristic of the body’s corrective action of falling below its normal weight (and, presumably, below its set point in this initially nondieting sample). The men became irritable, miserable, hungry, and obsessed with thoughts of food. Their basal metabolic rates decreased significantly, indicating their bodies’ desire to conserve as many calories as possible. They became apathetic and lethargic, avoiding as much physical activity and energy expenditure as possible. They had very strong urges to overeat, and when they

were allowed to eat during the refeeding phase of the experiment, they overate and demonstrated a preference for high-calorie foods that would increase their fat stores most quickly, a situation that is consistent with the predictions of set point theory.

In another study of the effects of overeating that also found evidence supporting the set point theory, Sims and colleagues recruited prison inmate volunteers to gain 25% of their body weights as part of an experiment. The men’s food intake was increased, and their physical activity was decreased and controlled. At first, the volunteers gained weight easily, but the rate of weight gain soon slowed and their daily caloric intake had to be increased for them to continue gaining. One man did not reach his goal weight even though he consumed more than 10,000 calories per day. Once the men reached their goal weights, the men continued to require extra calories to maintain their higher than normal weights. During the experiment, these volunteers began to be repulsed by food and had to force themselves to eat. Many considered dropping out of the study due to the discomfort of overeating. Physical responses included an increased basal metabolic rate and profuse sweating, indications that their bodies were eliminating the excess calories they were ingesting. After the experiment, there were differences in how quickly the men returned to their preexperiment weights, with two participants (both with family histories of obesity) never reaching their original weights.

In sum, there is evidence that our body weights and shapes have a genetic component, but changes in eating behavior, hormones, or other variables can also produce weight gain or loss. Because of this apparent contradiction, some researchers have abandoned the set point theory of weight regulation in favor of a “settling zone” alternative. In 2002, Levitsky argued that within the biologically determined range or zone of body weight, actual body composition may “settle” at a value determined by behavior. Furthermore, the width of one’s settling zone may also depend on individual factors such that some individuals will naturally experience greater weight fluctuations over time than will others.

6. OBESITY AND THE PROBLEM OF EATING TOO MUCH

Although genetics can predispose individuals to higher than average weights, there is no doubt that overeating can contribute to obesity. Because of societal pressure

to be thin and the stigma against overweight persons in many parts of the world, the obese and dieting populations overlap considerably. Therefore, many of the disinhibiting factors discussed in the preceding section operate regularly on the eating behavior of obese persons, leading to frequent episodes of overeating. In the preceding section, it was pointed out that overeating can occur beyond the point of satiety and until stomach capacity is eventually reached. Binge eating consists of eating episodes that involve consuming large quantities of food (e.g., twice a normal serving) combined with a feeling of being out of control. For binge eaters, food intake may continue until they reach capacity, and there is never really a sense of feeling as if they have eaten enough to satisfy their hunger. Binge eating combined with compensatory behaviors, such as self-induced vomiting, excessive exercise, extreme food restriction, and laxative abuse, is the hallmark of bulimia nervosa, an eating disorder. "Binge eating disorder," although not currently a formal diagnostic category, is characterized by regular binge eating episodes without attempts at compensation and is estimated to be highly prevalent in the obese population.

There is little consensus on the technical definition of obesity. Traditionally, charts that provide normal weight ranges for various heights and body frame sizes were the standard tool for determining normal weight and overweight. These charts were originally published by the Metropolitan Life Insurance Company in 1959, were based on associated mortality rates, and have undergone revisions during more recent years. Another method that gained popularity during the 1990s is the body mass index (BMI), which is defined as $BMI = \text{kg}/\text{m}^2$. A BMI of 20 to 25 is considered to be medically ideal, and obesity is defined as a BMI of 30 or more. However, unlike the Metropolitan Life Insurance charts, BMI does not take into account gender, age, or body frame. Body fat distribution can be estimated through one's hip-to-waist ratio. A low hip-to-waist ratio indicates that the person is carrying fat around their midsection, whereas a high hip-to-waist ratio indicates a relatively small waist and larger hips. The skinfold technique measures the thickness of a pinch of skin, usually under the upper arm. Despite the convenience and low cost of all these techniques, none of them is very accurate at measuring body fat. The most accurate method for assessing body fat is the water displacement method, whereby the individual is immersed in a tank of water and the displaced amount of water is measured. Obviously, this method has its practical drawbacks.

Obesity is unquestionably socially undesirable in many cultures today. But is it actually unhealthy? Unfortunately, the research is unclear as to how much weight gain is associated with increased health risks such as hypertension and cardiovascular disease. Being obese ($BMI > 30$) has reliably been shown to put people at a significantly elevated risk for all-cause morbidity, premature death, type 2 diabetes, gallbladder disease, high blood pressure, sleep apnea, respiratory problems, liver disease, osteoarthritis, reproductive problems (in women), and colon cancer. However, those in the overweight category ($25 < BMI < 30$) might not experience much more risk than do those in the normal weight range. Furthermore, weight loss itself can be a health risk for some. Most experts agree that there is a U-shaped relationship between weight and mortality and that a person's optimal weight range is uniquely determined by his or her own biology, varying with age and even ethnic background.

7. OVERCOMING OBSTACLES TO WEIGHT CONTROL

Of course, the most common method for weight loss is caloric restriction through dieting. However, most normal-weight dieters would be healthier if they did not diet at all. Dieting has psychological costs (e.g., irritability, hunger, food obsession), may be ineffective in improving health, and can worsen body dissatisfaction. Anorexia nervosa, another eating disorder, is characterized by extreme food restriction despite very low weight. The dieting of anorexics typically has a compulsive quality to it, and anorexia nervosa is routinely a difficult disorder to treat.

There are several obstacles to weight loss through dieting. A person's genetically influenced set point may be higher than his or her desired weight, and efforts at reducing caloric intake may be counterproductive and result in decreased metabolism and increased fat stores. Dieting individuals show an increased preference for restricted or forbidden foods and are more sensitive to sensory food cues, eating more good-tasting foods—foods that are also likely to be higher in sugar and/or fat content. Emotional states may lead to overeating or binge eating. Finally, calorically dense foods are all too available and convenient, leading to unbalanced food choices.

With an increasingly thin and lean physical ideal for both men and women, it is not surprising that there has been a rise in more drastic weight loss methods over recent years. All of the drastic weight loss methods are

TABLE I
Suggestions for Successful Weight Control

-
- Spread daily caloric intake evenly throughout the day. Do not skip meals.
 - Try to eat only in a regular place and at regular times.
 - Observe suggested serving sizes.
 - Avoid buffets and second helpings.
 - Eat slowly.
 - Eat in the company of others.
 - Do not read or watch television while eating.
 - Limit intake of high-calorie foods.
 - Allow for variety. Do not label any foods as “forbidden.”
 - Do not try to lose weight too quickly.
 - Find non-food-related ways in which to cope with negative emotional states.
 - Combine diet with exercise.
-

unhealthy. Extreme restriction and elimination of a food category from an individual’s diet are nutritionally ill advised. Fasting, surgery, and diet drugs have significant and sometimes fatal health risks associated with them. Even when weight loss is achieved (and regardless of the method used), weight loss is very difficult to maintain in the absence of permanent lifestyle changes and good nutritional habits.

However, despite the low success rates of weight loss methods in general, most experts agree that the way in which individuals select foods and eat can have a positive impact on their weight and health. **Table I** displays suggestions for achieving a healthy and stable weight. The goal of these behaviors is to bring one’s eating more in line with bodily cues of hunger and satiety and to try to override many of the psychological factors that can lead to overeating.

In addition to these practical ways in which to make eating more in tune with the body’s needs, cognitive factors can be modified to reduce a reliance on dieting. Specifically, there is evidence that many dieters demonstrate unrealistic expectations for weight loss. They believe that profound and positive changes will result from losing weight in terms of their success in

personal, social, and/or professional realms. In reality, weight loss rarely brings about the type of happiness that dieters anticipate. In addition, many chronic dieters demonstrate “false hope beliefs” around dieting. That is, despite numerous failed attempts in the past, these dieters believe that the next diet will surely work. Previous diet failures are frequently attributed to lack of will power or perseverance on the part of the dieters rather than to the intrinsically difficult nature of successful long-term weight loss. Not only is this belief incorrect, but it can also be demoralizing, often exacerbating the poor self-image that precedes dieting efforts.

reviews some of the main areas of interest to economic psychology, including those at the microeconomic level (e.g., consumption, investing, working) and macroeconomic level (e.g., rates of inflation, unemployment, economic growth). The convergence and deviation of economics and psychology are also discussed.

GLOSSARY

economic behavior The behavior of individuals that involves economic decisions and the causes and effects of those decisions.

macroeconomics The study of the overall levels and changes in societal economic activity.

microeconomics The study of the economic behavior of individuals and small groups.

neoclassical economics Traditional economic models that assume that agents are rational and act out of self-interest (narrowly defined).

rationality assumption The position that individuals choose alternatives that maximize expected utility.

self-interest assumption The view that individuals choose options of greatest benefit to themselves.

Economic psychology is the study of the behavior of individuals that involves economic decisions and the causes and effects of those decisions. This article

1. THE NATURE OF HUMANKIND IN ECONOMIC THEORY AND THE NEED FOR PSYCHOLOGY

One might expect that the disciplines of economics and psychology are integrated because both study behavior. Historically, however, economics and psychology have been distinct, and the few intellectual contacts between them up to 1920 were unhappy ones for economists who, like Jevons, tried to exploit psychological principles (e.g., pleasure, pain) but failed to add much to economic theories. Apart from the unhappy experiences, another reason for the disciplinary separation is that, in the interest of precision, economics has chosen mathematics as its methodology and metaphor. Notwithstanding the separation, economics has made crucial assumptions about the nature of human decision making, which is also the subject matter of psychology.

One such assumption in neoclassical economics is “rationality,” in which individuals are said to choose alternatives that maximize expected utilities. In

particular, the neoclassical view is that individuals rank all possible alternatives according to how much satisfaction they will bring and then choose the alternative that will bring the most satisfaction or utility (provided that they believe the alternative is attainable). However, psychological research has shown that people often do not choose the alternative with the greatest utility due to limited information processing capacity, motivational biases, and other psychological processes.

Examples of biases and errors in judgment constraining rationality are numerous. For instance, Simon argued that people often use cognitive heuristics, or shortcuts, to reduce the amount of information processing required for making a decision, but this may lead them to select an alternative that is merely satisfactory rather than the alternative with the highest utility (a process Simon described as “satisficing” and a form of bounded rationality). People are also known to give different weights to costs and rewards that are of the same magnitude (i.e., the opportunity cost effect). They are sensitive to framing and context, misjudge prior probabilities, and ignore sample size (i.e., the representativeness bias). They have an intransitive choice set (e.g., they might prefer $A > B$ and $B > C$ and yet they prefer $C > A$) and assign a higher value to an item once it becomes their possession (i.e., the endowment effect). Their preferences are present biased (i.e., a slight delay in gratification is perceived to be worse if the delay occurs today than if a delay of the same magnitude occurs in the distant future), as are their personal experiences (i.e., greater weight is assigned to recent experiences). Finally, individuals are sensitive to social comparisons and often judge their economic well-being in social terms rather than purely economic terms.

A second assumption in neoclassical economics, closely allied to the first, is that individuals act out of self-interest (narrowly defined). That is, people will choose the option that will give them the most. However, psychological research challenges this assumption as well. For instance, people are affected by satiation and personal considerations of fairness (e.g., when asked to split a pile of money between themselves and a stranger, many people choose a 50–50 split, whereas neoclassical economics would predict a 100–0 split).

Psychological research suggests that many individuals are unlikely to meet both the rationality and self-interest assumptions of neoclassical economics (although psychology and economics are not as far apart as is implied herein). Some economists suggest that the rationality and self-interest violations in neoclassical economics can be dealt with by redefining rationality

and interest. Other economists argue that these breaches can be ignored because individual differences and biases “wash out” at the macro level of analysis.

An alternative strategy pursued by economic psychology is to model economic behavior in a way that is psychologically realistic. In particular, economic psychology is the study of the behavior of individuals that involves economic decisions and the causes and effects of those decisions. Most decisions are economic ones in some form, making economic psychology a broad field. Many of the areas of interest to economic psychology are also key topics of research in other fields such as applied psychology, economics, sociology, and political science. This article provides a brief overview of the micro- and macroeconomic issues of interest to economic psychology.

2. MICROECONOMICS AND PSYCHOLOGY: THE BEHAVIOR OF CONSUMERS, INVESTORS, AND WORKERS

The psychological approach to microeconomics examines the behavior of individuals and small groups with regard to diverse areas such as saving, buying, investing, gambling, working, giving, and paying taxes. For instance, theories of saving suggest that people choose how much to save by considering the amount saved by a reference group, choosing a fixed percentage of their disposable income, or varying their saving and spending of savings at different stages of their life cycle. This section reviews the behavior of individuals as consumers, investors, and workers.

2.1. Consumers

Consumer behavior is one of the most extensively researched areas in microeconomics. Initially, the field was dominated by approaches based on neoclassical economics. The most fundamental of these early approaches was expected utility theory, which argued that consumers have complete information about each product, evaluate that information in a deliberate and exhaustive manner, and ultimately choose the product that has the greatest utility (subject to constraints of money, availability, etc.). Critics argued, however, that it is unrealistic to assume that consumers choose the brand with the maximum utility because, as noted previously, individuals have limited information

processing and make errors in judgment. Consumers are also unlikely to have all of the information about all brands, and the information they do have is subject to perceptual and motivation biases. For instance, one well-documented effect is that consumers place higher value on products that appear to be in short supply (a phenomenon that Brehm in 1966 explained as psychological reactance to the loss of freedom). Similarly, consumers' reference point for deciding whether the price for a product is fair is not only the absolute price, as neoclassical economics posits, but also the change in price and frame of reference (i.e., prospect theory).

Consequently, the field of consumer behavior now largely draws on psychological insights. That is, although some recent consumer decision-making models do leave room for extended rationality (e.g., expectancy value theory), other models recognize that consumers do not maximize expected utility and might simply compare brands on a single attribute (e.g., the lexicographic model). The neoclassical economic approach to consumer behavior also assumes that consumer preferences are stable and makes no mention of where consumers derive their preferences in the first place. Hence, consumer socialization and social influence are major areas of study by economic psychologists. Psychological approaches to understanding consumer behavior also investigate the roles of emotions, motivations, lifestyles, and the self-concept that have largely been absent from the neoclassical view of the consumer.

2.2. Investors

A common model in neoclassical economics for predicting how individuals make investment decisions involving risk and uncertainty is the expected utility theory, according to which the probability of an outcome is multiplied by the utility of the outcome (and is added across all outcomes). For instance, an individual deciding whether to invest in a new venture would gauge the probability of the venture's success times the financial payoff of that success. Hence, expected utility theory assumes that people objectively and rationally judge risk. In contrast, psychological research has shown that decision makers consistently over- or underestimate probabilities, interpret independent outcomes as dependent ones, and weight gains differently from losses of the same magnitude (i.e., prospect theory). Moreover, personality differences mean that individuals differ in their perceptions of

risk, in their willingness to take risks, and in their ability to delay gratification (which investing necessitates).

Social psychological processes also underpin risk taking. For instance, the "risky shift" effect, in which group discussion shifts individuals toward taking greater risk in decisions where the initial preference already favors risk, indicates clearly the transformational power of group dynamics in decisions that involve risk taking. This may help us to understand why overvalued markets continue to rise (and why undervalued markets continue to fall).

2.3. Workers

Another area of microeconomics studied by economic psychologists is how individuals behave at work. In the traditional economic view, the goal of an organization is profit maximization. On the one hand, this maximization might be achieved through a rational mathematical calculation involving the selling price, the output level, and costs such as labor, materials, and transportation. On the other hand, labor is about people and so is inherently psychological. That is, although the number of hours an employee works is prescribed by the firm, how much effort the worker exerts is dependent on psychological factors such as motivation, conditioning and reinforcement, social context, and ability.

For instance, needs-based approaches to work motivation suggest that humans have certain deeply felt needs and that each individual's motivation to perform depends on whether the specific features of the job fulfill his or her needs. A second approach to understanding the amount of effort an individual exerts at work is reinforcement theory (and other learning and conditioning principles). According to this view, effort at work is a result of reward for positive performance and/or punishment for negative performance. A third approach examines how an individual's work behavior and effort are influenced by the social context. For instance, research has demonstrated a "social loafing" effect whereby individuals exert less effort when they work in a group than when they work alone (although the effect varies by task difficulty and cultural values).

In addition to the issue of whether people are motivated to perform at work, the effectiveness of the workforce depends on workers' job-related abilities. Here, psychological research finds scientific ways in which to match the skills, education, and training of individuals with the requirements of the job. Economic psychology also studies the effect of unemployment on the

individual. In particular, it examines the negative and positive sides of unemployment, the psychological stages an individual goes through when losing a job, and the link between unemployment and health.

3. MACROECONOMICS AND PSYCHOLOGY: PERSPECTIVES ON INFLATION, UNEMPLOYMENT, AND ECONOMIC GROWTH

Macroeconomics studies the overall levels and changes in societal economic activity. Topics include economic growth, inflation, recession, unemployment, and income distribution. Often, economists explain the overall levels and changes in economic activity as issues involving the demand for goods and services, the money supply, and/or (more recently) the supply of goods and services. For instance, macroeconomic approaches to solving inflation are to decrease the demand for goods and services, decrease the money supply, and/or increase the supply of goods and services. However, each of these approaches overlooks, to varying degrees, the psychological aspects of economic activity and the position of that action in a larger sociocultural environment.

3.1. Inflation

The neoclassical economic view asserts that individuals objectively gauge the rate of inflation. This “expected inflation” allows individuals to make decisions about saving, purchasing now, and going into debt. However, psychological research has revealed that people often do not accurately remember past prices and make poor guesses about the future rate of inflation. Furthermore, wage increases during times of high inflation may be perceived as positive by workers because “money illusion” leads them to evaluate wages on their nominal value rather than their real value. On the other hand, people assess their satisfaction with wages not only by comparing wages with an absolute standard but also by comparing them with a reference group. Hence, people may demand increases in wages simply to keep up with their neighbors. This illustrates that inflation is, in part, a social psychological phenomenon.

In 1984, Maital and Maital also suggested that inflation can be profoundly psychosocial and can be researched using the prisoner’s dilemma experimental procedure. In this case, an individual can gain

financially if he or she demands a large wage increase and raises the prices of any products the individual may sell. However, if everyone in society does the same, the result is inflation. In addition to seeking to contribute to an understanding of the causes of inflation, economic psychology examines the psychosocial effects of inflation on the individual such as helplessness and perceived lack of personal control.

3.2. Unemployment

Whereas the effects of unemployment on the individual are an area of concern in microeconomic psychology, how society explains unemployment is a focus in macroeconomic psychology. Three broad types of social explanations have been identified: individualistic (e.g., laziness or lack of effort on the part of unemployed people, fussiness of unemployed people when it comes to taking jobs, poor education, qualifications of unemployed people), societal (e.g., policies of the government, less competitive industries that go bankrupt, prior overmanning in industry, weak trade unions), and fatalistic (sickness and physical handicaps among unemployed people, bad luck). Individualistic explanations are most common among conservative (right-wing) voters, whereas societal explanations are stronger among labor (left-wing) voters. This underscores that individuals’ beliefs about how the economy functions is less about economic models and more about morality and political persuasion.

3.3. Economic Growth

One final macroeconomic area of current interest is how cultural values and personal attitudes are linked to economic growth. The strict economic view is that the economic growth of a nation stems from conventional economic factors such as labor force and capital. However, Reynaud argued in 1981 that these factors per se cannot fully account for economic growth and that psychosocial factors must also be considered. In support of Reynaud’s position, some theorists claim that cultural values such as the Protestant work ethic and individualism produced the economic growth seen in Western nations (i.e., a cultural determinism claim). On the other hand, other theorists suggest that economic development leads to changes in cultural values (i.e., economic determinism).

In addition to the issue of economic determinism versus cultural determinism, researchers are divided regarding the extent to which human values are

aligned with economic growth and development. One form of modernization theory suggests that development proceeds in a series of linear stages; hence, as nations develop, their cultural values will become more similar to those of developed nations. However, the extent that the values of nations are converging is unclear because the values that predict economic growth are shifting as Asian economies expand.

4. CONCLUSIONS AND FUTURE DIRECTIONS

Despite the polarized way in which economics and psychology have been presented here, the two disciplines are in fact deeply interconnected. Central and historically significant branches in psychology also assume that individuals are rational and act out of self-interest. For instance, attribution theory assumes that people are naive scientists who seek rational explanations for their own and others' behaviors, behaviorism assumes that organisms act out of self-interest by seeking rewards and avoiding punishments, and social exchange theory suggests that individuals compare their inputs and outputs with those of others to gauge whether the relationships are satisfactory.

Similarly, economics is more psychological than is reported here, as evidenced by the 2002 Nobel Prize in economics being awarded to Daniel Kahneman for his work on human judgment (which integrates economics and psychology). Another example of psychological constructs being central to economic analysis is Katona's use of the attitude construct in his consumer optimism–pessimism index.

Notwithstanding that some models incorporate both psychology and economics, the two fields need greater integration. For instance, Lea and colleagues argued in 1987 that economic psychology should examine how the individual affects the economy and vice versa (i.e., dual causation). More recently, in 1995, Lewis and colleagues called for a better understanding of post-modern economic behavior and how economic behavior has communicative and identity functions.

One way in which to integrate psychology and economics is to propose models that include the neoclassical economic view and the psychological perspective within the same conceptual framework. These models would accept that the rationality and self-interest assumptions of economics and the

alternative explanations offered by psychology both are applicable, depending on the context and the individual. For instance, Allen and Ng's dual-process model of how human values guide consumers' product decisions, as described in their 1999 article, suggests that consumers make both rational and "nonrational"/emotional choices, depending on the type of product or on the motivation driving the consumer. That is, consumers motivated by a need for instrumentality will make a rational, attribute-by-attribute judgment of the product's utility, whereas those motivated by a need for self-expression will make a holistic, emotion-laden, and spontaneous judgment of the product's image. Similarly, hybrid approaches were proposed in the important area of social welfare by Taylor-Gooby in 2000 and in how people's views about the economy affect their political party choices by Allen and Ng in 2000.

GLOSSARY

cultural difference theory Theory that maintains that schools in the United States are based on the majority (European American) culture, which differs in many ways from the minority cultures; these cultural differences interfere with the learning of these students and affect their motivation to do well.

deficit theory The ethnocentric idea that students who do poorly in school are considered to be deficient in some way compared with those who do well in school; most social scientists now consider this idea to be out of date.

direct participation An educational environment in which parents are actively involved in helping their children with their schoolwork, maintaining good communications with the school, participating in school activities, and the like.

ethnocentrism The belief that one's own cultural ways are superior to those of other people.

expectation theory A belief that some children do poorly in school because their teachers have a low expectation for their success.

genetic epistemology The study of the development of knowledge.

indirect support An educational situation in which there is not direct participation of the parents in their children's education; rather, parents work to maintain a home environment that is highly supportive of their children's learning (e.g., arranging for ample time to study, paying for private lessons).

individualized assessment Evaluation of individual student needs, skills, and performance.

involuntary minority groups Those who are incorporated into the U.S. society against their will (e.g., African Americans).

pedagogical model A design of systematized learning or instruction with an emphasis on the goals, principles, and methods of teaching.

standardized curricula and evaluations A set of formally designed and accepted teaching materials along with methods for measuring and comparing performance on them.

student-centered teaching Nontraditional instruction in which primary responsibility for learning is on students (rather than on teachers); students work independently or in groups on specific assignments or projects.

teacher-centered instruction Traditional approach to learning in which teachers provide information, typically through lectures along with textbooks and/or assigned readings.

triarchic model A holistic approach to understanding differences in educational achievement that looks at multiple factors (e.g., school, family, student) that contribute to ethnic differences in educational achievement.

voluntary minority groups Those who come to the United States by their own choice (e.g., early Europeans, Asian Americans).

Culture plays a crucial role in educational achievement. Pedagogical models and practices tend to be culturally embedded. A significant portion of cross-cultural and cross-ethnic differences in achievement may be attributed to cultural factors.

1. INTRODUCTION

Educational achievement is an important concern for parents, educators, psychologists, policymakers, and others in cultures throughout the world. Many factors (e.g., pedagogical practices, educational resources, socioeconomic status [SES], parental education level) contribute to differences in the learning outcome of students. Culture has been found to play a critical role in educational achievement in cross-cultural and cross-ethnic studies. Significant differences in educational achievement have been reported among students from different countries as well as among different ethnic groups within the United States. For example, compared with many other countries, the United States has a wide range of ethnic groups that share within-group backgrounds, languages, values, beliefs, thinking, and norms of behavior. Available research has shown that some ethnic minority groups of students (e.g., African Americans, Hispanic Americans) achieve below the national average of all students. One exception is the high educational achievements demonstrated by Asian American students. These ethnicity-related differences have been documented in standardized achievement test scores, grades, high school graduation rates, dropout rates, and other measures of educational achievement. However, in understanding cultural or ethnic differences in educational achievement, it is important to note that there are vast variations among students within each cultural or ethnic group. Research findings that reflect between-group patterns in achievement may or may not apply to individual students within the groups. In other words, despite reported patterns of group differences, there are high-achieving students and low-achieving students within each cultural or

ethnic group. Therefore, it is important to avoid stereotyping in understanding educational achievement and culture. One should be wary of prejudging students based on their cultural or ethnic status.

This article first presents an overview of cultural approaches to teaching, learning, and achievement. Then, it discusses research on cross-cultural differences in mathematics achievement and the explanations for the differences. This is followed by a review of different theories that have been proposed to explain cross-ethnic differences in academic achievement in the United States. In addition, the article discusses ethnic differences on several cultural factors that are important to educational success. Finally, it recommends directions for future research on cross-cultural and cross-ethnic achievement.

2. OVERVIEW OF CULTURAL APPROACHES TO TEACHING, LEARNING, AND ACHIEVEMENT

North and South America represent an extremely diverse hemisphere characterized by struggles for quality and equality in education. In 2000, Mazurek and colleagues discussed educational practices and reforms in the United States, Canada, Brazil, Mexico, and Chile. They pointed out that in the United States and Canada, demands for reforms come from interest groups, the media, politicians, and parents organizations. In Brazil and Chile, national social/political movements and a return to democracy are behind educational reforms. In Mexico, reforms appear to be a response to a combination of social and political turmoil within the country.

In Western Europe, education has taken on a new priority involving technology and business orientation at all levels. In some countries, this includes a particular focus on vocational education to prepare students for entry into the workforce. Some countries (e.g., Switzerland, Sweden) have introduced a stronger emphasis on vocational training in their schools, whereas others (e.g., France, Spain) continue to focus on the teaching of traditional academic subjects. At the same time, a number of Middle Eastern and African nations (e.g., Israel, Palestine, Turkey, Pakistan, South Africa), characterized by some as “nations in turmoil,” are struggling to solve serious political, social, and economic problems while modernizing their countries and reforming their educational systems—a task that each country takes very seriously. At the postsecondary

level, most countries throughout the world are trying to determine what should be the proper direction and focus of their educational efforts.

2.1. Cultural Models of Schooling

Schools throughout the world are experiencing a period of rapid change and, in many cases, are finding it extremely difficult to achieve a balance among a number of critical concerns. Some of the issues that educators and schools are facing include uncertainty about what academic and cultural knowledge and skills will be needed by students in the future, wholesale revisions of curricula, experimentation in teaching strategies, the need for teachers and students to become aware of and competent in using new technologies, dramatic changes in bureaucratic and legislative policies and regulations, and increased demands on teachers.

With the exception of the education system in the United States, perhaps no other education system has been studied more intensively than that of Japan. In 2001, in a well-balanced presentation of the Japanese model of schooling, including its similarities to and differences with that in the United States, Tsuneyoshi characterized the American approach to education as one that places an emphasis on competitiveness, individual attention from teachers along with individual accomplishment on the part of students, development of cognitive abilities, and separation of teachers in terms of their disciplines. In contrast, the Japanese approach (particularly at the elementary school level) focuses on the “whole child”; close interactions between teachers and pupils for long periods of time in cooperative settings with attention to collective goals, tasks, and rewards; and efforts to provide the same or very similar treatment for all students. One advantage of the American approach that is seriously missing in the Japanese approach is the former’s attention to diversity and a sensitivity and concern for minority rights. On the other hand, the Japanese approach has a clear advantage in its ability to focus on the whole child within a community structure designed to provide close, cooperative, face-to-face student–teacher relationships.

2.2. Approaches to Teacher Training

There appear to be as many approaches to teacher training as there are teacher training programs. As several recent studies show, a majority of the world’s cultures have made substantive changes in teacher training and certification, whereas others are just beginning to do so. For example, in Brazil, a secondary education teacher

must pass a course of study corresponding to a teaching degree. In Russia, teachers are generally trained to teach one or two specific subjects, although many rural teachers can, and frequently do, teach between three and five subjects. An early unique feature of teacher training in Turkey was the establishment of “village institutes” where elementary teachers were trained to work with selected bright village children. Today, teachers are required to be university graduates, preferably from education faculties; however, they can receive teaching certificates if they graduate from other 4-year programs.

Yet in 1998, Murray strongly suggested that teacher education reform has largely failed, and he argued for the position that teacher education, developmental theory, and research are important and interlocking elements in bringing about a reform in school practices as well as the modification of school outcomes. It is for these reasons that Murray recommended that efforts to establish or change teacher education curricula should seriously consider the use of developmental psychology, especially pedagogical content knowledge and genetic epistemology, as a foundation.

In closing, research shows that pedagogical models tend to be embedded within cultures and that attempts to transplant them from one society to another, no matter how beneficial some may believe this will be, might not always be possible and, if attempted, will require serious planning, preparation, and attention to indigenous concerns.

Mazurek and colleagues, in discussing the debate over pedagogy, pointed out that while some countries are employing so-called progressive approaches such as student-centered teaching and individualized assessment, others are continuing to use traditional approaches such as teacher-centered instruction and standardized curricula and evaluations. Still others are experimenting with a wide variety of alternative and combined approaches. At the same time, these authors pointed to a common theme, namely that countries appear to be moving away from pedagogical strategies that are uniform and system-wide in their approach and toward those that are represented by greater diversity.

3. CROSS-CULTURAL DIFFERENCES IN MATHEMATICS ACHIEVEMENT

Research literature reports very few well-designed and carefully conducted cross-cultural studies in the area of mathematics achievement. Most notable are those carried out by Stevenson and colleagues, nearly all of which

showed American students lagging behind their counterparts in other industrialized countries. In 1990, in a classic study of math achievement among American, Chinese, and Japanese children, Stevenson and Lee attributed American children's poor performance to several factors, including a lack of emphasis on academic activities, the absence of a shared goal in academic achievement, an overestimation of children's accomplishments by parents and children themselves, low parental standards for achievement and little direct involvement by parents in their children's schoolwork, and a belief that all children, except those who may be seriously disabled, should be able to learn and do well in elementary school.

In 1998, in another study of differences in mathematical achievement among students in China, Taiwan, Japan, and the United States, Lee demonstrated that achievement differences are closely related to cultural expectations about teaching and learning. For example, in general, Asians believe and expect that everyone is capable of learning, whereas Americans believe that individual differences are inherent and, as a result, that people are expected to behave and perform differently. Lee concluded that it is this American philosophy that prevents the development of common standards and makes it difficult to institute new teaching strategies. Lee suggested that this view may seriously impair efforts to improve teaching and learning among students and teachers in the American culture for quite some time into the future. In fact, evidence from several sources shows little improvement in American mathematical performance over the past decade or so, with proficiency being even lower than it was during the 1970s.

In 2005, Gardiner and Kosmitzki reported trends similar to those just cited. In 2001, in an earlier summary of the themes and results of cross-cultural studies of mathematical achievement, Gardiner pointed first to the dominant role in this process played by mothers and second to cross-cultural evidence strongly suggesting that informal learning styles, such as those found in many Asian cultures that focusing on building interest, are more effective in teaching children a variety of skills, including math.

4. CULTURAL EXPLANATIONS FOR CROSS-ETHNIC DIFFERENCES IN ACHIEVEMENT IN THE UNITED STATES

The relationship between educational achievement and culture is also shown in research in the United States. As

indicated earlier, cross-ethnic comparisons of educational achievement have shown that Asian American students outperform European American students, who in turn outperform African American and Hispanic American students. A significant portion of these differences may be attributed to cultural factors in values, beliefs, expectations, cognitive styles, and the like. These factors directly or indirectly influence students' motivation for learning and their approaches to school achievement. Over the years, several theories have been advanced to explain ethnic differences in educational achievement.

An early explanation was the so-called deficit theory. According to this theory, students who do poorly in school are considered to be deficient in some way compared with those who do well in school. The deficit may take the forms of inferior ability, culture deficiencies, and/or language problems. Proponents use these deficits to explain why some minority group students underachieve in education. These students are viewed as incapable or inferior because they exhibit cultural backgrounds, thinking, learning styles, and communication patterns that are different from those of the dominant culture. The deficit explanation stems from ethnocentrism, that is, the belief that one's own cultural ways are superior to those of other people. It is also known as the "blaming the victims" model. When children are not doing well in school, it is assumed that something is wrong with the students or with their particular culture. Most social scientists now consider the deficit explanation to be out of date.

A second explanation comes from the expectation theory, which was first made popular by Rosenthal and Jacobson in 1968. This theory posits that some children do poorly in school because their teachers have low expectations for their success. Subsequently, research has found that racial and ethnic backgrounds are factors that affect teachers' expectations of students. Teachers often have low estimations of the academic potential of students from certain racial and ethnic minority groups and do not expect much of these students. Because of the low expectations, teachers may unknowingly teach and interact with minority students in ways that are different from the ways in which they teach and interact with other students. This may, in turn, affect the students' own expectations and learning and result in low academic performance. The entire cycle becomes a self-fulfilling prophecy. The expectation theory holds that academic performance of certain minority group students can be improved if teachers can reduce their subjectivity and modify their behavior in working with these students.

The third explanation is the cultural difference theory. This theory maintains that schools in the United States are based on the majority (European American) culture, which differs in many ways from the minority cultures. Therefore, there is a mismatch or incompatibility between the school culture and the home cultures of minority students. The values, languages, cognitive styles, interaction patterns, and behaviors required in the school are often not the same as those that minority students have learned at home. These cultural differences interfere with the learning of these students and affect their motivation to do well. As a result, schools generally fail to tap the competence of minority students. Proponents of the cultural difference theory contend that it is important for teachers to develop better cross-cultural understanding and to adopt instructional practices that are more responsive to minority cultures. A learning environment that is more congruent with the minority cultures is necessary to foster effective learning of minority students and to enhance their academic achievement.

However, not all cultural differences lead to conflicts and underachievement among minority students. For example, Asian American students have cultural and linguistic backgrounds that are different from those of the majority culture in significant ways, yet these students consistently do well in school. In 1991, Ogbu proposed an explanation to account for this phenomenon. He differentiated between minority groups as involuntary immigrants and voluntary immigrants. Involuntary minority groups are those whose members are incorporated into the U.S. society against their will (e.g., African Americans), whereas voluntary minority groups are those who came to the United States by their own choice (e.g., Asian Americans). Involuntary minority students view maintaining their own cultural identities as very important and are not inclined to become enculturated to the majority culture. In addition, sometimes there is also social pressure from parents and peers discouraging these students from conforming to the school culture. For these reasons, it is not uncommon for involuntary minority students to develop a resistance to schooling and to reject behaviors that would make them successful in school. Consequently, their academic performance suffers. On the other hand, voluntary minority students have less difficulty in crossing cultural boundaries and are less affected by identity conflict. They are able to adjust to the school culture and do well in school.

Finally, a more recent explanation was proposed by Okagaki in 2001. Okagaki developed a triarchic model to explain ethnic differences in achievement. Unlike

previous explanations that focus on a single perspective, this triarchic model takes a holistic approach and looks at multiple factors that contribute to ethnic differences in educational achievement. The three major factors identified in the model are characteristics of (a) the school (e.g., the structure of school and perceived function of education by various groups within a society), (b) the family (e.g., cultural beliefs and practices of parents and families), and (c) the student (e.g., ethnic and academic identities). Okagaki maintained that all three factors shape the ways in which students approach and perform in school. Therefore, all three factors need to be examined for a thorough understanding of cultural influences on minority students' achievement. Because of its comprehensive nature, the triarchic theory is able to explain some of the variations in minority students' achievement that cannot be explained satisfactorily by the earlier theories.

5. ETHNIC DIFFERENCES IN CULTURAL FACTORS AFFECTING ACHIEVEMENT

Research on ethnic differences in educational achievement over the past 20 years or so has identified a number of cultural factors that contribute to school success. Five major factors are considered in this section: educational effort, cultural values and beliefs, parental educational expectations, parental involvement, and peer influence. These factors are important because they can enhance the educational achievement of all students regardless of race or ethnicity.

5.1. Educational Effort

Educational effort has a direct impact on school performance. Students who spend more time learning and doing homework perform better than do students who spend less time studying. Educational effort has also been found to be associated with culture and ethnicity. For example, a number of studies have found that Asian American students, and to some extent European American students, are more task oriented, pay more attention in class, exert more effort, spend more time doing homework, and participate more in academic-related activities compared with other ethnic minority students. Asian Americans are also more likely to believe that high achievement is the result of motivation and hard work. On the other hand, students from other ethnic

groups are more likely to attribute academic success to ability or talent—factors that are outside of their control.

5.2. Cultural Values and Beliefs

Another factor that influences educational achievement is cultural values and beliefs related to education. All ethnic groups value education. However, in 1990, Mickelson indicated that it is not the abstract belief that education is important; rather, it is the more concrete pragmatic belief about the benefit of education that separates high-achieving students from low-achieving students. Specifically, students who do well in school believe that education serves an important function for them (e.g., getting better paying jobs, improving family financial or social conditions, overcoming occupational discrimination). Conversely, students who do not see education as critical to serving a particular pragmatic function show less motivation to do well in school. In a study conducted by Steinberg and colleagues in 1992, it was found that African American and Hispanic American students did not believe that doing poorly in school would hurt their chances for future success. Asian American and European American students, on the other hand, were more likely to believe that academic success would have a significant payoff. These different beliefs among various ethnic groups affect their behaviors related to education.

5.3. Parental Educational Expectations

Research has shown that parental educational expectations is another contributing factor to success in school and is closely associated with students' academic performance. Differences in parental expectations exist among ethnic groups. For example, compared with parents in other ethnic groups, Asian American parents place greater emphasis on educational accomplishments and have higher expectations for achievement for their children. They expect their children to receive better grades in school and to earn higher educational degrees than those of their counterparts in other ethnic groups.

5.4. Parental Involvement

Parental involvement is empirically linked to academic performance. Research has shown that parental involvement can improve children's school performance. In general, parental involvement may take place in two

broad forms: direct participation and indirect support. In direct participation, parents are actively involved in helping their children with their schoolwork, maintaining good communications with the school, participating in school activities, and the like. On the other hand, indirect support does not involve direct participation of the parents in their children's education. Rather, parents work to maintain a home environment that is highly supportive of their children's learning (e.g., arranging for ample time to study, paying for private lessons). In terms of direct participation, research has shown that European American parents show the highest level of involvement in their children's education. In comparison, Asian American parents show the least direct participation in their children's education. They seem to perceive direct involvement with the school as less important due to cultural beliefs and/or language barriers. Instead, Asian American parents provide more indirect support to their children's education than do parents in other ethnic groups. Asian American parents are willing to make sacrifices for their children's educational pursuits to make sure that their children have sufficient time to do schoolwork and to create a climate in which their children's job is to study and do well in school.

5.5. Peer Influence

In addition to parental influences, studies have shown that students tend to do better with peer support for academic achievement. In some cases, peer influence is even greater than parent influence. In a 1992 study with adolescents, Steinberg and colleagues found that European American and Asian American adolescents were more likely to have friends who place a great deal of emphasis on academic achievement and, as a result, worked hard to keep up with their friends. In comparison, Hispanic and African American adolescents were less likely to receive peer support for academic achievement.

6. DIRECTIONS FOR FUTURE RESEARCH ON CROSS-CULTURAL ACHIEVEMENT

Making reliable and valid comparisons across cultures is often a bewildering and difficult task if not an impossible one. Conducting cross-cultural and cross-ethnic studies in educational achievement is fraught with a variety of methodological difficulties. Therefore, one

must exercise caution in drawing definitive conclusions from such studies. Also, as mentioned earlier, vast variation exists within any cultural or ethnic group. It is critical that research findings on achievement differences among cultural and/or ethnic groups be understood in the context of differences within groups.

Several researchers have recommended possible solutions that are worthy of further consideration. For example, in 1998, Stigler outlined the benefits and problems associated with his large-scale video survey approach to teaching and learning used in the Third International Mathematics and Science Study (TIMSS) Videotape Classroom Study. Among the advantages is the fact that video data are concrete, are grounded in practice, allow for merging of quantitative and qualitative analyses, and enable study of complex processes. However, if these data are to be used successfully, a number of disadvantages must be addressed, including sampling of only a few instructional lessons, standardization of camera procedures, problems of observer effects, sampling and validity, and confidentiality.

In another approach, in 1998, Paris and van Kraayenoord demonstrated the usefulness of specially designed tasks for assessing young children's literacy and development (e.g., asking students to examine and select books they find personally interesting and to construct meaning and stories from pictures or wordless picture books). They suggested that this approach can provide a blueprint that could lead to consistent and sensible instruction and assessment practices that are more easily understood by children, parents, and teachers.

The authors of the current article recommend that researchers seriously consider the development of a variety of new approaches, including large-scale, interdisciplinary, multimethod, longitudinal studies that focus on important aspects of educational achievement such as cooperative learning environments, multicultural literacy, and pedagogical changes in teaching and learning.

description, diagnosis, prediction, or explanation of the child's behaviors containing three components: implicit and explicit psychological theories and constructs, test theory representing the constructs in a quantitative model, and instruments, tests, or procedures constructed in accordance with theories and their representation in the model.

GLOSSARY

assessment A procedure whereby the assessor's reformulation of the client's problem or question is answered (or solved) using scientifically sound methods with relevant and reliable information about the child's behaviors and environment.

educational and child assessment An assessment that is focused on "maximum and typical performance," that is, on the child's intelligence, aptitude, school achievements, and typical behaviors.

individual differences approach to achievement and typical performance An approach that determines specific content domains of achievement (e.g., reading, arithmetic, biology, history, science) and of typical behaviors (e.g., socioemotional behaviors, personality); experts decide which content must be acquired as a result of a curriculum, and other experts design instruments that measure the level of acquisition of this knowledge and children's skills.

psychological assessment The professional process of investigating and judging a client's behaviors, resulting in a

The assessment process is the professional procedure whereby a client's question (or problem) is answered (or solved) using psychological theories and constructs that are modeled by test theoretical and statistical techniques and that result in reliable and valid instruments to measure the child's achievement and typical behaviors. The goal is a valid description, categorization, prediction, and/or explanation of the child's behaviors (e.g., cognitions, emotions, observable behaviors). These are the points of departure for answering the client's question or deciding on the treatment for his or her behavioral problems.

1. INTRODUCTION

What is educational and child assessment? How do we assess the educational level of the child and his or her social behaviors and personality? In this article, first the child as the subject of an assessment is described. Second, some specific issues in assessing children are

reported, four goals of assessment are distinguished, and assessment is provisionally defined. Third, assessment is comprehensively defined with the following three components:

- Implicit and explicit behavioral theories and constructs
- Test theory and statistical models to represent these theories and constructs
- Instruments for measuring these constructs

Fourth, the assessment process, which consists of compiling these three components and contains several steps from the client's question or problem to the answer or solution, is described. This process includes the integration of diagnostic information and is subject to judgmental errors. Fifth, the possibilities and limitations of assessing achievement in children are described. Finally, the case of "Bryan" is reported using this article's definition of assessment.

Assessment in children is considered if cognitive, emotional, or behavioral problems are experienced by parents, teachers, the social environment, the institution, and/or the child himself or herself. The help of a professional assessor is sought when the implicit assessment of the parents, teachers, or child does not result in a satisfying solution. Assessment is the procedure whereby the assessor reformulates the client's question (or problem) in psychological terms and answers the question (or solves the problem) using scientifically sound methods and information about the child and his or her environment.

In assessing children, one is confronted by special issues. First, parents, teachers, and/or the school or institution—but rarely the child—ask for an answer or for help. They may or may not agree about the presence and nature of the problem. For example, Lewis reported in 1999 that the manifestation of child depression is not shared by children, parents, and teachers. Second, given that children develop rapidly and are "moving targets," how do we know whether the current behaviors are advanced or behind or whether they are normal or abnormal? An accurate picture of behavioral development is needed to make that determination. Third, assessing a child is a social process. The child must consider the assessment as a task and not as a game. Fourth, in (young) children, the nature and source of diagnostic information deviate from procedures used with adults, for example, because questionnaires cannot be used with children. Their behaviors must be observed, and parents, teachers, and peers must be interviewed.

2. FOUR GOALS OF ASSESSMENT

Although assessment is not a psychological subdiscipline such as educational and developmental psychology, it depends largely on psychology's knowledge base and methodology. Assessment refers to gathering and integrating relevant diagnostic information about the child's behaviors so as to help him or her. In their definition of developmental assessment in 1999, Johnson and Sheeber stressed the child's levels of cognitive, sensorimotor, language, and socioemotional behaviors in presenting the weak and strong sides of the child's functioning. So, assessment contains deciding, problem solving, information gathering and integrating, helping, constructing a whole picture of the child's behaviors, and using teachers, parents, peers, and the child as sources of information.

Assessment has four practical and scientific goals. The first goal is a valid description of the child's cognitions, emotions, and behaviors (hereafter referred to as "behaviors") and of his or her social environment. The practitioner needs valid descriptions that enable him or her compare children, to describe the "natural" course of development of behaviors, and to establish the effects of social contexts on behaviors. This description is also needed to estimate the relationships between behaviors, to determine context conditions that influence the behaviors, and to describe and explain their course in time. The second goal is diagnosis, which refers to how experts assign the child to a category (e.g., the attention deficit/hyperactivity disorder category). This is relevant for the practitioner and the scientist. The quality of these assignments depends on the probability of false positives and false negatives and on differential diagnoses and comorbidity of two or more behavioral syndromes. The third goal is prediction, which allows the scientist to test a nomological network and enables the practitioner to predict the child's future school achievement and social adaptation. The fourth goal is explanation, which is expressed in the hypotheses testing model of assessment. Explanation fits the dominating empirical-analytical approach in psychology.

Educational assessment is focused primarily on maximum performance. "Child assessment" in the title of this article is viewed as measuring the child's the socioemotional behavior and personality (or "typical performance"). Intelligence, aptitude, and school achievements are called "achievements."

Intelligence refers to a general ability that includes reasoning, planning, problem solving, abstract thinking,

understanding complex ideas, and learning from experience. It is not rote learning or school achievement, and it differs from creativity, character, and personality. Closely related to intelligence is aptitude, which refers to the ability to achieve in a professional field after specific training.

School achievement is related to both of these concepts but refers to what a child has achieved in a specific domain as a result of specific training or of attending a curriculum (e.g., reading or arithmetic at the primary school level, achievements at the high school or university level).

Socioemotional adaptation and personality refer to the maturity level, adaptation, lack of pathology, and individual differences in temperament and personality.

3. A COMPREHENSIVE DEFINITION OF ASSESSMENT

Psychological assessment is a process of investigation and judging that results in a description, diagnosis, prediction, or explanation of the child's (problem) "behaviors." This process involves the following three components:

- Implicit and explicit psychological theories and constructs
- Test theory representing the constructs in a quantitative model
- Test construction using theories and their representation in the model

The three components are combined in the assessment process, with the assessor acting as the "composer." The components and the process constitute the comprehensive definition of assessment used in this article and are illustrated in the following subsections. The process consists of the composition of the three components. In this process, the assessor must integrate the diagnostic information and formulate advice. Information integration is known to be subject to errors.

3.1. Psychological Theories and Constructs in Assessing Children's Achievements and Social Adaptation and Personality

Assessment involves content (i.e., behaviors) that is inferred from observations and that fits in a theory or network of constructs. The many theories and constructs

for children's achievements and personality are subsumed under the "three central orientations" or approaches used in psychology:

- The individual differences orientation
- The developmental orientation
- The (social) context orientation

The prototype of the individual differences orientation is Spearman's approach to intelligence. Spearman insisted on the study of individual differences as being the main way in which to understand intelligence. He discovered or invented the "G" (general) factor because he assumed that one general dominating ability was present in all of the activities requiring mental effort. In 1998, Jensen characterized the G factor as a discovery that can be compared to Skinner's laws of reinforcement and Thorndike's law of effect.

Thurstone was the father of the multiple intelligence theories. He accepted the G factor but attached little significance to it. He viewed it as an abstract, "second-order factor" that "floated above" more interesting specific factors. Thurstone discovered or invented the seven "primary mental abilities": verbal comprehension, word fluency, number, space, associative memory, perceptual speed, and reasoning. Later, Guilford distinguished 120 factors, and Vernon created order among the many factors by formulating a hierarchical model with G on top and two broad groups of factors below: verbal-educational (e.g., English, history) and spatial-mechanical (e.g., automotive repair). Below these, he defined all kinds of specific factors.

The orientation of Spearman and the other authors is known as the psychometric approach to intelligence. This approach combines intelligence and aptitude because Thurstone's multiple intelligence resulted in measuring aptitudes in the same way as the primary mental abilities.

The individual differences approach to school achievement does not aim to discover factors in school achievement; rather, it aims to determine specific content domains such as reading, arithmetic, biology, history, and science. Experts decide what knowledge must be acquired as a result of a curriculum, and other experts (e.g., from the Educational Testing Service [ETS]) design instruments that measure the level of acquisition of this knowledge and the children's skills. The results can be used to describe individual differences in children's achievements, the level reached by a class or school, and/or the degree of success of the curriculum and teachers. In addition, the individual differences approach has had a great impact on child

assessment in measuring dimensions of personality, temperament, and social adaptation.

This approach served the goal of providing a reliable and valid description of the ranking order of a child's achievement and personality. It helped to categorize children, for example, distinguishing cognitively retarded children from nonretarded children and distinguishing well-adapted children from not well-adapted children. The individual differences were used for predicting the future levels of achievements, school and vocational success, and levels of adaptation.

The prototype of the developmental orientation is Piaget's cognitive developmental theory. Piaget was convinced that to understand human cognition, one must study its historical and ontogenetic development (i.e., within the life course). His original question was an epistemological one: How could humankind change from biological beings to logical scientific ones? Piaget was not interested in individual differences or in fostering cognitive development by curricula or training. His subject was not a specific pupil but rather the epistemic subject, and the environmental stimuli were only an "aliment" (nourishment) to existing cognitive structures. Piaget's theory was also applied to social adaptation (e.g., the development of levels of perspective taking). This developmental orientation implied that children's stages of cognitive and social development had to be assessed. The stage concept hypothesized the existence of qualitatively different stages, ordered in time, that resulted in an inevitable and equilibrated final stage and that were characterized by sudden transitions. Empirical support for these claims was scarce and circumstantial.

This developmental orientation could be readily applied because many achievements at school (e.g., understanding simple scientific laws, understanding the concept of living beings, understanding economic laws) can be ordered along the Piagetian developmental dimension from prelogical thought to formal operational thought.

The impact of the developmental orientation on educational and child assessment is limited. Instruments for measuring stages were scarce, and measurements were more difficult to conduct and interpret than were the traitlike individual differences measurements.

The prototype of the contextual orientation to educational and child achievements is the attempt to influence achievements and socioemotional adaptation by curricula and programs. The latter are the independent variables that should change the dependent variables of intelligence, aptitude, and school achievements and

socioemotional adaptation. This orientation is also considered to be the only road to describing and explaining behaviors by efficient causes, and it fits well the dominating empirical-analytical approach in psychology. The methodology was important, because the effect of independent variables could be revealed. It served the goal of determining the effect of training, intervention, and situational change (i.e., the context) on achievements and on social adaptation and personality. These independent variables of training and the like could vary from small manipulations in content and form of curricula to big programs such as Head Start. The dependent variables were either borrowed from the individual differences orientation (e.g., intelligence, aptitude, and school achievements; level of socioemotional adaptation) or constructed for a specific question (e.g., change in a memory retrieval strategy).

The context orientation was not aimed at constructing instruments for measuring children's achievements and personality. This is possibly one reason why assessors underestimate the role of the context in understanding and explaining achievements and typical performance. However, the effects of schooling on intelligence and the effects of the cultural influence on generational growth of intelligence are present (e.g., in the Flynn effect).

Educational and child assessment is dominated by the individual differences approach, partly because this approach contained the simplest road to developing instruments for measuring maximum and typical performance in children.

3.2. Modeling Children's Achievements and Socioemotional Adaptation

3.2.1. Modeling Individual Differences in Intelligence and Aptitudes

Spearman combined conceptual analysis and test-theoretical and statistical modeling. His two-factor theory implied that individual differences in true scores could be attributed to two factors: general (present in all tasks) and specific (present in tasks of the same type, e.g., verbal, spatial). His type of factor analysis was suited to discover a first strong factor (e.g., with the now obsolete centroid method).

Thurstone's multiple intelligence construct required a search for a simple structure, that is, where items loaded high on one intended factor and low on all other factors. Orthogonal rotation and a specified number of factors

were appropriate. This simple structure concept is usually applied to the measuring of aptitudes (e.g., in the differential aptitude test). Moreover, simple structure analysis is often applied in an exploratory way to reduce many items to a few dimensions.

Guilford needed a factor analysis that discovered many factors. He “forced” the items in these factors by using the Procrustes technique. The hierarchical model was developed to rank the many factors.

The analysis of dimensionality and of the quality of individual items is now supported by the many possibilities of modern test theory or item response theory (IRT). These theories contain models to test the unidimensionality of a scale and to weight the individual items according to their contributions to the total test score.

The analysis of school achievement was a matter of experts deciding what to measure and how to measure it. There was no effort to find any dimensionality for school achievement. Modern test theory (IRT) is however, used more and more to construct one-dimensional achievement tests.

3.2.2. Modeling Development of Achievements

Developmental psychology was characterized by Cronbach as an individual differences discipline, whereas Wohlwill tried to define a real developmental orientation. By considering the developmental orientation as an individual differences orientation, developmental research was biased toward investigating stability with the help of tests, that is, rank order and normative stability. Because researchers were looking for stability, they found it. However, there was never complete stability, even after correction for measurement error. The dominating message from this research is that achievements are relatively stable, predictable, and foreseeable. Moreover, the message is that achievements increase over time in the individual and sample because children grow older and because of the Flynn effect. Rarely is a developmental construct used to model the development of achievements in the course of time.

3.2.3. Modeling the Context of Achievements

The effects of manipulations of independent variables, interventions, programs, events, stimuli, and situations on achievements can readily be modeled with (multiple) analysis of variance (ANOVA). True and quasi-experimental designs have been well elaborated. This technique is appropriate for determining the existence of significant differences at the group level, and

computing effect sizes, that give a fair estimate of gain. However, these differences do not apply to every element of the sample, and the differences do not necessarily last forever. Both are partly reasons for the disappointing results seen in programs to improve children’s achievements. In addition, behaviorists’ optimism for the extent to which social change can be effected by educational programs has proven to be misguided.

The modeling of social adaptation and personality does not deviate from this pattern in modeling intelligence, aptitude, and school achievements. The individual differences approach and factor analysis also rule these domains, and IRT is rarely applied in measuring personality and socioemotional adaptation.

3.3. Instruments for Assessing Children’s Achievements and Socioemotional Adaptation

Theories and constructs, on the one hand, and test-theoretical and statistical modeling, on the other, can be balanced and produce theory-driven instruments for educational and child assessment. However, practical questions have dominated test construction, resulting in the gathering of items that could predict practical criteria such as school and vocational success and adaptation and pathology. Examples of instruments measuring the following eight domains are presented next:

- Screening of developmental backwardness
- Cognitive and sensorimotor development
- School achievement
- Socioemotional adaptation
- Childhood pathology
- Personality and temperament
- Social status in a peer group
- Children’s social environments

3.3.1. Screening of Developmental Backwardness

Screening instruments attempt to measure developmental backwardness or disturbance. An example is the Denver Developmental Scale. Children from 6 days to 6 years 6 months of age are investigated with tasks, and the parents are interviewed. Despite its name, this instrument is an individual differences instrument and considers backwardness to be a one-dimensional scale. The McCarthy Developmental Scales presuppose

orderly development in several domains. However, this presupposed “natural” development has not been tested empirically. These instruments contain different scales for cognitive and sensorimotor behaviors, and the children (2–9 years of age) are investigated using tasks and games to elicit problem-solving behaviors. Some items must be answered by the parents. The Gesell Motor Scales measure motor, speech, and social behaviors in children from 4 weeks to 6 years of age. Gesell presupposed a developmental scale in these behaviors.

3.3.2. Cognitive and Sensorimotor Motor Development

Cognitive and motor development can be investigated in young children using the Bayley Developmental Scales. Tasks are given to babies and toddlers, and their parents are interviewed. Two scores result: one for mental development and one for motor development. This is an individual differences test, and the two factors are rationally defined. The Wechsler scales for preschool children (Wechsler Preschool and Primary Scales of Intelligence [WPPSI]) and for school children (Wechsler Intelligence Scale for Children [WISC]) are the most widely used intelligence tests. Wechsler defined intelligence as the aggregate or global capacity of the individual to act purposefully, to think rationally, and to deal effectively with his or her environment. Intelligence was considered to be an individual differences phenomenon. The performance and verbal intelligence factors were rationally distinguished and, in fact, usually correlate at approximately .70. Many factor analyses were conducted. The “three Kaufman factors” (verbal comprehension, perceptual organization, and freedom from distractibility) interpretation of the WISC is popular. The existence of these factors is supported by factor-analytical results. The Stanford–Binet scale is the oldest intelligence test. The intelligence quotient (IQ) is defined as a comparison between what is normal for a certain age and what is observed in a specific child.

3.3.3. School Achievement

School achievement tests (SATs) are found in every Western country and many other countries. These were developed to cover a content domain and are treated as individual differences variables. It is not the primary goal of these measures to distinguish underlying factors that generate or cause these individual differences. SATs and grade point averages are useful in selecting and placing children in various

educational levels, and they do predict future school achievements fairly well. The Differential Aptitude Test contains nine subtests (e.g., sentences, analogies, technical ability, arithmetic skill, words) that resemble Thurstone’s multiple intelligence factors.

3.3.4. Socioemotional Adaptation

Social emotional adaptation can be measured using many instruments, but all are based on the individual differences orientation, for example, Harter’s scales for measuring the aspects of self (e.g., academic, social, and motor skills; being socially accepted).

3.3.5. Childhood Pathology

Childhood pathology can be measured by Achenbach’s Child Behavior Check List (CBCL). It is based on the individual differences approach, and its factors are partly rational and empirically defined (e.g., the distinction between internalizing and externalizing behaviors). In 2000, Wenar and Kerig described several pathological syndromes in children using the fourth edition of the *Diagnostic and Statistical Manual of Mental Disorders* (DSM-IV). Although this system was originally developed for persons 18 years of age or over, it can be used for childhood pathology as well. In addition, many lists are available for teachers to judge the social and task behaviors of pupils. Kovacs’s questionnaire to measure depression is a downward extension of the Beck Depression Scales and allows one to define clinical cases of depression in children. The Attention Deficit/Hyperactivity Disorder (ADHD) is a short questionnaire to measure impulsivity, lack of attention, and the level of undirected activity in children 4 to 18 years of age. The Bender consists of prescribed figures that children must draw and helps to screen neurologically based deficits in perception and expression of simple and complex “Gestalts.”

3.3.6. Personality and Temperament

Personality characteristics are considered to be individual differences variables. In addition to the “Big Five,” there are the “Small Five” for children measuring extraversion, agreeableness, conscientiousness, emotional stability and openness. The California Q sort of Block’s Berkeley group distinguished three types of children: ego resilient, overcontrolled, and undercontrolled children 2½ to 18 years of age. These can easily be connected to the five personality factors.

Temperament is often considered to be a precursor to the personality traits. Several distinctions can be made: easy, slow to warm up, and difficult children.

3.3.7. Social Status in a Peer Group

Social status is an important variable because children have peers who influence their behaviors. In this procedure, children nominate peers with whom they like to play or work. This results in three types of children: popular, unpopular, and neglected children.

3.3.8. Children's Social Environments

Family and school relationship instruments measure individual differences in families and schools. Moos's social climate scales usually consist of approximately 100 items and result in three to nine dimensions underlying these items. The three most general dimensions are relationship (e.g., cohesion, conflict), personal growth (e.g., autonomy, task oriented), and system continuity/change (e.g., control, order, leadership). There are several questionnaires to measure the parental styles: authoritative, authoritarian, or laissez-faire. The school environment is also measured, that is, how this environment fosters achievement motivation, well-being, and self-confidence in pupils. The mental measurement yearbooks offer results from research on all of these instruments. The *Standards for Educational and Psychological Tests*, published in 1999, contains guidelines to judge the theoretical and psychometric qualities of these tests and questionnaires. Recent meta-analyses are a good source for judging the construct and criterion validity of many instruments.

In conclusion, all of the preceding instruments are based on the individual differences orientation. There are only a few instruments that use a developmental construct (e.g., Loevinger's sentence completion test to measure the level of ego development, Kerssies and colleagues' scales for sensorimotor development). However, these latter instruments are not frequently used by assessors. In the contextual orientation, the dependent variables usually are the well-known individual differences variables.

3.4. The Assessment Process in Children

The assessment process starts with the client's question (or problem) and ends with the advice (or solution). It

is modeled according to the procedure of empirically testing hypotheses in a true experiment and contains the following:

- The problem/question as formulated by the client
- The assessor's reformulation of the problem in psychological constructs
- The assessor's formulation of several hypotheses containing different causes of the (problem) behaviors
- The choice of instruments to "test" the hypotheses
- Integration of all the information from dossiers, anamnesis, test results, and interviews with parents, teachers, and institutions into a coherent picture
- The professional advice or solution, including recommendations for a specific intervention, training, therapy, or program

Assessment differs from testing in that the latter is more oriented to measuring variables, whereas assessment is more oriented to answering a client's question or solving his or her problem. Testing is limited to the use of standardized instruments, whereas in assessment the judgmental processes and information integration play a significant role. Testing requires skills to conduct and score tests, whereas the assessor must also be familiar with the three components involved in assessing children. Assessment involves choosing, conducting, and interpreting tests and their results, the analysis of each specific case, and the weighing and integration of information. Finally, the assessor should be able and willing to account for all of the steps taken in this process.

Traditionally, pitfalls threaten the assessor. This issue concerns the integration of all the information from the various sources and is known as the clinical prediction versus statistical prediction controversy. In 1999, Garb reviewed all of these pitfalls and concluded that clinical prediction usually performs less well than statistical prediction. Pitfalls include the halo effect, fundamental attribution error, ignoring the base rate of phenomena, overestimating a salient detail and neglecting available statistical information, and giving information a wrong differential weighting.

It is recommended that the assessor use decision aids, such as the multi-attribute utility theory and the Bayesian rule, as much as possible to integrate information. A recent meta-analysis showed that clinical prediction is weaker than statistical prediction, but not to such a large extent as has been suggested. In addition, tests that traditionally demand much of the assessor's interpretive abilities, such as projective tests and interviews, are not as unreliable and poorly valid as is often

claimed. So, clinical prediction and controlled information gathering, using interviews and projective tests, and disciplined interpretation, using formulas whenever possible, can contribute to sound assessment of children's achievements and social adaptation.

4. POSSIBILITIES AND LIMITATIONS IN ASSESSING CHILDREN

Assessment is performed using the composition of three components in the assessment process. This section addresses the possibilities and limitations. First, theories and constructs offer the possibility of defining the core elements of children's achievements and adaptation but are often not specific enough for testing in a model. Second, the individual differences approach dominates the measuring of achievements and social adaptation, but more developmental theorizing that allows instrument construction is necessary to gain a more complete picture of children's achievements and socioemotional adaptation in the course of time. Even more constructs may be necessary to model the diverse and real developmental pathways. Third, the quality of test construction can be fostered using the *Standards for Educational and Psychological Tests*, especially the standards for reliability and validity of tests. Fourth, achievement test construction was usually controlled by practical questions and contained much practical wisdom, but it can be enriched by clear theoretical considerations about the structure of achievements and adaptations. Fifth, the assessment process was structured after the empirical cycle for conducting scientific research, but this process can be supported by models and decision aids to minimize errors. Sixth, the assessor should be sensitive to the pitfalls in choosing, integrating, and interpreting the diagnostic information.

The assessment process requires disciplined assessors, whereas clinical assessors sometimes act freely and creatively to do justice to their "unique" clients.

Educational and child assessment poses specific problems.

5. CONCLUSION

The assessor must be aware of the relevant three components and integrate these into his or her assessment

process. The first component is biased toward measuring individual differences on one or more dimensions, and this may detract attention away from real development in the child's achievements and typical behaviors and from the influence of the context of these achievements and behaviors (e.g., events, stimuli, programs).

The assessor can be biased. Using formulas to integrate diagnostic information and standardized procedures in tests that usually allow for subjective interpretations helps to reduce such biases.

The assessor must operate in the complex environment of the child, parents, teachers, the institution, and the wider society, on the one hand, and in the psychological discipline, on the other. The latter offers much for accomplishing assessment but is so broad that the assessor must specialize in-depth. Recently, many meta-analyses have appeared and offer an equilibrated summary of the qualities of instruments and interventions. An assessment is best conducted by a team representing the knowledge and skills of several disciplines, thereby preventing individual biases.

6. CASE STUDY: AN EXAMPLE OF EDUCATIONAL AND CHILD ASSESSMENT

"Bryan" is a 10-year-old boy who is in the fifth grade. He has a younger sister who is in the fourth grade. Bryan's mother has no paid employment, and his father is a small businessman. The parents went to a school psychologist for advice because the teacher reported problems with Bryan's behavior in the classroom, and they wondered what was causing this. The teacher recommended that the parents seek professional advice for Bryan. The school psychologist listened to the parents and formulated their question as follows: "They want to know more about Bryan's lack of concentration and ask whether he himself experiences this lack of concentration. They would appreciate advice on how the teacher could help him." The psychologist reformulated the parents' question into the following diagnostic question: "How much are concentration and behavioral problems present, and how can these be explained?" This case was submitted to a professional institution, and it was decided to assess Bryan so as to give a professional and scientifically sound answer to the diagnostic question that

reflected the perceived problem of the parents, the teacher, and Bryan.

Bryan's problem was discussed with his parents and teacher. The parents had had no early problems with Bryan in starting to talk and walk. He cried a lot because he was eager to do more than he could. The preschool noted nothing special except that Bryan was inaccurate in fine motor tasks. He had to take the third grade of primary school twice because his reading and calculating were behind those of his classmates. Bryan could not concentrate well, and he quarreled a lot with the teacher. Some improvement was seen in the fourth and fifth grades, but concentration remained a problem and his writing was slovenly. In the eighth grade, Bryan said that he hated school and liked to stay at home. He often interrupted his tasks when sitting in front of the teacher, so he was placed at the rear of the class where he was quieter. The parents themselves said that Bryan needed order and structure, that he was willing to do his utmost, and that he was pleased with good results. He has broad interests. He has no steady friend, but this does not seem to bother him. He gets on very well with his father. Bryan is a scout, and the troop leaders consider him to be a "model child." The parents do not understand why he should need special help.

The teacher, on the other hand, called Bryan a chaotic boy who is not motivated to achieve. The teacher punished him, but this did not lead to any noticeable change in Bryan's behavior. His reading is average compared with his classmates, but it is actually 1 year behind the national average. His handwriting is bad, and he is forced to do many of his writing tasks twice. He makes too many errors in arithmetic because he is careless. He tries to finish his tasks as quickly as possible and then bothers other pupils. Sometimes he is very introverted. He is involved in conflicts in the schoolyard and when he works in a small group. He is not willing to admit that he makes mistakes. The teacher has suggested that Bryan be given professional help.

These complaints were clustered by the assessor into the following: lack of concentration, chaotic behavior, demanding attention, poor arithmetic, low reading level, bad reading and writing, low achievement motivation, conflicts with peers, and lack of social relationships at school. A first guess at the possible causes resulted in the following: inadequate visual organization, no planning, insufficient fine motor development, bad relationship with teacher, needs more structure, inefficient compulsion and punishment, low self-esteem, avoids contacts with peers at school.

Hypotheses as definite answers to the question were formulated, including criteria to test the answers:

1. Lack of perceptual organization, reduced concentration (WISC, observation, concentration test)
2. ADHD (DSM, 16-item ADHD questionnaire, observation)
3. Low self-esteem (observation, interview, two questionnaires)
4. Lack of achievement motivation (questionnaire)
5. Bad relationship with the teacher (interview, observation in the classroom)

The hypotheses were tested using a criterion set prior to the start of testing. The answers were as follows: 1, yes; 2, no; 3, no; 4, no; and 5, yes.

6.1. Summary of the Results for the Client (Bryan, Teacher, School, and Parents)

Bryan has an average IQ, his perceptual organization is more than 1.5 *SD* below average, his attention and concentration are more than 1 *SD* below average, his relationship with the teacher is very tense, and Bryan avoids going to school. His self-esteem and achievement motivation are average.

Advice for treatment was concrete, and its implementation was feasible. It was considered that it would be better if Bryan could change class for the next year. The relationship with the teacher had to be improved. A daily planning of tasks was made and agreed on by both Bryan and the teacher, and the tasks were divided into small units. Instructions were short and clear, a time limit was given for each task, and he could ask questions at fixed times. The teacher was informed about the assessment results.

6.2. Three Months Later

Bryan had started the new school year with renewed vigor. The relationship with his new teacher was normal. He still showed easily "off task" behavior, but this was simple to correct, and he ended his tasks within the time limits if supervision was available. His results were average, with only his progress in arithmetic still being slow; he had made progress compared with the past year. Bryan was more involved in peer activities and had a steady friend now. His parents said that Bryan was somewhat pleased about going to school.

6.3. The Psychological Investigation of Bryan and the Assessment Components

Concerning the instruments, all of the tests were constructed according to classic test theory, and results of IRT-based educational tests were used. The choice of these instruments was accounted for by the hypotheses; that is, definite testable answers to the questions were needed. The criteria for acceptance and rejection of the hypotheses were formulated in advance. There were several “rival” hypotheses to explain Bryan’s problem behaviors; two of these were not rejected, and three were rejected. Although the rival hypotheses were not really independent, the process did contain steps for trying to discover the “real cause” of the problem. There was no ordering in the hypotheses; that is, there was an educated guess as to the most or least successful. The cause of the problem was sought mainly “in the pupil,” although one hypothesis considered the relationship between Bryan and the teacher. There were more tests and questionnaires available to test the hypotheses. There was no argument for the specific choices (e.g., the quality according to *Standards for Educational and Psychological Tests*). Every instrument was about individual differences, and Bryan’s results are compared with those of a norm group or a criterion. Projective tests, often used in socioemotional problems, were not used.

There was no concept of development involved in the assessment; however, there was a follow-up interview with the parents and Bryan’s new teacher. There were nonspecific ideas about the effect of changing the classroom environment for Bryan. What was the exact condition changed (independent variable), and what was the precise behavior (dependent variable)? The process followed the prescriptions of the hypotheses testing model of assessment. Theory, as present in the instruments used, was scarce. Assessment was focused on answering concrete questions, but the theoretical base could have been stronger.

It is clear that this assessment protocol depended on the components of classic test theory and that IRT was used only because of the available educational tests. The individual difference orientation dominated, but implicitly a contextual orientation was present (changing the structure of the tasks with some effect on Bryan’s behaviors), whereas there was very little developmental orientation. Theoretical possibilities for explanation of the behaviors were not structured and possibly were insufficiently exploited. The hypotheses were not

ordered, and no real rival explanations of the problem behaviors were stated. The instruments were chosen because of the questions posed, and there was an attempt to use various methods to assess the same behaviors (e.g., tests, observation, interview). The assessment was discussed by a team, and the parents, the teacher, and Bryan himself were informed of the results.

The preceding analysis, using the comprehensive definition of assessment used in this article, helps to pinpoint the stronger and weaker elements in a concrete psychological investigation of a child. It is recommended that these components be used in conducting such investigations of clients.

1. Introduction
 2. Overview of Effective Classroom Instruction
 3. Planning for Content Coverage
 4. Using Effective Teaching Strategies
 5. Promoting Effective Inclusive Instruction
- Further Reading

Effective classroom instruction refers to the application of the “teacher effectiveness” variables, that is, those variables that have been demonstrated to bear the strongest relation to student achievement. These variables include time on task, content coverage, pacing, scope and sequence, questioning, feedback, and praise. Systematic application of these elements has been demonstrated to increase academic achievement.

GLOSSARY

- allocated time on task** The amount of time that teachers plan for instruction.
- alterable variables** The variables that teachers can actually alter (unlike age, gender, and personality) to improve student achievement.
- engaged time on task** The amount of time that students are actively engaged in instruction.
- guided practice** Student practice activities that are undertaken with direct teacher supervision.
- independent practice** Student practice activities that are undertaken independently.
- pace** The rate at which teachers proceed through instructional content; it also refers to the rate of presentation of information.
- teacher effectiveness** Teacher behaviors, identified through empirical research, that bear the strongest and most consistent relation with student achievement.
- time on task** The amount of time that students are working on instructional materials or attending actively to instructional presentations and discussions.

1. INTRODUCTION

Researchers over the years have been interested in what makes a “good” teacher. Early investigations focused on nonalterable behaviors such as personality, gender, intelligence, and even style of dress. Later, research focused on curriculum comparisons (e.g., phonics vs look–say methods of teaching reading) to determine effective teaching. Over the past several decades, researchers began to examine alterable variables, that is, those variables that teachers could alter in themselves to improve student achievement. This “teacher effectiveness” literature, although not without its critics, has been instrumental in identifying how teachers can best engage students in instruction to maximize their learning. Some important variables identified by teacher effectiveness research are provided in Table I.

Teacher effectiveness research has sometimes been criticized for its supposed emphasis on

TABLE 1
Some Teacher Effectiveness Variables

<i>Variable</i>	<i>Description</i>
Time on task (engaged)	Direct student engagement with instructional presentations or materials
Planning for content coverage	Content presented to students during a given time period
Scope and sequence	Content to be covered and order of presentation
Objectives	Behavioral outcomes of instruction
Curriculum	Instructional materials and course of study
Pacing	Rate at which objectives are met
Teacher presentation	Teacher delivery of information, including elements such as structure, clarity, redundancy, and enthusiasm
Feedback and praise	Teacher acknowledgment and provision of information regarding performance and positive consequence of student responding
Guided and independent practice	Opportunities for student practice of acquired content or skills in supervised or unsupervised circumstances
Weekly and monthly review	Activities to promote long-term retention of academic content or skills

teacher-determined (rather than student-generated) curricula, transmission of knowledge by direct instruction (rather than construction of knowledge by student discovery and inquiry), and pointed emphasis on achievement test scores as outcomes (rather than measures of affect, classroom tests, performance or portfolio assessments, etc.). However, it has also been suggested that the “effective instruction” variables are important regardless of the type of teaching, learning, or assessment that is being undertaken. For example, even when curricula are student generated, learning is inquiry based, and outcomes are measured with classroom performance assessments, it is important that students be actively engaged in relevant activities and instructional materials. Likewise, regardless of content or approach to instruction, it is important that students receive relevant feedback and praise for their positive efforts.

2. OVERVIEW OF EFFECTIVE CLASSROOM INSTRUCTION

Effective teaching variables include those that involve planning for content coverage and that use effective teaching strategies. Planning for content coverage includes scope and sequence, objectives, curriculum, and pacing, whereas variables relevant to delivering instruction include maximization of academic engaged time, effective teacher presentations, appropriate use of practice activities, review, and formative evaluation. Making effective use of these variables can help to maximize the performance of general education students as well as that of students with disabilities or other special needs.

3. PLANNING FOR CONTENT COVERAGE

The importance of content coverage is obvious in that students almost certainly will not learn content or skills that have not been covered. Nevertheless, teachers vary greatly in planning for content coverage, and these differences are strongly related to student achievement. An important consideration in content coverage is that the amount and type of content covered must match the preskills and abilities of the students learning the content. Variables relevant to the general area of content coverage include objectives, scope and sequence, curriculum, and pacing.

Academic content is learned better if it is based on instructional objectives. Objectives state the desired outcomes of instruction so that the effectiveness of the instruction can be determined. Typically, an objective specifies (a) the content being addressed by the objective, (b) the conditions under which the student’s performance is to be assessed, and (c) the criteria established for acceptable performance. For example, consider the following objective: “The student will identify 5 homonyms from a list of 10 word pairs with 100% accuracy.” The content of the objective is homonyms, the conditions specify that students will be presented with a list of 10 word pairs, and the criterion for acceptable performance is identification (rather than production) with 100% accuracy. Another example of an objective is as follows: “The student will read four pages from the grade-level reading materials at a rate of 150 words per minute and will answer five comprehension questions with 100% accuracy.” This

objective also specifies content, conditions, and criteria to be achieved.

Scope and sequence refer to the breadth and depth of content to be presented and the order in which the content will be presented. Scope and sequence considerations allow for long-term planning of instruction and can provide implications for time allocations and the overall pace of instruction through the curriculum. Scope and sequence of instruction can help to prevent instructional redundancy and can help to ensure that students have mastered prerequisite content or skills before learning new content. Most states have developed standards for learning across the curriculum areas as well as grade levels that are used to define the scope and sequences selected for use at the school and classroom levels. These state standards present the basic learning that is expected at each grade level in every subject area. For example, the state of Virginia has standards for learning from kindergarten through 12th grade in mathematics, science, English, history, and social sciences, and these subjects are then assessed on statewide achievement tests. These standards can be accessed on each state's education department Web site.

The curriculum includes the instructional materials used for learning as well as the course of study and the scope and sequence within each grade level. The curriculum serves as an interface between the student and the learning objectives. Curriculum materials do not determine what instructional objectives will be; however, when they are used appropriately, they support and enhance the meeting of instructional objectives. For example, a teacher stating "Today we'll cover Chapter 12" is not specifying an instructional objective but merely stating which curriculum will be employed. However, curricula do carry implications for how instructional content will be presented. For example, a "hands-on" science curriculum that includes materials for student construction of electromagnets and telegraphs implies a model of instruction that is very different from that of a curriculum that includes a textbook with a chapter on electromagnetism.

Curricula are most effective for a variety of learning needs when they are directly relevant to the learning objectives, are carefully sequenced, provide sufficient redundancy of key concepts, and contain relevant activities for teacher evaluation of student progress toward meeting objectives. The most effective curriculum materials are meaningful and relevant for all students, including male and female students and students from a variety of cultural backgrounds, and should

include adaptations (or suggestions for adaptations) for students with disabilities or other special needs.

4. USING EFFECTIVE TEACHING STRATEGIES

The most consistently identified teacher effectiveness variable is time on task. That is, the more time that students spend learning specific academic content, the better they will learn it. Distinction is made between allocated time on task (the time that teachers allocate to particular instructional activities) and engaged time on task (the time that students actually spend engaged in instruction). Although no consistent relation has been seen between allocated time on task and academic achievement, research has demonstrated that engaged time on task is positively related to academic achievement. Strategies for maximizing engaged time on task have been identified and include effectively managing transitions, avoiding digressions and other irrelevant verbalizations, and managing classroom behavior. Sometimes, teachers can improve student-engaged time on task by examining the amount of allocated time for class and monitoring their own teacher behaviors more closely. For example, teachers may find that they start classes 5 minutes late, end classes 5 minutes early, stop during the middle of class to search for relevant instructional materials, and stop to manage inappropriate classroom behaviors. Once such target areas are identified, teachers can design strategies to improve each area that will result in increasing the amount of student-engaged time on task during classes.

Effective teacher presentations have also been identified. Teachers maximize achievement when their presentations contain elements such as structure of lesson, clarity of teacher presentation, redundancy in emphasizing important concepts, and enthusiasm. Structure includes enlisting students' attention, providing a lesson overview that includes lesson objectives, providing outlines of the lesson and indicating when transitional points occur, and summarizing and reviewing key points as the lesson proceeds. It is important that students be made aware of the structure and objectives of the lesson so that they will know what is to be accomplished and how it will be accomplished. For example, teachers who begin with statements indicating the order of the learning activities (e.g., "First, we will . . .," "Second, we will be . . .," "Finally, we

will . . .”) provide the structure for the lesson for all students. Clarity includes presenting clearly and directly to the point of the lesson, avoiding vague or unfamiliar terminology, and providing concrete understandable examples. All teacher dialogue should be directly pertinent to the objective of the lesson. Redundancy does not refer to unnecessary repetition; rather, it refers to reemphasis and restating of the key elements of a lesson, particularly significant concepts and rules. Redundancy refers to the provision of multiple opportunities to practice learning newly presented content. Additional practice opportunities can vary in format and length given that the goal is to provide students with many chances to practice learning new information. Many students not only benefit from redundancy but also require redundancy prior to mastering new content. Teacher enthusiasm helps to maintain students’ attention and helps to model a positive attitude toward learning. Components of teacher enthusiasm include appropriate body movements and gestures, animated facial expressions, vocal inflections, positive acceptance of relevant student contributions, and a high overall display of positive energy.

Teachers also can increase achievement when they teach at an appropriate rate of presentation and when they maximize active student engagement with instruction or instructional materials. Selecting an appropriate rate of instruction not only is very important but also can be very challenging for teachers during the current era of statewide high-stakes testing. For example, if it is apparent that students have not learned a concept, it becomes necessary to back up and reteach that concept. This may require taking an additional class period or more depending on the students and the knowledge level required. The challenge for teachers is to ensure that all necessary content is covered before the end of the school year.

During teacher presentations, appropriate use of feedback and verbal praise is also associated with higher achievement. For example, praise that acknowledges student effort, specifies what the student did to merit praise, and demonstrates the association between effort and achievement is positively related to student achievement. Another important characteristic of praise is that it be genuine.

Following teacher presentation, guided and independent practice activities are associated with long-term learning and academic achievement. Guided practice activities are conducted under teacher supervision until it is certain that students are able to proceed independently. Students undertake independent

practice activities when the students have demonstrated acquisition of skills or concepts being taught and need independent practice to further reinforce learning. With both guided and independent practice, instructional tasks and materials must be directly relevant to instructional objectives.

Overall, a model of effective instruction for an individual lesson includes daily review, statement of objective, teacher presentation, guided practice, independent practice, and evaluation of learning objectives. Weekly and monthly review activities are also related to long-term learning and retention of important concepts.

5. PROMOTING EFFECTIVE INCLUSIVE INSTRUCTION

Research has supported the use of teacher effectiveness variables with students with special learning needs as well as with normally achieving students. In inclusive classrooms (i.e., classrooms in which students with special needs are included with normally achieving students), use of teacher effectiveness variables has been seen to increase learning for all students. In inclusive classes, awareness of the range of student needs is even more important, and consideration of the effective classroom instruction variables can guide teachers’ instructional decision making.

Many of the teacher effectiveness variables have a direct impact on the characteristics of students with special learning needs. For example, because time is an important mediator of achievement, maximized time on task can directly address students who are having difficulty in assimilating academic content. Structure, clarity, and redundancy in teacher presentations can be directly beneficial to students who have difficulty in sustaining attention as well as to those who do not grasp new concepts quickly. Enthusiasm is helpful for students who are less motivated to succeed in school, and appropriate rate (or pace) of presentation of information and maximized engagement can be critical variables for those who must maximize efficiency to make adequate progress. Frequent review and evaluation can help to determine whether instruction was successful and when further intervention is needed.

Teacher effectiveness variables have also proven to be useful as a model for addressing specific learning problems. For example, if a student is having particular difficulty in mastering specific academic content,

teachers can consider whether certain variables can be adjusted. That is, teachers can increase the amount of engaged time on task, or they can adjust the rate of presentation or overall pace of instruction for meeting instructional objectives. Likewise, they can adjust their teacher presentations, the rate of presentation, or student engagement. Practice and review activities can also be adjusted. By attending to these alterable variables, student learning in inclusive settings can be addressed.

GLOSSARY

biopsychosocial model Model that describes how the interaction between the social, physical, and psychological characteristics of individuals results in a physical, mental, and emotional health outcome that influences their future behavior.

elder abuse (1) Intentional actions that cause harm or create a serious risk of harm (whether or not harm is intended) to a vulnerable elder by a caregiver or other person who has a relationship of trust with the elder. (2) Failure by a caregiver to satisfy the elder's basic needs or to protect the elder from harm.

feedback loop Scheme by which outcomes are continually processed back to the variables that determined the outcome. The new outcomes result in new interpretations of the variables, which results in new outcomes.

financial abuse Misuse of another person's funds or theft of money, property, or possessions.

neglect A type of physical abuse that can be either intentional or unintentional. In terms of elder abuse, neglect is

the failure to provide the basic needs of the elder or to provide goods or services that are necessary to avoid or prevent physical harm, mental anguish, or mental illness.

physical abuse An act that may result in pain, injury, and/or impairment. Physical abuse includes bodily harm, neglect by others, and medical mismanagement.

psychological abuse A deliberate act inflicted on another to cause mental anguish.

sexual abuse Forcing another to take part in any unwanted sexual activity.

stakeholders Those who are invested in the lives of a particular individual. For the elderly, stakeholders can be health care personnel, social service agencies, friends, and families.

transgenerational violence Abuse that is "passed down" or continually generated throughout generations of a family.

Elder abuse is a social and public health problem that affects over half a million abused elderly victims in the United States as well as their caregivers, family, and community institutions. Abuse results in physical, emotional, and mental angst for victims, some of whom are cognitively and/or functionally impaired. There are also societal economic repercussions of elder abuse due to the increased need and demand for greater health care and social services to assist the victims. Although health care and law enforcement participation have helped assuage the situation, elder abuse detection, assessment, and treatment remain challenging. Adding to the difficulty of combating elder abuse is the booming

geriatric population, which is predicted to increase the strain on caregivers and societal institutions. This stress may perpetuate greater incidences of elder abuse in the future. Currently, multidisciplinary teams of psychologists, physicians, social workers, and public health advocates work together to educate, prevent, and intervene earlier in potential elder abuse cases. This article discusses the ways in which professionals are attempting to ameliorate elder abuse, in addition to providing a brief background of the causes and effects of this problem. The discussion includes methods of identifying victims and abusers, assessment of abuse, methods of intervention, and factors to account for in treatment.

1. INTRODUCTION

1.1. Background

Elder abuse has been a phenomenon recognized in medical and social practice since the 1970s, when the terms “granny battering” and “granny bashing” were mentioned in literature from the United Kingdom. In the same decade, work on aging populations established the presence of similar incidents in the United States. Terms such as elder mistreatment, elder abuse, and battered elders syndrome have variously attempted to describe abuse against elderly individuals.

1.2. Definition

The Institute of Medicine defines elder abuse (or elder mistreatment) as (1) intentional actions that cause harm or create a serious risk of harm (whether or not harm is intended) to a vulnerable elder by a caregiver or other person who stands in a trust relationship to the elder, or (2) failure by a caregiver to satisfy the elder’s basic needs or to protect the elder from harm. While the terms elder mistreatment and elder abuse are frequently used to describe this behavior, the term elder abuse will be used in this article.

1.3. Types of Abuse

Elder abuse occurring either in the home or in an institution can be described as one or more of the following types: physical abuse, neglect, psychological abuse, financial abuse, and sexual abuse. This article focuses on the issues of elder abuse as it occurs in the home.

1.3.1. Physical

Physical abuse is an act that may result in pain, injury, and/or impairment. Physical abuse includes bodily harm, neglect by others, medication misuse, and medical mismanagement. Bodily harm or physical assault can take many forms, such as beating, shaking, tripping, punching, burning, pulling of hair, slapping, gripping, pushing, pinching, kicking, and the use of physical restraints.

1.3.1.1. Neglect and Self-Neglect Neglect, which is considered a type of physical abuse, can either be intentional or unintentional. Intentional neglect is the deliberate failure to provide the basic needs of the elder. It also includes the failure to provide goods or services that are necessary to avoid or prevent physical harm, mental anguish, or mental illness. Unintentional neglect occurs when the caregiver is not knowledgeable about the elder’s needs or when the caregiver is restricted in the care they can provide due to his or her own infirmities.

Self-neglect is a failure to engage in activities that a culture deems necessary to maintain socially accepted standards of personal or household hygiene and to perform activities needed to maintain health status. Self-neglect has been categorized as a type of physical abuse by some authors. The highest national percentage of reported cases of abuse are those of self-neglect.

1.3.2. Psychological/Emotional Abuse

Psychological and/or emotional abuse can occur independently or can be related to physical abuse such as neglect or other forms of abuse. It is a deliberate act inflicted on the elder that is intended to cause mental anguish. Psychological abuse may include isolation, verbal assault (name calling), threats that induce fear (intimidation), humiliation, harassment, ignoring, infantilization, and emotional deprivation.

1.3.3. Financial Abuse

Financial abuse is the misuse of an older person’s funds or theft of money, property, or possessions.

1.3.4. Sexual Abuse

Sexual abuse involves forcing the elder to take part in any unwanted sexual activity, such as touching that makes the elder feel uncomfortable or photographing the elder person while he or she is changing clothes or bathing.

1.4. Epidemiology of Abuse

The National Center on Elder Abuse (NCEA) reports that in 1996 an estimated 551,011 persons aged 60 and over experienced abuse, neglect, and/or self-neglect in a 1-year period. The report also adds that there were four times as many new, unreported cases of elder abuse. Another study noted that more than 105,000 elderly Americans were victims of non-fatal violent crimes in 2001.

An anticipated increasing geriatric population is predicted to expand the elder abuse problem. According to the 2000 U.S. census, the number of individuals over the age of 65 has increased from 31.2 million in 1990 to 35 million in 2000. Population specialists predict that with these continuing trends, by the mid-21st century there will be more elderly people than young people in the United States. The increasing number of senior citizens creates greater dependency on the immediate and extended family and demand for health and social services to accommodate to the increased longevity and chronic medical care of the elderly. Higher costs of health care, inadequate support for caregiving, and personality conflicts between the elder and the family or caregiver can strain relationships and may contribute to the possibility of abuse.

2. LAW

Federal policymakers first addressed the issue of elder abuse through the Older Americans Act of 1965, which was followed by the Vulnerable Elder Rights Protection Program in 1992. Since then, states have developed their own laws governing elder abuse management. State elder abuse statutes have primarily been based on laws developed to address child abuse and spousal/intimate partner abuse. The primary focus of elder abuse laws in most states has been mandatory reporting statutes and follow-up investigational procedures. Forty-two states have mandatory reporting laws, and eight states have voluntary reporting requirements. Psychologists are mandated reporters in 29 states and are encouraged to report elder abuse in five states. The investigating agency and the scope of authority of the agencies varies from state to state, but the Adult Protective Services (APS), the Long-Term Care Ombudsman, and the local law enforcement agency are the most commonly recognized organizations to whom a report can be made about suspected or confirmed elder abuse. Penalties for not reporting elder

abuse, the time frame for emergency reports, and the maximum length of investigation also depend on the state. It is recommended that interested parties become familiar with the reporting requirements specific to each state (<http://www.elderabusecenter.org>).

3. THEORIES OF ABUSE: RISK FACTOR PROFILES

The literature suggests that all older adults may be at risk of abuse. Reviews of the literature have found conflicting profiles of both victims and possible abusers, indicating that it is not fitting to eliminate any particular profile; nor is it appropriate to say that a typical profile exists. The following sections discuss factors clinicians should be aware of when working with older adults.

3.1. Impairment of the Elder

Alcohol abuse by the elder is one of the most common risk factors for elder abuse. Although research shows variations in the impact of alcohol abuse on elder abuse, it has been found that the victim's risk for elder abuse could increase up to 10-fold. Other commonly established risk factors for elder abuse include low cognitive abilities and physical functional impairment. Those with depression, dementia and psychiatric illness are more likely to be abused. Elders who have difficulty eating are also at greater risk of abuse. These impairments may lead elders to live with family members. Elders are more likely to be abused if they live with family but do not have a living spouse. This places women, who are more likely to be widowed, at a greater risk for abuse. However, women may also be abused when they care for a spouse who may have been or continues to be abusive.

3.2. Perpetrator Characteristics

Other risk factors of elder abuse have also been proposed. Anetzberger suggested that elder abuse is primarily a function of the perpetrator's characteristics. This means that the caregiver's problems, pathologies, and perceptions may be the key to understanding who becomes an abuser. Per G. Anetzberger, life stresses, financial problems, mental disabilities, and lack of empathy for older people with disabilities may render some caregivers "ill-suited for caregiving and, given the potential dynamics associated with

caregiving, can make them prone to inflict abuse” (2000, p. 48). Research from the Three Model Projects on Elder Abuse found that in many cases the abuser was emotionally or financially dependent on the victim. Substance abuse by the caregiver was also related to risk for elder abuse.

3.3. The Interaction between Caregiver and Care Receiver

The caregiver–elder relationship also affects the potential for abuse. Risk may increase if the caregiver perceives the care recipient as difficult, combative, excessively dependent, or any combination of these. Homer and Gilleard found that socially disruptive behavior by the care receiver was related to elder abuse. However, others have found no such relationship. The duration, type, and intensity of care needed, cultural values, and individual family expectations also contribute to the possibility of abuse. Among ethnic minority caregivers, burden may be less likely to be an issue expressed by caregivers. Some studies have found risk factors associated with non-white or ethnic minority populations.

3.4. Multi-Factor Clinical Assessments

Given the conflicts that have emerged in research, the prudent clinician will continue to use all of these factors in his or her assessments. Many clinicians often overlook the importance of understanding the caregivers of older adults. Clinicians should recognize that caregiving is a risk factor for abuse, and paying close attention to the caregivers’ attitude toward their roles may be useful in preventing abuse from occurring or being overlooked. Therefore, they need to observe the dynamics of the family relationship when meeting either the caregiver or the care receiver.

4. CLINICAL MANAGEMENT OF ELDER ABUSE

Elder patients can self-refer or be referred for a psychological review by their primary care physician or other health care provider. Whether the health care provider refers elders for suspected elder abuse or for changes in emotional and/or psychological and cognitive status, it is necessary that psychologists always screen elder patients for incidences of abuse.

The theoretical model that guides clinical management is described more fully in a 2003 Institute of Medicine Report. This model is adapted from Engel’s biopsychosocial model. According to the elder abuse model, the social, physical, and psychological characteristics of the elder interact with those of the caregiver or trusted other. The interaction between the elder and the caregiver or trusted other person occurs in an environment governed by the socioeconomic conditions of the involved parties, the level of economic dependency, and the normative expectation of other stakeholders (health care personnel, social service agencies, friends, and relatives). Also important to the interaction between the caregiver and the elder is the sociocultural context in which they live, which encompasses the institutional or organizational locus (such as nursing home, private household), race or ethnic group, and social network of the elder and caregiver. The presence of social ties of the stakeholders to the elder and the caregiver may serve as a monitoring control on their interaction. Literature suggests that absence of this social network increases the vulnerability of the elder to the risk of abuse.

The physical, mental, and emotional health outcomes of the interaction between the elder and the caregiver impact their future behavior. These outcomes continually feedback to and remold the elder’s and caregiver’s social, physical, and psychological characteristics that will produce new outcomes. The feedback loop may sometimes result in the occurrence of abuse, either as a one-time incident or as a progression of violent episodes. This process-oriented model can help expand understanding of the etiology of specific types of elder abuse, help develop suitable interventions, and eventually lead to a reversal of the process.

4.1. General Evaluation and Analysis

4.1.1. Approach

The person who elicits the elder’s history during a clinical visit should be patient and tolerant. Elders who arrive at a clinic for assessment may speak slowly. It is important to talk clearly and slowly to an elder patient, as he or she may have hearing impairments. Care should be taken not to infantilize the patient and not to subscribe to ageist attitudes and myths about the elderly such as forgetfulness, senility, dependency, ineptness, unproductivity, and unattractiveness. Cultural and ethnic differences between the physician and patient must be respected and considered. Tact, belief,

and discretion are paramount to developing a trusting relationship with the patient.

4.1.2. Observation

Anyone who assesses an elder for signs of abuse needs to pay close attention to patient–caregiver interactions. Increased discomfort, silence or monosyllabic responses, and fear exhibited by the patient when the caregiver is present may be indicators of elder abuse. In such situations, it is advisable to interview the patient when the caregiver is not present. Patients' responses and body language need to be critically observed. Fear, anger, infantile behavior, agitation, rocking (in the absence of other motor diseases), and sucking are some behavioral responses that may indicate possible abusive situations in the patient's life. Other indicators include, but are not limited to, confusion or disorientation while providing responses, withdrawal, denial of events and happenings, failing to talk openly, and providing implausible stories. Physical signs provide vital clues to possible elder abuse incidences. Cuts, lacerations, bruises, welts, dehydration, loss of weight, and burns should raise suspicion of abuse.

4.1.3. History Taking

4.1.3.1. Past History Theories about elder abuse indicate the role of transgenerational violence as a high risk factor for violence against a senior adult. Past history of domestic violence in the life of the victim (either as the perpetrator or the victim) needs to be elicited with a nonjudgmental and sensitive approach. A history of past relationships, family dynamics, the number of household members, education levels, and available societal resources such as visits from friends, other relatives, and neighbors provide clues to detect isolation and incidences of neglect. History of substance abuse (alcohol and or chemical dependency), employment status, housing, and financial status provide insights into possible cases of dependency and potential abuse. Sexual history should also be considered.

4.1.3.2. Family History Death of a spouse or partner and history of alcoholism among family members are areas that need to be explored. Serious psychiatric disorders in the family might provide a clue to the level of caretaking and dependency that the elder might be responsible for in his or her home.

4.1.4. Screening

Detection of elder abuse can be accomplished by routinely screening for abuse. The American Medical Association urges every clinical setting to use a routine protocol for the detection and assessment of elder mistreatment. There are several instruments available for screening the patient and/or the caregiver. Table I contains a list of screening methods and instruments along with information on their measurement properties. Once a case is identified as suspected positive, an intervention plan has to be developed and applied with the consent of the patient. The following sections describe other assessments that aid in identifying incidences of elder abuse.

4.2. Assessment of Cognitive Status and Personality of the Patient

Psychological assessment of an elder should include a comprehensive assessment of age-related conditions such as anxiety disorders, depression, mood disorders, sleep disorders, sexual dysfunction, substance abuse, and personality. Especially important are those tests that assess for risk factors of elder abuse, such as alcohol abuse and depression. The American Psychological Association recommends the following measures for assessing the psychological and cognitive status of the elder patient: The Beck Anxiety Scale, the Hamilton Depression Rating Scale, and other oral and written forms of depression-assessing instruments such as the Geriatric Depression Scale (GDS). Some authors also recommend the Beck Depression Inventory or the Yesavage Depression Scales. The CAGE instrument assesses alcohol usage. Additionally, the geriatric version of the Michigan Alcoholism Screening Test can be specifically used with older adults. The Mattis Dementia Rating Scale or Cummings Inventory for Alzheimer's Dementia helps evaluate dementia.

Health care providers need to look for overt and covert clinical signs of the patient's psychological and cognitive status during evaluations. Overt signs such as crying, silence, and irritability indicate a possible depressive state or social withdrawal; they could also be learned passive behavior. Prior to performing any assessments, the elder patient should be familiarized with the tests and procedures. Elders should have appropriate assistive devices such as eyeglasses and hearing devices. For those who are non-English speakers, the tester should be able to converse in the language spoken by the elder or seek the assistance of a professional interpreter.

TABLE I
Elder Mistreatment Measures^a

Measure	Summary	Characteristics	Properties
The QUALCARE Scale (Philips <i>et al.</i> , 1990a, 1990b)	Assessment of six areas: physical, medical management, psychosocial, environmental, human rights, and financial	Fifty-three-item observational rating scale designed to quantify and qualify family caregiving	Extensive psychometrics reported: Interrater agreement range: 0.79–0.88. Chronbach's alpha: 0.81–0.95 on six subscales
Hwalek-Sengstock Elder Abuse Screening Test	Assessment of physical, financial, psychological, and neglectful situations	Fifteen-item assessment screen for detecting suspected elder abuse and neglect	Discriminant function analysis: nine items identified 94% of cases. Three conceptual domains: violation of personal rights, characteristics of vulnerability, and potentially abusive situations
Fulmer Restriction Scale (Fulmer and Gurland, 1996)	Assessment of physical, psychological, and financial restriction of older adults	Thirty-four-item scale designed to elicit information regarding unnecessary restriction of the older adult	Chronbach's alpha: 0.78 Interrater agreement: 0.93 Available in Spanish

4.3. Risk Factor Assessment

An assessment of possible risk factors by a home care team or social worker can help identify needs and possible resources. Incidences of substance abuse, the availability of a caregiver and/or a support system from the patient's family or friends, financial dependency on the patient by other family members, and caregiver stress are factors that influence the plan of action. Any course of action that is recommended by the psychologist should be relayed to the elder's primary care physician. Available options should be discussed with the patient and the social worker if possible.

4.4. Treatment and Management

Once suspicion of elder abuse has been confirmed, the next step is to establish a plan of action to minimize the abuse or effects of abuse. A safety assessment is performed to ensure that preventive measures are adapted to the elder's needs. The elder's physical appearance, home environment, and personal surroundings should be considered when determining the immediacy of danger. A multidisciplinary team of professionals

should be involved in the diagnosis, management, and prevention of suspected elder mistreatment.

If the elder is in imminent danger, immediate action should be taken to remove the elder from the situation. One possible method of intervention is to admit the elder to the hospital. In the hospital, the elder will receive medical treatment and not be endangered. Less serious cases of suspected elder abuse can be dealt with through continuous monitoring of the elder. A safety plan may also be developed to ensure that the elder knows what to do if placed in a compromising situation. This may include packing a bag of clothes and keeping copies of important papers, keys, money, and other necessary articles to take if the elder needed to quickly leave his or her home.

If the danger involves the caregiver's burden, an intervention should be designed to lessen the stress of the caregiver through services including home health aides, adult day care, and other types of respite programs. Community resources should also be consulted for possible safety, educational, caretaking, and social support services.

When determining a plan of action, it is important to consider the capacity of the elder and the caregiver, due to the need for cooperation of both parties and the

desire to accommodate the individual to whom services are directed. One such method of intervention is psychotherapy. However, no specific psychological intervention is preferred for elders. Instead, treatment options are individualized, led by the nature of the problem, therapeutic goals, preferences of the involved elder, and convenience for the involved parties. During psychotherapy, the psychologist must remember to be culturally sensitive and respectful of the individual's race, gender, sexual orientation, and social class when assessing issues of mistreatment and formulating interventions. The psychologist should also be attentive to the sensory deficits of the elder, particularly hearing and vision loss, which may hinder communication. Last, psychologist should consider whether psychological symptoms are caused or exacerbated by underlying medical problems. This will enhance the patient-psychologist relationship and enable more effective and productive therapy sessions.

Another method of intervention is education. Elders can learn how to protect themselves and gain empowerment through education. Education may be used to assist psychological interventions by providing additional information regarding the rationale, structure, and goals of psychotherapy. Psychoeducation can also help families caring for cognitively impaired elders. It can familiarize the family with the nature of cognitive loss, problem solving for practical problems, and providing emotional support to cognitively impaired elders who have experienced abuse. Additionally, education teaches other professionals about aging and how to investigate suspected elder abuse. These professional can advocate for the safety of elders while providing psychological services to this population.

Physicians can also prescribe medications to elders to cope with the involved abuse. These prescriptions may enable elders to function well within society or address the repercussions of the abuse. If an elder is abusing his caregiver, medication may be used to normalize the elder's behavior and prevent him or her from doing further harm.

Patient/family cooperation should also be considered when creating a plan of action. For the plan to be useful, it must be implemented by the assisting family. Thus, interventions that consider abused elders' families and their shared values are needed. If the family of the abused elder disagrees with the chosen method of intervention, it is suggested that psychologists be sensitive to the family's opposition and work with them to create modifications to an intervention.

The key to success in each of these intervention methods is the follow-up process. To determine the

efficacy of the proposed intervention, the elder or caregiver must be contacted to ensure that the elder's needs are being met, that a safe environment is preserved, and that wellness of the abused individual is maintained. If interventions are ineffective, physicians must modify their plan of action by re-evaluating the abused elder's needs. One reason that physicians may need to re-evaluate action plans is a change in the elder's access to resources. Interventions must consider the elder's standard of living. This will guarantee the potential for intervention use by the abused elder.

An additional note of concern involves identifying potential challenges to suggested interventions. Challenges may include the resistance of elders to disclosing their personal experiences of neglect or abuse. This resistance may be associated with feelings of embarrassment or shame involving their mistreatment. Elders may also feel uncomfortable with the notion of receiving mental health services for their abuse. Their reservations require physicians to attend to their needs through reassurance of confidentiality during scheduled meetings, by participating in active listening with the elders, and by actively engaging with elders and their caregivers. This may require the enlistment of an individual who has a trusting relationship with the abused victim.

One specific way to counter sentiments of resistance is to validate both the positive and the negative feelings expressed by family members and victims. This validation will cause resistance to slowly diminish as elders begin to feel that their physician is trustworthy and wants to help them. This gradual progression toward an open relationship will foster an environment suitable for the disclosure of sensitive material.

Intervention efforts may be impaired if the elder is cognitively unaware. Should the abused elder suffer cognitive impairment, it is necessary for psychiatrists or geriatricians to ensure that the elder receive adequate care from a reliable caregiver. If the caregiver is a possible abuse perpetrator, or if he or she is unable to handle the elder's impairment, additional respite care or institutionalization should be considered.

5. ETHICAL ISSUES

When developing interventions in elder abuse cases, the clinician needs to be cognizant of the basic principles of autonomy, justice, beneficence, and nonmaleficence.

5.1. Autonomy

Autonomy is the right of self-determination. It is the right to choose one's actions or course in life as long as they do not interfere unduly with the lives and actions of others. A clinician must respect the options and choices made by the elder in regards to his or her living situation and caregiver. If the patient decides to continue living in the abusive situation, written information regarding emergency assistance, a follow-up plan, and a safety plan should be developed in consultation with the victim. However, it is imperative to assess the cognitive status and mental stability of the elder and caregiver.

5.2. Justice

The principle of justice allows everyone the right to that which he or she is due. Some elder patients may not receive adequate care because the caregiver and/or family is exploiting the finances of the patient. Although the caregiver may use the patient's funds to care for the elder, any unequal distribution of resources that jeopardizes the health and well-being of the elder and that which is done against the wishes of the elder is a violation of the rights of the patient.

5.3. Beneficence and Maleficence

Any intervention that is developed to address elder abuse should do no harm to the patient. The psychologist developing interventions should consult the patient, the patient's doctor, and the social worker before deciding on a course of action. Decisions that raise ethical dilemmas should be weighed for the merit of potential good in relation to the potential harm. This involves recognizing the limitations of the available resources for the patient, the caregiver, and the cognitive and general health of the patient and the caregiver.

6. FUTURE DIRECTIONS

Psychologists and other public health personnel should educate the public about elder abuse. Culturally relevant materials and messages tailored to suit the needs of minorities conveyed in English and other languages will help inform the general public about the issue. Information for caregivers on their role and the availability of resources in the community will improve

early detection and management of elder abuse. Advocacy for the rights of elders, especially in the area of mental health, to support their social and emotional well-being is necessary. Collaborative research with community organizations and academic institutions involved in research will help identify new areas for development.

7. SUMMARY

Forms of elder abuse include physical abuse, neglect, psychological abuse, financial abuse, and sexual abuse. These types of abuse may occur independently or coexist with another form of abuse and may be difficult to detect. When assessing for signs of abuse, a clinician should pay attention to visible marks as well as emotional and mental expressions of fear, anger, confusion, and sadness. The caregiver's circumstance, competency, and relationship to the elder should also be considered in the assessment. One difficulty in recognizing and diagnosing potential elder abuse is that its symptoms and risk factors may resemble otherwise normative age-related illnesses such as dementia and depression. Also, no typical profile exists for either the caregiver or the victim. When assessing for abuse, a range of psychological tests should be performed and extensive past histories and current circumstances should be elicited to gain a full understanding of the elder's situation. After diagnosis, possible methods of intervention include psychotherapy, psychoeducation, and separation of the elder from the caregiver. In formulating an intervention, the needs and abilities of the victim and caregiver should be taken into consideration, as must the rights of the victim. Plans of actions should be routinely re-evaluated to judge the intervention's effectiveness and should be adjusted according to changes in the circumstances of the victim and caregiver. The clinician should approach the process of assessment to intervention with patience for disabilities that the elder might have and without discriminating against factors such as age, culture, gender, and social class.

GLOSSARY

activities of daily living (ADLs) Basic activities necessary for a person to perform on a daily basis, specifically bathing, dressing, toileting, making transfers, continence control, and eating.

culture Worldview, values, norms, and behavior guidelines shared by a group of individuals that influence and form the group's way of life.

ethnicity A group's shared personhood based on a distinctive social and cultural heritage passed on from generation to generation.

formal caregiver Any person who provides assistance or care to another for financial compensation such as a nurse, a home health aide, or a social worker.

informal caregiver Any person who provides assistance or care to another without financial compensation such as a family member, a friend, or a church volunteer.

instrumental activities of daily living (IADLs) Basic activities necessary for a person to perform to be able to live independently, specifically managing money, using the telephone, grocery shopping, personal shopping, using

transportation, housekeeping, doing chores, and managing medications.

Caregiving for older adults is a prominent occurrence in the daily lives of many Americans. It is a topic that has received considerable attention from a variety of sources, including research, popular media, and society as a whole. This article offers an overview of the current body of knowledge in the field, including but not limited to specific topics such as the stressors associated with caregiving, the impact of caregiving, and interventions that may be beneficial.

1. INTRODUCTION

This article provides an overview of important issues faced by family caregivers, a topic that is of increasing interest in our society. Although illness and disability can strike at any time in the life cycle and lead to care by family members, this article focuses on caregivers for older adults. It reviews the importance and growth of family caregiving; stress process models used to guide research and clinical practice; common stressors faced by family caregivers; the impact of caregiving on psychological, social, and health functioning; individual differences in response to caregiving; and psychosocial interventions for caregivers.

2. OVERVIEW OF ELDER CAREGIVING

As the population ages and an increased number of individuals are faced with the responsibility of caring for aging loved ones, the topic of elder caregiving becomes increasingly prominent as an area of research, clinical practice, and public policy. Broadly defined, caregivers are individuals who provide assistance of varying levels to other people who are unable to perform these tasks for themselves. Often the term “caregiver” is associated with a group of individuals who are thought of as homogenous; however, the open nature of the definition allows a high degree of variability within this group. One important distinction is that caregivers can be either paid (formal) or unpaid (informal). Formal caregivers are those who receive financial compensation for the services they perform (e.g., nurses, home health aides), whereas informal caregivers are those who volunteer their time to assist loved ones (e.g., family members, friends). It is estimated that between 80 and 90% of individuals with physical impairments reside in the community and receive the vast majority of their care from informal sources.

The cost of informal caregiving in the United States, including things such as lost wages, keeping an individual out of a nursing home, and performing tasks that otherwise someone would have to be hired to do, was estimated to be \$196 billion in 1997, the year of the most recent national reliable estimates. This dollar figure is more than twice the amount estimated for nursing home care during that same year. Informal caregiving, although substantially less of an economic cost to the family members compared with institutional care, is often coupled with a number of other physical, psychological, and social costs to the individual (discussed in greater detail later).

Individuals choose to take on the responsibility of caring for a loved one for a variety of reasons, including economic conditions, perceived obligation, a cultural ethic that caregiving is expected, and a positive desire to provide care as a meaningful and worthy activity. Formal care for a chronically ill individual is very expensive, whether provided by professionals who come into the home, in an assisted living facility, or in a nursing home. Medicare and Medicaid rarely cover such services fully; thus, many families simply cannot afford such care. However even in situations where financial considerations are not the primary concern, many

families consider it their duty to provide the necessary care and keep their loved ones at home. It is also common for caregivers in these situations to report that they believe they can provide better care than can staff members who do not have personal relationships with their loved ones.

3. STRESSORS OF CAREGIVING: WHAT DO CAREGIVERS DO?

Depending on the nature of the illness, caregivers may face a variety of daily demands. These can include impairments in self-care and cognition as well as development of changes in personality and behavior. Other stressors can include physical care demands and issues specific to end-of-life caregiving.

Self-care impairments include higher level instrumental activities of daily living (IADLS) and more fundamental activities of daily living (ADLs). IADLS include tasks such as managing finances, housekeeping, using transportation, and taking medications independently. Loss of independence in IADLS occurs relatively early in the course of progressive dementias but can also occur due to less serious medical problems (e.g., arthritis) that may limit mobility. ADL impairment occurs during middle and later phases of dementia and includes loss of independence in fundamental skills such as bathing, dressing, feeding, and continence of bowel and bladder. Family caregivers who assist with self-care impairments may provide only minor intermittent assistance (e.g., assistance in balancing a checkbook). Assistance with personal care, such as bathing and managing incontinence, is more psychologically stressful because it may involve embarrassing personal care. With assistance with ADLs and IADLS, families may face issues such as role reversal.

Cognitive impairment produces its own unique stressors. In addition to producing decrements in ADL and IADL functioning, dementia can lead to problems such as becoming disorientation, repeating questions, and forgetting to do tasks. Dementia also leads to behavioral problems such as wandering, agitation, and delusional behavior. *Table 1* lists 10 patient problems reported to be the most stressful by a large sample of caregivers for older adults with dementia. Of particular note is that behavioral problems were reported to be much more stressful than self-care problems—even incontinence.

Caregiving for persons with terminal illness creates additional stressors. Beyond the actual tasks of caregiving, other issues include stressors that are more difficult

TABLE I
Patient Problems Reported as Stressful by Caregivers

to define. One of these is witnessing the suffering of the care recipients. Caregivers may also be responsible for management of complex medical regimens.

Interaction with the formal care system can be another important stressor. Caregivers report that it is very difficult to negotiate care, manage in-home assistance, and deal with nursing homes. Research has also shown that when caregivers receive formal assistance, it does not decrease their involvement in or commitment to informal caregiving; instead, it simply supplements the informal caregiving activities.

A national survey of family caregivers conducted in 1996 found that the overall mean number of hours of care per week was 17.9; however, this number ranged from 3.6 hours for individuals whose relatives were mildly impaired to 56.5 hours for those whose relatives had significant physical and/or cognitive disabilities. In addition, the stage of the illness is a major factor in affecting how much care a person provides. Research examining spousal caregivers of persons with end-stage lung cancer in hospice has shown that an average of 120 hours per week of care is provided by these individuals. The actual services performed by family caregivers can vary from occasional shopping and household assistance for a frail elder; to assistance with bills and organization for an individual with early-stage dementia; to assistance with dressing, bathing, and ambulation for an individual who has suffered a moderate stroke; to complete responsibility for toileting, eating, and medications for an individual with end-stage cancer.

To get a better understanding of the broader picture of caregiving in the United States, the National Caregiver Survey was conducted in 1996. This study

included 1500 family caregivers of individuals with both dementia and non-dementia diagnoses and provided very valuable insight into the differences between the two. The participants in this study had been providing care for slightly longer than 5 years regardless of diagnosis; however, the dementia caregivers reported significantly more hours per week in the caregiving role. In addition, a significantly higher percentage of dementia caregivers were providing care for each of the ADLs surveyed than were non-dementia caregivers. These findings suggest that the dementia caregivers in this study experienced greater demands while in the caregiving role, which apparently carried over into other areas of their lives. The dementia caregiving group reported greater impacts in terms of family conflict, caregiver strain, time for leisure and other activities, and mental and physical health problems.

4. INDIVIDUAL DIFFERENCES IN REACTION TO CAREGIVING

A number of studies have shown that high levels of stress experienced by caregivers of elders, in particular those with Alzheimer's disease or other types of dementia, often lead to a number of negative psychosocial and health outcomes such as feelings of burden, social isolation, depression, and health problems. However, although most caregivers endure immense stress, they vary in their ability to cope successfully. Researchers have found that it is not necessarily the objective level of stress experienced by caregivers that affects their mental and physical health; rather, it is actually a combination of factors, including context of the caregiving experience, individual appraisal of the caregiving role and competence in that role, coping style, and social support.

First, the context variables, such as the caregiver's gender, age, and health, the quality of the caregiver's relationship to the care recipient, and the length of time providing care, are believed to exert influence throughout the caregiving experience. Socioeconomic status, such as income and education, can affect caregiving outcomes, including morbidity and mortality. It is well established that there is a negative relationship between socioeconomic status and chronic morbidity and mortality, especially among older persons. Socioeconomic characteristics can exert an indirect effect via stress, social relations, and/or health status.

It is common for one individual to take on the role of primary caregiver, with women being the most likely to provide care either for themselves or for their own spouses. It is estimated that 70% of all family caregiving responsibilities are taken on by women and that more than 50% of all women provide this type of care at some point in their life courses. This is significant because studies that examine the effect of gender on the caregiving experience have consistently found that female caregivers may be at greater risk for negative mental health outcomes. Female caregivers tend to report higher levels of depressive symptomatology and anxiety, and lower levels of life satisfaction, than do male caregivers. Such gender effects seem to exist among both spousal and adult child caregivers.

The quality and nature of the relationship between caregivers and care recipients can also influence caregiving outcomes. It is generally recognized that positive social ties have a beneficial influence on general well-being. In caregiving situations, greater affection or intimacy with care recipients can reduce perceived burden or strain and can lower psychological distress among caregivers. Negative social interactions while caregiving, such as family conflict and criticism of caregivers, are a risk factor for greater caregiver depression. Other problematic situations include caregivers who suffer abuse from care recipients and estranged family members who are left with "unfinished business." Spousal caregivers generally spend a substantially greater number of hours per week in the caregiving role, do so for a longer period of time, and report more difficulty in sleeping, less energy, and more fatigue than do nonspousal caregivers. Spousal caregivers are also generally more willing to provide care even when care recipients need extensive care, and they are much less likely to place care recipients in nursing homes, than are adult children. In addition, spousal caregivers consistently have been shown to be in poorer health than noncaregivers. This finding is also shown for adult child caregivers; however, the increased age of spousal caregivers places this group at an even higher risk for personal physical health conditions. These findings, taken together, suggest that spousal caregivers are very committed to their roles and responsibilities, even at the expense of their own health. The vast majority of nonspousal caregivers are adult children for elderly individuals; however, African Americans are more likely to be cared for by members of their extended family than are their European American counterparts. In addition, the societal changes in marital status and number of

children per family have introduced an increasing number of friends, primarily older, never married, childless women, who care for each other, and this population of caregivers is likely to increase during the coming years as the baby boom generation ages.

A second important variable in the caregiving experience is appraisal. Caregivers vary greatly in their subjective reactions to the same circumstances. Caregivers who appraise the problems they face as highly stressful are at increased risk for depression, whereas caregivers who are able to find meaning and benefit from their caregiving experience, and who have high levels of self-efficacy in caregiving, are more resilient to the negative effects of caregiving. Caregiver appraisals are often influenced by caregivers' personalities, with a number of studies showing that neuroticism leads to negative appraisals and higher depression. Anger tends to be one of the most common negative affects among caregivers, especially the ones caring for Alzheimer's patients and those who have poor physical health. One common cause of anger in caregivers that can be addressed therapeutically is inappropriate attributions that care recipients' problems are intentional rather than being the effect of Alzheimer's disease, stroke, or other brain impairments. In contrast, caregivers with personality characteristics such as high levels of optimism may be protected from some of the negative consequences of stress.

Third, research has demonstrated that coping style and social support are critical in explaining the tremendous variability in physical and mental health outcomes for caregivers. The role of resources such as social support and coping strategy is to buffer the effect of stressors on the outcome. In general, informal support networks lessen the negative consequences of caregiving such as emotional distress, health concerns, and economic strain. It is important to note that social support can be viewed not only in terms of quantity but also in terms of subjective perceptions of the quality of support. Coping is considered another important buffer and is usually separated into two categories: problem-focused coping and emotion-focused coping. Caregivers may use problem-focused coping by seeking information about their relatives' conditions, pursuing medical advice or rehabilitative care, and/or arranging for assistance with caregiving duties. In contrast, emotion-focused coping by caregivers may include adaptive efforts such as finding meaning in adversity and distracting themselves from caregiving concerns as well as maladaptive efforts such as engaging in excessive rumination, denial, and/or substance abuse. Problem-focused coping is generally

adaptive but may reach limits when little or nothing can be done to improve the objective aspects of the care recipients' functioning. At such a point, the ability to accept limitations may be most adaptive.

5. RACIAL AND ETHNIC DIVERSITY ISSUES

The sociocultural adaptation of the stress and coping model suggests that the role of ethnicity is greater than merely being a status variable reflecting the disadvantaged socioeconomic status of members of ethnic minority groups. This view asserts that one's ethnicity and culture exert an influence on nearly all domains and stages of the stress process model, including who provides care, how caregiving demands are expected to be handled and shared among family members, how caregiving experience is interpreted and perceived, how people cope and deal with stress during caregiving, and what stress outcomes are expected. As to why caregiving experiences differ by race and/or ethnicity, some studies suggest that racial/ethnic differences in values and beliefs about aging and caregiving may be responsible for the observed differences. Although it is dangerous to generalize about racial/ethnic differences due to the risk of stereotyping, the existing literature suggests that there may be important cultural differences in caregiving; however, the individual must clearly be viewed in his or her totality and not just as a member of a racial/ethnic group.

The literature indicates that African Americans often hold different role expectations and attitudes about providing care and coping mechanisms compared with those held by European Americans. African Americans tend to hold more positive attitudes toward older adults and perceive cognitive and/or physical decline in health among elders as part of a normal process of aging. In terms of caregiving experience, African Americans report heavier workloads and more unmet needs than do European Americans; however, African American caregivers also report that they experience lower levels of stress and burden as well as higher levels of satisfaction. Moreover, African American caregivers report increased levels of religiosity in response to caregiving. They are more likely to use their religious faith and activities (e.g., prayer) as a coping strategy than are European American caregivers.

Although studies on Hispanic caregivers are limited and there is great diversity among members of this

ethnic group, traditional values of Hispanic families influence their caregiving experience. One of these traditional values is familism, which emphasizes the importance of the family connection and interaction as well as the family serving as the core of the social support system. Thus, the kinship network is considered to be a very important source of social support for Hispanic elders. Family loyalty and filial piety among Asian Americans, and importance of relational networks among Native Americans, are known to be other important cultural values of ethnic groups that help to create a strong support system among them.

6. BIOPSYCHOSOCIAL IMPACT OF CAREGIVING

The beginning of this article noted that although informal caregivers ease the financial burden of long-term care for society, they do so at the risk of experiencing a variety of psychological, physical, and social consequences of caregiving. Research at this point has clearly demonstrated diverse effects of caregiving, but questions remain as to what degree and in which areas such effects occur.

One of the most consistent and well-researched relationships regarding the effects of caring for chronically or terminally ill individuals is the increased risk of depression. The availability of validated quantitative tools for evaluating depression has led to comparability across studies and confidence in the strength of the results. The actual rates of depression vary; however, most studies find that caregivers who are involved in dementia care, or in other extensive caregiving, are two to three times more likely to be at risk for clinically significant depression than are their noncaregiver counterparts. In addition, many caregivers experience subsyndromal or subclinical levels of depression. Caregivers are also much more likely to use psychotropic medications for mental health problems, such as depression and anxiety, than are noncaregivers.

To better understand the relationship between caregiving and increased risk of mental health problems, it is necessary for researchers to identify risk factors. Documented risk factors for increased distress during caregiving include being female, experiencing other stressful life events (e.g., bereavement), lacking social support, experiencing family tension, being younger, being in poorer physical health, ruminative thinking, and having lower education. Research has

also identified a number of factors that appear to be protective against negative mental health outcomes, including high levels of self-esteem and mastery, high ratings of optimism, high ratings of life satisfaction, and low ratings of neuroticism. The findings regarding patient diagnosis have been inconsistent, with some reporting that caregivers for individuals with Alzheimer's disease experience higher rates of depression and others reporting that the rates are comparable between diagnoses such as cancer and Alzheimer's disease.

An important emphasis of research in this area seeks to determine how long these changes in mental health status last, with a fairly large number of studies finding that elevated levels of depression are seen in some individuals for as long as 2 to 5 years following the loss of loved ones, although there is also evidence that some caregivers experience improvements in mental health when their caregiving ends. Additional longitudinal data are needed in this area to better understand what places an individual at risk for this type of chronic bereavement reaction.

Research on the physical health effects of caregiving has varied greatly in its sophistication in assessing health outcomes. A common assessment of physical health status in caregiving studies is a single-item self-rated health question, and more of these caregivers rate their health as poorer than do noncaregiving controls or population norms. Many studies in this area have used this single item as a proxy for physical health in the participants, and although research has demonstrated that this method can be reliable, more sophisticated methods are needed for success in this research.

There have been few longitudinal studies of the impact of caregiving on physical health. One large study comparing caregivers with noncaregivers of similar ages indicated that caregivers showed increased physical health symptoms over a 2-year period, whereas noncaregivers showed no increase over time.

Other studies have used more sophisticated measures of physical health. These studies indicate that caregiving can lead to increased health risk behaviors (e.g., drinking alcohol, smoking cigarettes), lower levels of physical exercise, changes in sleep patterns, decreased immune system functioning, altered response to the influenza vaccination, slower wound healing, increased blood pressure, and altered lipid profiles. There has also been interest in whether or not these physical health changes lead to increased mortality in caregivers, and this question was examined in the Caregiver Health Effects Study. This prospective, population-based

cohort study followed caregivers for an average of 4½ years and reported that caregivers who experience strain while in the caregiving role showed a 63% increase in mortality as compared with caregivers who did not experience strain and noncaregiving controls. Additional work is needed in this area to identify the mechanisms underlying these physical health changes and increases in mortality; however, this research has been very valuable in demonstrating that caregiving can represent a major and clinically significant strain.

Caregivers commonly report that their responsibilities infringe on their personal and social lives. Caregivers often are unable to take part in leisure activities, vacations, and/or valued activities such as church attendance. Spousal caregivers become devoted to their roles and the responsibilities they entail, often at the expense of their own needs, including social interaction. They report spending less time engaging in social activities (e.g., having lunch with friends, spending time with grandchildren) and in personal hobbies (e.g., gardening, sewing). A small group of caregivers, particularly adult daughters, are sometimes described as the "sandwich generation"; in some cases, they are responsible for caring for their own children as well as for their parents. Some researchers believe that this may become an increasing phenomenon given the current trend toward women holding off on having children until later in life. These caregivers very commonly report significant changes in their employment status (e.g., decreased hours, extended leave, leaving the workforce altogether) as a result of time constraints due to the needs of their aging parents. The specific effects vary based on relationships to care recipients; however, the overall pattern appears to be consistent in that caregivers sacrifice their social and personal roles to accommodate the needs of their loved ones.

The cyclic relationship among mental health, physical health, and social engagement is a concern for health care workers and clinicians. Increases in depression and physical health problems can lead to decreased social interaction; however, the reverse is also true in that role constraints that inhibit social activities can lead to negative mental health outcomes, specifically increased depression. An additional concern is in the case of bereavement following a period of caregiving. The literature has demonstrated that low social support and mental and physical health problems during caregiving can lead to complications during bereavement. Therefore, if individuals have experienced these changes as a result of the caregiving experience, they are at risk. It is important to identify caregivers who are at risk for

these negative psychological, physical, and social outcomes so that they can be targeted for assistance before the complications progress.

Finally, it should be noted that caregiving can lead not only to negative impacts but also to benefits. Recent studies show that caregivers often report benefits from caregiving such as a sense of satisfaction, a feeling that they are repaying care they received when they were young, and feelings of mastery and accomplishment. These positive feelings can occur simultaneously with negative effects.

7. INTERVENTIONS FOR CAREGIVERS

Each individual in a caregiving situation can experience his or her responsibilities and role as a caregiver differently due to that person's unique characteristics and circumstances. Moreover, caring for loved ones can be a meaningful and positive experience. However, caregiving can also lead to negative psychosocial and physical outcomes such as depression, lowered level of physical health, and lowered sense of well-being. Thus, many caregivers are in need of psychosocial and instrumental support. With an increased knowledge of how various stressors and other caregiving characteristics interact with each other and lead to different outcomes, various intervention methods have been developed and provided to caregivers in different caregiving settings. These interventions have also been evaluated for their clinical significance and effectiveness in both statistical and practical ways. A number of studies that summarize, evaluate, and examine the strengths and weaknesses of currently available caregiving intervention research literature have been published. These review studies can provide further detailed knowledge and information on the progress of caregiving intervention research. However, this article focuses on providing an overview of the caregiving intervention research, including primary entities being targeted by the interventions, types of interventions, and effectiveness of these interventions.

In general, interventions need to be tailored to specific needs of caregivers who have diverse and unique characteristics and caregiving experiences. For example, a caregiver who is dealing with severe behavioral problems due to dementia might want to learn about the nature and course of disease progression and how to handle behavioral problems effectively. On the other hand, a caregiver who has recently placed a loved one in a

nursing home might seek an intervention that can help him or her to cope with feelings of guilt. Therefore, caregiving interventions are designed to reduce different types of stress outcomes so as to meet unique individual needs of caregivers and their care recipients.

There are a few major domains of stress outcomes for which various intervention methods aim to improve. These outcomes include how caregivers respond to stress in terms of mental and physical symptoms, improved general sense of well-being and quality of life, and delayed institutionalization of care recipients. Symptoms that caregivers often exhibit in reaction to caregiving stress include elevated levels of depression, anxiety, anger, and hostility as well as lowered health status (often measured by self-reported health and blood pressure). Also, quality of life of caregivers is often measured broadly by life satisfaction, sense of burden, mood, and social support. Finally, other outcomes targeted for intervention include care recipient outcomes such as functional status and delay of institutionalization of care recipients and use of formal and informal support as well as services available to caregivers.

Caregiver interventions are focused on either improving quality of life and coping skills of caregivers or reducing the objective stressors such as amount of care provided by caregivers. These interventions include psychoeducational, psychotherapeutic, supportive, and service-based interventions. The psychoeducational intervention is often offered with other types of interventions and aims to improve caregivers' knowledge about themselves, care recipients, and the environment. This type of intervention focuses on teaching caregivers to develop skills in dealing and coping with stressors through providing comprehensive information on characteristics of disease process of care recipients, resources and services that caregivers can use, and other specific coping skills. Psychotherapy is another form of intervention that is often used in conjunction with psychoeducation involving individual counseling to caregivers by trained professionals. This type of intervention is usually designed to teach coping skills and problem-solving techniques with the cognitive behavioral approach.

Supportive intervention is another type, and its main goal is to build support systems or networks among caregivers and to create an environment for them to discuss and share problems and feelings related to caregiving. Thus, supportive intervention is focused on allowing participants (i.e., caregivers) to exchange ideas and strategies for coping with stressors and

difficulties. Service-based intervention programs usually provide respite and/or adult day care services. Respite and adult day care programs are designed for caregivers to take some time off from caregiving responsibilities by providing assistance with ADLs and/or certain activities for care recipients. Other types of intervention methods include providing memory training, activities, and medications to care recipients as well as relaxation training to caregivers.

Most of these interventions are multifaceted in their design and method, and they usually are offered in conjunction with other methods. This makes it difficult to attribute any specific component of intervention to the success of intervention outcomes. Moreover, the caregiver intervention literature shows that most of these interventions show some level of effectiveness, yet it appears that there is no single method that is clinically significant and effective across caregivers. However, in general, a combined form of individual educational and psychotherapeutic interventions tends to result in better outcomes than do group interventions. Moreover, psychoeducational and psychotherapeutic interventions are found to be effective in reducing

levels of depressive symptomatology as well as anxiety and anger. In addition to psychoeducational and psychotherapeutic interventions, behavior management training, stress management, and use of certain medications are known to be effective in increasing sense of well-being and quality of life of caregivers as well as in delaying nursing home placement of care recipients with Alzheimer's disease.

The majority of caregivers are likely to benefit from gaining knowledge about the diseases, caregiving tasks, and available resources. Some caregivers can obtain additional help by receiving training in coping and problem-solving skills as well as in behavioral management of care recipients. In addition, some studies have found that providing a mixed form of interventions that are given to both caregivers (e.g., psychoeducational intervention) and care recipients (e.g., medication, therapeutic activities) can also be effective. Furthermore, a fairly new approach to caregiving interventions involves using technologies such as enhanced telemedicine, computers, and the Internet. Table II provides an overview of some of the types of interventions described previously, including definitions and examples.

TABLE II
Definitions and Types of Caregiving Intervention

Type	Definition	Example
Psychoeducational intervention	This aims at improving knowledge of caregivers about themselves, care recipients, and the environment. This type of intervention focuses on teaching caregivers to develop skills to deal and cope with stressors.	Problem solving, coping skills training
Psychotherapeutic intervention	This involves individual counseling to caregivers by trained professionals. It is mostly designed to teach coping skills and problem-solving techniques with the cognitive behavioral approach.	Cognitive behavioral therapy
Supportive intervention	The main goal is to build a support system or network among caregivers and to create an environment for them to discuss and share problems and feelings related to caregiving.	Support group
Service-based intervention	Goals include facilitating caregivers' use of formal services, improving competence of care recipients, and delaying institutionalization of care recipients. Services provided include respite care for caregivers and drug and activity therapy for care recipients.	Respite care, adult day care, medication therapy, and memory clinic (for care recipients with dementia)

8. CONCLUDING COMMENTS

Family caregiving is a topic that demands greater attention from researchers, clinicians, and those concerned with public policy. The aging of the baby boom generation may stimulate greater attention to the possibility of changes in public policy that provide more support for caregiving families. For example, in other countries, family caregivers may receive pay in recognition of their efforts, adjustments to their retirement benefits, vouchers that can be used to purchase community services, and other forms of support that recognize the value of family caregivers in preventing expensive and unnecessary institutional care.

GLOSSARY

anger An emotion elicited by the appraisal that a demeaning offense or injustice has been committed against one's self or one's own; anger communicates the intent to redress the perceived wrong.

anxiety An emotion characterized by threat and vigilant cognition that can impair performance when conditions are perceived as providing a challenge that exceeds capacity; low levels of anxiety can enhance performance, but high levels of anxiety can impair ability.

emotional expression Displays of experienced emotion in the face, body, voice, gesture, and gaze; expressions of emotion convey important information to others about the sender's current state, likely behavior, and enduring dispositions and help to shape social interactions in important ways.

happiness The broadest and most recognizable positive emotion; the display of happiness is characterized by the Duchenne smile, which involves movements of muscles around the mouth and eyes.

interpersonal Emotion processes that occur at the level of ongoing social interaction where two or more people are interacting; in this more social context, emotions coordinate social behavior and smooth the progress of social relations.

intrapersonal Emotion processes that occur at the level of the individual, including the cognitions, physiology, perceptions, and behaviors associated with individual response to environmental opportunities or challenges.

social function The particular problem that an emotion was designed to solve and how it does so by structuring coordinated social interactions; recent theory argues that emotions solve problems related to reproduction and the raising of offspring, the problems of group governance and cooperation, and the negotiation of social hierarchies.

Emotions are distinct, biologically based psychological entities characterized by short-lived coherent patterns of perception, experience, physiology, and communicative action. At both the intrapersonal and interpersonal levels, emotions shape experience and outcomes in important domains of life, including health, work, and school.

1. INTRODUCTION

What role do emotions play in human social life? Western philosophy has traditionally regarded emotions with suspicion, as a disruptive force. The Stoics advocated distancing oneself from an emotional life,

whereas more recently Hobbes and Freud believed that following natural inclinations would lead to uncontrolled emotion and societal havoc. Still others, such as Aristotle, took the perspective that at least certain emotions (e.g., anger, jealousy) should be controlled or moderated.

Mounting evidence and theory within psychology has led to the opposite view of emotion, that is, that emotions are well-organized coherent systems that enable humans to respond quickly and effectively to environmental and social problems and opportunities. This article outlines this latter perspective, termed a social functional approach, and delineates how social functional approaches lead to an improved understanding of how emotions influence health, work, and school.

2. DEFINING EMOTION

Emotion is easily recognized and difficult to define. Currently, emotion researchers define an emotion as a short-lived, biologically based pattern of perception, experience, physiology, and communication that occurs in response to specific physical and social challenges and opportunities. This definition helps to differentiate emotions from related phenomena. Whereas emotions are elicited by fairly flexible interpretations of stimuli and have specific intentional objects, moods have less specific causes and endure for longer periods of time. Sentiments are consistent emotional responses to objects that can endure for lifetimes and be passed from one generation to the next (e.g., intergroup hostility). Emotion-related traits, such as hostility and shyness, reflect consistent ways of responding emotionally to broad classes of stimuli. Sensations (e.g., pain, an itch) are not explicitly related to the individual's strivings.

Most emotion researchers now agree that emotions serve adaptive functions but differ in the questions for which they seek answers. Psychologists who study the structure of emotion systems consider the origins of specific emotions, the behavior associated with emotion experience, and the personal and social consequences of behavior prompted by emotion. Psychologists who study questions of communication and cross-cultural universality focus on facial displays of emotion, taking care to document the distinct muscle movements that characterize some emotions. Their counterparts who are more interested in cultural variation use ethnographic or lexical methods that emphasize unique aspects of emotional experience

such as emotion words with no ready translations outside of the society of origin. Researchers who study appraisals of events that lead to emotional experience use narrative methods to study the patterns of stimulus interpretation that differentiate emotions. These various lines of inquiry have led to remarkable discoveries during the past 20 years or so regarding the role of emotion in development, psychopathology, memory, and brain function.

3. MEASURING EMOTION

Emotions have many facets and can be measured in many ways. Researchers interested in the expression of emotion can capture facial expression with the Facial Action Coding System (FACS) developed by Ekman and Friesen or can rely on ethologically significant gaze, posture, vocal, and/or gestural activities. These methods are fairly nonobtrusive and allow researchers to study emotion outside of the laboratory. Researchers interested in emotion-related appraisal or the understanding of emotion have turned to narrative methods and interview techniques and elaborate coding schemes to discern the meaning processes that give rise to and differentiate emotions from one another. Categorizing emotion words into prototypes of an experience is a method used to understand how individuals conceptualize everyday emotion experience. Other researchers have recorded activity in the autonomic nervous system to ascertain when emotions occur and how they differ from one another, for example, by assessing heart rate, respiration pattern, blood flow to the periphery, and skin conductance. Finally, a great deal of research continues to rely on self-reports of emotion experience through the administration of either formal Likert-type scales, such as the PANAS (which measures the disposition to feel positive or negative emotion), or through more direct inquiry of emotion experience.

4. SOCIAL FUNCTIONS OF EMOTION

Darwin and James laid the foundation for the study of emotion in significant and enduring ways. In *The Expression of the Emotions in Man and Animals*, Darwin contended that emotions must be serviceable. That is, emotions should be functional adaptations that prepare

the organism to act and communicate a readiness to engage in a particular behavioral action. This preparation should be expressed through nonverbal displays that should be universal across human cultures. Darwin also argued that particular expressions of emotion should be directly connected to the behavior they prepare the individual to enact. Disgust, for example, is a serviceable habit that prepares an individual to expel harmful contents before they are ingested and whose display includes protrusion of the tongue. This thinking laid the foundation for the study of facial expression and functional accounts of emotion that are so widespread today.

In his 1884 essay titled “What Is an Emotion?,” James extended some of Darwin’s claims in proposing that each emotion should be defined by a specific physiological response. This radical notion fell out of favor but is now supported by studies indicating that amusement, anger, disgust, embarrassment, fear, love, surprise, and sadness all are associated with distinct physiological responses in the autonomic nervous system. More controversially, James also claimed that emotional experience followed rather than preceded emotion-relevant behavior. For example, crying would precede feelings of sadness. During the mid-20th century, this counterintuitive idea generated a great deal of interest among psychologists who prioritized cognitive and information explanations over motivational and emotional explanations of human behavior.

What distinguishes contemporary social functional approaches to emotion? First, a social functions perspective builds on Darwinian theorizing about emotion to consider how the challenges and opportunities of the human evolutionary environment led to the development of specific emotions. Importantly, this perspective is complemented by a consideration of how human cultural practices elaborate on human biology to influence emotion experience and meaning. Second, a social functions approach considers the effects of specific emotion processes at the intrapersonal level of individual experience and at the interpersonal level of ongoing social interaction among individuals. Thus, there is consensus that the experience of emotion guides information processing in functional ways, triggering specific memories and patterns of perception and categorization. The autonomic nervous system activity of emotion is thought to support specific kinds of action (e.g., fight or flight). And the communication of emotion conveys specific feelings, intentions, and dispositions, evoking specific and adaptive responses in observers. Finally, a

social functions approach is concerned with the consequences of emotion, emphasizing how emotions facilitate the successful navigation of the social environment.

In contrast to previous approaches that viewed emotions as disruptive forces, a social functional perspective regards emotions as evolved answers to the problems and opportunities presented by human social life across our evolutionary past. In this view, emotions are specific efficient responses tailored to address the problems of physical survival and social living. Emphasis is placed on the utility of emotion in the contexts in which it evolved, whether it remains useful in current environments or has become inappropriate or maladaptive. Framing emotion in this way generates a series of important and interrelated questions about emotion:

1. Why do humans have emotions?
2. How do emotions influence survival and adjustment?
3. What are the interrelated parts of the emotion system?
4. What are the beneficial consequences of emotion?

A social functions approach naturally directs attention to the role of emotion in navigating the complications of human social life. Diverse theorists converge on three classes of problems and opportunities that emotions were designed to solve. Several emotions, such as disgust and fear, help humans to meet the problems of survival, including avoiding predators and toxins. Still other emotions, including filial love, desire, compassion, and rage, help humans to meet the problems of reproduction that center on finding mates, maintaining monogamous bonds, and raising offspring to the age of viability. Finally, still other social emotions, such as gratitude, anger, embarrassment, and awe, help humans to meet the problems and opportunities related to group governance. More specifically, these emotions are thought to promote and maintain cooperative alliances and help humans to fold into social hierarchies and mete out justice and punishment. The article draws on this perspective to outline an understanding of seven emotions that will prove to be particularly relevant to health, work, and school settings.

4.1. Anger

Anger is historically regarded as one of the most disruptive emotions. Functional accounts of anger have shed light on the beneficial aspects of this misunderstood emotion. Anger has been shown to be elicited by the perception that an injustice has

been intentionally committed against the self by another. This attribution of blame for an unfair outcome motivates an individual to (a) seek redressive action and (b) signal the intention to aggress if redressive action is not taken. To this end, anger is received as a threat by the target. According to emotion theorist Robert Frank, anger has two beneficial consequences. First, anger prepares an individual to aggress in response to serious transgressions, if need be, by directing blood to the face and arms. More important, signaling that one is genuinely likely to aggress is threatening and reduces the likelihood that a given individual will be cheated or taken advantage of by another. Signaling honest anger may be all the self-defense that is necessary to motivate a target to take redressive action or flee. Indeed, incidents of anger leading to actual aggression or violence are infrequent relative to the emotional experience.

4.2. Anxiety

Unlike anger, anxiety is not always defined as an emotion. It has not been documented to have a distinct nonverbal display or to be accurately decoded. Instead, anxiety has been related to fear, either as a subset of the broader fear category or as a more generalized mood-like state. The experience of anxiety appears to be a concomitant of threat-related cognitions when an individual perceives a challenge in the environment that may exceed resources. Small amounts of anxiety have been shown to enhance performance on a challenging task, but profound levels of anxiety have been shown to impair the ability to perform.

4.3. Embarrassment

The emotion of embarrassment is a clear example of individual experience diverging from larger social consequence. Embarrassment is marked by a brief display consisting of a downward gaze, a brief non-Duchenne smile, and the movement of the hand to the face. It is felt in response to unintended inappropriate behavior such as social gaffes, pratfalls, and uncontrolled bodily functions. Calling someone by the wrong name and tripping in public are typical triggers of embarrassment. Although embarrassment is an unpleasant individual experience, the audience present for an embarrassing incident is frequently amused or sympathetic toward the target. For this reason, embarrassment has been posited to serve an appeasement function. By feeling and displaying embarrassment, a person signals

to others that he or she realizes the inappropriateness of the behavior and is asking to be absolved of blame. At the level of the social interaction, the display of embarrassment restores social balance. Studies have shown that individuals who display embarrassment are better liked than their nonembarrassed peers and show greater concern for social norms. Adolescent boys who display embarrassment, for example, are less likely to engage in delinquent behavior than are their less embarrassment-prone peers.

4.4. Fear

The emotion of fear prepares an organism to flee from threats that pose an immediate danger or are perceived to be likely to overwhelm the system. Displayed through raised eyebrows, opened eyes, and an open mouth, the biological basis of fear has been well documented. In contrast to anger, which sends blood to the arms, fear sends blood to the legs, facilitating a flight response. In studies of fear response, young monkeys exposed to either a snake or a flower for the first time expressed a fear of snakes immediately, suggesting that they are prepared to feel a fear of snakes. Interpersonally, humans have been shown to be sensitive to the fear cues of others, valuing the warning that fear displays can provide. When a facial expression of fear is presented among a large group of smiling faces, the fear face is identified more quickly than is a happy face among a large group of fearful faces. The work of LeDoux has connected fear to the amygdala, an almond-sized structure of the brain shown to process fear-related information. Amygdala damage is associated with deficits in perceiving and attending to obvious threats.

4.5. Happiness

The emotion of happiness comprises the most general and recognized level of positive emotion. Happiness is universally recognized and signaled by the Duchenne smile, a combination that lifts the muscles of the mouth and crinkles the skin around the eyes. Unlike other types of smiling, Duchenne smiling reflects an individual's internal positive emotional state. The disposition to experience happiness has been associated with higher levels of life satisfaction and a cognitive style marked by optimism and diminished concern with social comparison. There is also some evidence that displays of happiness promote positive social relationships, perhaps by evoking positive social responses in others. A recent study showed that

women whose college yearbook pictures showed Duchenne smiling married earlier, had more positive relationships with partners and children, and reported higher levels of life satisfaction up to 30 years later.

4.6. Love

Love is traditionally regarded as an enduring attitude of affection toward another or a style of relating to romantic partners, and recent research on love has found evidence of emotion-like properties. Love is signaled through a series of affiliation cues that generate movement toward the love object and has been theorized to promote commitment between love partners. Consistent with this theorizing, the self-reported experience and display of love correlate with constructive conflict resolution and perceived trust during moments of relationship threat. Feelings of love are also associated with a greater willingness to engage in prorelationship behavior, even at a cost to self-interest.

4.7. Sadness

Felt in response to a perceived uncontrollable loss, sadness is marked by eyebrows pulled in toward the nose and a downturned mouth. Initially, sadness is marked by crying and other intense displays of grief, but prolonged sadness shuts down the body. This shutting down of the body is theorized to conserve the body's energy until a time when a person is better able to cope with the loss. Sadness is associated with cognitions of having little control over personal outcomes. For example, individuals who attribute positive life events to external causes and regard negative life events as having been brought on by internal characteristics of the self are prone to episodes of sadness.

The preceding seven emotion states do not cover the range of emotions currently studied by emotion researchers, nor do they encompass the states whose status as emotions generates the most agreement. Instead, these seven states comprise emotions whose relevance to the applied settings of health, work, and school has been most clearly documented.

5. EMOTIONS AND HEALTH

The literature on emotions and health is vast but can be summed up schematically with two fairly robust claims. First, positive emotions promote positive health and a

longer and more satisfying life. Second, negative emotions impair health and place individuals at risk for poor health outcomes ranging from depression to heart disease. These empirical summaries are based on studies of specific emotional states (e.g., fear) but more typically emerge out of studies of emotion-based dispositions such as anxiousness, hostility, and happiness.

The emphasis on the beneficial aspects of positive emotions notwithstanding, positive emotion routes to better health remain understudied relative to negative emotions. Rather, the disposition to positive emotion and the cognitive concomitants of positive emotional experience have been related to better health. For example, dispositional optimism, which is related to happiness, is associated with longer life in the face of terminal illness. The positive illusions of individuals who overestimate the likelihood of surviving cancer or a stroke appear to act as protective resources, prolonging life and helping individuals to find positive meaning despite illness.

The relationship of positive illusions to health has been the subject of lively debate. In one study, optimism was measured in men recovering from coronary artery bypass surgery. A man's dispositional optimism was related to the release of liver enzymes that promoted recovery, and these men were quicker to recover the ability to sit, walk, and return to work than were their less optimistic counterparts. Other studies show that dispositional optimists are more likely to engage in health-protective behaviors such as taking vitamins, eating a well-balanced diet, and exercising. Still, researchers have contended that happiness and positive illusions should negatively affect health, perhaps by promoting denial or underestimation of the likelihood that illness will happen. In support of this view, unrealistically high levels of optimism have sometimes been related to a diminished likelihood of engaging in health-protective behaviors. Nonetheless, positive illusions remain one avenue through which positive emotional states have been shown to lead to improved health outcomes.

Turning to the negative emotional dispositions, it has become increasingly clear that anger, sadness, and (more recently) shame can have deleterious effects on health. Although previous research connecting health outcomes to the disposition to experience anger or sadness has oversimplified the relationship, the connection exists. Prolonged episodes of negative affective states, rather than a brief episode of negative emotion, are chiefly responsible for the relationship between negative emotion and health. Small doses of

negative emotion, such as anxiety and guilt, are associated with engaging in preventive health behaviors and being willing to seek help. However, more enduring chronic affective states, such as depressed mood and chronic anxiety, have been linked to impaired immune functioning, coronary heart disease, memory decrements, and other major health conditions.

Similarly, the propensity to experience frequent and intense episodes of anger is commonly related to poor health outcomes. The association of "Type A" behavior with heart disease is well known in scientific and popular circles. More recent research has shown that one component of the Type A profile, the propensity to experience hostility and anger, is the principal mediator of this association. Studies of Type A individuals who are less prone to hostility show that the goal-driven persistence that marks Type A may actually promote compliance of rehabilitative regimens, whereas the hostile component of Type A predicts future coronary episodes.

Prolonged episodes of sadness are also predictive of heart disease, but the emotional experience of sadness and its related cognitions have been most directly linked to depression. An attributional style that blames the self for negative life events and perceives little ability to control or create positive outcomes has been associated with the development of depression. More directly, the tendency to ruminate on negative events by persistently directing thoughts toward negative events and possible negative outcomes leads to a greater likelihood of suffering depression. In one study of coping in the aftermath of a strong earthquake, individuals who reported ruminating about their quake experience during the weeks afterward also reported more depressive symptoms and were more likely to seek health services. This coping style is more characteristic of women, and indeed, women make up a disproportionate number of depression sufferers.

Depression is associated with both increased negative affect (e.g., sadness, anxiety, anger) and decreased positive affect. Administration of selective serotonin reuptake inhibitors (SSRIs) tends to decrease experience of negative affect and increase experience of positive affect in clinically depressed populations. These drugs produce parallel effects in normal populations. Nondepressed individuals administered SSRIs for 4 weeks were rated as less hostile by clinicians, self-reported less negative affect, and showed more affiliative behavior in a dyadic social interaction than did individuals administered a placebo.

The experience of shame and self-blame may uniquely relate to negative immunological changes. Relative to a control condition, individuals induced to feel shame by writing about a past traumatic experience for which they blamed themselves showed increases in proinflammatory cytokines, negative immunological response, and the stress hormone cortisol. Self-reports of shame, but not of guilt or other negative affect, specifically correlated with these physiological changes. A study of HIV-positive gay men found that shame-related cognitions, such as poor self-worth and excessive concern with social rejection, are associated with lower CD4 count (a negative immunological marker) and higher AIDS mortality.

The literature connecting the disposition to feel negative emotion to poor health is extensive, but emerging advances in this area suggest that parts of this story have yet to unfold. Guided by social functional analyses emphasizing the beneficial aspects of emotion, researchers have begun to examine how negative emotion experience might affect health in positive ways. One proposed path through which negative emotions may positively affect health is by promoting "toughness" or resistance to the harmful effects of stress. For example, mice exposed to repeated stressors at an early age showed faster patterns of both physiological arousal and recovery, suggesting an increase in the effectiveness of the stress response over time.

In a related vein, the disclosure and free expression of negative emotions have also been shown to promote health. According to Pennebaker, one source of ill health is a repressive coping style that is characterized by an effortful inhibition of emotional thoughts, feelings, and behaviors. In support of this view, repressive coping has been associated with the release of cortisol. Focusing primarily on trauma sufferers who have not shared their experiences with others, Pennebaker found that sharing traumatic experiences by either talking or writing in journals leads to reduced physiological arousal and fewer visits for health care during the ensuing months. Similarly, other studies have shown that confiding or disclosing traumas, even secondhand traumas, is associated with better immune system functioning.

Consistent with a social functional account of emotion, negative emotion is not harmful per se and can be an adaptive response to a situation. Grief, for example, is not associated with the negative immunological changes that characterize depression. Grief may be an adaptive response to loss, whereas depression is maladaptive. Studies of HIV-positive individuals who have

lost partners or close friends to AIDS find that depressed mood is associated with negative immunological changes and more rapid HIV progression, whereas high levels of grief without depressed mood are not.

6. EMOTIONS AND WORK

A great deal of modern-day social interaction takes place in work environments. Consequently, a consideration of emotion in the workplace is particularly benefited by an interpersonal perspective. In the workplace, individuals must initiate relationships, strive for distinction and status, seek cooperation, seal commitments, and optimally, be personally satisfied with their work lives. These endeavors are facilitated by the communicative aspects of emotion, where people observe and respond to each other's emotions in ways that often help to resolve or change the relational problems of everyday life.

How do emotions influence work satisfaction and productivity? As with health, positive emotion is also associated with beneficial outcomes. The expression of positive emotion has been shown to positively relate to both work satisfaction and achievement. In one study of 272 employees, the expression of positive emotion was associated with more favorable supervisor evaluations, higher pay, and more support from supervisors and coworkers 18 months later. A related issue, and perhaps a conceptually dominant one, concerns the contextual factors that support the experience and display of positive emotion. Research suggests that much of the variance associated with job satisfaction is attributable to a perceived sense of efficacy in carrying out a task. Perceived efficacy is related to lower levels of chronic stress and higher levels of subjective well-being. Individuals who are given tasks that challenge, but do not exceed, their ability may achieve a state of "flow" in their work, where interest is high and the tasks are engaging. In contrast, perceiving the challenges of the work environment to be overwhelming can lead to unhappiness and high levels of job stress.

Serious negative occupational outcomes are also closely tied to interpersonal emotion. Job burnout is a response to interpersonal stressors on the job, where an overload of contact with people results in changes in attitudes and behaviors toward them. Field research has established that burnout involves three dimensions, with each dimension highlighting different emotions. Anger and anxiety are expected to be high in the dimension defined as emotional exhaustion, that

is, feelings of being emotionally overextended and drained by one's contact with other people. Reduced experience of empathy and compassion is implicated in the depersonalization dimension, defined as an unfeeling and callous response toward people on the job. Decreased experience of pride appears to be central to the third dimension, where feeling low competence and low successful achievement in one's work leads to a reduced sense of personal accomplishment.

Another area of study has examined required emotional displays such as expressing positive emotion toward customers by workers in the retail industry or negative emotion toward debtors by workers at collection agencies. Termed "emotional labor," the use of positive emotional expression has been shown to elicit liking and a desire on the part of the customer to reciprocate in kind. On the other end of the spectrum, debt collectors are pressed to convey irritation to debtors and adjust their expressed emotions in response to debtor demeanor. This emotionally difficult work can clash with the collectors' genuine feelings toward debtors. This use of emotion may be task-effective, but emotional labor has been associated with decreases in felt positive emotion for expressing workers, and some organizations openly encourage employees to develop cognitive reappraisal skills to better cope with the emotional demands of the job.

How do emotions help individuals to navigate the social interactions of the workplace? How do they help them to initiate relationships, manage hierarchy, and procure the cooperation of coworkers? Anger and gratitude play important complementary roles in promoting cooperative alliances and creating stable long-term relationships. The initiation of cooperative relationships is assisted by liking and gratitude, which motivate the initiation of bonds and reward cooperation, respectively. Expressed anger can punish actions that threaten to undermine cooperation such as inappropriately taking credit and overusing resources. Threats that induce fear rather than anger have been found to be successful in changing the behavior of others. However, threats risk inducing anger rather than fear, and eliciting a strong angry response might pose a worthwhile risk only when interest and positive emotional interaction have proven to be ineffective.

The formation and maintenance of cooperative alliances take place within an existing hierarchical structure, and successful management of hierarchy is important to workplace success. Research suggests that the emotions of high-status individuals are of

primary relevance for two reasons. First, the outcomes of subordinates are strongly tied to individuals at higher ends of the hierarchy in most work environments. Second, the emotional experience of high-power individuals has been shown to differ from, and exert an effect on, the emotional state of subordinates. High-power individuals are more disinhibited in their emotional expression, expressing both negative and positive emotions and being less attune to how their emotional expressions are perceived by others. Status is conferred and reinforced by displays of anger rather than sadness, in part because the display of anger is associated with greater personal competence. Over time, the emotions of lower status people have been shown to converge to be more similar to the emotional experience of high-status people. This convergence is proposed to help coordinate the thoughts and behaviors of relationship partners, increase mutual understanding, and foster social cohesion. In the workplace, this emotional cohesion is likely to foster stable, mutually satisfying hierarchies.

In a workplace, decisions must be made and courses of action must be agreed on by relevant parties. How do emotions influence workplace decision making? One means is through emotion-related appraisals. Happy people view the world optimistically, perceiving situations to pose low risks and expecting positive outcomes. Fearful people perceive the world as threatening and are vigilant about risks and negative outcomes. These emotion-specific appraisal tendencies produce emotion-congruent effects on perception, reasoning, and decision making. People who feel happy readily notice and remember positive information, including other people's happy expressions. Bolstered by the accessibility and salience of positive information, happy people tend to view risks optimistically and make more risk-seeking choices. They label people using more positive categorizations (e.g., "good worker") and are more reliant on mental short-cuts in their decision making, and this can lead to less thorough information processing. In contrast, sad people tend to notice and remember negative and sad information, memories, and facial expressions. They tend to process information thoroughly when making judgments, presumably because doing so might help to explain or resolve their underlying negative mood. Appraising the world as threatening, fearful people assess risks pessimistically and make more risk-averse choices than do happy people. However, not all negative emotions lead to more careful decision making or judicious risk assessment. Anger is associated with

certainty and feeling control over a situation, and angry people behave more like happy people, assessing risks optimistically and making risk-seeking choices. Perceiving the world as under their own and others' control, angry people are more likely to blame individuals than to blame situational factors for negative events.

7. EMOTIONS IN SCHOOL

A large literature has addressed the factors that undermine academic achievement and social adjustment in school. The subset of the literature that relates to emotion has chiefly examined how anxiety leads individuals to underperform in, avoid, and mistrust particular academic domains or school in general. At a more interpersonal level, research on peer relations suggests important roles for anger, fear, sadness, and embarrassment in social adjustment.

Anxiety is considered to be the major cause of student underperformance on examinations. Students who consistently experience severe levels of anxiety are proposed to have a trait tendency known as test anxiety that involves increased anxiety and stress when specifically taking tests. Test anxiety has been associated with reduced motivation, suppressed immune functioning, and impaired test performance. Several mediators have been proposed, drawing on appraisal tendencies associated with anxiety and fear. Feeling afraid heightens a person's vigilance for threats in the environment. Studies find that test anxiety can impair performance by increasing a student's susceptibility to threatening external distractors. Other studies find that internally generated anxious thoughts disrupt performance by reducing the available cognitive resources in taking the test.

Anxiety is also considered to be a major cause of stereotype threat, a specific type of academic underperformance. Stereotype threat occurs when a negative stereotype about a group of which a person is a member becomes personally relevant, usually in the context of an experience the person is having. Stereotype threat is the resulting sense that the person can be judged or treated in terms of the stereotype or that the person might do something that would inadvertently confirm the stereotype. At each of level of academic skill, students sharing certain social identities get lower scores than do other students. Female students are outperformed by male students in math at each level of skill. Relative to White students, African American, Native American, and Hispanic American students

underperform on tests measuring overall academic ability. The anxiety-related processes believed to underlie stereotype threat have been proposed to be a primary cause of these groups' impaired performance. Self-reported anxiety has sometimes been found to mediate these groups' impaired performance, although in some cases only for those individuals who are sensitive to the group stereotype. One study found that African Americans did not report more anxiety than did Whites during an intellectual ability test; however, African Americans' blood pressure increased significantly from baseline relative to that of Whites.

How can the anxiety of stereotype threat be mitigated? Over a decade of research has found that the performance of students vulnerable to stereotype threat is improved when stereotype threat is removed from the test-taking situation, for example, when students are told that a particular test produces no group differences in performance. Other means of reducing stereotype threat include creating an academic setting that communicates identity safety, for example, when a teacher tells minority students that he or she will hold them to high academic standards and believes the students can meet them. The importance of combating stereotype threat is evident in the link with negative outcomes in academic domains that are negatively stereotyped for an individual's group identity. Students experiencing stereotype threat tend to avoid the domain where the stereotype applies, self-handicap in that domain, and/or situationally disengage their self-esteem and ability appraisals from performance on tests in that domain. The chronic experience of stereotype threat risks instilling devaluation of success in that domain, a disengagement of identity from that domain, and a distancing from careers relevant to that domain.

Other emotions play critical roles in another dimension of school, that is, psychological adjustment and the negotiation of peer relationships. Anger is an important component of conduct disorder and externalizing problems in children. Children's self-reported tendency to experience and express anger correlates with their "acting out" behaviors in normal and clinically diagnosed populations. Children who engage in antisocial behavior are rated by parents, teachers, and peers as being more hostile and angry. Anger-prone children are found to expect hostility from their peers and respond to ambiguous situations with hostile behavior, which elicits rejection from other children. In contrast, children experiencing internalizing disorders, such as depression and anxiety, tend to feel fear and sadness. For example, measures of depression in fifth

graders are associated with self-reports of sadness as well as anger in the case of boys.

The social-moral emotions, those that encourage moral behavior, socialization, and adaptive assimilation into society (e.g., embarrassment, shame, guilt), appear to motivate children to avoid social transgressions. Less guilt, for example, is positively associated with externalizing problems such as antisocial behavior and is negatively associated with moral development. One study of the psychological adjustment of adolescent boys tested for the roles of anger, fear, and embarrassment by coding facial expressions during a structured social interaction (an intelligence test). Boys categorized by teachers as having externalizing problems displayed increased expressions of anger, whereas boys categorized as having internalizing problems displayed increased fear. Interestingly, both groups of boys displayed less embarrassment during the task than did nondisordered boys, indicating that embarrassment signals normal social-moral development.

8. CONCLUSION

The three domains of health, work, and school are important contexts where life outcomes are shaped. Emotional experience and disposition shape individual experience and social interaction in ways that influence these life outcomes.

GLOSSARY

comorbidity The co-occurrence of two or more mental disorders in the same person.

externalizing behaviors Behaviors that are undercontrolled (e.g., hyperactive, oppositional, delinquent, aggressive, disruptive).

internalizing behaviors Behaviors that are overcontrolled (e.g., withdrawal, anxiety, somatic complaints, obsessions).

symptoms Behaviors that are inappropriate or excessive and are of clinical significance.

syndrome A cluster of symptoms that occur together in a consistent and recognizable pattern.

This article presents characteristics of students with emotional and behavioral problems within the conceptualization of child and adolescent psychopathology. Implications for children in clinical and school settings are included.

1. INTRODUCTION

Students who have significant emotional and behavioral problems necessitating professional intervention often are described as being “emotionally disturbed,” “behaviorally disordered,” “emotionally and behaviorally disordered,” or some similar term. Although these labels are in common use, they are broad and ambiguous and offer little help in understanding the nature, extent, prevalence, and implications of these problems in children and youth. This article describes current conceptualizations of children’s emotional and behavioral problems and implications for schooling and effective interventions.

2. CONCEPTUALIZATIONS OF CHILD AND ADOLESCENT PSYCHOPATHOLOGY

The development of research and knowledge in child and adolescent psychopathology has burgeoned during the past two decades or so. The current state of the research suggests that children’s emotional and behavioral problems can be conceptualized as internalizing or externalizing. Internalizing problems are characterized by anxiety, depressed mood, somatic complaints, withdrawal, and similar behaviors. These behaviors

often are referred to as “overcontrolled” because the children show inhibited behaviors and spend much energy in controlling behaviors. These problems also are similar to what are commonly termed “emotional problems.” Externalizing problems refer to behaviors such as impulsiveness, aggression, inattention, hyperactivity, and distractibility. These behaviors are termed “undercontrolled” because the children lack the ability to control the behaviors. They are often referred to as “behavior problems.” Internalizing and externalizing behaviors can be conceptualized as being on a continuum where the range of behaviors shown may be from very withdrawn (internalizing) to highly active and perhaps even aggressive (externalizing). However, this range does not represent a true continuum because children may show many behaviors simultaneously, although some may predominate. For example, 25 to 40% of children with conduct disorder (CD) also are depressed, although the conduct problems may be observed more readily. Research has shown that the correlation between internalizing and externalizing patterns ranges from approximately .25 to .40. Moreover, some behaviors are associated with both internalizing and externalizing problems, for example, social skills deficits and academic difficulties.

When children demonstrate internalizing or externalizing behaviors of such seriousness that personal, social, and/or academic functioning is affected, they may be referred to mental health professionals. Children with externalizing behaviors are more likely to be referred for mental health care because they are more disruptive at home and in the classroom. Children with hyperactivity, aggression, and other externalizing behaviors account for approximately 50% of all referrals to mental health professionals. Inattention without hyperactive behaviors is seen most readily in the classroom. Children with internalizing problems are less likely to be referred because they generally are not disruptive and the problems are less likely to be detected easily by parents or teachers. However, exceptions to this trend do occur, for example, severe phobia or depression that leads to suicidal ideation or behavior.

Another important conceptualization of behavior is trait and state, which complements the internalizing–externalizing perspective. “Trait” refers to behaviors that are characteristic of children and are seen across a variety of settings and circumstances. “State” refers to behaviors that are a manifestation of the impact of the environment. The state–trait concept is important for helping to understand why children’s behaviors vary across settings. In schools, for example, it is common for children to exhibit

off-task behaviors in one classroom but be more attentive in another classroom. Thus, the difference in behaviors might not be due to a trait; rather, it may reflect factors such as teacher management skills (state). Therefore, interventions may focus on the teacher and the setting rather than on the children. Children who have a high degree of a trait, however, may be more likely to show the behaviors in specific situations. Spielberger has conducted extensive research on anxiety and anger as having state and trait dimensions. Anxiety and anger tend to be constant traits, placing children at an increased likelihood of becoming anxious or angry in specific situations (state). Interventions often are directed toward reducing the magnitude of the trait as well as helping children to cope with anxiety and anger-producing situations.

2.1. The Taxonomy of Mental Disorders

A taxonomy is an orderly classification of objects, people, or other phenomena according to their presumed natural relations with each other. A taxonomy classifies according to mutually exclusive criteria; that is, the criteria can apply to only one specific member of a class, making the class unique. The concept is most often used in the physical sciences, such as botany and zoology, but it is also applied to human behavior. The taxonomy of mental disorders most commonly used in the United States is the fourth edition of the *Diagnostic and Statistical Manual of Mental Disorders* (DSM-IV). There are more than 300 possible diagnoses of mental disorders in the DSM-IV, and determining which one is the most accurate description of the behaviors presented to the clinician can be challenging. The primary reason for the difficulty in formulating clear diagnoses is the problem of comorbidity; that is, many behaviors shown by children are seen in more than one disorder. When more than one disorder exists within the same individual (i.e., not mutually exclusive), they are considered to be comorbid disorders. Comorbidity is the rule rather than the exception in children and youth, occurring in more than half of all cases referred to mental health professionals.

2.2. Behaviors, Symptoms, Syndromes, and Disorders

Children’s emotional and behavioral problems typically are first noticed by parents or teachers, who may refer these children to a physician, a psychologist, or other mental health professional. Symptoms are behaviors of

clinical significance that interfere with functioning. When behaviors occur together to form distinct patterns, they are termed “syndromes.” When syndromes occur with such intensity, frequency, or duration that personal, social, or academic performance is affected negatively, the children may be given a diagnosis of a mental disorder by a psychologist or physician.

As an example, consider the case of “Eric,” a 6-year-old boy in the first grade. As a preschooler, Eric exhibited some behaviors of concern such as high activity level, impulsiveness, and noncompliance with parents’ requests in and out of the home. However, the parents were able to manage these behaviors successfully, and they did not view them as problematic. In school, Eric was required to participate in groups, take turns, and follow directions. Instead of these prosocial behaviors, a pattern of noncompliance, difficulties in participating and cooperating, blurting out answers, talking without permission, and interfering with other children developed. These behaviors were considered symptoms of a problem. When the symptoms occurred together in an identifiable pattern, they comprised a syndrome that was of clinical and educational significance because it interfered with the performance of Eric and others. He was evaluated by a psychologist, who considered the behaviors/syndrome in light of current diagnostic criteria and assigned a diagnosis of attention deficit/hyperactivity disorder (ADHD)–combined type. In this example, individual behaviors became symptoms that occurred together to become a pattern (syndrome). Because the syndrome was determined to be at a clinically significant level of impairment, a formal diagnosis of a mental disorder of ADHD was given.

3. MENTAL DISORDERS IN CHILDREN AND ADOLESCENTS

The majority of mental disorders listed in the DSM-IV can be seen in children and adults. The concepts of internalizing and externalizing patterns are applicable because most of the disorders can be described in those terms. There are some disorders, however, that are considered to be applicable specifically to children and adolescents, for example, separation anxiety disorder (SAD) and CD.

3.1. Internalizing Disorders

The most common internalizing disorders in children and adolescents are the same types that are seen in

adults, although there may be some differences in symptoms. Internalizing disorders include conditions such as major depressive disorder, dysthymia, and bipolar disorder. Anxiety disorders occur in approximately 5 to 10% of children, and the prevalence of depression is approximately 3 to 5%. Table I summarizes characteristics of anxiety problems.

Recent research indicates that bipolar disorder may be more common in children and adolescents than was previously believed. Bipolar disorder was formerly known as manic–depressive disorder and shows a range of mood symptoms from high-energy mania to severe incapacitating depression. However, it is less common than anxiety or depression. Another internalizing anxiety disorder is posttraumatic stress disorder (PTSD), which was initially identified in soldiers who experienced extreme combat exposure, which was followed by “flashbacks” of the events, difficulty in sleeping, and generalized anxiety. In children, PTSD symptoms can be seen as a result of experiences such as abuse, divorce, and other traumatic events, although flashbacks are less common in children. The only anxiety disorder unique to childhood is SAD, which is an unwillingness to separate from parents at a level inappropriate for the age or developmental level of the

TABLE I
Characteristics of Anxiety in Children

<i>Cognitive</i>	<i>Behavioral</i>	<i>Physiological</i>
Difficulties with concentration	Shyness Withdrawal	Trembling or shaking
Memory problems	Frequent asking of questions	Increased heart rate
Overreaction and “catastrophizing” relatively minor events	Frequent need for reassurance Need for sameness	Excessive perspiration Shortness of breath
Worry	Avoidant	Dizziness
Irritability	Rapid speech	Chest pain or discomfort
Perfectionism	Excessive talking	Flushing of the skin
Thinking rigidity	Restlessness, “fidgety”	Nausea, vomiting, diarrhea
Hypervigilant	Habit behaviors such as hair pulling and twirling	Muscle tension
Fear of losing control	Impulsiveness	Sleep problems
Fear of failure		
Difficulties with problem solving and academic performance		

children. It is common for children to show some anxiety about leaving their parents, even during the early days of school. When the behaviors exceed what is expected developmentally and the children cannot separate in a manner typical of most children, SAD may be an appropriate diagnosis. The presence of SAD may indicate parent-child or family issues; for example, a parent may have difficulty in allowing a child to have increased independence and may encourage and reinforce the child for refusing to separate. A similar pattern may exist in cases where a child exhibits "school refusal" (sometimes referred to as "school phobia"). If there is no rational basis for a child to not want to go to school (e.g., being the victim of bullying), it may suggest parent-child or family problems.

Depression occurs in less than 1% of preschool children and increases during the school years from approximately 0.3 to 2.5% in prepubertal children. By adolescence, however, the incidence of depression increases to approximately 4.3%, with lifetime prevalence rates of major depressive disorder in adolescents ranging from approximately 8.3 to 18.5%. Clearly, depression is a major concern with children and youth and is associated with suicidal ideation and attempts. Depression is a leading cause of death in adolescents after accidents. Some of the major characteristics of depression are presented in Table II.

3.2. Social Correlates of Internalizing Patterns

Children who have internalizing patterns, such as anxiety and depression, may tend to withdraw from social interactions as a way in which to cope with chronic feelings of distress. Withdrawal, social ineptness, and avoidance of interactions due to low self-esteem may be evident. These children may be perceived as "lazy" and unmotivated, despite the fact that they likely want to have social relations but are uncomfortable in initiating interactions due to perceived incompetence and lack of social skills. There is some evidence that anxious and withdrawn children are at higher risk for being the victims of bullies at school and may demonstrate reactive behaviors such as school refusal, sleeping problems, inconsistent performance, lack of assertiveness, poor peer relationships, low self-esteem, and low self-efficacy.

3.3. Academic Correlates of Internalizing Behaviors

Children who show anxiety and depression tend to have academic problems that can lead to more distress, causing a cycle of problems that persist over time. These children tend to avoid academically challenging tasks, withdraw from classroom activities, have poor

TABLE II
Characteristics of Depression in Children

<i>Cognitive</i>	<i>Behavioral</i>	<i>Physiological</i>
Arbitrary inferences	Withdrawal	Hyposomnia or hypersomnia
Selective abstraction	Lack of assertiveness	Increased or lowered appetite
Overgeneralization	Impaired social relations	Weight loss or weight gain as a function of change in eating habits
Catastrophizing	Lack of energy	Fatigue
"All-or-none" thinking	Lowered performance at school	Cries easily
Magnification and minimization	Loss of interest in hobbies, activities, and friends	
Personalization of too many or inappropriate events	Low self-esteem	
Absolutist thinking	Seclusiveness	
Dichotomized thinking, leading to inefficiency in generating alternatives and problem solving	Low participation	
Attributional styles: internal, stable, and global or external, unstable, and specific	Irritability	
	Reduced concern about personal appearance	
	Negative statements about self and others	

achievement, lack persistence on difficult tasks, and show signs of “learned helplessness.” They also tend to worry about appearing academically inferior to others, worry about incompetence, do not use effective learning strategies, and blame themselves for academic failure.

3.4. Externalizing Disorders

The most common externalizing disorders in children and adolescents are ADHD, CD, and oppositional defiant disorder (ODD). Collectively, these disorders often are referred to as disruptive behavior disorders (DBDs) because they have the common characteristic of showing disruption in home, school, and other settings.

ADHD is the most common DBD and accounts for a large percentage of referrals to mental health professionals. It is shown in approximately 3 to 5% of children and is three to six times more common in boys than in girls. It is a developmental disorder that appears to have some neurological substrates present at birth. With adequate assessment procedures, approximately 50% of cases can be identified by 4 years of age, although many children, especially those who tend to be inattentive, might not be identified until they enter school. There are three subtypes: predominantly inattentive type, predominantly hyperactive-impulsive type, and combined type. The inattentive type tends to be more common in girls than in boys and is more likely to be noticed at home and in situations where high degrees of attention are needed such as in studying, reading, and following directions. The hyperactive-impulsive type is characterized by displaying impulsive behaviors, engaging in off-task behaviors at school compared with peers, acting “fidgety,” making noises, bothering others, and engaging in similar types of behavior. A list of DSM-IV criteria for ADHD subtypes is presented in Table III.

ODD is characterized by a pattern of oppositional behaviors such as noncompliance with requests or directives of parents, teachers, and/or other adults. Most of these children are resistant and defiant to authority and may engage in disruptive behavior but do not demonstrate significant antisocial behaviors. However, boys and girls with ODD are at high risk for developing more serious problems, primarily CD. CD is a well-established pattern of oppositional and defiant behaviors and is accompanied by antisocial behaviors such as stealing, fighting, truancy, and bullying. There are two forms of the disorder: (a) early-onset CD, which occurs before 7 years of age, and (b) late-onset CD, which is first seen during the preteen or early teen years. As might be expected, children with early-onset CD tend to have

TABLE III
Symptoms of ADHD

<i>Inattention</i>	<i>Hyperactivity</i>	<i>Impulsivity</i>
Fails to attend to details	“Fidgety” Leaves seat without permission	Blurts out answers
Difficulty in sustaining attention	Runs about or climbs on objects inappropriately	Difficulty in taking turns
Does not listen to directions	Difficulty in playing quietly	Interrupts others
Avoids tasks requiring sustained effort	On the “go,” seems driven like a motor	
Often loses things	Talks incessantly	
Distractible		
Forgets things and events		

more serious problems, are more likely to get into trouble with adults who attempt to exercise authority over them, or come into conflict with legal authorities. If the behaviors in early-onset CD are not corrected by late childhood or early adolescence, the prognosis for positive outcomes is guarded at best. Many children with early-onset CD are at high risk for developing antisocial personality disorder as adults, many of whom come into repeated conflict with society, including a high divorce rate, legal difficulties, alcohol or drug abuse, and employment problems. Children with early-onset CD are at a higher risk for school failure and for dropping out of school before graduation. Adolescents with late-onset CD are less likely to engage in significant antisocial behaviors. Instead, they are more prone to behavior problems such as poor academic performance, sexual risk taking, smoking, and noncompliance. Many children who are given a diagnosis of CD have met criteria for ODD at some time in their lives but might not have been given that diagnosis. Although most children with CD have met criteria for ODD, the reverse is less common because many children who present with ODD remain oppositional and do not develop the more significant antisocial behaviors associated with CD. ODD appears to set the pattern for CD by evoking coercive, harsh, and inconsistent parenting behaviors that lead to repeated conflict and management difficulties.

ADHD shows comorbidity with ODD and CD, but the relations are varied. Boys with ADHD are at higher risk for developing CD than are boys without ADHD; this

appears to be the result of high comorbidity of ADHD and ODD. In boys, ODD appears to be a precursor to CD, but ADHD is not a precursor to CD. Much less is known about these associations with girls; the associations may or may not be similar to those with boys. ADHD begins during the preschool to early school years and, if accompanied by early-onset CD, leads to more significant behavioral problems through the elementary school years.

3.5. Social Correlates of Disruptive Behavior Disorders

Children with DBDs are at higher risk for developing poor relationships with typical peers and adults, including parents and teachers. Their behaviors tend to be annoying and unacceptable to others, leading to punitive reactions by adults and social rejection and ostracism by peers. If the pattern continues, these children are likely to be seen as “outsiders” to their peer groups and will seek out other children with similar patterns, leading to reinforcement of the behaviors and even greater social alienation.

3.6. Academic Correlates of Disruptive Behavior Disorders

Children with externalizing behavior problems or disorders are more likely to do poorly in school, have academic skill deficits, exhibit frequent off-task behaviors, have poor peer relations in the classroom, and be disruptive to the educational process. They also may show signs of frustration, inferiority, anger, and aggression. Angry and aggressive children appear to have a greater number of fears, concerns, feelings of being victimized by others’ actions and provocations, and beliefs that others have negative attitudes toward them. These feelings distract angry and aggressive children from focusing on academic tasks and acquiring necessary learning skills. Much as with the tendency toward social alienation, children with these behaviors may cause teachers and others to be less willing to help them, thereby creating more avenues for academic failure. Continued failure is likely to occur, creating a cycle of frustration and alienation. These children may, however, show “bravado” by exhibiting confidence in their academic skills while, at the same time, harboring resentment and anger at teachers whom they believe are not interested in helping them and at their peers who reject them. They may project the reasons for failure onto others and show boredom and lack of interest in school-related tasks.

4. INTERVENTIONS

4.1. Programmatic Interventions

Children who have emotional and behavioral problems might need help at school to assist them in achieving as much as possible. In the 2001 U.S. surgeon general’s report, it was reported that 70% of all mental health services provided to children are delivered in the school setting. In general, there are two avenues for providing interventions in the school setting. The first avenue is through general education such as might be provided by school psychologists, counselors, and social workers. These interventions are based on clinicians’ evaluations of children’s needs and may take the form of individual or group counseling, consultation, or parent involvement.

The other avenue for intervention is determining whether children are eligible for special education services. Public schools in all states are required to have special education programs and services for children whose behaviors interfere with academic performance. These programs and their associated regulations must be consistent with the federal Individuals with Disabilities Education Act (IDEA), which provides assurance that all children who have disabilities are properly identified, assessed, and given appropriate instruction and support. For children with emotional and behavioral problems, IDEA uses the term “emotional disturbance” (ED), which is defined as follows:

- (i) The term means a condition exhibiting one or more of the following characteristics over a long period of time and to a marked degree that adversely affects a child’s educational performance:
 - (a) An inability to learn that cannot be explained by intellectual, sensory, or health factors
 - (b) An inability to build or maintain satisfactory interpersonal relationships with peers and teachers
 - (c) Inappropriate types of behavior or feelings under normal circumstances
 - (d) A general pervasive mood of unhappiness or depression
 - (e) A tendency to develop physical symptoms or fears associated with personal or school problems
- (ii) The term includes schizophrenia. The term does not apply to children who are socially maladjusted unless it is determined that they have an emotional disturbance.

Although not all states are required to adopt this specific definition, many use the same or similar

terminology (e.g., “emotional disability,” “behavior disorder”). The IDEA definition is problematic, however, because many of the terms are ambiguous and are not operationalized (e.g., “inability to learn,” “satisfactory,” “inappropriate,” “normal circumstances”). The school psychologist is the professional most responsible for assessment of a child suspected of having ED, although the final determination of eligibility for special education services is done by a case conference committee that includes the parents, the school psychologist, a counselor, teachers, specialists, and others.

The child must have a “condition” that contributes to impairment in educational performance, which most often includes both academic and social development. It is important to note that having a formal DSM-IV diagnosis does not ensure that a child will receive special education services. It is not uncommon for parents to bring a diagnosis from a physician or psychologist to school, asking for special education services, only to be told that the child is not exhibiting problems that are interfering with educational performance. In those cases, the child might not be found eligible for services, despite having a formal psychiatric diagnosis. Conversely, a child could be found eligible for services for students with emotional disturbance and not have a formal psychiatric diagnosis.

A particularly enigmatic provision of the IDEA definition is the “social maladjustment” exclusion clause, which indicates that such children might not be found eligible for services. There is no definition of this term, and this can lead to difficulties for school-based professionals. The term, as originally considered, was to apply to children who exhibited delinquent behaviors that were controllable. Many professionals tend to equate “social maladjustment” with externalizing problems and equate “emotional disturbance” with internalizing conditions. This distinction would suggest that children with oppositional and conduct problems and ADHD would not be eligible for services unless there were accompanying internalizing problems that negatively affected performance. Conversely, because social maladjustment is not defined, one could argue that children with either internalizing or externalizing problems are socially maladjusted. Therefore, operationalizing the social maladjustment criterion for purposes of establishing eligibility is problematic. However, children with externalizing behaviors may qualify for special education services under IDEA or for general education accommodations under Section 504 of the Rehabilitation Act if needed to benefit from their education. They are not automatically excluded from receiving special education services.

If a student is found eligible for special education services for emotional or behavioral problems, an individualized education plan (IEP) is written in collaboration with the parents, school professionals, and the student if appropriate. In the IEP, goals and objectives are written to address the problems that are affecting educational performance. Services may include counseling, behavioral interventions, consultation with teachers, working simultaneously with the parents, and/or other appropriate interventions. The goal of special education services is not to provide comprehensive mental health services but rather to assist the student in performing at an appropriate level and in gaining educational benefit. The content of the IEP specifies what those services will be and how the outcomes will be measured. Counseling services may be provided if they are made a component of the IEP, or they may be included as an additional service under general education.

4.2. Individual Interventions

Individual interventions for students’ emotional and behavioral problems are numerous and cannot be discussed extensively here. In general, research shows that cognitive-behavioral, behavioral, and multisystemic interventions are among the most effective. A brief summary of the major types of interventions and their goals are presented in the following subsections.

4.2.1. Internalizing Patterns

The majority of internalizing problems are seen in anxiety and depression, which have several common characteristics. Cognitive-behavioral therapy techniques focus on the faulty cognitions and attributions and include components such as attribution retraining, self-talk strategies, self-control methods, self-monitoring, and self-reinforcement. For older students with anxiety, progressive muscle relaxation coupled with systematic desensitization techniques have been shown to be effective in reducing the physiological symptoms of anxiety and in lessening phobic behaviors. Children with depression also tend to be socially withdrawn and to derive relatively little enjoyment from their environment. In these cases, activity increase strategies and reinforcement for increased social interactions may be useful adjuncts to cognitively oriented therapies.

4.2.2. Externalizing Patterns

Children with externalizing patterns, particularly those with aggression, hyperactivity, and impulsiveness, are

best addressed with behavioral intervention strategies that emphasize providing consequences for behavior, including rewards and negative consequences. Behavioral contracts, reward systems, token economy methods, reinforcement, and punishments often are effective methods for increasing prosocial behavior while decreasing undesirable behaviors. Aggression replacement training is a method that includes both cognitive and behavioral techniques to address aggression problems. Including parents and teachers in behavior management training, behavioral contracts, and reinforcement programs can be effective in helping students to change behavior over settings. If negative consequences are used, they should be used sparingly and coupled with positive reinforcement. Although physical punishment (e.g., spanking) is used by some parents, research indicates that it has only temporary effectiveness, at best, in stopping a behavior and does little toward teaching prosocial behavior. Other strategies include positive behavioral supports, cognitive-behavioral strategies, and multisystemic therapy.

Children and youth with either internalizing or externalizing problems often have difficulty with social interactions, self-control, and self-regulation of their emotions and behaviors. Therefore, teaching social skills, self-control strategies, and anger management techniques using cognitive-behavioral and behavioral techniques often is necessary to help children function more effectively with peers and adults in the school setting.

4.2.3. Medications

Prescribing medications to address emotional and behavioral problems in children and youth is controversial. The majority of psychotropic medications used with children were developed for adults and then adapted to children with dosage adjustments. In general, the research on short- and long-term effects of medications with children is sparse. The exception to this pattern is stimulant medications used to treat ADHD and associated symptoms. Historically, stimulants have been used to treat ADHD and been shown to be effective in approximately 70% of cases with few short- or long-term side effects. Some of the newer medications to treat ADHD are not stimulants and show promise of being effective as well as of reducing side effects such as sleeping problems. In the author's experience, parents tend to be reluctant to agree to use medication with their children, whereas school personnel are more likely to advocate its use, particularly for behaviors such as inattention, off-task, and hyperactivity. It is clear from research and clinical practice that medications, when

used appropriately, can be effective in helping to address emotional and behavioral problems. Medication is most often prescribed to treat ADHD in children. The research literature demonstrates that medication combined with behavioral, cognitive, and self-management interventions is more effective than medication alone for the treatment of ADHD. Many children with ADHD have concomitant social and academic problems that are not affected directly by medication, thereby requiring behavioral interventions. Medication should be neither advocated nor completely ruled out for all cases; rather, it should be considered with regard to the needs of the individual child. School personnel are in a particularly good position to observe and monitor the effects of medication and can be valuable collaborators with the prescribing physician.

GLOSSARY

action readiness An inclination to achieve a particular change in one's relationship with the social environment; action readiness is an essential part of emotional experience.

antecedent event Any event that evokes an emotional response from an individual.

appraisal An individual's evaluation of the meaning an event has for him or her; an appraisal of the situation is an essential part of emotional experience.

cultural model A culture's construction of reality that organizes relationships and illustrates what a person is and should be; cultural models refer to understandings as well as the ways in which life is arranged.

dimensions of emotions Specific parts that make up the overall emotional experience of an individual such as the way in which the person evaluates an event and the way in which he or she is inclined to respond to it.

facial expressions Patterns of facial movements that are associated with emotion.

physiological response patterns Specific patterns of physiological events, such as muscle activity and heart rate,

that are associated with the experience of a specific emotion.

prevention focus A psychological state in which an individual's primary goal is the pursuit of positive outcomes and rewards.

promotion focus A psychological state in which an individual's primary goal is the avoidance of negative outcomes and consequences.

vocal expressions Nonverbal aspects of vocal utterances that are associated with emotion.

Do people in different cultures experience similar emotions, or are the emotions of people in other cultures different from one's own? This is the primary question addressed in the research on culture and emotions. This question has important practical implications for a variety of issues. For instance, can one accurately recognize the emotional tone of parent-child relations in other cultures? Do Western and non-Western business partners understand each other's emotional expressions correctly when they are at the negotiating table? Is it possible to counsel people from other cultures? Can one interpret the aggressive threats or the populist emotional addresses of the leaders of antagonistic countries in other parts of the world? The question of the cross-cultural diversity of emotions is important in light of any social relations across cultures. To understand the answers to these questions, one must first understand what research shows about cross-cultural similarities and differences in emotional experience.

I. ARE THERE UNIVERSAL EMOTIONS?

Many people believe that, regardless of one's culture, there are certain things that we all experience as humans. Emotion is one such example. Quite a few studies in the domain of culture and emotion have aimed to make precisely this point—that some emotions are “basic” to all humans. Researchers who take this approach believe that, regardless of the culture in which one lives, certain emotions are experienced by everyone wherever they may live. In addition, these scientists suggest that each of these basic emotions has unique features. For example, many people believe that anger is a basic emotion and that the events that cause it, and the ways in which an individual responds to it, are fairly similar for everyone. An assumption underlying this viewpoint is that each of these basic emotions is characterized by a unique experience of the emotion itself and that this unique experience is not directly measurable by scientists. However, characteristic features of each of these emotions are measurable, and when they are observed, they identify the emotion being experienced by the individual. Researchers who seek to prove the existence of basic emotions have attempted to establish the presence or absence of these emotion characteristics (and hence the emotions themselves) in various cultures. Features of emotions include unique facial and vocal expressions, behaviors, and physiological arousal patterns. Thus, for these scientists, the question is a straightforward one: Does a particular emotion occur across cultures or not? The search to prove the existence of universal (basic) emotions has yielded some evidence for cross-cultural similarity in expressive behaviors and physiological responses.

1.1. Facial and Vocal Expression Research

Most research in support of universal emotions has focused on facial expressions. These studies have made use of a simple but elegant method. People from various cultures are typically asked to look at a picture of a face showing a given expression and to associate it with one emotion word from a list. The list consists of words for basic emotions such as happiness and anger. Across all cultures, people recognize a small number of facial expressions as representative of several emotions. This is true even for people and cultures with minimal exposure to the West.

Recognition studies on vocal expression (modeled after the facial recognition studies) also have found evidence for universality in the recognition of certain types of emotion expression. Individuals from various cultures were asked to identify the vocal expressions of emotions in either a nonsensical phrase or a phrase with meaning. People are clearly able to identify characteristic vocal expressions for a number of emotions (e.g., anger, happiness) even if they do not have information about the content of the utterance.

Cross-cultural studies on facial and vocal expressions show that humans have several universal modes of communicating their emotions. Therefore, certain elements of the emotion repertoire appear to be part of the human makeup. This evidence shows that emotions cannot be completely culturally defined.

However, the solid evidence for universality in facial expressions does not rule out the possibility of cultural differences or prove the existence of basic emotions. For instance, even though people can recognize facial and vocal expressions of other cultures, they are better at recognizing the expressions from their own culture. Thus, people judging faces and voices have an in-group advantage. Clearly, culture plays an important role in an individual's ability to recognize the expression of emotions.

The established recognition of facial and vocal expressions is not necessarily due to a direct correspondence between these expressions and distinct emotions. The results of facial recognition studies definitely suggest that people are able to know something about a person's psychological state from facial expressions (just as they can from anything else that a person does), but there is some evidence indicating that people would not spontaneously conclude that a particular basic emotion is occurring and that people draw this conclusion only when confronted with a scale that forces them to choose among various emotions.

1.2. Physiological Response Patterns Research

A few studies have also measured the physiological aspects of the autonomic nervous system associated with so-called basic emotions. In these studies, some individuals from various cultures were asked to relive an emotion from the past, and some were asked to move specific muscles in the face in motions that are assumed to mimic basic emotions. These studies showed some

evidence for similarity in physiological response patterns produced for several emotions across cultures.

However, there is reason to use caution in interpreting these data as conclusive evidence for basic emotions. First, in Western studies of emotions, it has not been resolved that emotions have characteristic physiological states. Scientists have pointed out, for example, that the physiological experience of fear from a loud sudden noise differs considerably from the physiological experience of fear of failing an examination. In addition, researchers have shown that there are no differences in the heart rates of people reliving fear, anger, and sadness expressions. Therefore, if a few studies show cross-cultural similarity in physiology of certain emotions, this does not prove that the same physiological responses always reflect the same emotions.

A second reason to use caution in interpreting these results is that participants from various cultures do not always experience those physiological patterns as emotions. In one study, people were asked to move their faces into the facial expressions typical of various emotions. The physiological responses of Minankabau men in Indonesia corresponded with those of American men who made the same facial expressions. However, the Minankabau reported experiencing no emotions, whereas the Americans reported experiencing emotions. Therefore, even if the pattern of physiology is similar across cultures, the emotional experience might not be.

In sum, scientists who believe that there are basic emotions have searched for unique patterns of features that are characteristic of particular emotions across all cultures. The research on facial and vocal expressions and on physiological response patterns shows that there are universal features of emotions. However, one cannot conclude that emotions themselves are universal because (a) some other features are culture specific and (b) the feeling associated with certain emotion features might be different across cultures.

2. WHAT COMPONENTS OF EMOTIONS ARE UNIVERSAL?

During the past two decades or so, some scientists searching for universalities have shifted away from the perspective that there are universal emotions. Instead, these researchers take the position that the building blocks, or “features,” of emotions can be the same cross-culturally and that research should be done to establish the similarity of the features of emotions across cultures.

Two classes of features of the emotional experience are appraisal responses and action readiness responses. Appraisal is an individual’s assessment of the meaning an event has for him or her. For example, a student who fails an exam will probably feel unpleasant (e.g., sad, angry) and be aware that the event has negative consequences. Action readiness is an individual’s impulse to behave in some way toward objects in his or her environment in response to the emotion being experienced. The student might feel like “disappearing” or condemning the professor, even if these reactions are not feasible.

For scientists who investigate the features of emotions, then, people of all cultures are likely to evaluate emotional events in terms of how they rate on certain features (e.g., pleasantness, expectedness, controllability, agency). Where an event falls on such dimensions is also thought to correspond universally to similar types of experience. For example, the appraisal that a situation is positively relevant to oneself is an important feature of a positive emotional experience to everyone regardless of culture; likewise, a situation judged to be negatively relevant to oneself universally implies the experience of a negative emotion. Another example is the aspect of agency (responsibility). An individual who attributes responsibility for an event to another person might feel anger instead of the sadness he or she might have experienced if no such attribution of responsibility were made. Therefore, the same appraisals are thought to lead to the same emotions cross-culturally. Similarly, action readiness aspects contribute to emotional experience. The tendency to aggress toward another person is a central feature of the anger experience, and the tendency to quit doing anything at all is central to sadness.

Although emotion component theorists assume that the building blocks of emotions are largely similar across cultures, they do not assume that people appraise or desire to react to situations in the same manner across cultures. In this way, emotional experience may differ across cultures despite some universality in the building blocks. The extent to which emotions are actually different across cultures is a question that must be resolved by future research.

2.1. Universal Dimensions of Appraisal and Action Readiness

There is some evidence that the same dimensions of appraisal and action readiness help to distinguish among emotions across cultures and that they do so at similar levels. The ability to distinguish among emotions

is, to a large extent (~40%), due to appraisal dimensions. Among the dimensions that appear to be universally discriminative among emotions are pleasantness, expectedness, novelty, and agency (responsibility and control). Similar levels of the ability to discriminate among emotions are accounted for by action readiness dimensions. Current evidence suggests a core of action readiness dimensions that include moving away from, moving toward, and moving against the objects of emotions. So, there is some evidence supporting the idea of universal appraisal and action readiness dimensions that make up and help to distinguish various types of emotional experience across the world.

It should be noted that differentiation among emotions on the basis of appraisal and action readiness is only a partial explanation of what distinguishes emotions from one another, and this is true across cultures. There remains the possibility that some important dimensions have not been included, and there may be other important components of emotional experience (in addition to appraisal and action readiness).

2.2. Appraisal and Action Readiness Dimensions and Emotions

To what extent are certain emotions characterized by similar patterns of appraisals? For example, are experiences of emotions in the category of anger across cultures associated with the same appraisals? Studies have suggested that a number of emotions (e.g., joy, anger, sadness) share patterns of appraisals that are quite similar across cultures. For instance, joyful situations have been cross-culturally characterized as expected, very pleasant, requiring no action, and enhancing self-esteem. However, in these studies, cultural differences in appraisal patterns, in addition to these core similarities, have been established. Thus, happiness can be appraised as good for social relationships in some cultures (e.g., United States) and as bad for social relationships in others (e.g., Japan). Current research shows that the cultural differences in appraisals are smaller than the similarities. However, there are some reasons why this conclusion might not reflect the true picture. First, most studies have used relatively homogenous samples such as college students from various countries. The differences among students who are exposed to education with Western influences are likely to be smaller than differences among populations in cultures that are less influenced by Western culture. Second, because appraisal dimensions have been suggested by Western theorists, there

may be a Western bias in the proposed dimensions. There is a possibility that non-Western cultures have important appraisal dimensions that have been missed so far. For example, several studies that included East Asian cultures have suggested the importance of the dimension of interpersonal connection, a dimension not typically included in current appraisal research.

Studies addressing the cross-cultural similarity in action readiness have been relatively scarce and less systematic. There is some evidence that a small set of emotions are universally characterized by core action readiness modes. Culture plays an important role, however, in lending specific contextual features that help to clarify differences in action readiness modes. For example, across many cultures, shame has been associated with the urge to “disappear.” In some other cultures, however, shame is associated with aggressive tendencies when it is caused by the behavior of someone very close to the affected individual.

In sum, research has shown that certain emotions have cross-culturally overlapping similarities in their core features. This finding supports some degree of the universality of emotions. At the very least, it suggests that similar patterns of appraisal or action readiness exist across cultures, and so there are similarities in the features of emotions. A limitation to this approach is its nearly exclusive reliance on retrospective self-report studies. So, one cannot be entirely sure to what extent the results reflect the ways in which people in various cultures think about their emotions or the ways in which emotions actually differ. On the other hand, it may be argued that emotional experience does not happen independently from the way in which people think about it and that self-reports provide a window on this experience that cannot be obtained in any other way. An additional limitation to this approach is that researchers of emotion features have been more interested in predicting similarities than in predicting differences. The differences that exist are equally informative about the nature of emotions and have been addressed by another group of researchers.

3. ARE EMOTIONS CULTURE SPECIFIC?

During the past two decades or so, some scientists have approached the issue of culture and emotion quite oppositely. Instead of looking for similarities in emotions and their components, these scientists have focused on the

cultural differences in emotions. These culture researchers believe that emotional experiences can be truly understood only by taking into consideration the culture in which they occur. Thus, some researchers try to understand how individuals' emotional responses relate to the values and practices of the culture.

The search for differences in emotions among various cultures begins with an insight into the ways in which cultures organize relationships and understand what a person is and should be. These social arrangements and understandings are referred to as cultural models. For example, achievement is one prevalent middle-class American cultural model. The belief that one should stand out from the crowd, the value placed on positive rewards, and the emphasis on personal influence and responsibility all are integral parts of this cultural model. Culture researchers have established that the particular models that are most important differ according to the culture in which one lives. For instance, this American cultural model can be contrasted with an important middle-class Japanese cultural model that stresses an individual's harmonious fit with his or her social environment. Culture scientists regard these cultural models as key ingredients in the overall emotional experience.

Although these scientists rely on cultural models as a context for understanding and predicting emotional responses, they do not assume that all people within a culture are alike. Because individuals in a culture will regard a given model in different ways, their individual emotional experiences will differ as well. For example, not all Americans value personal achievement equally, and they certainly differ in how they define achievement personally or in how they go about accomplishing success. What is critical, however, is that the overall culture still powerfully endorses the dominant cultural beliefs and social practices for how things are done in that culture, for example, when we are encouraged to "just do it" by a sports equipment company. The cultural models, therefore, set the reality boundaries within which emotions occur and are expressed. According to culture researchers, the models that are important to a culture will influence several aspects of emotions.

3.1. Antecedent Events

Cultural models are important in determining the occurrence of the events that cause an emotion to occur. How an event transpires is not part of the emotion itself, but it is an important determinant of which emotion will occur and what the responses of the individual will be. In other

words, certain situations may be especially likely to lead to certain emotions. If these situations occur more often in one culture than in another, the accompanying emotion is also more likely to occur in the former culture than in the latter. Likewise, if a situation is relatively unlikely to occur in a particular culture, the emotions that typically go with that situation are probably less likely to occur as well. How likely an event is to occur depends, at least in part, on how well it agrees with the overall values of the culture. Cultures tend to create more opportunities for events that are consistent with the prevailing models, whereas they tend to suppress opportunities for events that are at odds with these models. For instance, consistent with the cultural models, Americans create and encourage many contexts in which people are made to feel good about themselves because they stand out (e.g., praise, compliments, awards, trophies). The creation of many of those events has been shown to result in high occurrences of happy feelings. Similarly, in cultures that value a harmonious fit with other people (e.g., Utku Inuit, Chewong of aboriginal Malaysia, Tahitians, Japanese), acts of upsetting and frustrating those around a person are largely absent. The absence of frustrations is reflected in the relatively low levels of anger reported in these cultures.

People also selectively pay attention to certain aspects of situations in ways that are consistent with the cultural models. People in cultures that stress autonomy and uniqueness (e.g., United States) focus on good events and good qualities in the self so as to feel unique and independent. Therefore, individuals in this kind of culture are predisposed to strive for positive rewards. This focus on approaching positive outcomes is known as a promotion focus. In cultures where harmonious interaction with others is emphasized (e.g., Japan), individuals strive to avoid the occurrence of negative events by examining what could be improved about oneself. This focus on the prevention of bad outcomes (e.g., not living up to the standards) is referred to as a prevention focus. These cultural differences in predispositions for attending to certain events have implications for the emotions experienced as well. Consistent with their prevention focus, Chinese individuals report relaxation or relief when goals have been met and report anxiety when goals have not been reached. Americans' promotion focus leads them to report happiness when goals have been met and to report feelings of sadness when goals have not been reached. Thus, cultural models form the emotional lives of individuals within the culture by promoting events that are consistent with the models

and by focusing people's attention on particular aspects of situations that occur.

3.2. Appraisal

Cultural models also influence the ways in which people appraise or evaluate events. Certain appraisals are more likely to occur in certain cultures than in others. The prevalence of a particular appraisal will also differ across cultures, depending on the various cultural models. For instance, the appraisal of agency (responsibility) is markedly different across cultures. A key aspect of North American cultural models is success through independent personal accomplishment. Claiming responsibility and a personal sense of control are at the center of what it is to be a good person in this culture. In keeping with this model, North Americans typically attribute personal "responsibility" (either to oneself or to others) in many situations (especially positive ones), and they strive for a state of responsibility and control.

In contrast, East Asian cultural models emphasize the role of fate, how events are determined by many factors other than individuals themselves, and how individuals are interwoven with others in their social environment. Individual control and responsibility are not very relevant to the East Asian way of thinking. Accordingly, East Asians do not view control (or lack thereof) as an important aspect of emotional situations.

Thus, agency appraisals are markedly different across cultures. These evaluations of personal control or responsibility have important roles in the emotional experience. One implication of feeling responsibility, or feeling that someone else has responsibility, is that a person can influence or control other people in specific ways that fate or the world in general cannot. Claiming responsibility for an event results in active ways of emotionally reacting to, and coping with, the event. This differs considerably from the case of an event where one believes that the event could not have been humanly controlled.

Cultural models can also account for differences in the most frequent patterns of appraisal. For example, research has shown that there are differences in the events that are associated with feelings of pleasantness. In cultures that stress individual autonomy, pleasant experiences are those that are associated with evaluations of high self-esteem and personal control, whereas in cultures that stress interpersonal engagement and harmony, pleasantness is associated with events that make one feel connected with other people. Thus, pleasantness can be a

different experience in different cultures, depending on what each culture associates with pleasantness.

3.3. Relationship Goals and Action Readiness

Cultural models also outline desired goals for relationships with other people, thereby affecting an individual's impulses in a situation. In a series of studies in which people from various cultures reported what they felt like doing in a variety of emotion situations, Americans reported that they desired to (a) affirm or salvage positive self-esteem, (b) actively change the situations to make them consistent with their personal goals, and (c) prioritize their own personal concerns over those of their relationships. For example, in response to negative interactions, Americans reported the urge to break off their relationships and protect self-interests at the expense of their relationships. In contrast, Japanese reported action readiness modes that served to (a) maintain or improve their relationships and (b) adjust to other people's wishes and expectations. For instance, in negative interactions with others, Japanese wanted to reestablish closeness with the other persons and to keep their emotions to themselves.

Cultural differences in emotions are not random. Rather, they make sense when one considers the role of cultural models. The influence of cultural models goes beyond providing the content to fill in the blank of an otherwise standard emotion process in that cultural models affect the entire process of emotional experience. The context in which an emotion occurs, the ways in which the situation is perceived and evaluated, and the coping that is generated by the emotions experienced all are guided by cultural models. Thus, the cultural approach focuses on cultural differences instead of aiming to establish universalities. It is important to study both similarities and differences for a complete body of knowledge about emotions. However, the claim that emotions are primarily universal has been challenged by cultural researchers. During recent years, the methods adopted by cultural studies have established many cultural differences in emotion.

4. CONCLUSION

So, can one accurately interpret the emotions of people from other cultures? Few researchers of emotion are likely to answer with an unconditional "yes." However,

scientists' answers differ according to the ways in which they approach the question. Researchers who seek basic emotions believe that the most important emotions are similar across cultures. Researchers who have analyzed the separate building blocks of emotions in search of similarities contend that emotions in other cultures can be understood if one knows how certain situations are appraised and reacted to in other cultures. Finally, culture researchers believe that one must know and understand the major cultural concerns, meanings, and relational practices to have a sense of the emotional experiences in other cultures.

GLOSSARY

experience The totality of characteristics, both past and present, that make up the particular quality of a person's performance; three aspects of experience are situational experience (states), relatively stable patterns of experience, and meta-experience (knowledge, attitudes, and preferences for [or rejections of] a person's experiences).

individual zones of optimal functioning An action-oriented framework for analysis of idiosyncratic emotional experiences related to athletic performance.

in–out of the zone principle The assumption that specific intensity of emotion has a beneficial (or detrimental) effect on individual performance; a high probability of individually successful performance is related to being in the optimal zone of intensity.

psychobiosocial state A situational, multimodal, and dynamic manifestation of the total human functioning.

resources Psychobiosocial (cognitive, affective, motivational, bodily, behavioral, operational, and communicative) assets determining an athlete's ability to perform up to his or her potential.

Understanding emotion–performance relationships is of crucial importance for applied sport psychologists. This article reviews an individual- and action-oriented framework, termed the Individual Zones of Optimal Functioning (IZOF) model, that describes, predicts, and explains individually optimal and dysfunctional emotional experiences related to athletic performances. To describe emotion–performance relationships, the IZOF model proposes a multidimensional conceptualization of emotions as a component of the psychobiosocial state. Finally, the model suggests several empirically substantiated guidelines for person- and task-relevant assessments focused on emotion self-regulation and optimization of performance.

1. INTRODUCTION

One of the key questions in sport psychology is how and why pleasant and unpleasant emotional states affect

sport performance. Indeed, are unpleasant emotions always bad for performance? For instance, can anger sometimes be useful in competition? On the other hand, are pleasant emotions always good for performance? For instance, can self-confidence lead to poor performance through complacency and underestimation of task demands? Moreover, do athletes perform up to their potential when they are stress free or when they are deliberately using competitive stress to their advantage? Is precompetition anxiety bad for all athletes? Finally, is it possible to predict an athlete's performance based on content and intensity of emotional experiences? Researchers, applied sport psychologists, athletes, and coaches often need straightforward answers to these practical questions. Most of the existing models in sport psychology focus mainly on interindividual differences between successful and unsuccessful athletes. On the one hand, there are exceptional athletes who reach the top and stay at the top with remarkable consistency. On the other hand, it is important to realize that even the winners have bad days and often exhibit inconsistent performance. In other words, performers across the full range of skill and experience are quite familiar with occasional performance slumps and "choking." Thus, instead of comparing high achievers with underachievers, an alternative approach would be to focus more on performance experiences of each individual athlete. Such an approach has direct practical implications and can be applied to a particular athlete or a team. This article describes an individual-oriented, research-based framework, termed the Individual Zones of Optimal Functioning (IZOF) model, to show how the understanding of emotion–performance relationships at the individual level can be helpful in optimization of athletic performance.

2. INDIVIDUALIZED APPROACH TO PERFORMANCE EMOTIONS

Successful performance enhancement interventions in sport should (a) focus on unique challenges and concerns facing coaches and athletes, (b) emphasize practical application of research-based principles, and (c) realize that athletes are healthy achievement-oriented people who are "forced" to cope with performance-induced stress. The IZOF model aims to match these requirements with a special emphasis on individual athletes. The following subsections briefly describe the basic assumptions of the model.

2.1. The Meaning of the IZOF Acronym

The IZOF model, developed in high-achievement sport settings during the past 30 years or so by Hanin, is a sports-specific, action-oriented framework. It focuses on analysis of the structure, dynamics, and function of situational emotional experiences (e.g., nervous, worried, calm, confident) related to individually successful and less than successful performances. The model also examines relatively stable patterns of these experiences and meta-experiences (i.e., beliefs about expected effects of feeling nervous, worried, or calm on performance). The IZOF acronym reflects selected features of the model.

2.1.1. Individual

The model is an idiographic approach that focuses on idiosyncratic emotional experiences of individual athletes (or teams). Therefore, the main emphasis is on the within-individual dynamics of subjective emotional experiences and meta-experiences related to performance.

2.1.2. Zones

The zone principle implies a specific relationship between the perceived intensity of emotional state and the quality of performance. Individually optimal intensity (high, moderate, or low) reflects an athlete's past performance history and available resources. Being in the optimal zone implies a high probability of individually successful performance. Thus, the zones serve as empirically established individualized criteria for prediction of performance, and the "in–out of the zone" concept is used to evaluate a match (or mismatch) between the currently experienced level of emotion intensity and previously established optimal and dysfunctional zones.

2.1.3. Optimal

Optimal emotions are defined as most relevant and appropriate for a particular athlete performing a specific task. The optimal performance state results in a total task involvement and the best recruitment and use of available resources. This usually results in a high-quality performance process and achievement of individually successful performance outcomes (although not necessarily "peak or best ever"). The optimal performance state tends to include both pleasant and unpleasant emotions reflecting idiosyncratic strategies that athletes use in recruitment and use of their resources. Therefore,

the functionally optimal state (e.g., situational anger, high anxiety) is different from the “ideal” or preferred state (e.g., “flow”), which usually has only positive characteristics. Finally, the concept of optimality is multidimensional and is related not only to emotion intensity and content but also to time and context dimensions.

2.1.4. Functioning

The term “functioning” emphasizes the fact that a detailed description of performance emotions is just a tool to understand their optimal and dysfunctional effects on task involvement and the quality of performance process. Optimal function is manifested in an athlete’s efficient recruitment (effort) and use (skill) of available resources. This usually results in energizing and organizing effects on performance. In contrast, emotion dysfunction usually reflects a failure to recruit resources and their inefficient use, resulting in deenergizing and disorganizing effects of emotion on athletic performance.

2.2. Basic Assumptions of the IZOF Model

The IZOF model holds that emotion is a component of adaptive or maladaptive response in person–environment interactions; emotion is an integral part of a person’s psychobiosocial state, performance process, and total functioning; emotion is triggered by appraisals of a person’s relationships with the environment; and emotion is a reflection of critical moments of imbalance in person–environment interactions. The model describes the nature of the emotion–performance relationships as follows. First, emotions are triggered by a person’s appraisal of the probability of achieving expected individually relevant goals. Second, because sport activity is repetitive, situational emotional experiences gradually develop into relatively stable emotion patterns. Third, emotion patterns are specific to the individual, task, and setting, and this specificity is manifested in the form, content, intensity, time, and context dimensions of the psychobiosocial state. Fourth, emotion–performance relationships are reciprocal. Emotions affect performance; however, changes in the ongoing performance process and intermediate (and final) outcomes produce a shift in a personal meaning of the situation, resulting in a shift in emotion content and intensity. A shift in the direction of impact (causality) is usually determined by ongoing appraisals of the performance process. Fifth, prediction of performance should be based on

assessment of interaction effects of a cluster of really experienced emotions (optimal and dysfunctional) rather than on separate effects of selected “pure” emotions. Sixth, because athletes often reflect on their experiences in successful and less than successful performances, they gradually develop meta-experiences. For instance, an athlete could notice that high anxiety sometimes helps him or her to focus better or that it does not affect performance negatively. This knowledge leads to a positive attitude toward anxiety, which is then interpreted as an indicator of this athlete’s readiness for competition. Emotion self-regulation and individual-oriented interventions in the IZOF model are based on the concept of optimal personal meaning and adequate meta-experiences triggering specific emotions.

3. MULTIDIMENSIONAL DESCRIPTION OF PERFORMANCE EMOTIONS

The IZOF model defines the performance-related psychobiosocial state as a situational, multimodal, and dynamic manifestation of the total human functioning. A multi-level and system description of performance-related states includes at least five interrelated dimensions: form, content, intensity, time, and context. Three of these dimensions (form, content, and intensity) describe the structure of subjective experiences and meta-experiences, and two of these dimensions (time and context) characterize the dynamics of performers’ subjective experiences. When viewed collectively, these five basic dimensions provide a framework for a relatively complete description of the phenomenon and can guide data collection, analysis, interpretation, and generation of new ideas.

3.1. Form Dimension

An athlete’s psychobiosocial state manifests itself in seven basic forms (modalities): cognitive, affective, motivational, bodily, motor–behavioral, operational, and communicative. All seven modalities are interrelated and provide a relatively complete description of a performance state, including experiences and their displays (expression or suppression). Thus, emotion is construed as an important component of the performance-related psychobiosocial state. Current individual-oriented research focuses on affective (emotional), motivational, and bodily components of the performance state and their interactive effects.

3.2. Content Dimension

The content dimension is a qualitative characteristic of the performance state. The IZOF model as an alternative individual-oriented approach categorizes emotion content within the framework of two closely related but independent factors: a hedonic tone (pleasure–displeasure) and functionality (optimal–dysfunctional impact of emotion on athletic performance). Both factors reflect qualitatively different experiences related to individually successful and poor performances. The four broad emotion categories derived from these distinctions are pleasant and functionally optimal emotions (P+), unpleasant and functionally optimal emotions (N+), pleasant and dysfunctional emotions (P–), and unpleasant and dysfunctional emotions (N–). These four categories provide an initial robust and sufficiently broad structure to generate a wide range of idiosyncratic, individually relevant, and task-specific emotions really experienced by athletes prior to, during, and after successful and less than successful performances. Finally, the content of these athlete-generated emotions can be recategorized to see how idiosyncratic descriptors match or mismatch the existing “basic” or discrete emotion frameworks proposed in mainstream psychology.

3.3. Intensity Dimension

The intensity dimension as a quantitative attribute of subjective experiences is expressed in either objective or subjective metrics on a selected component or modality of the performance state. Different levels of intensity can produce different functional effect related to energizing (deenergizing) and organizing (disorganizing) aspects of the performance process. The in–out of the zone notion describes a selected range of emotion intensity producing optimal, neutral, or dysfunctional effects on individual performance. For instance, a high probability of successful performance is expected if an athlete’s actual state is in (or close to) the earlier established optimal zone of intensity. In contrast, if an athlete’s actual state is out of the optimal zone, the athlete is likely to perform below his or her potential.

3.4. Context Dimension

The context dimension is an environmental characteristic reflecting the impact of situational, interpersonal, intragroup, and organizational factors on emotion intensity and content in sport setting. Situational impact is observed in emotional reactions triggered in practices

and competitions by athletes’ anticipated or real contacts and interactions with significant others (e.g., partners, coaches, teammates). This dimension also includes culturally coded and culturally determined beliefs of participants about the expected impact of specific emotions on their performance and about the rules of emotion display in a particular subculture.

3.5. Time Dimension

The time dimension includes topological (e.g., phases, cycles, sequencing, periodicity, timing) and metric (e.g., duration, frequency) characteristics reflecting the dynamics of performance-related experiences. The short-term dynamics in sporting activity is observed in emotional states prior to preparation for an action, during task execution, and after performance in a single competition (practice). The long-term temporal dynamics is related to emotion–performance relationships during a competitive season(s), a 4-year Olympic cycle, or an athlete’s sports career.

4. PREDICTION OF EMOTION–PERFORMANCE RELATIONSHIPS

There are certain myths in sport psychology about emotion–performance relationships based on unsubstantiated beliefs that have been challenged recently. Some examples include the notions that there exists a universally optimal intensity of emotions facilitating performance of all athletes (e.g., moderate anxiety), that all negative emotions are always dysfunctional for athletic performance, and that all positive emotions are always optimal for athletic performance. In contrast, IZOF-based individual-oriented and empirically supported predictions of emotion–performance relationships indicate that these notions are not the case.

4.1. Interindividual Variability

As predicted, research revealed a high degree of interindividual variability in the intensity and content of idiosyncratic optimal and dysfunctional emotions accompanying individually successful and poor performances. Thus, different athletes can perform up to their potential experiencing emotions of different content and intensity. Optimal emotional states reflect (a) individual differences in available resources, (b) athletes’ ability to recruit and use these resources

efficiently, and (c) athletes' individual coping strategies to compensate for either a lack or an insufficiency of resources (low situational readiness for competition).

4.2. In–Out of the Zone Principle

The prediction of individually successful, average, or poor performance based on the in–out of the zone principle has received some empirical support in several studies. Thus, a player's emotional state is first described in terms of individually relevant emotion content and intensity. Then, current emotion intensity is contrasted with the previously established individually optimal and dysfunctional intensity zones. A high probability of successful performance is expected when emotion intensity is within the optimal zones and outside dysfunctional ranges. Therefore, a large discrepancy (in intensity and emotion content) between the actual state and the individually established optimal zones indicates a high probability of less than successful performance.

4.3. Interactive Effects

Research indicates that most emotional experiences involve clusters of “mixed” rather than “pure” emotions. For instance, an international-level tennis player, prior to his best ever match, felt high intensity of pleasant optimal emotions (P+). He felt highly determined, confident, excited, dynamic, and comfortable. At the same time, he felt moderately aggressive, alarmed, and somewhat uncertain (N+). Moreover, his unpleasant dysfunctional emotions (N–) (e.g., nervous, afraid, worried, intense) were of low intensity. This pattern was similar to that during his best match; however, he felt alert and quick but not excited too much without premature satisfaction. In contrast, in the worst match of his career, this player felt highly nervous and worried (N–), and these experiences were more intense during the match. Interestingly, at the same time, his optimal pleasant emotions prior to and during the match were of moderate and low intensity, respectively. If applied sport psychologists measured only anxiety, for instance, they would miss the entire picture of emotional clusters. Therefore, the interactive effects of emotions enhancing and impairing sporting activity are of crucial importance for an accurate prediction of emotion–performance relationships. In this case, a high probability of individually successful performance is expected when combined maximum-enhancing and minimum-impairing effects are observed. On the other hand, a high probability of individually average and impaired performance is

expected when a combination of high-enhancing and high-impairing effects or of low-enhancing and low-inhibitory effects is observed. Finally, a high probability of poor performance is expected when low-enhancing and high-inhibitory effects are observed.

4.4. Dynamics and Bidirectionality

Emotion–performance relationships are dynamic and bidirectional. In other words, precompetition emotions affect performance, and ongoing performance affects the dynamics of mid- and postcompetition emotions. Thus, to predict the entire process of emotion–performance relationships, it is important to establish patterns of emotion impact on performance and of performance impact on emotions.

All of these predictions were tested empirically across various samples and sports in different countries. Initially, the IZOF model focused on precompetition anxiety as a discrete stress-related emotion syndrome with a “fixed” emotion content. The main emphasis in the IZOF–anxiety research was on identifying individually salient intensity of state anxiety. Specifically, it was revealed that each athlete had an individually optimal intensity level (which could be high, moderate, or low) and zones of anxiety enhancing the athlete's performance. The analysis of an athlete's past performance history identified these optimal level and intensity zones, which served as tentative individualized criteria in the prediction of current and future performances. Thus, the probability of successful performance was high when current precompetition anxiety was near or within the previously established individually optimal intensity zones. When precompetition anxiety fell outside the zones (i.e., higher or lower), individual performance usually deteriorated. Recently, similar results were obtained in the studies of optimal and dysfunctional effects of situational anger on athletic performance.

Research indicated that an exclusive focus on precompetition anxiety or anger was limited because these syndromes were only a part of athletes' emotional experiences related to performance. Therefore, the IZOF model was extended to the study of pleasant and unpleasant emotions enhancing and impairing individual performance, and more consideration was given to the saliency of other dimensions of emotion (content, time, and context). A recent extension of this line of research tested the validity of the preceding predictions in motivational, bodily, and performance correlates of the psychobiosocial state.

5. EXPLAINING EMOTION– PERFORMANCE RELATIONSHIPS

Most of the existing approaches in sport psychology focused mainly on antecedents and consequences of selected emotion syndromes (e.g., anxiety, anger, depression). In contrast, the main emphasis in the IZOF model was first on an accurate and detailed description of various forms of idiosyncratic emotional experiences in athletes. To explain the antecedents (emergence and dynamics) and consequences (impact on performance) of performance-related emotional experiences, the model uses several constructs that are briefly reviewed in the following subsections.

5.1. Appraisals and the Emotion Process

Person–environment interactions are important in the IZOF model; therefore, a psychosocial perspective is central in the functional interpretation of the dynamics of emotion–performance relationships. First, emotion is conceptualized as an unfolding process reflecting person–environment interactions. Ongoing appraisals of these interactions result in a change in personal meaning of the situation, and this exerts the influence on emotional experiences related to performance. Second, changes in personal meaning reflecting the dynamics of the performance process trigger functional shifts in emotion content and intensity. Specifically, anecdotal evidence and practical experience indicate that functionally optimal pleasant and unpleasant emotions (P+N+) prior to and during activity are usually anticipatory and are triggered by the appraisals of challenge and threat. In contrast, situationally dysfunctional pleasant and unpleasant emotions (P–N–) during activity are usually triggered by perception of “achieved” outcomes (appraisals of gain and loss) before the task is completed.

5.2. Emotion Impact on Performance

Two constructs with their opposites related to energizing and organizing aspects of emotion account for the impact of emotions on the athletic performance process. These include the concepts of energy mobilization (and demobilization) and energy use (and misuse). Therefore, optimal and dysfunctional emotion function in the IZOF model is conceptualized within the framework of two closely related but independent factors: (a) energy mobilization (e.g., optimal effort,

intensity) and (b) energy use (e.g., efficiency, optimal information processing). The former is related to the situational resources available to an individual performer, whereas the latter characterizes the efficiency of using these resources. Based on these two factors, four relatively independent global emotion functions are derived: (a) energizing or energy-mobilizing function, (b) energy demobilizing function, (c) energy use or regulation function, and (d) energy misuse or deregulation function. These four functions provide a framework for interpretation of separate and interactive effects of positive and negative emotions on individual performance. Based on the nature of these interactions, the total impact of emotions on athletic performance can be optimal (regarding effort and skill), paraoptimal (with only effort or skill, but not both, being optimal), or dysfunctional (regarding effort and skill).

From the functional effect perspective, the constructs of energy mobilization and use (and their opposites) seem to be useful in explaining why in some athletes optimal emotions are predominantly pleasant, whereas in other athletes they are unpleasant. For instance, low-anxious athletes are typically “smart users” of available energy and are less distracted by task-irrelevant and energy-wasting concerns. In contrast, high-anxious athletes typically generate more energy, especially in stressful or emergency situations, because they are often less efficient in its use due to a narrow attention focus and an overload in the information-processing function. Thus, unpleasant emotions, such as anxiety, are functionally useful for these athletes in that they help to generate additional energy to compensate for the apparent limitation in information processing or the use of energy. Because the quality of athletic performance is usually related to both the amount of available energy and its efficient use, different athletes can be successful by using different resources. In other words, the same level of performance may be achieved either through the increase of total effort or through skillful (smart) use of available resources (efficiency).

6. INDIVIDUALIZED ASSESSMENTS AND MONITORING OF EMOTIONS

An accurate individualized assessment and monitoring of performance-related emotional experiences provides a basis for predictions of emotion impact and self-regulation. In the following subsections, selected data collection techniques that have been used to assess

individually relevant idiosyncratic emotion content in sport are briefly described: interviews, emotion profiling, self-generated metaphors, and narratives.

6.1. Interviews

The first and most popular data collection technique for eliciting idiosyncratic emotion content is structured and semistructured in-depth interviews with open-ended and probing questions activating an athlete’s recall of thoughts and feelings prior to and during best and worst performances. It is usually recommended in pilot and exploratory studies to generate idiosyncratic labels and then to aggregate most selected items into a stimulus list or standardized emotion scale. Identifying idiosyncratic content and personally meaningful labels to describe athletes’ subjective experiences is a clear advantage of these interviews over questionnaires with researcher-generated items and “fixed” emotion content. Experienced and verbally skillful athletes can provide detailed and meaningful accounts of their experiences (how they felt) and meta-experiences (how they interpreted and coped with these feelings) prior to and/or during the competition. Athletes who are less aware of their performance-related experiences might require some assistance initially in structuring and focusing their recall.

6.2. Individualized Emotion Profiling

A person’s perspective is central in the reconstruction of athletes’ emotional experiences and meta-experiences related to successful and less than successful performances. The individualized emotion profiling aims to analyze athletes’ past performance history and significant emotional experiences and meta-experiences. Specifically, athletes generate individually relevant emotion words that best describe their optimal (helpful) and dysfunctional (harmful) pleasant and unpleasant emotional experiences accompanying their performances in best and worst competitions. A stimulus list, compiled from existing emotion scales or based on previously generated items, can assist athletes in generating emotion descriptors. The IZOF-based emotion list consists of 46 pleasant emotions (arranged in 14 synonymous rows) and 50 unpleasant emotions (arranged in 14 synonymous rows). Table I shows a group-oriented functional categorization of pleasant and unpleasant emotions based on several studies of athletes representing various sports. However, research also indicates that in each individual case, optimal and dysfunctional emotions can be different from those in the aggregated group data. Therefore, individualized emotion profiling is strongly recommended.

TABLE I
Functionally Categorized Emotion Stimulus List for Individualized Profiling

<i>Pleasant emotions</i>	<i>Unpleasant emotions</i>
P+ <ul style="list-style-type: none"> • Active, dynamic, energetic, vigorous • Quick, rapid, fast, alert • Confident, certain, sure • Determined, set, settled, resolute • Brave, bold, daring, dashing • Inspired, motivated, stimulated • Excited, thrilled 	N+ <ul style="list-style-type: none"> • Angry, aggressive, furious, violent • Intense, fierce • Tense, strained, tight, rigid • Annoyed, irritated, distressed • Anxious, apprehensive, worried • Concerned, alarmed, disturbed, dissatisfied • Nervous, jittery, uneasy, restless
P- <ul style="list-style-type: none"> • Delighted, overjoyed, exhilarated • Relaxed, comfortable, easygoing • Calm, peaceful, unhurried, quiet • Cheerful, merry, happy • Glad, pleased, satisfied, contented • Lighthearted, carefree • Nice, pleasant, agreeable Your own emotion:	N- <ul style="list-style-type: none"> • Discouraged, dispirited, depressed • Afraid, fearful, scared, panicky • Doubtful, uncertain, indecisive, irresolute • Helpless, unsafe, insecure • Inactive, sluggish, lazy • Sorry, unhappy, regretful, sad, cheerless • Tired, weary, exhausted, worn out Your own emotion:

Individualized emotion profiling involves several steps. First, to identify optimal emotion patterns, athletes select four or five positive items and then four or five negative items that best describe their emotions related to their individually successful performances in the past. Then, athletes identify their dysfunctional emotions related to individually poor performances by selecting four or five positive items and four or five negative items. Although athletes use the emotion stimulus list to generate individually relevant descriptors, they can also add emotion words of their own choice. The focus of recall is either on a specific situation (precompetition) or on repeated experiences across several similar situations. Individually optimal and dysfunctional intensities for each emotion item are established using the Borg's CR-10 scale (ranging from "nothing at all" to "maximal possible").

In sum, individually oriented and task-specific emotion profiling identifies (a) individually relevant emotion content, (b) individually optimal and dysfunctional emotion intensity, (c) individually relevant context, and (d) interaction effects of optimal and dysfunctional emotions. In a comprehensive IZOF-based assessment program, first, the individual's past performance history is examined within the context of the current situation. Then, individually relevant emotion content is generated. Next, optimal (and dysfunctional) intensities for each emotion item are identified. Finally, the emotion profiles (with intensity zones for each individual item) are validated and refined in a series of repeated self-ratings in specific performance situations (practice or competitions). For monitoring emotional states in a field setting, the total emotion profile can be condensed to a few most important markers (e.g., three items for each of the four emotion categories). The major emphasis in individualized emotion profiling is on analysis and reconstruction of athletes' performance-related idiosyncratic experiences and meta-experiences by using their own vocabularies.

Research shows that athlete-generated emotion descriptors usually have strong connotations with none-motion concomitants of the psychobiosocial state such as cognitive (e.g., alert, focused), motivational (e.g., willing, determined, motivated), and bodily (e.g., relaxed, tense, jittery) experiences. Therefore, there is a clear need to extend the focus of individualized profiling from emotions to other modalities of an athlete's state.

Moreover, a mere description of emotional experience (e.g., the same high level of precompetition anxiety in an athlete on two occasions) might not explain why the athlete was very successful in the first competition and less than successful in the second competition. Here, additional qualitative data (e.g.,

motivational domains or causes of these experiences and resulting self-talk) could be instrumental. For instance, a highly anxious athlete in a successful race could feel "psyched up," "perceive the race as important," and "focus on competing with tough opponents." This athlete's self-talk would be clearly self-empowering (e.g., "I can run at this level," "I'll show them all," "It is my day today"). In contrast, prior to a less than successful race, this athlete's thoughts included "doubts in her current shape," "insufficient recovery," "health problems," and/or "poor team climate," and the resulting self-talk was clearly self-defeating in that there was too much focus on opponents' strengths (e.g., "they are going to beat me," "I've got no chance in this race," "today is not my day," "the race is meaningless").

6.3. Self-Generated Metaphors

Although the individualized emotion profiling may be successful in generating idiosyncratic descriptors of emotions, there is still a need for a more holistic description of the psychological meaning of the performance situation and an athlete's role in it. To address this concern, Hanin and colleagues proposed a metaphor self-generation method to examine the feasibility of symbolic representation of performance-related experiences using idiosyncratic athlete-generated metaphors. The approach is based on the symbolizing ability of people and on the notion that people give structure, meaning, and continuity to their activities by symbolizing their experiences.

A metaphor is always related to a certain image, which is holistic and meaningful for a person. Therefore, words, objects, mental images, stories, and the like are the units of metaphor. A symbolic nature of a metaphor provides a picture of one's understanding of something, with an emphasis on most personally relevant and important aspects and shades of meaning. Well-known metaphors describing performance-related states in sport include being "in the zone," "in the groove," "in the cocoon," and "in the flow state" as well as having "choked." Research suggests that athlete-generated idiosyncratic metaphors may be useful in the practice of sport psychology for holistic and personally meaningful description and better understanding of performance-related situational experiences and relatively stable patterns of experiences.

The metaphor self-generation method is an instrument identifying metaphors and accompanying interpretive descriptors of feeling states prior to, during, and after best and worst competitions. Thus, the

focus is on assessment and symbolic representation of idiosyncratic content (quality) of emotional experiences in a high-achievement setting. Several studies using a metaphor generation method in various performance situations revealed that athletes in various sports, and at various age and skill levels, are able to generate highly idiosyncratic images symbolically representing their high or low action readiness in successful and poor performance situations.

Metaphors reflecting available resources (e.g., “a boat with an engine,” “a mountain river”) and ability to recruit resources (e.g., “a horse in a light cart,” “a man who can move a mountain”) have been used to describe athletes’ states in best ever competitions. A lack of resources (e.g., “a sinking boat,” “an empty bottle”) and inability to recruit resources (e.g., “a man with weights on his legs,” “a bird unable to fly”) are characteristic of metaphors that athletes have used to describe their states in worst ever competitions. In addition, metaphors describing best ever competitions have reflected highly efficient use of resources (e.g., “Batman in flight,” “a fisherman catching a golden fish”), whereas metaphors describing worst ever competitions have reflected inefficient or poor use of resources (e.g., “a bear after hibernation,” “a soldier in a burning tank”).

An example of using metaphors to monitor feeling states of a Finnish Olympic-level track and field male athlete in a series of international competitions during the season illustrates a practical utility of the method. A chain of metaphor images generated by this athlete for various contests included “a colt on a spring pasture” (very strong but too excited to control his own performance), “a tractor” (started moving in the right direction), “a Volvo” (good routines, self-confident, and reliable performance), “a Mercedes” (ready and knew what to do, enjoying successful performance), and “a Ferrari” (feeling great, powerful, and in control). These metaphors helped to identify and anchor the athlete’s optimal level of confidence, the right focus, and self-control skills prior to and during competition.

Taken together, research findings indicate that idiosyncratic content and personally relevant meaning of metaphors are either self-empowering (usually in best competitions) or self-defeating (usually in worst competitions) images. Furthermore, the quality of metaphors is culturally coded and determined by the specific contexts in which athletes perceive and experience performance-related episodes. Context-induced beliefs about potential effects of pleasant and unpleasant emotions can have a strong impact on perception of consequences of emotional experiences for athletic performance. Thus,

athletes can perceive competitive stress either as an undesirable factor to be avoided or as a part of their job with which they must cope. Consequently, if athletes believe that high precompetition anxiety is detrimental to their performance, the quality of such anxiety will be different from that of anxiety perceived as an indicator of high readiness for the competition. Therefore, before attempting any intervention program, sport psychologists must identify these context-determined beliefs based on past idiosyncratic experiences.

Research findings also indicate that metaphors differentiate various contexts (e.g., best ever and worst ever competitions) and capture the dynamics of personal meaning across pre-, mid-, and postcompetition situations. For instance, in best ever competitions, metaphors symbolizing strength, power, speed, and skillfulness were generated 5 to 10 times more often than in worst ever competitions. In contrast, in worst ever competitions, metaphors symbolizing weakness, slowness, and powerlessness were generated 5 times more often than in best ever competitions. Similar and even stronger relationships were observed regarding the efficient recruitment and use of available resources.

Idiosyncratic metaphors symbolically representing the content of feeling states experienced throughout competitions were different (low content overlap) across pre-, mid-, and postcompetition situations. These data provide support for the notion that a performance task usually involves three interrelated, but functionally and qualitatively different, stages: preparation for, execution of, and evaluation of performance. The findings also suggest that the functional and personal meaning of these three situations, as represented symbolically by idiosyncratic metaphors, is different for each athlete. A change in meaning triggers a change in emotional states. In other words, emotion dynamics is observed not only in the intensity of emotions but also in the content (quality) of emotions. Therefore, in research and applications, it is important to identify a specific constellation (a set or cluster) of emotion content that is optimal or dysfunctional for an athlete’s performance. Moreover, metaphors reflecting even slight changes in personal meaning of each performance situation could be useful markers for applied sport psychologists in monitoring the dynamics of performance states and in evaluating the effectiveness of individualized interventions.

6.4. Narratives

A narrative is an account of several interconnected occurrences. It is a scheme by means of which people

give meaning to their experiences. It also provides a framework for understanding the past events of one's life and for planning future actions. It is the primary scheme by means of which human existence is rendered meaningful. As Bruner argued in 1991, narratives are self-stories conveying intention and feeling related to a sequence of events; therefore, they provide a holistic picture of unfolding processes. Narratives (as self-stories told by athletes and coaches) can describe concrete performance situations and can identify automatic thoughts and emotional responses. Thus, they help to recreate a high-level performer's experiences, meta-experiences, and available (or unavailable) coping strategies.

The following transcript illustrates how a 16-year-old ice hockey goaltender perceives and describes his problem during important games:

This is perhaps a silly question, but can someone help me? I am very good technically and physically with the qualities needed for a goaltender. I always train much and well. For instance, I trained on the average 12 times per week during the summer season. However, I have one very big problem. In the game, I start feeling very nervous and fear that I will play badly. Then usually easy things become very difficult. . . . This is especially often in the games where it is necessary to win. Sometimes the tension goes away if the play starts well. I know that I am really good. My coach thinks that my flexibility and other qualities are top level in Finland. . . . In training, I can tend off really well, but in really tough situations, I cannot stand it. . . . Now it is again the time when I have to succeed, especially in training games. Based on these results, they will select a future national junior team.

This narrative describes briefly the goaltender's feelings and performance in practices and tough games, accompanied by his general self-ratings and expectations. However, the main advantage of narratives is that they provide a means for holistic and dynamic reconstruction of the unfolding process of athletic performance in a real-life setting. Narratives focus on the functions of emotion feelings and displays in the episodes of everyday life (or a specific activity). Thus, of special value is the fact that storytelling includes not only emotion words as descriptors of real idiosyncratic experiences but also an athlete's interpretations of these experiences and culturally determined beliefs within a specific context (i.e., meta-experiences). Although the main emphasis so far was on emotion experiences, it is important to realize that emotion displays (i.e., expression and suppression of feelings)

also have specific features and stereotyped views in the context of competitive and high-achievement sport. In this setting, athletes also learn to read the body signals of their opponents to identify the opponents' feeling states and action readiness.

7. PRACTICAL IMPLICATIONS

Applied sport psychologists assisting athletes in assessments and self-regulation of emotions usually face three issues: (a) identification of emotional states related to individually successful and poor performances, (b) prediction of emotion–performance relationships, and (c) selection of person- and task-relevant techniques of self-regulation. Compelling empirical evidence in support of the IZOF model provides several tentative guidelines on how to deal with these three issues.

First, to identify individually optimal and dysfunctional emotional experiences, establishing an individually relevant cluster (constellation) of emotions and their intensities prior to, during, and after successful and less than successful (poor, average, or customary) performances is recommended. These qualitatively and quantitatively extreme situational experiences serve as individualized criteria in the evaluation of current and anticipated emotional states. In addition, it is important to identify athletes' specific beliefs and attitudes about their emotion impact on performance. Are they aware of such effects? How do they usually cope with stress- and complacency-producing situations? Are these situational emotional experiences random or relatively stable patterns that athletes try to reproduce in important competitions? The main purpose of such individualized assessments is to enhance athletes' awareness and acceptance of these experiences.

Second, prediction of emotion–performance relationships is based on the in–out of the zone notion using categorical or continuous approaches. A categorical approach predicts performance based on the comparison between previously established individual zones and actual scores of intensity. A continuous approach is based on perceived “intensity impact” contingencies along the entire working intensity range of each emotion. Here, the emphasis is on an estimation of partial and total effects rather than on only a selected optimal range of each emotion. In both cases, a decision about emotion regulation (increase or decrease) is based on the magnitude of deviations either from optimal and dysfunctional zones or from a total effect in the selected modality. Furthermore, the intervention should aim not

TABLE II
Conventional and IZOF-Based Features of Emotion Assessment and Self-Regulation

<i>Basic principle</i>	<i>Conventional feature</i>	<i>IZOF-based feature</i>
Multimodality	One to three components	Seven basic forms
Multirange/-content	Fixed/Same for all	Idiosyncratic
Multizone/-intensity	Moderate or nonspecified	IZOF/Idiosyncratic intensity
Multistage	Mainly precompetition	Pre-, mid-, or postcompetition
Multidirection	Decreases or nonspecified	Individualized up/down
Multitask	Nonspecified	Specified and identified
Multifunction	Nonspecified	Effort or skill focused
Multimethod	One or two researcher generated	"Own," tailored or combined

only at helping athletes to enter or reenter their optimal zones but also at staying away from the dysfunctional zones. Finally, predictions should also consider the total functional impact of emotion on performance that is usually manifested in an increase or a decrease in effort (energy) and in efficiency or inefficiency in the use of available resources.

Third, there are numerous techniques of emotion self-regulation in the practice of applied sport psychology. Effective emotion self-regulation should be based on already described individualized assessments and predictions of emotion–performance relationships. Moreover, a selected method or intervention strategy (technique) should be optimal for both the athlete and the situation. In other words, the method should match previously established individual patterns of coping with emotion-triggering situations. In addition, the effective intervention program usually includes several appropriate methods of self-regulation.

Finally, there are several directions for effective emotion regulation. Most of them focus directly on emotional response by using various mental skills. However, there are other options that include a change of the current situation or its perception (personal meaning) by an athlete or a special organization of athletic activity for an athlete or a team (role expectations and game tactics). Table II shows IZOF-based and conventional (group-oriented) features reflecting several practical guidelines that are important to consider in assessments and regulation of emotional states.

8. CONCLUSION

The main purpose of this article was to provide an overview of the IZOF model as an alternative

individual-oriented idiographic approach to studying performance-related emotions. The IZOF model suggests some tentative answers to the questions asked at the beginning of the article.

First, unpleasant emotions as strong situational experiences are not always detrimental to athletic performance. Thus, anxiety, anger, and/or tension could be helpful in generating more energy and effort, and sometimes they could even compensate for a situational lack of needed resources. These emotions, if well channeled on task process, can postpone fatigue, sustain alertness, and keep the right focus. Coaches and athletes, as well as sport psychologists, begin to realize that coping with stress and using stress to enhance performance are possible.

Second, pleasant emotions are not always beneficial for performance, especially in sports requiring sustained focus, effort, and persistency for a relatively long time. A special problem in a high-achievement setting often presents a demotivational impact of excessive complacency following repeated success. Moreover, high self-confidence can sometimes lead to complacency or the underestimation of a "weak" opponent, resulting in insufficient alertness, lack of focus, and/or carelessness. These, in turn, can have a debilitating effect on performance, often leading to unexpected and season-ending injuries. In such cases, idiosyncratic experience is the best indicator of how athletes can perform up to their potential, either stress free or using competitive stress to their advantage.

The IZOF model provides a conceptual framework and methodological tools to describe, predict, assess, and explain situational emotional experiences related to performance, relatively stable patterns of these experiences, and meta-experiences. It is a clearly idiographic and person-oriented approach, with the main focus on

TABLE III
Comparison of Group-Oriented and IZOF-Based Models

Feature	Group oriented	IZOF based
Analysis level	Global/Contextual	Situational
Target	Groups, samples	Individual athletes
Emphasis	Between-individuals	Within-individual
Content	Global/Narrow	Task and person relevant
Performance	Unrelated	Related to, induced by
Setting	Nonspecific	Sport specific
Time	Static, stable	Dynamic, changeable
Assessment	Group referenced	Self-referenced
Scales	Standardized	Individualized

within-individual comparisons that provide the basis for athlete-tailored and interindividual generalizations. Although the IZOF model is consistent with several existing orientations in psychology, it differs mainly in its emphasis on intraindividual dynamics in emotion–performance relationships (Table III). From the applied perspective, the major advantage of the individualized approach to studying emotion–performance relationships is its ability to capture and explain the unique findings that are often missed or ignored in group-oriented models. However, both individualized and group-oriented perspectives can be useful in applied sport psychology.

GLOSSARY

actuarial prediction Predicting future behavior only on the basis on actual data; very much like predictions made in the insurance industry.

Age Discrimination in Employment Act of 1967 (ADEA) A U.S. federal law that prohibits discrimination against persons over 40 years of age.

Americans with Disabilities Act of 1990 (ADA) A broad federal law that prohibits discrimination against persons with disabilities in many areas, including employment.

bias A systematic effect; that is, the same degree of bias occurs for every member of the group of interest.

Civil Rights Act of 1964 A comprehensive equal opportunity federal law that includes prohibition of employment discrimination on the basis of race, color, religion, or national origin.

concurrent study A criterion-related study of employment methods that involves obtaining predictor and criterion data at approximately the same time.

criterion-related validity The relationship between test results and a criterion that is a measure of an outcome of legitimate interest to an employer.

differential item functioning (DIF) The possibility that some items on an employment test function differently for distinct groups; it is difficult to conduct proper studies in this area, but it has become apparent that DIF is not found very often.

disparate impact theory The requirement that an employer justify the employment method, even if it seems neutral, if the employment method has a disparate impact on a legally defined group.

disparate treatment theory Intentional discrimination not necessarily involving tests or employment methods.

Equal Employment Opportunity Commission (EEOC) A U.S. enforcement agency created by the Civil Rights Act of 1964.

fairness A social term; there are various conceptions of what is fair given that what appears to be fair to one person might not be seen as fair by another person.

flagging the score A practice (considered controversial) of communicating to various members of management whether an employment test was administered under specially accommodating conditions.

holistic assessment Essentially a method for predicting future behavior on the basis of judgment given assorted data of several kinds; it is akin to clinical prediction by psychologists.

internal structure Any of the relationships among items or scales comprising a test; it can affect reliability or replicability of test results.

predictive bias An effect that occurs when a group of interest does significantly better or worse than would be predicted from scores for the whole group of applicants; the groups

of interest in this situation are differentiated on some characteristics not relevant to criterion performance.

predictive study A criterion-related study of employment methods that yields an indication of how accurately test results can predict criterion scores that are obtained at a later time.

race norming Selecting employees in terms of their standing in their own group and not on their standing in the whole job applicant population.

test Any procedure used in making employment decisions; this broad definition is frequently used in professional standards and guidelines, and it reflects the fact that employment discrimination is possible over a wide range of employment methods and not just paper-and-pencil testing.

validity The accuracy of inferences drawn from test results.

validity generalization The extent to which one can generalize from results of analyses and apply them in a particular employment context; with due care, a professional wishing to use tests can review the published validity generalization evidence and make an informed decision about what selection procedures to use in a given situation.

The selection of employees, whether in terms of hire, promotion, or other personnel actions, is a matter of concern relative to civil rights. Issues regarding the application of psychology in making selection decisions have become a major focus of legal activity. Employment discrimination on the basis of membership in some specific groups is prohibited by law. Legal challenges are frequently directed toward the methods used in employee selection. In particular, certain types of psychological tests and their use have come under close legal scrutiny. Concepts that have been associated with testing, such as validity and reliability, have been incorporated into various government guidelines and regulations that have, in turn, greatly influenced the development of laws relating to civil rights. Testing concepts and their application have been subject to considerable debate, research, and (in some cases) redefinition. Bias in selection is now better understood, and associated concepts have been evaluated thoroughly. It is clear that there are different psychological considerations associated with the selection and treatment of different groups. Despite advances in knowledge relative to employee selection, there are still research needs related to selection of some groups. Nevertheless, the large amount of psychological study that has been devoted to understanding employment

discrimination and its many aspects has added greatly to the database of psychological knowledge.

1. BASIC CONCEPTS IN EMPLOYMENT DISCRIMINATION

There are many situations in which there are fewer desirable rewards than there are seekers of those rewards. For example, except in unusual circumstances, there are fewer job openings than there are candidates for the jobs. Thus, there must be a means of selecting from among the job seekers. An analogy to a gatekeeping function may be drawn; in this case, the employment process serves as a gate, and the gatekeeping involves the application of psychology. In particular, the psychology of individual differences and its associated procedures have been widely applied in making employment decisions.

No two adult individuals are exactly alike, and each can be expected to behave in unique ways in many situations. Even identical twins, depending on the circumstances, can show noticeable differences in behavior. Within every definable group in society, there are individual differences, and often there is a wide distribution of these differences in, for example, scores on a test.

In addition, relative to some psychological processes and achievements, there are consistent differences among groups on average. Many of the gatekeeping functions in employment involve procedures that indicate average differences among groups. The term "average" is important because it represents a situation far less dramatic in terms of discrimination than many believe. For example, because of individual differences, there will generally be a number of different scores within each definable group. The distributions of scores for the separate groups will probably overlap. That is, given two groups, some members of the group that has lower scores on average will score higher than the group that has higher scores on average. Obviously, when there are average differences among groups on a test or another selection procedure, there is the potential for discrimination on the basis of group membership. Discrimination based on group has undoubtedly been a feature of every employing society in the world. So long as there are discernable group differences—and there always will be some differences with regard to some aspects of the employment process—there is the possibility of discrimination.

2. EARLY LAW RELATING TO EMPLOYMENT DISCRIMINATION

In many ways, the laws regarding employment discrimination started with a relatively narrow focus in the United States. However, during recent years, new legal developments have resulted in the scope of the issues being increased, and new aspects of psychology have come to the forefront. For example, new research has been done relative to the employment of the aging and of persons with disabilities, and the results of that research have been widely applied.

The abolishment of slavery by the 13th Amendment to the U.S. Constitution in 1865 and the Reconstruction Era after the Civil War brought forth the first legal approaches to employment discrimination. Thus, race was the focus of early laws in this area. Unfortunately, equal treatment of Black Americans in most aspects of life really did not receive much impetus until the 20th century. Significant early events of this era were President Franklin Roosevelt's 1941 order to end discrimination in the defense industry, President Harry Truman's 1948 order to desegregate the military services, and President Dwight Eisenhower's 1957 order to send troops to enforce desegregation of a high school in Arkansas. Thus, the stage was set for the emergence of the modern civil rights movement that involved a major march on the U.S. capital in 1963, numerous other marches and demonstrations, and a series of major urban confrontations.

These events greatly influenced congressional action on the Civil Rights Act of 1964, a comprehensive equal opportunity statute that included prohibition of employment discrimination on the basis of race, color, religion, or national origin. Many of the aspects of this broad law and subsequent amendments and court interpretations have influenced the employment practices of all major employers into the 21st century. The 1964 act had profound effects on the direction and focus of applied psychology in the workplace. This came about mainly due to an amendment prompted by a then recent situation in Illinois. A Black job applicant had filed a complaint with the state's fair employment commission because he was denied employment as a result of failing a cognitive ability test. A commissioner ordered the test replaced by a more culturally balanced one. This case received considerable national attention and was the impetus for considerable congressional debate, which ended in the eventual passage of an amendment that, on the surface, appeared to protect employers' use of ability tests in employment.

This amendment stated that it is not unlawful for an employer to give or act on the results of any professional developed ability test, provided that the test is not designed, intended, or used to discriminate. Mainly as a result of this amendment and other developments in the civil rights area, there was an extraordinary growth of interest in differences in group cognitive ability, especially in applied areas. Academic journals were flooded with research articles, and various theories and mathematical concepts of discrimination were debated. Furthermore, new studies related to group differences were extended beyond those relating to cognitive abilities. For example, as women moved into physically demanding jobs, studies of sex differences in various job-related physical aspects multiplied. Because the Civil Rights Act of 1964 specifically designated testing as a matter of concern, various agencies at both the federal and local levels began to promulgate guidelines on employee selection. All of these emphasized testing, and all other employee selection procedures, such as the interview, were defined as tests. The position taken by the U.S. Equal Employment Opportunity Commission (EEOC), an enforcement agency created by the 1964 act, was that a "professionally developed ability test" is one that is "professionally developed and used." This definition, which implied that validity (i.e., the accuracy of inferences drawn from test results) is the primary basis for professional use, appeared in the brief EEOC guidelines issued in 1964. In 1970, the agency issued detailed prescriptions for studying and evaluating validity. Furthermore, professional organizations began to issue their own guidelines on employee selection, and various professional standards on testing were modified.

3. ROLE OF VALIDITY

Validity, its definition, methods for conducting validation studies, and methods for assessing possible discrimination have become increasingly complex over the years. Testing standards have been revised not only to respond to technical advancements but also to address new issues associated with testing of groups that became the focus of civil rights acts passed after 1964. Nevertheless, validity remains a unifying theme in many of the laws involving possible discrimination in employment. Many local laws, which are even broader in group coverage than are federal laws, incorporate validity concepts.

The emphasis on validity in the 1970 EEOC guidelines was codified through the landmark 1971 U.S. Supreme Court decision in *Griggs v. Duke Power*

Company. In this case, the court ruled that if a test tends to exclude Blacks, the employer has the obligation to demonstrate that the test is manifestly related to the requirements of the job. Thus, business necessity could justify employment procedures. Also, the court addressed the question of relative qualifications and how high employment standards could be set. The novel feature of the *Griggs* decision was the introduction of disparate impact theory. Under this theory, if an employment method, although neutral of its face, has a disparate impact on a legally defined group, the employer must justify the employment method. Intention to discriminate is not a necessary element of a disparate impact case. Intentional discrimination is covered under a separate theory called disparate treatment theory. The emphasis on validity was continued in various government pronouncements at both federal and local levels. The most influential of these was the Uniform Guidelines on Employee Selection Procedures issued by several federal agencies in 1978.

The complicated further development of case law and legislation in the area of employment discrimination resulted in change to the conduct of a case brought under disparate impact theory. The Civil Rights Act of 1991 delineated three steps in a disparate impact case. First, the plaintiff must prove that the use of the selection procedure has a disparate impact on his or her legally defined group. The burden of proof then shifts to the defendant, who must prove that the procedure is job related (i.e., valid). The plaintiff then has the option of showing that a specific equally valid selection procedure not having the same degree of adverse impact could have been used. The 1991 act incorporated case law that eliminated an onerous provision of the 1970 EEOC guidelines requiring that an employer using a selection procedure that had a disparate impact must prove that there was no suitable alternative. In formal logic, this is known as “proving the negative”—which cannot be done.

4. DISCRIMINATION IN EDUCATION

Constitutional rights apply to both the education and employment venues. However, many of the laws relating to discrimination in the field of education are not the same as those governing employment. Nevertheless, many concepts developed in law relevant to education have been applied in employment contexts. For example, “diversity” as a suitable employment goal evolved

from a U.S. Supreme Court decision in 1978, when the issue was admission to medical school. In a subsequent major and narrowly tailored decision on university admissions in 2003, the court allowed race and other factors to be taken into account in university admissions. The reason why the court allowed for this action is to achieve student body diversity. This is to be done on a time-limited basis, and no fixed quotas may be set. In addition, weighting techniques, such as point systems that favor some groups over others, are prohibited. The court supported a holistic system involving a number of methods such as testing, essay writing, and interviewing. This action brings into focus the major psychological question of the validity of clinical prediction as opposed to actuarial prediction. The holistic assessment endorsed by the court is essentially a method for predicting future behavior on the basis of judgment given assorted data of several kinds and is akin to clinical prediction. Actuarial prediction, very much like predictions made in the insurance industry, involves predicting future behavior only on the basis on actual data. For example, the quality of work that would be done by a job applicant, if hired, is predicted from actual test scores.

5. VALIDATION

In an employment situation, the inferences made through the application of employee selection procedures are predictive in nature regardless of the nature and format of the methods used in making the personnel decisions. Throughout this discussion, the term “test” is used to cover any procedure used in making employment decisions. This broad definition of test is frequently used in professional standards and guidelines and reflects the fact that employment discrimination is possible over a wide range of employment methods and not just paper-and-pencil testing.

The term “validity” has had a number of definitions over the years. Today, validity is not seen as a property of the test. Instead, it refers to the accuracy of inferences made on the basis of test scores. For example, if it is inferred that persons with low test scores will not do the job as well as will persons with higher test scores, and this inference is confirmed as a result of proper study, one may say that the inference is accurate and, hence, valid.

Validity is not an all-or-none concept; there are varying degrees of validity. Validation is the process of conducting a study to assess the degree of validity. In this case, the term “validation” is not used in its other sense as an approval process.

The legal use of the term “job related,” as opposed to “valid,” clearly and appropriately narrows the scope of any validation evidence to that related to the workplace activities of the concerned persons. It should be noted that activities other than actual job performance can be the focus of the test. For example, tenure, training grades, accidents, and absences may be legitimate concerns of the employer, who may use tests designed to predict them.

Furthermore, it is important to recognize that validity in psychology, as in many fields, is never perfect. There are always errors in prediction. However, the lack of perfect prediction need not necessarily deter an employer from using a test. How useful a test will be depends very much on the particular situation. Under some conditions, a test with relatively low validity can be quite useful to the employer. Certain factors, such as labor market conditions and job difficulty, must be taken into account. Professional judgment, as well as available data, should inform decisions on test use.

6. EVIDENCE OF VALIDITY

There are five generally recognized sources of evidence. Sources for evidence of validity are based on (a) content, (b) response processes, (c) internal structure of the test, (d) relationships of test scores with other variables, and (e) consequences of test use.

6.1. Evidence Based on Content

Content validation involves an initial thorough analysis of the work in terms of work behaviors and activities and/or knowledge, skills, abilities, or other personal characteristics related to job demands. The work analysis may be as detailed as need be, depending on the situation. Again, professional judgment is required. A work analysis for a parachute packer job should be rigorously detailed. For other jobs that are less rigid in terms of critical requirements, a broader analysis might be appropriate.

A selection procedure developed on the basis of content need not necessarily cover the whole job. If it is critical that every task involved in a job be done precisely, every task should be covered in minute detail. However, for many jobs, only some of the job duties are of critical interest, and only these parts may be covered by the test. For example, a person doing word processing may also answer the telephone on occasion. The employer may test on word processing

skills and not test on telephone answering skills. Measuring abilities of various sorts presents particular problems. In general, content validation is appropriate only for relatively narrow abilities. If one wants to measure broad abilities such as leadership, content should not be the primary source of evidence.

Developing a test on the basis of content is essentially a sampling process in which a sample of the work or the worker characteristics of interest is taken. Evaluation of the adequacy of the sampling is difficult. Validity is established mainly on scrutiny of the processes used in sampling from the content area of interest and the procedures used in developing the test. Professional judgment is usually the only feasible way in which to assess the adequacy of the evidence. However, some psychologists contend that evidence can be gathered through judgments regarding job tasks or the skills, knowledge, abilities, and other characteristics required for the job and their linkage to the content of the test.

Many of the disputes involving employment discrimination have arisen in situations involving validity evidence based on content. Because of the large judgmental component involved, there is opportunity for both employment discrimination and disputes about the adequacy of the sampling process used and the product developed. Also, many of the tests used in the public sector are based on content, and much of the case law regarding employment discrimination has been generated in the public sector. In particular, selection for public safety jobs that are sought by thousands of applicants, such as police work and fire-fighting, is a source of contention. Most public sector merit systems have legal rules and rigid requirements for employee selection. For example, job applicants are put in rank order in terms of standing on tests, and the final selection must be from among the top three candidates. Furthermore, lists of candidates may be used to fill openings for months or even years, and applicants might have a long wait before a new test is developed and they have the opportunity to be tested again. Private employers generally have more options in the use of selection procedures and, consequently, can make adjustments to the selection process when there are questions about employment discrimination.

There are other issues related to applied psychology in the use of content-based evidence. One of these is whether it is appropriate to rank order candidates on the basis of scores on a content-based test. It appears that most industrial psychologists believe that such ranking is permissible. Another related issue is how to set “cut” (i.e., passing) scores on such tests. There

are still disagreements about how high passing scores should be set. The main issue is whether they should be consistent with the average proficiency of the workforce or whether an employer trying to improve the company's workforce may set higher standards. Another is whether changing test formats, such as moving from a paper-and-pencil test to a more complicated and costly procedure involving pictures or exercises that simulate job duties, will reduce disparate impact on various groups. The Civil Rights Act of 1991 allows cost to be a consideration in determining whether specific alternative selection procedures should be adopted.

A specific source of contention is the application of content-based physical ability tests to both genders. The differences in performance between the genders on many physical ability tests is marked on average, and issues related to ranking, passing scores, and the possibility of alternative selection procedures becomes magnified. For example, a content-based test for firefighters might involve activities such as dragging a firehose up a flight of stairs. There have been questions about whether simpler physical tests, including those involving activities such as push-ups, can be justified on the basis of content. Persons with certain types of physical disabilities have raised similar questions about such tests.

Some employers have representatives of various groups that are likely to be subject to discrimination review the test content to detect possible discriminatory items or those that might be offensive to particular groups. There are questions about the effectiveness of this procedure, and more research concerning the value of this method in preventing discrimination is needed.

6.2. Evidence Based on Response Processes

Where employment is concerned, evidence based on response processes (e.g., how long an examinee requires to respond to a particular type of item), is not so relevant as most of the other types of evidence of validity. Response processes do have some value in determining how a test is functioning and what abilities the applicant is using in taking some types of tests.

These processes have been assessed by various methods such as having an examinee talk about what mental techniques he or she is using while trying to solve an arithmetic problem. Physical measurements based on recording eye movement are often used, as are observations by judges. It has been suggested that

such monitoring of response production may eventually be able to discern differences in the ways in which different groups respond to the same test material. However, relevant literature on research in employment settings is lacking.

6.3. Evidence Based on Internal Structure

The third type of evidence is based on the internal structure of the test. An example of internal structure would be the extent to which test items are in the same format such as solving analogies problems. Internal structure can affect reliability or replicability of test results. Such reliability is important in supporting validity. In general, validity is limited by lack of reliability of test results. Reliability may be estimated by various methods. The choice of exact estimation procedure depends on a number of factors. In some respects, a finding of validity is, to some extent, evidence of reliability.

Relative to discrimination, the possibility that some items function differently for distinct groups is often studied. This effect is called differential item functioning (DIF). It is difficult to conduct proper studies in this area, but it has become apparent that DIF is not found very often. When found, reasons for such differential functioning are not usually easily identified.

6.4. Evidence Based on Relationships with Other Variables

The fourth type of evidence, relationships of test scores with other variables, has been the major source of statistically based definitions of discrimination and of much confirmable information in psychology about group differences. This type of evidence will undoubtedly be a mainstay in studying employment discrimination and related topics for some time to come.

In an employment situation, the relationship of most interest is the relationship between test results and a criterion that is a measure of an outcome of legitimate interest to the employer. This relationship is called criterion-related validity, and the generic predictive model of validity is merely a generalization of the criterion-related model. Despite the fact that criteria can take many forms, supervisors' ratings appear to be the most commonly used criteria. The design of a criterion-related study can involve a number of specific procedures, but these can be subsumed under the general headings of "predictive" and "concurrent" studies.

A predictive study yields an indication of how accurately test results can predict criterion scores that are obtained at a later time. For example, job applicants may be tested and the results might not be used in hiring. Then, at a later date, job performance or other job outcome data that form the criterion may be collected. A concurrent study involves obtaining predictor and criterion data at approximately the same time. Typically, present employees are used in these studies. In the area of employment, it is very difficult to conduct predictive studies and complete them in a reasonable period of time. Consequently, much of the validation relevant to employee selection is based on concurrent designs. For cognitive ability, it appears that validation results from predictive and concurrent studies do not vary much from each other. More studies need to be done relative to other types of tests.

Relative to discrimination, one of the major findings resulting from the application of the criterion-related model is that validities in the cognitive ability area do not differ greatly between Caucasians and African Americans. As the United States becomes more multicultural, there is a need for research with newly emergent racial and cultural groups. Also, it is necessary to determine the extent of group differences relative to tests that reflect characteristics other than cognitive ability.

Differences between gender groups are a matter of concern. However, they are difficult to study because during test development, particularly of the most widely published cognitive ability tests, efforts have been made to reduce some gender differences. Still, there are some well-documented findings relative to possible discrimination. Women are at a disadvantage when selection procedures involve some spatial and mechanical abilities. Also with respect to cognitive ability tests, women generally have a narrower range of scores than do men. Some of the practical effects of this phenomenon are that there are more males than females classified as mentally retarded, and there are more males than females who qualify for prestigious scholarships and other honors that are awarded on the basis of high-level cognitive ability.

6.5. Evidence Based on Consequences

Within a broad social context, concern about the consequences of testing, particularly that some types of testing can result in unequal distribution of rewards to various groups, has led some major researchers to

define validity partially in terms of consequences of test use. In an employment context, consequences may influence decisions regarding the use of particular selection practices. However, when validity is defined as it has been historically, consequences alone do not form acceptable evidence of validity. Socially undesirable consequences in employment should prompt a thorough investigation of possible sources of problems and corrective actions available.

6.6. Other Evidence-Related Issues

With the possibility of pressure to substitute clinical prediction for actuarial prediction in employment operations, there is a real need to conduct further studies on the decision processes involved in clinical judgments as they relate to employment. Questions about validity and effects on groups are a matter of concern. Past findings clearly demonstrate that the actuarial prediction process produces valid results to the same extent as does clinical prediction. In many cases, actuarial prediction is associated with greater validity. Among the major problems that have plagued clinical prediction in the past is the basing of judgments on methods that have not been shown to produce valid results. Despite the fact that use of multiple methods forms the basis for clinical prediction, the possibility that some of these methods do not add to the accuracy of such prediction should be considered. This is particularly important when tests that are not designed for use in employment inform the clinical judgment process used in selecting new hires from among job candidates. Another problem is that judges might not weigh the available information optimally. Too much weight can be attached to the results of methods that yield marginal validity.

An extraordinary amount of evidence has been accumulated regarding the validity that can be expected from the application of various employee selection methods. A mathematical technique known as meta-analysis has afforded the opportunity to analyze the results of accumulated research so that general conclusions relative to various research findings can be drawn. In employment psychology, meta-analysis has been applied to the accumulated validity studies done over a period of many decades. The extent to which one can generalize from results of these analyses and apply them in a particular employment context is known as "validity generalization." With due care, a professional wishing to use tests can review the published validity generalization evidence and make an

informed decision about what selection procedures to use in a given situation. The published validity generalization research results have been based on a substantial amount of data in some areas, including those involved with cognitive ability; however, in some other areas, the evidence is still accumulating. Nevertheless, it is clear that most professionals consider the validity generalization data first before they make decisions about the use of selection procedures.

7. FAIRNESS AND BIAS

Although the term “fairness” was used in early federal and local guidelines on testing, it has become customary in applied psychology to distinguish between “fairness” and “bias.” The former is a social term; what appears to be fair to one person might not be seen as fair by another person. Thus, there are various conceptions of what is fair. Conversely, latter term has a specific meaning in employment psychology. This definition is based on results of research with the criterion-related model and is generally accepted in applied psychology.

First, fairness may be viewed as equitable treatment in the employment process. For example, all applicants should have the same selection procedures applied to them under the same conditions. Second, fairness may be conceptualized as all applicants having the same opportunity to learn material covered by employment tests. With a few exceptions, this notion, conceived in the context of educational achievement testing, does not apply to employee selection. Third, fairness may be viewed in terms of whether the employment process provides equal outcomes for different groups. In other words, the same proportion of each group involved in the process should be selected. In the interest of affirmative action, various techniques have been applied in attempts to achieve equal outcomes. One method is to add points to the scores of members of selected groups. Another method is race norming, that is, selecting employees in terms of their standing in their own group and not on their standing in the whole job applicant population. In this case, a person from a group that has low average scores would be more likely to be selected than would a person with the same test score if the latter person belongs to a group with higher average scores. Other mathematically complicated methods have been used with the objective of reducing group differences in selection. For example, a method known as the sliding band, which seeks to lessen the disparate impact associated with ranking systems in the public

sector, has been developed. Considerable controversy has arisen regarding the application of these and other methods developed in the context of affirmative action. Fourth, fairness may be seen as a lack of “predictive bias,” which is defined technically as occurring when a group of interest does significantly better or worse than would be predicted from scores for the whole group of applicants. The groups of interest in this situation are differentiated on some characteristics not relevant to criterion performance. Examples of such characteristics might be race and gender. Bias is a systematic effect; that is, the same degree of bias occurs for every member of the group of interest. So far as African Americans and Caucasians are concerned, when cognitive ability tests are used in employment, bias is seldom found. This situation might not be seen when other groups are compared. The rapidly changing composition of the labor force, coupled with the need for large samples of research participants, renders the proper conduct of studies of possible bias very difficult except in military organizations and other large employers.

A number of other issues are related to more general questions of fairness and bias. It is well known that many groups are judged in terms of stereotypes. Gender, ethnic, racial, and other stereotypes can affect employment decisions. Considerable research in the area of social psychology has been devoted to stereotypical thinking as it applies to employment. Some controversy still prevails regarding the application of this research.

As a result of women being paid less than men, there are both federal and (some) local laws requiring equal pay for equal work that involves the same duties. To determine whether the work done is indeed equal requires the work analysis methods developed by applied psychologists. Legal issues concerning pay equity for the genders continue. There have been major efforts to extend the laws to require equal pay for jobs of comparable worth. The determination of comparable worth for jobs with different job duties is extremely challenging for industrial psychologists.

8. SPECIAL SELECTION SITUATIONS

8.1. Aging

Employment issues involving possible age discrimination are covered by special laws and regulations both at the federal level and in many local jurisdictions. The Age Discrimination in Employment Act of 1967 (ADEA) prohibits discrimination against persons over

40 years of age. As the population ages and people extend their working lives past what was once considered normal retirement age, issues relevant to employment discrimination against the aging have increased both in scope and in intensity. The use of measures of cognitive ability is a particularly sensitive issue. It is now known that many of the major abilities decline with age more slowly than had once been believed. However, the possible onset of debilitating diseases, such as Alzheimer's disease, must be considered in some cases. Also, there may be interactions among mental functioning, physical condition, and other variables (e.g., gender).

Test results might not have the same meaning for the aging as they do for other groups protected by law. At the ages when individuals over 40 years old are likely to seek employment, major age-related deficits in mental functioning are relatively unlikely. When there are deficits, the more likely case is that the individuals involved have had long histories of obtaining low scores on measures relating to cognitive functioning. Another possibility to be considered is that discrimination against older persons may be associated with other characteristics such as gender and ethnic origins.

It appears that it would be unrealistic to strictly apply all of the law that has been developed under the Civil Rights Act of 1964 and its progeny to the aging population. The application of disparate impact theory is particularly controversial. The issues relative to mental functioning of older persons are more complicated than most of those involving younger people.

Considerable legal attention has been directed toward the various processes involved in terminating the employment of older persons. Any techniques used in making termination decisions, such as performance appraisals, should be treated as tests and subjected to the same professional scrutiny. The economic issues involved in retirement and other forms of termination have been the focus of considerable legal attention. Among the major situations that involve the potential for age discrimination is the provision of health care benefits to retirees. An understanding of the needs for mental health care for the elderly can inform employer decisions regarding health care benefits for both retirees and older persons still employed. Psychologists can provide useful input in this area.

8.2. Individuals with Disabilities

The Americans with Disabilities Act of 1990 (ADA) has received considerable attention by applied

psychologists because the statute applies to both mental and physical disabilities. This broad law prohibits discrimination against persons with disabilities in many areas, including employment. This law involves a number of ambiguities and, thus, is subject to continuing legal interpretations. Some of the requirements of the law remain to be clarified. It appears that the courts are progressively limiting the scope of ADA. Furthermore, solid research bases to support actions under this statute are unavailable. To conduct proper research in this area, one needs a substantial number of research participants with the same disability and the same level of symptoms. Such large groups of people are generally unavailable. Basically, ADA recognizes the individual nature of disabilities and the need to treat each person with a disability in a different way. ADA is basically an extension of earlier acts dealing with rehabilitation and employment of veterans.

Under ADA, disability is defined as a physical or mental impairment that substantially limits at least one major life activity. According to EEOC guidance, among the activities covered are learning, working, thinking, concentrating, and interacting with others. Specifically excluded are certain conditions such as current illegal drug use, a number of conditions dealing with sexual behavior and gender identification, certain compulsive disorders such as kleptomania, and impairments that are expected to be temporary. In addition, employers are not expected to hire individuals who may be a danger to themselves or others. Questions about diagnoses clearly involve the application of psychological knowledge about mental impairments. In addition, making predictions about future behavior is necessary.

The Americans with Disabilities Act of 1990 applies only to qualified persons with disabilities. These individuals must be able, with or without reasonable accommodations, to perform the essential functions of the job. Determining the essential functions of the job may involve an adaptation of the work analysis methods used in conventional employee selection situations. Such analysis is not legally required, but many employers conduct it. During prehire questioning, such as might be done on an application blank or during an interview, the employer cannot ask questions that would require the applicant to indicate the existence of a disability. However, the employer can give a psychological examination unless the test is used for medical reasons, in other words, to determine whether the individual is mentally impaired or otherwise mentally disabled. Diagnostic psychological tests and related procedures may be used in a medical

examination, which can be given only after a job offer has been made, with the same questions being asked of all applicants for the same job category.

In testing situations before a job offer is made, the job candidate may ask for an accommodation relative to the medium of testing, test format, testing conditions, or testing time. For example, a person with impaired vision may ask for a test booklet with enlarged print. The most commonly requested accommodation is extra time to take the test. Accommodations are to be done on an individual basis. Nevertheless, psychologists try to be reasonably consistent in devising accommodations for similar types of impairments. In many cases, psychologists collaborate with physicians and other professionals in developing accommodations in testing and other aspects of the employment process.

Most employers ask job candidates for documentation regarding disabilities that are not obvious when either tests or job accommodations are requested. Documentation regarding mental disabilities is usually carefully scrutinized. Many employers have internal requirements for documentation. For example, a family practice physician's diagnosis of a learning disability might not be accepted. Accommodations in working conditions on the job are often developed with input from several types of specialists. Some employers have standing committees to make decisions about job accommodations. Most job accommodations are not particularly expensive. In any case, the employers are not expected to undergo undue hardship. In general, legal interpretations of what constitutes hardship have been quite narrow.

The issue of indicating whether a test was administered under accommodating conditions should be recorded, and whether this information should be communicated to various members of management is quite controversial. This is called "flagging the score." At a minimum, a psychologist usually makes some record of the accommodation and maintains it in a filing system that is separate from other test score files. Various other legal and practical issues are related to the employment of persons with disabilities. In particular, violence in the workplace might be related to the failure of the employer to recognize that a person claiming a disability was a danger to himself or herself and others. Other aspects of workplace security, such as developing a crisis management plan in the event of disaster (natural or otherwise), may involve paying special attention to the needs of persons with disabilities. Of obvious importance are plans for the evacuation of such individuals. Psychologists can provide

input to a number of other aspects of such plans and can advise on training and practice needs.

The role of disabilities with respect to a number of other laws may require the attention of psychologists. Included among such laws are the federal Family and Medical Leave Act and the various workers' compensation and unemployment compensation laws, all of which may have some features that can lead to discrimination against persons with mental disabilities.

8.3. Linguistic Minorities

Discrimination on the basis of national origin may occur due to the language in which a test is written or administered. Linguistic considerations in employment are not straightforward. One of the first distinctions to be made is that between a language and a dialect. Some have contended that tests should reflect dialects shared by sizable groups of people. As the United States becomes more multicultural, attending to all of the various dialects, whether regional or group associated, would be an onerous task for even the largest employers. If job proficiency in the language of the workplace is required, employment processes usually use the language needed to communicate on the job. A distinction should be made between oral communication and written communication. For example, a given individual's lifestyle may involve proficiency in writing but not in speaking. This could occur in cases where English was the language of the schools attended, but some other language was spoken in the home. Others may speak in a mixture of two languages, and others with backgrounds in two languages may have difficulty in using both. Any translations of tests should be done by persons qualified not only in the languages but also in psychometrics. There are a number of procedures necessary to ensure that the original test and the translated version yield equivalent results.

9. SEXUAL HARASSMENT

A major issue in the area of employment discrimination is sexual harassment. This subject has been a major source of litigation since the early 1970s. Sexual harassment can be physical, verbal, or visual. It is not always directed toward women, but in any event it is always unwelcome. Legally, the conduct should be, at a minimum, pervasive or severe enough to create a hostile or abusive work environment and be

such that a reasonable person would find it to be offensive. In legal terms, sexual harassment unreasonably interferes with work performance, is physically threatening or humiliating, and involves more than isolated utterances. Voluntariness is not a defense against a sexual harassment charge; a person might submit to sexual advances due to fear of an unfavorable tangible job action such as termination.

The U.S. Supreme Court defined two types of sexual harassment. The first of these is “quid pro quo,” where sexual involvement is explicitly or implicitly made a condition of employment or where submission or rejection of harassing conduct is used as a basis for employment decisions about the employee. The second type of harassment is “hostile work environment,” where the conduct has the purpose or effect of interfering with the employee’s work performance.

More recently, the courts have formulated standards for assessing employer liability in sexual harassment cases. A tangible employee action constitutes a significant change in employee status, such as hiring, firing, failing to promote, or reassigning with significantly different responsibilities, or a decision causing a significant change in benefits. If the alleged harasser is a supervisor and there is a tangible employee action, the case is considered quid pro quo and the employer is potentially vicariously liable. If there is no such action but the harassment is severe or pervasive, the employer may present an affirmative defense by showing that reasonable care was exercised to prevent sexually harassing behavior and to ensure that such behavior was corrected promptly and that the employee failed to take advantage of preventive or corrective opportunities or to otherwise avoid harm. There are variations of these rules for alleged harassment by coworkers or outsiders such as vendors associated with the employer.

Many employers have established firm policies to prevent and correct such harassment. At a minimum, these policies involve accessible and effective complaint processes, training for all employees, and detailed investigative procedures. The sensitivities involved in carrying out these policies and the possibility of sensational disclosures require the application of psychological knowledge. During the mid-1990s, Congress extended the so-called federal rape shield law to civil proceedings. Thus, a woman’s current and past sexual behavior is admissible in court only if the defendant can show that its evidentiary value outweighs any prejudicial effect on the plaintiff. Thus, sexual harassment cases, which are civil cases, may

involve all of the applications of psychology now applied in rape cases. As would be expected, there are a number of legal gray areas in sexual harassment cases. Perhaps this is one of the reasons why the courts and legislatures have been reluctant to extend current laws beyond relationships between persons of the opposite sex. Even disgusting and gross behavior, as has occurred in same-sex horseplay at work, has not been considered legally as sexual harassment. Civil rights laws are not being considered to be general civility codes.

10. CONCLUSION

Although there are other pertinent connections between psychology and employment discrimination, it is clear that psychological knowledge and methods can have a major role in preventing and understanding such discrimination. In addition, knowledge in other psychological areas that are not generally considered to be applied can inform activities involved in possible employment discrimination. Applied psychology has become more highly developed in many respects due to the research and debates spurred by the civil rights movement and the emphasis on employment discrimination. The database of psychological knowledge has been greatly enhanced by these efforts in applied psychology.

GLOSSARY

critterion-related validity The correlation between a predictor (e.g., test, interview) and the criterion that it is designed to predict (e.g., job performance).

critical incidents Structured stories about good and poor job performance, including the situation in which the incident occurred, the behavior describing the performance, and the result of the incident.

incremental validity The validity of one predictor over and above that of another predictor.

interrater reliability An estimate of the reliability of a measure assessed by the correlation between ratings made by two raters independently.

meta-analysis A set of statistical techniques used to summarize research results across studies to draw generalizable conclusions.

past behavior interview question A question in which the interviewee is asked to describe his or her performance in a similar, but more specific, situation (e.g., "Describe a time when you had to give bad news to a client. What was the situation? What did you do? What was the result?").

situational interview question A question that poses a situation to the interviewee and asks how he or she would likely perform in that situation (e.g., "What would you do if . . .?").

This article is organized into two sections: overview and psychometric characteristics of the interview. The overview section provides a definition of interviews, a description of various levels of structure, and methods for enhancing the structure of the interview. It also provides examples of questions using the job of a civil aviation security inspector. The psychometric section describes research on reliability, validity, correlations with other constructs, subgroup differences, and incremental validity beyond general mental ability.

1. OVERVIEW

1.1. Definition

An interview involves interactions (face-to-face, telephone, or written) between an interviewer and an interviewee. An interview typically is initiated to achieve one or more objectives (e.g., obtaining data in response to a survey, disciplining employees, providing feedback as part of performance appraisal, career counseling, selecting employees from a pool of applicants) and occurs as part of a sequence of activities (e.g., reviewing resumes, interviewing a subset of candidates, and administering cognitive ability tests for the purpose of selecting applicants; reviewing training curricula and interviewing employees for the purpose of assessing training needs). The interview's objectives and the sequence of activities in which the interview takes place are known as the context of the interview. In this article, interviews are

described in the context of selection, that is, interviews used to select employees from a pool of applicants. In this setting, interviews typically focus on past, present, or future behavior, beliefs, opinions, attitudes, and/or convictions of applicants. Information about an individual's previous experience, education, and vocational aspirations reported during the interview, as well as behavior observed during the interview, is considered the content of the interview. Interviewers are required to interpret information and draw inferences about traits, attributes, attitudes, and skills that the applicants possess. These inferences often take the form of ratings on dimensions of personal attributes or rankings of applicants.

1.2. Levels of Structure

There are two broad types of employment interviews: structured and unstructured. Structured interviews have a fixed format or a fixed set of questions, and the questions are based on a job analysis. Conversely, unstructured interviews do not use a standard procedure for the administration of questions or scoring. In fact, questions may vary from applicant to applicant.

In 1992, Huffcutt reviewed the literature on interview structure and described four progressive levels of structure. Level 1 was the typical unstructured interview characterized by no constraints on the questions and a global evaluation of responses. Level 2 imposed limited constraints by specifying the topics to be covered by the questions and some degree of structure on response evaluation. Level 3 required the prespecification of questions, although applicants were not asked precisely the same questions because different interview forms were used or interviewers were allowed to choose among alternative questions and to probe responses to the specified questions. An example of this kind of interview is the behavioral patterned description interview as described by Janz in 1982. Responses were evaluated using some degree of structured response evaluation. Level 4 involved asking applicants precisely the same questions with no deviation or follow-up probes, and responses were scored according to benchmark answers. In 1980, an example was provided by Latham and colleagues, who discussed situational interviews.

Situational and past behavior are two primary types of structured interviews. Situational questions provide a situation to the interviewee and ask how he or she would likely perform in that situation (e.g., "What would you do if . . .?"). The situations resemble those in situational judgment tests (SJTs). Past behavior questions provide a broad situation for the interviewee.

The interviewee is asked to describe his or her performance in a similar, but more specific, situation (e.g., "Describe a time when you had to give bad news to a client. What was the situation? What did you do? What was the result?"). Both of these kinds of questions derive from critical incidents provided by subject matter experts (SMEs). Critical incidents are structured stories about good and poor job performance. The three-part structure of critical incidents involves having the SMEs respond to three questions: "What was the situation/task?," "What did you do?," and "What was the result?"

Interviews can be very appealing to organizations because questions can be created to tap cognitive and noncognitive skills as well as abilities. Interviews can focus on a range of applicant qualities such as communication skills, interpersonal skills, decision making, and substantive knowledge. Examples of situational and past behavior interviews are provided in [Tables I and II](#), respectively.

1.3. Methods for Enhancing the Structure of Interviews

In 1997, Campion and colleagues reviewed the use of structure in selection interviews and identified 15 components of structure that may enhance either the content of the interview or the evaluation process in the interview:

1. Base questions on a job analysis.
2. Ask the exact same questions of each candidate.
3. Limit prompting, follow-up questioning, and elaboration on questions.
4. Use better types of questions (e.g., situational, past behavior, background, job knowledge).
5. Use a longer interview or a larger number of questions.
6. Control ancillary information.
7. Do not allow questions from the candidate until after the interview.
8. Rate each answer or use multiple scales.
9. Use detailed anchored rating scales.
10. Take detailed notes.
11. Use multiple interviewers.
12. Use the same interviewer(s) across all candidates.
13. Do not discuss candidates or answers between interviews.
14. Provide extensive interviewing training.
15. Use statistical prediction rather than clinical prediction.

TABLE I
Situational Interview Example

Critical Incident

During an air carrier assessment, an inspector noticed that the screeners at checkpoints appeared to be unsure about the proper use of metal detector equipment and procedures for screening passengers. The inspector interviewed all of the screeners on-site and discovered that the screeners on duty at the metal detectors had not received required training. The inspector immediately informed all air carriers represented at the checkpoint and requested that carriers implement additional screening procedures. The screeners who had not been trained were removed immediately.

Situational Question

You are conducting an air carrier assessment and you notice that several of the screeners at the metal detectors appear to be unsure of how to operate the equipment. What would you do?

Response Anchors to Situational Question

<i>Highly ineffective</i>			<i>Average</i>			<i>Highly effective</i>					
<ul style="list-style-type: none"> • Have the inspector on the next shift train the screeners • Do nothing, assuming that the screeners will get better using the machinery with practice (e.g., learning by doing) 	<ul style="list-style-type: none"> • Tell another inspector about the problem • Watch for multiple instances in which screeners appear to be unsure of how to operate the equipment to make sure that you are correct in your assessment 	<ul style="list-style-type: none"> • Inform the air carriers being represented at the checkpoint • Have the untrained screeners removed and/or trained immediately 	1	2	3	4	5	6	7	8	9

These components of structure are based on research literature and continue to be replicated. The more of these components that are incorporated into the interview, the more structured the interview becomes.

2. PSYCHOMETRIC CHARACTERISTICS OF THE INTERVIEW

2.1. Reliability

An interview is reliable to the extent that it is free of measurement error. Typically, reliabilities of interviews are assessed by interrater reliability, that is, the correlation of the interview ratings made by two independent raters. There are at least two meta-analytic reviews that investigated the reliability of interviews. In 1995, Conway and colleagues found the average reliability of structured interviews to be .67. In 1994, McDaniel and colleagues found mean reliabilities of .84 for job-related structured interviews (across 167 coefficients) and .68 for job-related unstructured interviews (across 20 coefficients).

2.2. Validity

The validity of the interview is typically assessed by correlating an interview score with a measure of job performance. This is one application of criterion-related validity. McDaniel and colleagues broke down interviews by content and found that situational interviews were superior to job-related and psychological interviews with respect to job performance (criterion-related validity coefficients of .50, .39, and .29, respectively). Structured interviews, regardless of content, were more valid (.44) than unstructured interviews (.33) for predicting job performance criteria. Individual interviews (.43) were more valid than board interviews (.32).

In 1995, Pulakos and Schmitt found that experience-based interview questions yield higher validities (.32) than situational questions (-.02). This result was replicated by Huffcutt, Weekley, and colleagues in 2001. Their behavioral description interviews (BDI) (i.e., experience-based interviews) were a reasonably strong predictor of leadership performance in training for Canadian military officers, whereas their total situational interview (SI) scores were not ($r = .49$ vs $.22$ after correcting for range restriction). This result was replicated again by Huffcutt and colleagues using a

TABLE II
Past Behavior Interview Example

Critical Incident

A senior inspector wanted on-the-job training (OJT) for new inspectors in the office on the procedure used by the legal counsel to close a case or hold informal hearings. The senior inspector contacted the legal counsel's office and discussed the matter with several lawyers who handled security cases. The lawyers agreed to provide OJT for the new inspectors. Consequently, new inspectors now routinely attend informal conferences with legal counsel and receive firsthand instruction on how informal hearings are conducted and how to close a case.

Past Behavior Question

Tell me about a time when you needed to have people trained as soon as possible and you did not have the expertise to provide the training yourself. What did you do?

Response Anchors to Past Behavior Question

<i>Highly ineffective</i>			<i>Average</i>			<i>Highly effective</i>		
<ul style="list-style-type: none"> • Have new inspectors “learn it on their own” on the job • Perform work on own that could be delegated if inspectors were trained • Give more assignments to top performers rather than train new Inspectors 			<ul style="list-style-type: none"> • Read a book and learn the subject area yourself • Identify and suggest training needs for new inspectors in a variety of areas of expertise • Coach new inspectors as they learn new things 			<ul style="list-style-type: none"> • Identify individuals who are knowledgeable in the subject area and ask them to teach the new inspectors • Provide developmental opportunities to new inspectors who wish to learn a new function • Create opportunities for inspectors to try things they have not done before 		
1	2	3	4	5	6	7	8	9

sample of district managers. The BDI total scores correlated with the performance evaluation ($r = .31$), whereas the SI total scores did not ($r = .02$).

2.3. Correlations with Other Constructs

In 2001, Huffcutt, Conway, and colleagues developed a taxonomy of seven types of constructs likely to be measured by interviews. Analysis of 338 ratings from 47 actual interview studies indicated that basic personality and applied social skills were the most frequently rated constructs, followed by mental capability and job knowledge and skills. These authors also found that high- and low-structure interviews tend to focus on different constructs. Furthermore, they suggested that the reason why structured interviews tend to have higher validity is because they focus more on constructs that have stronger relationships with job performance. High-structure interviews focus more on applied mental skills, direct job knowledge, applied social skills (e.g., communication, interpersonal skills, leadership) and organizational fit, whereas low-structure interviews focus more on general mental ability, background credentials (e.g., education, training, experience), some aspects of

personality (e.g., agreeableness, emotional stability), and physical attributes. For Huffcutt and colleagues' analysis across all studies, the validity coefficients ranged from .24 to .58. As expected, the mean validities for constructs rated in more structured interviews were higher (.39) overall than the mean validities for constructs rated in less structured interviews (.24).

Two meta-analytic studies documenting the relationship between interview ratings and cognitive ability scores are described later.

2.4. Subgroup Differences

Most employment-related assessments show race differences in mean scores. On average, White job applicants obtain higher mean scores than Hispanic job applicants, who in turn have higher mean scores than Black job applicants. These mean score differences are typically large enough to sharply curtail the number of Blacks selected for employment. Mean race differences in employment interview scores are often smaller than other measures because the interview is often the final selection procedure used in a multiple-procedure process. For example, if a written job knowledge test is used, Blacks and Whites will likely show large mean

score differences. However, if only those who score high on the job knowledge test are interviewed, the Blacks and Whites who are interviewed will be more similar in job-related skills than will the pool of all applicants who took the job knowledge test. This effect, known as “range restriction,” will result in an interview showing small or no race differences. Pulakos and Schmitt found very small mean differences between subgroups on interview scores. However, they used job incumbents in both of their samples, suggesting that selection to enter the job may have absorbed most of the adverse impact. Pulakos and Schmitt generally concluded that interviews yielded fewer subgroup differences and widely recommended their use. However, in 2002, Roth and colleagues found that two forms of a behavioral interview were associated with standardized ethnic group differences of .36 and .56 when corrected for range restriction. These differences were three to five times as large as the previously estimated value of .10 obtained by Huffcutt and Roth in 1998. Roth and colleagues attributed these differences largely to the fact that applicants were previously screened on measures with high subgroup differences (e.g., cognitive ability), similar to the Pulakos and Schmitt study. They recommended that when examining the psychometric properties of a predictor, analyses should focus on the applicant level, especially applicants who have not been prescreened on another predictor.

2.5. Incremental Validity beyond General Mental Ability

In 2000, Cortina and colleagues found that interview scores contribute to the prediction of job performance over and above cognitive ability and conscientiousness to the extent that they are structured, with scores from highly structured interviews contributing substantially to prediction. Specifically, they found that the incremental validity for Level 1 (lowest level of structure) interview scores ranged from 0.9 to 2.2% of the variance in job performance. Level 2 (moderate level of structure) interview scores explained an additional 1.8 to 6.2% of the variance in job performance. Level 3–4 (highest level of structure) interview scores explained an additional 12.3 to 22.2% of the variance in job performance over and above cognitive ability and conscientiousness. Pulakos and Schmitt also found that interviews had incremental validity beyond mental ability.

In 1996, Huffcutt and colleagues explored the extent to which employment interview evaluations reflect

cognitive ability. A meta-analysis of 49 studies found a corrected mean correlation of .40, suggesting that on average 16% of the variance in interview constructs represents cognitive ability. In fact, their results suggest that interview ratings that correlate higher with cognitive ability tend to be better predictors of job performance.

3. CONCLUSION

Employment interviews are frequently used selection tests. Employment interviews vary in their degree of structure. Structured interviews permit a more systematized collection of job applicant information than less structured interviews, resulting in the former providing better predictions of future behavior. The reliability of interviews is typically assessed by correlating the interview ratings of two independent interviewers. Interview structure tends to enhance reliability. Interviews can be used to measure a variety of job-related personal characteristics, including personality, applied social skills, job knowledge, and cognitive ability. Like most selection procedures, employment interviews tend to show mean differences in scores as a function of race. There is some evidence that interviews provide incremental prediction beyond that of general mental ability. In general, it is recommended that employment interviews be structured and based on knowledge of the job.

GLOSSARY

advance care planning (ACP) The process of preparing for medical status change events at the end of life.

advance directive A legal document that explains a competent individual's wish for future medical care (as in a living will) or that designates a surrogate decision maker who can make medical treatment decisions for the individual when he or she is unable to communicate these treatment preferences independently (as in a durable power of attorney for health care, also known as a health care proxy).

anticipatory grief A process of grieving for losses encountered during the course of illness and prior to death.

hospice care Palliative and supportive services that provide physical, psychological, social, and spiritual care for dying persons and their families; patients must have a prognosis of 6 months or less to live, receive no life-prolonging medical treatments, and have an identified primary caregiver.

palliative care Extends the principles of hospice care to a broader population who can benefit from receipt of aggressive comfort care earlier in the disease process than the point at which life expectancy is 6 months or less; provision of palliative care is not exclusive of receipt of life-prolonging medical treatments or independent living situations.

treatment delivery An aspect of treatment implementation that pertains to the degree to which project staff adhered to treatment guidelines and documented their treatment package (i.e., development of interventionist training manuals).

treatment enactment An aspect of treatment implementation that pertains to the usefulness of the treatment to the individual and/or family as indicated by their spontaneous use of treatment skills in everyday life.

treatment receipt An aspect of treatment implementation that pertains to the individual and/or family's understanding of treatment components and acquisition of skills.

Everyone must deal with the deaths of those they love as well as his or her own mortality. Yet one rarely considers the certainty of the end of life until confronted with the immediate needs of a loved one who is dying. This article reviews the differentiation of hospice and palliative care, predictors of mortality, advance care planning within a family context, caregiving stressors as well as positive aspects of caregiving, and assessment and treatment issues surrounding the end of life.

1. INTRODUCTION

Issues surrounding the end of life are receiving increased attention due to the “graying of America.” In 2000, the average life expectancy for all individuals at birth in the United States, regardless of gender or race, was 77 years. The National Center for Health Statistics reported that the leading causes of death in 2001 were heart disease, cancer, stroke, and respiratory disease. Alzheimer’s disease was listed as the eighth leading cause of death, although this is likely an underestimate given that Alzheimer’s is rarely listed as the direct cause of death on death certificates. Fully 80% of individuals who die do so in an institutional setting such as a hospital or nursing home. However, individuals report a desire to die at home.

One reason for the increased interest in end of life issues has to do with the U.S. Supreme Court’s 1990 decision in *Cruzan v. Director, Missouri Department of Health*, requiring “clear and convincing evidence” of an individual’s wishes regarding medical treatments that may be used to prolong life (e.g., artificial nutrition and hydration). Many cultural and psychosocial issues influence individual preferences for end of life medical treatments, receipt of hospice or palliative care, nursing home placement, and the experience of caregiving. These include a need for education regarding the benefits and drawbacks of life-prolonging (or life-sustaining) treatments in comparison with receipt of hospice and palliative care, socioeconomic factors, religiousness and spirituality, prior experience with end of life issues, and style of family decision making.

2. DEFINITIONS AND DIFFERENTIATION OF HOSPICE AND PALLIATIVE CARE

Hospice care includes palliative and supportive services that provide physical, psychological, social, and spiritual care for dying persons and their families. The National Center for Health Statistics reported that hospice patients in the United States are still predominantly cancer patients (e.g., 58% in 2000). However, guidelines to determine hospice eligibility have been developed for severe chronic illnesses such as heart disease, chronic obstructive pulmonary disease, cerebrovascular disease, and dementia. There are dramatic racial/cultural differences in the receipt of hospice care. Hospice patients are most often elderly White individuals who live with a

primary caregiver in a private or semiprivate residence and are covered by Medicare or private insurance. Only 5% of hospice services are paid for by Medicaid. Although the Medicare hospice benefit provides for care during the final 6 months of life, the average length of service in hospice programs nationally is only 46.9 days (median = 15.6 days).

A primary restriction to the provision of hospice care is that patients must have a life expectancy of 6 months or less. In addition, no life-prolonging treatments (e.g., artificial nutrition and hydration, chemotherapy, ventilation) can be ongoing during the provision of hospice care. This may be a primary barrier to receipt of hospice services by individuals who identify themselves as members of racial/ethnic minority groups. For example, African Americans are more likely to initiate life-prolonging medical treatments than are Whites. Another barrier to receipt of hospice services is the absence of an informal or formal in-home caregiver.

In contrast, palliative care extends the principles of hospice care to a broader population who could benefit from receiving aggressive comfort care earlier in the disease process. Palliative care is not restricted to individuals with a life expectancy of 6 months or less. Furthermore, provision of palliative care is not exclusive of receipt of life-prolonging medical treatments or independent living situations. Therefore, palliative care models are ideal for more medically frail elders who may benefit from aggressive comfort care well before they qualify for current hospice guidelines. Ideally, palliative care would segue into hospice care as the individual’s illness progresses. However, recognizing the signs of disease progression that can signal a need for palliative care can be difficult. Recent research has attempted to clarify some of these signs and symptoms.

3. PREDICTORS OF MORTALITY

Events that can signal medical status change include a nonchronic condition that calls for medical follow-up by a physician (e.g., weight loss, difficulty in breathing, heart trouble, chest pain, and trouble in swallowing) and a disease process that calls for a medical decision involving the individual’s family. In 2003, Covinsky and colleagues examined data from the final 2 years of life of frail older adults in the community and found that declines in functional status were evident at least 1 year prior to death. The degree of functional impairment was greater for those with cognitive impairment.

Medically frail individuals are at risk for various types of cognitive impairment, including dementia, confusion associated with opioid medication, delirium, and (in the case of cancer) brain metastases. In 2003, Schonwetter and colleagues found that advanced age and impaired nutritional and functional status were associated with shortened survival among patients admitted to a community hospice with a diagnosis of dementia. Three-fourths of patients meeting local Medicare fiscal intermediary guidelines for hospice eligibility died within the required 6-month window.

In addition, continued weight loss has been associated with an increase in the likelihood of dying. Weight loss is a common symptom in many types of cancer, although fluid buildup is not uncommon. Older age and feeding dependence are also associated with increased risk of mortality. However, the most prevalent symptom of impending death during the final 48 hours appears to be respiratory symptoms.

Perhaps the most common symptom of medical status change, and certainly the most troubling for the patient and the family caregiver, is pain. Individuals with more severe cognitive impairments might not be reliable in, or even capable of, self-reporting pain or discomfort. Individual pain reports might not coincide with proxy pain reports. Pain is common among nursing home residents regardless of proximity to death. In 2002, Happ and colleagues noted that most nursing home residents died without family members present and with little documented evidence of pain or symptom management. According to Engle and colleague's 1998 research, African American nursing home residents may be at particular risk for inadequate pain relief.

The National Hospice and Palliative Care Organization (NHPCO) has recommended continuous assessment of an individual's needs and treatment preferences in the context of family values. This process may be considered continual treatment planning for the end of life, and some have argued that this should occur within a family context.

4. ADVANCE CARE PLANNING WITHIN A FAMILY CONTEXT

Advance care planning (ACP) is the process of preparing for medical status change events at the end of life. ACP typically involves discussion and assessment of the understanding that the person with life-limiting illness has regarding his or her medical history, current condition,

values, preferences, and resources. ACP tends to emphasize decisions regarding the withholding of life-prolonging medical treatments rather than treatments that are desirable. It is important to note that ACP is not merely the completion of an advance directive, although completion of an advance directive may be a part of ACP.

Older adults tend to believe that others will take care of their future health care. This belief may, in turn, preclude completion of advance directives or interfere with ACP. Individuals who possess advance directives tend to be older, White, more educated, classified as middle class, and in poor health.

ACP is typically conducted in a family context because family members are often involved in end of life care. Family members tend to be present throughout the individual's illness and play an important role in end of life decisions. Sometimes, family members advocate the individual's end of life treatment preferences when he or she cannot voice these wishes independently. However, this substituted judgment is not always an accurate representation of the individual's wishes. This discrepancy may be influenced by the lack of prior discussions of end of life preferences with caregivers or family members; however, a growing body of research suggests that even with such discussions, surrogate decision makers do not always respond with the same treatment preferences as indicated by their loved ones. Many factors may contribute to this discrepancy, including differences in how healthy and unhealthy individuals view illness and quality of life. Although research is still inconclusive as to whether ACP and completion of advance directives aid in maintaining patient control over the dying process, there seems to be some suggestion that at least ACP may ease the minds of patients, caregivers, and family members concerning end of life issues.

5. FAMILIAL CAREGIVER STRAIN AND GROWTH POTENTIAL

On the topic of caregiving, research to date has focused on caregiving for chronic illnesses, most predominantly Alzheimer's disease and other forms of dementia. However, there are differences in the impact of caregiving across various diseases and racial groups. When reviewing research on caregiving at the end of life, important themes emerge, including the relationship between caregiver and patient; the search for meaning/purpose, spirituality, or religiousness; and the adjustment to bereavement.

In general, caregivers experience more negative health outcomes than do noncaregivers. Specifically, caregivers are at increased risk for developing negative mental and health outcomes such as depression, perceptions of burden, lowered immune system function, and mortality. Female caregivers experience less participation in social and recreational activities, and more movement out of the workforce, than do noncaregivers. Research has suggested that Alzheimer's disease produces similar negative effects on caregivers' well-being and mental health when severity of illness is considered.

Other important aspects to consider when evaluating the long-term effects of caregiving are the quality and type of the relationship between caregivers and the individuals for whom they are providing care. In 1998, Lawrence and colleagues found that better relationship quality was directly related to lower levels of depression and a decreased sense of role captivity for caregivers. Familial relationship has been found to influence the average number of hours per week spent in the caregiving role and the extent of burden experienced. Specifically, spouses tend to spend more time caregiving than do adult children or other family members. In addition, spousal caregivers report more fatigue and more sleep difficulties than do nonspousal caregivers.

Regarding racial differences, African Americans are more likely to be cared for by members of their extended families than are Whites, whereas adult children are a prominent source of care for both African Americans and Whites. African American caregivers also experience higher levels of overall coping mastery than do White caregivers. In contrast, Aranda noted in 2001 that Hispanic/Latino caregivers generally, but not always, report higher levels of depressive symptoms than do other ethnic/racial groups.

Beyond the impact of type of relationship or the length of care provided, the course of the illness also affects the relationship and caregivers' response to caregiving. Although a good deal of research has focused on caregiving for chronic illness, very little has focused on caregiving at the end of life. Most of what is known in this area comes from clinical reports of the dying process or observations of experienced clinicians who work with families through hospice and palliative care programs. These qualitative accounts portray the extremely difficult circumstances experienced at the end of life by caregivers, who are simultaneously caring for a loved one while also dealing with the anticipatory grief related to their loved one's impending death as well as the frustrations of dealing with an often unresponsive health care system.

Notably, few studies address potential positive aspects of palliative caregiving for persons at the end of life. Caregivers may face needs that could be identified as existential or spiritual, including finding purpose and meaning, forgiving and receiving forgiveness, maintaining hope, saying good-bye, and coming to terms with expectations for what may occur after death. In 2003, Haley and colleagues found that hospice caregivers who have high levels of social activity and social support, and who are able to find meaning and benefit in caregiving, reported lower levels of depression and higher levels of life satisfaction. This recent finding suggests that activities in which caregivers find meaning and benefit in caregiving are beneficial.

The impact of religiousness and spirituality on coping has been a particularly neglected area of research. Religiousness and spirituality may reduce the sense of loss of control and helplessness that can accompany end of life caregiving. Religious and spiritual beliefs provide a cognitive framework that reduces stress and increases purpose and meaning in the face of illness. Spiritual and religious activities may reduce the sense of isolation and increase caregivers' sense of forgiveness or control over the illness. However, religiousness and spirituality might not always have a positive influence. For example, if a person who is dying feels remorse over past failings and believes in a punishing God, he or she may experience great anxiety.

When death comes after a sustained period of chronic illness and family caregiving, family members often react with a mixture of relief, grief, and guilt. Relief at the end of the caregiving process and the end of the loved one's suffering is accompanied by a deep sense of loss. Family members experience increased stress following a decision to terminate end of life care, but in cases where there is no verbal or written advance directive, the stress levels tend to be higher and last longer. Family members may experience anticipatory grief during their loved one's dying process. This anticipatory grief process may be beneficial to adaptive coping after bereavement, but this has not been supported consistently by research.

Although most people go through the grieving process effectively and eventually resume their normal functioning, a considerable portion (perhaps 10–25%) experience some form of pathological grief. A number of risk factors for complications with bereavement have been found, including the quality of the relationship between the bereaved individual and the deceased loved one (worse outcome in conflictual relationship), gender (worse outcome in male caregiver), and the

nature of the death (worse outcome in sudden, unexpected, or socially unacceptable death). The impact of caregiving does not end at death, nor is this impact the same for every caregiver. Substantial racial/ethnic differences in subjective reactions to death have been found. Specifically, African American dementia caregivers are more likely than White dementia caregivers to initiate life-prolonging medical treatments, are less likely to have their loved one die in a nursing home, and report less acceptance of their loved one's death and greater perceived loss. Consequently, more research is needed to understand the impact of caregiving, and an individualized approach to working with these families in clinical settings is needed.

6. THERAPEUTIC ASSESSMENT

Careful assessment is a precursor to effective treatment, and effective treatment leads to enhanced quality of life for individuals with life-limiting illnesses. The importance of fine-tuned information on patient prognosis becomes more apparent as treatment options increase. Communication of such information to individuals and their families allows time to explore family values and goals for future medical treatment. Such medical treatment can be viewed as life sustaining or life prolonging, depending on the perspective of each individual and family.

Assessment of patients' preferences regarding future medical treatment can be conducted formally through the use of advance directives or informally through discussions with family members. One assessment tool that may be helpful in promoting informal discussions and in clarifying wishes for future medical care is the Life Support Preferences/Predictions Questionnaire (LSPQ). This instrument was designed to identify treatment preferences in specific illness scenarios. Each scenario differs from the others in severity, level of pain, prognosis, and/or impairment. Following presentation of each scenario, respondents are asked to indicate which treatment options they would desire given that situation. Data from such assessments can provide guidelines for appropriate treatment and disease management.

Clinicians also may wish to conduct needs assessments with individuals and family members throughout the course of the individuals' chronic life-limiting illnesses. Continuous and comprehensive assessment of individual and family perception of need can provide a medium for matching specific individual and family characteristics with appropriate therapeutic interventions. Data from

such assessments can provide education and support for individuals living with illnesses at the end of their lives. Such information can also provide education and support for family members regarding their own risk for disease and available preventive measures.

7. THERAPEUTIC INTERVENTIONS AND TREATMENTS

Many families and individuals with life-limiting illnesses have difficulty in accepting the inevitable consequences of the diseases and may resist engaging in interventions such as advance care plans, psychotherapy, support groups, and respite services or seeking information about the benefits of palliative care to alleviate suffering. Clinicians must recognize the potential of such resistance and approach individuals and families with the utmost sensitivity and empathy. However, once individuals and families are engaged in discussions of therapeutic interventions at the end of life, the opportunity for meaningful interaction and the potential for individual growth and growth in relationship become more apparent. Some interventions that target various stages of life-limiting illnesses and end of life treatment issues are reviewed briefly in the following subsections.

7.1. Study to Understand Prognoses and Preferences for Outcomes and Risks of Treatments

The Study to Understand Prognoses and Preferences for Outcomes and Risks of Treatments (SUPPORT) project, conducted in 1995 by the SUPPORT principal investigators, implemented and evaluated a physician-assisted intervention for dying patients in hospitals. The intervention was aimed at addressing inadequate communication regarding prognoses and patient care preferences. Specifically, the intervention was aimed at (a) providing accurate and timely prognostic information to physicians, (b) documenting the views of patients and families surrounding the patients' prognoses and treatment options, and (c) providing skilled nurses to carry out discussions and communicate relevant information.

To assess whether the intervention had a positive effect, SUPPORT researchers focused on (a) when and if "do not resuscitate" (DNR) orders were written, (b) patient-physician agreement regarding preferences to withhold resuscitation, (c) the number of days patients spent in intensive care units, (d) the frequency and

severity of the pain experienced by patients, and (e) the amount of hospital resources used during patients' hospital stays. The research investigators found no differences on any of the five outcomes between those who received the intervention and those who did not.

The specific reasons why the intervention did not work are unclear, but there are some suggested possibilities. The SUPPORT investigators recognized that one limitation in their ability to detect a positive impact of this treatment might be that individuals, families, and physicians were generally satisfied with the care received at that critical time. According to the researchers, another possible explanation is that the hospitals in which the SUPPORT study was conducted might have provided better care than is typically available to the general public.

Although these are plausible explanations, another possibility is variability in the implementation of the intervention itself in terms of treatment delivery by the investigators, treatment receipt by the participants (i.e., understanding), and treatment enactment (i.e., the degree to which the information provided by the SUPPORT team was used by the families in the study). SUPPORT was the first intervention of its kind to submit to the rigors of scientific testing and represents seminal research in this area. The investigators chose to maximize generalizability by conducting the research in as natural a way as possible in their chosen hospitals. However, in so doing, the experiences of individuals and families in the treatment group varied dramatically.

Delivery of the treatment was allowed to vary based on the SUPPORT nurse's discretion and ranged from informational support to intense emotional support. In addition, the nurse did not always meet with the families or the patients, nor did the nurse discuss the same topics with each participant. This variation in treatment can be beneficial to the individuals involved, but it makes it difficult to determine whether the treatment as a whole was effective or ineffective due to the variety of interventions delivered.

The only measure of receipt of treatment was the physicians' indications of receipt of the reports regarding DNR or the placement of the reports in the medical charts. Although the placement of these reports in the charts could be conceptualized as treatment enactment, there is little information on whether these reports were ever actually used by those in constant contact with the patients or families. Efforts to standardize the treatment provided by the interventionists, measures of treatment receipt for both physicians and patients/families, and a measure addressing the use (enactment) of the

treatment are needed before such interventions can be deemed beneficial or ineffective.

7.2. Advance Directives, Values Assessment, and Communication Enhancement

In 2001, Ditto and colleagues implemented an intervention that consisted of patients completing an advance directive in the presence of family members. In some groups, discussions were also encouraged to facilitate communication between patients and family members regarding medical treatment preferences. One group had advance directives with discussions, one group had advance directives without discussions, one group had discussions without advance directives, and a control group had neither advance directives nor discussions. The results of this study showed that none of the interventions resulted in an increase in patient-family member agreement when family members were asked to predict patient preferences. Although the study revealed no increase in agreement, it did reveal an increase in comfort and understanding as reported by patients and family members regarding end of life decisions. As with the SUPPORT study, data regarding treatment implementation were not reported systematically, although there seemed to be variability in the delivery of treatment to the various groups.

7.3. Meaning-Centered Group Interventions

William Breitbart and colleagues are currently testing an intervention designed to enhance a sense of meaning and purpose and to improve quality of life among advanced cancer patients. The treatment is delivered in a group format (eight sessions) and targets the creation of a supportive environment to facilitate understanding of the possible sources of meaning before and during cancer illness. Basic concepts include the achievement of transcendence through creativity (e.g., work, deeds, causes), experience (e.g., nature, art, relationships), and attitudes toward suffering. Group sessions include information about sources of meaning, a storytelling life project, and hopes for the future. Anecdotal reports from Breitbart and colleagues indicate that the intervention may be effective in decreasing hopelessness and desire for hastened death while increasing meaning and spiritual well-being. No treatment implementation data are yet available.

7.4. Individual Problem-Solving Skills Training

Another type of intervention used at the end of life is problem-solving skills training. Susan McMillan's "Caregiver Intervention to Improve Hospice Outcomes" is one example of a problem solving-based intervention. This intervention takes place over a period of 9 days, during which time three intervention visits occur. In these visits, caregivers receive the "COPE" intervention involving the following: Creativity (viewing problems from different perspectives to find new strategies), Optimism (having a positive but realistic attitude toward the problem-solving process), Planning (setting goals and thinking out steps to reach those goals), and Expert information (learning what caregivers need to know about the patient's condition, when to seek professional help, and what can be done by caregivers to help the patient).

The three problem areas on which McMillan focused regarding the hospice patient's condition were pain, constipation, and dyspnea. For each of these problems, a specific module was designed for caregivers to learn assessment and problem-solving techniques they could implement to help the patient. In addition, caregivers were asked to keep a patient symptom diary in which they recorded patient symptoms to monitor and share this information with the hospice staff as needed.

Treatment implementation was measured in this study. Delivery of the treatment was monitored by case conferences to reduce the possibility of drift from the protocol or cross-contamination of the treatment conditions. In addition, visits in the intervention group were tape-recorded, and 10% of the tapes were reviewed monthly to ensure adherence to protocol. At monthly case conferences, the possibility of an undesired change in hospice staff behavior was assessed by a question regarding any noticed changes by caregivers with respect to the hospice staff's behavior toward the patient.

Treatment receipt, or caregivers' understanding of the intervention, was verified by the interventionist's inquiry, "What would you do if . . .?" Clarification regarding specific skills was provided to caregivers if needed to facilitate adequate treatment receipt. At the end of the intervention, receipt was assessed by asking caregivers to rate their ability to manage symptoms successfully and comparing their responses prior to the intervention with their responses following the intervention.

Treatment enactment can be examined through the caregivers' diary to determine the extent to which caregivers complied with the daily assessment and

recording of patient symptoms. If caregivers found the information and monitoring system provided by the project to be helpful, they would be expected to use the skills in providing care to the patient.

7.5. Ongoing Studies by the Authors

Our team has developed two interventions that combine problem-solving skills training with social support and meaning-centered therapeutic activity. One intervention is the care integration team (CIT), which focuses on caregivers of terminally ill patients enrolled in hospice care. The intervention consists of four weekly home visits and has a randomly matched minimal support treatment control group. The intervention for caregivers focuses on use of problem-solving skills in four topic areas: (a) symptom management, (b) communication with hospice staff, (c) caregiver self-care, and (d) anticipatory grief. Treatment implementation measures are included in this ongoing study.

Unlike the CIT intervention, the legacy intervention focuses on both the individual with life-limiting illness and the caregiver. The legacy intervention is an effort to help patients and caregivers to find meaning through intergenerational activities. This is achieved through the joint development of the patient's "personal legacy" for future generations. This legacy can take multiple forms: a family photo album, a family cookbook or scrapbook, audiotaped or videotaped stories of the older adult's life, personal letters to younger family members, and the like. The intervention consists of three weekly 60- to 90-minute sessions in which the caregiver and patient learn about what a legacy is, select a legacy, obtain materials to create the project, and review their experience with members of the research team. A control group receives weekly 5-minute telephone calls and answers questions about spontaneous intergenerational activities to promote family ties. Encouraging families to develop lasting memories with their loved one at any stage of the disease process can enhance meaning in relationships and provide a focus to heal prior conflicts.

These interventions were designed with the three components of treatment implementation in mind. Both the CIT and legacy projects use audiotapes of intervention sessions (10%) in evaluations by an independent professional clinician not involved with the research project. The independent evaluator monitors the tapes and transcripts for interventionists' adherence to research protocol in treatment delivery. Both projects have caregiver and interventionist training manuals that are provided as guides to treatment components.

The CIT intervention measures treatment receipt by knowledge assessments at the first week of training and immediately following the intervention. If caregivers do not achieve an 80% score on these assessments, further training is provided to ensure receipt of the skills. Both the CIT and legacy interventions also use contact logs to document the content and length of all sessions so as to measure receipt of treatment, including who initiates the contact and the purpose of the contact.

The CIT project assesses treatment enactment by interventionists' review of caregivers' personal tracking forms. The interventionists then rate caregivers' compliance with all aspects of treatment on a Likert-type scale evaluation. For treatment enactment, interventionists working on the legacy project note the extent to which a legacy was completed by the family, again using a Likert-type scale evaluation.

8. CONCLUSION

This article has reviewed issues associated with personal and familial stressors and potential for growth when facing end of life issues during adulthood. Because of increased numbers of individuals living to very old age today, research and clinical attention are being directed at end of life care. Of necessity, end of life issues such as ACP, choice of medical treatment, assessment of treatment needs, and delivery of therapeutic treatments involve both individuals with life-limiting illnesses and their family members. Knowing when to initiate aggressive curative or aggressive palliative treatments is difficult given variable predictors of mortality across disease categories. This article has attempted to provide a broad overview of current clinical research efforts surrounding end of life issues. Without question, these topics will continue to be a focus for research, service, and policy efforts during the coming decades.

task analysis Any process for analyzing the behavior of a human within a human–machine system that determines the interactions between humans and equipment or machines with the underlying working conditions in mind.

usability The degree of ease with which humans can interact with a system or a piece of equipment.

The subject of engineering psychology is the optimization of the exchange of information within the human–machine system with the use of planning, analysis, design, and evaluation.

GLOSSARY

cognitive task analysis Any further development of traditional task analyses that yields information about the knowledge, thought processes, and goal structures that underlie observable task performance.

compatibility Consistency in the direction of the movement of relationships and operator expectations.

human–machine system A convenient abstraction of the goal-oriented cooperation between persons and technical systems to accomplish a self-determined or assigned task.

human reliability The probability of the successful performance of the human activities necessary for a human–machine system.

interface design The construction of that technical part of the machine directly interacting with the human operator on the basis of empirically grounded rules and heuristics to achieve efficient human–machine interaction as well as high system performance.

operator The human working in a human–machine system.

1. HISTORICAL BACKGROUND

Changes in work in all branches of industry, transportation, and services after World War II led to an increasing amount of monitoring, control, supervision, and planning activities for operators. To match the equipment to the needs and cognitive capacities of the human operators, engineers, psychologists, physiologists, and anthropologists have outlined general principles for an optimal layout of technical systems that involve people.

Since the late 1940s, the framework of specialists has focused on that topic developed as a part of human factors engineering called engineering psychology. At the beginning of the 1960s, the subject was examined in Europe, especially in England, France, and Germany. Similarly, many studies were undertaken in the Soviet Union in this new field of technical design under the

label of *ingenemaja psychologika*. In Japan, research in engineering psychology also spread quickly. Similar subjects were worked on in the United States, although socially and culturally different foci were set.

During the initial phase of engineering psychology up to around 1960, systems design research was focused on the developmental design principles of machine displays, controls, and interaction between humans and machines. However, this changed quickly due to the fast development of computing technology. By the end of the 1960s, ever more portions of the mental work of humans were already automated and new questions about the allocation of functions between humans and machines had to be answered. This led away from the “dials and knobs” optimization of the early 1950s to human–machine/computer interaction as an area of engineering psychology. Although the adjustment behavior of humans was initially modeled as an automatic controller, the field of research spread soon to investigations of the operator as a dialogue partner and interactive problem solver. System design issues requirements are currently driven, and will also be driven in the future, largely by trends in technology such as computerization, automation, knowledge, and information processing.

The new field of activity engineering psychology is closely related to other spheres of research such as human factors or human factors engineering (United States), ergonomics (United Kingdom and Germany), and cognitive ergonomics. However, differences in the core psychological matter and methodology of engineering psychology clearly separate it from these subjects in that engineering psychology focuses on information exchange in human–machine systems. The methods and tools used for analysis in the human–machine information exchanges are predominantly derived from cognitive psychology, which developed numerous paradigms to investigate fundamentally human information processes. During recent decades, an increasing trend is to incorporate and transfer methods from other scientific areas to the field of human–machine interaction studies.

2. THE HUMAN–MACHINE SYSTEM AS THE SUBJECT OF ENGINEERING PSYCHOLOGY

In general, the numerous definitions of engineering psychology can be summarized as follows: the optimization

of the interchange of information within a human–machine system with the use of planning, analysis, design, and evaluation.

The concept of human–machine systems refers to a convenient abstraction of the goal-oriented cooperation between persons and technical systems to accomplish a self-determined or assigned task. This more abstract definition covers the relevant features of the diverse variations of the goal-oriented information interchange between humans and machines in different situations. The concept of a human–machine system implies that at least one person and at least one machine work together.

The general structure of a human–machine system (Fig. 1) is a control system in which an operator and/or a team make decisions to steer the technical system according to organizational basis, goal, task, and perceived feedback about the environment and process conditions. The behavior of the human–machine system is thereby determined by qualitatively different processes. On the one hand, it is shaped by human data processing based on social, psychological, and biological regularities. On the other hand, it is influenced by technical processes that obey physical laws.

The reception of information concerning process data and environmental properties takes place either directly or indirectly (e.g., a direct visual approach, an indirect instrumental approach). Information can also be entered either with appropriate devices or through language, muscle activities, and the like.

The location of these interferences and/or of the machine can be nearly arbitrary spatially. If this aspect of informational coupling is more intensely differentiated (i.e., if machines and their maintenance or control are handled by persons at different places), the term “distributed human–machine systems” may be used as well. Subtasks, responsibility, decisions, and knowledge are distributed among different human participants in different hierarchical levels so that the classical problem of task allocation arises again.

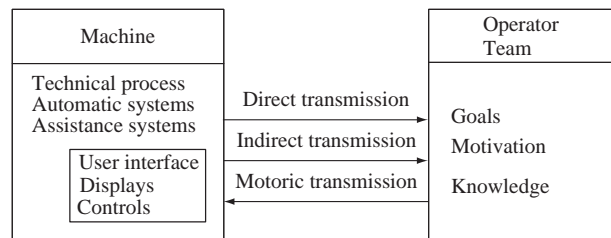

FIGURE 1 Schematic representation of information interchange in human–machine systems.

The substantial components of the technical entity “machine” in human–machine systems are indicating and control units, automated subunits, and computer-aided assistance systems (e.g., assistance or diagnostic systems) as well as the technological process controlled. Information indicators and control components are often integrated, for example, in control rooms, cockpits (for vehicles and airplanes), conning bridges, control desks, and control panels and screens.

(perception), the memory with its substructures (information retrieval, selection, and recognition), and the system for the execution of the (motoric processing) action (Fig. 2). It is assumed that all utterances and actions by the operators are the result of information processing (e.g., comparisons, judging, decisions) in the nervous system. These processes are essentially steered by signals from the environment and by knowledge stored in memory. As shown in Fig. 2, the data are received and decoded by receptors in the eyes, in the ears, and in the haptic system (i.e., the information is perceived). The decoded information reaches the brain, where it is compared with previously stored information. The result of this comparison can be recognition or comprehension, but it can also prompt a process for behavioral decisions that result in sensomotoric activity (e.g., as steering activities). Engineering psychology considers information processing on three different levels: knowledge based, rule based, and skill based.

As a result of research in the field of general psychology, it has been shown that the evaluation of the information processed has a strong influence on

3. HUMAN INFORMATION PROCESSING IN HUMAN–MACHINE SYSTEMS

3.1. Circulation of Information in Human–Machine Systems

Three components can be differentiated in information circulation and are represented separately for didactical reasons: the system of the initial processing of stimuli received by the receptors of an appropriate sense

FIGURE 2 Information circulation processes in human–machine interaction (based on a structural model of human cognitive systems).

performance. This is why mental processes cannot be investigated without taking activating processes into account. This means that the interrelationship between information processing and evaluation, as well as activation processes, is an important field of research for engineering psychology (e.g., for measures of workload and situation awareness).

3.2. Goal Setting

All actions in a work context need to set a specific goal that is expected to be achieved by the actions. The goal-setting process includes an assessment of a cost-efficiency ratio as well as of a demands/effort ratio. Furthermore, the process is affected by the interpretation, motivation, and values of the operator. This can be described as an anticipation of future action and its result. The goal is to resolve problems in a definite time, to anticipate changes in the state or in the process, and/or to develop a process of execution so as to set means and define results. Goal setting can be processed at different levels of detail, depending perhaps on the amount of experience in the domain of action, on the complexity of the task, and on the degree of freedom implicated in it. Goals can be differentiated as those that are set by or taken over from another authority and those that are self-determined. However, self-determined goals are achieved with more motivation and involvement than are assigned ones. The process of goal setting is completed by means of the resolution to execute a specific action. Goal setting can be supported by the unambiguous design of displays and controls that give the operator useful hints for the current action needed.

3.3. Perception and Interface Design

Human perception is distributed over diverse channels of information intake (i.e., the senses) that are integrated into the process of perception. The senses are usually distinguished as the visual sense, auditory sense, somato-visceral sense (including the haptic sense), the olfactory and equilibrium sense, and the sense of taste. The research on perception in experimental psychology during the past 50 years or so has been predominantly directed toward the visual and auditory sensory system. In addition to these two senses, the haptic sense—especially the sense of touch and kinesthetics—has been “rediscovered” for the interface design of advanced human-machine systems (e.g., to synthetically model force feedback in distributed or virtual human-machine systems).

Psychological theories of perception differ in how they assume that information is taken in, describing the process as follows:

- A direct process that rests on the spatio-temporal invariance of the environment (ecological approach of perception)
- An indirect process involving different stages in the active construction of the percept from receptor sensations based on processing rules, the referential system, and the experience of the person involved (constructivist approach)

Current theories of perception often assume that bottom-up processes, as well as top-down processes, are involved in the various levels of perception.

Engineering psychology relies particularly on the findings of Gestalt psychology, the laws of perception, and psychophysics to offer recommendations for the design of icons for visual displays as well as of acoustic feedback. The laws of perception are related to the perceptual grouping of visual and acoustic stimuli depending on their properties. Following are a couple of examples:

- *The law of similarity*: Similar items tend to be grouped together.
- *The law of proximity*: Items with spatio-temporal closeness tend to be experienced as belonging together.

The laws of perceptual organization also explain the figure-ground disjunction and can be applied for adequate display design in human-machine systems. For example, smaller and symmetrical pieces, as well as orthogonally oriented figures, can be more easily perceived as objects.

Psychophysical findings, which are important for the design of human-machine systems (especially for information coding), are the minimal and maximal thresholds of perception for the individual senses, their discrimination thresholds, and their spatio-temporal resolution.

To support the operator in the comprehension of information, this information can be coded into features that are easy to perceive and distinguish (e.g., the color red for “hot”). Most of these kinds of codes are understandable due to knowledge about cultural conventions.

3.4. Cognition

In the future, many fields of technical design, diagnostic processes, modern management, and so forth will not remain competitive without the help of technical

aids for knowledge processing, (group) decision making, and other aspects of cognitive tasks. The ultimate aim is to support cognitive tasks as effectively and transparently as possible. Knowledge-based supporting aids and decision support systems have been developed based on findings from cognitive psychology.

3.4.1. Knowledge-Based Supporting Aids

A knowledge-based supporting aid is a technical entity for information processing that helps the operator to achieve his or her tasks in a human-machine system by taking over certain subtasks. These knowledge-based supporting aids for technical design have become an important field of engineering psychology in research and practice.

However, this knowledge must first be prepared and presented in such a way that it can be implemented in a supporting system. But this is not a matter of acquiring knowledge for knowledge's sake. Instead, it is a matter of being able to implement the relevant knowledge related to the specific task. A wide range of psychological methods (Table I) are available for the elicitation of the relevant procedural and declarative knowledge that exists, for example, as semantic networks, production rules, or schemata.

Knowledge-based diagnostic systems have been developed and applied in numerous areas, for example, for troubleshooting in medicine, mechanical engineering, or technical design. This field is witnessing a trend where engineers, engineering psychologists, and computer scientists are working together. Although the body of knowledge has been developed particularly by engineering psychologists, it has been implemented by engineers and computer scientists.

3.4.2. Decision Support Systems

Findings from the psychology of cognition should be applied to decision support or decision analysis systems. These systems contain axiomatically grounded decision procedures for managers and operators working in complex systems. Often, these working conditions are complicated by time pressure, uncertainty, information overflow, and high importance. Decision support systems in this field are frequently based theoretically on normative and descriptive perspectives on the process supported (e.g., multiattributive value theory [MAVT], multiattributive utility theory [MAUT]).

TABLE I
Methods in Engineering Psychology

Objective area	Method examples
System validation	Measurement of performance data Physiological measurements Verbal protocols Interviews Questionnaires
Cognitive task analysis	Observations Interviews Verbal reports Analysis of team communication Critical decision method Cognitive walkthrough GOMS
Knowledge elicitation	Association techniques Sorting techniques Structure formation technique Discussion in groups Grid techniques
Human reliability analysis	Analytical methods (e.g., THERP, CREAM, ATHEANA) Time-reliability correlations (e.g., HCR) Structured expert ratings (e.g., SLIM)
Usability testing	Thinking aloud method Constructive interaction Retrospective testing Coaching method Heuristic evaluation
Cognitive modeling	Computer simulations based on cognitive architectures (e.g., SOAR, ACT-R, GOMS)
Workload	Subjective measures (e.g., rating scales, psychometric techniques) Performance measures (e.g., primary task measures, secondary task measures) Physiological measures (e.g., cardiac function, muscle function, eye function, brain function)

In up-to-date systems, a team makes decisions more often. But practical design recommendations are not yet possible for the automated support of team decision making because a generally accepted concept does not yet exist. In the future, team decision support will become an important research and application domain of engineering psychology.

3.5. Motoric

Since the 1940s and 1950s, general principles for the choice and design of controls depending on working demands have already been established. Today, this information can be found in handbooks on human factors engineering or ergonomics that pertain, for example, to the optimal control/display ratio, directions of movement relationship, or coding and arrangement of controls, especially in terms of compatibility.

Compatibility is one of the most important factors to be considered in systems design. This is especially significant in stressful situations where learned habits often break down and can cause errors in action. These results from early engineering psychology can be found in all relevant compendia.

With ongoing technological development, and especially with digitalization, new concepts of human-machine interaction have been developed. Today, the research in engineering psychology is paying much attention to setting up design recommendations for speech and gesture interaction in cars and planes as well as in conventional computing. Some of these input devices are recognized as convenient and highly standardized (e.g., mice, touch screens, keyboards). They are manufactured for different practical purposes due to their widespread application in different work domains. The number of specific input devices for defined domains (e.g., endoscopic surgery) is increasing. These devices must fulfill the special demands of specific domains as well as general ergonomic criteria for evaluation. Speech input and automated image processing input (e.g., gesture input) are currently not used universally due to problems in recognition reliability, costs, and unsolved technical constraints (e.g., noise from the environment, changes in the brightness of the surroundings). The cultural aspects of the design of user interfaces, and especially of input devices, are more obvious today than they were previously due to the globalization of industrialization, and they constitute a limiting factor in standardization.

Another well-elaborated research area in engineering psychology is the modeling of the sensomotoric regulation of operators in flight and driving tasks. Formal descriptions of human sensomotoric regulation were sought at the end of the 1940s due to the requirements of military engineering. The goal of this research was to develop an analytical representation of the dynamics of a human-machine system for the choice of optimal system dimensions and to train operators on the model of the new system.

Human sensomotoric control can be described in terms of the mathematical control theory based on a

structural analogy between an automatic control circuit and a human-machine system. The results of this intensive research, well known as tracking experiments, are numerous mathematically descriptive equations for the "control person's" behavior. The crossover model, the quasi-linear model, and the time-optimized model are frequently cited in this context.

Admittedly, such equations are valid only for skill-based level activities. Higher cognitive procedures, particularly the motivational and behavioral strategies of an operator, cannot be described with these equations. Today, research is concerned with developing complex operator models by means of fuzzy logic approaches, artificial neural networks, and so forth.

3.6. Attention

Attention is one of the frequently used psychological concepts relating to the main problems of automated human-machine systems design such as the following:

- Holding operators in the loop
- Maintaining the operator's positive situation awareness and availability
- Reducing the consequences of information overflow

The concept of attention refers to the human ability to focus information processing on selected events or contents over a specific amount of time. The selection of information is an important precondition for precise action. Attention lapses in interaction with a technical system may cause dangerous states or situations. But the selection of current important events is more difficult due to potentially important information and time pressure. These circumstances contribute to the mental workload of the operator. Another problem in advanced working domains is to maintain readiness for action at an adequate level of vigilance. This problem is caused by long periods of monitoring an automated system in which nothing that requires action happens or by lengthy tasks (e.g., truck driving for hours during the night). The consequences of decreasing attention or vigilance for the performance of the human-machine system are often the same: Performance falls and strain on the operator increases. Different methods have been developed to quantify actual workload levels.

4. HUMAN RELIABILITY

It is estimated that in 60 to 90% of all system failures, human actions are the main cause. In light of

these statistics, the study of human error has emerged as an important discipline of engineering psychology.

Errors in work activities are considered to be a result of inadequate training, poor working conditions, and organizational factors that are also a consequence of learning and adaptation to different situational conditions. This multifaceted interrelation means that no homogenous theory about human errors exists. Taxonomies are required for the measurement of human error. There are two main approaches for classification. The first refers to the manifestation of errors such as observably incorrect actions. These taxonomies are widely used in human reliability analysis where error frequencies must be estimated. The second approach concentrates on variations in underlying psychological mechanisms, that is, the internal causes of human error. The origin of errors resulting from incorrect action is described in various ways in the psychological literature. Both approaches are related to “active errors” that have an immediate and direct impact on the system.

To meet the requirements of the influence of organizational factors, the concept of latent errors has been established. Latent errors originate in decisions taken in the managerial and organizational spheres and may lie dormant for long periods of time.

The concept of human error is closely related to the concept of reliability. The term “reliability” has its origins in the engineering sciences and is based on the theory of probabilities. The frame of reference is the frequency of errors. On the basis of different assumptions concerning error distributions, system structures, and time intervals, the reliability of a system is calculated. The concept of reliability has been transferred from technical systems to human actions. Several attempts have been made to detect human error probabilities just like in technical systems.

Engineering psychology focuses mainly on operators and their cognitive competencies and resources. But it also must consider the organizational and situational aspects of working conditions for to evaluate the reliability of an entire human-machine system.

5. METHODS

The most important objective areas and dedicated methods used in engineering psychology are shown in Table I. They are described briefly in this section.

5.1. System Validation

System validation examines whether a machine is matched to the needs and cognitive capacities of the human operator. Validation normally takes place in an experimental setting within a controllable environment where disturbing variables can be eliminated or controlled.

During early phases of the development of a new human-machine system, single subsystems are evaluated in the laboratory. The performance of a human-machine system should be investigated under realistic conditions to achieve integrated system validation. The preparation and investigation of early prototypes have become less costly during recent years with the further dissemination and use of simulators. Technical possibilities, such as log file recordings and freezing a situation, make possible techniques of investigation that are not feasible in the real world.

A broad inventory of empirical methods from psychological research can be employed to validate new systems in laboratories or in simulators (e.g., measurement of performance data such as speed and accuracy, physiological measurements, verbal protocols, interviews, questionnaires). Workload and situation awareness are typical concepts used for system validation in engineering psychology.

5.2. Cognitive Task Analysis and Knowledge Elicitation

A new area of engineering psychology, cognitive task analysis, concentrates on cognitive aspects of human-machine interaction that are not directly observable. As a further development of traditional task analysis techniques, cognitive task analyses are performed to gain insight into the knowledge representations, thought processes, mental strategies, and goal structures that underlie task performance. The results are used for the design of human-machine interactions (e.g., task allocation, preparation of procedures); for the development of training, testing, and selection tools; for the development of expert systems; and as a basis for computer simulations.

In addition to observations, verbal statements from job experts are the main source of information for data collection. Information about cognitive processes is collected by using interview techniques and verbal reports or with the analysis of team communication. Visualization tools and sorting methods are applied for illustration. Further methods for a cognitive task analysis

are the critical decision method, cognitive walkthrough, and the GOMS architecture.

A special field of cognitive task analysis is knowledge elicitation. A wide range of psychological methods are available for elicitation of procedural and declarative knowledge necessary for the development of knowledge-based supporting aids. In addition to common methods (e.g., interview techniques, questionnaires), other methods employed include association techniques, sorting techniques, structure formation techniques, and grid techniques.

5.3. Human Reliability Analysis Techniques

Human reliability analysis is concerned with prediction of the likelihood that human performance within a human-machine system will fail. Numerous methods for human reliability analysis have been developed. Traditional HRA techniques can be divided into analytical methods, time-reliability correlations, and structured expert ratings.

Analytical methods (e.g., THERP) are based on the breakdown of a task into partial tasks or actions. Error probabilities are determined for these tasks, and actions and then integrated into an overall error probability for the analyzed task. Time-reliability correlations (e.g., THERP diagnostic model, HCR model) are used for the assessment of critical events when interpretations, diagnoses, and decisions about necessary actions must be made. They are based on a simplified correlation between available time and error probability. Structured expert ratings are used if no numerical data about the analyzed task exist. Experts can carry out an assessment with the SLIM method, which provides numerical ratings of the strength and importance of a relatively small number of factors that influence performance. Newer human reliability analysis techniques (e.g., CREAM, ATHEANA) focus on errors resulting from cognitive processes.

5.4. Usability Testing

In general, usability refers to how well individuals can interact with a product or a piece of equipment. Usability is connected with attributes such as learnability, flexibility, intuitiveness, and likability. Usability tests can be performed as a formative or summative evaluation. Formative usability tests are done to improve a system design as part of the design process.

Summative usability testing aims at assessing the overall quality of a product.

Quantitative and qualitative methods for performance measurement are used for usability testing. Primarily qualitative methods are used for formative usability testing, especially variants of the thinking aloud method (e.g., constructive interaction, retrospective testing, coaching method). Usability testing can be combined with heuristic evaluation to rely on a list of established usability principles when applied by an expert.

5.5. Computer Simulations

Models are used to analyze the attributes of a human-machine system on the basis of an abstract description of the structure and the performance of the system. In the engineering field, computer simulations have been increasingly applied in the design and evaluation of new systems. Simulations of the technical subsystem must be connected with human operator models to simulate interactive systems. In engineering psychology, models from cognitive psychology are adapted to include human behavior in the simulation of interactive systems. Cognitive architectures such as SOAR, ACT-R, and GOMS represent theories for simulating and understanding human cognition that are used for the simulation of human behavior. Detailed cognitive task analyses are needed to construct computer simulations that represent human behavior.

6. DEVELOPMENT AND PLANNING OF HUMAN-MACHINE SYSTEMS

The goal of engineering psychology is to create demands for human-oriented work design within the framework of modern information technologies. The theoretical foundations for this type of work have already been securely laid and are supported by both experimental and empirical evidence. They have been developed for successful application to systems design:

- Eliminating the negative effects of work (e.g., workload)
- High dependability
- High performance
- High usability
- General well-being and health

The main objective is to create the best possible system and to ensure that numerous components of human

information processing and task performance are included in the job requirements so that well-balanced jobs can be designed.

To achieve this goal, one must move away from the corrective systems design that dominated the initial phases of engineering psychology and move toward a preventive and flexible form of systems design. Therefore, the system's layout should be based on a dynamic task allocation rather than on a strategy of static engineering or of static human-centered automation. A system-centered automation strategy distributes functions to both the operator and the technical system so that the operator can flexibly decide whether to use automation to accomplish a task or to do it manually.

The influence of new automation strategies has moved the process of systems design from a linear-sequential design to a parallel-hierarchical and iterative procedure. Numerous process models for systems design have been developed (e.g., the V-model, the spiral model, the prototyping model). These models all incorporate empirical evaluation and phased correction into

the various stages of engineering human-machine systems. Figure 3 is a rough schematic representation of this principle.

This transition from a linear systems design to a parallel one that takes the user into consideration is a major step toward reaching the goals that engineering psychology hopes to achieve by influencing the nature of modern work. The presentation of the relevant psychological theories, concepts, and empirical data in a technically usable form is crucial to the success of such a procedure. Rapid and successful developments have been made in this field, especially in aviation, automotive, and production engineering. These developments, as compared with corrective design procedures, require considerably less effort and are more economical.

7. FUTURE DEVELOPMENTS

The future development of human-machine systems is closely related to technological progress, especially to

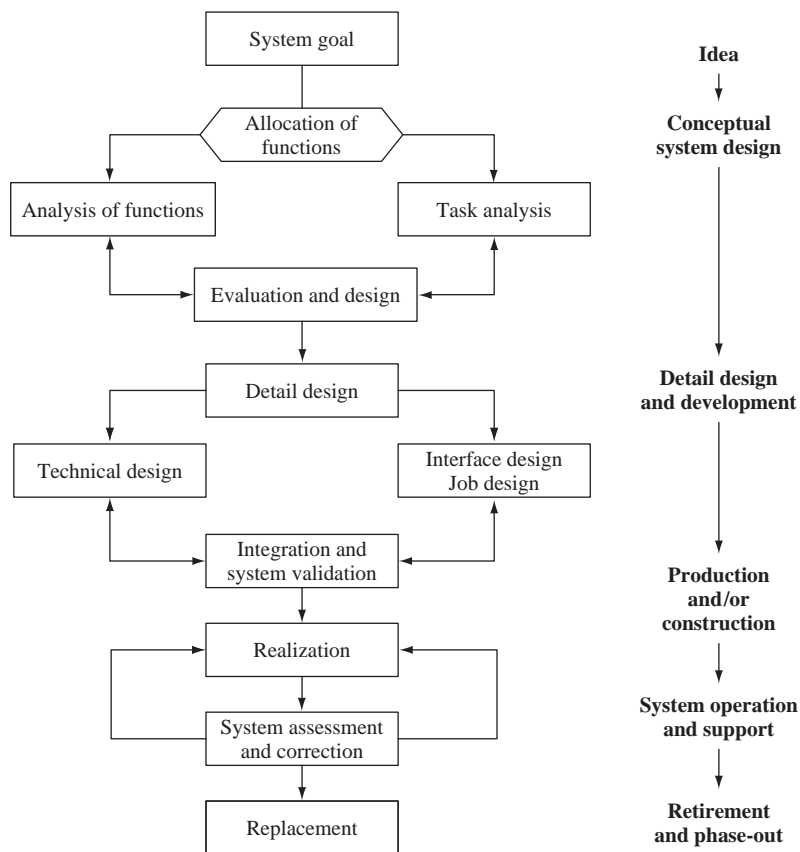

FIGURE 3 Parallel iterative systems design that includes the user.

information technology. The information exchange between human and machine will be further developed to include new interaction concepts and interaction technologies. Auto-stereoscopic perception, as well as the combined interaction of gaze, speech, and hand gestures, has been integrated into multimodal human-computer interfaces that could be applied in task environments with changing cognitive, sensomotoric, and/or attentional demands. New generations of assistance systems will observe the state of the human operator and collect safety- or task-relevant information from the environment to actively support the operator in achieving his or her aims. The development of multimodal interfaces has formulated new research questions for application and design in the field of engineering psychology, for example, about the transmission of concepts in natural communication to human-machine interaction. A special point of research in the design of interaction related to information technology is to provide access to disabled people for better living conditions.

An important concept for the supervision of complex human-machine systems is ecological interface design. This approach attempts to visualize complex processes in technical systems. The easily understandable representation of a system's states should support

operators in situations where safety is critical. Other sustained work domains of engineering psychology consider the increasing amount of distributed human-machine systems throughout nearly all branches, the replacement of leftover allocation with a humanized task approach, and/or the simulation of complex human-machine systems.

GLOSSARY

behavior settings Units of the environment composed of interrelated physical, organizational, and behavioral properties.

environmental assessment The conceptualization and measurement of characteristics of environments that influence human behavior.

institutional policies Rules and regulations that organize everyday social interaction and the overall functioning of a setting.

institutional structure Objective characteristics of organizations such as their size, ownership, and centralization of authority.

physical and architectural features Objective characteristics of the natural and built environment, including the landscape, cities, and buildings.

social climate The social characteristics and expectations of a setting such as its level of support, task orientation, and structure.

suprapersonal factors The aggregate characteristics of the individuals in a setting, including their preferences, abilities, and behavior patterns.

An integrated perspective on human environments is essential for one of the central tasks of applied psychology, that is, to help create optimal and sustainable conditions that enhance individuals' quality of life. At its most basic level, environmental assessment involves the conceptualization and measurement of characteristics of environments that influence human behavior. More broadly, environmental assessment encompasses the linkages among aspects of the environment as well as the processes by which environmental factors influence human behavior.

1. MAJOR DOMAINS OF ENVIRONMENTAL FEATURES

The main characteristics of environments can be conceptualized in four interrelated domains: physical and architectural features, institutional structure and policies, suprapersonal factors, and social climate.

1.1. Physical and Architectural Features

The assessment of physical and architectural features typically involves direct observation. Four main sets of dimensions have been identified: (a) physical amenities that improve convenience and comfort, (b) physical features that provide support for individuals, (c) size

allowances for personal activities, and (d) physical integration with the surrounding community as assessed, for example, by the extent to which the community and its resources are convenient and accessible.

A related area of research focuses on landscapes and natural environments. The assessment of natural settings involves ratings of perceived environmental quality as well as cognitive mapping techniques that tap people's environmental comprehension. Natural settings have been described in terms of physical attributes (e.g., the presence and extent of hills, water, trees, and grass) and aesthetic qualities (e.g., beauty, harmony, complexity). Cognitive mapping, or the study of people's internal representation of the external world, is especially helpful for understanding the value of environmental cues for orientation and "way finding."

1.2. Institutional Structure and Policies

There are four sets of characteristics in this domain. The first set encompasses structural factors such as ownership, size, and centralization. The second set of dimensions focuses on the balance between individual freedom and institutional order as measured by how much participants individualize their activities and routines and how much they are involved in managing the environment and influencing its policies. The third set of dimensions involves behavioral requirements such as expectations for individuals' functioning and acceptance of problem behavior. The fourth set of dimensions involves the provision of services and activities such as health services, daily living assistance, and social activities. These characteristics can be measured by direct observation or by ratings of participants or outside experts.

1.3. Suprapersonal Factors

When individuals come together in a social group, they bring with them values, norms, and abilities. Because of selective mechanisms, groups draw their members from the general population in a nonrandom manner and produce distinctive blends of these individual characteristics. The aggregate of the individuals in a setting, or the suprapersonal environment, in part defines the subculture that develops in a group.

In the vocational or work domain, Holland showed that occupations can be categorized into six groups (realistic, investigative, artistic, social, enterprising, and conventional), each of which represents a different

personality type. Because people in a vocational group tend to have similar personalities, they are likely to create characteristic interpersonal environments. Thus, there are six types of environments that correspond to the six personality types. In this way, an average background characteristic of a group (i.e., its dominant vocational preference) creates a characteristic environment with unique demands, rewards, and opportunities.

1.4. Social Climate

The social climate is the "personality" of a setting or environment such as a workplace, a classroom or school, a social group, or a neighborhood. Three sets of dimensions characterize the social climate of diverse settings. First, relationship dimensions measure how involved, supportive, and expressive people are in a setting. Second, personal growth dimensions tap ways in which an environment encourages personal growth such as by emphasizing autonomy, achievement or task orientation, competition, intellectual orientation, and moral-religious orientation. Third, system maintenance and change dimensions measure the settings' organization, clarity, control, and responsiveness to change. In general, social climate has been measured by the shared perceptions of the individuals in an environment and by outside observers' ratings.

2. LINKAGES AMONG ENVIRONMENTAL FEATURES

The four domains of environmental features are interconnected. Physical and architectural features, institutional structure and policies, and suprapersonal factors shape each other and combine to create behavior settings with particular social climates. In turn, behavior settings and the social climate influence individuals' health and well-being both directly and indirectly through the other environmental domains.

2.1. Behavior Settings

Behavior settings, which are composed of groups of individuals behaving together (e.g., working on a shared task, participating in a social group, learning in a classroom), have four essential attributes. First, behavior settings have one or more standing patterns of behavior such as sitting, listening, talking, and note taking during a union meeting. Second, behavior settings involve a

physical milieu that may include both natural and constructed features of the environment. Third, these settings have shared policies and expectations about acceptable behavior. Fourth, the physical milieu and standing patterns of behavior are interdependent so that, for example, chairs in a classroom typically face the teacher for listening and observing. The physical milieu and policies help to shape the standing patterns of behavior in a setting. These three characteristics, in turn, tend to create a particular social climate.

2.2. Physical Features and Social Climate

Physical features that improve convenience and comfort, such as physical amenities and social-recreational aids, are associated with a more cohesive and well-organized social climate. Residential settings with more supportive physical features, such as prosthetic aids and safety features, tend to develop a social climate oriented toward independence. In contrast, crowding and lack of adequate space are associated with a lack of cohesion and goal direction as well as with ambiguity and disorganization.

2.3. Institutional Structure and Policies and Social Climate

Ownership and size are related to social climate. Policies in nonprofit facilities are more accepting of problem behavior and more likely to promote residents' personal control. Accordingly, residents in nonprofit facilities see them as more cohesive, self-directed, and better organized than do residents in proprietary facilities. With some exceptions, large size is related to a less cohesive and less well-organized social climate with somewhat more conflict. Policies that enable individuals to determine their daily routine and to influence the operation of the setting, and those that have more provisions for privacy, tend to promote a cohesive social climate oriented toward autonomy and independence. When the rules and regulations in a setting are clear, the social climate is likely to be more cohesive and self-directed.

2.4. Suprapersonal Factors and Social Climate

The modal personal characteristics of individuals in various occupations are associated with the work climates they create. For example, individuals in realistic

occupations, such as engineers and air traffic controllers, tend to see their work groups as high in control and lacking in cohesion, autonomy, and innovation. In contrast, employees in social-type work settings, such as teachers and social workers, tend to report more emphasis on supportive relationships, autonomy, clarity, and innovation.

Individuals' abilities, personal resources, and typical patterns of behavior help to determine the social climates in residential facilities. Facilities with more women and more socially privileged individuals tend to develop more cohesive, self-directed, and well-organized social climates. Facilities with more older and mentally impaired individuals are likely to be less supportive and goal-directed as well as higher on control.

3. INFLUENCE OF ENVIRONMENTAL FACTORS

Each of the four sets of environmental factors has an impact on individuals' health and well-being. In addition, part of the influence of environmental factors depends on the personal competence, orientation, and preferences of the individuals in the environment. In turn, these individuals select and shape the environment they inhabit.

3.1. Environmental Impacts

Physical and architectural features, institutional structure and policies, and suprapersonal factors tend to exert their effects through specific behavior settings and the social climate they create. Most basically, social systems tend to maintain and accentuate individual qualities that are congruent with their dominant aspects. Accordingly, youngsters in families that value independence, achievement, and intellectual and recreational pursuits are likely to develop more self-confidence and social competence. A workplace that values independent decision making, complex and challenging tasks, and high-performance expectations promotes intellectual flexibility and self-efficacy. More cohesive and socially integrated neighborhoods characterized by adult guardianship and monitoring tend to promote responsible parenting and youth behavior.

Some emphasis on each of the three domains enhances positive emotional and behavioral development, but too much focus on any one domain can lead

to distress and dysfunction. Highly achievement-oriented and structured families can create anxiety and erode youngsters' self-confidence. Similarly, high work demands can lessen employees' job morale and elicit depression and physical symptoms. Difficult and competitive learning environments encourage cognitive growth, but they also can erode students' self-confidence and produce high absenteeism and dropout rates.

3.2. Person–Environment Matching Models

Part of the influence of contextual factors depends on the personal competence, orientation, and preferences of the individuals who experience them. The competence–demand model of person–environment congruence states that high environmental demands should have more positive consequences for individuals who are functioning well than for those who are functioning poorly, whereas environmental resources should have more benefit for less competent individuals. Specifically, a self-directed setting that has high performance expectations and relatively little structure should have the most benefit for functionally able individuals. In contrast, less competent individuals need more support and structure and often find high performance expectations and self-direction to be disruptive. As individuals' cognitive and psychosocial skills improve, they should be able to cope with more demanding and less structured environments.

The conceptual-level model describes people in terms of their cognitive complexity and describes environments in terms of their structure. It posits that individuals at a high conceptual level are able to organize their own environment, whereas individuals at a lower conceptual level need the stabilizing influence of a well-structured setting. The model also proposes that individuals with less cognitive complexity are more affected by changes in structure than are those at a more mature level.

3.3. Transactional Models

Most of the research in this area reflects a social causation perspective in which the environment is seen as a causal factor that shapes individuals' development and maturation. However, there also is a social selection process by which individuals select and shape existing environments and create new environments. According to behavior setting theory, four transactional processes

explain how ongoing interactions among participants and other aspects of behavior settings produce a stable patterned set of behaviors and environment–behavior congruence. These processes involve goal circuits (i.e., how participants set goals and achieve them), program circuits (i.e., how participants control and organize the program or agenda of a setting), deviation-counteracting circuits (i.e., the ways in which unwanted modifications or problems in the setting are altered or corrected), and vetoing circuits (i.e., the ways in which deviant components of a setting are eliminated).

More generally, there are four main processes by which individuals and environments influence each other. In a passive process, individuals find themselves or are placed in an environment that shapes their behavior, for example, when a child is placed in a group care home. In an evocative process, individuals select specific responses that become part of their environment, for example, when a youngster with a sunny disposition elicits a supportive context. In an active process, individuals select social contexts that maintain and accentuate their dispositions or skills, for example, when a youngster joins a soccer team or a debating club. Finally, in a transcending process, individuals build entirely new physical and social contexts, for example, when individuals bereaved and maimed in a cataclysmic disaster rebuild their community.

4. CONCLUSION

Environmental assessment provides conceptual and empirical tools that make environmental determinants of human behavior accessible to psychological inquiry. Researchers have identified four main domains of environmental features, assessed specific dimensions in these domains, and examined their interconnections. Conceptual models of how contexts influence individuals, of person–environment matching, and of how individuals select and create contexts have led to a better understanding of how the interplay of environmental and person factors shapes individuals' health and well-being. Environmental assessment complements the traditional person-centered focus in psychology by providing a more holistic and integrated understanding of human behavior as it occurs in real-world settings.

GLOSSARY

civil society The part of social life that lies beyond the immediate reach of the state and that must exist for a democratic state to flower; it is the society of households, family networks, civic and religious organizations, and communities that are bound to each other primarily by shared histories, collective memories, and cultural norms of reciprocity.

community A group or network of people who share something in common or interact with each other; it is a place where solidarity, participation, and coherence are found.

distributive justice The equitable distribution of resources and nuisances among groups within the society differentiated by factors such as power, social class, ethnicity, and so forth.

empowerment The process by which people achieve more control (perceived and actual) over their lives, destiny, and environment; it is the process of overcoming powerlessness and its outcomes (e.g., despair, marginality, estrangement).

environment An all-encompassing term that includes all aspects of the world—the physical, ecological, social,

economic, cultural, political, institutional, technological, and individual.

participation/involvement Situations in which individuals (or groups), who are not elected or appointed governmental officials and who are not professionals working for such officials, voluntarily take part in decision-making processes to influence these processes, change them, or improve them; participation is the activity of such individuals, whereas involvement is the activity of the officials and professionals who initiate such a process.

participatory democracy A democratic system in which citizens have opportunities for taking part in governmental decision-making processes relevant to their lives on a regular basis and not just in elections once every 4 years.

participatory governance The transfer of authority and responsibility from those who hold power by virtue of law, contract, or organizational role to those not so empowered; this is a step above participatory democracy because it makes explicit the authority and responsibility given to the participants within the governmental procedure.

procedural justice A system in which the decisions as to the distribution of resources and nuisances are made in an equitable manner.

social capital The bonds of the community that enrich people's lives in a variety of ways; it includes resources that inhere in social relationships such as mutual trust, a sense of reciprocal obligations, and civic participation aimed at benefiting the group or community as a whole.

sustainability The goal for development that recognizes the interwoven nature of economic, social, and ecological–environmental factors and that strives for intergroup and intergenerational equity.

sustainable development The process of balancing three development processes: economic, community, and ecological; it is development that meets the needs of the current generation without compromising the ability of future generations to meet their own needs.

Participation relates to people taking part in public decision-making processes or private initiatives with public implications. The recent movement in planning and design toward more participatory and empowering decision-making processes is a significant step in the direction of accommodating the needs and preferences of different groups of people. Introducing individuals into the decision-making process forces politicians, planners, and architects to consider the micro level and to meet the people, see their faces, and hear their voices. The interest in such processes within environmental psychology forces one to consider the macro level and to understand the decision-making system and the constraints and pressures within which planners operate. This article addresses various issues that reflect the complexity of the participatory process, the discussion of which also illustrates the interdependence of these issues. Finally, the article looks at the role of environmental psychology in the public participation arena.

1. INTRODUCTION

- “I don’t need to involve the public. I know what’s good for them.”
- “They didn’t like the Eiffel Tower at first either.”
- “Of course I’m in favor of public participation . . . but . . . the public isn’t ready, or they don’t understand, or it takes too long, or it costs too much.”
- “Who are you to claim that you represent the public?”
- “Why aren’t there more people here?”
- “We’ve been working on this plan for you for 3 years, and now when it’s ready you’re against it!”
- “You’re only interested in your own backyard and your own selfish interests, while I’m concerned with the larger picture and the common good.”

These are quotes of statements made by elected officials and professionals with regard to the principle of public

participation in decision making. They illustrate some of the problems encountered by those who are interested in facilitating or promoting the principles of public participation, whether they are professionals, elected politicians, or members of the public themselves.

Participation, in the sense that the term is used in this article, relates to people taking part in public decision-making processes or private initiatives with public implications, not those occurring within an organization or a group of people. Arguments over what should and should not be considered participation illustrate both the ambiguity and the political nature of the concept. For example, there are those who talk about participation in terms of voting in elections, and others who see it in terms of taking part in groups of various kinds. It is clearly a value-laden concept, which for some represents the very essence of democracy, a basic human right, and an ethical good in and of itself. Others value participation as a pragmatic means to various ends, some instrumental and some strategic. Participation is seen as having the potential for major benefits for the individual, for the community, and for society as a whole; as enabling decisions that are better able to fit the needs of the people; and as making support for policies and programs more probable.

Because participation has implications for the nature of the distribution of power among individuals and groups, it arouses tensions and emotions, and this makes it difficult to relate to participation dispassionately. On the whole, politicians, officials, and professionals see it as a threat to their power and as a bother. They argue that ordinary people are not capable of being part of the decision-making process due to the complexity of the issues at hand. They also argue that they see the larger picture, and make their decisions “objectively,” for the greater good. Residents, on the other hand, are “subjective” and concerned only with their own private good.

The concept of public participation appears in the writings of philosophers, theoreticians, and practitioners in the fields of political science, sociology, planning, architecture, landscape architecture, community psychology, community social work, and environmental psychology. Because one of the basic tenets of environmental psychology is the importance of identifying the context of a phenomenon for understanding it, the next few paragraphs are devoted to identifying the historical, political, intellectual/theoretical, practical/professional, cultural, and psychological contexts of public participation.

Participation is a multifaceted and multidisciplinary project, with theoreticians mainly to be found in political science and planning. The current discourse surrounding participation is rooted in the theories of Habermas and Giddens that have been further developed in the planning context by Healey and Friedmann. Freire has had an important influence on the thinking in this area as well. Recently, Putnam's theory of social capital has also found its way into the discussion of the role of the civil society and of participation in current democracies. There is also a body of knowledge about participation within community psychology, both theoretical and empirical. On the other hand, one can find professionals actively involving others within the fields of community organization, architecture, planning, and environment-behavior studies, including environmental psychologists. There are private design offices that specialize in participatory work (particularly in the United States), and there is growing interest in participatory research and participatory evaluation.

Attempts at involvement and at participation appear within rather varied contexts with different professions involved, depending on the context and often with different motivations and methods, with regard to environmental quality issues, health, housing, neighborhoods, schools, public spaces, and community development in general. United Nations (UN) agencies and documents, such as the Convention on the Rights of the Child, Agenda 21, Habitat 2, and the Healthy Cities Program, strongly recommend (and sometimes require) involvement of the public. In the European Union, the Aarhus Convention emphasizes public participation in decision making as a necessary component of governmental activity in the area of environmental policy. An interesting phenomenon during recent years is the promotion, or even requirement, of public participation by international agencies, such as the World Bank, operating in developing countries. Public participation appears to be the recent offspring of community development, which was a UN strategy for "developing" those that were then called Third World countries. That approach to development occasioned much intellectual and academic criticism due to its poor outcomes in those countries, and it would seem that a more empowering involvement approach is the new consensus. Because a democratic system is the basic necessity for the right to participation in that it requires inclusiveness, transparency, and accountability on the part of those in positions of power, attempts to apply its principles in nondemocratic systems are limited to topics that are perceived as not threatening the system as a whole.

The development over time in the approach to participation can be seen in the changes that have occurred in the language used to discuss the ideological bases for it—from democracy, participatory democracy, and power to justice (both distributional and procedural), sustainability, empowerment, social capital, and participatory governance. These changes in language reflect changes both in the theoretical underpinnings of the concept and in the degree to which it is embedded within public decision-making processes. These reflect the change from the 1960s "modern" and positivistic view of the professional and the needs-based participation process to the "postmodern" times of reflective practitioners and the Foucauldian thinking that knowledge is not where (and what) it was traditionally believed to be and that power must be shared or at least viewed with suspicion.

In many countries and cities, resident involvement now appears in the language of master plans as a basic requirement. For example, this is the case in Australia, virtually all of Europe (but particularly Great Britain and The Netherlands), Canada, the United States, and Israel. In these and other cities and countries (e.g., Brazil, Mexico, Venezuela, India, South Africa), there are examples of participatory processes of greater or lesser scope. Participatory processes have been conducted with adults and children, with men and women, with poor people and middle-class people, and with people with and without formal education.

Furthermore, "in the beginning" there was involvement, and even though the term used might have been participation, most of the discourse in the planning and architecture fields was about the activities of the professionals and how they should or could involve others. Whereas once the discourse of public participation was dominated by professionals who were "doing it" and the voice of the participants was never heard, there is much more recognition now that professionals are not responsible for the participation but rather are responsible for effectively involving people in processes that, until recently, professionals have controlled on their own. Thus, there is growing awareness today that the participants, their motivation, and their concerns should be more in focus.

To use an image suggested by Kidder and Fine in 1987, the lens used in planning is to a large extent a zooming-out one, whereas the lens used in environmental psychology is a zooming-in one. Public participation was usually discussed through the zooming-out lens, and this article zooms in on it. The movement in planning and design toward more participatory and

empowering decision-making processes is a significant step in the direction of accommodating the needs and preferences of various groups of people. Introducing individuals into the decision-making process forces politicians, planners, and architects to consider the micro level and to meet the people, see their faces, and hear their voices. The interest within environmental psychology in such processes forces one to consider the macro level and to understand the decision-making system and the constraints and pressures within which planners operate.

On a very basic level, many of the assumptions of environmental psychology should lead to the conclusion that participation is the only way, or the best way, in which to achieve the desired “fit” between the environment and its users. These assumptions include (a) that the physical environment has implications for people’s lives; (b) that people are different and have different needs and, therefore, that one cannot specify, identify, or posit one universal model of the person–environment relationship; (c) that people are active and not passive in the sense that they interpret, evaluate, and use their environment in ways that they desire or are able; (d) that freedom of choice is an important element in people’s behavior; (e) that aggregates (or groups) that have some needs and characteristics in common can be identified, for example, by age, gender, health status, socioeconomic status, and cultural background; and (f) that the purpose of the environment is to afford opportunities for achieving each individual’s own subjective definition of quality of life. The fact that participation is not yet seen as a *sine qua non* of environmental psychology is an unfortunate circumstance.

2. ISSUES BEDEVILING PARTICIPATION

This section addresses various issues that reflect the complexity of the participatory process, the discussion of which also illustrates the interdependence of these issues.

2.1. Why Involve Others and Why Participate Oneself?

If participation is seen as an end in itself, perhaps the question of what it is good for is unnecessary. However, if participation is seen only (or also) as a means to other ends, major questions arise as to whether it indeed can

achieve (or does achieve) these ends. Related to this question is the distinction between the process of involvement and/or participation and the products and/or results of this process. For example, one could look at how many people participated or who they were. One could look at whether participants improved their skills and abilities, whether there was individual or community empowerment, or whether there was a change in the level of trust between the involvers and the participants. Then, one could look at the product of the decision-making process. Is it a “better” one (and by whose criteria)? Did it lead to an improvement in the quality of the environment? There are a number of issues pertinent to this distinction. Which is more important, process or product? For whom is it more important, involvers or participants? Under what circumstances? How does one measure and evaluate the elements of the process or the results (e.g., quantitatively or qualitatively, by effectiveness or by efficiency, subjectively or objectively)? How does one determine that particular results are directly related to the process?

Another question that arises is whether the adherents of participation are too ambitious or unrealistic in their expectations and goals. Are their assumptions, theories, or hypotheses ones that can be achieved? Just as it has been argued that architects and planners should not make deterministic statements that promise specific results from their plans, it might not be appropriate to promise too much from a participatory process and raise expectations that might not be possible to achieve. When this happens, it may doom the project of participation to disappointment and rejection, both by the participants and by the involvers. It would seem that what is needed is (a) a careful analysis of what is possible to achieve under what circumstances, (b) a serious effort at implementing the process in a manner that has the potential for achieving those results, and (c) research and evaluation that will enable one to learn what does and does not work. On the other hand, the participants must understand and accept the fact that they might not be able to achieve all that they wish to achieve, that compromise might be necessary, and that consideration for the views and needs of others is an essential part of the process.

If one focuses the lens on the participants themselves, one can ask whether it is enough if the results are mainly on the psychological level, which is also the hardest level to demonstrate. If results happen on the behavioral level, such as attendance at meetings, how does one know that there are also results, such as personal empowerment, on the psychological level? To

be sure that the claims for the results of participation are valid, one must develop tools for evaluation that include indicators and “signs” of the psychological, educational, and environmental impacts or outputs of participation.

To paraphrase the words of Schorr, to be more assertive about what one knows, one must first be more systematic in assembling and trying to understand what one knows. One will not disappoint if one bases his or her recommendations on “what works” in its specific context. If one is systematic about documenting participatory processes—and the works of Fung, Chawla, Couto, Horelli, Sanoff, Schneckloth, Schorr, and others show that this is the trend now—one will be able to say more confidently, with accumulating evidence, what results are caused by the process. The accumulation of research results pointing in the same direction helps to build confidence in the hypotheses.

2.2. Why Is Involving Others So Difficult?

Many of those who discuss participation or practice involvement are unaware of the complexity of the concept and of the variety of ways in which it can be implemented. A one-dimensional approach to involvement, such as public hearings as the sole medium, ignores the various possible goals for involvement and participation and the differences among the participants themselves. This article has already noted that some see participation as an end in itself, whereas others see it only (or also) as a means to other ends. Some of these other goals focus on the participants and on the manner in which they can achieve personal and group change through participation. Other goals focus on the decision-making process and the manner in which participation can change this process and its results. Different professions focus on different goals, although it is important that all professions are cognizant of all such goals. For example, environmental psychologists and architects and planners may focus mainly on the goal of achieving environments that better fit the needs and preferences of the various users, whereas community psychologists may focus more on the manner in which the participatory process leads to more community cohesiveness or personal skills. However, if the former ignore the fact that participants have personal and group motivations that may drive their willingness to participate, and if the latter ignore the fact that participants are also concerned with other kinds of tangible results, both

groups may fail to achieve their goals. Until now, those working in this area have not really examined systematically whether individual goals are realized. One reason is that they are too busy doing participation to do this. Another reason is that one faces the dilemma of how to “prove” that there is a cause-and-effect relationship. To gain the trust of the people, one must be honest about the constraints within which the process will be operating and be careful not to raise expectations beyond what is likely to be possible.

Part of the problem stems from a lack of understanding of the complexity of participatory processes, that is, that there is not one way that is appropriate for every context or situation. Furthermore, many lack knowledge as to how to work with people; working with people is perceived as something that anyone can do easily. If one really wishes to involve people, one must make sure that he or she has the necessary skills of listening, knowing how to talk to lay people, honesty, perseverance, and understanding of people’s needs and interests. It must be a process in which people will be able to participate and will want to participate and that will allow people to make decisions on questions that are meaningful to them. One must demystify the professional process, avoid jargon, and exemplify the essence of better communication, namely simplicity, clarity, and adaptability.

2.3. Who Is the Public?

The issue of how to define the public concerns the involvers, who wish to have some assurance that those participating “represent” the public at large. Considering the fact that every “public” contains many different groups with diverse and sometimes conflicting interests, this is not a trivial demand. It raises the issue of the possible conflict between what is called the common good and the self-interest of individuals or groups. There are a number of answers to these questions. One is that there is no objectively defined common good; it is always a value judgment as to which interests to prefer over others. Another answer is that self-interest is not necessarily “selfish-interest.” Recognizing self-interest can be seen as helping to advance distributive justice. The more groups and interests participate in the deliberations, the more differences can be clarified and conflicts can be addressed. Still another answer is that those who participate can be viewed as informal representatives of those who do not attend, particularly if serious efforts

have been made to inform all of those relevant to the topic of the possibilities for participation.

Although the participants themselves might not be particularly concerned about this issue of representativeness, it does affect the degree of legitimacy of their claim to attention and their ability to influence the process. Some address the issue in quantitative terms (e.g., how many attend a particular event or process), whereas others do so in more qualitative terms (e.g., how varied or how serious those who participate are).

In a situation where there are professionals or decision makers who initiate the participatory process, it is incumbent on them to make sure that there are no initial stumbling blocks to the participation of as many people as possible (e.g., meetings at inconvenient times or in inconvenient places, notices that people cannot read or understand). In some situations, this requires preparatory work within the neighborhood or surroundings so as to raise people's awareness of and interest in the problems being addressed. The process itself must be a welcoming one that speaks to people in ways that they understand, that does not condescend or mislead, and that enables the empowerment of the participants. People must be provided with the information relevant to the questions being addressed, both those questions considered to be relevant by the involvers and those considered to be relevant by the participants.

On the other hand, those who are to be affected by the decisions taken must be willing to be part of the process, to understand that it is not only their right but also their responsibility to take on the role of participants. It is to their advantage to do so in terms of the personal and social capital that they can accrue and in terms of the manner in which they can work toward changing both the system and its decisions to better reflect their needs. However, such participation requires skills that not everyone has, and it may be necessary to help participants to acquire those skills and, in so doing, enhance their self-confidence and self-efficacy. Furthermore, it must be accepted that there are members of the public who are not interested in the topics or in the process and that this also is their right. Some people have such serious problems of various types that they have no time or energy to devote to other interests.

In other circumstances, there are cases where it is the public (or parts of it) whose members demand to be part of the decision-making process. They too have a duty to create a democratic process within their group and to work toward the inclusion of people with different characteristics and different ideas. In this way, they

will have a stronger case when they are confronted with the inevitable questions of "Who are you?" "Why should we listen to you?" and "Who chose you?"

2.4. Whose Values Are Primary?

Very often in participatory processes, there is conflict between the values of the professionals and decision makers and those of the public. The former, particularly in the environmental quality area where some of the issues seem to be more clear-cut, believe that they cannot leave the decisions up to the "ignorant" public. With these environmental issues, there is an agenda that they want to push where there are ostensibly more objective kinds of issues with which to deal, and the professionals are convinced that they have the answers. The fact that people are likely to mistrust the statements and pronouncements of politicians and professionals makes their task much more difficult. One way in which to gain (or regain) trust is to conduct a sincere participatory process.

However, there is a general value that should be recognized—one that agrees to disagree and that understands that the dialogue itself is important. The involvement/participation process should acknowledge the conflicts among various groups and, instead of denying them and deciding that the politicians and professionals will have their way each time, should encourage the democratic participation of others involved in the decision-making process and enable the expression of the differences of opinion that exist in the social arena. This is the whole purpose of what Couto called "making democracy work better." Rather than a question of whose values are primary, it is a question of representing the diversity of values involved in the issue. Sandercock called this working for a society in which differences can flourish based on principles of social justice, of multiple citizenships, of heterogeneous publics, and of coalitions building bridges across differences.

2.5. How Does One Involve Others?

Currently, there are a number of excellent sources that present many different techniques for involving the public, some more detailed than others but all extremely valuable for illustrating the variety of techniques available and thereby expanding the ways in which participation is viewed. These include, but are not limited to, the works of Chambers, Driskell, Horelli, Sanoff, Sarkissian and colleagues, and Wates. Many of

these publications are useful not only in presenting the techniques but also in spelling out the pitfalls to avoid in involvement processes. In addition, there is growing use of geographic information system (GIS) and Internet techniques, although limitations on their use with groups whose members might not have access to computers or the Internet must be taken into account, just as the use of plans or models raises questions as to whether or not nonprofessionals understand them.

3. THE ROLE OF ENVIRONMENTAL PSYCHOLOGY IN THE PUBLIC PARTICIPATION ARENA

The contribution of environmental psychology to the discourse and practice of public participation in decision making lies in a number of directions and stems from theoretical developments and practical experience. On the theoretical level, environmental psychology contributes a number of basic tenets, including (a) the definition of environment as an all-encompassing term, (b) the emphasis on context and on the relationship between sociophysical aspects of the environment and human behavior and attitudes, (c) the knowledge that both physical and social conditions can be acted on rather than accepted fatalistically as fixed and unchangeable, and (d) the recognition of the differences in behavior and attitudes among different groups of people and the importance of this for the basic philosophy of participation. The research is based on notions that are also basic to participation—that there is no one best solution to a design problem, that expert decisions are not necessarily better than lay decisions, and that a design or planning task can be made transparent. Environmental psychologists believe in the principle that the environment works better if it is designed and planned in such a way that it fits the needs of the people affected by its changes. Environmental psychologists involved in participation add to this the condition that these people are actively involved in its creation and management. Their role is to focus the spotlight on the people themselves—on participation rather than involvement and on the people and their lives rather than on abstract concepts.

In more specific terms, the research contributes an understanding of, for example, how people perceive environmental problems, what the determinants and predictors of environmental concern are, attitudes toward risk and perceived lack of control, and the relative importance

of different environments for different groups. The latter point is particularly relevant given the finding by many that people are more concerned with immediate and local issues than with wider and more abstract ones. Environmental psychologists have experience in research that focuses on real-world complex issues, the kind of research that is essential when it comes to researching participatory processes. This focus on research, if applied to the phenomena of participation, will enable the examination of what does and does not work and thereby further the paradigmatic shift that participatory processes entail. However, this will require that more environmental psychologists make that paradigmatic shift themselves, both in their research and in their work within design, planning, and policy decision-making processes.

GLOSSARY

affordances Characteristics of environmental objects that are related to both their physical properties and the possible actions that each perceiver can perform with them.

conservation behaviors Actions that contribute to environmental preservation and/or conservation.

environmental stressors Physical characteristics of the environment that produce stress.

Hawthorne effect An increase in work productivity deriving from a worker's awareness of being monitored by an external observer.

participatory governance The transfer of authority and responsibility from those who hold power by virtue of law, contract, or organizational role to those not so empowered.

personal space The emotionally tinged zone around the human body that people feel is "their" space.

place The product of physical properties of the environment, people's cognitions of the environment, and people's actions in the environment.

place attachment An affective bond between an individual and a particular place that is not interchangeable with another with the same functional quality.

privacy regulation The selective control of access to the self or to one's group.

residential satisfaction The experience of pleasure or gratification deriving from living in a specific place.

restoration The process of renewing, recovering, or re-establishing physical, psychological, and social resources or capabilities diminished in ongoing efforts to meet adaptive demands.

social dilemma A situation of intrinsic conflict between the pursuing of individual gains and the maximization of collective outcomes.

spatial cognition The internalized reflection and reconstruction of space in thought.

sustainable development Development that meets the needs of present generations without compromising those of the future.

territory A fixed geographical space marked and defended by an organism and used for life-sustaining activities.

Environmental psychology is that branch of psychology that studies the relationship between people and the sociophysical features of the built and natural environment, in order to enhance human well-being and to improve people–environment relations. It emerged as an autonomous field of scientific inquiry at the end of the 1950s and during the 1960s. The main

conceptual roots of environmental psychology can be found in various theoretical proposals within psychology, all of them underlining the ecological or transactional basis and the context-specificity of human psychological processes. The emergence of environmental psychology is also related to the need for responding to specific demands from other technical and disciplinary fields, such as architecture and natural-ecological science, that face the problem of designing and managing the physical features of people's everyday environments. Due to the influence of these different factors, present-day environmental psychology can be characterized by four distinctive aspects: (1) the attention paid to the physical characteristics of the environment where human behavior occurs; (2) the wide variety of the research methods adopted; (3) the interest in problems with a clear social relevance; and (4) the interdisciplinary collaboration with other environmental fields. The first part of this article briefly outlines the basic historical and conceptual backgrounds of environmental psychology as a scientific discipline. Then, the main areas of interest and the related outcomes of current environmental psychology are briefly reviewed. (These aspects will be more thoroughly discussed within each of the single articles included in the present section.) Finally, perspectives on the future developments of environmental psychology are summarized.

1. THE HISTORICAL AND CONCEPTUAL BACKGROUNDS OF ENVIRONMENTAL PSYCHOLOGY

The starting date of environmental psychology as an autonomous disciplinary field within psychological science is commonly placed at the end of the 1950s. The environmental psychology that was formed during the 1950s and 1960s focused its attention on the physical features of the environment in which human behavior occurs. Its aim was to better understand the relationship between human behavior and the everyday physical or sociophysical environment. This environment was considered to be directly perceptible through the sensory organs, and was defined and considered in spatial and physical terms, whether built or natural, or on a small or large scale. At that time, there were two contrasting ideas about the relationship between human behavior and the physical environment. On the one hand, human behavior was conceived of as the "result" of the physical

environment, particularly when the built-up physical environment was considered. On the other hand, human behavior was conceived of as a "cause" of the physical environment, particularly when the natural environment was considered. However, this distinction was increasingly overcome by environmental psychology's growing emphasis on the necessity of adopting a transactional approach in the study of person-environment relationships. This approach led to the person-in-place as the main unit of analysis for environmental psychological inquiry.

Various converging factors, originating inside, around, and outside the psychological field, contributed to the emergence and development of environmental psychology. The origin, the past, and the present of this branch of psychology can be better understood by looking at all these factors in order to outline a disciplinary identity that goes beyond the general label of applied psychology. Because of the influence of these different factors, present-day environmental psychology can be characterized by four distinctive aspects: the attention paid to the physical characteristics of the environment in which human behavior occurs; the wide variety of the research methods adopted; the specific interest in problems with a clear social relevance, and the adoption of interdisciplinary collaboration practices with other environmental fields devoted to the design and management of our everyday life environment.

1.1. Environmental Psychology within and around the Psychological Tradition

Psychology has been traditionally interested in environment-behavior interactions in a very general way. The major interest of environmental psychology rested on the discovery of the importance of the physical and spatial dimension of the environment as a constituting part of human actions and experience. This interest emerged within a wider ecological or transactional perspective coming from various domains of psychological inquiry.

Therefore, environmental psychology has always been concerned for the spatial-physical properties of the surroundings in which human behavior occurs, that is, of its physical setting. At the same time, it stressed the importance of considering these physical properties in a "molar" rather than "molecular" sense. It is also important to stress that the influence of the physical environment on human psychological processes often remains outside our individual and collective awareness.

Some pioneering studies in psychology highlighted the importance of the physical and spatial context in shaping human behavior, albeit often as an incidental outcome or a small part of other research aims. An example is the widely cited field experiments, conducted at the Western Electric Company by Elton Mayo in the 1930s, that investigated the effects of the lighting conditions in work settings upon workers' performance. Other pioneering works are the studies on the development of social influence networks by Leon Festinger and colleagues and the analysis of the "stream" of human behavior in natural settings by Roger Barker and colleagues. All of these earlier contributions were guided by a common methodological interest in studying human behavior in its natural setting, as researchers recognized the need for overcoming the usually low external validity of the traditional laboratory experiments. To this end, they preferred methods such as field experiments or non-obtrusive observation.

Other authors also played a crucial role in the emergence of environmental psychology, especially those who were more open to receive and develop ideas coming from areas that bordered on psychology, but that were traditionally interested in studying behavior in natural contexts. Areas such as cultural anthropology, about human proxemics, animal ethology, and microsociology are some examples. In other words, in order to be concerned with the spatial-physical environment, psychology had to get out from its habitual setting (i.e., the research laboratory), which was by definition a "non-environment." Just like as the earlier pioneers mentioned previously, these contributors also were generally opposed to the laboratory methods used by mainstream psychological research, and consequently were more willing to use other methodologies such as field experiments and field observations, both natural or systematic. R. Sommer and I. Altman's studies on personal space and social behavior, which remain as cornerstones of the early environmental psychology, are good examples.

The enthusiasm over the emergence of this new field of inquiry was then linked with the previously mentioned dissatisfaction for both the poor ecological validity and the low social relevance of much laboratory research. This resulted in a search for a "real world psychology." This frequent dissatisfaction can be traced to the various forms of ecological demand raised since the 1940s and 1950s by various authors and psychological schools, which later developed into what has been called "contextualism" or "contextual revolution." This revolution is certainly at the core of the development of environmental psychology, particularly in its

transactional-contextual approach, which has characterized environmental psychology since its beginning.

Initially, the increased awareness of the crucial effect played by the physical features of the everyday environment on human behavior was based on two main theoretical psychological traditions. The first is the psychology of perception, especially in its more ecological orientations, such as the lens model by E. Brunswik, the transactional school of the Princeton group, and the ecological approach to perception of J. Gibson. Gibson, for example, introduced the neologism affordances, which identifies the physical properties of environmental objects that are related to the possible actions that can be performed with them. The second psychological tradition is based on the social psychology approach, through the pioneering work of K. Lewin, E. Tolman, R. Barker, and U. Bronfenbrenner. It embraces a more "holistic" or "molar" perspective, which later developed into the transactional-contextual approach to person-environment relationships, as systematically outlined by many contributors to the first *Handbook of Environmental Psychology* edited in 1987 by D. Stokols and I. Altman. In this perspective, the physical environment or physical setting has been increasingly considered as a sociophysical environment, with a growing emphasis on the social aspects of both the physical environment and the psychological processes involved. The notion of place, and its related environmental-psychological processes, also became a central unit of analysis for many environmental psychologists. Typically, places were defined from an environmental psychology point of view as a product of three main dimensions: physical properties, people's cognitions, and people's actions.

1.2. Environmental Psychology and Other Environmental Fields

The problem-oriented demands rising in technical and disciplinary fields distant from psychology are also an important factor that contributed to the emerging of environmental psychology. Examples of these fields are architecture, engineering, urban planning, human geography, natural and ecological science. Typically, architects and engineers are concerned with problems regarding the relationships between people and the built or "human-made" environments. In contrast, geographers and natural scientists are more interested in the relationships between people and the natural features of the environment.

In architecture and urban planning, those who were dissatisfied with an egocentric approach to design desired to move toward a user-centered approach to design, as well as to move from “product” design and planning to “processes” design and planning. A seminal work in this area is that of the urban planner Kevin Lynch at the Massachusetts Institute of Technology. His famous book *The Image of the City*, published in 1960, is considered a cornerstone of the collaboration between urban planning and environmental psychology. Lynch proposed that the point of view or the image that users form of the urban environment should be kept in mind when designing and planning urban spaces. Likewise, in engineering and technology, many scholars and practitioners became interested in the human-use dimension of technological systems.

The collaboration between psychology and architecture was mainly guided by an interest in the influence of specific and localized spatial characteristics of the built-up environment on human behavior. A different orientation, however, characterizes the interest in human behavior that arose in the fields of natural and ecological science, which is the other main external domain contributing to the establishment of environmental psychology. Here, the focus was placed on the possible (and usually negative) impact that human behavior can have upon the natural environment, at both a local and a global or biospheric level. Therefore the importance of paying attention to the human dimension—considered at an individual, social and cultural level—of global environmental changes, such as the greenhouse effect and climate changes, the loss of biodiversity, the depletion of the ozone layer, and so forth, was recognized. In parallel with the increasing relevance assumed by these environmental problems, ecologists also became increasingly aware of the need to integrate the natural and social sciences when dealing with environmental phenomena. The growing interests of current environmental psychology in topics such as environmental concern, pro-environmental values and attitudes, ecologically relevant behaviors, sustainable lifestyles, and natural resource management is also a consequence of this increased awareness.

2. THE MAIN AREAS OF INTEREST OF CURRENT ENVIRONMENTAL PSYCHOLOGY

Contributions in environmental psychology can be grouped into five general domains: spatial behavior,

environmental cognition, environmental stress and restoration, environmental assessment, and environmental concern and resource management. In this section of the article, the main empirical results and outcomes of environmental psychology are briefly introduced for each of these five domains. The various single articles composing this section provide a more exhaustive treatment of the different topics related to these five domains.

The environmental psychological processes grouped into these five domains can be considered transverse to the variety of specific settings in everyday life. However, since environmental psychology has also been increasingly characterized by the adoption of a place-specific approach to people–environment interactions, many environmental psychologists have been increasingly interested in a number of specific places that have a particular impact on everyday life and well-being, such as offices, schools, houses, stores, hospitals, museums, prisons, cities, etc. Three articles in this section focus on three particularly important places in our everyday experience: the workplace, the school, and the city.

2.1. Spatial Behavior

The concept of spatial behavior relates to how individuals regulate and use (in terms of appropriation and defense) their spatial environments at different personal, interpersonal, and group levels. Environmental psychology interested in spatial behavior focuses on the role of the spatial properties of the environment in shaping and regulating social interaction in everyday situations. Four major environmental psychological concepts are considered in this field: territoriality, personal space, privacy, and crowding. The articles by R. Sommer and by C. Werner, B. Brown, and I. Altman review the relevant empirical findings of these domains of environmental psychology, as well as their implications for daily life.

These domains encompass the variety of strategies by which people and communities set up and regulate the spatial boundaries of their living environment (territoriality) and the very personal sphere of the amount of space we put between us and the others (personal space). The concept of privacy encompasses both of these aspects, as it refers more generally to the various personal and group-based processes through which people set and control their mutual closeness in daily interactions.

The article by R. Sommer thoroughly illustrates the concept of human territoriality. As Sommer outlines, territoriality is the spatial appropriation, marking, and defense of our living spaces. Following an evolutionary orientation, territories can be defined as those spatial

areas that deserve to be defended from external intruders. An intriguing issue connected with human territoriality is that of crime prevention, through the concept of defensible space. As the article describes, there is a widely documented negative correlation between the presence of physical and symbolic territorial markers (e.g., well-maintained dwellings, tended yards, signs of occupancy) and the likelihood of criminal intrusion and vandalism in residential areas. The relationship between the presence of markers and crime, however, may be mediated by social variables. Notably, clear territorial markers are related to stronger residential identification, place attachment, sense of community, and higher feelings of safety among residents. Thus, architectural defensive features might play an indirect role in reducing the likelihood of crime. They reflect and communicate strengthened community-based ties and greater social cohesion; these make potential intruders less willing to perpetrate criminal activities. Another important outcome of the concept of territoriality is related to urban planning. Sommer's article in fact points out how specific design features encouraging residents' identification with and control over a specific territory may promote its proper maintenance. Furthermore, common areas such as urban parks or playgrounds should not be placed between the territories of rival gangs, as they would then run the risk of being abandoned and vandalized. Other domains in which the study of human territoriality has offered useful insights are sport (as sport teams perform better on their home field), police investigations (as many criminal gangs mark their territories by the use of graffiti and other symbols), and environmental conflict resolution (as the creation of ad hoc territories reserved to different stakeholders may prevent the emergence of land use disputes).

A second article by R. Sommer illustrates the environmental psychological concept of personal space. As opposed to territoriality, which is a place-based or site-based concept, personal space is a person-related, and thus trans-place, concept. In his seminal studies in this field, Sommer defined personal space as that emotionally tinged area that people desire to maintain around themselves and that they feel is "their space." Sommer's article also provides a review of the various individual, situational, group, and cultural factors regulating personal space. As this article reveals, personal space has relevant implications for several domains of human-environment interaction. For example, the personal space concept has provided insights for the design of institutional settings with fixed seating, as well as in the domain of mass transportation. Likewise, issues

regarding personal space were incorporated in the design of public or semi-public settings (e.g., offices, stores, banks). These should be set up in order to provide spaces that leave the users as free as possible to shift among different degrees of desired mutual closeness. Many guidebooks describing the appropriate spacing in different social encounters are also available. For example, salesmen are trained about how their selling activities might profit from an appropriate spatial interaction with customers. Finally, the issue of personal space has serious implications for the legal field: for example, the invasion of personal space has been an issue in court cases concerning prison crowding and sexual harassment. It is also an aspect considered during jury selection in high-profile trials, where professional consultants advise lawyers in order to detect potentially biased jurors.

Personal space and territoriality are both involved in the more general concept of privacy regulation. In this sense, they can be seen as two different strategies that people use to regulate their privacy, and through which people strive for psychologically satisfactory level of openness or closedness to others. A seminal contribution to the definition of privacy in environmental psychology comes from I. Altman. Within this section, the reader will find a detailed presentation about the psychological mechanisms of privacy regulation in the article written by C. Werner, B. Brown, and I. Altman. As they report, privacy regulation is defined as the process of selectively controlling access to one's self or group. In their article, Werner et al. underline how environmental psychology treats privacy as a dialectic process: that is, people might avoid or seek social contact, depending on the specific situation they are in. An important point is that individuals feel more comfortable when allowed to be as open or as closed to the others as they desire. This is also related to another important issue in the environmental psychology of spatial behavior, that is, crowding. As reported by Werner et al. in their article, crowding can be defined as one's perception that there are too many people present in a given situation. The possibility of a proper privacy regulation therefore becomes very important when people experience crowding. Environmental psychology has also treated crowding as a specific environmental stressor.

The article of Werner, Brown, and Altman also refers to how environmental psychology has identified a number of physical features that either allow people to experience a satisfactory regulation of privacy or do not. As a consequence, the privacy concept has many practical implications for the design of various specific environments such as workplaces, schools, prisons,

hospitals, and public residences. For example, university dormitories designed as suites or apartments can promote the formation of small subgroups of occupants; this is meant to buffer the possible negative consequences of crowding upon the possibility of privacy regulation. When designing the layout of a home, architects should place rooms that are usually considered more private (e.g., the bedrooms, or the family bathrooms) far from the entrance. Likewise, privacy-related concepts have been applied to urban planning and community development. The article illustrates how, for example, public spaces provided with design features encouraging interpersonal contacts (e.g., streets that invite walking, tree-shaded streets, low speed limits, green areas) might be used to promote strengthened community bonds and social ties among neighbors.

Beyond the effect that specific design features can have in affording or impeding people's mutual interactions, a central factor in people's satisfaction or dissatisfaction with privacy conditions is the possibility of regulation and control. A general recommendation is that the physical environment should be designed in order to provide to its users the possibility of regulating privacy, by seeking or avoiding social contact according to their situational and personal needs and desires.

2.2. Environmental Cognition and Cognitive Mapping

Since its beginning, environmental psychology has focused on the relationship between cognitive processes and physical space. The article of R. Golledge on spatial cognition thoroughly reviews this area of study. As Golledge notes, spatial cognition is a multidisciplinary area involving psychological science (e.g., cognitive and developmental psychology, neuropsychology) as well as other disciplinary and technical fields (e.g., geography, anthropology, architecture and urban planning, computer science).

A core concept in the environmental psychology of spatial cognition has been cognitive mapping. The term cognitive mapping refers to the process of mentally acquiring, representing, storing, and using information about the spatial properties of the physical surroundings and the relations among its constitutive elements. The interest in cognitive maps in psychology can be traced back to the works of E. Tolman in 1948. Studies on cognitive mapping have focused on the different kinds of information people rely on when forming a map of a given spatial setting.

Studies on cognitive mapping have dealt with the representation of large-scale urban environments, as well as with the representation of the interior of buildings. One goal of this kind of research was to investigate how to aid people's orientation, memory of places, and wayfinding in complex environments.

Kevin Lynch's seminal book *The Image of the City* influenced several ensuing works on the formation of mental maps of urban settings. Urban planners can use principles highlighted by these studies in order to design urban spaces that are capable of facilitating people's orientation in the city. For example, some spatial features of the residential environment, such as spatial prominence, sharp contours of buildings, easy accessibility, and the presence of natural surroundings might facilitate the overall comprehension and use of neighborhoods. Likewise, principles drawn from the cognitive mapping literature have been used for aiding wayfinding in complex interior structures, such as university buildings, hospitals, or museums. The presence of proper signs (floor plans, large graphic aids) and the availability of visual accesses may be effective in enhancing users' proper orientation.

As Golledge points out in his article, there is now a particular interest in the study of spatial cognition in aged people. The increased trend of aging in western societies has in fact led to an increased concern for the quality of life of older people. Research in this field is therefore being devoted to trying to identify how the layout of the physical space can be designed and managed in order to buffer the declines in spatial competence associated with aging, and the negative consequences of this decline for the safety, effectiveness, and autonomy of the elderly.

2.3. Environmental Stress and Restorative Environments

The environment in which most of humankind currently lives is often characterized by the presence of several potentially adverse physical conditions that can be a chronic, powerful, and uncontrollable source of psychological distress. The article by G. Evans and S. Cohen on environmental stress, included in this section, provides an exhaustive review of this traditional area of study of environmental psychology.

Environmental stressors can be defined as those actual or perceived adverse properties of the physical environment that are capable of producing a negative (physiologically and psychologically costly) effect

upon a person. It is important to note that one's everyday environment is often a source of simultaneous and interdependent multiple stressors. The article by Evans and Cohen addresses this particular aspect of environmental stress. The effects of different environmental stressors frequently add or interact with each other. As Evans and Cohen outline, individuals must make a remarkable adaptive effort in order to cope with such adverse conditions. Because humans have great powers of adaptation in adopting strategies to cope with stressors, the coping activity may become a stressful condition itself, particularly in the long-term. The article focuses on the four main costs of adapting to poor environmental conditions: cumulative fatigue, learned helplessness, physiological mobilization, and overgeneralization. These adaptive costs are caused by chronic exposure to a number of different environmental stressors, such as crowding, noise, or pollution.

Some of these main environmental stressors can be a very common experience for a great number of people, in particular for residents of cities. Conversely, there are other critical environmental conditions that are very uncommon that are also of interest to environmental psychologists. The article by R. Bechtel on extreme environments and mental function elaborates on this issue. As Bechtel points out, there are two principal classifications of extreme environments. On the one hand, there are permanent extreme environments, such as high mountains, deserts, cold regions, and jungles, and on the other hand, there are temporary extreme environments, such as Antarctic polar stations, space shuttles, and simulation laboratories. The main goal of environmental psychology concerned with extreme environments is to better understand how human mental function and behavior can be affected by these kinds of environmental conditions in order to buffer their potentially negative impact on mental function: that is, how to make these environments less extreme for their users.

In recent decades, environmental psychology has also addressed stress-related issues from an opposite viewpoint: that is, how the physical environment can restore human mental functions, and therefore promote psychological well-being. The article by T. Hartig on restorative environments provides an exhaustive review of this promising literature. As the article explains, restorative environments are those that not only permit, but promote, restoration, where restoration is defined as the process of recovering physical, psychological, and social resources being diminished by efforts to adapt to external demands.

In his article, Hartig reports how a considerable amount of empirical research has demonstrated the

existence of specific environmental conditions capable of positively affecting people's feelings of well-being, although different theoretical elaborations have been proposed to explain it. Perhaps the most well-documented effect within this area of research is that natural settings appear to be more restorative than built-up ones, because they stimulate people's interest and provide people with the possibility of being away from their usual experience. Furthermore, natural environments are highly restorative because of various specific features, such as visual depth and visual complexity.

Research on restorative environments can have a high relevance for the design of health care structures. A widely cited study by R. Ulrich, published in *Science* in 1984, showed for example that providing hospital patients with the possibility of contact with nature (even just visual contact) might positively impact the effects of medical therapies. Restorativeness is a relevant issue for the domain of urban planning as well. Setting up urban green areas that are easily accessible to urban dwellers can provide them with more frequent opportunities for psychological restoration in a highly stressful environment such as the city.

2.4. Environmental Assessment

Although a theoretical and conceptual distinction between environmental assessment and environmental appraisal has been proposed, the former being more place-centered, the latter being more person-centered, here both of these aspects of assessment are considered. Environmental psychology interested in environmental assessment has encompassed a large amount of empirical contributions and theoretical models aimed at answering very important questions. For example, how do people evaluate, judge, or express preference for different kinds of environments? How do the physical features of a setting interact with people's personal and social characteristics when they evaluate an environment? In particular, which physical properties of the environment are related to positive evaluations and which are related to negative ones? Furthermore, what are the individual and group differences that may lead to differing environmental evaluations? And also, how do cognitive and affective judgments interact when a certain environmental scene is evaluated?

Generally speaking, different affective qualities have been found to characterize different environments. These qualities vary according to two main bipolar axes, pleasure (pleasant/unpleasant) and arousal (high/low). The physical surroundings of people's everyday

lives can generate positive or negative emotions in terms of the pleasure they afford to the perceiver, or in terms of the amount of arousal they provide to the perceiver.

According to a more cognitive model proposed by R. and S. Kaplan, there are four main physical characteristics predicting the pleasantness or unpleasantness of an environmental setting: coherence, complexity, legibility, and mystery. Coherence and complexity are two features of environmental scenes that immediately strike the perceiver. Conversely, legibility and mystery are two features that can be inferred after viewing an environmental scene for more time. The Kaplans' model also offered interesting insights into the study of landscape preference.

Whether a setting will generate positive or negative emotions in its users/perceivers is also a function of the prior state of the perceiver him- or herself. People's affective appraisal of a given environment is an adaptive process, in the sense that it is a function of both the properties of the environment and the characteristics of the perceiver. For example, high sensation seekers prefer highly arousing environmental scenes, and vice versa.

Several studies have also showed that natural environments are usually preferred to built environments by a large number of subjects. This preference seems to be consistent across different cultures, genders, ages, and so forth. Regardless if they are evaluated in terms of general preference, aesthetic beauty, or perceived restorativeness, natural landscapes are judged more positively than built settings. The presence of water in an environment is also positively judged. Moreover, as previously mentioned, exposure to natural views has been proved to have positive effects upon physiological and cognitive indicators, such as the rapidity of healing after hospitalization and the relief of mental fatigue. Such a nature favoritism, or biophilia, has been explained in evolutionary terms: people are still attracted by nature because it provided sources of sustenance and shelter in the earlier stages of human evolution. The psychological benefits of contact with nature can be due to the fact that evolution favored those who could benefit more from exposure to nature.

Despite this apparently generalized nature favoritism, a limited degree of human intervention within a natural environment is associated with positive evaluations. That is, scenes in which the human presence is visible (although not too intrusive) are usually preferred to scenes of total wilderness. This leads to the importance of another factor in shaping environmental evaluations, perceived control. People tend to judge more positively those environments that they perceive as controllable, compared to those that they perceive as uncontrollable.

Typically, the perception of control is associated with higher perceived safety. Speaking more generally, environmental evaluation could be conceived of as a function of the perceived cognitive, affective, and behavioral fit between the characteristics of the person (e.g., needs, goals, values, expectations) and the actual physical properties of the environment. In other words, people will prefer those environments they see as matching their needs, goals, and expectancies in that specific context at that given time.

The processes driving environmental assessments are relevant for the study of residential preference and satisfaction. The article written by M.V. Giuliani on residential preference and attachment across the lifespan, and the article by M. Bonaiuto on residential satisfaction and perceived residential environment quality, both included in this section, specifically deal with these issues. As both Giuliani and Bonaiuto describe in their articles, residential preference and satisfaction are multidimensional processes, given the tendency of people to combine different aspects when judging the quality of a residential setting. At a macro-level (e.g., the neighborhood) these aspects are related to (1) the physical and aesthetic characteristics of residential areas, (2) the social relations that people can establish in a specific residential area, and (3) the actions and behaviors that people can perform in a specific residential area. At a micro-level (e.g., the home) these aspects are related to (1) the quality of the interior arrangement and decoration of the house, (2) the specific architectural style of the house, and (3) the location of the house, in terms of both proximity to functional services and distance from the city center.

An important outcome of studies on environmental assessment has been the development of psychometric tools for the measurement of environmental preference and satisfaction, such as perceived environmental quality indicators (PEQIs). Because environmental quality assessment is conceived as a multi-dimensional process, PEQIs should encompass a sufficient variety of dimensions: the most widely shared qualities are aesthetics, functionality, safety, social relations, noise and pollution, and green spaces.

The information gathered through these tools can often represent the first step in developing more inclusive and participatory methods in environmental design and planning. Why is including users' perspectives or letting people take part in decisions considered so important in the environmental domain, as well as in many other domains? The article by A. Churchman and E. Sadan on participation in environmental design and planning thoroughly illustrates this issue. As Churchman and

Sadan outline, the major argument in favor of public participation is that it enables decisions that better fit the needs of the people. The positive consequences of this better fit are twofold, as both public support for environmental policies and people's care for a proper maintenance of their environments will be more likely. Nonetheless, Churchman and Sadan also identify and discuss a number of factors that may bedevil the effective implementation of participatory processes in the environmental domain. For example, public leaders and politicians sometimes see participation as a threat to their power. It is important to outline here how this article presents various arguments that support the crucial role of environmental psychology in promoting and improving participatory processes in environmental design, planning, and management. This aspect is particularly relevant, as it relates to the issue of improving the processes of inclusive environmental governance, which is currently seen as a crucial goal by many international and intergovernmental authorities.

2.5. Environmental Concern, Environmentally Friendly Behaviors, and Natural Resources

A shared belief among the scientific community and among public opinion is that the quality of our environment at the local and global level has rapidly decreased almost everywhere in the last decades. As a matter of fact, the major reason for that progressive and often dramatic deterioration is the impact of many human activities and rapid industrial growth on the ecosystems. Therefore, the healthy or unhealthy state of the environment primarily depends, and will depend in the future, on those human activities that can cause relevant and often irreversible environmental local and global changes.

In order to deal with these kind of problems, environmental psychology has increasingly addressed the issue of environmental concern in the last two decades. Two articles included in this section illustrate this important area of interest in present-day environmental psychology.

In his analysis of conservation behavior, F. Kaiser focuses on the psychological factors at the basis of the actions contributing to environmental preservation. As Kaiser suggests, people's conservation behaviors can be approached from two rather different perspectives. Conservation behavior, in fact, can be defined either from an observer's or from an actor's viewpoint. The first implies a focus on the consequences for the environment and considers apparently similar actions (e.g.,

recycling paper and recycling used batteries) as distinct behaviors. The second perspective focuses more directly on the human motivations driving conservation behaviors and groups even apparently different actions (e.g., recycling glass and owning solar panels) into the same behavioral category. Kaiser's article also illustrates how this second approach is more directly linked to a psychological perspective. On the contrary, a too strict focus on environmental consequences may lead to underestimating the psychological determinants of conservation actions.

But what are the psychological determinants of environmentally friendly behaviors? The article by H. Staats on pro-environmental attitudes and behavioral change deals more directly with this question. In particular, this article focuses on the relationship between environmentally friendly attitudes and behaviors: that is, the congruence or incongruence between what people believe and feel and how they behave toward the environment.

Pro-environmental attitudes are increasingly shared by many people in western societies. Some social structural variables (e.g., age, gender, level of education, place of residence, political orientation) appear to be related with this concern. Typically, young, female, highly educated, urban, and liberally oriented subjects express a stronger concern for the environment. The increased concern for environmental issues has been summed up by the concept, introduced by R. Dunlap and K. Van Liere at the end of the 1970s, of a new environmental paradigm (NEP). The core idea of NEP is that an increased number of people are developing a new perspective toward the environment, based on the belief that the state of the earth's ecosystems is becoming more and more precarious, therefore compromising human survival.

However, people often do not coherently translate such a positive concern into consequent pro-environmental behaviors. The reason for this lack of correspondence has been explained in different ways. Staats' article guides the reader through two important social psychological models of attitude-behavior relations: the theory of reasoned action (TRA) and the theory of planned behavior (TPB). As Staats points out, the basic tenet of these models is that the relation between attitudes and behaviors is mediated or moderated by other variables, such as behavioral intentions and perceived behavioral control. TRA and TPB have been applied, sometimes successfully and other times less successfully, to several environmentally relevant behavioral domains, such as waste recycling, travel modes, water use, energy use, and green consumerism.

At any rate, the role of variables other than attitudes seems to be crucial for explaining pro-environmental actions: among them there are past behaviors and habits, environmental knowledge, social and personal norms, and value orientations. Well-established habits are often difficult to quit, even when their performers are aware of the possible negative consequences for the environment. Likewise, a lack of specific knowledge about environmental issues, or about the environmental consequences of a specific behavior, may function as a barrier to pro-environmental actions: people are in fact frequently unaware of, or uncertain about, the actual state of the environment and the negative consequences of their behaviors on it. For example, a deeper knowledge of environmental issues seems to distinguish committed environmental activists from the general public, although it is difficult to state whether knowledge comes before activism, or vice versa. Both social and personal norms are also related to pro-environmental behaviors. Although some explicit pro-environmental norms are socially shared, people might not always behave according to these social norms, especially because several, sometimes conflicting, norms can be present at the same time in a given situation. In particular, the divergence between prescriptive (what is explicitly prescribed) and descriptive (what is observed in others' behaviors) social norms can hamper pro-environmental actions. A series of interesting experiments conducted by R. Cialdini and his colleagues showed that the context in which prescriptive and descriptive norms are framed and made salient can account for a particular environmental behavior such as littering. The role of values and ethical principles in shaping pro-environmental behaviors has been explored as well. A distinction has been proposed between two major value orientations about environmental issues: ecocentrism and anthropocentrism. Ecocentric people value environmental preservation for its own sake; conversely, anthropocentric people value environmental preservation because of the positive consequence that it can have upon human well-being. The former are more likely to behave coherently with their pro-environmental attitudes compared to the latter, even when this implies some personal or economic cost.

But what are better methods for the promotion of environmentally responsible behaviors and for the prevention of environmentally adverse behaviors? In his article, Staats outlines various possible strategies that seem to be effective to this end; they can be information-based (e.g., communication campaigns, education,

advertising), incentive-based (e.g., monetary rewards/punishments), prescription-based (e.g., laws, rules, regulations), or community-based (e.g., public involvement and participatory programs). Different kinds of behaviors in different contexts deserve different kinds of strategies. As P. Stern has recently pointed out, there are some basic principles to be followed for enhancing the likelihood of changing environmentally relevant behaviors: the use of mixed intervention strategies, the adoption of an actor's perspective, the constant monitoring of programs, and the promotion of public participation.

The models trying to explain the lack of correspondence between pro-environmental attitudes and behaviors that were briefly reviewed above rely on the role of various factors that could interfere with the supposed positive association between attitudes and behaviors. This theoretical position, however, may not adequately account for other social and societal processes involved in people-environment relations, in particular, the mutual interdependency of people's actions in the environment. A theoretical approach that delves more directly into this direction is the social dilemma paradigm.

Social dilemmas (SDs) are situations in which two or more people are faced with a choice between pursuing individual gains or maximizing collective benefits: if everyone (or too many) chooses the former option, everyone is worse off than they would be if everyone (or sufficiently many) chose the latter. In other words, in a SD, the interest of a single person is in conflict with a more general collective interest, and one is faced with a choice between a defective (or selfish) option and a cooperative (or altruistic) alternative. Such a conflicting situation often exists in the environmental field when individual and collective interests clash over the exploitation of a limited natural resource. These dilemmas are usually referred to as commons dilemmas.

As Staats suggest in his article, almost every environmental problem can be framed and approached as a commons dilemma situation. Most of the times the individual-collective conflict in the exploitation of a limited resource has a temporal dimension as well. That is, maximizing individual gains in the short term will result in a collective loss in the long run (the common resource will be extinguished); conversely, limiting the individual gains in the short term will result in a collective benefit in the long run (the common resource will be guaranteed). This process is at the core of the political concept of sustainable development, and has been well illustrated by G. Hardin in his famous 1968 article entitled "The Tragedy of the Commons."

On the basis of the SD paradigm, it is not surprising that people frequently find out that behaving in an environmentally negative way is in the short term more advantageous, easier, more comfortable, less costly, and so forth. To an extreme extent, in many daily situations, environmentally unfriendly behaviors are the rule and not the exception.

In addition to the Staats' article, two other contributions included in this section deal, more or less directly, with the SD paradigm. In particular, in his article on environmental versus individual risk taking, C. Vlek reviews the literature on individual risk taking in order to understand how to manage environmental risks as a collective risk. As Vlek illustrates, various traditional psychological theories on risk can be considered when dealing with environmental risk perception, such as classical decision theory, prospect theory, risk homeostasis, protection motivation theory, and emotional approaches to risk. Furthermore, it is shown that many collective risks for the environment are often the result of the summed external negative effects of numerous individually advantageous activities. To this extent, the SD paradigm is directly called into question by Vlek's article, as it shows how the minimization of environmental collective risks and the maximization of individual benefits may be incompatible goals in many everyday situations.

Likewise, the article on travel and the environment by T. Garling illustrates how concepts deriving from the SD paradigm can be relevant to the domain of motorized transportation. As Garling shows, the increasing trend of private car use in urban areas is starting to pose serious threats to the global environment and to the health and well-being of urban dwellers. These threats are overwhelming the individual benefits of the single car users. The choice of whether to shift from private to public motorized transportation systems or from motorized to un-motorized vehicles can be framed as a social dilemma for many car and motorbike drivers. Therefore, a number of policy measures aiming at reducing private car use among urban dwellers that are outlined by the Garling's article can be seen as attempts to solve that dilemma.

But which are the main factors orienting our choices in social dilemma situations? Three crucial components of SDs are information, communication, and social identification. The possibility of monitoring others' behaviors and the possibility of communication may promote cooperation. Likewise, high social identification may result in stronger cooperation, although the opposite may be true. In fact, when a dilemma involves two or more groups competing for the same resource,

identification with a specific group may result in diminished cooperation.

These aspects may also have relevant implications for legitimizing and facilitating the acceptance of authority structures regulating citizens' environmental behaviors in our societies. The way a situation is structured by the authorities and interpreted by the individuals acting in it is crucial for approaching environmental dilemmas. An example can be found in the domain of biodiversity conservation. Here, highly centralized environmental policies (e.g., land use regulations, designations of National Parks) can represent a dilemma in the perception of local stakeholders. A strong sense of local identification might then form a basis for in-group biased environmental perceptions, in which public authorities are seen as a conflicting out-group by local identifiers. This can lead to the emergence of local protests against specific environmental regulations.

In sum, the SD paradigm is increasingly being used to address many current environmental problems regarding the management of limited natural resources. The results from studies based on this paradigm suggest that strategies for solving collective environmental dilemmas in our societies should stress the common fate between individual group members, in particular because they show the crucial importance of communication and shared identities among individuals for the promotion of cooperative and pro-environmental choices.

2.6. Place-Specific Environmental Psychology

The articles in this section described above refer to environmental psychological processes that can be considered as transverse to the places where people's everyday experiences occur. However, current environmental psychology has been increasingly characterized by the adoption of a place-specific approach to people-environment interactions. This has led many environmental psychologists to concentrate their interest on specific places, ranging from the micro-scale of home interiors, to the meso-scale of workplaces, schools, and hospitals, to the macro-scale of neighborhoods and cities. There are three articles in this section that focus more directly on three specific places considered as particularly relevant to many people's daily lives: the workplace, schools, and the urban environment.

The article written by R. Walden on working environments reviews some of the main theoretical and empirical contributions addressing environment-behavior

relations in the workplace. In her contribution, Walden notes how the study of the physical characteristics of workplaces can be traced back to the beginnings of psychological inquiry. The studies by E. Mayo and his coworkers at the Western Electric Company on the effects of the physical environment upon work performance date back to the first half of the 20th century. These pioneering works clearly highlighted how the physical features of the work settings can interact with the interpersonal relations and organizational aspects at work in shaping work performance. Present-day models of environment–behavior relations in the workplace, such as one recently proposed by R. Gifford, still reflect the influence of Mayo’s earlier findings. The model by Gifford mentioned in Walden’s article places a particular emphasis on the different degrees of congruence or incongruence resulting from the interaction between the personal characteristics of workers (e.g., experience, job level, personality, skills, motivation) and the physical characteristics of the work setting (e.g., noise, temperature, light, spatial density, quality of materials). The higher the congruence, the better the outcomes of the working activities. These can be assessed in terms of workers’ stress or well-being, individual and collective performance, job satisfaction, or organizational commitment. In addition, various psychological processes (e.g., arousal, adaptation, overload, emotions, personal control) may act as mediators of the relationship between the environment–person fit and the outcomes of the working activities. As Walden notes in her article, future trends in the design of workplaces point to rapid development of communication technologies as well as to the role of these in matching the augmented concern for sustainability that characterizes human societies. One example is the possibility for off-site working, or telecommuting, through the use of remote cable connections or wireless systems. This possibility could partly offset the disadvantages of traffic congestions among commuters.

A second article by R. Walden, on school environments, focuses on another place that has also been widely investigated by environmental psychology. As with workplaces, the attention devoted to schools is a long-standing tradition in environmental psychology. In fact, the interest of environmental psychology for schools can be traced back to the pioneering studies of Barker and colleagues in the 1960s. Generally speaking, environmental psychology has clearly outlined how the physical features of schools have a considerable impact on the effectiveness of the educational

program. Different physical characteristics of schools can either promote or hamper the education process. As Walden reports, there is consistent evidence showing that small schools do a better job than large schools. Empirical research has showed how smaller schools are characterized by a better relationship between students and teachers, diminished rates of vandalism and violence, faster career advancement of children with disadvantaged backgrounds, increased participation in and commitment to school activities, and greater satisfaction of parents. Therefore, Walden states that schools with no more than 500–700 pupils appear to be a reasonable solution, while schools with more than 2100 students have shown the worst performances. Apart from school size, several other characteristics of the educational physical setting may affect the quality of the education process. The most important are the state of maintenance of the school buildings, the presence of design features affording proper privacy regulation, good acoustics in classrooms, the availability of daylight in classrooms, the presence of playgrounds and schoolyards furnished with nature and natural materials, and the presence of carpets and decorations. Finally, the design of new schools can benefit from the involvement of students, teachers, parents, and members of the local communities.

A third article focuses on another important location that encompasses the two previously mentioned places: the city. As G. Moser outlines in his contribution on urban environment and human behavior, about half of the world’s population spends the majority of their lifetime in big cities.

As reported by Moser, cities are more and more becoming places in which daily conditions are far from optimal for their inhabitants: cities are by and large considered as bad places to live. In line with this trend, environmental psychology has introduced the concept of urban stress to indicate the sources of stress that are typical of urban life, and therefore that affect a large percentage of the population. Living in a large-scale urban settlement can frequently become a source of multiple stressors, because of the simultaneous presence of several adverse environmental conditions. This aspect has also been discussed in the Evans and Cohen article on stress. For example, urban settings can amplify the relationships among crowding, social withdrawal, social support, and pro-social behaviors. Moreover, urban life presents several conditions in which people perceive a very low degree of control over events: this often results in diminished self-efficacy and helplessness.

On the other hand, despite their bad reputation, cities continue to attract a large part of the human population. Therefore, as the Moser's article reminds, it is not surprising that urban settlements have been a specific object of analyses for many scholars in environmental psychology. Some important psychological processes related to the everyday urban experience were actually pointed out by environmental psychology, such as place- and urban-related identity and urban attachment. In that sense, cities are a primary arena in which almost any environmental psychological theory and empirical finding can be considered. As a consequence, cities can be thought of as a wide field-laboratory for testing environmental psychological theories. But what are the main trends of environmental psychological research on urban settlements? The article by Moser describes the increased concern for issues of sustainability and sustainable development that have emerged in the scientific community in the last decade. It is worth stressing how cities, considered as ecosystems, were seen as having a crucial role by the many intergovernmental agencies concerned with the promotion of sustainability. As a consequence, the concept of sustainable cities has been proposed in order to define the major environmental transformations needed to improve urban systems in order to enhance their ecological "performance." These issues are the next major challenge for environmental psychology focused on urban issues. Embracing this perspective, Moser also shows how urban-related identity is an important environmental psychological factor that may account for the adoption of sustainable lifestyles among city dwellers. As an example, Moser mentions the city-identity-sustainability (CIS) model that has been recently proposed by E. Pol and others. According to the CIS model, a strong sense of identification with the city can lead urban inhabitants' to a stronger and more durable engagement in pro-environmental activities.

3. THE FUTURE OF ENVIRONMENTAL PSYCHOLOGY

Since its beginnings, environmental psychology has been a frontier field within psychological science. On the one hand, following the ecological demand coming from several fields of psychology, environmental psychology has tried to underlie the importance of a contextual/transcendental approach to psychological inquiry. Within this

approach, environmental psychology has focused on an aspect that was typically underestimated by mainstream psychology: the role of physical features of everyday life environments in affecting human psychological processes, behavior, and well-being. On the other hand, environmental psychology has tried to respond to specific and urgent demands coming from various technical fields devoted to the design, change, preservation, and management of these everyday environments.

In many aspects, environmental psychology is still a frontier field of psychological inquiry, as its primary aims have not substantially changed over the decades. The whole story about the context-related character of human behavior and mental function is still far from being known due to the wide variability and diversity of the physical contexts in which human behavior takes place. At the same time, many of the urgent environmental problems that generated an external demand for the development of environmental psychology have not been solved yet. Some of them have become even more serious, as the quality of the environment and the availability of life-supporting resources have diminished consistently in many parts of the world.

Thus, the research agenda of environmental psychology has broadened considerably in the last 20 years. For example, the collaboration between psychologists and architects has increasingly included people-natural environment relations together with people-built environment relations. The domain of political ecology with its concept of sustainable development has influenced the fields of architecture, engineering, and urban planning. The increased relevance of various new technological and architectural domains such as bio-architecture and landscape architecture is an example of such an influence. Also, an increasing focus has been placed on the human dimension of global environmental and biospheric changes.

To address these issues, many different psychological theories can be used, coming from a broad range of psychological research domains, such as perception psychology, social and developmental psychology, cognitive psychology, and behavioral decision theory. The task of environmental psychology is still to combine these existing theories as well as to develop new ones for better understanding specific people-environment relations, and for supporting environmental designers and managers in enhancing the well-being of present and future generations.

Overall, present-day environmental psychology can be characterized not only as a highly socially relevant field of applied psychology, but also as an opportunity

for developing psychology in a more context-related direction, that is, toward that real world psychology continuously envisaged in environmental psychology from its beginnings to the present.

GLOSSARY

adaptation level shifts in environmental perception History of experience with an environmental stressor changes referential criteria for environmental perception of current environmental conditions.

behavioral aftereffects Performance deficits following exposure to environmental stressors.

cognitive consequences of learned helplessness Lower mastery, reduced self-efficacy, or greater externality in locus of control from chronic environmental stressor exposure.

coping perseverance The use of well-learned coping strategies when an environmental condition is no longer present.

cumulative fatigue The buildup of fatigue from expenditure of energy to cope with an environmental stressor; the three types of cumulative fatigue are behavioral aftereffects, spillover, and diminished coping with multiple stressors.

diminished coping with multiple stressors The reduced ability to cope with a subsequent stressor following exposure to an environmental stressor.

effort by environmental stressor interaction Physiological mobilization produced by cognitive or physical effort to maintain task performance during stressor exposure.

environmental stressors Physical characteristics of the environment that produce stress (e.g., commuting, crowding, noise, pollution).

learned helplessness The realization, caused by uncontrollable environmental events, that one cannot control one's environment. This may result in diminished motivation to assert control even when feasible to do so, the inability to learn that subsequent challenges that are objectively controllable can be controlled, and feelings of anxiety and depression.

overgeneralization Strategies for coping with chronic environmental stressors may become overlearned so that coping perseveration occurs in the absence of the stressor; adaptation level shifts in environmental perception may also occur.

physiological mobilization Elevated physiological stress produced by chronic exposure to environmental stressors; also caused by acute environmental stressor exposure in combination with the effort to maintain optimum task performance.

spillover The negative affect, strained interpersonal relationships, or fatigue produced by exposure to an environmental stressor in one setting that carries over into another setting.

Apart from the direct physical insults produced by toxins, mental health, psychophysiology, performance, and human motivation are all affected by environmental quality. In this article, we present a theoretical framework for understanding how environmental quality impacts human behavior. Human beings are not passive recipients of environmental conditions; instead, they work to optimize the balance between environmental conditions and human needs. Human beings thrive in a vast array of ecological niches.

However, we pay a price for our enormous adaptational capacities. The adaptive costs of coping with suboptimal physical conditions provide a theoretical framework for describing how the physical environment influences human behavior. We develop this theoretical framework and illustrate psychological impacts of poor environmental quality.

1. THEORETICAL FRAMEWORK

There are four categories of the adaptive costs of coping with poor environmental quality that have psychological consequences. These categories are cumulative fatigue, learned helplessness, physiological mobilization, and overgeneralization.

1.1. Cumulative Fatigue

It takes energy to cope with suboptimal environmental conditions. Expenditure of energy, particularly when demands are high or prolonged, causes fatigue. Three types of cumulative fatigue are behavioral aftereffects, spillover, and diminished coping with multiple stressors.

1.1.1. Behavioral Aftereffects

Behavioral aftereffects refer to impaired task performance following exposure to an environmental demand. In a typical aftereffects paradigm, an individual works on a task during a physical stressor such as noise. Following cessation of stressor exposure, the individual is asked to perform another task. Compromised performance on the second task, when the stressor is no longer present, is an index of behavioral aftereffects.

In the Glass and Singer behavioral aftereffects paradigm, subjects work on a simple task while exposed to an environmental stressor. Environmental stressors that have been studied include noise, crowding, temperature, and air pollution. During the environmental exposure period, subjects worked on simple tasks (e.g., anagrams). Performance during exposure is generally unaffected. Immediately following task performance under the environmental stressor, the stressor is terminated, and the subject is given a behavioral aftereffects task. Two commonly used aftereffect measures are persistence on a difficult or unsolvable puzzle and ability to detect errors in a proofreading task. Table I depicts a typical set of findings from one of Glass and Singer's studies, in which immediately after uncontrollable noise exposure was terminated, subjects were

TABLE I
Glass and Singer Aftereffects Data Following Uncontrollable Noise

	Noise	Quiet
Number of attempts on two unsolvable puzzles	10.88	41.20

administered a task that assessed their persistence on unsolvable puzzles.

In addition to the large number of replications of the Glass and Singer aftereffects data across a wide array of environmental stressors, another aspect of this paradigm is noteworthy. Several investigators have examined behavioral aftereffects of chronic environmental stressors such as commuting, crowding, and noise. Bullinger *et al.* noted that the longer the duration of noise exposure in the case of the opening of a new airport, the stronger were the impacts of chronic noise exposure on behavioral aftereffects (see Fig. 1).

1.1.2. Spillover

A second type of cumulative fatigue produced by poor environmental conditions is spillover. Spillover occurs when conditions in one setting influence a subject's well being in another location. A common example of spillover is when poor working conditions interfere with

FIGURE 1 Task persistence among elementary aged school children in relation to airport noise exposure before and after the opening of a new airport. Controls matched on SES.

home life. A more congested commute creates interpersonal strains with family members at home. Epstein and Karlin reported that men but not women following a short term crowding experience in the laboratory felt less cohesive and more competitive. Immediately following exposure to crowded shopping conditions or high noise levels in a laboratory, individuals are less likely to behave altruistically when given a chance to provide help in a low stress setting. Table II provides illustrative data. A stranger (experimental confederate) appeared to be looking for a dropped contact lens on the floor of a shopping center in a low-density, inactive area of the center. Immediately prior to the assessment of spillover, subjects had been randomly assigned to perform a series of shopping tasks in noisy and crowded or relatively desolate areas of a mall.

1.1.3. Diminished Coping with Multiple Stressors

The effort applied in coping with environmental stressors can result in reduced capacity for coping with subsequent demands. Reduced coping capacity has been found following exposure to noise, crowding, high temperature, and pollutants. For example, the adverse effects of traffic noise on blood pressure in school children are accentuated if they also live in noisy homes. Residents of noisy areas respond more negatively to stressful events than residents with similar backgrounds (SES) who live in quiet areas. Crowding exacerbates the impact of high temperature on negative affect. Maxwell noted that the adverse influence of high-density daycare conditions on children’s levels of behavioral disturbances was accentuated by crowding levels in the child’s home. Researchers have also investigated crowding interactions with psychosocial rather than physical stressors. For example, elementary school aged children experienced greater physiological stress and psychological

TABLE II
Altruistic Behavior Following a Simulated Shopping Task in a Crowded or Uncrowded Shopping Center

Seconds spent looking for contact lens	15	41

distress in relation to greater family turmoil if they lived in more crowded homes and the effects of daily hassles on psychological health in adults were accentuated in high density homes.

Air pollution also accentuates adverse responses to other stressors. The effects of polluted working conditions on respiratory and dermatological symptoms were greater for workers also contending with higher levels of job stress. Evans and colleagues found that ozone was linked to psychological distress, but only among individuals also experiencing stressful life events (see Fig. 2).

1.2. Learned Helplessness

Attempts to cope with uncontrollable environments can result in learned helplessness. Individuals who try to abate a negative environmental condition and are unable to do so eventually learn that their efforts to control their environment are fruitless. They become unmotivated to assert control (motivational consequences), even when it is feasible to do so, unable to learn that subsequent challenges they confront that are objectively controllable can be controlled (cognitive consequences), and become anxious and depressed (affective consequences).

1.2.1. Cognitive Consequences

Experiencing uncontrollable environments can lead to the inability to learn that controllable environments

FIGURE 2 Psychological distress as a function of the interaction of exposure to pollution and recent stressful life events among a representative sample in Los Angeles.

can be managed or affected by personal effort. For example, individuals living under crowded conditions report less perceived control or feelings of mastery over their immediate surroundings compared to others living under less crowded conditions. Traffic congestion levels negatively impact feelings of control over commuting itself and in general among car drivers. Bus drivers facing more traffic congestion report significantly less control over their job.

Community airport noise exposure has also been linked to diminished feelings of personal control. For example, the typical maturational trajectory of increased internal locus of control was altered among elementary school children living for longer periods of time in airport noise impact zones (see Table III). SES controls were incorporated.

1.2.2. Motivational Consequences

As discussed previously, exposure to uncontrollable noise, crowding, or air pollution leads to deficits in behavioral aftereffects tasks. In the original aftereffects studies, Glass and Singer included an independent variable that points toward learned helplessness as a possible mechanism for behavioral aftereffects. When subjects were led to believe they could terminate the noise if it became too aversive by pushing a button, there were no behavioral aftereffects of noise. This occurred even though no one in this “perceived control” condition actually pushed the button. In short, aftereffects occurred only among those exposed to “uncontrollable” stressors. Table IV adds the noise with perceived control condition to our original behavioral aftereffects example shown before in Table I. Subjects were randomly assigned to conditions.

This salutary effect of perceived control over noise on behavioral aftereffects has been widely replicated. Parallel results have been uncovered in studies of crowding and pollution.

	Noise	Quiet	Noise with perceived control
Number of attempts on two unsolvable puzzles	10.88	41.20	41.67

More direct evidence that suboptimal environmental quality can produce helplessness comes from two paradigms. In one paradigm, participants performed a task in order to avoid a noxious stimulus. For some subjects, exposure to the noxious stimulus was contingent upon their performance—by performing well, they could minimize exposure to the noxious stimulus. Other subjects were “yoked” to the first group in that they were exposed to the same noxious stimulus for the same duration of time. For these subjects, however, exposure to the noxious stimulus was independent of their performance. These conditions (contingent vs noncontingent performance and punishment) were then followed by a second phase in which a performance contingent task was administered. For this task, avoidance of the noxious stimulus was possible for all subjects. Prior exposure to the inescapable stimulus condition induced learned helplessness in the second phase. Even when an instrumental response was available, subjects who had been in the initial inescapable condition took much longer to learn the escape response. Of particular interest is the fact that exposure to inescapable noise versus escapable noise reliably produces learned helplessness in adults.

In a second paradigm, vulnerability to the induction of helplessness is related to chronic environmental conditions. Cohen *et al.* gave elementary school children in either airport noise-impacted or quiet schools a jigsaw puzzle to work on. More children from high-noise areas failed to solve the puzzle. Of those children who failed, a larger percent of children from noise-exposed areas failed the puzzle because they simply gave up trying prior to the end of the testing period (see Table V). SES controls were included.

Crowded living conditions similarly affect learned helplessness in children. For example, the longer college students lived in a crowded dormitory, the greater their helplessness behaviors compared to students in

TABLE V
Percentage of Children Who Gave up on a Solvable Jigsaw Puzzle prior to the Total Time Available^a

	Noisy school	Quiet school
Percent giving up	31	7

^aTotal time available was 4 minutes.

uncrowded dormitories. Moreover, these helplessness behaviors closely mirrored the extent to which they felt powerless to regulate social interaction in their dormitory.

1.3. Physiological Mobilization

The marshalling of coping resources requires energy. This expenditure of energy requires mobilization of physiological resources, as reflected by elevated physiological stress. This occurs primarily in cardiovascular and neuroendocrine systems. Mobilization of energy in response to acute environmental demands is adaptive. The problem occurs with chronic physiological mobilization in order to meet repeated environmental demands. These elevations produce wear and tear on the body, alter the body's ability to turn off these systems when external demands cease, and can eventually lead to physical and psychological morbidity.

Effort and physiological mobilization are interrelated. When performing a task under a stressor, if effort is high, task performance is maintained but physiological mobilization escalates. If effort is low under a stressor, performance suffers, but physiological mobilization is minimal. Thus, there is an effort by stressor tradeoff.

1.3.1. Physiological Stress

A large number of studies have been conducted on occupational noise exposure and blood pressure. The data are mixed and methodological flaws plague many of these studies. Community noise studies have used better designs and revealed consistent elevations in blood pressure in children exposed to airport noise. Fig. 3 shows data comparing school children's physiological stress levels before and after the opening of an airport. Children were tested 1 year before the airport opened, 1 year after, and then again 6 months later.

Crowding has similar effects on the physiological stress response. Crowding has been associated with elevated blood pressure in the laboratory and among institutional populations and in some but not all studies of crowded housing and neighborhoods. Traffic congestion has been associated with elevated blood pressure and stress hormones; more crowded or more difficult train commuting elevates stress hormones as well.

FIGURE 3 Physiological stress responses in children in a prospective study of airport noise. The samples were well matches on SES.

1.3.2. Effort by Stressor Tradeoff

Some of the physiological stress accompanying environmental stressors is caused by increased expenditure of effort to maintain task performance. Cardiovascular and neuroendocrine responses to acute noise rapidly habituate, returning to baseline levels. This habituation does not occur, however, when subjects simultaneously work on cognitively demanding tasks during noisy conditions. More direct evidence for the role of effort emanates from studies showing a performance–physiological stress tradeoff. For example, Tafalla and Evans manipulated cognitive effort and noise in a laboratory experiment, finding that noise adversely affected performance but had little impact on cortisol when effort was low. When participants worked under high effort on a task during noise, the opposite profile emerged: no performance effects of noise but elevated physiological stress. See Table VI for an illustration of some of their findings.

Field studies have uncovered analogous job demand by occupational noise interactions on physiological stress. In one study, the impact of noise on blood pressure more than doubled under high- vs low-demand jobs. A similar effort by stressor interaction on performance and physiology was found in a laboratory investigation of crowding.

1.4. Overgeneralization

Humans respond to environmental insults with strategies to optimize the balance between demands and resources. If the demands are chronic, however, coping strategies can become habitual, persevering even when they are not appropriate. Adaptation level shifts in environmental perception may also occur. This is when the reference criterion one uses to judge a current stimulus is influenced by prior history with that

same stimulus. These shifts in referential criteria reflect habituation or reduce sensitivity to the stimulus.

1.4.1. Coping Perseveration

Children chronically exposed to noise appear to adopt a cognitive strategy of tuning or filtering out the noise. This strategy, while adaptive when noise is present, may be harmful if it becomes a characteristic strategy for processing auditory information, including meaningful stimuli such as speech. Cohen *et al.* showed that the louder the exposure to traffic noise at home, the more trouble children had in a task that assessed their abilities to discriminate between phonemes (e.g., the sound for b and d, or p and b). The children were prescreened for normal hearing thresholds. As shown in Table VII, noise exposure impairs phoneme perception, which in turn damages reading acquisition. SES controls were incorporated. Other noise studies have found similar relationships.

Perseveration of coping strategies has also been uncovered in studies of crowding. A common strategy for coping with crowding is social withdrawal. If people cope with overcrowded living conditions by socially withdrawing, an unintended consequence might be the breakdown of socially supportive relationships. Evans *et al.*, Lakey, and Lepore *et al.* found evidence for lower levels of perceived support in more crowded residences. The higher the ratio of people per room, independent of SES, the lower the levels of social support. These studies also showed that the link between residential crowding and poor psychological health was mediated by social support.

The adverse effects of residential crowding on social support appear to be caused by social withdrawal. In one study, college students who lived in high- or low-density apartments were brought into the laboratory. The lab was not crowded. The subject and a

confederate were placed into situations in which they each needed social support at different times. As shown in Fig. 4, subjects who lived in crowded homes were significantly more unresponsive to the confederate's offers of support. The obverse occurred as well.

1.4.2. Adaptation Level Shifts

People may become so accustomed to suboptimal environmental conditions that they become desensitized to poor environmental quality. For example, an auditory stimulus will be perceived as softer if loud sounds have recently been experienced. Berglund *et al.* found that a given level of noise is less annoying if one has a history of living in a noisy area. Parallel results have been found for chronic residential crowding history and judgments of perceived crowding.

Wohlwill and Kohn examined residential histories and judgments of environmental quality. Adults who had recently migrated to a medium-sized community (Harrisburg, Pennsylvania) were asked to judge the attributes of their new community. Migrants from urban areas judged Harrisburg as significantly less noisy, less crowded, and less polluted than did their counterparts from small towns. In a second study, photographs of environmental qualities of communities varying in scale were shown. Adults from small towns consistently perceived greater levels of noise and crowding for a given photograph compared to individuals from large metropolitan areas.

People's judgments of perceived air quality habituate with continued experience of pollution. Flachsbart and Phillips showed that smaller changes in smog are

FIGURE 4 Proportion of residents from crowded and uncrowded apartments who ignored, acknowledged, or accepted confederate's social support.

TABLE VIII
Signal Detection Data for Recognition of Smog for People with Long-Term or Little Prior Experience with Air Pollution

History of air pollution	Response criterion	Detection sensitivity
Long-term experience		
Scene 1	.709	2.171
Scene 2	.637	2.052
Little prior experience		
Scene 1	.211	2.751
Scene 2	.276	2.340

required to alter judgments of perceived air quality for those unaccustomed to poor air quality compared to those who have prior familiarity with smog. Evans *et al.* analyzed pollution perception with signal detection theory. Signal detection theory enables one to separate perceptual processes from response criteria when judging stimuli. For example, if one is expecting an important phone call, one's threshold (response criteria) for responding to auditory stimuli shifts. It takes less of an indication that a bell has rung under these circumstances in order for someone to check the phone. Note that actual detection sensitivity to hear a bell is not changed, just response criterion.

College students who had recently migrated to southern California were tested. The students were well matched except with respect to prior histories of experience with air pollution. The students were shown two different, unfamiliar scenes of a distant vista. Each scene was shown multiple times with varying degrees of photochemical smog present. Subjects reported whether they saw smog and rated their confidence in their judgments. Students with prior histories of air pollution were less likely to report that pollution was present in a scene compared to people relatively unfamiliar with pollution (Table VIII). Actual visual thresholds of seeing air pollution (detection sensitivity) were equivalent.

2. CONCLUSION

The adaptive capabilities of human beings enables us to cope with a wide range of environmental conditions. Table IX provides a summary of some of the psychological consequences of human attempts to cope with suboptimal environmental quality.

TABLE IX
Adaptive Costs of Coping with Suboptimal Environmental Conditions

Category of adaptive cost	Types of effects

GLOSSARY

commons dilemma The (un)balance between individual interests and collective goods, depending on the discounting of temporally, spatially, and/or socially distant decision consequences of those involved.

coping appraisal Overall judgment of one's potential to handle an external threat, in terms of response efficacy, self-efficacy, and costs and barriers of action.

external versus internal control Events may occur through (external) "acts of god," (internal) human factors, or both. This underlies the difference between gambling tasks and control tasks.

frequency versus scenario information Historical relative frequencies versus future possible ways of accident occurrence, as bases for probability estimation.

judgmental heuristics and biases Simplified ways and tendencies to estimate probabilities and other uncertain quantities.

perceived risk Personal judgment, on various grounds, of the nature and seriousness of risk, often contrasted with expert-assessed or calculated risk based on scientific models and/or databases.

precautionary principle The willingness to decide for (costly) protective measures or against risky activity if there is reasonable suspicion of serious threat.

risk The possibility of a negative event (harm, loss, accident, disease, or disaster).

risk attitude The tendency either to venture something or not in view of the safe(r) status quo, depending on utilities of possible decision consequences.

risk homeostasis A risk taker's tendency to use externally increased safety for enhanced benefit achievement, thereby maintaining or returning to the original (target) risk level.

threat appraisal Overall judgment of an external threat, in terms of perceived seriousness, vulnerability, and associated benefits.

utility function The formal relationship between personal utility and the objective value of decision consequence variables (e.g., monetary outcome, driving speed, number of fatalities).

Managing risks is an everyday task of life, appearing in different scopes and scales. To understand environmental

risk management, we must be familiar with individual risk taking. In this article, basic concepts and theories about risk are reviewed, along with empirical findings about judgmental and behavioral mechanisms. For risk taking, perceived control often is more important than calculated gambling. The major dimensions of perceived technological risk are the undesirability of the consequences, perceived controllability, and importance of associated benefits. Collective risks often arise from negative external effects of numerous individual activities, such as driving a car. Several factors of collective rationality (or cooperation) are discussed, along with various intervention strategies for achieving a sustainable balance in such commons dilemmas. Conclusions focus on psychologically enlightened safety management, both small-scale and large-scale.

1. RISK LEVELS, DEFINITIONS, AND COMPLICATIONS

On December 9, 2003, four Latvian mountaineers were climbing Mount Cook, the highest peak of New Zealand. To ensure each other's safety, they were all connected to the same rope. Suddenly, one of them slipped on the icy slope. The other three at that moment were not standing firm enough to absorb the shock of their falling colleague. Unfortunately, the four sportsmen fell 300 meters and died on the spot.

In November 2003, more than 200 people died, an entire village was destroyed, and much farmland was turned useless by abundant river floods in the Northern Sumatran district of Lankat (Indonesia) following days of heavy monsoon rainfall. Wholesale deforestation, undertaken for the benefit of logging companies, appeared to be the major cause; it had been unofficially tolerated for many years despite the warnings from environmental protection groups and local communities.

1.1. Research Origins

Things can always go wrong. However promising or well-intended, any activity or situation may result in loss, harm, accident, or disaster (henceforth referred to as loss). Sometimes we are personally responsible and have to bear the damage ourselves. In other cases, risks are collective, arising through natural events, through the actions of others, or through both.

Statistics and economics have long dominated the thinking of researchers and policymakers about risk.

Mathematical statistics has laid the grounds for probabilistic risk analysis in the engineering sciences. Some 25 years ago, this elicited psychometric research on perceived risks of technologies. Neoclassical economic theory has evoked 40-year-old behavioral decision research, in which psychologists gradually developed authentic concepts and theories of their own. Social psychologists increasingly study commons dilemmas, capturing the tension between individual interests and collective goods, such as environmental sustainability.

Here, an overview of concepts, models, and findings on human risk judgment and decision making about safety is provided. The emphasis is on conceptual clarification and interrelation from different research directions. First considered is the concept of risk and individual risk taking, then the evaluation and management of collective environmental risks.

1.2. Different Levels of Risk

In risk taking there seem to be two extremes. On the small-scale side, the quality of a challenging activity, such as mountain climbing, car driving, or tight-rope walking across Niagara Falls, may actually suffer from the risk awareness of the participant, since that awareness might distract attention and raise worries, whereas the self-confident subject tries to perform optimally and prevent accidents from occurring. On the large-scale side, people may feel uneasy or threatened by environmental conditions such as ambient air pollution, street crime, or the chance of flooding. Such situations stimulate explicit risk assessment and the design of coordinated safety strategies, often involving many people.

For the moment, loosely defining risk as the possibility of undesirable consequences of an activity or situation (henceforth: activity), risks may be categorized as occurring on seven different levels of complexity, as shown in Table I, together with illustrative examples.

Table I shows varieties of risk associated with single, low-level activities that are normally accompanied by a relative unawareness of risk; safety is warranted by due attention, motivation, and experienced behavioral control. Table I also gives examples of worrisome risks whose cause or (more often) effective control is not sufficiently clear. One may roughly distinguish three types of risks: clearly perceptible risks (as in car traffic), scientifically clear but not publicly well-known risks (as from soil pollution), and new, unknown, or ambiguous risks (as from genetic engineering) that may call for precautionary measures.

TABLE I
Different Scale Levels of Risk and Risk Management

Level	Key words to illustrate risk (as "possible loss from ...")
Personal	Smoking, drinking, illness, sports
Indoor	Air quality, radon, do-it-yourself jobs
Local	Traffic, toxic waste, urban smog
Regional	Air, soil, and groundwater pollution; GMO crops
Fluvial	Pollution of rivers, lakes, coastal zones; flooding
Continental	Acid precipitation, deforestation, glacier melting
Global	Ozone-layer depletion, climate change, sea level rise

1.3. Definitions of Risk

Following traditional statistics, risk is the probability of loss, where probability is estimated on the basis of long-term observed relative frequency of comparable losses. In business economics, in decision theory, and in practical safety management, risk also has other, both extended and more subjective definitions. Table II lists six formal definitions of risk that may be used for quantitative estimation.

The psychological problem with any definition in Table II is that both probability and size of loss are essentially judgmental components. Probability may be objectified, but only under rather limiting conditions, such as, for example, the assumption that the relevant system will behave in the future as it did in the (observed) past and, obviously, that a sufficient

TABLE II
Formal Definitions of Risk

<ul style="list-style-type: none"> • Probability of specified loss • Size of possible loss • Product of probability and size of loss • Variance of total distribution of losses and benefits of decision alternative • Relative weight of possible loss versus comparable gain (following utility curve) • Two-dimensional set of points indicating probabilities of possible different losses^a
--

^aThis may characterize, e.g., a factory, household, or transport on a multi-annual basis.

number of observations is available to compute relative frequencies. Size of loss similarly presupposes a fair specification of what such loss really means and how it eventually all works out (or not). Multi-attributable notions of loss (as a function of, e.g., people killed and wounded, property damage, environmental pollution) do not easily fit into classical risk definitions.

On an aggregate level (Table I), the international debate on climate change illustrates the scientific difficulties of environmental risk assessment and management.

1.4. Development of Risk Psychology

In critical response to technological risk analysis, social scientists, particularly psychologists, have explored people's risk perceptions and behaviors. Thus, a body of theoretical and empirical knowledge has developed that represents nontechnical and noncomputational ways of conceptualizing and grasping risk as an essential component of human performance, deliberation, and emotionality.

One result of this development is that nowadays the objectification of technological risk has limited (only "bandwidth") potential and that the actual assessment, decision making, and control of external risks is to a large extent a procedural and often multi-stakeholder matter involving attention, effort, competence, and communication with respect to technical as well as behavioral and social components of risky activities. Many environmental risks came to be seen as collective effects generated by numerous individual activities in commons dilemma situations (see Section 5). One challenge for psychology is to expand from existing theory and methodology about small-scale risk taking toward a better understanding of human judgment and behavior vis-à-vis large-scale environmental risks.

2. MODELS AND MECHANISMS OF INDIVIDUAL RISK TAKING

This section reviews a number of theoretical models and issues, giving various insights into the way we judge risks and deal with risky situations.

2.1. Classical Decision Theory

Following classical economic theory, a simple choice between two gambles may be portrayed as in Fig. 1,

FIGURE 1 Decision tree representation of the choice between gambles A (flipping a coin) and B (throwing a die with possible outcomes 1–3, 4–5, or 6) and monetary consequences in euros.

which shows the perspective of a decision maker in terms of present options, possible outcomes of uncertain factors, and monetary consequences. Note that the expected value (EV) of both gambles A and B, that is, their long-term average return on repeated playing, amounts to €10. For a single play, which gamble would you prefer, and why? A rational EV maximizer’s answer would be, “Either, because both gambles are equally worthy.” EV theory, however, has been succeeded by expected utility (EU) theory, in which the subject’s utility function for money is crucial. One traditional shape of such a curve is drawn in the right half of Fig. 2, which reflects the subject’s supposed decreasing marginal utility of money. This would, for example, imply the subject’s refusal to play a 50–50 bet for a fixed (sizeable) amount of money, since the possible loss weighs heavier than the comparable gain. Thus, in the example of Fig. 1, both gambles would be unattractive, but actually gamble A has a higher EU than gamble B.

As regards risk, in view of Table II, we may note that A and B have an equal (total) probability of loss, B has the highest possible size of loss, B has the highest (summed) product of probability and size of loss, and B has the highest outcome variance. So, gamble B is the most risky. One should realize, however, that not risk but EU is the rational basis of choice.

FIGURE 2 Two-component value function following prospect theory, indicating risk avoidance in the domain of gains and risk seeking in the domain of losses. Monetary amounts are indicated on the horizontal axis, utilities on the vertical one.

The negative acceleration of the utility curve in Fig. 2 fits the well-known Weber–Fechner law of psychophysics: as stimulus intensities increase, people become less sensitive to given intensity differences. For monetary amounts, the difference between 1020 and 1000 euro is psychologically less than the difference between 120 and 100 euro. This notion of decreasing marginal utility also applies in the negative (see Fig. 2). For example, the psychological difference between 120 and 100 (possible) accident fatalities is less than the difference between 20 and 0 fatalities.

2.2. Prospect Theory

The preceding reasoning is captured in a generalized value function following prospect theory as proposed by Kahneman and Tversky in 1979; see Fig. 2. Here, the utility function for losses is steeper than the utility function for gains: “losses loom larger than gains.” This double utility function has special implications for gambling in the domains of (only) losses and gains. Suppose the subject is offered the choice between receiving €50 for sure and a 50–50 bet to win either €100 or nothing (written as [100, .50, 0]). Following the utility (u) curve for gains, $u(+50)$ is significantly higher than $u[100, .50, 0]$; see the “positive utility” axis in Fig. 2. Thus, the subject will avoid the risk of getting nothing and will prefer the sure amount of €50.

Now suppose that the same subject is offered the choice between a sure loss of €50 and a 50–50 bet to lose either €100 or €0 (written as [−100, .50, 0]). As the “negative utility” axis reveals, $u(-50)$ is significantly lower (more negative) than $u[-100, .50, 0]$. Hence, the subject will prefer the bet over the sure loss, thus choosing the risk of losing as much as €100, in the hopes of actually obtaining the “loss” of €0.

The main implications for risk taking of the double utility function represented in Fig. 2 are the following:

- Following Weber–Fechner, the greater the absolute value of two possible outcomes (losses or gains), the smaller a given difference between them is perceived.
- Losses weigh more heavily than do comparable gains (this means, for example, that a 50–50 bet of losing or winning €100 will be rejected).
- Subjects are risk seeking in the domain of losses but are risk averse in the domain of gains.
- The perception of gains and losses depends on the subject’s reference point, which may be, for example, current assets, last year’s earnings, maximum outcome, or “worst case.”

From a rationalistic perspective, the last point is rather worrying. As Kahneman and Tversky and others have shown, smart reframing of a decision problem may induce a preference change in the subject, who thereby would behave inconsistently across different frames. Framing may also be conducted in other ways, as for example when any particular accident scenario or risk dimension is expressly presented in a conspicuous way in order to cause it to be more heavily weighted than other scenarios or dimensions.

2.3. Probability Estimation

Considering risk, probability is the likelihood of a future loss. Probability, however, is subject to different conditions, interpretations and estimation heuristics, so that numerical values may be of limited validity and reliability.

2.3.1. Probability Interpretations

Debates about risk may be complicated by three different interpretations of probability.

1. Frequentistic probability is the limit of a (past) relative frequency in a theoretically endless number of observations of an uncertain event (e.g., the flip of a coin or the crossing of a road junction) for a specified outcome (e.g., “tails” or a car accident) under substantially similar conditions.
2. Logical probability is a quantitative characteristic of a chance apparatus such as a coin, die, or wheel of fortune, which may be derived from its properties such as the number of possible outcomes, symmetry, and lack of bias.
3. Personalistic probability is someone’s degree of belief in the future occurrence of an uncertain outcome (e.g., a nearby forest fire next year), which may be expressed in the subject’s relative willingness, expressed in the odds proposed, to bet on it.

2.3.2. Estimation Heuristics

For practical risk assessment involving small likelihoods, probability estimation often is as crucial as it is difficult. Assessment difficulty may be due to

- incomplete or inconsistent information from various sources,
- unrepresentativeness of historical frequency data,

- impossibility or implausibility of logical system modeling (e.g., for industrial process failure), and
- lack of substantive knowledge, experience, and imagination as a basis for expert judgment (e.g., about system failure scenarios).

Moreover, in many practical situations, the probability of things going wrong is rather elusive, as, for example, in mountain climbing, road transport, and marine navigation. Thus, risk takers may use various mental tricks to estimate probabilities (when required) as a basis for risk comparisons, acceptance decisions, or safety maneuvers. Well-known probability heuristics are estimation by representativeness, cognitive availability, and anchoring and adjustment.

An event, for example, a particular series of sunny, cloudy, and rainy days, may be judged to be more probable when it is believed to be more representative of the underlying event-generating process, namely, the local climate.

Cognitive availability plays a role to the extent that examples may come to mind (e.g., financial losses, sad divorces, environmental accidents) that resemble the outcome whose probability is to be estimated. This availability heuristic also explains the great sensitivity and fear of car (or bus or train) passengers, especially non-drivers, who have actually experienced an unforgettable accident. "Never again" is often a motive for quickly enhanced safety measures in otherwise normal risk situations.

Anchoring and adjustment is an heuristic maneuver for coming up with a numerical probability estimate under a fair amount of second-order uncertainty. The idea here is that either a middle or an end scale value offers an anchor for an initial estimate, which is then conservatively adapted.

2.3.3. Frequency versus Scenario Information

Probability estimates are based on differing kinds of information: relative frequencies, logical system properties,

process similarities, remembered cases, and anchor values for adapted judgment. More-encompassing foundations for probability estimation are causal schemas, cognitive scripts, or mental images of future scenarios. The fundamental difference between frequency thinking and scenario thinking is indicated in the columns of Table III. Obviously, the frequentistic probability interpretation applies to the left column, while the personalistic (belief) interpretation applies to the right column. The logical probability interpretation may be applicable to both columns, in order to compute probability estimates without performing repeated observations (left column) or after some logical modeling of a multi-component system or process (right column), such as, for example, a petrochemical plant. Experimental subjects appeared to be sensitive to both frequency and scenario information. However, in a combined presentation of frequency and scenario information, the role of frequency information appears to be significantly suppressed. This suggests that for risk estimation, future orientation is more important than looking at performance history.

Remarkably enough, many great accidents or disasters have actually occurred because they had not occurred before (frequency information was lacking) and because responsible authorities did not believe them to be possible (there were no plausible scenarios) and thus failed to take the necessary precautions.

2.3.4. External versus Internal Control

The rows of Table III represent a second categorization of information about probabilities, namely, external versus internal control of the outcome-generating process. A simple example is the following: in flipping a coin, the outcome is externally determined by various physical factors. In contrast, in throwing a dart at a bull's eye, success depends very much on internal factors such as experience, skills, and effort. Estimating the probability of tails for the coin flip may be done using logical or

TABLE III
Different Kinds of Uncertainty, Depending on Available Information

	<i>Repeated events (frequencies)</i>	<i>Unique events (scenarios)</i>
External, environmental control	Relative frequencies of fortuitous or random events, as in casino gambling	System properties, inclinations, strategic plans, policy scenarios, all outside the subject's control
Internal, human control	Relative frequencies of successes and failures, as in repetitive games of skill	Suppositions, ideas, arguments, feelings about the feasibility of one's own plan, task, or ambition

frequentistic data about the coin's likely behavior. Estimating the probability of success in throwing the dart is rather a matter of talent, self-confidence, and determination.

The most relevant contrast in Table III is between repetitive uncertain events under external control (upper left cell), as in pure gambling, and unique uncertain events under internal control (lower right cell), as in the execution of a rare performance task, such as tight-rope walking across Niagara Falls.

2.4. When Risks and Benefits Correlate: Risk Homeostasis

In many practical situations, greater benefit may be obtained when one is willing to take higher risk; per activity, benefits and risks often correlate. This was already realized by Coombs and Avrunin in 1977, when they tried to explain so-called single-peaked preference functions. These radically differ from the standard decreasing marginal utility functions adopted by neoclassical economists; see, for example, the positive-utility function in Fig. 2. Examples are the speed of transport, the bravado of mountain climbing, and the difficulty of medical operations.

2.4.1. Optimal Risk Taking

For the example of car driving, Fig. 3 shows positive and negative utility as a function of increasing speed. The upper dashed curve represents the (positive) utility of expected benefits: the faster you drive, the more mobile you are and the earlier you will arrive at your chosen destination; however, there is a decreasing marginal utility of increasing benefits. At the same time, however, the driving costs (e.g., through fuel use and tire wear) and accident risks are increasing disproportionately. The negative utility curve indicates the growing marginal disutility of increasing costs and risks. Thus, as Coombs and Avrunin wrote: "The good satiates and the bad escalates." The solid middle curve in Fig. 3 represents the sum of positive and negative utilities, that is, the overall net expected utility at the various driving speeds. As this sum curve shows, the optimal speed lies somewhere halfway along the speed axis; the subject has a single-peaked preference function for driving speed.

Now let us imagine (not drawn in Fig. 3) that by some external safety measure, for example, the installation of crash barriers along freeways or air bags in cars, the negative utility curve for costs and risks moves slightly

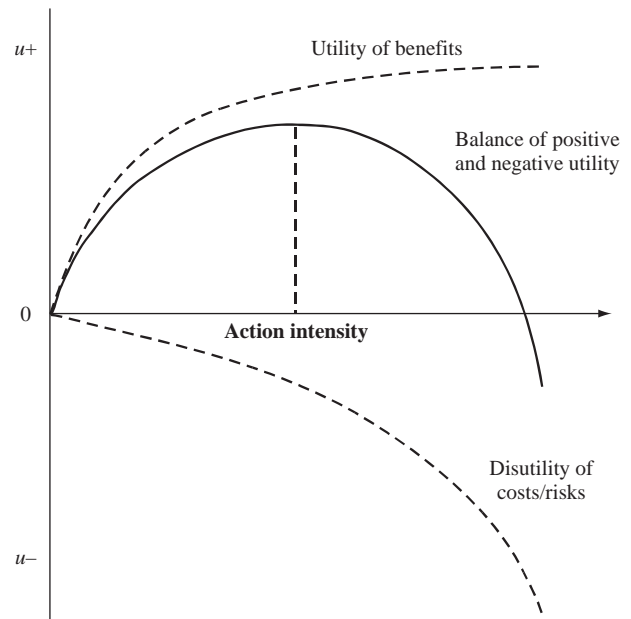

FIGURE 3 Single-peaked utility function (solid curve) for action intensity (e.g., driving speed) as the sum of positive utility of benefits and negative utility of costs and risks, both increasing as action intensifies.

upward. As a result, the summed (solid) expected utility curve would also move slightly upward, so that the optimal car speed is increased (toward the right). This, however, would put the car driver back at roughly the previous negative utility level for costs and risks, thus undermining the intended effects of the external safety measure. In fact, it appears that the subject uses the increased external safety for realizing increased mobility, while the average number of costly incidents and accidents remains the same.

2.4.2. Risk Homeostasis and Safety Regulation

The basic idea expressed by Coombs and Avrunin in 1977, as represented in Fig. 3, has independently been developed in Wilde's risk homeostasis theory. By now, the latter has been well validated, particularly in the domains of road transport, health care, and sports. The great lesson from this work for safety policymakers is that the effects of external safety measures may be canceled by subjects' desire for (even) greater performance benefits.

Risk homeostasis, however, would only apply to activities that leave subjects enough freedom to either intensify their performance or not, as in mountain

climbing, car driving, or performing medical operations. Putting an upper limit to the activity's intensity, for example, by declaring a prohibition on climbing certain mountain slopes or by setting a speed limit on highways, would prevent subjects from using increased safety for achieving greater benefit.

Therefore, increasing the safety of human endeavors seems to require the fulfillment of either one or both of two basic conditions:

1. The extent or intensity of the activity is limited.
2. The performer of the activity enhances his or her intrinsic safety motivation; that is, he or she will perceive the risks as higher than before.

For difficult-to-limit activities such as road transport, challenging sports, and competitive medical care, ultimate safety levels especially depend on the seriousness of perceived risks and the performer's self-control, thereby preventing serious accidents from occurring. On the other hand, when subjects persistently underestimate or belittle the risks, policymakers have no other recourse than to limit the relevant activity.

2.4.3. Risk-Taking Illusions

With reference to Fig. 3, two kinds of illusion may be identified. First, subjects may unrealistically believe that, on further behavior intensification (e.g., faster driving), significantly more benefit may be obtained. Second, subjects may erroneously believe that, on behavior intensification, the costs and risks of the activity will still be manageable. Both the illusion of achieving (still) greater benefit and the illusion of effective risk control may tempt subjects to perform at a higher than optimal level. The end result may be a serious accident involving great loss plus the loss of any benefit originally aspired for. As the saying goes, "It's better to arrive a little late than to end up in hospital."

2.5. Protection Motivation Theory

Used chiefly in health psychology, protection motivation theory (PMT) was developed by Rippetoe and Rogers in 1987 to explain individuals' risk taking and safety policies. PMT is strongly built on cognitive stress theory as developed by Lazarus, Folkman, and others prior to 1984. In 1996, PMT was correspondingly adapted by Gardner and Stern for application to situations of environmental risk. Like cognitive stress theory, PMT comprises a threat appraisal process and a

coping appraisal process. See Fig. 4, in which a motivational element has been added to each.

First, threat appraisal rests on the subject's values ("What do I cherish?") and involves perceived severity and vulnerability as well as a judgment of associated benefits; one result is the subject's feelings of fear and/or temptation. Second, coping appraisal pertains to perceived response efficacy ("Could anything be done?"), self-efficacy ("What could I do myself?") and costs and barriers of acting; one result here is the subject's perceived control and his or her motivation to act.

To the extent that the appraisal of coping potential measures up to the appraisal of threat severity, the subject may engage in problem-focused coping aimed at reducing the threat and/or increasing his or her own coping potential. If, however, severity of threat is perceived as overwhelming the subject's coping potential, the subject may (have to) resort to emotion-focused coping, aimed at living with the threat (which may amount to denying it).

Perceived controllability appears to be so important that, psychologically, risk may well be defined as a lack of perceived control in view of significant possible (i.e., non-excludable) negative consequences of an activity or situation. When threat appraisal is low and so is coping appraisal ("Little could be done anyway"), engagement in any other behavior is unlikely. Alternatively, under low threat appraisal and high coping appraisal, subjects would easily take some safety precautions or adopt a safer behavior alternative.

Note that under PMT, subjects have to weigh their coping potential (right side of Fig. 4) up against the appraised threat (left side). This cognitive-affective balancing ("Can I handle the situation?") should somehow accompany the motivational balancing between the utility of associated benefits and the disutility of expected costs and risks, as discussed in Section 2.4 ("Am I willing to take the risks?").

Thus, the essential message of adapted PMT is that risk (and/or stress) management always has two sides. On the one hand, you may work on reducing the threat and the demands of the external environment, which, however, may tempt you via associated benefits. On the other hand, you may work on reducing the vulnerability and enhancing the self-efficacy of the (potential) victims, which, however, may be costly and difficult.

2.6. Emotional Significance of Risk

As marketing specialists very well know, emotions can deeply influence human judgment and decision making.

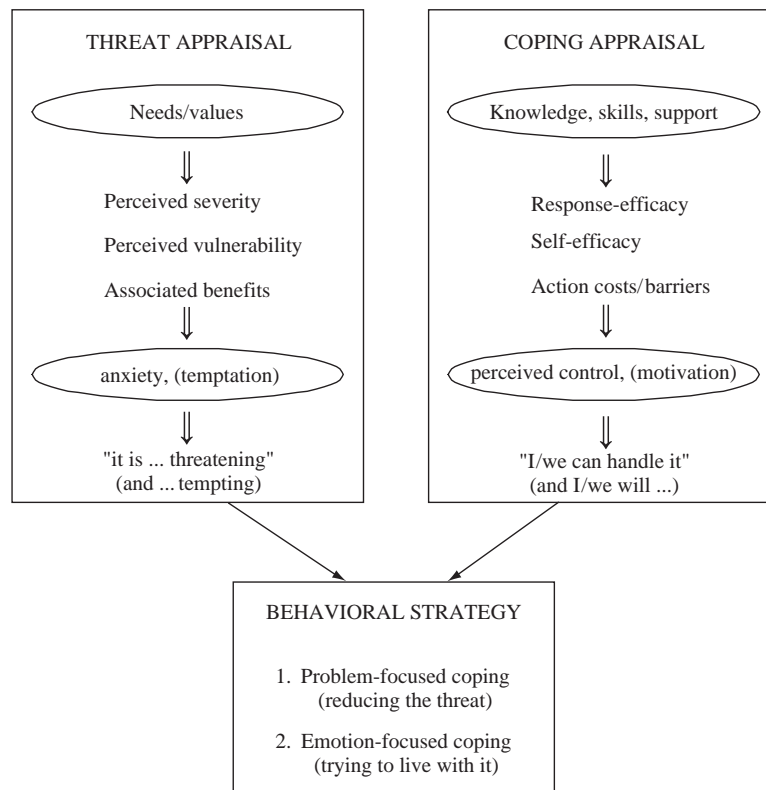

FIGURE 4 Adapted version of protection motivation theory (PMT), with behavioral strategy as a result of the balance between threat appraisal and coping appraisal.

Emotions may be triggered by images of possible decision consequences, which themselves may be based on personal experiences, vivid presentation, proximity in time, and/or cultural conditioning. “Hot” anxiety-sensation thinking is the natural counterpart of “cool” risk-benefit thinking. Just as risks and benefits are balanced cognitively, so must anxiety and sensation be balanced emotionally. This may happen in mutual correspondence, so that cognitions and emotions accompany or even support each other. Not infrequently, however, emotional (“gut”) responses may precede and dominate cognitive responses, as may be easily seen in cases of extreme anxiety, fear or time pressure.

2.6.1. Negative Meaning of Risk

Anxiety and fear are prominent emotions in the face of risk. Fear may severely restrict or virtually suffocate deliberate problem solving. Fear of great loss may lead to gambling behavior aimed at trading the greater loss for a smaller one (see Section 2.2). Chronic fear is expressed in phobias, for example, for crowded

places, air travel, heights, or certain kinds of animal. Under great anxiety or fear, most people are mentally shortsighted and rather insensitive to rational, economic aspects of risky decision making, especially probability.

The strong priority effect of fear on information processing and (thus) decision quality may block subjects’ attention for reassuring information and arguments from more distant authorities. In cases of large-scale involuntary risk, this may cause serious problems of communication between risk-exposed lay subjects and non- (or less-) exposed experts and regulators. Debates about nuclear power generation, liquefied petroleum gas transport, and storage of toxic wastes may provide examples here.

As further elaborated in Section 3.3, subjects’ trust in technical experts and responsible authorities is another vital source of emotions. The building of trust not only requires the provision of essential, balanced, and credible information, but also demands that subjects’ emotions are recognized and appreciated, as a start toward more deliberative thinking.

2.6.2. Positive Meaning of Risk

Why do people rope-walk across Niagara Falls? Why do they hang-glide from the Eiffel Tower, bungee jump from a high railway bridge into a deep canyon, or start fights with other fans in European soccer stadiums? Why does the public flock to see motor races, air shows, or hazardous circus acts? What explains the increased popularity of so-called survival holiday tours?

As these examples suggest, risk taking can be fun. It can give a kick. Facing risks can challenge our capacities and self-confidence. Successfully completing a risky activity may be a true learning experience. Effectively managing risks may enhance our self-esteem and social status. Without risks, life would be dull and boring. Without a certain willingness to take risks, we would not be able to develop ourselves, to learn new things, and to innovate the physical, social, and economic environment on which future safety and well-being depend.

Also, in line with protection motivation theory (Section 2.5), when coping appraisal is high, that is, when subjects feel capable, skilled, and well-equipped, a given external demand is more easily perceived as a challenge than as a threat, and people's willingness to take risks should be greater.

Even large-scale disasters can have significant positive effects. Afflicted individuals may be forced to get creative and go beyond their everyday limits. Mutual solidarity may be enhanced and social coherence stimulated. After a catastrophe, many people feel that they have endured their ordeal in rewarding togetherness.

3. COMPARATIVE JUDGMENT OF MULTIDIMENSIONAL RISKS

In the past 25 years, a fair amount of research on perceived risk has followed the "psychometric paradigm." The purpose of this inductive approach was to discover the variables and dimensions underlying comparative judgments for a great variety of different risks from industrial activities, transportation, medical treatments, and technologies, as well as household and recreational behaviors. In a much-desired response to limited technical-statistical risk analyses from the engineering disciplines, this work was aimed at answering the following basic questions:

1. If it is not just probability of loss or accident, what (else) is it that causes a particular activity to be perceived as more or less risky and/or acceptable?

2. What might explain the differences in risk perceptions between different groups of people, for example, lay persons and experts, men and women, or people of different political inclination?

3. How meaningful and how feasible are risk comparisons as a basis for risk acceptance and/or the allocation of public funds for relevant scientific research?

3.1. Multidimensionality of Risk

The most powerful conclusion from psychometric research is that risk is a multi-attribute construct whose meaning goes far beyond the classical notions of risk as given in Table II. In the empirical studies underlying this conclusion, various tasks have been presented to respondents. Examples are ratings of risky activities on a set of explicit risk variables, rank ordering of different activities following their perceived riskiness and/or acceptability, and sorting a collection of activities into groups of similar items. The data were analyzed using factor analysis, multidimensional scaling analysis, and/or multiple regression analysis, all capitalizing on patterns of correlation among judgment variables. In addition, theoretical analyses of risky activities were carried out by various other researchers. Based on this varied work, Table IV presents a condensed list of dimensions underlying variations in perceived risk.

The message of Table IV is twofold. First, by rating an activity (insofar as possible) on the 11 risk dimensions, one may understand why subjects consider risks to be as high or low as they seem to believe (thus, the investigator also needs some overall risk criterion measure). Second, the same 11 dimensions hold suggestions of

TABLE IV
Dimensions of Perceived Risk and Corresponding Safety Measures

1. Potential degree of harm or fatality
2. Physical extent of damage (area affected)
3. Social extent of damage (number of people involved)
4. Time course of immediate and delayed effects
5. Probability of undesired consequence
6. Controllability (by self or expert) of situation
7. Experience with, imaginability of consequences
8. Voluntariness of exposure (freedom of choice)
9. Clarity, importance of expected benefits
10. Social distribution of risks and benefits
11. Harmful intentionality

corresponding safety policies to be followed should any dimension be a prominent driver of perceived risk.

3.2. Group Differences in Risk Judgment

The reasons for perceived risk listed in Table IV may be weighted differently by different groups of people. For example, some groups may care less than others about delayed consequences, or they may put unusually high trust in relevant authorities. Major factors underlying intergroup differences in multidimensional risk judgments are the following:

- people's attitudes toward or their interest in the expected benefits involved (cf. dimension 9 in Table IV; see also Section 2.4); a general finding here is that between different activities, perceived risk is lower when associated benefits are larger;
- people's knowledge, capacities, and perceived control as regards the risk (cf. dimension 6 in Table IV; see also Section 2.5); it is in these respects that differences between experts and lay persons may occur, as well as differences between women and men;
- people's world view or general sociopolitical orientation, particularly with respect to authority, technology, and environmental resource use.

3.3. Importance of Trust

As already indicated, perceived controllability (dimension 6 in Table IV) is a crucial risk variable. For the lower level, everyday types of risk following Table I, it is the subject him- or herself who could do much to prevent or control risks and/or to mitigate any accident effects. However, for the higher level, large-scale risks following Table I, many people are dependent on scientific experts, policymakers, and safety inspectors for their information and personal security. Thus, in many cases personal trust in others who are responsible for the matter is a vital component of subjects' feelings of safety.

In 1997, Slovic noted—like others before him—that trust is slowly developed but may be quickly destroyed. Four reasons were listed for this “asymmetry principle”:

1. Negative (trust-destroying) events are more visible or noticeable than positive (trust-building) events.
2. When well defined and noticed, negative (trust-destroying) events carry much greater weight than positive events.

3. Sources of bad (trust-destroying) news tend to be seen as more credible than sources of good news.
4. Distrust, once initiated, tends to reinforce and perpetuate distrust.

3.4. Undermining of Self-Confidence

The preceding four reasons were given in connection with technological, social, and environmental risks involving industry, government, and segments of the general public. However, reasons 1, 2, and 4 also pertain to individual risk taking, for example, in traffic, sports, or gambling casinos. Personal losses or accidents stand out and remain cognitively available for a long time, and they thus undermine future self-confidence (reason 1). “Losses loom larger than gains,” Kahneman and Tversky noted in 1984, and their greater weight keeps many people from straight-forward gain–loss gambling (reason 2). And once in doubt about one's own performance capacities, one may lack sufficient self-confidence for future endeavors (reason 4). Taking this together, we may generally conclude that distrusting oneself takes away the fun or kick, the learning experience, the self-esteem, and the social status of risk taking; cf. Section 2.6.2.

3.5. Meaning and Feasibility of Risk Comparisons

Risk comparisons may be needed

- to decide on the safest way to carry out a given activity (e.g., a medical operation);
- to decide between two or more rather different ways to achieve the same goal (e.g., electric power generation by means of coal, wind, hydro, or nuclear energy);
- to decide on the allocation of investments in various risky activity domains (e.g., road traffic, aviation, food security, sports or medical care) in order to make them safer;
- (and, as we know from above, to find out why and in what respects respondents in psychometric studies find one hazardous activity, situation, or product more risky than another).

Statistical risk comparisons (e.g. between different occupations) have often been made by following a “probability of someone dying” definition, whereby probabilities were estimated on the basis of observed relative frequencies of past deaths. However, the

psychometric research previously discussed has made it clear that in many practical cases fair risk comparisons should be multidimensional. Indeed, multidimensional risk may be formalized (e.g., on the basis of Table IV) in terms of measurements, eventually yielding a bar diagram or a graphic semantic differential representing the risk profile of a particular activity or situation.

Quantitative risk comparisons based on such multidimensional representations are rather difficult to make. They can be completely formalized, and should then follow an explicit evaluation procedure involving attribute (or dimension) selection, activity rating, attribute weighting, and weighted summation of activity ratings across all attributes. Or multi-attribute risk profiles should just be qualitatively presented as such to responsible judges for their intuitive evaluation and rank ordering of activities.

Thus, making risk comparisons is a difficult and often tricky thing to do. In any case, one needs a clear and standardized definition of risk. The safest strategy is to limit risk comparisons to alternative options that fall into the same category (e.g. train versus car; one medical treatment versus another; coal- versus gas-powered electricity generation). Indeed, psychometric risk research itself is based on the somewhat paradoxical assumption that lay respondents can compare multidimensional risks of activities that do not meaningfully fit into a single decision problem.

4. EXTERNAL RISK ACCEPTANCE: RULES, HEURISTICS, AND PROCEDURES

Theoretically, risk acceptance is implied in the choice of a preferred course of (more or less risky) action, whereby expected benefits constitute the primary motivating factor (see Section 2.1). In many cases, however, risk-exposed people do not directly enjoy the benefits of the relevant activity. Under such involuntary (or nonbeneficial) risk exposure, explicit rules and procedures may be needed to determine the acceptability of a given risk situation.

4.1. Risk–Benefit Trade-Offs

Whether we deal with a static gambling situation (as in Section 2.1) or with a dynamic control situation

(Section 2.4), risk taking often requires a weighing of risks against benefits. The larger the benefit involved, the higher the risk accepted. So, if you see someone voluntarily take a high risk, always ask yourself which compensating (or seductive) benefit the subject expects to achieve. Of course, several other factors may play a significant role as well, for example, a possible unrealistically optimistic underestimation of the probability of loss (“It won’t happen to me”), time-discounting of long-term risk (“Who cares about later?”), and an exaggerated need for the benefit involved, for example the “kick” from a hazardous sporting event. For society at large, important economic benefits often justify the toleration of appreciable risks.

4.2. Risk-Limiting Standards

For the sake of cognitive convenience, in many practical situations risk–benefit trade-offs are “frozen” into simple risk acceptance standards. Examples are vehicle speed limits on highways, the degree of attentiveness in descending a staircase, or the limitation of preservatives in food products. In such cases, without giving up the intended benefits, one is willing (or forced) to adapt the activity, at some explicit or implicit cost, in order to make it safer. Acceptance standards often have a third-party protection function, too, as illustrated by speed limits on highways.

4.3. Risk as Low as Reasonably Achievable

Some consequences of a risky activity may sooner or later be fatal. Thus, one should naturally be willing to reduce such risks to a level that is “as low as reasonably achievable.” This ALARA principle, however, may lead to a kind of phobia. For example, some may refuse to eat shellfish, some would never take an airplane trip, and some, knowing they are a carrier of a genetic disease, would decide to never have children. The ALARA principle means that personal safety strategies, although primarily benefit-driven and perhaps somehow standardized in terms of risk limits, may further involve efforts to reduce the probability of some sad loss as much as possible, even if the subject considers the situation to be safe enough otherwise. The result, however, may be that an activity becomes very costly or no longer feasible.

4.4. Justification, Risk Limits, and ALARA

Risk–benefit weighing, the testing of risk acceptance standards and subsequently trying to get risks ALARA, may constitute an effective combined strategy for risk management. For example, for involuntary risks to radiological workers (e.g., in hospitals and nuclear energy laboratories), the International Commission on Radiological Protection has recommended the use of such a joint set of safety principles. This strategy comes close to an empirical conclusion drawn by Hendrickx in 1991, that in a dynamic control task, risk acceptance consists of a deliberate choice of a safe-enough course of action followed by an allocation of effort to keep the risks under sufficient control. A triple heuristic conclusion on risk acceptance was also drawn on empirical (psychometric) grounds by Vlek and Stallen in 1981: for most lay people, risk acceptance hinges on: (1) the importance of expected benefits, (2) limitation of the maximum possible accident, and (3) the perceived controllability of the activity as a whole.

4.5. Societal Risk Acceptance: Importance of Procedures

Involuntary exposure to industrial or environmental risks easily raises public concerns, protests, and feelings of being treated unfairly. To the extent that expected benefits are the main driving force of risk acceptance, we may expect involuntary and mostly nonbeneficial exposure to cause much trouble for responsible decision makers. “NIMBY,” or “not in my back yard” is one protest often heard regarding the question of where to build hazardous facilities such as municipal waste incinerators, electric power stations, and airport expansions.

The reactions of involuntarily risk-exposed persons toward responsible authorities have been widely studied, and various suggestions have been formulated to facilitate the processes of decision making and eventual risk acceptance. Table V lists six different diagnoses of public protests together with recommended policy approaches.

Specialists believe that in most practical cases, several diagnoses may be valid at the same time. Hence, they recommend that administrative procedures for planning, decision making, and undertaking of a hazardous activity involving involuntary risk should follow a carefully designed procedure incorporating all or most of the therapeutic ingredients mentioned in Table V.

TABLE V
Six Possible Diagnoses and Corresponding Therapeutic Approaches Toward “NIMBY” (“Not in My Backyard”) Attitudes

<i>Diagnosis</i>	<i>Policy approach</i>	<i>Labelling name</i>
1. Ignorance	Communication	Technocratic approach
2. Unfairness	Compensation	Market approach
3. Exclusion	Participation	Participation approach
4. Social inequity	Redistribution	Social justice approach
5. Policy criticism	Strategic alternative	Transformation approach
6. Pure local egoism	Government coercion	Regulatory approach

5. COLLECTIVE RISKS IN COMMONS DILEMMAS

Involuntary exposure often occurs in connection with environmental risks at the higher scale levels following Table I. In quite a few cases, collective risks are generated in a process of accumulating small contributions from numerous individual actors.

5.1. Definition of a Commons Dilemma

A commons dilemma is a situation of conflict between an aggregate collective interest and numerous individual interests; see Hardin’s inspiring 1968 analysis of the disastrous consequences of common pasture land (“the commons”) being overgrazed by ever more cattle owned by individual farmers, each trying to improve their individual income. A present-day example is the urban air pollution resulting from accumulation of exhaust fumes from many individual cars.

5.2. Macro and Micro Level Perspectives

At the macro level of society, a commons dilemma presents itself as a permanent contrast between a collective risk, such as air pollution, and a large collection of individual benefits, such as the benefits of car driving, for example. Minimization of risk and maximization of benefits are incompatible social goals,

between which a trade-off must be made. In contrast, individual actors at the micro level of society are naturally focused on their own benefits “here and now”. Individuals may not recognize a commons dilemma as such

- because they are unaware of any collective damage;
- because they do not appreciate their own responsibility for collective problems;
- because they do not feel that the long-term collective risk is serious enough in relation to the numerous short-term benefits; and/or
- because they know there is a collective risk, but feel that little can be done about it.

In particular, the combination of short-sightedness, personal benefit, and perceived lack of control over the situation may readily lead to a denial or playing down of the risk and thus to a refusal to participate in risk control efforts.

5.3. Key Issues for Research and Policymaking

Understanding commons dilemmas and managing the collective (environmental and social) risks generated by individual activities revolve around problem diagnosis, policy decision-making, practical intervention, and evaluation of policy effectiveness. These four categories can be expanded into 12 focal issues, as listed in Table VI. The 12 issues listed in Table VI imply rather different tasks to be performed by experts from different backgrounds, not just psychologists. Also, the 12 activities would have to be carried out in reasonably good order, so that subjects of intervention strategies understand why they are asked to accept or cooperate, and to what future improvements this might lead.

5.4. Structural and Individual Factors of Social Cooperation and Defection

A multitude of experiments and field studies have clarified the main factors governing people’s tendency to either cooperate or defect (i.e., behave selfishly) when faced with a commons dilemma. Table VII reviews the structural and individual psychological factors governing cooperation.

In connection with this, seven general strategies may be used for the promotion of cooperation in managing

TABLE VI
Twelve Key Issues for Research and Policymaking on Commons Dilemmas

I. Problem diagnosis
A. Analysis and assessment of collective risk, annoyance, and stress
B. Analysis and understanding of sociobehavioral factors and processes underlying risk generation
C. Assessing problem awareness, risk appraisal, and actors’ individual values and benefits
II. Policy decision making
A. Weighing of collective risk against total individual benefits (“need for change?”)
B. If “risk unacceptable”: setting objectives for reduction of environmental and/or social risks
C. Translation of risk reduction objectives into individual behavioral goals
III. Practical intervention
A. Focusing on individual target groups and considering essential conditions for policy effectiveness
B. Specifying feasible behavioral alternatives and selecting effective policy instruments
C. Targeting group-oriented applications of strategic programs of behavioral change
IV. Evaluation of effectiveness
A. Designing a monitoring and evaluation program to determine policy effectiveness
B. Systematic, comprehensive evaluation of observable effects and side effects
C. Intermittent and <i>post hoc</i> policy feedback and possible revision of policies

collective risks. These are briefly indicated in Table VIII, along with one default strategy.

Policymakers regularly use separate strategies in a piecemeal fashion. However, they rarely apply a comprehensive approach to managing collective risks in commons dilemmas, involving problem diagnosis, policy decision making, and practical intervention following various related strategies.

5.5. Precautionary Principle

Large-scale commons dilemmas (e.g., motorized transport or genetic engineering) may yield great environmental risks that may be hard to characterize. Not only is there a variety of threatening consequences whose time of occurrence is rather uncertain, but also there is great ambiguity about the probabilities of catastrophic

TABLE VII
Factors Facilitating Cooperation to Reduce Collective Risks in Commons Dilemmas

<i>Structural factors</i>	<i>Individual psychological factors</i>
<ul style="list-style-type: none"> • Smaller group • Stronger group identity • Higher visibility of others' behavior • Availability of cooperative alternatives • Lower cost of cooperative choice • Higher cost of defective choice • Legal obligation to cooperate 	<ul style="list-style-type: none"> • Environmental problem awareness, insight into causal processes • Feeling of responsibility, moral obligation • Perceived (relative) appeal of cooperation • Self-efficacy in making cooperative contributions • Trust in others' cooperation (low social uncertainty) • Ability to resist bad social examples ("rotten apples") • Perceived environmental effectiveness of cooperation (outcome efficacy) • Altruistic and cooperative social value orientation

events. What people do realize is that possible catastrophes are caused by humans and so should eventually be controlled by humans.

For environmental policymakers, a reasonable suspicion of a serious threat may offer sufficient grounds for applying the precautionary principle. This means that various risk avoidance, prevention, and/or reduction actions are implemented, aimed at reducing the threat without there being sufficient scientific evidence to conduct a justifiable risk–benefit analysis. Because this is a controversial practice, psychologists might contribute to the debate by investigating the extent to which everyday safety decisions involve precautionary

TABLE VIII
General Strategies for Behavioral Change in Managing Commons Resource Dilemmas

<ul style="list-style-type: none"> • Provision of physical alternatives, (re)arrangements • Regulation and enforcement • Financial-economic incentives • Information, education, communication • Social modelling and support • Structural, physical, and/or social change • Changing values and morality
--

measures either preceding or falling outside well-informed rational decision making.

6. CONCLUSION

Both small- and large-scale levels of risk offer their own problems of analysis, judgment, decision, and control. Many risks are difficult to reliably quantify, due to lack of experience and information and because of the dynamic nature of the relevant activity. Thus, expert judgment, perhaps that of the subject assessing the risk, becomes an important factor, and total process control becomes more important than single gambling types of acceptance decision. Therefore, psychologists may define risk as a lack of perceived control (or of coping potential) in view of significant possible negative consequences.

In many cases, an activity or situation is considered to be risky for a variety of reasons (see Table IV). Multidimensionality implies that these activities or situations could be made (to appear) more safe in a corresponding variety of ways. Thus, classical definitions of risk as a function of probability and size of loss have limited practical significance. Multidimensionality of risk also implies that one should be very careful in making risk comparisons across different domains: comparisons variable(s) should be similar and well defined.

As regards large-scale social and environmental risks, sophisticated strategies are possible to limit such risks in view of the numerous social and economic benefits involved. The commons dilemma is a useful model that allows comprehensive problem diagnosis, policy decision making, and well-tuned practical interventions. For highly ambiguous environmental threats, the precautionary principle may be invoked, but this needs psychological investigation to support its practical applicability.

Finally, for future studies on risk, psychologists should familiarize themselves more deeply with specific domains such as industry, transportation, health care, and environmental protection to make their work less abstract and give it more practicality. This would also enable psychologists to work together with experts from other disciplines, whose concepts and tools may be instructive but will likely also need psychological enrichment.

GLOSSARY

“no-go” decisions A term meaning that the research in question is wholly unacceptable with respect to specific research questions on the ground of social and ethical objections.

“slow-go” decisions A term that may include cases in which there is insufficient knowledge to properly appreciate and control the social or moral consequences of the research with respect to specific research questions on the ground of social and ethical objections; in such instances, results should be temporarily suspended until the ethical implications have been subjected to public discussion and consensus or at least a reasonable majority agreement has been reached.

Wissenschaft als Inhalt A morally neutral term referring to science as a product (i.e., the accumulated body of knowledge) solely subject to methodological–scientific norms.

Wissenschaft als Tätigkeit A term referring to science as the process of knowledge accumulation subject to ethical and political norms.

For quite some time, academic psychologists have incurred risks of accusations of “superbia” by developing an “ivory tower” attitude in which any accountability for human and social effects of their

research is repudiated: “Science is about how things are, not about they should be.” During the past few decades, however, the question of science and values has become a major subject of discussion again—certainly within psychology. Attacks on the autonomy and sovereignty of scientific psychology have come from various sources. First, there was the antiestablishment movement of the 1970s in which the political–scientific reflections of authors such as Marcuse, Adorno, Habermas, and Holzkamp became quite popular and were willingly embraced by student activists and (mostly junior) staff. Their criticism certainly contributed to the dismantling of the misconception that freedom of science would imply a negation of societal responsibility. A second attack resulted from the economic recession in many Western countries during the 1980s that led to a severe reduction of public and private funding for research. Acknowledged (and published) research output became an important condition for the survival of research personnel. This challenged another misconception of scientific freedom, namely, the license to freely think, meditate, and explore without caring much about output or quality. A third attack on the free and autonomous academic psychology came from the cry for “utilization” of scientific research at the end of the 1980s and during the 1990s that was heard in both governmental and industrial circles: Scientific goals should be seen as subordinate to those of economic and technological development, and criteria such as utility, applicability, and economic relevance should be given priority over pure scientific standards. Industrial, societal, and/

or technological relevance became an important consideration for funding research. It is ironic how much the neo-Marxist principles of the 1970s coincide with the industrial utility touchstones of the 1990s. Fourth, during recent years, the question of the autonomous and value-free character of science versus the relevant and value-bound character of science has received ample attention. A more detailed discussion of this issue is presented in this article.

1. SCIENCE: VALUE FREE OR VALUE BOUND?

The question phrased in the heading of this section has become an important issue during the past few decades, although opinions still diverge. On the one hand, many defend that scientific knowledge is value free and has no moral connotations. Science tells us how the world is, whether we like the story or not. Basic research is driven by scientific curiosity and not by the hope that it will be put to practical use. Ethical and moral issues can arise only when science is applied and is expected to produce usable objects. But then it has become technology and is not science anymore. Technological objects or processes can be used for better or for worse. Science produces insights, ideas, and pieces of knowledge that are in themselves neutral and can be corrupted only if they are mixed with political, social, economic, or other nonscientific aims.

On the other hand, there is a different view that does not accept the premise that science should be concerned only with producing reliable knowledge and, consequently, should be value free. The following arguments for the value-bound character of science can be brought forward.

- It is a basic obligation of all scientists and scholars to reflect on the paradigmatic presumptions and socio-historical entrenchment of their scientific activities. This reflection is, in itself, a metascientific and value-embedded phenomenon. Scientists must realize that their conceptualizations and models are always abstractions of reality and that only an approximation—or “reconstruction”—of reality can be achieved.

- Recently, the distinction between basic science and applied science has become less clear-cut. There is a good deal of overlap between the two spheres, and it is increasingly difficult to identify parts of science that do not affect, or are not affected by, technology. In this light, it will become clear that reserving “value-free

autonomy” for science and “value-bound heteronomy” for applied science and technology is no longer tenable.

- Scientists, and especially behavioral scientists, deal with a social, political, or psychological reality that is continuously affected and changed by the very scientific findings they produce. Health, safety, communication, privacy, mobility, welfare, economic development, and many other valuable goals of humankind are influenced radically by the advances of modern science. At the same time, many ethical or sociopolitical problems result directly from these same advances. Scientists should be aware of this and should anticipate the changes they bring about and the problems these changes raise.

- Even if scientists refrain from actually making political or ethical choices and restrict themselves to presenting probabilities and risks coupled with certain options, their reasoning is not value free. Risks do involve values and normative choices that scientists must face. Questions such as the following arise. Risks for whom? How far does the “right to know” go? What is the balance between self-determination of the individual and the interests of larger groups or the society as a whole? At what level of certainty does the scientist have to warn, especially in case of irreversible developments?

- Scientists cannot avoid the metascientific question of whether or not it is worth knowing what they pursue. They must justify—not only for themselves but also publicly if taxpayers’ or sponsors’ money is involved—why scientific issues must be addressed. This justification implies, in essence, nonscientific choices and decisions.

These arguments warrant the following conclusion in scientific research. On the one hand, objectivity must be maintained against the pressure from ideological movements, industrial lobbies, governmental strain, and/or political pressure groups. On the other hand, it has become ever more difficult to separate the functions of producing knowledge and making value-bound choices in extending research findings to the public or to the society at large. Here it may be helpful to distinguish between science as a product of knowledge (i.e., the accumulated body of knowledge) and science as a process of knowledge accumulation. The former, which was referred to as *Wissenschaft als Inhalt* by the Swiss philosopher Bochenski at the 1990 Engelberg Forum, is morally neutral and subject solely to methodological–scientific norms. The latter, which Bochenski described as *Wissenschaft als Tätigkeit*, is

subject to ethical and political norms that stipulate the choice of hypotheses to be researched, the manner in which data are gathered and experiments are conducted, and the question of what is ultimately done with research data.

Thus, research is embedded in the context of values, interests, and political objectives. Rather than denying this or retreating to the safety of the ivory tower, scientists would do well to realize this and take the appropriate responsibility seriously.

2. ETHICAL AND SOCIAL RESPONSIBILITY

This article does not discuss the ethical and social responsibilities of the professional psychologist in everyday practice. It is clear that in the application of psychology, be it in a clinical, pedagogical or social/organizational setting, the professional worker comes across many moral problems and dilemmas. Most national psychological associations have dealt with these issues, and many have developed codes of ethics for the professional application of psychology in various settings. A discussion of these codes falls outside the scope of this article.

But it has become clear that if one looks at the ethical and social responsibility of the psychologist as a scientist, his or her liabilities do not stop at the gate of the laboratory. This responsibility reaches further than the limits of purely scientific norms. It concerns the choice of the subject to be researched (or not), the proper conduct of experiments and surveys with due respect for human participants and/or animal subjects, and accountability for the application and use of the scientific results. More specifically, the following precepts are obtained. One can defend that the psychologist as a scientist should do the following:

- Promote and take an active part in the national and international discourse on ethical and social conditions and consequences of scientific research in psychology and its implementations.
- Be on the alert for selective and biased interpretation of the research findings by opponents or advocates of this research and deprecate such bias whenever discovered.
- Be observant of possible improper use or abuse of the research findings, warn against such possible misuse, and take corrective actions wherever possible.

- Provide careful, complete, and understandable information about the research results, not only in scientific journals but also in professional magazines and popular media (if possible). The latter should be considered important particularly if the research tends to have a substantial social, political, or economic impact.

- Promote the development and the acceptance of a set of rules and regulations for ethical conduct for professional practice in psychology, and train and educate students and young professionals to obey these rules and to develop conscientious attitudes and integrity in applying research results in their future professional work.

- Advocate and develop conditions that inhibit improper applications of scientific products (e.g., tests, instruments, treatments, intervention methods), including restrictive sales, extension of copyrights, and penal sanctions.

In other words, the responsibility of the psychologist as a scientist would have to be translated into very practical efforts and activities and specific rules of conduct.

3. “NO-GO” OR “SLOW-GO” DECISIONS?

An interesting question is whether scientific curiosity should be uninhibited and scientific research should be unrestrained, or whether social or ethical constraints should be imposed on science in some cases—in other words, whether there could be a need for “no-go” or “slow-go” decisions with respect to specific research questions on the ground of social and ethical objections. No-go means that the research in question is wholly unacceptable. At this time, there are cases in which such a constraint would find wide support, including attempts to make human–ape hybrids, applications of germline genetic manipulation to enhance intelligence, and human cloning for procreation. Slow-go would apply in instances where results should be temporarily suspended until the ethical implications have been subjected to public discussion and consensus or at least a reasonable majority agreement has been reached. This area might include cases in which there currently is insufficient knowledge to properly appreciate, and thus control, the social or moral consequences of one’s research.

It should be noted first that any discussion on constraints to be imposed on research is fraught with

danger. Throughout history, there have been too many examples of scientists who were repressed and whose research was stifled because the research outcomes were not consonant with the ruling ideologists, did not curry favor with powerful authorities, or were opposed to the interests of influential movements and action groups. Even if some of these movements have reputable objectives, such as peace and détente, equal rights for women, environmental protection, and non-discrimination, infringement of the right to investigate on the basis of political unacceptability of possible outcomes to external groups is highly precarious.

It would be equally wrong to refrain from doing research in a given area because it might possibly be abused or applied irresponsibly. This would virtually mean the end of all scientific research given that no scientific result is secured against willful abuse.

Therefore, it is not easy to identify incontestable ethical constraints to scientific research. Such constraints should refer to basic and peremptory values that would be imperative for scientists and responsible citizens alike. With respect to this issue, the European Federation of National Academies of Sciences and Humanities has discussed and accepted the following principles that could also be endorsed by researchers in psychology:

1. Research is not justifiable if unacceptable damage is inflicted on the object of research or its wider environment (e.g., social environment, society, nature) before, during, or after the experiment or the gathering of data. This applies to all objects of research, whether they be people, animals, nature, or culture.

2. Research is not justifiable in cases where the nature or the consequences of the research are in conflict

with basic human values. These values include, in any case, (a) respect for human dignity, which guarantees the autonomy and freedom of choice of all individuals, informed consent prior to participation in research, and the rejection of every intent to commercialize the human body; (b) solidarity with humankind, which guarantees regard and acceptance of fellow humans on the basis of equality; and (c) solidarity with posterity, which embodies the broader responsibility for sustained development of a planet that is to be left to future generations.

GLOSSARY

applied behavior analysis A scientific method for educating all students; its basic premise is that all behavior is controlled by its consequences, and so all behavior can be changed.

continuum of services The range of special education placement options, ranging from the least restrictive environment to the most restrictive environment.

functional behavior assessment A critical method for determining the function or purpose of behavior; it involves determining not only the consequences of behavior but also the antecedents of or precursors to behavior.

high-incidence disabilities Specific learning disabilities, speech and language impairments, mental retardation, and emotional disturbance.

inclusion When an exceptional student is a member of a regular class and receives instruction in the regular education setting for the majority of the school day; it may also refer to the philosophy of educating all students in a nonsegregated environment.

individualized education plan (IEP) A plan whereby a contract is devised among the school district, educational placement

(i.e., the school), and a parent(s) outlining a student's educational plan for the school year; it includes the type of educational placement, services to be provided, progress from the past school year, recent test scores and evaluation results, and goals and objectives for the school year.

low-incidence disabilities Nine disabilities identified under the Individuals with Disabilities Education Act (IDEA): other health impairments, multiple disabilities, autism, orthopedic impairments, hearing impairments, developmental delays, visual impairments, traumatic brain injury, and deafness/blindness.

mainstreaming When an exceptional student is a member of a special class but attends a regular class for certain periods of the day; a student with special needs can be mainstreamed for academic or nonacademic subjects.

reinforcement The principle of behavior stating that a desirable consequence delivered immediately after a behavior will serve to increase the likelihood that the behavior will occur again in the future.

related services Supplemental services that may include speech and language therapy, physical therapy, occupational therapy, nursing services, counseling, hearing services, and/or visual services.

self-contained classroom A special class that consists solely of students with disabilities; it has a smaller teacher-to-student ratio and may include teaching assistants or paraprofessionals.

self-fulfilling prophecy When low expectations are set and students only learn to meet these lower standards.

self-injurious behavior Repetitive or nonrepetitive behavior that results in bodily harm to the individual, either immediately or over time (e.g., scratching, hair pulling, face slapping, scab picking, head banging).

stereotypy Repetitive behaviors that appear to have no function other than the sensory enjoyment of the behaviors themselves; stereotypic behaviors are often emitted by students who are diagnosed with autism or mental retardation.

Exceptional students comprise nearly 13% of all American school-aged children. Approximately 10% of students in the United States are diagnosed with disabilities, whereas 2 to 3% of the population is characterized as gifted or talented. The education of students with disabilities in the United States is governed for the most part by Public Law 94-142, also known as the Individuals with Disabilities Education Act (IDEA). Although exceptional students can be separated into 13 disability categories under IDEA, each student is unique. The learning, social, and behavioral characteristics of exceptional students, including gifted and talented students, differ for each individual student. The individualized educational needs of exceptional students must often be determined using alternative types of assessments. According to these assessments, the most appropriate placement, services, and instructional modifications are put into place for each student. Exceptional students can be educated in a range of educational settings, including the regular classroom. Under IDEA, students with disabilities receive an education according to an individualized education plan (IEP) designed around their unique needs and goals. Special educational plans may also be arranged for gifted or talented students. Because of the careful identification of goals and individualization of instruction, collaboration between professionals and families is critical for the successful education of exceptional students.

1. WHO ARE EXCEPTIONAL STUDENTS?

Exceptional students comprise the population of students with disabilities who require specialized educational services as well as students who are characterized as gifted or talented. Approximately 10% of students in the United States are diagnosed with disabilities, whereas approximately 2 to 3% of the population is considered to be gifted or talented.

The term “exceptional” has often been used to describe unusual, unique, or outstanding qualities of people or objects. Consider the following phrases: “His artwork is exceptional” and “She is exceptionally bright.”

In this case, the term “exceptional” refers to students who learn and develop differently from most others or students who have exceptional learning styles, exceptional talents, or exceptional behaviors. Exceptional students are those who fall outside of the normal range of development. Some disabilities are identified at birth or soon after birth, whereas others go undetected until the students enter school, where learning problems first become apparent. In the case of gifted or talented students, their abilities may also go undetected until they reach school. Some exceptional students have learning problems, some have behavioral problems, some have communication difficulties, and some have social deficits. Many students with exceptionalities have two or more of these problems, although they may also excel in certain areas. Students who are gifted or talented may also display behavioral or social difficulties. For exceptional students, the most important distinctions are made in the area of educational needs.

2. THE INDIVIDUALS WITH DISABILITIES EDUCATION ACT

The education of exceptional students in the United States is governed by a federal law known as the Individuals with Disabilities Education Act (IDEA), which was first enacted in 1975 and was then known as the Education of All Handicapped Children Act. Prior to 1975, U.S. schools were not mandated to educate students with disabilities. Very often, students with disabilities were deemed to be uneducable and were barred from entering schools. Now, their educational rights are protected, and dictated, by IDEA. Students are protected under IDEA from 3 years of age until the end of the school years in which they reach their 21st birthdays unless the students graduate earlier. The education of students who are exceptionally gifted or talented is governed by individual states. However, not all states have legislation pertaining to the education of gifted or talented students.

According to the U.S. Department of Education, a total of 5,762,935 students with disabilities ages 6 to 21 years were served under IDEA during the 2000–2001 school year. IDEA recognizes 13 disability categories. The number of students in each disability category served under IDEA during the 2000–2001 school year is listed in Table I. Each category of exceptionality has its own set of criteria for diagnosis. Students must meet all criteria to be diagnosed with a particular disability.

TABLE I
Number of Children Ages 6 to 21 Years Served under IDEA During the 2000–2001 School Year by Disability Category

<i>Disability category</i>	<i>Number of students served</i>
Specific learning disabilities	2,879,445
Speech and language impairments	1,092,105
Mental retardation	611,878
Emotional disturbance	472,932
Other health impairments	291,474
Multiple disabilities	121,954
Autism	78,717
Orthopedic impairments	73,011
Hearing impairments	70,662
Developmental delay (ages 3–9 years)	28,683
Visual impairments	25,927
Traumatic brain injury	14,829
Deafness/Blindness	1,318
All disabilities	5,762,935

Source. From U.S. Department of Education, Office of Special Programs, Data Analysis System. (2002). *To assure the free appropriate public education of all children with disabilities: Twenty-fourth annual report to Congress on the implementation of the Individuals with Disabilities Education Act.* Washington, DC: U.S. Department of Education.

Sometimes, students are impaired in more than one area, and these students may receive a diagnosis of multiply handicapped. The first four disability categories—specific learning disabilities, speech and language impairments, mental retardation, and emotional disturbance—are considered to be high-incidence disabilities because they affect the majority of students with disabilities. Specific learning disabilities affect nearly half of all students with disabilities. The other disability categories are considered to be low-incidence disabilities.

2.1. The Six Principles of IDEA

Exceptional students often require specialized education to meet their unique needs or to accommodate and build on their special talents. The majority of students with disabilities and students who are gifted or talented require special education. IDEA ensures a free and appropriate public education (FAPE) to all students with disabilities. Under IDEA, there are six important principles that dictate how students with disabilities are diagnosed, evaluated, placed in educational settings, and educated. These principles are discussed in the following subsections.

2.1.1. Zero Reject

The zero-reject principle ensures that no student can be denied an education due to the presence or severity of a disability. A student with a severe learning difficulty or severe behavior problem may not be denied services or expelled from school due to his or her disabilities. Under this principle, a student who is terminally ill or has a contagious disease may not be denied a FAPE either.

2.1.2. Nondiscriminatory Evaluation

The second principle of IDEA ensures nondiscriminatory evaluation of any student who has, or is suspected of having, a disability. Several types of assessment are conducted by an interdisciplinary team of nonbiased members. No evaluations may be conducted without parental consent. All decisions pertaining to a disability diagnosis and to educational evaluation are made by a committee that includes the parent(s) or guardian(s) of the child. The committee seeks to answer three important questions. Does the student have a disability? If so, does the student require special education services? If so, what educational placement and which services will best serve the student's needs?

2.1.3. Appropriate and Beneficial Education

The third principle of IDEA ensures an appropriate and beneficial education. This means that the student must be placed in an educational setting that best suits his or her needs. The student must be making educational progress for the placement to be deemed beneficial. An individualized education plan (IEP) is devised for each student, outlining the progress, placement, services, and goals to be addressed for the student. Appropriate placement means that the student is placed in the least restrictive environment (LRE).

2.1.4. Least Restrictive Environment

IDEA requires that the student be educated with his or her nondisabled peers to the maximum extent possible. The LRE is the educational setting that is closest to the regular educational setting that can still meet the student's individual needs. Only if a student's needs are too great to be met in the regular education environment should a more restrictive placement be considered. The range of educational placement options is known as the continuum of services.

2.1.5. Procedural Due Process

The fifth principle of IDEA ensures procedural due process. This means that there are safeguards in place in case the parents and school district disagree about what is best for the student. Impartial officials preside over due process hearings and make decisions according to what is best for the student. The principle of procedural due process also dictates how parents are informed of all decisions regarding their child, including the child's educational progress.

2.1.6. Parent and Student Participation

Parent and student participation is encouraged and mandated under the sixth principle of IDEA. This means that no decisions shall be made regarding the education of an exceptional student without parental consent and input. Student input is also encouraged whenever the student is capable of contributing. The student should have the opportunity to make decisions about his or her own future.

2.2. The Continuum of Services

Under IDEA, students with disabilities must be educated in the LRE, which is the educational environment that is closest to the general education classroom and that still meets the students' needs. There is a range of educational placements for students with disabilities, known as the continuum of services. Figure 1 illustrates the continuum of services.

At the top of the spectrum is the general education classroom. The student may receive supplemental services, known as related services, while in this placement (e.g., speech/language therapy, physical therapy), but

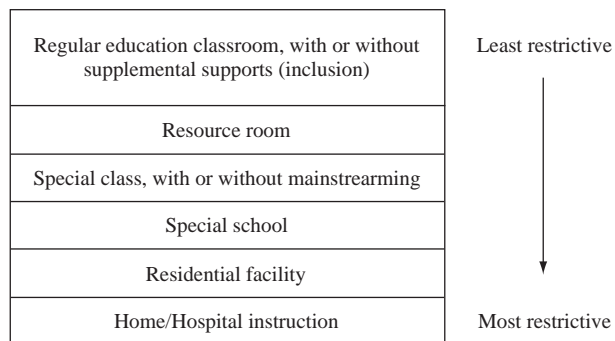

FIGURE 1 The continuum of services from the least restrictive environment to the most restrictive environment.

the student is a member of the regular class. When a student with a disability is a member of a regular class and spends the majority of the school day in that classroom, this is known as inclusion. An inclusion setting is an appropriate and beneficial placement only if the student is making educational progress. The social benefits of the inclusion setting are also taken into account and weigh heavily when determining whether an inclusion setting is the best placement option.

The next option is a resource room. Here, the student is a member of the regular class but spends up to two periods each day in a special class taught by a special education teacher. Usually, particular goals are worked on in the resource room (e.g., math, reading, study skills). The next placement option on the continuum of services is a special class or self-contained setting. Here, the student is placed in a class consisting solely of students with special needs. Special classes have smaller student-to-teacher ratios and usually include one or two teaching assistants or paraprofessionals. There are a variety of student-to-teacher-to-teaching assistant ratio options available. Sometimes, students who are placed in self-contained classes actually excel in one or more subject areas. For example, a student may require specialized instruction for reading and all content-area subjects but be on grade level for math. This child may attend a regular math class during the school day. This is known as mainstreaming. In keeping with IDEA, the student is spending as much time as possible with nondisabled peers.

The next placement option is a special school. Here, the student attends a school composed solely of students with disabilities. This restrictive setting ensures that programs and accommodations are available consistently. Beyond a special day school is the next placement option on the continuum of services, that is, a residential facility. The student attending a residential facility requires 24-hour continuation of instructional programs and care. The final placement on the continuum of services is home or hospital instruction. Here, instruction must be provided by a special education teacher for at least some portion of the school day.

3. LABELING AND CLASSIFICATION OF EXCEPTIONAL STUDENTS

There are several advantages and disadvantages to labeling students with disabilities. The first advantage is that it allows these students to be served under IDEA.

Another advantage to labeling students with disabilities is that it ensures that these students receive the proper types of assessment and the proper types of educational placements. A third advantage to labeling students with disabilities is that it ensures that these students are provided protection under the law and that they continue to receive protection under the other laws that afford rights to individuals with disabilities (e.g., the Americans with Disabilities Act) after they leave school. Lastly, some students and their families actually welcome disability labels because they provide an explanation for issues that these children and their families may have been struggling with for a long time.

There are several disadvantages to labeling students with disabilities. First, labeling a child may cause segregation of that child from his or her peers without disability labels. Placing a label on a child leads others to treat that child according to the label rather than as an individual. Labels cause stigmas that can lead to decreased self-esteem. Labels can also lead to the self-fulfilling prophecy, which occurs when low expectations lead to lower performance. When lower expectations are placed on students, those students are never challenged and so only learn to perform to lower standards. On the other hand, setting high expectations and challenging students can lead to greater achievement.

Person-centered language refers to the way in which students with disabilities are described. Placing the disability label first leads to identification of the disability first and the individual second. Instead, it is correct to refer to the individual with a disability first and the disability label second. For example, one should say "student with a learning disability" instead of "learning-disabled student." Focusing on the disability label causes others to view the student only in terms of his or her deficits or areas of weakness. If people focus on the individual first, they are more likely to see ability first and disability second.

4. ASSESSMENT OF EXCEPTIONAL STUDENTS

Under IDEA, students are entitled to nondiscriminatory evaluation. This means that they are evaluated using a variety of measures, including both formal and informal assessments. Students with disabilities should participate in the same assessments as their nondisabled peers to the maximum extent possible. This means that many students with special needs are

required to participate in statewide assessments such as standardized achievement tests. Exceptional students may be easily identified by their scores on standardized tests such as intelligence quotient (IQ) tests. The bell-shaped curve refers to the distribution of scores from such tests. The majority of students fall in the middle of the distribution or the average range. Very few students fall at the extreme low or high ends of the spectrum or outside of the normal range. Students who fall at the extreme high end of the spectrum are typically students who are gifted or talented, whereas students who fall at the extreme low end of the scale are typically students with cognitive delays.

Not surprisingly, students with disabilities often perform poorly on standardized tests. There are several alternative assessment options available for students with disabilities. One of these is criterion-referenced assessment. Some commercial criterion-referenced assessments exist (e.g., Sparrow and colleagues' Vineland Adaptive Behavior Scales), whereas many are teacher-made. A criterion-referenced assessment consists of an inventory or hierarchy of repertoires across several domains, including social skills, communication skills, academic skills, leisure skills, self-help skills, and maladaptive behavior. These inventories provide a way of identifying which repertoires a student has mastered and which skills need to be taught. Identification of deficits leads to easier selection of goals. Criterion-referenced assessments are time-consuming because they may contain hundreds of items that need to be assessed with individual students, but the end result is a clear picture of the student's current skill levels.

Portfolio assessments include several different components, including samples of the student's work, progress reports and evaluations, and (sometimes) student self-evaluations. Portfolios demonstrate a student's progress over time in that samples of the student's work or tests are taken over the course of a school year or several years. For example, a writing sample taken in June may be substantially better than one taken in September. Videotapes or audiotapes may also be included in portfolio assessments.

Curriculum assessments involve teacher-made tests or assessments that come with commercially published curricula. Curricular assessments allow real measurement of student progress through items that have been taught directly over the course of the school year.

Other forms of assessment may be extremely valuable, although they are considered to be "informal" assessments. These may include reviews of records and past progress reports, observations of the student in the

classroom environment, anecdotal reports, and interviews with parents, teachers, and even the student himself or herself. Informal assessments can be valuable in obtaining information that could not be obtained from standardized or criterion-referenced tests.

5. CHARACTERISTICS OF EXCEPTIONAL STUDENTS

Exceptional students include students across 13 disability categories and students who are gifted or talented. Although some disabilities are diagnosed based solely on behavioral characteristics, no two students are alike. However, it is possible to give some general overviews of student characteristics across three broad categories: learning, social, and behavior.

5.1. Learning Characteristics

Some exceptional students excel in certain areas or learn better through certain modes of instruction. Some students, such as students with autism or mental retardation, excel in the areas of memory and fact retention but are severely deficient in the areas of language and social skills. Similarly, students with specific learning disabilities may experience difficulty in one area (e.g., verbal reasoning) but excel in another (e.g., math). Gifted and talented students and students with certain disabilities may possess one or more of what Gardner identified as multiple intelligences (e.g., bodily/kinesthetic, logical/mathematical, linguistic, spatial, musical, interpersonal, intrapersonal, naturalistic). Some exceptional students are visual learners, others learn kinesthetically, and still others learn through multiple modes of instruction. It is recommended that instruction always be presented in several ways and that students be exposed to various instructional methods, including hands-on activities, to enhance learning.

On the other hand, many exceptional students experience severe learning difficulties. Possible sources of learning problems may result from attention and memory difficulties, motivational difficulties, and/or organizational problems. Still other problems may result from a lack of generalization. Generalization can fail to occur across settings (e.g., from school to home), across individuals (e.g., from teachers to parents), and across stimuli (e.g., instructional materials presented in different formats). Teachers must plan for generalization and teach across settings, individuals, and stimuli to ensure

that responses learned under one condition are emitted under other conditions. There are several strategies available to remedy learning problems after the source of the problems has been identified.

Although some learning problems may result directly from a cognitive delay, as is the case with students with mental retardation and students with autism, other learning problems may occur due to other factors. Behavioral problems may impede learning but may also result from inappropriate instruction. If the task presented to a student is too difficult or too easy, if the pace of instruction is too fast or too slow, or if the size of the task is too large or too small, frustration or boredom may result. Frustration and boredom may lead to behavior problems. Gifted and talented students may also emit inappropriate behaviors due to boredom in their classes. Teachers must always ensure that these students have the prerequisite skills to perform the task under instruction and that they are properly motivated. It is important to figure out the learning styles of exceptional students to ensure that instruction will maximize their learning.

Because the learning styles and characteristics of exceptional students are so diverse, the IEP becomes a critical document for ensuring that students are receiving the specialized and individualized instruction they need. Certain instructional modifications that have been useful in improving learning will be outlined in the IEP to assist teachers in providing the best education possible to their exceptional students. Sometimes, however, exceptional students experience poor academic performance as a result of other factors such as social or behavioral problems that impede learning.

5.2. Social Characteristics

Exceptional students may also experience difficulties with social interactions. They may appear awkward in social situations, have difficulty in making friends, and respond differently to social situations. Often, exceptional students may have the language skills to communicate but lack knowledge of the rules of conversation such as body language, proximity, turn taking, and staying on topic. The conversational skills of students with disabilities might seem egocentric or one-sided. These students might not listen to the responses of other students or might not play the role of both speaker and listener in conversations. Exceptional students often do not learn from appropriate modeling, do not pick up subtle cues, and do not interpret the feelings of

others appropriately. Gifted or talented students may also emit awkward social behavior, perhaps because their level of maturity is above that of their same-aged peers or because they have not had experiences similar to those of their peers. Difficulties with social skills may also lead to behavior problems.

5.3. Behavioral Characteristics

Behavior problems are probably most common among exceptional students. Behavior problems may range from assaultive behaviors (e.g., hitting, screaming, throwing objects) to severe withdrawal. Behavioral issues may also include inappropriate or bizarre behaviors (e.g., stereotypy, self-talk, self-injurious behaviors). The important thing for educators and parents to realize is that all behavior has a purpose or function. Sometimes, bad behavior is the result of an inability to communicate due to a lack of language skills. Other bad behaviors may result from attempts to gain attention or to escape or avoid an aversive task. Still other behaviors (e.g., stereotypy) are emitted because the behaviors themselves are reinforcing (e.g., sensory stimulation).

Attention-seeking and escape behaviors are often mistaken for willful disobedience or are seen as a result of the disability itself. Often, fictitious explanations of behavior result from placing the locus of control within the child (or within the parents) instead of looking to environmental variables to explain behavior. From a behavioral standpoint, all behavior is controlled by its consequences. This means that a student will continue to emit only behaviors that are reinforced or that are followed by desirable consequences. If the child screams in an attempt to gain attention and an adult responds to the child's screams, the child is more likely to scream to gain attention in the future. The consequences that educators and parents deliver, such as telling the screaming student to be quiet or asking the student what he or she wants, do not serve the purposes that were intended. Attention comes in many forms, including speaking to the child and making eye contact with the child. Escape behaviors are maintained by consequences that allow the child to get out of doing the task.

Functional behavior assessment involves determining what the function or purpose of the behavior is or what consequences are maintaining the behavior. Functional behavior assessments also seek to identify the antecedents or precursors for behavior as well as environmental and motivational variables. Behavior that continues to occur is behavior that is reinforced. The function of the behavior may be communication,

attention seeking, escape, or sensory reinforcement. Under IDEA, functional behavior assessments must be conducted for all aberrant behavior. Behavior plans then become part of the student's IEP.

6. IMPLICATIONS FOR PROFESSIONALS AND FAMILIES

It is very important for educators and parents to remember that undesirable behavior always has a function. If the function of the behavior can be determined, a solution to the problem behavior is usually suggested. Blame for the behavior should not be placed on the child or on the child's disability. Although the learning, social, and behavior difficulties of exceptional children might seem overwhelming, there is a great deal of research in the field, especially in applied behavior analysis, that demonstrates successful strategies and tactics for remedying bad behavior and teaching important skills. Sometimes, the most important skills for exceptional children to learn are how to manage their own behavior, how to seek help when necessary, and how to advocate for themselves. Fortunately, under IDEA, exceptional children have access to a wealth of pedagogical practices designed to prepare them to live as independently as possible.

strategic thinking Understanding and setting distinctive competitive goals and actions for an organization.

Executive development and coaching includes a variety of assessment tools and interventions that have been designed to help executives improve their knowledge, skills, abilities, and performance and to build the talent needed to meet strategic objectives and new business challenges in an organization.

GLOSSARY

- coaching* Helping others to improve their knowledge, skills, abilities, and/or performance.
- development* Learning or strengthening knowledge, skills, abilities, or performance.
- executive* A general manager, head of a functional area, or corporate officer in an organization.
- general manager* A manager who has multiple organizational function responsibilities for running a business (e.g., production, sales and marketing, product development, human resources, finance).
- global executive* An executive who can work effectively and comfortably across cultural borders and who typically has lived and worked in at least two different countries.
- organizational culture* The shared values, beliefs, practices, rituals, and behavioral patterns in an organization.

1. WHAT IS THE HISTORICAL CONTEXT?

A greater focus on executive development and coaching emerged during the 1990s. During prior decades, executives were not given as much attention; instead, the emphasis was on selecting individuals who had management potential and on using basic management training to teach functional skills.

During the 1980s, the world of business changed significantly. There was a significant globalization of business markets and a destabilization of many companies and industries due to increased global competition, to a wave of business mergers and consolidations, and to an expanding acceptance of management talent moving across companies. The speed of business and decisions

greatly increased and forced people to work hard to keep up with the rapid changes. This led to a need for fungible managers and executives who can learn quickly and be effective in a range of business situations. Managers who can do this are highly valued, and they often leverage this demand for talent to aggressively negotiate for career opportunities that move them into executive roles so that they can help run a company.

During the 1990s, executives emerged as the key to effective corporations. They were seen as critical decision makers and were given a lot of personal visibility and credit in the press. In addition, many managers viewed being an executive and running their own businesses as viable career goals. However, it became evident that many managers and executives did not have the skills and abilities to effectively handle an executive role or to adequately adapt to major and rapid changes occurring in the business world. Because of the increased competition for the best talent, companies aggressively pursued initiatives to better train and develop their current internal managers and executives.

Initially, these executive development initiatives focused on sending current executives and managers with executive potential to graduate business schools for executive development classes and executive MBA programs. These efforts focused on providing individuals with additional business knowledge, particularly in corporate finance. Because of the cost and the limited number of participant openings in these external programs, companies began to conduct internal executive development classes and tailoring them to the specific needs and business situation of each company. Later, these programs expanded to also include some emphasis on the development of executive performance skills such as strategic thinking, media and press interviewing, and decision-making skills.

As corporations went through broad reorganizations and rapid changes, some executives had difficulty adapting to the changes. This led to the increasing turnover of executives and chief executive officers (CEOs) in companies, which in turn placed new performance demands on the remaining executives in a company. The existing executives were expected to retune their skills to fit the new expectations and strategic directions of the recently hired CEO. Human resource officers began to hire executive development experts, including retired business executives and organizational psychologists, to work in groups and individually with these executives in order to “fix their skills.” After some success in getting executives retrained and aligned with the new CEO, these development experts were then assigned to help well-

performing executives and high-potential managers who wanted to continue to build their executive skills. Slowly, the field of executive coaching emerged and evolved from fixing performance problems to further building the skills of strong performers.

This article reviews some of the current techniques used in executive development and coaching. When a company considers starting an executive development initiative, it typically must consider a few fundamental issues. How a company or development professional thinks about these issues has a direct bearing on the nature, approach, and success of the development effort.

2. WHO IS AN EFFECTIVE EXECUTIVE?

There are many opinions on which knowledge, skills, and abilities (KSAs) an executive needs to perform effectively. Although some people use the term loosely, this article will reserve the term “executive” for general managers, functional area heads, and corporate officers in an organization. Many companies, human resource professionals, and industrial/organizational psychologists have identified their own lists of the necessary executive competencies. In 2002, Silzer and a range of respected experts reviewed executive skills and abilities from a variety of angles, while others, such as Fulkerson, McCall, and Hollenbeck, focused on the requirements to be an effective global executive. Silzer, in his chapter on selecting executives, outlined the challenge of selecting individuals who would be successful over the long term and across a variety of business challenges. He discussed the complexity of the selection process in terms of “executive fit” on four different levels:

- Person–position fit (matching the executive with the specific job requirements)
- Person–group fit (matching the executive with the existing executive team and direct reports)
- Person–organization fit (matching the executive with the organizational culture)
- Person–cultural fit (matching the executive with the country culture)

Some people argue that the executive job is so complicated, individually tailored, and ever changing that it is impossible or useless to identify one set of KSAs that apply across all executives and all situations. Unfortunately, this view leads down an empty path and provides little help when trying to structure

and implement executive selection and development approaches. Others would argue that while the executive role is very complex, there are some fundamental performance areas that do apply to a wide range of executives and business situations. A list of key executive KSAs that are relevant to most executive positions probably would include the following:

- Sound judgment and decision making
- Strategic thinking and strategy management
- Interpersonal influence
- Communication effectiveness
- Leadership confidence and impact
- Results orientation
- Business and financial acumen
- Customer focus
- Integrity
- Organizational insight and management

Executives are also typically expected to have some knowledge of general business practices, functional areas, organizations, financial management, and human resource management. Lately, knowledge of information technology, marketing, and customer service has become more important to executives, whereas knowledge of particular industries or products has become less important because executives now frequently switch companies and industries during their careers.

Of course, executives also need to handle their own, ongoing job responsibilities. These vary widely depending on the specific executive role, but there are some performance areas that apply to a broad range of executive positions, including the following:

- Accomplishing annual goals
- Managing the organization and financial budgets
- Building, motivating, and developing leadership talent
- Pursuing innovative ideas and distinctive competitive strategies
- Defining and supporting the organizational culture

3. WHAT IS EXECUTIVE DEVELOPMENT?

In the past, there was a strong “selection bias” in human resource management. That is, there was a widespread belief that managers and executives had limited ability to grow or change, so executives, managers, and human resource professionals relied almost exclusively on selection to find the right person for a management or executive job. If someone was performing poorly, that

person was fired or moved aside so that another person could be selected to fill the position. Most psychological assessment tools and techniques in organizations were used to select the best person for the jobs.

However, during the 1980s, the field of training and development started to emerge as useful and relevant to management and executive effectiveness. For example, assessment centers that previously had been used exclusively for selection were being used to develop current and future incumbents to be more effective in these roles. Particularly in the fast-changing business environment of the 1980s and 1990s, companies had to figure out how to quickly redeploy and redevelop current employees for new roles and jobs because it often was infeasible to fire everyone and hire an entirely new workforce and executive team (although some companies did exactly that). As a result, there was a wave of interest in management, leadership, and executive development techniques.

The term “executive development” means learning or strengthening the KSAs needed to be effective in an executive position. There was significant interest by organizations in identifying and further developing those individuals who were seen as having significant potential to be effective in higher level executive positions. This led to the development of a range of new initiatives, including succession management systems, executive classes and programs based in graduate business schools, and the widespread use of management and executive competency models to specify the KSAs that a manager or an executive needs to be effective.

4. WHAT ARE TYPICAL EXECUTIVE DEVELOPMENT APPROACHES?

Companies and development professionals have devoted a good deal of attention and creativity to designing management and executive development programs. In 1999, Conger and Benjamin outlined some development approaches used by different companies. In thinking about executive development, it is helpful to separate the approaches that focus on the assessment of executive KSAs and performance from those techniques that are used as development interventions.

4.1. Assessment Approaches

Some executive development programs are designed so that all executives, regardless of their individual skills

and performance, go through the same program either as individuals or as groups. Another approach that gained support and acceptance during the 1980s is to first identify the development needs of individual executives and to provide a development experience that is appropriate for those specific needs. This leads to an expanding role for assessment in the process.

Assessment of an executive's development needs has typically used one of three general approaches:

- Performance reviews
- Multisource feedback
- Individual (psychological) assessment

4.1.1. Performance Reviews

The most common assessment approach is to use the annual performance review to identify an individual's performance/KSA strengths and development needs. Nearly every organization has designed an annual executive evaluation process that reviews an executive's behavior and performance in several areas that may include looking at results against annual goals, general executive performance, executive skills and abilities, and how well the executive demonstrated company values. Some review programs include specific behavioral standards of expected performance as review guidelines, whereas others are more open-ended and rely on the broad judgment of the reviewer.

4.1.2. Multisource Feedback

Another assessment technique that has gained widespread acceptance is a multisource feedback approach. This relies on collecting structured feedback on an executive's performance and KSAs from a range of people who have had an opportunity to interact with the executive and to observe the executive's behavior. This group might include immediate or higher level bosses, peers, direct and second-level reports, internal and external customers, members of the board of directors, outside community and financial contacts, vendors, and suppliers. The feedback is typically collected either through a structured written questionnaire (often referred to as a 360-degree feedback instrument), telephone interviews, or one-on-one meetings. A written questionnaire provides a more standardized approach that can cover quite a broad range of performance areas and KSAs. The interview and meeting approaches allow for a deeper discussion of key issues and the identification of numerous examples of behavior that illustrate the feedback.

4.1.3. Individual Assessment

A third approach that has been gaining significant support is an individual (psychological) assessment of the executive. This approach was initially used by companies to help select executives but is now also being used extensively for development. In 1998, Jeanneret and Silzer provided a good resource on how psychological assessment tools and approaches can be used effectively in organizations. When used for development, this approach is typically designed to assess current performance, KSAs, development needs, career direction, and potential for other roles. The approach usually includes a range of tools and techniques such as the following:

- Cognitive ability tests
- Personality and career interest inventories
- Structured behavioral interviews
- Behavioral exercises and simulations (e.g., role-play, "in" basket, and presentation exercises)
- Multisource feedback

Assessment techniques are usually used with individuals, although it is becoming more common for all executives to go through an assessment process at the same time. This group approach not only allows the company to understand the strengths and weaknesses of each individual executive but also provides a profile of the entire executive group. The CEO, and often the board of directors, can then see the shared strengths and shortcomings of the group. This approach can be very useful when the organization is going through a significant change such as a merger, downsizing, reorganization, or change in strategic direction. It can lead to a valuable reshuffling of executive talent across the organization to better match individuals to executive roles. In addition, the process can identify common performance weaknesses that can then lead to a group development initiative or even a modification in the company's strategic goals. For example, in some cases, organizations have used an executive group profile to determine the strategic direction of the companies by looking for opportunities that leverage the strengths of the existing executives and that minimize any reliance on areas that are group weaknesses.

4.2. Intervention Approaches

Once the development needs or goals have been identified, then appropriate development intervention approaches can be identified that specifically address those needs. There are myriad intervention tools and

techniques that have been used to develop executives. They might be categorized into four general types:

- Learning through the experience of others as an individual.
- Learning through the experience of others with a group.
- Learning by personal experience as an individual.
- Learning by personal experience with a group.

4.2.1. Learning through the Experience of Others as an Individual

Initially, this was probably the most common development approach, with individuals learning from their immediate bosses or the previous incumbents in their roles. When business started to go through widespread change, many bosses and previous incumbents no longer were the best sources for the executives on how to handle the new challenges. So, executives started turning to others with more experience for help. Some approaches to executive development in this category include the following:

- Working with an internal or external mentor
- Locating a tutor or an expert on a specific topic
- Establishing an internal or external network of resources and experts
- Taking a temporary assignment with a customer or vendor
- Initiating a personal reading program
- Conducting a study or writing a white paper on a critical business issue
- Visiting competitors, suppliers, and customers
- Attending conferences and seminars
- Teaching a business class

4.2.2. Learning through the Experience of Others with a Group

This has been a frequently used approach, often relying on attending business classes or executive programs at graduate business schools. The high cost of these programs limited the number of executives who could attend and eventually led to a decrease in attendance but also to an increase in internal executive programs designed to meet the same goals. A group approach to development typically means that all executives go through the same program without regard for their individual development needs. However, in some cases, executives with similar needs have joined together to address those specific

common needs as a group. In 2002, Marcos described some innovative group approaches. Some examples of group development include the following:

- Attending a business school course or an executive program
- Participating in an internal leadership or executive training program
- Starting a reading discussion group
- Participating in a peer group shared learning program
- Initiating an internal speaker presentation series

4.2.3. Learning by Personal Experience as an Individual

As the executive development field moves to assessing and identifying individual development needs, there is a growing focus on activities in this category. Many development action plans are being written that focus on the specific development needs of the executive. These plans initially and primarily consisted of taking courses, but the field soon adopted the now widely accepted idea that the best development occurs on the job in a “learn-by-doing” approach. This shifted quite a bit of attention to experiential learning at the executive level. One very visible technique is the “action learning” approach described by Dotlich and Noel in 1998. Other examples include the following:

- Starting an on-the-job skills building program
- Initiating an action learning assignment and project
- Rotating through different core businesses or functional areas in the company
- Becoming an executive assistant to an officer
- Leading a strategy review or a negotiating process
- Taking an overseas or global assignment
- Managing a start-up, turnaround, or high-growth business
- Managing a large, highly complex, or matrixed business
- Taking responsibility for a liaison role such as government lobbying or community affairs

4.2.4. Learning by Personal Experience with a Group

Some of the preceding approaches evolved into group experiences. In some companies, “action learning” means group projects. A selected team of executives or high-potential managers is assigned to work on a

special project that addresses a major organizational issue or problem. The team learns a great deal about the issue and the organization, while the company gains some sound recommendations on how to address the issue. Examples of group learning approaches include the following:

- Joining an action learning project team
- Volunteering for a corporate task force
- Being part of a new business start-up team
- Pursuing an internal or external business partnership
- Joining an industry-wide committee
- Serving on a business review team

5. WHAT IS EXECUTIVE COACHING?

During the past 10 years, executive coaching has become a widespread executive development tool. It can be defined as a one-on-one helping relationship between an executive and a coach that helps to improve the executive's performance and combines learning through the experience of others with learning from personal experience. Often, this process focuses on the executive's KSAs and behavior. It is different from mentoring in that coaching seeks to change the executive's on-the-job behavior and performance and not just to provide advice. Hollenbeck, in his enlightening 2002 chapter on executive coaching, distinguished it from psychotherapy by noting that the goal of coaching is "better job performance," whereas the goal of psychotherapy is "a more fully functioning person."

In some cases, every executive in a company is assigned a personal external coach. A number of companies later backed off of this sweeping approach due to the high cost. Executive coaching turned into something of a fad and attracted the interest of a wide range of coaching service providers. Because there are no credential standards, anyone can assume the title of executive coach. This includes human resource consultants, trainers, psychologists, retired business executives, health care providers, and MBA graduates. As a result, the field of executive coaching and executive development has been swamped with people who do not have the necessary coaching skills or business knowledge. Corporations are often fairly indiscriminate in selecting executive coaches. Many coaches are probably ineffective, but corporations do not spend much time in evaluating the effectiveness of coaching interventions. Under significant

cost reduction pressures, companies are now starting to better manage these assignments. This has resulted in a few emerging trends in executive coaching, including the following:

- A more discriminating use of external coaches
- Written standards for the selection and evaluation of coaches
- The training of current internal executives as peer coaches

Good coaches need to have knowledge of business and executive performance issues as well as skills in communicating, interpersonal influencing, and changing behavior. Many coaches fall far short of this. The coaching process typically lasts from 6 to 18 months, although many companies have started to put a 1-year time limit on these interventions. The process generally consists of five phases:

- Initial agreement and contract
- Assessment
- Feedback and planning
- Coaching intervention
- Follow-up

Moving through these phases depends on success at each step. Coaches need to be able to demonstrate progress in changing an executive's behavior. Too many interventions are just pleasant bimonthly conversations with little focus or impact. Coaches must also be trustworthy and be able to carefully manage the confidential information shared by the executive and the executive's immediate bosses. Many coaching interventions fail because of a poor coaching contract at the beginning of the process, a lack of confidentiality, or a lack of change in the executive's behavior.

Recent interest in executive coaching has focused on a few key issues:

- How can the process be made more cost-effective?
- How can the effectiveness of coaching interventions be rigorously evaluated?
- How can individual coaches be objectively selected, assigned, and evaluated?

6. WHICH PERFORMANCE AREAS ARE MORE AMENABLE TO DEVELOPMENT?

Over the years, coaching experts have gained a good deal of insight into how to effectively change the

behavior and performance of executives. There is some agreement that interpersonal and communication skills are the most common areas that coaches focus on for development. They also are the areas where good coaches can have significant impact. Other areas that seem fairly amenable to development include personal organization, planning, administrative skills, business knowledge, presentation skills, financial knowledge, and project management.

On the other hand, there are a number of areas that are difficult to develop either due to the complexity of the area or because it requires specific preliminary abilities. These areas include complex decision making, innovative thinking, strategic planning, personal and career motivation, leadership versatility and influence, and personal integrity.

The field still needs to better define which development approaches are best suited for which performance areas. It is now known that interpersonal role-playing and behavioral exercises do seem to be useful approaches in changing an executive's interpersonal skills. However, there is little research matching development interventions with other performance areas. In general, an executive needs to go through four stages for changing behavior: understanding the behavioral issue, learning new effective behaviors, practicing the new behaviors, and getting feedback from others on those behavioral attempts.

7. WHICH EXECUTIVES ARE MORE LIKELY TO DEVELOP?

There also has been growing agreement that some executives are more likely to develop than others. Although there is not total agreement on what separates these two groups, there are a few markers that seem to distinguish the developable executives. These executives generally have strong cognitive skills in order to adequately understand the development that is needed. They also need to be mentally flexible and behaviorally adaptive to try new behaviors, and they should have a clear motivation and willingness to change. That is, they should see the need to change their behavior. In addition, it helps if they have a learning orientation, that is, an intellectual curiosity and interest in learning new things. Executives who do not develop generally are inflexible, unwilling to change, or unable to learn new behaviors.

8. WHAT ARE THE HALLMARKS OF DEVELOPMENT SUCCESS AND FAILURE?

Companies typically spend significant financial resources on executive development each year. There is a large group of internal and external development specialists and consultants who have been very successful in providing executive development services. Although many companies have recently worked to reduce development costs, many expensive development approaches, such as business school programs and executive coaching, are still widely used.

Executive development efforts often fail to have any impact on an executive, although companies rarely hold these programs accountable for producing measurable results. It may be some time before companies implement tough outcome standards. There are some known reasons why many of these efforts fail, including the following:

- Lack of clear objectives
- Inappropriate or irrelevant development activities
- Lack of follow through on a development plan
- Failure of the executive to learn the right behavior or lessons
- Inability of the executive to learn or change
- Lack of leadership support in the organization for the change
- Lack of business application for the change

At the same time, there are some hallmarks of successful development efforts, including the following:

- An executive who is able and motivated to learn
- Use of the right approaches and techniques for the development need
- Clear learning and behavioral objectives
- Hands-on learning experience
- Focus on specific behaviors and outcomes
- Clear connection to business applications
- Regular feedback and guidance from others
- Support from senior leaders

The emphasis on executive development is likely to continue and even increase in the future as the globalization of business increases. The demand for effective fungible executives will remain high, and corporations will see the benefit of having well-integrated executive selection and development efforts to meet new business challenges and to achieve difficult strategic objectives.

GLOSSARY

- Altiplano* The highlands of Peru.
chacheeko Local name for a newcomer in Alaska.
cold soaked Frozen.
dehydration Loss of water in the body.
desertification Land turning into a desert.
diurnal rhythms The daily cycle of the sun.
head bolt An electrical outlet for cars to plug into at a parking lot.
heat exhaustion Collapse due to overheating and loss of water.
heatstroke More serious condition due to body's failure to deal with heat.
hypothermia Loss of body heat.
hypoxia Lack of oxygen.
Monge's disease Altitude sickness.
photophobia fear of light.
puna Local word in Bolivia for altitude sickness.
soroche Local word in Peru for altitude sickness.
tacya Ironwood digging stick used in the Peruvian Altiplano.
the 200 Club Initiation rite at the U.S. polar station; one joins by running naked to the pole and back when the temperature is -100° F.

Extreme environments are of two kinds: the permanent ones where people live year-round (e.g., high mountains, deserts, cold regions, jungles) and the temporary ones such as space flight, simulation laboratories, and the temporary incursions into the permanent extremes (e.g., mountain climbers, missionaries, explorers). Problems of function are most frequent in the temporary incursions into the permanent areas and places such as Antarctica, space flight, and the simulation laboratories. Extremes are being made more endurable by introducing communications technology and more creature comforts.

1. DEFINITIONS

The definition of extreme environments is very geocentered. People living in the heavily populated and industrialized latitudes around the tropics of Capricorn and Cancer assume that equatorial and arctic climates are extreme, whereas those living in these "extreme" latitudes think of them as normal. Similarly, those near sea level think of altitudes of a mile or more as extreme, whereas those living at these altitudes think of them as healthier. Thus, one person's extreme can be another person's normal surrounding. "Extreme" as a label acquires some credence when it involves environmental conditions that bring about physiological responses that

interfere with the normal functioning required to get the business of living done. In high altitudes, this includes hypoxia (i.e., lack of oxygen); in colder climates, it includes frostbite and hypothermia; and in hot climates, it includes heat stroke, heat exhaustion, and dehydration. In jungles, what it includes is less clear, but extreme humidity, exotic diseases, and a myriad of insects make it at least unusual compared with more temperate climes.

When it comes to environments such as space travel, balloon exploration, and experimental laboratories that simulate space travel, no one has any trouble calling these extreme. Similarly, when mountain climbers, explorers, and skiers climb to great heights, these are also seen as extreme.

A distinction must be made, however, between those latitudes and altitudes where people live year-round and have a chance to adapt through generations and those extremes where visitors enter for a brief time and then leave. The latitudes and altitudes where people live year-round under harsh conditions are a permanent situation, whereas those where there are only short incursions are best labeled “temporary.”

2. THE ENVIRONMENTS

2.1. The Temporary Environments

2.1.1. Antarctica

Although Antarctica is now inhabited year-round by people from a variety of countries, all of these people are there on assignment and will rotate home at some point. No one has been born in Antarctica, although some have died there (largely by accident). Antarctica has been characterized as the highest, driest, and coldest desert on earth. No one thinks of it as a desert due to the miles of ice that have accumulated there in glaciers, but its average precipitation makes it comparable to deserts at more northern latitudes. Thus, Antarctica combines all of the climatic elements that make environments extreme—cold, altitude, unusual diurnal rhythms, and dryness—in addition to another element: isolation.

At an average altitude of 9000 feet (2743 meters), many people experience hypoxia (i.e., lack of oxygen). Hypoxia can cause sleep disturbances, and this can lead to loss of memory, hallucinations, and other mental aberrations. Therefore, sleep deprivation alone could account for failure to perform duties. The average person who goes there, however, experiences less

dramatic symptoms such as failure to attend properly at random times and the resultant mistakes.

The diurnal effects on sleep are also notorious. When Burgess Ledbetter and the author were doing their work in Alaska, they encountered a man who had not slept in 10 days. Thus, the effects of long daylight, as well as the long, dark, and cold nights, can be felt.

The cold of Antarctica has a dramatic effect. Jerri Nielson, the doctor who was rescued from Antarctica due to her cancer, described how the impact of the cold made her forget the orientation lecture. Rivolier, in his field studies, found that the impact of even minimal exposure to the cold was measurable. One reaction that affects performance is the extension of reaction time. This is especially troublesome in outside activities such as driving vehicles and repairing. Perhaps the most common malaise reported in Antarctica is the semicomatose state referred to by many names such as “cabin fever,” being “stir crazy,” having the “big eye,” and just “staring into space.” Not everyone experiences or reports this, but nearly everyone reports periods of wandering attention. The lack of attention can be serious when a schedule must be followed, and there are many reports of personnel who have let schedules slip.

Often overlooked in the concentration on negative experiences are the more positive outcomes reported by many inhabitants of the Antarctic stations. For some, the winter in Antarctica is the “experience of a lifetime.” Nielsen pointed out that Antarctica can be habit forming.

Finally, there is the form of madness called “the 200 Club.” This rite of initiation occurs at the pole station when the temperature drops to -100°F (-73.3°C). The initiates are heated up in a room at $+100^{\circ}\text{F}$ ($+37.7^{\circ}\text{C}$) and then run naked (with shoes on) to the pole and back. The spectacle is commemorated with photos of icicles dripping from appendages.

2.1.2. Space Travel

Most of the experience in space travel comes from the Russian space station *Mir*, the space shuttle, and the exploratory *Apollo* missions to the moon. The greatest danger in space travel, radiation from the sun, has largely been avoided by rotating the vessels, traveling at times of the quiet sun, and experiencing just plain good luck. The second most serious problem has not actually been dealt with in a remedial fashion. Weightlessness causes the body to dissolve calcium out of the bones. This can cause a serious disability such as osteoporosis. Russian cosmonauts who spent a

long time on *Mir* had to be carried out of the return capsule and took weeks to recover sufficiently to walk normally again. A program of 6 to 8 hours of strong exercise aboard *Mir* did not help alleviate the problem. There seem to be large individual differences in the loss of calcium. Some astronauts were able to walk after landing, whereas others were not. There remains a question as to whether the bone density ever returns to normal. Although bones have not been broken due to this problem so far, it would be a serious problem for longer voyages such as one to Mars.

The trip to Mars constitutes the most extreme of any environment to date. This is due to the communications lag between Earth and Mars of up to 40 minutes and the length of time spent traveling to, staying on, and returning from Mars that could take up to 3 years. Because it is not known whether there is any water on Mars, urine will have to be recycled through a purifying filter (Fig. 1). The “home” on Mars will consist of a reused rocket body (Fig. 2). A human factors problem is the need for windows that considerably weaken the structural integrity of the rocket body.

As in other isolated confined environments, space travel wreaks havoc on sleep patterns. Astronauts and cosmonauts can lose 2 hours of sleep every 24 hours and end up with serious sleep deprivation. Although this has not resulted in hallucinations or psychotic behavior, the lack of attention to detail and time can result in serious mistakes.

2.1.3. Simulation Laboratories

In September 1991, eight biospherians were confined in a Mars colony simulation and remained there for 2 years (Fig. 3). Before the 2 years were up, oxygen had to be pumped into the biosphere structure and higher calorie foods were introduced. The atmosphere was reduced to the equivalent of 13,000 feet (3962 meters), and the number of calories in the diet had fallen to 1800 per day. In addition, a conflict had developed among the crew members. This experience was similar to those of Russian attempts at simulation. Nevertheless, the crew finished the mission. Much earlier, the Tektite Lab, an underwater laboratory, had uncomfortable conditions of crowding, humidity, and disturbed sleep. But this crew also finished the mission and did even more work than is done under normal conditions.

The experiences with the simulation laboratories are mixed. Some result in conflict, whereas others do not. The simulations are often considered to be good training.

2.2. Permanent Extreme Environments

2.2.1. High Mountains

There are really only three areas on Earth where significant numbers of people live permanently at high altitudes: the Tibetan Plateau, the Andes, and the highlands of Ethiopia. These are also areas where mountain climbers and miners sometimes work. The continent of Antarctica does not qualify because all persons there are on temporary assignment. Only visitors to these places have the kind of symptoms that seriously interfere with mental function. Lack of oxygen is the primary environmental element that leads to interference with normal functioning (hypoxia) at high altitudes. There are two types of altitude sickness: acute mountain sickness and

FIGURE 2 Rocket body simulating crew quarters for Mars.

Source: Space Biospheres Ventures, Oracle, Arizona

FIGURE 3 Diagram of Biosphere 2. Apt., apartment; Bd, board; Mech, mechanical; Vet, veterinary.

chronic mountain sickness. Acute altitude sickness, which is what visitors experience, is also known as Monge's disease; it is also known locally as *soroche* in Peru and as *puna* in Bolivia. The person with hypoxia experiences restless nights, headache, vomiting (sometimes), tightness in the chest, irritability, and a fear of light (photophobia). Acute altitude sickness can also produce hallucinations and erratic behavior. There are many tales of this kind of behavior. One woman, a native of Peru, described her companion's constant efforts to turn off the car lights while driving on a mountain road. It was the most frightening ride of her life. Another traveler to the high mountains told of his wife's description of a blue horse. These symptoms usually disappear by the fifth day.

Chronic mountain sickness involves swelling of the brain and lungs. This can lead to death, and people who suffer from the symptoms must be quickly removed and taken to lower altitudes. The military has established a rule that oxygen masks should be used above 10,000 feet (3048 meters). Mount Everest is more than 29,000 feet high (8839 meters), yet in 1978 Reinhold Messner climbed to the top without supplemental oxygen. He went on to do it alone in 1980 and then, again without supplementary oxygen, climbed all 14 mountains in the world that are more

than 8000 meters high. This represented another monument to human adaptability.

2.2.2. Deserts

Deserts are characterized as being hot, dry, and devoid of the same kind of plant and animal life found in more temperate areas. Authorities disagree on definitions of deserts. Some prefer an extreme of 2 inches or less of rainfall per annum. Others' definitions go up to 15 inches of rain per annum. Some compromise and call these "arid lands." The definition of an arid land can be any place that requires irrigation. Areas on Earth that are seen as deserts include places such as the Sahara in Africa (the largest), the Namib in southern Africa, the Atacama in South America, and Death Valley in the southwestern United States. Areas such as the Sonoran Desert in the southwestern United States and northern Mexico, the Great Sandy in Australia, the Gobi in Mongolia, and nearly all of Saudi Arabia (Fig. 4) are also some of the more obvious ones. It should also be noted again that great parts of the Arctic and Antarctica are also considered desert if desert is defined by low precipitation. The main symptoms suffered in deserts seem to be chiefly from exposure to the sun with the result of heatstroke or heat exhaustion. Both involve many of the same symptoms: faintness, confusion, fainting, and vomiting. But the treatment is very different. Heatstroke, the most serious, requires immediate cooling, whereas heat exhaustion requires immediate water intake (salt is no longer recommended). Heatstroke is best recognized by a lack of perspiration. Thus, dragging the person into the shade and cooling with a water hose or any other method are critical.

It is estimated that the longest the average person could last if lost in the desert is 2 days. Death occurs when the body temperature rises above 113° F (45° C). Having said this, it should also be remembered that in 1905, Pablo Valencia got lost in the desert near Yuma, Arizona, and survived after 6½ days. He traveled only at night and rested during the days. Although many may regard the Grand Canyon as not in the desert category, in 1996 there were 482 search and rescue operations, the result of which 18 people died. It is estimated that more than 700 people have died in the Grand Canyon, with some of these dying from freezing during the winter. Most of the distress came from dehydration. Thus, the canyon seems to fit the temporary extreme category, even though people live at the rim and at the bottom year-round.

FIGURE 4 The Rub Al Khali (The Hidden Quarter) desert in Saudi Arabia.

Recently, the Sonoran Desert claimed a large number of deaths: more than 30 in 2002 and more than 50 in 2003 due to the illegal migration from Mexico into the United States. All of these people died from dehydration.

2.2.3. Cold Regions

The far northern communities in the U.S. state of Alaska as well as those in Canada, Greenland, and the former Soviet Union are easily seen as cold regions, and for many reasons parts of Norway and Finland, all of Iceland, and even the U.S. New England states and Montana winters can seem extreme. Antarctica qualifies as well, but this continent is in a class by itself, as mentioned earlier.

Frostbite is the most immediate danger in northern climates. The military coined the phrase "30–30–30," meaning that flesh freezes in 30 seconds in a 30-mile per hour wind at –30° F (–34.4° C). Despite this, one

can see the black scabs hanging from the cheeks of many Inuit from riding their snowmobiles on the streets of many communities in Canada and Alaska. The average human body stops functioning below 77° F (25° C).

Hypothermia begins with shivering and is then replaced by muscular rigidity, confusion, and loss of consciousness. The confusion has caused many deaths, and to this day it is still sometimes reported in Alaskan newspapers that people, usually *chacheekos* (newcomers), have frozen to death while trying to walk back to gas stations that were within sight after their cars had stalled.

Having set the preceding limits by clinical data, it should be noted that in October 1992 at Point Hope, Alaska, Morris Sage and Sayers Tuzroyluck fell into a lake while fishing. Sage chose to stay in the water because it was +25° F (−3.9° C), whereas the air was −10° F (−23.3° C). Tuzroyluck chose to walk back to the town 7 miles away. Medical authorities say that the average person can last no more than approximately 30 minutes in such conditions. Both men spent 3½ hours in the cold, and Sage's body temperature was measured at 75° F (23.9° C) when he was found. Both men survived without ill effects. This is perhaps testimony to the adaptation of the Inuit people to their climate or to the tremendous variability of humans in response to extreme conditions.

Automobiles can be a hazard in cold regions. They require a complete overhaul, with all fluids (e.g., brake fluid, crankcase oil) being replaced with a thinner variety, the crankcase being wired with a heated dipstick, and the entire apparatus being wired to connect with an electric "head bolt" while parked. If not, the car will freeze—get "cold soaked" in local parlance—in approximately 45 minutes. Many choose to let the engine idle when head bolts are not available.

Diurnal rhythms are a great disrupter of sleep. Many residents of Alaska use blackout curtains and shades during the long summer daylight period to help them sleep.

2.2.4. Jungles

Perhaps too much has been claimed for jungles as extreme climates. They do not have the extreme heat of the desert, nor do they have the heights of the mountains. Yet the humidity combined with a fairly high temperature makes activity uncomfortable and can produce heat exhaustion and heat stroke under certain conditions. Diseases such as malaria as well as exotic animals such as leeches, ticks, poisonous snakes, and

biting insects can test the limits of tolerance. Some even claim that the side effects of anti-malaria drugs are nearly as bad as malaria itself. Certainly, these distractions can produce the same kind of errors as are produced in deserts and cold regions. Also, the alertness required to keep a lookout for pests can often be as distracting as any malaise. Natives to the jungles show remarkable adaptations to their environment, and these cases are reported in many anthropology texts.

2.3. The Overlap

People who are assigned to extreme environments but are more than just visitors—who have a designated or indefinite length of stay—can often acquire some of the adaptations of persons living permanently in extreme environments. Peace Corps volunteers on the Altiplano in Peru have adapted to the lack of oxygen from which shorter term visitors may suffer. Likewise, Federal Aviation Agency personnel in Alaska have "cold adapted" after a certain length of stay. Military personnel also report being able to adapt to cold and hot regions. A caution that needs to be applied here is that many of these individuals can have high variability in their adaptation levels depending on age, physical condition, and personal habits.

In the Cold Regions Habitability Study, Burgess Ledbetter and the author encountered a few military wives who had not been out of their houses from October to April. Some of these were suffering from the symptoms of cabin fever, but others were taking the confinement in stride. The important point is that these longer term visitors have a longer time period during which to adapt.

2.4. Isolation: The Changing Extreme

With the advent of cell phones and the ability to carry sophisticated communications equipment literally anywhere in the world, the terms of isolation are being changed. During the investigation and remedial intervention in the Biosphere 2 Study, some of the biospherians stated that they had met more people by video and phone than they had during their entire lives prior to the confinement. If this trend continues, it raises a whole new question about the quality of isolation. Will it come to the point where any worker in Antarctica, any space station astronaut, or any missionary in the field can call home at will and see the

faces of his or her spouse and children? This alternative to complete isolation cannot be overlooked if it helps to alleviate the conditions that extreme environments otherwise impose.

3. CONCLUSIONS

3.1. The Temporary Environments

What seems clear is that no extreme environment has just one variable affecting function. There are always combinations. In cold regions, it is the cold and the diurnal rhythms. In the deserts, it is the heat and the dryness. Sometimes, there are three or more variables such as cold, dryness, and diurnal rhythms. And these effects can be cumulative over time. Sleep deprivation builds over time and becomes more and more debilitating.

But extreme environments are slowly getting less extreme. Compared with the expeditions and studies done just decades ago, the communications and comforts have improved greatly. Even Antarctica can now get fresh vegetables.

Another element that has improved is the selection of personnel. After years of screening and experiments with various instruments, the selection process has virtually eliminated mental pathology from the remote stations in the world. This technology has been shared across nations, resulting in more stable environments in places such as Antarctica, the space shuttle, and other remote government stations. But is there a price to pay for this? Researchers such as Suedfeld and Palinkas have pointed out the positive benefits of isolation: the quiet, the close fellowship, and the sense of being in another world. Will this be lost in the clutter of modern communications?

Finally, will there be permanent space stations and colonies on the moon and Mars? Will people who stay there for a long time be able to return to Earth and readapt to its strong gravity? There seems to be some evidence that they will not. Stays on the space station, and even in the low-gravity colonies, might have to be limited.

3.2. The Permanent Environments

Much is being revealed about the permanent extreme environments that raises questions about the variables that affect the occupants of these environments. Migration is evident in the Altiplano, the jungles, and the deserts. Economic forces may be the most relevant of all variables, and they are sending people to places where they can earn a better living. The use of a digging tool, the *tacya*, in Peru is being replaced with machinery, making much labor surplus. The Brazilian jungle is fast disappearing, and the deserts seem to be spreading, causing a new term to be coined: desertification. These new, largely economic variables are changing not only the populations of these environments but also the actual geography itself. Political aspects enter as well, especially in places such as Tibet. But even these are changing the character of the land. Only one thing is certain: change.

GLOSSARY

arousal Nonspecific excitation of the brain or one of its major subsystems (e.g., the cerebral cortex).

factor analysis A family of multivariate statistical techniques that aim to explain covariance among variables in terms of a smaller number of latent factors.

interactionism A popular contemporary approach to personality that sees traits as interacting with situational factors to generate behavior.

personality disorder An enduring pattern of abnormality in personality that is typically referred to in terms of various discrete disorder types described by the fourth edition of the *Diagnostic and Statistical Manual of Mental Disorders* (DSM-IV).

personality trait A stable personality characteristic that describes a continuum of individual differences in behavior expressed consistently across a variety of different situations.

self-regulation The cognitive processes and behaviors that support the pursuit of personal goals within a changing external environment.

Extroversion–introversion (E–I) is a major personality dimension that is an essential part of comprehensive trait models, including the Five-Factor Model. Various questionnaires provide valid and reliable measurement of E–I. The person's level of extroversion versus introversion depends on both biological and social–cognitive factors. The mechanisms that shape the development of E–I are not well understood. On the biological side, brain systems for arousal and reward have been implicated. On the social–cognitive side, biases in various aspects of self-regulation may be important. E–I is modestly associated with many criteria related to real-life functioning, including mental health, social behaviors, and work performance. E–I should be understood within an interactionist context, such that both person and situation factors are important as determinants of behavior. Empirical studies support clinical and occupational applications based on the assessment of E–I.

1. PSYCHOMETRIC FOUNDATIONS

1.1. Origins and Early Studies

The extroversion–introversion (E–I) trait refers to a dimension of personality that contrasts qualities such as sociability, assertiveness, and enthusiasm with qualities such as social reserve, quietness, and thoughtfulness. Its place as a central element of personality has been recognized since antiquity. Jung popularized the

idea of extroverts and introverts as distinct types characterized by their tendencies to channel “psychic energy” outward and inward, respectively. However, the typological approach is no longer representative of mainstream personality research. Current research assumes that E-I is a continuous dimension or trait, such that the level of E-I is approximately normally distributed in the general population.

Dimensional models of personality traits, including E-I, are typically based on factor analysis of questionnaire data. The first questionnaire measure of E-I developed on this principle, the Inventory of Factors STDCR, was published by Guilford in 1940 and included social introversion and thinking introversion factors as two of five basic personality traits. Eysenck conducted especially influential factor-analytic research that generated a series of reliable questionnaires, beginning with the Maudsley Personality Inventory in 1956. He also pioneered the use of experimental methods for validating questionnaire assessment and investigated the role of E-I in mental illness.

1.2. Assessment of Extroversion-Introversion

A parallel approach to assessment was based on analysis of the personality-descriptive terms that appear in natural language (i.e., the lexical approach). Fiske identified five factors in personality ratings of this type, including a factor of “confident self-expression” that has been subsequently identified with extroversion. Lexical studies have converged with research based on personality questionnaires in suggesting that there are five fundamental personality traits (the “Big Five”), each of which is defined by more narrowly defined lower order traits, within a hierarchical model.

Costa and McCrae’s Revised NEO Personality Inventory (NEO-PI-R) questionnaire assesses extroversion as one of the Big Five. The Five-Factor Model (FFM) has gained support from the identification of the Big Five, through factor analysis, in various questionnaires developed for other purposes. Furthermore, E-I meets four criteria listed by Costa and McCrae for a trait to be considered fundamental: E-I appears to be biologically based, it is culturally universal, it refers to important psychological concepts, and measures of E-I have good criterion and predictive validity.

There has been some controversy over the lower order traits that define extroversion as a broad trait. Eysenck distinguished sociability and impulsivity as

important constituents of the trait, whereas the NEO-PI-R assesses warmth, gregariousness, assertiveness, activity, excitement seeking, and positive emotionality as primary facets. Sociability and outgoing self-confidence are universally seen as defining features of extroversion, but the place of traits such as impulsivity, activity, and dominance is still being debated. Thus, although various assessments of E-I converge, the composition of the E-I factor differs somewhat across various psychometric models. A more radical proposal was advanced by Hogan, who suggested dividing extroversion into separate factors of sociability and ambition, with the latter being seen as more predictive of job performance.

The NEO-PI-R and other questionnaire scales for E-I are internally consistent and substantially intercorrelated with one another, showing convergent validity. Measures are also stable over time, showing test-retest correlations of 0.6 to 0.7 over periods of several years. Published measures of E-I do not appear to be strongly biased by response sets such as social desirability, although such concerns should not be ignored in applied research. In addition, self-ratings of E-I converge quite well with ratings made by other persons, perhaps because E-I is one of the most salient and visible aspects of personality.

2. BIOLOGICAL BASES

2.1. Behavior and Molecular Genetics

The heritability of E-I has been investigated using twin and adoption studies. Structural equation models fitted to behavior genetic data suggest that broad heritability of E-I is approximately .50. The remaining variance is attributed to the environment, gene-environment interaction, and measurement error. Models suggest that the influence of the unshared environment, unique to each child, is considerably stronger than that of the shared environment related to the family. Molecular genetic studies are beginning to investigate specific alleles that may correlate with E-I. For example, variations at the D4 dopamine receptor gene have been found to correlate with some traits related to E-I, such as excitement seeking and positive emotionality, although the variance explained by any single allele is likely to be small.

2.2. Psychophysiological Studies

The two leading biological theories of E-I are arousal theory and reinforcement sensitivity theory (RST).

Zuckerman conducted important work on possible biochemical bases of E-I, but that is beyond the scope of this article. Eysenck's arousal theory identified arousability of a reticulo-cortical circuit controlling alertness as the key system that underpins E-I. Introverts are said to be more easily aroused, so that they regulate arousal by avoiding intense stimuli, whereas less readily aroused extroverts are prone to seeking stimulation. Numerous psychophysiological studies provide mixed support for the greater arousability of introverts, with studies of evoked potentials and phasic electrodermal responses providing the most consistent results. Replicable results are obtained only with careful control of experimental parameters.

Gray's RST links E-I to sensitivity of primarily dopaminergic brain systems controlling reward and sensitivity to positive reinforcement signals. This system may be more sensitive in extroverts than in introverts, so that extroverts are more readily conditioned by reward signals than are introverts. It may also influence positive emotion. Some studies suggest that extroverts are more psychophysiological responsive than introverts in rewarding situations, but the data are often inconsistent. It seems likely that multiple neural mechanisms may influence E-I. Both arousal theory and RST may have some validity, but neither fully explains the data currently available.

3. COGNITIVE-SOCIAL PERSPECTIVES

3.1. Information-Processing Studies

E-I correlates modestly with a wide variety of measures of information processing. These relationships vary with task demands. Typically, extroverts show superior performance on verbal short-term memory, divided attention, speech production, and speeded motor response tasks, whereas introverts do better on sustained attention, long-term memory, and reflective problem-solving tasks. Extroverts also tend to show a lower response criterion, and favor speed over accuracy, in some task paradigms. In addition, extroverts tend to outperform introverts in arousing conditions, although this effect may reverse during evening hours.

Biological theories have difficulty in explaining the dependence of E-I effects on the information-processing demands of tasks. Instead, it seems that extroversion is associated with a complex pattern of multiple processing advantages and disadvantages relative to introversion.

Matthews proposed that the information-processing correlates of E-I have an adaptive function in preparing extroverts and introverts for the cognitive-social environments they prefer. For example, the superior verbal short-term memory and speech production skills of extroverts may support the development of conversational skills that facilitate adaptation to demanding social environments.

3.2. Social Cognition

Extroverts and introverts tend to differ in various high-level aspects of cognition, including self-cognitions. Extroverts are more likely than introverts to appraise demanding situations as challenging and to cope through use of proactive problem-focused strategies. Extroverts also report greater levels of social participation and affiliative needs than do introverts. Although extroversion is associated with superior social skills, the trait may also be associated with some maladaptive aspects of social cognition such as a tendency toward narcissism. In addition, extroversion has been linked to likelihood of divorce, perhaps due to impulsivity in forming and dissolving intimate relationships. Extroverts and introverts may differ in self-regulation, pursuing somewhat different goals in life supported by different styles of social cognition. However, much of the variance in social cognition is unrelated to personality traits and should be understood with reference to the individual's life circumstances and social learning.

4. CLINICAL APPLICATIONS

4.1. Emotional Disorders

The trait most strongly linked to anxiety and mood disorders is neuroticism, but extroversion may also be implicated. Typically, patients tend to be somewhat introverted, and introversion predicts various symptoms of emotional pathology in longitudinal data to a modest degree. Introverts are also somewhat more vulnerable to subclinical stress symptoms than are extroverts. Introversion may be especially linked to anhedonia (i.e., lack of positive affect) in depression. Many non-clinical studies suggest that introverts experience less positive affect and happiness than do extroverts, although the magnitudes of the association between E-I and affect vary considerably across studies. Some authors propose that extroverts are temperamentally disposed to experience positive affect irrespective of

circumstances, whereas others emphasize the role of situational modifiers such as social involvement.

Longitudinal studies suggest that social introversion may be a risk factor for depression, although the emotional disorder itself may raise introversion as a consequence of the patient's difficulties in social functioning. Assessment of extroversion may be useful to the clinician in understanding the patient, selecting a treatment, and anticipating the course of therapy. For example, extroverted patients may respond better to interpersonal therapy than do introverted patients.

4.2. Personality Disorders and Criminality

Traditional diagnoses of discrete personality disorders may be complemented with dimensional approaches that describe abnormal personality in terms of continuous dimensions. Dimensional studies have related several features of abnormal personality to E-I. Extroversion has been linked to excessive stimulus seeking and impulsivity, whereas introversion overlaps with social avoidance and inhibition, including schizoid personality. Thus, extremes of E-I may create a potential for personality disorders linked to these qualities. Eysenck's theory predicted that extroversion, especially in combination with neuroticism, should be related to a higher incidence of criminality and deviant behaviors because underarousal prevents effective conditioning. Although some studies have supported this prediction, the data are inconsistent. For example, persons incarcerated for long periods of time tend to show rather low levels of extroversion. It seems likely that impulsivity, rather than extroversion per se, is linked to criminality, and the more harmful aspects of impulsivity may be related more to traits such as psychoticism and low conscientiousness than to extroversion.

5. OCCUPATIONAL APPLICATIONS

5.1. Vocational Choice

Extroverts and introverts exhibit clear differences in their occupation choices. Extroverts tend to predominate in jobs that are people oriented (e.g., sales) and/or stressful (e.g., financial dealing), whereas introverts appear to be attracted to jobs that are more solitary and reflective in nature (e.g., scientific research). Similarly, studies of vocational interests show that extroverts have

stronger social and enterprising preferences. In general, E-I is only weakly related to job satisfaction, but the nature of the job seems to influence whether extroverts or introverts are better adjusted. For example, introverts show better tolerance for repetitive monotonous work than do extroverts.

5.2. Job Performance

There is an extensive literature on E-I and job performance. Often, correlations are small, as demonstrated by meta-analyses. However, such analyses may be misleading in that they neglect the likely role of the nature of the job as a factor moderating the extroversion-performance association. Research driven by a priori hypotheses has been more successful in demonstrating the occupational relevance of E-I. Extroversion relates to better performance in more jobs requiring social skills such as sales. Extroversion also relates to superior performance during training, perhaps because extroverts handle novelty better than do introverts. Conversely, introverts may perform better than extroverts in monotonous work environments. Introverts may also be less accident prone than extroverts in transportation and industrial settings, although this relationship may be mediated by impulsivity rather than by E-I per se.

6. CONCLUSIONS

E-I is a robust trait that is an essential component of any comprehensive account of human personality. There is good convergence among various questionnaire measures of the trait, although there is still debate over its constituent traits. Behavior genetic studies show that both genotype and environmental influences are important influences on phenotypic E-I. Psychophysiological and cognitive-social studies have made some progress in revealing the sources and consequences of an individual's level of E-I, but current theories of the trait are not fully satisfactory. Nevertheless, assessment of E-I may be important in a variety of applied contexts, including clinical and occupational psychology.

GLOSSARY

blank lineup (target absent lineup) A lineup in which all the members are known to be innocent.

cognitive interview An interview technique designed to enhance memory and communication of events through the use of guided retrieval techniques.

effective size The number of plausible members in a lineup.

encoding specificity principle If cues that were present at encoding are also present at retrieval, recall of stored information is more likely.

estimator variables Factors in eyewitness situations whose influence can only be estimated and are not under the control of the justice system.

eyewitness A person who observes an event and can provide information about that event.

lineup bias A lineup constructed in a manner that leads the suspect to stand out from the other lineup members.

mock witness A person who is not a witness to a crime but is asked to identify a perpetrator from a lineup based on another source of information, such as a verbal description.

postevent (mis)information Events that occur after a crime that influence eyewitness memories of the crime.

sequential lineup A lineup presentation procedure in which one lineup member is presented to the witness at a time.

showup The presentation of a single suspect to a witness in order to determine if that suspect is the perpetrator.

simultaneous lineup A lineup presentation procedure in which all lineup members are presented to the witness at the same time (i.e., in a line).

system variables Factors that may influence eyewitness memory and are under the control of the criminal justice system.

verbal overshadowing effect When the act of verbally describing a perpetrator decreases the witness's ability to accurately identify a perpetrator from a lineup.

An eyewitness's identification of a perpetrator is a prevalent form of incriminating evidence presented in a criminal case. However, eyewitnesses are frequently mistaken, and their errors have led to the conviction of innocent individuals. For more than a century, psychologists have sought to understand the variety of factors that may influence the accuracy of eyewitness identification. This article reviews the current state of

knowledge in the science of eyewitness identification according to the sequence of events that is likely to unfold from the time that an eyewitness makes an observation to the prosecution of the perpetrator of the crime.

1. INTRODUCTION

The testimony of eyewitnesses is an important factor in many criminal cases. Cases that hinge on eyewitness testimony can bring perpetrators of crimes to justice, set innocent people free, and enable the police and courts to carry out their prime societal responsibilities of preserving law and order. However, eyewitnesses are frequently mistaken, leading to the conviction and imprisonment of innocent people for crimes they did not commit. The extent of this problem is becoming clearer with the exoneration of innocent people through DNA evidence. According to The Innocence Project, a New York-based legal team that reviews case records of incarcerated individuals who claim their innocence, there are currently more than 140 documented DNA-exoneration cases in the United States. Mistaken eyewitness identification is generally the most frequent source of evidence used to convict an innocent defendant. Of the current database of DNA exonerations, approximately 85% are estimated to have involved faulty eyewitness identification evidence.

Acknowledgment of the dangers of eyewitness identification is not new. In England, for example, the Criminal Law Revision Committee of 1972 gave explicit recognition to this fact: "We regard mistaken identification as by far the greatest cause of actual or possible wrong convictions." Psychology and law researchers have long recognized the vagaries of eyewitness identification, conducting original empirical research from as far back as the late 19th century. This research has made a significant contribution to police and legal practice, partly because psycholegal researchers bring an empirical and scientific perspective to a legal problem, which is an approach that is quite unnatural for lawyers and jurists to take. In the current discussion of eyewitness identification, we structure our review, as far as possible, according to the sequence of events that is likely to unfold when an eyewitness makes an observation. The processes that eyewitnesses go through at each stage of the process can vary greatly, and the interests of researchers are quite different at each stage, as are the challenges they face.

1.1. Stages in the Eyewitness Process

There are three main stages of the eyewitness process: (i) perception of an event and the persons central to it, (ii) storage and assimilation of the information extracted from that experience, and (iii) remembering aspects of the experience and acting on it. Time delays between the first and third stages can vary greatly. Some information may be requested almost immediately, as when a witness at the crime scene is asked to describe an event or an offender. Other information may be requested much later, such as when a suspect is presented for identification and the witness is asked to make a complex set of judgments and decisions.

1.2. Categorization of Variables

Pertinent psychological variables differ at the various stages of the eyewitness process, and different bodies of theory and research may apply to each variable to understand them. Two important categories of variables are system variables and estimator variables, distinguished by Gary Wells in 1978. Estimator variables arise during the first stage of the eyewitness process and are those factors over which the criminal justice system has no control, whose degree and magnitude can only be estimated after the fact. By definition, these include attributes of the witness, the event, and the perpetrator, and they may involve such things as the opportunity the witness had to view the event and perpetrator, the state of mind of the witness at the time, the attentional constraints that have impinged upon the witness as a result of the demands made on the witness's attention, or any person variables (such as race or gender) that may have influenced memory performance. System variables, on the other hand, are under the control of the criminal justice system. These variables focus on the treatment of the witness, the manner in which law enforcement officers attempt to obtain information from the witness, and the interaction of person attributes with these processes. System variables occur at later stages of the process (e.g., the second and third stages), at the points where information is requested of the witness.

The demands on research vary depending on the stage of the witnessing process and the type of variable under study. For early stage estimator variables (such as the quality of memory encoding), an effective understanding requires one to simulate them in the laboratory or to study them *in situ*, in collaboration with law enforcement. The latter is rarely done. Law

enforcement generally has a very limited interest in and capability for studying these matters, although worldwide there are a few major law enforcement agencies that engage in research in this field. Many other estimator variables cannot feasibly be studied in laboratory simulations for ethical or logistical reasons, such as high levels of stress, fear, and violence. We review, in general terms, what is known about major estimator variables in this article.

System variables are quite different from estimator variables in that they are implemented in similar ways by law enforcement and researchers, and they act upon persons who have already been through the first stages of a criminal event. Thus, witnesses will naturally vary in the amount of information they have encoded about the event and the perpetrator. Witnesses in laboratory studies of system variables will often participate in crimelike events, but these are not intended as precise simulations of criminal events. Rather, they are merely ways of giving witnesses a temporal event, with some degree of complexity, and that includes information about an event and a perpetrator about which they might later be tested. Of most interest is the effect of various system variables (such as the structure of a lineup or the instructions provided to a witness) on the accuracy of information obtained from the witness.

1.3. General Research Assumptions

Generally speaking, the following assumptions underlie research in this area. First, all individuals function according to the same general set of psychological processes. For example, perception and memory do not work differently for different people in any fundamental sense, and the psychological processes that witnesses engage in do not fundamentally change in different contexts or situations. Second, information must be encoded at the time of the witnessed event for it to be reported later. If the witness does not attend to the event or to information within the event, then information about that event will not be available for subsequent recall or recognition. Any distractions of attention away from portions of an event will result in decreased encoding and therefore an absence of subsequent memory for such information. Likewise, attraction of attention to some elements will result in superior encoding of such information. Finally, the willingness of the witnesses to identify someone from a lineup involves a decision process that can be somewhat controlled by those administering the identification procedure. Although the specific factors leading to identification

may differ from person to person, the decision processes utilized are assumed to be highly consistent.

2. THE EVENT

An eyewitness is defined by an event: This is something he or she directly observes and will later be asked to provide information about. In order to study eyewitnesses, then, we need to study the kind of events to which they bear witness. However, witnessed events range from the mundane to the terrifying and are potentially infinite in their diversity. Eyewitness researchers are thus faced with the daunting task of understanding how eyewitness memory and related processes function across a wide range of possibilities. It is important to understand that eyewitness recognition and identification of the criminal offender is based (for the most part) on comparing a face (person or photo) shown to the witness with an image of a face stored in memory. In general, the lower the quality of the image stored in memory, the less likely an eyewitness is to make an accurate recognition decision. Any event or process that degrades perception (i.e., acquisition of the original image) also reduces the likelihood of a correct recognition or identification. The following factors contribute to a witness's opportunity to encode information about an event or an individual.

2.1. Time to View the Event/ Perpetrator

The duration of the witness's exposure to the offender is related to later recognition performance, such that limiting exposure time generally reduces eyewitness accuracy. This has been shown in both laboratory and archival studies. Although a range of specific times has been employed across studies, it is difficult to calibrate specific time durations to specific levels of identification accuracy, particularly given the many other factors involved. Furthermore, it is difficult to accurately assess the time a witness had to view the perpetrator *in situ*, as studies have shown that witnesses' post hoc recollection of time estimates can be very inaccurate.

2.2. Distance from the Event/ Perpetrator

The physical distance between the witness and the offender is also related to later recognition performance,

with longer distances leading to poorer rates of identification. Again, it is difficult to calibrate specific distances with specific levels of identification accuracy. In addition, witnesses can be very inaccurate at estimating the distance between themselves and the offender, so the information may not be helpful or reliable even if we were able to calibrate accuracy in a laboratory.

2.3. Visibility

Light levels (e.g., time of day) and obscured illumination (e.g., sun shining in the witness's face) have been studied by eyewitness researchers and shown to influence both perceptual and identification processes. Specifically, poor lighting and obscured illumination result in lower rates of accurate identification.

2.4. Stress, Fear, and the Presence of a Weapon

A witness's attention may be impaired or distracted if he or she focuses on the psychological stress or fear accompanying a criminal or otherwise traumatic event. Even if a witness tries to be attentive, high fear or stress may hinder the accuracy of subsequent identifications. Psychologists have often described the effects of stress or fear according to the Yerkes–Dodson law, which posits that very low or very high amounts of arousal are most likely to impede encoding and recognition. The presence of a weapon, which may be accompanied by stress or fear, has also been shown to divert a witness's attention away from the face of the offender. In general, the presence of a weapon reduces both the subsequent quality of the description provided by the witness and his or her attempts at perceptual identification of the perpetrator.

3. THE WITNESS

Individual eyewitnesses may differ along a number of dimensions or attributes, and it is natural to ask whether any of these attributes are relevant to an eyewitness' performance. Research has identified several important characteristics.

3.1. Witness Age

Although eyewitness memory remains relatively stable across a wide age range, it is less reliable for individuals

in certain age groups. For example, very early in life, children demonstrate a limited ability to recall information and show lower accuracy in the identification of faces. They also have a proclivity toward choosing (or guessing) during a lineup identification task, leading to an increased likelihood of mistaken identification of an innocent person. By early teen years, their performance is generally indistinguishable, on average, from that of adults. Although children tend to recall less information when compared with adults, the overall proportion of correct information recalled does not typically differ. Older adults also become somewhat variable, but in the absence of a disease process (e.g., dementia), older adults are indistinguishable, on average, from younger adults. Sensory changes, such as cataracts or changes in the contrast or sharpness of vision, may affect an elderly witness's ability to gather and encode information about a situation or offender. Elderly adults also appear to be more susceptible to the effects of suggestive questioning or postevent misinformation than the average adult. Although children may also be susceptible to suggestion, this is presumed to be due to their unwillingness to challenge an adult's authority. The elderly are more likely to forget the sources of their information.

3.2. Alcohol and Other Drugs

There is very little research specifically on the effects of alcohol and other drugs on eyewitness memory for faces. Although research shows that alcohol somewhat impairs memory for verbal materials, its influence on face recognition or person identification tasks has varied across studies. Whereas some studies have shown no effect of alcohol on lineup identification, others have demonstrated impairment in both recall and lineup identification performance, particularly when witnesses consumed alcohol prior to viewing the event and arousal was limited. Of course, drugs that impair or disrupt perception necessarily impair encoding and memory process as well.

3.3. Witness Race, Gender, and Occupation

No reliable evidence demonstrates any general advantage or disadvantage in eyewitness memory or identification associated with the race, gender, or occupation of the eyewitness [although, it will be noted later that the race(s) or gender(s) of the eyewitness and perpetrator may interact]. However, men and women appear to differ in the type of information they recall about an

event. For example, women tend to recall more items such as clothing, whereas men focus on items such as the type of vehicle or weapon.

Law enforcement officers are commonly assumed to be superior at identifying faces and remembering the details of events. Although research has generally found that the level of experience police officers have, either in years on the job or through training, does not significantly enhance their recognition ability, it does have a positive influence on the quality of the descriptions they provide. Officers are generally able to provide more detailed accounts of an event, and they appear to be less susceptible to the effects of postevent (mis)information when compared to laypersons. Officers also provide more correct descriptive information about the perpetrator than do laypeople, without an increase in incorrect information, and tend to elaborate on action details more than laypeople. This elaboration on action details, however, must be weighed against officers' greater tendency to misperceive innocent actions as criminal in nature. Empirical studies attempting to train individuals to remember events and faces have demonstrated a similar pattern; namely, individuals' recall accuracy can be improved for details of an event, but it is difficult to improve recognition accuracy for faces.

3.4. Witness Confidence

Eyewitnesses will often claim to have great confidence in their ability to identify a perpetrator, but for more than 30 years, research examining the utility of confidence as a predictor of accuracy has generally demonstrated a weak relationship between degree of certainty and identification accuracy. However, there are some conditions in which a stronger relationship may exist. Initial judgments made with very high confidence, for instance, have been shown to be quite diagnostic of witness accuracy.

Even though a witness's confidence may initially be related to the accuracy of the memory, that relationship can be changed dramatically by events that occur after the eyewitness makes a positive identification. If eyewitnesses are told immediately following a positive identification that they have correctly identified a suspect, not only does their degree of confidence increase but also their memory for the crime itself may change. For example, they may become more likely to report that they saw the criminal longer and under better viewing conditions than they had previously reported. In summary, although evidence exists for a relationship between confidence and accuracy under some conditions, confidence has been

shown to be quite malleable. Thus, a witness's statement of confidence, in general, may prove to be a poor indicator of identification accuracy.

4. THE PERPETRATOR

Thus far, we have considered only one of the main actors in the drama that unfolds when an eyewitness observes an event, namely the eyewitness himself or herself. The other actor is, of course, the perpetrator (or perpetrators) of the crime, and several factors have been shown to influence memory for the perpetrator.

4.1. Disguise

Disguises are frequently used during the commission of a crime, and their presence can significantly impair encoding of the perpetrator's face. Disguises may include masks, sunglasses, or anything that obscures significant portions of the face. In general, the upper portions of the face (e.g., eyes and hair) provide the most important information for later identification, and disguises that hinder the encoding of these parts of the face are more likely to prevent identification of the perpetrator.

4.2. Distinctiveness and Typicality of the Perpetrator

In general, typical faces are more difficult to distinguish from other faces in memory, resulting in a higher likelihood of false identification. In contrast, if the offender is distinctive in some way, recognition may be enhanced because the presence of unusual attributes (such as Richard Nixon's chin or Mikhail Gorbachev's forehead birth mark) can make a face easier to remember and help to distinguish it from other faces in memory. However, if the lineup identification procedure is carried out properly (as discussed later) the distinctive suspect will be placed among others who share the same distinctive attribute, requiring the witness to identify him or her without relying solely on the memorable attribute. If the witness's attention was previously drawn to the distinctive attribute, to the neglect of other attributes or away from a holistic perception of the face, then the witness's identification accuracy may be decreased.

Other facial attributes, such as attractiveness or facial "typicality," have been shown to increase the sense that a face has been seen before, resulting in an increase in

the rate of false identifications. There also appear to be a number of widely held stereotypes about general facial appearance, which influence the encoding of information about faces and may therefore influence lineup identifications by eyewitnesses. For example, faces that are stereotyped as “criminal” in appearance are more likely to be identified from a lineup.

4.3. Familiarity Due to Repeated Viewing

Not surprisingly, if the offender was previously unknown to the witness, recognition is less likely than if the offender was known to the witness. However, even when a perpetrator seems familiar, witnesses may not always be correct in their perceptions, especially if a sense of familiarity develops later in the investigative process. If the suspect was viewed committing the crime, the witness may have increased feelings of familiarity at the time of recognition and identification. However, if the suspect did not commit the crime, it is still possible that familiarity can develop after the witness views mug shots and photo spreads containing pictures of the innocent suspect. Following repeated viewings, the appearance of the suspect begins to seem familiar to the witness. Errors caused by repeated viewing have been attributed to errors in source monitoring, or source confusion. According to the source monitoring hypothesis, memory errors occur when a person attempts to identify where the memory (i.e., of the perpetrator) originated following the receipt of post-event information that leads the witness to erroneously attribute the new information (i.e., the innocent suspect) to the original witnessed event. For this reason, in-court identifications of a defendant provide little real evidence that the defendant actually committed the crime. Familiarity at this point has either been artificially strengthened (when the suspect is the offender) or created by previous viewing of the suspect’s person or photo (when the suspect is not the offender).

4.4. Perpetrator Race and Gender

Although the race of the perpetrator alone generally has little influence on identification accuracy, when the race of the perpetrator and the witness are different, the interaction can impair identification accuracy. Studies of the cross-race effect or the own-race bias have shown that memory for same-race faces is generally superior to memory for faces of another, less familiar race. The effect

has been consistently demonstrated over a 35-year period and has been reliably observed with various ethnic groups (e.g., Europeans, Southern Africans, Americans, Asians, and Hispanics). The cross-race effect is of most significance to the criminal justice system when individuals mistakenly identify a suspect who is not the perpetrator.

Although female faces are generally better recognized than male faces, a similar interaction between the gender of the perpetrator and witness has also been noted. Studies of the own-gender effect have demonstrated that female participants tend to outperform male participants in remembering female faces. Curiously, though, male and female participants do not differ consistently in their ability to remember male faces.

5. OBTAINING INFORMATION FROM THE WITNESS

Eyewitness accounts of criminal events play a vital part in solving crimes and prosecuting criminals, but research has shown that very little of what witnesses actually see ever gets reported to the authorities. One reason for this limited communication has to do with the manner in which information is elicited during police interviews of witnesses. Police interview techniques are often passed on from veteran officers to rookies or learned by trial-and-error on the job. Research has shown that even police officers without formal training tend to share similar interviewing styles, and police interviews of eyewitnesses are often very loosely structured. After requesting open-ended descriptions, officers frequently interrupt witnesses by asking specific, directive questions about the crime, typically pertaining to perpetrator height and weight. These questions usually elicit brief answers from witnesses and disrupt the flow of information. This directive interview style limits the information that witnesses convey and also appears to set up a dynamic between witnesses and officers in which witnesses wait passively for officers to direct the interview. As a result, information not specifically requested by the officer may never get mentioned during the interview, despite its importance to the case.

Interview methods can seriously influence the quality of information given by witnesses in other ways, producing information that is less accurate or even fabricated. A classic example of interviewer influence on witness reports comes from the highly publicized *McMartin* preschool case in which accusations of ritual child sexual abuse were made against seven preschool teachers.

Videotaped interviews revealed that the children were subjected to highly suggestive and leading questions. When these methods were applied in laboratory studies, children's false allegations greatly increased. Experiences such as the McMartin case and studies of actual police interviews reveal the importance of understanding the effects of interviewer influence on eyewitness reports.

5.1. The Cognitive Interview

One interview technique developed by psychologists explicitly for the purpose of enhancing the retrieval of eyewitness memory (and limiting the detrimental effects of interviewer influence) is the cognitive interview. Developed by Geiselman and Fisher in the early 1980s, the cognitive interview consists of four main components: (i) context reinstatement, which includes mentally reinstating the environmental and personal context of the original event; (ii) instruction to "report all" information including partial information, even if it seems unimportant; (iii) recounting the event in a variety of temporal orders; and (iv) reporting the events from a variety of perspectives. A wealth of research has investigated the potential benefits of this technique, both in laboratory and field settings. A meta-analysis of these studies revealed a large increase in the number of correct details elicited by the cognitive interview and a smaller, yet significant, increase in the number of incorrect details elicited. However, the meta-analysis also indicated that accuracy rates (i.e., the proportion of correct details generated) elicited using the cognitive interview were about the same as accuracy rates using traditional interview methods (84% for the cognitive interview and 82% for standard interviews).

In subsequent research, Fisher, Geiselman, and colleagues devised the enhanced cognitive interview, a modified technique that attempted to incorporate strategies such as rapport building to manage the social dynamics of communicating effectively with a witness. These changes resulted in further increases in the amount of correct information obtained, although some studies also observed significant increases in the amount of incorrect details. Additional research is warranted. Training law enforcement officers and others to consistently employ all the aspects of the cognitive interview has proved difficult.

5.2. Guided Memory

Research shows that when various aspects of the cognitive interview are broken down, context reinstatement

instructions appear to play a vital role in the effectiveness of a cognitive interview. Context reinstatement takes place when witnesses are provided with contextual cues about the to-be-remembered event. The basis for the effectiveness of context reinstatement comes from Tulving's encoding specificity principle, which maintains that retrieval cues will enhance memory when the information contained in the retrieval cues matches information contained in the original memory trace. A meta-analysis of facial recognition studies revealed that context reinstatement strategies produce some of the most substantial benefits to identification accuracy.

The guided memory technique was primarily designed to utilize context reinstatement strategies for enhancing memory. This technique involves having witnesses visualize aspects of the event, including physical features and traits of the perpetrator, along with various emotions and reactions elicited by the surrounding event. Although this method has been effective in enhancing correct recognition of perpetrators, little is known about the effects of guided memory on description quality or accuracy. Nevertheless, the guided memory technique, along with other context reinstatement strategies, has been shown to enhance the retrieval of descriptive information from witnesses and offers a promising alternative to current interview techniques.

5.3. Generating Descriptions

Archival research has shown that although descriptions provided by witnesses are frequently vague and lacking in detail, they are generally quite accurate. The descriptors most often reported by witnesses relate to action events. Besides action events, witnesses are called on to provide person descriptions, crime scene descriptions (i.e., objects and environmental details), and accounts of what was said during the crime. With regard to the perpetrator, research indicates that witnesses are much more adept at describing character traits (e.g., he looked like an accountant) and psychological attributes (e.g., he was/looked crazy, kind) than physical aspects of a face, and that such global or holistic judgments improve subsequent attempts at recognition.

5.4. Verbal Overshadowing

Although generating a description of the perpetrator is regarded as a benign activity, studies have indicated that verbally describing a target face may have a detrimental influence on subsequent accuracy at lineup identification. This phenomenon is referred to as verbal overshadowing.

Witnesses who provide a description of a target face perform worse on a subsequent identification task compared to witnesses who did not provide a description. The effect occurs regardless of whether the perpetrator is present or absent from the lineup or whether the lineup is administered sequentially or simultaneously. The negative effect is most pronounced when witnesses are encouraged to adopt a liberal response criterion and to report their memory in great detail.

5.5. Postevent (Mis)Information

Many things can happen to eyewitnesses between the time they give their report to the police and the time they subsequently attempt a lineup or in-court identification. Some intervening events can adversely (or positively) affect their identification accuracy. Eyewitnesses may read newspaper reports about the event they witnessed, they may talk to other eyewitnesses about the same event, or they may be exposed to additional information during the course of the police investigation into the crime. This is known as postevent information. Its (potentially) strongly biasing effects on eyewitness testimony have been extensively investigated and documented by Elizabeth Loftus and colleagues.

5.6. Mug Shot Collections and Composite Reproductions

Following the initial interview with the witness, police may seek to obtain a potential physical likeness of the perpetrator by having the witness attempt to recognize the perpetrator from among a library of criminal mug shots or by having the witness create a composite image based on his or her memory.

5.6.1. Searching Mug Shot Collections

Mug shot collections are maintained by many law enforcement agencies for the simple reason that criminal recidivism rates are high, and many perpetrators have been photographed by the police on a previous occasion. Researchers have investigated the influence of searching mug shot collections on later identification accuracy. This question has very important legal ramifications since eyewitnesses who have been exposed to a mug shot collection prior to making an identification of a suspect from a lineup may be more susceptible to a source monitoring error, mistaking the intervening mug shot for the perpetrator. Some studies demonstrated that mug shot

exposure can “contaminate” an eyewitness’s memory, but others did not. Legally, the fact that an eyewitness has been subjected to a potentially biasing and avoidable procedure may be enough to discredit that witness.

A second, often neglected, research question concerns the cumbersome manner in which mug shot searches are conducted. Typically, large collections of photographs are stored in albums (printed or electronic), leaving the eyewitness to page through several thousand photographs in a vain attempt to “spot” the perpetrator. Some researchers have tried to improve mug shot search procedures. For example, English researchers devised a description-driven system in the late 1980s called FRAME, which appeared to work quite well but was later criticized for depending on a limited database. For instance, there were very few mug shots of old men in the database; thus, it was comparatively easy to search the database for old men, inflating the accuracy rate. A similar, description-based system has been developed in Canada, and although it appears promising, there is not enough research to draw a definitive conclusion. Researchers in Hong Kong are exploring ways of structuring mug shot searches according to the physical similarity of faces, but initial results have been disappointing.

5.6.2. Making and Utilizing Composite Portraits

Law enforcement agencies in many parts of the world rely on practical technologies to help crime witnesses reconstruct likenesses of faces. These technologies range from sketch artistry to proprietary computerized composite systems such as Identikit, Photofit, E-Fit, Mac-a-Mug, Faces, and Comp-U-Sketch. Unfortunately, these technologies have not performed well under empirical examination. In most instances, they appear to produce poor-quality composites, which are difficult to match to target faces, even when the target is in full view of the witness. There was some hope that the move to computerized composite software would result in systems containing much larger libraries of features that would be easier to search and graphically “post process” (e.g., allowing the easy addition of specific facial features such as scars or alteration of the aspect ratio of a face). There is no evidence that computerized systems (e.g., Faces and E-Fit) lead to better reconstructions than “manual” systems (e.g., Identikit and Photofit), except when the target is in full view of the witness during the reconstruction, in which case there is a clear advantage for computerized systems.

Recent improvements in computing power have produced more versatile, mathematically sophisticated composite systems. Several groups of researchers are experimenting with “eigenface” systems that potentially allow witnesses to search limitless populations of faces with the assistance of genetic algorithms. Results are promising when witnesses are allowed to reconstruct faces while they are in full view but not from memory. There is evidence that verbal descriptions may be of more assistance to eyewitnesses than visual likenesses or reconstructions.

6. THE WITNESS IDENTIFICATION

6.1. Measuring Lineup Fairness

There are two key events for an eyewitness, as far as the law is concerned. The first is the event they witnessed, and the second is the identification of the person whom they saw commits the crime. When and how the second event unfolds is just as critical as the first because this identification will constitute the evidence against the defendant. Historically, eyewitnesses were primarily asked to identify perpetrators in court, but this practice is frowned upon nowadays since it is very suggestive (indeed, the witness would look foolish if he or she pointed anywhere but at the defendant). An alternative approach is for police to arrange an encounter between the eyewitness and the accused and to hope for a spontaneous identification (i.e., a “show-up” identification). This slightly less suggestible technique still jeopardizes the liberty of innocent people.

The most widely used alternative to in-court identifications in the United States, and in many other countries, is the “lineup,” in which the suspect is placed alongside a number of men (or women) of reasonably similar physical appearance and demeanor, and the witness is asked to choose the perpetrator if he or she is present in the array. Police lineups originated in English criminal law and procedure, and it is clear that the notion of “fairness” is their *raison d’être*. Lineups are intended to secure an identification that can potentially incriminate the perpetrator, but one that is fair to innocent people who might be suspects. Lineups are not invariably fair in everyday practice since innocent people have been convicted on the basis of eyewitness identification from a lineup. One of the strongest strands of eyewitness research is that investigating all aspects of the fairness of lineups, from their construction to their administration. An array of

methods and measures that can be applied to police lineups has been developed.

In a method known as mock witness evaluation, researchers ask people who did not see the crime event and are “blind” to the identity of the perpetrator (or innocent suspect) to try and identify the suspect in the lineup. This is usually achieved by giving mock witnesses a brief description of the perpetrator (preferably the very description the eyewitness gave to the police) and asking them to indicate the lineup member who best matches this description. If mock witnesses are able to identify the suspect at a rate greater than $1/k$ (where k is the number of lineup members), the lineup is said to be biased. The proportion of mock witnesses choosing the suspect is a measure of “lineup bias.”

A second aspect of lineup fairness concerns the number of plausible foils it contains. There are records of police lineups in the United States and other countries where the suspect was the only representative of a particular race or ethnic group in the lineup. In such lineups, the suspect’s identity is immediately suggested to the identifying witness. The number of plausible lineup members is referred to as the effective size and is distinguished from the nominal (or actual) size of the lineup. There are currently two measures of effective size in use: (i) a descriptive measure formulated by Malpass in 1981 and (ii) a closely related inferential measure formulated by Tredoux in 1998. For a lineup to be considered fair, it should receive favorable scores on measures of both lineup bias and lineup size.

The validity of lineup fairness measures has been evaluated in a small number of studies, with positive results. Lineup fairness is frequently assessed by researchers examining police lineups in specific legal cases. A small literature exists regarding proactive use of researchers in constructing lineups that meet fairness standards on a priori grounds. A substantial discussion of lineup fairness appeared in a special edition of the journal *Applied Cognitive Psychology* in 1999.

6.2. Lineup Instruction Effects

Some legal and criminal jurisdictions prescribe the instructions, or admonitions, that officers are to provide to eyewitnesses when presenting them with a lineup. The key question is whether these warnings have an effect on the rate of incorrect identification of innocent suspects, which is the main scourge of police lineups. Empirical studies have explored the effect of biased instructions, and several staged-crime experiments have shown that instructions that presuppose the

presence of the criminal in the lineup (“Point out the person who committed the offence”) lead to much higher error rates than instructions that do not (“Note that the criminal may not be present. If the criminal is present, point him out”). The implication is that the instructions given to witnesses should be tempered quite carefully with a warning indicating the perpetrator’s possible absence. Research comparing a set of clearly biased instructions with instructions usually given by the Los Angeles Police Department and a set of “more balanced” instructions showed an increase in mistaken identifications for the biased instructions but no such increase with either of the other two sets of instructions.

6.3. Alternative Strategies: Blank Lineups, Sequential Lineups, and Relative Judgments

That lineups produce high rates of false identification has been known for a long time, and researchers have puzzled over the causes. The cause was long thought to be that witnesses are led to frame their decision task as choosing the offender from among the people in the lineup, thereby selecting the best choice from among the alternatives presented. The witness enters the identification task presuming that the police would not conduct a lineup if they did not have a suspect firmly in mind and thus interprets the task as requiring him or her to identify the lineup member that the police suspect.

A number of additional strategies to reduce erroneous identifications, apart from the lineup instructions and admonitions discussed previously, have been proposed. One solution, suggested approximately 50 years ago by Glanville Williams, the famous English legal authority, is to present the witness with a blank lineup (a lineup known not to contain the offender/suspect) to “trap” people who feel they must make an identification into making a harmless one. Witnesses who choose someone from this blank lineup are clearly mistaken and are dismissed as too unreliable to complete the main identification task. Only witnesses who do not pick from the blank lineup are presented with a suspect-present lineup. Studies have employed blank lineups in staged crime experiments and discovered that witnesses who choose a member of the blank lineup are almost twice as likely to make an incorrect identification from a subsequent perpetrator-present lineup and likewise only about half as likely to correctly identify the perpetrator.

There are a number of problems introduced by such an approach. First, blank lineups are not feasible in practice since the public would quickly learn that a lineup consists of two parts, only the second of which involves the real suspect, rendering the blank lineup ineffectual. Second, it burdens law enforcement with constructing twice as many lineups as they currently construct. (The use of modern computing systems and large mug shot databases may solve this problem in the near future.) Third, law enforcement resists “throwing away” a witness who has not yet been given a chance to view the suspect on grounds that a witness may make a choice from the blank lineup and subsequently, when presented with the suspect-present lineup, enthusiastically identify the suspect, claiming that he or she was mistaken before but is now sure this is the offender. Expecting police officers to forego the potential for this “evidence” might be too much to ask.

Another structural manipulation or alteration that has attracted a great deal of attention from psychological researchers is known as the sequential lineup. Instead of presenting multiple lineups in sequence, or members of one lineup simultaneously (exposing the witness to the suspect and a number of foils at the same time), the individual lineup members are presented one at a time and the witness is required to identify the perpetrator from the members of this sequence. Witnesses are led to believe that there are more photos to be seen than they are actually shown and are instructed to decide if each photo is or is not the perpetrator. This procedure is based on an analysis of the lineup task articulated by Glanville Williams in 1963 (“The witness may . . . be inclined to pick out someone, and that someone will be the one member of the parade who comes closest to his own recollection of the criminal”) and psychologically interpreted by Rod Lindsay and Gary Wells in 1985. They suggested that the structure of the conventional police lineup (all members presented at once) invites witnesses to compare the members of the lineup to one another and identify the person that “best matches” the witness’s memory, leading to a decision based not on the virtual correspondence of the witness’s memory of the perpetrator to one of the lineup members but on the relative correspondence of the lineup members to the witness’s memory, a relative judgment strategy. Presenting lineup photographs sequentially is said to inhibit eyewitnesses from relying on relative judgments and, instead, fosters absolute judgments made by comparing their memory of the perpetrator with each lineup member. Empirical studies have demonstrated that the use of sequential lineups can reduce false identifications and increase correct rejections of lineups that do not

contain the perpetrator, although a significant reduction in the rate of correct identifications in lineups that do contain the perpetrator has also been noted.

The apparent advantages of sequential lineups has made them attractive to law enforcement authorities in some jurisdictions, and they have been promoted very actively to law enforcement by some members of the eyewitness research community. Research on sequential lineups has been very important, but there is also controversy over whether the research has been extensive and careful enough to warrant promotion of sequential lineups as a replacement for traditional police lineups.

6.4. Lineups Involving Other Sensory Modes

The lineup is usually a test of visual memory, but most legal systems also recognize that additional cues to identity may reside in the voice, mannerisms, and gait of the perpetrator.

6.4.1. Earwitness Identification

The case of voice identification has attracted much attention in the research literature. The most pertinent finding has been that familiarity of the voice plays a key role in identification, and that identification of unfamiliar voices is prone to yield alarmingly high false-alarm rates. Unfamiliar voices are very difficult to recognize and especially easy to confuse. Similar to the own-race bias in facial identification, several studies have observed that voices of another, less familiar race are also more difficult to recognize. In addition, a witness's memory for the voice of the perpetrator is equally susceptible to the many estimator variables discussed previously, including opportunity to hear the voice clearly and various factors that may draw the witness's focus of attention away from the auditory stimulus.

6.4.2. Multimode Lineups

Lineups typically used in Western countries restrict the presentation of the lineup to one mode, most frequently involving visual presentation. However, cues from a single (sensory) domain may be degraded with respect to the original context (e.g., physical disguise), and it is easier to identify the perpetrator with the assistance of cues from other domains. Researchers have begun to explore the utility of multimode lineups on witness identification performance. Although there is little

published research, the idea of allowing witnesses access to cues that are not solely visual in nature is already in practice in Sweden. The lineup is formed in a room in which lineup members are allowed to sit down, smoke, communicate, and behave in general as they ordinarily would over an extended period of time. These individuals are then viewed by the witness from behind a one-way mirror, and members of the lineup are not aware when the witness is present. Unfortunately, no systematic evaluation of this strategy has been performed.

6.4.3. Live vs Photographic Lineups

Lineups currently differ within single sensory modes, such as the practice of eliciting identifications from photographic lineups as an alternative to corporeal (live person) lineups. In many areas of the United States, for example, photographic lineups are favored over corporeal lineups. In many foreign jurisdictions, however, identifications from corporeal lineups are required if eyewitness identification evidence is to be presented in court. Intuitively, corporeal lineups would seem to have an advantage: The detail to be obtained from a live inspection of the suspect must surely exceed the detail present in a photograph. However, the consensus from several studies is that there is either very little difference between the capacity of photographic and corporeal lineups to elicit identifications or no difference at all. An extensive review of the literature reported no notable difference between live, video, or photographic lineups. There is no evidence to suggest that media that embellish cues will aid identification accuracy or reduce false alarms.

7. THE PROSECUTION

After the police obtain a positive identification from the eyewitness that their suspect is indeed the perpetrator, they are ready to hand the case over for prosecution. The district attorney (or attorney general or director of public prosecutions) may decide not to prosecute, but in most jurisdictions eyewitness identification is considered strong evidence against the perpetrator and the case will proceed to court. A number of factors in the court process can influence an eyewitness's accuracy and can change the impact that an eyewitness's testimony will have at trial. For instance, the prosecution (or defense) can pose leading questions to the witness, eliciting false recollections, or an

expert can be called to testify on the vagaries of eyewitness identification. In the following sections, some of the research on two potentially important factors is summarized. First, we briefly discuss a debate that concerns the role and value of expert testimony by eyewitness researchers in legal trials. Second, we discuss research that has examined the effectiveness of jurors in assessing the reliability of eyewitness testimony at trial and whether juries benefit from expert assistance on eyewitness memory.

7.1. Expert Testimony

Many researchers have offered expert testimony to the courts in cases in which eyewitness evidence has been at issue, although this undertaking has been somewhat controversial within the discipline of psychology. A variety of arguments have surfaced on this issue, including disputes over the consistency of findings and the adequacy of current knowledge for presentation to the courts. Several surveys of researchers and experts in the eyewitness literature by Saul Kassin and colleagues have attempted to address these concerns by identifying areas of agreement. In 1989, this survey revealed that the following areas were considered “reliable” by the majority of respondents: limited exposure time, lineup instruction effects, prior expectations on the part of the witness, postevent misinformation, and the weak relationship between confidence and accuracy. An update to this survey of experts in 2001 demonstrated some additions to this listing that included confidence malleability, mug shot-induced biases, child witness suggestibility, the effects of alcohol intoxication, the cross-race effect, the weapon focus effect, forgetting over time, and lineup presentation manipulations (simultaneous vs sequential lineups). Given the developing nature of the science of eyewitness identification, it is reasonable to assume some shifts in experts’ opinions regarding various phenomena. Nevertheless, Kassin and colleagues noted the remarkable consistency in ratings across the two surveys for the majority of topics covered.

7.2. Jurors’ “Common Knowledge” of Problems with Eyewitness Identification

One basis for rejecting an eyewitness expert’s testimony in court is the belief that factors affecting the reliability of eyewitness identification are common knowledge to the

lay juror. Researchers have sought to determine exactly what laypersons know about factors affecting eyewitnesses. Three basic methodologies have been used to investigate this information: (i) surveying jury-eligible citizens as to their knowledge and beliefs, (ii) assessing jurors’ ability to predict the outcome in an eyewitness identification experiment, and (iii) using mock trials to assess the influence of trial techniques (such as cross-examination of the eyewitness or the presence/absence of expert evidence on eyewitness memory).

First, survey studies have been conducted by administering questionnaires, such as the Knowledge of Eyewitness Behavior Questionnaire, in order to assess beliefs about factors that affect the accuracy and reliability of eyewitness identification. The results of such studies have demonstrated that respondents appeared insensitive to such effects as the age of the witness (young or old) and the retention interval prior to identification, and that respondents tended to believe (contrary to research findings) that training could improve identification accuracy. Second, studies have asked participants to read written summaries of identification experiments and then to “postdict” the accuracy of participant-witnesses. Results in such studies have indicated that participants overestimate accuracy rates, suggesting that individuals often believe witnesses to be much more accurate in their judgments than they truly are. Finally, research employing the “mock trial” as a method for assessing jurors’ common-sense knowledge has manipulated different factors known to influence, or not to influence, identification accuracy and then assessed whether participant-jurors are sensitive to these factors in their verdicts. A common outcome is that witness confidence is given too much weight, with jurors believing confident witnesses to be more accurate, which may not necessarily be the case. In contrast, jurors failed to assign sufficient weight to other factors, such as opportunity to observe the perpetrator or the presence of a weapon, which should have been considered. Taken together, this research appears to demonstrate that lay jurors lack the requisite knowledge to appropriately evaluate eyewitness identification evidence, and that expert witnesses may be useful for providing such information at trial. Several studies have also attempted to assess the benefits of expert testimony within the mock trial paradigm. Their results have generally shown that exposure to an eyewitness expert leads jurors to more appropriately weight identification evidence based on factors known to influence the reliability of an identification.

8. CONCLUSION

In a 1978 paper that has been extraordinarily influential in the eyewitness literature, Gary Wells argued that the quintessence of eyewitness research is its application to a legal problem and advised that it is incumbent on eyewitness researchers to show the practical utility of their research. This approach has indeed yielded great rewards: One of the most important pieces in the eyewitness literature is the coconstruction of guidelines by psychologists, lawyers, and criminal justice professionals for collecting evidence from eyewitnesses, sponsored by the National Institute for Justice.

There is a cost, though, to the near-exclusive applied research focus taken by eyewitness researchers. An applied focus typically leads to research that is interested in improving practice (e.g., lowering the rate of false-positive identifications) but is less concerned with explaining how and why a particular intervention works. For example, we know that the sequential lineup returns a lower rate of false positives than the traditional police lineup, but we do not have a good answer for why this is the case. In general, eyewitness research has not appreciated the value of theoretical explanations and models. This is not surprising given the explicit applied orientation of researchers in the area, but it may now be time for researchers to redress the imbalance. A key reason for promoting such a redress is the belief that the applications that stem from applied eyewitness research could be more powerful if they were based on an explanatory model. If we understood the mechanism, for instance, that makes conservative instructions reduce the false-positive rate, then we might be able to design alternative forms of lineup that maximally reduce this rate.

We do not wish to propose that eyewitness research jettison its applied orientation: On the contrary, we wish to strengthen that orientation. The question is how this should be done. Our contention is that a return to the laboratory might, paradoxically, create a stronger applied foundation for the discipline.

GLOSSARY

amygdala A brain structure, located in the anterior part of the temporal lobe, that modulates the strength of emotional memories.

flashbulb memory An unusually vivid and detailed memory of a surprising and consequential event.

misinformation effect The tendency for erroneous postevent information to lead to memory distortions.

postevent information Information introduced after the experience of an event.

source amnesia The inability to recall the origin of the information that comes to mind when attempting to recall an event.

weapon focus Witnesses' tendency to focus on and remember the weapons in crime scenes, often at the expense of memory for other information.

Law enforcement officials rely heavily on eyewitnesses to identify the perpetrators of crimes and to make decisions about exactly what happened at the times of

legally relevant events (e.g., what led to an accident). Eyewitness testimony also has a major impact on the verdicts returned by juries. Although eyewitnesses are often correct, and in some cases their testimony is the only evidence available, mistakes do occur and can lead to the wrong people being convicted and to the actual perpetrators of crimes remaining at large. How do these mistakes happen? Far from being a complete and objective record of past events, memory is malleable. Leading questions, differing recollections of others, and vividly imagining events at a later time can lead to memory errors and even to the creation of "memories" anew. Scientific research on the causes of eyewitness testimony errors has been used to develop recommendations for preventing errors and reducing the rates of wrongful convictions.

1. EYEWITNESS ERRORS AND WRONGFUL CONVICTIONS

It is estimated that as many as 7500 people in the United States are wrongfully convicted of serious crimes each year. One of the key factors leading to wrongful convictions is eyewitness error. Indeed, eyewitness misidentifications are responsible for more wrongful convictions than are all other causes combined. In 1996, Huff and colleagues analyzed factors that led to 205 cases of proven wrongful convictions of innocent people. Most cases resulted from a combination of errors, but slightly more than

half of all cases examined were convicted on the basis of eyewitness misidentification. In a report published the same year by the U.S. Department of Justice, Connors and colleagues analyzed 28 cases of wrongful conviction with DNA exoneration. They found that 80% of these innocent people had been convicted due to faulty eyewitness memory. These findings highlight the risks of uncritical reliance on eyewitness reports.

2. THE MALLEABILITY OF MEMORY

Memories for past events can change over time. After people first witness an event such as a crime or an accident, new information can become incorporated into memory. People may mingle memories of different events and fill in gaps in their memories based on more recent information. “Source amnesia,” or the inability to recall the origin of a memory of a given event, is an important contributor to memory malleability. Over time, people forget whether information that comes to mind when attempting to recall an event originated from actual past experience, from subsequent suggestions by others, or from vividly imagining an event. Once the source of the information has been forgotten, people can confuse suggested and imagined events with the true event. Because the malleability of memory has important implications for evaluating the reliability of eyewitness testimony in court proceedings, psychologists have examined the conditions under which erroneous information is likely to be mistaken for witnessed events.

3. THE MISINFORMATION EFFECT

Research conducted by Loftus indicates that “postevent information,” or information introduced after the experience of an event, can lead to errors in people’s memories for witnessed events. Even subtle differences in the way in which a question is asked (e.g., changing from the indefinite article “a” to the definite article “the”) can lead to distortions in memory. This was shown in a study where participants first viewed a brief film of a traffic accident. Afterward, they were asked a number of questions that were phrased in one of two forms: “Did you see the broken headlight?” or “Did you see a broken headlight?” Participants who were asked the question including the word “the” were more likely to report seeing a nonexistent broken headlight than were participants who were asked the question using the word “a”.

In another study, people viewed slides of an automobile collision. Later, they were asked one of two questions: “How fast were the cars going when they hit each other?” or “How fast were the cars going when they smashed into each other?” The verbs, “collided,” “bumped,” and “contacted” were also used. Participants’ speed estimates varied considerably depending on how the question was phrased. For example, estimates of the cars’ speed averaged 40.8 miles per hour when the verb “smashed into” was used, whereas they averaged only 31.8 miles per hour when the verb “contacted” was used.

Memory errors of this type become more frequent as the gap of time increases between the occurrence of an event and the reporting of it. With increasing time, details of the actual event are forgotten or become less accessible, and the fragmentary memory tends to be filled in with information that is currently available. This information may be drawn from schematic knowledge, or knowledge of the ways in which events typically occur, from suggestions by others and even from the phrasing of a question (e.g., use of the verb “smashed” instead of “contacted”). Thus, the way in which a police officer or attorney questions a witness can influence what the witness recalls.

More broadly, scientific research shows that a person does not simply experience an event, file it away in memory, and then retrieve it whole at some later date and read off what was stored; instead, at the time of recall, past events are partially reconstructed using information from many sources. These sources include the person’s original perception of the event and inferences drawn later after the fact. Over a period of time, bits of information from these sources become integrated, so that the witness becomes unable to say how he or she knows a specific detail. Only the unified reconstructed memory remains. Memories, then, are neither wholly accurate nor wholly distorted. They typically incorporate both memory traces from the experience of the actual event and postevent information.

4. CREATING NEW MEMORIES

Not only can memories be altered, they can be created anew. A simple reliable method for creating false memories for words was developed by Deese, Roediger, and McDermott and is referred to as the DRM paradigm. After studying a list of related words (e.g., rest, bed, night, snooze), people are asked whether or not particular words were on the list. They often claim to

clearly remember seeing a word that was not presented but that was closely associated with other words on the list (e.g., sleep). Hancock and colleagues' 2003 research demonstrated that these phantom words can be even more accessible in memory than words that actually appeared on the list.

Memories of complete events that never occurred also can be created in the minds of normal adults by enlisting the help of their mothers, fathers, and other older relatives. In a 1995 study, Loftus and Pickrell told participants that their relatives had provided researchers with descriptions of events that had occurred during their childhoods. In fact, three of the events had actually occurred, but one was a fabricated account of being lost in a shopping mall at 5 or 6 years of age for an extended time and ultimately being rescued by an elderly person and reunited with the family. Approximately a quarter of the participants fell sway to the suggestions and described memories, either complete or partial, of having been lost in this specific way. Using the same procedure in 2001, Heaps and Nash found that 37% of the participants fell sway to the suggestion that they were in trouble in the water—nearly drowning—and had to be rescued by a lifeguard.

Suggesting to participants that relatives had witnessed an event is a strong form of suggestion, but distortions in memory can occur even with weaker suggestions such as guided imagination. This was demonstrated in Garry and colleagues' 1996 study in which participants first rated how confident they were that a number of childhood events had happened to them before 10 years of age (e.g., "broke a window with your hand"). Later, some participants were told the following: "Imagine that it's after school and you are playing in the house. You hear a strange noise outside, so you run to the window to see what made the noise. As you are running, your feet catch on something and you trip and fall." The script went on to guide participants through a detailed scenario in which they would break the window with their hand and get cut and bloody. During the final phase of the study, they once again answered questions about their childhood experiences. The results showed that the 1-minute act of imagination led a significant minority of participants to claim that an event was more likely to have happened (relative to a control group of participants who were not asked to imagine the event), even though they had previously said the event was unlikely to have occurred.

Imagination has also been shown to influence memory for complex events such as witnessing a crime. As

with the misinformation effect, the impact of imagining an event becomes more pronounced over time. Imagining an event increases its familiarity. As both the event and the act of imagination recede into the past, people become less able to distinguish whether the source of the event's familiarity is that they imagined it or that it actually occurred.

5. CONFIDENCE AND MEMORY ACCURACY

Jurors often understand that memory is fallible and look for cues as to whether an eyewitness's testimony can be believed. One commonly used indication of memory accuracy is confidence. Juries find confident witnesses to be far more believable than those who admit that they could be mistaken. Unfortunately, the assumption that confidence is a clear sign of accuracy is unfounded. Bothwell and colleagues' 1987 review of 35 studies involving staged incidents showed that the average correlation between witness confidence and accurate identification of the perpetrator was modest (the average correlation coefficient was $r = .25$). Thus, with increasing confidence, only a slight increase in memory accuracy was found.

Further weakening its predictive power, witness confidence is highly malleable. Witnesses can become more or less confident about the accuracy of their memories for an event or individual as a result of events that happen afterward. Confidence increases when witnesses describe past events repeatedly or receive confirming feedback such as being told that another witness identified the same individual as the culprit. Confidence is more strongly predictive of recall accuracy when viewing and reporting conditions are optimal, for example, when a witness had a long time to observe a perpetrator's face and was not exposed to repeated or suggestive questioning.

6. EMOTION AND MEMORY

Witnessing a crime, and certainly being the victim of a crime, is a highly emotional event. How does intense emotion affect the accuracy and completeness of eyewitness testimony? In comparison with mundane events, memories for emotional events tend to be long-lasting, vivid, and detailed. When asked to describe how they first learned about highly emotional events (e.g., the terrorist attacks on the World Trade

Center and U.S. Pentagon on September 11, 2001), people can typically report, in considerable detail, where they were, what was happening at the time, who told them the news, and how they felt. In their classic 1977 article on flashbulb memories, Brown and Kulik argued that because of the obvious survival value, there may be some mechanism in the brain that leads to remembering biologically crucial but unexpected events with close to photographic accuracy.

More recently, animal and brain imaging studies have been conducted to investigate the biological underpinnings of the effects of emotion on memory. The results indicate that the amygdala, an almond-shaped structure located in the anterior part of the temporal lobe, modulates the strength of emotional memories stored elsewhere in the brain. The greater the level of amygdala activation, the more enduring the emotional memory. For example, in Canli and colleagues' 2000 study, participants viewed negative and neutral pictures. Functional magnetic resonance imaging (fMRI) was used to assess the level of activation in the amygdala as participants rated each picture for emotional intensity. The more emotionally intense participants found the pictures to be, the more activation was found in the amygdala. Three weeks later, participants were given a surprise recognition test with previously seen and new pictures. They were asked to indicate whether they had seen each picture before and, if so, whether it seemed familiar or whether they clearly remembered seeing it. For those pictures rated as emotionally intense, the degree of amygdala activation predicted whether the picture would be forgotten, would appear to be familiar, or would be clearly remembered.

Emotional memories, then, are more lasting and vivid than nonemotional memories, but this does not mean that they are error free. Indeed, Neisser and Harsch's 1992 research showed that inaccuracies were the norm when college students recounted how they found out about the explosion of the *Challenger* space shuttle after a delay of 2½ years. Furthermore, emotional arousal might not enhance memory for all aspects of emotional events. Several laboratory studies have shown that, in comparison with their memory for neutral events, people showed enhanced memory for information that is central to emotional events but showed poorer memory for the peripheral details. In real-world settings, a similar phenomenon has been termed "weapon focus." This refers to witnesses' tendency to focus on and remember the weapon in crime scenes where a knife or gun is present, often at the expense of memory for other information such as the culprit's face.

In summary, emotional arousal improves memory for central or gist information but can disrupt memory for details that are peripheral to a witness's current concerns (e.g., survival). Investigators are currently working to define more precisely the types of information that are "central" to people experiencing intense emotion and whether this information varies depending on the particular emotional state being experienced (e.g., fear vs anger). This issue is important because, in the case of eyewitness testimony, memory for details (e.g., a license plate number, the color of a jacket) can be telling.

What about memory for emotions themselves? Victims of crimes or accidents due to negligence may seek damages for the suffering they endured, but how accurately can people remember their own past emotional reactions? Levine and Safer's 2002 review of recent research showed that memories for past emotions, like memories for past events, can be biased by postevent information. In one study, Levine and colleagues asked people to recall how they felt when they first learned that O. J. Simpson had been acquitted of murder. Participants rated the intensity of their emotions shortly after the verdict was announced. Two months later, and then again after more than a year, they recalled how they had felt. At each time point, they also described how certain they were of Simpson's innocence or guilt. The results showed that the more people's beliefs about Simpson's guilt changed over time, the less stable their memories were for how happy or angry they felt when Simpson was acquitted. For example, those who came to believe that Simpson was guilty overestimated their feelings of anger, and underestimated their feelings of happiness, relative to their initial reports.

In another study, Safer and Levine had undergraduates recall how anxious they had felt before a major exam. Students who learned that they had done well on the exam underestimated how anxious they had felt before the exam (in comparison with a control group of students who had not yet learned their exam grades), whereas students who learned that they had done poorly overestimated how anxious they had felt before the exam. Thus, postevent information about their grades led to distortions in students' memories for their past feelings of anxiety.

Like memories of events, then, people's memories of their emotions are partially reconstructed; that is, they change subtly over time and become more consistent with current beliefs about the emotion-eliciting event. Put differently, people are constantly learning. Memories of past events are not sealed off from this subsequent learning; instead, they are informed by it.

The malleability of memory may be adaptive in some circumstances, but it makes it necessary to use caution when evaluating eyewitness testimony, whether that testimony concerns a neutral event (e.g., a traffic violation), an emotional event (e.g., a crime), or even a person's own past emotional reaction.

7. FACILITATING ACCURATE TESTIMONY

Scientists investigating the factors that lead to inaccurate memories have developed recommendations to ensure that witnesses provide as complete and accurate testimony as possible. Careful questioning of witnesses is essential for minimizing errors in eyewitness testimony. Using verbal or nonverbal cues, an interviewer can unwittingly influence witnesses toward identifying the person who the interviewer believes is the culprit and toward remembering events in the way in which the interviewer believes they occurred. Therefore, experts recommend that witnesses be interviewed by individuals who have no preconceptions concerning the facts surrounding the case.

Witnesses can be biased simply by limiting the answer options with which they are provided. Thus, interviewers are advised to phrase questions in a clear and open-ended manner that avoids suggesting that a particular response is the correct one (e.g., "They drove away in the white van, didn't they?"). Attention also should be paid to the wording of questions because the use of one term can produce a different response from the use of another, even when the two terms have similar meanings (e.g., "smashed" vs "hit").

Based on a detailed review of scientific evidence concerning eyewitness identification errors, Wells and colleagues in 1998 developed recommendations regarding the best procedures for constructing suspect lineups and photo spreads. When eyewitnesses are asked to identify a culprit from a lineup or photo spread, they tend to identify the person or photo most resembling the culprit they remember relative to the other members of the lineup. If the culprit is not present in the lineup or photo spread, this relative judgment process often leads to a false identification. Wells and colleagues recommended that eyewitnesses be informed that there is a good possibility that the perpetrator is not present in the lineup or photo spread. This makes it less likely that an innocent individual will be selected simply because he or she resembles the criminal. They also recommended that suspect lineups and photo spreads be

composed of individuals who fit the basic recollection of the witness. For instance, if the perpetrator was of a certain race, having only one person of that race present in the lineup or photo spread makes that person more likely to be selected regardless of whether he or she committed the crime. Because people recall the same events differently, it may be necessary to have individual witnesses view different lineups composed of suspects who resemble each witness's description.

Witnesses' confidence in their recollections can be influenced by subsequent events and suggestions. Therefore, experts recommend that confidence be assessed and recorded at the time a perpetrator is first identified or an event is first described. Interviewers should avoid making comments to witnesses regarding their accuracy afterward because this may inflate confidence in witnesses' memories and affect the quality of testimony at later stages.

Inaccurate eyewitness testimony can lead to a double tragedy: an innocent person being punished and the actual perpetrator remaining free to victimize others. Although memory errors can never be completely eliminated, adopting identification and interview procedures that are informed by scientific evidence will minimize inaccuracies and help to safeguard the justness of the criminal justice system.

GLOSSARY

classism Differential treatment based on social class or economic status; the privileging of the wealthy social group so that that group has greater power and status than other social class groups.

equality Identical treatment across social groups.

equity Fair treatment, but not identical treatment, across social groups; equal access to necessary opportunities and resources.

ethnicity A social category characterized by cultural heritage, including norms, values, and customs.

ethnocentrism Differential treatment based on ethnicity; the privileging of one ethnic group so that the group has greater power and status than other ethnic groups.

heterosexism Differential treatment based on sexual orientation that privileges heterosexuals over other sexual orientations; stigmatizes behaviors, identities, and relationships that are not heterosexual.

nationalism Differential treatment based on national origin or country of residence; the privileging of people of one

nation, or group of nations, so that the group has greater power and status than people of other nations.

race A social category characterized by biological or genetically transmitted traits.

racism Differential treatment based on race; the privileging of one racial group so that the group has greater power and status than other racial groups.

sexism Differential treatment based on gender; the privileging of one gender so that the group has greater power and status than other ethnic groups.

social class A social category based on economic position in society, including income, wealth, education, occupation, and social connections.

social justice Social tolerance ensures that people of all social groups have the necessary resources and opportunities.

social prejudice Systematic mistreatment, bias, or bigotry toward people based on social group membership.

stereotypes Characteristics perceived to be shared by members of a social group, without consideration for individual differences.

Fair treatment in sport occurs when there are equitable resources and opportunities for all participants, regardless of social group membership (e.g., gender, race, ethnicity, nationality, sexual orientation, and social class). Sport offers the opportunity to traverse social identities, but it also can be divisive. In some cases, differential treatment occurs in which minority social group members are treated unfairly. In other

situations, sport is an avenue to educate people and increase awareness about a wide range of social issues, fight social injustice, and provide humanitarian assistance. Applied sport psychologists may employ a variety of strategies to promote fair and equitable sport.

1. INTRODUCTION

Sport often is considered a microcosm of society: Common practices in everyday life are replicated in sport environments. Issues such as equitable or non-equitable conduct found in society generally are reproduced in sport settings. Sometimes sport seems to traverse racial, ethnic, social, national, and gender boundaries; sport has the power to bring diverse people together while deemphasizing social or cultural differences. International sport is predicated on the ideal of achieving peace and friendship among world peoples. It provides a common language, connects people worldwide, and offers an avenue for cultural exchange and enhanced understanding across national boundaries. This is seen in events such as the Olympics, Football World Cup, Tour de France, and the Commonwealth Games. Athletes who may be from divergent cultural groups will cooperatively engage in sport. This has occurred with such disparate groups as Iranians and Iraqis or Arabs and Israelis. In fact, competitions have been created specifically to mend political strife. The Goodwill Games, for instance, were constructed to bring together the United States and former Soviet Block nations after the boycotts of the 1980 and 1984 Olympic Games.

Although sport offers the opportunity to traverse cultural identities and unite different peoples, it also can have the opposite effect. Cultural differences may be exacerbated through sporting events, which in turn become propaganda for the victorious side. Sport reproduces dominant ideologies and is accessible disproportionately to members of privileged social groups. Obviously, these matters negatively affect sport experiences.

2. SOCIAL PREJUDICE IN SPORT

People naturally group like individuals into social groups; this categorization is a perceptual process that allows individuals to make sense of the vast social world. Stereotypes emerge as people identify characteristics perceived as common among the members of a social group. Sometimes these common characteristics

are benign (e.g., basketball players are tall). However, some stereotypes may be incorrect (e.g., black people cannot swim) or even malicious (e.g., Islamic men are violent or terrorists). Prejudice occurs when stereotypes lead people to have negative attitudes toward all members of certain social groups, whereas discrimination occurs when people behave negatively toward members of a social group.

Unfair treatment in sport, as in society at large, often arises from prejudices such as racism, ethnocentrism, sexism, heterosexism, classism, and nationalism. These terms reflect various forms of social exclusion based on socially constructed categories or identities (e.g., gender, race, nationality, sexual orientation, and ethnicity). Identities are socially constructed as social norms and expectations create and reinforce attitudes toward individuals based on social categories. For example, beliefs about how males and females should behave and look are based on social customs. These customs create expectations for males and females that affect actual behavior, values, and beliefs. Social beliefs and social norms often lead to stereotypes about certain groups of people, which reflect societal values and convey acceptable and unacceptable behaviors and values. They also deprive people of their individuality and limit opportunities.

Stereotypes and negative attitudes are the major roadblocks to sporting achievement, not lack of ability. Innately, there is no reason that people in various social groups should have any less athletic talent than individuals in majority social groups, but examples of disproportionate accomplishments abound. For example, far fewer African, Latino/a, or Asian athletes are represented on Canadian, UK, or Australian professional sport teams compared to white athletes. Stereotypes such as “black players are not as smart as white players” and “Asians lack athletic ability” impede their progress in sport. Beliefs that “women are not interested in sport” or that “Aboriginal people are not as ‘civilized’ or cognitively developed as white people” reduce their opportunities in mainstream (i.e., majority-ruled) sport.

Because these athletes are not expected to succeed, it is likely that coaches will treat them differently than athletes expected to be more skilled. The athletes for whom coaches have low expectations likely receive less constructive feedback, less praise, fewer practice opportunities, fewer chances to correct mistakes, and more criticism. This feedback, in turn, may decrease confidence and increase anxiety or may not provide learning opportunities for certain groups of athletes. Thus, these athletes do not attain the same skill level as

athletes from majority social groups, reinforcing the correctness of the stereotype. The concomitant lack of successful role models and inability or unwillingness of sport clubs to support minority athletes further minimize their chances of excelling in sport. Additionally, individuals with minority identities are often socially or economically disadvantaged and therefore do not have the resources to develop their athletic abilities.

Cultural and prejudicial attitudes evolve and change over time; therefore, they are socially and historically bound. For example, although today black players appear to be represented proportionately in British football, Asian players are not. However, not long ago, black players were struggling for representation. As social values change, so do attitudes toward various social groups in sport. Judgments about specific social groups also may differ across cultures. French fans, for instance, backed openly lesbian, professional tennis player Amelie Mauresmo, whereas in other countries she would not be supported. There is not a single way to explain prejudice or inequity in sport because it is played out in a myriad of ways given the dominant culture where it occurs. The underlying commonality, though, is that opportunity, status, and power are disproportionately afforded consistent with the social hierarchy supporting the dominant social group.

2.1. Racism

Inequitable treatment due to racial or ethnic identities occurs across sporting environments. Racism affects university, professional, and elite sports, from youth to masters' levels. It has been documented in sport worldwide. Incidents of racist fan behavior at World Cup or international rugby events, for example, are not uncommon. Racist actions in sport result in fewer racial minority athletes engaging in particular sports (e.g., swimming and golf), minimal numbers of athletes of color competing at elite levels of sport, few individuals of color as coaches or managers of athletic programs, overt prejudicial behaviors toward racial minority athletes, lack of fan support for minority athletes, and limited opportunities to learn sports. Conflated with these indignities, female athletes of color face additional barriers, as do disabled, indigenous, or lesbian, gay male, bisexual, or transgendered (LGBT) athletes of color.

A common racist action in sport is stacking, which occurs when a certain social group of athletes is funneled into peripheral positions on athletic teams. For example, in Western team sports, white athletes historically held the leadership and central positions.

(White) coaches believed that black athletes were not smart enough to take on the responsibility of this position. Rather, black athletes were guided into positions requiring speed and jumping ability (e.g., pass receivers). This practice led coaches to encourage young black players to gain skills in peripheral positions if they wanted an opportunity to participate in higher levels of the sport. It also encouraged self-selection into positions where there were black role models. Stacking ultimately limited the number of athletes of color on a team because these players competed for only a few positions. This practice occurs across a wide array of sports.

Although the overt practice of stacking has declined in many sports, lack of minority representation in sport administration and coaching is widespread. Because these are the powerful, decision-making positions, minority athletes have little representation in how sport is conducted or who is selected for teams or management positions. Additionally, sport has become a big business. The owners, managers, and organizers in the business of sport have become quite wealthy and powerful, allowing them to wield considerable power concerning how sport is run and who can be involved. Few men of color rise to these positions and almost no minority females are sport team owners or managers.

2.2. Sexism

Research on gender in sport consistently documents fewer opportunities and less support for female sport participants compared to males. International competitions, such as the Olympics, have more events for male athletes; governing bodies are male dominated so women have little voice in how sport is managed; the media reinforces gendered ideologies and provides limited coverage of female athletes; sexual harassment toward female athletes is widespread; and females in sport must contend with stereotyping and "accusations" of being lesbians. These actions have led to sport being considered a patriarchal institution; that is, it is dominated by males who hold social, political, and economic power.

Sport also reinforces and supports hegemonic masculinity and femininity. These ideals reinforce socially sanctioned mannerisms specific for males or females. Most societies encourage males to be masculine and females to be feminine. Characteristics associated with hegemonic masculinity include strength, competitiveness, assertiveness, confidence, and independence. Being gentle, compassionate, emotional, and dependent, for example, are

characteristics of hegemonic femininity. These characteristics are considered hegemonic because they are accepted and reinforced by social norms, customs, and behaviors. Hegemonic customs and behaviors are so widely visible that they are rarely questioned; rather, they are accepted as “natural.” Males who act contrary to hegemonic masculinity or females who counter hegemonic femininity face discrimination. Because sport is considered a masculine domain, especially contact sports, there is more support (financially and socially) for boys and men in sport than for girls and women.

Fundamental, non-Western societies are even more restrictive toward women’s sport participation. Within traditional Islamic cultures, women face rigid barriers for participation in sport. This culture also emphasizes modesty, and for women this encompasses completely covering their bodies in clothes. This expected attire may impede participation in sport altogether or limit women’s ability to compete in elite events in which competitive attire is inconsistent with Islamic culture. Only in all-female environments may Islamic women wear shorts and t-shirts; otherwise, they are expected to be covered properly. For Islamic women to compete at elite events, they must forsake traditional attire and modesty, participate in mixed-gender venues, and resist the strongly patriarchal social structure. They also risk severe reprisals for doing so. Female Islamic athletes have received public disavowals and death threats for participating in settings not consistent with Islamic law. Although facing different ideologies of intolerance, Aboriginal women have similar struggles. Whereas women in general are underrepresented in sport, women who are non-white, economically disadvantaged, older, physically challenged, or lesbian, bisexual, and transgendered are even less visible.

2.3. Heterosexism

LGBT individuals in sport face paradoxical circumstances. On the one hand, they may be able to “pass” and be undetected in sporting environments. In which case, they may avoid overt discriminatory actions based on their sexual orientation. On the other hand, that they must conceal their LGBT identities suggests the depth of prejudice toward this social group. LGBT athletes often are perceived as countering hegemonic femininity or masculinity, which appears to underscore prejudice against this social group.

Bias against LGBT athletes is well documented in Western societies. They face verbal harassment, lack

of media attention and endorsements, negative bias by officials or judges, and prejudicial treatment by administrators and coaches. Incidents of physical and verbal abuse by teammates are also documented. Some sport organizations have rules specifically aimed toward prohibiting LGBT participants. For example, the U.S. Ladies Professional Golf Association only allows women who were born female to compete, effectively barring transsexuals from participation. An athlete marching in the opening ceremonies at the 1998 Gay Games exemplified the heightened fear of detection among LGBT athletes from fundamental Eastern countries. Holding a placard for Lebanon, he wore a mask over his face. In Lebanon and other countries with fundamental religious-based governments, LGBT individuals may be imprisoned because of their sexual orientation.

2.4. Nationalism

As international competitions bring together individuals from around the world, they also encourage nationalism. International sport and politics seem inextricably linked. Often, governmental involvement in sport reflects a desire for global recognition or prestige. In the Olympics, for example, if the ideal of promoting world togetherness was truly embraced, news agencies would not report the numbers of medals won by participating countries. However, these medal counts are used by various countries to confirm their sovereignty. This was most evident during the Cold War era when the campaign for democracy versus socialism was partially played out in the international sport scene.

International sport is important economically in terms of world recognition and global esteem. Today, rising industrial nations vie to host the Olympics, and other prominent international sport events, to demonstrate their new strength in the international market. Nationalism also is seen as the sport media constructs national identities through coverage of major sporting events. Positive national identities are reinforced, whereas stereotypes about, and difference between, athletes from other countries are accentuated. Nationalism has led to situations of poor sporting behaviors, such as fan hooliganism, fights during competitions, and unfair judging or refereeing. Additionally, some national sport organizations, such as in Japan, only support people of local heritage. Foreigners and immigrants are excluded due to institutionalized nationalism.

2.5. Religious Intolerance

As previously discussed, religious beliefs may influence sport experiences. One social group particularly affected by religious influence on sport is Islamic women. Discrimination based on religion may include situations in which important sporting events are scheduled on non-Christian religious holidays, religious expectations are not accommodated, religious customs are belittled, prejudicial jokes are shared or prejudicial comics are displayed, or players are overtly discriminated against because of their religious beliefs.

Perhaps the most evident occurrence of religious intolerance manifest in sport was at the 1972 Olympics when 11 Jewish athletes and coaches were assassinated by terrorists. In the current global climate, sportsmen of Arab descent are viewed cautiously and considered potential terrorists due to their heritage. Also, the revealing uniforms common in Western women's sport are not consistent with the modesty espoused in many Asian and Islamic cultures. Still, some international sport organizations require athletes to wear these styles. Similarly, many sport settings do not accommodate the religious practices of Islamic athletes who engage in obligatory prayer times.

2.6. Interactions among Social Prejudices

The various forms of social exclusion interact to create a hierarchy of status and power in sport. For example, when examining racism in sport, the focus is often on men's sport. The omission of considering race in women's sport is a form of sexism and neglects consideration of the interaction between racism and sexism. Female athletes of color face challenges related to their gender as well as their race. Across sporting cultures, males seem to reap the most privilege, particularly white, heterosexual males. Male athletes of color are afforded the privilege of being male, although they are marginalized due to their race or ethnicity. In countries where people of color are the high-status majority, heterosexual males still garner the most privilege and power. Additionally, it is important to consider the influence of social class. When examining sport across diverse countries, people of color or ethnic minorities disproportionately are the most socially disadvantaged people. Females are also represented disproportionately in socially disadvantaged classes; in this case, racial and ethnic minority females face the largest social and economic challenges.

Throughout the world, LGBT individuals face much discrimination, regardless of, or in addition to, their race, ethnicity, social class, or gender. However, white, gay males still have more social benefits than females or people of color in these communities. All of these patterns of gender, racial, ethnic, and sexual orientation superiority are consistently evident across Western societies. In non-Western societies, there may be different cultural forces affecting different patterns of privilege and discrimination, but discernable patterns are evident. As global sport becomes more commodified, minority participants continue to become even more distanced.

3. CELEBRATING DIFFERENCE THROUGH SPORT

A number of sporting events have been developed to provide safe and comfortable environments for individuals who commonly experience discrimination in traditional sporting venues. These events cater to specific social groups and include competitive, social, and cultural activities. Examples include competitions for Jewish athletes, LGBT athletes, Arab athletes, and Islamic athletes. Such events promote cultural pride and self-esteem. Participants engage in competitive events, but they also are surrounded by individuals with similar social identities. They are able to work toward sporting goals and immerse themselves in a setting that celebrates their unique culture. Athletes are freed from discrimination and inequity, creating a personally and athletically empowering environment.

The Maccabiah Games are an Olympic-style event held in Israel every 4 years. The best Jewish athletes in the world are invited to participate in athletic, cultural, and educational events. The games offer the opportunity to share participants' customs and heritage in a competitive setting. The Gay Games offer a similar setting for LGBT athletes. Every 4 years the Gay Games celebrate the sporting and cultural practices of the participants. These games began as a venue for competition in an environment free from discrimination. They also counter stereotypes about LGBTs as well as celebrate the distinctiveness of LGBT life.

The Arab Games were created as a competitive event for male athletes from the nations of the Arab League. These games cater only to Arab males; participation by women is contrary to dominant religious beliefs in these countries. Recently developed, the Islamic Countries Women's Sport Solidarity Games provide a

competitive environment for women consistent with Islamic law. Competitive events are held in an all-female environment. Males may be spectators only at the opening ceremonies, where the women wear traditional Islamic attire.

To promote national pride and enthusiasm in European small nations, the Games of the Small States of Europe bring together athletes from Andorra, Cyprus, Iceland, Liechtenstein, Luxembourg, Monaco, San Marino, and Malta. Because athletes from these nations generally cannot keep up competitively with athletes from larger countries, these games provide the opportunity to compete successfully at an elite level. The North American Indigenous Games celebrate native people in the United States and Canada. A variety of competitions also exist for Australian indigenous peoples. These events often include traditional Aboriginal games as well as contemporary sport competitions.

The personal and cultural influence of these types of competitions is remarkable. For many athletes, these are the only places where they can compete devoid of prejudice and discrimination. Personal, cultural, and athletic empowerment often result. Athletes celebrate their shared history and culture while also engaging in international competition. Typically, there is extraordinary energy and excitement in such compassionate environments. However, the necessity for these types of competition may be questioned because they may be perceived as separatist. In the current social climate, worldwide, these competitions seem to provide an important experience for the athletes. When athletes with devalued social identities can participate comfortably and safely in integrated competitions, perhaps independent competitions no longer will be needed.

4. SOCIAL EQUITY IN SPORT

Although examples of inequitable treatment in sport are evident, in many ways, sport brings together people from diverse social groups. It has the potential to counter stereotypes and inequitable treatment of minority athletes. For example, Amir Hadad, an Israeli Jew, and Aisam-Ul-Haq Qureshi, a Pakistani Islamic, competed as doubles partners in the 2003 Wimbledon tennis tournament. During international events such as the Olympics, diverse athletes are seen interacting on the playing fields as well as socializing in the Olympic Village. After the September 11, 2001, terrorist attack on the United States, American athletes were met with great encouragement and support throughout the world.

Sport has become a platform to increase awareness of health concerns such as breast cancer and AIDS. Races and bicycle rides are used to raise money for research and assistance programs. Examples of sport as social agent are widespread: In Kenya, sport helped fight AIDS; through sporting events money was raised to fight cancer in the United Kingdom; sport programs are used to reduce crime in Germany and the United States; and sports assist in overcoming religious intolerance in Ireland and the Middle East. Many sport stars have created programs to reach out to disadvantaged children to provide them the benefits of sport. For example, Tiger Woods created the Tiger Woods Foundation, which introduces golf to minority and at-risk, inner-city youth. Sport organizations, such as the Professional Golf Association and the National Hockey League, are also reaching out to minority youth. The potential of sport to educate people and increase awareness about a wide range of issues, fight social injustice, and provide humanitarian assistance is immeasurable.

4.1. Opposing Social Prejudice through Sport

Because of the wealth, status, power, and popularity associated with sport, it can be a strong catalyst for social change. Many national and international sport organizations are working toward more equitable sport environments. A wide array of international sport organizations and conferences have addressed issues of inequity in sport. Sporting organizations are making policy to minimize sexism, racism, and heterosexism. Attempts to provide sport opportunities for economically disadvantaged people are also incorporated into these policies.

4.2. Reducing Racism in Sport

Perhaps the most poignant example of sport as an agent of social change was during the anti-apartheid movement. Most international sport events banned South Africa from participating until apartheid was abolished. Along with other political pressures, South Africa eventually succumbed and changed its social system. This international campaign in sport helped bring down the horrific racism in South Africa and permanently changed international sport. This effort toward reducing racism continues today. For example, participation in the Commonwealth Games is contingent upon commitment to countering racism in disadvantaged countries.

Sport, the Olympic Games in particular, led to serious reconsideration of the inequitable treatment of Aboriginal people in Australia. In response to national protests after being awarded the 2000 Olympic Games, the International Conference on Human Rights and Sports was held in Sydney in 1999. Here, the plight of the Aboriginal people was highlighted and propositions to reduce prejudice and discrimination were developed. The Indigenous Sport Program, developed to increase sport opportunities at all levels as well as provide economic assistance for rising elite Aboriginal athletes, was one outcome of this conference.

Many professional sport organizations have enacted policies specifically to counter racism. FIFA, soccer's world governing body, held an antiracism conference in Buenos Aires in 2001. Delegates from 200 football (soccer) national associations engaged in brainstorming to develop strategies to minimize racism in football. Ultimately, FIFA passed a resolution expecting that all clubs, associations, and officials actively take steps to eradicate racism in football. In 1999, Football against Racism in Europe (FARE) was developed, involving organizations from 13 countries. FARE assists and links various local and national endeavors to counter racism in football (soccer). By 2003, all 92 European professional soccer clubs supported the "Kick Racism out of Football" campaign. "Show Racism the Red Card" is another antiracist education campaign in the United Kingdom. This program engages professional footballers as antiracist role models. Sportscotland developed a comprehensive equity strategy for sport. It encourages all sport governing bodies to address inequities related to race, ethnicity, gender, sexuality, ageism, religion, and disability. Similar programs have emerged throughout the world.

4.3. Reducing Sexism in Sport

A variety of international organizations to counter sexism in sport have emerged. The International Association of Physical Education and Sport for Girls and Women was founded in 1949. This group represents and lobbies for women and girls in sport and physical education at the international level. It is a member of the International Council for Sport Sciences and Physical Education and therefore is involved in developing international policy regarding women's sport.

In 1994, the International Working Group on Women and Sport was established during the first World Conference on Women and Sport. This group drafted the Brighton Declaration, which implored governments

and sport organizations to "comply with the equality provisions of the Charter of the UN, the Universal Declaration of Human Rights, and the UN Convention on the Elimination of all Forms of Discrimination Against Women." The Second World Conference on Women and Sport was held in Windhoek, Namibia, in 1998. It resulted in the Windhoek Call for Action, which reaffirmed these principles. In response to these declarations supporting women's sport, many conferences and resolutions worldwide followed. For example, in 2001, the First Asian Conference on Women and Sport was held in Osaka, Japan. At this conference, delegates reaffirmed their commitment to the Brighton Declaration and the Windhoek Call for Action and dedicated themselves to the advancement of women in sport.

In addition, the Women's Sport Foundation in the United States, United Kingdom, and Australia lobbies for increased sport opportunities for women and girls in sport. In Canada, the Canadian Association for the Advancement of Women in Sport works with Sport Canada to increase opportunities for girls and women in sport and to ensure healthy environments for female participants. Similarly, the Australian Sports Commission expressly supports women's sport. The European Women and Sport organization, representing 41 nations, promotes gender equality in European sport organizations.

National policies to reduce sexism and increase opportunities for women have been applied to sport. In the United States, Title IX makes it illegal to discriminate against individuals based on sex in any public educational setting, including sport. This law greatly affected women's sport by decreeing that girls and women receive equitable opportunities, funding, coaching, and facilities. Although still not equal to boys and men, since the enactment of Title IX, the number of girls and women participating in sport, and social acceptance of female athletics, has greatly increased. In Canada, the Charter for Rights and Freedoms protects the sport opportunities for girls and women.

4.4. Securing Child Welfare in Sport

Concern for the well-being of child participants is another area in which sport organizations encourage fair treatment. An international organization, Defense for Children International, based in Switzerland, raised concerns about the exploitation of children in elite sport. It advocated that children should have the following rights in sport: "(i) to do as one chooses with one's body, (ii) to be consulted, (iii) to physical and

psychological integrity, (iv) to associate freely with whom one chooses, and (v) to education.” In the United Kingdom, the British Association for Sport and Exercise ratified a welfare policy mandating that its members safeguard and protect children and vulnerable adults from sexual abuse.

4.5. Economic Reforms through Sport

Through sport, international awareness has increased concerning the horrendous working conditions of sweatshops in developing countries. United Students against Sweatshops (USAS), an international student movement among university students, has led the campaign fighting for better working conditions and rights for workers. It has lobbied universities and colleges to be proactive and discerning when making contracts with various sporting goods companies that sell items with university logos. Groups such as USAS have led boycotts against sporting goods companies (e.g., Adidas, Nike, and Umbro), imploring the elimination of exploitive child labor, procurement of fair wages, and safe work environments.

Although all the organizations and sport group actions described previously focus on specific social justice issues (e.g., racism or sexism), they also recognize the interactions among these issues. For example, groups fighting sexism also forward policies against heterosexism and racism. While focusing on the abysmal working conditions in sweatshops, it is apparent that women and children of color are most likely to be engaged in these positions. Sport organizations such as national Olympic committees, professional sport organizations, and national governing bodies have programs encouraging diverse athletes to participate in sport as well as policies countering sexism, racism, and other social injustices.

When considering fair play in sport, there are two sides to the issue. Certainly, inequitable treatment of diverse sports people occurs. Individuals with minority social identities may be marginalized and devalued in sport; they may face stereotypes, prejudice, and barriers. However, sport also brings together diverse people. In the name of fair play, sport celebrates achievements of all people and provides an environment in which divergent social groups can leave behind political agendas and simply engage in sport. Sport also has become a tool for social justice activities. Through sport, intolerance is challenged and social change continues.

5. APPLIED SPORT PSYCHOLOGY AND SOCIAL JUSTICE

Given the potential of sport to encourage social justice and to challenge unfair treatment, sport psychologists are in an ideal position to effect such action. Applied sport psychologists work with athletes, coaches, parents, and administrators to develop productive sport behaviors leading to improved or consistent performance and enjoyment. Inequitable sport settings limit both of these possible outcomes. Thus, efforts to resist inequitable treatment logically complement more customary sport psychology goals.

Challenges to inequitable treatment may be focused on a societal level, as previously discussed, or it may be approached on a local level by creating positive and fair team environments. Teaching young athletes to value fairness and rebuke prejudice and discrimination will eventually affect all of sport. One team or league can make a major difference. For example, when teenage members of a golf team refuse to compete because a teammate is not allowed to play due to his or her skin color, their action speaks volumes to the larger society. Members of sport teams that engage in community service learn about people living in different situations than their own. College athletes in the United States, for instance, help build shelters for homeless people and tutor economically challenged children. Sport psychologists can engage the team in discussions highlighting the social justice issues inherent in such settings.

Many sport psychologists already endorse the importance of developing constructive team climates through creating mastery or task-oriented sport environments. In such settings, coaches emphasize skill development, cooperation, improvement, and development of peer relationships. In contrast, performance- or ego-oriented climates emerge when coaches encourage interpersonal competition and promote a “win at all costs” attitude. When athletes are rewarded for effort, improvement, and teamwork, they are likely to have a long-term investment in sport, use healthy training techniques, and adopt positive sporting behaviors. These athletes also tend to believe that success in sport is due to hard work and working cooperatively with others. Athletes who are rewarded primarily based on social comparison (e.g., winning) are likely to be willing to do whatever it takes to win, such as using aggressive or harmful behaviors including trash talking in a prejudicial manner or other overtly discriminatory behaviors.

A logical extension of traditional means of creating a task-oriented team setting is to address issues of social justice and encourage fair treatment of all athletes. It seems reasonable that athletes who participate in a task-oriented climate will be likely to accept the importance of being sensitive to individual differences. If, for example, athletes of different races or ethnicities are dedicated to team improvement and are invested in being successful, they will also be willing to work together in a productive manner. Creation of a task-focused environment may be the first step toward promoting fair treatment within sport teams or sport leagues.

Sport psychologists and coaches wanting to challenge unfair treatment due to prejudice may employ a variety of strategies. An initial, but important, step in this direction is to consider the language used by leaders and team members. Coaches and sport psychologists should model appropriate language. Racist, sexist, homophobic, or any other prejudicial comments should not be tolerated. As individuals point out the inappropriateness of such language and reinforce its unacceptability, athletes will become more aware of how their words may be hurtful. Situations in which prejudice or discrimination occur provide opportunities to open dialogue about sensitive issues. Furthermore, most strategies to encourage team cohesion will also promote acceptance of diverse people within a team. Creating team goals that include cooperative efforts, providing athletes opportunities to learn about athletes with different social identities, and emphasizing team diversity as a strength will lead to enhanced cohesion while also minimizing prejudice. Athletes should also be encouraged to “do the right thing.” Empowering athletes to acknowledge and challenge prejudice and discrimination will further increase the likelihood that sport settings will promote fair treatment of all participants.

Ensuring equitable treatment in sport will require the involvement of athletes, coaches, and administrators.

Sport psychologists are positioned to interact and educate each of these factions. As sport psychologists make social justice in sport a priority, it is more likely that sport will achieve its potential to bring together diverse people for fair competition, create avenues for cultural exchange, and ensure positive experiences for majority and minority athletes alike.

There are two general approaches to the study of family. One approach has been the focus on the family, its structure, interactions between family members, child development, and other issues. The second approach has been the study of the family within its cultural context. This approach assumes that the family is one system within other social systems of a culture, and that the study of the family necessarily entails studying its relationships with the institutions and other aspects of the culture. In addition, the usual approach in cultural psychology studies the family in one culture or society, whereas the cross-cultural approach is comparative, studying universals and differences in families across cultures or countries. Cultural anthropology, sociology, psychology, cross-cultural psychology, psychiatry, economics, political science, and geography have each contributed to the study of family from the perspective of its own discipline. However, there is considerable overlap in theories and methods so that one can also talk about a multidisciplinary approach employed by many in each field. A number of issues are related to

the study of family and culture. There are different family types: nuclear families, extended families, and one-parent families. Family types differ according to subsistence patterns, social systems, religion, and other cultural features. Marriage takes place in different ways in different cultures. Kinship ties, postmarital residence, and descent are important determinants of family types. The social power of the mother and the father is related to the institutional structure and values of the culture. Socialization of children by the family is related to ecocultural variables and family types and results in different psychological characteristics across cultures.

1. CULTURE

Culture is a very broad term referring to all human-made patterns of activity, including societal institutions, practices, norms, rules, means of subsistence, symbols, communication, settlements, transportation, art, religious beliefs, ideas about nature and humans, interactions among humans, child-rearing practices, values, beliefs, cognitive processes, personality, and social behavior. There are many definitions of culture, each stressing different elements, including the patterns of human activity, the unique symbols in each culture, the symbols transmitted through language, the achievements of the group, the artifacts, the transmission of the traditions from generation to generation, and the mutual process of humans creating cultural elements and culture-shaping human and social patterns.

The term culture, however, is also used to designate a group with a common heritage as described in the previous definition of culture. That is, culture is used as a synonym for “ethnic group,” “nation,” “society,” or “country.” Anthropologists initially employed the term to refer to small exotic groups of people, often referred to in the past as primitive peoples, savages, or indigenous groups. Employed in this sense, larger geopolitical groups are referred to as nations or countries. However, culture is also employed in taxonomies of nations, such as Western culture or Islamic culture. If culture is used to define an ethnic group with a specific “culture,” then the number of cultures has been estimated by anthropologists to be in the thousands, whereas there are approximately 200 nations or countries throughout the world.

Thus, culture is employed in both ways in family research: It refers to a specific country or to those elements that characterize the society.

2. FAMILY THEORIES

Family theories have been developed in sociology, cultural anthropology, psychology, psychiatry, and cross-cultural psychology. The first family theories were developed in the 19th century. A form of social Darwinism theorized that the structure and function of family adapted, as a social organism, to the environment. Marxist theory employed the concept of economic determinism to explain how economic resources determined social power, which in turn determined class struggle. The concept of social power was extended to explain authority and power structures of the father and mother. Durkheim’s theory explained the existence and the changes in family structure and function in terms of the family’s functional role in the preservation of society. Functionalism analyzed the role of family as part of a greater whole, in which an equilibrium with other social institutions was established. This was essentially a systems theory, in contrast to the biological or economic determinism of social Darwinism and Marxist theory.

One of the most influential theories of family in the second half of the 20th century was Parsons’ structural–functional perspective, in which society was viewed as an organism striving to resist change and to maintain itself in a state of equilibrium. Structure refers to the members of the family (parents, child, and kin), and function refers to how families satisfy physical and psychological needs for survival and maintenance. According to Parsons, the adaptation of the family

unit to the industrial revolution required a nuclear family structure that could carry out societal functions and satisfy the physical and psychological needs of family members. However, in its urban setting, the nuclear family is fragmented from its kinship network, leading to psychological isolation. Distancing itself from the extended family results in loss of its productive, political, and religious functions. Social mobility, particularly in the highly mobile U.S. culture, was made possible by the breaking of family ties.

However, most sociologists, anthropologists, and psychologists today disagree with Parsons’ depiction of the nuclear family as isolated from its kin. Evidence from studies of family networks indicates that ties are maintained between members of the nuclear family and kin at different generational levels in the United States and many European countries. Many ethnic groups in the United States maintain fairly close family and kinship ties, whereas others do not. Cross-cultural studies have indicated that there are not polar opposites of no family ties versus close family ties but, rather, different degrees of family ties. In countries such as the United States, Sweden, and Britain there are looser ties between the nuclear family and kin, whereas the ties are closer in countries such as China, India, and Greece.

Family theories based on systemic concepts have also been developed (Parson’s theory is also a systems theory). Family system theory has been developed within general systems theory, and its basic concepts apply to physics, biology, and social sciences, among other sciences. The family is a system within larger suprasystems of society and attempts to maintain equilibrium by adapting to demands and to changes in the larger system. The focus is on communication processes between family members and on recurring family transactional patterns. Family system theory was developed in the fields of clinical psychology and psychiatry as a psychotherapeutic method. This has resulted in the construction of models of family functioning and techniques of psychotherapy directed toward the family. Ecological theories of family trace the relationships between environment, social institutions, the family, and psychological variables. The human ecology theory of Bronfenbrenner is basically a family systems model. One of the earliest ecological models is that of cultural anthropologists John and Beatrice Whiting and Irvin Child and their many collaborators in their six-culture study. Their basic hypothesis was that child training throughout the world is in many important aspects identical and that there are universal

aspects of behavior but also differences from culture to culture. Six cultures were studied in detail: those of Raira, Okinawa; Tarong, the Philippines; Khalapur, India; Nyansongo, Kenya; Juztlahuraca, Mexico; and Orchard Town, United States. The elements of the model were the environment (climate, flora, fauna, and terrain), history of the settlements, maintenance systems (subsistence patterns, means of production, settlement patterns, social structure, etc.), the child's learning environment (caretakers and teachers, mothers' workload, etc.), psychological variables (behavioral styles, skills and abilities, values, conflicts, and defenses), innate needs, and projective expressive systems or elements of the culture (religion, magic beliefs, ritual and ceremony, etc.) (Fig. 1). Cultural features such as the economy, social structure, settlement pattern, and household and family organization were found to be related to behavior. For example, the complexity of the socioeconomic system and the composition of the household were predictive of social behavior of the system. This is a classic cultural anthropological model for cross-cultural studies of family.

Other family theories employed include feminist theory, symbolic interactionism, family development, phenomenology, family power, and exchange theory.

3. FAMILY

3.1. Definition of Family

Currently, there are many definitions of family based on different theoretical perspectives. An early definition of the family was that of the anthropologist Murdock: "The family is a social group characterized by common residence, economic cooperation, and reproduction. It includes adults of both sexes, at least two of whom maintain a socially approved sexual relationship, and one or more children, own or adopted, of the sexually cohabiting adults." The functions of family were considered to be sexual, reproduction, socialization, and economic. The sociologist Popenoe defined family in terms of recent changes in the social and economic position of the family, the increase in one-parent families [divorced, adoptive, widows(ers), or unmarried mothers], and homosexual families. In this definition of the family, the minimum number is one adult and one dependent person, the parents do not have to be of both sexes, and the couple does not have to be married. The functions of the family are procreation and socialization of children, sexual regulation, economic cooperation, and provision of care, affection, and companionship.

FIGURE 1 A model for psychocultural research. From Whiting and Whiting (1975).

3.2. Family Typology

As inferred in the previous definitions, there are different types of families. The structure refers to the positions of the members of the family (e.g., mother, father, daughter, grandmother, etc.) and the roles assigned to the family members by the culture. For example, traditional roles of the nuclear family in North America and northern Europe in the mid-20th century were the wage-earning father and the housewife and child-raising mother. Cultures have social constructs and norms related to the proper roles of family members—that is, what the role of the mother, father, etc. should be.

Family types or structures have been delineated primarily by cultural anthropological studies of small cultures throughout the world. However, family sociologists have also contributed to the literature on family typology, although sociology has been more interested in the European and American family and less interested in small societies throughout the world.

There are a number of typologies of family types, but a simple typology would be the nuclear and the extended family systems. To these can be added the one-parent family.

The nuclear family consists of two generations: the wife/mother, husband/father, and their children. The one-parent family is also a variant of the nuclear family. Most one-parent families are divorced-parent families; unmarried-parent families comprise a small percentage of one-parent families, although they have increased in North America and northern Europe. The majority of one-parent families are those with mothers.

The extended family consists of at least three generations: the grandparents on both sides, the wife/mother and the husband/father, and their children, together with parallel streams of the kin of the wife and husband. There are different types of extended families in cultures throughout the world. The following is one taxonomy:

- The polygynous family consists of one husband/father and two or more wives/mothers, together with their children and kin. Polygynous families are found in many cultures. For example, four wives are permitted according to Islam. However, the actual number of polygamous families in Islamic nations is very small (e.g., approximately 90% of fathers in Qatar, Kuwait, United Arab Emirates, Oman, Bahrain, and Saudi Arabia have only one wife). In Pakistan, a man seeking a second wife must obtain permission from an arbitration council, which requires a statement of consent from the first wife before granting permission.

- In a few societies in Central Asia there are polyandrous families, in which one woman is married to several brothers and thus land is not divided. However, this is a rare phenomenon in cultures throughout the world.

- The stem family consists of the grandparents and the eldest married son and heir and their children, who live together under the authority of the grandfather/household head. The eldest son inherits the family plot and the stem continues through the first son. The other sons and daughters leave the household upon marriage. The stem family was characteristic of central European countries, such as Austria and southern Germany. The lineal or patriarchal family consists of the grandparents and the married sons. This is perhaps the most common form of family and is also found in southern Europe and Japan.

- The joint family is a continuation of the lineal family after the death of the grandfather, in which the married sons share the inheritance and work together. Joint families were found south of the Loire in France, as were patriarchal families, whereas the nuclear family was predominant north of the Loire. Joint families are also found in India and Pakistan.

- The fully extended family, or the *zadruga* in the Balkans countries of Croatia, Bosnia, Serbia, Montenegro, Albania, Macedonia, Bulgaria, had a structure similar to that of the joint family but with the inclusion of cousins and other kin. The number of kin living and working together as a family numbered in the dozens.

A point needs to be made regarding the different types of extended families. Historical analyses of the family by anthropologists and sociologists indicated that people considered to be members of a family or a household were not necessarily kin. For example, in central European countries until the 18th century, servants (who were often relatives), semipermanent residents, visitors, workers, and boarders were considered to be members of the household. The term *familia* was used to denote large households rather than “family” in the modern sense. Until the 18th century, no word for nuclear family was employed in Germany but the term “with wife and children.” Frédéric Le Play, considered to be the father of empirical family sociology, discussed the emergence of the nuclear family as a product of the industrial revolution. He also characterized the nuclear family, the *famille*, as unstable in comparison with the stem family.

One theory regarding the change from feudal *familia* to the *famille* of Western Europe is based on

the following analysis. After the reformation, vassals left the feudal towns to seek work in the cities. This led to the separation of the dwelling place and place of work and resulted in privacy and the sentimentality of the nuclear family. This pattern, however, was not found among the peasants in the agricultural areas. The strengthening of the relationship between parents and children was also a result of the religious influence of the Age of Enlightenment. These changes led to the releasing of servants from the close community of the household. Servants and workers became less personal and part of the household and more contractual. This led to the emergence of many new nuclear families (e.g., those of early factory workers and clerks). A new word in German, *Haus*, referred only to those living within it.

Historical analyses of the family during this period in Western Europe also emphasize that not all families were large extended families because establishing this type of household was dependent on land ownership. Most families worked for large feudal types of households and were essentially nuclear in structure. In England during this period, where land ownership was restricted to the nobility, the vast majority of families, which either worked for the landowners or rented small plots, were necessarily nuclear families.

3.2.1. The Nuclear Family: Separate or Part of the Extended Family?

The key element in studying different types of family structure and its relationships with psychological development of the children, its economic base, and its culture is the nuclear family. In 1949, Murdock made an important distinction regarding the relationship of the nuclear family to the extended family: "The nuclear family is a universal human social grouping. Either as the sole prevailing form of the family or as the basic unit from which more complex familial forms are compounded, it exists as a distinct and strongly functional group in every known society."

Murdock made an important point: The nuclear family is prevalent in all societies, not necessarily as an autonomous unit but because the extended family is essentially a constellation of nuclear families across at least three generations. Parsons' theory that the adaptation of the family unit to the industrial revolution required a nuclear family structure resulting in its isolation from its traditional extended family and kinship network, leading to psychological isolation and anomie, has had a strong influence on psychological and

sociological theorizing about the nuclear family. However, studies of social networks in North America and northern Europe have shown that the hypothesized isolation of the nuclear family is a myth. Nuclear families, even in these industrial countries, have networks with grandparents, brothers and sisters, and other kin. The question is the degree of contact and communication with these kin, even in nations of northern and southern Europe.

A second issue relates to the different cycles of family, from the moment of marriage to the death of the parents or grandparents. The classic three-generation extended family has a lifetime of perhaps 20–30 years. The death of the grandparent, the patriarch of an extended family, results in one cycle closing and the beginning of a new cycle with two or three nuclear families, the married and unmarried sons and daughters. These are nuclear families in transition. Some will form new extended families, others may not have children, some will not marry, and others (e.g., the second son in the stem family) will not have the economic base to form a new stem family. That is, even in cultures with a dominant extended family system, there are always nuclear families.

A third issue is the determination of a nuclear family. This is related to place of common residence or the "household" of the nuclear family. Demographic studies of the family usually employ the term household in determining the number of people residing in the residence and their roles. However, there is a paradox between the concepts household and family as employed in demographic studies. Household refers to counting the number of persons in a house. If there are two generations, parents and the children, they are identified as a nuclear family. However, this may lead to erroneous conclusions about the percentage of nuclear families in a country. For example, in a European demographic study, Germany and Austria had lower percentages of nuclear families than Greece. This appears to be strange because Greece is known to be a country with a strong extended family system. However, demographic statistics provide only "surface" information, which is difficult to interpret without data about attitudes, values, and interactions between family members. Nuclear households in Greece, as in many other countries throughout the world, are very near to the grandparents—in the apartment next door, on the next floor, or in the neighborhood—and the visits and telephone calls between kin are very frequent. Thus, although nuclear in terms of common residence, the families are in fact extended in terms of their relationships and interactions.

In addition, there is the psychological component of those who one considers to be family. Social representation of his or her family may consist of a mosaic of parents, brothers and sisters, grandparents, uncles, and aunts and cousins on both sides, together with different degrees of emotional attachments to each one, different types of interactions, bonds, memories, etc. Each person has a genealogical tree consisting of a constellation of overlapping kinship groups—through the mother, father, mother-in-law, father-in-law, but also through the sister-in-law, brother-in-law, cousin-in-law, etc. The overlapping circles of nuclear families in this constellation of kin relationships are almost endless. Both the psychological dimension of family—one’s social representation—and the culturally specified definition of which kin relationships are important determine which kin affiliations are important to the individual (“my favorite aunt”) or the family (“our older brother’s” family) and which are important in the clan (the “Zaman” extended family) or community (the “Johnsons” nuclear family). Thus, it is not so important “who lives in the box” but, rather, the types of affiliations and psychological ties with the constellation of different family members or kin in the person’s conception of his or her family, whether it is an “independent” nuclear family in Germany or an “extended family” in Nigeria.

3.3. Subsistence Patterns and Family Types

Ecological theories specify relationships between the family structure and function, the ecological context (physical environment, climate, flora, fauna, terrain, and settlement patterns), the sociopolitical context (social structure, subsistence patterns, traditions, religion and beliefs, language and means of communication, etc.), and psychological variables (cognition, personality, values, social interactions, etc.). The ecological context and the sociopolitical context can shape family types, but the model is not strictly deterministic: Individuals or the community can also shape family types. The number of wives, the dowry system, and relationships with kin in a family type can be shaped by traditions and religion. However, perhaps the most important determinant of family type is the subsistence system, which is also shaped by the ecological context, particularly in small societies. In hunting and gathering societies, in which mobility of the family is necessary in order to obtain food, the nuclear family type is

prevalent. In agricultural and pastoral societies, in which there is a permanent base and many hands are necessary for cultivation of the land, the extended family types are prevalent. In modern industrial society, in which people are hired to provide services or to work in industries, money is a means of exchange, people live in urban areas, and apartments or houses are expensive, the nuclear family is prevalent.

4. KINSHIP PATTERNS AND FAMILY MATTERS

4.1. Kinship Relationships

Cultural anthropology has categorized the different types of kinship relationships in extended families in a variety of cultures. These are called lineal, collateral, and affinal relationships. Lineal relationships are those between the grandparents and the grandchildren. Collateral relationships are those with uncles and aunts, cousins, and nephews and nieces. Affinal relationships are those between parents-in-law, children-in-law, and siblings-in-law as well as with matrilineal and patrilineal kin. However familiar the terms for these kin are in Europe and North America, they are critical concepts in different cultures because they are also related to the types of relationships and obligations toward affinal, collateral, and affinal kin, to lines of descent, to residence, to inheritance of property, and to roles.

The terms for kin are more differentiated in various cultures. Murdock employed a system with six categories based on categorization of cousins: Hawaiian, Eskimo, Sudanese, Iroquois, Crow, and Omaha. Other categorizations are based on classification of paternal and maternal relatives. For example, in Iran the term in Farsi for mother’s sisters is *khaleh* and it is *ammeh* for father’s sisters, with analogous terms for father’s brothers. In Pakistan, several cousins may be raised together in the same household. They are referred to in Urdu as brothers or sisters, with the prefix added, “through-my-maternal-aunt” or “through-my-paternal-uncle.” Generic words, such as aunt, uncle, or even grandparents, have no equivalent in Urdu, but specific terms related to matrilineal kin, as in Iran, are employed; for example, *khala* is the mother’s sister and *phuphee* the father’s sister.

4.2. Residence

Residence refers to where the couple resides after marriage. One theory is that subsistence patterns

determine rules of residence, which in turn affect the rules of descent. The theory is based primarily on small, noncomplex societies.

- Patrilocality refers to residence with or near the husband's patrilineal kinsmen. This is the most common form of postmarital residence, with approximately 50% of small societies sampled.
- Virilocality refers to residence near the husband's father and is similar to patrilocality. The difference is the absence of patrilineal kin groups. This represents the second largest percentage (20%) of postmarital residence after patrilocality. The remainder of residence patterns sum to the remaining 30% of societies.
- Matrilocality is similar to patrilocality but refers to residence with or near the wife's matrilineal kinsmen. This is the case, for example, with the Chiapas of Mexico.
- Avunculocality refers to residence with or near the maternal uncle or other male matrilineal kinsmen of the husband.
- Bilocality is residence with or near the parents of the husband or the wife.
- Matrilocality–avunculocality is similar to bilocality but can be either matrilocality or avunculocality residence.
- Avunculocality–virilocality is also similar to bilocality but can be either avunculocality or virilocality residence.
- Neolocality means residence apart from the relatives of both spouses. This is characteristic of nuclear family residence in northern Europe and North America. In complex industrial societies in which there are few small independent farms, the economy is based on wages rather than land ownership. Thus, land ownership as a basis of production is not a factor, and small nuclear families with neolocality residence are more functional.
- Duolocality means separate residence of each spouse in the paternal and maternal household.

4.3. Descent

Descent refers to the relationships with paternal and maternal kin. The relationships concern many aspects of life, such as economic activities, religious activities, child-rearing practices, political behavior, inheritance, and residence. These aspects of living are organized around strict sets of rules with kin, many of them as ritualized behaviors. Societies with specific rules for different kin are usually hierarchical in structure and in the distribution of power. The following are rules of descent in different cultures.

Bilateral: Affiliation is with both mother's and father's relatives.

Patrilineal: Affiliation is with kin of both sexes through the maternal and paternal fathers only, but not through maternal and paternal mothers.

Matrilineal: Affiliation is with kin of both sexes through the maternal and paternal mothers only, but not through maternal and paternal fathers.

Ambilineal (cognatic): Affiliation is with kin through either the maternal parents or the paternal parents. Some may affiliate with kin through their mothers and others through their fathers.

Double: Affiliation is with both father's patrilineal kin and mother's matrilineal kin.

4.4. Marriage

Societies have norms regarding whom one is permitted to marry (endogamy) and restrictions regarding whom one cannot marry (exogamy). In some societies, such as in India or Pakistan, endogamy means that marriage is restricted to the same caste, the same village, the same religion, and the same race. These social norms are not as restrictive in North America and Europe, although marriage to someone of another racial or ethnic group or to someone of a different level of education or social status may not be accepted in some groups. Exogamy means that, e.g., marriage to a member of the nuclear family, or incest, is a universal taboo in almost all societies. In China, marriage to someone with the same family name was disapproved. In many societies, marriage is not permitted with first cousins or with the son or daughter of a godparent. In other societies, such as Saudi Arabia, marriage with first cousins is desired, specifically to the sons and daughters of the paternal brother (uncle) or to members of the clan. In other societies, if a husband dies, the wife must marry the brother.

In the past, in most societies throughout the world, marriages were arranged between two families, and a verbal or written contract was agreed upon regarding the dowry or the bride wealth; however, this is changing gradually in many societies in Africa and Asia. In patrilineal societies, the fathers usually made the decision. In the few matrilineal societies in the world, the mother's brothers made the decision. Decisions to unite their sons and daughters in marriage are based on certain criteria. Because endogamy is an important restriction, families look for the best possible alliances between them, which may be based on social and economic factors and, in many cases (such as in Saudi

Arabia, where marriage between paternal first cousins is highly desirable), strengthening the wealth, prestige, and social power of the extended family within the clan or tribe. The decision of a young couple to marry on the basis of love with or without the consent of the parents occurs in a minority of societies, including North America and northern Europe, although this is changing rapidly in many societies. One theory is that in societies with neolocal postmarital residence, romantic love as a basis of marriage is more common. It is suggested that marriage based on love and companionship provides a stronger union when the couple must depend on their own economic assets and not on their parents' aid for survival.

The dowry is an integral part of the marriage contract between the two families of the couple. There are three general types of dowries. The dowry system refers to the transfer of property, money, or animals by the bride's parents to the husband after marriage. The bride wealth system, the most common dowry system, is the opposite of the dowry system: The transfer is from the husband's family to the bride's family. A third type is bride theft, in which the man abducts the woman without the consent of the respective families. In the past, the dowry system was in effect in European countries, in addition to other societies, whereas the bride wealth system was in effect in Islamic nations as well as other societies.

Inheritance of property is an integral part of marriage and lineal descent. Japan and China adapted differently to industrialization in the 19th century. Both had an agrarian economy, rapid population growth, and extensive but corrupt and inefficient bureaucracy. In China, inheritance was egalitarian, but in Japan a single child inherited the property, which made it possible to accumulate capital. In China, loyalty was to the family and nepotism a duty, so every family member could benefit from upward social mobility. In Japan, which had a more feudal system, a father could disinherit his son and adopt a young man who seemed more worthy.

4.5. Divorce

There is considerable cultural diversity regarding divorce. Divorce is socially disapproved in all societies, and families usually make great efforts to keep the couple together. The reasons for this are many: the social stigma of divorce, the consequences for the children, the financial provisions, and the issues of property and inheritance.

Societies differ in the degree to which divorce is controlled and by which institutions. In some societies,

divorce is controlled directly by the family, whereas in others there is indirect control by social institutions and by the dominant religion. For example, Catholicism does not permit divorce except under highly unusual situations requiring a special dispensation. The Orthodox Church permits three marriages and three divorces. Islamic law, the *sharia*, permits polygamy up to four wives and also divorces. However, in Islamic nations, the intent of a husband to take a second wife may lead to the first wife seeking a divorce. Despite the conventional notion in the West that in Islam husbands can divorce a wife by stating three times the phrase, "I divorce you," divorce is not an easy matter because of its legal and social consequences. According to Islamic law, the daughter inherits property from the father—half of the sum of the son's. The wife retains property in her name after marriage, even gifts from her family, and the husband has no legal claim to her property. After divorce, the woman retains her property and custody of the children until they reach 7 years of age. However, the father remains the legal guardian and is responsible for the financial care of the children. Remarriage of a divorced woman is permitted, but the children of the first marriage are subsequently raised by the maternal grandmother.

5. FAMILY ROLES AND POWER

Role theory refers to the cultural norms regarding psychological and interactional aspects of members of society, such as mothers, fathers, sons, daughters, and grandparents. The originators of role theory are Ralph Linton in sociology and George Herbert Mead in social psychology. Role refers to the social expectations and the social scripts of family roles—how roles have been shaped by cultural conventions and by the collective ideologies of a society. One aspect of role theory studies how roles are learned during the process of social interaction. That is, people interact with others, they see themselves and others as occupants of particular statuses, and they learn guides for action. In other words, there are certain social scripts or expectations associated with certain roles.

Structural role theory as developed by Linton and Parsons refers to the structural and functional aspects of status and role. By structure is meant the positions recognized by the specific social system and the content of the role. That is, what are the social scripts associated with the roles of mother and father in the society? For example, social scripts of gender roles in a society might

be that the place of mother is in the home, she should raise the children, cook, etc., whereas in other societies mothers should work, share with the husbands the daily work of the home and care of children, etc. The functional analysis is concerned with the function of role. That is, what are the consequences for the rest of the social system of the specific role? How does the role contribute to the maintenance of the system? How does a particular role help in the achievement of the goals of the system? How does the role help solve the process of adaptation to the social system and contribute to the maintenance of patterns, such as the values system? Structural role theory also has a comparative element, attempting to determine which structure features of social systems are universal through cross-cultural analysis.

Power, the degree of gender equality, and the division of resources within the family are another aspect of family dynamics in the family. Anthropology has established that power is related to the control of the economic activity or land ownership and institutionalized through the norms of the society. Power can be defined as the influence of the spouse, children, and other relatives. However, the influence is not a personality trait, although there may be individual differences in the ability to influence others. The basis of the influence is the authority bestowed by social norms to different family roles and internalized in terms of values. Power may be expressed in the control of the finances, in the ability to command respect and obedience, in feelings of autonomy and control over one's life, in the capacity to regulate one's dependency on others, in the power to decide where the family lives and whose career is given priority, and in the freedom to be able to leave difficult family situations.

Most agricultural societies are patrilineal, but some are matrilineal. In some agricultural societies, the male does most of the plowing or animal tending and the woman's role is to care for the house and the children. However, in many patrilineal agricultural societies, the woman does much of the work, such as harvesting and tending the crops, in addition to the household tasks and caring for the children. Boys learn the roles of the males and the fathers, and girls learn the roles of the females and the mothers in small societies. The roles in small societies are hierarchical, in which the patriarch of the family has the ultimate power and males have more power than females. In matrilineal societies, the matriarch has more power than the father. The brothers of the matriarch have more power than the father, who is absent from the family and may visit the matriarch secretly at night. However, although the father

may have the institutionalized social power within the family, the influence of the mother in extended families regarding many family matters may be greater than that of the father.

It is important to note that role theory refers to social values and social scripts—what the social scripts should be in the society. However, there is also a psychological dimension; there are individual differences in each society regarding agreement with these roles. Some members of society insist on the strict application of these roles, whereas some members rebel against these roles. In many societies throughout the world undergoing transition, women are rejecting the traditional roles of mother, housewife, and caretaker and are entering the workforce, as in Western societies. However, the process is more painstaking in these societies, and working mothers often experience strong family pressures, which may come from the grandparents or the in-laws, to be both a working mother and fulfill the traditional roles of housewife and caretaker. The structure of the traditional family in many countries provides an alternative caretaker of the child while the mother works—the grandmother.

6. PSYCHOLOGICAL DIMENSIONS

So far, the discussion has covered features of culture and family. Societies differ in terms of degree of complexity, from small, simple societies of a few hundred members who subsist through fishing or hunting to large, complex societies of western Europe and North America in which the economic basis is industry and services. Societies also differ in terms of family structure and function. Family type is related to the subsistence system, property and residence, and descent. This section discusses whether there are different psychological characteristics related to different family types.

As indicated previously, there are relationships between means of subsistence and family types. Agricultural and pastoral societies tend to have extended families, whereas hunting, fishing, and gathering societies tend to have nuclear societies. Agricultural societies tend to have a base, land and permanent houses, and large families and kin nearby. A large number of kin is necessary for crop cultivation. Cultivation is a process that requires patience and the cooperation of many, and it is affected by droughts, floods, and other natural forces. Studies have found that children in agricultural and pastoral societies are taught to be responsible, compliant, obedient, and to respect their elders. Hunting and

gathering societies move about in order to obtain food, hunting requires particular skills, and good hunters are respected no matter what their age. Children in these societies tend to be self-reliant, independent, and achievement oriented. It is likely that these personality traits and the social values that promote them are a function of the adaptation of the individual and the family to the ecological constraints of their environment through their means of subsistence.

In the six-cultures studies of Whiting *et al.*, relationships between the economy, social structure, settlement pattern, household and family organization, and the behavior of children were studied. Minturn and Lambert studied the effects of differences in living patterns and economic activities on child-rearing practices and the behavior of children (e.g., succorance, achievement, self-reliance, obedience, nurturance, responsibility, sociability, dominance, and aggression). Mothers were least warm in Mexico and India, where the living patterns were characterized by courtyard or semicourtyard living. In African and Philippine societies, where mothers lived in separate houses surrounding a partially enclosed yard, mothers were intermediate in warmth. Okinawan mothers, who had more privacy, were the warmest. New England mothers, who had the most privacy and almost exclusive responsibility for child care, ranked lowest in warmth. In general, children in nuclear, joint, and lineal family households were treated more warmly and were indulged when alternate caretakers, such as grandparents, sisters, and aunts, were available.

Kagitcibasi's model of family change based on socioeconomic development posits three family interaction patterns: the traditional family in developing countries characterized by total interdependence between generations in material and emotional realms, the individualistic nuclear family model of Western society based on independence, and a dialectical synthesis of these two involving material independence but psychological interdependence between generations. The parenting orientations differ significantly among these patterns, as do the distinctive characteristics of the emergent selves. With increasingly urban lifestyles and increasing affluence in collectivistic cultures, material interdependence between generations decreases because elderly parents no longer depend on the economic support of their adult offspring, but emotional interdependence continues. This leads to increased autonomy in child rearing, but together with psychological interdependence.

These changes are theorized to lead to the development of three types of the self in the three family models: the related self, high in relatedness but low in autonomy

in the family model of total interdependence; the separated self, high in autonomy but low in relatedness in the family model of independence; and the autonomous-related self, high in both relatedness and autonomy in the family model of psychological interdependence, revealed in the changing family in collectivistic societies.

The previously discussed studies refer primarily to personality and emotional variables. Family type is also related to cognitive variables. An example is Berry's ecocultural framework, which traces the relationships between ecological, cultural, and acculturational variables and cognitive styles. Initially, links were established between hunting-based and agriculture-based peoples regarding ecological demands and cultural practices and the required cognitive performances (i.e., visual disembedding and analytic and spatial abilities). These links were analyzed in detail in terms of the variables subsistence patterns, settlement patterns, population density, family type, social/political stratification, socialization practices, education, and wage employment. It was found that nomadic hunters and gatherers, with a loose social structure, nuclear family systems, and an emphasis on assertion in socialization, were relatively field independent (i.e., were able to focus on an object without being influenced by its context), whereas sedentary agriculturalists, with tight social structures, extended family systems, and an emphasis on compliance in socialization, were relatively field dependent (i.e., strongly influenced by the context of stimuli). In addition, people in societies undergoing acculturation and developing Western types of education became more field independent (Fig. 2).

7. CONCLUSION

This article presented a picture of the family primarily from the perspective of cultural anthropology, sociology, and cross-cultural psychology. In this brief synopsis, it was not possible to present the contributions of other social sciences, such as economics, geography, psychiatry, and political science. The primary goal was to focus on the study of family from the standpoint of cross-cultural psychology and psychological anthropology. Thus, emphasis was placed on an ecological or ecocultural perspective: the ecological context, social structure, maintenance systems, means of subsistence, the family, child development, roles, and psychological consequences. The picture may appear to be like a kaleidoscope in that there is wide cultural variety and there are many variations of families and social structure.

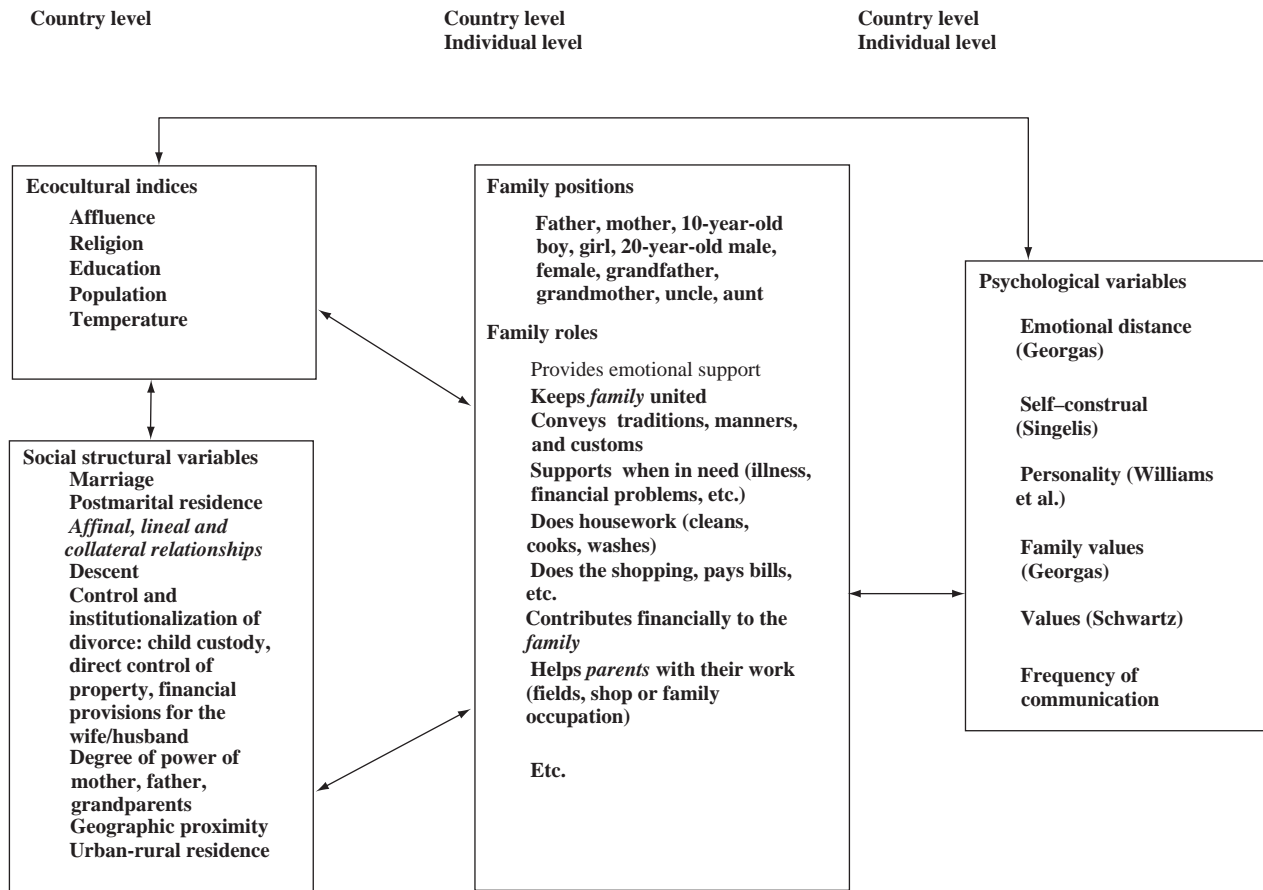

FIGURE 2 An ecocultural framework for the study of family.

However, there have been many efforts to determine the structure underneath this seemingly chaotic plethora of findings. This entails a comparative approach, consistent with the approach of psychological anthropology and cross-cultural psychology in seeking universals in family structure and function as well as variations due to cultural differences. A criticism of sociology, which has made significant contributions to the study of the family, is that it has been concerned primarily with the study of the family, particularly the nuclear family, only in the countries of northern Europe and North America.

An important issue in making sense of results from thousands of societies is the chronological dimension. That is, anthropologists have been studying small societies for more than a century. Thus, some findings refer to the study of a culture 100, 80, 40, or 30 years ago and some to recent studies. However, in a changing world in which small societies have been exposed to economic changes, technology, television, tourism, and trade with economically developed nations of the West and Asia,

these societies have also been adapting. Acculturation and enculturation in response to these pressures for change have also affected the links between ecology, social structure, family types, and psychological variables. There is a trend toward more families becoming structurally nuclear, even in small societies. However, one must be careful in employing the phrase “becoming nuclear.” There is increasing evidence from studies of small societies or developing nations that the predictions of modernization theory that the driving force of modernization, the economic engine, will eventually lead to the Western type of nuclear family system may be incorrect. The number of nuclear families is increasing in many developing societies; the traditional family systems are no longer totally dependent on subsistence systems, such as hunting, gathering, or even agriculture; young couples are increasingly choosing their spouses rather than entering arranged marriages; women are increasingly entering the workforce; traditional family roles have changed; and the male is no longer the

absolute patriarch in the family. However, even though the number of nuclear families is increasing in most societies, these families still maintain very close relationships with their kin. It appears that although the structure of the family is changing from extended to nuclear, the functions of the family and the kin relations have not changed as much. Interactions and relations with kin are the psychological components of the family, which are of particular concern to psychologists.

The study of culture, family, and the psychological consequences is thus in a very dynamic phase and of considerable interest to social scientists and students.

GLOSSARY

feminist ethics A philosophical stance carrying the assumption that women and their experience have moral meaning, focusing attention on feminine ethical values such as the ethic of care, implying a critique of all discriminatory distortions, and promoting the necessary social action to get rid of all kinds of oppression.

moral reasoning The ways in which people analyze and resolve ethical questions.

psychoanalytic critical posture Theoretical stance based on women's libidinal and genital differences from men.

Feminism is mainly a political, social, and cultural perspective that is pro-women. That is, it is an ideology or an intellectual posture that attempts to explain why things are the way they are while advocating for political, social, and cultural equality between women and men. It also tries to eradicate gender discrimination in society.

Feminist psychology refers both to a collection of efforts to understand the different ways in which women and women's issues have been considered (or not considered) in psychology and to a body of knowledge about women gathered since the 1960s. Feminist psychology, also known also as psychology of women, analyzes the process through which gender is constructed, emphasizing the worth in women's perspectives and experiences. One can recognize different perspectives in feminist psychology, but all of them poignantly signal and challenge the invisibility of women in psychology. Furthermore, it is a double exclusion; women are not considered, and one does not even recognize that there is an omission. Feminist psychology challenges the validity of gender role stereotypes and expectations that have traditionally maintained patterns of male dominance and female subordination in our society. More specifically, feminist psychology disputes unquestioned premises, some research traditions, and theoretical positions that maintain a patriarchal order in which women remain secondary. At the same time, it questions those professional practices and institutional and societal structures that limit the understanding, treatment, professional achievement, and responsible self-determination of women and men.

1. HISTORICAL BACKGROUND

Historically, feminist psychology has emerged as a grassroots movement, but it is possible to trace its origins and

identify some landmarks in the United States, especially in the works of Weisstein and Gilligan, where they denounced prevailing sexist biases and women's non-existence in psychology. These pioneers emphasized that there were no female authors in any of the major theories of human development and psychological functioning and that women have been missing and ignored, even as research participants, at the formative stages of psychological theories. As Weisstein pointed out in 1971, "psychology is men's fantasy." That is, scientists draw their conclusions from investigating men and blindly generalize men's experiences to the experiences and lives of women but not vice versa. Weisstein's article, "Psychology Constructs the Female," challenged the predominant sexism in psychology while pointing out a double criticism of mainstream psychology: that it lacks scientific rigor and that it ignores the role played by social contexts. The lack of scientific rigor refers to the omission of the experiences of half the population (i.e., of women) in research that supports psychological theorizing. This lack of awareness about social context refers to the individualist emphasis that has characterized psychology in methodology as well as in theory construction, for example, ignoring the importance of power and gender in behavior. These criticisms are still valid, and many feminist psychologists reiterate this assertion. Today, the goal is still to do "improved science," taking into account all relevant variables and not just men's experiences. Cole's 1979 work was a pioneering study, titled *Fair Science*, that focused on sex-based discrimination and the stratification of science. Its main contribution was an increased understanding of women's challenges, opportunities, and obstacles when attempting a career in science.

Some interest and emphasis in the matters of sex differences started to appear from the beginning of psychology in the United States at the end of the 19th century and the beginning of the 20th century. Functionalism then grew as central theory strongly associated with prevailing Darwinian postures, especially with the variability hypothesis (men would have more variations among them than would women) and the functional variability hypothesis (women's intellectual performance would be affected by the menstrual cycle). These beliefs about a supposed female inferiority (despite the early disagreement and opposition found in the research done by Bradford Thompson, Puffer, Whiton Calkins, and other psychology female pioneers) prevailed for many decades as a subtext in psychological theorizing. This supposed inferiority showed itself in different social and professional fields,

and a succession of studies developed during the 1970s and 1980s revealed that sexism was clearly present at several levels. Discrimination against women hindered women's access to, and success in, certain professions. Women encountered discriminatory practices when applying for graduate training, in hiring, and in publishing their research. In addition, research methodology and practice were characterized by male bias that influenced the selection of research design, assessment measures, and sex of participants studied as well as the analysis and interpretation of data.

Based on this new awareness, and because they were interested in achieving real changes in the theory, research, and practice of psychology, Weisstein, Chesler, Evans Gardner, and others in 1970 founded American Women in Psychology, now Division 35 of the American Psychological Association, created in 1973. In Canada, some of the most important events that marked the beginning of feminist psychology were the Underground Symposium, the Canadian Psychological Association (CPA) Task Force on the Status of Women in Canadian Psychology, the founding of the CPA Interest Group on Women and Psychology, and the establishment of the CPA Status Women Committee. These and other initiatives, mainly in the academic domain, contributed to highlight the presence and experiences of women in various subfields of psychology (e.g., moral reasoning, feministic ethics, history of psychology, clinical psychology, community psychology).

2. PSYCHOANALYSIS AND FEMINIST PSYCHOLOGY

Outside mainstream psychology, the feminist perspectives most known are related to psychoanalytic perspectives. Using her own mothering experience, Deutsch, one of the first woman analysts in the Vienna Psychoanalytic Society, underlined the consequences of the Freudian undervaluing of women in women's developmental psychological well-being in her pioneering text, *The Psychology of Women*. Horney, a psychoanalytic feminist, criticized Deutsch for equating women with masochism, challenging the role of gender in personality development while stressing the importance of society and culture as determining factors for normal and pathological development. Contemporary stances have also embraced a critical position, particularly object relations theory as developed by Chodorow and Benjamin as well as by French psychoanalysts such as Kristeva, Cixous,

and Irigaray. The French feminist project of “writing the body” is an especially revolutionary effort to provide women’s writings with an authority based in women’s libidinal and genital differences from men. Theories about the body are particularly important for feminists because historically the body has been considered equivalent to the feminine, the female, or the woman—and, as such, has been denigrated as weak, immoral, or unclean.

3. FEMINIST PSYCHOLOGY AND MORAL REASONING

In regard to moral reasoning, Kohlberg, in his well-known developmental research, studied the ways in which people resolve ethical questions and proposed the postconventional stage as the highest level of moral reasoning. This level is characterized by the adult’s ability to base morality on the logic of principled decision making, which in turn is based on principles thought to be universal and not dependent on culture—the ethic of justice, in Kohlberg’s words. But given that all of his research participants were male, Kohlberg could not have taken into account the different socialization of little girls and little boys in our culture. Males are traditionally socialized to be autonomous and independent, whereas females are supposed to be passive but loving caretakers of others. Gilligan argued that these differences in socialization practices lead to different values. For men, these differences lead to a morality based on equal rights and acceptance of abstract principles, even at the sacrifice of people’s well-being. For women, these differences lead to a morality based on caring in which increasing maturity broadened the scope of their sense of responsibility and compassion. So, women have a different way—not an inferior one—of solving ethical dilemmas—the ethic of care. Olsen, in her 1978 book *Silences*, documented the history of women writers and pointed out the relative silence of women as literary voices. Gilligan, in her 1982 book *A Different Voice*, delineated one of the most well-known psychological theories about women’s development. By listening to girls and women resolve serious moral dilemmas in their lives, Gilligan formulated the development of a moral reasoning organized around concepts of responsibility and care. She argued that the experiences of inequality and subordination that outline the lives of women and girls creates a moral sense of self that is grounded in human attachments and characterized by a strong connection with relationships. Gilligan and other representatives of the Harvard Group of

Women Studies expressed it using the metaphor of “voice” and “silence.” There were two voices, or two ways of experiencing oneself in relation to others, but only one voice—the male’s—was acknowledged and delineated in the field of psychology and education. To give voice to women and listen to the unheard voice was the new motto. Gilligan recognized a deep affinity with the work of Baker Miller, and she was inspired by the radical consciousness regarding the situation of women as key for understanding the psychological order and voice central to women’s experience and women’s exercise of power. These American feminists saw women’s strength emerging from the experience of recovering an authentic voice and the capacity to express it. Conversely, women’s subordination was rooted in the silencing of their voice. But Gilligan’s work has not been free of controversies. The question of sex differences is not always considered a feminist question, and her proposal of an alternative moral system reflecting women’s experience can also be understood as a consequence of a male-biased culture.

4. A FEMINIST ETHIC

New developments in feminist psychology and in the domain of ethics suggest a feministic ethic that draws from women’s experience and feminist theory to describe its principles. Feminist ethics embraces much of traditional ethics but goes beyond and provides unique lenses for determining what one ought to do and how to decide on courses of action in situations involving competing ethical principles. Because moral philosophy has been largely a male enterprise, feminists seek to expose the individual and institutional practices that have negated and devalued feminine thinking. Feminist ethics assumes that women and their experience have moral meaning, and it focuses attention on feminine ethical values such as the ethic of care. This perspective also implies that a feminist critique must be accompanied by a critique of all discriminatory distortions and by the necessary social action to get rid of all kinds of oppression and not just women’s oppression.

5. THE FEMINIST PERSPECTIVE IN THE HISTORY OF PSYCHOLOGY

In the history of psychology, mainly U.S. and Canadian psychologists denounced the androcentric bias in the

chronicling of the discipline. As with history, sociology, literature, and other disciplines, evidence shows that in psychology women have been systematically excluded as protagonists when historicizing the discipline. The growing awareness of this absence gave rise to a body of research that enriched the field and introduced the names of several female pioneers in the historic chronicle, as shown today in registers of the American Psychological Association and Canadian Psychological Association. In the United States, Bohan, Scarborough, Felipe Russo, and Furumoto have assumed the task of repositioning women in the history of psychology. In Canada, Pike and Wright, among others, have assumed this task. Bosch and Ferrer, from Spain, have developed multidisciplinary research that undertakes to reflect about psychological thought and to identify androcentrism and misogyny in the theories of Freud, Jung, and others. They also have formulated the idea of a nonandrocentric science. The reconstruction of female participation and contributions in various countries of Latin America is an unfinished task.

6. CLINICAL PSYCHOLOGY AND THE FEMINIST PERSPECTIVE

In clinical psychology, feminism has a strong hold in psychotherapy. Feminist psychotherapy emerges as a response to male dominance of mental health professions and institutions, and it objects to the role performed by the mental health establishment in maintaining social and power inequities between men and women as well as between members of the dominant culture and those of ethnic minority groups. Although feminist therapists use diverse therapeutic techniques, they have a common goal of raising awareness of the harmful effects of discrimination on clients, for example, the effects of job discrimination based on gender, race, or sexual orientation. Probably more important still is that feminist therapists dispute the tendency of traditional (male-centered) psychotherapies to catalog as normal those attributes identified with the male-dominated mainstream culture and to label as abnormal those characteristics associated with femininity and with minority cultures. Feminist therapists advocate that women's expressions of anger and distrust toward dominant group members can be seen as successful adaptive responses to prejudice and discrimination. In denouncing traditional psychotherapies

for failing to recognize the harmful effects of sexism, racism, and heterosexism, feminist therapists assert that traditional therapies categorize any behaviors that do not fit the interests of the dominant group as problematic. In so doing, traditional therapies silence women. Feminist psychology also mandates that therapists explore, recognize, and understand their own social biases; that is, they should cultivate awareness of the influence and importance of those biases in their work as therapists. Feminist theorists assume that social inequality, rather than individual psychopathology, often plays a main role in creating and maintaining many of the difficulties presented by clients in psychotherapy, especially when those clients belong to the oppressed groups. Furthermore, the main process in feminist therapy is the search for clients' sources of power rather than the search for pathologies in people. Supervision, advocacy for victims of sexual harassment, and treatment of eating disorders also constitute important topics in feminist psychotherapy where gender is of utmost importance.

7. COMMUNITY PSYCHOLOGY AND THE FEMINIST PERSPECTIVE

Between community psychology and feminist psychology, we find notable convergence, not only in similar values but also in a common historical background, with both having emerged during the 1960s as part of broad movements for social justice and equality. Both perspectives share in criticizing victim-blaming ideologies and reject simplistic or restrictive standards of health, normality, and behavior. Respect for differences, distributive justice, and equality are some of the distinctive values that community psychology and feminist psychology endorse. Both perspectives dispute individual and adjustment-oriented analyses, explanations, and answers. Instead, both elaborate models and strategies emphasizing social policy, advocacy, prevention, and empowerment. In particular, the social community psychology represented by Latin American psychologists Montero and Serrano-García shares the commitment to the empowerment of the powerless, including social action and promotion of social change. Nevertheless, community psychology has not fully embraced feminist perspectives. It has been criticized for not adequately integrating women into the profession, not addressing women's issues in graduate training and

professional practice, and not incorporating feminist perspectives and processes into research, theory, and practice.

8. FEMINIST PSYCHOLOGICAL METHODOLOGY

In the methodological arena, feminist psychology states that more socially situated methods are needed because individualistic research methods have dominated feminist psychology and feminist research despite the theoretical command to study and understand people in context. It is suggested that the inclusion of more socially oriented methods, such as group interviews and focus groups, may help to overcome this deficiency. In addition, from a feminist ethics perspective, new questions arise about the role of power inequalities between the researcher and the researched and about the risk of the imposition of meaning. The task is to generate high-quality interactive data offering the possibility of theoretical advances through of the co-construction of meaning in which both the researcher and the researched participate.

Not only gender inspires different types of discrimination. In 1998, Burman denounced feminist psychology's exclusion of the experiences and voices of women whose cultural identities differ from those of White Western women. She included studies and reflections from contributors who lived and worked in diverse countries such as South Africa, Yugoslavia, and Puerto Rico. In these other cultural contexts, feminist psychology itself has only incipient development and has yet to influence mainstream psychology in any meaningful way.

From its beginnings, feminist psychology has continually expanded its scope of inquiry and its modes of studying gender. Over time, the frontiers that demarcate different approaches have become more visible. Postmodern feminist psychologists reject the possibility of a whole identity that includes a single true voice, and they sustain that diverse contradictory identities can have a liberatory potential. On the other hand, in 2001, Marecek delineated what she termed "feminist skepticism," an approach that draws on postmodern thought and critical theory. The principal question is whose interest and ideas are served by psychology as science, assuming that psychology is not engaged in a harmless and disinterested search for the truth. Contemporary feminist theory calls into question the

possibility of finding fixed, reliable, objective meanings that are applicable to everyone. New categories within current feminist analysis emerge, and differences among women are now in the foreground.

9. CONCLUSION

In synthesis, feminism has forced psychology to take a stand that includes women in theory as well as in research and practice. The introduction of women's psychology and girls' psychology as legitimate topics of study is no less important than the naming and exploring of main issues in women's lives and experiences. By now, feminist psychology has shown the power of women's voice in broadening our understanding of human development, and it is slowly succeeding in putting gender issues on mainstream psychology's agenda. Other dimensions of feminist psychology's contributions involve reconstructing research methods and priorities to study women in the context of their experiences, integrating multiple diversities into all subfields of the discipline, developing innovative approaches in psychotherapy, and transforming institutions toward being more inclusive and collaborative. Last, but not least, this perspective dictates advocacy for social action and public policies that benefit the health and well-being of both women and men.

Feminist's insights are transforming our understanding and the study of psychology and human development. Women's psychology faces future challenges—the call to address diversity among women, to promote and achieve developments in different countries and places, and to become more interdisciplinary as the discipline becomes more inclusive, especially in the task of integrating new ethnic and gender identities.

GLOSSARY

forensic mental health assessment The evaluation of defendants or litigants, usually conducted by mental health professionals such as psychologists, psychiatrists, or social workers, that is performed to assist the court in making better informed decisions or to help the attorney present evidence relevant to his or her case.

John Muhammad and Lee Boyd Malvo were charged in the offenses that became known as the “Washington, DC, sniper shootings.” Both were charged with capital (death penalty) offenses and tried separately. What forensic mental health assessment might be important in such cases? Possibilities include juvenile transfer to criminal (adult) court, competence to stand trial, competence to proceed as one’s own attorney (Muhammad briefly attempted to act as his own attorney), sanity at the time of the offense (Malvo entered a plea of not guilty by reason of insanity), and aggravating and mitigating factors in capital sentencing (both Muhammad and

Malvo were convicted of capital murder). This article will help you understand the nature of forensic mental health assessment, the kinds of questions it tries to answer, as well as the limits of its applicability and usefulness.

1. INTRODUCTION

The field of forensic psychology has developed almost entirely during the past 50 years. The broad meaning of “forensic psychology” might include the research or professional activities of any psychologist—developmental, social, cognitive, human experimental, or clinical—when performed in anticipation that the work might be used by a judge or attorney as evidence to promote better informed legal decision making. However, this article focuses more specifically on one aspect of forensic psychology: assessment. This aspect, forensic mental health assessment (FMHA), refers to the evaluation of defendants or litigants by psychologists (or other mental health professionals such as psychiatrists or social workers) that is performed to assist the court in making better informed decisions or to help the attorney present evidence relevant to his or her case.

Described in this way, forensic psychology is a fairly new specialty within the broader field of psychology. Psychologists have not always been welcomed by the courts. In an important 1962 case, *Jenkins v. United States*, a federal appellate court ruled that psychologists with appropriate training and expertise were qualified

to offer expert testimony on questions regarding mental disorder. Prior to *Jenkins*, courts typically required mental health experts to have a medical degree. Since the *Jenkins* decision, however, there has been a steady increase in psychologists' involvement in legal questions requiring mental health expertise.

Just how frequently do forensic psychologists provide FMHA? We do not have good studies that would answer this question, but the estimated frequency for certain kinds of evaluations, such as criminal defendants' competence to stand trial, is more than 25,000 annually, according to Otto and Heilbrun. Other common legal questions that may be informed by FMHA include competence to waive Miranda rights, sanity at the time of the offense, sentencing (capital and noncapital), juvenile commitment, juvenile waiver to criminal court and reverse waiver back to juvenile court, child custody, and personal injury. Psychologists are involved in conducting many of the evaluations performed in these areas.

2. CONTEXT AND PRINCIPLES OF FMHA

2.1. Sources of Authority in Forensic Assessment

2.1.1. Courts, Statutes, and Case Law

The law is the first place forensic psychologists look in structuring FMHA. Many legal questions are defined, to some extent, by existing statutes. When the criteria for a given legal decision are described in a statute or related evidence code or administrative code, these criteria can be used in the report and possible testimony. This use indicates that the psychologist is both familiar with the relevant law and has structured the evaluation around it, thus making the evaluation more relevant to the proceedings. For any given issue, it is up to the court to answer the ultimate legal question, so it is not the most desirable focus for the report. However, it is helpful to show that the evaluator is aware of the legal standard and can use the defining criteria to structure the report.

Other sources of legal authority may also be helpful, although they may be less directly relevant to the legal criteria used in the report. Appellate case law (particularly cases from the U.S. Supreme Court) and "model" law (e.g., the *Criminal Justice Mental Health Standards*, published in 1989 by the American Bar Association) can provide useful background on the sources of and

reasoning behind the current legal standard in the jurisdiction in which the evaluation is being conducted.

2.1.2. Ethical Standards

Forensic psychologists rely on two major sources of ethical authority. First, the *Ethical Principles of Psychologists and Code of Conduct* (Ethics Code), published by the American Psychological Association (APA) in 2002, serves as the strongest authority for ethics in psychology. Those conducting FMHA are ethically obligated to do so in a way consistent with the ethics code and can be sanctioned by the APA for violating it. A second important source of guidance is the *Specialty Guidelines for Forensic Psychologists*, published by the Committee on Ethical Guidelines for Forensic Psychologists in 1991. This document was written for those who regularly conduct FMHA, and it provides more specific guidance for those in legal settings. Finally, and most specifically, there are documents such as the "Guidelines for Child Custody Evaluations in Divorce Proceedings," published by the APA in 1994, that offer direction for particular kinds of FMHA such as child custody evaluation.

2.1.3. Scientific Literature

FMHA is based on and informed by science. Studies in areas such as mental health disorders, behavioral functioning, violence and antisocial behavior, response to treatment, and the assessment of specific functional legal capacities are all important to the development of FMHA procedures and the practice of FMHA in particular cases. Under the 1993 holding of the U.S. Supreme Court in *Daubert vs. Merrell Dow Pharmaceuticals, Inc.*, and the subsequent 1999 Supreme Court decision in *Kumho Tire Company, Ltd. vs. Carmichael*, FMHA evidence is weighed by the trial court judge for admissibility based in part on whether it is based on procedures consistent with science. (Not all states have the *Daubert* standard for admissibility of expert evidence; some continue to use the standard described in the 1923 *Frye vs. United States* case, in which a technique must be sufficiently established to have gained general acceptance in the field to which it belongs to yield admissible expert evidence.)

2.1.4. Professional Literature

Finally, there is a literature that might best be described as "professional," describing recommended approaches to FMHA based on experience and emerging or

established standards in the field. Often such literature appears in practice-oriented journals or books, particularly those that are interdisciplinary. Leading interdisciplinary journals in forensic psychology include *Law and Human Behavior*, *Behavioral Sciences & the Law*, *Criminal Justice and Behavior*, *International Journal of Forensic Mental Health Services*, and others focusing both on empirical studies and on more practice- or theory-oriented approaches to FMHA. This literature forms another important source of authority and guidance for the forensic psychologist.

2.2. Principles of FMHA

Evaluations conducted by psychologists are typically performed to help reach a diagnosis or problem formulation and to plan appropriate treatment (we might call these evaluations “therapeutic assessment”). However, FMHA differs from this usual process and goals in some important ways. Heilbrun pointed out the following 10 differences (Table I) in his 2001 book, *Principles of Forensic Mental Health Assessment*:

TABLE I
Principles of Forensic Mental Health Assessment^a

Preparation

1. Identify relevant forensic issues.
2. Accept referrals only within area of expertise.
3. Decline the referral when evaluator impartiality is unlikely.
4. Clarify the evaluator’s role with the attorney.
5. Clarify financial arrangements.
6. Obtain appropriate authorization.
7. Avoid playing the dual role of therapist and forensic evaluator.
8. Determine the particular role to be played within the forensic assessment if the referral is accepted.
9. Select the most appropriate model to guide data gathering, interpretation, and communication.

Data collection

10. Use multiple sources of information for each area being assessed.
11. Use relevance and reliability (validity) as guides for seeking information and selecting data sources.
12. Obtain relevant historical information.
13. Assess clinical characteristics in relevant, reliable, and valid ways.
14. Assess legally relevant behavior.
15. Ensure that conditions for evaluation are quiet, private, and distraction free.
16. Provide appropriate notification of purpose and/or obtain appropriate authorization before beginning.
17. Determine whether the individual understands the purpose of the evaluation and the associated limits on confidentiality.

Data interpretation

18. Use third-party information in assessing response style.
19. Use testing when indicated in assessing response style.
20. Use case-specific (idiographic) evidence in assessing clinical condition, functional abilities, and causal connection.
21. Use nomothetic evidence in assessing clinical condition, functional abilities, and causal connection.
22. Use scientific reasoning in assessing causal connection between clinical condition and functional abilities.
23. Do not answer the ultimate legal question.
24. Describe findings and limits so that they need change little under cross-examination.

Communication

25. Attribute information to sources.
 26. Use plain language; avoid technical jargon.
 27. Write report in sections, according to model and procedures.
 28. Base testimony on the results of the properly performed FMHA.
 29. Testify effectively.
-

^aAdapted from Heilbrun (2001).

1. The purpose for which the evaluation is conducted
2. The nature of the relationship between the evaluator and the individual being evaluated
3. The need for a formal notification of purpose
4. Who is being served
5. The nature of the standard(s) applied in the evaluation
6. The sources of data considered
7. The response style of the individual being evaluated
8. The need to clarify the reasoning and limits of knowledge
9. The nature of the written report
10. The expectation of expert testimony

When these differences are considered, it becomes very clear that FMHA is not simply psychological assessment that is conducted in a legal setting. Instead, it is a specialized form of psychological assessment that takes into account that there may be very different questions asked, standards applied, motivations observed, and approaches to communicating results.

General principles that describe therapeutic assessment do not necessarily apply to FMHA, so it is helpful to review the FMHA principles described by Heilbrun in 2001. These principles, discussed in the following section, are summarized and elaborated in how they might apply in FMHA in [Table II](#).

These 29 FMHA principles each apply, to some extent, to the many forms of FMHA. Heilbrun *et al.* provided examples of case reports on different legal questions to which these principles can be applied, so it seems that both theoretically and practically these principles are potentially useful. They are reviewed in the remainder of this section, with a comment about each principle and the associated general guideline:

1. *Identify relevant forensic issues.* This principle distinguishes between the legal question, to be decided by the judge or the jury in the case, and the forensic issues, which are the capacities and abilities included within the legal question. These capacities and abilities can be described and measured more readily than the broader legal question, which typically contains questions of both science (e.g., Did the defendant have a mental illness?) and values (e.g., Was the individual sufficiently disturbed to be unable to know the wrongfulness of his behavior?). The associated guideline suggests that both the legal question and the forensic issues be described in the first section of the report.

2. *Accept referrals only within area of expertise.* Expertise in FMHA has two components: (i) clinical

and didactic training and experience with individuals similar to the one being evaluated and (ii) forensic training and experience in evaluating similar individuals and questions. The forensic psychologist can demonstrate both kinds of expertise by submitting a professional resume (a *curriculum vitae*) when requested by the lawyers or the judge and by displaying professional credentials, such as degree, licensure, and board certification, on the letterhead used for the report.

3. *Decline the referral when evaluator impartiality is unlikely.* The evaluator's impartiality is important in FMHA. If the psychologist has personal beliefs or experiences circumstances that would interfere with his or her ability to be fair and even-handed in collecting data and drawing conclusions, then this principle and guideline suggest that the forensic clinician should decide not to conduct the FMHA in this particular case. For example, psychologists with strong feelings about the death penalty that they cannot set aside in a particular case should decline to conduct a capital sentencing evaluation.

4. *Clarify the evaluator's role with the attorney.* When psychologists conduct an FMHA, they may do so upon order of the judge or by request of one of the attorneys involved in the litigation. A psychologist may also serve as a consultant to one of the attorneys, without any expectation that a report or expert testimony will result. These roles have differing expectations for who will receive the results of the evaluation or consultation and in what circumstances. These expectations stem from relevant evidence law, applicable ethical guidelines, and professional practice standards. It is important, though, that the psychologist make it clear which role is being played so the appropriate expectations will guide his or her professional conduct. When roles are unclear or merged, there can be substantial problems with the evaluation or consultation.

5. *Clarify financial arrangements.* Psychologists are paid for conducting FMHA as they would be for any professional service. The details of such payment, however—the rate or total amount, who will be responsible for payment, and whether there are special arrangements to be made (such as a retainer or an escrow account)—should be agreed upon by all parties before the FMHA is begun. If the payment process is established under law or policy, then arrangements are not needed; the evaluator simply bills the court, the government, or whoever is designated under policy for the purpose. In other instances, however, the financial arrangements must be discussed and clarified in the beginning.

TABLE II
Principles and Guidelines for Application of FMHA Principles in Forensic Contexts^a

<i>Principle</i>	<i>General guidelines for application in FMHA</i>
Identify relevant forensic issues.	Cite legal question and include forensic issues in first section of report.
Accept referrals only within area of expertise.	Give degree and licensure, board certification status. Provide curriculum vitae and/or summary of qualifications if requested.
Decline the referral when evaluator impartiality is unlikely.	Avoid involvement in cases in which there is substantial incentive for the forensic clinician (personal, professional, or monetary) to have case decided in a particular direction.
Clarify the evaluator's role with the attorney.	Ensure that both the forensic clinician and the referral source are clear on whether the clinician will serve as court-appointed evaluator, attorney-requested evaluator, or consultant.
Clarify financial arrangements.	Ensure that terms of payment for evaluation are understood by both the forensic clinician and the party responsible for payment.
Obtain appropriate authorization.	Cite basis for evaluation request (e.g., court ordered or attorney requested). Describe whether informed consent was obtained, if evaluation was not court ordered.
Avoid playing the dual roles of therapist and forensic evaluator.	Minimize the frequency of this combination. If such roles are combined, it should be with explicit justification, advance planning, and clear notification to the individual involved.
Determine the particular role to be played within forensic assessment if the referral is accepted.	If report will be submitted into evidence, evaluator should be <i>impartial</i> —tone of report should reflect this.
Select the most appropriate model to guide data gathering, interpretation, and communication.	Use the Morse model (mental disorder, functional abilities, and causal connection) or the Grisso model (functional, contextual, causal, interactive, judgmental, and dispositional characteristics).
Use multiple sources of information for each area being assessed.	Obtain self-report, psychological testing data, third-party interviews, and collateral records data.
Use relevance and reliability (validity) as guides for seeking information and selecting data sources.	Use data sources with demonstrated reliability and validity (when this has been researched) and that will provide information relevant to the area being assessed.
Obtain relevant historical information.	In a separate section, document the individual's history and previous functioning in areas relevant to current clinical condition and functional legal capacities.
Assess clinical characteristics in relevant, reliable, and valid ways.	Describe clinical characteristics using measures that are reliable, valid for the purpose used, and/or weighed against information from collateral sources.
Assess legally relevant behavior.	Document information collected from multiple sources regarding the individual's functional legal capacities.
Ensure that conditions for evaluation are quiet, private, and distraction free.	Note any deviation from reasonably quiet, private, and distraction-free conditions. Describe impact on data collected.
Provide appropriate notification of purpose and/or obtain appropriate authorization before beginning.	Describe elements of notification of purpose or informed consent given to individual being evaluated and to third parties who are interviewed.

Continues

Continued

Principle	General guidelines for application in FMHA
Determine whether the individual understands the purpose of the evaluation and the associated limits on confidentiality.	Document how the individual's understanding was assessed and to what extent he or she understood the relevant information.
Use third-party information in assessing response style.	Describe the consistency of third-party information with self-reported information, and be particularly cautious about self-report when it is significantly different from third-party accounts.
Use testing when indicated in assessing response style.	Administer a test(s) sensitive to response style, particularly when there is concern about the accuracy of self-report.
Use case-specific (idiographic) evidence in assessing clinical condition, functional abilities, and causal connection.	Describe the individual's clinical condition and functional legal abilities in the context of his or her history of symptoms and demonstrated capacities.
Use nomothetic evidence in assessing clinical condition, functional abilities, and causal connection.	Describe the results of psychological tests, structured instruments, and specialized tools validated for assessing (i) clinical condition or (ii) functional legal capacities.
Use scientific reasoning in assessing causal connection between clinical condition and functional abilities.	Describe explanations for clinical condition and functional abilities that have the most supporting evidence and least disconfirming evidence.
Do not answer the ultimate legal question.	When evidence is mixed, or competing explanations seem comparably well-supported, say so.
Describe findings and limits so that they need change little under cross-examination.	Present conclusions about forensic capacities but not the larger legal question(s).
Attribute information to sources.	Be careful, impartial, and thorough in presenting data and reasoning.
Use plain language; avoid technical jargon.	Consider alternative explanations.
Write report in sections, according to model and procedures.	Describe data so that the source(s) of any specific finding is clear.
Base testimony on the results of the properly performed FMHA.	Make minimal use of technical language, and define technical terms when they must be used.
Testify effectively.	Include sections on referral information, sources of information, relevant history, clinical functioning, relevant functional legal capacities, and conclusions.
	Describe causal relationship between clinical symptoms and functional legal capacities.
	Master the contents of the report, which contains thorough documentation of evaluation, and use report contents to guide testimony.
	Use effective style in presenting substantive FMHA findings in testimony.

^aAdapted from Heilbrun (2001).

6. *Obtain appropriate authorization.* The nature of the authorization needed to conduct the evaluation varies, depending on who requested it and the role being played by the evaluator. The forensic clinician needs a signed order from the court for a court-ordered evaluation. Consent from both the referring attorney and the individual being evaluated is necessary when

the forensic clinician is in the role of expert for the defense/prosecution/plaintiff.

7. *Avoid playing the dual roles of therapist and forensic evaluator.* Serving as both therapist and forensic evaluator for the same individual should be avoided because it can create significant problems for the psychologist, the person being evaluated and treated, the

lawyers, and the judge. Occasionally, such a dual role cannot be avoided. When it cannot, the guideline emphasizes the importance of making the reason clear, doing the planning in advance, and informing the affected individual(s) in plain language.

8. *Determine the particular role to be played within forensic assessment if the referral is accepted.* If the forensic psychologist respects the previous principle, then most FMHA cases will involve only a single role. The psychologist must identify this role first. When it involves writing a report and possibly testifying, the psychologist must strive to be impartial, focusing only on the questions that are requested. In addition, this role should be maintained throughout the entire case.

9. *Select the most appropriate model to guide data gathering, interpretation, and communication.* Stephen Morse, in 1978, and Thomas Grisso, in 1986, each described a model to guide the ideas, procedures, interpretation of results, and reasoning that are important components of FMHA. Each model helps the psychologist describe the relationship between clinical symptoms and functional legal capacities, making it easier for the reader to understand how the individual being evaluated might meet the applicable legal test. They also help describe the deficits that keep him or her from doing so and the source of these deficits when the individual does not.

10. *Use multiple sources of information for each area being assessed.* A single source of information is usually less accurate than multiple sources considered together. This is particularly applicable in FMHA because some of the information sources can be particularly distorted. A defendant might be inclined to exaggerate or minimize symptoms or capacities, depending on the possible implications of each in litigation. A psychological test might not be sensitive to such deliberate exaggeration or minimization. An individual who was interviewed to provide more information about the defendant might have some bias against or for the defendant. When multiple sources are considered, however, the psychologist can be more sensitive to particular distortions from any single source and better gauge the overall accuracy through considering consistency across sources.

11. *Use relevance and reliability (validity) as guides for seeking information and selecting data sources.* Whether evidence will be admitted into a legal proceeding depends on its relevance to the matter before the court and its reliability (accuracy). Therefore, this principle emphasizes both relevance and reliability in sources of information that are part of FMHA. Some

sources of information, such as psychological tests and structured interviews, have measured levels of reliability and validity as part of their development. It is fairly straightforward to select such tests and interviews with higher levels of reliability and validity. Other sources of information, such as the interviews with the individual being evaluated and with collateral observers, may be more difficult to gauge in their validity—but may be selected because they are so clearly relevant to the issues being assessed.

12. *Obtain relevant historical information.* Relevant historical information about the individual being evaluated is almost always important in FMHA. The level of detail needed varies, however, according to the type of FMHA. Some evaluations, such as those of competence to stand trial, are present-state oriented and need a more focused history in areas such as criminal and mental health history. Other evaluations, such as capital sentencing, are much broader and demand a history that is much wider in scope.

13. *Assess clinical characteristics in relevant, reliable, and valid ways.* The decision about which symptoms and problems should be assessed, and how to assess them, is informed by using relevance and reliability, according to this principle. This guideline calls for using appropriate measures, such as psychological tests and structured interviews, and considering these results in conjunction with information from collateral sources in order to assess the relevant clinical aspects under consideration.

14. *Assess legally relevant behavior.* There are particular capacities and behaviors that are part of the specific legal question(s) being considered by the court. These capacities and behaviors (sometimes called functional legal criteria) are a very important part of FMHA. For some kinds of evaluations, there are validated measures that can be used to help the evaluator learn how the individual being evaluated compares with other such individuals on certain relevant legal capacities. Such measures have been developed for competence to stand trial, competence to consent to treatment, and competence to waive Miranda rights. However, for many legal questions, there has not yet been a validated measure developed. Therefore, evaluators must identify the functional legal demands and obtain information about the individual's thinking, feeling, and behavior at the appropriate time, when they do not have a validated measure available.

15. *Ensure that conditions for evaluation are quiet, private, and distraction free.* FMHA is often conducted in detention centers, jails, prisons, or secure

psychiatric hospitals. Security is important in these settings; staff are responsible for preventing escape, harm to others, or harm to self. The need for evaluation conditions that are quiet and distraction free (without significant noise or visual distraction) as well as private (in which communication cannot be overheard by a third party) must therefore compete with security, sometimes in the context of a physical plant that was not designed to facilitate privacy or quiet. This principle emphasizes that the FMHA cannot be performed meaningfully unless there is a certain degree of privacy and limit on distraction afforded during the evaluation period.

16. *Provide appropriate notification of purpose and/or obtain appropriate authorization before beginning.* The forensic psychologist provides a notification of purpose or obtains informed consent before starting the evaluation. Informed consent is needed when an attorney retains a forensic psychologist to evaluate the attorney's client because the evaluation is legally voluntary and the client is under no legal obligation to participate. However, a client undergoing a court-ordered evaluation does not have a legal right to refuse to participate. An evaluatee in these circumstances should receive the same information that would be provided as part of obtaining informed consent—the nature and purpose of the evaluation, its authorization by the court, and the associated limits on confidentiality, including how it might be used. However, since there is no legal right to refuse, the necessity for consent is eliminated when a court-ordered evaluation is conducted.

17. *Determine whether the individual understands the purpose of the evaluation and associated limits on confidentiality.* If the information provided in the notification of purpose or request for informed consent is not understood, or is only partly understood, then the process is less meaningful. The forensic psychologist must gauge how well such information is understood by the individual being evaluated. To the extent it is not understood, the psychologist should describe the limits on understanding and what deficits interfere with such understanding.

18. *Use third-party information in assessing response style.* Some individuals evaluated through FMHA respond to questions openly and honestly. Others exaggerate or fabricate symptoms and problems. Yet others minimize or deny symptoms that are genuinely experienced. Response style is a term used to describe how an individual reports his or her own symptoms, behaviors, and problems, and it is used to classify an

individual's responding as (i) reliable, (ii) exaggerated/malingering, (iii) defensive, or (iv) uncooperative. Self-reported information from an individual who is not reliable will have significant inaccuracies. This principle emphasizes the value of third-party information (records and interviews of collateral observers) in both detecting and correcting these inaccuracies.

19. *Use testing when indicated in assessing response style.* In addition to third-party information, there are also tests that have been developed and validated to assess response style. These are reviewed by Rogers in his 1997 book titled *Clinical Assessment of Malingering and Dissimulation*. This principle advocates using tests and specialized measures whenever available and appropriate for assessing malingering or defensiveness.

20. *Use case-specific (idiographic) evidence in assessing clinical condition, functional abilities, and causal connection.* Science is an important part of FMHA. The first way it can contribute is through promoting the gathering of individualized information, specific to the case and present functioning of the individual, and comparing it to that individual's capacities and functioning at other times. This approach is consistent with the law's goal of individualized justice, so it may appeal particularly to judges and attorneys.

21. *Use nomothetic evidence in assessing clinical condition, functional abilities, and causal connection.* Science can also contribute to FMHA through empirical data collected with groups of individuals similar to the person being evaluated and by using tests developed and validated on similar groups. Such tests facilitate the reliable measurement of relevant abilities and symptoms and allow their comparison with those in "known groups." For example, a validated test to measure capacities relevant to competence to stand trial would allow the psychologist to compare an individual's performance on a given capacity (e.g., understanding the adversarial nature of the legal system) to that of other known groups, such as (i) defendants who had been adjudicated incompetent to stand trial, (ii) defendants for whom the issue had been raised but were not adjudicated incompetent, and (iii) defendants for whom the issue had never been raised.

22. *Use scientific reasoning in assessing causal connection between clinical condition and functional abilities.* Scientific reasoning, as contrasted with scientific data, can also contribute to FMHA. The results obtained from one source of information (such as the interview) can be treated as "hypotheses" to be supported or

rejected through further information obtained from other sources of information. Hypotheses that account for the most information with the simplest explanation are likely to be the most accurate.

23. *Do not answer the ultimate legal question directly.* Many in the field of forensic psychology have debated whether experts should directly answer the “ultimate legal question” before the court. Some have argued that this is permitted under the law of evidence in most jurisdictions, that many judges seem to want it, and that there is little harm in doing so. Others have suggested that ultimate legal questions (such as “Is the defendant competent to stand trial?”) have embedded moral and community values to a greater extent than do functional legal capacities (such as whether the defendant understands his charges and can assist in his defense). Thus, answering ultimate legal questions directly intertwines clinical and scientific conclusions with moral values, possibly to the confusion of the judge or jury. This principle suggests that functional capacities rather than ultimate legal questions should be the focus of FMHA.

24. *Describe findings and limits so that they need change little under cross-examination.* FMHA should be a careful and thorough process, incorporating multiple sources of information and accompanied by acknowledgment of the limits on data accuracy and consistency. Using this approach, the forensic clinician can expect that the description of findings and conclusions will not change significantly during cross-examination.

25. *Attribute information to sources.* All information in the FMHA report should be attributed by a specific source(s). This allows the evaluator to describe consistency across sources. It also means that the judge and opposing counsel can directly assess the credibility of specific information by source.

26. *Use plain language; avoid technical jargon.* The “consumers” of FMHA, such as judges, attorneys, and jurors, usually do not have advanced training in psychology or other behavioral science. Thus, it is useful for FMHA results to be communicated without the use of technical jargon. When important points or concepts are conveyed in nontechnical language, it is usually possible to capture their essential meaning. Occasionally, a technical term may be needed, but a parenthetical definition can help ensure that it is understood by the reader or listener in the way its meaning is intended.

27. *Write reports in sections, according to model and procedures.* There is a great deal of information in an FMHA report. Without an organizing structure for the report, the reader can become lost or fail to understand some of the important aspects of the report. One

organizing structure for reports was suggested by Heilbrun in his 2001 book *Principles of Forensic Mental Health Assessment*:

1. Referral: with identifying information concerning the individual, his or her characteristics, the nature of the evaluation, and by whom it was requested or ordered
2. Procedures: times and dates of the evaluation, tests or procedures used, different records reviewed, and third-party interviews conducted, as well as documentation of the notification of purpose or informed consent and the degree to which the information was apparently understood
3. Relevant History: containing information from multiple sources describing areas important to the evaluation
4. Current Clinical Condition: appearance, mood, behavior, intellectual functioning, thought, and personality
5. Forensic Capacities: varying according to the nature of the legal questions
6. Conclusions and Recommendations: addressed toward the relevant capacities rather than the ultimate legal questions

28. *Base testimony on the results of the properly performed FMHA.* Contrary to what is often perceived, most of FMHA does not result in expert testimony. Often, reports are accepted and presented in evidence without such testimony. Sometimes, reports may not be used, depending on the circumstances involved in requesting the report (e.g., court ordered vs attorney requested) and whether the attorney has that choice under the evidence law in the jurisdiction. However, when expert testimony is provided, it should be firmly based on the results of a thorough evaluation documented in the FMHA report. This allows the referring attorney to present the expert’s findings effectively, the opposing attorney to challenge them, the judge or jury to understand them, and the expert to communicate them.

29. *Testify effectively.* Effective expert testimony combines strong substance with useful style. The substance of FMHA has been discussed in the previous 28 principles. The style of expert testimony involves appearing knowledgeable, credible, likeable, interesting, and professional. Without both substance and style, the expert testimony provided by a forensic psychologist cannot be maximally effective. Strategies and suggestions for improving style while testifying have been documented by Brodsky in his 1991 book, *Testifying in Court*:

Guidelines and Maxims for the Expert Witness, and his 1999 book, *The Expert Expert Witness: More Maxims and Guidelines for Testifying in Court*.

3. CLINICAL–LEGAL ISSUES

3.1. Criminal

Forensic psychologists may provide FMHA that is focused on a variety of legal questions in criminal, civil, and juvenile/family areas. These are described in detail in the 1997 book by Melton *et al.* titled *Psychological Evaluations for the Courts*. In some cases, only one of these questions will be addressed in a single FMHA; in other instances, the forensic psychologist may be asked to address two or three questions in a single evaluation. Some of the most commonly evaluated legal questions evaluated through FMHA for adult criminal defendants include the following:

1. Competence to waive Miranda rights—whether the defendant waived his or her Fifth Amendment right to remain silent and Sixth Amendment right to counsel in a knowing, voluntary, and intelligent fashion when questioned by the police while in custody
2. Competence to stand trial—whether the defendant understands his or her legal situation and can assist counsel in his or her own defense
3. Sanity at the time of the offense—the particular test varies across jurisdictions; in many states, it involves whether the defendant did not know the nature or wrongfulness of criminal behavior as a result of mental disease or defect; in others, there is the additional question of whether the defendant was unable to conform his or her conduct to the requirements of the law as a result of mental disease or defect
4. Non-capital sentencing—often involving the broad questions of the defendant’s risk for recidivism and rehabilitation needs and amenability; in specific kinds of cases, such as those involving sexual offenders, the questions are focused particularly on the need for specialized treatment
5. Capital sentencing—whether the defendant has characteristics, symptoms, or history specified in the aggravating and mitigating factors outlined in the law of the jurisdiction

3.2. Civil

In addition to FMHA in criminal contexts, forensic psychologists conduct assessments for judges and

attorneys on questions within civil law. Two of the most frequent legal questions for FMHA in the civil area concern (i) civil commitment (whether an individual, because of mental illness, meets the criteria for involuntary hospitalization as presenting a danger to self or others) and (ii) personal injury [often whether an individual, allegedly the victim of a tort (or noncriminal wrong), suffered psychological injury as a consequence, and what might be needed to treat this injury].

3.3. Juvenile/Family

There are several legal questions within the juvenile and family area that are often addressed through FMHA. These include (i) juvenile commitment (whether a youth adjudicated as delinquent should be committed for residential placement or can be served in a less restrictive intermediate placement such as boot camp or in a community-based placement; often involving the criteria of reoffense risk and treatment/rehabilitation needs and amenability), (ii) juvenile transfer and reverse transfer (whether an adolescent charged with a crime should be handled in juvenile court or adult criminal court, with the criteria for assessment often similar to those for juvenile commitment), and (iii) child custody (in divorce cases, the question of whether custody should be awarded solely to one of the divorcing parents or jointly can be informed by FMHA addressing the needs of the children and the parenting capacities of each parent).

4. IMPORTANT DEVELOPMENTS

As forensic psychology has matured, there have been important developments in the areas of training, research, and practice that may enhance the quality of FMHA that is conducted by forensic psychologists.

4.1. Training

Specialized training is crucial to the goal of high-quality forensic practice. One important development in this area during the past decade has been the approval of forensic psychology as a formal applied specialization within the APA. Forensic psychology joins the areas of clinical, counseling, school, behavioral, clinical health, clinical neuropsychology, clinical child, family psychology, and psychoanalysis in psychology as approved APA specializations. This will promote the development and structure of formal postdoctoral training in forensic

psychology because postdoctoral programs will be able to apply for APA accreditation with a specialization in forensic psychology.

There are a number of such postdoctoral fellowship programs in forensic psychology today, which is another important development in the training area. With a total of 16 fellowships available nationally, those training to become forensic psychologists have the opportunity to receive broad-based training in clinical or counseling psychology prior to the doctoral degree followed by specialized forensic training during the fellowship year. Accreditation of such fellowships should further enhance the quality and uniformity of training in FMHA.

However, not all psychologists wishing to provide FMHA have had the opportunity to receive such specialized training. For those who received the doctoral degree before 1980, postdoctoral fellowship training was not available, nor was formal training during internship or doctoral training available except in rare instances. The role of continuing education in the form of workshops presented to practicing professionals has therefore been quite important. Some continuing education is provided by university–state partnerships, as in the state of Virginia. Other continuing education programs are offered by specialty organizations, such as the American Academy of Forensic Psychology. Such continuing education efforts have filled a gap between formal education and experience that was important to more senior psychologists conducting FMHA but have also been helpful in providing relevant research and new tools and approaches to even those who are already largely specialized in forensic.

4.2. Research

The development of specialty tools has been very important in the maturation of the field. Such tools, developed and validated through scientific research and designed to measure functional legal capacities described in the law, have allowed forensic psychologists to consider individualized impressions and compare the individual being evaluated to others in similar circumstances. Tools have been developed during the past decade to measure constructs such as those relevant to competence to waive Miranda rights, competence to stand trial, competence to consent to treatment, violence risk assessment, and response style. As a consequence, FMHA on these issues can be conducted with more sophistication and scientific support than was possible before the development of these specialized, validated FMHA tools.

Foundation support of research networks has been a second significant development in research relevant to FMHA. In particular, the John D. and Catherine T. MacArthur Foundation sponsored the MacArthur Research Network on Mental Health and Law, which developed and carried out important programmatic research in the areas of violence risk, competencies, and coercion in the decade between the late 1980s and the late 1990s. Currently, the MacArthur Foundation sponsors two additional research networks—one on mandated community treatment and the second on juveniles—that have also designed and conducted important research that will enhance the quality and scientific foundation of FMHA conducted in these areas in the future.

One of the areas that have witnessed the most active research and development during the past decade is risk assessment of violent behavior. The field has moved from the relatively primitive approach to violence risk seen in the 1970s and early 1980s to a far more sophisticated, theoretically coherent, and empirically supported process. The research conducted by the MacArthur Research Network on Mental Health and Law is described in the 2001 book by Monahan and colleagues titled *Rethinking Risk Assessment: The MacArthur Study of Mental Disorder and Violence*. In addition to this research, other works have yielded a number of tools assessing both risk factors for violence and needs for risk reduction (sometimes called risk-needs tools). As a consequence of this research, practitioners of FMHA can now address violence risk and risk reduction needs in those they evaluate in a way that is far more coherent and empirically supported than was ever possible before.

4.3. Practice

Finally, there have also been important developments in the practice of forensic psychology, particularly FMHA. Some states (e.g., Massachusetts) have developed training curricula for practicing psychologists in the forensic area and developed a formal certification process for those wishing to become certified examiners in FMHA. More advanced individual certification has been available since the late 1970s from the American Board of Forensic Psychology, which has continued to offer a rigorous board certification examination to those who meet the criteria for training and experience and wish to be certified as forensic practitioners at an advanced level. The development and publication of specialty guidelines for the practice of FMHA was an additional important step. The Committee on Ethical Guidelines for Forensic Psychologists, which published the *Specialty Guidelines*

for *Forensic Psychologists* in 1991, effectively provided the field with standards that were consistent with the APA ethics code but more specific to forensic contexts, allowing both psychologists and legal professionals a view of aspirational standards of practice in forensic psychology.

5. FUTURE DIRECTIONS

The field of forensic psychology has undergone tremendous change during the past two decades. The practice of FMHA, as an integral part of forensic psychology, has become more legally relevant, better supported by empirical research, and more theoretically sophisticated. There are three developments that are likely to continue this growth and improvement during the next decade. The first involves the development of more formal practice standards and updating the *Forensic Specialty Guidelines* published in 1991 to reflect the changes in the field since that time. The second involves additional research, particularly in the functional legal capacities of legal questions that have not been researched in a way that promotes specialized tool development. With the development of an increased number of empirically supported, legally relevant specialized tools, the overall quality of FMHA will certainly be enhanced. Finally, it will be important to continue to expand formal training in forensic psychology. In part, this will involve the accreditation of postdoctoral fellowships specializing in forensic psychology and the development of additional fellowships. As more psychologists receive forensic specialty training, however, it will become feasible to offer less specialized but still relevant forensic training at the predoctoral and internship levels to psychologists who would provide FMHA less frequently or in a more targeted fashion but who still wish to provide courts and attorneys with a product that promotes better informed legal decision making in areas served by the field of forensic psychology.

6. CONCLUSIONS

How might the questions raised in the Washington, DC, sniper case be addressed through FMHA? One of the defendants, John Muhammad, briefly attempted to act as his own attorney. Was he competent to do so? Although this question is evaluated less frequently than a defendant's competence to stand trial, it is one that could be addressed through FMHA that described his mental state

and his abilities under relevant law to represent himself. Since Mr. Muhammad was tried and convicted of capital murder, the jury had to consider whether he should receive a sentence of life in prison or death. FMHA describing Mr. Muhammad in terms of the aggravating and mitigating factors under the law of Virginia could have helped the jury consider this question carefully. Lee Boyd Malvo, Mr. Muhammad's accomplice, was tried separately and also charged with capital murder. Malvo was 17 years old at the time of the offense, so the defense might have argued that he should be tried in juvenile court. (Many states do not permit adolescent defendants charged with murder to be treated as juveniles, but this would have been a possibility if the charge had been less serious.) The defense next argued that Mr. Malvo was insane at the time of the alleged offense. Both defense and prosecution introduced evidence based on FMHA conducted by various experts describing Malvo's mental state at the time of the offense. Finally, FMHA on capital sentencing, describing the existing aggravating and mitigating factors for this defendant, could (and did) help inform the jury considering the death sentence. The Washington sniper case illustrates the different ways that FMHA could be used to assist the court in making various kinds of decisions. The continued growth and expansion of the field of forensic psychology promises to bring more relevant and reliable information into the courtroom to continue to assist legal decision makers.

- Further Reading

In addition to the traditional academic instruction typically provided in public schools, full-service schools offer an array of integrated health and social services to children and their families. This model of service delivery is based on the assumption that children will be successful learners if their social, emotional, and physical needs are met, and that many of these needs can be addressed effectively, conveniently, and efficiently through school-based service delivery.

GLOSSARY

categorical funding A system of funding that allocates resources to separate programs with specialized professionals who address narrow domains of functioning.

developmental psychopathology An area of study focused on understanding how emotional, behavioral, and learning problems develop over time. The influence of interacting risk and protective factors is emphasized.

ecological theory A theoretical perspective that views human behavior and human development in the context of interconnected social systems.

intervention Services delivered to ameliorate identified problems in learning, behavior, health, or mental health. Examples include medication, psychotherapy, and behavior modification.

prevention Services delivered to promote healthy functioning thereby reducing the chances that problems will develop.

1. INTRODUCTION

Although schools exist primarily to teach children academic skills, links between educational systems and other services have existed for more than a century in the United States (Fig. 1). Public health, in particular, enjoys a natural partnership with public education. Requiring all children attending school to be immunized, for example, benefits schools by protecting students and staff from many communicable diseases and advances the public health goal of universal immunization. As Joy Dryfoos noted in her 1994 book, *Full Service Schools: A Revolution in Health and Social Services for Children and Adolescents*, this collaboration dates back to 1870 when the New York City Board of Health (founded 4 years earlier in response to a cholera outbreak) began working with the New York City Board of Education to vaccinate school children. At the turn of the century, several cities initiated school nursing

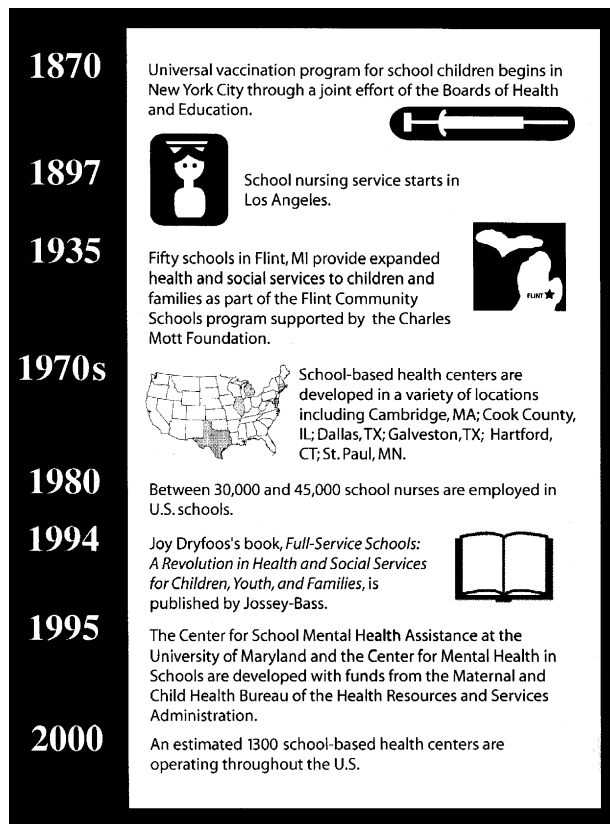

FIGURE 1 History of expanded school-based services.

programs allowing children to be treated for minor health concerns at school rather than being sent home.

The full-service school model represents an expanded version of such cross-disciplinary collaboration in the provision of services designed to enhance children's social, emotional, physical, and intellectual development. Although the idea has yet to take hold in a permanent, universal way, a number of relevant model programs and social experiments have appeared over the years, with fluctuating support from such sectors as state and federal government, private foundations, and professional organizations such as the American Medical Association.

There is considerable variation in what these programs offer and how they are structured. The label "full-service school" has been applied to schools with on-site health clinics, to schools with expanded hours of operation and social services aimed at violence prevention, and to schools that offer mental health services to students and families. Even schools that do not offer these services on-site may be labeled full-service schools if they have well-developed links (e.g.,

referral agreements) with relevant agencies in their communities. In this article, the underlying rationale and approach to service delivery that tie these diverse programs together are articulated. Variations in the organizational structure and function of full-service schools, potential roles for psychologists within these service delivery systems, and implications for in-service and preservice training are also discussed.

2. RATIONALE FOR FULL-SERVICE SCHOOLS

2.1. Theoretical Background

Rather than focusing narrowly on academic goals, full-service schools are designed to address children's needs holistically. This approach is consistent with the theoretical perspectives of developmental psychopathology and ecological psychology. Developmental outcomes in the physical, social-emotional, and cognitive domains are assumed to be influenced by a variety of interconnected risk and resilience factors. These include characteristics of the individual child (e.g., temperament and cognitive abilities), the contexts in which the child develops (e.g., family, school, and neighborhood), and transactions within and between these systems. For example, a child's temperament is assumed to influence and be influenced by the skills and parenting style of his or her primary caregivers, which in turn may be shaped by a host of environmental factors, including cultural norms, neighborhood characteristics, and workplace experiences.

2.2. The Developing Child in Context

At the level of the individual child, development may be influenced by biological factors such as prenatal exposure to alcohol, illegal drugs, and tobacco; birth weight; and genetics. When children grow older, their development is also influenced by their own behavior as they engage in (or avoid) such activities as substance abuse, gang involvement, unsafe sex, dangerous driving, and other health-related risky activities.

Children develop in the context of proximal environments or microsystems, including families, schools, neighborhoods, and peer groups, each of which has the potential to influence outcomes. In the family context, the quality and quantity of children's interactions with their primary caregivers often provide a basis for developmental trajectories leading in desirable or undesirable

directions. For many children, these interactions are limited as a result of increasing divorce rates, large numbers of children growing up in single-parent homes, and increasing numbers of two-parent families in which both parents are employed outside of the home. In some cases, family functioning is further compromised by the presence of parents with mental health or substance abuse problems, illiteracy, family violence, or economic strain associated with unemployment and poverty.

At school, children's social and academic experiences may include overcrowded classrooms, bullying, and peer rejection as well as a range of development-enhancing opportunities. In their neighborhoods, many children must contend with risk factors such as poverty, drug trafficking, exposure to traumatic events, and gang activity. Other systemic influences include mass media, which exposes children to images of violence and risky behavior but may also deliver health-promotion messages; government policies and laws, which often dictate how resources are allocated to needy children and families; and many ideologies and values that underlie much of U.S. society. These macrosystemic influences include institutionalized racism and sexism.

Development is influenced not only by the characteristics of these systems but also by the transactions within and between systems. For example, it has been established that risky behavior among adolescents (including violence and unsafe sex) is most likely to occur during late afternoon and early evening hours. To understand this finding, it is necessary not only to consider the role of the family, the school, the neighborhood, or the peer group but also to recognize the ways in which these systems (along with other, more distal systems) work together to increase (or reduce) children's risk levels.

Related to this is the idea that sets of common risk factors (such as those that produce daily blocks of time during which most adolescents within a community have little to do and little adult supervision) often lead to a variety of divergent emotional and behavior problems. It is becoming increasingly clear, for example, that outcomes as conceptually distinct as adolescent pregnancy, school drop-out, violent behavior, and substance use may represent different end points of very similar causal pathways.

2.3. Child Outcomes of Concern

The consequences of the many risk factors described previously are seen across a variety of domains of children's functioning. Specifically, increasing rates of mental health problems, substance use and abuse, and

dangerous behavior have been observed among young people in recent years. An estimated 20% of youth between the ages of 9 and 17 have diagnosable mental or addictive disorders, and approximately 4 million children and adolescents suffer from major mental illnesses associated with significant impairment in functioning. Additionally, an increasing number of deaths among young people are attributed to risky or dangerous behavior, including homicide, suicide, HIV-AIDS, and automobile accidents.

2.4. Full-Service Schools: Comprehensive, Integrated, and Preventative

Full-service schools address the risk factors that contribute to these worrisome outcomes by providing comprehensive and integrated educational, mental health, medical, and social services. Prevention programs also represent an important response to the wide variety of biological and environmental risks and stressors affecting school-age children and adolescents. Designed to promote positive quality of life and adaptive functioning across settings, and to reduce the incidence of psychopathology, prevention programs fit naturally into the full-service school model.

One important advantage of full-service schools is the opportunity for families to access coordinated, multidisciplinary services through "one-stop shopping." A second advantage, from both an intervention and prevention perspective, is that full-service schools provide access to most (if not all) children and their families in a key setting. Typically, parents may be more comfortable accessing a variety of mental health, medical, and social services in the more familiar setting of a school as opposed to a local community mental health center.

3. GENERALIST APPROACH TO SERVICE DELIVERY

The full-service school model requires a high level of collaboration among diverse professionals, such as clinical, school, and community psychologists; physicians; nurse practitioners; social workers; family educators; and educators. This integrated, multidisciplinary model represents a generalist approach to service delivery, in which children's functioning and needs are viewed holistically. Whereas traditional service delivery systems divide problems into separate,

specialized domains, each assigned to a different profession (e.g., with medical professionals concerned with physical health, educators concerned with learning, mental health professionals responsible for emotional and behavioral functioning, and social workers responsible for family environment factors), the generalist approach emphasizes the interconnections among these domains.

For example, under a more traditional or specialist model, a child who is having trouble learning to read might be referred to a school psychologist for assessment and a reading specialist or special educator for intensive reading services. The student may have received vision screening through a pediatrician and eyeglasses through a social service agency. Contact between these various agencies and professionals would be limited. The generalist model, in contrast, would simultaneously consider health, mental health, family, and community factors that might influence the child's functioning. Such issues as vision, nutrition, family members' literacy (and English language proficiency), and family resources would be considered as possible explanations for the child's difficulty and would be integrated into any intervention plan.

4. THE OBSTACLE OF CATEGORICAL FUNDING

Traditionally, one of the major barriers to the generalist approach to service delivery is the categorical nature of

funding sources. Resources controlled by separate agencies are allocated to separate programs with specialized professionals who address narrow domains of functioning. Proponents of full-service schools have argued that this system results in fragmented, inefficient services that may duplicate efforts, on the one hand, and miss opportunities to influence meaningfully the common factors that underlie many of the devastating outcomes that children experience across domains of functioning, on the other hand. Some foundations as well as federal, state, and local government agencies have responded to this problem by relaxing restrictions on how funds may be used.

5. VARIATIONS IN ORGANIZATIONAL STRUCTURE AND FUNCTION

Full-services schools, also referred to as school-based or school-linked health centers, differ in their degree of comprehensiveness and integration of services, whether services are primarily preventative or treatment oriented, and whether the services are delivered in the school or in locations within the community (Fig. 2). On the surface, it appears that school-based services enjoy certain advantages over school-linked services. These advantages include convenience for the children and their families as well as enhanced opportunities for collaboration between health and

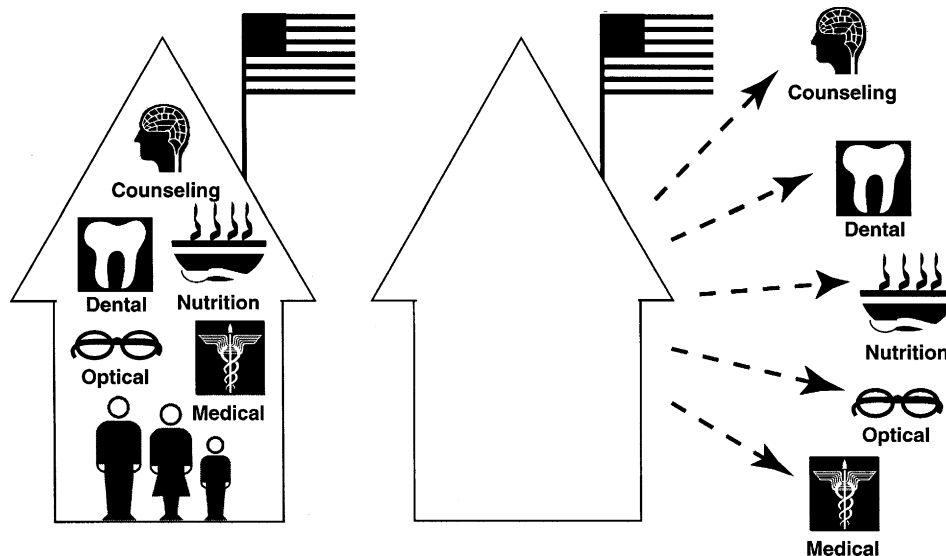

FIGURE 2 School-based vs school-linked models.

social service providers and school personnel, such as teachers, counselors, and administrators.

Despite the intuitive appeal of the distinction between the school-based service models and school-linked models, there is evidence that the location of services may be less important than originally assumed. A nationwide survey conducted by Steven Shaw and colleagues in 1996 found no significant differences between school-based and school-linked services in terms of types of programs offered (acute and preventative medical services, and mental health counseling focused on drugs, alcohol, family, and violence). Neither model provided many social services, such as employment or financial counseling or parole/probation counseling, and both were more likely to offer medical than mental health services. With respect to cross-disciplinary collaboration, it was found that school-based clinics were no more likely to be integrated with education than were school-linked clinics. Thus, despite a large body of literature stressing the importance of a clinic's location as it relates to integration of services, many of the school-based clinics operated autonomously from core educational services.

6. PSYCHOLOGISTS IN FULL-SERVICE SCHOOLS

Psychologists join other professionals in the staffing of full-service schools. Roles for psychologists include providing a range of mental health services, such as screening for conditions such as depression and eating disorders; intervention, including individual, group, and family therapy/counseling; and prevention activities particularly related to substance abuse, pregnancy and sexually transmitted diseases, other high-risk health behaviors, and violence.

Psychologists in full-service schools may also serve as consultants to other professionals, such as teachers, administrators, and medical personnel, with regard to mental health and systemic issues. Psychologists who are skilled in collaborative problem solving and teaming may serve as effective team leaders.

Related to the role of collaborative consultant, psychologists may also function as full-service school administrators and grant writers. Many different funding sources exist for full-service schools, including state and federal mental health, public health, compensatory, and special education funds and also third-party funding

such as private insurance and Medicaid. Funding from private sources, including the Robert Wood Johnson and Hogg Foundations, and public and private hospitals also supports the development of full-service schools.

Researcher/program evaluator represents another potential role for the psychologist. As is true in any new initiative, it is important to document outcomes for students and their families. However, this is particularly challenging when prevention is one of the services offered. Psychologists with expertise in applied research and program evaluation could help fulfill this function.

7. IMPLICATIONS FOR CONTINUING PROFESSIONAL DEVELOPMENT OF PSYCHOLOGISTS

Efforts to expand and reconceptualize current training are called for to help prepare psychologists to offer the broad range of services necessary to perform many of the previously mentioned functions in full-service schools. These changes could occur at the preservice level, including practicum and internship experiences, as well as at the in-service level, including opportunities for continuing professional development. Relevant foci for training include the rapidly growing research base on behavioral health and behavioral management of medical problems. In addition, prevention of academic failure, mental health problems, and health risk behaviors such as smoking and substance abuse as well as promoting healthy development through the use of health education, health services, and guidance are important areas of emphasis.

Because learning is one of the primary missions of the school, psychologists would benefit from knowing how factors such as health, nutrition, substance abuse, and conflict with family or peers influence the learning process. Empirically supported interventions to address these factors at the individual, community, and societal level should also be included in preservice and continuing professional development programs for psychologists who wish to work in full-service schools. Also important are such areas as psychopharmacology (e.g., the effects of various medications on children's learning and behavior), family systems, health promotion, and individual and group therapy. Knowledge of interventions that target multiple microsystems of the child's environment,

including the classroom, the family, peers, the school, and the community as a whole, may be required.

Development of full-service schools will involve significant system reform. In order to succeed, the mission of the full-service school must be integrated into the mission of the school and communicated to decision makers. Thus, information about school reform efforts and initiatives should also be provided as part of the preservice and continuing professional development of psychologists who want to work in full-service schools. Understanding how expanded services fit into the typical organization and structure of the school and familiarity with system change strategies are particularly important for the psychologist. Background in community psychology would also be helpful, as would training in program administration and supervision for the role of program administrator.

Training in group dynamics, collaborative problem solving/consultation, and teaming represents a necessary focus for those who wish to work in the collaborative environment of a full-service school. Areas of concentration include systems-level consultation, coordination of service delivery, obtaining financial reimbursement for services, and overcoming resistance.

Training in the use of technology in providing effective health services to students and their families would be beneficial as well. Technology can be used for data management to enhance and support intervention evaluation activities and to empower students and their families to develop self-help skills and increase self-sufficiency. Technology, including the Internet, can be used to access a wealth of information and resources.

8. WHAT IS THE FUTURE OF FULL-SERVICE SCHOOLS?

In the future, schools will likely be challenged to meet the increasingly complex academic, physical, and mental health needs of children and their families. One way to accomplish this may be to expand the network of full-service schools from the current level of approximately 1300 nationally. In order for this movement to reach its objectives, reform efforts are needed to restructure schools beyond instructional and management systems to providing comprehensive, integrated services addressing all barriers to learning and promoting physical and mental health. This includes continuing efforts to make effective coordinated health care available to poor children and children of color.

To achieve the goals of the full-service school, more effective methods of coordinating and integrating existing school and community resources must be developed. Disciplines involved with full-service schools will need to address barriers to more effective coordinated efforts. One way to do this is to provide interdisciplinary training in evidence-based prevention and interventions at the graduate, postgraduate, and continuing education levels to allow health, mental health, and education personnel to work collaboratively and effectively in full-service schools. In this context, psychologists may be able to assume leadership roles in outcomes-based program evaluation activities so as to apply the science of psychology to better inform practice, resulting in implementation of maximally effective full-service schools.

sex Term generally used to describe the anatomical and physiological differences between males and females, but it may also be related to social and behavioral differences.

sex role ideology Beliefs about the appropriate roles and relationships of men and women. They are often described as varying from traditional to egalitarian.

GLOSSARY

culture A dynamic system of customary rules and expectations shared by a group of people and incorporating the beliefs, attitudes, norms, social practices, and organizations of that group.

gender Term used to describe the differences between males and females, often by emphasizing social and behavioral factors.

gender roles The social roles (e.g., familial, interpersonal, occupational, and recreational) in which males and females participate with differential frequency.

gender stereotypes The psychological traits that are believed to occur with differential frequency between males and females (e.g., men are more “aggressive” and women are more “emotional”).

masculinity/femininity The degree to which females and males perceive that they or others possess traits or behaviors that are considered “woman-like” and “manlike” in their culture.

Gender is a term used to describe a set of psychological, behavioral, and physical attributes that characterize members of either sex. Among any group of people, the psychological and behavioral components of gender often lead to various degrees of maleness and femaleness with considerable overlap between the two. Because gender is defined by the beliefs groups of people have regarding what it means to be male or female, gender is a subjective concept and an appealing topic for psychologists who study multiple cultures. Anyone who has visited different countries has surely noticed differences in the way men and women dress, the kinds of work they do, and the way they interact with one another. Such behavioral differences and their corresponding expectations regarding what is proper for men and women within a particular culture are referred to as gender roles. This article discusses cross-cultural research on gender roles; the degree of cross-gender similarity within cultures in comparison to the substantial variability often observed across cultural groups may be surprising. This article also examines gender theories from developmental,

social, and personality perspectives, with particular attention to various means of studying and measuring gender across the life span.

1. GENDER DEVELOPMENT ACROSS CULTURES

1.1. Distal Considerations

Developmental influences can be grouped into two somewhat overlapping categories: distal and proximal factors. Distal factors are those experienced by many or all within a culture. These include socioeconomic (e.g., national economy and type/availability of work), political, and religious factors as well as prevalent societal expectations. Discrepancies exist within cultures to the extent that job opportunities, political roles, governmental regulations, and social norms for proper behavior differ for men and women. By growing up with continuous exposure to these overarching factors, children learn the gender role expectations of their culture.

1.1.1. Socioeconomic Influences

National standards of living tend to be related to parents' reasons for having children. The nine-nation Value of Children study found that parents in agrarian cultures (e.g., Indonesia) frequently endorsed utilitarian reasons for having children. These values typically indicated a desire for fulfillment of fundamental needs, such as financial support in old age. In contrast, parents in industrialized nations (e.g., Germany) reported reasons for having children that related to fulfillment of emotional needs, such as affection. Parents in agrarian societies tended to bear more children, perhaps in response to environmental conditions. Particularly relevant to gender development, parents in agrarian societies favored boys over girls, but the two were valued equally by parents in industrialized nations. Similarly, males in societies marked by labor-intensive economies tend to be more successful than females at securing jobs and generating income for their families. Gender role expectations for women may limit their ability to contribute financially to the family, often preventing them from working in jobs outside of the home. Additionally, a young woman may marry into another family and cease contributing to her biological family.

1.1.2. Cultural Environments

Cultures also differ with regard to the religious practices endorsed by the people and/or the political/governmental organization. Religious doctrines vary greatly in the status and freedoms they grant to men and women. The three most predominant religions throughout the world are Christianity, Islam, and Hinduism. In theory, Christian teachings endorse considerable gender equality. However, the Christian God is generally personified as male, and the principal religious servants, ministers, and priests are almost exclusively men. The Hindu pantheon has goddesses as well as gods, and both men and women serve in the temples. In contrast, in Muslim theology, all the significant figures are male and religious practice is controlled by men, as is Muslim society. In nations in which religion and government are mostly separate, religion may not exert a universal influence on the developing child. However, when there is a union between religious doctrine and governmental rule, religious beliefs may strongly influence the relations between men and women as well as child-rearing practices.

Language is one of the most noticeable ways that cultures differ, and indeed this fundamental difference can lead to divergence in gender roles. Languages differ in terms of the frequency and connotation of gender-related words. Recent estimates indicate that approximately 7000 different language systems exist throughout the world. Obviously, the potential for cross-cultural differences in the way children mentally represent and verbally express gender-laden information is substantial. For example, in English it is grammatically correct to use the pronoun "he" to mean he or she, but research has shown that psychologically "he" is not a sex-neutral or generic term and may create a male bias in communication. In inflected languages, such as French or German, which have gender-specific endings for words, it is virtually impossible to communicate without introducing gender. Although such linguistic messages may seem trivial, their prevalence in everyday speech make them a subtle but pervasive influence on sex differentiation practices.

The aforementioned distal environmental influences can interact with biological factors to produce adaptive but distinctive cultural differences. When cross-cultural gender differences exist, they may in part be the result of contrasting environmental triggers that elicit different behaviors. Consistent with this perspective, David Gilmore proposed that the male macho behavior pattern could be an adaptation to divergent economic conditions. This speculation is supported by an

examination of the gender roles of two South Pacific islands, Truk and Tahiti. In the Trukese culture, men are violent, competitive, and sexually promiscuous, whereas women are expected to be submissive. Tahitian culture differs dramatically in that the men engage in submissive behaviors and avoid violent or competitive encounters. In contrast, Tahitian women tend to be sexually active. Gilmore explained these gender role discrepancies by a consideration of each culture's means of obtaining food. Tahitians fish in a protected lagoon where fish are plentiful. However, the Trukese must fish in the open ocean with continuous exposure to life-threatening situations. From this account it appears that the Trukese male gender role is an adaptive response to increase one's chances of survival. This evolutionary theory of gender role development is generally consistent with widely held views of the interaction of nature and nurture. However, many criticisms of the theory exist and research has often failed to support some of its assumptions.

Considering these distal influences, it is undeniable that culture can have profound effects on individual development. Sex differentiation messages are clear and cultural practices that emanate from these determine how babies are delivered, how children are socialized, how women and men dress, what tasks they pursue, what languages they speak, and what roles they adopt. Distal cultural factors are also related to the more immediate, proximal factors in development.

1.2. Proximal Considerations

Proximal developmental factors are more localized than distal ones. They are essentially developmental influences that are relevant to a particular individual or family. In a sense, they are the case-by-case manifestation of the distal factors in one's culture. Although many distal features of a culture are objectively consistent for all members in the culture, subjective experiences of those distal factors can vary greatly. In a Third World country, everyone is not poor, nor are all of the poor people poor to the same degree. Everyone in a particular culture is exposed to and influenced by a faltering national economy, but the impact of the economy on individual lives varies widely. For example, in the Value of Children study, Turkish parents with low income and education valued their children for their ability to contribute financially to the family. However, as income and education increased, Turkish parents valued their children less for old-age security reasons and more for emotional ties. Although the distal economic influence

was objectively consistent for all Turkish participants, their subjective experiences and subsequent responses varied greatly.

1.2.1. Biological Factors

Biological factors are perhaps the most significant contributor to the development of observable gender differences. Although the term biological is often used to refer to genes, in this case sex chromosomes, it also includes an organism's prenatal and postnatal environment. Although these developmental components intuitively appear to be fixed, considerable cultural variation actually exists. Differences in general nutrition and prenatal care can have profound effects on the prenatal experience. In the postnatal environment, biology and environment work together to yield cultural differences in behaviors, such as young children's sleep patterns, and attainment of developmental milestones, such as sitting and walking.

Observable gender differences are influenced by biological factors essentially from birth. Males tend to be more biologically vulnerable from the moment of conception (e.g., male:female ratio at conception of 140:100 versus 105:100 live births) and throughout the life span. However, males tend to be larger and have higher activity levels, higher basal metabolism, more muscle development, and higher pain thresholds than females at the time of birth. Physical sex differences in body structure and hormonal state are minimal throughout the preadolescent years, but the differences that exist are consistent with subsequent development. By adulthood, males tend to be taller, have a more massive skeleton, a higher muscle-to-fat ratio, higher blood oxygen capacity, increased body hair, and different primary and secondary sex characteristics. In part, these differences result from a longer growth period for boys and hormonal changes that occur after age 8. These changes generally relate to greater physical strength and stamina of males relative to females, although males tend to die an average of 6 or 7 years earlier than females. Note that these differences appear within cultures rather than across all cultures and at group rather than individual levels.

1.2.2. Socialization of Girls and Boys

Many attribute the emergence of sex-specific behaviors for boys and girls to differences in socialization. Surprisingly, many of these differences appear to be consistent across numerous cultures. Herbert Barry,

Margaret Bacon, and Irvin Child studied the socialization practices of more than 100 preindustrial societies and found that boys were generally raised with an emphasis on achievement, self-reliance, and independence; conversely, girls were typically socialized to be nurturant, responsible, and obedient. Note that these differences emerged between boys and girls within the same cultural group and not necessarily between cultures. Girls in some societies are raised to be more independent and self-reliant than boys in other cultures.

Studies in North American and Western countries have found that parents more consistently reinforce sex-typed behaviors and use higher levels of physical punishment with boys than with girls. However, cultures differ widely in how frequently physical punishments are used, and the differential treatment of males and females appears to dissipate with age. The infinite human variation in the biological and experiential influences that comprise each person's developmental history allows for many different interpretations of the same experience.

1.2.2.1. Cultural Differences in Role Socialization The impact of cultural differences in socialization was seen in the classic six-culture study, an intensive investigation of socialization practices in India, Kenya, Mexico, Okinawa, the Philippines, and the United States. Of central interest was the occurrence of aggressive, nurturant, responsible, helpful, and attention-seeking behaviors among 3- to 11-year-old children. Less gender differentiation was found in cultures in which both boys and girls helped with sibling care and household chores (i.e., Kenya, the Philippines, and the United States). In contrast, more gender discrepancies emerged in cultures in which females participated more than males in sibling care and household chores (i.e., India, Mexico, and Okinawa). Overall, girls spent more of their time in responsible, productive work, and boys spent relatively more time playing.

Further evidence for discrepant patterns of caretaking roles of males and females comes from an examination of the care-taking practices of 186 nonindustrialized societies. Thomas Weisner and Ronald Gallimore found that mothers, female adult relatives, and female children were the primary caretakers of infants. However, as infants reached early childhood, responsibility for child care fell upon siblings of both sex groups. Because young children in some societies spend as much as 70% of each day in the care of their siblings, sibling caretakers constitute an integral part of

the gender role socialization process. Although mothers in such societies spend considerable proportions of their time in nonmothering, family provider roles, children in virtually every culture view mothers as responsible for children.

Fathers often fulfill the role of primary financial provider for the family, and this may limit their contributions to caretaking. Father-child interactions in many cultures are structured around play-oriented activities. Although the father's role may not appear to be essential, research has shown that fathers play an important role in the socialization of children. When fathers are absent for lengthy periods of time, boys may display effeminate behaviors, high levels of dependence, excessive fantasy aggression, and overly masculine behaviors. However, the criteria for judging behaviors as "effeminate" may vary across cultural groups. Indeed, fathers tend to exhibit higher levels of gender role socialization than mothers and they pay less attention to daughters than to sons. These findings suggest that fathers' influence is more critical for sons than for daughters.

In addition to parents, peers play an important socialization role for children in all cultures, and this role tends to increase with age. Eleanor Maccoby identified three gender-linked phenomena in children's social development with peers: gender segregation, dissimilar interaction styles, and group asymmetry (e.g., boys groups are more cohesive, sexist, exclusionary, and separate from adult culture than girls' groups). The six-culture study found that as early as age 3, children tend to seek out same-sex peers and to avoid other-sex children, and this tendency strengthens throughout grade school. In their segregated groups boys strive for dominance, take risks, and are reluctant to reveal weaknesses to each other. In contrast, girls self-disclose more, try to maintain positive social relationships, and avoid conflict. Compared with girls' groups, boys' groups are more cohesive, more exclusionary, and more separate from adult culture. Segregated groups may lead to different activities and toy choices, which may in turn lead to differences in intellectual and emotional development.

1.2.2.2. Education Across cultures, educational settings are common sources of differential gender role socialization. For example, observations of fifth-grade students in Japan and the United States revealed that teachers devoted more than half of their attention to boys, but that much of this attention was negative. Research studies have consistently found teacher expectations for student achievement to play a critical role in

predicting discrepancies in classroom performance. As one would expect, parental expectations also play an important role in academic achievement. Robert Serpell confirmed this notion with his observation in Zambia, where education is intended for boys rather than girls. Harold Stevenson and colleagues found that mothers in China, Japan, and the United States expected their sons to outperform their daughters in mathematics and their daughters' reading abilities to exceed those of their sons; however, boys and girls perform equally well in some aspects of both disciplines.

Interestingly, during the second half of the 20th century women's level of education has increased and even surpassed that of men in the United States and in several other Western countries. This is a profound shift considering that in some countries women are not permitted to participate in formal education.

2. BEHAVIORAL DIFFERENCES AMONG BOYS AND GIRLS

The aforementioned developmental considerations include some of the potential factors that contribute to different gender role behaviors. A more in-depth discussion of behavioral domains in which males and females show divergent patterns is presented here.

2.1. General Patterns of Activity

Cross-cultural consistency can be found through an examination of the characteristics of male and female group behaviors. Daniel Freeman studied 5- to 7-year-olds in eight different cultures: Australian Aboriginal, Balinese, Ceylonese, Japanese, Kikuyu, Navajo, Punjabi, and Taiwanese. He found that, relative to males, young females remained closer to home and engaged in repetitive, conversation-oriented behaviors. Males, on the other hand, frequently played in larger groups, participated in more physical activities, covered more physical space in play, and performed more unpredictable behaviors. In general, boys tend to spend most of their time with other boys, but girls often choose to interact with adults.

Children's drawings also shed light on their segregated gender preferences and gender role-consistent interests. Boys tend to produce more drawings of other boys, vehicles, monsters, and violent themes, whereas girls' drawings more often depict other girls and flowers.

2.2. General Behavioral Styles

Cross-cultural studies have generally found preadolescent males to exhibit higher rates of competitive, aggressive, and dominance-seeking behaviors and females to demonstrate higher levels of nurturance. In particular, the six-culture study found sex differences in aggression and dominance, consistent levels of aggression across many age groups, and increased physicality among the eldest boys. Indeed, fathers may play a particularly important role in the socialization of aggressive behaviors in boys. Sex differences have also emerged from a consideration of the manner in which both boys and girls engage in aggressive interactions. Initially, males display more restraint than females but are more violent when they do act. Female aggression is often marked by emotion-laden, verbal tirades.

With regard to nurturant behaviors, because infants elicit more nurturant behavior than do older children, girls who spent more time with infants displayed more nurturance than boys who did not engage in as much interaction with infants. Herbert Barry and colleagues examined socialization practices in more than 100 societies and found that generally boys are reared to achieve and to be self-reliant and independent, whereas girls are reared to be nurturant, responsible, and obedient.

2.3. Self-Esteem

Girls have often appeared to be less satisfied with being girls, and boys generally perceive themselves to be more competent than girls. However, some studies suggest that these differences tend to be domain specific and can even be reversed depending on what aspect of self-esteem is examined. David Watkins found that girls in Australia, Nepal, and the Philippines reported lower self-esteem than boys in the areas of physical abilities and mathematics. Additionally, Nigerian boys felt they were more intelligent overall than girls. However, Australian and Nigerian girls perceived themselves to be more competent than boys in reading. As one can see, male and female differences in self-esteem across cultures are not as robust as general behavioral patterns. Perhaps the inconsistencies in self-esteem across genders are due to cultural differences in the appropriateness of various behaviors. Cultures that consider certain behaviors to be more negative than do other cultures may associate them with greater maladjustment, such as low self-esteem.

3. DEVELOPMENT OF GENDER ROLES AND STEREOTYPES

Research has consistently shown that gender-specific knowledge emerges early in a child's development. In the United States, children as young as age 2 begin to stereotype objects as masculine or feminine, and by age 3 or 4 they reliably use stereotypic labels with toys, activities, and occupations. Similar patterns can be found in countries as distinct as West Africa, where girls tend to play with dolls and boys often build vehicles and weapons. Although the contextual details of children's play differ across cultures, most general play patterns are not culture specific.

3.1. Sex Trait Stereotypes

Research in the United States revealed that children's understanding of sex trait stereotypes may emerge more slowly than their stereotypic knowledge of toys and occupations. John Williams and Deborah Best developed the Sex Stereotype Measure (SSM) to assess children's understanding of adult notions of sex stereotypes. In this task, children were shown a silhouette drawing of a man and a woman while they were read stories consisting of various sex stereotype traits (e.g., aggressive, emotional, and gentle). Children were then asked to tell which silhouette each story was about. European American children's knowledge of sex trait stereotypes showed a consistent pattern of growth from kindergarten through high school. Scores showed the most dramatic gains during elementary school years and often appeared to plateau after junior high school. African American children's knowledge of the same stereotype traits also increased with age, but at a slower rate. This observation suggests that different nationalities within one country may vary somewhat in their stereotype knowledge base.

3.2. Findings across Cultures

Williams and Best used the SSM with 5-, 8-, and 11-year-old children from 25 different nations. In general, they found that the frequency of stereotyped responses increased from approximately 60% at age 5 to 70% at age 8. At all ages, items consistently associated with males were strong, aggressive, cruel, coarse, and adventurous; weak, appreciative, softhearted, gentle, and meek were consistently associated with females.

Scores were exceptionally high in Pakistan and relatively high in England and New Zealand, indicating that children in these countries had a considerable understanding of sex stereotypes. Conversely, scores were particularly low in Brazil, France, Germany, and Taiwan, suggesting consistent stereotype trait knowledge may develop more slowly in these countries. The general pattern across all countries was characterized by the onset of stereotype learning prior to age 5, accelerated learning during the school years, and functionally complete stereotype knowledge during adolescence.

Boys and girls acquired stereotype knowledge at the same rates, but there was a tendency for both groups to learn about the male stereotype at a faster rate. However, this tendency was reversed in Latin/Catholic cultures (i.e., Brazil, Chile, Portugal, and Venezuela), in which the adult female stereotype was more favorable than that of the adult male. Male stereotype items were better known than female items by both sexes in 17 of the 24 countries studied. Germany was the only country in which there was a clear pattern of greater knowledge of female stereotype items. Like the Latin/Catholic cultures, German female stereotype knowledge at age 5 was greater than male stereotype knowledge. Differences emerged at 8 years due to the persistence of greater female stereotype knowledge among German children but a change to greater male stereotype knowledge among 8-year-olds from Latin/Catholic cultures.

Five-year-olds in predominantly Muslim countries differentiated more between the sexes than 5-year-olds in non-Muslim countries. Furthermore, children in Muslim countries learned the stereotypes, particularly the male stereotype, more quickly than children living in predominantly Christian countries. Because adult stereotypes tend to be less well differentiated (i.e., overlap more) in countries in which a majority of people practice Christianity, children in these countries may acquire stereotype knowledge at a slower rate than children living in cultures distinguished by rigid boundaries that separate the characteristics generally considered to be typical of males or females.

Studying older children, Margaret Intons-Peterson found that 11- to 18-year-olds in Sweden had more similar male and female stereotypes than children in the United States. However, little overlap was found in the Swedish children's ideal occupational choices. Swedish boys were interested in business careers, whereas Swedish girls reported a preference for occupations in the service industry, such as nanny, hospital worker, and flight attendant.

4. THEORIES OF GENDER-RELATED LEARNING

Although most theories of gender role learning were developed in the United States, they consistently emphasize the gender-relevant knowledge that is available within a particular cultural context. The theories differ on many points, but they each accommodate cross-cultural patterns of gender role development.

4.1. Social Learning

From the perspective of social learning theories, gender role development is conceptualized as the accumulation of experience with socialization agents in one's environment. Socialization agents such as parents, teachers, and peers concurrently shape a child's gender-related behaviors by rewarding gender-appropriate behaviors, punishing gender-inappropriate behaviors, modeling gender-appropriate activities, selecting gender-appropriate toys, and generally treating boys and girls in a differentiated, sex role-consistent manner. Parents in the United States, and fathers in particular, have been found to treat their children differently depending on the sex of the child. For example, boys are often given more freedom and independence than girls, and they tend to receive more physical stimulation. However, studies in other countries have shown less differential treatment on the basis of sex relative to that found in the United States.

Deborah Best and colleagues observed parents and their preschool children in public parks and playgrounds in France, Germany, and Italy, and they found variation in parent-child interaction patterns across both gender and culture. In comparison to French and Italian parent-child pairs, German parents interacted less frequently with their children. Furthermore, German children showed and shared more objects with their mothers, whereas French and Italian children engaged in the same behaviors more frequently with their fathers. These observations suggest that German children, relative to those in other countries, may engage in a disproportionately greater amount of interactions with their mothers relative to their fathers, possibly fostering more rapid development of the female stereotype relative to the male stereotype. Similarly, these data suggest the opposite pattern for French and Italian children. This pattern is consistent with the aforementioned findings from the cross-cultural work of Williams and Best, which

indicated that Germany was the only nation in which the female stereotype was learned more rapidly than the male stereotype and persisted at higher levels into later childhood.

It is clear that social factors play an important role in children's learning of gender roles, and there is wide variation in how girls and boys are treated across cultural groups. Surprisingly, differential treatment of boys and girls is not consistently related to gender differences in the behavioral patterns observed across cultures.

4.2. Cognitive Development

Cognitive developmental theory focuses on the way cognitive structures affect the influence of the environmental factors that are often studied by social learning theorists. Determining the role that cognitive structures play in the development of gender knowledge and gender-typed behaviors is a difficult task due to the changing nature of children's cognitive structures across childhood. As these structures change with age, so too does the manner in which children interpret and remember gender-relevant experiences.

Consistent with Jean Piaget's stage theory of cognitive development, Ronald Slaby and Karin Frey identified four developmental stages that characterized children's gender knowledge acquisition in North America. Prior to age 2, children did not distinguish between men and women, but in the second stage by age 2 or 3 they used physical characteristics to differentiate between the sexes. By the third stage at approximately 4 years of age, children understood that gender was stable, and by age 5 or 6 they knew that gender remained constant.

Ruth and Robert Munroe and Harold Shimmin tested the predictions of cognitive developmental theory in a study of children in societies marked by differing degrees of gender differentiation. They predicted that in societies with high gender differentiation (i.e., Kenya and Nepal), children would progress through the cognitive gender stages at a faster rate than children living in less differentiated settings (i.e., Belize and Samoa). Contrary to these predictions, attainment of gender classification capabilities was not related to cultural variations in gender differentiation. Although the degree of gender differentiation varied between these cultures, the discrepancies within each culture may have been sufficient to promote the development of gender discrimination skills. Furthermore, it is possible that the extensive gender differentiation in Kenya and Nepal may have been superfluous for children's learning.

5. GENDER AT THE ADULT LEVEL

It is apparent from the research on the development of gender roles and stereotypes that children's cultural environment influences much of what they learn. Children are socialized by adults whose social behaviors, gender stereotypes, and self-perceptions reflect differences between men and women.

5.1. Sex Role Ideology

Sex role ideology concerns an individual's beliefs about men's and women's proper role relationships, ranging along a continuum from traditional to modern. The traditional end of the continuum is characterized by beliefs that men are more "important" than women and that women should be subservient to men. Modern ideologies are more egalitarian and are consistent with the notion that women and men are equally important and that neither sex has the right to dominate the other.

Because of the juxtaposition of traditional and modern ideologies among its inhabitants, India has been a fascinating nation in which to study adult sex roles. Khavita Agarwal, David Lester, and Nisha Dhawan asked university students in India and the United States to identify the qualities men and women should possess in their respective cultures. They found that North American students expressed more modern views than Indian students; however, across both cultures, women were more liberal (modern) than men. Rehana Ghadially conducted a more in-depth analysis of Indian women and found that those with the most modern sex role ideologies grew up in nuclear families, had educated mothers, and worked in professional disciplines.

Atsuko Suzuki conducted similar studies in Japan and the United States and found education and job status to be strong predictors of sex role attitudes among women. North American women with jobs held more egalitarian views than women without jobs. In Japan, women with career-oriented professional jobs reported more egalitarian views than all other women.

Judy Gibbons, Deborah Stiles, and Gina Shkodriani studied attitudes toward family roles and gender among adolescents studying in The Netherlands. The students originated from 46 different countries and formed two groups based on origin: individualistic, wealthier countries and collectivistic, less wealthy countries. Students from this second group of countries reported more traditional attitudes than students

from the first group, and across both groups, boys reported more traditional attitudes than girls.

In studies of sex role ideology, the United States has often served as a comparison group, and the beliefs of U.S. adults are generally found to be more liberal than those of adults of other nations. However, this was not the case in a 14-country study of the attitudes of university students by Williams and Best. Northern European countries (i.e., The Netherlands, Germany, Finland, and England) had the most modern ideologies, the most traditional attitudes were found in African and Asian countries (i.e., Nigeria, Pakistan, India, Japan, and Malaysia), and the United States was in the middle of the distribution. With the exception of Malaysia and Pakistan, women reported more modern attitudes than men. However, within a given country, men's and women's sex role ideology scores were highly similar; that is, greater differences existed between cultural groups (men and women combined) than within cultural groups (men compared to women).

In cross-cultural research it is necessary to show that differences between cultural groups are related to other cultural variables before one can conclude that the differences of interest are due to cultural factors. In the 14-country study noted previously, sex role ideology scores were related to socioeconomic development, supporting the role of cultural factors. Specifically, sex role ideology scores were more modern in more developed nations, in countries in which Christianity was more predominant, in more urbanized countries, and in countries at higher latitudes (i.e., countries at higher latitude tend to have greater socioeconomic development).

5.2. Gender Stereotypes

Gender stereotypes are the psychological traits believed to be more characteristic of one sex relative to the other. These stereotypes are closely related to sex role ideologies, and they have often been used to account for variations in sex role ideologies across cultures. Williams and Best presented university students in 27 countries with the Adjective Checklist, a standard personality measure consisting of 300 person-descriptive adjectives. Students indicated whether, in their culture, each adjective was more characteristic of men, more characteristic of women, or not differentially associated with either sex. Students generally agreed about the characteristics differentially associated with men and women, but differences between the male and female

stereotypes did emerge. Male and female stereotypes varied the most in The Netherlands, Finland, Norway, and Germany and least in Bolivia, Scotland, and Venezuela. Additionally, greater stereotype variation was found in Protestant compared to Catholic countries, in more developed countries, and in countries higher in individualism.

Analysis of the qualitative aspects of the male and female stereotypes revealed that the male stereotype items were stronger and more active across cultures. Across all countries, items representing dominance, autonomy, aggression, exhibition, and achievement were associated with men, and nurturance, succorance, deference, and abasement were consistently chosen to describe women.

Recent work examined these stereotype findings in terms of the Five Factor Model of personality, an approach based on the assumption that five dimensions can fully capture the aspects of personality. The pan-cultural male stereotype, which consisted of items consistently associated with men across most cultures, was found to be higher on the dimensions of extraversion, conscientiousness, emotional stability, and openness, whereas the female stereotype was higher on the dimension of agreeableness.

In contrast to these cross-cultural generalities, variation between the countries emerged as well. No consistent pattern emerged for stereotype favorability, with the male stereotype items being more favorable in some countries (e.g., Japan, South America, and Nigeria) and the female stereotype items exceeding the male items in others (e.g., Italy, Peru, and Australia). Greater variation in the perceived strength and activity of the male and female stereotypes was found in countries that were less socioeconomically developed and had lower literacy rates and lower percentages of women attending universities. These findings suggested that economic and educational advancements were accompanied by reductions in the tendency to view men as stronger and more active than women. Note, however, that these effects were only reduced, not eliminated.

5.3. Masculinity/Femininity of Self-Concepts

The paired concepts of masculinity and femininity essentially mean manlike or woman-like, and a person can be characterized as masculine or feminine along a number of dimensions, such as dress, mannerisms, or

tone of voice. One aspect of masculinity and femininity relates to self-concepts and the degree to which individuals incorporate traits that are differentially associated by men or women into their self-concepts. Researchers have used a variety of measurement techniques to assess individual differences in the masculinity and femininity of self-concepts. For example, some researchers have used self-descriptive questionnaires, some have analyzed only socially desirable characteristics, and others have examined gender-associated characteristics without considering social desirability. Certainly, a conjunction of the three would provide a more comprehensive examination.

Valid measurement is a continuing concern for researchers studying the similarities and differences between various cultural groups. Measurement problems can arise when a scale is developed in one culture and then applied in other cultures without attention to the validity of the instrument in the new context. A prime example of questionable measurement validity occurred in a cross-cultural study of masculinity and femininity by Robert Helmreich and Janet Spence. They used the Personal Attributes Questionnaire, which contains traits associated with either males or females in the United States, to compare the self-descriptions of men from Brazil and the United States. They found that Brazilian men endorsed more feminine than masculine traits, whereas men from the United States endorsed the opposite pattern. On the surface, these results suggested that men in the United States were more masculine than men in Brazil, and, surprisingly, that Brazilian men may have been more feminine than masculine. However, these accounts do not consider cultural differences in the definitions of masculinity and femininity. It is equally plausible that, from the Brazilian perspective, the self-descriptions of men in the United States are more feminine than those of Brazilian men.

The aforementioned difficulties were addressed in a study by Williams and Best in which the masculinity and femininity of items were determined within each culture. These authors assessed the masculinity and femininity of the self-concepts of university students in 14 countries. Participants selected the items from the Adjective Checklist that they believed described their actual and ideal self-concepts (i.e., who they really were vs who they would like to be). These descriptions were scored according to university student ratings of the masculinity and femininity of each item in prior studies in each of the 14 countries. Therefore, the stereotyped items reflected culture-specific conceptualizations of

masculinity and femininity. As one would expect, the self-concepts of men were more masculine than those of women in each culture. Surprisingly, members of both sexes rated their ideal selves as more masculine than their actual selves. Considering the preceding discussion of the affective features of male and female stereotypes, this trend of desired masculinity may reflect a universal desire for a stronger, more active self.

Variation did exist in the self-concepts of men and women across the cultures studied, but this variation was not related to meaningful cultural comparison variables, such as socioeconomic development. When self-concepts were scored in terms of the relevant culture's standards for masculinity/femininity, no evidence was found to suggest cross-cultural differences in the degree of masculinity among men or femininity among women.

In contrast, the discrepancy between ideal and actual self-concepts varied considerably across cultures, and much of this variation was systematic. In particular, the differences between men's and women's actual and ideal self-concepts were smaller in cultures characterized by greater socioeconomic development, higher rates of female employment outside the home, higher rates of female enrollment in universities, and modern sex role ideologies.

6. RELATIONS BETWEEN WOMEN AND MEN

6.1. Mate Preferences

Social scientists have often considered mate preferences to be culture bound and therefore inconsistent across cultures. However, findings by David Buss and associates suggest quite the contrary. In the most extensive investigation of mate preferences to date, these researchers collected responses from more than 10,000 individuals in 33 countries. Using two lists of potential mate characteristics, participants indicated their preferences by ranking or rating the items. Surprisingly, a high degree of similarity in the preferred characteristics of mates emerged for women and men across cultural groups. For the 13 items considered, both sexes ranked "kind and understanding" first, "intelligent" second, "exciting personality" third, "healthy" fourth, and "religious" last. However, women tended to place a higher value on a potential mate's earning capacity than did men, and men generally valued physical appearance more than women. In a reanalysis of the Buss data, Alice Eagly and Wendy Wood also found

that men valued a good cook and housekeeper more than women.

In contrast to the aforementioned similarities, cultural differences were found for nearly every item. The greatest variation was found for the item "chastity." Groups in China, India, and Iran placed considerable importance on this item, but those in northern Europe viewed it as relatively unimportant. In general, men valued chastity more than did women.

Considering the remarkable degree of similarity across samples, Buss suggested that substantial unity exists in human mate preferences, and that this unity may be regarded as "species typical." However, no sample was identical to another, and each group showed unique tendencies in the ordering of characteristics, indicating at least modest degrees of cultural variation.

Not only are there similarities along with some differences in preferences for human mate characteristics, but the recent International Sexuality Description Project of 16,288 people across 10 major world regions revealed similar findings regarding desire for sexual variety. Universal sex differences were found, with men possessing greater desire than women for a variety in sexual partners, for less time to elapse in a relationship before consenting to sexual intercourse, and for more active seeking of short-term sexual partners. However, for each of these sex differences, there was significant variation by world region. For example, compared with other regions of the world, East Asian men and women were lower in their desire for more than one partner in the next month.

6.2. Romantic Love

Romantic love and intimacy, as with mate preferences, are assumed to be primarily under cultural influences. In general, romantic love is valued in more modern cultures, such as the United States, in which individualism is emphasized and few have extended family ties. However, romantic love is viewed as less essential in cultures in which strong family ties reinforce the family relationships brought about through marriage, such as in Japan. There does appear to be some degree of universality when one considers an analysis of the ethnographies and folklore materials from 166 societies. This review found at least one incidence of passionate love in 147 (88%) of the cultures examined, suggesting that the potential for romantic love may be a human universal that is overwhelmed by other cultural variables.

A study by Josephine Naidoo addressed these issues with Asian Indian immigrants in Canada by examining

generational changes in the attitudes reported toward love and marriage. Although nearly two-thirds of the immigrants had arranged marriages, a substantial proportion of them believed that “love marriages” were an option for their offspring. More than 70% of the second generation believed love should precede marriage and wanted their children to have greater freedom in mate selection than they had experienced.

6.3. Harassment and Rape

Kaisa Kauppinen-Toropainen and James Gruber conducted one of the few cross-cultural studies of male harassment and hostility toward women. After examining blue-collar and professional women in Scandinavia, the former Soviet Union, and the United States, these authors found that Americans reported the most woman-unfriendly experiences. Relative to Americans, Scandinavians reported fewer job-related or psychological problems, more autonomy, and better work environments. Professional women in the former Soviet Union reported fewer negative experiences than blue-collar women but more than professional women in the United States and Scandinavia.

Colleen Ward and colleagues conducted a comprehensive assessment of attitudes toward rape victims with university students from 15 countries. Cross-cultural variation in attitudes toward rape victims followed patterns of attitudes toward women more generally. That is, countries with more modern sex role ideologies reported more favorable attitudes toward victims, whereas less favorable attitudes emerged in countries with lower percentages of women in the labor force and lower literacy rates. In particular, more favorable attitudes were reported by university students in Germany, New Zealand, and the United States, and less favorable attitudes were found in India, Malaysia, Mexico, Turkey, and Zimbabwe.

7. GENDER DIFFERENCES AT THE CULTURAL LEVEL

7.1. Masculinity and Work-Related Values

Using attitude survey data from thousands of IBM employees who were predominantly male, Geert Hofstede compared work-related values in 40 countries. One scale derived by Hofstede focused on the extent to which values of assertiveness, money, and things prevail instead of values of nurturance, quality of life, and people.

This scale was labeled Masculinity (MAS) due to the fact that male employees assigned greater importance to the first set of values, whereas females assigned greater importance to the second set. A MAS index was computed for each of the countries in Hofstede's study; the five highest rated countries on the MAS dimension were Japan, Austria, Venezuela, Italy, and Switzerland, whereas the five lowest rated were Sweden, Norway, The Netherlands, Denmark, and Finland. High MAS countries were characterized by stronger beliefs in independent decision making, stronger achievement motivation, increased job stress, and a view of work as central in people's lives.

The significance of the MAS dimension is unquestionable; however, many researchers have challenged the appropriateness of labeling the scale Masculinity. This label leads to the expectation that variation on the MAS scale would be associated with cross-cultural variation on other gender-related constructs. Contrary to these expectations, Williams and Best have not found relationships between their sex stereotype or masculinity/femininity measures and Hofstede's MAS dimension. Other researchers have also failed to find the expected relationships.

7.2. Gender Division of Labor

Conceptions of masculinity and femininity vary widely across cultures, but two universals are plausible: (i) To varying degrees, every society assigns traits or tasks on the basis of sex, and (ii) the status of women is inferior to the status of men in every society. As one would expect based on these generalizations, extensive differences do exist in the work roles of men and women. Examining jobs and tasks in 244 societies, Roy D'Andrade found that men were involved in hunting, metal work, and weapon making and tended to travel further from home than women. Women were responsible for food preparation, carrying water, caring for clothing, and various child-rearing responsibilities. Although women's subsistence activities generally included child-rearing demands, some did hunt in societies in which this activity did not compete with child care. The strong sex segregation for child-rearing duties was mirrored by another study that found that men were significant caretakers in only 10% of the 80 cultures examined. However, both sexes seemed to be flexible enough to adapt to a range of socioeconomic roles.

Today, women account for a substantial proportion of the world's labor force. With decreases in infant mortality and fertility, women now spend less time in child-rearing

roles. Furthermore, technological advances have allowed women in many parts of the world to separate child-bearing from child-rearing and thereby contribute to the family through jobs outside the home.

However, women's increased autonomy has not been paralleled by increased acceptance or equality. For example, in a 56-country study of labor trends from 1960 to 1980, the job market was marked by declines in women's occupational opportunities and increases in sex segregation. When measured by per capita gross national product and women's level of education, modernization was associated with increased segregation of the sexes. Additionally, increased workplace involvement for women correlated with decreases in total fertility rate. Women continue to be disadvantaged in the workplace, most overtly through persistent salary discrepancies that favor men. In addition to women's lower salaries is evidence suggesting that women prefer traditionally female jobs, especially those offering extensive contact with other people. Moreover, these jobs tend to be low paying. On the contrary, men tend to prefer jobs with high income and promotion opportunities.

Even in the countries with the highest proportion of females in the labor force, women continue to face inequality within the home. Studies in several North American and European countries have found that women perform a majority of the housework, regardless of the extent of their occupational demands. Along with children and larger homes comes reduced male involvement in domestic chores. This is surprising in light of the previous suggestion that increases in education and income are associated with more modern sex role views (i.e., equality in the workforce). However, studies suggest that systematic differences in sex role ideology persist in these more modern countries. For example, in the United States, Great Britain, West Germany, and Austria, people with relatively high levels of education and women with employed husbands indicated less support for efforts to reduce gender inequality compared to those with less education and women without employed husbands. Such findings suggest that even the subjective change in perceived life quality associated with improved socioeconomic conditions may be greater for men than women.

8. CONCLUSION

Sex differences continue to pose challenging questions for social and biological scientists, and with increased

interest in the role of culture, new questions will certainly emerge. Although males and females are biologically more similar than different, they lead different lives, regardless of their society's tendencies toward traditional or egalitarian views.

Considering the degree of gender stereotype similarity across cultures suggests a pancultural model in which cultural nuances produce relatively small variations around general tendencies. Within this model, the relatively modest biological differences are perceived to set the stage (e.g., women bear children, men have greater physical strength) and subsequently lead to a division of labor such that women are responsible for child-rearing and other domestic duties, whereas men are providers (e.g., hunting) and protectors. From the perspective of this model, gender stereotypes evolved to support this division of labor. Gender stereotypes lead to an implicit assumption that members of either sex have or can develop characteristics that are consistent with one's assigned role. Once they are established, such stereotypes can guide differential sex role socialization for boys and girls and lead boys to become more independent and adventurous, whereas girls become more nurturant and affiliative. Additionally, such boundaries heighten the salience of people who differ from societal expectations of gender-appropriate behavior, possibly creating social difficulties for those people. Although the accuracy of such a model is difficult to test due to its reliance on evolutionary processes, its usefulness is apparent because it demonstrates a means by which people in widely different cultures can come to associate one set of characteristics with men and another with women, with only minor deviations from these central themes. The relatively modest biological differences between the sexes appear to be enhanced or diminished by cultural practices; however, even small differences in gender roles and behaviors can have important cultural implications.

unified discipline approach A method of handling discipline that involves partnerships and consistency between schools, families, and communities rather than conflicting or contradictory policies between these groups.

GLOSSARY

academic retention A school's decision to keep a student in a grade for another year rather than having the student matriculate to the next higher grade.

the boy code A set of unwritten rules that require boys to act tough, independent, and confident even in situations in which they feel frightened or unsure.

classroom dynamics The interactions occurring between individuals in a classroom.

disorders of body image Negative perceptions and attitudes about one's own body (often manifest as being too fat among girls or not having enough muscle among boys).

externalizing behavior Disruptive behavior, such as non-compliance or aggression.

gender equity Girls and boys experiencing equal opportunities in educational settings.

gender stereotypes Commonly held beliefs about characteristics deemed appropriate for males and females.

relational aggression A form of aggression that damages others' relationships (e.g., social exclusion and rumor spreading).

self-contained classroom A classroom serving only students in special education, most commonly because of a perception that the students' needs cannot be accommodated in the general education classroom.

In most industrialized countries, laws have been established to mandate equal educational opportunities for boys and girls. For example, in 1972, the United States passed Title IX, a federal law that mandates that no person be discriminated against on the basis of sex in any educational program receiving federal funds. One might assume, then, that gender does not have much of an impact on education (i.e., that there are no appreciable differences in how girls and boys experience school). In contrast to this assumption, research shows that gender can have a major impact on a child's educational experiences. This article reviews the literature on gender and education with a particular focus on the issue of gender equity.

1. WHAT IS GENDER EQUITY?

When applied to education, the term gender equity refers to girls and boys experiencing equal opportunities in educational settings. The term not only refers to academic learning but also applies to a much broader range of activities and experiences that are a part of the educational process. In an equitable educational environment, boys and girls have similar opportunities to

master the academic curriculum, experience a sense of comfort and belonging, have interactions with teachers and peers that promote both competence and confidence, be recognized for their contributions, and participate in extracurricular activities that are enjoyable and build self-esteem. In order to create such an environment, educators must understand and appreciate boys' and girls' unique developmental issues and needs within schools. Educators must also seek to eradicate gender stereotypes that limit opportunities for youth (e.g., that girls cannot be successful in math or that boys should not be interested in cooking or sewing). Funding (e.g., of athletic teams) and access (e.g., to vocational programs that lead to higher paying jobs) also must be given careful consideration in a gender-equitable educational environment.

2. GENDER EQUITY IN SCHOOLS: ISSUES OF CONCERN

2.1. Concerns for Girls

Much of what has been written about gender equity in education has focused attention on educational inequity for girls. Frequently noted concerns include girls receiving less teacher attention than boys, biased curricular materials presenting women in subordinate roles to men and/or failing to recognize the significant accomplishments of women (e.g., excluding the work of female scientists from textbooks), attitudes toward sexual harassment that accept such behavior as being a normal part of the adolescent school experience, and stereotypes indicating that girls are less able than boys in mathematics and the sciences.

Several publications from the early to mid-1990s did much to raise awareness of gender inequity in schools. For example, David and Myra Sadker, in their book, *Failing at Fairness: How Our Schools Cheat Girls*, summarized research showing that boys stand out in the typical classroom (receiving both more positive and more negative attention than girls), whereas girls quietly do their work and blend into the classroom landscape. It is notable that research has shown that low-achieving girls are less likely to be referred for special education services than low-achieving boys, even when their levels of achievement are similar. This is because low-achieving boys tend to manifest more behavior problems, which makes them stand out more. Also, when girls are in need of a self-contained classroom experience, especially a classroom for children

with emotional or behavioral problems affecting their learning, there tend to be very few appropriate classroom placements since these classes are dominated by boys.

Importantly, many of the types of problems that are more common among girls than boys (particularly in adolescence) and may be related to diminished opportunities for classroom learning (e.g., adolescent depression, eating disorders, disorders of body image, sexual harassment, and relational aggression) often do not come to the attention of teachers or other school personnel because they tend not to disrupt classroom activities. Thus, teachers may not know that girls in their classrooms are underperforming because of unaddressed social or emotional issues. Boys are much more likely to act out their problems than girls and thus are also more likely to come to the attention of those who might be able to provide assistance (e.g., school psychologists and counselors).

2.2. Concerns for Boys

Systematic inquiry into the ways in which boys are underserved in schools has only begun to emerge in the past 5–10 years. One important source of concern for boys centers on the fact that most educational environments, while becoming increasingly tolerant of girls engaging in traditionally male activities (e.g., playing physical contact team sports), are still highly stereotyped for boys. For example, William Pollock, in his book, *Real Boys: Rescuing Our Sons from the Myths of Boyhood*, noted that boys are more likely than girls to be criticized by teachers for expressing feelings of fear (e.g., on the first day of school) or affection (e.g., hugging another child). Male peers also are likely to chastise boys for any behavior that is perceived as feminine or as being “like a girl” (e.g., boys whose athletic skills are not well developed might be criticized as “throwing like a girl”). These observations exemplify the fact that boys are still restricted by what Pollock calls “the boy code,” which stipulates that boys must act tough, independent, and confident even in situations in which they feel frightened or unsure. Most educators are much more likely to tolerate cross-sex interests and behavior from girls than boys.

Another important concern regarding educational equity for boys is related to the observation that so many more boys than girls experience academic or behavioral failure in school. Boys are considerably more likely than girls to be retained, to be identified as having special needs and placed in a special education program, and to

experience school discipline (e.g., suspension and expulsion). Whether such gender differences are related to biological or social factors (or a combination of the two) is unclear. Nonetheless, given these outcomes, the possibility must be considered that the types of educational environments currently existing in our schools are not meeting boys' unique needs. Some researchers have noted that many boys begin kindergarten behind their female peers in terms of fine motor skills, verbal skills, attentional capabilities, and other important indicators of readiness for formal learning. This appears to be due to slower overall maturation in boys compared to girls. However, instead of conceptualizing boys as having different needs in early elementary school than girls (e.g., more opportunities for learning through gross motor as opposed to fine motor activities), educators tend to be quick to label boys as deficient, leading to early elementary retention in grade or referral for special education testing. If educational environments gave more careful consideration to boys' unique needs, gender differences in educational failure might be reduced.

3. INCREASING GENDER EQUITY: STRATEGIES FOR EDUCATORS

There is much that educators can do to ensure that children's educational experiences are consistent with their needs. With regard to enhancing gender equity in educational settings, there are three primary areas to be considered: classroom dynamics/instructional style, the curriculum, and behavior management/intervention.

3.1. Classroom Dynamics/ Instructional Style

As noted previously, David and Myra Sadker's work focused on the fact that, in general, girls receive less teacher attention in the typical classroom than boys. As such, boys experience the benefits of a more intense educational climate, receiving both more attention from teachers overall and more precise attention (e.g., greater feedback when responding to a teacher-posed question) than girls. It is likely that the discrepancy in the way teachers treat boys and girls is related to gender differences in activity level and interactional style, with boys demanding more attention through their behavior than girls. Nonetheless, differences between boys and girls in teacher attention could be reduced if teachers were more aware of these issues.

Thus, one of the primary means for increasing gender equity in classrooms is to educate school staff about the ways in which they may be treating boys and girls differently. Because at least some of this behavior is unintentional, it can be helpful for teachers to have someone such as the principal, school psychologist, or guidance counselor (i) educate teachers about the truths and myths of gender differences (e.g., boys are not inherently better at math and science than girls), (ii) train teachers directly in gender-fair teacher-student interactional practices (e.g., through modeling and/or role-playing gender-fair expectancies, practices, and attitudes), and (iii) observe and provide feedback on the degree to which teachers are engaged in gender-fair teaching methods and strategies. Many teachers may not realize that they never ask a girl to help if they are having a problem with the TV or VCR or that they communicate to boys that they should act tough even if they are hurt or scared. Bringing these issues to awareness is the first step in creating positive change.

3.2. The Curriculum

A second important issue to address is the curriculum. It is important that educational materials used in schools (e.g., textbooks, posters, media, and Internet resources) represent the diversity of the human experience. In terms of gender, this includes depicting both men and women of various ethnic and racial backgrounds in positions of leadership and achievement. Students should have the opportunity to learn about the important contributions that both women and men have made to society and to see depicted in their educational materials role models who help them to envision possibilities for themselves that defy gender role stereotypes. It also includes balancing the number of books or other educational materials created by men and women as well as the gender of the strong central figure in these materials.

In addition to carefully considering educational materials, there are a number of other ways for school administrators to reflect to students, staff, and the larger community that students at their school will not be limited by traditional gender role stereotypes. These include developing nontraditional career mentoring programs, providing similar levels of financial support for girls' and boys' athletic teams, and establishing awards programs that recognize teachers for excellence in promoting gender equity and students for significant accomplishments in areas traditionally considered to be more appropriate for the opposite

gender (e.g., girls in science or math and boys in writing or the arts). Additionally, at the middle and high school levels, it is particularly important for schools to find proactive ways to address the problems of teenage pregnancy, sexual harassment, and sexual violence. These are concerns that many school administrators (and parents and teachers as well) do not believe should be discussed in schools. Nonetheless, research demonstrating the disproportionate negative impact of these issues on young women's schooling experiences is cause for concern. It also is recommended that schools have a policy prohibiting sexual harassment. It is particularly important that this policy include student-to-student sexual harassment because this is the primary form of sexual harassment that students experience in school.

Finally, with regard to the curriculum, educators must address the question of how well the curriculum at each grade level is meeting the needs of both boys and girls. For example, if twice as many boys as girls are being retained in kindergarten, the question of whether the current kindergarten curriculum is meeting the needs of boys must be raised. One sex should not set the standard to which the other sex is compared. Differences in development and unique needs must be recognized. Similarly, if girls are not opting to take upper-level science and mathematics courses in high school, the reasons behind this should be investigated. Are those courses being taught in a way that optimizes girls' learning potential? Are girls choosing other alternatives because they have been socialized (even inadvertently) to believe that they cannot be successful in these courses? Do they realize that their college options may be limited without this coursework in high school? These types of questions can help educators assess the degree to which they are meeting unique gender needs at different levels of the curriculum.

3.3. Behavior Management/ Intervention

It has been noted that boys are greatly overrepresented with regard to grade retentions, referrals to special education, and school disciplinary action compared to their female peers. In part, this is because many more boys than girls demonstrate problems with externalizing behavior in the classroom (e.g., noncompliance and aggression). Thus, in order to meet boys' unique needs, it is very important, from a preventive

standpoint, to put in place behavioral strategies that attempt to curtail disruptive classroom behavior. Most school suspensions—which have a disproportionate impact on boys—are for classroom disruptions and disobedience. Research has shown that such behaviors can be reduced through preventive programs that involve positive behavior management, social skills instruction, a unified discipline approach (involving partnerships between schools, families, and communities), and shared expectations for socially competent behavior.

It also is important to recognize that in schools, problems that cause disruption in the classroom are those that are most likely to be recognized and further assessed. Thus, the fact that more boys than girls express problems outwardly (e.g., through fighting) while more girls than boys tend to internalize their problems means that boys' problems come to the attention of teachers more often than girls' problems. Boys are thus more frequently referred to the school's student support team for assistance. Educators need to become more aware of the types of problems that are more common in girls than boys (e.g., learning problems that occur in the absence of behavioral problems, depression, eating disorders, and relational aggression), the warning signs associated with these problems, and the necessity of involving members of the student support team in intervening with girls in these situations.

Additionally, it is important to recognize that there are sex differences in the degree to which boys and girls feel comfortable sitting down with an adult to discuss their thoughts and feelings. William Pollock noted that boys have been socialized to believe they should handle their problems on their own rather than reach out to others for help. As a result, it is less likely that boys, compared to girls, will readily open up to a teacher about their feelings when asked about a problem. This may be particularly true when the teacher is female and/or of a different racial background. Pollock's research suggests that in such situations, boys may feel more comfortable focusing on an activity (e.g., games and role plays) and having discussions of thoughts and feelings arise out of the activity rather than simply being asked to share what is on their minds.

4. SUMMARY

This article has described how gender impacts educational experiences and what can be done to

increase gender equity in education. The resources listed in Further Reading give interested readers additional insight into how gender role stereotyping can limit opportunities for children and what can be done to ensure that both boys and girls receive equal opportunities to maximize their own personal potential.

GLOSSARY

ageism The discrimination of individuals based on societal stereotypes of age and aging.

blatant sexism The transparent harmful and unequal treatment of an individual based on his or her sex.

covert sexism The intentional, hidden, and hostile sexism focused on assuring the failure of a member or members of a particular sex.

cultural feminism Type of feminism that emphasizes the qualities and characteristics generally applied to women, such as the qualities of caring, nurturing, and concern for the needs of others, which society usually devalues and ignores.

feminism The belief that women and men are equal and should be equally valued as well as have equal rights.

gender A social construction based primarily on sex, consisting of traits, interests, and behaviors ascribed to each sex by society.

liberal feminism Type of feminism that focuses on the promotion of legal and social equality between men and

women; advocates for a revision of values, laws, and mores associated with the inequality of women in society.

radical feminism Type of feminism that focuses on men's control over and oppression of women, which remains the primary source of women's oppression economically and socially.

sex The biological differences in genetic composition and reproductive structures and functions of men and women.

sex discrimination The unequal and harmful discrimination of individuals based on their sex.

sexism The experience of discrimination based on sex.

socialist feminism Type of feminism that focuses on social relationships and the preservation and promotion of male dominance in social institutions and that seeks to exact economic institutional change in order to achieve equality between men and women.

subtle sexism The expression of internalized negative cultural messages regarding the inferiority of members of one sex.

Gender remains an important, and often overlooked, consideration in psychological research, theory development, and practice. The cultural, structural, and cognitive components of gender contribute to the life experiences of both women and men. Cultural pressures, along with gendered cognitions, affect people of both sexes differently throughout the life cycle. Gender stereotypes and expectations regarding gender appropriate behavior bombard men and women from birth. Often these gender role expectations create difficulties for individuals socially, sexually, physically, and psychologically. The concept of feminism, loosely

defined as a belief in the equality of women and men, provides a framework for the treatment and study of individuals of both sexes. The articles contained in this section address a broad range of gender issues, including gender development, cultural impact on gender, gender and sexuality, homosexuality, homophobia, sexual harassment, rape, and issues pertaining to women's health in old age. Sensitivity to the cultural, structural, and cognitive origins of gender and gendered behavior contributes to the field of applied psychology in considering the different experiences of men and women throughout the life cycle.

1. THE DIFFERENCE BETWEEN GENDER AND SEX

The terms sex and gender are often misunderstood and misused. The term sex refers to the biological differences in genetic composition and reproductive structures and functions of almost all organisms. While the actual number of sexes existing in non-mammalian species remains controversial (some organisms are asexual, or have both male and female sex characteristics), scientists currently recognize two biological sexes in mammals, male and female.

Human males and females differ in their chromosomal makeup, genetically, hormonally, and neurologically. These differences create confusion and widespread misunderstanding regarding male and female biological processes and the ways in which these processes interrelate. These misunderstandings often create unfounded beliefs and confusion regarding the distinction between the male and female sex. For example, many individuals believe that females alone produce the hormones estrogen and progesterone. In addition, many hold the belief that only males produce testosterone. However, these hormones exist in both sexes to varying degrees depending on individual genetic composition, development, and biological sex.

While species may be divided in terms of sex, only humans are differentiated by both sex and gender. Gender, although based on primarily on sex, remains a social construction. Societies ascribe various gender differences based on traits, interests, and behaviors. Social context, the social sphere in which an individual exists and interacts, remains the greatest determinate of the designation of gender, that of "masculine" and "feminine." Personal history, immediate situation, society, and culture comprise the social context in which

individuals behave and interact. This interaction, the reciprocal activities that encompass being male and female, continues throughout day-to-day existence and society as individuals abide by society's prescriptions for gender.

1.1. The Construction of Gender

Gender remains a socially constructed concept that refers to the creation and explanation of the differences between girls and boys and women and men. The socially constructed nature of gender debases the concept of absoluteness in the biological differences between women and men. Therefore, biological differences between the sexes account for very little of the observations of different behaviors and attitudes among women and men. Rather, the social construction of gender and the societal pressures regarding behavior and attitudes deemed gender appropriate contribute to the manifestation of gender in individuals. The acquisition of gender-appropriate behavior occurs through several psychological processes involved in the etiology of beliefs regarding the adoption and maintenance of gender and gender-related activities.

Currently, there exist three approaches to conceptualizing the evolution of the construct of gender: the cultural approach, the structural approach, and the cognitive approach. The cultural approach suggests that the acceptance of culture and society's values and norms occurs through societal rewards and that punishments contribute to the appearance of gendered behavior. Through rewards and punishments, children become socialized to behave according to cultural and societal demands. The acceptance of cultural gender values continues throughout the life cycle and leads to the reinforcement and eventual perpetuation of gender stereotyping.

Another approach, the structural approach, suggests that the constant evolution of structural and social role requirements guide individual experiences in both the societal and family levels. The structural approach places less emphasis on the socialization of gender-typed behaviors and traits; rather, it examines the common positions occupied by certain groups within the existing social structure. For example, researchers found that occupational roles outweighed gender information as a strong determinant of traits assigned men and women.

Stereotyping is another cognitive process by which gendered beliefs become perpetuated and solidified. Stereotyping presents an avenue through which information becomes cognitively categorized in order for

individuals to process unmanageable amounts of complex information. The formation of stereotypes allows people to form manageable categories based on similarities in which newly encountered people and objects fit. Although stereotypes represent highly efficient modes of organizing information, they often become generalized and oversimplified. Stereotypes represent widely shared and socially validated beliefs or cognitions regarding whole groups of people that become applied to individual members of that group. Stereotypes differ from prejudice, as prejudice refers to an attitude toward a group that often manifests itself as hostile and negative. Therefore, a stereotype represents a cognition or thought, whereas prejudice represents an attitude and often a behavior brought about by that attitude. The cognitive process and the inherent danger of stereotyping applies to gender in addition to ethnicity, socioeconomic class, and religion, for example.

2. GENDER ACQUISITION IN CHILDHOOD

Gender socialization, or the process of learning gender roles, begins at the onset of human life and occurs through cultural, structural, and cognitive avenues. The first statements at the birth of a child include references to the sex of the infant. Parents and friends alike agonize over the purchase of blue or pink gift items according to the sex of the newborn. Beyond the acquisition of items that are “blue for boys” and “pink for girls” and the inherent information presented by these items, infants encounter different treatment based on their sex. Adults, whether knowingly or not, handle infant girls more gently than infant boys, and comment upon the delicate features of girls but on the strong features of male infants. For example, as soon as 24 hours following the birth of a child, mothers and fathers describe female infants as finer featured, softer, smaller, and more inattentive as compared to male infants. This occurs despite the lack of significant differences between female and male infants in both birth length and weight. This difference in treatment occurs even prior to children’s acquisition of language and before they become cognitively aware of gender-appropriate behavior.

The acquisition of gender identity becomes apparent in children by the age of three. Social learning theory offers an explanation for the development of gender roles and gender-typed preferences at such an early age. It suggests that children learn gender-appropriate

behavior through the observation of others. This occurs through observational learning in which the child watches the behavior of others, parents and other adults alike, and mimics their behavior. In addition, adults reinforce children for acceptable gendered behavior and punish them for violating gendered expectations. For example, if a young boy begins to play with his sister’s doll, his parents may look at him disapprovingly or even remove the doll from his play area. In addition to experiencing reward contingencies directly, children witness vicarious reinforcement. Vicarious reinforcement refers to the observed reinforcement or punishment of parents, friends, teachers, and television characters for their gender-consistent or -inconsistent behavior, which children imitate depending on the anticipated reward. The reinforcement of observed others sends messages to the child regarding the acceptability of the observed individual’s actions. Therefore, children receive information regarding not only the actual mechanics of behaviors but also the social value in imitating them.

The process of gender socialization also takes place bidirectionally, with children participating in their own socialization. Children cognitively categorize the information they actively learn through the reinforcement and modeling of gender-appropriate behavior. Cognitive-developmental theory suggests that children desire to display prescribed gender-appropriate behaviors. While reward contingencies shape some gendered behavior, children also form their own preferences regarding toys, activities, and same-sex individuals. In a cyclical fashion, social and cognitive processes maintain these gender preferences, and both encourage the reinforcement and performance of gender-consistent behavior. In turn, the performance of appropriate gendered behaviors increases the reinforcement of gendered activities and cognitions.

Children often prefer to wear gender-appropriate clothing and play with same-sex peers. Often this occurs due to children’s own inability to remember or categorize same-sex behaviors and traits correctly. Therefore, children use general in-group (individuals perceived as belonging to the child’s own group) and out-group (individuals perceived as not belonging to the child’s own group) favoritisms to guide their own behaviors. For example, a girl may express the belief that her same-sex peers are more friendly, honest, and humorous than the same-sex boys group. However, the boys feel the same way toward their same-sex peers and feel negatively toward the opposing group of girls.

Child peer preference also occurs due to the propensity of parents and child-care facilities to segregate children into same-sex play groups based on gender-typed activities. These activities (such as sports or group projects) encourage bonding among their participants and the formation of in-group and out-group stereotyping and grants children a venue for developing more same-sex relationships. In addition, children, like adults, pay attention to and remember behavior consistent with their gender stereotypes. Conversely, gender-inconsistent behavior passes unnoticed and unassimilated into the child's general gender schema. As a result, children learn that boys and girls normally spend time apart and in different activities.

3. THE HARMFUL EFFECTS OF GENDER STEREOTYPING

Due to the classification of gender into "feminine" and "masculine" qualities, traits, behavior, or activities, gender becomes prone to stereotyping. Due to the salience and visibility of sex, it becomes the basis for cognitive categorization (age, race, and ethnicity offer some other examples), and a number of gender stereotypes become founded on the perception of an individual as a member of the male or female sex. Whether stereotypes actually reflect differences between men and women remains debatable. Biology, the environment, or an interaction of the two may actually be responsible for differences in males and females. However, applying stereotypes to individuals presents some danger, despite any apparent truth at the group level. The deeply engrained and subtle nature of gender-associated processes causes most individuals to remain unaware of their impact on behaviors, attitudes, cognitions, language, interpersonal relations, and the structure of social institutions.

3.1. Sex Discrimination and Sexism

Gender stereotyping becomes problematic, especially for women, considering that judgments of female gender are formed in regard to ambiguous and intangible traits such as an individual's "congeniality," "warmth," or "interpersonal communication skills." Research conducted during the 1970s and 1980s indicated that women were portrayed as more expressive and communal. Men were viewed as more competent, agentic, and instrumental. In addition, these gendered differences in

beliefs regarding personality traits superseded beliefs regarding appropriate roles and occupations.

Stereotypes of women also differ based on race, class, or ethnicity. For example, traits such as "warm," "vain," "dependent," and "intelligent" were frequently applied to White women, while traits such as "dirty," "hostile," "emotional," and "superstitious" were generally applied to Black women. In addition, people view middle-class women as more "intelligent," "ambitious," "competent," and "happy." Lower class women became viewed as "talkative," "irresponsible," "dirty," and "dependent." Stereotypes of women become especially hazardous considering sex discrimination and sexism.

3.1.1. Sex Discrimination

In general, the term sex discrimination refers to the harmful and unequal treatment of individuals based on their sex. Sex discrimination occurs as a function of cognitive internal processes coupled with the power men exert in invoking anti-female prejudices in everyday practices, resulting in the denial of the same privileges enjoyed by men. Women remain the frequent targets for sex discrimination, which produces greater disadvantage for them. While men experience discrimination based on other social variables (religion, age, race, or sexual preference), their gender neutralizes the experience of these sources of discrimination. However, being female remains the largest predictor of discrimination over any other variable because it is interlaced with other social variables (such as age, race, social class, and ethnicity), which produces a greater disadvantage.

3.1.2. Sexism

The experience, impact, and severity of sexism varies depending on its intentionality, visibility, and ease of documentation. Blatant sexism occurs when women face transparently harmful and unequal treatment. This type of sexism includes physical violence, sexist jokes, degrading language, sexual harassment, and unequal treatment under the law or in employment. Less apparent, subtle sexism remains less visible to others and the targeted individual. More often it lacks the focus of other forms of sexism in its intention, maliciousness, and manipulateness. This type of sexism might occur when, for example, a male friend jokes about women always leaving to go to the bathroom together. The friend's comment lacks the harmful intention, manipulateness, or maliciousness of other forms of sexism. This type of sexism can be easily

documented; however, it often passes unreported due to the lack of a perceived threat.

Sexism in the form of deliberate behavior designed to sabotage women's efforts socially or in the work place represents an intentional, hidden, and frequently hostile attempt to thwart women and ensure their failure. For example, a man may go out of his way to slash a woman's tires, making her unable to arrive at work on time, or he may erase the content of her computer prior to an important presentation. This type of sexism presents difficulties in documentation, as the strategies used remain easily denied.

3.2. Suggestions for Minimizing Harmful Stereotypes

The danger of applying gender stereotypes negatively through sex discrimination or through blatant, subtle, or covert sexism raises the question, How do parents and other adults minimize gender stereotyping? Some parents believe that by avoiding the imposition of gender role constraints and pressures their children will develop more fully. There exist different reasons for parental focus on reducing gender constraints on their children, as well as implications of gender role research on parenting practices. Parents give a number of reasons for their desire to decrease their children's exposure to gender-stereotyped roles. First, many parents believe that androgynous characteristics and gender flexibility contribute to mental health. Second, many of these parents believe that the attainment of gender equality depends on the debasement of gender roles in the separate spheres of influence traditionally inhabited by females and males (e.g., the home as the women's sphere of influence and the workplace as the man's sphere of influence). Third, they believe that men and women remain more similar than different. Finally, these parents also believe that traits belonging to both genders increase success in today's technologically savvy world. Parents with such goals sometimes find their efforts frustrated, and psychological evaluations of parenting practices oriented toward decreasing gender-stereotyped cognitions and behaviors remain mixed. This is discussed in the article on gender role development in this section.

Parents who desire to minimize the effects of cultural pressures on gender role identity formation can take several steps. First, to take advantage of children's propensity to display interest in activities preferred by same-sex individuals, parents can give examples to their

children of same-sex individuals participating in those activities. For example, if parents want their daughter to participate in track and field competitions, they should show their child pictures of a female world-class athlete winning an Olympic medal. Second, parents should present their children with a range of activities and playthings with the hope that they prefer some non-gendered objects and activities. In addition, parents should request that other family members give gifts intended for both sexes, or those intended for the other sex, and encourage their use equally. Third, due to the powerful effect of parents as role models, parents should attempt to display gender-inconsistent behavior as often as possible. Parents should also seek out other role models, such as teachers, who value nontraditional gender roles, refrain from segregating groups on the basis of gender, and attempt to minimize children's exposure to traditional gender roles through television and literature. Fourth, parents should give their children gender-neutral toys and encourage their participation in activities that both sexes enjoy, thereby decreasing the amount of time children spend in stereotypic gender play. Fifth, parents should remain consistent regarding children's exposure to gender-inconsistent and gender-neutral material and behavior. Often this includes refraining from discouraging gender-inconsistent behavior in their children, such as a boy playing "dress-up." Finally, as children approach middle childhood (ages 9 to 12), they become more cognitively developed. By teaching children critical thinking skills and challenging their dogmatic gender cognitions, parents may successfully counter the effects of gender stereotypes.

4. GENDER'S SEXUAL COMPONENT

Gender roles manifest themselves culturally, structurally, and cognitively in many spheres of human interaction, including sexual interaction. Sexual gender role behavior begins in childhood and develops through life. Gendered sexual behavior becomes learned early in life through biological and social reinforcements ("nature" versus "nurture"). These biological and social reinforcements occur differently for males and females and continue throughout the life cycle.

Early childhood sexual behavior begins as children explore their surroundings and themselves. Children experience pleasure through contact with their genitalia, and this pleasure serves as conditioning for future self-stimulation. Genital pleasure also occurs accidentally through the child's contact with objects that create

stimulating responses. Through exploration children learn about the pleasure that results from masturbation. These biological processes serve a purpose for the developing child, both providing the child with sexual reflexes and assisting in the development of neural pathways in the brain necessary for the experience of sexual pleasure. However, the responses of parents and caretakers to young children's self-initiated stimulation determine the ways in which children feel about sexual behavior and their own sexuality.

Parents differ in their responses to their child's self-stimulation. Some parents adopt a normative view regarding their child's exploration and self-touching. Parents who allow their children to explore their sexuality allow positive Pavlovian conditioning and decrease sexual inhibitions. However, some parents regard self-pleasuring behavior as abnormal, and according to cultural beliefs as dirty or sinful, and often use punishment in response (e.g., spankings, harsh tones, or physical reprimand). Unfortunately, children receiving harsh punishment for self-touching repress their masturbation and experience long-lasting inhibitions. Many parents allow some forms of self-touching but punish others, thereby inhibiting and punishing their child.

Young children encounter many different double standards in regard to sexuality and sexual pleasure. Baldwin and Baldwin, in their article on sexual behavior in this section, discuss parents' unequal treatment of sexual behaviors exhibited by their children. First, parents punish girls for masturbation more often than boys, leaving boys with a greater impression of acceptance of sexual self-stimulation. This causes girls and women to become more uncomfortable with exploring different forms of self-pleasuring. Second, even the language used in naming and referencing of children's genitalia gives evidence to this double standard. While boys genitalia becomes referred to as "pee-pee" or "wee-wee," parents give socially detailed information to their girls in the names they provide, such as "treasure box, to open after marriage." Parents often neglect to inform their children about the uses of their genital organs, especially their use in pleasurable activities.

Throughout their childhood, children learn about sexuality from information gathered through observation of parents, other adults, television, film, and literature. Contrary to adult beliefs, children often remain more attentive to sexual information and learn from observation. Parents often assume that children remain oblivious to the sexual content and innuendos present in media and adult behavior. However, considering children's attention to the abundance of sexually

suggestive material available to them, they are more exposed to sexually explicit material than their parents might think. Some concerned parents offer their children explanations of sexual material, thereby opening a dialog and equipping their children to better process sexual information and to incorporate the parent's values into this process. However, some parents fail to offer advice regarding sexually explicit material and risk their children accepting sexual violence as normal and natural. For example, while sexual harassment and rape represent a manifestation of power inequality between men and women in which men view women as objects designed to fill their sexual desires, learned gender stereotypes and sexual scripts contribute to the view of men as the initiators of sexual contact and of women as the gatekeepers who rebuff sexual contact.

Parental lessons taught to children regarding their sexual self-pleasure and their observations carry social implications for adolescent and adult sexual behavior. Parents tend to offer girls more guidance regarding sexually explicit media as compared to boys, possibly due to the fear of possible detriment to girls resulting from sexually transmitted infections, pregnancy, and internal injuries resulting from forcible sexual activity. Parents, adults, and media messages therefore convey a message of responsible sexual behavior for girls, but neglect to focus this message on boys. This message becomes especially potent during adolescence, when secondary sex characteristics emerge, causing males and females to appear more adult-like. Baldwin and Baldwin suggest that biological differences in males (e.g., their more visible and often spontaneous sexual arousal and orgasms, and the more visible changes in outward genital appearance) cause them to become more curious and interested in sexual activity at an earlier age. However, this level of curiosity and interest differ depending on the inhibitions and positive associations formed in childhood through interactions with parents, other adults, and media influences.

The interaction of nature and nurture during adolescence creates gender-related sexual behavior differences. Adolescent females, for example, become more concerned regarding possible pregnancy, abortion, sexually transmitted infections (STIs), and sexually transmitted diseases (STDs). In addition, certain social stigmas become evident during adolescence. For example, adolescent females become labeled as "sluts," "easy," or "loose" if they participate in sexual behavior with a number of partners. However, male adolescents receive the label of "stud," which often improves their social status or popularity, if they participate in sexual

behavior with many females. As a result, female adolescents develop more inhibitions regarding sexual behavior, and they tend to become more concerned about the number of partners they engage in sexual behavior with.

The social context of double standards in sexual behavior also contributes to the actual content of sexual activity in adolescence and often in adulthood. Adolescent females often take passive roles in sexual encounters, due to the belief that “nice girls” do not initiate or aggressively pursue sexual pleasure. In addition, females tend to feel uncomfortable and worry about how their partner perceives them if they seem too eager or display too much sexual knowledge. Conversely, actively pursuing sexual contact and obtaining vast amounts of sexual experience become the expectation for male adolescents. In addition, men often state their motivation for seeking sexual activity as oriented toward sexual pleasure or enjoyment, whereas women view their motivation for sex as the desire for love and commitment. The biological differences between men and women fail to offer any support for the differences between male and female sexual behavior. Rather, sexual behavior differences may result from the role expectations conferred upon both men and women.

4.1. Cultural Views of Sexuality

In a larger cultural context, sexual behaviors and values remain important aspects of all societies. Societies differ in the various meanings attributed to sexual intimacy according to their sexual permissiveness, the expression of their sexual values, views regarding contraception and birth control, and the health issues involved. Some broad generalities exist within this infinite variety and the individual differences existing within each culture. Cultural, socioeconomic, historical, global, and technological contexts determine the commonalities and differences in beliefs and behaviors occurring in societies. The large amount of information available to people through globalization and technology allow them to engage in social comparison and augment their understanding of what is natural and normal, thereby shaping their attitudes toward sexual issues and the acceptability of different sexual behaviors.

The permissiveness or restrictiveness of the culture in which an individual lives determines sexual behavior for both genders. A culture’s technological advancement, religious orientation, socioeconomic importance placed on marriage, and significance placed on reproduction influence the degree to which it becomes permissive and accepting of sexual behavior. Positive attitudes toward

sexual development as part of healthy social adjustment characterize societies with permissive attitudes toward sexual behavior. Permissive cultures place less restrictions on sexual activities and provide children with sexual information (e.g., through ritual or institutional practice, or through exposure to nudity). Restrictive societies limit exposure to sexual information and attempt to repress sexual expression. These societies often view sexual behavior as dangerous, sinful, or harmful. This view toward sexual behavior often stems from societal values regarding the expected goals of its members. For example, parents in the United States often expect their children to obtain college degrees and marry at older ages. The possible risks of participating in sexually intimate activity (e.g., pregnancy or the contraction of AIDS) run counter to the goals of educational success and economic prosperity. Sexual activity, therefore, becomes risky in these cultures due to the possible threat to an individual’s social status, physical health, or psychological well-being. In restrictive cultures, abstinence prior to marriage is stressed, often for women more than for men.

The risks of sexual activity often dictate cultural views of sexual activity prior to marriage. Agrarian and hunter–gatherer cultures often perceive premarital sexual intimacy negatively due to the lack of availability of birth control options. In contrast, industrialized societies increasingly view premarital sexual activity more permissively due to advances in birth control technology, the increasing time gap between sexual maturity and marriage, and rising economic equality between men and women. Societies also differ in their permissiveness of other forms of sexual expression, such as homosexuality and transgenderism.

4.2. Homosexuality

As with heterosexual sexual behavior, cultures display either permissiveness or restrictiveness regarding homosexual sexual behavior according to the socio-historical and socioeconomic contexts. Generally, homosexuality refers to sexual attraction to members of an individual’s own sex. Cultural differences in the definition of “sex” and the meanings attributed to different sexual behaviors between people of the same sex often lead to contrasting ideas regarding what homosexual behavior entails. Cultures with a narrow definition of sex, such as consisting solely of penile–vaginal intercourse, may accept a great deal of same-sex intimate behavior.

Gender role perception remains linked to conceptualization of homosexuality in many societies. In some

cultures, men participate in homosexual relationships yet refrain from identifying themselves as homosexual. The roles that these men undertake during homosexual activity assist them in avoiding the stigma that accompanies this behavior. These men may remain considered heterosexual due to the adherence to the masculine norms of their gender. For example, males in prison may participate in homosexual sexual activity; however, because they maintain “masculine” gender characteristics, may escape the social label of homosexual.

In other cultures, such as the United States, homosexuality is defined less according to gender roles, but rather becomes perceived as an intrinsic aspect of the individual. In cultures ascribing homosexuality as part of the individual, individuals experience flexibility in the sexual roles they assume. Increasingly, many cultures are adopting Western views regarding homosexuality, especially due to the proliferation of scientific and political information regarding a possible genetic basis for homosexuality. Due to the Puritanical nature of Western society and its history of discrimination directed toward homosexual individuals (including hate crimes), the shift in values creates a difficult atmosphere for those with other sexual orientations.

4.3. Transgendered Individuals

Some individuals adopt the gender roles of the opposite sex. These transgendered individuals prefer the gender roles or identities of the opposite sex and either continue to behave in accordance to the roles granted them by society or outwardly display the identity and roles they perceive as their true gender. Some transgendered individuals choose to adopt the dress and mannerisms of the other sex, or pursue sex reassignment surgery. Transgenderism does not necessarily apply to cross-dressing, because the motivation for cross-dressing does not always entail a strong preference for opposite gender roles and identities.

4.4. Homophobia

The tendency of other cultures to adopt Western views regarding homosexuality becomes increasingly problematic due to the reflection of Puritan attitudes regarding sexual behavior and gender roles in the United States. Individuals fundamentally threatened by homosexual attractions and relationships claim that traditional morals and family values become eroded by the acceptance of homosexuality. These attitudes rest at the root of discrimination based on sexual orientation. Individuals

identifying themselves as homosexual, or even appearing to display homosexual “traits,” experience discrimination (e.g., in the workplace, regarding club membership, in school attendance, in obtaining housing and credit, and in obtaining services at places of business) despite the outlaw of discrimination and violence directed toward individuals based on sexual orientation. Discrimination based on sexual orientation, while illegal, occurs frequently in Western society.

On the individual level, part of the discrimination against homosexuals, bisexuals, lesbians, gays, transsexuals, or transgendered individuals occurs due to homophobia, or anti-gay attitudes or behaviors. The term homophobia implies an intense fear of homosexuals (being touched, looked at, or approached by a homosexual) due to the use of the Greek word “phobia,” meaning fear. However, while some individuals exhibit an intense fear of homosexuals, the term best describes a heterosexual bias in which heterosexuality is viewed as the norm and superior compared to homosexuality. Often this bias causes individuals to ignore other forms of attraction and attitudes, focusing solely on heterosexual attractions and attitudes. The same prejudices found to contribute to the discrimination faced by women also apply to the discrimination faced by homosexual individuals. Homosexual individuals become evaluated or judged as a group toward which many members of society express negative attitudes and beliefs. Heterosexuals who adhere to a more “traditional” ideology of family and gender, who hold strong religious beliefs, and who maintain friendships with people expressing anti-homosexual attitudes tend to express stronger anti-homosexual beliefs and attitudes. Heterosexuals who experience more contact with homosexual individuals express fewer negative attitudes toward homosexuality as compared to those with little contact with homosexual individuals.

Homophobia affects homosexual individuals’ social well-being as well as their emotional and psychological well-being. Internalized homophobia occurs when homosexual, lesbian, gay, bisexual, transgendered, or transsexual individuals feel negatively about themselves based on their sexual orientation. Homosexual individuals also risk adjustment difficulties arising not only from internalized homophobia, but also from the social stigma attached to homosexuality. In addition, very pronounced fears regarding the AIDS pandemic and its labeling as a “gay” disease caused many homosexual individuals to resist their sexual orientations in order to avoid contraction of the virus. Although the stigma of AIDS as confined to the homosexual and

intravenous needle-using population abated and this belief became replaced by more informed views, many homosexual individuals still experience the stress of anti-gay sentiment.

Homosexual men and women experience high levels of stress due to their marginalization in society. Historically, the mental health field confronted homosexuality as a form of psychopathology; however, this view evolved somewhat and many mental health professionals remain supportive of gay and lesbian identities. Although both the mental health field and society are moving toward a more accepting view of homosexuality, greater attention is needed in addressing the social stressors contributing to the developmental difficulties faced by homosexual individuals.

5. MARRIAGE AND PARENTHOOD

5.1. Marriage

Marriage represents another social context in which gender plays a large part. In most societies, marriage remains an antecedent of the nuclear family, consisting primarily of a husband, wife, and children. The larger, extended family consists of those related by blood to the members of the nuclear family, for example, the grandparents, aunts, uncles, and cousins. The socio-historical context of the family frames the gender roles occurring within its influence.

During most of human history, people perceived marriage as essential due to the needs of both men and women. The labor of caring for and maintaining a family became shared by both the man and the woman, usually with the man undertaking the role of the hunter and breadwinner and the woman being responsible for the care of children. Both men and women needed the product of the other's labor, not only for their individual survival, but also for the survival of the next generation. In addition, in many cultures marriage remains beneficial in regulating sexuality, providing legal ties between women, men, and their children, and creating economic and social stability.

Women receive the greatest amount of social pressure to marry. The importance of the family remains paramount in most modern societies, despite the existence of many opportunities for women to work and participate in social life, politics, and religion. From a very young age, girls receive education regarding their eventual role as wife and mother. Women who remain unmarried, or elect to forgo marriage, face social stigma

(e.g., they receive the name "spinster") and pity unless they take on a socially accepted role such as a nun. As a result of the social stigma attached to remaining unmarried, many women experience a feeling of inadequacy or deprivation. Consequently, families attempt to ensure marriage for their daughters (in some cultures, with arraigned marriages).

For many married women, large segments of daily life remain occupied by the roles of wife and mother, with family obligations at the forefront, despite other obligations. For example, many women in the United States work and care for their families, often maintaining the role of primary caretaker for their children as well as full-time employment. In most Western societies, household maintenance remains unequally allocated between husband and wife, often with the wife assuming the lion's share of daily domestic activities such as cooking, cleaning, laundry, and child care. Evidently, the increase of time-saving technology, the changing social landscape in regarding the increase of women in the workplace, and the rise of gender equality ideals have failed to fully evaporate traditional gender roles.

Evidence of the asymmetry in traditional marriages occurs in various facets of marriage customs, including the assumption of the husband's last name. This also occurs in the conceptualization of marriage in regard to occupations. The expectation of the wife as a "junior partner" in a man's occupation occurs presently in many societies. For example, the wife of a baker becomes the "baker's wife," or the wife of a wealthy banker becomes the "banker's wife." The wife becomes incorporated into the husband's occupation, as an extension of himself. The "baker's wife" may not appear on the payroll; however, she participates in the daily activities of the bakery. The "banker's wife" may appear as the social face of her husband's occupation, contributing to charities and attending social functions. Wives of politicians provide another example; society expects them to place their aspirations aside in order to participate and contribute to their husbands' endeavors. To a large extent, societal expectations of gender roles in marriage dictate the experiences of married women.

In some societies, wives remain subservient to their husbands. In fact, in most parts of the world women's rights and entitlements remain secondary to those of their husbands. A woman may lack control over finances, lack legal rights to inheritance, be considered the property of her husband, and in some societies become the ward of her children in the event of her husband's death. In past extreme cases, women in India were expected to burn themselves alive following

the death of their husband (suttee). The Indian government outlawed the practice, and the actual current incidence remains questionable. The *Code of Manu* (a list of life rules well established by 200 B.C.E.) stated, "She must on the death of her husband allow herself to be burnt alive on the same funeral pyre; then everybody will praise her virtue" (Noss & Noss, 1984; p. 181). Although suttee represents an extreme situation, many women still face societal judgment based on their ability to live up to gender role stereotypes such as maintaining a cleanly and ordered household.

In the past, societies expected individuals to marry for greater financial stability, to reproduce through engaging in socially approved forms of sexual activity, and to form family alliances. In many societies, marriage forms the foundation of families and basis of society. However, other political, social, and economic institutions in industrial urban societies often debase the perceived social function of marriage. Improved technology and economic organization decrease the need for the division of labor based on gender. However, the perception of marriage and the inherent expectations that accompany the institution contribute to the perpetuation of gender role stereotypes and expectations. In addition, due to continued inequalities for women, such as unequal pay, women still maintain strong financial and social motivations for marriage. Same-sex marriages bear mentioning here. While some countries allow same-sex marriages, homosexual couples in the United States struggle for the permission to marry. (Massachusetts is the only state in the United States currently permitting same-sex marriage.) Same-sex couples desire the social, financial, and legal security afforded to heterosexual couples. Therefore, the motivations behind same-sex couples' desire to marry remain the same as the motivation behind heterosexual marriages.

5.2. Parenthood

While many couples choose to marry later and improve their quality of life prior to the birth of their first child, the decision to have children often accompanies a shift toward traditional gender roles in the family. This occurs in part because of the perception of motherhood as the ultimate fulfillment of womanhood. For example, until recently, pregnant women left the workforce in anticipation of children and became full-time homemakers and mothers.

The expectation of women assuming the sole role of motherhood following childbirth grew out of the view that mothers maintained the most important influence

over the child's development. However, further research suggested that children with fathers who play an active role in child rearing develop higher intellectual capacity and higher levels of empathy toward their peers. This affects fathers as well; they display higher self-esteem in general, greater satisfaction in their role as a father, and higher confidence in their parenting abilities. Fathers sharing in household responsibilities and childcare also experience greater marital stability.

Despite the benefits of father participation in household and childcare responsibilities, the mother remains more likely to remain home with the child after birth, at least part-time. The mother, therefore, participates more fully in meeting the child's needs, primarily because she remains in the household while the father continues to work. Often this causes the woman to undertake the management of the family's emotional life (including worrying about the state of the marital relationship), the child's everyday needs, and social relations with extended family members.

Yet women in Western societies often return to work, either following the termination of their maternity leave or after their children depart the home. However, parenting demands remain stronger for women. Even with provisions for childcare, working mothers often experience conflicting demands of their jobs and their children, sometimes to the detriment of their mental health. This conflict often becomes exacerbated in the case of single-parent households.

5.3. Single Parenthood

Single parents face a different set of difficulties, as they assume both gender roles. Single mothers and fathers may experience role overload as they attempt to ensure their family's economic survival in addition to managing the household and finances. Employers are often insensitive to the conflicting needs of work and home, expecting full commitment from their employees. Single-parent difficulties become compounded due to the antiquated design of the workplace, which best suits men with wives who manage the household. These issues become especially difficult for single mothers, who face the same discrimination experienced by other working women; however, the situation becomes more desperate considering their status as the provider for the family.

While some single parents encounter social difficulties fitting in with married couples and encounter difficulties in dating, as the number of single parents increases, more opportunities for forming social support networks

are arising. In addition, some divorced women express a sense of accomplishment and fulfillment, while many single mothers enjoy their autonomy and independence. Single fathers also make caring for their children an important priority. Despite the difficulties faced by single parents, single parenthood offers the custodial parent an opportunity to experience both gender roles.

5.4. Gay and Lesbian Parents

Gay and lesbian parents, either single or in committed relationships, find themselves in a unique position. These parents face many problems resulting from the social stereotypes regarding their abilities as role models for children. Despite the concerns put forth by society, many homosexual parents have children from previous heterosexual relationships, adopt children, obtain the assistance of a surrogate, or undergo in vitro fertilization. Contrary to public concerns regarding gay and lesbian parents' abilities to raise well-adjusted heterosexual children, studies indicate that children raised in households with gay and lesbian parents enjoy outcomes similar to children raised in households with heterosexual parents. The raising of children by homosexual couples does not increase the likelihood of children becoming homosexual later in life. While these results show promise, homosexual parents still struggle to protect their children from the negative public opinion of gay and lesbian parenthood.

6. GENDER AND OLD AGE

6.1. Gender and Medical Concerns

Men and women experience the aging process differently, both physically and psychologically. Both medical and psychological literature contain gender bias, as researchers often falsely assume either equalities or differences between the sexes. Many researchers conduct their research using only male samples and then generalize the results to females. For example, researchers receive promising results when using vitamin therapy to decrease hair loss in men and advocate the therapy for use by both men and women. However, the vitamin therapy may not work as well, or at all, in women. While this is a fictitious example, some researchers approve treatments for women regardless of their biological differences, sometimes with detrimental results. In addition, researchers also overlook the incidence of diseases, defects, and illnesses by labeling them as either

“men’s” or “women’s.” For example, many prevention strategies target women for osteoporosis. Television commercials advertising calcium consistently refer to women’s bone loss and the necessity of increased calcium consumption. However, although women have a higher rate of osteoporosis (one in two women experiences osteoporosis), men also experience bone loss (one in eight experiences osteoporosis). This may lead men to ignore the signs of bone loss or seek treatment later after serious damage occurs.

In addition to the research and prevention strategies for illnesses and disease, men and women experience different illnesses based on their biology. Women have different medical concerns throughout their lifespan (during pregnancy, menstruation, contraception, and menopause, for example). In addition, men and women differ in the incidence and severity of mental illness, due to their differing physiology and environmental stressors. Researchers and other health professionals now seem to recognize that both similarities and differences exist between females and males. In fact, the recognition of women’s health as a distinct entity attests to the growing acceptance of quantitative and qualitative differences in the effects of health-related issues on both men and women.

6.2. Gender and the Psychological Experience of Aging

Women and men also experience aging differently psychologically. Women often view aging negatively as the loss of youth characterized by the loss of attractiveness, and the loss of the ability to produce and nurture children. Men, however, view the graying of hair and wrinkling of skin as adding character. The appearance of age does not threaten the traditional gender stereotypes of men as competent, autonomous, and self-controlled; in fact, the appearance of age often serves to “add character.” This creates a double standard: as women become viewed as less attractive due to the appearance of age, men become viewed as more attractive for the very same age indicators (e.g., some extra pounds, wrinkles, and gray hair). Youth-oriented society plays a large part in reinforcing views of aging and its experience, especially for women. One study found that the promise of “youth, youthful appearance, or the energy to act youthful” appeared in 57% of monitored television advertisements. However, senior citizens in

these same advertisements dealt with loose dentures, constipation, and backaches.

6.3. External Perceptions of Aging

The emphasis placed on youth and the appearance of youth in culture also influences the ways in which aging individuals are perceived. Researchers found that older women were perceived as more active in the community, more personally acceptable, less self-centered, more nurturing, and more sensitive as compared to older men. However, an older woman perceived as lacking competence is judged more harshly and is perceived as experiencing cognitive decline.

6.4. Ageism

Because women often outlive their male counterparts and make up the majority of the elderly population, they necessitate greater medical and psychological consideration. Older men usually are cared for by women, making them less susceptible to the effects of ageism. Often women do not share this luxury. The lack of any buffers against ageism causes women to become the subject of more age-related jokes. This becomes especially problematic if the loss of her husband and the constraints of living on a restricted budget require an elderly woman to seek employment. Age discrimination occurs in large part due to the view that women's responsibilities as child caregivers decline and end in middle age, therefore placing them at the end of their responsibilities and accomplishments.

7. FEMINISM

Feminism represents one approach to addressing the necessity of different perspectives on gender, as opposed to a purely male-oriented perspective, in research, theory, and practice. The term feminism refers to a belief in and commitment to the social, legal, and economic equality of women. This includes the belief in the equal value of women as well as their equal rights. The broad-based perspective and the incorporation of different ideologies provide feminism with a unique frame of reference. There exist different kinds of feminism (socialist, radical, cultural, and liberal); however, each viewpoint and theory intersects and maintains commonalities with other theories of feminism.

Socialist feminism focuses on social relationships and the preservation and promotion of male dominance in

social institutions. The necessity of change in the economic system remains the primary focus of socialist feminism, as economic and sexist oppression reinforce each other in society. Inequalities stemming from race, socioeconomic class, and ethnicity also become the focus of research under this theory. This type of feminism stresses the unity and integration of all aspects of women's lives in order to produce unified feminist theory. Social feminists desire the restructuring of social relationships and social institutions to create economic equality, and therefore social equality, between men and women.

Radical feminism focuses on men's control over and oppression of women, which remains the primary source of women's oppression economically and socially. This theory advocates for the destruction of existing class and gender inequalities and the creation of a new culture and society founded upon shared power between the sexes. Radical feminists believe that women-centered beliefs and systems remain essential to the end of women's oppression. In contrast to other feminist groups, radical feminists reject all forms of feminism based in male-developed theories. In their view, women must create and develop feminism and root it in their own experiences. Radical feminist research often examines the relation between men's societal power and sexuality and violence.

Cultural feminism emphasizes the qualities and characteristics generally applied to women, such as caring, nurturing, and concern for the needs of others, which society usually devalues and ignores. Cultural feminism focuses on increasing the acknowledgement and honor of women's contributions (usually unpaid) to society and culture.

Liberal feminism, or "equal opportunity feminism," focuses on the promotion of legal and social equality between men and women. This theory advocates for a revision of values, laws, and mores associated with the inequality of women in society. In addition, the concept of males and females as more similar than different remains central to this theory, as liberal feminists believe that women and men will exhibit similar behavior if afforded equal opportunities. Liberal feminists call for equal consideration regardless of gender; they do not seek special privileges. Liberal feminism claims responsibility for revisions in language, media representation of women, and changes in religious practices, which formerly contributed to stereotypical views of women in society and inequality based on gender. Due to the stigma attached to the term feminism, many people avoid classifying themselves as feminists.

However, many individuals express beliefs in gender equality consistent with liberal feminism.

8. SUGGESTIONS FOR APPLIED PSYCHOLOGY

The adoption of feminist ideals regarding gender equality in scientific research, theory, and practice would serve to increase sensitivity regarding the needs of both men and women. These ideals serve to exact change in the cultural, structural, and cognitive views of gender, gender roles, and gender-appropriate behavior. The expansion of ideologies pertaining to gender role development, behavior, and attitudes to include often-neglected alternative views (such as those inherent in homosexuality and transgenderism) might serve to lessen the incidence of the discrimination of historically marginalized groups. In addition, a closer understanding of gender stereotypes and their formation along with social and cultural ideological change might contribute to fewer incidences of medical and psychological problems associated with gender discrimination, sexual harassment, and rape.

This article describes psychological, social, and cultural factors that lead to the development of gender roles. It provides advice for parents who wish to encourage their children to be more individualist and less gender stereotyped in their behavior.

1. TOWARD A MODERN INDIVIDUALIST SOCIETY

GLOSSARY

gender A term used to classify individuals based on psychological and behavioral characteristics, social activities, and cultural expectations that are often based on beliefs about people's sex; the terms girl/woman/feminine and boy/man/masculine are gendered classifications.

gender identity A term used to describe an individual's own belief about his or her gender classification (e.g., "I am a girl," "I am a boy"); by 3 years of age, most children's gender identity is fixed, and in most cases, it matches their biological sex.

gender role Social norms for the behavior of girls/women and boys/men; these are considered to be meta-roles in that they also influence expectations of people's behavior in subroles.

sex A term used to classify individuals based on biological characteristics related to reproductive capacity (e.g., chromosomes, hormone levels, gonads, genitalia); most cultures maintain a binary classification of individuals as either female or male, although some have long recognized the presence of intersex individuals by providing three or more categories of sex.

Parents who describe themselves as modern, liberal, feminist, and/or nontraditional often say that they want to raise children who are free from gender role constraints and, thus, are able to develop into full human individuals who can be "themselves." These parents set that goal for various reasons, including some (or all) of the following: (a) the belief that the flexibility of androgyny is good for people's mental health; (b) the conviction that women and men will never reach political and economic equality so long as traditional gender roles maintain the expectation of separate spheres (i.e., that women belong in the private sphere and should exercise power in the home, whereas men belong in the public sphere and should exercise power in business and government); (c) the belief that women and men are more alike than they are different and that, therefore, similarities (rather than differences) should be emphasized; and (d) the fact that technology (e.g., contraceptives, power tools, computers) has changed modern life to such an extent that the specialized talents (e.g., nurturance, physical strength) that gender

roles describe are no longer essential for success in modern life and that, instead, both women and men need combinations of feminine and masculine traits to succeed. These parents tell their children that they can be or do anything they choose, provide them with both traditional and nontraditional toys and games, and try to model androgynous behavior themselves, for example, by deliberately showing their children that both women and men can be both competent and kind.

How successful are these parents in reaching their goal? The results are mixed, and parents find that it is especially difficult to encourage androgyny in boys and in both girls and boys when they are young. The parents become frustrated and confused, and sometimes they abandon their goal. They ask psychologists questions such as the following: "Why are my sons macho and my daughters girly despite my efforts to provide them with all sorts of opportunities? What am I doing wrong?" The answer is that the parents might not be doing anything wrong; in fact, they might be doing everything right. Powerful messages from peers and popular culture can override parents' best efforts.

2. LEARNING TO CONFORM TO ONE'S GENDER

Gender socialization (i.e., the process of learning one's gender role) begins as soon as babies are born. The hospital staff members announce, "It's a boy!" or "It's a girl!" As soon as the newborn is cleaned up and weighed, it is wrapped in either a pink or a blue blanket. Relatives and friends of the new parents rush to the store to buy congratulatory cards, and they find themselves confronted with an array of blue or pink cards containing gendered messages about how active a baby son is and how sweet a baby daughter is. One must search long and carefully to find a unique nongendered card, which might be yellow and green and discuss how much happiness a new baby can bring. Before babies can even begin to understand spoken language, adults and older children greet them with gendered exclamations such as the following. "What a big boy!" "How's my little girl?" "He has such a strong grip!" "She has beautiful eyes!" Adults handle baby girls more gently and play with baby boys more vigorously. Some of these actions are done deliberately because people believe that it is proper to treat boys and girls differently. Other actions are done without thinking

about their repercussions. The phrases "big boy" and "sweet girl" just seem to go together because people have heard those phrases uttered so often.

3. ACQUISITION OF GENDER IDENTITY

Children acquire their gender identity by 3 years of age, and they begin to exhibit gender-typed preferences even earlier. In 2002, Poulin-Dubois and colleagues demonstrated that 2-year-olds spent more time looking at photographs of people behaving in gender role-inconsistent ways (e.g., a man putting on makeup) than they spent looking at photographs of people behaving in gender role-consistent ways (e.g., a woman ironing). This suggests that even at that young age, the children found the gender role-inconsistent photographs to be surprising or puzzling. Social learning theory has often been used to explain the development of gender roles and gender-typed preferences. The theory posits that children learn about gender by watching how others behave (i.e., by observational learning or modeling), that children are rewarded by others when they behave according to gendered expectations, and that children are punished by others when they do not (i.e., reinforcement contingencies are applied).

Although parents are the most powerful models that young children observe, they are certainly not children's only important models. Grandparents and other relatives, teachers, coaches, neighbors, religious leaders, television characters, and other children also are influential. In addition to modeling gendered behavior, all of these (with the exception of the fictional characters) are also able to reward children for exhibiting gender role-consistent behavior and to punish them for exhibiting gender role-inconsistent behavior. Rewards take forms such as smiles, nods, hugs, kisses, praise, and gifts. Punishments take forms such as frowns, head shakes, withdrawal of affection, verbal corrections, and even spankings. For example, "Susie" may notice that her older sister has a doll collection, whereas her older brother does not. Susie's grandmother may give her a doll for her birthday and exclaim, "I'm so glad that you like it, sweetheart!" In preschool, Susie may notice the teacher frown when she joins the boys in playing with the transportation toys, and her girlfriends may offer a behavioral correction by calling out, "Susie! Come play dolls with us."

3.1. Media Influences

The media are very strong influences on children's behavior, and they teach lessons of all kinds about the world and people's roles in it. Researchers have found that 3- to 5-year-old North American children watch an average of 15 to 20 hours of television per week. By 7 years of age, this drops to an average of 15 hours or less, mainly because the children are spending more hours per week in school. The youngest children may watch primarily educational programming, such as *Sesame Street* and reruns of *Mister Rogers' Neighborhood*, which tend to emphasize the uniqueness of individual children. However, older children watch primarily cartoons, action/adventure shows, sports, and situation comedies, all of which portray gender role stereotypes. On average, boys watch more television than do girls. Children who watch television learn many things about women/girls and men/boys. They learn that boys are noisy and active, that girls are quiet and passive, that women are victims who need to be rescued by men (heroes) from other men (villains), that boys and girls play with different toys and games, that women and men pursue different hobbies and careers, that girls should be pretty, and that boys should be strong. Children's books and movies contain similar messages, and these messages are repeated frequently as children reread and rewatch their favorite books and videos.

3.2. Division Along Gender Lines

Children's worlds are divided along gender lines. Toy stores are clearly demarcated by gender, with "girls' toys" on one side and "boys' toys" on the other. An adult who enters a toy store and asks a clerk for help in choosing a gift for a 5-year-old will immediately be asked, "Are you shopping for a boy or a girl?" Children who enter the store generally know exactly where to go because they have seen girls and boys modeling toy use on television commercials, and they head for the area of the store that features the "appropriate" toys. If there is any doubt about which aisles are for them, the colors of the toys, the packaging, and sometimes even the walls and shelves of the store will serve as clues, with bold colors (especially blue and red) being for boys and pastel colors (especially pink and purple) being for girls. Children's clothing is similarly color coded and is often decorated with gender-typed emblems, for example, a football or firetruck for boys and a flower or rainbow for girls. Girls' bibs, socks, and hats are often

lacey, and stores sell barrettes and headbands for use even with newborn girls who have very little hair. When children start to attend day care, preschool, or other organized activities, they will find themselves addressed as "boys and girls" far more often than as "children," a pattern that will continue through the elementary school years. Although the phrase may be more habitual than deliberate on the part of the adults who use it, it communicates powerfully to children that people come in two "types."

4. ACTIVE PARTICIPATION IN GENDER SOCIALIZATION

Gender role socialization is not a passive process. Once children realize that people come in two types and figure out which type they are, they tend to categorize by gender everything they possibly can. Cognitive developmental theory posits that children want to behave in a gender role-consistent manner; therefore, they begin at an early age to gather information about what boys and girls are supposed to be and do. The modeling and reinforcement contingencies described previously are sources of information for children to categorize. However, external rewards and punishments might not be the only forces that shape gendered behavior. Children's own internal contingencies are also at work as they come to state their preferences for gendered toys and activities and even for same-sex people. Thus, children's inner desire to act like girls or boys may be responsible for the dynamics that causes their parents to complain to psychologists as in the following ways: "I prefer to dress my daughter in pants for her warmth and comfort, but she insists on wearing dresses to school." "I want my son to have a variety of toys and games, but all he wants for his birthday are trucks and guns."

Social and cognitive processes help to maintain children's gendered preferences. Children spend a lot of time in gender-segregated play groups, that is, all-boys groups or all-girls groups. This segregation is, in part, both a cause and an effect of children's preference for same-sex peers. This preference is maintained in part by children's tendency to misremember, or miscategorize, people's traits and behavior so that same-sex traits and behavior are more highly valued. For example, boys believe that boys are nicer, smarter, and funnier than girls, and girls believe that girls are nicer, smarter, and funnier than

boys. In-group/Out-group processes also help to maintain gender stereotypes and preferences for same-sex others. Any groups whose members bond together (e.g., gender groups, ethnic groups, sports teams, artificially created groups in a social psychology experiment) look for ways in which to distinguish themselves (the in-group) from others (the out-group). They exaggerate the differences between the in-group and the out-group, form a strong preference for in-group members over out-group members, and believe that in-group members have more variability in traits and behaviors than do out-group members, who are all thought to be alike. Furthermore, once traits and behaviors are categorized by gender, children tend to notice and remember instances that are consistent with gender categories, whereas they might not notice or might forget instances that are inconsistent. These processes may help to explain the logic of a boy who values soccer, thinks that it is a boys' game, and believes that girls do not like soccer even though he has seen some girls play it and knows that not all boys like it.

Gender segregation during childhood also occurs because children are assigned gender-stereotyped tasks (e.g., "Boys, go help your father with the yardwork," "Girls, I want you to help mother with the holiday baking") and because children engage in gendered activities. For example, children learn from older children, as well as from television and books, that girls take ballet lessons and boys play Little League baseball. Of course, one can find boys dancing ballet and girls playing baseball, but they are few in number. Children who choose gender-typed activities will generally find themselves in segregated groups. These activities provide the opportunity to make more same-sex friends and strengthen children's beliefs that it is normal for girls and boys to spend a lot of their time apart. Maccoby's research in 1998 showed that spending so much time with same-sex peers leads boys and girls to develop different play styles. Boys play in larger groups, and their games are often described as rough and competitive. Girls play in smaller, more cooperative groups, and their games are often based on fantasies about becoming attractive (even glamorous) grown-ups. Once these play styles become well established, it is even more unusual for a child to join a cross-sex play group. Boys are more likely than girls to enforce gender-segregated groups; they often actively exclude girls from their games and tease other boys who voluntarily play with girls.

So, what's a parent to do? Is it impossible to raise androgynous children? Should parents give up and accept the status quo? Parents should not give up,

but they probably need to be more realistic about what can be achieved, especially at early ages. Until greater social, cultural, and political changes are achieved, parents will face an uphill battle because children will receive dozens of stereotypical messages for every stereotype-inconsistent message parents may provide. However, once children are old enough to have achieved a high level of cognitive development, parent may have greater success.

5. SHAPING FUTURE WOMEN AND MEN

This section contains some advice for parents who wish to raise androgynous children as well as some reasons for these parents to remain hopeful. First, researchers have shown that children show more interest in unfamiliar objects and activities when they are told that the objects and activities are preferred by same-sex people. For example, if parents want their son to take violin lessons, they should show him a picture of Pincus Zuckerman playing his violin and say something about the many famous men who play the violin so expertly. If parents want their daughter to join a soccer team, they should show her a picture of Mia Hamm playing soccer and tell her about the number of girls who are playing in the local youth soccer league. If the first message children receive about something novel is that it is gender appropriate, they may maintain interest in it long enough to find out whether they like it. If they like it, it may become part of the in-group variability discussed previously. A later comment from a peer that "violins are for girls" may be countered by "No, they're not! Lots of boys like to play the violin."

Second, recent studies indicate that both children and adults are more likely to apply gender stereotypes to other people than to themselves. Although this phenomenon is not going to aid in promoting social, cultural, and political change, it does allow individuals to exercise more freedom of choice in their own activities and preferences. Thus, parents should expose their children to a range of toys, games, and activities in hopes that some nongendered objects and activities may become preferred. If children ask only for gendered toys for their birthdays, family members can agree to fulfill some of the requests and to provide some nongendered gifts as well. It would not hurt if the father or grandfather reacts enthusiastically when a boy unwraps a nongendered gift by exclaiming,

“Wow! Candyland [or finger paints]—I loved that when I was a little boy.” Researchers have found that boys are less likely to play with a feminine or gender-neutral toy if they think that their fathers would disapprove.

Third, parents should continue to model gender-inconsistent behavior as often as they can. Parents are powerful role models for their children, and children do pay attention to what their parents do, although sociocultural pressures may cause them, at least at younger ages, to deny that gender inconsistency occurs or that it is good. Some studies have shown that children from single-parent homes, where one parent must be both nurturant and agentic, display less gender-stereotypic behavior and fewer gendered preferences than do children from two-parent homes. Also, children who grow up in two-parent homes where the parents are nontraditional in their own gender roles display less gender-stereotypic behavior than do children whose parents are traditional in their role enactment. Furthermore, researchers have found that children in nontraditional preschools spend half as much time in gender-segregated groups as do children in traditional preschools. Parents can also enroll their children in day care centers and preschools where the teachers value and reward nontraditional gender roles, and parents can try to limit the amount of exposure young children have to books and television shows that reinforce traditional gender roles.

Fourth, parents can encourage children to play with gender-neutral toys and to engage in activities that both girls and boys enjoy. Gender-stereotypic thinking is, at least to some extent, context dependent. The more time people spend in gendered activities, the more likely they may be to maintain rigid gender categories. A focus on what all children have in common may help to reduce in-group/out-group divisions. Research on in-group/out-group phenomena suggests that breaking up the existing groups or challenging them to work together to attain a goal will also reduce divisions. Therefore, instead of dividing children in a classroom or at a party into a boys' team and a girls' team for a spelling bee or a game of tag, gender-integrated teams could be formed and given color or animal names (e.g., the reds vs the greens, the dogs vs the horses).

Fifth, parents should be careful not to send contradictory messages about gender expectations, for example, by rewarding traditional behavior one minute and punishing it the next. Parents must remember that they themselves have been exposed to millions of gender-stereotypic messages during their lives; thus, they need

to take care to pass on as few as possible. For example, people often interpret the same behavior differently depending on whether it is demonstrated by boys or girls. A child who cries with frustration may be thought to be angry if a boy or upset if a girl, and a parent who applies one or the other of these terms to a child's behavior is teaching a powerful, if unintended, lesson about emotionality. Many parents find it more difficult to be accepting of feminine behavior in their sons than to be accepting of masculine behavior in their daughters because “tomboyism” is not considered by most people to be a problem, whereas “sissy” behavior usually is considered problematic. Parents' concern that boys who play “dress up” will become gay men, or that boys who do not like sports will be unpopular with other boys, can override the encouragement that they give their children to try gender-inconsistent activities.

Finally, as children reach middle childhood (ages 9–12 years), parents can begin to contradict children's dogmatic gendered statements and can actively teach critical thinking skills to counter gender role stereotypes such as in the following ways. “What makes you think that boys shouldn't take violin lessons?” “Oh, look at the skinny girls in this magazine ad. I don't think they look healthy, do you?” It is appropriate for parents to share their values with children who are old enough to understand. This is the time for parents to say, “We want you to dream your own dreams, to follow your heart. We believe that you can succeed at anything you want to try. Whatever you decide to do, we will support you with pride.” Children at this stage often become more flexible in their beliefs about, and attitudes toward, gender roles. With encouragement, they may blossom into the androgynous individuals that their parents always hoped they would be.

Over the past 15 to 20 years, applied geropsychology has undergone vast and fundamental changes. This article provides an overview of the excellent articles on the topic of applied geropsychology that are included in this encyclopedia, the four major directions in which the field has grown, and the three primary principles that will guide future growth and development. The four major changes that are touched upon by multiple articles in this section are (1) the emergence of applied and clinical geropsychology tools to prevent and treat health problems, (2) the increasing cultural heterogeneity of the aging population, (3) the explosion of knowledge relative to mental and behavioral health disorders in older adults, and (4) the increasing use of applied geropsychology in understanding and assisting with major life transitions.

1. THE MERGING OF APPLIED AND CLINICAL GEROPSYCHOLOGY

In the recent past, applied and clinical geropsychology did not intersect. Applied geropsychologists examined issues relevant to healthy aging and the healthy aged, and the basic process of aging. Clinical geropsychologists examined issues relevant to those older adults needing intervention for aspects of pathological aging, e.g., dementia or depression. The National Institutes of Health (NIH), and in particular the National Institute on Aging (NIA), envisioned the coming together of these seemingly disparate fields of inquiry. By focusing its funding on applications of cognitive aging and other basic knowledge for healthy living, the NIA stimulated the basic understanding of aging with applications of primary prevention and health promotion. At the same time, clinical geropsychology and related disciplines extended their knowledge into the earliest manifestations of pathologies related to aging. For example, the focus on mild cognitive impairment and its relation to dementia has extended early detection from the clinical arena to recognizing that cognitive changes in otherwise healthy aging may be early manifestations of Alzheimer's disease.

The confluence of applied and clinical geropsychology is illustrated in four articles that are included in this section of the encyclopedia. Gould examines aging, cognition, and medication adherence, and how basic cognitive processes of aging are used in designing intervention tools. Ball, Wadley, Vance, and Edwards examine how cognitive skills can be maintained and enhanced. Their

review of the links between cognitive skills and functional skills and the promising results of intervention trials forecasts a continued growth in the area of cognitive training. Laffeche and Verfaellie analyze the syndrome of amnesia and the problems of clinical patients suffering from one of many disorders that cause amnesia. Cowart's article provides an excellent description of dementia as a clinical syndrome and the use of conceptual models to guide prevention, early detection, and treatment methods. All four articles address the usage of cognitive theories to guide interventions, and demonstrate the ever-increasing convergence between healthy and pathological aging, and the ability to prevent and detect pathology and intervene in clinical syndromes.

2. THE INCREASING CULTURAL HETEROGENEITY OF THE AGING POPULATION

Heterogeneity in aging has traditionally been represented in approaches to healthy versus pathological aging. More recently, it has another, broader meaning in the aging field in terms of the tremendous differences in cultural and ethnic backgrounds among the nation's older adults. Changes in older adult immigration patterns have contributed to a much broader diversity of ethnicity and culture within the elderly in the United States. These dramatic changes are directly examined in the articles by Antonucci and Akiyama and by Brown and Jackson. Antonucci and Akiyama note that cultural experience refers to the interaction between immigration and acceptance. They also emphasize that a life span perspective helps in understanding how individuals become more different from each other as they develop over time, and that the differences among individuals from unique cultural backgrounds may be heightened as they grow older. Brown and Jackson use a life course framework to examine socioeconomic and health disparities between minority groups and European Americans who reside in the United States, and vividly illustrate the heterogeneity in aging between and within minority populations.

3. KNOWLEDGE RELATING TO MENTAL AND BEHAVIORAL HEALTH DISORDERS IN OLDER ADULTS

Applied geropsychology has witnessed an incredible explosion of knowledge in mental and behavioral

health relative to epidemiology, measurement tools, treatment and relapse prevention, and the importance of family education. The articles in this section relating to these topics demonstrate the increased sophistication regarding chronic health problems and their assessment and treatment. Related articles on psychotherapy and personality illustrate the growth of knowledge and its application with older adults.

Knight and David's article on psychotherapy presents a conceptual framework that incorporates the similarities of psychotherapy with older and younger adults, while illustrating the unique features of psychotherapy with older adults. Alea, Diehl, and Bluck examine continuity versus the changing nature of personality across older adulthood and the role of emotion in later life. Both frameworks guide their interpretation and thinking about major issues, and provide information that can be used in working with older adults in community and clinical settings.

Depression and anxiety are the two most common forms of mental health disturbance in older age. Late-life depression, which has been the focus of much research in older adults, is examined in the article by Edelstein and Shreve-Neiger. These authors review conceptual models that identify unique aspects of depression in older age and mental and physical health comorbidities. They also examine instruments for use in depression assessment and the interventions used by geropsychologists. Anxiety disorders in older age is examined by Carmin, Mohlman, and Buckley.

Although more prevalent than depression, anxiety lags behind as an area for investigation, possibly due to the confusing array of types of anxiety disorders, each with its own unique diagnostic criteria. Anxiety disorders include a group of syndromes under a single umbrella, such as social phobia, which is clearly distinguished from generalized anxiety disorder. Despite being grouped together, anxiety disorders represent a wide variety of symptom constellations. In contrast, although depression is known to have many different possible etiologies, this disorder is nevertheless defined by a single constellation of symptoms. Consequently, knowledge about anxiety in older adults has lagged behind depression. Carmin, Mohlman, and Buckley examine the contributions that geropsychology is making to the assessment and treatment of anxiety.

Tools from geropsychology have strongly impacted populations such as those with alcohol problems and advanced dementia. People in both groups can easily find themselves isolated and neglected. The unique aspects of alcohol misuse in older adults have been

more clearly identified in recent years. New and broader treatment approaches have also been introduced and used successfully in a variety of settings. Cohen-Mansfield's article on assessment and interventions for behavioral disorders in dementia documents the effective multi-modal approaches developed in geropsychology.

Rybarczyk's article on behavioral medicine issues in late life is a likely precursor to a huge growth of interest in this area of applied geropsychology. His review of pain and sleep disorders and their treatment in older adults reflects the increasing expertise in geriatric rehabilitation that accompanies chronic diseases. Rybarczyk also examines the concept of frailty, which is defined differently by individual researchers. Most work on frailty examines the experience of illness and the adequacy of functioning in the oldest-old. Given the growing numbers of oldest-old, this area will, no doubt, be greatly enhanced by geropsychology in the coming years.

4. INCREASING USE OF APPLIED GEROPSYCHOLOGY IN MAJOR LIFE TRANSITIONS

Applied geropsychology is becoming ever more important in contributing to greater understanding and more effective assistance with major life transitions. This is an exciting area in which society will increasingly look to geropsychology for advances and contributions. Each of the four distinct areas of applied geropsychology that are covered in this encyclopedia reflects increased activity and growing awareness. Individual articles focus on the interrelated topics of caregiving and competency in older persons and end-of-life abuse. Caregiving involves the stressful experience of caring for an older adult with chronic dementia and/or disease, whereas competency focuses on the advanced stages of illness in which an older individual may need help with basic decisions, usually from a caregiver.

Applied geropsychology has developed a much broader understanding of caregiving in the past two decades, including the normative experience of stress, as well as the impact of stress felt by caregivers. Interventions for caregivers continue to proliferate and are badly needed. Burton, Kwak, and Haley examine the ever-growing phenomenon of caregiving for an older relative, which challenges applied geropsychology to develop multiple methods for intervention. Moyer discusses the growing knowledge about capacity

and competence and reports on research findings and on ethical issues connected to competency. Given the growing knowledge in assessment and measurement, applied geropsychology offers considerable expertise for dealing with issues relating to competency and capacity disputes. The legal system is not well versed in age-related diseases and how they impact specific and broader capacities.

Elder abuse and end-of-life issues in applied geropsychology are two areas of late life in which exploration, to date, has lagged. Elder abuse is an important aspect of caregiving; it is increasingly prevalent and needs greater vigilance. Rodriguez reviews research on elder abuse and examines relevant ethical issues, noting that there are no typical descriptions of abusers or victims of abuse. He also provides clear guidelines for assessment, evaluation, and successful intervention. Allen, Phillips, and Payne review the emerging role of geropsychology in end-of-life issues regarding advanced care planning, palliative and hospice care, and other evolving end-of-life treatment approaches.

5. PRINCIPLES TO GUIDE FUTURE ACTIVITIES IN APPLIED GEROPSYCHOLOGY

The three principles listed below are relevant to all of the articles in the emerging field of applied geropsychology. These principles are also related to and can be used to anticipate future developments.

5.1. Principle 1: Cohort Considerations

Researchers and clinicians must continue to consider the ever-expanding interactions between the physical effects of aging and the psychological effects of cohorts. There are several major developments that are prominent for the first time in research on cohorts. The current cohort of older adults witnessed the great promise of medicine, for example, the discovery of vaccines to prevent polio and other devastating and contagious diseases. These discoveries have contributed to optimism in regard to conquering disease, and to healthy living throughout the lifespan.

Compared to previous cohorts, older adults today are more knowledgeable about the effects of aging and are living longer and healthier lives. Consequently, both clinicians and researchers must be prepared to adapt

when working with more knowledgeable and diverse populations. The growth of the older population, both today and in the future, will impact our society on many levels. Older adults will become a more visible group and will be more often targeted by government, media, and businesses.

In addition to being more numerous, current and near-future cohorts are also characterized by greater diversity in their cultural practices and ethnic backgrounds. The effects of aging are also more diverse than ever before due to these differences. Because there are numerous differences between the current elder cohort and previous and later cohorts, the importance of considering cohort effects, along with the effects of aging, cannot be overstated.

5.2. Principle 2: Conceptual Frameworks

In the previous decade, applied and clinical research developed in parallel and in a relatively noninteractive fashion. There were few applications and limited theoretical understanding (e.g., it was only after 40⁺ years of research that Schaie's longitudinal data were applied to clinical conditions). These new theoretical frameworks are reflected in the contributions of applied geropsychology to this encyclopedia, and are being applied to healthy and pathological aging. Behavioral theory is now used in assisting with treatment adherence among well elders and for decreasing agitation in demented elders. Hopefully, late-life depression theories, such as late-onset and vascular depression, will lead to early detection methods and better depression treatment outcomes.

In the past two decades, clinicians have brought meaningful conceptual frameworks to the study of aging and older adults. Applied geropsychology advances most when theoretical and conceptual frameworks are used in the study of age-related syndromes, and in the application of assessment tools and treatment techniques. These enhanced theoretical frameworks

provide a more logical rationale for evaluating and building upon the results of empirical research results.

5.3. Principle 3: Comorbidity

People are living longer lives, which makes them vulnerable to multiple chronic diseases (comorbidities). Among the ever-increasing number of persons surviving one or multiple strokes, there is a concurrent increased risk because their systems are more vulnerable to developing depression, dementia, and delirium. Recent epidemiological evidence suggests that chronic conditions during mid-life, such as high cholesterol, hypertension, and diabetes, place people at much higher risks for developing dementia in later years. Thus, issues of comorbidity are often central to applied geropsychology and need to receive increasing attention.

foreground As distinguished from background, that aspect of experience that is the focus of attention at any given point.
gestalt A German word that has no direct translation in English. “Configuration,” “structure,” and “whole” are used as translations, but none of these capture the complete meaning. “Figure” and “gestalt” are often used interchangeably.
organismic self-regulation The process whereby homeostasis is maintained via the figure formation/destruction process.

GLOSSARY

background As distinguished from figure or foreground, that which is not uppermost in awareness; provides the context and is the source from which figures emerge and become prominent in awareness.

closure The result of the natural movement toward the completion of perceptual or experiential units.

contact The experience at the self/environment boundary that leads to assimilation and growth. Good quality contact involves awareness and excitement.

contact boundary The dynamic relationship at the meeting point of self/other or self/environment; where experience occurs, and the focus of therapeutic intervention.

creative adjustment A person’s best adaptation to dealing with feelings and needs in response to environmental inadequacy in meeting the needs or competing environmental requirements.

figure What stands out from the background as a focus of interest and attention; generally related to a need or desire.

figure formation/destruction process The process whereby a figure of interest emerges, becomes a focus of attention, and is acted upon, resulting in the dissolving of that figure.

Gestalt therapy has roots in psychoanalysis, Gestalt psychology, Reichian character analysis, and the work of the early phenomenologists. It was developed in the 1940s primarily by Frederick Perls, Laura Perls, and Paul Goodman. Gestalt therapy is humanistic, holistic, and experiential. It is a process-oriented and relational approach based on a theory of healthy functioning. The focus in therapy is on disruption of the natural process of self-regulation. The goal of treatment is the restoration of awareness, which allows for increased choice and flexibility in all aspects of living.

1. DESCRIPTION OF TREATMENT

1.1. Philosophical Foundations

Gestalt therapy method is guided by three philosophical foundations. The first of these is field theory, a concept that derives from physics. The “field” is a dynamic interrelated system, each part of which influences every

other part. Nothing exists in isolation. Gestalt therapy is a field theoretical and process-oriented approach, which means the therapist attends to the total field, including content and subject matter, as well as the here-and-now process occurring in the moment. This involves things such as the patient's tone of voice, style of communication and interaction, facial expression, physical gestures, posture, breathing, sensation, and affect. The therapeutic field also includes the patient's history and current situation, the therapeutic relationship, feelings experienced by the patient and the therapist, and their mutual impact on one another.

The second philosophical foundation is phenomenology. The Gestalt therapist attempts to bracket off preconceived biases, beliefs, theories, and interpretations and attend as much as possible to what is actually understandable through the senses, with the focus on the patient's subjective experience. The therapeutic stance is one of meeting the patient where he is, and the therapist describing what she observes, rather than explaining or interpreting. The patient is encouraged to do the same. The therapist also brings her own feelings, sensations, and awareness into the interaction with the patient when useful for the treatment.

The third philosophical foundation is dialogue. A dialogic stance requires that the therapist be "present," confirm the patient, and be available for an I-Thou way of relating. Presence is the therapist bringing all of himself to the encounter in the here and now. Confirmation involves seeing and accepting patients for all they are and all they are capable of being. The I-Thou mode of relating has the qualities of immediacy, directness, presence, and mutuality. These qualities create a therapeutic relationship that is not hierarchical and a meeting between patient and therapist that is in and of itself healing.

1.2. Goal of Treatment/Theory of Change

In Gestalt therapy, the goal is increased awareness. Although the patient presents specific symptoms, such as anxiety, depression, stress-related physical complaints, relationship difficulties, or character/personality issues, the Gestalt therapist does not focus only on symptoms or behavior change. Rather, Gestalt therapy provides a holistic perspective in which symptoms and problematic behaviors are seen as the person's best attempt to deal with conflicting needs or needs conflicting with environmental requirements. Psychological

problems, symptoms, and difficulties in interpersonal relationships result from what were originally creative adjustments that have become rigid, reflexive, and unaware, restricting the experience of self and possibilities. By focusing on moment-to-moment process in the therapy session, the Gestalt therapist works with how the person creates and maintains her particular experience of self and other and how this experience impacts the current situation.

Change then occurs spontaneously as a result of this increased awareness. Gestalt therapy's change theory is paradoxical in the sense that change occurs not as a result of attempting to change (one part of the self trying to control and dominate another part) but as a result of the patient attending to, investing more fully in, and living more completely the actual current experience—what is. Doing this enables new responses to emerge that better fit current needs. Increased awareness leads to choice and opens up new options for behavior and interaction.

As aspects of the personality that have been disowned are reidentified with, an expanded sense of self is also restored. For example, the patient increases her capacity to experience and express grief, anger, or tenderness, which expands her ability to live authentically and to connect more with other people. Gestalt therapy does not focus directly on problem solving but rather on what limits the patient's capacity for creative solutions. As the saying goes, "Give a person a fish and he eats for a day; teach a person to fish and he eats for a lifetime." A Gestalt therapist is interested primarily in the latter.

1.3. Therapy Method

By attending to observable behaviors that indicate blocked awareness and interruptions to acting on needs, desires, or interests, Gestalt therapy captures the essence of a person's existential position in the world, which impacts all aspects of self-experience and relationships. For example, the patient speaks softly, apologizes frequently, becomes slightly tearful but cannot cry, changes the subject, or shuts down if strong feelings threaten to emerge. Can the patient become aware of how she clamps down on herself? What makes this shutting down necessary? How might holding back or not allowing herself to take up space be a theme in this patient's life? How many areas of her experience and relationships are impacted by it? How is it related to her presenting symptoms of anxiety or depression or to the dissatisfactions in her life?

The therapy process enables increased awareness of these blocks and how they are maintained and also examines why they were initially developed. For example, if the experience or expression of sadness has been criticized, punished, or even ignored by the parent, the child learns to cut off the feeling, its expression to others, or both. If a child's needs have been met with resentment, criticism, or disgust, the child's creative adjustment is to learn to block awareness of needs or to learn to avoid showing or expressing them to others.

Through focused attention, the patient can become aware of how he blocks feelings/expression, for example, tightening muscles to hold back tears and also internal messages such as "Don't be weak" or "Men don't cry." The patient will discover the etiology—what made this necessary in his development. Symptoms then resolve as the patient reconnects with his authentic self and experience. For example, anxiety may result from a fear that certain "unacceptable" needs or feelings will surface in a particular situation. Depression may result from holding in anger or grief or from poor self-esteem from directing frustration or criticism toward the self that needs to be expressed to another. Relationship problems may result from an inability to open up and reveal feelings or difficulty needing another person.

Gestalt therapy's method is experimental and experiential. Experiments can be diagnostic as well as serving to highlight current experience and uncover new possibilities. For example, an unassuming person who does not make eye contact and qualifies most of what she says complains that people do not listen to her or take her seriously. In therapy she might be asked to experiment with lecturing the therapist on the proper way to do something that is in her area of expertise. She might then show and experience the side of herself that is a knowledgeable expert. She may begin to speak more directly and forcefully. In this process she can get more in touch with this aspect of herself as well as increase her awareness of her reluctance to show this aspect of herself to others or her anxiety in doing so. Conversely, the patient may speak to the therapist as if she is not an expert, when in fact she is. Her language might be filled with reflexive use of qualifying phrases. She might speak without conviction. In either scenario, the patient can see and understand how she contributes to others not giving her the respect she desires.

The patient also learns what made this way of being necessary. She could have been told "Children should be seen and not heard," or one of her parents might

have become angry or silently disapproving if she expressed an opinion of her own. She might have been told she was stupid or wrong. Prior to therapy, she may not have remembered these incidents, she may have dismissed them, or she may have minimized their impact. She may not even have been aware that she presented herself as timid and unsure of herself or why it was important to do so. With the new awareness, she regains the possibility of a wider range in experience and behavior.

Gestalt therapy uses experimentation to increase awareness. Meaning for the patient then comes from experienced awareness rather than being imposed by the therapist's interpretation. The therapist tries to have no goal, agenda, or desired outcome in proposing an experiment, other than to observe and work with what happens next. An experiment can also be used to highlight an aspect of the patient's way of communicating. For example, a person who qualifies much of what he says by use of words such as "maybe," "possibly," or "I guess" could experiment with either exaggerating the use of qualifying words or eliminating them entirely and adding after every sentence "and I mean that." The therapist encourages the patient to pay attention to his experience as he does an experiment and to express any reluctance in doing it.

Experiments can also enrich what a person is saying and transform it from "talking about" to a lively present encounter. For example, the patient might imagine the person she is talking about is present in the room and express her feelings directly to that person. This use of the empty chair or two-chair experiment can also be effective in highlighting an internal conflict. The patient might imagine a part of herself in the empty chair and create a dialogue between the conflicting aspects of herself, such as the part that wants to be more creative and take more risks and the part that is more logical and conservative. This type of experiment can also explore an area of impasse or stuckness, for example, suggesting the patient develop a dialogue between the part of herself that wants to leave her marriage and the part that wants to stay.

As an example of some of the previously discussed concepts, a patient who learned to stifle her feelings and needs and to nurture herself with food enters treatment depressed and with a poor self-concept, complaining that she has "tried everything" to control her eating and has been unsuccessful. Turning to food to meet emotional needs was at one time her creative adjustment; it was the best option available given the needs she had and the lack of available gratification

possibilities—in this case, a mother who was stern and unaffectionate and sent the patient to her room if she was “too emotional.”

The Gestalt therapist observes this patient’s responses in the moment and helps to facilitate her awareness of them. For example, the therapist notices that the patient speaks more quietly and holds her breath when she talks about a hurtful or frustrating experience. The therapist can either make an observation (“It looks like you’re tightening your jaw” or “I notice you holding your breath”) or ask the patient to attend to what she is currently aware of (“What is your experience right now as you tell me this?”). The patient becomes aware that she is trying to control herself. The therapist attends to her need to control herself. He also attends to what she is controlling—verbalizing feelings and showing anger or tears. Through this process the patient becomes aware that there is also a part of her that would like to express itself and feels held back. Both aspects are explored.

The working-through process involves the patient becoming aware of the importance of holding back feelings to prevent reexperiencing the rejection she felt from her mother or the anger she felt toward her mother when she had feelings or needs. She might remember a forgotten traumatic experience. She might also discover that she expects the therapist to have a similar response. This patient learned over time to identify with her “nonfeeling, nonneeding” self. Her eating behavior may be one of the only remaining vestiges of her “feeling, needing” self. In therapy, she can also experiment with giving voice to the part of her that wants to eat and reidentify with her needs and desires, instead of only wanting to suppress these needs. For example, she might realize that although part of her wants to stop overeating, part of her—out of her awareness—also wants to continue eating as a way to take care of feelings and to comfort herself. This part might say something like “Don’t take food away from me, it’s all I have.” Change becomes possible as she invests more fully in being where she is—feeling those needs she translates into a desire for food—and may take the form of learning to nurture herself in other ways or to get her needs met in relationship with others.

2. THEORETICAL BASES

Many central concepts of Gestalt therapy theory are based on laws of perception discovered and studied by Gestalt psychologists in the early 1900s. Gestalt therapy

applies these laws more broadly to all aspects of experience and psychological functioning. Importantly, these Gestalt psychologists discovered that we are not simply passive recipients of perceptual stimuli, but that we are active in organizing our perceptual field. Laws discovered by the Gestalt psychologists include the natural tendency to perceive a figure against a background as a way of organizing experience and a natural tendency toward completion or closure.

Gestalt therapy takes its theory of healthy functioning from a biological concept called organismic self-regulation. This describes the organism’s process of taking in from the environment what is needed (food and oxygen) and expelling into the environment that which is not required (waste products and carbon dioxide) in order to maintain balance or homeostasis. Applied to psychological functioning, this theory states that in health, people will naturally go to the environment to get emotional and psychological needs met—the need to be listened to and the need for support, sex, physical comfort, and social contact—and will discharge as needed by talking, expressing feelings, crying, touching, doing, and creating. Gestalt therapy does not view the individual as separate from the environment but rather considers the individual/environment field.

According to Gestalt therapy theory, such self-regulation occurs via the figure formation/destruction process. This process is central to any human functioning and as such is a core characteristic of people. In all functioning there is an ongoing process of the formation of a figure of interest and the eventual gratification and dissolution of this need or interest. This cycle has several stages: (1) awareness, (2) clarification of need/interest, (3) scanning self-environment, (4) action, (5) contacting, (6) assimilating, and (7) withdrawing. For example, I am on my way to my favorite restaurant for lunch and see an old friend across the street. I become aware of sensations of excitement and increased energy (stage 1). I recognize my interest in talking to my friend (stage 2). I understand that walking across the street will facilitate meeting this need (stage 3). I walk across the street (stage 4). I say hello and give my friend a hug, and we talk (stage 5). As we say good-bye, I tell my friend and acknowledge to myself what this meeting meant to me (stage 6). I walk back across the street with a feeling of satisfaction, resolve to see my old friend more often, and my focus shifts to what I want to eat for lunch (stage 7).

In healthy functioning, a person will maintain balance by intake and discharge as required for the

satisfaction of emotional and psychological needs by this continuous process of figure formation/destruction. Assuming there is no interference in this process (a disruption that causes the person to misperceive her needs, an environment that is hostile to the needs, or both), what becomes figural or foreground is based on the most pressing need at any given moment. After a need is met, this figure recedes (closure) and is replaced by whatever is next in the hierarchy of needs.

When there is a disjuncture between needs and what is available in (or required by) the environment, a person adapts. A creative adjustment is the best possible accommodation she can make at the time, given her experience, perceptions, and limitations. Over time, these creative adjustments may become obsolete, rigid, and maintained out of awareness, limiting a person's potential for satisfaction and growth. Psychotherapy involves examining and understanding how the natural self-regulatory process has become disrupted, preventing closure on units of experience.

Disruption can occur at any stage of the figure formation/destruction process and diminish a person's experience of himself and his ability for contact. A person who is experiencing disruption interferes with his own development of a strong and clear figure (stages 1 and 2) or with the ability to maintain the excitement and energy necessary for action (stages 3 and 4) or to move into satisfying contact (stage 5), which allows for assimilation (stage 6) and closure (stage 7). Either the interference with the development of a strong figure or the blocking of excitement and action can interfere with good quality contact. A Gestalt therapist is trained to observe both where in the cycle the disruption occurs and how it occurs. Often, the focus is on how the disruption dilutes or distorts interpersonal contact.

In health, a person will perceive, experience, identify with, and act on needs and desires. Healthy functioning requires the ability to readily identify "This is me" or "This is for me" versus "This is not me" or "This is not for me." When disturbances exist in perceiving, experiencing, identifying with, and acting on needs, this loss of functioning is observable by the trained therapist at the contact boundary, which refers to the dynamic relationship at the point where the person and environment meet and interact.

The five processes discussed next are the "how" of any disruption of contact. These processes can occur at any stage of the figure formation/destruction process. It is via these processes, maintained rigidly

and out of the person's awareness, that the experience of self and the ability for contact that includes satisfaction of needs and closure is diminished.

Introjecting is experiencing something in the environment as if it is part of the self. An introject is an idea that has been "swallowed whole" without the "chewing" necessary to assimilate it and make it truly a part of the self. Introjecting is particularly problematic if it is a person's primary way of dealing with the world and relationships (such as doing things for others and ignoring one's own needs out of a sense of duty or obligation) or when the introject is destructive (such as a parental introject "You're good for nothing").

Projecting is disowning a feeling, behavior, attitude, or trait of one's own and attributing it to another or the environment. For example, a person who is not able to be angry—due to an introject—may inaccurately perceive another person as angry at him.

Retroreflecting is when energy or action that could be directed toward the environment is directed at oneself. Retroreflecting is of two types. In the first type, a person directs toward herself a feeling or action meant for someone or something in the environment. For example, the person who is unable to experience anger toward another person—again due to an introject—might end up blaming herself. Any unaware suppression or shutting down is also accomplished by this type of retroreflecting. The second type of retroreflecting is doing for/to oneself what one would like another person to do for/to oneself. For example, a person might soothe herself, buy herself gifts, or hug herself instead of getting these needs met by interacting with another.

Confluence is the attempt to deny the existence of a self/environment boundary. Confluence requires a lack of discrimination and articulation of points of difference or otherness. Although there is the possibility of a "healthy" confluence during which two people feel so joined that they seem "as one" (such as at the moment of orgasm) and there is momentary dissolving of the boundary, prolonged attempts to maintain confluence prevent satisfying contact.

Deflecting is behavior that dilutes or reduces the intensity of contact. Examples are avoiding eye contact, laughing off what one says, circumlocution, and understating one's true feelings. There is disagreement among Gestalt therapy theorists as to whether this is to be considered a separate self-regulatory boundary process or whether it is the behavioral manifestation of the others—that is, a result of introjects, retroreflection, projection, or desire to maintain confluence.

3. APPLICATIONS AND EXCLUSIONS

Because Gestalt therapy is not an adjustment therapy and strives to be value-free, with a focus on understanding each unique individual and the individual's subjective experience as opposed to an "objective" standard for psychological health, there is no population that would be excluded from treatment. The phenomenological and field theoretical stance, whereby the therapist is striving to understand the patient's subjective experience rather than impose his own, make this orientation valuable for different cultures and minority groups. The Gestalt therapist does not claim to know what is right for the patient, nor does he desire any particular outcome: The only goal is increased awareness for the patient that leads to more choice.

Gestalt therapy can be used with all patient populations (children, adolescent, adult, geriatric, physically/mentally challenged, prison inmates, and inpatient and outpatient psychiatric patients) as well as in a variety of modalities (individual, couples, family, group, and organization). It is applicable to a wide array of problems [e.g., eating disorders, substance abuse, affective disorders, personality disorders, posttraumatic stress disorder (PTSD), adjustment disorders, loss, and grief]. It is an approach that can be used in both long- and short-term therapeutic work. Of course, not every therapist is equally effective with all patient populations, modalities, and diagnoses. The experienced and well-trained Gestalt therapist would be aware of personal limitations and areas of expertise and refer those patients who fall outside of these limits to other practitioners, just as a responsible therapist of any orientation would.

4. EMPIRICAL STUDIES

Research on the effectiveness of Gestalt therapy is scant and primarily confined to specific aspects of the approach. Most research has been focused on one technique that derives from Gestalt therapy method—the empty chair (or two-chair) experiment. It is important to note that use of this or any other single technique does not actually constitute a Gestalt therapy approach, without application of the three philosophical principles described in the treatment section. Although no single technique can be said to represent the essence of the Gestalt therapy approach, a technique has the advantage of being easily defined and thus accessible to the manipulations of empirical research.

The majority of research used the empty chair technique. Subjects were asked to have a dialogue with either a part of themselves or someone else relevant to the issues with which they were grappling. Most of the studies that used the empty chair technique found it to be more effective than other forms of therapy or control groups. It was also found to be more effective in reducing anger and producing positive attitudes than either intellectual analysis or emotional discharge. It was more effective than empathic reflection or focusing for creating a greater depth of experience. For resolving "unfinished business," it was more effective than an attention-placebo condition.

In one study, K. M. Clark and L. S. Greenberg found the empty chair technique to be more effective than either a cognitive decision-making task or a waiting list control group for resolving decisional conflict. During the process of using this technique, the original decision the person had wished to make often unfolded into a deeper related decision.

In summary, studies have shown this technique to result in an increase in affect, depth of experience, and the resolution of related emotional issues. Results have included a decreased sense of decisional conflict, reduced anger, increased positive attitude, lower systolic blood pressure, and the resolution of unfinished business.

Two studies found no benefit in using the empty chair technique for resolving grief issues or dealing with mild depression. In a study conducted by N. P. Field and M. J. Horowitz, the intervention consisted of placing subjects in a room alone and asking them to talk to their deceased spouses for 5 minutes through the direction of a taped recording. Nothing like this would ever be done in an actual Gestalt psychotherapy, which requires a focus on moment-to-moment process and the presence of the therapist. This technique was not found to be effective in reducing symptomatology 6 months later. Another study found the empty chair technique to be no more effective than time for decreasing mild depression. The researchers stated that the lack of positive results may have been due to the short duration of treatment, gravitation toward the mean over time, or experimenter bias.

Focused expressive therapy (FEP) was used in several research studies. FEP borrows from Gestalt therapy method and uses such procedures as directed fantasy, two-chair dialogues, and awareness exercises. It emphasizes the importance of emotional insight and the magnification of internal experiences, but it also includes a high level of authoritative guidance and

confrontation that is inconsistent with a Gestalt therapy approach. FEP was not found to be as effective as either cognitive group therapy or self-directed therapy. However, the description given for self-directed therapy was actually more similar to Gestalt therapy as it is practiced than the more authoritarian FEP method used to represent Gestalt therapy in this study.

Few studies have examined a more complete Gestalt therapy approach. Most of these yielded positive results, such as an increase in levels of self-actualization and more positive attitudes toward body image. Gestalt therapy was found to increase internal locus of control and the assumption of personal responsibility in prison inmates. A Gestalt therapy approach resulted in more behavior change than empathic reflection. Gestalt therapy was found to help Vietnam veterans with symptoms of PTSD. In couples therapy, it was effective in replacing power struggles with self-definition, limit setting, and intimacy, resulting in greater clarity, acceptance, and understanding.

5. CASE ILLUSTRATION

The following case example illustrates the treatment process and application of the theoretical concepts that have been presented. The therapist in this case was S. Zahm.

5.1. Kim

Kim, a 44-year-old successful professional woman, was referred by her physician due to recurrent periods of depression. She had been depressed off and on for much of her life. The bouts of depression had worsened recently in both duration and severity. She had not been able to tolerate antidepressant medications, and two previous experiences with therapy, both brief, had not yielded lasting improvement.

Kim presented as a smart, attractive, stylishly dressed woman. Her wit and humor were evident despite her somewhat depressed affect. Her facility with language, keen observations, and easy manner made it clear why she had achieved success professionally. During the initial session, Kim asked perceptive questions about my experience, my therapy orientation, and how I thought therapy could help her. She had been disappointed in her previous therapy experiences. When asked what she hoped to get from therapy, she answered "Not just a Band-Aid. I'd like to get to the bottom of what this depression is about."

Kim described herself as "an overeducated over-achiever" who had been successful in school and in

her profession. She worked long hours but wondered what was the point of all her hard work because she took little enjoyment from her accomplishments. Kim saw her life as lacking in meaning, with little that gave her pleasure. She said she felt "down" a lot, woke up in the morning dreading the day ahead, and said she was just "going through the motions" of social interaction.

Kim described her relationship with her husband Bill as "pleasant enough" but lacking a sense of emotional connection or passion. She reported little interest in sex and stated that their infrequent lovemaking was "more for him." She said "it's like I'm dead inside, or just numb." Kim reported that most of her friends were work acquaintances, and that she had only one "good friend" but did not really confide in her. Kim and her husband had no children. Kim and I agreed to meet for weekly individual psychotherapy sessions and to track whether she felt the sessions were useful and whether she was getting what she needed.

In describing her history, Kim reported that her parents had divorced when she was 8 years old. Her father abandoned the family, moving to another state to avoid paying child support. Kim, the oldest of three, became responsible for helping her mother with her younger siblings and doing household chores so that her mother could go back to work to support the family. Kim also became her mother's confidant and emotional support. She reported that she never really "got to be a kid" after that, and that her mother "never had time" for her. Kim's mother died approximately 8 months prior to our first meeting. She minimized her feelings about her mother's death, saying she thought she had "dealt with it."

Kim's therapy themes emerged right away in her relationship with me. In our initial sessions, her fear of showing or revealing vulnerable feelings to me stood out. For example, when Kim talked about her mother's death she would reflexively shut down. I noticed her retroreflections and deflections, including choking back tears, changing the topic, and looking away. I pointed these out in an attempt to sharpen this figure, to clarify what was most important to her at that point. I observed that although she had strong feelings about this loss, it was also important to her not to show these feelings or talk about them to me right then.

This process helped Kim focus on her reluctance to open up and share vulnerable feelings. The theme of having a variety of "softer" feelings (sadness, loss, and emptiness) and the reluctance to express them to me was something we worked with over the course of the

therapy. The essential components involved introjects such as “Be strong” and “Don’t show weakness” and the belief that no one would be interested in her feelings.

Within the first few months of therapy, Kim became more aware of these internal mandates and saw how they were connected to her relationship with her mother. Kim had learned not to reveal her feelings and emotional needs but rather to focus on taking care of her mother and siblings and deal with any of her needs by herself. Initially, it was a major step for Kim to identify that she felt a need and to also feel her difficulty and discomfort in expressing it to me.

I suggested Kim experiment with looking at me and imagining allowing herself to let down and cry with me. She imagined me having a critical and rejecting response. As she worked with her reluctance over a period of weeks, and felt supported by me in doing only what she was comfortable with, her reluctance moved into the background and her organismic desire and need to experience and express her feelings became more figural. At that point she was able to let down into her feelings of loss and grief, thus beginning the process of getting the closure she needed with regard to her mother’s death.

Afterwards, Kim was surprised to discover that this felt OK. It was still difficult for her to ask me how I now felt toward her. Her strong pull was to be satisfied with not knowing how I felt and what my reaction had been to her crying. I pointed out how not asking me about that left her with a blank space that might then be filled with her own fears. She decided to ask the question, “How do you feel about me now?” I was touched by her courage in asking the question and told her so, and I gave an honest response to her question. This was a pivotal moment in the therapy because Kim could take in and assimilate my genuine caring for her.

As we did this work and Kim opened up to deeper levels of feeling, another theme became apparent to both of us. Kim became fearful of relying on me and afraid that I would leave her if she needed me. She had a first-class radar system that detected the slightest sign of my lack of interest, lack of energy, or attention wandering. For example, if I looked at the clock she became silent and withdrew. When I told her of planned vacations, her response was to joke that she wondered if I would want to come back. When we explored this, it became clear that my going away evoked fear that I would abandon her or lose interest in her.

We worked with this theme in a number of ways. As Kim focused on feelings and sensations, she was able

to remember particular events with her father, such as his leaving the house in a flurry of loud words and emotion and yelling things such as “I never get any peace in this house!” One time, Kim tried holding on to him to keep him from leaving and he pushed her away, saying something like “Why can’t you kids leave me alone?” The meaning Kim extracted from these experiences and his ultimate abandonment of the family was that it was her fault that her father had left and that she must have been unlovable and “too much” for him.

As we worked with these awarenesses, Kim could feel a little girl part of her that “had always been there” that she tried to ignore. I asked Kim to focus on this sense of herself and to talk to me as the little girl. What emerged from this was that she felt shameful and desperately wanted to hide or disappear. She went back to her adult perspective and told me she wished that little girl would disappear or at least “grow up.” I suggested a dialogue between the adult Kim and the little girl. As the dialogue developed, the adult Kim began to feel sad and realized that rather than wanting the little girl to disappear, she wanted to hold and comfort her. She did not see her as “unlovable” or “too much” but instead felt compassion for her loss and pain and was able to tell her so. This newfound ability to experience compassion toward herself was a key in helping Kim integrate her softer “little girl” feelings with her “adult.” This occurred over a number of months as she continued to work with these aspects of herself.

When we worked directly with Kim’s father she was able to, in fantasy, tell him she was hurt and angry that he had not loved her enough to stay in her life even if he had to leave her mother. She finished her tearful dialogue with him by saying, “It wasn’t my fault you left. You failed me, not the other way around.” She also became aware that she had never been able to grieve the loss of her father and that her mother would not tolerate her tears and told her she had to be strong and that crying “wouldn’t do any good.” At that point, she was able to grieve the loss of her father with me and have more of a sense of closure.

In our sessions Kim came to see how the belief “I’m too much” affected major aspects of her emotional and interpersonal existence. This was especially evident in how she experienced her relationships with men and the type of contact she could have with them. She saw that with her husband, she made no demands, rarely got angry, and focused her attention on his needs to the exclusion of hers. Our work

included Kim experimenting with new ways of interacting with her husband, such as being more assertive with her needs. Initially, this made her anxious. As we worked with the anxiety and she realized the responses she feared were not likely ways that her husband would respond to her, she became less anxious and more excited and playful with the possibilities of being bolder about asking for things she wanted. This affected all aspects of their relationship, including their sexual relationship.

Slightly more than 1 year into the treatment, Kim reported that she “couldn’t remember the last time” she had felt depressed. She said she felt better about herself, her relationships, and the possibilities for her life than she ever had. She began to spend less time working and signed up for a beginning ballet class, which was something she had “always wanted to do.” She developed closer relationships with a few women friends, revealing more personal things and accepting support from them.

I asked Kim to reflect on where she was now and where she had been when she entered treatment. Kim reported that she felt more at peace with her parents, even though she still felt sad about her childhood. She said that it had been “life changing” to risk opening up to another person and allowing herself to need and depend on me. Kim saw the connection between her process of shutting down on her feelings—her self-criticalness, rejecting the little girl part of herself, avoiding feeling her anger and grief, and not allowing herself to need anything from others—and the depression she had experienced for so long.

Kim and I agreed that she was ready to terminate therapy and we allowed 1 month for this process. Given Kim’s issues of abandonment and loss, it was important to set an ending date and not dilute the fact that we were ending by meeting less frequently. In this way, Kim had sufficient support and a structure for dealing directly with the loss of her relationship with me. We celebrated her gains together and cried together. At our last session, we said good-bye in a complete way that Kim said she had never had the opportunity to do with anyone else.

5.2. Outcome

Growing up, Kim experienced a lack of awareness of and responsiveness to her emotional needs from both of her parents. Her father abandoned Kim completely, and her mother was unavailable for Kim’s needs, requiring Kim to attend to her needs instead. Kim’s

creative adjustments involved both the awareness stages and the action/expression stages of the figure formation/destruction process. She learned to cut off the experience of certain feelings and to avoid showing and expressing them. The meaning she made of her father’s leaving (“I’m unlovable” and “I’m too much”) and introjects such as “Be strong” created her retroflective process of cutting off and alienating aspects of herself, focusing on the needs of others, and not showing or expressing her own feelings and needs. This process resulted in unfinished emotional situations in which she had not been able to get closure. It resulted in the sense of emptiness, lack of meaning, and numbness that she described at the beginning of treatment as well as in unsatisfying interpersonal relationships that lacked depth. It also contributed to her career success, which was in part based on her skill in attending to the needs of others and her willingness to work hard so that she would not be rejected or abandoned.

All these issues emerged and were worked on in the context of the therapy relationship. As Kim’s awareness increased, she was able to work through her fears and reluctance and to feel the need to express and show her authentic feelings. She came to feel compassion for a part of herself she had previously cut off and wanted to be rid of, and through this experience of compassion she was able to reidentify with and integrate this part of her that included needs and softer feelings. She was able to redirect her self-criticism and see that it was not her being “too much” that caused her father to abandon her and her mother to be unable to attend to her needs. She came to feel that her little girl had deserved to be better taken care of.

In Kim’s relationship with me, she could experience my genuine caring and also see that when I was not there for her (e.g., when I went on vacation) it was not because she was unlovable or “too much.” She learned to express disappointment with my limitations, or anger at me for leaving, in a way that she had never had the opportunity to do with her parents.

The therapy carried over to and influenced every aspect of Kim’s life and interactions. Her relationship with her husband deepened, and she began to consider what she wanted to do in her life besides working. However, it was Kim’s relationship with herself that changed most dramatically. Kim no longer criticized herself or felt she was weak if she had feelings and needs. She no longer cut off and numbed a major part of who she was. She had greater range of emotional experience and expression. Kim understood that her

lifelong depression was the result of ignoring, denying, and cutting off her feelings, which led to an inability to identify and act on her needs. This resulted in a lack of closure on difficult emotional situations as well as unresolved issues of grief and loss.

6. CONCLUSION

The practice of Gestalt therapy is based on the philosophical foundations of field theory, phenomenology, and dialogue. Gestalt therapy is a process-oriented approach that focuses on the person/environment field. The goal in Gestalt therapy is increased awareness, and change occurs through focused attention on “what is” and not by attempting to achieve a particular goal or agenda. Because the therapist brings himself or herself to the meeting with the patient, a type of contact that is in itself healing becomes possible. Gestalt therapy is based on a theory of health, and the focus is on how the patient interrupts his or her natural self-regulation process. The method is experiential and experimental, relying on meaning emerging from experience rather than interpretation. Gestalt therapy has wide applicability with a variety of patient populations, problems, and treatment modalities.

Although limited, research indicates its usefulness for a variety of populations and issues.

GLOSSARY

aptitude Specific ability in an academic area such as mathematics, spatial tasks, science, or verbal activities.

elitism An attitude critical of special programs for gifted and talented youth because they provide benefits not available to all students.

enrichment programs Special services for gifted youth that avoid the regular school program and curricula and that often offer projects and creative activities. Students are often pulled out of regular classes during the school day for these programs.

gifted Youth who have high general mental or artistic abilities.

intelligence General mental ability as often represented by gifted students.

live-in experience A service for gifted, talented, and/or precocious youth in which they leave their homes and go to live at the site where a special program is offered, often a college or university campus.

precocity Achievement or performance that surpasses the average performance of youth at a given age level. The term precocious is often used as a synonym of gifted.

talent Specific ability in an applied area such as mathematics, science, leadership, music, art, or writing.

Gifted, talented, and precocious students can be identified with intelligence and aptitude tests, rating scales, achievement test scores, and teacher observations. Once identified, schools can offer special classes, programs, and services to facilitate the growth of their gifts and talents. Colleges and universities also provide special programs and services in the forms of early admission to highly precocious youth as well as special weekend and summer programs.

1. INTRODUCTION

Gifted, talented, precocious, high aptitude, high achieving, and creative are all terms used to designate children and youth of high or superior ability. There is little agreement about test instruments, rating scales, and observational procedures used to identify these children, or cutting levels on the various test instruments that are used. However, there is some agreement that test scores 2 standard deviation above the mean or percentile scores at or above 90% are appropriate identification criteria. There is also agreement that it is desirable to gather two or more measures to identify candidates for special programs.

2. DEFINING GIFTED

The field of gifted education has generated a large research base, beginning with the work of Lewis Terman. Shortly after his development and publication in 1916 of the first intelligence test in the United States, the Stanford–Binet, he began a major longitudinal study of 12-year-old children with IQs of 135 or higher who were followed throughout their lives, with special interest in their long-term achievements. Another pioneer and researcher in the field was Leta Stetter Hollingworth, whose work focused on highly gifted youth and their education. Terman’s research established the initial focus on high IQ as the major means of identification, and his following research established that those who go on to high-level creative production in life profited from early grade advancement or acceleration and motivation to achieve at a high level. Hollingworth’s work established the critical need of highly gifted youth for challenging and motivating instruction and the problems they face in regular grade-level classrooms, often with teachers who do not understand them and their special needs.

3. WHY SEPARATE STUDENTS?

The major purpose of identification of children for gifted programs or educational services is, or should be, to determine if they need a special regimen beyond the services of a regular classroom program and what particular services or resources might be needed. Decisions about a child’s special education needs can best be made through the assessment of the child’s special aptitudes and talents or areas of high achievement. Then, if both aptitude and achievement tests reveal high mathematical ability and the need for higher level mathematics instruction, a decision may be made to place the child in the next higher grade level for mathematics instruction or in a special mathematics enrichment program. Alternately, if the child’s achievement test scores are all above the 95th percentile, after conferences with the child and his or her parents, a decision may be made to move the child to the next higher grade level for all instruction.

In some schools or communities, gifted or precocious children are grouped together in special classes or even in special schools for gifted children only. Teachers of such classes often have received special training and certification for work with gifted children and youth and use curricula designed especially for gifted and precocious children.

Several states have established schools for precocious secondary students, often with major academic focus on mathematics and science and offering a full-time experience. These schools are comparable to the special day schools offered in several cities such as New York and Chicago, again stressing mathematics and science. Admission may be strongly competitive, but the instruction and curriculum as well as association with other academically superior students make these schools ideal programs for academically precocious youth.

4. IDENTIFICATION AND NURTURING

Much of the attention given to gifted and talented youth has turned diagnostically, in the past decades, to identification and nurturing of their special talents. Rather than offering a general, homogeneous regimen and curriculum for all gifted youth, the new programs offer a variety of classes and services focused on their special and emerging talents. Thus, a child who has been identified as having exceptional art talent can participate in an after-school arts class, another who shows strong leadership ability may enroll in Saturday morning leadership classes, and yet another who is precocious in science can be matched up with a mentor-professor at a community college and spend one afternoon a week at the college working with the mentor-professor in a science lab. Talent-oriented programs use a wide variety of services and resources in the school and community to foster the development of children’s special talents.

Saturday and summer programs are also now widely available to gifted and talented children with or without school identification or endorsement. Although some of these programs make no pretense of identifying and serving the gifted, many of them explicitly aim to identify and serve gifted and talented youth. These programs often offer talent-oriented classes taught by experts in that field. For example, an actor or director may teach a class in dramatics, a computer professional may teach a class on computers, a math teacher may teach an advanced math class, an attorney may teach a class on the law as a profession, and a local novelist may teach a creative writing class. These classes supply a knowledge base in the field of the talent, offer a motivating challenge for talented youth, and provide mentors and models

in areas related to youth talents. Some programs, such as one at Purdue University, also offer mentoring experiences as a follow-up to the classroom in areas of youth talent.

5. WORLDWIDE SUPPORT

The field of gifted and talented education is now fostering identification and special education for gifted and talented youth in countries throughout the world through the auspices of the World Council for Gifted Education. Its major publication, *The International Handbook of Giftedness and Talent* (2000), is an excellent resource, with chapters written by the leading experts in gifted education from throughout the world. In the United States, the major professional organization with focus on gifted and talented youth is the National Association for Gifted Children, based in Washington, D.C. Most of the U.S. states also have professional organizations focused on gifted and talented youth.

6. LITERATURE REGARDING GIFTED STUDENTS

There are a number of publications devoted to the nature and educational needs of the gifted and their teachers, notably *The Gifted Child Quarterly*, the major publication of the National Association of the Gifted Children, Washington, D.C.; the *Gifted Child Today*, Prufrock Press, Waco, Texas; the *Journal of Secondary Gifted Education*, Prufrock Press, Waco, Texas; *Roeper Review*, the Roeper Institute, Bloomfield Hills, Michigan; the *Journal for the Education of the Gifted*, the Association for the Gifted, of the Council for Exceptional Children, Reston, Virginia; *High Ability Studies*, the journal of the European Council for High Ability, Bonn, Germany; *Gifted and Talented International*, World Council for Gifted and Talented Children, College of William and Mary, Williamsburg, Virginia; and *Gifted Education International*, AB Academic Publishers, Oxon, United Kingdom.

7. CURRENT RESEARCH

The field of gifted and talented education is diverse in the nature of its research and the direction of

educational services. Research runs the gamut from studies of the nature of talent and abilities to personality and attitudinal aspects of giftedness, methods of testing and identifying gifted youth and the appropriate test instruments, creativity and problem solving abilities of gifted and talented youth, gender differences in abilities, models' and mentors' roles in the development of gifts and talents, and nature versus nurture in the development of giftedness. Research on gifted and talented youth and in the field of gifted education is widely reported in the journals of the field and at conferences.

The field of gifted and talented education is also diverse in its conceptions and identification of giftedness, and in its educational services and programs for gifted and talented youth. It is sometimes viewed as elitist by mainstream education, and there is some opposition to special classes and services for these youth. Funding for research in gifted education is limited, but several centers at universities carry on excellent programmatic investigations, notably at the University of Connecticut, the University of Iowa, and Purdue University. It appears that educational programs for gifted and talented youth are now well established in many cities, U.S. states, and other countries, and they will continue to grow and provide valuable educational experiences for gifted youth.

GLOSSARY

discrete goal A particular performance standard or objective.

ego-involved goal A goal of revealing superior competence relative to others.

failure-oriented goal-setting style Individual difference reflecting a concern about not demonstrating low ability compared to others and thus a tendency to set very easy or extremely difficult goals.

goal orientation Dispositional tendency regarding achievement goal focus.

goal proximity Having both short-term and long-term goals.

goal-setting style An individual difference factor capturing an athlete's preferences regarding the type of discrete goals that are set in training and/or competition.

moderately challenging goals Standards that are of an optimal difficulty (i.e., not too easy and not beyond one's capabilities).

motor endurance task A physical task that requires muscular or cardiovascular endurance for successful performance.

outcome goal A goal based on a competitive or comparative performance standard.

performance goal A goal to secure some discrete standard or end product that is self-referenced (e.g., a "personal best" achievement).

performance-oriented goal-setting style Individual difference reflecting a tendency to set goals related to learning, performance improvement, and increasing one's self-referent ability.

pre-competitive anxiety The cognitive (e.g., degree of worry) and somatic (e.g., heart racing) anxiety experienced by an athlete before a competitive event.

process goal A goal of trying to meet some standard of proficiency concerning technique or employment of strategy.

success-oriented goal-setting style Individual difference reflecting a tendency to set competitive outcome goals or strive for standards that entail social comparison.

task-involved goal A goal that entails an emphasis on demonstrating personal competence in a self-referenced way and that centers on energetic attempts at task mastery and/or improvement.

Any perusal of applied sport psychology texts, examination of prevailing research topics in major sport psychology journals, or conversational engagement with those involved in sport usually points to the relevance of goals, goal setting, and motivation in this domain. Indeed, investigations of youth, intercollegiate and Olympic athletes, and coaches have supported their propensity for the setting of goals in competition and training. Interestingly, though, this descriptive research also

indicates that athletes and coaches consider their goal-setting efforts as only marginally effective. That is, although the formulation of and striving for some target(s) or objective(s) appear to be endemic in the athletic context, the employment of goal setting in sport seems less productive than one would readily assume. A major premise of the present contribution is that the implementation of goal setting will remain inconsistent and the efficacy of such strategies unconvincing and restricted in scope unless the meaning of the goals and their link to variations in motivation processes are considered.

In this article, the underpinnings, directions, and major findings of research on goal setting in sport will be summarized. Limitations of this work will also be highlighted. We then move into a discussion of the concept of achievement goals. In particular, attention will turn to the ways in which the constructs and assumptions embedded in con-temporary achievement goal frameworks provide further insight into the types of goals that individuals strive for within the athletic milieu. Moreover, the implications of these different goal perspectives for athletes' motivation to achieve and the overall quality of their sport engagement will be addressed. In essence, it is argued that a consideration of variability in achievement goals helps complete the picture in terms of when goal setting will be effective and what contributes to motivationally sound and adaptive goal setting. The article concludes with a discussion of future directions and considerations regarding work linking goal setting and achievement goals.

1. GOAL SETTING IN SPORT

In the view of Locke and colleagues (1981, p. 126), goals capture what "an individual is trying to accomplish; it is the object or aim of an action." Weinberg (1992) takes this definition a step further by proposing that meeting a goal means "attaining a standard of proficiency on a task, usually within a specified time limit" (p. 178). According to Locke and Latham, we typically are consciously aware of our goals, but, on some occasions, goals can reflect unconscious intentions or purposes. Particularly in terms of the former, it is held that goals initiate and regulate behavior. That is, goals are conceptualized in Locke's model to be the antecedent that is most proximal to performance.

Locke and Latham further argue that goals can have a direct and indirect effect on performance. It is assumed that goals directly influence performance outcomes by

centering our attention on task-relevant cues (and attenuating our attending to cues that are not task-relevant) and encouraging persistence and appropriate levels of exerted effort. With respect to the proposed indirect consequences of goal setting, resulting strategic planning and problem solving are held to be mediators of the goal setting and performance relationship. Clearly, the latter mechanisms are especially essential when individuals are trying to meet complicated, challenging, and long-term objectives. However, sometimes focusing on a task, trying one's hardest, and persevering are not enough to secure goal attainment. Before any of these direct or indirect influences are likely to come into fruition, it is suggested that individuals must be committed to the goal(s) at hand and possess the necessary ability or skills. Feedback in relation to goal progress is another proposed moderator that is viewed as being essential to goal-setting effectiveness.

Almost exclusively, research on goal setting in sport has been grounded in Locke's goal-setting theory. The major assumptions of this theoretical framework, particularly in terms of the existent sport-related work, are described next. All in all, these predictions indicate which type of goal is most likely to have the most substantial positive impact on performance.

1.1. Basic Tenets of Locke's Goal-Setting Theory

There are three central propositions in Locke's model of goal setting as it has been tested in sport; namely, that (1) hard goals result in higher levels of performance than do less-demanding goals, (2) specific goals give rise to superior performance when contrasted with no goals, very general goals, or a vague goal such as "do your best," and (3) using short-term goals in conjunction with long-term goals will lead to better performance than using long-term goals exclusively. Overall in the goal-setting literature, and specifically in terms of research conducted within organizational settings, evidence has been garnered indicating that difficult and specific short- and long-term standards result in superior performance when contrasted with more vague goals or no goals. Indeed, a number of large-scale narrative reviews and meta-analyses have heralded the effectiveness of explicit, difficult, short- and long-term goal setting. What is especially impressive about this body of work is that

the value of specific and challenging goals has been supported in the field and in the laboratory, with respect to diverse settings, across different tasks, in the case of various populations, and in terms of short- and long-term performance indicators. Moreover, the proposed direct and indirect mechanisms by which goals are held to influence performance have been generally sustained in the general and organizational psychology literatures.

1.2. Testing of Locke's Theory in Sport/The Physical Domain

In an attempt to encourage more systematic investigation of the efficacy of goal setting in the sport realm, Locke and Latham proffered that the impact of goal setting on sport performance would be even more striking than what is observed in work-related or organizational situations. Further, they proposed a number of hypotheses regarding when, where, and why goal setting functions in the physical domain. With respect to research in real-life sport settings or laboratory experiments involving sport or physical-based tasks, however, the literature on the effectiveness of goal setting is a bit more conflicting and slightly less compelling than has been the case in work settings. In the available sport-focused narrative reviews, it is typically concluded that research has provided only qualified support for the specific standard versus "do your best" hypothesis in Locke's framework, and, on the whole, the findings in terms of goal proximity (i.e., having short-term along with long-term goals) and goal difficulty (i.e., more difficult goals result in better performance) have been equivocal.

In 1995, Kylo and Landers published a meta-analysis that provided a slightly more optimistic but still rather constrained evaluation of studies on the effect of goal setting on physical task performance. Overall, in terms of the observed relationship between goal setting and performance witnessed in 36 studies, a mean effect size of .34 was revealed. This result is considerably more modest than what has been reported in omnibus meta-analyses not specific to the physical domain (i.e., the latter have found overall effect sizes ranging from .42 to .80). Providing only partial support for one of Locke's propositions, Kylo and Landers also found moderately challenging goals to be associated with a greater effect size (.53) than difficult (.09) or easy (.07) goals. Consonant with Locke and Latham's hypothesis, combined short- and long-term goals were coupled with a

larger effect size (.48) than short-term (.38) and especially long-term (.19) goals only.

In their more recent appraisal of 56 published goal-setting studies in sport and physical activity, Burton *et al.* reported a 78.6% effectiveness rate. As this rate was greater than what was reported in an earlier version of the review chapter in question (in particular, 7 years previously, 66% of the published studies reviewed revealed a positive overall goal-setting effect), Burton and colleagues suggested that more support for the consistency of goal-setting effects is accruing as more research has been undertaken. This is a promising conclusion, but caution is warranted when such a deduction comes from a sample of published papers. That is, published research is more likely to show significant and expected effects when contrasted with non-published studies. Further, it is important to keep in mind that the conclusions of Burton and associates did not stem from a systematic, meta-analytic review.

There has been diversity in the methods used to test the veracity of Locke's theory when applied to sport. Particularly during the earlier work on this topic, more laboratory-based experiments flourished. The trend for such investigations was to focus on a simple, motor endurance-type task (e.g., sit-ups), recruit physical education or sport science majors as subjects, have the experimenter assign the goal(s), and then contrast a specific goal versus a general and/or vague "do your best" goal with respect to the impact on performance, often over a short time period. Sometimes a control group that was assigned "no goals" was incorporated in the design. Other investigations in the sport milieu have been field-based studies and/or interventions employing single-subject designs to examine the efficacy of goal-setting programs.

Another contemporary extension of work on goal setting that emanated particularly within the sport and exercise psychology literature is the distinction between outcome, performance, and process goals. When focused on a process goal, the athlete is trying to meet some standard of proficiency concerning her or his technique or employment of strategy. For a performance goal, the athlete is reaching to secure some discrete standard or end product that is self-referenced (e.g., trying to better one's sprint time). An outcome goal is based on a competitive or comparative performance standard, such as winning a contest. On the whole, sport research suggests that athletes focus on all three types of goals, and they may serve different purposes in terms of maximizing skill development and performance.

1.3. Limitations of Sport Goal-Setting Work

When trying to explicate the mixed results and typically more moderate effects when goal setting is tested in regard to sport or physical task performance, researchers have offered a number of methodological artifacts and design limitations for consideration. These factors, which to some degree can be considered interrelated, include: (1) the inclusion of individuals who tend to be highly motivated in the physical domain as study participants, (2) the tendency for study participants in the control or “do your best” groups to spontaneously set goals, (3) the likelihood of competition being manifested between study participants, and (4) the failure to consider study participants’ personal goals with respect to task performance. Without a doubt, such methodological shortcomings pose a serious threat to the internal validity of this research. Moreover, not systematically taking account of such factors in goal-setting research diminishes our understanding of why, when, and how goal setting may work in sport.
